Abstract

Following a request from the European Commission, the EFSA Plant Health (PLH) Panel performed a pest categorisation of *Anisogramma anomala*, a well-defined and distinguishable fungal species of the family Valsaceae. The pathogen is regulated in Annex IIAI of Council Directive 2000/29/EC as a harmful organism whose introduction into the EU is banned on plants of *Corylus* L., intended for planting, other than seeds, originating in Canada and the USA. The fungus is native to eastern North America and causes eastern filbert blight on cultivated hazel, *Corylus avellana*, as well as on wild hazel (*Corylus* spp.). In the 1960s, the disease spread on infected plant material to Oregon, where it then threatened US hazelnut production in the Willamette Valley. The pest could enter the EU via plants for planting. Hosts and favourable climatic conditions are common in the EU, thus facilitating establishment. The pest would be able to spread following establishment through infected plants for planting and ascospore dispersal. *A. anomala* leads to canopy and yield loss and can cause death of *Corylus* trees. Should the pathogen be introduced into the EU, impacts can be expected not just on hazel as a crop and as an ornamental but also in coppices and woodlands, where *Corylus* species provide an important habitat. In Oregon, scouting for cankers, therapeutic pruning and copious fungicide applications are reported to be necessary (but costly measures) to continue hazelnut production in the presence of the disease. Breeding for resistance led to the selection of resistant cultivars. The main knowledge gaps concern (i) the role of deadwood and cut branches as potential entry pathways and means of spread and (ii) the susceptibility of *C. avellana* cultivars and of *Corylus* spp. in the wild in the EU. The criteria assessed by the Panel for consideration as a potential quarantine pest are met. For regulated non-quarantine pests, the criterion on the pest presence in the EU is not met.

1. Introduction

1.1. Background and Terms of Reference as provided by the requestor

1.1.1. Background

Council Directive 2000/29/EC\(^1\) on protective measures against the introduction into the Community of organisms harmful to plants or plant products and against their spread within the Community establishes the present European Union plant health regime. The Directive lays down the phytosanitary provisions and the control checks to be carried out at the place of origin on plants and plant products destined for the Union or to be moved within the Union. In the Directive’s 2000/29/EC annexes, the list of harmful organisms (pests) whose introduction into or spread within the Union is prohibited, is detailed together with specific requirements for import or internal movement.

Following the evaluation of the plant health regime, the new basic plant health law, Regulation (EU) 2016/2031\(^2\) on protective measures against pests of plants, was adopted on 26 October 2016 and will apply from 14 December 2019 onwards, repealing Directive 2000/29/EC. In line with the principles of the above mentioned legislation and the follow-up work of the secondary legislation for the listing of EU regulated pests, EFSA is requested to provide pest categorizations of the harmful organisms included in the annexes of Directive 2000/29/EC, in the cases where recent pest risk assessment/pest categorisation is not available.

1.1.2. Terms of reference

EFSA is requested, pursuant to Article 22(5.b) and Article 29(1) of Regulation (EC) No 178/2002\(^3\), to provide scientific opinion in the field of plant health.

EFSA is requested to prepare and deliver a pest categorisation (step 1 analysis) for each of the regulated pests included in the appendices of the annex to this mandate. The methodology and template of pest categorisation have already been developed in past mandates for the organisms listed in Annex II Part A Section II of Directive 2000/29/EC. The same methodology and outcome is expected for this work as well.

The list of the harmful organisms included in the annex to this mandate comprises 133 harmful organisms or groups. A pest categorisation is expected for these 133 pests or groups and the delivery of the work would be stepwise at regular intervals through the year as detailed below. First priority covers the harmful organisms included in Appendix 1, comprising pests from Annex II Part A Section I and Annex II Part B of Directive 2000/29/EC. The delivery deadline of all pest categorisations for the pests included in Appendix 1 is June 2018. The second priority is the pests included in Appendix 2, comprising the group of Cicadellidae (non-EU) known to be vector of Pierce’s disease (caused by Xylella fastidiosa), the group of Tephritidae (non-EU), the group of potato viruses and virus-like organisms, the group of viruses and virus-like organisms of Cydonia Mill., Fragaria L., Malus Mill., Prunus L., Pyrus L., Ribes L., Rubus L. and Vitis L. and the group of Margarodes (non-EU species). The delivery deadline of all pest categorisations for the pests included in Appendix 2 is end 2019. The pests included in Appendix 3 cover pests of Annex I part A Section I and all pests categorisations should be delivered by end 2020.

For the above mentioned groups, each covering a large number of pests, the pest categorisation will be performed for the group and not the individual harmful organisms listed under “such as” notation in the Annexes of the Directive 2000/29/EC. The criterion to be taken particularly under consideration for these cases is the analysis of host pest combination, investigation of pathways, the damages occurring and the relevant impact.

Finally, as indicated in the text above, all references to ‘non-European’ should be avoided and replaced by ‘non-EU’ and refer to all territories with exception of the Union territories as defined in Article 1 point 3 of Regulation (EU) 2016/2031.

---

\(^1\) Council Directive 2000/29/EC of 8 May 2000 on protective measures against the introduction into the Community of organisms harmful to plants or plant products and against their spread within the Community. OJ L 169/1, 10.7.2000, p. 1–112.

1.1.2.1. Terms of Reference: Appendix 1

List of harmful organisms for which pest categorisation is requested. The list below follows the annexes of Directive 2000/29/EC.

**Annex IIAI**

(a) Insects, mites and nematodes, at all stages of their development

- Aleurocanthus spp.
- Anthonomus bisignifer (Schenkling)
- Anthonomus signatus (Say)
- Aschistonyx eppoi Inouye
- Carposina niponensis Walsingham
- Enarmonia packardi (Zeller)
- Enarmonia prunivora Walsh
- Grapholita inopinata Heinrich
- Hisynomus phycitis
- Leucaspis japonica Ckll.
- Listronotus bonariensis (Kuschel)

(b) Bacteria

- Citrus variegated chlorosis
- Erwinia stewartii (Smith) Dye

(c) Fungi

- Alternaria alternata (Fr.) Keissler (non-EU pathogenic isolates)
- Anisogramma anomala (Peck) E. Müller
- Apiospora morbosa (Schwein.) v. Arx
- Ceratocystis virescens (Davidson) Moreau
- Cercocephalospora pini-densiflorae (Hori and Nambu) Deighton
- Cercospora angolensis Carv. and Mendes

(d) Virus and virus-like organisms

- Beet curly top virus (non-EU isolates)
- Black raspberry latent virus
- Blight and blight-like
- Cadang-Cadang viroid
- Citrus tristeza virus (non-EU isolates)
- Leprosis

**Annex IIB**

(a) Insect mites and nematodes, at all stages of their development

- Anthonomus grandis (Boh.)
- Cephalcia lariciphila (Klug)
- Dendroctonus micans Kugelan
- Gilphinia hercyniae (Hartig)
- Gonipterus scutellatus Gyll.
- Ips amitinus Eichhof
- Ips cembrae Heer
- Ips duplicatus Sahlberg
- Ips sexdentatus Börner
- Ips typographus Heer
- Stenochetus mangiferae Fabricius
(b) Bacteria

*Curtobacterium flaccumfaciens* pv. *flaccumfaciens* (Hedges) Collins and Jones

(c) Fungi

*Glomerella gossypii* Edgerton

*Hypoxylon mammatum* (Wahl.) J. Miller

*Gremmeniella abietina* (Lag.) Morelet

1.1.2.2. Terms of Reference: Appendix 2

List of harmful organisms for which pest categorisation is requested per group. The list below follows the categorisation included in the annexes of Directive 2000/29/EC.

**Annex IAI**

(a) Insects, mites and nematodes, at all stages of their development

Group of Cicadellidae (non-EU) known to be vector of Pierce’s disease (caused by *Xylella fastidiosa*), such as:

1) *Carneocephala fulgida* Nottingham

2) *Draeculacephala minerva* Ball

Group of Tephritidae (non-EU) such as:

1) *Anastrepha fraterculus* (Wiedemann) 12) *Pardalaspis cyanescens* Bezzi

2) *Anastrepha ludens* (Loew) 13) *Pardalaspis quinaria* Bezzi

3) *Anastrepha obliqua* Macquart 14) *Pterandrus rosa* (Karsch)

4) *Anastrepha suspensa* (Loew) 15) *Rhacochlaena japonica* Ito

5) *Dacus ciliatus* Loew 16) *Rhagoletis completa* Cresson

6) *Dacus curcurbitae* Coquillet 17) *Rhagoletis fausta* (Osten-Sacken)

7) *Dacus dorsalis* Hendel 18) *Rhagoletis indifferens* Curran

8) *Dacus tryoni* (Froggatt) 19) *Rhagoletis mendax* Curran

9) *Dacus tsuneonis* Miyake 20) *Rhagoletis pomonella* Walsh

10) *Dacus zonatus* Saund.

11) *Epochra canadensis* (Loew)

(c) Viruses and virus-like organisms

Group of potato viruses and virus-like organisms such as:

1) Andean potato latent virus

2) Andean potato mottle virus

3) Arracacha virus B, oca strain

4) Potato black ringspot virus

5) Potato virus T

6) non-EU isolates of potato viruses A, M, S, V, X and Y (including Yo, Yn and Yc) and Potato leafroll virus

1) Blueberry leaf mottle virus

2) Cherry rasp leaf virus (American)

3) Peach mosaic virus (American)

4) Peach phony rickettsia

5) Peach rosette mosaic virus

6) Peach rosette mycoplasm

7) Peach X-disease mycoplasm

8) Peach yellows mycoplasm

9) Plum line pattern virus (American)

10) Raspberry leaf curl virus (American)

11) Strawberry witches’ broom mycoplasm

Annex IIAI

(a) Insects, mites and nematodes, at all stages of their development

Group of Margarodes (non-EU species) such as:
1) Margarodes vitis (Phillipi) 3) Margarodes prieskaensis Jakubski
2) Margarodes vredendalensis de Klerk

1.1.2.3. Terms of Reference: Appendix 3

List of harmful organisms for which pest categorisation is requested. The list below follows the annexes of Directive 2000/29/EC.

Annex IAI

(a) Insects, mites and nematodes, at all stages of their development

Acleris spp. (non-EU)  Longidorus diadecturus Eveleigh and Allen
Amauromyza maculosa (Malloch)  Monochamus spp. (non-EU)
Anomala orientalis Waterhouse  Myndus crudus Van Duzee
Arrhenodes minutus Drury  Nacobbus aberrans (Thorne) Thorne and Allen
Choristoneura spp. (non-EU)  Naupactus leucoloma Boheman
Conotrachelus nenuphar (Herbst)  Premnotypus spp. (non-EU)
Dendrolimus sibiricus Tschetverikov  Pseudopityophthorus minutissimus (Zimmermann)
Diabrotica barberi Smith and Lawrence  Pseudopityophthorus pruinosis (Eichhoff)
Diabrotica undecimpunctata howardii Barber  Scaphoideus luteolus (Van Duzee)
Diabrotica undecimpunctata undecimpunctata Mannerheim  Spodoptera eridania (Cramer)
Diabrotica virgifera zeae Krysan & Smith  Spodoptera frugiperda (Smith)
Diaphorina citri Kuway  Spodoptera litura (Fabricus)
Heliothis zea (Boddie)  Thrips palmi Karny
Hirschmanniella spp., other than Hirschmanniella gracilis (de Man) Luc and Goodey  Xiphinema americanum Cobb sensu lato (non-EU populations)
Liriomyza sativae Blanchard  Xiphinema californicum Lamberti and Bleve-Zacheo

(b) Fungi

Ceratocystis fagacearum (Bretz) Hunt  Mycosphaerella larici-leptolepis Ito et al.
Chrysomyxa arctostaphyli Dietel  Mycosphaerella populorum G. E. Thompson
Cronartium spp. (non-EU)  Phoma andina Turkensteen
Endocronartium spp. (non-EU)  Phyllosticta solitaria Ell. and Ev.
Guignardia laricina (Saw.) Yamamoto and Ito  Septoria lycopersici Spec. var. malagutii Ciccarone and Boerema
Gymnosporangium spp. (non-EU)  Thecaphora solani Barrus
Inonotus weirii (Murrill) Kotlaba and Pouzar  Trechispora brinkmannii (Bresad.) Rogers
Melampsora farlowii (Arthur) Davis  

(c) Viruses and virus-like organisms

Tobacco ringspot virus  Pepper mild tigré virus
Tomato ringspot virus  Squash leaf curl virus
Bean golden mosaic virus  Euphorbia mosaic virus
Cowpea mild mottle virus  Florida tomato virus
Lettuce infectious yellows virus
(d) Parasitic plants

Arceuthobium spp. (non-EU)

Annex I AII

(a) Insects, mites and nematodes, at all stages of their development

Meloidogyne fallax Karssen  
Rhizoeus hibisci Kawai and Takagi

Popillia japonica Newman

(b) Bacteria

Clavibacter michiganensis (Smith) Davis et al.  
Ralstonia solanacearum (Smith) Yabuuchi et al.

sepedonicus (Spieckermann and Kotthoff) Davis et al.

(c) Fungi

Melampsora medusae Thümen  
Synchytrium endobioticum (Schilbersky) Percival

Annex I B

(a) Insects, mites and nematodes, at all stages of their development

Leptinotarsa decemlineata Say  
Liriomyza bryoniae (Kaltenbac)

(b) Viruses and virus-like organisms

Beet necrotic yellow vein virus

1.2. Interpretation of the Terms of Reference

Anisogramma anomala is one of a number of pests listed in the Appendices to the Terms of Reference (ToR) to be subject to pest categorisation to determine whether it fulfils the criteria of a quarantine pest or those of a regulated non-quarantine pest for the area of the European Union (EU).

2. Data and methodologies

2.1. Data

2.1.1. Literature search

A literature search on A. anomala was conducted at the beginning of the categorisation in the ISI Web of Science bibliographic database, using the scientific name of the pest as the search term. Relevant papers were reviewed, and further references and information were obtained from experts, from citations within the references and grey literature.

2.1.2. Database search

Pest information, on host(s) and distribution, was retrieved from the EPPO Global Database (EPPO, 2017) (https://gd.eppo.int).

Data about the area of hosts grown in the EU were obtained from EUROSTAT (http://ec.europa.eu/eurostat/web/agriculture/data/database).

Information on EU Member State (MS) imports of Corylus plants for planting from North America was sought in the ISEFOR database (Eschen et al., 2017).

The Europhyt database was consulted for pest-specific notifications on interceptions and outbreaks. Europhyt is a web-based network launched by the Directorate General for Health and Consumers (DG SANCO) and is a subproject of PHYSAN (Phyto-Sanitary Controls) specifically concerned with plant health information. The Europhyt database manages notifications of interceptions of plants or plant products that do not comply with EU legislation as well as notifications of plant pests detected in the territory of the MSs and the phytosanitary measures taken to eradicate or avoid their spread.
2.2. Methodologies

The Panel performed the pest categorisation for *A. anomala*, following guiding principles and steps presented in the EFSA guidance on the harmonised framework for pest risk assessment (EFSA PLH Panel, 2010) and as defined in the International Standard for Phytosanitary Measures No 11 (FAO, 2013) and No 21 (FAO, 2004).

In accordance with the guidance on a harmonised framework for pest risk assessment in the EU (EFSA PLH Panel, 2010), this work was started following an evaluation of the EU's plant health regime. Therefore, to facilitate the decision-making process, in the conclusions of the pest categorisation, the Panel addresses explicitly each criterion for a Union quarantine pest and for a Union regulated non-quarantine pest in accordance with Regulation (EU) 2016/2031 on protective measures against pests of plants, and includes additional information required as per the specific terms of reference received by the European Commission. In addition, for each conclusion, the Panel provides a short description of its associated uncertainty.

Table 1 presents the Regulation (EU) 2016/2031 pest categorisation criteria on which the Panel bases its conclusions. All relevant criteria have to be met for the pest to potentially qualify either as a quarantine pest or as a regulated non-quarantine pest. If one of the criteria is not met, the pest will not qualify. A pest that does not qualify as a quarantine pest may still qualify as a regulated non-quarantine pest which needs to be addressed in the opinion. For the pests regulated in the protected zones only, the scope of the categorisation is the territory of the protected zone, thus the criteria refer to the protected zone instead of the EU territory.

It should be noted that the Panel’s conclusions are formulated respecting its remit and particularly with regard to the principle of separation between risk assessment and risk management (EFSA founding regulation (EU) No 178/2002); therefore, instead of determining whether the pest is likely to have an unacceptable impact, the Panel will present a summary of the observed pest impacts. Economic impacts are expressed in terms of yield and quality losses and not in monetary terms, while addressing social impacts is outside the remit of the Panel, in agreement with the EFSA guidance on a harmonised framework for pest risk assessment (EFSA PLH Panel, 2010).

Table 1: Pest categorisation criteria under evaluation, as defined in Regulation (EU) 2016/2031 on protective measures against pests of plants (the number of the relevant sections of the pest categorisation is shown in brackets in the first column)

<table>
<thead>
<tr>
<th></th>
<th></th>

</thead>
<tbody>
<tr>
<td>Identity of the pest (Section 3.1)</td>
<td>Is the identity of the pest established, or has it been shown to produce consistent symptoms and to be transmissible?</td>
<td>Is the identity of the pest established, or has it been shown to produce consistent symptoms and to be transmissible?</td>
<td>Is the identity of the pest established, or has it been shown to produce consistent symptoms and to be transmissible?</td>
</tr>
<tr>
<td>Absence/presence of the pest in the EU territory (Section 3.2)</td>
<td>Is the pest present in the EU territory? If present, is the pest widely distributed within the EU? Describe the pest distribution briefly!</td>
<td>Is the pest present in the EU territory? If not, it cannot be a protected zone quarantine organism</td>
<td>Is the pest present in the EU territory? If not, it cannot be a regulated non-quarantine pest. (A regulated non-quarantine pest must be present in the risk assessment area)</td>
</tr>
<tr>
<td>Regulatory status (Section 3.3)</td>
<td>If the pest is present in the EU but not widely distributed in the risk assessment area, it should be under official control or expected to be under official control in the near future</td>
<td>The protected zone system aligns with the pest free area system under the International Plant Protection Convention (IPPC) The pest satisfies the IPPC definition of a quarantine pest that is not present in the risk assessment area (i.e. protected zone)</td>
<td>Is the pest regulated as a quarantine pest? If currently regulated as a quarantine pest, are there grounds to consider its status could be revoked?</td>
</tr>
</tbody>
</table>
The Panel will not indicate in its conclusions of the pest categorisation whether to continue the risk assessment process, but, following the agreed two-step approach, will continue only if requested by the risk managers. However, during the categorisation process, experts may identify key elements and knowledge gaps that could contribute significant uncertainty to a future assessment of risk. It would be useful to identify and highlight such gaps so that potential future requests can specifically target the major elements of uncertainty, perhaps suggesting specific scenarios to examine.

3. Pest categorisation

3.1. Identity and biology of the pest

3.1.1. Identity and taxonomy

<table>

The fungus has the following synonyms: *Apioporthe anomala*, *Cryptospora anomala*, *Cryptosporella anomala* and *Diatrype anomala* (Index Fungorum: http://www.indexfungorum.org/names/names.asp).

### 3.1.2. Biology of the pest

*A. anomala* is an obligate biotrophic fungus causing eastern filbert blight on cultivated common hazel, *Corylus avellana*, where 'filbert' is the commonly used term for commercial *C. avellana* in North America (EPPO, 2009). The fungus is a native and non-consequential pathogen on *Corylus americana* (American hazelnut), an understory tree in northeastern North America (Bush, 2015).

The fungus produces infectious ascospores in perithecia, which mature by late summer in ascostromata on diseased host branches (Gottwald and Cameron, 1979). Spore maturation begins in late summer, but the proportion of spores germinating increases through autumn (Pinkerton et al., 1998). Ascospores are released when stromata are wet from rain but not from dew (Pinkerton et al., 1998b) and dispersal is triggered by precipitation (EPPO, 1997; Pinkerton et al., 1998), with dissemination over long distances on air currents having been reported (Pinkerton et al., 1998).

Although ascospore release can begin in late autumn (Pinkerton et al., 1998b), the major host, *C. avellana*, is not susceptible to infection until vegetative buds and shoots resume growth in the spring (Pinkerton et al., 1998a). It has been reported that eriophyid mites might facilitate infection of vegetative buds (Johnson et al., 1994). Infection occurs by means of ascospores infecting young vegetative tissue in the spring (Gottwald and Cameron, 1980), after budburst, through leaf emergence and shoot elongation (Stone et al., 1992; Johnson et al., 1994). Once established, the fungus colonises the cambium layer resulting in the development of a canker (Gottwald and Cameron, 1980). However, some 12–16 months are normal before symptoms appear in the disease cycle of *A. anomala* (Gottwald and Cameron, 1980) and sometimes longer (up to 26–28 months) (Mehlenbacher et al., 1994). Death of the cambium in the area of the canker results in a sunken appearance as the surrounding cambium continues to grow (Gottwald and Cameron, 1980).

Cankers expand at an average rate of 30 cm per year (Gottwald and Cameron, 1980a). Cankers girdle branches, causing dieback of tree canopies and death of mature trees in 5–15 years, while younger trees may be killed within 4–7 years (EPPO, 1997). New susceptible shoots may continue to develop from the root system.

### 3.1.3. Intraspecific diversity

Studies on the genetic diversity of *A. anomala* based on Single Sequence Repeats (SSR) markers revealed (i) distinct genetic differences between populations of genotypes collected from different regions and (ii) that tested isolates were more genetically diverse than initially hypothesised based on prior internal transcribed spacer region sequence studies (Muehlbauer et al., 2014). A preliminary study on 11 polymorphic SSR loci in 30 *A. anomala* genotypes revealed that genotypes grouped into two clades: one including genotypes from New Jersey and the other genotypes originating from areas surrounding the Great Lakes (Cai et al., 2013). Genotypes from Oregon clustered in this last clade (Cai et al., 2013).

### 3.1.4. Detection and identification of the pest

Are detection and identification methods available for the pest?

**Yes**

A full description of *A. anomala* useful for diagnostic purposes is available (Gottwald and Cameron, 1979; EPPO, 2009). *A. anomala* can be grown in culture only with difficulty (Stone et al., 1994). A real-time polymerase chain reaction (PCR) assay for the early detection of the pathogen in asymptomatic host tissues was developed by Molnar et al. (2013).

### 3.2. Pest distribution

#### 3.2.1. Pest distribution outside the EU

*A. anomala* is native to a wide area east of the Rocky Mountains, where it occurs on the wild American hazelnut, *C. americana* (Molnar et al., 2013). The fungus is currently reported from both Canada and USA, including areas in the Pacific Northwest (Figure 1).
In Canada, the fungus is present in British Columbia, Manitoba, Nova Scotia, Ontario and Quebec. In the USA, reports are from Connecticut, Delaware, Illinois, Iowa, Maine, Maryland, Massachusetts, Michigan, Minnesota, New Jersey, New York, North Carolina, Oregon, Pennsylvania, Washington and Wisconsin (EPPO, 2017).

**3.2.2. Pest distribution in the EU**

Slovenia reported the pest as absent in 2017 (EPPO, 2017).

**3.3. Regulatory status**

3.4. Entry, establishment and spread in the EU

3.4.1. Host range

The fungus has been reported to be causing symptoms on various species of the genus Corylus. While A. anomala is indigenous on the common understorey shrub C. americana (EPPO, 1997), its major host is the cultivated hazel C. avellana (EPPO, 1997), which is native to Europe and adjacent areas in Asia (Martins et al., 2015). C. maxima, a species of hazel native to southeastern Europe and southwestern Asia, is also reported as a wild host (EPPO, 2017).

As the pathogen is regulated on plants of the genus Corylus (see Section 3.3), the hosts for which the pest is regulated are comprehensive of the host range. Wood and cut branches of Corylus spp. are not regulated but might provide a pathway of entry (see Entry Section 3.4.2).

3.4.2. Entry

Is the pest able to enter into the EU territory?

Yes, the pest could enter the EU through the movement of infected planting material

The introduction of the pathogen in western Washington (Davidson and Davidson, 1973) is thought to have occurred through the importation of infected C. avellana nursery stock or of wild C. americana seedlings from the Eastern regions of the USA (EPPO, 1997).
Therefore, the pathogen could enter the EU through the movement of:

- plants for planting.

In the ISEFOR database of plants for planting, there are some records of shipments of Corylus spp. plants for planting imported by the EU from the USA.

As of November 2017, there were no records of interception of A. anomalá in the Europhyt database.

- Other pathways

Infected living wood of Corylus spp. can be a source of inoculum (in Oregon, infected wood in the affected area near Portland is burnt to prevent this from happening; Mehlenbacher et al., 1994). A. anomalá is a biotrophic parasite and needs a living host to grow, but not necessarily to release ascospores (Heckert et al., 2014). The role of infected deadwood and cut branches as a potential pathway of entry is thus unclear. Information is lacking on EU import from North America of Corylus spp. cut branches for ornamental purposes (e.g. of the variety ‘Contorta’).

There is no evidence that the disease is a nut-borne disease, either in the kernel or as a surface contaminant (Mehlenbacher et al., 1994).

### 3.4.3. Establishment

| Is the pest able to become established in the EU territory? | Yes, the pest could establish in the EU, as hosts and favourable climatic conditions are widespread. |

### 3.4.3.1. EU distribution of main host plants

The major host C. avellana is native to Europe and is widely distributed in the EU either as an understorey species in mixed deciduous forests or as a cultivated species, although its presence is mostly marginal (Figure 2).

According to EUROSTAT, about 94,000–96,000 ha of hazel were cultivated in the EU between 2012 and 2015. About 71–73% of this hazelnut crop area was located in Italy (between about 66,800 and 69,100 ha), and about 14–15% of it was located in Spain (between about 13,300 and 13,900 ha). Other EU MSs reporting significant (> 1,000 ha) hazelnut cultivation for the same period are Croatia, France and Poland, whereas Bulgaria, Greece, Hungary, Portugal, Romania and Slovenia reported cultivation areas smaller than 1,000 ha. Italy produces about 17% of the hazelnut crop worldwide (Molnar et al., 2010).

C. avellana is absent only in Iceland, in some Mediterranean islands (Cyprus, Malta and Balearics) and in the northernmost and southernmost areas of the continent (reviewed in: Enescu et al., 2016).
3.4.3.2. Climatic conditions affecting establishment

The distribution of *A. anomala* in North America (Figure 1; Section 3.2.1) covers areas with cold and temperate Köppen–Geiger climate types (Peel et al., 2007). These climate types overlap to a large extent with the distributions of *C. avellana* in Europe. Therefore, the Panel assumes climate will not be a limiting factor for the establishment of the pathogen in most of the EU.

3.4.4. Spread

Although dissemination of ascospores over long distances on air currents has been reported (Pinkerton et al., 1998a), spread usually occurs locally (Gottwald and Cameron, 1980a) by means of spores released through precipitation (EPPO, 1997; Pinkerton et al., 1998a). In Oregon, the annual rate of disease spread has been reported as 2–3 km per year (Johnson et al., 1996), assumed to be through ascospore dispersal.

Despite quarantine laws established in the early 1900s to prevent the introduction of the pathogen into the western United States (Molnar et al., 2010; Bush, 2015), movement of infected plants from New England (USA) is thought to have been responsible for the introduction of *A. anomala* in the Pacific northwest (EPPO, 1997) and to have contributed to the current population structure of the fungus in North America (Cai et al., 2013; Muehlbauer et al., 2014).

Infected trees of *Corylus* spp. can be a source of inoculum (ascospores are produced in stromata associated with cankers on living wood; Johnson et al., 1994), but there is evidence that also cankered deadwood, prunings and cut branches can produce ascospores and thus be a potential means of spread (Heckert et al., 2014).

---

**Figure 2:** Plot distribution and simplified chorology map for *Corylus avellana*. Frequency of *C. avellana* occurrences within the field observations as reported by the National Forest Inventories. The chorology of the native spatial range for *C. avellana* is derived from several sources (cited in Enescu et al., 2016).

**Is the pest able to spread within the EU territory following establishment? How?**

Yes, by human movement of infected plants for planting and by dissemination of ascospores.
As noted in the Entry Section 3.4.2, there is no evidence that the disease is nut-borne (Mehlenbacher et al., 1994), and therefore, movement of nuts would not contribute to spread.

### 3.5. Impacts

**A. anomala** is responsible for canopy and yield loss (Figure 3) and can cause death of mature trees in 5–15 years with younger trees being killed within 4–7 years. As the canopy dies back, new shoots and suckers may emerge from the tree base and these in turn become infected and die.

**A. anomala** is considered to be the major limiting factor of hazelnut production in the eastern United States (Thompson et al., 1996). In fact, when **C. avellana** was introduced to North America and cultivation was attempted at the beginning of the 20th century, eastern filbert blight was identified and found to be so destructive that cultivation of European hazelnut was abandoned (Bush, 2015).

The pathogen was discovered in a commercial orchard in southwest Washington in the late 1960s (Davidson and Davidson, 1973). Most orchards within a 10-km radius of the putative introduction site of the disease are reported to have been destroyed (EPPO, 1997). Since then, the disease has spread southward throughout the Willamette Valley of Oregon where it threatens the long-term viability of the US hazelnut industry (Mehlenbacher et al., 1994; Mehlenbacher, 2005).

Should the pathogen be introduced into the EU, similar impacts can be expected not just on hazelnut as a nut crop (see Section 3.4.3.1 on the cultivated areas in the EU) but also in coppices and woodlands. However, wild hazel might be more resilient than cultivated hazel due to its higher genetic diversity, lower host density and variety of habitat conditions. **C. avellana** is commonly found in understorey of mixed-hardwood stands, along forest edges and in meadows and provides an important habitat and food resource for many organisms. **Corylus** plants are also a valued ornamental shrub often planted in gardens and parks (Enescu et al., 2016).

---

4 See Section 2.1 on what falls outside EFSA’s remit.
3.6. Availability and limits of mitigation measures

3.6.1. Phytosanitary measures

Phytosanitary measures are currently applied to plants for planting of *Corylus* spp. other than seeds (see Section 3.3.2). However, wood and cut branches of *Corylus* spp. are not regulated, but might provide a pathway of entry (see Section 3.4.2). The following phytosanitary measures are available for them: import banning of the commodity, chemical and heat treatment.

3.6.1.1. Biological or technical factors limiting the feasibility and effectiveness of measures to prevent the entry, establishment and spread of the pest

- A 12–16 month latent period is deemed normal in the disease cycle of *A. anomala* (Gottwald and Cameron, 1980b)
- Use of fungicides in nurseries may mask symptom development
- Long-distance spread of the disease due to human movement of infected planting material will make local attempts to limit spread of the disease ineffective
- In Oregon, eradication was attempted but without success as wild *Corylus* plants in nearby woodland provided an unmanageable source of inoculum (EPPO, 1997)

---

**Figure 3:** Symptoms of *Anisogramma anomala* on ornamental *Corylus avellana*. Picture of Tom Creswell, Purdue University, Bugwood.org, available online at [https://www.forestryimages.org/browse/detail.cfm?imgnum=5505565](https://www.forestryimages.org/browse/detail.cfm?imgnum=5505565)

---

Are there measures available to prevent the entry into, establishment within or spread of the pest within the EU such that the risk becomes mitigated?

**Yes**, please see Section 3.6.1.
3.6.1.2. Biological or technical factors limiting the ability to prevent the presence of the pest on plants for planting

- The length of the latent period makes sanitation measures, including destruction of infested wood, of little importance (EPPO, 1997)

3.6.2. Control methods

- In Oregon, scouting for cankers, therapeutic pruning and copious fungicide applications are reported to be necessary (but costly measures) to continue hazelnut production in the presence of the disease (Johnson et al., 1996).
- Breeding for resistance led to the selection and release of resistant cultivars producing nuts of commercial quality (Mehlenbacher et al., 2007, 2009, 2011; Capik et al., 2013).

3.7. Uncertainty

There is a lack of knowledge on the level of susceptibility of European Corylus species other than C. avellana, including C. maxima, for which there is uncertainty on the distribution in the EU.

Similarly, there is uncertainty about the susceptibility of C. avellana cultivars and of Corylus spp. in the wild in the EU, although European Corylus spp. germplasm has been used for resistance breeding programmes in the US (Capik et al., 2013).

Whether infected deadwood and cut branches could play a role in entry or spread is unknown.

4. Conclusions

A. anomala meets the criteria assessed by EFSA for consideration as a potential quarantine pest (Table 4).

Table 4: The Panel’s conclusions on the pest categorisation criteria defined in Regulation (EU) 2016/2031 on protective measures against pests of plants (the number of the relevant sections of the pest categorisation is shown in brackets in the first column)
