(57/61) patients indicated that SHSC addressed anticipatory guidance needs and helped them feel supported by other pregnant patients (60/61, 98.3%). Over 95% (67/68) reported lectures were helpful. In free-text responses, participants reported benefit from anticipatory guidance from providers, reassurance and education regarding COVID-19, and sharing experiences with other pregnant patients.

Initial data from our novel virtual pregnancy support group are promising, and indicate potential to provide critical psychosocial support. Future work is ongoing to more deeply examine the participant experience and mental health outcomes. While SHSC was developed in response to the COVID-19 pandemic, it adds a more widely applicable, innovative dimension to prenatal care by bridging medical and non-medical needs using widely available technology. This creative method of delivering anticipatory guidance and psychosocial support in prenatal care can benefit pregnant patients facing barriers to these services even beyond the COVID-19 pandemic.

P. ovale infection, hence chloroquine was continued for 3 days. After treatment, blood smear became negative for plasmodia. Follow-up instructions were given and postpartum eradication with primaquine was planned. The remainder of her pregnancy was uneventful, and she delivered a healthy baby weighing 2664 g at 41+0 weeks of gestation.

SARS-CoV-2 infection causes immune system impairment that leads to higher vulnerability to other infections and reactivation of latent infections. P. ovale infection was diagnosed 5 months after her journey to Burkina Faso. Since the incubation period of malaria ranges between 10 and 17 days, primary malaria infection was excluded, and the final diagnosis was a relapse of P. ovale infection. This is in accordance with a reported median of 17 weeks (range 2–60 weeks) between primary infection and first relapse of P. ovale. The primary infection was presumably asymptomatic.

SARS-CoV-2 infection occurred in March, which could have facilitated P. ovale resurgence by impairing the woman’s immune response. In the present study, the patient’s presentation was similar in the two admissions, and SARS-CoV-2 infection was the initial diagnostic hypothesis on both occasions. Many febrile diseases can mimic COVID-19, and SARS-CoV-2 infection itself may facilitate the onset or reactivation of infectious diseases. In the middle of the COVID-19 pandemic, we should not overlook other infectious diseases with similar clinical presentations.

SARS-CoV-2 has been identified in nasopharyngeal secretions, feces, urine, semen, and tears. Foundational research about the presence of SARS-CoV-2 in the female genital tract may help to determine the risk of sexual transmission, as well as the risk of mother-to-child
