Results: NitaVNS significantly reduced DAI, the severity of colitis associated with rectal bleeding, stool consistency, weight loss, the decrease of colon length, and the macroscopic score. In addition, NitaVNS decreased histological scores, as indicated by mucosal damage, crypt loss, and immune cell infiltration. NitaVNS colitic mice demonstrated unaltered IL-10 protein levels in the colon. However, NitaVNS increased the mRNA expression of IL-10 in both colitic and non-colitic mice and the expression of TGF-β in non-colitic mice. NitaVNS significantly downregulated the mRNA expression of BAX, BAK1, and caspase-8 in colitic mice. Conversely, NitaVNS upregulated BAD mRNA expression in non-colitic conditions. Although the splenic protein levels of IL-1β and IL-6 were not modified under all conditions, NitaVNS decreased TNF-α levels in non-colitic mice. NitaVNS did not alter splenic protein levels of IL-10 but significantly increased TGF-β levels in colitic and non-colitic mice.

Conclusion: These findings suggest that NitaVNS can attenuate the severity of experimental colitis and the inflammatory process by modulating pro-apoptotic, pro-survival molecules and anti-inflammatory cytokines. The use of NitaVNS may lead to novel therapeutic strategies in ulcerative colitis.

Introduction: Crohn's disease (CD) is characterized by chronic intestinal inflammation due to genetic and environmental factors. Microbiome studies have consistently shown dysbiosis in patients with CD. Diet is an important risk factor in the development of CD and may contribute to changes in the gut microbiota (GM). We conducted a prospective diet intervention study in CD patients and compared one time diet counseling versus catered meals that were high fiber (17g/1000 calories) and low fat (20-25% calories from fat) for 8 weeks (w) and followed for a total of 36w.

Aims & Methods: We hypothesized that metaproteomic characterization of the GM in CD in the context of dietary manipulation could edify response to diet intervention therapy. Patients chose to receive diet coun-

seling alone (group 1), catered food for 8 weeks (group 2), or catered food for a patient (group 3P) and a household control (HHC) (group 3C) as well as participate in Dyadic Psychosocial Support (DPS) sessions (group 3P and 3C). A total of 70 patients and 22 HHC were followed prospectively and collected stool at baseline, week 8, and week 36. Samples were processed with a proven pipeline to isolate and digest bacterial proteins to perform LC-MS analysis.[1] Samples with bacterial protein groups lower than 1800 were not included for further analysis. The resulting dataset was processed with the MetaLab 2.3 application to build a sample specific database (SS-DB) from the integrated gene catalog (IGC)-DB.[2] Taxonomic assignment to identify peptides was performed using the Unipept desktop version.[3]

Results: The average taxon-specific peptide distribution in the GM, especially at less specific taxonomic levels, did not show a striking difference between the groups at baseline. At the species level, after 8 weeks of a catered diet there was a general reduction of Collinsella aerofaciens that was more marked in groups 2 and 3P than in the HHC in group 3C. Collinsella aerofaciens has been linked to TLR2 activation, pro-inflammatory responses, and CD.[4] We also observed a continuous increase in Prevotella copri over time in CD patients ultimately resulting in similar patterns as seen in the household controls. P. copri has recently been recognized as an important biomarker for diet improvements in dysbiosis[5]. In particular, there was an increase of proteins associated with carbohydrate metabolic processes in P. copri in the CD patients over time. Large scale annotation of the metaproteins and their related functions is ongoing.

Conclusion: Evidence suggests that a catered high fiber, low fat diet induces a change in the GM of CD patients more than in healthy subjects. The ability to compare the effect of a diet intervention in CD patients versus matched household controls will give additional power to understanding how diet can be used to manipulate the microbiome in the context of dysbiosis.

Introduction: The complications of Crohn's disease (CD) are many and varied. Among them are thromboembolic complications that can occur during the course of the disease or reveal it. The aim of our work is to study the epidemiological, clinical and evolutionary aspects of these complications.

Aims & Methods: This is a monocentric retrospective study spread over a period of 23 years (January 1998 to October 2021). It focused on patients hospitalized for CD and presenting with a venous thrombosis confirmed by imaging.

Results: Out of 1084 cases of Crohn's disease, 17 cases of venous thrombosis were recorded, representing a prevalence of 1.7%. The median age was 35 years [28-41] with a M/F sex ratio of 1.

According to the Montreal classification, 7 cases (41.2%) were L2, 6 cases (35.3%) were L3, 3 cases (17.6%) were L1 and 1 case (5.9%) was L4. Four patients (28.6%) had ano-perineal manifestations. The phenotypic profile was B1 in 10 cases (58.8%), B2 in 5 cases (29.4%) and B3 in 2 cases (11.8%).

Apart from 2 cases of deep vein thrombosis (DVT) that revealed CD, the other 15 cases occurred during a relapse of the intestinal disease after an average evolution of 40 months, of which two cases (11.8%) were already under heparinoprophylaxis.

These were 12 cases (70.6%) of DVT of the lower limbs associated in one case with pulmonary embolism, 2 cases of cerebral venous thrombosis (11.8%) associated in one case with pulmonary embolism, one case of ovarian vein thrombosis, one case of superior mesenteric vein thrombosis, and one case of port-sinusoidal thrombosis (porto-sinusoidal vascular disease).

Associated risk factors were identified: 4 cases (23.5%) of recent surgery associated in two cases with smoking, and in one case with diabetes, one case of pregnancy, one case of prolonged immobilisation and one case of hypertension.

Biologically, there was one case of protein S deficiency and one case of vitamin B12 deficiency. It should be noted that hypoalbuminemia was found in 13 cases (76.5%) and that homocysteinemia measured in 3 cases was normal.

Apart from one death, the evolution under specific treatment was favourable in 94.1% of cases.

Conclusion: Thromboembolic complications in CD are potentially serious and dominated by DVT of the lower limbs. They usually occur during the active phase of the disease, highlighting the importance of preventive treatment.

Introduction: Inflammatory bowel disease (IBD) shares many features with other chronic inflammatory diseases (CIDs), such as rheumatoid arthritis and psoriasis, which are characterized by dysregulated immune responses and systemic manifestations. While IBD is primarily associated with inflammation in the gut, it can also lead to extra-intestinal symptoms, including joint pain and skin lesions, which are commonly observed in these other diseases. Understanding commonalities and differences

among these chronic inflammatory conditions is important for developing more effective therapies that can target the underlying immune dysregulation and improve patients' overall quality of life.

Aims & Methods: We aim to identify both the common disease signatures shared between IBD and other CIDs, as well as the disease-specific signatures unique to each condition. A cross-sectional cohort of 650 patients with CIDs, including Crohn's disease, ulcerative colitis, rheumatoid arthritis, psoriatic arthritis, psoriasis, and systemic lupus erythematosus (SLE), were recruited from the University Hospital Kiel. Peripheral blood samples were collected from this cohort, along with samples from 202 healthy controls, and subjected to RNA sequencing and methylation profiling. At the time of sample collection, the patients in the cohort underwent detailed clinical phenotyping including assessments of disease activity and symptoms. Additionally, these patients were followed up for up to 5 years to record any potential future complications that may arise.

Results: We performed differential expression and methylation analysis between each CID diagnosis and the healthy control group to identify shared molecular signatures. Our analysis showed that IBD shared the most differential signatures with rheumatoid arthritis, indicating common pathways in their pathogenesis. Psoriatic diseases also shared a significant proportion of differentially expressed and methylated patterns, while SLE had the least in common with other CIDs, suggesting distinct molecular pathways driving its pathogenesis. Interestingly, we were able to identify core transcriptomic changes that persisted even during inactive disease by separating the analysis by disease activity. These signatures were shared across different CIDs and were correlated with DNA methylation changes, reflecting the molecular mechanism of chronicity. Commonly upregulated genes across all CIDs were enriched in pathways related to inflammatory response, cytokine signaling, neutrophil chemotaxis, and humoral immune response. Disease-specific pathways included interferon-beta production in SLE, several metabolic processes in psoriasis, and complement activation in ulcerative colitis. Disease-specific methylation signatures were mainly located in CpG islands, while methylation signatures in enhancers were shared among most diseases. Our large cohort design enabled us to identify subgroup of patients across CIDs that share molecular characteristics, including a cluster of genes related to interleukin and interferon signaling upregulated in 71 samples belonging to different CIDs.

Conclusion: In conclusion, our study identified common and disease-specific molecular signatures in CIDs. Our findings suggest shared immune dysregulation pathways underlying the pathogenesis of IBD and rheumatoid arthritis, as well as potential commonalities between psoriatic diseases. We show the clear presence of core signatures of disease regardless of disease activity, which could represent insights into actionable targets for causative treatments and better disease control of CIDs.

Introduction: Ulcerative Colitis (UC) is a chronic, idiopathic intestinal inflammatory disease whose diagnosis requires colonoscopy with biopsy. There is an unmet need for sensitive, and easy-to-detect biomarkers helping a rapid and non-invasive diagnosis, and suitable for following disease progression. Extracellular vesicles (EVs) have been proposed as promising carriers of biomarkers. Nevertheless, their plasma levels remain very low and thus difficult to detect.

Aims & Methods: We explored Low-Intensity Pulsed Ultrasound (LIPUS) as a novel and safe approach to enhance the mucosal release of EVs in experimental models of UC. LIPUS was applied at a frequency of 38 kHz and at an intensity of 150 mW/cm^2 for 3 min, using devices dedicated to *in vitro* or *in vivo* studies. Primary intestinal fibroblasts, Human Intestinal microvasculature endothelial cells (HIMEC) and peripheral blood mononuclear cells (PBMC) were isolated from UC patients and healthy volunteers (n=6). Cell viability was tested in Caco-2 and all primary cells using MTT assay. Computer acoustic simulations, allowing a reliable control of the energy dose in the colon, were carried out using k-Wave software to translate in vivo the LIPUS. Acute and chronic colitis models were induced in C57BL/6N mice by administration of dextran sodium sulfate (DSS) respectively 2 and 2.5% *ad libitum* in their drinking water for seven days for the acute and three cycles of DDS for the chronic. Mice were monitored daily for body weight loss, bleeding and stool consistency. EVs were characterized in supernatants, plasma and mucosa at NanoSight and inflammatory mediators detected 1, 2 and 24 h after LIPUS by ELISA assay. A profile of miRNAs was performed by using next generation sequencing. Apoptosis and cell proliferation were evaluated by TUNEL and Ki67 stainings.

Results: After LIPUS, all cells appeared 100% viable and no pro-inflammatory changes were observed. In Caco-2 cells, fibroblasts and HIMEC, LIPUS significantly decreased the levels of IL-8. The maximum release of EVs, range in size from 100 to 120 nm, was recorded after 60 min in resident cells from both UC and healthy-derived cells. Conversely, PBMC displayed a progressive decrease.

In both acute and chronic models, the physiological cellular turnover of the mucosa resulted unchanged after LIPUS. A significative increase of EVs was observed after 2 h of stimulation, and dropped down after 24 h. The

levels of EVs were higher (p<0.01) in the chronic rather than acute phase of colitis. 2 clusters of miRNAs each characterized by 3 and 6 genes were significantly up-regulated by LIPUS after 2 hours in acute and chronic phases respectively.

Conclusion: LIPUS proved to be a safe and non pro-inflammatory approach to boost the release of miRNA cargo packaged in EVs accumulated into the mucosa increasing their levels in the bloodstream. This feature is transient and more evident in the short term. Overall, the LIPUS could pave the way to a new era of a gut disruptive liquid biopsy.

Disclosure: Nothing to disclose.

PP0561

IN A PRECLINICAL MOUSE MODEL OF ULCERATIVE COLITIS, PANCREASTATIN INHIBITION REGULATES COLONIC MUCOSAL BARRIER FUNCTION IN A SEX-DEPENDENT MANNER

D. Tshikudi[1], F. Hesampour[1], J.-E. Ghia[2]
[1]University of Manitoba, Immunology, Winnipeg, Canada, [2]University of Manitoba, Immunology & Internal Medicine, Winnipeg, Canada

Contact E-Mail Address: tshikudi.malu_diane@yahoo.com

Introduction: Ulcerative colitis (UC) is an inflammatory disorder of the colon of unknown aetiology characterised by intestinal barrier dysfunction associated with colonic epithelial goblet cell depletion and a shift in intestinal stem cell retention and function[1,2]. Pancreastatin (PST), an intestinal epithelial cells-derived peptide highly expressed in colonic tissues of patients with active UC, positively correlates with UC early onset, disease severity, and inflammatory markers[3]. However, the effect of PST inhibition on colonic epithelial barrier function remains undetermined.

Aims & Methods: This study aimed to investigate the impact of pancreastatin inhibitor 8 (PSTI8) on colonic epithelial barrier function in a preclinical mouse model of UC. Male and female C57BL/6 mice were treated intrarectally with PSTi8 (2.5mg/mL/kg) or PBS for six days and received 5% dextran sulfate sodium (DSS) to induce colitis or water (control) for five days. The disease activity index (DAI) was assessed daily. ELISA quantified inflammatory cytokines, interleukin (IL)-6, IL-18 and IL-22. Markers to characterise differentiated goblet cells (Mucin, MUC2), transcription factors for goblets' lineage commitment (growth factor independent, GFI1 and Kruppel-like factor, KLF1), and colonic stem cells plasticity (fast-cycling Lgr5, fetal-like Ly6a, and reserve Hopx cells) were quantified via RT-PCR and immunofluorescence.

Results: PSTi8 treatment increased stool consistency (p<0.01) and delayed the onset of bleeding in colitic male mice compared to PBS-treated mice (2-4 days). Conversely, no differences in the DAI were noted between colitic PSTi8 and PBS-treated female mice. In non-colitic conditions, PSTi8 treatment increased (p<0.03) IL-22 in males and decreased (p<0.01) its level in female mice with no effect of IL-6. In colitic conditions, although IL-22 levels were decreased (p<0.01) in female mice and IL-6 levels were increased (p<0.001) in male mice, PSTi8 treatment did not show any effect. Conversely, in colitic females, IL-18 was significantly increased (p<0.02), and PSTi8 abolished that increase. The mRNA expression level of MUC2 remains unaltered in male and female non-colitic and colitic mice treated or not with PSTi8. Yet, immunofluorescence staining in non-colitic and colitic conditions demonstrated a decrease of MUC2 in PSTi8-treated female mice. In concordance, transcription factors KLF1 and GFI1 were significantly increased (p<0.001 and p<0.02, respectively) in colitic female mice, and PSTi8 treatment abolished that increase. No differences were seen in male mice except for a significant increase of KLF1 in PSTi8-treated colitic mice. In colitic conditions, fast-cycling cells marker Lgr5 expression in both sexes was significantly decreased (p<0.0001), and treatment with PSTi8 did not show any effect. However, in colitic male mice, fetal-like stem cells makers Ly6a expression was significantly increased (p<0.007), and PSTi8 treatment significantly decreased (p<0.02) that expression. Although a significant decrease (p<0.0001) of reserve cells marker Hopx was only seen in colitic female mice, PSTi8 treatment did not regulate that marker in male and female mice.

Conclusion: PST inhibition protects male mice from DSS-mediated colitis while exacerbating susceptibility to colitis in female mice. PST inhibition regulates the expansion of goblet and intestinal stem cells in a sex-dependent manner. Further investigation is needed to delineate the signalling pathways involved in PST action on the mucosa in both sexes. Targeting PST may lead to novel therapeutic strategies in UC.

THE EFFECT OF COMMONLY PRESCRIBED MEDICATIONS ON THE TRANSCRIPTOME OF PATIENTS SUFFERING FROM IBD AND OTHER CHRONIC INFLAMMATORY DISEASES

G. Credidio[1], N. Mishra[1], F. Tran[2], K. Aden[3], J. Blase[1], C. Wolff[4], B. Hoyer[4], R. Zeuner[4], W. Lieb[5], S. Schreiber[4], P. Rosenstiel[1]
[1]Kiel University, University Hospital Schleswig-Holstein, Institute of Clinical Molecular Biology (IKMB), Kiel, Germany, [2]University Medical Center Schleswig-Holstein, Campus Kiel, Department of Internal Medicine I, Kiel, Germany, [3]IKMB + First Medical Department, Kiel University, Kiel, Germany, [4]University Hospital Schleswig-Holstein, Department of Internal Medicine I, Kiel, Germany, [5]Kiel University, Institute of Epidemiology, Kiel, Germany

Contact E-Mail Address: n.mishra@ikmb.uni-kiel.de

Introduction: Transcriptomics is a fast-evolving field with translational applications and is broadly used in research. However, gene expression (GE) can be affected by many environmental and biological factors. The effect of commonly prescribed medications on GE is still understudied, especially in the context of a large cohort of chronic inflammatory disease (CIDs) patients. The unravelling of transcriptomic changes induced by therapies used by CIDs patients can further aid in the minimization of disease-unspecific signals and contribute to insights into medications' mechanisms of action and repurposing.

Aims & Methods: The study aimed at the identification of prednisolone (PRED), azathioprine (AZA), and anti-TNF biologics signatures on the transcriptome of patients with inflammatory bowel disease (IBD) and other CIDs. RNA-seq was performed in peripheral blood samples of 625 CIDs patients included in a cross-sectional cohort. CIDs comprised IBD, rheumatoid arthritis, psoriasis, psoriatic arthritis, systemic lupus erythematosus, and arthrosis. Patients using the systemic therapies PRED and AZA, and anti-TNF biologics were compared against patients using no systemic therapies or no biologics, respectively. Linear mixed models were used with sex, age, body mass index (BMI), diagnosis, and C-reactive protein (CRP) as covariates. Differentially expressed genes (DEGs) (q-value < 0.05)

were compared to the overall top 2000 varying genes (TVGs) to investigate how much the medication DEGs contribute to the general variation in gene expression.

Results: PRED investigation with low clinical disease activity patients revealed 224 down and 602 upregulated genes that were among the TVGs. Significantly enriched gene ontology (GO) terms of downregulated genes included adaptive immune response, immunoglobulin production, and B cell proliferation, whereas upregulated genes were related to acute inflammation, innate immune response, and positive NF-κB regulation. The AZA investigation comprised 24 IBD patients using AZA and 103 IBD patients using no systemic therapies, all with low clinical disease activity. Significant GO terms from the 144 downregulated genes part of the TVGs were related to cytokine production, cell proliferation, and T, B, and NK cell activity, whereas GO terms from the 301 upregulated genes included platelet aggregation and erythrocyte development. IBD, T-helper cell differentiation and NK cell-mediated toxicity were among suppressed enriched pathways. Variance partition analysis revealed that 151 genes have AZA as the driver of at least 25% of variation and 70 of those were part of the TVGs. GO terms of the upregulated DEGs in common with TVGs from the anti-TNF analysis were related to B cell and innate immune response activities, whereas the downregulated DEGs terms showed no direct relation to immune processes.

Conclusion: Transcriptomics analysis revealed that AZA and PRED, two commonly prescribed therapies to treat CID, modulate the expression of genes that contribute to the overall variation in gene expression and are potentially involved in other gene expression analyses. We suggest that the use of these medications should be considered when performing other transcriptomic analysis on blood samples from CID patients.

Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel disease (IBD) constitutes a group of chronic and relapsing idiopathic inflammatory disorder of the intestine that includes Crohn's disease (CD) and ulcerative colitis (UC). Both diseases characterized by a cyclical nature alternating between active and quiescent states, that markedly diminish physical functioning and quality of life in patients.

Our previous study have indicated that exercise of moderate intensity can be recommended as the alternative therapy in prevention and healing of experimental colitis in obese mice.

Aims & Methods: The intestinal alkaline phosphatase (IAP) is an important apical brush border enzyme, released from cells walls during stressful events maintains tight junction and barrier integrity It remains unknown, whether IAP treatment besides its protective action against colitis, can influence the gene expression of proinflammatory genes in adipose tissue, liver and skeletal muscle of obese mice forced to exercise on treadmill. In this study two major series of C57BL/6 male mice were fed ad libitum high fat diet (HFD, 70% energy from fat, series A) or standard diet (SD,10% energy from fat, series B) (Altromin, Lage, Germany) for 12 weeks and subjected to forced treadmill exercise (15 min/day, 6 wks., Panlab, Harvard Apparatus, MA, USA) with or without the intragastric treatment with AP (200 U/day) and trinitrobenzene sulfonic acid (TNBS) colitis was induced. Following colitis, the colonic blood flow (CBF) was examined by Laser Doppler flowmetry, the disease activity index (DAI) as well as histology of intestinal mucosa were determined. The biopsy samples of abdominal fat, liver and skeletal muscle were excised, and shock frozen in liquid nitrogen for determination of the gene expression of antioxidative enzymes SOD, GPx and fat biomarkers leptin and adiponectin as well as proinflammatory biomarkers IL-1β, IL-6, TNF-α, HIF-1α and iNOS by qPCR.

Results: In obese mice the DAI was significantly increased and a significant fall in CBF as compared with sedentary SD fed mice ($P<0.05$). Treadmill exercise exacerbated the DAI activity in obese mice and decreased CBF vs. SD fed mice ($P< 0.05$), and this effect was significantly inhibited by treatment with IAP ($P< 0.05$). In fat tissue and liver of obese mice, the adiponectin mRNA expression was downregulated, while the mRNA leptin expression being upregulated ($p<0.05$), and this ratio in expression of these factors was restored by IAP. In the skeletal muscle, the mRNA expression ratio of adiponectin to leptin remained unchanged. The SOD and GPx mRNA expression was unchanged in the liver, while the mRNA expression of proinflammatory markers HIF-1α, TNF-α and IL-1β was significantly increased ($P< 0.05$) in all tissues collected from the high fat diet fed mice forced to exercise as compared to SD animals. The treatment with IAP significantly reduced the expression of these markers in liver, skeletal muscle, and adipose abdominal tissue.($p<0.05$).

Conclusion: We conclude that forced treadmill exercise not only exacerbates the severity of colonic damage and diminishes the colonic blood flow in obese mice but also exerts deleterious effect as manifested by the increased expression of local proinflammatory biomarkers in fat, liver, and skeletal muscle. IAP downregulates gene expression of proinflammatory biomarkers and deserves an attention as may exert the multi-organ protective activity in the treatment of IBD in humans.

Supported by National Science Centre (NCN) within the framework of project grant (UMO-2015/19/B/NZ4/03130) and grant from UJCM, No.: N41/DBS/000783.

LACTOBACILLUS REUTERI ALLEVIATES GUT INFLAMMATION-INDUCED BONE LOSS IN INFLAMMATORY BOWEL DISEASE THROUGH MODULATING EPITHELIAL BARRIER AND OSTEOCLAST FUNCTION

L. Liu[1]

[1]Shenzhen Hospital, Southern Medical University, Shenzhen, China

Contact E-Mail Address: 13246837972@163.com

Introduction: The inflammatory bowel disease (IBD) can affect the systemic metabolism of patients, and the majority of patients also suffer from bone loss and osteoporosis[1·2].

However, research into the pathogenesis and treatment of bone diseases associated with IBD is sluggish. The gut microbe-bone axis has emerged as a key regulator of bone homeostasis, and mucosal damage-induced bone loss is closely linked to an altered microbiome[3·4].

However, the underlying mechanisms continue to be unknown.

Aims & Methods: This study examined the effects of gut microbes on bone loss associated with IBD in mice, delineating the underlying mechanisms responsible for the beneficial effects, with a focus on the gut barrier and osteoclast reprogramming.

16s rDNA sequencing was conducted on fecal samples collected from IBD patients with osteoporosis (IBDO) and those with normal bone mass (IBDN). Then, using a chronic colitis mouse model induced by dextran sulfate sodium (DSS), we performed fecal microbiota transplantation (FMT) and *Lactobacillus reuteri* (L.reuteri) gavage colonization. The micro-CT was used to assess the bone mass and microarchitecture of mice. *In-vivo* imaging, immunofluorescence, histological examination, flow cytometry, scRNA-seq and western blot were used to determine intestinal permeability, pro-osteoclastic cytokine expression, osteogenic and osteoclastic activity. Furthermore, RAW264.7 was used to induce osteoclast differentiation under various conditions.

Results: According to 16S rDNA gene sequencing, gut microbiota in the IBDO group had a considerably lower amount of the genus Lactobacillus than that in the IBDN group. In animal experiments, mice in the DSS-induced chronic IBD model group lost significantly more weight and had a higher disease activity index, as well as lower bone mass, as evidenced by lower bone volume fraction, trabecular number and thickness, and higher trabecular separation, bone surface/bone volume ratio. The detrimental effects of IBDO-derived FMT on epithelial barrier damage, excessive osteoclastogenesis and bone loss were reversed by IBDN-derived FMT and L.reuteri gavage. As for the mechanism, high fluorescent signals detected in the femur and tibia of mice orally or intravenously administered with the DIL-labeled extracellular vesicles secreted from L.reuteri (LREVs) revealed that LREVs could translocate into the mice bone tissues, inhibiting local pro-inflammatory responses and osteoclast activity. Moreover, LREVs-treated colitis mice kept their bone volume relatively higher than controls. *In vitro*, LREVs surpressed RANKL-induced osteoclastogenesis in a concentration-dependent approach. And the results of an investigation on the transmission of signals within cells showed that LREVs inhibited ERK/JNK signaling, which led to a reduction in the formation of osteoclasts. The protective effects of L.reuteri and LREVs on bone mass were also linked to their control of intestinal permeability and up-regulation of tight junction protein expression (ZO-1,claudin-1 and Occludin).

Conclusion: Through the gut microbiota-bone axis, L. reuteri and LREVs may act as a safe and effective therapeutic agent or target for IBD-related bone diseases.

Introduction: Diagnosis of ulcerative colitis with IBS-like disorders presents significant difficulties for practitioners.

Aims & Methods: Objective - to study the possibilities of electromyography (EMG) for the diagnosis of ulcerative colitis (UC) with IBS-like disorders.

Materials and methods. 134 patients were examined and divided into three groups: group 1 - 56 patients with IBS-diarrhea (IBS-D). The diagnosis met the Rome IV criteria.

group 2 - 48 patients with UC in remission, confirmed by laboratory, endoscopic and morphological methods of research were on maintenance therapy with mesalazine preparations. Clinically noted diarrhea up to 4±1 times a day, without pathological impurities, pain before defecation, Mayo index 0 ;

Group 3 comparison - 30 volunteers without diseases of the digestive system. Colon electromyography (EMG) was used as a research method, which was recorded on a Nihon Kohen polygraph (Japan). Statistical analysis was performed using the Statistica 12 program (StatSoft Inc., USA), the significance level was $p < 0.05$.

Results: Results. With EMG in patients of the first group (IBS-D), the frequency of slow waves was 12.2 ± 2.7 / min (103.3%, $p < 0.001$), the frequency of spikes was 5.0 ± 0.2 / 100 slow waves (400 .1%, $p < 0.001$) and propulsive activity 18.4 ± 1.8/min (206.6% $p < 0.001$), which corresponded to the presence of hypermotor dyskinesia with a pronounced spastic component, which indicated a pronounced excitation of the neurons of the Meisner and Auerbach nerve plexuses.

In patients of the second group with UC in remission, the frequency of slow waves was 9.0 ± 0.3 / min (50.%, $P < 0.05$) and the spike frequency was 1.8 ± 0.3 / 100 slow waves (80%, $P < 0.05$), propulsive activity 15 ± 1./ min (150%, $p < 0.002$), which corresponds to the presence of hypermotor dyskinesia with a spastic component.

In patients of the third group (volunteers), the motility of the left sections of the colon corresponds to normal values, the frequency of slow waves was 6 ± 0.3 / min ($p > 0.1$), the frequency of spikes was 1.0 ± 0.1/100 slow waves ($p > 0.1$, propulsive activity -6, ± 0.1 ($P > 0.1$).

Conclusion: Conclusion. In all patients with UC in remission and with IBS-like disorders, the identified violation of the motor activity of the left sections of the colon corresponded to the disorders observed in functional bowel diseases. The data obtained served as the basis for the appointment of myotropic antispasmodics, EMG is an additional method for diagnosing UC with IBS-like disorders. IBS-like syndrome in UC is characterized by mild hypermotor dyskinesia with moderate spastic activity of the colon.

Introduction: Inflammatory bowel disease (IBD) is a chronic condition of the gastrointestinal tract. Around 20% of patients develop at least one extraintestinal manifestation, the most frequent being articular, followed by cutaneous, ocular and hepatobiliary. Among those involving the skin, erythema nodosum (EN) and pyoderma gangrenosum (PG) are frequently observed.

Aims & Methods: Our aim was to describe the characteristics of PG and EN in both ulcerative colitis (UC) and Crohn's disease (CD), and provide a detailed description of their treatment, prognosis and their impact on IBD management. This was a retrospective, multicenter study including all patients with a diagnosis of EN or PG between January 2013 and February 2023. Patients were identified from the ENEIDA registry, a prospectively-maintained database supported by GETECCU. Demographic and clinical characteristics (subtype, date of diagnosis, number of cutaneous lesions, distribution, and location), along with therapeutic requirements and prognosis were registered. Descriptive statistics were used, followed by non-parametric comparisons by chi-square tests.

Results: A total of 542 patients (401 with EN and 141 with PG) fulfilled the inclusion criteria among 52,555 IBD patients included in the ENEIDA registry at the time of data extraction.

EN was predominantly observed in women (77%), with a mean age of 47 years (SD 15) and CD (76%). It was mostly located in the lower limbs (97%), followed by upper limbs (9%); lesions were frequently multiple (75%) and bilateral (65%). EN modified the management of IBD in 18% of cases. Steroids were the most frequently used drugs (73% oral, 17% topical, 13% iv); 18% of patients were treated with biologicals, mostly anti-TNF agents. After 8 weeks of diagnosis, partial response was observed in 19% of patients, and remission in 77%. Recurrence rate of EN was 21%, with 60% of patients developing multiple episodes.

PG was mainly seen in women (60%), with a mean age 52 years (SD 14) and UC (52%). It was usually located in the lower limbs (75%), but it was also observed in arms, thorax or periostomal (12-13%). The most common type was classic (77%), followed by pustular (19%). Multiple lesions were observed in 56% of patients and unilateral distribution in 62%. PG modified the management of IBD in 29% of cases. Oral steroids were commonly used (54%), followed by biological agents (38%), oral antibiotics (27%), and cyclosporin (18%). PG modified the management of IBD in 29% of cases. After 8 weeks of diagnosis, 49% of patients showed partial response and 43% achieved complete remission. Recurrence rate of PG was 21%, with 55% of them developing multiple episodes.

Conclusion: Up to 1% of patients in the ENEIDA registry developed EN and/or PG. They are usually located in the lower limbs and with multiple lesions. Steroids are the mainstay of their treatment, being anti-TNF the main biological agents. These cutaneous manifestations modify the clinical management of IBD in 21% of cases. Clinical remission rates are higher in EN than in PG, although recurrence occurs in one fifth of patients.

Introduction: The pathogenesis of IBD is precipitated by a complex interaction of genetic and environmental factors.[1] Changes in genetic susceptibility in the population alone cannot explain the sharp increase in the incidence of IBD during the last decades, and interaction with environmental factors is suggested to play an important role in the development of IBD.[2,3] Data from population-based studies investigating trends in environmental factors associated with inflammatory bowel disease (IBD) is lacking.
Aims & Methods: We aimed to assess long-term time trends of environmental and socioeconomic factors in IBD patients from a well-defined population-based cohort from Veszprem, Hungary.
Patients were included between January 1, 1977, and December 31, 2020. Trends of environmental and socioeconomic factors were evaluated in three periods based on the decade of diagnosis, representing different therapeutic eras: cohort-A,1977-1995; cohort-B,1996-2008(immunomodulator era); and cohort-C,2009-2020 (biological era).
Results: A total of 2,240 incident patients with IBD were included [UC 61.2%, male 51.2%, the median age at diagnosis: 35 years (IQR29-49)]. There was no significant difference in the proportion of patients with a positive familial anamnesis of IBD amongst the three cohorts in both UC (p=0.584) and CD (p=0.246). Rates of active smoking significantly decreased over time in CD;60.2%,49.9%, and 38.6% in cohorts A/B/C (p<0.001). In UC, the rates were low and stable;15.4%,15.4%, and 14.5% in cohorts A/B/C(p=0.981). Oral contraceptive use was more common in CD compared to UC (25.0% vs. 11.6%,p<0.001). In UC, the prevalence of appendectomy before diagnosis decreased over time;6.4%,5.5%, and 2.3% in cohorts A/B/C(p=0.013). No significant changes were found in the socio-geographic characteristics of the IBD population [urban living: UC;59.8%/64.8%/62.5% (p=0.309) and CD; 62.5%/62.0%/59.0%(p=0.636), in cohorts A/B/C]. A greater percentage of patients had completed secondary school as the highest education level in the latter cohorts in both UC(42.9%/50.2%51.6%,p<0.001) and CD (49.2%/51.7%/59.5%,p=0.002) and a higher percentage of skilled workers (34.4%/36.2%/38.9%,p=0.027) were found in UC, but not CD(p=0.454). (Table 1)
Conclusion: The association between trends of known environmental factors and IBD is complex. Smoking has become less prevalent in CD, but no other major changes occurred in socioeconomic factors over the last four decades that could explain the sharp increase in IBD incidence.

BURDEN OF PERIANAL DISEASE AND PERIANAL SURGERY IN CROHN'S DISEASE OVER DIFFERENT THERAPEUTIC ERAS – A POPULATION-BASED STUDY FROM WESTERN HUNGARY BETWEEN 1977–2020, DATA FROM THE VESZPREM COUNTY COHORT

L. Gonczi[1], L. Lakatos[2], P.A. Golovics[3], T. Pandur[4], G. Dávid[2], Z. Erdelyi[2], I. Szita[2], P.L. Lakatos[5]

Introduction: Few population-based studies have investigated rates and management of perianal disease and long-term perianal surgery rates in Crohn's disease (CD). The present study is a continuation of the Veszprem IBD population based cohort with a follow-up osince 1977.

Aims & Methods: Our aim was to analyze the long-term rates of perianal surgical procedures over different therapeutic eras in a prospective population-based database from Veszprem Province, including incident CD patients. Patient inclusion was between January 1, 1977 and December 31, 2018; follow-up ended December 31, 2020. Both in-hospital and outpatient records were collected. Perianal surgical procedure was defined as any perianal surgical procedure including fistulotomy, abscess drainage or seton placement. Surgery rates were examined in three different eras based on time of diagnosis: cohort-A, 1977-1995; cohort-B, 1996-2008; and cohort-C, 2009-2018.

Results: Data of 946 incident CD patients were analyzed (male/female: 496/450; median age at diagnosis: 28 years(y) [IQR: 22-40]). Median follow-up time for the entire cohort was 15 years (IQR: 9-21). Perianal disease at diagnosis was present in 17.4% (n=165) of the total cohort, and in 24.7%/ 18.5%/ 13.2% in cohorts A/B/C, respectively. By the end of follow-up, an additional 9.3% (n=88) of the total cohort developed perianal disease.

Cumulative immunosuppressive and biologic therapy exposure increased by time. Cumulative probability of biological therapy after diagnosis in patients with perianal disease was 0.0±0% / 15.1±3.2% / 42.5±6.2% at 5 years after diagnosis between cohorts A/B/C. Biologic use was higher in patients with perianal disease compared to the overall population. [pLogRank<0.001]. The overall rate of perianal surgical procedures was 44.7% (113/253) in patients with perianal disease during the total follow-up.

The cumulative probability of perianal surgical procedure in patients with perianal disease was 28.3±2.9% after 10 years, 41.0±3.5% after 20 years, and 64.1±5.1% after 30 years. No statistically significant differences have been observed in the cumulative probability of perianal intervention between cohorts A/B/C: 24.2±5.4%/ 19.9±3.5%/ 29.4±5.8% after 5 years; 33.9±6.0%/ 23.6±3.8%/ 31.7±6.1% after 10 years; [pLogRank=0.594]. Cox-regression multivariate analysis showed that stenosing or penetrating disease (B2/B3) behavior (HR 1.81; 95%CI 1.19-2.75; p=0.005) was independent predictor of perianal surgical procedure. *Table 1.*

Conclusion: The burden of perianal disease and perianal surgical interventions was high in this cohort. Patients with perianal CD had higher exposure to biologicals.

No difference was observed in perianal surgical intervention rates despite the increasing use of immunosuppressives and biologicals over time, however these procedures may partly represent a medical decision and the complex management of perianal disease.

Disclosure: Nothing to disclose.

Factor variable	Multivariate HR	(95% CI)	p-valve
Era of diagnosis (cohort A / B / C)	-	-	0.357

Introduction: Few population-based studies have investigated the long-term surgery rates of Crohn's disease (CD). The present study is a continuation of the Veszprem IBD population based cohort with a follow-up since 1977.

Aims & Methods: Our aim was to analyze the long-term disease course and surgery rates over different therapeutic eras in a prospective population-based database from Veszprem Province, including incident CD patients. Patient inclusion was between January 1, 1977 and December 31, 2018; follow-up ended December 31, 2020. Both in-hospital and outpatient records were collected and comprehensively reviewed at diagnosis and during clinical follow-up. Immunomodulators became widespread in Hungary from the mid-1990s, while biological therapies have been covered by the National Health Insurance Fund since 2008. Surgery rates were examined in three different eras based on time of diagnosis: cohort-A, 1977-1995; cohort-B, 1996-2008; and cohort-C, 2009-2018.

Results: Data of 946 incident CD patients were analyzed (male/female: 496/450; median age at diagnosis:28 years(y) [IQR: 22-40]), with a median of 15y(IQR 9-21) follow-up. Overall immunosuppressive therapy use was increasing by time (48.0%/62.4%/65.5%), as well as the probability of biological therapy initiation within 5 years of diagnosis (0.0±0%/7.3±1.2%/22.7±2.2%) in cohorts A/B/C. The probability of disease behavior progression from luminal (B1) disease to stenosing or penetrating phenotype (B2/B3) was significantly decreasing (27.1±SD5.3%/ 21.5±2.5%/11.3±2.2% in cohorts A/B/C after 5 years [pLogRank<0.001]). The probability of first resective surgery between cohorts A/B/C were 33.3±3.8%/26.5±2.1%/28.1±2.4% after 5 years; 46.1±4.1%/32.6±2.2%/33.0±2.7% after 10 years; and 59.1±4.0%/41.4±2.6% (cohorts A/B) after 20 years. There was a significant decrease in surgery risk between cohorts A and B [pLog Rank=0.002]. Surgery risk remained similar between cohorts B and C [pLog Rank=0.665]. The cumulative probability of re-resection in cohorts A/B/C was also decreasing (17.3±4.1%/12.6±2.6%/4.7±2.0% after 5 years [pLog Rank=0.001]). A cox-regression multivariate analysis showed that stenosing or penetrating

disease (B2/B3) behavior (HR 4.52; 95%CI 3.60-5.68; p<0.001) and ileal (L1) location at diagnosis (HR 1.30; 95%CI 1.05-1.61; p=0.016) were independent predictors of resective surgery. *Table 1.*

Factor variable	Multivariate HR	(95% CI)	p-valve
Resective surgery			
Era of diagnosis (cohort A / B / C)	-	-	0.889
Male gender	1.09	0.89-1.33	0.414
Complex (B2 or B3) behavior at diagnosis	4.52	3.60-5.68	<0.001
Ileal (L1) location at diagnosis	1.30	1.05-1.61	0.016
Perianal manifestation at diagnosis	1.24	0.96-1.59	0.099
Smoking history	1.11	0.90-1.36	0.326

Table 1. Predictive factors for first resective surgery in incident CD patients diagnosed between 1977 and 2018 – Cox-regression analysis.

Conclusion: We report a gradual decline in reoperation rates and disease behavior progression in CD over time with the lowest values in the biological era. In contrast, there was no further decrease in the probability of first major resective surgery after the immunosuppressive era.
Disclosure: Nothing to disclose.

Introduction: The number of epidemiological population-based studies on unclassified inflammatory bowel disease (IBD-U) patients are very limited. The present study is a continuation of the Veszprem IBD population based cohort with a follow-up of the incidence and disease course of IBD-U since 1977.
Aims & Methods: Our aim was to evaluate incidence, prevalence, disease course, time to biological therapy and surgery rates in a prospective population-based database of incident IBD-U patients diagnosed between 1977 and 2018, with follow-up until 2020. Both in-hospital and outpatient records were collected. The source of age- and gender-specific demographic data was derived from the Hungarian Central Statistical Office. Medical therapy, time to first biological therapy, disease progression, and colectomy was registered.
Results: Data of 119 incident IBD-U patients were analyzed (male/female: 55/64; median age at diagnosis: 34 years(y) (IQR: 24-47)). Adjusted mean incidence rate was 0.76 (CI95%: 0.63-0.9) /10^5 person-years in the total study period, and 0.96 (CI95%: 0.79-1.16) /10^5 person-years between 1990-2018. Disease extent at diagnosis was proctitis in 7.6%, one-sided colitis (left-sided colitis, or isolated right-sided colitis) in 36.1%, and extensive (pancolitis) in 56.3%. The probability of progression in colonic disease extent was 6.7% (SE:2.3) at 3 years, 10.3% (SE:2.8) at 5 years and 15.3% (SE:3.4) at 10 years. The probability of developing terminal ileitis, thus disease classification change – Crohn's disease was 2.6% (SE:1.5) at 5 years and 3.5% (SE:1.7) at 10 years. Perianal disease developed in 5% (n=6) of all patients during the total follow-up. The probability of receiving biological therapy in patients diagnosed after the year 2000 (n=62), was 15.5% (SE:4.8) at 5 years, and 19.4% (SE:5.3) at 10 years. The overall resective surgery rate was 16.8% at the end of follow-up. Segment resection was performed in 5.0% of the patients, and 11.8% underwent subtotal- or total colectomy. The cumulative probability of resective surgery was 7.6% (SE:2.4) at 1 year, 9.3% (SE:2.7) at 5 years, 13.5% (SE:3.3) at 10 years, and 18.5% (SE:3.9) at 20 years.
Conclusion: Initial disease phenotype was severe in most cases of IBD-U and colonic progression is substantial over time. Disease classification change to Crohn's disease with development of terminal ileitis or perianal disease was low. High rates of biological therapy and surgery are suggestive of a severe disease course of IBD-U.
Disclosure: Nothing to disclose.

Contact E-Mail Address: martavernero@gmail.com
Introduction: Being two immune-mediated diseases (IMIDs), the association between multiple sclerosis (MS) and inflammatory bowel disease (IBD) is plausible, but data in the literature are conflicting.
Aims & Methods: The aim of our study was to evaluate the possible association between IBD and MS in a cohort of patients with IBD.
Results: In a retrospective study, we examined the medical records of 5,739 patients with a confirmed diagnosis of IBD followed in our clinic between 1978 and 2022.
Among these patients, we identified 14 with MS, with a prevalence of 0.24%. The reported prevalence of MS in general population in northern Italy in 2021 was 0.18% (P = 0.24). For each of the patients with MS identified, more than ten patients without MS were analyzed. The 14 MS cases were then compared with 342 controls. From the 14 MS patients, 12 (85.7%) were female and 2 (14.3%) were male, while in the control group, 158 (46.2%) were female and 184 (53.8%) were male (P = 0.004). As for therapy, significant differences were found on mesalazine (5 (41.7%) cases vs. 317 (92.7%) controls, P < 0.0001) and anti-TNF treatment (0% cases vs 26.6% controls, P = 0.03, respectively) at the time of MS diagnosis. Moreover, Kaplan-Meier curve analysis showed that the 20-year survival probability was 98.4% for patients with IBD, while for patients diagnosed with MS and IBD it was 82.1% (P = 0.02).
Conclusion: In conclusion, patients with IBD have a similar risk of developing MS compared to the general population, but female sex appears to increase the risk. Indeed, life expectancy at 20 years for patients with IBD and MS is lower than for patients with IBD alone.

Introduction: It is well known that cutaneous lesions may be frequent extraintestinal manifestations of inflammatory bowel diseases (IBD) [1,2]. During literature analysis we found out that there is an obvious lack of epidemiological data regarding this issue.

Aims & Methods: Aim: To establish the prevalence of cutaneous lesions among IBD patients in the university hospital.

Methods: Prospective study included patients with IBD who were managed in the hospital of Lithuanian University of Health Sciences. Patients completed questionnaires including the demographic and IBD data and history or present state of cutaneous lesions. Cutaneous lesions were considered as related to IBD if they were diagnosed following the diagnosis of IBD. Skin lesions which were reported before the diagnosis of IBD were considered as not related to IBD.

Results: 162 patients were included in the study, mean age (MA) – 42.5±14.2 years. There were 93 (57.4%) males and 69 (42.6%) females. MA of men – 42.1±14.4, women – 42.9±14.0 years, p>0.05. Ulcerative colitis (UC) was diagnosed in 117 (72.2%) patients, Crohn's disease (CD) – in 45 (27.8%) patients. MA of UC patients was 43.1±14.0, CD – 40.9±14.9, p>0.05. In total, skin lesions were indicated by 66 (40.7%) subjects. According to our criteria, in 47 (29%; 95% CI: 22.0-36.1%) cases, cutaneous lesions were considered as obviously related to IBD. We further analyzed the latter cases.

Among UC patients, 35 (29.9%; 95% CI: 21.5-38.3%) had skin lesions related to IBD, among CD patients – 12 (26.7%; 95% CI: 13.2-40.1%), p>0.05. Erythema nodosum was reported by 6 (3.7%) patients, pyoderma gangrenosum – 6 (3.7%), acne – 2 (1.2%), psoriasis – 10 (6.2%), vitiligo – 2 (1.2%), epidermolysis bullosa acquisita – 1 (0.6%), hemorrhagic vasculitis – 1 (0.6%), eczema – 11 (6.8%), allergic rash – 5 (3.1%), other (unspecified) – 8 (4.9%).

The detailed comparison of different skin lesions among UC and CD patients is presented in table 1.

Cutaneous lesions	Ulcerative colitis (N=117) n (%)	Crohn's disease (N=45) n (%)	p-value
Erythema nodosum	3 (2.6%)	3 (6.7%)	>0.05
Pyoderma gangrenosum	5 (4.3%)	1 (2.2%)	>0.05
Acne	1 (0.9%)	1 (2.2%)	>0.05
Psoriasis	8 (6.8%)	2 (4.4%)	>0.05
Vitiligo	2 (1.7%)	0 (0%)	>0.05
Epidermolysis bullosa acquisita	1 (0.9%)	0 (0%)	>0.05
Vasculitis	1 (0.9%)	0 (0%)	>0.05
Eczema	9 (7.7%)	2 (4.4%)	>0.05
Allergic rash	4 (3.4%)	1 (2.2%)	>0.05

Table 1. Prevalence of cutaneous lesions among patients with ulcerative colitis and Crohn's disease.

Among UC patients, cutaneous lesions were reported by 2 out of 17 (11.8%) subjects with proctitis, 7 out of 30 (23.3%) subjects with left-sided colitis and 27 out of 70 (38.6%) subjects with pancolitis, p<0.05 between proctitis and pancolitis.

Comparing different types of CD, skin lesions were indicated by 2 out of 17 (11.8%) patients with ileitis, 4 out of 11 (36.4%) patients with colitis and 6 out of 17 (35.3%) patients with ileocolitis; p>0.05.

Conclusion: In our study the prevalence of cutaneous lesions among IBD patients is 29%. There were no differences in the prevalence of skin lesions between the UC and CD patients. The most common cutaneous lesions in UC were skin eczema and psoriasis, in CD – erythema nodosum, psoriasis and eczema. We observed the obvious trend of more frequent skin lesions in patients with more extensive UC. There is also the trend for more frequent skin lesions in Crohn's disease patients with colonic damage.

Introduction: Most of the data concerning the epidemiology of inflammatory bowel disease (IBD) in Asia originated from the Eastern population and there are limited studies conducted in the Middle East. We aimed to describe the clinical phenotype, disease course, and medication usage of IBD cases from Iran in the middle east.

Aims & Methods: We conducted a cross-sectional study of registered IBD patients in the Iranian Registry of Crohn's and Colitis (IRCC) recruited from 2017 until 2022. IRCC is a nationwide registry with at least one center in every province of Iran.[1] More than 400 gastroenterologists collaborated with IRCC, which was reported as approximately 87% of total gastroenterologists working in Iran. Demographics characteristics, past medical history, family history of IBD, disease extent and location, clinical behavior, extraintestinal manifestations, IBD medications, IBD activity using the IBD-control-8 questionnaire and the Manitoba IBD index, admissions in the past 3 months, emergency visits in the past 12 months, history of colon cancer, and IBD-related surgeries were gathered.

Results: Overall, 9746 patients with confirmed IBD, including 7793 patients with ulcerative colitis (UC) and 1953 patients with Crohn's disease (CD) were reported. The ratio of UC to CD patients was 3.99. The median age at diagnosis was 29.2 (IQR: 22.6,37.6) and 27.6 (IQR: 20.6,37.6) for patients with UC and CD, respectively. 17.9% of patients with UC had a positive family history. Majority of patients with UC had pancolitis (47%). The most common treatment received by patients was 5-ASA (93.5%) followed by immunomodulator, prednisolone, and anti-TNF. Among patients who received immunomodulators, 96.2% was azathioprine followed by 6-mercaptopurine (2.8%) and methotrexate (1%). Of patients who used anti-TNF, 68.8% were adalimumab and 31.2% were infliximab. Among patients with CD, only one peak was observed in the distribution of age at diagnosis at 30-40 years. Male to female ratio was 1.28 in patients with CD. Patients with CD most commonly had ileocolonic involvement (43.7%) and stricturing behavior prevalence was 4.6%. Moreover, 38.4% of patients with CD had been treated with anti-TNF. Among patients who received immunomodulators, 90.4% was azathioprine followed by 6-mercaptopurine (4.6%) and methotrexate (5%). Of patients who used anti-TNF, 71.9% were adalimumab and 28.1% were infliximab.

Variables	IBD	
	UC (N=7793)	CD (N=1953)
Extra Intestinal Manifestations, n (%)	408(5.2)	70(3.6)
Active disease during the past 2 weeks, n (%)	4966(63.7)	1088(55.7)
Active disease during 6 months, n (%)	1359(17.4)	493(25.2)
ER visits in the past 12 months, n (%)	986(12.7)	276(13.1)
Admissions in the past 3 months, n (%)	778(10.0)	299(15.3)
History of colon cancer, n (%)	21(0.3)	10(0.5)
IBD-related surgeries, n (%)	209(2.7)	278(14.2)

Conclusion: This first report of IBD behavior, clinical outcome, and medication usage from the Iranian Registry of Crohn's and Colitis as a representative population of the Middle East highlights the differences in IBD characteristics based on geographical location.

EXPLAINABLE ARTIFICIAL INTELLIGENCE PREDICTING REFRACTORY ULCERATIVE COLITIS AT FIRST VISIT: ANALYSIS OF A JAPANESE NATIONAL DATABASE FROM BEFORE THE SPREAD OF BIOLOGICS

Y. Kanatani[1], S. Nemoto[2], M. Sano[3], M. Kaneko[3], M. Hirai[3], T. Ueda[3], H. Suzuki[3]

Introduction: In Japan, the Ministry of Health, Labor, and Welfare (MHLW) registered all patients with ulcerative colitis (UC) from 2003 to 2014, and real-world data (RWD) are available in a national database. Deep learning models have been used to analyse RWD, but visualising the relationship between outcomes and explanatory variables is difficult.

Aims & Methods: Therefore, in this study, we used explainable artificial intelligence (AI) to calculate the regression coefficient for each parameter to determine the explanatory variables involved in steroid-resistant UC and constructed a model to predict steroid-resistant UC at the time of a patient's first visit. We obtained data on all patients with UC newly registered in the MHLW database between 2003 and 2011 (before the spread of biologics in Japan). Of the 79,096 patients identified, 4,003 who had three years of data, a Mayo score of 3 or higher at the first visit, and who had been using steroids from the time of the first visit were included in the analysis. For explainable AI, a point-wise linear model (PWL) was used to generate a custom-made logistic regression model for each case. Clustering analysis was performed based on the similarity of the coefficients (weights) of these logistic regression models. Finally, the association with outcomes was evaluated by analysing the weights of factors with a significant difference ($p<0.01$) between the clusters.

Results: The area under the curve (AUC) of the PWL model was 0.628 for the training set and 0.627 for the test set. The likelihood ratio was 1.36. By clustering, the analysed population was classified into two groups (S group, predicted to be in remission after three years: 2,040 cases; R group, predicted not to be in remission: 1,963 cases). In both groups, female sex (R group: median weight 0.0027), positive stool culture (R group: median weight 0.0041), and colonic mucosal abnormalities (R group: median weight 0.0113) had a strong relationship with steroid resistance. The R group tended to have significantly higher frequencies than the S group. In the R group, pseudopolyposis (median weight = 0.0351), caecal lesions (median weight = 0.024), CRP (median weight = 0.0163), ascending colon lesions (median weight = 0.0133), and transverse colon lesions (median weight = 0.0107) were observed. Conversely, the white blood cell count (S -0.0021 vs R -0.0037), frequency of defecation (S -0.0053 vs R -0.0055), bloody stool (S -0.0021 vs R -0.0016), stool form (S -0.0347 vs R -0.0367), and abdominal pain (S -0.0291 vs R -0.0383) were not significantly related to steroid resistance in both groups.

Conclusion: Explainable AI in a national database with three years of records allowed us to build a predictive model for refractory UC. Female sex, positive faecal bacterial cultures, colonic mucosal abnormalities, and lesions extending into the right colon were important predictors of steroid resistance. Understanding the predictors of steroid resistance and dependence at the time of steroid introduction, based on national data before the spread of biologics, can facilitate prompt and timely treatment plans for patients with UC.

OBSTRUCTIVE LUNG DISEASE IN INFLAMMATORY BOWEL DISEASE: A NATIONWIDE COHORT STUDY

H. Albæk Jacobsen[1,2], A. Karachalia Sandri[2], U. Møller Weinreich[3,4], T. Jess[1,2], L. Larsen[1,2]

[1]Aalborg University Hospital, Department of Gastroenterology and Hepatology, Aalborg, Denmark, [2]Center for Molecular Prediction of Inflammatory Bowel Disease, PREDICT, Department of Clinical Medicine, Aalborg University, Copenhagen, Denmark, [3]Aalborg University Hospital, Department of Respiratory Diseases, Aalborg, Denmark, [4]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark

Contact E-Mail Address: henrik.jacobsen@rn.dk

Introduction: Prior research has established an association between inflammatory bowel disease (IBD) and obstructive lung diseases (OLD), such as asthma, bronchitis, COPD (chronic obstructive pulmonary disease), and bronchiectasis. Studies have suggested that there may be a bidirectional relationship between IBD and OLD, with patients diagnosed with either condition being more likely to develop the other.[1] While previous studies

have mainly examined the prevalence of this association,[2–4] only two incidence studies have been conducted, both of which focused on the risk of IBD in individuals who were already diagnosed with asthma or COPD.[5,6] Consequently, there is a need for further investigation to determine the risk of disease development in people with IBD.

Aims & Methods: The aim was twofold: firstly, to determine the likelihood of OLD prior to the onset of IBD; and secondly, to evaluate the risk of OLD after the onset of IBD.

The present study employed data from the Danish National Patient Registry and the Danish National Prescription Registry, from January 1, 1999, to December 31, 2018.[7,8] Incident cases of IBD in Denmark from 2003 to 2013 were identified based on relevant International Classification of Diseases, 10th revision (ICD-10) diagnosis codes.[9] A matched population without IBD was included for comparison in a 1:10 ratio. Individuals with OLD were identified based on relevant ICD-10 codes or ATC codes (two on different dates within a year). Additionally, a sensitivity analysis was performed using only ICD-10 codes to estimate the risk of obstructive lung disease.

Logistic regression was applied to estimate the prevalence odds ratio for OLD up to four years before IBD diagnosis/index date. Time-to-event analysis (Cox proportional regression) was then used to explore the risk of OLD. In the sensitivity analyses, the time-to-event analysis was repeated based solely on ICD-10 diagnosis codes.

Results: The total study population consisted of 266,618 individuals: 24,238 with IBD and 242,380 without IBD. Individuals with IBD had a 60% higher likelihood (adjusted odds ratio [aOR]: 1.60, 95% CI: 1.53-1.67) of OLD before diagnosis compared to non-IBD individuals, whereas the risk was over 40% higher after IBD diagnosis. A sensitivity analysis confirmed the elevated risk after IBD diagnosis, with a higher adjusted hazard ratio (aHR) of 1.63 (95% CI: 1.53-1.73).

Conclusion: Our findings suggest a significant bidirectional association between IBD and OLD. We demonstrate in an unprecedented nationwide cohort study, an increased risk of OLD among individuals diagnosed with IBD. Further studies concerning the gut-lung axis are warranted to explore the mechanisms underlying this association.

VACCINATION STATUS AND ATTITUDES TOWARDS VACCINES IN A NATIONAL COHORT OF PATIENTS WITH INFLAMMATORY BOWEL DISEASES

A. Costantino[1,2], M. Vecchi[1,2], M. Michelon[3], D. Noviello[3], S. Leone[4], F. Caprioli[1,2]

[1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Gastroenterology, Milano, Italy, [2]Università degli Studi di Milano, Pathophysiology and Transplantation, Milano, Italy, [3]Università degli Studi di Milano, Milano, Italy, [4]AMICI ITALIA ETS, Milano, Italy

Contact E-Mail Address: andreascostantino@gmail.com

Introduction: Patients with inflammatory bowel diseases (IBD) often require immunosuppressive therapies which may increase the risk of opportunistic infections.[1]

Patients' vaccination status should be investigated at diagnosis and/or before starting any new treatment, and vaccinations against vaccine preventable diseases (VPDs) performed when required.[2]

Nevertheless, vaccination rates in IBD patients are known to be suboptimal and may also be lower than in the general population.[3]

Aims & Methods: The aim of this study was to investigate the vaccination coverage, attitude towards vaccinations, and its possible determinants among a national cohort of IBD patients.

An anonymous web-based questionnaire was sent by the Italian IBD patients' association (AMICI Italia) in February 2021.

The questionnaire consisted of an adapted version of a previously validated questionnaire on vaccine hesitancy [10] and was divided into 2 sections seeking information on: (1) sociodemographic characteristics, lifestyle, and IBD characteristics, (2) attitude towards vaccinations. Patients were asked to self-report their previous vaccinations and their attitudes towards them (with a multiple-choice test), which were defined as opposed to vaccinations, indifferent, or in favor of vaccinations.

The study was approved by the Ethics Committee of AMICI and patients signed a digital informed consent.

Previous vaccination status and patients attitude towards vaccinations were recorded. The factors influencing their attitudes were examined using crude and adjusted odds ratios (AdjORs) with 95% confidence intervals (CIs).

Results: The questionnaire was sent to 4720 patients and had a response rate of 26.5% (1252 patients, 729 women, median age 47.7, interquartile range 37–58, 49% with Crohn's disease, 48.9% with ulcerative colitis) answering from each of the 20 Italian regions. Of note, 46.7% of the patients were in therapy with biological or immunosuppressive drugs.

Patients declared being vaccinated against the following diseases: 74.1% tetanus, 67.7% flu (during last season), 43.3% (measles, mumps, and rubella) MMR, 37.1% hepatitis B (HBV), 29.1% pneumococcus (pneumococcal conjugated 13-valent vaccine, PCV13, or pneumococcal polysaccharide 23-valent vaccine, PPSV23), 20% meningitis, 16% hepatitis A (HAV), 15.3% varicella-zoster virus (VZV), 7.6% human papillomavirus (HPV). Two hundred and fifty-nine (20.7%) did not remember every previous vaccination.

Among the respondents, 1154 (92.2%) stated they wanted to be vaccinated in the future against VPDs. A previous negative experience with vaccinations, whether personal or referred by relatives, was reported by 163 (13.2%) among the 1238 respondents to this question.

One thousand one hundred and twelve (88.8%) stated a positive attitude towards vaccination, 91 (7.3%) were indifferent, 49 (3.9%) reported being opposed to vaccinations; 456 (36.4%) stated that the main reason for vaccination adherence was due to their IBD.

The belief of possible return of VPDs with decline of vaccination coverage rates was the factor related to a positive attitude towards vaccinations was (AdjOR 5.67, 95% CI 3.45-9.30, p-value <0.001).

Conclusion: Despite a general positive attitude towards vaccinations, there is a low vaccination coverage against some VPDs in Italian IBD patients.
This might suggest a possible role of physicians in under-prescribing vaccinations, or a difficulty in organizing them.
This is one of the biggest IBD cohort investigated both for vaccination coverage and hesitancy. These results should inspire to develope specific campaigns aimed to increase vaccination rates.

IRON-DEFICIENCY REFRACTORY ANEMIA (IDRA) IN SARDINIAN INFLAMMATORY BOWEL DISEASE PATIENTS: A LONGITUDINAL OBSERVATIONAL STUDY

A. Favale[1], R. Piras[1], C. Carpineti[1], M. Cadoni[1], S. Paba[1], I. Ibba[1], S. Onali[2], M.C. Fantini[2]
[1]University of Cagliari, Cagliari, Italy, [2]University of Cagliari, Department of System Medicine - Gastroenterology, Monserrato, Italy

Contact E-Mail Address: m.fantini@med.uniroma2.it
Introduction: Anemia represents the most frequent extra-intestinal manifestation of Inflammatory Bowel Disease (IBD) and it is most frequently caused by iron deficiency.
Despite iron replacement therapy, most IBD patients fail to recover from anemia thus contributing to fatigue and reduced quality of life. Many genetic mutations cause iron-deficiency refractory anemia (IDRA), and their frequency in IBD patients remains unknown. Furthermore, the great prevalence of thalassemic trait in Sardinian IBD patients may further complicate the management of anemia in this population.
Aims & Methods: Aim: To describe the prevalence of IDRA-related genetic mutations in Sardinian IBD patients and their role in the management of anemia.
Methods: All IBD patients matching the criteria for the diagnosis of IDRA, according to WHO criteria, and without known causes of anemia other than IBD, were included in the study. Blood analysis to evaluate Hb, MCV, Tsat, MCH, ferritin, serum iron, vitamin D, vitamin B12, folate, CRP and stool analysis for fecal calprotectin were performed at T0, after 4 (T4) and after 8 (T8) weeks. Iron-replacement therapy was given to all patients. All patients were genetically tested for mutations in ABCB7, ALAS2, HSPA9, MPL, TMPRSS6, TRNT1, GLRX5, SLC11A2, SLC19A2, SLC25A38, YARS2, HBA1, HBA2, HBB, PUS1 genes. Therapy response/remission and safety were evaluated at T4 and T8. The presence of genetic mutations and their correlation with therapy response at T8 was evaluated as primary endpoint and analyzed by correlation tests (Chi-squared and Fisher's exact test).
Results: Twenty-two IBD patients matching the inclusion/exclusion criteria were included in the study. At baseline, mean Hb concentration was 10.86 ± 1.18 gr/dL, mean MCV 71.64 ± 9.61 fL, MCH 23.55 ± 3.49, and median ferritin concentration 12.75 ng/ml (range 3.8-93.3). At T8, 19/22 (86%) pts were therapy failure, 3/22 (14%) were
responders, while 8/22 (36%) had anemia resolution. 8/22 (36%) pts carried genetic mutations: 3/22 (13.6%) had single HBB gene mutation, 1/22 (4.54%) single ALAS2, 2/22 (9.09%) double HBA1, 1/22 (4.54%) had both HBA1 and HBB, and 1/22 (4.54%) had both HBA2 and ALAS2 gene mutations. The presence of genetic mutations was significantly correlated to iron-replacement therapy failure at T8 (p=0.0423). No biochemical parameter or clinical disease characteristics were found to be predictors of therapy response through logistic regression analysis. No sides effects were recorded during the study period.
Conclusion: The presence of unknown thalassemic trait and other allele variants involved in iron metabolism may explain the iron-replacement therapy refractoriness in Sardinian IBD patients.
Disclosure: no conflict of interest to declare.

INCREASED RISK OF CIRRHOSIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A DANISH REGISTRY-BASED COHORT STUDY (1998-2018)

P. Deepak[1], S. McHenry[1], M. Zamani[1], A. Karachalia Sandri[2], T. Jess[3]
[1]Washington University in St. Louis, Gastroenterology, St. Louis, United States, [2]Aalborg University, Copenhagen, Denmark, [3]Aalborg University Copenhagen, Center for Molecular Prediction of Inflammatory Bowel Disease, PREDICT; Department Of Clinical Medicine, Hellerup, Denmark

Contact E-Mail Address: deepak.parakkal@wustl.edu
Introduction: Prior studies suggest an increased risk of non-alcoholic fatty liver disease (NAFLD) in patients (pts) with inflammatory bowel disease (IBD). There is no data available on the risk of cirrhosis in IBD. Our aim was to investigate the risk of cirrhosis (compensated or decompensated) in IBD pts compared to a matched non-IBD population in a population-based cohort.
Aims & Methods: A registry-based cohort study was conducted in the Danish health registries (including the pathology register) using data, between (and including) 1998 and 2018. Incident IBD was identified using ICD-8/10 codes for Crohn's disease (CD) or ulcerative colitis (UC), with two IBD registrations up to two years apart, living in Denmark for at least one year prior to their first IBD registration and without a diagnosis of cirrhosis prior to their IBD registrations. Those with IBD were matched 1:10 to non-IBD persons on the basis of sex, age, calendar year, and the municipality of residence. Persons were followed from index date (IBD diagnosis date/matching date) until a diagnosis of cirrhosis (study outcome), death, emigration, or end of follow-up, whichever came first. The diagnosis of cirrhosis, including both compensated and decompensated cirrhosis, and the underlying etiology, were recorded by ICD-8/10 and SNOMED codes. Kaplan-Meier approach was used to calculate the cumulative incidence of cirrhosis and Cox proportional regression analysis to calculate hazard ratios (HRs) with corresponding 95% confidence intervals (CIs) for cirrhosis among pts with IBD, compared to the non-IBD population.
Results: In a study population of 495,220 persons, a total of 2,741 cirrhosis cases were identified (median [IQR] time in years between index date and diagnosis of cirrhosis: 6.3 [3.0-10.7]), with a higher proportion of cases among pts with IBD (N = 45,020) compared to non-IBD persons (0.9% vs. 0.5%, respectively). After adjusting for sex, age, and index year, pts with IBD had a higher risk of cirrhosis, compared to non-IBD persons (adjusted HR (95% CI): 1.84 [1.65 – 2.04]). Cirrhosis was diagnosed on the basis of liver biopsy and/or imaging (ultrasound, CT or MRI) in 77.3% of IBD pts vs. 69.3% of non-IBD persons. The leading etiology of cirrhosis was NAFLD (51.6%) followed by alcohol (39.0%). The risk of cirrhosis among IBD pts (compared to non-IBD persons) was more pronounced among younger persons (adjusted HR (95% CI): 3.08 [2.45-3.87] among ≤ 40 years of age; 1.63 [1.45-1.84] among > 40 years of age, p-value <0.001) and CD pts (adjusted HR (95% CI): 2.20 [1.80-2.67] among CD; 1.72 [1.52-1.95]; among UC, p-value 0.0402). The risk was also consistent across the year of cohort entry (IBD diagnosis year/index year): 1998-2001 (794 events, 1.37 [1.07-

1.66]), 2002-2005 (776 events, 1.98 [1.63-2.40]), 2006-2009 (612 events, 1.94 [1.56-2.41]), 2010-2013 (378 events, 2.01 [1.53-2.64]), 2014-2018 (181 events, 2.89 [2.03-4.10]).

		No. of events	Adjusted HR (95% CI)	p-value
Overall		2,741	1.84 (1.65-2.04)	
IBD type	UC/UC controls	2,033	1.72 (1.52-1.95)	0.04
	CD/CD controls	708	2.20 (1.80-2.67)	
Sex	Female	1,208	1.93 (1.65-2.25)	0.42
	Male	1,533	1.77 (1.53-2.04)	
Age group (in years) at IBD diagnosis/index date	≤ 40	414	3.08 (2.45-3.87)	<.0001
	> 40	2,327	1.63 (1.45-1.84)	

Table. The hazard ratio for cirrhosis in IBD compared to matched controls in Denmark 1998-2018.

Conclusion: IBD pts had a higher incident risk of cirrhosis compared to matched non-IBD persons, especially with age at IBD diagnosis ≤ 40 years and those with CD. These data point towards a need for focused screening for cirrhosis among IBD pts, especially in certain risk groups.
Disclosure: Nothing to disclose.

MICROSCOPIC COLITIS AND RISK OF INCIDENT ACUTE PANCREATITIS: A NATIONWIDE POPULATION-BASED MATCHED COHORT STUDY

D. Bergman[1], B. Roelstraete[1], O. Olén[2], B. Lindkvist[3], J.F. Ludvigsson[4]
[1]Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Solna, Sweden, [2]Karolinska Institutet, Division of Clinical Epidemiology, Department of Medicine Solna, Solna, Sweden, [3]Sahlgrenska University Hospital, Dept. of Medicine, Gothenburg, Sweden, [4]Karolinska Institutet, Medical Epidemiology and Biostatistics, Stockholm, Sweden

Contact E-Mail Address: david.bergman1@gmail.com
Introduction: Several gastrointestinal diseases have been linked to acute pancreatitis, but the risk of acute pancreatitis in microscopic colitis (MC) has not been studied.
Aims & Methods: To assess the risk of acute pancreatitis in patients with MC, we conducted a nationwide, population-based, matched cohort study in Sweden of 12,140 patients with biopsy-verified MC (diagnosed in 2003-2017), 57,806 matched reference individuals, and 12,781 siblings without MC with follow-up until 2021. Data on MC were obtained from all of Sweden's regional pathology registers (n=28) through the ESPRESSO cohort. Data on acute pancreatitis were collected from the National Patient Register. Adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) were calculated using Cox regression.
Results: During a mean follow-up of 9.9 years (SD=4.3), 146 MC patients and 437 reference individuals were diagnosed with acute pancreatitis (127.8 vs. 80.1 per 100,000 person-years), corresponding to an aHR of 1.57 (95%CI=1.30-1.90). Moreover, we found a positive association between MC and acute non-gallstone-related pancreatitis (aHR 1.99 (95%CI=1.57-2.51)), but not with acute gallstone-related pancreatitis (aHR 1.08 (95%CI=0.78-1.49)). Comparing patients with MC to their unaffected siblings yielded an aHR of 1.28 (95%CI=0.92-1.78).
The risk of acute pancreatitis remained elevated also for MC patients with a follow-up exceeding 10 years (aHR 1.75 (95%CI=1.14-2.67)).
Conclusion: This nationwide study of more than 12,000 patients with MC demonstrated an increased risk of acute pancreatitis after MC. Hence, clinicians should have a low threshold for evaluation of acute pancreatitis in patients with MC. Also, these patients should receive advice and care aimed at reducing the risk of acute pancreatitis.

INFLAMMATORY BOWEL DISEASE IN THE LGBTIQ+ POPULATION: ESTIMATES OF PREVALENCE IN ENGLAND & WALES AND THE IMPLICATION FOR SERVICES

M. Colwill[1], K. Patel[1], A. Poullis[1]
[1]St George's Hospital, University of London, Department of Gastroenterology, London, United Kingdom

Contact E-Mail Address: michael.colwill@nhs.net
Introduction: Societal trends in recent decades have led to greater expression and awareness of gender and identity. This was demonstrated by the 2021 census in England and Wales asking, for the first time, whether respondents still identified as the same sex as at their birth. Inflammatory bowel disease (IBD) affects close to 500,000 people in England and Wales and is known to have long term effects on patients' physical, mental and sexual health. However, it's prevalence within the LGBTIQ+ population and the specific service provisions this population requires, given that LGBTIQ+ individuals may have greater psychological needs[1], has not been previously studied.
Aims & Methods: To calculate the prevalence of individuals identifying with LGBTIQ+ and living with IBD within England and Wales, census data for England and Wales from 2021 were analysed to calculate the percentage of population identifying as LGBTIQ+[2]. Data was also collected from the Crohn's and Colitis UK (CCUK) national report 2021 on disease prevalence as well as the provision of psychological support[3].
This data was then cross-referenced with census data to determine the estimated prevalence of LGBTIQ+ people diagnosed with IBD.
Results: 45.7 million census responses were received in 2021 across England and Wales. 262,000 (0.5%) respondents identified as a gender different to their sex at birth. 48,000 (0.10%) identified as a trans man, 48,000 (0.10%) identified as a trans woman, 30,000 (0.06%) identified as non-binary, 118,000 (0.24%) did not give further information regarding their gender and 18,000 (0.04%) provided another response. The highest levels were seen in London (0.46%) and the lowest in Wales (0.14%). 1.5 million (3.2%) people answered as gay, lesbian, bisexual or other sexual orientation with the highest prevalence in London (2.23%) and lowest in the West Midlands and East of England (1.21%). CCUK data suggests 485,000 people suffer from IBD in England and Wales[4].
The calculated number of IBD patients identifying as lesbian, gay, bisexual or other sexual orientation was 15,520 whilst the calculated number identifying as a gender different to their sex at birth was 2,425. The CCUK National IBD report from 2020 identified that 2% of services were sufficiently staffed with psychologists to meet the previously defined IBD standards[3].
Conclusion: This analysis suggests that there are over 17,000 people in England and Wales suffering from IBD who identify as LGBTIQ+ however the true prevalence is likely to be higher. Whilst there is no specific data

on the impact of IBD in this population, individual statements published by patient support groups show that these patients have unique requirements in simultaneously navigating a chronic disease and the challenges of identifying as LGBTIQ+[5]. There is extensive data suggesting that both LGBTIQ+ people[1] and IBD patients[6] have a higher burden of mental health disorders and thus these patients are more likely to require, and benefit from, increased psychological support.

However, the national provision of psychologists as part of the IBD multidisciplinary team is extremely low and this represents an unmet need. Further research is required to gain more insight into LGBTIQ+ patient experience to identify deficiencies in service provision and help modify IBD services to better support the holistic needs of this patient group.

Introduction: Microscopic colitis (MC) has been associated to various autoimmune diseases. Previous studies on the association between MC and psoriasis have focused on psoriasis as a risk factor for MC. Data from large scale cohort studies investigating the risk of future psoriasis in MC, however, are lacking.

Aims & Methods: We aimed to examine the association between MC and psoriasis by conducting a nationwide, population-based, matched cohort study in Sweden from 2007-2021. In total, we identified 8,404 patients with biopsy-verified MC (diagnosed in 2007-2017), 37,303 matched reference individuals, and 8,381 siblings without MC. Information on MC was obtained through the ESPRESSO cohort (a histopathology database containing data on all gastrointestinal biopsies in Sweden from 1965-2017). Data on incident psoriasis was gathered from the National Patient Register. Using Cox regression, we calculated hazard ratios (HRs) and 95% confidence intervals (CIs).

Results: During a median follow-up of 9.2 years (interquartile range=6.7-11.7), 179 MC patients and 440 reference individuals were diagnosed with psoriasis (241 vs 131 events per 100,000 person-years), corresponding to one extra case of psoriasis in 91 patients with MC followed for 10 years. After adjustment for the matching variables (birth year, sex, county of residence and calendar period) and level of education – as a proxy for socioeconomic status - we computed an aHR of 1.82 (95%CI=1.53-2.17). Stratifying by sex, estimates were similar and when examining the aHR across different lengths of follow-up, we found significantly elevated estimates up to 10 years after MC diagnosis. Compared to MC-free siblings, the aHR was 1.85 (95%CI=1.36-2.51).

Conclusion: Patients with MC are at an almost doubled risk of being diagnosed with psoriasis compared to the general population. Our findings suggest clinicians should consider psoriasis in MC patients with skin lesions.

CLINICAL CHARACTERISTICS AND OUTCOMES OF APPENDICEAL NEOPLASMS IN INFLAMMATORY BOWEL DISEASE: A TERTIARY CARE CENTER EXPERIENCE

S. Urquhart[1], J. Kisiel[1], N. Coelho-Prabhu[1]

[1]Mayo Clinic, Gastroenterology and Hepatology, Rochester, United States

Contact E-Mail Address: urquhart.siri@mayo.edu

Introduction: Primary cancer of the appendix is rare and accounts for 0.4% of all gastrointestinal (GI) malignancies with an incidence of approximately 1.2 cases per 100,000 people per year in the United States. Patients with inflammatory bowel disease (IBD), including ulcerative colitis (UC), Crohn's disease (CD), and indeterminate colitis (IC), face increased risk for the development of colorectal dysplasia and carcinoma. Although appendiceal inflammation occurs histologically in 40-80% of colectomy specimens from patients with IBD, appendiceal neoplasms have been reported only infrequently. A direct association between IBD and appendiceal neoplasia, including whether IBD predisposes to the development of appendiceal neoplasia, is unclear.

Aims & Methods: We aimed to describe the clinical characteristics, outcomes, and incidence of appendiceal neoplasms in patients with IBD. Using bioinformatics and natural language processing tools to mine the electronic medical record at our large referral center, all patients ≥ 18-years-old with IBD who had an appendiceal neoplasm were identified from January 1992 to April 2023. Relevant demographic and clinical data were abstracted.

Results: In total, 44 patients were included (61.4% female) with a median age of 53 years at appendix neoplasm diagnosis. A majority had UC (68.2%). Of these, four (13.3%) had backwash ileitis, 27 (90%) had extensive colitis, 12 (40%) had a history of colorectal neoplasia, and 6 (20%) had primary sclerosing cholangitis (PSC). Median duration of IBD prior to appendix neoplasm diagnosis was 17 years. The most common type of appendix neoplasm was adenocarcinoma (36.4%), followed by appendiceal mucinous neoplasm (34.1%), and carcinoid or neuroendocrine tumor (22.7%). The most common presenting symptom associated with diagno-

sis of appendix neoplasm was abdominal pain/distension (36.4%). Appendix neoplasm diagnosis was made by cross-sectional imaging in a majority of patients (47.7%). The most common type of IBD-directed therapy at the time of appendix neoplasm diagnosis was 5-aminosalicylate (5-ASA) agents (25%). All patients had appendix neoplasm surgically resected. Median appendix neoplasm size was 2.7 cm. The most common histologic tumor grade was grade 1 (31.8%). Two (4.5%) patients had lymph node involvement and 7 (15.9%) patients had metastatic disease at the time of appendix neoplasm diagnosis. Twelve (27.2%) patients received adjuvant chemotherapy. Three patients with UC (6.8%) had recurrence of appendix neoplasm after surgical resection due to peritoneal seeding with a median time to recurrence from initial diagnosis of 78 months.

Conclusion: Appendix neoplasms are more commonly seen in patients with longstanding extensive UC in those presenting with abdominal pain/distension. The most common types of appendix neoplasia included adenocarcinoma and appendiceal mucinous neoplasms. A minority of patients had metastatic disease at the time of appendiceal neoplasia diagnosis. Although the incidence and recurrence of appendix neoplasia in patients with IBD is relatively low, likely related to the small area of mucosa at-risk relative to the colorectum, the recognition of appendix neoplasms as a potential complication of longstanding disease remains unclear. Further studies to compare appendiceal neoplasia in patients with and without IBD are needed to determine if IBD predisposes to the development of this neoplastic complication.

CLINICAL FEATURES AND PROGNOSIS OF SPORADIC NEOPLASIAS DETECTED IN ULCERATIVE COLITIS PATIENTS

Introduction: Sporadic neoplasias (SNs) and ulcerative colitis-associated neoplasias (UCANs) can occur in patients with UC. Differences in the characteristics and prognoses between UCANs in patients with UC and SNs in patients without UC have been assessed in numerous previous studies. However, only a few studies have focused on the characteristics and prognoses of SNs in patients with UC. It is important to distinguish between UCANs and SNs, because they have different prognoses and therefore need different treatment strategies.

Aims & Methods: This study aimed to evaluate the clinical features and prognoses of SNs detected in patients with UC, both within and outside the affected area. A total of 141 SNs in 59 patients with UC, which were detected by surveillance colonoscopy (SCS) at Hiroshima University Hospital between January 1999 and December 2021, were included. In our hospital, we perform SCS for UC patients with left-sided or total colitis and with a disease duration of more than 7 years, if possible, in the remission stage. SNs were diagnosed based on their location, endoscopic features, and histopathological findings. The final diagnosis was made by histopathological evaluation of the excised specimens and confirmed by more than one gastrointestinal pathologist. The histopathological diagnosis of SN was made according to the pathological features described in the recent European Crohn's and Colitis Organization and the European Society of Pathology statement on histopathology. Immunohistochemical evaluation of Ki67 and p53 was performed in all cases. SNs, especially sporadic adenomas, have regular neoplastic glands with low amounts of stroma, and rarely have a mixture of benign/dysplastic crypts. Although UCANs sometimes have a surrounding flat area with overexpression of p53, SNs have no such area and have a distinct border between the neoplastic glands and non-neoplastic mucosa. SNs have Ki67 expression mainly in the superficial zone and have low levels of p53 expression.

Results: The mean age at first SN detection was 58.8 years, and the mean duration of UC was 9.9 years. Male patients represented 64.4% of the enrolled patients. The most common type of UC was the total colitis type (47.5%). With regard to their clinical course, approximately half of the patients (49.2%) presented with the relapse-remitting type. Among the 141 SNs, 129 lesions (91.5%) were diagnosed as adenomas, five (3.5%) as Tis carcinomas, two (1.5%) as T1a carcinomas (superficially submucosal invasive carcinoma: <1,000 μm), and five (3.5%) as T1b carcinomas (deeply submucosal invasive carcinoma: ≥1,000 μm). There were 86 (61.0 %) SNs in the right colon, 44 (31.2%) in the left colon, and 11 (7.8%) in the rectum. When classified as outside or within the affected area of UC, 100 (70.9%) SNs occurred outside and 41 (29.1%) within. Most SNs (135 lesions, 95.7%) underwent endoscopic resection, and only six lesions (4.3%) underwent surgical resection. Among the 59 patients included in this study, synchronous SNs occurred in 14 (23.7%), and metachronous multiple SNs occurred in 24 (40.7%) patients. The 5-year cumulative incidence of metachronous multiple SNs was higher in patients with synchronous multiple SNs (54.2%) than in those without (46.4%). The histology, size, and background mucosa of the initial SNs were not associated with the incidence of metachronous SNs in our study.

Conclusion: UC patients with synchronous multiple SNs were at higher risk of developing metachronous multiple SNs and may require close follow-up compared to patients without synchronous SNs.

Disclosure: Nothing to disclose.

Contact E-Mail Address: sgarciamateo7@gmail.com

Introduction: Nowadays, Non-Alcoholic Fatty Liver Disease (NAFLD) is a leading cause of liver disease and liver transplantation. Although obesity is a well-recognized risk factor for NAFLD, there are data to support that not all patients with NAFLD are necessarily obese. However, the evidence on the prevalence and risk factors for NAFLD in lean individuals with Inflammatory Bowel Disease (IBD) is scarce.

Aims & Methods: The aim of the study was to assess the prevalence and risk factors for NAFLD in lean population with IBD. This is a cross-sectional, case control study including lean individuals with IBD (cases) and lean individuals without IBD (controls), matched for age and sex. Patients with risky alcohol consumption, previous diagnosis of chronic liver disease (immune, viral, genetic) and secondary causes of NAFLD were excluded. All included patients were performed a liver ultrasound, transient elastography and laboratory tests. Lean individuals were defined as Body Mass Index < 25 kg/m^2, and NAFLD as ultrasound steatosis and/or Controlled Attenuation Paremeter >248 dB/m. A descriptive analysis was carried out, and the relationship between variables was assessed using Chi square test/Fisher´s test (categorical variables) or T-student/Mann-Whitney U test (quantitative variables), as appropiate. In addition, a multivariate analysis was performed, presented as adjusted Odds Ratio (OR) and 95% Confidence Interval (95%CI).

Results: A total of 443 participants, 363 lean cases and 80 lean controls, were included in the study. No differences were observed in terms of age, sex and metabolic risk factors between both groups (***Table 1***). The prevalence of NAFLD in lean individuals with IBD was significantly higher compared to lean individuals without NAFLD (22% vs. 10%, p=0.015). Multivariate analysis confirmed that IBD was an independent risk factor for NAFLD in lean population (OR 2.75 95%CI (1.18-6.41)). In addition, male sex (OR 1.78 95%CI (1.04-3.05)) and older age (OR 1.03 95%CI (1.01-1.05)) were identified as risk factors for NAFLD in lean individuals.

Characteristics	Lean cases (IBD) n= 363	Lean controls (non-IBD) n=80	p-value
Female sex, n (%)	215 (59.2)	46 (57.5)	0.776
Age, mean ± SD	46.3±13.7	44.1±15.5	0.198
CV disease, n (%)	8 (2.2)	0 (0.0)	0.361
Arterial hypertension, n (%)	30 (8.3)	8 (10.0)	0.616
Type 2 DM, n (%)	13 (3.6)	3 (3.8)	1.000
BMI (kg/m2), median (range)	22.4 (15.4-25.0)	22.4 (16.7-24.8)	0.902
Total cholesterol (mg/dl), mean ± SD	188.0±40.6	197.0±36.1	0.070

Legend: CV: Cardiovascular. IBD: Inflammatory Bowel Disease

Table 1. Baseline characteristics of cases and controls.

Conclusion: The prevalence of NAFLD is significantly higher in lean population with IBD, suggesting that IBD could play a role in the development of NAFLD in lean individuals.

Introduction: Apelin, an adipokine secreted from visceral fat, has been associated with endothelial cells dysfunction-related chronic inflammatory diseases. Decreased serum apelin levels have been found in patients with cardiovascular disease (CVD). Higher apelin levels have been measured in mesenteric adipose tissue and inflamed colonic epithelium of patients with Inflammatory Bowel Disease (IBD), but data on the role of serum apelin levels in IBD patients are lacking.

Aims & Methods: We aimed to a) compare serum apelin levels between 104 consecutive IBD patients and 104 age and sex matched healthy controls (blood donors), b) to evaluate the correlation between serum apelin levels with demographics, disease characteristics, treatment and disease course. Serum apelin-13 levels were measured using ELISA (Wuhan Fine Biological Technology Co., Ltd). Statistical analysis was performed with SPSS 24 (SPSSInc. Chicago, IL, USA).

Results: Mean apelin levels were significantly higher in IBD patients compared to their matched healthy controls *(1996.29 ± 1592.96pg/ml vs 1552.99 ± 809.64, p=0.012).* Among the examined parameters only smoking was found independently associated with serum apelin levels in IBD patients *(p<0.001).*

IBD patients with CVD (25) had lower but not significant different serum apelin levels compared to patients without CVD (79) (*1743.01 ± 1116.26pg/dl vs 2465.09 ± 2006.51pg/ml, p=0.122*). In a subgroup analysis of patients without CVD (79 IBD patients) significantly elevated serum apelin levels were found in patients with extended UC, history of immunomodulator use and absence of musculoskeletal EIMs (*2539,69 ± 1969.29pg/ml vs 1164.45 ± 818.89pg/ml, p=0.044, 2317.69 ± 1867.99pg/ml vs 1451.40 ± 1024.20pg/ml, p=0.043 and 2340.58 ± 1850.16pg/ml vs 1392.09 ± 1054.99pg/ml, p=0.027, respectively*).

Finally, a moderate positive correlation was found among UC extent and serum apelin levels in patients without CVD *(r=0.525, p=0.004)*. Negative correlations were found among age at study entry and serum apelin levels in both IBD patients without CVD and all IBD patients (r=-0.263, p=0.001 and r=-0.214, p=0.002, respectively) and between immunomodulator use, history of musculoskeletal EIMs and serum apelin levels in patients without CVD (r=-0.26, p=0.021 and r=-0.336, p=0.005, respectively).

Conclusion: The circulating serum apelin levels are significantly increased in IBD patients compared to matched healthy controls. Increased apelin levels are independently associated with smoking status and disease extend (in UC). IBD patients with musculoskeletal manifestations have decreased serum apelin levels compared to IBD patients without musculoskeletal manifestations. Further investigation with larger studies on the role of serum apelin in IBD is needed.

Disclosure: None.

RISK OF EATING DISORDERS AND DISORDERED EATING IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: FOCUS ON ORTHOREXIA NERVOSA

F.M. Di Giorgio[1], S.P. Modica[1], S. Ciminnisi[1], L. Di Prima[1], M. Saladino[1], S. Muscarella[1], P. Melatti[1], D. Brinch[1], S. Petta[1], M. Cappello[1]

Contact E-Mail Address: marica.cappello61@gmail.com

Introduction: Patients with inflammatory bowel disease (IBD) often adopt restrictive diets in the belief that certain foods can trigger disease symptoms. This behavior may prelude to eating disorders. Orthorexia nervosa is the pathological obsession with healthy eating consisting of organic, non-artificially processed foods. To date, it is not yet recognized as an eating disorder by the DSM-V and there is no gold standard for diagnosis. In recent years, some studies have investigated the prevalence of eating disorders in IBD patients but there are no studies regarding orthorexia nervosa. The aim of this study is to assess the risk of orthorexia in patients with IBD.

Aims & Methods: 158 consecutive subjects (113 IBD patients, 45 healthy controls) were prospectively recruited from February to October 2022. The following data were collected: clinical and demographic data and disease characteristics. The control group (45 subjects) was enrolled among the hospital staff and their relatives. The ORTO-15 test developed by Donini et al. was administered by trained dieticians to assess the risk of orthorexia; the cut-off validated by Donini for the diagnosis of orthorexia nervosa is a score <40.

Results: Of the 113 IBD patients who participated in the study, 48 (42%) had UC and 65 (58%) had CD, mean age 50 ± 16 years, range 18- 84 years, 54% were males, mean BMI 25± 5 kg/m^2. Disease duration was less than 5 years in 40% of patients, between 5 and 20 years in 49.5%, while only 11.5% of patients had a disease duration longer than 20 years. Regarding disease activity, 58% were in remission, 27% had mild activity, 13% moderate activity, and only 2% had severe activity. 16% have undergone previous surgery for IBD and 2.6% are oostomy carriers. Regarding therapy 75% of patients were on biologics while 25% on conventional therapy. The control group consists of 45 subjects, 60% female, mean age 32 ± 12 years, range 18- 58 years, mean BMI of 23 ± 4 Kg/m2. Patients with IBD had a 77% risk of orthorexia, significantly higher than the 47% observed in the control group (p<0.001). No statistically significant differences were found between patients with risk of orthorexia and patients without risk of orthorexia in relation to age (p=0.66), gender (p=0.37), marital status (p=0.78), educational qualification (p=0.88), and occupation (p=0.64), although a non-significant trend for lower BMI (mean BMI 26.7 vs 25 Kg/m2 , p=0.12). Regarding the characteristics of IBD, the prevalence of orthorexia did not differ in relation to the diagnosis of UC or CD (p=0.98), nor to the duration of the disease (p=0.75), type of therapy (p=0.42) and disease activity as measured by Mayo score/HBI (p=0.47) or the presence of ostomy (p=0.33). The only statistically significant difference was related to the history of previous surgery for IBD (19.5% in patients at risk for orthorexia, 3.8% prevalence in patients not at risk (p=0.05).

Conclusion: To our knowledge, this study is the first that shows a higher risk of orthorexia nervosa in patients with IBD as compared to healthy controls and that this risk is more frequent in patients with lower BMI and history of previous surgery.

Further studies are needed to confirm our results and assess the impact of orthorexia nervosa and its possible relationship with eating disorders such as Avoidant Restrictive Food Intake Disorder (ARFID) and anorexia.

The presence of an expert dietitian in centers caring for IBD is strongly warranted to ensure adequate nutritional counselling in order to prevent inappropriate disordered eating and nutritional deficiencies.

Disclosure: All authors have declared no conflict of interest.

Introduction: 20-50% of patients with inflammatory bowel disease (IBD) experience chronic pain during remission (1-5). The clinical features of IBD patients with and without abdominal pain during remission remain unknown.

Aims & Methods: In a cross-sectional pilot study of IBD patients in remission, our aims were to assess patient recruitment, compliance, feedback to optimise the questionnaires for future use and to determine clinical features that distinguish patients with and without abdominal pain.

Online validated questionnaires about disease activity, symptoms and psychological assessment were sent to participants of the UK IBD BioResource (total sample 30,000 patients). Inclusion and exclusion criteria of the IBD BioResource main cohort were applied.

Descriptive statistics were used in all participants to assess disease status. Descriptive and inferential statistics were applied to all participants in remission.

Results: 2,050 patients were approached and 291 (14.2%) participated. 249 completed the study and 244 patients were included in the analysis. Technical problems, lack of understanding of the relevance of some questionnaires and their length were identified as factors which affected completion in 35 participants. 244 patients were full responders with 122 (50%) participants in remission, out of which 33 (27%) experienced chronic abdominal pain. Comparison of the remission groups with (N=33) versus without (N=89) chronic abdominal pain yielded higher scores in patients with pain for the following: use of azathioprine (p=0.021); patient health questionnaire 15 score (p<0.001); gastrointestinal symptoms rating scale total score (p<0.001); coping resources inventory health in general ((p=0.046); big five questionnaire neuroticism (p=0.019); highly sensitive person scale- short form total score (p=0.007); cognitive and behaviour responses questionnaire catastrophizing score (p=0.010); Pittsburgh sleep quality index poor sleeper (global score > 5, p=0.03).

Variable	Chronic pain (n=33)	No chronic pain (n=89)	p-value*
Sample	Mean ± SD or N (%)	Mean ± SD or N (%)	
Use of azathioprine	12 (36.64%)	15 (16.85%)	0.021
PHQ15 score	8.67 (±3.76)	5.09 (±4.0)	<0.001
GSRS total score	2.06 ±0.48	1.52 ±0.54	<0.001
BFQ neuroticism	4.63 (±0.85)	4.25 (±0.82)	0.019
HSPSF total score	4.00 (±0.81)	3.50 (±0.91)	0.007
CBRQ catastrophizing score	4.64 (±3.63)	2.78 (±2.84)	0.010

*Applied tests were either chi-square, Fisher's exact, Fisher-Freeman-Halton Exact test, independent t-test or Mann-Whitney U test
Abbreviations: IBD= inflammatory bowel disease, SD= standard deviation, N=number, PHQ15= Patient health questionnaire 15, GSRS= Gastrointestinal symptoms rating scale, BFQ= Big five questionnaire, HSPSF= Highly sensitive person scale - short form, CBRQ= Cognitive and behavioural responses questionnaire

Table 1. Comparison of patients with inflammatory bowel disease with chronic pain and without chronic pain in remission.

Conclusion: Rectifiable factors affecting recruitment and compliance were identified. Differences in symptoms and psychological characteristics exist in patients with IBD in remission with and without chronic abdominal pain. Further research is warranted to translate these preliminary findings into meaningful and personalised holistic treatment options for IBD patients with chronic pain.

PERIODONTITIS IS ASSOCIATED WITH INCREASED DISEASE ACTIVITY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

G. Madsen[1,2], K. Bertl[3,4], N. Pandis[5], A. Stavropoulos[4,6], J. Burisch[1,2]
[1]Copenhagen University Hospital - Amager and Hvidovre, Gastrounit, Hvidovre, Denmark, [2]Copenhagen University Hospital - Amager and Hvidovre, Copenhagen Center for Inflammatory Bowel Disease in Children, Adolescents and Adults, Hvidovre, Denmark, [3]Sigmund Freud University Vienna, Department of Periodontology, Dental Clinic, Faculty of Medicine, Vienna, Austria, [4]University of Malmö, Department of Periodontology, Faculty of Odontology, Malmö, Sweden, [5]University of Bern, Department of Orthodontics and Dentofacial Orthopedics, School of Dental Medicine, Bern, Switzerland, [6]Medical University of Vienna, Division of Conservative Dentistry and Periodontology, University Clinic of Dentistry, Vienna, Austria

Contact E-Mail Address: gormmadsen@hotmail.com

Introduction: Periodontitis (gum disease) and inflammatory bowel disease (IBD) are both chronic progressive inflammatory diseases with many similarities in their aetiopathogenesis. In addition, patients with IBD are reported to be at increased risk of developing periodontitis, which in turn seems to impact IBD activity and disability as shown in recent studies. However, these findings need to be validated.
Thus, we aimed to assess whether the presence of periodontitis is associated with increased IBD activity, disability, and severity, and/or reduced IBD specific quality of life, in a Swedish patient cohort.

Aims & Methods: An on-line questionnaire was distributed to the members of the Swedish patient organisation for gastrointestinal diseases. The survey included questions on social demographics, oral health, as well as IBD-related characteristics. Oral health was assessed by the number of missing teeth, self-reported state of teeth and gums, and the Periodontal Screening Score (PESS), which is a validated instrument to screen for severe periodontitis. Disease activity in patients with Ulcerative Colitis (UC) and Crohn's disease (CD) was assessed by the Simple Clinical Colitis Index (SCCAI) and the Harvey & Bradshaw's Activity Index (HBI), respectively. Disease related disability was assessed by the Inflammatory bowel disease disability index (IBD-DI). IBD-specific health-related quality of life measured by the short inflammatory bowel disease questionnaire (sIBDQ).

Results: A total of 786 IBD patients responded to the invitation, including 371 patients with CD and 415 patients with UC. For both CD and UC, self-reported severe periodontitis was significantly associated with a higher level of current disease activity [OR 1.72 (1.86;2.49); p=0.004] based on the HBI (for CD) and the SCCAI (for UC), an increased IBD disability score [Coef. 5.07 (1.86;8.27); p=0.002], and an increased self-reported disease activity in the last 12 months [OR 1.44 (1.05;1.98); p=0.025]. Likewise, number of missing teeth (tooth loss is the ultimate outcome of untreated periodontitis and as such an indirect indicator of its severity), was associated with an increased IBD disability score [Coef. 4.47 (0.71;8.22); p=0.020]. IBD severity (analysed as composite parameter of history of IBD-related surgery and/or treatment with biological therapy) was neither associated with tooth loss [OR 1.57 (0.97;2.52); p=0.065], nor with self-reported severe periodontitis [OR 1.20 (0.80;1.80); p=0.367]. IBD-specific health-related quality of life measured by sIBDQ score showed a tendency to be decreased in the presence of self-reported severe periodontitis [OR -1.45 (-3.01;0.10); p=0.067] but was not associated with tooth loss [Coef. -1.20 (-3.01;0.62); p=0.194].

Conclusion: The present study provides further evidence that the presence of periodontitis is associated with an increased disease activity and disability in IBD patients. These results underline that increased attention should be given to the oral health of IBD patients.

Disclosure: Nothing to disclose.

Introduction: The Epi-IBD cohort is a prospective European population-based cohort of 1,390 patients diagnosed with inflammatory bowel disease (IBD) in 2010 and 2011 according to Copenhagen criteria. Of these, 482 were diagnosed with Crohn's Disease (CD), 817 with ulcerative colitis (UC) and 91 with IBD unclassified (IBDU). The Epi-IBD cohort was established to examine differences in incidence, treatment strategies, disease course and prognosis among IBD patients in Eastern and Western Europe.

Aims & Methods: This study aims to describe the use of biological therapy as well as the treatment prior to biological therapy. IBD patients were followed prospectively from the time of diagnosis until the 31st December 2020, death, emigration or loss of follow-up. Clinical data on surgery, hospitalizations, and medical treatment, were captured throughout the follow-up period and entered into a validated web-database, www.epi-ibd.org.

Results: During a median follow-up period of 10.7 (interquartile range (IQR), 10.0-11.4) years, 34% (N=165/482) of CD and 15% (N=122/817) of UC patients were started on biological therapy. Biological therapy was initiated within the first year after diagnosis in 16.8% (N=81/482) of all CD and 3.8% (N=31/817) of all UC patients. In median biological therapy was started at 1.0 year (IQR, 0.3-3.1) and 2.7 years (IQR, 1.6-4.0) after CD and UC diagnosis, respectively. First-line biological therapy was infliximab in 74% (N=213/287) and adalimumab in 22% (N=64/287) of the patients. The remaing (N=10/287) received either Golimumab, Vedolizumab, Ustekinumab or were part of a trial/unknown. The sequences of biological therapies are displayed in Sankey diagrams, Figures 1 and 2. Herein illustrated is that 34% (N=56/165) CD and 34% (N=41/122) UC received at least two different biological drugs. Immunomodulators were initiated simultaneously to the first biological therapy in 19% (N=31/165) of CD patients and in 9% (N=11/122) of UC patients. Overall 63% (N=104/165) CD and 51% (N=62/122) UC patients were receiving concomittant immunomodulators with the first biological therapy.

The sequences of therapy leading up to biological therapy are displayed in Sankey diagrams, Figures 3 and 4. Herein illustrated is that the most common sequence of treatment before the first biological therapy for CD was 1) Steroids, 2) Immunomodulators (21%, N=34/165), and for UC was 1) 5-aminosalicylic-acid (5ASA), 2) Steroids, 3) Immunomodulators (39%, N=48/122). Prior to the first biological therapy one, two and three or more courses of systemic steroid were used in 41%, 28% and 17% (N=67, 47 and 28) of CD patients and 43%, 24% and 26% (N=52, 29 and 32) of UC patients. In 14% (N=23/165) and 7% (N=9/122) of CD and UC patients, systemic steroids were not used prior to first biological therapy. In patients having immunomodulators prior to biological therapy, these were administered for a median of 0.5 (IQR, 0.1-1.9) years and 1.1 (IQR, 0.2-3,2) years in CD and UC, respectively. For 5ASA this was 0.8 (IQR, 0.2-1.5) years for CD and 2.2 (IQR, 0.8-4.3) years for UC.

Conclusion: In this multicenter European population-based cohort, different prescribing patterns for biologics emerge: 34% of CD and 15% of UC patients received biologics within 10 years after diagnosis. Infliximab was the most common first-line biological therapy. Only about half of the patients received concomitant immunomodulators. Prior to the first biological therapy, most patients were exposed to systemic steroids and many to repeated courses.

Disclosure: Nothing to disclose.

THE USE OF ANTIBIOTICS INCREASES THE RISK OF RELAPSE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE – A POPULATION-BASED NESTED CASE-CONTROL STUDY USING THE DANISH NATIONAL PATIENT REGISTRY

B. Lo[1,2], L. Biedermann[3], G. Rogler[3], B. Dora[3], A. Kreienbühl[3], I. Vind[1,2], F. Bendtsen[2,1], J. Burisch[1,2]

Contact E-Mail Address: bobby.lo@regionh.dk

Introduction: Inflammatory bowel disease (IBD) is a chronic gastrointestinal disease with unknown causes. Patients experience periods with active disease and symptoms such as diarrhoea, pain and weight loss. Little is known about environmental factors that trigger flare-ups, including the effects of commonly used medications. Recent studies suggest a link between microbial factors and IBD, making it important to investigate the impact of antibiotics on flare-ups.

Aims & Methods: We aimed to investigate whether certain antibiotics increase the risk of flares in patients with IBD. We utilized a previously described[1] cohort of all patients with IBD in Denmark between 1974 and 2018. The cohort is based on the Danish Nationwide Patient Registry, which registers all healthcare related visits, treatments and procedure on an individual level. We utilized data between 1994 and 2018 and two distinct cohorts was created for the purpose of identifying flares. The first cohort was characterized by having an IBD-related hospital stay. The second cohort was characterized by experiencing a flare of IBD in need of systemic steroids. Patient were matched 1:5 using K-nearest neighbour. Antibiotics were grouped into the 3rd level of the Anatomical Therapeutic Chemical (ATC) classification system, with anthelmintics grouped into the 2nd level due to low numbers and all given within 60 days before the outcome. Logistic regression analysis was used to calculate odds ratios (ORs) with a 95% confidence interval (95% CI), with adjusting variables including year of remission/flare, sex, age at diagnosis, year of diagnosis, type of IBD, socioeconomic status[2], use of 5-ASA, use of budesonide, use of immunosuppressants, and use of subtypes of biologics.

Results: There were in total 69,908 IBD patients in the original cohort. After applying the abovementioned algorithm, a total of 15,636 and 5,178 patients were included in the cohort for hospitalisation and steroid use, respectively.

Using a multivariate logistic regression model, both cohorts observed a significant increase in odds ratios for certain antibiotics in relation to hospitalization and steroid course. Specifically, for the need of a course of steroids, quinolones (OR 3.83 (95% CI: 2.73-5.35)), antimycotics (OR 2.30 (95% CI: 1.53-3.40)), agents against amoebiasis and protozoal (OR 2.06 (95% CI: 1.39-3.01)), betalactam antibiotics (OR 1.35 (95% CI: 1.10-1.66)), and intestinal anti-infectives (OR 2.12 (95% CI: 1.08-3.98)) were associated with an increased risk for a flare requiring steroids.

Regarding the need for an IBD-related hospitalization, agents against amoebiasis and protozoal (OR 3.48 (95% CI: 2.72-4.44)), quinolones (OR 3.10 (95% CI: 2.48-3.86)), intestinal anti-infectives (OR 2.42 (95% CI: 1.54-3.76)) and antimycotics (OR 1.58 (95% CI: 1.17-2.12)) were all found to be significantly associated.

Conclusion: This study provides evidence that certain types of antibiotics increase the risk of flare-ups in patients with IBD. Quinolones, antimycotics, agents against amoebiasis and protozoal, betalactam, and intestinal anti-infectives were all associated with increased odds ratios for hospitalization and a need for a course of steroids. These findings highlight the importance of carefully considering the use of antibiotics in IBD patients and the need for further research on the effects of different antibiotics on disease progression.

BIOELECTRICAL IMPEDANCE ANALYSIS REVEALED DIFFERENCES BETWEEN LEAN AND NON-LEAN NON-ALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH CROHN'S DISEASE

M. Lin[1], Z. Huang[1], N. Diao[1], K. Chao[1]
[1]The Sixth Affiliated Hospital, Sun Yat-sen University., Department of Gastroenterology, Guangzhou, China

Contact E-Mail Address: linmzh23@mail2.sysu.edu.cn

Introduction: About 30% of Crohn's disease(CD) patients complicated with non-alcoholic fatty liver disease(NAFLD), and it was mainly lean NAFLD. Whether the patients with lean NAFLD have specific characteristics in human body composition is unclear. This study aimed to analyze the body composition in lean NAFLD patients in a CD cohort.

Aims & Methods: Consecutive patients diagnosed between January 2021 and June 2021 were retrospectively enrolled in a tertiary center in China. NAFLD was diagnosed by clinical characteristics and CT imaging. Human body composition was calculated by bioelectrical impedance analysis (BIA). The differences of clinical characteristics and human body composition of lean NAFLD was analyzed and compared to non-NAFLD and non-lean NAFLD.

Results: A total of 422 CD patients were enrolled. The overall prevalence of NAFLD was 13.03% (55/422), with 37 lean and 18 non-lean NAFLD. Compared to Non-NAFLD patients, CD patients with NAFLD tend to had a higher body fat mass (BFM) (13.70[8.20-20.30] vs. 10.20[7.50-14.30], P=0.001) and visceral fat level (VFL) (5[3-8] vs. 4[3-5], P=0.002). These differences may mainly contributed by the non-lean NAFLD, for no difference was found between lean NAFLD and non-NAFLD group. When compared to non-lean NAFLD, CD patients with lean NAFLD showed a lower body mass index (BMI) (19.10[17.50-20.30] vs. 25.45[24.45-27.70], P<0.001), protein (8.30[6.95-9.40] vs. 10.40[7.85-11.43], P=0.007), minerals (2.92±0.52 vs. 3.40±0.68, P<0.001), body fat mass (BFM)(10.62±4.24 vs. 23.52±6.98, P<0.001), percent body fat (PBF)(17.40[13.00-27.75] vs. 29.55[27.73-33.98], P<0.001), skeletal muscle mass (SMM) (23.10[18.85-26.55] vs. 29.35[21.70-32.40], P=0.008) and VFL (4[2-5] vs. 9[7-11], P<0.001).

Conclusion: Different to non-lean NAFLD in the present CD cohort, lean NAFLD showed a strong relationship to malnutrition. It suggested that different mechanisms may exist in lean and non-lean NAFLD in CD population.

Contact E-Mail Address: ammarzaka10@gmail.com

Introduction: There is conflicting data on the risk of acute coronary syndrome (ACS) in patients with inflammatory bowel disease (IBD). Furthermore, the risk amongst younger patients with IBD in the absence of traditional risk factors is yet to be characterised. We performed the largest to date systematic review and meta-analysis to identify the risk of ACS in patients with IBD.

Aims & Methods: A thorough computer-based search was performed using 5 major databases (PubMed, MEDLINE, EMBASE, CENTRAL, Web of Science) up until 27th October 2022 for observational cohort studies evaluating ACS in adults with IBD. Odds ratios were calculated using a random-effects model. Subgroup and sensitivity analyses were conducted in order to explore sources of heterogeneity.

Results: Eleven eligible studies were included (169,013 IBD patients). Patients with IBD were associated with an increased risk of ACS in both adjusted (HR 1.23; 95% CI 1.06-1.42) and unadjusted analyses (HR 1.46; 95% CI 1.16-1.84). Substantial heterogeneity was observed ($p < 0.001$, $i^2 = 86\%$). Younger patients (≤ 40 years of age) with IBD demonstrated a higher risk compared to older patients (relative HRR 1.50; 95 CI 1.15-1.96) without heterogeneity ($i^2 = 0$). Patients with Crohn's disease demonstrated a greater risk of ACS than patients with ulcerative colitis [(HRR 1.72; 95% CI 1.22-2.41) versus (HRR 1.28, 95% CI 1.06-1.55) respectively].

Conclusion: Patients with IBD demonstrated an independently increased risk of ACS, which is more pronounced in younger patients less than 40 years of age. Prospective studies are required to explore the relationship with disease activity and duration, concomitant medication use and angiographic characteristics and outcomes.

ELDERLY INFLAMMATORY BOWEL DISEASE IN A TUNISIAN POPULATION

N. Ben Safta[1], N. Ben Mustapha[1], W. Khemiri[1], S. Laabidi[1], M. Serghini[1], M. Fekih[1], A. Labidi[1], J. Boubaker[1]
[1]La Rabta Hospital, Gastroenterology Department "A", Tunis, Tunisia

Contact E-Mail Address: Khemiri.wafa00@gmail.com

Introduction: Chronic inflammatory bowel disease (IBD) is an early onset disease most often between the 2nd and 3rd decade, a second peak of incidence between 50 and 70 years old has been recognized.

Aims & Methods: The aim of our study was to describe the prevalence of elderly patients in IBD as well as the epidemiological, evolutionary and therapeutic profiles of these patients. Then, we compared the evolution of their IBD to younger patients.

We conducted a retrospective, descriptive, comparative study including patients hospitalized for IBD over a 9-year period [January 2011-January 2020]. Patients with less than 2 years of follow-up were excluded. We defined the elderly patients group, or group 1, as patients in whom IBD was diagnosed at an age ≥ 60 years. Group 2 represented younger patients.

Results: Of the 452 patients included, 6.8% (n=31) were elderly patients. We first described this group of patients. The mean age was 64 years with extremes ranging from 60 to 80 years. The sex ratio M/F=1.6. Fourteen were smokers and 9 were occasional drinkers. For the history, 6 patients were diabetic, 7 had hypertension, and 2 were dyslipidemic. Only one patient had an associated autoimmune disease such as ALS-like syndrome. Fourteen patients had a BMI > 25kg/m^2. Sixteen patients had Crohn's disease (CD) and 15 had ulcerative colitis (UC). UC was of pancolic location in 7 patients, left in 3 and distal in 5 of them. For CD, it was mainly a colonic localization (n=6) and an inflammatory phenotype (n=9). A phenotypic progression was noted in only one patient, from stenosing phenotype to fistulizing phenotype. Twelve patients had extra-intestinal manifestations, exclusively rheumatological. Severe acute colitis was noted in 10 patients. Corticosteroids were used in 61% of the patients with a good response in 87% of them. Immunosuppressive therapy was used in 9 patients. Thiopurines were used in 100% of cases. Treatment with an anti-TNF α was indicated in 3 patients. Eight patients underwent surgery. These were mainly ileo-caecal resections (n=6).

After comparison, we found that patients in group 1 were significantly more overweight and obese compared to group 2 (45.2 vs 23%, p=0.006). The proportion of UC was significantly higher in group 1 (p=0.001). For patients with CD, there were significantly more ano-perineal manifestations in group 2 (p=0.015), however, the proportion of upper GI tract involvement was equivalent in both groups (p=1). The rate of surgical intervention was comparable in both groups (p=0,9). Nevertheless, the rate of use of immunosuppressive therapy was higher in group 2 (30% vs. 60%, p=0.045). Similarly for the rate of use of anti-TNF α therapy which was 9.6% and 33% in group 1 and 2 respectively (p=0.009).

Conclusion: In our study, we showed that elderly IBD has a mild disease course compared to younger patients. We found significantly lower rate of initiation of IBD medications in elderly patients.

Disclosure: Nothing to disclose.

PP0594

ASSESSMENT OF PHYSICAL ACTIVITY LEVELS AND ITS BARRIERS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES: THE "BE-FIT-IBD" STUDY RESULTS IN SOUTHERN EUROPE

R. Pellegrino[1], S. Auletta[1], R. D'Onofrio[1], G. Palladino[1], A. Coppola[1], A. Federico[1], A.G. Gravina[1]
[1]University of Campania "Luigi Vanvitelli", Hepatogastroenterology Unit, Department of Precision Medicine, Naples, Italy

Contact E-Mail Address: donofriorossella@gmail.com

Introduction: The place that regular Physical Activity (PA) should occupy in managing patients with Inflammatory Bowel Diseases (IBD) is unclear. Unfortunately, there is little data on PA in patients with IBD, although it appears to be reduced compared to the general population. Nevertheless, PA may provide several multidimensional metabolic, anti-inflammatory, and sarcopenia benefits. Therefore, the World Health Organization recommends for each age group and patients with disabilities regular PA adapted to individual ability/tolerance. However, there are no precise guidelines on the best PA and the intensity to recommend for patients with IBD. Therefore, this study aims to assess PA levels and barriers to PA in a southern European Italian IBD population.

Aims & Methods: IBD patients with non-severe disease activity [assessed with partial Mayo score for Ulcerative Colitis (UC) and Harvey-Bradshaw index for Crohn's Disease (CD)] were approached to receive an anonymous online questionnaire to assess PA levels using the International Physical

Activity Questionnaire (IPAQ) and to assess disease activity as Patient-Reported Outcomes 2 (PRO-2) and finally to assess habits, beliefs and barriers in conducting regular PA. Clinical, anthropometric and demographic data of patients were also collected. PA was expressed as continuous units of resting metabolic rate (Met) in minutes/week (Met min/wk). Three PA groups were identified: inactive (< 700 Met min/wk), sufficiently active (700-2500 Met min/wk) and Health Enhancing PA (i.e., HEPA active, > 2500 Met min/wk) patients.

Results: Included patients (219) showed overall PA levels of 834.5 Met min/wk, with a large proportion (94, 42.9%) classified as inactive while only a minority (9, 4.1%) as health-enhancing PA (see Table). Patients without dyslipidaemia ($p < 0.0001$) or on biologics therapy ($p=0.022$) showed better IPAQ scores in moderate activities. UC PRO-2 correlated negatively with IPAQ intense activities scores ($\tau= -0.156$, $p=0.038$). PRO-2 did not show notable sensitivity/specificity in predicting IPAQ inactivity (AUC < 0.6). IBD activity did not differ between active and inactive patients ($p > 0.05$). Active patients expressed the need to discuss PA with their gastroenterologist. Some barriers (e.g., diagnosis of IBD and fear of flare-ups after PA) are significantly more reported by inactive patients.

PA variable	Crohn's disease (N=92)	Ulcerative colitis (N=127)	P-value*
Intense activities *(Met min/wk)*	0 (0 – 192)	0 (0 – 240)	0.099
Moderate activities *(Met min/wk)*	208 (0 – 536)	140 (0 – 540)	0.590
Mild activities *(Met min/wk)*	293.75 (158.12 – 711.6)	350 (120 – 840)	0.940
Sitting time at work *(min)*	210 (113 – 292.5)	215 (125 – 292)	0.719
Sitting time at home *(min)*	174 (118.75 – 221.75)	177 (115 – 229)	0.855
Total score *(Met min/wk)*	828.25 (339.37 – 1343.5)	839 (390 – 1451)	0.678
PA level			
Inactive	39 (42.4%)	55 (43.3%)	0.995
Sufficiently active	50 (54.3%)	66 (52%)	
HEPA active	3 (3.3%)	6 (4.7%)	

HEPA: Health Enhancing Physical Activity. *The P-value was calculated by checking the difference in the distribution of different variables between the two identified groups (i.e., Crohn's disease and ulcerative colitis). Data are expressed for continuous variables as median (interquartile range) and, for categorical and ordinal variables, as numerosity (%).

Conclusion: There was a significant rate of physical inactivity in patients with IBD in this setting. Many IBD southern European patients are inactive and may be exposed to all the complications of not practising regular PA. This does not seem dependent on disease activity but is affected by patients' beliefs about PA's impact on baseline IBD. There is some patient interest in discussing PA with their gastroenterologist that should be used to inform them about the available evidence on PA and the risks of impact on IBD that they fear.

Introduction: Natural history of anal stricture observed in Crohn's disease (CD) remains poorly known, especially in pediatric onset CD.

Aims & Methods: All patients with a diagnosis of CD before the age of 17 years between 1988 and 2011 within the population-based registry EPIMAD were followed retrospectively until 2013. At diagnosis and during follow-up, the clinical and therapeutic features of perianal disease were recorded.

Results: Among the 1,007 included patients (females, 451 (44.8%); median age at diagnosis 14.4 years (IQR, 12.0-16.1)), one (0,1%) had an anal stricture at diagnosis and 26 (2.6%) during follow-up. Cumulative incidence of anal stricture at 5 and 10 years from diagnosis was 0.6% (95%CI, 0.1-1.1) and 1.4% (95%CI, 0.5-2.3), respectively. Twenty-five (n=25/27, 92.6%) patients had at least one episode of anal ulceration or fistulizing perianal Crohn's disease (pCD). In multivariable analysis, the presence of extra-intestinal manifestations (HR 2.3 (95%CI, 1.1-4.9), p=0.0378), colonic location (L1 vs L3 HR 0.0 (95%CI, 0.0-na), L2 vs L3 HR 1.2 (95%CI, 0.5-2.7), p=0.0246) and history of fistulizing pCD (HR 7.6 (95%CI, 3.2-17.9), p<0.0001) were significantly associated with the onset of anal stricture. Eleven (40.7%) patients needed at least one dilatation. After a median follow-up of 6.2 years (IQR, 2.4-10.6), after anal stricture diagnosis, healing was observed only once. One patient (3.7%) had an anal cancer seven years after stricture diagnosis and nine (33.3%) patients needed a stoma. Anal stricture was significantly associated with the need of stoma (HR 5.8, 95%CI 2.3-14.3), p=0.0002).

Conclusion: The occurrence of anal stricture is an infrequent event in pediatric onset CD, since only 1.5% of patients will present an event after 10 years. Anal stricture increased the risk of stoma by a factor of 5.

Disclosure: Nothing to disclose.

Introduction: Proton pump inhibitors (PPIs) are among the most commonly prescribed drug classes in most western countries. Their clinical effect is mediated by inhibition of acid secretion from stomach parietal cells, and relieve gastro-esophageal reflux disease, peptic ulcers, and dyspepsia (1).

Despite the perceived safety of PPIs, increasing evidence links PPI treatment to bacterial enteritis, and *clostridium difficile* enterocolitis (2).

Alteration of gut microbiota seems to be the common denominator of these adverse outcomes (3), which may trigger inflammation in IBD (4).

Several studies link proton pump inhibitor (PPI) use and adverse outcomes in patients with inflammatory bowel disease (IBD) (5-7). On the other hand, PPI prescription may also mark the onset of symptoms from IBD flare-ups, and in that case indicate confounding by indication – a protopathic bias.

Thus, it remains unresolved whether PPI use have an adverse impact on the clinical course of IBD, or whether an association between PPI use and deterioration of IBD is the result of a protopathic bias. An analysis of the interaction between time since PPI prescription and the adverse outcomes would aid to the clarification of that (8).

Aims & Methods: We aimed study the association between PPI use and hospitalizations/surgery in IBD patients.

We identified all Danish residents diagnosed with IBD in 2000–2018 in a nationwide healthcare register (18). The data were analyzed as separate PPI treatment episodes allowing an individual to enter with more than one PPI episode.

We used propensity score weighted Cox regression to estimate the hazard ratio (HR) for hospitalization and surgery for PPI-users compared with non-users adjusted for age, sex, IBD duration, calendar year of diagnosis, disease category (Crohn's disease / Ulcerative colitis), Charlson Comorbidity Index score, previous IBD-related hospitalizations, previous IBD-related surgery, maintenance therapy (5-aminosalicyclic, thiopurines or anti-tumor necrosis factor-a agents [infliximab/adalimumab], and prescription of NSAIDs).

Results: We identified 40,767 patients with IBD (69.2% with ulcerative colitis, 30.8% with Crohn's disease). Before first IBD diagnosis, 34.0% had filed at least one PPI prescription. Five years after IBD diagnosis, 39.9% had had at least one PPI prescription. The weighted HR for hospitalizations was 1.71 (95% CI: 1.62–1.81) during the first year after PPI prescription, and 1.33 (95 % CI: 1.18–1.50) thereafter. The weighted HR for IBD-related surgery was 1.39 (95% CI: 1.18–1.50) the first year and 1.40 (95% CI: 1.20–1.64) thereafter.

Conclusion: We identified a 40–70% higher rate of hospitalization and surgery the first year after PPI prescription in IBD patients, and a 10–30% higher rate for the remaining follow-up.

PREVALENCE OF SURGERY IN PATIENTS WITH CROHN'S DISEASE IN AUSTRIA – A NATIONWIDE RETROSPECTIVE STUDY FROM 2011 THROUGH 2019

K. Wisniowski[1], V. Ritschl[2,3], S. Riss[4], B. Reichardt[5], C. Primas[1], P. Schreiner[1], L. Kazemi-Shirazi[1], S. Dabsch[1], T. Stamm[2,3], W. Reinisch[1], G. Novacek[1]

Introduction: Crohn's disease (CD) is a chronic inflammatory bowel disease that may result in progressive bowel damage and complications requiring surgery. Despite an increasing number of available advanced targeted therapies, the literature reveals conflicting results concerning the prevalence of surgeries in CD.

Aims & Methods: The aim of the study was to examine the number of intestinal and perianal fistula surgeries in patients with CD in Austria from 2011 through 2019. We conducted a retrospective analysis of real-world data on surgery in CD patients of the Austrian health insurance funds (covering 98% of the Austrian population) from 2011 through 2019. Data before 2011 were unavailable, and the years after 2019 were excluded due to a potential influence caused by the coronavirus pandemic. All patients with a recorded CD-specific intestinal (bowel resection and/or stricturoplasty) or perianal fistula surgery and an ICD-10 diagnosis of CD(K50.x) during the observation period were included. We calculated the absolute number of operations per year, the prevalence per 100,000 persons of the Austrian population (the prevalence of CD in Austria is unknown) and the change in the operation rate per year.

Results: During the observation period, 4,812 intestinal and 4,802 perianal fistula operations were performed. We observed an increase of +8.8% and +58.9%, respectively, in bowel and perianal fistula operations from 2011

through 2019, see Table. If the numbers were adjusted for the increase of the Austrian population, the number of bowel operations remained stable (+1.9%), however, the number of perianal fistula operations still increased significantly (+48.8%).

Year	Austrian population	Intestinal operations	Perianal fistula operations	Prevalence of intestinal operations/ 100,000	Prevalence of perianal fistula operations/ 100,000
2011	8,388,534	503	423	6.00	5.04
2012	8,426,311	555	481	6.59	5.71
2013	8,477,230	539	491	6.36	5.79
2014	8,543,932	491	514	5.75	6.02
2015	8,629,519	537	509	6.22	5.90
2016	8,739,806	505	487	5.78	5.57
2017	8,795,073	538	586	6.12	6.66
2018	8,837,707	597	639	6.76	7.23
2019	8,951,520	547	672	6.11	7.51

Conclusion: Despite novel therapies, the number of patients requiring intestinal surgery for CD remained stable while the number of perianal fistula operations increased. A potential increase in the prevalence of CD in Austria, as described in other European countries, might reveal a decrease in the rate of intestinal surgeries.

Introduction: Emerging evidence points towards a plausible link between psoriasis, a common chronic inflammatory skin disease, and inflammatory bowel disease (IBD), as both diseases share similar inflammatory pathways(1).

Aims & Methods: Our aim was to identify patterns and potential predictors for the development of IBD in a psoriasis patients cohort.

This retrospective electronic health records-based study utilized data from the Meuhedet Health Maintenance Organization (MHMO) which contains 20 years of continuous follow-up. Patents' data were evaluated for demographic parameters, comorbidities, auto-antibodies, and medications used.

Prevalence and incidence of IBD were measured. The association between psoriasis and IBD was evaluated using both univariate and multivariate logistic regression models, with adjustments made for possible confounding factors. The prediction model was developed to identify predictors of IBD development in psoriasis

Results: Data between psoriasis patients (n=61,003) and age and gender-matched controls (n=244,012) was compared.

Among psoriasis patients, 2.5% were diagnosed with IBD, compared to 1.6% of controls (OR 1.57, 95%CI 1.48-1.67). The adjusted OR was 1.47 (95% CI 1.37-1.56), p<0.001. IBD was diagnosed before the onset of psoriasis in 51.9% and within 1 year of psoriasis onset in 7.2%. Predictors of IBD development in psoriasis patients were: older age (OR 1.01, 95%CI 1.01-1.02), male gender (OR 1.22, 95%CI 1.03-1.45), axial spondyloarthropathies (OR 1.78, 95%CI 1.29-2.45), severe psoriasis (OR 16.03, 95%CI 11.02-23.34), uveitis (OR 3.13, 95%CI 2.08-4.71), ASCA positivity (OR 10.71, 95%CI 7.38-15.55), and P-ANCA positivity (OR 7.71, 95%CI 2.04-29.04). The specific risk for IBD among psoriasis patients according to disease severity is shown in Table 1.

Decreased risk for IBD in psoriasis patients was observed in patients with obesity (OR 0.76, 95%CI 0.62-0.94), psoriatic arthritis (OR 0.49, 95%CI 0.34-0.72), phototherapy (OR 0.09, 95%CI 0.06-0.15), and methotrexate use (OR 0.13, 95%CI 0.08-0.21). The presence of ANA antibodies was not significantly associated with the risk of IBD within the psoriasis cohort.

		Psoriasis	Controls	Crude OR (95%CI)	Adjusted OR(95% CI)
IBD	All PsO patients	1495/61003 (2.5%)	3834/244012 (1.6%)	1.57 (1.48-1.67)**	1.47 (1.37-1.56)**
	Mild psoriasis	1009/53714 (1.9%)	3358/214856 (1.6%)	1.21 (1.12-1.3)**	1.17 (1.08-1.26)**
	Severe Psoriasis	486/7289 (6.7%)	476/29156 (1.6%)	4.3 (3.78-4.89)**	4.45 (3.87-5.12)**
Crohn's disease	All PsO patients	1208/61003 (2%)	2950/244012 (1.2%)	1.65 (1.54-1.76)**	1.52 (1.42-1.63)**
	Mild psoriasis	781/53714 (1.5%)	2582/214856 (1.2%)	1.21 (1.12-1.31)**	1.17 (1.07-1.27)**
	Severe Psoriasis	427/7289 (5.9%)	368/29156 (1.3%)	4.87 (4.22-5.61)**	4.99 (4.28-5.82)**
UC	All PsO patients	553/61003 (0.9%)	1525/244012 (0.6%)	1.45 (1.32-1.6)**	1.38 (1.25-1.53)**
	Mild psoriasis	389/53714 (0.7%)	1338/214856 (0.6%)	1.16 (1.04-1.3)*	1.12 (1-1.25)*
	Severe Psoriasis	164/7289 (2.2%)	187/29156 (0.6%)	3.56 (2.88-4.4)**	3.94 (3.15-4.94)**

Conclusion: Our study provides evidence for a significant association between psoriasis and IBD and identifies several predictors for the development of IBD in psoriasis patients. These findings may improve clinical decision-making and patients' outcomes.

Introduction: Colorectal cancer (CRC) risk is increased in patients with long-standing colitis related to Inflammatory Bowel Disease (IBD). A higher frequency of mucinous and signet-ring colonic adenocarcinoma has been suggested in IBD, but risk factors for these histotypes of CRC are undefined.

Aims & Methods: Primary aim was to compare the frequency of mucinous and signet-ring adenocarcinoma in patients with vs without IBD. Secondary aims were to search for IBD-related risk factors for signet ring

and mucinous adenocarcinoma and to compare the localization of these histotypes of CRC in patients with vs without IBD. From January 2002 to January 2023, all IBD patients with concomitant colorectal adenocarcinoma (Cases) were retrospectively enrolled. Each Case was matched with 2 patients with CRC and no IBD (Controls) for age at CRC diagnosis (±5 years). Inclusion criteria for Cases and Controls: 1) age ≥18; 2) well-defined diagnosis of CRC. Additional inclusion criteria for Cases: well-defined diagnosis of IBD, classified according to standard criteria. Exclusion criteria: Missing histological and surgical report. Data were expressed as median [range]. Student-t Test and $\chi 2$ test were used for comparisons. Univariate logistic regression model was applied for assessing risk factors for mucinous and signet-ring CRC (OR [95%CI]).

Results: The study population included 120 patients with colorectal adenocarcinoma: 40 IBD patients and 80 non-IBD Controls. CRC in the 40 IBD patients occurred in 24 (60%) patients with Ulcerative Colitis (UC) and in 16 (40%) with Crohn's Disease (CD). In patients with CRC, no differences were observed between IBD and non-IBD Controls in terms of gender (F) (13 [32.5%] vs 35 [43.7%]; p=0.32) and median age at diagnosis of CRC (54 [29-80] vs 58 [31-83] years; p=0.19). CRC in IBD was histologically defined as mucinous/ signet-ring in 17 (42.5%) and standard adenocarcinoma in 23 (57.5%) patients. Mucinous/signet ring CRC more frequently occurred in patients with IBD vs non-IBD Controls (17 [42.5%] vs 18 [22.5%], p=0.03). In IBD patients, rectal localization of CRC was significantly more frequent in mucinous/signet-ring vs standard CRC (4 [17.4%] vs 8 [47.1%]; p=0.04). In stricturing CD, there was a significantly higher frequency of standard vs mucinous/signet-ring CRC (7 [77.8%] vs 1 [14.4%]; p=0.04). Other IBD characteristics did not differ in relation to the 2 CRC histotypes, including gender (F): 8 [34.8%] vs 5 [29.4%]; p=0.98 and IBD duration at CRC diagnosis (14 [1-45] vs 17 [1-36]; p=0.74). In IBD, CRC stage at diagnosis was comparable between patients with standard vs mucinous/signet-ring CRC (stage I: 6 [26.1%] vs 1 [5.9%]; p=0.21; II: 9 [39.1%] vs 4 [23.5%]; p=0.48; III: 5 [21.7%] vs 7 [41.2%]; p=0.71; IV: 3 [13.1%] vs 5 [29.4%]; p=0.37)). At univariate analysis, no IBD-related risk factors for mucinous/signet-ring CRC were detected.

Conclusion: In the tested cohort, mucinous and signet-ring adenocarcinoma was more frequently observed in IBD than in non-IBD controls, although no IBD-related risk factors were identified. A higher frequency of rectal involvement is suggested for mucinous/signet-ring vs standard adenocarcinoma in IBD.

Disclosure: Nothing to disclose.

Introduction: In Crohn's Disease (CD),the natural history of post-operative recurrence (POR) after ileo-colonic (IC) anastomosis has been extensively investigated. Fewer evidences are available regarding the POR after other surgical resections for CD.

Aims & Methods: The primary aim was to investigate, in a retrospective study, the clinical outcome at 5 years (yrs) of patients (pts) with previous CD-related resection different from IC anastomosis. Secondary aim was to assess possible differences in terms of clinical outcome at 5-yrs between pts with small bowel anastomoses involving or not the colon. Data from all pts with CD-related resection different from IC anastomosis from Jan. 2002-Apr. 2018, were recorded.Inclusion criteria:1)age ≥18 yrs; 2)well-defined diagnosis of CD (Montreal)(1);3)history of CD-related bowel resection (index surgery);4) Available data 5-yrs after surgery.Exclusion criteria:1)IC resection; 2)ostomy; 3) strictureplasty. Parameters considered after surgery: need of corticosteroids (CS),biologics, immunomodulators (IMM),CD-related surgery, hospitalization. Data were expressed as median [range], Student-t-test or X^2 test to assess differences.

Results: The study population included 47 pts with CD-related surgery with anastomosis different from IC (females:18 [38.3%];age:50 [29-78] yrs; CD duration:26 [7-53] yrs; age at surgery:34 [14-63] yrs). CD characteristics A1 n=8 (17%), A2 n=34 (72.3%), A3 n=5 (10.6%) pts; L1 n=23 (48.9%), L2 n=5 (10.6%), L3 n=19 (40.4%); L4 n=14 (29.8%); B1 n=1 (2.1%), B2 n=25 (53.2%), B3 n=21 (44.7%), perianal disease in 5 (10.6%) pts. Time interval between CD diagnosis and index surgery: 8 [0-25] yrs.Surgical indication:penetrating CD in 15 (31.9%), occlusion in 27 (57.4%), perforation in 4 (8.5%), refractory CD in 1 (2.1%) pt. Surgical anastomoses were: ileo-ileal in 23 (48.9%), jejunum-ileal in 5 (10.6%) duodenum-jejunal in 1 (2.1%), jejunum-jejunal in 4 (8.5%), ileo-rectal in 9 (19.1%), colo-colonic in 5 (10.6%) pts. Anastomoses involved only the small bowel in 33 (70.2%) pts, while anastomoses involved also the colon-rectum (ileo-rectal or colo-colonic) in 14 (29.8%) pts. Clinical outcome after index surgery in the 47 pts (at 1-yr and 5-yrs, respectively): A) Additional CD-related surgery in 2 (4.4%) and in 6 (12.8%) pts; B) Clinical recurrence in 16 (34%) and in 34 (72.3%) pts; C) CD-related hospitalization in 7 (14.9%) and in 25 (53.2%) pts. Either CS or IMM were used in 11 (23.4%) pts at 1 yr and in 20 (42.5%) pts at 5 yrs, while biologics in 8 (17%) pts at 1-yr and in 29 (61.7%) at 5 yrs. When comparing pts with anastomoses involving only the small bowel or also the colon-rectum, a comparable clinical outcome was observed, including: additional CD-related surgery (at 1 yr: 1 [3%] vs 1 [7.1%]; p=0.87; at 5-yrs: 4 [12.1%] vs 2 [14.3%]; p=0.78), clinical recurrence (at 1 yr: 10 [30.3%] vs 6 [42.8%]; p=0.62; 5-yrs: 24 [72.7%] vs 11 [78.6%]; p=0.94), CD-related hospitalization (at 1-yr: 4 [8.5%] vs 3 [21.4%], p=0.71; at 5-yrs: 20 [60.6%] vs 6 [42.8%]; p=0.42), need of CS (at 1-yr; 10 [30.3%] vs 2 [14.2%], p=0.43; at 5-yrs:18 [54.5%] vs 5 [35.7%], p=0.38),IMM (at 1 yr:8 [24.2%] vs 2 [14.2%]; p=0.7; at 5 yrs: 17 [51.5%] vs 4 [28.6%]; p=0.26), biologics (at 1 yr: 5 [15.1%] vs 3 [21.4%]; p=0.92); 5 yrs: 21 [63.6%] vs 8 [57.1%]; p=0.92).

Conclusion: In a retrospective study, a severe clinical course characterized CD pts with a history of surgery different from ileo-colonic resection in the previous 5 yrs. Hospitalization or major treatments were required in more than half of cases.

THE IMPACT OF IMMUNOSUPPRESSIVE THERAPY ON SARS-COV-2 MRNA VACCINE EFFECTIVENESS IN PATIENTS WITH IMMUNE-MEDIATED INFLAMMATORY DISEASES: A DANISH NATIONWIDE COHORT STUDY

R. Elmahdi[1], D. Ward[1], M. Ernst[2], J. Hallas[2], A. Pottegaard[2], T. Jes[1]
[1]Aalborg University, Clinical Medicine, København, Denmark, [2]University of Southern Denmark, Clinical Medicine, Odense M, Denmark

Contact E-Mail Address: re107@ic.ac.uk

Introduction: Investigation of SARS-CoV-2 vaccine efficacy in immune-mediated inflammatory disease (IMID) patients receiving immunosuppressives have been restricted to small sized serological studies. We therefore undertook an investigation of immunosuppressants' impact on real-world effectiveness of vaccines in these patient groups.

Aims & Methods: We performed a nationwide cohort study to assess the risk of COVID-19 infection in vaccinated IMID patients exposed to immunosuppressives compared to propensity score matched unexposed patients in the period from 1 January 2021 to 30 November 2021. Exposure to immunosuppressives 120 days before receiving the second SARS-CoV-2 mRNA vaccination was assessed. Patients were followed from the date of second vaccination, and weighted Cox models were used to estimate the risk of infection associated with immunosuppressives. Secondary outcomes included hospitalisation and death following positive SARS-CoV-2 test. Subgroup analysis for risk of infection by immunosuppressive drug class was also undertaken.

Results: Overall, 152,440 patients were followed over 19,341 person-years. Immunosuppressives were associated with a significantly increased risk of infection in Inflammatory Bowel Disease (IBD; HR: 1.64, 95% CI: 1.42, 1.91), and Arthropathy (HR:1.27, 95% CI: 1.13, 1.43) but not Psoriasis (HR: 1.11, 95% CI: 0.89, 1.38). Meta-analysis of all IMID also showed a significantly increased risk of infection in immunosuppression (HR: 1.35, 95% CI: 1.24, 1.46). Meta-analysis showed no significantly increased risk of either hospitalisation (HR: 1.40, 95% CI: 0.80, 2.46), or death (HR: 0.92, 95% CI: 0.38, 2.23) was identified. Subgroup analysis by immunosuppressive drug class showed increased infection risk in anti-TNF (HR: 1.75, 95% CI: 1.56, 1.96), systemic corticosteroid (HR: 1.24, 95% CI: 1.00, 1.42), and Rituximab and other immunosuppressant (HR: 1.27, 95% CI: 1.14, 1.42) exposure.

Conclusion: Findings suggest reduced effectiveness against infection following two doses of mRNA SARS-CoV-2 vaccination in IBD and arthropathy patients receiving immunosuppressive therapies. Anti-TNF, systemic corticosteroids, and Rituximab and other immunosuppressants were particularly associated with increased infection risk.

Disclosure: Nothing to disclose.

Introduction: Crohn's disease (CD) is generally confined to the ileocecal tract. Upper gastrointestinal tract (UGIT) involvement is estimated to be between 0.5 and 4% of adult patients with CD.

Aims & Methods: The aim of our study was to describe the epidemioclinical and evolutionary profiles of patients with UGIT involvement in CD. A retrospective, descriptive and comparative study including all patients followed for CD in our department during the period from January 2011 to December 2020 was conducted. Patients with UGIT involvement were identified. Data were entered and analyzed via the software SPSS 26.

Results: Among 341 patients followed for CD, we included 49 with UGIT involvement (14.3%), with a sex ratio of M/F=1,1. The mean age at diagnosis was 29.27 ± 11.8 years. Fifteen patients were smokers. A family history of chronic inflammatory bowel disease was statistically more present in patients with UGIT disease (p=0.031). The mean duration of disease progression since diagnosis was 9.43 years. Only one patient had exclusive upper GI involvement; in the other cases, it was associated with another luminal involvement represented mainly by ileal involvement in 59.3% of cases, with a significant association (p=0.019). The CD behaviour was mainly fistulizing in 40.8%, stricturing in 36.7% and inflammatory in 22.5%. Extensive luminal disease, defined as damage exceeding 50 cm, was observed in 12 patients (24.48%) and was associated with UGIT involvement (p=0,001). Eight patients had complex anoperineal fistulas and one patient had an associated anal stenosis. Forty percent of the patients had an associated extra-intestinal manifestation. The mean body mass index at diagnosis was 20.41 kg/m² [13.7 - 32,4]. The mean albumin level at diagnosis was 31.94g/L. Histological severe activity was noted in 14 patients. Epithelioid and gigantocellular granuloma, found in 13 patients (26.5%), was associated with UGIT involvement (p=0.027). On the other hand, a history of severe acute colitis was associated with the absence of upper GI involvement (p=0.01). The median number of flares was 4 [1-16]. The median number of hospitalizations was 4 with a maximum of 13 hospitalizations and a mean duration of hospitalization of 21 days. The use of anti-TNF drugs was associated with UGIT involvement with p<0.001. Surgical treatment was required in 48,4% of the patients (n=24), mainly ileo-caecal resection, without any significant difference (p=0.05). We noted that the number of surgical interventions was significantly higher in the presence of granuloma on histology (p=0.043). However, the detection of granuloma or severe activity on histology was not associated with a greater use of anti-TNF drugs.

Conclusion: Upper gastrointestinal tract involvement in Crohn's disease is rare and is more likely to be associated with a severe disease course.

Disclosure: Nothing to disclose.

LET´S TALK ABOUT SEX: A CROSS-SECTIONAL STUDY ON SEXUAL DYSFUNCTION, SEXUAL SATISFACTION AND BODY SCHEMA DISORDERS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD)

J.G. Klaus[1], D. Lindenthal[1], K. Hirning[2], L. Schulte[1], A. Kranzeder[2]
[1]University Hospital Ulm, Department of Internal Medicine I, Ulm, Germany, [2]University Hospital Ulm, Department of Psychosomatic Medicine and Psychotherapy, Ulm, Germany

Contact E-Mail Address: jochen.klaus@uniklinik-ulm.de

Introduction: IBD patients suffer from a variety of physical and psychological problems. Sexual health is an often underestimated but important concern among patients. Despite its major impact, there has been little research on this topic in the past.

The aim of this study was to investigate sexual dysfunction, sexual satisfaction and body schema disorders in patients with IBD compared to a healthy control group.

Aims & Methods: A cross-sectional study was performed. 123 patients with IBD and 71 population controls were recruited for 12 months. Inclusion criteria for the patient group included a diagnosed IBD (Crohn's Disease or Ulcerative Colitis), age between 18 - 65 years and sufficient language skills to complete the questionnaires. For the control group inclusion cri-

teria were similar but without a diagnosed IBD. Data was collected using standardised questionnaries (IBDQ, IBD-F, pMS, HBI, IIEF, BISF-W, FKKS, PHQ15, PHQ9, HADS-D). Sexual dysfunction, sexual satisfaction and body schema disorders were mainly assessed by the "Frankfurter Körperkonzeptskalen" (FKKS) and "The Brief Index of Sexual Functioning for Women" (BISF-W).

Results: Significant differences ($p < 0.05$) could be found within the individual questionnaire scales. Regarding the FKKS, the control group scored higher in three of the nine scales: Health and physical condition scale (SGKB), Sexuality scale (SSEX) and Body self-acceptance scale (SSAK). A similar result was also shown in the BISF-W: population controls had higher scores in two of the seven dimension scores: "Arousal" (D2) and "Pleasure/Orgasm" (D5). Overall, when comparing the total scores of FKKS and BISF-W between patients and population controls no remarkable distinctions were identified.

Conclusion: Sexual health seems to be impaired in patients with IBD. Patients suffer from reduced sexual arousal, orgasmic sensation and physical well-being. In addition, they are also more inhibited in sexual contact with their partners and devalue their own body in terms of aesthetics and biological functionality.

Overall, these results can help to understand the disease´s complexity considering not only clinical but also psychological factors regarding sexual well-being and point to new therapeutical directions.

Disclosure: Nothing to disclose.

Contact E-Mail Address: david.wands88@gmail.com

Introduction: Inflammatory bowel disease unclassified (IBDU) is the least common subtype of IBD accounting for around 10% of incident cases in children.[1] It represents a distinct phenotype of colonic IBD where there are insufficient endoscopic and histological patterns to diagnose either ulcerative colitis (UC) or Crohn's disease (CD).[2] There is a lack of long-term longitudinal data to fully elucidate the disease course in IBDU.

We present nationwide data of an IBDU cohort with long-term (9-20 years) follow-up.

Aims & Methods: In a nationwide study, we analysed a prospectively identified cohort of IBDU patients diagnosed 01/01/03-31/12/13 via all Scottish paediatric IBD centres (Aberdeen, Edinburgh, Glasgow) with follow-up until 01/1/23. Data were obtained retrospectively from electronic medical records (demographics, diagnostic assessment, longitudinal disease severity based on defined global clinician assessment, medical treatment and surgical outcomes) at fixed time points (5-10 years post-diagnosis) and at the last follow-up.

Results: 99 patients were identified with IBDU, with 10 excluded as they emigrated out of area. 89 patients were included in the analysis (52/89 (58%) male, median (IQR) age at diagnosis 11.6 (9.2-13.5 years)). All had a diagnosis of IBDU based on the Porto criteria[3] using a combination of clinical, endoscopic, histological and radiological findings. The median (IQR) length of follow-up was 10.5 (8.7-14.0 years).

A change of diagnosis was made to UC in 24/89 (27%) and CD in 28/89 (31%) after a median (IQR) disease duration of 3.7 (1.6-7.7 years; 2.5 repeated endoscopies) and 4.38 (1.8-5.6 years; 2 repeated endoscopies) respectively. IBDU remained the diagnosis in 37/89 (42%) after a median (IQR) follow-up of 9.7 (8.0-13.8 years) and a median of 2 (1-2) repeated endoscopies.

At 5 and 10 years of follow-up, 37/83 (45%) and 36/67 (54%) patients were in clinical remission with a reduction in the proportion of patients with moderate to severe disease activity between 5 and 10 years (5-years 32/83 (39%), 10-years 10/67 (15%), p=0.001). No differences were found in remission rates at 5- and 10- years according to disease classification (IBDU vs CD/UC, 5-years p=0.29, 10-years p=0.60). However, compared to IBD-U, patients with active reclassified UC or CD were more likely to have had a moderate-to-severe disease course at 5 -years (IBDU 21% vs CD/UC 50%; p=0.01). 34/89 (38%) patients achieved longstanding clinical remission on aminosalicylates. Escalation to biologics was required in 30/89 (34%) with 7/89 (8%) requiring multiple classes; no differences in biologic use were found according to IBD sub-type (p=0.82).

Resectional surgery was required in 13/89 (15%; 6 UC, 5 CD, 2 IBDU) after a median (IQR) disease duration of 6.7 (1.24-12.7 years). Patients who changed diagnosis to either UC or CD were more likely to require resectional surgery than those remaining IBDU (UC 6/24 (25%) vs IBDU 3/37 (8%), p=<0.001; CD 6/28 (21%) vs IBDU 3/37 (8%), p=<0.001).

Conclusion: This population-based cohort with up to 20 years of follow-up showed that the majority of patients initially diagnosed with IBD-U are reclassified as either UC or CD. Those reclassified are more likely to have a severe disease course with a greater need for surgery.

EPIDEMIOLOGICAL PROFILE AND MANAGEMENT OF SPECIFIC ANAL FISTULAS

M. Konso[1], H. ELBacha[1], M. Cherkaoui Malki[1], S. Mechhor[1], S. Dilal[1], N. Benzzoubeir[1], I. Errabih[1]

[1]Mohammed V University Rabat., Hepato-Gastro-Enterology and Proctology Department "Medicine B" Ibn Sina Hospital-CHU Ibn Sina, Rabat, Morocco

Contact E-Mail Address: mariamkonso@gmail.com

Introduction: Anal fistulas are the most common clinical forms of anoperineal suppurations. They are defined by the initial infection of an anal gland of Hermann and Desfosses opening in the middle part of the anal canal. A specific origin is possible. The treatment is surgical and has two objectives: to treat the suppuration definitively and to preserve fecal continence, but also to have histological evidence for specific fistulas.

Aims & Methods: The aim of our work is to collect epidemiological, clinical, paraclinical, therapeutic and evolutionary data of this condition.

This is a retrospective, descriptive study over a period of 6 years: January

2015-December 2021, including 640 patients with anal fistula collected at the proctology unit, all patients with anal fistula and who received surgical treatment or biopsy for diagnostic purposes were included in our study. This work allowed to collect epidemiological, clinical, paraclinical, therapeutic and evolutionary data of this condition.

Results: 640 patients were included presenting with anal fistula. The average age was 39 years [25-59], with a male predominance of 570 patients (89%). Clinically, the predominant symptomatology was chronic purulent discharge in 416 cases (65%), 128 cases (20%) had an inaugural anal abscess, 77 cases (12%) had proctalgia, 19 cases (3%) had anal pruritus and 13 cases (2%) had diarrhea.

The proctological examination revealed: simple anal fistula in 575 patients (90%) and 65 patients had complex anal fistula (10%).

Out of 640 patients recruited for anal fistula, 45 patients (7%) had specific anal fistula and 595 patients (93%) had cryptoglandular anal fistula.

After a digestive, phtysiological and radiological assessment we concluded :

- 26 cases (58%) anal fistula occurring in patients followed for Crohn's disease or inaugural ano-perineal Crohn's disease having benefited from a seton drainage and put under combotherapy.
- 16 cases (36%) in favour of anal tuberculosis put on anti bacillary treatment.
- 2 cases (4%) of neoplastic fistulas that benefited from oncological management.
- 1 case (2%) in favor of anal sarcoidosis treated with corticotherapy.

Conclusion: Anal fistulas are a fairly common pathology. The diagnosis of anal fistulas is clinical. Cryptoglandular anal fistula remains the most frequent entity, requiring surgical treatment, while the management of specific anal fistula depends on the etiology.

Disclosure: No conflict of interest.

PP0606

PROTON PUMP INHIBITORS ARE ASSOCIATED WITH A DISABLING COURSE OF CROHN'S DISEASE

M. Barrau[1], G. Duru[2], A.S. Peaucelle[3], S. Nancey[4], A. Cheifetz[5], K. Papamichael[5], S. Paul[6], X. Roblin[1]

Contact E-Mail Address: mathilde.barrau@wanadoo.fr

Introduction: The impact of proton pump inhibitors (PPIs) on the evolution of inflammatory bowel disease (IBD) remains debated with only sparse data available. The primary objective of this study was to analyze the impact of PPIs on the course of IBD.

Aims & Methods: This was a single-center, retrospective cohort study. We included consecutive adult patients diagnosed with Crohn disease (CD) or ulcerative colitis (UC) who were followed prospectively in our day hospital over a 4-month period (from May to August 2022). PPI exposure was defined as PPI use for a cumulative duration of more than seven days from the date of IBD diagnosis until the end of follow-up. We performed a time to event analysis to investigate the association of PPI exposure with treatment failure defined as an IBD- related surgery or hospitalization and/or failure for more than four biologic treatment (Anti TNF, Vedolizumab, Ustekinumab).

Results: Among the 281 patients identified, 244 patients were eligible for analysis of the primary objective (152 with CD, mean age 45 years, sex ratio 1:1). 113 (46%) patients had been previously exposed to a PPI. PPI-exposed patients were significantly older (p=0.013), more often women (p=0.029), with more frequent active smoking (p=0.001). A total of 152 patients (62%) had treatment failure. Using Cox regression analysis, (Table 1), PPI use identified as an independent factor associated with treatment failure (HR = 1.920; 95% CI [1.084-3.403]; p0.025). In a subgroup analysis by IBD type, this remained statistically significant only for CD (HR = 3.190; 95% CI (1.412-7.206); p 0.005) but not for UC (HR = 0.981; 95% CI (0.384-2.504); p0.968). Survival without treatment failure (Figure 1) was significantly higher in patients without PPI exposure compared to patients with PPI exposure (175 months vs. 119 months, respectively, p=0.033 Log-Rank). In a subgroup analysis of infliximab-treated patients, PPI use was not associated with risk of immunogenicity (HR = 1.071; 95% CI (0.515-2.226); p0.854).

Conclusion: This study demonstrates the negative impact of PPIs on the disease course in patients with CD. The use PPIs should better be discussed on a case-by-case basis.

Disclosure: None.

Introduction: Microscopic colitis (MC) is a chronic inflammatory disease of the large bowel characterized by watery diarrhea, stool leakage, and nightly defecation, leading to impaired quality of life. Scarce consistent data suggest the association of MC with certain risk factors.

Aims & Methods: We aimed to assess MC's lifestyle and medical risk factors. Our protocol was prospectively registered with PROSPERO (CRD42022286624).

We systematically searched three medical databases from inception to the 18th of December 2021 (Pubmed, Embase, and Cochrane). Cohort, case-control, and cross-sectional studies, reporting on the number of risk factors in MC patients compared to controls with or without a histopathological examination, were included. We used the random-effect model to calculate pooled odds ratios (ORs) with 95% confidence intervals (CIs). The risk of bias assessment was made with the aid of the QUIPS tool.

Results: The systematic search yielded 7174 articles, and 43 were eligible for the study. Investigating lifestyle factors, current smoking was associated with a 1.64 odd (CI:1.06–2.52), while past smoking had a 1.28 odd (CI: 0.91–1.81) of MC compared to both types of controls. Regarding alcohol consumption, we could only do a comparison to controls who were not examined histologically, and no significant association with MC was found. Similarly, we could not show a significant association between MC and patients' level of education.

When investigating medical risk factors, we found a twofold increased chance of MC diagnosis in the case of non-steroidal anti-inflammatory drug (NSAID) use (OR=2.07, CI: 1.31–3.27), but the odds of MC were not significantly increased neither in the case of proton pump inhibitors

(OR=1.59, CI: 0.65–3.90) nor in the case of selective serotonin reuptake inhibitors (OR=2.10, CI: 0.73–5.98), compared to the overall control group. Most of the articles were deemed moderate or high risk of bias due to the low number of patients and the lack of confounding factors assessment.
Conclusion: Our data demonstrate a 64% increase in the odds of MC in the case of current smoking, and NSAID use is associated with a twofold risk for MC. Further prospective studies with longer follow-ups are needed to further investigate these associations.
Disclosure: None to declare.

PP0608

INFLAMMATORY BOWEL DISEASE WITH CONCOMITANT ENDOMETRIOSIS: CHARACTERIZATION AND 1-YEAR CLINICAL OUTCOME IN A PROSPECTIVE STUDY

B. Neri[1], C. Russo[2], M. Fiorillo[1], S.C. Schiavone[1], L. Babaiyan[1], M. Mossa[1], R. Mancone[1], S. Migliozzi[1], A. Moscardelli[1], A. Selntigia[2], F.G. Martire[2], E. Calabrese[1], C. Exacoustos[2], L. Biancone[1]

Contact E-Mail Address: benedettoneri@gmail.com
Introduction: Inflammatory bowel disease (IBD) and endometriosis are immuno-mediated chronic inflammatory diseases observed in young women, sharing some of the clinical manifestations (i.e. abdominal pain). The possible association and the relationship between endometriosis and IBD is undefined.
Aims & Methods: In a multidisciplinary approach, we aimed to assess in patients with IBD and concomitant endometriosis, the clinical outcome in terms of abdominal pain and endometriosis-related symptoms at 6 and 12 months and characteristics of endometriosis. All female IBD pts in childbearing age referring symptoms compatible with endometriosis were enrolled and referred to dedicated gynecologists for transvaginal ultrasonography (TVS). Inclusion criteria:
1) female gender;
2) age ≥18 and ≤55 years;
3)well-defined diagnosis of IBD;
4) symptoms compatible with endometriosis;
6) consent.
Exclusion criteria:
1) pregnancy;
2) menopause;
3) suspected pelvic malignancy at TVS.
Characteristics of IBD, endometriosis and adenomyosis were classified according to standard criteria. Data were expressed as median [range]. The Student-t Test and $\chi 2$ test were used for comparisons.
Results: Endometriosis was diagnosed in 25 (71%) out of 35 IBD patients with compatible symptoms. These 25 IBD pts included 12 (48%) Crohn's Disease (CD) and 13 (52%) Ulcerative Colitis (UC). CD and UC patients were comparable in terms of age (38 [28-47] vs 39 [25-53]; p=0.75). IBD characteristics included: IBD duration: 11.5 [1-35], CD 11 [1-25] vs UC 12 [1-35] years; p=0.8, CD localization: ileum 4 (33.3%), colon 1 (8.4%), ileum-colon 7 (58.3%), CD behavior: non-stricturing non-penetrating 6 (50%), stricturing in 3 (25%), penetrating in 3 (25%) pts, UC extent: proctitis 3 (23%), left-sided 5 (38.5%), pancolitis in 5 (38.5%) pts. Other IBD characteristics did not differ between CD and UC pts with endometriosis. In IBD patients with endometriosis, a comparable frequency of dysmenorrhea (9 [75%] vs 13 [100%] pts; p=0.47), dyschezia (5 [41.7%] vs 6 [46.1%] pts; p=0.85), dyspareunia (9 [75%] vs 10 [76.9%] pts; p=0.72), dysuria (0 [0%] vs 3 [23.1%] pts; p=0.24) was observed between CD and UC.
At transvaginal ultrasonography, deep infiltrating endometriosis was observed in all thr 25 patients with IBD and endometriosis. Moreover, a high frequency of rectal endometriosis was detected in these 25 IBD pts (6 [24%]). Adenomyosis was observed in 19 (76%) IBD pts with endometriosis, with no differences between CD and UC (8 [66.6%] vs 11 [84.6%]; p=0.56).
Among the 25 IBD pts with endometriosis, 10 (40%) underwent dienogest or estroprogestinic treatment. At 6 months, gynecological follow up was available in 9 pts, of whom 7 were on dienogest or estroprogestinic treatment. Among these 7 pts, 4 reported no endometriosis-related symptoms and 5 no abdominal pain. At 12 months, gynecological clinical follow-up currently includes 6 pts (25%), all on progestinic treatment. Of these, only 2 pts reported abdominal pain while 3 pts reported recurrence of endometriosis-related symptoms.
Conclusion: In the tested population, endometriosis was present in half of IBD pts with compatible symptoms, particularly DIE, with a high rate of rectal endometriosis. After endometriosis treatment, a lower proportion of patients referred abdominal pain. Endometriosis, often mimicking IBD, should be searched and treated in IBD young patients in order to avoid ineffective treatments.
Disclosure: Nothing to disclose.

IMPACT OF VITAMINS, PROBIOTICS, ANTIBIOTICS, AND THE HISTORY OF COVID-19 INFECTION ON THE GUT MICROBIOME IN ULCERATIVE COLITIS PATIENTS

Z. Straume[1,2], N. Krumina[2], M. Rozenberga[3], I. Elbere[3], D. Rudzite[1], J. Pjalkovskis[3], J. Ozolina[1,2], K. Megnis[3], V. Skuja[2], A. Krumina[2]
[1]Riga East Clinical Univeristy Hospital, Riga, Latvia, [2]Riga Stradins University, Riga, Latvia, [3]Latvian Biomedical Research and Study Centre, Riga, Latvia

Contact E-Mail Address: zanestraume@gmail.com
Introduction: It is well established that the gut microbiota plays an important role in host health and is perturbed by several factors including antibiotics and diseases like coronavirus disease 2019 (COVID-19). The microbiome contributes to the pathogenesis of ulcerative colitis (UC). Some vitamins have been shown to beneficially modulate the gut microbiome by increasing the abundance of presumed commensals. Also, probiotics could shape the intestinal microbiota leading to potential control of multiple bowel diseases and promotion of overall wellness.
Aims & Methods: In 6-month time (June 2021 to December 2021) 49 ulcerative colitis (UC) outpatients from Riga East Clinical University Hospital were included in a Cross-sectional study. All patients were divided into groups according to medically proven data about COVID-19 status (COVID-19pos vs. COVID-19neg) within the last 6 months. Information about vitamin, probiotic, and antibiotic intake, as well as fecal samples was collected. For taxonomical classifying of the gut microbiome metagenome data, MetaPhlAn v.2.6.0 tool was used. In further analysis gut microbiome (mostly bacteria phyla) and related data were analyzed with SPSS 20.0.
Results: Out of 49 patients, 31(63%) were male and 18(37%) were female, mean age was Md=38[IQR:34-51]. Fourteen patients (28.6%) have been COVID-19pos, 35(71.4%) COVID-19neg. Patients who were not using antibiotics in the last month had more *Firmicutes* Md= 64 [IQR:52.3-69.4] than users Md=31 [IQR:25.5-39.8], p=0.008. Only 9 patients (18.4%) consumed probiotics within the last month and 40 (81.6%) did not. Evaluating differences in bacteria composition in phylum level in-between probiotic users and non-users there were found no statistically significant difference. Most common used vitamins were vitamin D 18(64.3%), from those 15(42.9%) were COVID-19neg, 3(21.4%) COVID-19pos; vitamin C 7(32.8%),

from those 4(11.4%) were COVID-19neg, 3(21.4%) COVID-19pos, p>0.5. Evaluating vitamin D and C users and non-users and bacteria type there were found no statistically significant differences.

Conclusion: Patients who were not using antibiotics in the last month had more *Firmicutes* than users. There were no statistically significant differences between probiotic users and non-users, nor between vitamin users and non-users.

Disclosure: Nothing to disclose.

PP0610

ATOPIC PREDISPOSITION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A SYSTEMATIC REVIEW

C. O'Neill[1], E. Cologne[2], J. Sabino[3]

[1]Centro Hospitalar Lisboa Ocidental, Gastroenterology Department, Lisboa, Portugal, [2]Faculty of Medicine - KU Leuven, Leuven, Belgium, [3]Leuven University Hospitals, Gastroenterology and Hepatology Department, Leuven, Belgium

Contact E-Mail Address: oneill.catarina@gmail.com

Introduction: Inflammatory bowel disease (IBD) and atopic diseases, namely asthma, atopic dermatitis (AD), and atopic rhinoconjunctivitis (AR) show a rising prevalence worldwide and share some genetic and epidemiological risk factors. Consequently, observational studies have explored the potential association between IBD and atopic diseases, with some conflicting data.

Aims & Methods: The objective of this study was to systematically review and summarize the current evidence on the co-occurrence of IBD and these atopic diseases.

We searched Medline, Embase, Web of Science and CENTRAL (from inception to August 14, 2022) to identify observational studies on the incidence or prevalence of IBD in atopic diseases (asthma, AD; AR) and vice versa.

Results: We included 23 observational studies (17 cohort, 4 case-control, 2 cross-sectional) on the association between IBD and asthma, comprising approximately 2 million patients; 17 of them showed a positive association and only one study showed a negative association. Nineteen studies (12 cohort, case-controls, 4 cross-sectional) on the association between IBD and AD were included, with approximately 2,6 million patients; 16 showed a positive association and 3 showed no association. We included 4 cohort studies on the association between IBD and AR, covering approximately 2,2 million patients which all showed a positive statistically significant association.

Conclusion: Published literature supports that IBD is associated with asthma, AD and AR, and vice versa. These results may increase gastroenterologists' awareness for these diagnoses so that timely management can be initiated. Additional research is needed to determine if one disease influences the risk of developing the other or if the frequent co-occurrence of these diseases results from shared genetic, environmental and microbial factors. As far as the author's know, this is the first systematic review that reports the association between IBD and the three main atopic diseases.

Disclosure: Nothing to disclose.

Introduction: Transcriptomic analysis has potential to evaluate the molecular basis and pathophysiology of inflammatory bowel disease (IBD), discover therapeutic targets, and identify biomarkers. However, the value of this technology in clinical trials is limited by substantial methodological heterogeneity, which confounds interpretation, generalisability, and comparison of data across studies.

Aims & Methods: We conducted a 2-part study that aimed to develop recommendations for standardising transcriptomic analysis in multicentre IBD clinical trials. First, 3 public databases were searched from inception to May 2021 to identify clinical trials that included patients with IBD and transcriptomic analyses. Studies that collected blood or intestinal samples and utilised microarray, RNA sequencing, or other global RNA analysis methods were eligible. Data on study design and methodological approaches to transcriptomic research ranging from biopsy location to data analysis and reporting were extracted by 2 independent reviewers. The results of the systematic review (SR) informed the second part of the study, in which a panel of 16 IBD translational researchers participated in a modified Research and Development/University of California Los An-

geles appropriateness methodology (RAM) process. A list of statements focused on topics with substantial methodological heterogeneity (Table) was developed based on the SR and panel opinion and formed the basis for creation of a formal survey. Panellists rated the appropriateness of survey statements in 2 rounds, with panel input and survey modification between rounds.

Topic	No. of statements
Use of blood or intestinal mucosal samples for bulk RNA transcriptomics in IBD clinical trials	140
Sampling of intestinal mucosa for bulk RNA transcriptomic analyses	45
Analysing, interpreting, and reporting transcriptomics data	95
scRNA-seq, snRNA-seq, and spatial transcriptomics	136

Abbreviations: IBD, inflammatory bowel disease; RAM, Research and Development/University of California Los Angeles appropriateness methodology; RNA, ribonucleic acid; scRNA-seq, single-cell ribonucleic acid sequencing; snRNA-seq, single nucleus ribonucleic acid sequencing.

Table. Overview of RAM survey topics.

Results: The SR identified 37 reports (22 abstracts; 15 manuscripts) of 22 clinical trials (13 ulcerative colitis [UC]; 6 Crohn's disease [CD]; 3 UC and CD) that included transcriptomic analyses. The earliest report was published in 2009, with most (>75%) reports published between 2017 and 2021. Most (59%) analyses were conducted at phase 1b or 2 of clinical development. The appropriateness of 416 statements were rated by 15 panellists in the first survey. The final survey included 305 statements, of which 14 panellists rated 75% appropriate, 1% inappropriate, and 24% uncertain. In general, transcriptomic analysis for multiple research objectives using either mucosal biopsy or blood samples was considered appropriate at all phases of clinical development in patients with active disease. Validation of results with external datasets and/or orthogonal methods was considered appropriate, as was the complete reporting of individual patient metadata (ex, patient demographics, disease/treatment history, sample location, and local disease activity); the latter of which was viewed as a critical component for further analysis and utility of transcriptomic data.

Conclusion: Although inclusion of transcriptomic analysis in IBD clinical trials has increased over the past decade, persistence of existing methodologic heterogeneity will continue to limit the interpretation and generalisability of the results of this important research. This study provides an initial framework for expert recommendations to address and overcome these discrepancies and increase the value of this research in clinical development.

THE INTERACTION OF GENETIC VARIANTS AND TOBACCO SMOKING IN CROHN'S DISEASE AND ULCERATIVE COLITIS: A GENOME WIDE STUDY

J. Bai[1], K. van der Sloot[1], R.K. Weersma[1], E.A.M. Festen[1], G. Dijkstra[1]
[1]*University Medical Center Groningen, Department of Gastroenterology and Hepatology, Groningen, Netherlands*

Contact E-Mail Address: j.bai@umcg.nl

Introduction: Inflammatory bowel disease (IBD), consisting of Crohn's disease (CD) and Ulcerative colitis (UC), is a group of chronic, relapsing disorders in the gastrointestinal tract. The disease mechanisms are largely unknown. We hypothesized that the interaction of genetic variants and tobacco smoking can influence the disease risk of IBD and impact the disease progression in CD and UC differently.

Aims & Methods: 3530 IBD patients were included in the present study via Parelsnoer IBD Biobank (PSI), a Dutch prospective, nationwide biobank of IBD patients. Phenotypic data on smoking status at the time of diagnosis was obtained through the PSI questionnaire. Genome-wide genotyping was conducted on all PSI participants using the Global Screening Array and divided into two independent datasets, the discovery (N=990) and replication cohort (N=2540). Case-only study design was applied to estimate the interaction effects for IBD, CD, and UC separately with subsequent meta-analysis between discovery and replication cohorts.

Results: 572 lead single nucleotide polymorphisms (SNPs) were demonstrated with interaction effect of smoking (meta-analysis $P < 5e\text{-}5$, heterogeneity Cochrane Q test $P > 0.05$). 30 interacting SNPs showed distinct opposite effects between CD and UC (the ratio of interaction effect sizes between CD and UC > 5 or < 0.1). Our analysis also confirmed 9 previously reported interacting SNPs in the regions of *NOTCH4*, *TSBP1-AS1, HLA-DRA, HLA-DRA-HLA-DRB5, HLA-DRB9, DNMT3A, MUC22,* and *CCR3*.

Conclusion: Our present study identified a large number of new interaction loci for IBD on a genome wide scale and shed new light on the disease mechanisms.

Disclosure: Nothing to disclose.

*HLA-DQA1*05* ALLELE CARRIAGE AND ANTI-TNF THERAPY PERSISTENCE IN INFLAMMATORY BOWEL DISEASE

J. Doherty[1], A. Ryan[2], E. Quinn[2], J. Dolan[2], R. Corcoran[3], F. O'Hara[4], Y. Bailey[4], D. McNamara[4], G. Doherty[1], D. Kevans[3]
[1]*St Vincent´s Hospital, Dublin, Ireland,* [2]*Genuity Science (Ireland) Limited, Dublin, Ireland,* [3]*St James Hospital, Department of Gastroenterology, Dublin 8, Ireland,* [4]*Tallaght University Hospital, Gastroenterology, Dublin, Ireland*

Contact E-Mail Address: jaynedohertie@hotmail.com

Introduction: Carriage of *HLA-DQA1*05* allele is associated with development of antidrug antibodies (ADA) in patients with Crohn's Disease receiving anti-TNF therapy {1}. The presence of ADA is not uniformly associated with treatment failure. We aimed to determine the impact of carriage of *HLA-DQA1*05* allele on outcome of anti-TNF therapy evaluated by drug persistence and identify other risk factors impacting loss of response to anti-TNF therapy.

Aims & Methods: A multi-centre retrospective study of IBD patients treated with biologic therapy was performed. *HLA-DQA1*05* genotypes were generated by imputation from whole genome sequence using HIBAG. Primary endpoint was anti-TNF therapy persistence, expressed as time to discontinuation of anti-TNF therapy secondary to loss of response (LOR), segregated by *HLA-DQA1*05* allele genotype over a 700-day follow-up period. All patients treated with anti-TNF therapy in this study were biologic naïve. Secondary endpoints included investigating:

i. The impact of other risk factors on therapy persistence

ii. Anti-integrin and anti-interleukin therapy persistence segregated by *HLA-DQA1*05* allele genotype and;

iii. Formation and validation of the GPS-IBD risk score to predict loss of response (LOR) to anti-TNF therapy.

Results: 877 patients were treated with ant-TNF therapy. Median age was 34.7 years. 73.9% of our cohort had Crohn's disease. 543 (62%) had no copy, 281 (32%) one copy and 53 (6%) two copies of *HLA-DQA1*05* allele. Mean time to anti-TNF therapy discontinuation due to LOR in patients with 2 copies of *HLA-DQA1*05* allele was significantly shorter compared to patients with 0 or 1 copy at 700-days follow-up: 418 versus 541 versus 513 days respectively, p=0.012. Factors independently associated with time to anti-TNF therapy discontinuation included: carriage of HLA-DQA1*05 allele OR 1.2, p=0.02; female gender OR 1.6, $p=4.2 \times 10^{-5}$; CD phenotype OR 0.7, p=0.009; and anti-TNF therapy type (infliximab) OR 1.5, p=0.002. We developed and validated the GPS-IBD risk score (Table 1) to predict patients at higher risk of losing response to anti-TNF therapy. The scoring system ranges from 0 to 5 points. Mean time to anti-TNF therapy discontinuation due to LOR in patients with a score of 4-5 was significantly shorter compared to patients with a score of 2-3 with the patients at least risk being those with a score of 0-1: 406 versus 496 versus 580 days ($p < 0.001$). 98 patients were treated with vedolizumab therapy. Mean time to vedolizumab discontinuation in patients with 1/2 copies of *HLA-DQA1*05* allele was significantly shorter compared to patients with 0 copies ($p = 0.02$). 146 patients were treated with ustekinumab. No difference was seen in mean time to discontinuation of ustekinumab therapy dependent on *HLA-DQA1*05* allele status ($p = 0.33$).

Risk factors	Scoring System		
Carriage of HLA-DQA1*05 allele	0 copies - 0 points	1 copy - 1 point	2 copies - 2 points
IBD Subtype	Crohn's Disease - 0 points	Ulcerative colitis - 1 point	
Gender	Male - 0 points	Female - 2 points	

Conclusion: Carriage of two copies of the *HLA-DQA1*05* alleles is associated with a less favourable outcome of anti-TNF therapy with shorter time to therapy discontinuation. Female gender and a diagnosis of ulcerative colitis are also risk factors for LOR to anti-TNF therapy. We have developed and validated a risk scoring system to help predict LOR to anti-TNF therapy. Further prospective studies are required to validate the usefulness of this risk score in clinical practice.

MONITORING ADHERENCE TO SUBCUTANEOUS BIOLOGICS IN IBD CARE USING DIGITAL TECHNOLOGY – A NHS DIGITAL & INNOVATION PROOF OF CONCEPT STUDY FOLLOWING COVID-19 IN THE UNITED KINGDOM

A. Dhar[1,2], S. Ritchie[1], J. Bone[1], V. Rand[2], S. Wake[2]
[1]Darlington Memorial & Bishop Auckland Hospitals, Gastroenterology, Darlington, United Kingdom, [2]Teesside University, School of Health & Life Sciences, Middlesbrough, United Kingdom

Contact E-Mail Address: adhar@nhs.net

Introduction: During and following the COVID-19 pandemic, there has been a major expansion of self-administered subcutaneous biologics for the management of inflammatory bowel disease. These agents are more difficult to monitor since patients do not need to attend the Biologics infusion unit and there is no audit trail to confirm administration of the drug at the scheduled time points.

Aims & Methods: Following a successful NHS D&I bid for funding, a pilot proof of concept project to assess the feasibility and uptake of a digital technology (Health Beacon Digital Sharps Box®) to record and monitor subcutaneous injectable pen use was implemented in 50 consecutive IBD patients who were being treated with subcutaneous infliximab (Remsima®), Adalimumab (Amgevita®) or Vedolizumab (Entyvio®), on a 2-weekly schedule. The Health Beacon ICMS is comprised of a Smart Sharps Bin, pre-programmed with a patient's individual treatment schedule. The bin electronically captures each time a used injection is disposed of, to create a time-stamped record as a proxy for medication adherence. This is accompanied by Health Beacon's Companion App and Care Team support. Patients were also sent electronic dose reminders if they failed to dispose of a scheduled injection within certain time periods. Adherence data from the HealthBeacon ICMS, as well as patient satisfaction, transmission reports of data to

Results: Of 50 patients invited to join the programme, 45 registered patients had complete record of 6 months follow up; 4 patients deactivated recruitment and 1 left the programme. 21 patients were on Vedolizumab, 18 on Adalimumab and 8 on Infliximab, all 2-weekly SC injection. 45% patients were in the 36-50year age group, with the remaining spread between 18-75 years. M: F=21:24. Of 418 scheduled drops, 360 were made, with overall adherence being 86%. On time adherence was 76%. The study showed that up to 24% pts on SC Biologics at home delay their scheduled drug administration. Patient satisfaction was high. Reasons for delay in administration included forgetting, being away from home and being busy. Reminders were acknowledged.

Conclusion: This is the first study to our knowledge exploring adherence to subcutaneous biologics at home for IBD. It showed that a digital injection monitoring and support system is useful and acceptable to track adherence. Of the patients involved in the study there is an overall adherence of 90%, with up to 24% patients delaying their scheduled administration. Further studies are needed to analyse patient behaviour and impact on disease course.

Disclosure: Nothing to disclose.

PP0615

MALNUTRITION SCREENING IN A TERTIARY INFLAMMATORY BOWEL DISEASE OUTPATIENT CLINIC USING THE MUST TOOL

C. Amiama Roig[1], C. Suárez Ferrer[1], J.M. Arroyo Argüelles[1], B. Pillado Pérez[1], M. Sanchez-Azofra[1], J.L. Rueda García[1], J. Poza Cordón[1], E. Martín Arranz[1], I. González Díaz[1], C. Amor Costa[1], M.D. Martín-Arranz[1]
[1]Hospital Universitario La Paz, Gastroenterology and Hepatology, Madrid, Spain

Contact E-Mail Address: camiamaroig2@gmail.com

Introduction: Malnutrition is a common complication in patients with inflammatory bowel disease(IBD) that leads to a worse long-term prognosis, but is frequently underdiagnosed. The "Malnutrition Universal Screening Tool"(MUST) ia a simple, rapid, reproducible and already validated tool for screening. We describe the prevalence of patients at risk of malnutrition in a single tertiary IBD outpatient clinic using the self-administered MUST and we assess the applicability of the test evaluating the patients' opinion about its difficulty.

Aims & Methods: We conducted a transversal study at a tertiary Spanish center that included consecutive adult outpatients with IBD. Variables related to their IBD such as type, phenotype, location, current treatment, number of previous biological drugs and surgical interventions were collected. Disease activity was evaluated with the partial Mayo index for ulcerative colitis(UC), Harvey-Brasdhaw for Crohn's disease(CD), fecal calprotectin and CRP. Remission was defined as both Partial Mayo≤1 for UC and Harvey-Bradshaw≤4 for CD and CRP<5mg/dL and fecal calprotectin<150mcg/g. All patients with IBD completed a self-administered nutrition screening assessment using the MUST score. The risk of malnutrition was classified as low(score=0), medium/high(score≥1).

Results: 106 patients were included, 51 men(48.11%) and 55 women(51.89%), with a mean age of 54 years(SD 17.95). 38(35.85%) had UC and 68(64.15%) had CD. Regarding treatment, 40patients(37.38%) had received at least one biological drug previously and 29(27.35%) had prior surgery. In relation to disease activity, at the time of the survey, 84(79.25%) were in remission. 21 patients(19.81%) had an intermediate/high risk of malnutrition. Regarding posible predisposing risk factors, remission was significantly associated with a lower malnutrition risk. Among patients without remission 81.81% had an medium/high risk of malnutrition whereas only the 3.57% of patients in remission presented medium/high risk(p<0.001). No statistically significant differences were found in univariate analysis when comparing the IBD type(OR 0.08 CI 0.004-1.61), the number of biological drugs received(OR 0.96 CI 0.67-1.4) or whether they had undergone previous surgery(OR 1.1 CI 0.78-1.55). All patients were able to screen themselves and 105/106 reported the MUST questionnaire as either very easy/easy to understand and to complete.

Conclusion: The self-administered MUST is an useful and easy to apply tool in malnutrition screening, being able to detect 20% of patients at risk of malnutrition in an outpatient setting.

Disclosure: Nothing to disclose.

PREVALENCE OF INFLAMMATORY BOWEL DISEASE IN CELIAC DISEASE IN AN ALGERIAN POPULATION

Z. Kassama[1], M. Fermas[1], M. Boumendjel[1], A. Mhamdia[1], F. Boucenna[1], F. Boutra[1]
[1]*University Hospital Benbadis, Gastroenterology and Hepatology, Constantine, Algeria*

Contact E-Mail Address: kassamazakia@yahoo.com

Introduction: Celiac disease is a chronic, autoimmune disease that affects the small bowel in genetically predisposed persons precipitated by the ingestion of gluten. Celiac disease (CeD) and inflammatory bowel disease (IBD), principally Crohn's disease (CD) and ulcerative colitis (UC) are among the most common immune-mediated gastrointestinal diseases. Some studies have described the coexistence of the 2 diseases in the same patient.

Aims & Methods: The aims of the present study were to determine the prevalence of inflammatory bowel disease (IBD) and to elucidate the clinical features in patients with CeD with concomitant IBD.

We conducted a cross-sectional and single-center study. A total of 205 adults with CeD were included, and following up at the Gastroenterology unit of the Constantine University Hospital between 2015 and 2021. The diagnosis of CeD was made with the positive serology and histology of endoscopic duodenal biopsies and we identified those who were also diagnosed with IBD. The diagnosis of IBD associated to CeD was established based on clinical, endoscopic, histopathological, and radiological findings. Clinical, demographic, laboratory and morphological characteristics were analysed in these conditions. Osteodensitometry was performed on every patient with CeD and IBD.

Results: Among 205 patients with CeD, 14 had co-existent IBD (6,8%; n = 11 CD, n = 3 UC), their mean age at diagnosis of CeD was 29.7 ± 15.7 years. Females constituted 64,3%. The average delay of diagnosis between IBD and CeD was 6.4±3.8 years. The diagnosis of CeD preceded that of IBD in 35,7% (n=5) and 28,5% (n=4) of patients was concurrently diagnosed with IBD and CeD. Patients with CeD and concomitant IBD had a higher frequency of atypical symptoms of CeD (63,6%). Various extra-intestinal manifestations have been reported in 71,4% (aphthous stomatitis: 35,7%; depression: 42,8%). Osteoporosis was detected in 1 case with CD. Celiac disease serology was positive in all cases. The distribution of duodenal histology results according to Marsh-Oberhuber classification were 4/14 Marsh 3a, 6/14 Marsh 3b, 4/14 Marsh 3c. Other autoimmune disorders, including *autoimmune thyroiditis* (n=2) and type-1 diabetes (n=1). Of the patients diagnosed with CeD and CD, 7 had Ileocolonic involvement and only 2 had perianal disease. The dominant behaviour of CD was of the Stricturing type in 7 cases. Two patients with UC had extensive colitis. All patients were put on a gluten-free diet (GFD). IBD was treated with 5-aminosalicylic acid (n=1), immunomodulators (n=7) and biological therapy (n=6).

Conclusion: In our study of patients with CeD the prevalence of IBD was 6,8% (IC 95% 3,8%-11,2%). It's higher than previously reported in a number of studies. CD was more common than UC. Patients with UC and CeD were more likely to have pancolitis.

Disclosure: Nothing to disclose.

PP0617

CORRELATION OF SIMPLE LABORATORY MARKERS WITH ENDOSCOPIC REMISSION IN PATIENTS WITH CROHN'S DISEASE

A. Protopapas[1], N. Protopapa[1], A. Filippidis[1], V. Kyritsi[1], C. Savopoulos[1], A. Protopapas[1]
[1]*Aristotle University of Thessaloniki, AHEPA Hospital, First Propedeutic Department of Internal Medicine, Thessaloniki, Greece*

Contact E-Mail Address: adoprot@hotmail.com

Introduction: In patients with Crohn's disease, endoscopic remission is the most important endpoint for achieving a long-term course without clinical flare-ups and maintaining the patient's quality of life. Therefore, the use of simple laboratory markers to predict the presence of endoscopic remission without the need to perform colonoscopy could significantly simplify the management and follow-up of these patients.

Aims & Methods: The study included patients with Crohn's disease, that underwent a complete colonoscopy and laboratory workup to assess the disease, with the time interval between the two examinations not exceeding three months. Subsequently, the correlation between laboratory indicators and the endoscopic indicators Crohn's disease endoscopic index of severity (CDEIS) and SES-CD (Simple Endoscopic Score for Crohn's Disease) was investigated. Laboratory indicators included red cell distribution width (RDW), mean platelet volume (MPV), plateletcrit (PCRIT), C-reactive protein, erythrocyte sedimentation rate, neutrophil to lymphocyte ratio (NLR), lymphocyte to monocyte ratio (LMR), RDW to platelets ratio (RPR).

Results: The study included 76 patients (47 men, 29 women) under treatment, with a mean age of 38.4 years. Based on the CDEIS and SES-CD indices, 44 and 36 patients were in endoscopic remission, respectively. The endoscopic stage of the disease based on CDEIS showed a statistically significant correlation with the indices MPV (p=0.01), PCRIT (p=0.036) and NLR (p=0.022), while the stage based on SES-CD showed a significant correlation with MPV (p=0.016). Accordingly, the existence of endoscopic recession based on CDEIS showed a statistically significant correlation with the MPV (p=0.008) and NLR (p= 0.037) indices, while based on SES-CD it did not show a statistically significant correlation with any of the above indices.

Conclusion: The NLR and MPV indices showed a significant correlation with the endoscopic activity of Crohn's disease, and their use in a larger number of patients should be further investigated.

Disclosure: Nothing to disclose.

Introduction: The role of ustekinumab and vedolizumab in articular extra-intestinal manifestations of IBD remains unclear and most existing studies are retrospective.

Aims & Methods: The aim of this study is to analyze the incidence of new onset or worsening of a preexisting IBD-associated arthropathy in patients treated with ustekinumab or vedolizumab.

An observational prospective study in a tertiary care University hospital was conducted. IBD patients undergoing treatment with vedolizumab or ustekinumab with previous or new onset arthropathy were included. Articular manifestations were evaluated by a rheumathologist. IBD and rheumatological related variables were assessed at baseline and after 6 months, including demographics, clinical, biochemical, endoscopic and ultrasound data.

Results: 201 patients are treated with ustekinumab/vedolizumab for IBD in our center.

36 patients (17.1%) with previous arthropaties and 5 (3.3%) patients who developed new onset arthropathy after the starting of the treatment were included.

Most patients were anti-TNF experienced (26, 72.2%) or other biological therapy (9, 24.9%) with a median of 2 previous biological treatments per patient (IQR: 1-3).

Of the patients with new onset arthropaty 1 was treated with ustekinumab (20%) and 4 with vedolizumab (80%). Type of arthritis was: peripheral arthritis 3 (60%), axial 1 (20%) and mixed 1 (20%).

Among patients with previous arthropaties, 14 were under treatment with vedolizumab (38.9%) and 22 (61.1%) with ustekinumab for a mean time of 27.8 ± 19.7 months. 12 (38.7%) had worsening joint activity or flare-ups during ustekinumab/vedolizumab treatment. Of these, 5 (41.7%) had parallel intestinal activity (4 with ustekinumab and 1 with vedolizumab). There were no significant differences between the two biological therapy groups and worsening joint activity.

In our study, in most of the patients, joint symptoms were independent of clinical intestinal activity, although the differences were not significant. However, we did find that fecal calprotectin levels was significantly higher in patients with joint worsening (588.4 µg/g) vs. no joint activity (188.8 µg/g); p=0.05.

Conclusion: A significant proportion of patients treated with ustekinumab/vedolizumab have poor control of both axial and peripheral joint activity. In our experience, joint activity is not related to the clinical but biochemical activity of IBD.

Disclosure: Nothing to disclose.

ENDOSCOPIC, HISTOLOGICAL AND SEROLOGICAL ASSESSMENTS OF DISEASE ACTIVITY IN UC

M. Chen[1,2]

[1]Shanghai Fourth People's Hospital, School of Medicine, Tongji University, Shanghai, China, [2]Shanghai Jiaotong University School of Medicine, Shanghai, China

Contact E-Mail Address: chenmingqi1995@126.com

Introduction: Ulcerative colitis is a multifactorial immune-mediated inflammatory disease generally characterized by chronic recurrent mucosal inflammation and severe clinical symptoms which led to poor quality of life for patients. The methods for monitoring and follow-up of ulcerative colitis now are based on a combination of clinical and endoscopic findings but rarely involved serological and histological evaluation methods.

Aims & Methods: Aims: To investigate the consistency and correlation of endoscopic and histological scoring systems in assessing the disease activity of UC patients. Additionally, we explored the serological markers of endoscopic or histological activity of UC to achieve more accurate evaluation of disease activity.

Methods: A retrospective study was conducted in UC patients admitted from January 2014 to January 2020 at Renji Hospital, School of Medicine, Shanghai Jiao Tong University. The disease activity was examined endoscopically and histologically by Mayo Endoscopic Subscore and Simplified Geboes Score respectively. Blood samples were collected around the time of endoscopy.

Results: Altogether 143 UC patients were enrolled. Basal plasmacytosis is frequently seen in endoscopically active UC (OR=11.19, 95% CI: 4.80-26.09, P<0.001). Approximately half of the patients (53.7%) who achieved endoscopic remission still had inflammatory activity histologically. Kappa consistency test showed that the agreement between Mayo Endoscopic Subscore and Simplified Geboes Score for assessing disease activity was moderate (κ = 0.4, P<0.001). By Spearman correlation coefficient analysis, a moderate correlation between the two scoring systems was identified (rs =0.533, P<0.001). The histologically active group had lower hemoglobin (t=3.025, P<0.01) and higher percent (t=-2.113, P<0.05) neutrophils than the remission group.Blood biomarkers revealed a negative link to the Mayo score of UC patients, which includes large platelet ratio (ρ=-0.170, P<0.0001), hemoglobin (ρ=-0.275, P<0.0001) and albumin (ρ=-0.452, P<0.0001),while white blood cell count (ρ=0.205, P<0.01), neutrophil count (ρ=0.259, P<0.01), percentage of neutrophils (ρ=0.224, P<0.01), erythrocyte sedimentation rate (ρ=0.185, P< 0.05) and C-reactive protein (ρ=0.21, P<0.05) revealed a positive correlation.

Conclusion: In UC patients, the assessments of disease activities endoscopically and histologically are moderately correlated and are generally consistent. Basal plasmacytosis is predictive of endoscopically active UC. Decreased hemoglobin and elevated percentage of neutrophile granulocyte suggest endoscopic and histological activity.

Disclosure: Nothing to disclose.

PP0620

CAPSULE ENTEROSCOPY PROXIMAL SMALL-BOWEL INFLAMMATION IN CROHN'S DISEASE IS ASSOCIATED WITH MORE SEVERE MUCOSAL INJURY AND NEED FOR TREATMENT WITH BIOLOGICS

J. Carlos Goncalves[1,2,3], A.I. Ferreira[1,2,3], T. Lima Capela[1,2,3], V. Macedo Silva[1,2,3], C. Macedo[1,3,2], C. Arieira[1,2,3], S. Xavier[1,2,3], T. Cúrdia Gonçalves[1,2,3], P.B. Carvalho[1,2,3], F. Dias de Castro[1,2,3], J.L.T.M. Magalhães[1,2,3], M.J. Moreira Basto[1,2,3], B.J.F. Rosa[1,2,3], J. Berkeley Cotter[1,2,3]

Introduction: Small-bowel (SB) inflammatory activity in Crohn's Disease (CD) is variable among patients. Capsule Enteroscopy (CE) allows for visualization of the entire SB, which may be divided into three parts, known as tertiles.

Aims & Methods: The aim of this study was to determine the association between SB inflammatory involvement in CD of the first and second tertiles and the impact on the clinical outcome. A total of 53 treatment-naive patients with SB CD submitted to CE as part of the diagnosis workup were selected. Data regarding SB inflammatory activity quantified by the Lewis Score (LS; < 135, normal; 135–790, mild; ≥790 moderate-to-severe) were collected. Individuals with any colonic involvement, as well as stricturing or fistulizing phenotypes, were excluded from the analysis.

Results: Thirty-six (67.9%) patients displayed inflammatory activity in the first and/or second tertile together with third tertile involvement (Proximal+T3 group). Seventeen (32.1%) had inflammation in the third tertile only (T3 group). The LS accounts for the SB tertile with the highest degree of inflammation, yet we found that individuals in the Proximal+T3 group exhibited higher inflammatory scores (p=0.031). We performed a subgroup analysis for those with mild inflammatory activity. There were no differences regarding age or sex distribution, smoking habits, frequency in relatives with CD, perianal disease, extra-intestinal manifestations, or laboratory values. Notably, we found that patients with mild disease in the Proximal+T3 group initiated biologic drugs more often in the five years following the initial diagnosis (p=0.036).

Conclusion: This study shows that involvement of the first and/or second tertiles of the SB is significantly associated with more severe inflammatory activity overall. Additionally, in those with mild disease and proximal inflammation the need for biologics occurred more frequently. This suggests that early detection of proximal SB CD using CE may contribute to timely treatment.

Disclosure: Nothing to disclose.

PP0621

APPLICATION OF THE NUTRITIONAL RISK INDEX IN NUTRITIONAL ASSESSMENT OF PATIENTS WITH CROHN'S DISEASE

M. Mtir[1], M. Ayari[1], R. Bourguiba[2], H. Kallel[1], I. Abdelaali[1], J. Mohamed Taieb[1], M.H. Douggui[1]

[1]Internal Security Forces Hospital La Marsa, Gastroenterology Department, Tunis, Tunisia, [2]Internal Security Forces Hospital La Marsa, Internal Medecine, Tunis, Tunisia

Contact E-Mail Address: mtirmaha@gmail.com

Introduction: Malnutrition and weight loss are well-recognized complications of Crohn disease (CD), however nutritional routine assessment is not commonly performed, resulting in under-detection of both malnutrition and nutrient deficiencies. In fact, a number of nutrition screening tools are available including the Nutritional Risk Index (NRI).

The aim of this study was to assess the nutritional status using the NRI and to investigate the associated factors to malnutrition during CD.

Aims & Methods: We conducted a retrospective single-center study, including patients followed for CD over a 7-year period [2014 - 2021]. Malnutrition risk was estimated based on the NRI calculated at first presentation with the following formula: NRI = (1.519 × serum albumin (g/L) + 41.7× (present weight/usual weight).

Nutrition status of patients was categorized into four groups: NRI>100: no risk group, NRI= 97.5–100: mild risk, NRI= 83.5–97.5: moderate risk, and NRI< 83.5: severe risk group of malnurition. Radiologic sarcopenia was assessed by calculating the total psoas area index.

Results: In total, 50 patients were enrolled with a mean age of 44.3 years, a median disease duration of 106 months and a sex ratio M/F of 3.16.

Based on NRI, 11/50 (22%) patients had normal nutritional status, 27/50 (54%) mild-moderate risk of malnutriton and 12/50 (24%) had severe malnutrition.

In the univariate study, severe malnutrition risk was associated with the presence of anemia (p=0.002), thrombocytosis (p=0.05), hypocholesterolemia (p=0.024), the presence of radiologic sarcopenia (p=0.05), extensive ileal involvement of more than 50 cm (p=0.014), the occurrence of complications such as intra-abdominal collection (p=0.001) and thromboembolic complications (p=0.05). Regarding, patients who underwent surgical treatment, the occurrence of postoperative complications and extensive small bowl resection were factors associated with severe malnutrition with a p-value of 0.02 and 0.025 respectively.

On multivariate regression analysis, severe malnutrition risk was a predictive factor of developing intra-abdominal abscess (OR 10.5 95% CI 2.22-49.51), p=0.003).

Conclusion: Patients with Crohn's disease have a high incidence of nutritional risk and malnutrition witch was associated with severe course of CD. Nutritional Risk Index is a simple, validated and reproducible tool to identify patients at increased risk of malnutrition allowing adapted nutritional support.

Disclosure: Nothing to disclose.

PP0622

THE DUBLIN SCORE: A NEW VISION FOR ASSESSMENT OF ULCERATIVE COLITIS

M. Mtir[1], M. Ayari[1], W. Khemiri[1], I. Abdelaali[1], J. Mohamed Taieb[1], M.H. Douggui[1]
[1]Internal Security Forces Hospital La Marsa, Gastroenterology Department, Tunis, Tunisia

Contact E-Mail Address: mtirmaha@gmail.com

Introduction: Endoscopic assessment is a crucial part of the management of Ulcerative Colitis (UC). The DUBLIN score (DS) has the advantage of assessing both disease activity and extent. The aim of our study was to evaluate the performance of the DS compared to the UCEIS.

Aims & Methods: This is a retrospective study, among patients with UC. Clinico-biological and evolutionary data were collected. We calculated the UCEIS endoscopic score, the Nancy histological index and the DS as a product of the Mayo endoscopic score [0-3] and the disease extent [E1-E3].

Results: Fifty patients were enrolled with a mean age of 49.1 years [11-83] and a sex ratio M/F of 1.94. The DS showed a statistically significant correlation with both the UCEIS score [r=0.913, p<0.0001] and the Nancy index [r=0.857, p<0.0001]. Regarding biological parameters, there was a significant positive correlation between DS and CRP [r=0.660, p<0.0001] and a weak negative correlation between DS and both albumin [r= -0.575, p<0.0001] and hemoglobin [r=-0.443, p=0.001]. The DS and UCEIS were significantly associated with the occurrence of disease extension (p<0.0001), the need for colectomy (p<0.0001), as well as the need for immunomodulators (p=0.034 and 0.008 respectively). Both scores were not associated with the need for biotherapy (p=0.2 and 0.194 respectively). During follow-up, twenty patients (40%) were in therapeutic failure. When analyzing, the AUROC in predicting the occurrence of treatment failure in UC was 0.913 [95% CI 0.831–0.996] for DS and 0.924 [95% CI 0.846–1] for UCEIS.

Conclusion: Based on our study, although the DUBLIN score was correlated with inflammatory markers as well as clinical and histological data, it did not show superior performances to the UCEIS.

Disclosure: Nothing to disclose.

INFLAMMATORY BOWEL DISEASE AND IMPAIRMENT OF WORKING LIFE

M. Mtir[1], H. Kchir[1], N. Mechergui[2], D. Cherif[1], N. Maamouri[1]
[1]La Rabta Hospital, Gastroenterology B, Tunis, Tunisia, [2]Charles Nicolle Hospital, Occupational Medicine, Tunis, Tunisia

Contact E-Mail Address: mtirmaha@gmail.com

Introduction: Living with inflammatory bowel disease (IBD) affects physical, psychological and social dimensions, limiting the ability to engage in daily activities. It is a lifelong illness that mainly affects patients of working age, with a significant impact on their professional life. In fact, the maintenance and promotion of employees is one of the important social goals and can be considered as a determinants of health for IBD patients.

The aim of the study was to analyze the impact of disease on the working life among IBD patients and to characterize the breadth of challenges they experience in their workplace.

Aims & Methods: We conducted a cross-sectional study including patients followed for IBD and exercising a professional activity, over a 9-months period. We collected sociodemographic, clinico-biological and evolutionary data. Then, we performed a survey among these patients using a self-report questionnaires on employment status, IBD-related difficulties at work and sick leave.

Results: A total of 45 patients were included: 80% had Crohn disease (CD) and 20% had ulcerative colitis (UC). The mean age was 44 ± 12 years [extreme: 20-72 years], the sex-ratio M/F was 0.73 and the average of follow-up was 9 years [extreme: 1-18 years]. Civil servants represented 33% of the total population, those in the private sector 47%, and those in the liberal profession 20%. The most important socio-professional category was manual workers with 51%. Thirty-seven patients (82%) developed their disease after being employed with a mean delay of 11.8 years. The average number of working hours per week was 38.8 ± 11 hours [extreme: 9-60 hours]. The majority of the employees worked full time (85%), only seven subjects worked part-time, two of them because of their IBD. One in three patients (N=14) claimed to have been exposed to at least one harmful agent during their professional career, mainly organic solvents and chemicals. The main complaint reported by the patients during the daily exercise of the work was about physical fatigue which was omnipresent in the majority of the workers (69%). The digestive symptoms were mainly abdominal pain (53%) evaluated according to VAS with a mean intensity of 2.8 [0 - 10], subocclusive syndrome (40%), presence of diarrhea (38%), incontinence and fecal impaction (22%) which was worsened by the absence of accessible restrooms (33%). Psychological repercussions such as anxiety and depression were mentioned in 27% of cases. The average absenteeism during the last twelve months was 49.6 days [extreme: 0-240 days] and the average number of hospitalization days was 30.7 [extreme: 0-150 days]. Twenty patients (44%) claimed that they were subject to a salary restriction during their professional career because of their illness. Among the patients interrogated, a minority (5 people) had already benefited from a contact with the occupational medicine and health service.

Conclusion: IBD has a negative impact on the working life of patients, due to uncomfortable symptoms, days of absenteeism, and unadapted workplaces, which can affect career plans, professional achievement, and income. Appropriate supports and accommodations to the workplace are needed in order to improve their working experience.

Disclosure: Nothing to disclose.

PP0624

« WORK ABILITY INDEX » AS A SUITABLE INSTRUMENT TO ASSESS WORK ABILITY AMONG IBD PATIENTS

M. Mtir[1], H. Kchir[1], N. Mechergui[2], D. Cherif[1], N. Maamouri[1]
[1]La Rabta Hospital, Gastroenterology B, Tunis, Tunisia, [2]Charles Nicolle Hospital, Occupational Medicine, Tunis, Tunisia

Contact E-Mail Address: mtirmaha@gmail.com

Introduction: Inflammatory bowel disease (IBD) is a chronic disease usually diagnosed in early adulthood and characterized by unpredictable flare-ups and debilitating symptoms that can interfere with the patient's ability to work and perform daily activities. In fact, since work disability is difficult to quantify, several scores have been developed for this purpose. The Work Ability Index (WAI) is a validated practical tool to measure the work capacity of patients.

The objective of this study was to assess work performance in patients followed for IBD, using the WAI psychometric tool, and to identify predictive factors of work disability.

Aims & Methods: We conducted a cross-sectional study including patients followed for IBD and exercising a professional activity, over a 9-months period. We collected sociodemographic, clinico-biological and evolutionary data. Quality of life was assessed by the IBDQ questionnairy.

Work capacity was assessed using the WAI which classified work performance into four categories: poor (score between 7 and 27), moderate (28-36), good (37-43) and excellent (44-49).

In order to determine the factors of disability at work, we divided our patients into two groups according to the WAI:
- Patients with work disability: WAI between 7 and 27.
- Patient with retained ability at work: WAI between 28 and 49.

Results: A total of 45 patients were included: 80% had Crohn disease (CD) and 20% had ulcerative colitis (UC). The mean age was 44 ± 12 years [20–72], the sex-ratio M/F was 0.73, and the mean of follow-up time was 9 years [1-18]. The average number of working hours per week was 38.8 ± 11 hours [9-60]. The mean absenteeism during the last twelve months was 49.6 days [0–240]. The mean WAI value was 32.6, which corresponds to a moderate work performance. Assessment of work performance according to the WAI questionnaire showed that 38% of patients (n=17) had poor work ability, 24% (n=11) moderate work ability, 34% (n=15) good work ability and only two patients (4%) had an excellent work ability.

In univariate study, the work disability was more important in workers (p=0.008), employees in private or liberal sector (p=0.017), workers with atypical schedules (p=0.034) and in case of a professional seniority higher than 16.5 years (p=0.009). Patient-related factors were advanced age, low socio-economic conditions and low educational level. Disease-related factors were stricturing phenotype of CD, extensive UC, moderate to severe disease activity, presence of extra-intestinal manifestations (EIM) and corticotherapy.

In multivariate analysis, independent predictive factors of work disability among IBD patients were:

Predictive factors	p-value	Odds Ratio	[95% CI]
Osteoarticular extraintestinal manifestation	0,007	21,898	[2,302 - 208,356]
Moderate to severe disease activity	0,002	34,255	[3,585 - 327,269]

Furthermore, the assessment of health-related quality of life by the IBDQ questionnairy, showed a mean IBDQ value of 160.8 which corresponds to a moderate score relating a quality of life; 224 being the maximum score obtainable reflecting an optimal quality of life. In the analytical study and using Spearman's test, a statistically significant correlation was found between the WAI and IBDQ with a p-value <0.0001 and a correlation coefficient r=0.7, reflecting the impact of working life on quality of life.

Conclusion: According to our study, IBD would cause work disability in 38% of cases. Moderate to severe disease activity and the presence of osteoarticular EIM were both identified as independent predictors of work disability. Thus, the WAI can be used as a screening tool to identify the need for rehabilitation.

Disclosure: Nothing to disclose.

CLINICAL FACTORS ASSOCIATED WITH NAFLD IN IBD PATIENTS AND COMPARISON BETWEEN PATIENTS WITH NAFLD EXCLUSIVELY

M. Amorim Lopes[1], E. Oliveira[1], G. Herrerias[1], R. Fedatto Beraldo[1], N. Salvador Castelhano[1], D. Natan Shintaku[1], D. Salate Biagioni Vulcano[1], W. Barbosa[1], G. Faria Silva[1], L. Sassaki[1]
[1]São Paulo State University, Botucatu, Brazil

Contact E-Mail Address: ma.lopes@unesp.br

Introduction: Inflammatory Bowel Diseases (IBD) patients have increased risk for non-alcoholic fatty liver disease (NAFLD). The pathogenesis of NAFLD in IBD patients may be complex and related to multiple factors, such as gut dysbiosis, systemic inflammation, unhealthy nutritional behavior and body composition. NAFLD can lead to severe complications, such as NASH, cirrhosis and HCC, and its incidence is increasing worldwide. Therefore, this study aimed to evaluate NAFLD prevalence among IBD patients and compare their profile with NAFLD patients.

Aims & Methods: 138 IBD patients and 93 NAFLD from a public outpatient healthcare service in Brazil were included in this cross-sectional study. Patients were divided in three groups for comparison: IBD only, IBD+NAFLD and NAFLD only. The presence of NAFLD in IBD patients was assessed by ultrasonography. Exclusion criteria: preexisting liver disease in IBD group, history of alcohol intake >20g/day for women and >30g/day for men, and glucocorticoids treatment >20mg/day. Statistical analysis: descriptive statistics and association tests.

Results: In total, 58 IBD patients presented NAFLD (42.03%). Comparing the three groups, patients in NAFLD only were older (P=0.0279), presented more frequently clinical comorbidities and higher BMI (Table 1). When comparing patients "IBD+NAFLD" and "NAFLD only", we found difference regarding BMI (p<0.0027) and liver assessment scores, such as FIB-4 Index (1,11±0,69 vs 1.67±1.57, p=0.005) and NAFLD score (-1,34±1,84 vs 1.94±1.39 p=0.0467). Also, in biochemical tests, it was observed difference in platelet count (P=0.0009), ALT (P<0.0005), AST (P<0.0001), GGT (P<0.0001), ferritin (P<0.0001), glycosylated hemoglobin (P<0.0087), HDL cholesterol (P<0.0001) and insulin levels (P<0.0001). Mostly, patients in both groups presented moderate steatosis (46.55% vs 44.09%, p=0.0639).

	IBD only (n=80)	IBD+ NAFLD (n=58)	NAFLD only (n=93)	P
Age	43.39±15.05	48.50±12.41	50.63±12.58	0.0020
Female gender	73.75	51.72	62.37	0.0279
Clinical comorbidities	36 (45%)	34 (58.62%)	90 (96.77%)	<0.0001
Diabetes Mellitus	6 (7.5%)	8 (13.79%)	58 (64.44%)	<0.0001
High blood pressure	13 (16.25%)	19 (32.76%)	48 (54.55%)	<0.0001
Dyslipidemia	5 (6.25%)	11 (18.97%)	50 (61.73%)	<0.0001
Hypotyreoidism	6 (7.5%)	3 (5.17%)	17 (25%)	0.0008
BMI	24.93±4.67	29.64±4.29	32.08±4.07	<0.0001
Biochemical tests				
Platelet count	285150±84494.64	270465.52±79453	224279.57±79777.19	<0.0001
AST	24.42±7.88	28.70±15.1	36.42±18.98	<0.0001
ALT	18.76±8.54	27.96±15.62	43.46±35.66	<0.0001
Alkaline phosphatase	66.23±22.62	69.87±25.14	79.08±25.99	0.0204
GGT	29.01±18.14	41.29±27.58	68.76±66.91	<0.0001
Ferritin	75.45±122.9	186.42±297.07	493.98±2180.59	<0.0001
Fasting glucose	89.26±21.15	99.9±23.83	124.20±54.11	<0.0001
Glycated hemoglobin	5.49±0.75	5.8±0.96	7.03±3.59	0.0011
Triglycerides	124.22±68.56	180.21±107.93	182.70±160.62	0.0001
HDL cholesterol	58.17±14.34	48.3±15.09	45.46±10.94	<0.0001
Insulin	7.99±4.83	13.99±8.7	22.68±22.54	<0.0001

Table 1. Comparison among IBD only, IBD+NAFLD and NAFLD only groups. Data presented in mean (SD) and frequency (%)

Conclusion: We observed a high prevalence of NAFLD in patients with IBD (42.03%). NAFLD group had higher levels of BMI, AST, ALT, fasting glucose and blood insulin, in all comparisons – both groups and when compared to IBD+NAFLD group exclusively. We observed that patients without IBD presents higher levels of conditions associated to metabolic syndrome.

Contact E-Mail Address: vitorbmacedo@gmail.com

Introduction: Optimal strategies for monitoring isolated small bowel's Crohn's Disease (CD) remain uncertain. In 2020, the APEX score was developed, with a value between 4 and 7 presenting an excellent accuracy at stratifying patients relapse risk following a small bowel capsule endoscopy (SBCE) showing mucosal healing (MH)[1].

Aims & Methods: Our aim was to prospectively validate APEX score accuracy in predicting disease flares on the year following SBCE.

Our study prospectively included patients with isolated small bowel CD (Montreal L1±L4) undergoing SBCE, who were in clinical remission (CDAI<150) and corticosteroid-free for the previous 6 months. A blood sample was collected within a maximum of 15 days of SBCE. The score APEX (*Age ≤30 years +3 / Platelets ≥ 280 × 10^3/L +2 / EXtraintestinal manifestations +2*) was applied on patients whose SBCE reported MH. Disease flares were documented on the subsequent year.

Results: We have included 47 patients, from which 28 (59.6%) presented MH on SBCE. From these, 21 (75%) were female, with a mean age of 42±13 years. On the following year, a disease flare was documented on 4 (14.3%) patients. A high-risk APEX score was found in 5 (17.9%) of the patients.

The APEX score presented an excellent accuracy in predicting disease flares on the year following MH (AUC=0.97; 95%CI 0.92-1.00; *p*=0.003). The previously calculated optimal cut-off (APEX≥4) had a sensitivity of 100% and a specificity of 95.8% in predicting the outcome.

Conclusion: Patients with small bowel CD and MH still have a non-neglectable risk of disease flare on the subsequent year. The APEX score has prospectively demonstrated excellent accuracy at stratifying patients' relapse risk. Thus, it emerges as a helpful tool in patients with MH, by identifying those who will need earlier evaluations and more frequent monitoring.

Introduction: Ulcerative proctitis (UP) is an uncommon presentation in paediatric patients with ulcerative colitis, accounting for <10% of cases in most studies. Therefore, there is limited data on the clinical features and outcomes of these paediatric patients.

Aims & Methods: We aimed to characterize the clinical features and natural history of UP in children, and identify predictors of poor outcomes in a retrospective cohort study involving 37 sites affiliated with the IBD Porto Group of ESPGHAN. Data were collected from patients aged<18 years diagnosed with UP between 01/01/2016-31/12/2020. Associations between baseline characteristics at diagnosis of UP and different clinical outcomes were evaluated using univariable and multivariable Cox regression.

Results: Data were collected from 196 patients (median age at diagnosis 14.5 [IQR 11.9-15.9] years, 105 females [53.6%]). The most common presenting features were bloody stools (95%), abdominal pain (60%) and diarrhea (47%). The median Pediatric Ulcerative Colitis Activity Index (PUCAI) score at the time of diagnosis was 25 (IQR 20-35), with only 2 patients (1.1%) presenting with acute severe colitis (ASC). 125 patients (67.9%) had a PUCAI score of <35, reflecting mild clinical disease activity. Nevertheless, the majority of patients exhibited moderate-severe endoscopic inflammation, with a Mayo score of 2 in 103 (54.2%) and 3 in 40 (21.1%) patients. Most patients had normal inflammatory markers and albumin levels and the median fecal calprotectin value was 645 (IQR 238-1435) mcg/g, with 13/132 (9.8%) and 28/132 (21.2%) having a level of <100 mcg/g or <250 mcg/g, respectively. By the end-of-induction, 5-aminosalicylic acid administration orally, topically or both resulted in clinical remission rates of 52%, 50% 73%, respectively.

The median time to last follow-up was 2.7 (IQR 1.7-3.8) years. The rates of treatment escalation to oral steroids, thiopurines and biologics at 1, 3 and 5 years were 17.6%, 32.6% and 57.8%, 9.8 %, 24.3% and 43.2%, and 10.4%, 22.0% and 42.8%, respectively. Subsequent episodes of ASC were uncommon, involving up to 20% of the patients within 5 years of diagnosis. Nevertheless, IBD-related admissions were frequent, reaching 11.3%, 23.2% and 33.7% within 1, 3 and 5 years from diagnosis, respectively. Finally, only 6 patients (3.1%) had a colectomy by the end of follow-up. On multivariable cox regression analysis, only the PUCAI score was associated with poor outcomes, with a score ≥35 providing increased risk, including escalation to biologics (HR 3.5 [95% CI 1.8-6.6, P<0.001]), subsequent ASC event [HR 2.7 (95% CI 1.3-5.7, P=0.009]) and IBD-associated admission (HR 2.3 [95% CI 1.2-4.2, P=0.008]).

48% of patients that presented with UP and were rescoped exhibited proximal disease progression during follow-up. The presence of cecal patch at the diagnostic colonoscopy was more frequent in patients that subsequently exhibited proximal disease progression (4/58 [6.9%]) vs 11/51 [21.6%], [P=0.027).Moreover, the PUCAI score at the end-of-induction was significantly higher in patients that had subsequent disease progression.

Conclusion: This is the largest cohort, to date, of paediatric patients with UP. Children with UP exhibit high rates of proximal disease extension and requirement of systemic immunosuppressive medications, in the first years after diagnosis. Providers should consider to apply treat-to-target approaches, similar to other patients with UC, in the care of these patients with repeated sigmoidoscopies to document mucosal healing and a specific focus on quality-of-life measurements.

Introduction: Information and communications technology (ICTs) include computer applications for dialogical, informative, or social use. ICTs are resources in the management of chronic diseases such as inflammatory bowel disease (IBD).

Aims & Methods: To understand their use by IBD patients in Latin America (LatAm), we aimed to assess the barriers and preferences (B&P) of ICTs in this population. From May to June 2022, 17 centers from 9 Spanish-speaking countries in LaTam were invited to participate in a survey-based-study to assess patients with IBD. A 351 cases sample was calculated. Included patients were >15-year-old, with IBD confirmed by histopathology. Patients diagnosed <6 months, hospitalized, without IBD-specific treatment, with psychiatric or oncological disease, health care providers, and unable to answer the survey were excluded. An ad-hoc, anonymous, and online survey was designed. The use of ICTs was estimated using a Likert scale. Surveys with >25% blank data were excluded; in those with <25%, blank questions were counted as such. A sample of 205 was calculated.

Results: 341 cases from 11/17 centers of 6/9 countries were included: Argentina 216, Uruguay 58, Ecuador 33, Chile 16, Peru 12, Paraguay 6. Median age was 37 /28-51) years; 200 (58.7%) females; 240 (70.4%) ulcerative colitis (UC), 90 (26.4%) Crohn's Disease (CD), and 11 (3.2%) indeterminate colitis (IBDU); 14 (4.1%) rurality; 158 (46.3%) complete secondary education, and 111 (32.6%) higher education. 306 (89.7%) owned a smartphone. WhatsApp (WA) was the most frequently used ICT by 325 (95.3%), followed by Instagram (Ig) 199 (58.4%), email 195 (57.2%), Facebook (Fb) 192 (56.3%), and YouTube (YT) 175 (51.3%). For IBD-specific purposes, the most used were WA 130 (38.1%), Fb 93 (27.3%), email 83 (24.3%), YT 73 (21.4%), and Ig 72 (21.1%). 48% used at least one ICT daily. 61.3% stated that they totally/strongly agreed to use ICTs to seek information on self-care measures, 57% diets, and 54% symptoms. Only 15.8% stated that this information was easily accessible, 45.7% easy to understand, 34.9% of good quality, and 25% were concerned about data privacy. 91.5% stated

that they would use an IBD-specific application to obtain updated information on IBD and 88.6% stated a preference for mobile-availability (Figure 1).

Conclusion: IBD patients in LatAm use different ICTs for IBD-specific purposes. ICTs are means to transmit information and maintain communications with and among patients with IBD. However, it is necessary to improve access, accuracy, and understanding of such resources while ensuring patient data privacy. To our knowledge, this is the first study to describe B&P with ICTs use in LatAm IBD patients. NCT04893928.

PERIPHERAL JOINT AND ENTHESIS INVOLVEMENT IN NEWLY DIAGNOSED PATIENTS WITH INFLAMMATORY BOWEL DISEASE (IBD): SYMPTOMS, CLINICAL AND ULTRASONOGRAPHIC FINDINGS

Introduction: Peripheral musculoskeletal (MSK) symptoms are the most common extra intestinal manifestations (EIMs) in IBD patients, with substantial impact on quality of life. IBD related spondyloarthritis (IBD-SpA) often requires a multidisciplinary evaluation to enable optimal choice of treatment and patient care, but systematic rheumatological characterisation of this population is scarce [1].

Characterisation of IBD-SpA is challenged by the variety of MSK involvement (from arthralgia to ankylosing spondylitis), the co-existence of osteoarthritis, overuse enthesopathies or fibromyalgia, and by the heterogeneity in methodologies used to describe the SpA features. Recently developed recommendations for endpoints for EIMs in IBD trials [2] were applied in the present study.

Aims & Methods: To determine the prevalence and distribution of inflammatory lesions in peripheral joints and entheses in newly diagnosed IBD patients, assessed for presence of MSK symptoms, and by rheumatological and ultrasound (US) evaluation.

Patients from the IBD prognosis inception cohort (IBD-Pro) were consecutively included [2]. They reported MSK symptoms using a validated questionnaire (IBD-TASQ). A clinical examination was performed by rheumatologist, as was US examination (grey scale (GS) and colour Doppler (CD)) of 38 peripheral joints and 14 entheses, applying OMERACT-EULAR definitions and scoring systems for synovitis and enthesitis [3]. Synovitis was defined as GS score ≥2 and/or CD≥1 and entheseal inflammation was defined as presence of hypoechogenicity/thickening and/or CD score ≥1. Further, OMERACT-EULAR sum score (GLOESS) was calculated (0-114).

Results: 110 newly diagnosed IBD patients (mean age 42, 39% male) were included (34% Crohn's disease, 59% ulcerative colitis (UC), 5% unclassified IBD). The IBD disease activity scores indicated mild activity in UC patients (Simple Clinical Colitis Activity Index mean (SD) 6.7 (3.6), and low in Crohn's (Harvey-Bradshaw Index 4.5 (2.9)). Four patients received systemic glucocorticoids (2%) or biologics (2%) at the time of rheumatological evaluation. History of other SpA-associated features such as psoriasis was reported in 2% and uveitis in 5% of the patients.

40% of the patients reported positive history for ≥1 MSK symptom. Joint pain and swelling were the most common complaints (30%), followed by heel enthesitis (17%) and dactylitis in 20%. Patient pain VAS was low, mean (SD) 12(21).

Clinical examination revealed 52% of all patients had arthritis and/or enthesitis and 46% fulfilled ASAS classification criteria for peripheral SpA (25% ≥1 tender joint, 12% ≥1 swollen joint, 46% ≥1 tender enthesis (most affected sites were Achilles and lateral epicondyle).

US found inflammation in ≥1 joint or enthesis in 49% of the IBD patients - synovitis in 29%, mean GLOESS sum score 5.2 SD (4.6) and entheseal inflammation in 34% (US enthesitis sum, mean (SD) 2.6(2).

Among those patients reporting MSK symptoms, 69% had ≥1 tender/swollen joint and/or enthesis at clinical evaluation and 64% had joint/entheseal inflammation by US. Suggesting good overlap between patient-reported symptoms, clinical and US findings. 36% of the asymptomatic patients also had clinical and US signs of arthritis and/or enthesitis.

Conclusion: At the time of IBD diagnosis, more than half of the patients had musculoskeletal manifestations by clinical examination and half had objectively verified synovitis and/or enthesitis by ultrasound, indicating that SpA may be underdiagnosed among IBD patients.

THE IMPACT OF ENDOSCOPIC HEALING ON DISEASE-RELATED OUTCOMES IN PATIENTS WITH ULCERATIVE PROCTITIS

E. Liu[1], A. An[2], R. Battat[3], R. Longman[4], E. Scherl[4], D. Lukin[4]

Introduction: The impact of achieving endoscopic remission in ulcerative proctitis (UP) is unclear. The preferred long-term treatment goal in ulcerative colitis (UC) is achieving both the symptomatic resolution and endoscopic remission (ER),[1] which has been associated with reduced risk of complications, including colectomy.[2,3] UP is an anatomically limited form of UC, involving only the rectum. Unlike in extensive or left-sided UC, UP has not been associated with elevated colorectal cancer risk. Therefore, the achievement of endoscopic healing as compared to clinical remission in UP represents an uncertain therapeutic target.[4]

Aims & Methods: This study assessed the impact of achieving EH on subsequent outcomes in UP patients. This was a single-center retrospective cohort study including patients aged ≥ 18 with a confirmed diagnosis of UP based on clinical and endoscopic criteria. Included patients had at least two endoscopies and active endoscopic disease (Mayo endoscopy score [(MES) of 1, 2, or 3]) at the first (baseline) endoscopy. EH was defined as an MES of 0 or 1 at the second (follow-up) procedure. A minimum time of 1 month between scopes was required for inclusion. Descriptive statistics were used for baseline characteristics. The relationship of EH to IBD-related outcomes was assessed using univariate analysis (Pearson's

Chi-squared test; Fisher's exact test; Welch Two Sample t-test) and we identified those independently associated with EH using multivariable logistic regression analysis (odds ratio with 95% confidence interval).

Results: Among 200 UP patients with baseline endoscopic activity, 109 patients (54.5%) achieved EH at follow-up. The median time from baseline to follow-up was 15 months (IQR: 6, 31). EH at follow-up was significantly associated with fewer IBD-related ED visits (healing: 8.3%, no healing: 21%) or hospitalizations (5.5% vs 18%) and fewer GI visits (mean: 8 [SD: 9], vs 17 [22]) after the second scope. Patients with EH were less likely to have iron deficiency anemia (IDA; 23% vs 41%), iron infusion (10% vs 25%), *C. difficile* infection (0.9% vs 6.6%), or to initiate a new biologic after relapse (15% vs 33%). Patients with EH also had a greater time to clinical relapse (650 days [730] vs 270 days [416]). In multivariable analysis, patients with mucosal healing had 68% lower odds of an IBD-related ED visit (OR: 0.32, 95% CI: 0.13, 0.73), 74% lower odds of IBD-related hospitalization (0.26 [0.09, 0.67]), and 64% lower odds of biologic initiation after relapse (0.36 [0.13, 0.95]) compared to patients with no mucosal healing, adjusting for the index MES score.

	Overall, N = 200[1]	Healing, N = 109[1]	No healing, N = 91[1]	P-value[2]
IBD-Related ED Visit	28 (14%)	9 (8.3%)	19 (21%)	0.01
IBD-Related Hospitalization	22 (11%)	6 (5.5%)	16 (18%)	0.007
Total Number of GI Visits, mean (SD)	12 (17)	8 (9)	17 (22)	<0.001
IDA	62 (31%)	25 (23%)	37 (41%)	0.007
Iron Infusion	34 (17%)	11 (10%)	23 (25%)	0.004
C. Difficile Infection	7 (3.5%)	1 (0.9%)	6 (6.6%)	0.048
Biologic Initiation After Relapse (n=98)	24 (24%)	7 (15%)	17 (33%)	0.034

1. n (%)

2. Pearson's Chi-squared test; Welch Two Sample t-test; Fisher's exact test

Table.

Conclusion: UP patients with endoscopic healing had less IBD-related healthcare utilization (ED visits, hospitalizations, GI visits), fewer IBD-related complications (IDA, iron infusion, *C. difficile* infection), and were less likely to escalate to biologics after relapse. Our findings suggest that using a treatment target of endoscopic healing is desirable in UP and shed light on its potential utility in preventing disease-related complications and improving long-term outcomes.

Introduction: The use of mobile Health applications (mHealth apps) is increasingly frequent as telehealth provides clinical support for patients with chronic pathologies, including health education, symptom surveillance, follow-up, and promotes therapeutic adherence and compliance. There are mHealth apps directed to patients with inflammatory bowel disease (IBD) that have shown to significantly improve IBD disease knowledge level, therapeutic adherence, and even quality of life. Nevertheless, the vast majority is not available in Spanish, thus have limited access and use, no documented validation or user-patient acceptance test (UAT), little multifunctionality and/or difficulty handling.

Aims & Methods: We developed a multifunctional and intuitive free access mHealth app directed to Spanish speakers with IBD and we aimed to validate it with a UAT. The *Development and Assessment of a Mobile Application for Sanitary Support in Spanish speakers with Crohn's and ulcerative Colitis* (DAMASCO) is an independent and multicenter project in Latin America. It is an observational, analytic, and prospective study. During this phase, a prototype mHealth app was designed in Adobe XD and a UAT was used in ambulatory IBD patients, with a ≥6 months diagnosis, cared for in a 3rd level hospital during July/2022. The UAT was performed on-line using the *Mobile Application Rating Score (MARS),* a tool of 30 questions scaled with Likert. It was taken as a reference a Likert (L) 4-5 (very good-excellent). MARS was translated from English to Spanish using the Sperber method. This study was approved by the institutional ethics committee (633 LMiP0Se/22).

Results: The prototype has the following purposes: symptom registry, medication reminder, pending studies, and food diary. Of the 40 people invited for the UAT, 38 accepted and 33 showed ≥75% of the MARS. The sample had a median age of 35 (29-45), 20/33 (60.6%) women, 22/33 (66.7%) ulcerative colitis, and 11/33 (33.3%) Crohn's disease. There was a higher score between questions related to functionality (L4-5 96%), followed by adherence to mHealth app (L4-5 80.3%), content (L4-5 76.5%), and design (L4-5 68.7%). mHealth app specific IBD evaluation had a very good-excellent score in 93.1% of the input. The mHealth app was rated with four and five stars by 20/33 (60.1%) and 5/33 (15.2%), respectively. There was a 1.4% input loss (**Figure 1**).

Conclusion: The recently developed mHealth app constitutes an intuitive, easy-to-use multifunctional free access tool highly accepted among Spanish speaking patients with IBD.

PREVALENCE AND MANAGEMENT OF DASATINIB-INDUCED GASTROINTESTINAL DISORDERS: A STUDY AT OUR HOSPITAL

Y. Yamaguchi[1], M. Oshika[1], T. Ichidayama[1], M. Oshima[1], T. Tashiro[1], S. Kato[1], M. Takayama[1], K. Yamamoto[1], Y. Tamura[1], M. Ebi[1], N. Ogasawara[1], M. Sasaki[1], K. Kasugai[1]

Introduction: Dasatinib is a medication that inhibits the protein kinase activity of BCR-ABL chimeric protein and is used to treat chronic myeloid leukemia. However, reports of bleeding complications such as gastrointestinal bleeding have been reported despite its therapeutic effects.

Aims & Methods: To investigate the gastrointestinal symptoms and endoscopic findings associated with dasatinib administration.

We retrospectively reviewed medical records of 26 patients who received dasatinib for chronic myeloid leukemia or Philadelphia chromosome-positive acute lymphocytic leukemia at our hospital from July 2017 to June 2022. Patients with a history of dasatinib treatment for less than 1 year or bacterial or cytomegalovirus enteritis were excluded. We examined the duration of dasatinib treatment, adverse events including bloody stools, and endoscopic findings in 13 patients who underwent colonoscopy.

Results: The male-to-female ratio was 19:7, and the median age was 54.5 years (4-84). The median duration of dasatinib treatment was 48 months (12-132). Adverse events included edema (7 cases), pleural effusion (10 cases), rash (2 cases), hematotoxicity (8 cases), and muscle pain (2 cases). Gastrointestinal symptoms included chronic diarrhea (4 cases), gastric discomfort (2 cases), abdominal pain (1 case), and bloody stools (3 cases). Nine cases had occult gastrointestinal bleeding. The change in hemoglobin level from before to 1 year after treatment was -0.8, indicating a decreasing trend (13.1±2.2 before treatment, 12.3±1.1 after treatment; p=0.08). Colonoscopy findings included normal in 2 of the 13 patients, rough mucosa in the right colon in 10 patients, and total colitis in 1 patient. One case showed pseudomembranous colitis-like findings, and 2 cases showed inflammatory polypoid-like findings (1 case of solitary polyp and 1 case of polypoidosis).

Conclusion: Dasatinib has been associated with lower gastrointestinal bleeding, and its excretion in feces is thought to be one of the contributing factors. Various gastrointestinal disorders observed in this study are also suspected to be adverse reactions to the medication. Some cases had endoscopic findings suggestive of pseudomembranous colitis or inflammatory polypoid-like changes, requiring consideration of drug-induced enteritis due to dasatinib as a differential diagnosis.

Disclosure: Nothing to disclose.

PREDICTORS OF ILLNESS TRAJECTORY IN NEWLY DIAGNOSED ULCERATIVE COLITIS: A 3-YEAR FOLLOW-UP COHORT STUDY

L. Guadagnoli[1], M. Van Den Houte[1], H. Strid[2], M. Simrén[3], L. Van Oudenhove[1], J. Svedlund[4]

[1]KU Leuven, Laboratory for Brain-Gut Axis Studies, Translational Research in Gastrointestinal Disorders, Leuven, Belgium, [2]Karolinksa University Hospital, Department of Gastroenterology, Dermatovenereology and Rheumatology, Stockholm, Sweden, [3]University of Gothenburg, Institute of Medicine, Gothenburg, Sweden, [4]University of Gothenburg, Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, Gothenburg, Sweden

Contact E-Mail Address: Livia.guadagnoli@kuleuven.be

Introduction: Psychological symptoms are associated with negative ulcerative colitis (UC)-related outcomes, such as increased symptom severity and decreased health-related quality of life (HRQOL). However, the majority of research to date is cross-sectional, limiting our ability to assess the impact of psychological processes on longitudinal IBD-related outcomes and the directionality of such effects.

Aims & Methods: We aimed to identify patient subgroups based on the longitudinal evolution of GI symptom levels and HRQOL and disentangle the directionality of effects between GI symptom levels and levels of psychological distress. Self-reported symptom severity,[1] HRQOL,[2] inflammatory biomarkers, psychological distress,[3] and coping[4] were assessed in 98 newly diagnosed UC patients (mean age = 36 [range 18–74], 69% male) at baseline (before anti-inflammatory treatment) and yearly for 3 consecutive years. Latent-class growth analysis (LCGA) was used to determine subgroups in longitudinal trajectories of symptom severity (diarrhea, abdominal pain) and physical and mental HRQOL. Risk factor analysis was used to determine psychological and inflammatory baseline predictors of trajectory group membership. Cross-lagged structural equation models were used to disentangle psychological predictor – symptom severity temporal relationships.

Results: Different subgroups were found based on the progression of diarrhea, abdominal pain, and physical and mental HRQOL over time. Patients with more psychological symptoms at baseline had an increased probability of maintaining higher levels of diarrhea (p = 0.049) and abdominal pain (p = 0.009) over time. Conversely, patients with lower levels of baseline diarrhea (p < 0.001) and abdominal pain (p = 0.003) had higher chances of maintaining lower levels of psychological distress. Higher levels of C-reactive protein at baseline predicted greater improvements in mental health after anti-inflammatory treatment (p = 0.017), suggesting a subgroup of patients for whom initial poor mental health was inflammation-driven. Cross-lagged structural equation models indicated that reductions in abdominal pain preceded reductions in psychological symptoms in time (all β=0.75, p <.001). Both diarrhea and abdominal pain preceded reductions in coping resources in time (diarrhea: $\beta_{baseline}$= -0.16, β_1= -0.10, β_2= -0.12, all p <.05; abdominal pain: $\beta_{baseline}$= -0.31, β_1= -0.18, β_2= -0.21, all p <.001).

Conclusion: Baseline psychological distress is predictive of higher maintained levels of symptom severity over time, suggesting early assessment of psychological symptoms may identify patients with worse disease trajectories. IBD symptom and disease severity also contribute to mental health outcomes; indeed, low baseline symptom severity may be protec-

tive against subsequent decreased mental health and reducing inflammation may improve mental health functioning in a subset of patients. When evaluating the directionality of psychological predictor–symptom severity relationships over time, abdominal pain predicted increased psychological distress, but not the other way around. Thus, interventions aimed at reducing abdominal pain may help prevent or reduce future psychological distress.

COMBINING LEUCINE-RICH ALPHA-2 GLYCOPROTEIN AND FAECAL BIOMARKERS FOR ACCURATE MONITORING OF SMALL BOWEL ACTIVITY IN CROHN'S DISEASE

A. Kawamoto[1,2], K. Takenaka[1], S. Hibiya[1,2], Y. Kitazume[3], K. Ito[1], H. Shimizu[1], T. Fujii[1], E. Saito[1], K. Ohtsuka[1,2], R. Okamoto[1]

Introduction: Small bowel activity detected by endoscopy is known to be associated with unfavourable clinical outcome in Crohn's disease, regardless of symptoms. The treat-to-target approach whereby endoscopic remission is set as a treatment target is recommended. Imaging modalities for monitoring the small bowel are limited, as well as being invasive.

Aims & Methods: In this study, our objective was to investigate which of the existing biomarkers for Crohn's disease best indicates endoscopic small bowel activity, and whether combining the biomarkers can improve accuracy. 104 consecutive patients with ileal and ileocolonic type Crohn's disease who underwent balloon assisted enteroscopy (BAE) at our hospital from October 2021 to August 2022 were enrolled, with clinical and laboratory data prospectively collected and analysed. BAE was evaluated using the modified Simple Endoscopic Score for CD (modified SES-CD). Ulcers were defined as those ≧ 0.5 cm.

Results: Haemoglobin, platelet count, C-reactive protein (CRP), leucine-rich alpha-2 glycoprotein (LRG), faecal calprotectin, and faecal haemoglobin values all demonstrated a significant difference in those with ulcers found on BAE. All biomarkers significantly correlated with modified SES-CD. LRG and faecal calprotectin showed the highest areas under the curve (0.841 and 0.853) by ROC analysis for detecting small bowel ulcers. LRG showed a sensitivity of 78% and specificity of 80% at a cut-off value of 13 µg/mL, whereas faecal calprotectin showed a sensitivity of 91% and specificity of 67% at a cut-off value of 151 µg/g. Dual positivity for LRG and faecal calprotectin, as well as LRG and faecal haemoglobin, both predicted the presence of ulcers with a further improved specificity of 92% and 100%. A positive result for either LRG or faecal calprotectin/haemoglobin showed an improved sensitivity of 96% and 91%. Positivity for LRG and either of the faecal biomarkers was associated with poor clinical outcome in terms of hospitalisation, surgery, and relapse.

Conclusion: This is the first study comparing the major existing biomarkers for Crohn's disease in terms of monitoring for small bowel activity. LRG, faecal calprotectin, and faecal haemoglobin are accurate biomarkers, especially when used in combination. Patients who are dual-positive for LRG and faecal calprotectin or faecal haemoglobin should be assessed by early endoscopic evaluation of the small bowel and considered for change in treatment, as they are at higher risk for hospitalisation, relapse, and surgery.

Introduction: The disease course of ileal and ileocolonic Crohn's disease (CD) is highly heterogeneous, and continuous objective measures of disease activity are needed. Intestinal Ultrasound (IUS) is a non-invasive modality assessing disease activity in IBD. The International Bowel Ultrasound Segmental Activity Score (IBUS-SAS) is an index for grading CD activity. However, importance of the ultrasonic findings in the terminal ileum (TI) at diagnosis and the responsiveness of ultrasonic findings to different treatments is still limited.

We thus aimed to investigate the IUS characteristics of the TI at diagnosis and changes in IUS parameters in response to treatment 3 months after inclusion.

Aims & Methods: Patients with new-onset IBD are recruited in the ongoing multicentre prospective inception cohort study, the IBD Prognosis Study. IUS is performed at diagnosis and after three months (3M). IBUS-SAS (0-100) is scored for the TI and incorporates the bowel wall thickness (BWT), bowel wall stratification (BWS), colour Doppler signal (CDS), and inflammatory fat (I-FAT). Only patients with ileal and ileocolonic CD who had an available IBUS-SAS of the TI at diagnosis were included. Patient without subsequent assessment at 3M were excluded (except resected patients). Transmural remission was defined as IBUS-SAS < 12 (corresponding to BWT < 3 mm and no signs of inflammation). If the operator assessed the TI as complete transmural remission at 3M without providing numeric BWT values, the IBUS-SAS was set to 8. Patients treated with corticosteroids for > 72 hours or with any IBD treatment > two weeks prior to baseline IUS were excluded from analysis.

Results: Baseline IBUS-SAS at TI was available in 46 CD patients (ileal: 21, ileocolonic: 25). According to the Montreal classification, 31 patients had B1 (non-stricturing, non-penetrating disease), 9 patients had B2 (stricturing disease), and 6 patients had B3 (penetrating disease).

Among all patients, the mean IBUS-SAS was 60.7 at diagnosis vs. 33.7 at 3M (p<0.001). Mean baseline BWT decreased from 5.8 to 4.6 (p=0.011) at 3M. The other IBUS-SAS parameters also had significant reductions (p=0.021,

p=0.001, and p<0.001 for BWS, CDS, and I-FAT, respectively). After three months, 12/39 (30.8%) of non-resected patients were in transmural remission.

Changes in IBUS-SAS between diagnosis and 3M stratified by initiated treatment are presented in *Figure 1* (https://ibb.co/mBcVF9b). In total, 6 (13.0%) patients started only systemic steroids with a mean IBUS-SAS reduction of 20.6 (p=0.025), 5 (10.9%) patients started systemic steroids + biological therapy with a mean reduction in IBUS-SAS of 37.6 (p=0.022), 11 (23.9%) patients started on systemic steroids + immunomodulator with a mean reduction in IBUS-SAS of 35.6 (p<0.001), 4 (8.7%) patients started on immunomodulator + biological therapy with a mean reduction in IBUS-SAS of 24.8 (p=0.271), and 9 (19.6%) patients were started on budesonide with a mean reduction in IBUS-SAS of 9.4 (p=0.287). Finally, 4 (8.7%) patients did not commence on any treatment and these patients increased their IBUS-SAS by 6.75 (p=0.536), and 7 (15.2%) patients were resected as primary treatment with 1, 2, and 4 having the B1, B2, and B3 Montreal classification, respectively. Baseline IBUS-SAS was significantly higher for patients undergoing resection than patients without resection, (87.9 vs. 55.8, P<0.001).

Conclusion: IUS performed at diagnosis and after three months can effectively identify patients achieving ultrasonic response and / or transmural healing to multiple drug classes. All four IBUS-SAS activity parameters demonstrated responsiveness to treatment and patients without treatment increased their IBUS-SAS non-significantly. Transmural remission was achieved in up to 30 % of non-resected patients within 3M.

Disclosure: Nothing to disclose.

RISANKIZUMAB LEVELS ARE SIGNIFICANTLY CORRELATED AND PREDICTIVE OF BIOMARKER REMISSION IN CROHN'S DISEASE

S. Paul[1], L. Waeckel[1], L. Merle[2], A.-E. Berger[1], A.-S. Peaucelle[2], M. Barrau[2], X. Roblin[3]

[1]Hôpital Nord, Immunology, Saint Etienne, France, [2]Hôpital Nord, Gastroenterology, Saint Etienne, France, [3]University of St. Etienne, Gastroenterology, Saint Etienne, France

Contact E-Mail Address: xavier.roblin@chu-st-etienne.fr

Introduction: Risankizumab (RZB) is a P19 subunit blocking anti-IL-23 agent that has been shown to be effective in CD in a recent Phase 3 trial (Ferrante et al., Lancet 2022). Compassionate use has been possible since June 2022. The aim of this work was to investigate whether RZB levels correlate with biomarker-based remission.

Aims & Methods: Any CD patient on RZB (compassionate use or open-label phase 3 study) was eligible for the study. All patients were treated with a regimen of RZB (600mg/IV S0, S4 and S8) followed by 360 mg/sc every 8 weeks starting at S12. Patients who had received other regimens were excluded. Before each infusion or SC injection, fecal calprotectin, CRP and RZB levels were measured using an ELISA test. The assays were blinded to clinical and biomarker datas. Clinical remission was defined as CDAI score < 150 Conversly, clinical activity was definied by a CDAI score > 220. Biomarker remission was defined as fecal calprotectin levels below 250 µg/ml and CRP < 5 mg/l.

Results: 26 patients (mean age: 42 years, sex ratio M/F: 1.3) with 97 maintenance RZB samples (360mg/sc every 8S) were eligible. In 37 cases, RZB samples were taken while biomarkers were in remission. During, maintenance, mean RZB levels were significantly higher in cases of clinical remission than in the absence of clinical remission (22.5 versus 6.1 µg/ml; p<0.0001)(Figure 1). Mean RZB levels were similar between patients in clinical remission and patients in clinical and biomarker remissions (22.5 versus 19.6 µg/ml; p<0.0001). The higher RZB trough level quartiles tended to be associated with greater rates of clinical response [p = 0.001]. Clinical remission rates were 4% if RZB trough levels were ≤4.9 µg/mL [quartile 1] and 88% if RZB trough levels were >19.6 µg/mL [quartile 4] (Figure 2).

Conclusion: RZB levels are significantly higher in patients with clinical remission in CD. Trough concentration of RZB above 10.6µg/mL should be recommended in clinical practice.

Contact E-Mail Address: torsten.kucharzik@klinikum-lueneburg.de

Introduction: Transmural response (TR) and healing (TH) assessed by intestinal ultrasound (IUS) are gaining increasing relevance as treatment targets in Crohn's disease (CD) [1].

Even though less established in ulcerative colitis [UC], in which the inflammation mainly affects mucosa and submucosa, there is clear evidence that applying IUS in UC is beneficial to monitor short-term response to therapy [2].

However, the long-term IUS outcome, its association to clinical and lab parameters as well as the predictive value of early TR remain elusive.

Aims & Methods: The TRUST BEYOND study is an ongoing, prospective, non-interventional, multi-centre study in patients with active CD or UC who receive a biologic- or Januskinase-inhibitor (JAKi)-therapy at baseline. The study aims to assess the predictive value of TR or TH, evaluated at week 12 for the disease outcome after 52 weeks (TR: reduction of bowel wall thickness (BWT) of at least 25% and/or normalization; TH: normalization of BWT and Colour Doppler signal). For this interim analysis, we report IUS and clinical results as well as fecal calprotectin levels of 77 UC patients on the same therapy after 12 (W12) and 52 weeks (W52) and assessed the predictive value of TR at W12 for clinical remission at W52.

Results: Seventy-seven UC patients (63.6% were male, median age was 38.6 years (30.6 – 55.7) median disease duration of 5.85 years (2.49–12.77)) with clinically active disease (SCCAI 8.5 ± 2.2) with increased BWT at baseline had a documented visit after 52 weeks until February 2023. For the vast majority, the most affected bowel wall segment was the sigmoid colon with a mean BWT of 5.22 ± 1.28 mm at baseline.

At W12 after induction of therapy, the proportion of UC patients with TR and TH was 67.5% (n = 52) and 31.2% (n = 24). At W52, the rates of UC patients increased to 77.9% (n = 60) for TR and 41.6% (n = 32) for TH. Over the study course, patients with TR at W12 and W52 had a numerically lower SCCAI score and reduced fecal calprotectin levels than patients without TR.

Of note, 72.2% (n = 39) of patients with TR at W12 were in clinical remission at W52 compared to 27.8% (n = 15) of patients without early transmural response (p = 0.178).

Conclusion: In this interim analysis of the TRUST BEYOND study, UC patients demonstrated substantial rates of transmural improvements on IUS after 12 and 52 weeks. Patients with early transmural response were more likely to be in remission after one year. This suggests that in UC, IUS has to some degree a predictive value as observed for CD.

Introduction: Crohn's Disease (CD) is a chronic inflammatory disease of the gastrointestinal tract often requiring lifelong treatment. An important proportion of CD patients with ileitis or ileocolitis require bowel resection during the course of their disease. [1] Although ileocolonic resection (ICR) induces clinical and endoscopic remission, more than half of patients develop postoperative recurrence in the first years following surgery. [2] In the recent REPREVIO trial, we showed that vedolizumab treatment (VDZ) is effective to prevent the incidence and severity of recurrence. [3]

Currently, the gold standard to diagnose postoperative CD recurrence is through ileocolonoscopy using the Rutgeerts scoring system. A modified Rutgeerts score ≥i2b predicts early clinical recurrence. Given the invasive nature and high cost of endoscopy, we investigated the value of fecal calprotectin (FC) in a prospective cohort of patients enrolled in the REPREVIO trial.

Aims & Methods: CD patients were randomized to blinded treatment with 8-weekly IV VDZ 300 mg or placebo for 26 weeks within 1 month following ICR. Faecal calprotectin (FC) and serum CRP were measured at baseline, week 8, week 16 and week 24. At week 26-28 ileocolonoscopy was performed to evaluate CD recurrence and scored by blinded investigators. Statistical analysis was performed using SPSS (IBM). Predictors for endoscopic recurrence were examined by univariable and multivariable logistic regression analysis. Receiver operating characteristic (ROC) curves were used to assess accuracy of FC in predicting endoscopic recurrence.

Results: Eighty patients (median age 36 [IQR 27-52], median disease duration 8.5 years [IQR 1-16]) participated in REPREVIO, all having at least 1 risk factor for postoperative recurrence (smoking 16.3%, >1 prior resection 35%, perforating complications 36.3%, previous exposure to TNF inhibitors 48.8%).

Median FC at baseline (BL) was 157.2 µg/g [IQR 68.3-310.3] for all patients. In patients *without* week 26 endoscopic recurrence, FC decreased from BL to week 8 (from 139 to 80.5 µg/g, p<0.001). Conversely, FC remained stable or increased in patients who had week 26 recurrence independently from allocation (VDZ or PLC).

Week 8 FC levels were significantly higher in patients with week 26 endoscopic recurrence (Rutgeerts ≥i2b) (158 µg/g [IQR 53.9-397]) than in patients without recurrence (Rutgeerts ≤i2a) (80.5 µg/g [IQR 19.3-181.8], p= 0.011). After correction for treatment (PLC or VDZ), the predictive power of FC was only significant for patients in the PLC group (Rutgeerts ≤i2a 46 µg/g [IQR 18.8-139] versus Rutgeerts ≥i2b 200 µg/g [43.1-425.3])(p=0.018), respectively). ROC analysis revealed that FC had an area under the curve (AUC) of 0.703 for a cut-off FC value of 45 µg/g at week 8, with a sensitivity of 85% and a specificity of 40% to predict endoscopic recurrence. Further analysis of the predictive value of week 16 and 24 FC was hampered by the number of missing samples. Serum CRP was not predictive of recurrence.

	Remission (Rutgeerts ≤i2a)	Recurrence (Rutgeerts ≥i2b)	p-value
ALL PATIENTS Calprotectin baseline, Median, IQR, µg/g	139 [46-375.5]	189.6 [82.3-323.8]	0.527
Calprotectin week 8, Median, IQR, µg/g	80.5 [19.3-181.8]	158 [53.9-397]	0.011*
ONLY VDZ Calprotectin baseline, Median, IQR, µg/g	157.2 [52-399]	186.1 [74-467]	0.865
Calprotectin week 8, Median, IQR, µg/g	88 [20-199.5]	120.5 [65.5-225.3]	0.456
ONLY PLC Calprotectin baseline, Median, IQR, µg/g	233.5 [21.8-366.5]	193 [89-240]	0.512
Calprotectin week 8, Median, IQR, µg/g	46 [18.8-139]	220 [43.1-425.3]	0.018*

Conclusion: In the REPREVIO study, week 8 FC levels were predictive of clinically relevant endoscopic recurrence at week 26. A FC >45 µg/g 8 weeks post-surgery has a sensitivity of 85% to predict significant endoscopic recurrence and treatment escalation should be considered in these patients.

FACTORS ASSOCIATED WITH ABDOMINAL PAIN IN PATIENTS WITH ULCERATIVE COLITIS

T. van Gils[1], H. Törnblom[1], B. Jonefjäll[2], H. Strid[3], M. Simrén[1,4]
[1]University of Gothenburg, Department of Molecular and Clinical Medicine, Institute of Medicine, Sahlgrenska Academy, Gothenburg, Sweden, [2]Sahlgrenska University Hospital, Department of Medicine, Mölndal, Sweden, [3]Karolinska University Hospital, Gastroenterology Unit, Department of Gastroenterology, Dermatovenereology and Rheumatology, Stockholm, Sweden, [4]University of North Carolina at Chapel Hill, Center for Functional Gastrointestinal and Motility Disorders, Chapel Hill, United States

Contact E-Mail Address: tom_van_gils@hotmail.com
Introduction: Abdominal pain is a common but often overlooked symptom in patients with ulcerative colitis (UC). The causes of pain during deep remission remain incompletely known, although factors in the brain-gut axis may play a role.
Aims & Methods: The aim of this study was to determine factors associated with abdominal pain in UC patients. Three existing study cohorts of adults with UC were used. Cohort I included 133 patients (49 active), cohort II 287 patients (155 active) and cohort III 92 patients (20 active). The abdominal pain domain of the Gastrointestinal Symptom Rating Scale was used to assess the severity of pain, identifying subjects with at least mild severity of abdominal pain. The Hospital Anxiety and Depression Scale was used to identify subjects with anxiety and or depression (scores ≥8) Patients also completed questionnaires to assess severity of fatigue (Fatigue Impact Scale (FIS, cohort I)), and quality of life (QoL, the IBD questionnaire (IBDQ, cohort II)).
Results: In the three cohorts 39%, 24% and 20% of the patients with active disease and 20%, 7% and 15% of the patients in remission reported at least mild severity of abdominal pain. A higher proportion of UC patients with at least mild abdominal pain had anxiety (83%, 44%, and 40% vs 42%, 18% and 7%; p<0.01) and depression (40%, 33% and 40% vs 13%, 9% and 13% p<0.05). Disease-specific QoL was lower in patients with at least mild abdominal pain, both in patients with active disease (median [IQR] IBDQ score 182 [150-198] vs 144 [115-160], p<0.001) and in remission (IBDQ score 203 [190-213] vs 171 [141-181], p<0.001). In UC patients in remission, having at least mild abdominal pain was associated with more severe impact of fatigue on daily life, (FIS 81 [67-100] versus 29 [14-58], p<0.001).
Conclusion: Abdominal pain is relatively common in patients with UC with active disease as well as in remission. This is associated with anxiety, depression and more severe fatigue and a lower QoL. Hence, paying attention to abdominal pain and associated factors seems important to optimize clinical management of these patients.

Contact E-Mail Address: konstantinova2002@mail.ru
Introduction: A differential diagnosis of inflammatory bowel diseases (IBD) and irritable bowel syndrome (IBS) is one of the unresolved problems in modern gastroenterology. The absence of clear criteria for IBD detection leads to delay in the diagnostic process for months and years.
Aims & Methods: The aim of the study was to identify clinical and laboratory markers that could distinguish between IBD and IBS with a subsequent development of an artificial neural network (ANN).
We retrospectively evaluated the clinical symptoms, anamnesis data and laboratory tests of patients with verified exacerbation of Crohn`s disease (CD) and ulcerative colitis (UC), and IBS. We found parameters that could distinguish IBD and IBS and then CD and UC, and used them to create the ANN.
Results: Of the 1006 examined, 32% were patients with IBS and 68% with IBD. Patients with IBS were significantly more likely to have a tendency to constipation (34.8% compared with 5.0% in IBD patients), loose stool up to 2 times (26.9% compared with 17.0%), the absence of extraintestinal (EIMs) (94.1% compared to 66.3%) and perianal manifestations (PAM) (96.0% compared to 83.5%) (p<0.001). The patients with IBD had diarrheal syndrome ≥ 5 times a day more frequently (40.0% and 6.2% in patients with IBS, respectively), blood admixture (65.3% and 6.8%, respectively) and higher level of fecal calprotectin (p<0.001). All these data were used to create and train the ANN on general and test (15% of all cases) dataset. Multilayer perceptron showed the best results in IBD detection: the sensitivity was 95.8% and the specificity was 90.2%.
To create the ANN for IBD differentiation, we analyzed medical histories of 350 patients (51%) with UC and 333 (49%) with CD. Statistical analysis in the group with UC significantly more often had severe diarrheal syndrome (≥ 5 times a day) (48.3% compared to 42.3% among the patients with CD), blood in the stool (87.1% compared to 79.0%, respectively), the absence of EIMs (73,4% compared to 58,9%, respectively) and PAMs (97,4% compared to 58,9%, respectively) (p<0,001). Patients with CD compared with UC were significantly more likely to have constipation (7.2% compared to 2.9%, respectively) (p=0.002), increased stool up to 2 times (21,6% compared to 12,6%, respectively), subfebrile temperature (25.8% compared to 16.9%, respectively) (p=0.004) and surgical intervention on the small and large intestines in the anamnesis (20.1% in compared to 1.4%, respectively) (p<0.001). The clinical and anamnestic parameters identified in our study were used to create and train the ANN. The best results were shown by a linear set with 5 input neurons: the accuracy of detecting CD was 78.7% and UC - 75.4%, which shows a moderate ability of the ANN to differentiate UC and CD.

Conclusion: As a result of the study, we created the ANNs with high sensitivity and specificity in the differentiation of organic and functional intestinal diseases and with moderate accuracy in IBD differentiation. The developed ANN can help clinicians in the diagnosis of IBD and IBS, but further work for improving its accuracy and the possibility of implementation into clinical practice is required.

THE UROTENSIN-II RECEPTOR: A NEW PREDICTIVE MARKER OF STAGING OF ULCERATIVE COLITIS AND THERAPEUTIC RESPONSE TO INTRAVENOUS STEROID ADMINISTRATION

R. Pellegrino[1], M. Romeo[1], M. Cipullo[1], A. Coppola[1], L. Ventriglia[1], F. Scognamiglio[1], M. Dallio[1], A.G. Gravina[1], A. Federico[1]
[1]University of Campania Luigi Vanvitelli, Department of Precision Medicine, Hepatogastroenterology Unit, Naples, Italy

Contact E-Mail Address: marioromeo@virgilio.it
Introduction: Urotensin II (U-II) is a vasoactive peptide whose interaction with its specific receptor (UTR) plays a key role in promoting several phlogistic pathways in different inflammatory-related diseases, including ulcerative colitis (UC). The incidence of UC is increasing worldwide, becoming a contemporary important health and socio-economic problem due to the burden of optimal medical management, especially in the acute severe UC (ASUC) setting.
In the ASUC, in fact, the main goals for the clinicians at the moment of admission are represented by the rapid severity assessment and risk stratification to make the best therapeutic choice.
Aims & Methods: We aimed to assess the relationship between UTR expression and clinical, endoscopic, and biochemical severity of UC, exploring its predictivity predictive role for intravenous (iv) steroid administration therapeutic outcome. One-hundred patients receiving the first diagnosis of UC and 44 healthy subjects receiving a colorectal cancer screening colonoscopy were consecutively enrolled. UTR expression was assessed by quantitative polymerase chain reaction (qPCR), Western Blot (WB), and immunohistochemistry (IHC). Clinical, endoscopic, and histology activity of UC were evaluated by using Truelove and Witts (T&W) severity index, Mayo Endoscopic Score (MES), Truelove and Richards Index (TRI), Partial Mayo score (PMS) and Full Mayo Score (FMS). The "Albumin, C-reactive protein, Endoscopy" (ACE) index was also determined as a well-known score in the prediction of steroid response. Response to treatment was defined by combining bowel movements frequency and PCR levels according to the clinical practice guidelines.
Results: The UTR expression resulted higher in the lesioned mucosa of UC patients in comparison to healthy subjects ($p < 0.0001$ all). A direct relationship between UTR (mRNA and protein) expression and disease severity assessment (T&W, TRI, MES, PMS, and FMS) was highlighted ($p<0.0001$ all). Of 100 patients, 72 presented ASUC requiring iv steroid administration. UTR expression (mRNA and protein) was higher in these individuals than in those (28/100) who underwent alternative medications (budesonide, 5-aminosalicylic acid, and others) ($p<0.0001$). Of 72 steroid-treated patients, 40 were considerable responders. The 32 steroid-non-responders showed an increased UTR expression (WB, IHC, and qPCR from lesioned mucosa), compared to the 40 steroid responders (p:0.0002, p:0.0001, $p<0.0001$ respectively). Logistic regression analysis revealed the UTR expression levels associated with the negative iv. steroids administration therapeutic outcome ($p<0.05$).
ROC curves for the prediction of negative iv steroid therapeutic outcome were generated for IHC (AUC: 0.93, 95% CI: 0.86-0.99, $p<0.0001$), WB (AUC: 0.94, 95% CI: 0.87-1.00, $p<0.0001$), qPCR from lesioned samples (AUC: 0.99, 95% CI: 0.97-1.00, $p<0.0001$) UTR expression. The diagnostic performance of qPCR-UTR was superior to the ACE index (AUC: 0.94, 95% CI: 0.88-0.99) in the prediction of steroid response.
Finally, all the steroid responder patients (40/100) were undergone a second colonoscopy after one month and were considered "full responders" because of the reduction of at least two points of the continuous FMS in comparison to the baseline value.
Conclusion: UTR represents a promising inflammatory marker related to clinical, endoscopic, and histology disease activity as well as a predictive marker of steroid administration therapeutic outcome in the UC context.

DIAGNOSIS METHODS FOR INFLAMMATORY BOWEL DISEASES USING THE FECAL, HEMATOLOGICAL, SEROLOGICAL INDICATORS, FATTY ACIDS' LEVELS OF ERYTHROCYTE MEMBRANES, AND BLOOD SERUM

M.V. Kruchinina[1,2], A.V. Borisova[1], I.O. Svetlova[2,1], A.A. Gromov[1], M.V. Shashkov[3], A.S. Sokolova[4], I.N. Yakovina[5], I.V. Osipenko[5]

Contact E-Mail Address: kruchmargo@yandex.ru
Introduction: Inflammatory bowel diseases (IBDs), including Crohn's disease (CD) and ulcerative colitis (UC), are chronic advanced immune-mediated inflammatory diseases of unknown etiologies [1, 2]. There is still no unified "gold standard" for the diagnosis of IBDs; the diagnosis is usually made on the basis of data sets which include medical history, clinical manifestations, typical endoscopic views and histological signs, therefore, between 5% and 15% of cases of IBDs do not meet the strict criteria for either UC or CD, and in 14% of patients diagnosed with both UC and CD, the diagnosis can be changed over time [3, 4].
Aims & Methods: Research objective is as follows: To develop a diagnostic method for the IBDs including differential diagnosis, using a combination of indicators, such as fecal, hematological, serological, fatty acids' (FA) levels of erythrocyte (RBC) membranes and blood serum (BS).
A total of 91 patients (average age 37.7 ± 12.1 years old) with IBDs and 53 patients of the comparison group (43.3 ± 11.7 years old) have been examined. The group of patients with IBDs have included patients with ulcerative colitis (UC) – 50 persons and with Crohn's disease (CD) – 41 persons. In the examined patients, the red blood parameters and biochemical parameters have been studied by standard methods, as for the level of fecal

calprotectin, it has been researched by the enzyme-linked immunosorbent assay (ELISA), and the levels of fatty acids of erythrocyte membranes and blood serum have been investigated by the gas chromatography–mass spectrometry (GC-MS) (Agilent 7000B, USA).

Results: In a comparative analysis of patient groups using statistical analysis, a composite set of indicators has been found to be the most significant in distinguishing the patients with acute UC from comparison group individuals: hemoglobin levels ($p<0.00001$), sedimentation rate ($p<0.00001$), ferritin levels ($p<0.00001$), fecal calprotectin ($p<0.00001$), and oleic acid content ($p=0.0031$), polyunsaturated fatty acids in erythrocyte membranes ($p<0.05$), arachidonic acid in erythrocyte membranes and blood serum ($p<0.05$), and serum PUFAs ($p=0.0018$) and n6/n3 PUFA ratio ($p=0.0005$). Diagnostic models have been developed using machine learning methods using data analysis libraries of the Python programming language. The first model, which includes a combination of the above indicators, allows to perform the calculation of the diagnostic index Y_{D1} to differentiate healthy individuals from patients with IBDs (AUC 0.957, sensitivity 0.974, specificity 0.941). The second diagnostic model for distinguishing patients with acute ulcerative colitis from patients with active Crohn's disease (AUC 0.887, sensitivity 0.993, specificity 0.840) have considered the levels of hemoglobin, hematocrit, mean corpuscular volume of erythrocytes ($p=0.007$), mean cell hemoglobin concentration and content in the RBCs ($p<0.05$), ESR ($p<0.05$), C-reactive protein ($p=0.002$), ferritin ($p=0.014$), fibrinogen ($p<0.0001$), fecal calprotectin ($p=0.005$), and erythrocyte level of oleic acid ($p<0.05$).

Conclusion: The diagnostic models that have been created include fecal, serum markers of inflammation, as well as levels of fatty acids pathogenetically associated with the activity of IBDs, which ensures their high diagnostic accuracy. The non-invasive nature, an availability of indicators, and a convenient algorithm allow us to optimize and expedite the diagnosis of the IBDs.

Introduction: Sexual health is a major determining factor in the quality of life and psycho-emotional development of every individual, and may be affected by chronic diseases as inflammatory bowel disease (IBD). The aim of this study is to measure the impact of the disease on patient's sexual desire.

Aims & Methods: Cross-sectional descriptive study in which 107 patients over 18 years old anonymously undertook the Sexual Desire Inventory (SDI) survey validated in Spanish between the months of March and April 2022. The SDI consists in a questionnaire composed by 13 items that evaluate both dyadic (items 1-9) and solitary (items 10-13) sexual desire, measured from 1 to 8 with a total score of 101. Specifically, items 9 and 13 asked about patient's sexual desire compared to their peers. Furthermore, they were also asked if they believed their disease affected their sexual desire and to what extent. Sociodemographic data and general information about their disease were collected as well.

Results: 107 questionnaires were analyzed. Mean age was 47.21 years (± 13.54), 57.01% male. 39.01% of patients suffered from ulcerative colitis (UC), 59.81% from Crohn´s disease (CD). The average total score in the SDI of 52.99 out of 101 points. There is not a validated threshold to catalogue a reply as normal, considering that the higher the score, the greater the desire. When compared patients with UC and CD, their responses did not show statistically significant differences. Other variables that could have an impact on sexual desire as perianal disease or previous surgery were analyzed, again not showing differences with the overall average. When divided between dyadic and solitary sexual desire, results were constantly higher on dyadic answers (mean 4.6 vs 3.9), with statistically significant difference ($p=0.03$). However, when compared questions 1 to 8 (regarding dyadic sexual desire) with question 9 (compared to their peers), and questions 10 to 12 (regarding solitary sexual desire) with question 13 (compared to their peers), it did not showed differences. When asked whether they believed their disease affected their sexual desire, 41.12% (44) replied affirmatively, being women 24 of them. From those 44 patients, the average score on the degree to which their desire is affected of 5.43 out of 8, without differences between UC and CU. 38% of the 31 patients with perianal disease agreed with the affirmation as well, with a score of 6.16 out of 8. Patients who answered yes to this question tended to have lower score on the SDI, being statistically significant when compared to the answers on question 13 ($p=0.05$).

Conclusion: Sexual health is a complex issue which involves a great number of variables. Most statistically significative differences were seen regarding individual sexual desire, being impaired with respect to dyadic desire. There is a remarkable number of patients who felt their disease impaired their sexual desire, seeing a higher proportion between women.

Moreover, for the ones affected, it was to a large extent. It is an issue that needs further studies, especially because its impact on quality of life and the lack of quality evidence in this area.

DIAGNOSTIC DELAY IN INFLAMMATORY BOWEL DISEASE: STILL AN UNMET NEED

D. Brinch[1], E.L. Cavaleri[1], L.M. Amato[1], M. Saladino[1], S. Muscarella[1], P. Melatti[1], L. Carrozza[1], L. Di Prima[1], C. Celsa[1], C. Camma[1], M. Cappello[1]
[1]University of Palermo, Gastroenterology and Hepatology Section, Promise, Palermo, Italy

Contact E-Mail Address: marica.cappello61@gmail.com
Introduction: The diagnosis of ulcerative colitis (UC) and Crohn's disease (CD) is the result of a combination of clinical, endoscopic, histological and radiological data and is often delayed, especially for CD. Early referral to a specialist, timely diagnosis, and choice of appropriate treatment represent the most suitable strategy for improving outcomes and minimizing the onset of disease complications or the need for surgery.
Aims & Methods: Our study aims at evaluating diagnostic delay in CD and UC in an homogeneous cohort of patients followed up in a tertiary referral center. Patients with follow-up duration time < 9 months were excluded. Diagnostic delay was defined or as the time from onset of symptoms to the first visit to our IBD clinic or time from the first symptom to the diagnosis. A logistic regression model was used to analyze the relationship between baseline characteristics and diagnostic delay (defined as time greater than 2 years between the onset of symptoms and the diagnosis of IBD) and between diagnostic delay and disease outcome at 12 months follow up.

Diagnostic delay	CD	UC	p value
time from the onset of symptoms to IBD diagnosis (median, + SD + range)	15,9 ± 23 (0,1-116,2)	7,9 ± 11,7 (0,1-75,5)	0.013
time from the onset of symptoms to the first visit (median, + SD + range)	15 ± 23 (0,1-116)	8,9 ± 11,53 (0,5-75,73)	0.041
patients with diagnostic delay > 2 years (n)	18	5	0.031
patients with diasgnostic delay < 2 years (n)	68	58	

Table.1

Results: We retrospectively evaluated 149 IBD patients diagnosed from february 2017 to march 2022 at a tertiary referall center: 86 with CD (57.72%) and 63 with UC (42.28%). Age at diagnosis was 37±18 years for CD and 43±17 for UC. 18 patients with CD (20.93%) and 5 patients with UC (7.94%) received a diagnosis after more than 2 years from first symptom. Median diagnostic delay was significantly higher in CD patients (tab1.1) compared to UC patients (time from the onset of symptoms to the first visit: 15.9±23 months versus 7.9±11.7 months, p=0.013; time from onset of symptoms to diagnosis 15.4±23 versus 8.9±11.53, p=0.041; tab.2). CD (OR 3.07; 95% CI 1.07-8.78; p=0.036) and surgery at onset (OR 1.55; 95% CI 1.35-16.48; p=0.015) were significant predictors of diagnostic delay at univariate analysis.
In particular, in patients with CD, surgery at onset is associated with an approximately 4-fold higher risk of diagnostic delay. At multivariate analysis CD (OR:2.57 95% CI 0.87-2-55, p=0.086) and surgery at onset (OR 3.57; 95% CI 0.99-12.89, p=0.052) were independent predictors of diagnostic delay albeit with marginal statistical significance. Median follow-up was 13.19±2.90 . No significant association between diagnostic delay and outcomes at 12 months follow up were found.
Conclusion: Our study confirms that diagnostic delay is still common in IBD and is longer in CD patients compared to UC patients. An increased cooperation among specialists, primary care phisicians and referral centers and the development of dedicated integrated-care pathways are required in order to recognize red flags that raise clinical suspicion and lead to timely diagnosis in IBD patients.

Introduction: Colonoscopy plays a crucial role in management of ulcerative colitis (UC) that helps to assess mucosal healing. Different scoring systems are available to assess severity, however most of them do not correlate with disease extent.
Aims & Methods: Our study aimed to assess the predictive value and accuracy of PanMayo score compared to MES, UCEIS and Dublin in mid- and long-term disease outcomes. This is a retrospective, two-center study. UC patients, who underwent colonoscopy due to any reason between 2016 and 2018, were consecutively enrolled. PanMayo, MES, UCEIS and Dublin scores were recorded with clinical and demographical data at baseline. Disease flare, need for change in therapy (incl. initiation of biologicals, need for systemic steroids), hospitalisations and colectomy were collected during an at least 3-years follow-up. Patients were stratified by using baseline clinical activity (pMayo>1). Log-rank, logistic regression and Chi^2 tests were used to analyze outcomes and Kaplan Meier curves were plotted.
Results: A total of 250 UC patients (Table 1.) were enrolled. 157 (male ratio 0.49; mean age 46 IQR 19.5 years) UC patients had clinical remission, while 93 had active disease at baseline (male ratio 0.43; mean age 42 IQR 25 years). PanMayo, MES, and Dublin scores were positively associated with risk of flare-up (p=0.002; p<0.01; p=0.003).
Increasing MES score was coupled with risk of relapse. PanMayo score (above 12 points), but not MES or UCEIS, was associated with the need of new biological (p<0.001) and treatment escalation (p=0.018), similar trend was found for the Dublin score for need for new biologicals in the remission cohort.
All scores were strongly associated with the need for systemic steroids in patients with baseline remission. In the cohort with active disease at baseline, PanMayo (p=0.016) and Dublin (p=0.009) scores were associated to colectomy risk.

	Total cohort (n = 250)	Clinical remission (pMayo < 2) at baseline (n = 157)	Clinical activity (pMayo > 1) at baseline (n = 93)
Sex, *male (%)*	117 (46.8)	77 (49.0)	40 (43.0)
Age at inclusion, *years, median (IQR)*	45.0 (22.3)	46.0 (19.5)	42 (25.0)
Disease duration at inclusion, *years, median (IQR)*	10.0 (13.0)	11.0 (13.0)	8 (9.0)
Disease activity			
pMayo *median (IQR)*	1.0 (3.0)	0.0 (0.0)	4 (3.0)
MES *median (IQR)*	1.0 (2.0)	0.0 (1.0)	2 (1.0)
MES > 0 *n (%)*	158 (63.2)	71 (45.2)	87 (93.5)
PanMayo *median (IQR)*	2 (18)	0 (3)	18 (21)

Abbreviations: n: number of patients, pMayo: partial Mayo score; IQR: inter-quartile range; MES: Mayo endoscopic score.

Table 1. Baseline demographic and clinical characteristics of patients

Conclusion: Our study suggests that combined endoscopic assessment of the extent and severity may be more precise in predicting disease outcomes in UC. PanMayo score may be an alternative of the existing scoring systems and was associated more granularly with disease outcomes.
Disclosure: There are no conflicts of interest to disclose.

Introduction: Patients with inflammatory Bowel Diseases (IBDs) often present with inadequate control due to the limited efficacy of current treatments and suboptimal disease management. The IBD-PODCAST study aimed to estimate the proportion of Crohn´s Disease (CD) and Ulcerative Colitis (UC) patients with Inadequate Disease Control (IDC) based on the STRIDEII1 recommendations and assess the impact on their Quality of Life (QoL), in Portugal.

Aims & Methods: A non-interventional, multicenter study with a cross-sectional and retrospective assessments was conducted in Portugal gathering data from 130 patients (67 with CD, 63 with UC), from 5 Portuguese sites. The study collected real-world data of IBD patients regarding treatment and symptoms according to the STRIDE-II recommendations, to estimate the proportion of IBD patients with IDC. Patient's QoL was assessed with the Short Inflammatory Bowel Disease Questionnaire (SIBDQ). Analysis was descriptive in nature and performed separately for CD and UC.

Results: The 130 patients had a mean age of 41.9 (14.3) years and 74 (56.9%) were males. Ileocolonic CD was present in 26 (38.8%) patients and 26 (41.3%) of UC had extensive colitis. Regarding treatment, 55 (82.1%) patients with CD and 34 (54%) with UC were on targeted immunomodulators (biologics and small molecule drugs) and, according to STRIDE-II therapeutic windows, 85.1% of CD and 92.1% of UC patients were on treatment long-term phase. 56.7% (38/67) of CD and 31.7% (20/63) UC patients presented IDC and according to SIBDQ, 50% of CD and 35% of UC IDC patients showed impaired QoL.

ST: Lack of clinical improvement	At physician's discretion [point of reference: <50% reduction of SF/AP (CD) or SF/RB (UC) since therapy initiation]	
IM & LT: Lack of clinical remission (in combination with either a.) lack of CRP normalization OR b.) lack of fCAL reduction)	CD: PRO-2 SF score >3 OR AP score >1 OR Harvey-Bradshaw Index >4	UC: Mayo SF ss>0 OR RB ss>0
IM & LT: Lack of CRP normalization*(±2W)	CRP >5 mg/l	
IM: Lack of fCal reduction* (±2W)	fCal >250 µg/g	
IM & LT: Systemic steroid overuse	Prolonged (> 6 weeks) administration of prednisolone ≥ 10 mg/d (or equivalent) OR > 1 steroid course under the current therapy within the previous 12 months	
LT: Lack of endoscopic remission(±8W)	CD: Endoscopic detection of ulcers and/or inflammatory stenosis, fistula, or strictures	UC: Mayo ES >0 or at physician's discretion if no explicit scoring
LT: Impaired QoL	SIBDQ < 50 points	
LT: MRI, MRE, CT or ultrasound indicating active disease (±8W)	At physician's discretion (e.g. UC/CD: bowel wall thickening, inflammatory stenosis, contrast enhancement, free abdominal fluid; CD: abscess, fistula)	
LT: Treatment associated complications	UC/CD: IBD related anemia (Hb <11 g/dl females, <12 g/dl males), clinically significant extraintestinal manifestations; CD: perianal disease	

ST: Short term, IM: Intermediate, LT: Long term, Hb: hemoglobin, ss: subscore, SF: Stool frequency, AP: Abdominal pain, RB: Rectal bleeding, PRO: Patient related outcomes, W: weeks * IDC only in combination with lack of clinical remission.

Table 1: Definition of IDC based on STRIDE II with Cut-offs based on External Expert Panel.

Conclusion: This study presents the current status of treatment options and management of IBD patients in Portugal, and overall indicate a high proportion of IDC both in UC and CD, indicating the continuous need for strategies to improve long-term outcomes and QoL in IBD.

Introduction: Inflammatory bowel disease (IBD) is often associated with an altered nutritional status where malnutrition is common. The Global Leadership Initiative of Malnutrition (GLIM) made a global standard on the identification and diagnosis of malnutrition.

Aims & Methods: Although the updated 2023 ESPEN guideline of clinical nutrition in IBD recommend malnutrition assessment as part of the patient's standard follow-up, no data are available. A prospective cohort study of consecutive IBD outpatients was conducted and 700 out of 1068 patients were included. Malnutrition Universal Screening Tool (MUST) was performed to screen malnutrition risk. All anthropometric and clinical variables were collected by the same trained investigators. With all variables collected, malnutrition diagnosis was assessed by GLIM criteria. Statistical analysis was made using SPSS v.26. A binomial generalised linear model with logistic regression was used. For all tests a two-sided p value <0.05 was considered significant.

Results: Of 700 IBD patients evaluated, 50% were males with a median age of 50 years old (IQR-interquartile range- 40-60). Little over half of the patients (53.9%) had ulcerative colitis, and most of them (90%) were without disease activity. Female sex (OR IC95%; 0, (0-0.004), p=0.020), age (OR IC95%; 1.63 (1.06-2.50), p=0.26) and CUN-BAE (OR IC95%; 0.057 (0.005-0.615), p=0.018) were associated with an increased risk of malnutrition according to MUST test. According to GLIM criteria, only 6 (0.9%) out of 700 IBD outpatients met criteria of malnutrition. Phenotypic criteria were associated with female sex (p<0.001) and age at diagnosis (p=0.011) while etiologic ones were linked to need of any biologic therapy (p=0.036) and second line biologics (p=0.012). Both etiologic and phenotypic criteria were associated with worse scores in IBDQ-9 questionnaire (p=0.004, p<0.001 respectively).

Conclusion: Female sex and young patients were independent risk factors for malnutrition according to GLIM criteria in IBD outpatients.

Introduction: Nearly 25% of patients are diagnosed with Inflammatory Bowel Disease (IBD) under 18 years old of age. To date, there are no transition models established and recommended in IBD setting, so each center tends to develop a transition model based on its own needs and experience.

Aims & Methods: To compare the effectiveness on transition readiness and quality of life of two different modes of transition, one based on sending the subject to a first gastroenterological visit in the clinic with the support of a clinical report prepared by the pediatrician (letter-based transition) and the other one characterized by combined visits in the presence of both the pediatrician and adult gastroenterologist (combined-visit-based transition).

From 2018 to 2021, patients diagnosed with IBD, aged between 16 and 19 years, and followed at the Paediatric Gastroenterology and Hepatology Unit of the Azienda Ospedale Università Padova, were randomized to the letter-based transition or the combined- visits-based transition. The transition readiness was verified using the Transition Readiness Assessment Questionnaire (TRAQ), whilst the quality of life was analysed using the Pediatric Quality of Life Inventory TM at the start of the study, at six months and after one year.

Results: The final sample analyzed consisted of 40 patients, 22 assigned to the letter-based group (10 males, mean age 18.6 ± 0.4) and 18 to the combined-visits groups (10 males, mean age 18.6 ± 0.5) with similar age and sex distribution. Twenty-one and 18 reached T2, respectively, and 17 in both groups reached T3. The clinical activity and calprotectin value did not change along the study in both groups (p >0.05). Three azathioprine and 4 anti-TNF therapy were stopped after transition. The TRAQ questionnaire improved significantly during the study both in the letter-based group (from 72.1 ± 12.46 to 82.35 ± 5.88, p 0.002) and in the combined-visits group (from 66.52 ± 15.06 to 76.0 ± 12.83, p 0.008). No significant change was observed in patients' perceived quality of life along the study in the letter-based group (from 83.9±8 to 86.2 ± 9.54, p = 0.17) while it improved in the combined-visits group (from 82.5 ± 8.23 to 89.1 ± 7.63, p <0.05).

Conclusion: Our data suggest that both transition models are able to obtain a marked improvement in transition readiness, while the quality of life improves only in the combined-visits transition. Therefore, despite the letter-based transition approach is a good option interms of costs and time sparing, the combined-visits process should be preferable when possible to improve both transition readiness and quality of life.

Introduction: Fatigue is a significant predictor of worst health-related qualify of life in inflammatory bowel disease (IBD) patients. Nevertheless, the role of fatigue in IBD patients under infliximab (IFX) therapy has been poorly investigated.

Aims & Methods: The aim of the study was to evaluate the potential factors associated with fatigue in patients under maintenance treatment with IFX.

Methods: A prospective observational cohort study was designed. All IBD patients aged 18 and over under maintenance treatment with intravenous (IV) infliximab were consecutively included at the infusion day. Patients completed 3 self-administered questionnaires. Fatigue was assessed with the Fatigue Impact Scale (FIS), quality of life with the Inflammatory Bowel Disease Questionnaire-Short From (IBDQ-9) and anxiety and depression using the Hospital Anxiety and Depression scale (HAD). We considered the maximum total FIS as the highest fatigue perception. Disease activity was defined in Crohn's disease as a Harvey-Bradshaw index >4, and in ulcerative colitis (UC) as a Partial Mayo index >2. Patient demographics and disease characteristics were also collected: age, sex, disease duration, smoking habit, type of IBD, extra-intestinal manifestations, clinical activity, prior surgery, obesity, anemia, treatments (steroids, immunosuppressants, anxiolytics, antidepressants) and presence of anxiety or depression. Multiple linear regression was used to identify the variables associated with the presence of fatigue.

Results: Ninety patients were consecutively included (49 female, median age 42 years, interquartile range 19). Sixty three patients (70%) had Crohn's disease (46.8% fistulising and 25.8% stenosing behaviour) and twenty seven ulcerative colitis (30%). Nearly 27% were smokers, 35 (39%) presented anxiety and 18 (21%) depression. Approximately, 8% of the patients and 7% received treatment for anxiety and depression, respectively, but only 2/18 patients with current depression received antidepressants. Combotherapy was present in 41% of the patients and 75.6% were in clinical remission. Mean fatigue was 32.74 ± SD 17.27. The highest scores for fatigue were associated with female gender (B = 10.936; P= 0.009) and the presence of depression (B = 11.114; P = 0.029). Activity disease almost increased significantly the severity of the fatigue(B = 8.995; P= 0.063). The use of antidepressants not increased the risk (B = -4.995; P = 0.555). Patients with fatigue had significantly reduced the quality of life (r = -0.638; p < 0.001).

Conclusion: Uncontrolled depression and female gender increased the risk of severe fatigue more than disease activity in patients under maintenance treatment with IFX. Fatigue is related to worst health-related qualify of life.

Disclosure: Nothing to disclose.

Introduction: Immunomodulators and biologicals play an essential role in current IBD management, but are associated with increased risk of infections. In light of the growing number of treatment options, the benefit-risk balance of drugs is becoming increasingly important in clinical decision making. Post-marketing surveillance studies are pivotal to assess infection risk, yet mainly focus on severe infections. As a result, data on mild and moderate infections are scarce. However, mild and moderate infections take longer to clear in immunosuppressed patients, have been reported to be the most burdensome adverse drug reaction according to patients, and can negatively influence drug adherence.

Aims & Methods: Aim: To assess the incidence of all infections and identify risk factors for the development of infections in IBD patients.

Methods: We previously developed and validated a Patient-Reported Infections Questionnaire (PRIQ), with excellent diagnostic accuracy, covering 15 infection categories with a 3-month recall period. [1] The current prospective, multicentre, observational cohort study was performed between Jun, 1 2020 and Jul, 1 2021, enrolling consecutive IBD patients and using the PRIQ which was implemented in myIBDcoach, an established telemedicine platform. Infection severity was defined as mild (self-limiting or topical treatment), moderate (oral antibiotics, antivirals or antifungals) or severe (hospitalization or IV treatment). Incidence rates (IR) were calculated for all infections, stratified for severity and subtype. Multivariable logistic regression, adjusting for relevant confounders, was performed to identify risk factors for infections.

Results: In total, 629 IBD patients (n=346 CD, n=283 UC, 58.3% female, mean age at cohort entry 48.3 years [SD 14.8], mean disease duration 12.4 years [SD 10.8]) were included which completed 2391 PRIQs during 572 person-years (PY) of follow-up. This resulted in 990 reported infections, corresponding to IRs of 17.3, 11.8, 5.1, and 0.4 per 10PY for all, mild, moderate, and severe infections, respectively. Upper respiratory tract (IR 26.9/100PY) and urinary tract infections (IR 14.8/100PY) were the most commonly reported mild and moderate infections types, respectively (Table 1). Compared to patients without treatment, patients on immunosuppressive treatment more frequently experienced infections of any severity (mild vs. no treatment: IR ratio (IRR) 1.57 [95%CI 1.21-2.06] p<0.001, moderate vs. no treatment: IRR 1.42 [95%CI 1.20-1.69] p<0.001). On multivariable logistic regression, female sex (mild adjusted odds ratio [aOR] 1.96 [95%CI 1.38-2.79]; moderate aOR 1.71 [95%CI 1.15-2.54]), smoking status (mild aOR 1.66 [95%CI 1.15-2.41]; moderate aOR 1.86 [95%CI 1.05-3.28]),

higher BMI (moderate aOR 1.05 [95%CI 1.02-2.00]), and more comorbidities (mild aOR 2.41 [95%CI 1.46-3.98]; moderate aOR 1.82 [95%CI 1.07-3.11]) were all significantly associated with the development of mild and moderate infections.

n, number of infectious events; IR, incidence rate; PY, person-years; CI, confidence interval; URTI, upper respiratory tract infection; LRTI, lower respiratory tract infection. 95%CI calculated using Mid-P exact test

†Elaboration on infection types: URTI includes nasal cold, laryngitis, tonsillitis, sinus infection, ear infection and ‚common' cold. LRTI includes pneumonia and bronchitis.

Time at risk (572.5 PY) based on follow up of 629 IBD patients during 1 year.

Table 1. Incidence rates for all infections, and stratified for infection type and infection severity per 100 PY.

Conclusion: In this real-world prospective study, immune suppressive therapy was associated with mild and moderate infections of any kind in IBD patients. These infections particularly occur in females, smokers, patients with higher BMI and more comorbidities. This information should be considered in personalised treatment selection.

Introduction: Inflammatory Bowel Diseases (IBD) are gastrointestinal, auto-inflammatory disorders with a chronic relapsing and remitting course, mainly including Ulcerative Colitis (UC) and Crohn's Disease (CD). They are multifactorial diseases which still lack a clear etiology, making identification of reliable predictors of disease course and therapy response of great interest to the medical community. The existence of extrachromosomal circular DNA fragments (eccDNA) is well established and has become a promising diagnostic and prognostic biomarker for different types of cancer. Herein, we investigate for the first time the role of eccDNA in patients affected by IBD.

Aims & Methods: Consecutive patients with an established diagnosis of IBD and non-IBD healthy controls who underwent colonoscopy for colorectal cancer screening were prospectively enrolled at Fondazione Policlinico Universitario "A: Gemelli" in this monocentric, observational, case-controlled study. In all IBD patients, disease activity was assessed using Partial Mayo Score (PMS) and Mayo Endoscopic Subscore (MES) for UC patients, and Harvey-Bradshaw Index (HBI) and Simple Endoscopic Score for CD (SES-CD) for CD. Colonic biopsies were collected from both inflamed and healthy mucosa of IBD patients and from non-IBD controls. Circular DNA was enriched, sequenced, and eccDNAs were identified with Circle Finder from intestinal biopsies. Circles containing the same gene were grouped together for downstream pathway analysis and defined as Produced per Gene eccDNAs (PpGC). Enrichr analysis was used to assess the pathways different PpGC belonged to.

Results: Forty IBD patients (19 with CD and 21 with UC) and 13 healthy controls (HC) were enrolled. Colonic mucosal samples from patients with IBD showed increased average eccDNAs than did intestinal samples from HC. This increase was observed across all chromosomes, indicating that a

global increase in eccDNA production was across the human genome. Furthermore, there was a slight yet significant tendency for larger eccDNAs in IBD patients compared to HC.

Focusing only on eccDNA which came from genic elements, referred to as "genic eccDNAs", approximately 60% of the functional DNA found on genic eccDNA in both groups were fragments from protein coding genes, 32% from non-coding RNAs and 8% from pseudogenes. Furthermore, even when only taking genic eccDNAs into account, IBD patients still had, on average, significantly more eccDNAs in the intestine when compared to non-IBD controls. Eighty PpGC were more abundant in IBD patients as compared to HC; enrich analysis revealed that pathways involved in cAMP signaling were significantly overrepresented in this gene set.

Considering only PpGCs which appear in at least 25% of patients, we found 157 PpGCs only found in UC patients and 210 PpGCs in CD patients, indicating that there may be some differences in eccDNA production between the two IBD diagnoses.

Moreover, on average, patients with IBD in remission had fewer eccDNAs in their intestines when compared to those with active disease, although the difference was not statistically significant. eccDNAs from the phosphodiesterase genes and genes involved in lipid metabolism were particularly enriched in patients with active UC and CD, compared to patients in remission.

Conclusion: We are the first to uncover an IBD-specific pattern of eccDNA production. Furthermore, we have identified genic hotspots which characterize active vs. inactive disease. We propose that eccDNA identification could be a promising new prognostic marker for IBD patients.

Disclosure: Nothing to disclose.

CRP/ALBUMIN RATIO IN PREDICTING EARLY RESPONSE TO STEROIDS IN ACUTE SEVERE ULCERATIVE COLITIS

A. Darif[1], F.Z. Elrhaoussi[1], M. Tahiri Joutei Hassani[1], F. Haddad[1], W. Hliwa[1], A. Bellabah[1], W. Badre[1]

[1]University Hospital Center Ibn Rochd, Gatrostroenterology and hepatology departement, Casablanca, Morocco

Contact E-Mail Address: aicha.darif22@gmail.com

Introduction: The first-line treatment for patients hospitalized with Acute severe ulcerative colitis (ASUC) is intravenous corticosteroid therapy, but 30% require second-line ‚rescue' infliximab (IFX) therapy or colon resection due to incomplete response. Identifying patients with acute severe ulcerative colitis who are refractory to corticosteroid therapy remains challenging, as physicians have no markers to predict non-response to steroids on admission.

This study aims to investigate whether the CRP/albumin ratio on days 1 and 3 of hospitalization could predict early response to intravenous steroids.

Aims & Methods: Data from all admissions for acute severe ulcerative colitis over 4 years from January 2019 to December 2022 were retrospectively collected.

All patients initially received intravenous corticosteroids. Demographic, clinical, biological, and endoscopic data were collected; C-reactive protein (CRP) and albumin levels were recorded at baseline and during hospitalization. Receiver operating characteristic statistics were used to determine the optimal stool frequency, Lichtiger index, CRP, albumin, and CRP/albumin ratio (CAR) to predict steroid response.

Results: A total of 81 ASUC patients were admitted. Sixty-six patients (81.5%) were steroid responsive, 8 patients (10%) received rescue IFX and 7 patients (8.6%) required colectomy. By comparing two groups of patients (steroid-responsive and steroid-refractory), baseline stool frequency, Lichtiger index, CRP and CRP/Albumin ratio data didn't show any significant difference between the two groups. While baseline albumin was lower in the steroid-refractory group (Median 26, IQR 18-36, p=0.041). Day 3 stool frequency and Lichtiger index were significantly higher in the steroid refractory group (p<0.001).

By receiver operating characteristic statistics, day 3 CAR was a more accurate marker of steroid responsiveness than day 3 CRP or day 3 albumin alone [area under curve=0.911 (P<0.001)]. The optimal CAR to predict response to steroids on day 3 was 2.67 (sensitivity 80%, specificity 91%).

Conclusion: An elevated CRP and low albumin level on day 3 is an early predictor of steroid-refractory ASUC. When combined in a ratio, their predictive ability improves. In patients with predicted steroid nonresponse, early introduction of rescue IFX at this stage may be more effective, before serum albumin falls profoundly.

Disclosure: Nothing to disclose.

Contact E-Mail Address: pdy0615@kakao.com

Introduction: The impact of underweight and obesity on clinical outcomes for intestinal Behçet's disease (BD) is unknown. We aimed to identify the association between body mass index (BMI) and clinical outcomes in patients with intestinal BD.

Aims & Methods: We categorized 760 patients with intestinal BD according to the BMI at diagnosis into four groups (underweight, normal, overweight, obese) at Severance Hospital, Seoul, Korea between 1997 and 2021.We performed a Cox proportional hazard analysis to investigate the predictive capability of BMI for clinical outcomes such as biologics use, surgery, hospitalization and emergency room visit.

Variables		BMI				
		<18.5 (n=130) Underweight	18.5~22.9 (n=384) Normal	23~24.9 (n=152) Overweight	≥25 (n=94) Obese	*p* value for trend
Biologics use	Event	34 (26.2%)	50 (13.1%)	21 (13.8%)	9 (9.6%)	0.001
	Multivariable-adjusted[a]	Reference	0.619 (0.366-1.047)*	0.490 (0.241-0.966)**	0.312 (0.116-0.840)**	
Surgery	Event	45 (34.6%)	87 (22.7%)	35 (23%)	15 (16%)	0.008
	Multivariable-adjusted[a]	Reference	0.706 (0.484-1.029)*	0.669 (0.411-1.088)	0.556 (0.303-1.020)*	
Hospitalization	Event	87 (66.9%)	194 (50.8%)	69 (45.4%)	46 (48.9%)	0.002
	Multivariable-adjusted[a]	Reference	0.667 (0.483-0.922)**	0.589 (0.394-0.879)**	0.515 (0.321-0.828)**	
Emergency room visit	Event	71 (55%)	144 (37.6%)	61 (40.1%)	32 (34%)	0.003
	Multivariable-adjusted[a]	Reference	0.711 (0.513-0.985)**	0.775 (0.523-1.149)	0.602 (0.376-0.963)**	

*p <0.10

**p <0.05

[a]Multivariate Cox proportional hazard analysis, including the confounders such as, age, gender, medical aid, smoking, appendectomy history, family history of BD, marriage status, DAIBD score, extraintestinal manifestation, systemic BD, number of ulcers, shape of ulcers, depth of ulcers, type of ulcers, laboratory findings.

Results: Of the 760 patients, 130 patients were classified into underweight group (BMI<18.5), 384 patients into normal group (BMI 18.5~22.9), 152 patients into overweight group (BMI 23~24.9), and 94 patients into obese group (BMI≥25). Patients with a higher BMI group showed signifi-

cantly lower cumulative rates of biologics use (*p* trend = 0.001), surgery (*p* trend = 0.008), hospitalization (*p* trend = 0.002), and emergency room visits (*p* trend = 0.003) than those with a lower BMI group. In a multivariate analysis, normal BMI group (HR: 0.667, 95% CI 0.483-0.992, *p* =0.014), overweight group (HR: 0.589, 95% CI 0.394-0.879, *p*=0.010), and obese group (HR: 0.515, 95% CI 0.321-0.828, *p*=0.006) were negatively associated with future hospitalization compared to underweight group. Overweight group (HR: 0.490, 95% CI 0.241-0.996, *p* =0.049) and obese group (HR: 0.312, 95% CI 0.116-0.840, *p* =0.021) were negatively associated with future biologics use compared to the underweight group.

Normal BMI group (HR: 0.706, 95% CI 0.484-1.029, *p*=0.070) and obese group (HR : 0.556, 95% CI 0.303-1.020, *p*=0.058) were negatively associated with future surgery compared to the underweight group.

Normal BMI group (HR: 0.711, 95% CI 0.513-0.985, *p*=0.041) and obese group (HR: 0.602, 95% CI 0.376-0.963, *p*=0.034) were negatively associated with future emergency room visit compared to the underweight group.

Conclusion: Underweight could affect poor outcomes in intestinal Behçet's disease. Physicians should pay attention to the patients with underweight and make an effort to improve nutritional status.

Disclosure: Nothing to disclose.

TISSUE MICRO-RNAS AS MARKERS OF EARLY DIAGNOSIS AND MONITORING OF COLORECTAL CANCER IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

B. Barberio[1], C. Borga[2], G. Munari[2], M. Fassan[2], F. Zingone[3], E.V. Savarino[4]

[1]Azienda Ospedaliera Di Padova, Department of Surgery, Oncology And Gastroenterology, Padova, Italy, [2]University of Padua, Department of Medicine (DIMED), Surgical Pathology Unit, Padova, Italy, [3]University of Padua, Surgery, Oncology and Gastroenterology, Padova, Italy, [4]University of Padua, Division of Gastroenterology, Department of Surgery, Oncology And Gastroenterology, Padova, Italy

Contact E-Mail Address: brigida.barberio@gmail.com

Introduction: Although the rates of IBD-related-CRC are decreasing over time, probably due to improved medical therapies and colonoscopic screening and surveillance, CRC is still a leading cause of mortality and reason for colectomy in patients with IBD**.** Among the different cancer biomarkers, miRs have emerged as noninvasive tools for diagnosis, monitoring, and prognosis in tissues and biofluids of patients with IBD. Therefore, we aimed to investigate the role of miRNAs in the development and natural course of IBD-related CRC, in order to identify potential early biomarkers for IBD-related CRC screening and progression.

Aims & Methods: The cases were retrospectively collected from the archives of the Surgical Pathology and Cytopathology Unit at the University of Padua. We analysed nine miRs in colonic tissue specimens of patients with IBD with adenoma (group A) or dysplasia (group B), with IBD related-CRC (group C), other than two control groups of patients with sporadic CRC (sCRC WT_MSI and WT_MSS, group D and group E, respectively) and of healthy subjects (group F). In addition, we included tissue samples from a colonoscopy that patients with IBD with adenoma or dysplasia underwent some years before the development of mucosal lesions (from 2 to 5 years before), therefore without evidence of adenoma (group A2) or dysplasia (group B2). Results were analyzed with ThermoFisher Connected™ Software (Applied Biosystems™) and a p-value < 0.05 was considered significant.

Results: We found that, compared to healthy controls, all nine analysed miRs were significantly up-regulated in patients with sCRC, with IBD-related CRC and in IBD patients with adenoma. While, only 3 miRs (miR-135b, mir-21, miR-224) were significantly up-regulated in IBD patients with dysplasia (and in their own controls) compared to healthy controls (p<0.0001). Notably, no differences in miRs expression levels were found in patients with IBD-related CRC compared to those found in patients with sCRC. Moreover, among all miRs analyzed, only miR-135b and miR-21 resulted significantly up-regulated in patients with IBD. Particularly, considering the levels of miR-135b in the tissue samples of IBD patients, we observed an evident increasing trend going from tissue specimens without lesions to those with adenoma or dysplasia and then to those with neoplastic lesions. Finally, miR-21 was significantly up-regulated in patients with IBD-related CRC compared to both IBD patients with adenoma and their own control samples from a previous negative colonoscopy (p=0.003 and p=0.006, respectively). Likewise, a statistically significant difference in miR-21 levels was observed between patients with IBD-related CRC and those with dysplasia (p=0.02).

Conclusion: MiRNAs are attracting a growing interest in the scientific community due to their central role in the etiology of several diseases. We demonstrated that miR-21 and miR-135b are involved in the carcinogenesis process of patients with IBD. Considering their role in cancer development and that they can be detected rapidly and efficiently in tissues, they could be potential candidate biomarkers for diagnostic purpose, prognostic and predictive stratification of patients. In addition, the possibility of controlling upregulation of these miRs could lead to a breakthrough in the prevention of IBD-related CRC, potentially interfering with tumorigenesis. Although further larger and prospective studies are needed, developments in this field could open new therapeutic perspectives in the management of our patients, preventing neoplastic progression toward colon carcinoma.

Disclosure: Nothing to disclose.

NATURAL HISTORY AND IMPACT OF IRRITABLE BOWEL SYNDROME-TYPE SYMPTOMS IN INFLAMMATORY BOWEL DISEASE DURING ONE-YEAR OF LONGITUDINAL FOLLOW UP

B. Barberio[1], K.M. Fairbrass[2], D.J. Gracie[3], A.C. Ford[4]

[1]Azienda Ospedaliera Di Padova, Surgery, Oncology and Gastroenterology, Padova, Italy, [2]Leeds Gastroenterology Institute, St. James's University Hospital, Leeds, United Kingdom, [3]Leeds Teaching Hospitals, Gastroenterology, Wetherby, United Kingdom, [4]St. James's University Hospital, Dept. of Gastroenterology, Leeds, United Kingdom

Contact E-Mail Address: brigida.barberio@gmail.com

Introduction: Little is now about the natural history and impact of irritable bowel syndrome (IBS)-type symptoms on psychological health and quality of life in inflammatory bowel disease (IBD). We aimed to address this in a one-year longitudinal study of secondary care patients.

Aims & Methods: We collected demographic, Rome III IBS-type symptom, psychological, and quality of life data, with questionnaires at 3-month intervals, over 12 months of follow-up in patients with IBD in clinical remission at baseline. We assessed the natural history of Rome III IBS-type symptoms over the 12 months of the study and compared psychological and quality of life data between those reporting Rome III IBS-type symptoms at each of the points of follow-up with those not reporting such symptoms.

Results: Among 206 patients with IBD in clinical remission at baseline (104 (50.5%) women, mean age 56.9 years (range 18-83 years), 79 (38.3%) Crohn's disease), 33 (16.0%) reported Rome III IBS-type symptoms at baseline and 72 (35.0%) reported Rome III IBS-type symptoms at one or more time points. Among the 33 patients with Rome III IBS-type symptoms at

baseline, symptoms resolved in 6 (18.2%) patients, were present throughout in 6 (18.2%) patients, and fluctuated in the remaining 21 (63.6%) patients. Among the 39 patients with new onset of Rome III IBS-type symptoms after baseline, 24 (65.1%) had symptoms at one point in time only, 10 (25.6%) at two points, four (10.3%) at three points, and one (2.6%) at four points. At each point in time, reporting IBS-type symptoms was associated with significantly higher anxiety, depression, or somatoform symptom-reporting scores, and/or lower quality of life scores.

	Baseline		3 months		6 months		9 months		12 months	
	Rome III IBS-type symptoms		Rome III IBS-type symptoms		Rome III IBS-type symptoms		Rome III IBS-type symptoms		Rome III IBS-type symptoms	
	Yes (n=33)	No (n=173)	Yes (n=35)	No (n=171)	Yes (n=25)	No (n=181)	Yes (n=33)	No (n=173)	Yes (n=34)	No (n=172)
Mean HADS-A (SD)	7.8 (4.0)*	4.8 (3.7)	7.7 (4.2)*	4.9 (3.9)	8.5 (4.7)*	4.8 (4.0)	7.1 (3.9)†	4.9 (4.2)	6.1 (4.7)	5.1 (4.2)
Mean HADS-D (SD)	5.0 (3.3)*	2.8 (2.9)	5.4 (3.9)*	2.9 (3.0)	5.6 (4.2)	3.4 (3.5)	5.2 (3.6)†	3.2 (3.4)	4.7 (4.1)	3.3 (3.4)
Mean PHQ-12 (SD)	7.0 (3.6)*	3.8 (3.1)	6.5 (3.9)†	4.2 (3.3)	5.6 (2.8)	4.2 (3.6)	5.9 (3.9)	4.0 (3.1)	5.9 (4.1)	4.1 (3.4)
Mean SIBDQ (SD)	49.8 (8.6)*	60.0 (7.9)	50.2 (10.7)*	59.8 (8.3)	48.8 (12.9)*	59.3 (8.8)	49.8 (10.9)*	58.4 (9.8)	52.0 (9.8)†	58.1 (10.1)

Conclusion: In this 12-month follow-up study, one-third of patients with IBD reported presence of Rome III IBS-type symptoms at any point in time. Reporting such symptoms was associated with significant impacts on psychological health and/or quality of life.
Disclosure: none

SERIC HAPTOGLOBIN KINETICS MAY PREDICT CLINICAL OUTCOME IN PATIENTS WITH IBD UNDERGOING BIOLOGICS

A.-S. Peaucelle[1], S. Paul[2], N. Williet[1], M. Barrau[1], X. Roblin[1]
[1]Hôpital Nord, Gastroenterology, Saint Etienne, France, [2]Hôpital Nord, Immunology, Saint Etienne, France

Contact E-Mail Address: anne-sophie.peaucelle@hotmail.fr
Introduction: A recent study(1) showed that seric haptoglobin was a relevant biomarker to predict a relapse in patients with Crohn's Disease (CD) who had stopped Infliximab (IFX). We dosed seric haptoglobin levels among patients with CD or Ulcerative Colitis (UC) undergoing treatment by IFX or Vedolizumab (VDZ) to see if it could help predict a short-term relapse.
Aims & Methods: We collected serum corresponding to 4 clinically relevant times of visit in our unit from patients under IFX or VDZ. The cases were patients who had required an optimization : T1 was the week 2 of induction, T2 was the last time the patient was asymptomatic, T3 was the day of the optimization for a clinical relapse, T4 was a time the patient was in remission. In control patients who had not required an optimization, T1 corresponded to the week 2 of induction, T2 was an intermediary time and T3 another time when patient was still in clinical remission. Clinical remission was defined for CD by CDAI score < 150 and for UC by clinical Mayo score < 3. Clinical relapse was defined by CDAI > 220 for CD or by partial Mayo score > 4 with CRP > 5mg/L or fecal calprotectin (FC) > 250 µg/g stools with a modification of treatment. We practiced dosage of haptoglobin with Optilite kits that are designed for in-vitro haptoglobin dosage.
Results: 23 cases patients who had needed optimization and 17 control patients who had not were included in our study. We could not bring light to a cut-off of haptoglobin level that was associated with a relapse. Yet, our data showed that a positive haptoglobin delta > 0,1 g/L between T2 and T1 among cases could predict a relapse with equivalent performance than a FC level > 250 µg/g of stools in T2. Indeed, AUC of those two parameters showed no statistical difference : for a positive delta of haptoglobin > 0,1 g/L, AUC was 73,7% and 84% for a FC > 250 µg/g of stools (*p= 0,401*). A positive delta of haptoglobin level between T2 and T1 showed a sensibility (Se) of 68,8%, a specificity (Sp) of 78,6%, a positive predictive value (PPV) of 78,6% and a negative predictive value (NPV) of 68,8% to predict a relapse in T3. Moreover, we found that when haptoglobin level in T2 was <0,6 g/L comparing to T1, we could diagnose a clinical remission with a Sp and a PPV of 100%, a Se of 68,4% and a NPV of 50%, with an AUC of 79,4% that was not statistically different from a CF level <250 µg/g of stools in T2.
Conclusion: Haptoglobin level kinetics seems to be a promising biomarker in the monitoring of IBD among patients undergoing IFX or VDZ.

USING MACHINE LEARNING METHODS, CAN ANTIBIOTICS PREDICT A FUTURE RELAPSE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE? – A POPULATION-BASED NESTED CASE-CONTROL STUDY USING MACHINE LEARNING METHODS

B. Lo[1,2], L. Biedermann[3], G. Rogler[3], B. Dora[3], A. Kreienbühl[3], I. Vind[1,2], F. Bendtsen[1,2], J. Burisch[1,2]

Contact E-Mail Address: bobby.lo@regionh.dk
Introduction: Inflammatory bowel disease (IBD) is a chronic intestinal disease with unknown causes. Symptoms include pain and bloody diarrhoea. Little is known about environmental factors that trigger flare-ups, including the effects of commonly used medications. Recent studies suggest a link between microbial factors and IBD, making it important to investigate the predictive level of antibiotics on flare-ups. New machine learning methods may be able predict IBD flare-ups by analysing patient data to identify contributing factors.
Aims & Methods: We aimed to investigate whether certain antibiotics increase the risk of flares in patients with IBD. We utilized a previously described[1] cohort of all patients with IBD in Denmark between 1974 and 2018. The cohort is based on the Danish Nationwide Patient Registry, which registers all healthcare related visits, treatments and procedures on an individual level. We utilized data between 1994 and 2018, and two distinct cohorts were created for the purpose of identifying flares. The first cohort was characterized by having an IBD-related hospital stay. The second cohort was characterized by experiencing a flare of IBD in need of systemic steroids. Patients were matched 1:5 using K-nearest neighbour. Antibiotics were grouped into the 3rd level of the Anatomical Therapeutic Chemical (ATC) classification system, with anthelmintics grouped into the 2nd level due to low numbers. All were given within 60 days before the outcome.
Cohorts were divided into an 80/20 training/testing set and trained using a 5-fold cross-validation with eXtreme Gradient Boosted decision tree (GBDT) framework with variables including year of remission/flare, sex,

age at diagnosis, year of diagnosis, type of IBD, socioeconomic status[2], subtypes of IBD-medication, subtypes of biologics and subtypes of antibiotics. The final model was chosen based on the area under the receiver operating characteristic curve (AUROC). The final model was evaluated on the test set (i.e. unseen data for the model). Evaluation of the models was reported as accuracy (ACC), positive predictive value (PPV), and negative predictive value (NPV).

Results: There were in total 69,908 IBD patients in the original cohort. After applying the abovementioned algorithm, a total of 15,636 and 5,178 patients were included in the cohort for hospitalisation and steroid use, respectively.

The models achieved an AUROC of 0.71 (SD: 0.03) and 0.85 (SD: 0.008) for predicting a course of steroids and need for IBD-related hospitalization, respectively, on the training set. On the test-set, the models achieved an ACC of 82.72%, with a PPV of 36.36% and a NPV of 83.73% on predicting a course of steroids, and an ACC of 85.23%, with a PPV of 60.14% and a NPV of 87.80% on predicting IBD-related hospitalization. Quinolones and agents against amoebiasis and protozoal were identified as top 10 most important variables for making accurate predictions and for splitting decision trees. Other antibiotics, such as tetracyclines, betalactam, and intestinal anti-infectives, were also useful as splitting variables.

Conclusion: This study demonstrated the importance of antibiotics, particularly quinolones and agents against amoebiasis and protozoal, in predicting an IBD-related flare. The GDBT-trained models achieved a high accuracy in predicting hospitalization and steroid courses, with AUROC of 0.85 and 0.71, respectively. These findings highlight the impact antibiotics on the subsequent risk for a severer flare-up of IBD flare and may guide future research on the role of microbial factors in IBD.

Introduction: Both patients and clinicians would benefit from less invasive means than endoscopy for detection of gut inflammation in inflammatory bowel disease (IBD), such as faecal or serological biomarkers.

Aims & Methods: The aim of this study was to investigate the presence of the neutrophilic proteins: calprotectin (CP), myeloperoxidase (MPO), neutrophil gelatinase-associated lipocalin (NGAL) and the eosinophilic protein: eosinophil-derived neurotoxin (EDN) in faecal and serum samples from IBD patients with ulcerative colitis (UC) and Crohn's disease (CD) in relation to disease activity and intestinal inflammation localization. Their diagnostic potential in IBD was studied using irritable bowel syndrome (IBS) patients as controls.

Faecal (f) and serum (s) samples from 97 IBD (median: 38y, range 18-79y) and 100 IBS (median: 36y, range 18-75y) patients from the outpatient Gastroenterology Clinic, Uppsala University Hospital were included in the study. Active disease was defined as having a Partial Mayo score ≥ 2 (UC) or Harvey-Bradshaw score ≥5 (CD). Disease localization was obtained from patient journals.

CP and EDN were measured by commercial EliA and ImmunoCAP assays, respectively. MPO and NGAL were measured with in-house research assays based on the ImmunoCAP technology. All analyses were done using the automated Phadia 250 instrument.

Results: All four biomarkers were elevated in IBD compared to IBS in faecal samples (p<0.001) and serum (p<0.01), and most biomarkers were also elevated in the separate UC and CD groups (Table 1). Faecal EDN were higher in CD compared to both UC (p=0.016) and IBS.

	UC N=59	CD N=38	IBS N=100	p-value (UC vs. IBS)	p-value (CD vs. IBS)
fCP	305.8 mg/kg	165.8 mg/kg	16.51 mg/kg	<0.0001	<0.0001
fMPO	3.74 mg/kg	2.42 mg/kg	0.10 mg/kg	<0.0001	<0.0001
fNGAL	7.30 mg/kg	6.78 mg/kg	2.36 mg/kg	<0.0001	<0.0001
fEDN	0.50 mg/kg	1.79 mg/kg	0.29 mg/kg	0.049	<0.0001
sCP	4186 µg/L	4124 µg/L	3037 µg/L	0.0145	ns
sMPO	291.6 µg/L	291.2 µg/L	151.3 µg/L	0.0006	0.0038
sNGAL	240.2 µg/L	239.5 µg/L	162.2 µg/L	<0.0001	0.0004
sEDN	29.07 µg/L	24.54 µg/L	19.4 µ/L	0.0020	ns

Table 1. Biomarker levels in UC and CD patients in comparison to IBS patients.

Four biomarkers were elevated in active UC vs remission: fCP (610.9 mg/kg vs 45.5 mg/kg, p=0.0180), fMPO (6.84 mg/kg vs 1.30 mg/kg, p=0.0479), sCP (4599 µg/L vs 3128 µg/L, p=0.0194) and sNGAL (298.3 µg/L vs 189.3 µg/L p=0.0012). No association was observed between the biomarkers and disease activity in CD.

Patients with extensive UC had significantly higher levels, compared to patients with left-sided UC, of fCP (851.6 mg/kg vs 148.3 mg/kg, p=0.0135), fMPO (17.67mg/kg vs 2.84 mg/kg, p=0.0493) and fEDN (1.34 mg/kg vs 0.36 mg/kg, p=0.0146). None of the biomarkers were associated with disease localization in CD.

Conclusion: Faecal and serum CP, MPO, NGAL and EDN may be used as diagnostic biomarkers to differentiate patients with IBD from IBS. Our study indicates that fMPO may be used as an alternative to fCP as disease activity marker in UC, and that sCP and sNGAL are promising novel serum markers for disease activity. In addition to the neutrophil markers, fEDN could be of value for characterization of extensive disease in UC patients. The higher fEDN levels in CD compared to UC observed in the present study indicates an important role of activated eosinophils in the clinical manifestation of CD.

The biomarkers MPO, NGAL and EDN measured both in faecal and serum could, in addition to CP, potentially aid in the clinical decision-making in IBD.

Disclosure: H Ekoff, N Rydell and R Movérare are employed by Thermo Fisher Scientific.

DISEASE OUTCOMES CAN BE PREDICTED BY MEMBERSHIP OF NOVEL SYMPTOM CLUSTERS IN INFLAMMATORY BOWEL DISEASE: RESULTS FROM A PROSPECTIVE LONGITUDINAL FOLLOW-UP STUDY

C. Riggott[1,2], K.M. Fairbrass[1,2], C.J. Black[1,2], D.J. Gracie[1,2], A.C. Ford[1,2]

Introduction: Inflammatory bowel disease (IBD) exerts a significant socioeconomic burden in Western nations. Drugs are a consistent driver of direct healthcare costs. However, healthcare utilisation, which varies considerably between individuals, contributes substantially. Predicting the patients who are more likely to be higher utilizers of healthcare is challenging, as symptom burden does not always reflect underlying disease activity.

Aims & Methods: We aimed to establish whether model-based clustering could be used to identify novel subgroups, or clusters, of patients with IBD, and if baseline cluster membership could predict adverse disease outcomes during longitudinal follow up. We recruited patients with a diagnosis of Crohn's disease (CD) or ulcerative colitis (UC) between 2012 and 2015. In addition to baseline demographic data, we collected data regarding somatoform symptom-reporting using the patient health questionnaire-15, anxiety or depression using the hospital anxiety and depression scale, and stool frequency, extracolonic features, and general wellbeing derived from overlapping components of the Harvey Bradshaw Index for patients with CD, and the simple clinical colitis activity index for patients with UC, all of which were used as variables for modelling. Using Latent-GOLD version 6.0, we performed latent class analysis (LCA) to establish the novel clusters and select the optimal model. We measured clinical outcomes during longitudinal follow up, including flare or glucocorticosteroid prescription, treatment escalation, hospitalisation, and intestinal resection. We then performed multivariate Cox regression analysis, controlling for all baseline characteristics, to establish if individual cluster membership was an independent predictor for these outcomes, expressing results as hazard ratios (HRs) with 95% confidence intervals (CIs).

	Cluster 1: Below average levels of gastrointestinal and psychological symptoms (n=132)	Cluster 2: Average levels of gastrointestinal and psychological symptoms (n=352)	Cluster 3: Highest levels of gastrointestinal and psychological symptoms (n=208)	*p* value for trend
Multivariate HR for glucocorticosteroids/ flare (95% CI)	1.00 (Reference)	1.50 (1.07 – 2.09)	2.13 (1.46 – 3.10)	<0.001
Multivariate HR for escalation (95% CI)	1.00 (Reference)	1.61 (1.17 – 2.22)	1.92 (1.34 – 2.76)	0.001
Multivariate HR for hospitalization (95% CI)	1.00 (Reference)	1.07 (0.66 – 1.72)	1.61 (0.97 – 2.68)	0.048
Multivariate HR for intestinal resection (95% CI)	1.00 (Reference)	0.98 (0.49 – 1.98)	1.70 (0.82 – 3.56)	0.10
Multivariate HR for escalation, hospitalization, or intestinal resection (95% CI)	1.00 (Reference)	1.51 (1.11 – 2.05)	2.05 (1.45 – 2.88)	<0.001
Multivariate HR for glucocorticosteroids/ flare, escalation, hospitalization, or intestinal resection (95% CI)	1.00 (Reference)	1.48 (1.09 – 2.01)	2.06 (1.45 – 2.93)	<0.001

Table 1- Disease outcomes according to cluster membership at baseline.

Results: Of the 760 patients recruited, 692 (91.1%) provided complete baseline data (mean age 43.6 (age range 17 to 89 years), 382 (55.2%) female, 647 (93.8%) Caucasian, and 394 (56.9%) with CD). The best LCA solution was obtained using a three-cluster model.

Cluster 1 was defined by below average gastrointestinal and psychological symptom burden, cluster 2 by average gastrointestinal and psychological symptom burden, and cluster 3 by above average gastrointestinal and psychological symptom burden. Proportions with faecal calprotectin <250mcg/g at baseline were similar between clusters.

Compared with cluster 1, patients in cluster 3 were at significantly increased risk of glucocorticosteroid prescription or flare, escalation, a composite of escalation, hospitalization, or intestinal resection, or any of the endpoints of interest (table 1).

Effect sizes increased when only including individuals in biochemical remission at baseline. Healthcare utilization was highest in cluster 3.

Conclusion: It is feasible to derive novel clusters of patients with IBD, based not only on gastrointestinal symptoms, but also on measures of psychological health. The cluster with the highest psychological symptom burden identifies patients at higher risk of adverse disease outcomes who are high volume users of healthcare.

Disclosure: None.

SYSTEMIC INFLAMMATORY PROTEIN PROFILES OF INFLAMMATORY BOWEL DISEASE PATIENTS - A PRELIMINARY STUDY

T. Zhang[1], S.M. Sim[2], L. Liu[2], B. Tan[1], J. Mok[1], S.K. Pang[1], J. Lee[1,2], J.L. Hartono[1,2]

[1]National University Hospital, Division of Gastroenterology and Hepatology, Singapore, Singapore, [2]National University of Singapore, Yong Loo Lin School of Medicine, Department of Medicine, Singapore, Singapore

Contact E-Mail Address: tianjiao_95@hotmail.com

Introduction: A key feature of IBD pathogenesis is response dysregulation of both the innate and adaptive immune system[1,2]. Hence specific inflammatory protein profiles may be a promising biomarker approach for diagnosis and personalized therapy in IBD. Serum proteome of IBD, particularly in multi-ethnic Asian patients, remains less defined.

Aims & Methods: We aim to investigate the systemic inflammatory protein profiles in multi-ethnic Asian patients with IBD and compare them to healthy controls.

The study cohort was made up of 92 patients with IBD (50.0% Ulcerative colitis (UC), 43.5% Crohn's disease (CD), 6.5% Unclassified IBD)), and 42 control subjects, who are asymptomatic patients undergoing screening colonoscopy with no endoscopic pathology. Serum protein profiling was performed using the *Olink* Target 96 Inflammation assay. A partial-least square discriminant analysis was undertaken to identify additional discriminative inflammatory proteins. Univariate t-test analyses, with false discovery rate correction, were also performed to identify proteins unique to either UC or CD.

Results: Participants with IBD were younger (42.0 (±14.7) in UC, 43.2 (±15.1) in CD, p<0.01), with greater representation of South Asian ethnicity (32.5% amongst UC, 19.6% amongst CD, p<0.01) and males (75.0% amongst UC, 69.6% amongst CD, p=0.03), as compared to controls.

We found 18 proteins were differentially abundant amongst IBD patients (p<0.05). Half (n=9) of these inflammatory proteins (AXIN-1, CD8A, CXCL1, EN-RAGE, FGF-23, HGF, IL17A, OSM, TGF-alpha) were elevated in both UC and CD. The other six proteins were elevated only in patients with UC (4E-BP1, CCL11, IL-18R1, IL-20, MMP-10, TRANCE). Of the remaining three, two were less abundant in patients with CD (DNER, SCF) and TNF was elevated

only in patients with CD. Of interest, three immunoproteins were differentially abundant in participants with either UC or CD (i.e. CCL11, MMP10, TRANCE).

Molecular functions	Both UC and CD	UC only	CD only	UC vs CD
Cytokine mediated signaling (GO:0019221)	IL17A CXCL1 OSM HGF	CCL11 TRANCE IL20	TNF	CCL11 TRANCE
Positive regulation of protein kinase B signaling (GO:0051897)	FGF23 HGF OSM TGF-alpha	TRANCE	SCF* TNF	TRANCE
Immune response (GO:0006955)	CD8A CXCL1 IL17A OSM	IL-18R1 TRANCE		TRANCE
Inflammatory response (GO:0006954)	CXCL1 EN-RAGE IL17A	CCL11 IL-18R1	TNF	CCL11
MAPK cascade (GO:0000165)	FGF-23 HGF TGF-alpha		SCF* TNF	
Others	AXIN1^	MMP-10# 4E-BP1$	DNER*@	MMP-10#

*Table 1: List of immunoproteins differentially abundant (p<0.05) in varying IBD subtypes, grouped by their key common molecular functions. *indicates that the immunoprotein of interest to be less abundant compared to controls. ^AXIN1 functions - Activation of protein kinase (GO:0032147), WNT signaling process (GO:0016055). #MMP-10 function - extracellular matrix organization (GO:0030198). $4E-BP1 function - TOR signaling (GO:0031929). @DNER function - Notch receptor processing (GO:0007220).*

Conclusion: Our pilot study in a multi-ethnic Asian population found distinctive serum protein profile in IBD patients. While some protein changes were shared in both UC and CD, other changes were specific for either UC or CD, suggesting different disease pathways in these two IBD subtypes. We reaffirmed that inflammatory proteins, such as EN-RAGE[3], MMP-10[4] and OSM[5], were differentially abundant in IBD, consistent with previous reports in predominantly Caucasian cohorts.

Further studies with large sample sizes would be required to validate these biomarkers for IBD activity, and prognosis for biologic therapy response.

THE PREDICTIVE VALUE OF IRON DEFICIENCY ANAEMIA AND THE SEVERITY OF ANAEMIA ON THE ONE-YEAR DISEASE COURSE OF INFLAMMATORY BOWEL DISEASE

T. Resál[1], P. Bacsur[1], A. Balint[1], M. Rutka[1], A. Fabian[1], R. Bor[1], B. Farkas[1], S. Zoltán[1], K. Farkas[1], T. Molnár[1]

[1]University of Szeged, Department of Medicine, Szeged, Hungary

Contact E-Mail Address: resal.tamas@med.u-szeged.hu

Introduction: Anaemia develops through several pathomechanisms (e.g., occult bleeding, mucosal inflammation, medications) in inflammatory bowel disease (IBD). In true iron deficiency anaemia (IDA) biochemical markers are not elevated, however, due to the pathomechanism, activity at some degree is presumed.

Aims & Methods: Our aim was to compare the one-year disease course of IBD patients with IDA compared to non-anaemic patients. This was a retrospective, double centre, cohort study, including a tertiary referral IBD centre and a secondary IBD centre. The study was carried out between June 2020 and November 2022. IDA was defined as CRP >10 µg/ml, ferritin <30 µg/ml and transferrin saturation <20 % with the presence of anaemia. Biochemical activity was defined as CRP >10mg/l, and severe anaemia as haemoglobin <100 g/l. Baseline laboratory data was obtained. Outcomes were all complications during the one-year follow-up period, including introduction of new treatment, treatment escalation, corticosteroid treatment and major complications (hospitalization and abdominal surgery).

Results: In total, 713 consecutive patients (median age 43 years [IQR: 33 - 57]; male/female ratio 335/378; CD/UC ratio 402/311) were involved in our study, 195 patients (27.3 %) from the secondary and 518 patients (72.7 %) from the tertiary referral centre. Median follow-up period was 1.06 [IQR: 0.98 – 1.13] years. IDA (OR: 2.745; p<0.001) increased the risk of all complications, including major complications (OR: 2.606; p=0.002), except abdominal surgery. The anaemia increased the risk of all outcomes, and the severity of anaemia increased the prevalence of major complications (p<0.001). CRP level was associated with the severity of anaemia (p<0.001).

Conclusion: IDA was a predictor of worse one-year outcomes, including introduction of new therapeutic agent, treatment escalation, corticosteroid admission and major complications despite the absence of inflammation. In conclusion, IDA should be involved in the treat to-target approach, and should be monitored tightly. Furthermore, due to the worse one-year outcomes, we suggest therapeutic intervention, in addition to the iron therapy. In addition, the severity of anaemia correlates with the prevalence of major complications.

Disclosure: Nothing to disclose.

RECOMBINANT CALPROTECTIN AS A PROMISING TOOL TO HARMONIZE MRP-8/MRP-14 IMMUNOASSAYS

A. Ohmann[1], D. Guschin[1], J. Afonso[1], P. Spies[2], D. Meinel[2], C.-B. Gerhold[1]
[1]BÜHLMANN Laboratories AG, Schönenbuch, Switzerland, [2]Fachhochschule Nordwestschweiz FHNW, Muttenz, Switzerland

Contact E-Mail Address: ao@buhlmannlabs.ch

Introduction: Calprotectin is a major granulocyte-derived alarmin protein that natively occurs as a dimeric and tetrameric Mrp-8/Mrp-14 complex. While serum calprotectin is an emerging biomarker for rheumatoid arthritis and juvenile idiopathic arthritis, fecal calprotectin is already established as the gold standard for diagnostics and monitoring of inflammatory bowel diseases. However, standardization of fecal calprotectin assays differs significantly among providers leading to varying clinical cut-offs. One suspected reason is that the oligomeric state of calprotectin can lead to different quantitative results. However, controlling calprotectin's oligomeric state has been challenging.

Aims & Methods: The aim of this work was to produce pure calprotectin as calibrator material with a controllable oligomeric state. Recombinant Mrp8/Mrp14-fusion protein was expressed solubly in E. coli and the oligomeric state assessed by size-exclusion chromatography and label-free differential scanning fluorimetry. Direct comparison to native calprotectin regarding antibody affinities were measured and its use as calibrator material in various immunoassay formats was tested.

Results: The fusion protein was purified as a calprotectin dimer mimic and could successfully be transformed into a calprotectin tetramer upon calcium addition. Affinities to monoclonal and polyclonal calprotectin antibodies are comparable to native calprotectin. Spiking of different concentrations of recombinant calprotectin showed linear correlations in ELISA and turbidimetric assays. Turbidimetric measurements of 17 human serum samples based on native and recombinant calprotectin calibrators revealed a perfect correlation (slope=1.009; R^2=0.999).

Conclusion: The recombinant protein shows immunological properties comparable to native calprotectin and it can be purified in large quantities. Its oligomeric state can be controlled by calcium addition at similar concentration levels as native calprotectin. It therefore presents a promising tool to overcome the prevalent fecal calprotectin standardization problem and prevent future standardization discrepancies for serum calprotectin.

Introduction: Dysbiosis is a hallmark of Crohn's disease (CD). However, its relation to CD course is still unclear. We asked whether microbial signatures identify CD phenotype.

Aims & Methods: A cohort of patients with newly diagnosed CD (all-comers) were recruited and prospectively followed. Clinical data, inflammatory and serologic markers, dietary habits, microbial and fungal composition were detected. Complicated disease course was defined as steroid dependency, CD-related hospitalization, or surgery, and >1 biologics/year. Unsupervised analysis was used to construct baseline microbial clusters. Linear mixed effect models were used to evaluate the clinical, dietary, and fungal associations with microbial clusters, adjusted for treatment.

Results: A total of 251 patients with newly diagnosed CD were recruited (females- 50.6%, median age- 28 [IQR 22-39]) and followed up for a median of 25 months (IQR 14.5-39.8). During follow-up 131 (52.2%) patients were treated with biologics (93.8% with anti-tumor necrosis factor). Sixty-eight (27.1%) patients had complicated disease course, median time to first complication 3.9 months (IQR 2.3-7.7). Two baseline distinct microbial clusters were noticed. A "pathogenic cluster" identified patients with a complicated disease course (52.6% vs. 20.8%, p<0.001). This cluster was characterized by an increase of potentially harmful bacterial taxa including *Escherichia coli, Klebsiella, Gemmella*; and depletion of beneficial bacterial taxa including *Faecalibacterium, Lachnospiraceae* and *Roseburia*. The "pathogenic cluster" had lower Shannon diversity and higher microbial dysbiosis index (both, p<0.001). Additionally higher abundances of multiple fungal taxa including *Cladosporium* and *Aspergillus* were observed in the "pathogenic cluster" as well as a trend towards higher ASCA titer levels (p=0.08). Baseline macro and micronutrients composition were comparable between microbial clusters. Of note, in a sub-cohort of 109 patients, who presented with uncomplicated phenotype, only 11 patients developed complicated disease course. However, no specific bacterial signature was detected.

Conclusion: A distinct microbial cluster identified patients with newly diagnosed CD who had complicated disease course. Thus, baseline microbial signatures might be used to predict CD course.

Introduction: Non-alcoholic liver disease (NAFLD) is a leading cause of liver-related morbidity and mortality having an overall prevalence of about 30%. Inflammatory bowel diseases (IBD) are caused by a dysregulated immune response in the hosts, favored by genetic susceptibility. In addition to symptoms related to the digestive tract, about 40% of patients with IBD also experience extraintestinal manifestations. Although, NAFLD has been frequently associated with IBDs, the relationship between these two pathologies remains unclear.

Aims & Methods: The aim of this study was to investigate the prevalence of NAFLD among IBD patients, as well as the factors that connect these two conditions.From January 2022 to November 2022, consecutive IBD patients were enrolled from a tertiary care center hospital in Iasi. All patients' demographic information, clinical characteristics including blood pressure, biological parameters, and anthropometric measurements were collected. Following informed consent, participants underwent a fibroscan evaluation for liver stiffness measurement (LSM) and controlled attenuation parameter (CAP).

Results: A total of 93 patients with IBD were enrolled (65,3% men, 55,6% with ulcerative colitis). 45 (48,3%) of them were diagnosed with NAFLD, with a mean CAP score of 283 ± 33.4 vs. 215 ± 23.7 in patients with IBD only. Regarding liver fibrosis, mean LSM value in the NAFLD group was 6.8 ± 1.9 kPa *vs*. 5.7 ± 2.3 kPa in the non-NALFD group. Subjects with NAFLD exhibited higher body mass indexes than those with IBD only (26.2 *vs*. 33.1, $p<0.05$). In addition, the prevalence of diabetes was much greater among this group (27.5% *vs*. 0%; $p=0.0001$), as was the prevalence of elevated HbA1c levels in the absence of a diabetes diagnosis (14% *vs*. 7.35%; $p=0.23$). They also had a non-significantly higher mean systolic blood pressure and greater incidences of hypertension. Age ($\beta=0.357$, $p=0.034$), body mass index (BMI) ($\beta=0.185$, $p=0.048$), disease duration ($\beta=0.297$, $p=0.037$), C - reactive protein ($\beta=0.321$, $p=0.013$), fasting plasma glucose ($\beta=0.269$, $p=0.018$) and triglycerides ($\beta=0.273$, $p=0.021$) were strongly associated at the multivariate analysis with the diagnosis of NAFLD in our cohort of patients with IBD. Advanced fibrosis (LSM > 9.7 kPa) was associated with age, BMI and the level of triglycerides. After adjusting for classic metabolic risk factors, age and gender the multivariate logistic regression analysis showed that the presence of IBD (odds ratio, 2.45; 95% confidence interval,1.17–4.391; $p < 0.001$). Also, in regard to age and male gender they were independent risk factors for NAFLD. Of note, the 10-year risk of myocardial infarction or death estimated by the Framingham risk scores for hard coronary heart disease was higher in the NAFLD group (2.32% *vs*. 4.27%, $p=0.0024$).

Conclusion: NAFLD is an intricate condition that has become more common in IBD patients. The connection between these two pathologies is not fully understood, although metabolic disorders, age and male gender have a notable role. Current evidence in the literature suggests a minor risk for the progression of liver fibrosis, the cardiovascular risk appears to be of more concern. Given the information presented above, patients with IBD should be assessed using a multidisciplinary approach.

PROACTIVE NATIONWIDE IBD PATIENT MONITORING AND MANAGEMENT USING PROMS - IMPLEMENTATION AND INITIAL RESULTS

R. Kariv[1,2,3], L. Grinshpan[4,1], O. Haj Natour[1], E. Bar-Ratson[1], A. Ben Baruch[1]

[1]Maccabi Health Care Services, Tel Aviv, Israel, [2]Tel Aviv University, Internal Medicine, Tel Aviv, Israel, [3]Tel Aviv Sourasky Medical Center, Gastroenterology, Tel Aviv, Israel, [4]Haifa Universoty, Public Health, Haifa, Israel

Contact E-Mail Address: revitalk@tlvmc.gov.il

Introduction: Patient-reported outcome measures (PROMs) are recommended for assessing patient-centered outcomes and have been suggested as a tool for quality improvement (QA), which is crucial for IBD related outcomes and as clinical trials' endpoints. Real world use of IBD PROMS as a monitoring tool that enables quick access to caregivers, is still rare. Maccabi Healthcare Services (MHS), a state-mandated healthcare provider with over 2.6 million members, emphasizes patients' cooperation in improving their health and quality of life.

Aims & Methods: 1. To implement an IBD PROMS platform according to an operational process, which triggers a response from an IBD nurse and a multidisciplinary team, for routine HMO clinical use.

2. To compare the characteristics of responders and non-responders and study immediate actions.

We have used pre-existing research on the IBD PROMS platform (1) to implement validated questionnaires (IBD control PROMIS-10 measures and general health and nutritional items).

Questionnaires translated into four languages were sent every 3 months to IBD registry members (defined by EPI-IRN criteria) via text messages.

The calculated results and scores are directed to the electronic medical record (EMR) and are accessible to all caregivers. Digital alerts are sent to an IBD nurse in cases of "red flags" or low scores.

A steering committee designed an actionable plan defining specific nurse responses for each red flag, and whether to consult with the treating physician, dieticians or social worker. A pilot study with patients from 6 gastroenterologists included 2 rounds of PROMS.

Descriptive statistics were used to compare the responders to at least one questionnaire to non-responders for demographic and clinical characteristics, as well as for immediate reactions. An automated, language-specific, personalized messaging system according to patient response was accessible to the responders, with relevant information and general recommendations.

Results: Overall participation rate of the pilot study was 137/777(17.6%). Thirty one (23%) patients had red flags and 52(38%) had sub-threshold IBD-control scores.

Opening rate of the personalized messaging system was 41%. Comparison between responders and non-responders is shown in Table 1.

Responders tended to be significantly older and with a higher BMI. Medical treatment including biologics was not significantly different between responders and non-responders.

More disease related laboratory tests were performed among responders after their initial response.

Conclusion: IBD PROMS has been successfully assimilated and operated at MHS EMR by a multidisciplinary team, using a supporting personalized automated platform.

Significantly higher rate of disease monitoring actions such as calprotectin tests was detected for responders.

Responders did not necessarily have a more active or severe disease. The response rate should be increased via robust education and training.

Parameter (units, normal range)	Total (n=777)	No questionnaire completion (n=640)	Completed the questionnaire (n=137)	P value
Age (years)	41.43±16.65	39.85 ±16.04	48.80 ±17.50	< 0.001
Gender (male) %	43.60	44.10	41.60	0.599

Introduction: The use of ustekinumab (UST) and vedolizumab (VDZ) as first line therapies for inflammatory bowel disease (IBD) is increasing due

to safety reasons and contraindications of anti-TNFs. However, there are no studies assessing their efficacy and safety in clinical practice in this setting.

Aims & Methods: Aims: Therefore, our aims were to describe the features of those patients not previously exposed to biologicals who were treated with VDZ or UST and to evaluate their efficacy and safety profile in this scenario.

Methods: Observational, retrospective and multicenter study based on the ENEIDA registry (a large, prospectively maintained database of the Spanish Working Group in IBD –GETECCU). All IBD patients not previously exposed to biological agents who started VDZ or UST as first-line biological treatment, were identified from the database. Disease activity at baseline and different time points from the beginning of UST/VDZ use, as well as development of side effects, were carefully reviewed from medical records. Descriptive statistics were used, followed by non-parametric comparisons by chi-square test.

Results: Out of 29,450 IBD patients ever exposed to any biological drug included in the ENEIDA registry at the time of data extraction, 406 patients met the inclusion criteria, 149 (36.7%) treated with UST and 257 (63.3%) with VDZ, as first line biological therapy.

At baseline, 46.3% UST and 41.8% VDZ were women (P=ns), median age at the beginning of UST was 60 years (IQR 45-73) and, 61.5 years (IQR 47-71) in VDZ. UST was more frequently used in Crohn's disease (CD) (92.6% vs. 41%; P<0,001); conversely, VDZ was used significantly more often in ulcerative colitis (UC) (7.4% UST vs 59% VDZ; P<0,001). A higher proportion of extensive UC (81.8% UST vs 45;7% VDZ, P=0.029) and perianal disease (14.1% UST vs. 5.5% VDZ; P=0.002) was observed in the UST group. A past history of malignancy was common and evenly observed in both study groups (UST 33% vs VDZ 35.7%; P=ns), as were other comorbidities (47.7% UST vs 53.3% VDZ; P=ns). Concomitant immunosuppressants were used in 14% with UST and 13.9% with VDZ (P=0.671), and 32.4% and 49% were concomitantly treated steroids at the beginning of UST and VDZ, respectively (P=0.001). No differences were observed regarding disease clinical activity at baseline as assessed by the Harvey Bradshaw index (HBI) in CD and partial Mayo score (PMS) in UC. Endoscopic assessment was available in 106 (54.3%) CD patients and 132 (65.4%) UC patients, most of them having endoscopic activity (90% UST vs 91,8% VDZ ;P=ns).

During follow-up 37.8% UST vs. 46.5% VDZ required dose-escalation (P=0.024). No differences were observed regarding early and long-term clinical remission between UST and VDZ for both diseases (UC: week 14, 50% UST vs 68.5% VDZ; week 56, 83.3% UST vs 89% VDZ) (CD: week 14, 96.7% UST vs 92.7% VDZ; week 56, 74.6% vs 61.9% VDZ).

At the end of follow-up (median 21 months [IQR 13-41]) UST vs. 20.5 months [IQR 8-38.7]), treatment persistence was significantly higher among UST users (67.8% vs 43.2%; P=0.006).

Only 1.5% of patients discontinued UST because of adverse effects compared to 5.1% with VDZ (P=0.053).

Conclusion: In clinical practice, VDZ and UST are used as first-line therapies at older ages than anti-TNFs and mostly in patients with comorbidities or a past history of malignancy. Even in this scenario, both treatments have a good safety profile and a high persistence of treatment, although UST shows a higher persistence and a lower rate of treatment discontinuation due to side effects.

Contact E-Mail Address: tommaso.parigi@gmail.com

Introduction: Treatment targets of ulcerative colitis (UC) have evolved to include not only endoscopic but also histologic remission. However, the concept of histological activity is still in its early days. We aimed to capture the attitudes towards UC histology and the uptake of standardized reporting of endoscopy and histology of UC in daily practice.

Aims & Methods: We conducted a cross-sectional survey of physicians involved in the care of IBD worldwide. The survey included 21 questions divided into 3 sections. The first recorded demographics, specialty, and level of experience of participants; the second covered clinical practices and attitudes towards the use and reporting of endoscopy, and the third of histology.

Results: Participants: In total 359 physicians, from 60 countries (54.4% Europe, 24.4% Asia, 12.9% South America, 3.7% North America, 3.2% Africa, and 1.4% Oceania) responded; 87% were gastroenterologists, the remainder other specialists involved in the care of IBD. The majority practiced in academic hospitals (54.5%) or tertiary centers (22.1%), and only around one-fifth worked in secondary hospitals (12.8%) or local practices (8.1%).

Endoscopy: When performing endoscopy in quiescent UC, 72.1% of respondents reported taking biopsies also to assess microscopic activity, while 16.8% only for dysplasia detection, and 10.4% just in case of suspicious lesions; the average number of biopsies was 10.8 (SD 7.34, range 0 to 36). In the case of active UC, the percentage of operators collecting biopsies increased to 93.6%.

Endoscopy reports included a validated score in 91.9% of cases. Mayo was nearly always used (90%), with a large difference from the second most common score UCEIS (26.5%); other indices accounted for 1.7%. Of note, except for 1 respondent, all scores different from Mayo were used in addition to, and not instead of, Mayo. When restricting the analysis to participants working in high-volume centers (>500 UC patients cared for per year) all but one (117/118) reported using the Mayo score to grade endoscopic activity, and 32% (38/117) used also other scores in addition to Mayo, mainly UCEIS.

Histology: Centers represented in the survey were roughly equally split between those with a pathologist dedicated to IBD (46.2%) and those without (51%). UC histology was used by nearly all respondents (90.5%) for initial diagnosis, 72% to monitor disease course, 62.4% to determine microscopic extension, 59.9% to confirm deep remission when considering stopping treatment, and 42.3% to increase/optimize treatment. Nevertheless, 77.2% of participants reported that standard histological indices were not routinely available, although 21.7% of these used scores in selected cases, such as clinical trials or research. Among those who used (or worked in a center that used) standard scores (160/357) the choice of which index was mixed: 64.4% (103/160) used the Nancy index, followed by Geboes 31.9% (51/160), and Robarts 20.6% (33/160), a minority applied other scores.

The majority of respondents welcomed as useful or very useful an artificial intelligence system to automate scoring of endoscopy (69%) or histology (73%).

Conclusion: UC histology reports are less standard than endoscopy ones. Most physicians consider histological activity useful when managing UC and would welcome artificial intelligence systems to automate endoscopic and histological scoring.

PREDICTING *CLOSTRIDIOIDES DIFFICILE* INFECTION IN PAEDIATRIC INFLAMMATORY BOWEL DISEASE PATIENTS ACCORDING TO GUT MICROBIAL COMPOSITION AND SHORT CHAIN FATTY ACIDS PRODUCTION

A. Eindor[1], T. De Wolfe[2], K. Jacobson[2]

[1]Shamir Medical Center, Pediatric Gastroenterology, Hepatology and Nutrition, Zeriffin, Israel, [2]BC Children's Hospital, Pediatric Gastroenterology, Hepatology and Nutrition, Vancouver, Canada

Contact E-Mail Address: adiabarbanel@gmail.com

Introduction: Children with inflammatory bowel diseases (IBD) are particularly vulnerable to *Clostridioides difficile* infections (CDI) and experience significantly worse health outcomes including increased hospitalisation and shorter time to their first bowel resection. Previous studies have correlated these outcomes to specific gastrointestinal microbiome features. However, data regarding features that may predispose PIBD patients to CDI is lacking. Furthermore, it is not known whether CDI has long-term impacts on the microbiome of PIBD patients in remission.

Aims & Methods: Our primary aims were to investigate whether PIBD-CDI patients had a distinct microbiota at baseline compared to PIBD controls, to examine whether PIBD-CDI patients had a distinct microbiome during remission than those without CDI, and whether there were changes in their stool short chain fatty acids (SCFA) composition. Finally, we aimed to assess whether PIBD patients with CDI had worse outcome.

Patients aged 2-17 years and newly diagnosed with IBD between November 2014 and March 2019 were invited to participate. Each patient was requested to submit 4 stool samples in an interval of six months between samples and follow up continued until June 2021. Patients were divided into those that developed CDI (IBD-CDI) and those who did not (IBD controls). DNA was extracted from stool samples and the microbiota of each was profiled using 16S rRNA amplicon sequencing on an Illumina MiSeq. SCFA were quantified from the stool samples. Data analysis was further divided into 2 cohorts: Cohort 1 represented microbiome data from samples of patients who developed CDI and were collected prior to the infection. Cohort 2 represented microbiome data from samples of patients in remission who had CDI. Microbial composition and SCFAs were compared to non-CDI controls within each cohort. Hazard ratio (HR) was calculated to progression to biologic treatment and surgeries in patients who had a CDI compares to those who did not. Random forest classification model was used to predict CDI using microbial composition.

Results:

Patients who had CDI were more likely to progress to a biologic therapy (HR 1.85 P =0.06) and had significantly more hospitalisations (RR 2.20, P< 0.001) and surgery (HR 3.15, P= 0.019).

Cohort 1:

Patients who did not develop CDI had higher abundance of *Bifidobacterium bifidum*, *Blautia hydrogenotrophica*, *Clostridium sensu stricto* 2 *cadaveris*, *Eubacterium*, *Ruminococcus torques* group, and *Lachnoclostridium*.

The *Eubacterium, Blautia hydrogenotrophica*, *Ruminococcus torques group* and *Lachnoclostridium* were associated with high levels of stool SCFAs.

Random forest classification model was able to predict patient who did not develop CDI.

Cohort 2:

Patients post CDI had significantly lower beta diversity.

The *Oscillospirales* CAG 352, NK4A214 group and UCG 002 were all less abundant in post-CDI patients, and were associated with higher SCFA production. Specifically, propionic acid (CAG 352), isovaleric and isobutyric acid (NK4A214 and UCG 002). Additionally, *alistipes* was associated with higher levels of isovaleric and isobutyric acids.

Conclusion: We were able to predict paediatric IBD patients that were protected from CDI based on baseline microbial composition. Paediatric IBD patients who developed CDI during the course of the disease developed more severe outcome with more surgeries and hospitalisations. They had long term changes to their microbiome.

REAL WORLD ENDOSCOPIC AND HISTOLOGIC OUTCOMES IN INFLAMMATORY BOWEL DISEASE PATIENTS: A RETROSPECTIVE COHORT STUDY

M. State[1], A.M. Voiosu[1], B.R. Mateescu[1], C. Popp[2], A. Bengus[1], T.A. Voiosu[1]

Introduction: Histologic activity has emerged as an aspirational therapeutic goal in IBD management. It is not yet a formal treatment-target in either CD or UC. However, it could be used as an adjunct to mucosal healing to represent a deeper level of healing. Recent studies show that histologic healing is associated with decreased risk of clinical relapse, medication escalation and corticosteroid use, both in ulcerative colitis and Crohn's disease [1,2]. We investigated histologic remission (HR) rates and potential predictors of achieving histologic remission in an IBD cohort.

Aims & Methods: We conducted a retrospective subgroup analysis of data collected from IBD patients enrolled in an ongoing prospective cohort study. Clinical, biological, endoscopic data (including the Mayo endoscopic subscore and SES-CD score) and histopathology results were available at multiple time-points for the enrolled patients (annual visits). Mucosal healing was defined as SES-CD <3 or Mayo endoscopic score=0[3]. Histologic healing was defined as microscopic normalization of mucosal biopsies.

Results: 219 patients (88 CD, 131 UC) were enrolled in our study and were prospectively followed for a median length of 2 years (range 0-5 years), totaling 452 study visits. Mucosal healing was recorded for 51 (27 UC, 24 CD, 23,2%) patients at 76(16%) different study visits. Overall, only 35(15%) patients achieved histologic healing. In the mucosal healing subgroup, histologic remission was achieved in 30(58%) patients. After logistic regression analysis, none of the investigated factors was associated with histologic remission.

Conclusion: Mucosal healing and endoscopic remission rates are low in real-life settings. Frequently used patient and disease related factors, including mucosal healing are not reliable predictors for histologic remission.

CORRELATIONS BETWEEN THE INFLAMMATORY BURDEN AND QUALITY OF LIFE IN A PROSPECTIVE COHORT OF INFLAMMATORY BOWEL DISEASE PATIENTS

M. State[1], A. Bengus[1], M. Birligea[1], A.M. Voiosu[1], B.R. Mateescu[1], T.A. Voiosu[1]
[1]Colentina Clinical Hospital, Gastroenterology, Bucharest, Romania

Contact E-Mail Address: monicaionita4@gmail.com

Introduction: Therapeutic goals in inflammatory bowel diseases (IBD) have undergone considerable change in recent years, with a shift of focus from simply achieving clinical remission. Patient-related outcomes (PROs) have also become increasingly important as adjunctive tools in assessing the efficacy of medical therapy from the patients' standpoint. Health-related quality of life (HRQoL) questionnaires, correlate well with disease activity and can detect meaningful clinical changes in IBD patients who either suffer a relapse of disease or achieve remission [1,2].

Aims & Methods: We aimed to assess the utility of SIBDQ in the long-term follow-up of IBD patients compared to the conventionally used markers such as clinical indices, CRP levels and endoscopic activity scores. Patients were scheduled for evaluation every 12 months, but additional evaluations were performed as required in case of worsening clinical condition. The main data collected at each study visit included clinical aspects (disease activity, on-going medication, quality of life assessement-The Short Inflammatory Bowel Disease Questionnaire), endoscopic and histological findings.

Results: In a prospective setting, 176 patients were included in the study (65 Crohn's and 111 UC patients) , with a mean follow-up time of 16 months and 1.3 study visits per patient. Clinical activity was associated with significantly lower SIBDQ (median 4.3 vs 5.7 in those without clinical activity, p<0.001 mann whitney u) and increased inflammatory burden (median CRP levels 1,99 mg/L vs. 7.2mg/L, p<0.001 mann whitney u). SIBDQ scores were also significantly higher in patients showing mucosal healing compared to those with active ongoing inflammation (5.8 vs 4.9, p<0.001 MWU), while inflammatory burden was also significantly different between patients with and without ongoing mucosal activity (1.6 mg/L vs 4.2 mg/L, p< 0.001 MWU). SIBDQ significantly improved over time, with a median of 4.7, 5.4 and 5.8 at visits 1, 2 and 3 respectively (p<0.001 MWU), which was also consistent with a decrease in the overall inflammatory burden in the cohort (median CRP levels of 4.2, 3.4 and 2.5 mg/L respectively).

Conclusion:

Clinical activity is associated with significantly lower quality of life and increased inflammatory burden. QoL scores are significantly higher in patients showing mucosal healing compared to those with active ongoing inflammation.

Introduction: As yet, the genetic abnormalities involved in the exacerbation of Ulcerative colitis (UC) have not been adequately explored based on bioinformatic methods.

Aims & Methods: The gene microarray data and clinical information were downloaded from Gene Expression Omnibus (GEO) repository. The scale-free gene co-expression networks were constructed by R package "WGCNA". Gene enrichment analysis was performed via Metascape database. Differential expression analysis was performed using "Limma" R package. The "randomForest" packages in R was used to construct the random forest model. Unsupervised clustering analysis performed by "ConsensusClusterPlus"R package was utilized to identify different subtypes of UC patients. Heat map was established using the R package "pheatmap". Diagnostic parameter capability was evaluated by ROC curve. The"XSum"packages in R was used to screen out small-molecule drugs for the exacerbation of UC based on cMap database. Molecular docking was performed with Schrodinger molecular docking software.

Results: Via WGCNA, a total 77 high Mayo score-associated genes specific in UC were identified. Subsequently, the 9 gene signatures of the exacerbation of UC was screened out by random forest algorithm and Limma analysis, including BGN,CHST15,CYYR1,GPR137B,GPR4,ITGA5,LILRB1,SLFN11 and ST3GAL2. The ROC curve suggested good predictive performance of the signatures for exacerbation of UC in both the training set and the validation set. We generated a novel genotyping scheme based on the 9 signatures. The percentage of patients achieved remission after 4 weeks CS-IV treatment was higher in cluster C1 than that in cluster C2 (54% *vs*. 27%, Chi-square test, p=0.02). Energy metabolism-associated signaling pathways were significantly up-regulated in cluster C1, including the oxidative phosphorylation, pentose and glucuronate interconversions and citrate cycle TCA cycle pathways. The cluster C2 had a significant higher level of CD4+ T cells. The"XSum"algorithm revealed that Exisulind has a therapeutic potential for UC. Exisulind showed a good binding affinity for GPR4, ST3GAL2 and LILRB1 protein with the docking glide scores of –7.400 kcal/mol, –7.191 kcal/mol and –6.721 kcal/mol, respectively.We also provided a comprehensive review of the environmental toxins and drug exposures that potentially impact the progression of UC.

Conclusion: Using WGCNA and random forest algorithm, we identified 9 gene signatures of the exacerbation of UC. A novel genotyping scheme was constructed to predict the severity of UC and screen UC patients suitable for CS-IV treatment. Subsequently, we identified a small molecule drug (Exisulind) with potential therapeutic effects for UC. Thus, our study provided new ideas and materials for the personalized clinical treatment plans for patients with UC.

FAECAL CALPROTECTIN IS A NON-SPECIFIC MARKER OF INFLAMMATION IN ADULTS OVER THE AGE OF 50

R. Perry[1], P. Perez[1], A. Sharma[2], D. Zhang[2], S. Taylor[3], L. Hicks[1], H. Williams[1]

Contact E-Mail Address: robert.perry@imperial.ac.uk

Introduction: Faecal calprotectin (FC) is a well-established marker of gastrointestinal inflammation with multiple studies showing elevated levels in patients with Inflammatory Bowel Disease (IBD) relative to control groups such as patients with Irritable Bowel Syndrome (IBS) (1).

Multiple national and speciality guidelines therefore recommend its use to help identify patients with gastrointestinal (GI) symptoms who may benefit from further investigation (2).

However, there is uncertainty surrounding the role of FC in older adults due to a higher likelihood of colorectal cancer. Clinical guidelines often advocate a much lower threshold for endoscopic investigation with increasing age and studies of FC have therefore often excluded older adults, resulting in a lack of relevant data in the literature (3)(4). Despite this a large number of FC tests continue to be performed in this group and evaluation of its performance is therefore important.

Aims & Methods: Our retrospective study investigated patients over the age of 50 who had a FC test performed followed by a colonoscopy at our centre in Northwest London between May and October 2021. Patients with existing IBD were excluded. Endoscopy reports and electronic medical records of eligible patients were reviewed to establish both the indication for FC testing and any diagnoses made based on colonoscopy results as well as other clinical investigations and assessments performed.

Results: In total 247 patients were eligible for inclusion in the study (54% women, 46% men). The average age was 61 years (range 50-93) and the median FC value was 83µg/g (range 20-11603µg/g). The most common indication given for FC testing was diarrhoea in 35% (86/247) of cases. In total 16 patients (6%) were diagnosed with IBD and a further 39 (16%) with other significant organic GI pathology (defined as colorectal cancer, colonic polyps >1cm, microscopic colitis or infectious colitis). Using a cut-off value of 50µg/g gave FC a sensitivity of 93.8% (95% CI 71.7%-99.6%) but a specificity and positive predictive value (PPV) of 46.4% (39.4-53.4%) and 12.7% (7.9-19.9%) respectively for differentiating between IBD and patients with no significant organic GI pathology (including functional disorders) (p=0.0013). Increasing the FC cut-off to 150 µg/g improved the specificity of FC to 70.3% (63.5-76.3%) but the PPV remained low at 18.6% (11.2-29.2%).

In patients where a FIT test was performed the sensitivity of a FIT test for IBD vs no significant organic pathology, using a cut-off of 10 µg/g, was 75% (40.9-95.6%) and specificity 71.3% (62.7-78.6%) (p=0.0121). When looking at FC performance for significant GI pathology vs non-significant pathology a similar picture was seen with a sensitivity of 78.2% (65.6-87.1%), specificity of 46.4% (39.4-53.4%) and PPV of 29.5 (22.7-37.3%), using a FC cut-off of 50µg/g.

In total there were 5 patients diagnosed with colorectal cancer, all of which had a FC>50 µg/g but only 3 of which had a level over 150µg/g. 4 of these patients had a FIT test prior to their colonoscopy which was positive in all cases.

Conclusion: These data suggest that whilst FC remains a sensitive test for IBD in this age group it has a low PPV and specificity, particularly at the recommended cut-off of 50 µg/g. A possible reason for this is the high prevalence of other colonic pathology, such as colorectal polyps and di-

verticular disease, in this cohort that has the potential to cause mild elevations in FC levels. Further prospective studies are therefore needed to establish if there is a clear role for FC in diagnostic pathways for older adults.

Introduction:
Dermal lesions are often among patients with inflammatory bowel diseases (IBD), partialy could be associated with biological therapies [1,2]. Their occurrence frequently leading to dermatological consultations and causes diagnostic and therapeutic difficulties [3,4].

Aims & Methods: This is a retrospective, single-center analysis of occur dermal lesions in IBD patients treated with TNF at a tertiary center in Poland. A total of 541 IBD patients treated with TNF (case group) and 805 IBD patients without TNF therapy (control group) were included in the study since 2016 till 2022 in the study. The mean follow-up time last in the case group 19.86 vs. 20.78 months in the control group, p<0,46.

Results: Regular visits to the dermatologist during observation were performed in 531 (98,15%) cases vs. 92 (11.43%) controls, p<0,00001. Dermal lesions were presented in 34.75% (188) vs. 16.89% (136) during follow up, p<0,00001. The following dermal lesions were reported in the both groups: erythema nodosum 10 (1.8%) vs. 21 (2.6%), p<0,36; pyoderma gangrenosum 14 (2.58%) vs. 17 (2.11%), p p<0,57; psoriasis 9 (1.66%) vs. 9 (1.12%), p<0,39; hidradenitis suppurativa 9 (1.66%) vs. 15 (1.86%), p<0,79; vitiligo 4 (0.74%) vs. 5 (0.62%), p<0,79; phlebitis 1 (0.18%) vs. 1 (0.12%), p<0,78; urticaria 5 (0.92%) vs. 11 (1.37%), p<0,46; infusion reactions and injection site reaction 30 (5.55%) vs. 0 (0%)0, p<0,00001; xerosis and eczema 46 (8.5%) vs. 44 (5.47%), p<0,28; cutaneous infections 42 (7.76%) vs. 0 (0%), p<0,00001; psorasiform reactions 8 (1.48%) vs. 0 (0%), p<0,002; cutaneus malignancies 2 (0.37%) vs. 9 (1.12%), p<0,13; lupus-like symptoms 4 (0.74%) vs. 0 (0%), p<0,07; vasculitis 1 (0.18%) vs. 0 (0%), p<0,77; alopecia areata / totalis 2 (0.37%) vs. 2 (0.25%), p<0,96; lichenoid drug reactions 2 (0.37%) vs. 0 (0%), p<0,35. In 9 (1.66%) cases anti-TNF therapy led to drug change because of dermal lesions (alopecia, lupus-like syndrome, vasculitis or melanoma).

Conclusion: Dermal lesions during TNF therapy are common and often require dermatological consultation. Despite the lack of clear guidelines on dermatological supervision during biological therapy, its regular conduct seems to be justified and may facilitate the initiation of appropriate management at an early stage. Despite the commonness of dermal lesions, they are rarely the reason for changing treatment.

Introduction: Nephrolithiasis (NL) is a common extra-intestinal complication of inflammatory bowel diseases (IBD) with significant morbidity and mortality[1]. Its pathogenesis and risk factors still need to be completely elucidated. Because of intestinal malabsorption, enteric hyperoxaluria is a critical pathogenic mechanism responsible for the development of NL in IBD patients[2]. Growing evidence has highlighted the association between gut microbiota and NL, particularly emphasising the role of some oxalate-degrading bacteria, such as *Oxalobacter formigenes*, representing the mainstay of the so-called "gut-kidney axis"[3]. More recent studies also hypothesize the involvement of urinary microbiota[4], but no data on IBD patients are currently available. Thus, our study aims to analyse the urinary lithogenic profile in IBD patients and its relationship with gut and urinary microbiota.

Aims & Methods: Consecutive adult patients with IBD were prospectively enrolled. The presence of ileoanal pouch, ileostomy, colostomy or short-bowel syndrome were exclusion criteria. Demographic and clinical data,

including previous episodes of NL, were collected. Disease activity was evaluated using Harvey-Bradshaw index for Crohn's disease (CD) and Mayo score for ulcerative colitis (UC). All patients underwent abdominal ultrasound for NL detection. Blood tests of kidney function (notably creatinine, blood urea nitrogen, creatinine clearance, and electrolytes) were also measured, together with a 24h-urine collection for lithogenic profile analysis, including calcium oxalate relative saturation ratio (RSRCaOx). In a subgroup of patients, urinary and faecal microbiota were also analysed through 16S rRNA sequencing.

Results: 48 patients (52.1% men, mean age 42.6±17.4 years) were enrolled. Twenty-five patients were affected by CD and 23 by UC and 10 presented active disease at enrollement. NL was more frequent in CD than in UC (32% vs. 13%). In CD, 24-h urinary volume was lower and 24-h oxaluria was higher than in UC. Moreover, 24-h oxaluria was higher in patients with previous or present NL. Gut microbiota analysis was performed on 22 patients, stratified based on median RSRCaOx (higher or lower than the median). Significantly different β-diversity was observed between the two groups (p =0.025) and patients with an elevated RSRCaOx showed a higher relative abundance of Bacteroidetes and a lower abundance of Firmicutes (p value <0.05). No statistically significant difference was found in urinary microbiota composition between patients with high or low levels of RSRCaOx.

Conclusion: NL is more common in CD patients, who generally present lower urine volume and higher 24-h oxaluria than UC patients. Furthermore, NL is more frequent in IBD patients with higher oxaluria levels, confirming oxalate excretion's crucial role in NL pathogenesis. Again, our study reports an association between urinary stone development and Firmicutes/Bacteroidetes imbalance in the gut microbiota, suggesting possible further studies to identify patients at higher risk of NL.

CADE-IBD: A REALITY OR A DREAM? PROSPECTIVE EVALUATION OF A NOVEL NEURAL NETWORK FOR DETECTION OF NEOPLASIA IN IBD COLON

K. Siggens[1], H. Htet[2], Y. Iwadate[3], S. Namiki[3], A.A. Alkandari[2], J. Hamson[2], M. Abdelrahim[2], P. Bhandari[2]

Introduction: Patients with inflammatory bowel disease (IBD) have a higher risk of colorectal cancer requiring regular surveillance colonoscopy. However, neoplasia in IBD is subtle and difficult to detect so the use of chromoendoscopy is recommended, with or without multiple biopsies. Computer Aided Detection (CADe) is becoming increasingly used for polyp detection in standard colonoscopy, but its use has so far been restricted to non-colitic bowel.

We developed a novel CADe-IBD algorithm and prospectively evaluated it's performance for detection of neoplasia in IBD colon.

Aims & Methods: A dedicated CADe-IBD algorithm was developed. The study was conducted in two phases. In the first phase the system was tested on still images obtained from IBD colons. Three experts jointly reviewed the images to classify them into neoplastic or non-neoplastic to establish the ground truth alongside histology. Images were tested on both the dedicated CADe-IBD algorithm and a generic colon CADe system. In the second phase, the CADe-IBD algorithm was used in real-time in a select group of 30 IBD patients undergoing surveillance colonoscopy. Ground truth was established by a combination of expert endoscopists performing the procedure in real time followed by an independent review of the recorded videos by three additional experts. All lesions identified during colonoscopy were biopsied or removed to obtain histology.

Results: The image based test set consisted of 1,111 images (45 neoplastic lesions, 40 non-neoplastic and, 1026 colitic bowel with no lesions). The CADe-IBD algorithm demonstrated an overall sensitivity of 90.6% and specificity of 94.6% for lesion detection which was significantly better than the generic CADe engine (p<0.001) where the sensitivity and specificity was 69.4% and 94.5% respectively.

Further sub-analysis was performed based on lesion morphology (polypoid vs non-polypoid), presence of background inflammation and histology. Sensitivity results are summarised in table 1.

Real-time performance was assessed in 30 consecutive patients. 15 patients were male. Median age was 60. 80% (n=24) patients had Ulcerative Colitis, 20% (n=6) patients had Crohns colitis. There was mild patchy inflammation in 46.6% (n=14) of patients.

A total of 136 lesions were identified. 18.4% (n=25) were neoplastic, the remaining were non-neoplastic (hyperplastic, pseudo polyps or inflammatory lesions). The overall sensitivity for lesion detection was 90.4%. 25 neoplastic lesions (8 polypoid and 17 non-polypoid) were identified in 11 patients. The real-time sensitivity for neoplasia detection was 100%.

	Lesion morphology (Paris classification)		Background mucosal inflammation		Histology
	Non-polypoid (IIa/IIb)	Polypoid (Is)	Mayo 0	Mayo 1	Neoplastic
CAD-IBD algorithm	89.7%	91.3%	89.4%	94.7%	91.1%
Generic CADe algorithm	48.7%	87.0%	69.7%	68.4%	66.7%

Table 1. Sensitivity for CADe-IBD and generic CADe.

Conclusion: This is the first real-time use of a dedicated CADe algorithm for neoplasia detection in IBD colon. Our image based data proves the superior performance of dedicated CADe-IBD algorithm in detection of IBD neoplasia as compared to a generic CADe engine. The sub-analysis suggested that this may be due to its better performance for detection of flat lesions and lesions in the presence of inflammation.
Real-time data demonstrates the feasibility and efficacy of this algorithm. We believe that if proven in larger series this can transform clinical practice.

NEOPLASIA CHARACTERISATION IN IBD COLON: AN INTERNATIONAL MULTI-CENTRE STUDY OF ENDOSCOPIST PERFORMANCE AND A GENERIC COLON CADX ALGORITHM PERFORMANCE

K. Siggens[1], H. Htet[1], P. Aslam[2], H. Suthan[3], J. Hamson[1], M. Abdelrahim[1], G. Longcroft-Wheaton[1], A.A. Alkandari[4], P. Bhandari[1]

Contact E-Mail Address: katie.siggens@nhs.net
Introduction: Surveillance colonoscopy in patients with Inflammatory Bowel Disease (IBD) poses a unique challenge due to the subtle nature of flat dysplasia. But this challenge is further compounded by the number of additional lesions seen as a result of inflammation, such as pseudo-polyps and inflammatory polyps which can result in additional biopsies or unnecessary resection. Computer aided diagnosis (CADx) could improve lesion characterisation in this cohort of patients but a dedicated CADx algorithm has yet to be developed. Here we compare the performance of endoscopists and an existing generic colon CADx algorithm on lesion characterisation in IBD patients.
Aims & Methods: In phase 1, endoscopist performance on image based characterisation was assessed using still images of lesions in patients with IBD. Frames were taken in both white light imaging (WLI) and Image Enhancement (IE). Images were checked by an independent reviewer for the quality of images. Characterisation was then performed by 12 endoscopists (6 experts who regularly perform IBD surveillance and 6 non-expert) who categorised them as neoplastic (adenoma with low or high grade dysplasia) or non-neoplastic (hyperplastic, regenerative, inflammatory or pseudo-polyps).

In phase 2, an existing generic colon CADx algorithm was used in video based analysis of prospectively collected IBD colonoscopy videos. Lesions were characterised as neoplastic or non-neoplastic. Ground truth in both phases was histology.
Results: In phase 1, 57 lesions (34 neoplastic, 23 non-neoplastic) were characterised by endoscopists. For non-experts, sensitivity, specificity and accuracy were 73.0%, 55.3% and 65.9% respectively on white light and 73.9%, 49.1% and 64.7% on IE. For expert endoscopists, sensitivity, specificity and accuracy were 70.1%, 66.7% and 68.7% respectively on WLI and 78.3%, 60.8% and 72.0% on IE.

In phase 2, full withdrawal videos in 20 patients undergoing surveillance colonoscopy were collected. 17 patients had Ulcerative Colitis, 3 patients had Crohn's disease. 86 lesions were identified (21 neoplastic, 65 non-neoplastic). Video based CADx performance for sensitivity, specificity and accuracy was 88.89%, 80.64% and 74.44% respectively.

	Non-expert		Expert		CADx
	WLI	IE	WLI	IE	
Sensitivity (%)	73.0	73.9	70.1	78.3	88.9%
Specificity (%)	55.3	49.1	66.7	60.8	80.6%
Accuracy (%)	65.9	64.7	68.7	72.0	74.4%

Table 1. Performance of endoscopists vs CADx.

Conclusion: Our data highlights the challenges of lesion characterisation IBD patients, with a low sensitivity and specificity in both experts and non-experts. In particular, non-experts have a very low specificity meaning there may be a high number of unnecessary resections/biopsies performed. A generic CADx algorithm performed better than endoscopists and with dedicated training of this algorithm with IBD lesions could further improve characterisation and reduce the number of non-neoplastic lesions which are removed.

PP0677

TIME TO INFLAMMATORY BOWEL DISEASE DIAGNOSIS FOR PATIENTS PRESENTING WITH ABDOMINAL SYMPTOMS IN PRIMARY CARE AND ASSOCIATION WITH EMERGENCY HOSPITAL ADMISSION AND SURGERY; A RETROSPECTIVE COHORT STUDY

N. Umar[1,2], P. Harvey[3], N. Adderley[2], S. Haroon[2], N. Trudgill[1]
[1]Sandwell & West Birmingham Hospitals NHS Trust, West Bromwich, United Kingdom, [2]University of Birmingham, Birmingham, United Kingdom, [3]New Cross Hospital, Wolverhampton, United Kingdom

Contact E-Mail Address: nosheen.umar@nhs.net
Introduction: Making an Inflammatory Bowel Disease (IBD) diagnosis can be challenging as symptoms may mimic more common conditions such as irritable bowel syndrome or haemorrhoids. This can lead to delays in IBD diagnosis, which can be associated with the need for more complex treatment or surgery.
Aims & Methods: This study aims to quantify the time to diagnosis for IBD and examine associations with patient characteristics and faecal calprotectin (FC) and its impact on surgery and emergency hospital admissions. A retrospective cohort study was conducted using Clinical Practice Research Datalink (CPRD AURUM) from 1st Jan 2007 to 31st Dec 2019. Adult patients were followed from when they first presented with symptoms, signs, test results or alternative diagnosis potentially related to IBD in primary care in the 3 year period prior to IBD diagnosis. The association between patient level factors and FC with the time to IBD diagnosis were examined using logistic regression analysis. We examined changes in time to IBD diagnosis over the 10 year study period. The association of time to IBD diagnosis with IBD related surgeries and emergency admissions was also examined.
Results: Of 28,092 IBD patients: 60.0% ulcerative colitis (UC) and 40.0% Crohn's disease (CD). Median age 43(IQR 30-58) years; 51.9% female. Median time to diagnosis 15.6 (IQR 4.3- 28.1) months; UC 13.8 (3.2-27.1) months and CD 17.8 (6.5-29.2) months.
Factors associated with over 12 months to IBD diagnosis: female ((OR 1.64(95%CI 1.56-1.72)); Black (1.45(1.20-1.76)) or Asian ethnicity (1.55(1.40-1.72); older age compared to 18-30 years (>70 1.14(1.03-1.27));

obesity (1.09(1.01-1.17)); smoking (1.13(1.06-1.20)); lower socioeconomic status (1.15 (1.06-1.25)); anxiety (1.15(1.07-1.24)); depression (1.19(1.11-1.28)); non-steroidal anti-inflammatory drugs (NSAIDs) (1.45(1.33-1.59)); loperamide (1.56 (1.31-1.86)) and increasing comorbidity Charlson score >2 (1.46(1.32-1.61)).

Only 11.3% of IBD patients had FC testing. Time to diagnosis from FC date was median 4.0 (IQR 1.8- 8.8) months. Higher FC levels were associated with decreasing time to IBD diagnosis: 500-1000 (0.76 (0.66-0.89)),>1000 (0.61(0.51-0.72)).

No improvement in time to IBD diagnosis was observed over the last 10 years: 2010-2011 (14.4 (3.6 -27.6) months) compared to 2018-2019 median (15.6 (4.8-28.8) months).

Patients with time to diagnosis in highest quartile were at lower risk of surgery within a year of diagnosis (HR 0.91(0.81-1.03) but had more IBD related emergency admissions after diagnosis (IRR 1.06 (1.01-1.11).

Conclusion: Longer times to diagnoses were associated with females, minority ethnicities, increasing age, increasing comorbidity, deprivation, obesity, anxiety, depression, NSAIDs and loperamide use. Faecal calprotectin testing reduced time to diagnoses. Higher number of IBD related emergency admissions were observed in patients with a prolonged time to diagnosis.

Disclosure: No conflict of interest to declare.

PP0678

DEVELOPMENT OF A RISK PREDICTION TOOL FOR INFLAMMATORY BOWEL DISEASE (IBD) IN PATIENTS PRESENTING IN PRIMARY CARE WITH ABDOMINAL SYMPTOMS, A UK BASED STUDY.

Introduction: There are no prediction models for a diagnosis of inflammatory bowel disease (IBD) in primary care. Our aim was to develop an IBD risk prediction tool to reduce the length of time patients have undiagnosed IBD symptoms and improve IBD clinical outcomes.

Aims & Methods: We developed and internally validated a risk prediction tool for the diagnosis of IBD, ulcerative colitis (UC) and Crohn's disease (CD).

A population-based retrospective open cohort study using Clinical Practice Research Datalink (CPRD) database was undertaken between 1st January 2010 and 31st December 2019 of all the patients aged 18 years or older. Patients were followed from first presentation with lower gastrointestinal (GI) symptoms potentially related to IBD to IBD diagnosis. Candidate predictors were chosen based on clinical and substantive knowledge. Cox proportional hazards regression with backward elimination was used for model development of IBD, UC and CD risk prediction models. The predictive performance of the models was assessed using discrimination (C-statistic). Internal validation using 1000 bootstrap sampling repetitions was used to estimate the optimism-corrected measures of predictive performance.

Results: Of 2,056,398 patients with lower GI symptoms: 11,192 patients had an IBD diagnosis (7033 UC (62.8%) and 4138 CD (37.0%)). The final IBD model included demographic factors (age, sex, ethnicity, smoking, index of multiple deprivation, body mass index, Charlson comorbidity index, loperamide use) co-existing conditions (anxiety, depression, irritable bowel syndrome (IBS), haemorrhoids), extraintestinal (EIM) manifestations (mouth ulcers, ophthalmic, primary sclerosing cholangitis, dermatological), laboratory investigations (low haemoglobin (Hb), low Mean Corpuscular volume (MCV), low albumin, low ferritin, raised C-reactive protein (CRP), raised Erythrocyte Sedimentation Rate (ESR), raised calprotectin level). The UC model included all above except mouth ulcers, IBS, ophthalmic EIM. Depression and ferritin were excluded in the CD model though low vitamin B12 level was included. The risk score for each patient was the sum of individual risk factors. In the development dataset, models showed moderate discrimination.

For the IBD prediction tool: C-statistic 0.71 (95% CI 0.70-0.71),UC prediction tool: C-statistic 0.70 (95% CI 0.69-0.70) and CD prediction tool: C-statistic 0.75 (95% CI 0.74-0.76). The C-statistics of the models showed that the IBD, UC and CD prediction tools reliably differentiated patients with and without IBD,UC and CD respectively.

Conclusion: A risk score of patient demographics, symptoms and investigations performs well for IBD,UC and CD and may help in prioritising suspected IBD referrals in symptomatic subjects in primary care.

Disclosure: No conflict of interest to declare

REDUCING DIAGNOSTIC DELAY OF EXTRA-INTESTINAL MANIFESTATIONS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES: A COMPARATIVE STUDY OF A MULTIDISCIPILINARY IMMUNE-MEDIATED DISEASES OUTPATIENT CLINIC AND CONVENTIONAL REFERRAL SPECIALISTS

O.M. Nardone[1], G. Calabrese[2], A. La Mantia[2], E. D'Alessandro[2], M. Ferrante[2], G.D. Villani[2], A. Testa[2], A.D. Guarino[2], A. Rispo[2], F. Castiglione[2]

Introduction: Extraintestinal manifestations (EIMs) can occur in up to 47% of patients diagnosed with inflammatory bowel disease (IBD); hence the early detection of EIMs in IBD patients is crucial to prevent a disabling disease clinical course.

However, there is a substantial variation in the reported time to diagnosis of EIMs due to a lack of a standardised approach. The clinical characteristics leading to the diagnosis were rarely specified, and the diagnostic accuracy could depend on the experience of the individual specialist.

Conversely, care for IBD patients with EIMs should be multidisciplinary. We, therefore, evaluated the length of time to diagnose EIM through an integrated immune-mediated diseases (IMIDs) outpatient clinic compared to a conventional diagnosis and the impact of diagnostic delay on the disease course of IBD.

Aims & Methods: We conducted a single-center cohort observational study including IBD patients ≥18 yo presenting red flags for EIMs who underwent outpatient visits through a multidisciplinary IMIDs clinic between 2020-2022 and we compared this group to a historical cohort, with similar clinical features, who underwent conventional visits by individual referral specialists from 2017 to 2019.

The primary outcome was to assess the diagnostic delay, defined as the period from the occurrence of red flags onset to diagnosis of EIM.

Secondary endpoints included the rate of EIMs diagnosis in patients with red flags referred to IMIDs clinic and the impact of diagnostic delay on clinical outcomes, including therapeutic changes.

Results: We enrolled 176 IBD patients; 90 were referred to the IMIDs Clinic Group (IMID-G) and 86 to the Standard Outpatient Clinic group (SOC-G). Demographic details are summarised in Table 1.

Demographic characteristics	IMIDs Clinic Group (n=90)	Standard Outpatient Clinic Group (n=86)
Sex		
- Female	55 (61.1%)	53 (61.6%)
- Male	35 (38.9%)	33 (38.4%)
UC patients	41 (45.6%)	38 (33.2%)
- Proctitis	8 (19.5%)	5 (13.1%)
- Left colitis	16 (39%)	18 (47.3%)
- Pancolitis	17 (41.5%)	12 (31.6%)
CD patients	49 (54.4%)	48 (55.8%)
CD Montreal disease localization		
- Ileal	19 (38.8%)	16 (33.3%)
- Colonic	7 (14.3%)	7 (14.6%)
- Ileocolonic	23 (46.9%)	25 (52.1%)
CD Montreal disease behaviour		
- Inflammatory	15 (30.6%)	14 (29.2%)
- Stricturing	18 (36.7%)	21 (43.8%)
- Penetrating	16 (32.7%)	13 (27.1%)
Red flags for IMIDs		
- Chronic back pain	26 (28.9%)	26 (30.2%)
- Peripheral arthralgia	24 (26.7%)	31 (36%)
- Enthesitis	2 (2.2%)	-
- Dactilitis	7 (7.8%)	3 (3.5%)
- Skin erythema	22 (24.4%)	14 (16.3%)
- Skin ulcers	9 (10%)	12 (14.0%)

The average time to EIMs diagnosis was 2.6±1.7 months for IMID-G and 4.4±1.9 months for SOC-G, p<0.05. In both groups, the majority of patients referred red flags for spondyloarthritis (SpA). In IMID-G , chronic back pain was reported by 28.9% of patients and peripheral arthralgia by 26.7%, similarly in SOC-G , 30.2% had chronic back pain and 36% had peripheral arthralgia. At six months, 77 (85.5%) patients with red flags referring to the IMIDs clinic received diagnoses of EIMs, compared to 52 (60.5%) of those referred to the specialist of reference (p<0.05). Overall in IMID-G, 19 (21.1%) patients were diagnosed with peripheral arthritis and 28 (31.1%) with SpA, compared to 15 (17.4%) with peripheral arthritis and 21 (24.4%) with SpA in SOC-G. Survival curves were plotted to analyse the probability of diagnostic delay of EIMs between IMID-G and SOC-G and showed a significant reduction of diagnostic delay in IMID-G (log rank test, p=0.001). Additionally, in IMID-G, 42 patients (46.6%) changed therapy, and 13 (14.4%) added steroids in comparison to 27 (31.4%) and 11 (12.8%) respectively in the SOC-G cohort (p<0.05).

Conclusion: Attendance at a dedicated IMIDs clinic can improve the diagnostic process of EIMs in an IBD cohort and reduce the diagnostic delay. The most common EIMs were SpA and peripheral arthritis. This multidisciplinary approach can help to avoid diagnostic delays, choose the correct therapies, prevent complications, and improve clinical outcomes and hence the quality of life.

Introduction: Endoscopy is the gold standard for detecting mucosal inflammation in order to differentiate between Irritable Bowel Syndrome (IBS) and Inflammatory Bowel Disease (IBD) as well as for monitoring mucosal inflammation in diagnosed IBD patients. Fecal calprotectin has been established as an excellent surrogate biomarker of intestinal inflammation as it correlates well with endoscopic and histological disease activity. Most IBD diagnosis and treatment guidelines recommend using fecal calprotectin as an *aid in diagnosis* and to measure it routinely to follow the disease course in IBD patients. As there is no international standard to date, fecal calprotectin assay manufacturers rely on their own internal calprotectin standardization.

Assays can be based on various technologies from traditional enzyme-linked immunosorbent assays (ELISA), particle enhanced turbidimetric high throughput assays (PETIA), to rapid lateral flow assays (LFA). LFAs can be read by conventional tabletop lateral flow readers or by everyday smartphone applications using the phone's camera to acquire an image, detect the test cassette and calculate a quantitative result. It is essential that the biomarker is measured comparably across all assay methods. In this work, different assay methods were compared with clinical samples using a clinically relevant assay range.

Aims & Methods: 128 raw stool samples from patients with signs and symptoms suggesting intestinal inflammation and who underwent endoscopic evaluation to determine if patients had IBD or IBS were used in this study. Samples were extracted using the BÜHLMANN CALEX Cap stool extraction device. Each extract was measured on the BÜHLMANN fCAL ELISA, fCAL turbo (PETIA), Quantum Blue fCAL extended lateral flow assay and smartphone based IB*Doc* fCAL home test. For the home test two phones, iPhone 11 and Samsung Galaxy S7, were used to measure the test cassettes. Each sample was measured one time on each assay and a Receiver Operating Characteristic (ROC) curve analysis was performed.

Results: ROC curves for each method were calculated in respect of differentiating between IBS and IBD with area under the curve (AUC) values ranging from 0.827 (Samsung Galaxy S7)) to 0.835 (fCAL turbo). There was no significant difference between the methods. BÜHLMANN uses a cut-off of 80 µg/g and 160 µg/g for IBS/IBD differentiation and 100 µg/g and 300 µg/g for IBD monitoring.

For all methods, the sensitivity at the cut-off level of 80 µg/g was 90.8 % and specificity at 160 µg/g ranged from 67.3% to 71.2 %. Sensitivity at a cut-off of 100 µg/g ranged from 85.5% to 88.2% and specificity at 300 µg/g ranged from 82.7% to 86.5%.

Conclusion: This study shows that all BÜHLMANN fecal calprotectin assays are very comparable. They show an excellent clinical performance irrespective of the assay method performed. This allows for the use of the methods interchangeably, depending on the needs of the patients and their care team.

Introduction: Essential trace elements such as selenium (Se), copper (Cu) and zinc (Zn) are important in regulating the immune system. Deficiency in these elements can correlate with disease severity and mortality in COVID-19 infection; however, their observed impact on immune responses to COVID-19 vaccination is mixed.

Our aim was to determine the association between sub-optimal Se, Cu and Zn status in patients with inflammatory bowel disease (IBD) on Spike Protein (SP) immunoglobulin (Ig)G levels post-vaccination against COVID-19 and prevalence of SARS CoV2 infection.

Aims & Methods: IBD patients and healthy controls (HC) were recruited prospectively from four hospitals. Quantitative antibody responses, Se, Cu, Zn, ferritin, selenoprotein P (SELENOP) and Glutathione peroxidase 3 (GPx3) concentrations were assessed following third COVID-19 vaccination. Infection with COVID-19 was defined by a positive IgG nucleocapsid antibody test (IgGNC).

Results: 165 participants were included in analysis (117 IBD patients and 47 HC). We observed no statistically significant difference in median Cu (p = 0.06), Zn (p = 0.44), Se (p = 0.78), GPx3 (p = 0.28) or ferritin concentrations (p = 0.51) dependent on previous COVID-19 infection.

Participants with a previous history of COVID-19 infection had statistically significant lower SELENOP concentrations (3.9 versus 4.34 mg/L, p = 0.05). Ferritin (p = 0.14), Se (p = 0.34)(Table 1), Zn (p = 0.45), GPx3 (p = 0.59) nor Cu concentrations (p = 0.14) showed no relationship with vaccine response.

We observed participants with lower SELENOP concentrations (<3 mg/L) had significantly lower anti-SP IgG levels (5,250 versus 11,385 AU/ml, p = 0.05), which appears to be driven by the differences in patients with IBD (5,003 versus 8,190 AU/ml, p = 0.08) (Table 1).

	Selenium level (<65 ug/L)	Selenium level (>65 ug/L)	P value
Total	6,378 (2,989 – 28,904) (n = 41)	11,021 (5,003 – 28,710) (n = 123)	0.34
HC	15,617 (8,722 – 34,896) (n=9)	20,569 (10,571 – 31,890) (n = 38)	0.66
IBD	5,512 (1,946 -28,390) (n=32)	8,190 (3,675 – 21,953) (n=85)	0.42
	SelenoP (< 3 mg/L)	SelenoP (> 3 mg/L)	P value
Total	5,250 (1,876 – 18,151) (n=25)	11,385 (5,428 – 29,120) (n=140)	0.03
HC	26,702 (17,929 - _) (n=2)	18,363 (10,018 – 31,694) (n=45)	0.57
IBD	5,003 (1,797 – 14,893) (n=23)	8,190 (3,616 – 26,023) (n=95)	0.08

Table 1.

Conclusion: Lower SELENOP concentrations are associated with previous SARS CoV-2 infection and decreased anti-SP IgG levels in response to COVID-19 vaccination. The impact of SELENOP concentrations on COVID-19 infection and vaccine response requires further validation and investigation in prospective studies to better understand the mechanisms of attenuated response in patients with IBD.

Disclosure: Nothing to disclose.

Contact E-Mail Address: dr.dancarter@gmail.com

Introduction: Crohn's disease (CD) is a chronic inflammatory bowel disease that is characterized by periods of active inflammation followed by periods of remission. Current Methods for defining Crohn's disease activity are limited by various factors including low specificity, bias, invasiveness, high costs, radiation exposure and patient preference. Therefore, an easy, noninvasive, inexpensive, user-friendly, and repeatable method for the assessment of disease activity is warranted. Abnormal body temperature is a natural indicator of illness. Infrared thermography (IRT) can map body surface temperature remotely.

With the advent of modern infrared cameras, data acquisition, and processing techniques, it is now possible to have real-time high-resolution thermographic images. Inflamed bowel loops are hyper-vascular and hyperemic, as detected by high doppler signs of intestinal ultrasound and bowel wall contrast enhancement in MRE, and therefore can be detected using IRT.

Aims & Methods: Our aim was to examine thermal imaging using IRT as a noninvasive tool for detecting bowel wall inflammation and disease activity in Crohn's disease patients.

The design of the study was prospective non -interventional. Consecutive adult CD patients referred for an intestinal ultrasound (IUS) exam were included, and adult healthy volunteers were recruited from the general population. Thermal images were captured using a FLIR ONE thermal camera device (FLIR Systems, Inc. Wilsonville, OR, USA) that connects directly to smartphones and utilizes a frame rate frequency of 8.7 Hz, an object temperature range of -20°C to 120°C and thermal sensitivity of 100 mK . Disease activity was defined using IUS. Thermal images of the study population were processed and compared to the results of IUS in all participants. Our novel thermal image processing algorithms extracted texture and shape features of temperature distribution across the skin covering the region of interest (ROI).

Results: The study cohort included 147 CD patients and 14 healthy volunteers. Using IUS, disease activity was found in 100 CD patients (68%). All 14 healthy volunteers had a normal IUS. The average abdominal temperature measured in the Crohn's patients (both active and inactive) was significantly higher than that of the healthy volunteers ($30.4^0 \pm 2.9^0$ C vs. $28^0 \pm 2.9^0$ C, p=0.0032).

The average abdominal temperature measured in the Crohn's group with the active disease was also found to be significantly higher than that of the healthy volunteers (30.4±2.99 C vs. $28^0 \pm 2.9^0$ C, p=0.0035). To differentiate between active CD and CD in remission, a new parameter was defined

and extracted: the fractal dimension of gradient magnitude (FDGM). The mean FDGM was significantly higher in patients with active disease than in patients with normal IUS (1.66 vs 1.63, p=0.045).

Conclusion: We describe a novel easy-to-use tool for monitoring disease activity in CD. This new method can potentially be used by patients at home as well as an office-based exam that allows precise disease follow-up and disease activity monitoring.

Introduction: Ulcerative colitis (UC) is often complicated by Cytomegalovirus (CMV) colitis. The importance of CMV infection for the outcome of UC is still ill-defined. Common practice consists of obtaining colonic biopsies to search for CMV in patients with UC flares and treat infections with ganciclovir.

Aims & Methods: The aim of the present study is to describe the characteristics and management of patients with UC and concomitant CMV infection. For this purpose, we conducted a retrospective data collection from 2 Greek hospitals for the years 2017-2023.

The primary endpoint was defined as the need for colectomy in the first year after CMV infection diagnosis. The statistical program SPSS-23 was used for the analysis.

Results: In total, 47 cases of CMV infection in 37 patients with UC were reported as 7 patients experienced CMV recurrence. Most cases were observed in men (68%) with mean age of 47.5 years (SD 18.2), median UC duration 3 years (IQR 1-8) and Montreal classification E2 in 31.9% and E3 68.1% occasions.

The diagnosis was established by PCR in colonic biopsies in 46.8% cases, by immunohistochemistry in another 46.8% and solely by detection of inclusion bodies in 6.4%. At the time of diagnosis of CMV infection 7 (14.9%) cases were receiving combination therapy with a biologic agent and an immunomodulator, 20 (42.6%) monotherapy with a biologic agent, and 1 (2.1%) monotherapy with an immunomodulator. Nineteen patients (40.4%) were not on immunomodulatory therapy.

Most patients (22, 46.8%) received ganciclovir and concomitant corticosteroids, while 4 (8.5%) received infliximab, corticosteroids and ganciclovir and 2 (4.3%) ustekinumab, corticosteroids and ganciclovir. One case required treatment with Foscarnet due to CMV resistance to ganciclovir, and 18 received monotherapy with ganciclovir.

Regarding maintenance treatment in patients who did not require immediate colectomy, 18 (38.3%) received anti-TNF, 6 (12.7%) ustekinumab, 4 (8.5%) vedolizumab, 3 (6.4%) tofacitinib and 1 (2.1%) risankizumab. Colectomy rate in the first year after CMV infection was 21.3% with 4 patients undergoing surgery during initial hospitalization. In univariate logistic regression age >54 years (*P*=0.025), disease duration >6.5 years (*P*=0.035), serum albumin <3.8 mg/dl (*P*=0.026), UC PRO bowel movement >2 (*P*=0.016) and vedolizumab (*P*=0.035) as treatment at diagnosis were associated with a higher probability of colectomy in the first year.

Accordingly, in multivariate logistic regression UC PRO bowel movement >2 (*P*=0.041) remained a statistically significant factor for colectomy while a tendency remained for albumin <3.8mg/dl (*P*=0.082).

Conclusion: CMV infection is more common in patients with ulcerative pancolitis under immunomodulatory treatment and should be diagnosed via a combination of immunohistochemistry and PCR in biopsies. Patients with prominent diarrhea [UC PRO bowel movement >2] may be particularly prone to colectomy.

Introduction: In the "treat-to-target" era, the development of non-invasive markers to assess endoscopic healing in ulcerative colitis (UC) is essential. Fecal calprotectin (FC) and intestinal ultrasound (IUS) are alternatives to colonoscopy to assess UC activity. The objective of this study was to evaluate the performance of IUS and FC to assess endoscopic mucosal healing in UC patient.

Aims & Methods: All consecutive patients between January 2021 and August 2022 with UC who underwent (1) a complete colonoscopy (2) an intestinal ultrasound and/or (3) a fecal calprotectin (4) within 4 weeks were included in a prospective cohort. Bowel wall thickness (BWT) and color doppler signal (CDS) were assessed on each segment. Endoscopic mucosal healing was defined by a MAYO score of 0-1.

Results: A total of 57 patients were included, 57.9% had endoscopic healing (22/57 MAYO 0 and 11/57 MAYO 1). Thirty-two (56.1%) were female, the median age and disease duration were respectively 43 years (IQR, 30-58) and 29 years (IQR, 18-39). Respectively 16 (16/57, 28.1%) and 41 (41/57, 71.9%) patients had BWT < 3 mm and an absence of Doppler signal. The sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of BWT < 3 mm to predict endoscopic mucosal healing were 37%, 77%, 72% and 44%. The association of the absence of CDS with normal BWT did not modify these performances. The same values for fecal calprotectin < 150 µg/g were respectively 81%, 78%, 84% and 74%. The association of a fecal calprotectin < 150 µg/g, with a BWT < 3mm and the absence of Doppler signal increased the specificity and the PPV (Se 33%, Sp 94%, PPV 89%, VPN 48%). The same values were found for patients classified as MAYO 0 or MAYO 0-1 .

Conclusion: The combination of intestinal ultrasound and fecal calprotectin is effective to identify endoscopic mucosal healing in UC. A stricter definition of ultrasound healing could improve the performance of this tool.

Disclosure: Nothing to disclose.

Introduction: Endoscopy is still the gold-standard to assess disease activity in Crohn's disease (CD). Its invasiveness, acceptability and cost limit its use in the era of tight control and treat-to-target. Fecal calprotectin and intestinal ultrasound (IUS) are non-invasive alternatives to colonoscopy to assess disease activity.

The objective of this study was to evaluate the performance of IUS and fecal calprotectin to assess mucosal healing in CD.

Aims & Methods: All consecutive CD patients who underwent colonoscopy for mucosal healing assessment and IUS and/or calprotectin within 4 weeks between September 2019 and April 2022 were included in a prospective cohort. Bowel wall thickness (BWT) and color doppler signal (CDS) were assessed on each segment. Endoscopic mucosal healing was defined by a CDEIS score < 3.

Results: A total of 153 patients were included, of whom 122 had endoscopic mucosal healing. Eighty-two (53.6%) were female, the median age and disease duration were respectively 36 years (IQR, 28-46) and 10 years (IQR, 4-19). Respectively 56 (56/120, 46.7%) and 93 (93/120, 77.5%) patients presented a BWT < 3 mm and an absence of CDS. The sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of BWT < 3 mm to predict endoscopic mucosal healing were 56%, 88%, 95% and 36% (patients misclassified as endoscopic mucosal healing 2.5%). The association of an absent of CDS with a normal BWT did not modify the performances. For a calprotectin < 250 µg/g , The Se, Sp, PPV and NPV were respectively 91%, 63%, 90% and 67% for (patients misclassified 8%). The association of a calprotectin < 250 µg/g, with a BWT < 3 mm and the absence of CDS increased the specificity and the PPV (Se 58%, Sp 95%, PPV 97%, VPN 43%, patients misclassified 1%).

Conclusion: Ultrasound is an efficient non-invasive tool to identify patients with Crohn's disease who have achieved endoscopic mucosal healing.

Disclosure: Nothing to disclose.

Introduction: Crohn's disease (CD) is associated with disability by affecting physical and emotional well-being, and by altering social interactions. In the era of treat to target, endoscopic remission has become the therapeutic target to prevent parietal destruction and disability. A deeper remission such as transmural healing would reduce long-term complications related to CD. The impact of transmural healing on disability is currently unknown.

Aims & Methods: We conducted a monocentric cross-sectional study between September 2019 and January 2022. Patients followed for CD in endoscopic remission (CDEIS <4) who underwent within < 4 weeks an intestinal ultrasound (IUS) and a disability assessment by an IBD-disk were consecutively included. Four groups were considered: (A) transmural healing defined by the combination of complete endoscopic healing (CDEIS=0) and ultrasound healing (bowel wall thickness (BWT) less than 3 mm), (B) complete endoscopic healing, (C) ultrasound healing and (D) no healing. Moderate to severe disability was defined as an overall score ≥ 40.

Results: A total of 85 patients were included. Forty-four (51.7%) were female, the median age and disease duration were respectively 38 years (interquartile range [IQR], 33-44) and 12.0 years (IQR, 5-20). There was no difference between the four groups in terms of age, sex, BMI, smoking status, disease location or phenotype or number of biologics failure. The median global IBD-Disk score was 25 (IQR, 9-41) and 24 patients (28.2%) had moderate to severe disability. Transmural healing (group A) was observed in 40 patients (47.1%). Moderate to severe disability was identified in 17.5% (7/40) of patients with transmural healing, 25% (4/16) with endoscopic healing, 44.4% (8/18) with ultrasound healing and 45.4 % (5/11) without healing. In univariate analysis, transmural healing reduced the risk of severe disability (group C vs A OR = 3.77, 95% CI [1.10, 13.45], p = 0.035), group D vs A OR = 3 .75, 95% CI [0.91, 17.12], p=0.063). There was no difference in terms of severe disability between patients with transmural healing and complete endoscopic healing (group B versus A OR = 1.57 95% CI [0.36, 6.23], p = 0.525)

Conclusion: Transmural healing did not provide any benefit in terms of disability compared to complete endoscopic healing. Mucosal healing therefore remains the objective to be achieved in order to reduce the risk of short-term disability.

THE BURDEN OF BOWEL URGENCY IN ULCERATIVE COLITIS: A FRENCH MULTICENTRIC REAL-LIFE STUDY (THEFAR)

M. Fumery[1], C. Robert[2], I. Jamonneau[2]
[1]Amiens University Hospital, Gastroenterology, Amiens, France, [2]Eli Lilly and Company, Indianapolis, United States

Contact E-Mail Address: mathurinf@hotmail.fr

Introduction: Bowel urgency (BU) is the sudden or immediate need to have a bowel movement. Although it is a common symptom in ulcerative colitis (UC), its burden is poorly known. We aimed to assess the overall burden of UC patients with BU.

Aims & Methods: The THEFAR study is a non-interventional, cross-sectional and multicenter study carried out in France between July and December 2022 including adult patients with UC treated with biologics/targeted-synthetic drugs. Clinical and therapeutic management data were collected by gastroenterologists using a e-CRF. Quality of life, disability and work impairment (WPAI:UC) were collected using patient-self completion questionnaires. BU was defined as a UNRS (0-10 Urgency Numeric Rating Scale) >1, BU remission as a URNS ≤1 and incontinence as a Wexner score ≥5. Descriptive statistics and bivariate analyses were performed. Continuous variables were summarized with mean values and SDs using the Student's t-test or Wilcoxon test. Categorical variables were expressed as proportions and compared using the Pearson's Chi-Squared test or Fischer's exact test.

Results: Of the 293 patients enrolled at 41 sites, the median (IQR) age was 42.0 (31.0-55.0) years with a median (IQR) disease duration of 6.0 (3.0-11.0) years. 64.2% were employed. Respectively, 45 (15,4%), 117 (39.9%) and 131 (44.7%) had proctitis, left-side colitis and pancolitis. 38.9% had active

disease (partial Mayo score ≥2) and 53.6% experienced flares over the past year. Overall, 144 (49.1%) of patients were treated with TNF-inhibitors, 99 (33.8%) with vedolizumab, 35 (11.9%) with ustekinumab, and 13 (4.4%) with tofacitinib with a median treatment duration of 1.0 year (0.0 - 3.0). Of the 291 patients who answered patient-self completion questionnaires, 57.0% had BU [median (IQR) UNRS: 2 (0.0-6.0)] and 78.3% had fecal incontinence [median (IQR) Wexner score: 8.0 (5.0-11.0)] with 14.7% wearing pads at least once a month. Overall, half of patients (52.3%) had both BU and fecal incontinence. A significantly higher proportion of patients had active disease with BU (57.2%) compared to those with BU remission (15.2%) (p<0.0001). Patients with BU had twice more months flaring over the past year (2.3 vs 1.0 month, p<0.0001) and a significantly higher proportion of patients with BU (45.8% vs 14.4%, p<0.0001) received steroids over the past year. Rates of BU were similar regardless of disease location (p=0.74), UC treatment (all UC treatments p>0.05) or line of therapy (p=0.27). Median (IQR) Wexner score was almost twice higher in patients with BU [10.0 (8.0-13.0) vs 6.0 (0.0-8.0), p<0.0001]. QoL was significantly impacted in patients with BU with lower mean (SD) EQ-5D-5L utility [0.846 (0.186) vs 0.943 (0.099), p<0.0001] and Visual Analogue Scale (VAS) scores [66.2 (18.2) vs 82.1 (14.5), p<0.0001]. There was a significantly higher proportion of patients with moderate to severe disability (IBD-DISK score ≥40) in patients with BU (53.7% vs 16.9%, p<0.0001) and BU was significantly associated with the IBD-DISK (r=0.52447, p<0.0001). Mean (SD) absenteeism [11.5% (25.4) vs 3.9% (12.5), p=0.0013], overall work impairment [35.7% (29.4) vs 11.3% (18.9), p<0.0001] and activity impairment [33.0% (27.0) vs 7.9% (13.7), p<0.0001] were significantly higher in patients with BU.

Conclusion: Despite advances in UC therapies, more than one in two patients treated with biologics/targeted-synthetic drugs experience BU. Patients with BU have a high symptom burden, disability and impaired quality of life and work productivity. These findings highlight that the control of BU remains an unmet medical need in UC patients.

Introduction: Small bowel fibrostenotic strictures are common in patients with Crohn's disease (CD). No global consensus recommendations on definitions, diagnosis and clinical management are available.

Aims & Methods: Several systematic reviews followed by a RAND/University of California Los Angeles appropriateness study on the definitions, diagnosis and clinical management of fibrostenosing CD in clinical practice were performed. A panel of 27 global experts and a patient representative were convened. They assessed a total of 152 candidate items. The items were subsequently evaluated for appropriateness.

Results: No accurate predictive biomarkers are available for naïve or anastomotic fibrostenosing strictures. Accurate diagnosis of fibrostenosing CD requires cross-sectional imaging which should evaluate bowel wall thickness, luminal narrowing and prestenotic dilatation. A potential inflammatory component should be assessed. Abdominal cross-sectional imaging was considered necessary prior to any treatment decision. The panel proposed an approach to medical, endoscopic, and surgical therapies. Technical characteristics for endoscopic balloon dilation and follow up strategies after successful dilation therapy were identified. Appropriateness, types and performance of different surgical approaches in various settings were evaluated.

Conclusion: This global consensus provides clinical guidance for the diagnostic and therapeutic management of patients with fibrostenotic CD.

Disclosure: Nothing to disclose.

ARE RECTAL OR RECTOSIGMOID ENDOSCOPY SUFFICIENT TO ASSESS COMPLETE ENDOSCOPIC OR HISTOLOGICAL HEALING IN ULCERATIVE COLITIS: A CROSS-SECTIONAL STUDY

C. Yzet[1], C. Moreau[1], E. Meudjo[1], C. Robert[1], F. Brazier[1], A. Michaud[2], M. Fumery[1]

[1]Amiens University Hospital, Gastroenterology, Amiens, France, [2]Amiens University Hospital, Biostatistics, Amiens, France

Contact E-Mail Address: clara.yzet@gmail.com

Introduction: At the time of treat to target, endoscopic healing is the goal to achieve in ulcerative colitis (UC). Colonoscopy (CO), rectosigmoidoscopy (RS) or rectoscopy can be performed to assess endoscopic healing. The objective of this study was to compare the performance of rectosigmoidoscopy with colonoscopy to predict endoscopic healing (EH) and histological healing.

Aims & Methods: This is a monocentric, prospective cohort of UC patients. All UC patients with a total colonoscopy were included between January 2021 and January 2023. Endoscopic and histological activity were measured using the MAYO endoscopic scores on each colonic segment and the Nancy Score, respectively. The correlation between RS or rectoscopy alone and CO in terms of endoscopic and histological mucosal healing was assessed using Cohen's kappa coefficient.

The study population was calculated according to the following assumptions: (1) absence of rectosigmoidoscopy lesions if absence of total colonoscopy lesions (0%), (2) 10% of lesions not seen in RS, (3) expected difference of 10% between CT and RS. 80 patients had to be included to demonstrate a significant difference in terms of EH between RS and CT with a bilateral alpha risk of 5% and a power of 81%.

Results: 80 patients were included. 34 patients were MAYO 0 in RS and CO, 44 were not healed in RS and CO.. The correlation between the two exams was almost perfect with an index κ of 0.949 (p=0) for MAYO 0 (2 patients misclassified), and κ of 0.945 (p=0) for MAYO 0-1. The correlation between histological healing in RS and CO was almost perfect (κ=0.877, p<0.001). Additionally, the correlation between rectoscopy and CT for the evaluation of mucosal healing MAYO 0 and histological healing was almost perfect (κ=0.826 (p < 0.001) and κ=0.8 (p < 0.001), respectively.

Conclusion: RS is sufficient in UC to assess both endoscopic mucosal healing (whether defined by a Mayo score of 0 or 1) and histological healing. With a false negative rate < 10%, rectoscopy could be a less invasive exam to assess healing in UC.

Disclosure: Nothing to disclose.

Contact E-Mail Address: dominik.rex@gmail.com

Introduction: Many CD patients experience clinically "silent" disease with active inflammation leading to complications and disability. Invasive and resource consuming procedures such as endoscopy, MR enterography and CT imaging have long been the mainstay of monitoring disease activity in CD. Intestinal ultrasound (IUS) is becoming an established non-invasive alternative for everyday point-of-care management of patients with CD. The most important ultrasound parameters associated with active CD include bowel wall thickness (BWT), bowel wall stratification (BWS), color-doppler signal (CDS) and the presence of mesenteric fat (i-fat). Several ultrasound scoring systems using some of these parameteres have been proposed in order to facilitate monitoring of CD patients as well as standardise reporting of intestinal ultrasound findings.

Aims & Methods: The study aim was to compare performance of IBUS-SAS (International Bowel Ultrasound Segmental Activity Score), BUSS (Bowel Ultrasound Score), Simple-US (Simple Ultrasound Score), and SUS-CD (Simple Ultrasound score for Crohn's disease) in detecting disease activity in CD patients. A single center retrospective analysis of stored IUS images and corresponding CD patient charts with endoscopy findings at the time of the ultrasound has been performed. Endoscopic activity was defined as SES-CD>3. After assessment of normal distribution using Kolmogorov-Smirnov and Shapiro-Wilk tests continuous variables were reported as median and interquartile ranges (IQR) or as mean ± standard deviation, whereas categorical variables were reported as frequencies with percentages. ROC curve analyses were conducted in order to determine AUCs and predictive cut-off value scores, with endoscopy serving as the reference standard. The Z statistic and Hanley & McNeil methodology were used to compare ROC curves. P values less than 0.05 were considered statistically significant.

Results: A total of 83 patients were included, 45.8% female with a mean age 41 years and median disease duration of 8 years. Endoscopic disease activity was present in 55 (66.3%) patients. Isolated ileal disease was present in 48.2%. Stricturing and penetrating disease phenotype was present in 41% and 39.8% of patients respectively. The results for ROC analyses, cut-off values for remission, sensitivity and specificity of four different IUS scores are shown in table 1. Statistically significant differences among scores haven't been observed.

	AUC (95% CI)	Cut-off	Sensitivity %	Specificity%
IBUS-SAS	0.736 (0.62-0.85)	24	76,5	56
Simple-US	0.724 (0.61-0.84)	4,25	86,8	52
BUSS	0.718 (0.6-0.84)	4,1	81,5	60,7
SUS-CD	0.721 (0.61-0.84)	1,5	88,7	40

Table 1. Comparison of intestinal ultrasound scores for detecting active Crohn's disease

Conclusion: All IUS scores performed well for detecting CD endoscopic activity which shows IUS can reduce the number of endoscopies in the CD patient population without sacrificing accuracy. We found no significant difference in the sensitivity and specificity of different scores in out patient cohort, hence clinicans can rely on the IUS score they are comfortable with using. Our cut-off values are in line with published data further confirming method robustness.

ANTI-TNF MONITORING EXPERIENCE IN A 3RD LEVEL HOSPITAL IN LATIN AMERICA

M.E. Micheletti[1], M. Antoniska[1], J. Gonzalez[1], C. Eichhron[1], C. Weyerberg[1], A. Rocca[1], M. Contreras[1]

[1]Hospital ,Prof. Dr. Juan P. Garrahan', IBD Group, Buenos Aires, Argentina

Contact E-Mail Address: maeugeniamch@gmail.com

Introduction: Establishing the response to anti-TNF agents is a challenge in developing countries, including Latin America where reports on therapeutic monitoring are limited and empirical optimization is widely used.

Aims & Methods: To describe serum levels of IFX and anti-TNF antibodies (ADA) in a cohort of pediatrics patients from a high complexity hospital and their usefulness in clinical practice. Prospective, descriptive and observational study at Garrahan Hospital from July 2022 to February 2023 that included patients with IBD under treatment with IFX. The study population was divided into 2 groups: Group A patients in induction (determinations in weeks 12-15) and Group B patients in maintenance (determinations immediately prior to the next infusion of the drug). IFX blood levels were estimated as adequate between 3-7 ug/ml and ADA >10 AU/ml were considered high. Response and clinical remission were evaluated using activity scores (PCDAI-PUCAI).

Results: 67 determinations were made in 58 patients, 25 in Group A and 33 in Group B. The characteristics of each group are shown in Table 1. Variables related to the accelerated clearance of the drug were analyzed. Regarding sex, C-reactive protein, Albumin, early biological no significant differences were found with respect to the optimal levels. Patients with BMI<18.5 had suboptimal drug levels compared to eutrophic patients (p:s=0.01). Also non-VEOIBD patients, had significantly higher optimal levels compared to VEOIBD (p:s=0.01). In group A, median serum IFX level was 14 ug/ml (IQR 0-45) and 4 ug/ml (IQR 0.6-45) in group B. Median antibodies levels were 1 AU/ml (IQR 0-32) in group A and 98 AU/ml (IQR 0-252) in group B. No significant differences in levels were found between monotherapy and combined treatment in both groups (p:ns=0.48, p:ns=0.33 respectively); neither were differences found in ADA levels in both groups (p:ns=0.59; p:ns=0.16, respectively).Clinical response was 60%, with 12% achieving clinical remission. 28% were non-responders.

Analyzed by groups: In group A, loss of primary response was detected in 24%. 76% were responders, and 26.3% had to optimize treatment due to partial response. In group B, 35.5% were responders, while loss of response was detected in 64.4%, 24.1% due to pharmacodynamic failure and 75.8% due to pharmacokinetics failure, of which 31.8% also showed immunological mechanism (ADA>10).

	Group A INDUCTION	B Group MAINTENANCE
Pacients / Determinations	25 / 25	33 /42
Sex (M / F)	12 (48%) / 13 (52%)	17 (51%) / 16 (48%)
Age (median)	12 (RIC 2-18)	12 (RIC 1-18)
Phenotype (CD / UC)	22 (88%) / 3 (12%)	25 (81%) / 8 (18%)
VEOIBD	14 (56%)	17 (51%)
BMI body mass index (median)	17.1 (RIC 13.4-26.3)	16.4 (RIC 12.4-26.1)
Biosimilar	14 (56%)	11 (24%)
Optimized dose	12 (48%)	26 (57%)
Immunomodulators	13 (52%)	28 (62%)

Conclusion: The optimal timing for the use of monitoring in anti-TNF treatment of IBD is still debated, existing data on target levels are contradictory. Although the proactive strategy is emerging as a tool that shows a clear benefit, the target values for each phenotype (UC versus CD) and different periods (induction versus remission) are not clearly established, especially in pediatrics.

The treatment should be evaluated individually, prioritizing the benefit of monitoring over costs. Assuming empirically the lack of response implies opting for alternative treatments, which is a challenge when the options in our country are currently limited.

CORRELATION OF CALPROTECTIN AND BOWEL ULTRASOUND IN INFLAMMATORY BOWEL DISEASE (IBD)

T. Schierhoelter[1], C. Thon[1], R. Rosania[1], N. Hipler[1], A. Afifi[1], V. Keitel-Anselmino[1], U. von Arnim[1], A. Link[1]

[1]Otto-von-Guericke University, Department of Gastroenterology, Hepatology and Infectious Diseases, Magdeburg, Germany

Contact E-Mail Address: alinkmail@gmail.com

Introduction: One of the challenges in the management of inflammatory bowel disease (IBD) is the noninvasive and accurate assessment of disease activity and the prediction of treatment response and prognosis. Colonoscopy is limited due to its invasiveness; therefore, noninvasive methods are of high clinical relevance. Fecal calprotectin (FC), a surrogate marker for neutrophils, is a clinically relevant biomarker that correlates with intestinal inflammatory activity. Bowel ultrasound (B-US) is an established method that can be performed at any time and at low cost.

Aims & Methods: The aim of this study was to evaluate the correlation between B-US and FC in terms of inflammatory activity and disease severity in IBD patients. Patients were selected from a prospective study to compare FC and B-US. A total of 320 patients, including (n=188) with Crohn's disease (CD), (n=114) with ulcerative colitis (UC), and (n=18) control patients were included for further analysis. FC measurements were performed using the ELISA kit. The inflammatory activity was classified according to the FC cut-off (0: <100, 1: 100-200, 2: 200-400, 3: >400 in mg/g). The evaluation in B-US was based on the thickness of the intestinal wall (none: <2.9, mild: 3.0-4.9, moderate to severe: >5).

Results: Based on FC, patients were divided into inflammatory activity (n=211) and remission (n=109) groups. When comparing B-US and FC, there was a significant correlation regarding inflammatory activity (r=0.59, p<0.001). B-US in MC showed a better correlation (r=0.63, p<0.001) than

CU (r=0.45, p<0.001) with FC. Patients with unremarkable B-US had a median FC of 57.2 mg/g (95%CI: 41.5-94.1) compared to marked inflammation in B-US median 999 mg/g (95%CI: 751.8-1517). Among patients with pathological FC values (cut-off >100 mg/g), 75.4% had sonographic evidence of inflammatory activity. Localization of inflammation in the rectum was associated with lower diagnostic accuracy. Compared to FC, B-US showed a sensitivity of 75.4%, a specificity of 78.9% and a positive predictive value of 87.4%.

Conclusion: B-US shows good diagnostic accuracy compared to FC in assessing inflammatory activity in IBD patients. Both methods can be considered as complementary non-invasive diagnostic tools in IBD.

PP0693

CLINICAL CHARACTERISTICS AND RISK FACTORS OF INFLAMMATORY BOWEL DISEASE WITH METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE

J. Tian[1]
[1]*Nanjing Medical University, Nanjing, China*

Contact E-Mail Address: tjh0309@126.com

Introduction: Metabolic dysfunction-associated fatty liver disease(MAFLD) is one of the most common hepatic comorbidities of inflammatory bowel disease(IBD). The prevalence of MAFLD in IBD patients is higher than that in healthy controls.The purpose of this study was to to analyze the clinical characteristics and differences of patients with inflammatory bowel disease and non-inflammatory bowel disease complicated with MAFLD in China, and to explore the risk factors of patients with IBD complicated with MAFLD, so as to provide evidence for optimizing the prevention and management of IBD patients.

Aims & Methods: 1. Clinical data collection of the included population: 1.1Clinical data of IBD patients admitted to the Gastroenterology Department of the First Affiliated Hospital of Nanjing Medical University from January 2015 to March 2022 were collected. The control group was non-IBD patients from the health management center of our hospital. According to age, gender, BMI and type 2 diabetes, the IBD group and non-IBD group were 1:1 matched. To study the clinical characteristics of IBD with MAFLD.

1.2 The collected IBD group, excluding patients with infectious diseases (including chronic viral hepatitis, tuberculosis infection, Clostridium difficile infection, cytomegalovirus infection, Epstein-Barr virus infection and intestinal fungal infection), were divided into IBD with MAFLD group and IBD without MAFLD group according to whether they met the diagnostic criteria of MAFLD. To study the risk factors of inflammatory bowel disease associated with metabolic fatty liver disease.

2. Diagnostic criteria for IBD and MAFLD:

2.1 The diagnostic criteria for CD and UC in Consensus Opinions on the Diagnosis and Treatment of Inflammatory Bowel Disease (2018).

2.2 The diagnostic criteria for MAFLD refer to Expert Consensus Opinion on Metabolically Associated Fatty Liver Disease (2020). Hepatic steatosis was diagnosed by CT imaging.

3. Statistical methods: SPSS 23.0 was used for statistical analysis, and P<0.05 was considered statistically significant.

Results: 1. Among the 260 patients with IBD, 57 cases had MAFLD, with the prevalence rate of 21.9%, and the prevalence rate of 8.4% (23/274) in the non-IBD group(P < 0.001).

2. The clinical characteristics of patients in IBD with MAFLD group were compared with those in non-IBD with MAFLD group. The prevalence of hypertension, NLR and C-reactive protein levels were higher, while there was no significant difference in blood lipid levels.

3. After the exclusion of infectious diseases, 222 patients with IBD were analyzed to compare the clinical characteristics and risk factors of IBD with MAFLD. It was found that BMI, prevalence of hypertension, IBD duration, white blood cell count, neutrophil count, neutrophil-lymphocyte ratio, C-reactive protein and triglyceride in IBD patients with MAFLD were higher than those in IBD patients without MAFLD (P< 0.05).

4. Logistic regression analysis showed that BMI, hypertension, IBD duration, and white blood cell count were independent risk factors for MAFLD in IBD patients.

Conclusion: The prevalence of MAFLD in IBD patients is significantly higher than that in the non-IBD population when age, sex, T2D and BMI status are matched. Compared with non-IBD patients with MAFLD, IBD patients with MAFLD had a higher prevalence of hypertension, and higher neutrophil lymphocyte ratio, C-reactive protein. Priority screening and monitoring should be considered for IBDs with risk factors for MAFLD development, including high BMI, hypertension, longer IBD duration, and higher white blood cell levels.

TELEMEDICINE IN THE MANAGEMENT OF IBD PATIENTS: A SAFE AND FEASIBILE APPROACH WITH DEDICATED TOOLS

P. Melatti[1], M. Melodia[1], I.A. Salerno[1], M. Saladino[1], L. Carrozza[1], S. Muscarella[1], L.M. Amato[1], F.M. Di Giorgio[1], D. Brinch[1], C. Celsa[1], C. Camma[1], M. Cappello[1]
[1]*University of Palermo, Gastroenterology and Hepatology Section, Promise, Palermo, Italy*

Contact E-Mail Address: marica.cappello61@gmail.com

Introduction: Telemedicine could be an effective tool in the management of chronic diseases such as IBD, by allowing a two-way, real-time interactive communication between the patient and the physician at the distant site.

The Covid 19 outbreak and the social distancing rules led the clinicians to seek for a remote monitoring approach, capable of guaranteeing an adequate follow-up of domiciliary patients.

Aims & Methods: The aim of our study was to develop a telemedicine system suitable for IBD patients, and to verify the effectiveness of the system comparing two different groups of patients, whose follow up was done via

the telemedicine platform or via standard care, respectively, in the IBD clinic of our tertiary referral center.

A pre-existing platform MyHospitalHub Pro used for the remote monitoring of Covid19 patients was adapted in order to include suited parameters for IBD patients. Young patients, with an adequate educational level, who lived far from our center and with a mild disease activity or in remission were asked for participating in the study. One group was enrolled in the telemedicine group. The control group included patients with similar characteristics who refused the remote approach. . Furthermore, we evaluated disease activity using the validated questionnaire MIAH (Monitor IBD At Home questionnaire), and the satisfaction index of patients followed by telemedicine using the TSQM (Treatment Satisfaction Questionnaire for Medication) at baseline and after six months

Results: Seventy-six patients were enrolled in the study, 38 followed through telemedicine, and 38 followed through standard care. The two populations had the same characteristics at baseline: 71 % (54) had Crohn disease, 29 % (11) had ulcerative colitis; 55 % (21) were males, and 13% (5) were smokers. The MIAH score was significantly higher in the telemedicine group than in the standard care group at baseline (mean±DS 4.82±3.98 vs 1.82±2.24 p<0,001). No significantly differences were observed in both groups after six months. Moreover, the telemedicine group showed a significant improvement in MIAH score than the control group (mean difference -1.78 [IC95% da -2,92 a -0,65]; (p=0,003). As for the TSQM, 97% of the patients followed by telemedicine were satisfied and would be willing to carry out the visits in this modality. Looking at corticosteroid courses, emergency room access, and seek for medical advice, they were 5 (13%), 0, 8 (21%) in the telemedicine group, and 3 (7,9%), 1 (2,6%), 10 (26%) in the standard care group, respectively.

Conclusion: Our study confirms that telemedicine, using dedicated platforms and objective evaluation scores, is a valuable method to manage patients with IBD, especially those who have a mild disease. Its use could be implemented in clinical practice, since is a safe and feasible application well accepted by the patient. Moreover, it could lead to a reduction of indirect costs of treatment, an increased patient engagement, a reduction in the overcrowding of the IBD clinics, and a facilitation of early intervention for symptoms and signs of active inflammation.

Disclosure: Nothing to disclose.

CROHN'S DISEASE LIKE POUCH INFLAMMATION (CDLPI), IN ILEAL POUCH–ANAL ANASTOMOSIS (IPAA) FOR ULCERATIVE COLITIS (UC), IN A LATIN AMERICAN IBD REFERENCE CENTER

A.M. Sambuelli[1], E. Balaban[1], A. Gil[1], S. Negreira[1], S. Huernos[1], S. Goncalves[1], M.J. Rohwain[1], I. Candel[1], P. Tirado[1]

[1]Bonorino Udaondo Gastroenterology Hospital, IBD Section, Gastroenterology Department, Buenos Aires, Argentina

Contact E-Mail Address: alicia.sambuelli@gmail.com

Introduction: Restorative proctocolectomy with IPAA can be associated with diverse complications, acute pouchitis, chronic pouchitis (antibiotic dependent or refractory), and also Crohn's disease like pouch inflammation (CDLPI), a particularly worrying condition. The pathogenesis is unclear, probably multifactorial, and environment may play a role.

Aims & Methods: To describe clinical characteristics and outcomes of CDLPI (our main focus) in UC patients (pts) with colectomy and IPAA in a Latin American (LA) IBD reference Center. UC is reported more frequent in LA, but colon location reach half of CD casuistic in our hospital, other Argentina regions and Uruguay. Probably, this epidemiological feature could impact in our patient's evolution.Our hospital has a Coloproctology pioneer team of IPAA surgery in Argentine, and as Clinical IBD Service, we performed a revision in our electronic data base/Hospital records (included from 1990 to Dec. 2022, updated at this abstract time). Criteria to define CDLPI were adopted from Shen B, Clin. Gastroenterol hepatol 2008, 6:145-58. We studied the global prevalence of CDLPI and pts´s adverse outcomes in terms of: behavior complications, prevalence of extraintestinal manifestations (EIMs), treatment requirements, pouch failure, malignancy. To study behavior complications, we estimate by Kaplan Meier method cumulative probabilities of developing ¨typical¨ CDLPI complications as follow: 1- Penetrating (B3 behavior), 2- Perianal complications (PC), 3- Stricturing complication of Afferent limb (S-Aff-L). Also were studied for Kaplan Meier cumulative probabilities of CDLPI to receive biological treatment.

Results: Among 437 pts who underwent colectomy and IPAA for UC, who attended to our Clinical IBD Unit in mentioned period, we detect 46 cases with CDLPI features (prevalence 10.5%), male 27 (58.7%) female 19, mean age±SD at CDLPI presentation 33.8±13.8 yrs, median time (IQR) from IPAA: 1.34 (2.9) yrs, follow-up time 20.1 (10.9) yrs. B3 behavior was observed in 16 cases (34.8%), perianal complications (PC) -mainly complex- in 20 (43.5%). Cumulative probability at 1, 5, 10, 20 yrs to develop B3 pattern (%) were: 8.6, 20.0, 25.3, 34.1, and PC pattern:10.9, 28.6, 34.3, 34.3 respectively. Pouch vaginal, entero/pouch-cutaneous and pouch vesical fistulas were documented in 20%,11% and 4% of pts respectively. Aforementioned patterns were significantly more frequent and earlier than S-Aff-L complication (B2 behavior: observed in 9 (19.5%) pts; cumulative probabilities (%) at 10, 20, 25 yrs were 2.7, 11.7, 27.6, preceded several yrs before for prepouch ileitis (pattern B1) detected in 26 (56.52%) pts, often as initial diagnosis of CDLPI. Cuffitis in 13%. Different complications overlapped in 23.9% of pts. EIMs (%) 56.2%: (Articular 37.5%, Skin 10.9%, Aphtae (oral) 6.5%, Urologic 6.5%, Ophthalmologic 4.4%, Hepatic 3.4%). Arthritis, gangrenous pioderm, PSC,may implicate high burden. Pouch failure (permanent diversion or excision) was observed in 30% and 13% respectively, malignancy in 4.3%. Treatment modalities: frequent antibiotics, steroids (systemic or budesonide) mainly in S-Aff-L suboclusion (may require E.ballon dilatation), IMM tiopurines in 70%, Biologics in 67.4% (mainly Anti-TNFs, ≥2 biologics: 11%), with cumulative probabilities (%) at 1, 5,10, 20 yrs of: 2.2, 20.5, 25.8, 48.5.

Conclusion: CDLPI is a complication of colectomy with IPAA, with potentially severe outcomes. IPAA revolutionized UC surgery, but close multidisciplinary monitoring, and new research are required to detect and follow these patients, with the future hope of acting proactively.

Disclosure: no

A BIOMARKER OF EARLY MUCOSAL DESTRUCTION: NEUTROPHIL-MEDIATED TYPE IV COLLAGEN DEGRADATION IS ELEVATED IN PATIENTS WITH CROHN'S DISEASE AND ULCERATIVE COLITIS

M. Sorokina Alexdóttir[1], M. Pehrsson[1], M. Asser Karsdal[1], H. Grønbæk[2], L. Elberg Godskesen[3], A. Krag[4], J. Kjeldsen[3], J.H. Mortensen[1]

Contact E-Mail Address: mara@nordicbio.com

Introduction: Inflammatory bowel disease (IBD) is characterized by chronic inflammation due to an uncontrolled immune response orchestrated through, i.e. neutrophils. The basement membrane acts as a front-line defense promoting tissue integrity, where the α-3 chain of type IV collagen is solely expressed on the outermost layer of the mucosa. Detection of subclinical ulceration is crucial since early-stage IBD presents a unique window of opportunity for intervention, as the disease might become a self-sustaining process once deep inflammation becomes established. We therefore, wanted to develop a biomarker reflecting early tissue injury, aiding in the implementation of prompt treatment.

Aims & Methods: A competitive enzyme-linked immunosorbent assay quantifying a human neutrophil elastase (HNE) degraded fragment of type IV collagen α-3 chain was developed (C4A3-HNE). Dilution- and spiking recovery, inter- and intra-variability, and interference were evaluated. Acceptance criteria for technical validation were a recovery of 100% ±25 and an inter-intra variability of <15%. Commercial serum samples were purchased from ProteoGenex. Biological relevance was validated in an observational study from Odense University Hospital (OUH) and healthy controls. Groups were compared using Kruskal Wallis (Dunn's corrected).

Results: The technical validation of the C4A3-HNE assay demonstrated acceptable results for recovery, variation, and interference. Biological relevance was assessed in commercial IBD samples and healthy donors. C4A3-HNE was elevated in both CD and UC compared to healthy (p=0.001 and <0.0001)(AUC [95% CI]: 0.820 [0.669-0.971]; 0.875 [0.775-1.000]). The results were validated in an independent cohort of IBD patients (both p<0.0001). For UC, analysis showed that compared to patients in endoscopic remission, C4A3-HNE is elevated in patients with mild endoscopic activity, decreasing dose-dependently for moderate and severe disease (T1). Fecal calprotectin and CRP levels were also lower in IBD patients with high levels of C4A3-HNE (T1). With a cut-off value of 54.1 ng/ml, C4A3-HNE could significantly discriminate between mild and severe endoscopic disease (T1).

	Median conc. (ng/ml)	[IQR]	Patients (n)	
Remission	61.16	49.74, 65.52	10	
Mild	71.77	53.96, 79.17	18	
Moderate	56.07	39.21, 68.71	19	
Severe	40.52	25.65, 69.01	10	
	Low C4A3-HNE	High C4A3-HNE	Δ %	
CD: Fecal Calprotectin (µg/g)	721.8	365.7	67.7	
UC: Fecal Calprotectin (µg/g)	840.0	491.6	52.3	
CD: CRP (mg/L)	8.4	6.5	26.5	
UC: CRP (mg/L)	7.4	5.0	38.5	
	AUC [95% CI]	Cut-off value	Sens./Spec. (%)	OR
Remission vs. mild	0.68 [0.48–0.85]	68.8	61.1/90.0	14.1 (*) [1.7–166.6]
Mild vs. moderate	0.68 [0.51–0.83]	59.9	72.2/73.3	6.9 (*) [1.8–31.1]
Mild vs. severe	0.74 (*) [0.54–0.89]	54.1	77.8/70.0	6.4 (*) [1.2–33.5]

Conclusion: Our study demonstrates the biological and possible clinical relevance of the novel C4A3-HNE biomarker. The biomarker is elevated in patients with IBD compared with healthy, and high levels may reflect early mucosal damage in patients with UC.

Furthermore, inflammatory markers were lower in IBD patients with high levels of C4A3-HNE, pointing towards high levels being indicative of early disease. C4A3-HNE may provide early detection of mucosal damage or prediction of relapse; however, further studies are required to assess the clinical validity of this biomarker.

Contact E-Mail Address: doceredeepakc@yahoo.com

Introduction: Patients with ulcerative colitis (UC) and their treating physicians are currently looking beyond symptom resolution to achieve mucosal healing for a better long-term outcome. The assessment of this target requires invasive tests at several occasions that has an impact on the quality of life.

Aims & Methods: To evaluate the role of serum, fecal and urine biomarkers for predicting endoscopic healing, histological improvement and long-term outcomes after medical treatment of UC.

Patients with newly diagnosed acute UC or relapse of UC between September 2018 and February 2020 were included and followed for three years for relapse of symptoms. Disease activity was measured using clinical, Mayo Endoscopic Subscore (MES), and histological scores (Geboes score and Robarts Histological index). Biomarkers such as ESR, CRP, Fecal Calprotectin, Serum NGAL and 24-hour urine potassium were done at baseline and at clinical remission. The utility of biomarkers to predict endoscopic healing (MES ≤ 1), histological improvement (Geboes ≤ 3), and disease flare on follow up were analysed.

Parameter	Achieved endoscopic healing(n=36)			Achieved histological improvement(n=18)		
	Baseline	Clinical remission	P value	Baseline	Clinical remission	P value
Fecal calprotectin (µg/g)	612.57 (31.- 8249.2)	147.36 (10 – 4463)	0.01*	921.3 (79.4 – 8249.2)	66.26 (10.01 – 1345.2)	<0.001*
Serum NGAL (ng/ml)	35.4 (22.8 – 1077.8)	31.75 (19 – 682.6)	0.003*	36.04 (25.6 – 1077.8)	28.49 (19.08 – 682.6)	0.002*
24-Hour urine potassium (meq/day)	27 (6.6 -200)	36.8 (10-240)	0.002*	24.77 ± 12.05	47.47 ± 52.7	0.07#
	Endoscopic healing(n)			Histological improvement(n)		
	Yes	No	P value	Yes	No	P value
Flare	14	4	0.25$	4	14	0.02$
No flare	13	1		9	5	

*: Wilcoxon sign rank test, #: paired t test, $: chisquare test

Table.

Results: 40 patients (43 episodes of UC) with a mean age of 35 ± 10 years were studied. Majority of patients had moderate to severe disease activity by clinical score (88%), MES (93%) and histology (82%). There was a significant reduction in baseline serum and fecal biomarkers and a significant increase in 24-hour urine potassium at clinical remission and those with endoscopic healing while those with histological improvement had significant reduction in fecal and serum markers only. Patients without endoscopic healing or histological improvement didn't had significant changes in biomarkers.

Among patients achieving clinical remission, 83.7% (n= 36) had endoscopic healing and 41.8% (n=18) had histological improvement. 14 patients (35 %) had worsening of fecal calprotectin despite a clinical remission. A reduction in the baseline fecal calprotectin levels by 33.89% (AUC: 0.802, sensitivity: 0.72, specificity: 0.86) and 67.8% (AUC: 0.869, sensitivity: 0.83, specificity: 0.68) predicted endoscopic healing and histological improvement respectively.

A total of 32 patients completed the three year follow up and 54.5% (n=18) had at least one disease flare. Fewer patients with histological improvement (n=4; 12.5%) after treatment experienced flares compared to those with endoscopic healing (n=14; 77.7%). Although two-third with worsening fecal calprotectin achieved endoscopic healing on follow up, none had histological improvement and everyone had symptom relapse on follow up.

Conclusion: Our study confirmed that one-third to two-third decline in fecal calprotectin with treatment predicted endoscopic healing and histological improvement in UC. As the disease flares during follow up was better predicted by an improvement in histology, a two-third fall in baseline calprotectin may be a useful marker for better long-term outcomes in UC.

EFFECT OF VITAMIN D SUPPLEMENTATION ON VITAMIN D, ITS METABOLITES AND VITAMIN D BINDING PROTEIN IN INFLAMMATORY BOWEL DISEASE: DOES INFLAMMATION MATTER?

A. Aksan[1,2,3], J. Stötzel[2], L. Tessmer[2,4], O. Schröder[2,4], J. Stein[2,4,5]

[1]Justus-Liebig University Giessen, Institute of Nutritional Science, Giessen, Germany, [2]Interdisciplinary Crohn Colitis Centre Rhein-Main, Frankfurt am Main, Germany, [3]Immundiagnostik AG, Medical Affairs, Bensheim, Germany, [4]DGD Clinics Sachsenhausen, Gastroenterology and Clinical Nutrition, Frankfurt am Main, Germany, [5]Goethe University Frankfurt, Institute of Pharmaceutical Chemistry, Frankfurt am Main, Germany

Contact E-Mail Address: ayscak@gmail.com

Introduction: Vitamin D levels are associated with important clinical parameters and outcomes in patients with IBD. However, the complex interplay of inflammation with vitamin D (vitD) and its metabolites poses a vicious circle in which cause and effect are unclear. We previously showed that all vitD metabolites, including 1,25OH2D, 24,25OH2D, free and bioavailable 25OHD and VDBP, but not total 25OHD, were influenced by at least one inflammatory marker.

Aims & Methods: In this study, we aimed to assess effects of vitD supplementation on serum levels of vitD metabolites and VDBP in patients with IBD with and without inflammation. A comparative, cross-sectional retrospective study was conducted using medical records and routine samples of IBD patients and controls. Blood count, serum albumin, transferrin, ESR, hsCRP and faecal calprotectin (FC) concentrations were analysed. Inflammatory disease activity was defined as hsCRP ≥5mg/dL and/or FC ≥250µg/g. Serum total 25OHD and 24,25OH2D levels were measured using ImmuTube® VitD duo LC-MS/MS (Immundiagnostik AG, Bensheim, Germany). Concentrations of 1,25OH2D and VDBP were detected with direct competitive ELISA using the IDK® human VDBP immunoassay kit (Immundiagnostik AG). Free and bioavailable 25OHD were calculated according to Bikle et al. Subjects were treated with 20,000 IU cholecalciferol p.o. in different frequencies based on severity of vitD insufficiency/deficiency: Patients with 25OHD levels of 21-29ng/mL 1x/wk for 2 weeks; those with 25OHD levels 11-20ng/mL 2x/wk for 2 weeks; those with 25OHD levels ≤10ng/mL 3x/wk for 1 week and 2x/wk for 2 weeks. In each case, therapy was followed by 2 therapy-free weeks. Statistical data were collected in Microsoft Excel 2016 and analyzed with IBM SPSS Statistics 25, $p<0.05$ was taken to be statistically significant.

Results: Overall, 265 subjects were included, 68 in the control group (27m/41f; age range 18-65y; mean age (±SD) 42.9±15.6y) and 197 patients with IBD (96m/101f; 18-65y; 42.3±13.0y; 115 Crohn's disease, 82 ulcerative colitis). Inflammatory disease activity was seen in 96/197 (49%). No significant difference was found for season of blood sampling (with vs. without inflammation: $p=0.468$, IBD pats vs. controls: $p=0.613$; chi-square test for all results). As expected, vitD supplementation resulted in a significantly increased serum 25OHD, 24,25OH2D, free 25OHD and bioavailable 25OHD. Interestingly, vitD supplementation did not affect levels of VDBP or 1,25OH2D. After correlation coefficients were calculated, neither specific correlation nor statistical significance was observed between vitD parameters and ESR or FC. Also, no correlation was seen between hsCRP and serum 25OHD, 1,25OH2D, and 24,25OH2D regardless of vitD supplementation. However, for both supplemented ($r=0.481$, $p<0.001$) and non-supplemented groups ($r=0.421$, $p<0.001$), a significant moderate positive correlation was found for VDBP with hsCRP. Serum free 25OHD ($r=-0.496$, $p<0.001$; $r=-0.450$, $p<0.001$ respectively in supplemented and non-supplemented groups) and bioavailable 25OHD ($r=-0.532$, $p<0.001$; $r=-0.497$, $p<0.001$, respectively) showed a significant moderate negative correlation with hsCRP in both groups.

Conclusion: The vitD parameters VDBP, free vitD and 25OHD were primarily influenced by the presence of inflammation. The significant increase in VDBP observed in the presence of inflammation was uninfluenced by vitD supplementation. Since hsCRP and VDBP positively correlated, VDBP may have potential as a biomarker for inflammatory processes.

ALTERATIONS IN THE COURSE OF INFLAMMATORY BOWEL DISEASE FOLLOWING LIVER TRANSPLANTATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

A.R. Safarpour[1], M. Mehrabi[2], G.R. Sivandzadeh[3], S. Shojaei-Zarghani[4]
[1]Gastroenterohepatology Research Center, Gastroenterohepatology Research Center, Shiraz, Iran, [2]Department of e-Learning Planning in Medical Sciences, Shiraz University of Medical Sciences, Shiraz, Iran, [3]Gastroenterohepatology Research Center, Shiraz, Iran, [4]Colorectal Research Center, Shiraz, Iran

Contact E-Mail Address: safarpourar@gmail.com

Introduction: Inflammatory bowel disease (IBD) is a chronic relapsing autoimmune disorder affecting the gastrointestinal tract with two major types: ulcerative colitis (UC) and Crohn's disease (CD) (1). IBD is closely associated with primary sclerosing cholangitis (PSC) and some other hepatic disorders (2).

Despite emerging pharmacologic therapies, liver transplantation (LT) remains the only approved therapeutic strategy for PSC (3). Despite IBD remission being anticipated due to post-transplant immunosuppression maintenance therapy, IBD exacerbation is reported in some studies.

Estimates of both improvement and exacerbation of pre-existing IBD after LT vary widely across studies from 0% (8, 9) to 65% (4,5). Nevertheless, reliable estimates of exacerbation or remission of IBD severity following LT are critical for informing efforts to manage the condition.

Aims & Methods: This study aimed to systematically review and pool data regarding the alterations in the clinical course of inflammatory bowel disease (IBD) following liver transplantation (LT). Relevant prospective and retrospective observational studies were identified by searching databases and gray literature through December 2020. Random-effects models were used to calculate the pooled frequency of IBD patients with disease course alterations ("improved", "unchanged", or "aggravated") after LT and the corresponding 95% confidence intervals (CI).

Results: Twenty-five studies met our inclusion criteria, reporting the outcomes in two or three categories. In the analysis of studies with three-category outcomes (n=13), the pooled frequencies of patients with improved, unchanged, or aggravated IBD course after LT were 29.4% (95%CI: 16.9%-41.9%), 51.4% (95%CI: 45.5%-57.3%), and 25.2% (95%CI: 15.6%-34.8%), respectively. Subgroup analyses revealed that patients with ulcerative colitis (UC), younger age at LT, or shorter duration of follow-up were more likely to have an improved disease course.

Moreover, higher IBD exacerbation estimates were observed in studies with a low risk of bias. In the analysis of studies with two-category outcomes (n=12), the pooled frequencies of patients with improved/unchanged or aggravated IBD course were 73.6% (95%CI: 62.2%-85.0%) and 24.1% (95%CI: 15.1%-33.2%), respectively. The cumulative incidence of an exacerbated IBD course following LT was 0.22 (95% CI: 0.16-0.29, $P < 0.001$).

Conclusion: We conclude that IBD activity remains unchanged (or improved/unchanged) in most IBD patients following LT. Furthermore, IBD type, age, and follow-up length can influence the IBD course after LT.

Introduction:

Looking for reliable markers in the evaluation of nutritional and inflammatory status in the course of inflammatory bowel disease (IBD) constitutes a critical goal in he management of patients. Bioelectrical impedance analysis (BIA) is nowadays believed to serve an important role in the evaluation of body composition in the course of IBD. Simultaneously, non-invasive hematological markers are explored as easy to obtain potential indicators of inflammation. Nevertheless, reliable anthropometric measurements might constitute troublesome parameters to be evaluated in everyday clinical practice and even if we manage to obtain them - it is hard to interpret them in the context of underlying inflammation in the natural history of IBD. Thus, we aimed to explore a new potential model for the estimation of nutritional and inflammatory status in the course of IBD. In the light of the current knowledge, body composition assessed with BIA was not evaluated together with hematological indices in the single study on IBD patients, so far.

Aims & Methods: We decided to look for relationships between parameters of BIA and the results of hematological scales in IBD patients treated with biological agents. We enrolled 93 participants to the survey: 54 patients with Crohn's diseases (CD) and 39 - with ulcerative colitis (UC). They were treated with one of biologics: infliximab (n=48) or vedolizumab (n=45). We tried to look for notable associations between BIA measurements, clinical scales (CDAI, SES-CD, MAYO) and hematological markers (red blood cell distribution width to platelet ratio - RPR, red blood cell distribution width to lymphocyte ratio - RLR, neutrophil to lymphocyte ratio - NLR and mean platelet volume to platelet ratio - MPR) together with CRP.

Results: Significant dependences were noticed between BIA results, clinical IBD scales, hematological indices and CRP. We did not observe any notable differences according to the type of administered biological agent. In CD group body cell mass (BCM) correlated positively with SES-CD ($p<0.05$). On the other hand, there was a positive correlation between reactance (Xc) and total MAYO score among UC patients ($p<0.05$). Furthermore, Xc correlated negatively with MPR in the course of UC ($p<0.05$). Finally, two more significant relationships were observed in UC group: a positive one between BCM and RPR ($p<0.05$) and a negative one between extracellular water (ECW) and NLR ($p<0.05$). Finally, phase angle (PhA) correlated notably in the positive manner with CRP ($p<0,005$).

Conclusion: Our results give new perspectives for exploring combinations between two different diagnostic strategies in the evaluation of nutritional status in IBD. Achieved results suggest that changes in body composition in IBD patients can be reflected by deviations in hematological scales. Of note, our study group was administered biologics. Perhaps, further investigations could show some kind of certain relationships between the pattern of response on biological agents and the character of results in BIA analysis and hematological indices.

Introduction: Mucosal healing (MH) has become a treatment goal for inflammatory bowel disease (IBD), especially for ulcerative colitis. However, MH is less feasible to assess frequently in patients with Crohn's disease (CD). In this study, we investigated Protein Fingerprint Assays (PFA) of collagen degradation and formation, and neutrophil and macrophage activity markers in the ImageKids study as non-invasive markers of MH.

Aims & Methods: This is a proteomics planned sub-study of the multicenter prospective ImageKids study which included serum samples from children with CD (n=178) undergoing MRE and ileocolonoscopy concurrently (ImageKids study: NCT01881490). Serum from healthy age and gender-matched controls were obtained from BioIVT (n=83). PFA panel for mucosal damage (C1M, C3M, C4M, C6M, ELP-3), Immune cell activity panel (CPa9-HNE, VICM, C4G), and tissue fibrosis panel (PRO-C1, PRO-C3, PRO-C4, PRO-C5, PRO-C6, PRO-C11, PRO-C22) were determined. MH was classified as having an SES-CD score of 0 and global radiologist assessment of inflammation in the MRE of 0, using a visual analogue scale (VAS) 0-100mm, and mucosal damage (MD) was defined as having SES-CD or MRE VAS>0. Spearman rho correlations, one-way ANOVA with Tukey correction, and receiver operator characteristics (ROC) curves were applied for statistical analysis.

Results: Some of the previous biomarkers demonstrated to correlate with the SES-CD score and ulcer size (C1M, C3M, C6M, PRO-C4, VICM, PRO-C1, PRO-C3). CPa9-HNE, ELP-3, and PRO-C22 also correlate with the SES-CD score (table 1). The combined SES-CD and MRE VAS score of MH correlated positively with CPa9-HNE (r=0.30, p<0.0001), VICM (r=0.39, p<0.0001), C1M (r=0.29, p=0.0001), C3M (r=0.22, p=0.0022), C6M (r=0.35 p<0.0001), PRO-C4 (r=0.2, p<0.0001), PRO-C22 (r=0.32, p<0.0001), and showed significantly lower serum levels in pCD patients with MH compared to patients with mild, moderate, or severe mucosal damage (p<0.001). PRO-C3 correlated negatively with the combined SES-CD and MRE VAS score (r=-0.17, p=0.0211). These PFA biomarkers were combined in a multivariate regression model, demonstrating increased accuracy to identify patients in MH healing compared to the individual biomarkers (p<0.001, MH vs. MD: AUC=0.82 [CI:0.69-0.95), MH+Mild MD vs. moderate+severe MD: AUC=0.77 [0.70-0.84], (figure 1).

	r	95% confidence interval	P (two-taield)
CPa9-HNE	0.30	0.15 to 0.44	<0.0001
VICM	0.33	0.18 to 0.46	<0.0001
C1M	0.37	0.23 to 0.50	<0.0001
C3M	0.29	0.14 to 0.42	<0.0001
C4M	0.23	0.08 to 0.34	0.002
C6M	0.43	0.29 to 0.54	<0.0001
ELP-3	0.30	0.16 to 0.44	<0.0001
PRO-C3	-0.20	-0.34 to -0.05	0.0071
PRO-C4	0.35	0.20 to 0.47	<0.0001

Conclusion: PFA biomarkers of Neutrophil activity (CPa9-HNE), Macrophage activity (VICM), mucosal damage (C1M, C3M, C4M, C6M, ELP-3), and tissue fibrosis (PRO-C3, PRO-C22) are potential surrogate biomarkers for identifying pCD patients with mucosal healing and for monitoring of mucosal damage and stenosis.

Introduction: Endoscopy represents the gold standard of diagnosis for UC patients. It is an invasive investigation that can assess and stratify disease activity, evolution and treatment. Over the past few years, machine learning (ML) has become a potent instrument in the field of medicine,

thanks to its capacity for discrimination and decision-making. A suitable, non-invasive biomarker for assessing endoscopic disease activity (EDA) in ulcerative colitis (UC) has yet to be identified.

Aims & Methods: Our study aimed to develop a cost-effective and non-invasive machine learning (ML) method that utilizes the no-cost Inflammatory Bowel Disease Questionnaire (IBDQ-32) score and low-cost biological predictors to estimate EDA.Two random forest (RF) and 2 multilayer perceptron (MLP) classifiers were proposed. The first RF and MLP models were developed to predict EDA based on the selected variables, excluding IBDQ-32 score. The second RF and MLP classifiers were built to estimate EDA based on all the selected predictors, including IBDQ score.

Results: The results show that the inclusion of IBDQ-32 in the list of predictors that were fed to the models, improved accuracy and AUC for both the RF and the MLP algorithms. Moreover, the RF technique performed noticeably better than the MLP method on unseen data (the independent patient cohort).

Conclusion: This is the first study to propose the use of IBDQ-32 as a predictor in a ML model aimed to estimate UC EDA.The deployment of this ML model can furnish doctors and patients with valuable insights about EDA, a highly beneficial resource for individuals with UC who need long-term treatment.

PRETREATMENT SERUM MONOCYTE CHEMOATTRACTANT PROTEIN-1, BUT NOT TROUGH LEVEL, AS A PREDICTOR OF LONG-TERM OUTCOME BY USTEKINUMAB IN PATIENTS WITH CROHN'S DISEASE

S. Hosomi[1], Y. Kobayashi[1], R. Nakata[1], Y. Nishida[1], M. Ominami[1], S. Fukunaga[1], K. Otani[1], N. Kamata[1], F. Tanaka[1], Y. Nagami[1], K. Taira[1], Y. Fujiwara[1]

Introduction: Ustekinumab has been proven to be effective for treatment of patients with Crohn's disease; however, 30–40% of patients have been reported to lose clinical response within 2 years. We aimed to evaluate the efficacy of ustekinumab and identify predictors of short- and long-term efficacy in Crohn's disease.

Aims & Methods: Patients with Crohn's disease receiving their first ustekinumab infusion in our hospital between June 2017 and September 2020 were prospectively enrolled. Concentrations of serum cytokines and chemokines were measured using a multiplex bead array assay. Trough concentration of ustekinumab in serum samples collected after 8 weeks of intravenous administration were measured by ELISA.

Results: Fifty-nine Crohn's disease patients were enrolled in this study. Among 34 clinically active patients, 38.2% achieved a clinical response at week 8. None of the assayed factors were associated with short-term clinical response. Cumulative persistence rates of ustekinumab were 77.6% at 1 year and 58.9% at 2 years. Univariate Cox regression analysis revealed that Harvey–Bradshaw Index scores at baseline, concomitant immunomodulator treatment, and concentrations of interferon gamma-induced protein-10, monocyte chemoattractant protein-1 (MCP-1), and interleukin (IL)-1RA, IL-4, IL-6, and IL-8, but not other baseline parameters and trough concentrations of ustekinumab (hazard ratio (HR): 0.9846, 95% confidence interval (CI): 0.9561–1.014), were significantly associated with loss of efficacy. Multivariate Cox regression analysis found that biologic naïve status (HR: 0.1264, 95% CI: 0.02595–0.6158) and MCP-1 concentrations (HR: 1.037, 95% CI: 1.014–1.062) were significantly and associated with loss of sustained efficacy for ustekinumab treatment.

	Univariate analysis HR	Lower limit of the 95% CI	Upper limit of the 95% CI	p value	Multivariate analysis HR	Lower limit of the 95% CI	Upper limit of the 95% CI	p value
Biologic naïve, Yes	0.2367	0.05582	1.004	0.05061	0.1264	0.02595	0.6158	0.01047
Concomitant IM, Yes	2.644	1.144	6.113	0.02297				
IL-4, pg/mL	1.562	1.028	2.375	0.03685				
IL-6, pg/mL	1.07	1.02	1.123	0.00568				
IL-8, pg/mL	1.067	1.025	1.111	0.001415				
IL-1RA, pg/mL	1.003	1.001	1.005	0.00439				
IP-10, pg/mL	1.001	1.001	1.001	0.02067				
MCP-1, pg/mL	1.022	1.003	1.04	0.02055	1.037	1.014	1.062	0.001754
Trough level of UST at week 8	0.9846	0.9561	1.014	0.3029				

Furthermore, if patients were divided into four groups according to prior biologics use and MCP-1 level which cut-off value was determined from receiver operating characteristics (ROC) at 1 year, MCP-1 low and biologics naïve group had 100% cumulative persistence rate of ustekinumab at week 140. On the other hand, MCP-1 high and biologics exposure group had below 20%.

Conclusion: Our findings suggest that pre-treatment serum MCP-1 analysis, combined with a history of biologic use could be a novel biomarker for predicting the long-term efficacy of ustekinumab in patients with Crohn's disease. However, predicting of long-term efficacy by a trough concentration of ustekinumab at week 8 might be limited.

Disclosure: The authors declare no conflicts of interest associated with this manuscript.

Introduction: UC is a chronic, non-specific intestinal inflammation disease, with repeated recurrence and progressive characteristics. CMV is an opportunistic pathogenic virus. UC patients with CMV reactivation are more likely to relapse. However, the UC relapse condition and risk factors for relapse in UC patients with CMV reactivation remain unclear.

Aims & Methods: This study was a multicenter retrospective cohort study. The UC patients were divided into the CMV positive group and CMV negative group, according to whether or not CMV was reactivated. Clinical data, laboratory examination and endoscopic histology were collected to compare the recurrence of UC patients with CMV reactivation and analyze the risk factors of recurrence in UC patients with CMV reactivation.

Results: A total of 298 UC patients were included in this study, including 56 CMV positive patients and 242 CMV negative patients. Among the CMV positive patients, 19 patients were CMV colitis and 37 patients were active CMV infection. In terms of clinical characteristics, although the course of disease was longer in the CMV negative group than in the positive group (23.30±31.40 vs 44.77±66.55, p=0.004), the disease was more severe in the CMV positive group.

The modified Mayo score (9.18±2.18 vs 7.97±3.02, p=0.001), the Montreal (E1 1.79% vs 11.57%, E2 14.29% vs 25.62%, E3 83.93% vs 62.81%, p=0.005), CRP (36.42±38.13 vs 17.91±25.64, p<0.001) and PT (13.00±1.49 vs 12.52±0.98, p<0.001) were significantly different. In terms of treatment regimen, the CMV positive group also required a more intensive induction remission treatment, with significant differences in the use

of glucocorticoid (60.71% vs 23.55%, p<0.001) and biologics (25.00% vs 2.89%, p=0.001) compared with the CMV negative group. With 2 years of follow-up, there was no significant difference in the 1-year cumulative recurrence rate (51.79% vs 41.74%, 0.224) and 2-year cumulative recurrence rate (62.50% vs 51.65%, 0.187) between the positive and negative groups. There was no significant difference in 1-year cumulative recurrence rate between the CMV colitis group and the CMV negative group (63.16% vs 41.74%, p=0.115), but the 2-year cumulative recurrence rate in the CMV enteritis group was significantly higher than that in the CMV negative group (78.95% vs 51.65, p=0.030).

And univariate analysis showed that ALB (OR =0.91, 95%CI 0.83-1.00, p=0.043) and FC (OR =1.00, 95%CI 1.001-1.003, p=0.009) were risk factors for UC recurrence in the CMV positive group.

Conclusion: In conclusion, compared with the CMV negative patients, the patients with CMV colitis are more likely to relapse within 2 years. And we found that FC and ALB were risk factors for relapse in UC patients with CMV reactivation.

CROHN'S DISEASE (CD) OF THE SMALL INTESTINE: IS IT MORE SEVERE IN ASSOCIATION WITH ANO-PERINEAL LESIONS?

S. Belmaqrout[1], M. Cherkaoui Malki[1], S. Mechhor[1], H. El Bacha[1], S. Douihi Touzani[1], N. Benzzoubeir[1], I. Errabih[1]

[1]Ibn Sina University Hospital, Mohammed V University, Service of Hepato-Gastro-Enterology and Proctology, Medicine B, Rabat, Morocco

Contact E-Mail Address: belmaqroutsara.sb@gmail.com

Introduction: The small intestine represents a frequent localization of CD, it is associated with a higher risk of complications such as stenosis and perforation that can lead to intestinal resection.

Ano-perineal lesions (APL) are often associated with colonic involvement in CD. However, the relationship between the CD of small intestine and APL is not well understood.

The aim of our work is to study the clinical and evolutionary profile of CD of the small intestine associated to APL.

Aims & Methods: This is a retrospective, descriptive, and analytical study conducted from January 2017 to July 2022 involving 296 patients with CD. Included in our work were patients with a CD of the small intestine with and without APL, regardless of phenotype.

All our patients had a complete clinical examination with a proctological examination. CD activity was assessed by the two activity scores; the Crohn's Disease Activity Index (CDAI) and Harvey Bradshaw Index (HBI).

Data were collected through a data collection sheet and studied using SPSS 23.0 software. Quantitative variables with a Gaussian distribution were expressed as mean and standard deviation. And the qualitative variables in number and percentage. Normality was assessed by the Kolmogoroc-Smirnov test. The Student's t-test was used to compare quantitative variables with a Gaussian distribution, while the Chi-square test was used to compare qualitative variables.

Results: Among 296 patients with Crohn's disease, 28 patients or 9.45% had a small bowel location. The mean age was 37.8 ±12.7 years (extremes: 15-60 years), the sex ratio F/M was 2.

12 patients with ileal Crohn's disease had APL (42.8% of the cases); an anal fistula was noted in 8 patients (66.6%), 3 patients (25%) had an anal fissure, and 2 patients had anal ulceration (16.6%). While 16 patients with a small bowel localization, had no APL or 57.14% of cases. In the group of patients having APL, the stenosing form was in the majority 66.6% of the cases (8 patients), followed by the forms associating fistulas and stenosis in 31.25% of the cases (5 patients) the inflammatory form represented 8.3% of the cases (1 patient). In the group of patients without APL, the stenosing form was noted in 62.5% (10 patients), the inflammatory form in 31.25% of cases (5 patients), the fistulizing form associated with the stenosing form in 6.25% (1 patient). The mean CDAI and Harvey-Bradshaw index (HBI) were higher in the group of patients with APL compared with the group without APL (129.2 ± 60 vs 103.3 ± 60) and (3.08 ± 2.6 vs 2.8 ± 2.7). The comparison study of CDAI and HBI between the two groups shows that this difference is not statistically significant, with a p equal to 0.27 and 0.79, respectively.

On the other hand, recourse to surgery was noted in 36.6% of patients (11 patients), including 54.5% of patients without APL (6 patients) and 45.5% with APL (5 patients). This difference was not statistically significant with $p = 0.82$.

Conclusion: Nearly half of all patients with Crohn's disease of small bowel develop APL.

Although the presence of APL alters the quality of life because of the functional impact, in our sample, the presence of APL has no effect on the disease activity or on the risk of surgery in patients with small bowel's CD.

Disclosure: non conflict of interest

Introduction: Proper and timely risk stratification of inflammatory bowel diseases (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), is essential to tailor personalized treatment.

Aims & Methods: The aims of the current study were to report the early disease course of newly diagnosed UC and CD and identify risk factors for a severe disease course. Patients were identified from an ongoing prospective population-based inception cohort at Hvidovre University Hospital and Herlev University Hospital, IBD Prognosis Study, which includes all patients with newly diagnosed IBD since May 2021 and forth within a catchment population of 1.050.000 (~20% of the Danish population). We defined severe disease course as the need for surgery or initiation of biological therapies within six months of diagnosis. A Cox proportional hazard model with Bonferroni correction adjusting for multiple comparisons was constructed to identify predictors hereof.

Variable	Ulcerative colitis	Crohn's disease	IBD unclassified
Gender (Female)	0.22 (0.04-1.1)	1.3 (0.4-4.1)	2.5 (0.4-17.9)
Elderly-onset (≥60 y)	1.9 (0.5-7.3)	4.1 (0.3-12.3)	NA
Smoking (current or previous vs. never)	0.6 (0.1-2.5)	1.0 (0.34-2.9)	NA
Body mass index >30	0.6 (0.07-5.6)	3.6 (0.16-14.2)	NA
Diagnostic delay (>12 months vs. less)	1.5 (0.1-15.2)	1.4 (0.1-17.1)	NA
Treatment with systemic steroids at diagnosis	1.4 (0.1-16.4)	0.3 (0.1-0.8)	NA
Disease extent (E3) Disease location (L3) Disease behavior (B2/B3) Perianal disease	4.3 (1.6-12.5)	1.6 (0.4-8.1) 1.6 (0.4-8.1) 3.1 (0.7-15.2) 4.9 (1.6-14.9)	0.3 (0.04-2.2)

Hemoglobin < 7.3 mmol/L Platelet count > 450 10^9/L Albumin < 36 g/L C-reactive protein > 10 mg/L Fecal calprotectin > 1800	4.1 (1.2-14.1) 7.3 (1.3-41.9) 13.5 (2.8-64.2) 13.1 (1.8-20.3) 1.3 (0.3-5.9)	1.1 (0.29-4.1) 1.3 (0.3-6.5) 0.94 (0.3-2.9) 3.2 (0.8-11.7) 3.2 (0.11-2.44)	12.7 (1.2-145.6) NA 13.7 (0.3-37.5) 8.6 (0.8-16.6) 3.7 (0.4-31.8)

Table 1: Predictors of early severe disease course in newly diagnosed IBD in multivariate Cox proportional hazard model with Bonferroni correction (hazard ratio (95% confidence interval))

Results: As of April 15th, 2023, the cohort comprised 501 patients, including 287 with UC,180 with CD, and 34 with IBD unclassified (IBDU). The mean age (interquartile range (IQR)) at diagnosis was 39 years (27-56), 36 (25-54), and 36 (27-52), respectively. The cumulative risk of a severe disease course within six months after the onset of UC, CD and IBDU was 3.8% (95% confidence interval 1.9-6.8), 13.9% (95% CI 9.2-19.8) and 11.4% (95%CI 3.2-26.7).

In a Cox multivariable regression model adjusting for age and gender, a severe initial disease course for UC was predicted by extensive disease distribution, severe disease endoscopically at diagnosis, and affected biochemical inflammation parameters (Table 1). In patients with CD, perianal disease but no other phenotypic characteristics were predictive for the initial course.

However, in a sensitivity analysis of luminal CD, stricturing phenotype at diagnosis (adjusted hazard ratio (aHR) = 4.6 (95% confidence interval (CI) 1.5-13.6), the platelet count (HR= 1.3 (95% CI 1.2-10.6), and CRP > 10 mg/L (aHR= 14.2 (95% CI 1.9-108.5) were independently associated with a severe initial course, while initial use of systemic steroids was associated with a reduced risk. In patients with IBDU, only low hemoglobin was predictive for an initial severe disease course.

Conclusion: In this population-based study, we found 4%, 14%, and 11% of patients with newly diagnosed UC, CD, and IBDU, respectively, to experience an early severe disease course. Furthermore, systemic inflammation was predictive for a severe initial course in UC. In CD, perianal disease or stricturing disease phenotypes identify the subgroup of patients at high risk of early severe disease course.

ANAL STENOSIS IN CROHN'S DISEASE: A REAL CHALLENGE FOR THE GASTROENTEROLOGIST

S. Belmaqrout[1], M. Cherkaoui Malki[1], S. Mechhor[1], H. El Bacha[1], S. Douihi Touzani[1], N. Benzzoubeir[1], I. Errabih[1]

Contact E-Mail Address: belmaqroutsara.sb@gmail.com

Introduction: Anal stenosis is one of the most disabling ano-perineal manifestations in Crohn's disease. Its management is a challenge for the gastroenterologist because of the functional prognosis that it can engage. The aim of this work is to present the characteristics of this disease and to highlight the different therapeutic options.

Aims & Methods: This is a retrospective descriptive monocentric study conducted in our department, covering all patients with Crohn's disease with anal stenosis between January 2002 and July 2022. All our patients underwent a clinical examination with a proctological examination and a pelvic MRI. Data were collected using a data collection form and studied using SPSS software.

Results: Among 1035 patients with a Crohn's disease, 30 patients with anal stenosis were included (2.89%)

The average age of our series was 37.7 years with extremes between 17 - 56 years, the sex ratio M/F 1.9.

Clinical symptoms were dominated by rectal bleeding in 11 patients (36.6%), followed by diarrhea in 30% (9 patients), proctalgia in 23.3% (7 patients) and occlusive syndrome in 3% (3 patients).

On proctological examination, impassable anal stenosis was noted in 30% of patients (9 patients), while it admitted the fingertip in 70% of cases (21 patients). On MRI, stenosis was short in 83.3% of patients (25 patients) and >5 cm in 16.6% of patients (5 patients).

Dilatation by Savary Bougie was performed in 56.6% of patients in our series (17 patients), balloon dilatation in 23.3% (7 patients), surgical resection in 6.6% (2 patients), and 4 patients received medical treatment (anti-TNF monotherapy or combination therapy with immunosuppressive treatment) 13.3% of cases. 8 cases of recurrence after dilatation were reported (26.6% of patients), and 4 cases of secondary failure under anti-TNF treatment. One case of anal incontinence and one case of malignant degeneration were noted.

Conclusion: Anal stenosis is a real challenge for the clinician. Its management must be multidisciplinary. Several therapeutic options can be recommended depending on the anal stenosis but also on the functional impact and the patient's wishes.

Disclosure: none conflict of interest

HYPOPHOSPHATAEMIA PRIOR TO INTRAVENOUS IRON TREATMENT IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: IS IT MORE COMMON THAN IN THE GENERAL POPULATION?

A. Aksan[1,2,3], K. Siayor[2], L. Tessmer[2,4], O. Schröder[2,4], J. Stein[2,4,5]

Contact E-Mail Address: ayscak@gmail.com

Introduction: Although uncommon in the general population, a low serum phosphate level is associated with a risk for clinical symptoms including fatigue, proximal muscle weakness and bone pain. In inflammatory bowel disease (IBD), a few case reports have documented specific acute clinical symptoms associated with hypophosphataemia (HP). However, these symptoms are difficult to distinguish from clinical manifestations of IBD and iron deficiency/iron deficiency anaemia. Potential complications of HP, if severe, can include respiratory failure, rhabdomyolysis, haemolysis and left ventricular dysfunction. Additionally, it has been shown that prolonged HP can result in osteomalacia. HP is under discussion as one of the common adverse reactions of intravenous (IV) iron therapy in patients with inflammatory bowel disease. Since IV iron therapy is recommended as first-line therapy in many situations in IBD, it is important to define its frequency and possible causes for pre-existing HP.

Aims & Methods: The aim of this study was to investigate the occurrence of HP in patients with IBD, independent of iron therapy. The study was conducted as a comparative, cross-sectional, retrospective study in adults with IBD (n=562) and healthy controls (n=80). Blood count, serum phosphate, faecal calprotectin and hsCRP were analysed by routine tests according to guidelines of the German United Society for Clinical Chemistry and Laboratory Medicine at a local reference laboratory. Inflammatory disease activity was defined as hsCRP levels ≥ 5 mg/dL and or faecal calprotectin levels of ≥ 250 µg/g. Serum total 25(OH)D concentration was measured using ImmuTube® Vitamin D duo LC-MS/MS (Immundiagnostik AG, Bensheim, Germany). Mild, moderate and severe HP were defined as a serum phosphate level of 2.0–<2.5 mg/dL (mild), 1–<2.0 mg/dL (moderate), and <1 mg/dL (severe), the normal reference range being 2.5–<4.5 mg/dL. Statistical analysis was performed using IBM SPSS version 25.0.

Results: Ultimately, 562 patients with IBD (277 male, 285 female; 332 Crohn's disease (CD), 230 ulcerative colitis (UC); 159/562 with inflammation) aged 42.3±13.9 years, and 80 controls (31 male, 49 female), mean age 43.3±15.4 years, were recruited to the study. In the IBD patient group, 8.6% were found to have HP, of which 23.9% were moderate and 76.1% mild. In the control group, 10.0% were found to have HP (25% moderate, 75% mild). Thus, the frequency of HP was not found to differ between IBD and controls (p=0.910). None of the IBD patients and no controls had severe HP. Prevalence of HP did not differ between CD (8.8%) and UC (8.2%), while HP was slightly less common in vitamin D-deficient patients (7.0%) compared to patients without vitamin D deficiency, and similar in patients with iron deficiency/anaemia versus non-iron-deficient patients (p=0.690). Only the inflammatory status of the IBD patients was found to have effect on serum phosphate levels: The prevalence of HP was 14.0% and 6.7% in patients with versus without inflammation, respectively (p=0.006).

Conclusion: HP was not found to be more common in patients with IBD compared with controls. In the IBD group, HP had a similar prevalence in CD and UC patients. The prevalence of HP was only increased in the presence of inflammation. Therefore, to prevent severe HP, serum phosphate levels should be assessed in patients with IBD, especially those with active inflammation, before IV iron therapy is considered in the clinical setting.

THE ROLE OF VITAMIN D STATUS ON EFFECTIVENESS OF BIOLOGIC THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

O. Schütte[1], L. Tessmer[2,3], J. Stötzel[3], O. Schröder[2,3], A. Aksan[1,3,4], J. Stein[2,3,5]

Introduction: As well as having a major impact on bone metabolism, vitamin D (vitD) is recognised as an immunomodulatory hormone with a pivotal role in the pathogenesis of inflammatory bowel disease (IBD). Low vitD levels in patients with IBD are associated with active inflammation, disease severity, poor quality of life and adverse clinical outcomes. Furthermore, lower vitD levels in patients with IBD were shown to be associated with higher pro-inflammatory cytokine profiles.

Therefore, it is plausible that vitD may have use as a therapeutic agent in IBD. Our previous work suggests that pre-treatment with vitD may improve effectiveness of biologic drugs such as TNF-α inhibitors and the anti-integrin agent vedolizumab (VDZ). However, data in this context is limited.

Aims & Methods: The aim of this study was to explore potential effects of serum vitD levels on biologic treatment response in IBD patients. A retrospective cohort study was conducted to monitor ambulant treatment of IBD patients with biologics in relationship to their vitD levels. Medical records and routine blood and stool samples of 162 adult IBD patients were assessed at therapy start and 8-weekly thereafter. Samples were analysed for standard blood count, total 25OHD, albumin and inflammation parameters (hsCRP, ESR and faecal calprotectin (FC)) by standard methods. Biologic treatments (infliximab (IFX), its biosimilars (IFX-s), VDZ and ustekinumab (UST)) were administered over 1 year. Drug and anti-drug antibody (ADA) levels were measured with systems provided by Immundiagnostik AG, Bensheim, Germany. VitD values were dichotomized into deficient (≤ 30ng/mL) and sufficient (>30ng/mL). A positive treatment response was defined according to evidence of inflammation as shown by change in hsCRP-levels from baseline to the last two samples monitored. IBM SPSS Statistics 24 was used for statistical analysis.

Results: 162 patients with IBD (91 with Crohn's disease (CD)/ 71 with ulcerative colitis (UC); 81 f/81 m; age 40.2±11.5y) were enrolled. At baseline, 40.7 % used vitD supplementation, 10.5 % were biologic naïve and 50.6 % were vitD deficient. No conclusive relations were found between baseline vitD or supplementation status with drug or ADA levels. However, higher vitD levels over time were associated with positive treatment response for patients on IFX and UST ($p<0.05$). Treatment specific analysis revealed no significant associations between drug TCs and overall vitD status or treatment response. In descriptive analysis, pre-treatment vitD status was not associated with demographic or clinical characteristics but positively associated with mean corpuscular volume (MCV) and FC and inversely related to transferrin. Ultimately, 72.8 % of patients responded to biologic treatment. Response was related to disease location in CD ($p = 0.011$) and positively associated with naivety to biologics ($p = 0.040$). Treatment responders had significantly higher Hb, iron, TSAT and significantly lower ESR, hsCRP and FC.

Conclusion: Our results support a protective role of vitD in IBD patients treated with the biologic agents IFX and UST, shown here for the first time for UST. Interestingly, not the initial vitD status, but permanently sufficient vitD levels were decisive for improved treatment response. Therefore, regular vitD monitoring and long-term vitD substitution in patients with low vitD levels is indicated.

PP0710

THERAPEUTIC DRUG MONITORING (TDM) IN CROHN'S DISEASE: WHAT ABOUT IN REAL LIFE?

F.Z. El Hajoubi[1], S. Mechhor[1], M. Cherkaoui Malki[1], H. El Bacha[1], N. Benzzoubeir[1], I. Errabih[1]

[1]Ibn Sina University Hospital, Mohammed V University, Hepato-Gastroenterology and Proctology Unit, Medicine B, Rabat, Morocco

Contact E-Mail Address: Elhajoubi5@gmail.com

Introduction: Therapeutic Drug Monitoring (TDM) has been shown to be useful in patients with Crohn's disease. It consists of measuring the residual serum level of anti-TNF and screening for antibodies to the molecule. TDM is a tool for therapeutic adjustment thanks to the introduction of algorithms based on pharmacokinetics and immunogenicity, allowing the therapeutic objectives of Crohn's disease to be reached, which must meet the STRIDE II objectives, notably clinical, biological and endoscopic remission.

Aims & Methods: The aim of the study was to demonstrate the value of monitoring in therapeutic decision making during the management of Crohn's disease, and to study its place in current practice.

This is a retrospective descriptive and analytical study including 296 patients with Crohn's disease. 57 patients receiving biotherapy, collected from January 2017 to July 2022. For the study of factors predictive of the occurrence of complications, a binary logistic regression was performed using SPSS 20.0 software, with a retained p of 0.05.

Results: 57 cases of patients followed for crohn's disease under biotherapy were included. The mean age of our patients was 40.8 years +/-13.5 with a sex ratio W/M: 1.85. The location was mainly ileo-colic in 49% of cases (n=28). The fistulizing phenotype was dominant in 45% of cases (n=26). Infliximab was indicated in 88% (n=50), and Adalumimab in 12% (n=7). TDM was performed in 33% (n=19). The indication for drug testing was based on a primary non-response in 16% of cases (n=3), loss of response in 84% of cases. The therapeutic decision was changed in 84% of cases. The evaluation of clinical and biological response after therapeutic adjustment showed a higher clinical and biological response rate in the TDM group compared to the non-TDM group, this difference being statistically significant with a $p = 0.034$ and 0.039 respectively. 71% of patients in the TDM group achieved endoscopic remission compared to 34% in the non-TDM group, this difference is statistically significant with a $p = 0.034$. 42.1% patients from TDM group had complications such as moderate to severe flare, endoscopic recurrence or sub-occlusive syndrome compared to 68.4% in the non-TDM group. This difference is statistically significant with a $p <0.005$.

Conclusion: In our study, reactive TDM was able to demonstrate its value in guiding our therapeutic management in cases of loss of response or primary non-response. In these indications, the cost/effectiveness ratio is very favourable. However, our study has limitations: the small number of patients and the high cost of these assays which constitutes a real obstacle in practice.

Disclosure: None conflict of interest.

Contact E-Mail Address: mmanosa.germanstrias@gencat.cat
Introduction: Endoscopic postoperative recurrence (POR) of Crohn's disease (CD) occurs in up to 70% of patients within the first 12 months after ileocecal resection (ICR) with anastomosis if no prophylactic therapy is started. Early postoperative prophylaxis with thiopurines or anti-TNF agents may lower this number to 30-50%. However, scarce data on POR are available in the long-term.
Aims & Methods: To evaluate the long-term outcomes of patients without endoscopic POR at the first endoscopic assessment.
We performed a retrospective, observational study including consecutive CD patients undergoing ICR with anastomosis at four European referral centres since 1998. All patients underwent a first endoscopic assessment within 18 months from ICR demonstrating no endoscopic POR (Rutgeerts score i0-i1), and had a clinical follow-up ³24 months including at least one further endoscopic assessment.
Main outcomes were endoscopic (Rutgeerts >i1), clinical (development of digestive symptoms together with a disease recurrence seen at endoscopic or radiological examination that prompted changes in the treatment) and surgical (new intestinal resection) POR, need for rescue therapy and "delayed POR" (any need for rescue therapy or clinical or surgical POR) during follow-up.
Results: One-hundred eighty-five patients were included (133 Rutgeerts i0, 52 Rutgeerts i1), of whom 88 (48%) started thiopurines or 17 anti-TNF (9%) early after surgery and 80 (43%) patients did not start any prophylactic therapy. No clinical risk factors for POR were present in 38%, whereas 27% met ³1 (active smoking, penetrating disease, perianal disease and/or previous ICR). By the last endoscopic assessment that was performed a median (IQR) of 58 (24-133) months after the first one, endoscopic POR was observed in 39% (17% i3-i4).
Cumulative probability of remaining free of endoscopic POR in the total cohort was 97% at 1 year, 68% at 5 years and 61% at 10 years, from the index colonoscopy.
During a median follow-up of 104 (IQR, 55-196) months, 30% of the patients developed clinical POR and 31% required rescue treatment (thiopurines in 14 patients, biological therapies in 43 and dose-escalation in 1). Cumulative probability of remaining free of clinical POR for the total cohort was 97.5% at one year, 81.8% at 5 years and 72.1% at 10 years. Finally, 5% of the patients had surgical POR at the end of follow-up.
In multivariate analysis, no risk factors were observed for endoscopic, severe endoscopic and surgical POR. However, early prophylactic treatment was protective for clinical POR (OR 0.54 [95%CI 0.32-0.96]; p=0.026) and need for rescue therapy (OR 0.43 [95%CI 0.23-0.79]; p=0.007), whereas a Rutgeerts score i0 at index ileocolonoscopy was the only factor that prevented from "delayed POR" (OR 2.00 [95%CI 1.18-3.31]; p=0.009).
Conclusion: Most patients without endoscopic POR after ICR will remain free of endoscopic and clinical POR in the long-term, although the risk steadily increases over time. Moreover, early postoperative prophylactic therapy seems to prevent the long-term risk of clinical POR and reduces the need for rescue therapies. Therefore, periodical non-invasive monitoring seems a suitable strategy for patients without endoscopic POR at the first postoperative endoscopic assessment, particularly if early prophylaxis was started or no endoscopic lesions (i0) were observed at index ileocolonoscopy.
Disclosure: Nothing to disclose.

HIGH-RESOLUTION VISUALIZATION OF INTESTINAL MICROCIRCULATION USING ULTRA-MICROANGIOGRAPHY: EXPERIENCE FROM A TERTIARY CENTER

S. Albaladejo Fuertes[1], E.-M. Jung[2], C. Buechler[1], A. Kandulski[3], S. Kempa[4], M. Müller-Schilling[5], H. Tews[1]
[1]University Hospital Regensburg, Internal Medicine I, Gastroenterology, Hepatology, Endocrinology, Rheumatology and Infectious Diseases, Regensburg, Germany, [2]University Hospital Regensburg, Institute for Diagnostic Radiology and Interdisciplinary Ultrasound, Regensburg, Germany, [3]University Hospital Regensburg, Department of Internal Medicine, Regensburg, Germany, [4]University of Regensburg, Department of Plastic, Aesthetic and Reconstructive Surgery, Regensburg, Germany, [5]University Hospital Regensburg, Department of Internal Medicine I, Gastroenterology, Hepatology, Endocrinology, Rheumatology and Infectious Diseases, Regensburg, Germany

Contact E-Mail Address: sheila.fuertes@gmail.com
Introduction: Ultrasound examination of the intestine is an important component in assessing disease activity, both in diagnosis and in monitoring the course and therapy of inflammatory bowel disease (IBD). Pathophysiologically, hyperemia of the intestinal wall and possibly also of the surrounding structures can be used as a measure of the severity of the inflammatory activity.
Aims & Methods: This study aimed to compare imaging of intestinal vascularization of color-coded duplex sonography (CDS) with the new ultra-microangiography (UMA) ultrasound technology. This method allows high-resolution imaging of the microcirculation in surface structures. The use of a special algorithm minimizes artifacts and background noise.
A structured ultrasound examination of the bowel, initially using B-scan and CDS and after identification of the affected regions using UMA, was performed in 13 IBD patients by an experienced investigator. A cohort of 28 patients without IBD served as a control group. Image data were evaluated concerning the imaging quality of the intestinal microcirculation in comparison between CDS and the 3 new modalities cUMA (color-UMA), pUMA (power-UMA), and sUMA (subtraction-UMA). All examinations were performed on the RESONA R9 (Mindray Bio-Medical Electronics Co., Ltd) ultrasound machine using a multifrequency linear sound probe (3-15 MHz, Mindray, Resona R9).
Results: Intestinal microcirculation as an expression of inflammatory activity in patients with IBD could be visualized and quantified with high sensitivity using UMA ultrasound. Using UMA, a better visualization accuracy by a factor of 1.8 was achieved in IBD patients compared to visualization by CDS. In the control cohort, visualization of intestinal perfusion via UMA was improved by a factor of 2.2.

Conclusion: UMA ultrasound technology significantly improves the visualization quality of intestinal microcirculation of the bowel in both IBD and non-IBD patients. Thus, ultrasound continues to move into focus as a non-invasive method for assessing inflammatory activity in the gut as a primary diagnostic tool. Imaging using UMA increases diagnostic precision by providing unprecedented resolution accuracy and interference-free imaging.

Disclosure: Nothing to disclose.

Contact E-Mail Address: delgaudioangelo@gmail.com

Introduction: Endoscopic evaluation offers essential prognostic information in the field of postoperative management of patients with Crohn's disease(CD). Although not validated, the Rutgeerts score is the most widely used. A recent study has introduced the POCER postoperative index (score 0-4), which includes the circumferential extent and depth of anastomotic ulcers.

Aims & Methods: Our study aims to evaluate the POCER Index in a real-life cohort, its correlation with the Rutgeerts score, and its prognostic value of subsequent disease courses.

We conducted a single center, retrospective study evaluating clinical and endoscopic outcomes of patients with CD who underwent ileo-colonic resection. All patients underwent the first endoscopic evaluation within 6-12 months to assess postoperative recurrence(POR). This evaluation was performed using the Rutgeerts score and the POCER Index. POR was defined as Rutgeerts ≥ 2 or POCER ≥ 2. A clinical assessment was performed at 18-24 months for all patients by calculating the Harvey-Bradshaw Index (HBI). A second endoscopic evaluation at 18-24 months was available for a sub-cohort.

Results: We included 103 patients, with a median age at surgery of 38 years old. 79% of the patients had no previous bowel resection surgery history. The main indication for surgery was the presence of stenotic disease. 63% of patients had at least one risk factor for post-surgical recurrence between smoking or penetrating disease. 35 patients were bionaïve (34%). All patients underwent prophylactic biologic therapy (27% with Infliximab, 48% with Adalimumab, 7% with Vedolizumab, and 17% with Ustekinumab. At 6 month, POR was observed in 50 (48.3%) and 17 (16.5%) patients, according to Rutgeerts and POCER scores, respectively. Mean Rutgeerts and POCER scores were 1.39 (± 1.31) and 0.70 (± 1.08); a moderate correlation (r=0.613) between the two was observed. During postoperative follow-up, a sub-cohort of 50 patients underwent further endoscopic examination at 18-24 months. POR was observed in 30 (60%) and 9 (18%) patients, according to Rutgeerts and POCER scores, respectively. Mean Rutgeerts and POCER scores were 1.82 (± 1.34) and 0.86 (± 1.02); a moderate correlation (r=0.571) between the two was observed. Finally, we assessed the ability of Rutgeerts and POCER scores at 6-12 months to predict subsequent clinical relapse (HBI ≥ 5) at 18-24 months. A Rutgeerts score ≥ 2 predicted subsequent clinical relapse with an AUROC of 0.781 (sensitivity 88.24% and specificity 58.82%), while a POCER score ≥ 2 predicted subsequent clinical relapse with an AUROC of 0.714 (sensitivity 35.29% and specificity 86.42%). Interestingly, when evaluating the performance of the combination of the two scores (mean of Rutgeerts + POCER score), we observed that a mean score ≥ 1.5 could predict subsequent clinical relapse with an AUROC of 0.768 (sensitivity 88.24% and specificity 67.06%).

Conclusion: Rutgeerts and POCER score can be used to assess POR and they show only moderate correlation between each other. In predicting subsequent clinical relapse, the Rutgeerts score appears to have greater sensitivity, while the POCER score seems to have greater specificity. The combination of the two might outperform each of them with a good compromise between sensitivity and specificity.

Disclosure: The authors declare no conflict of interest.

Introduction: Patients with Inflammatory Bowel Disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC) are at high risk of developing malignancies, so prevention and adherence to cancer screening may improve its detection.

The aim of this study was to assess the compliance with medical recommendations, especially primary and secondary prevention of cancer.

Aims & Methods: The aim of this study was to assess the compliance with medical recommendations, especially primary and secondary prevention of cancer.

This one-center cross-sectional study was carried out between June and December 2021r. amongst patients from the Department of Internal Medicine and Gastroenterology with IBD Division, National Health Institute of Ministry of Interior Affairs and Administrations or outpatient clinic. Patients were asked to complete anonymous questionnaire which included 42 questions concerning lifestyle, cancer risk factors, cancer history and checkups in patients with IBD. The results of the qualitative variables were expresses as frequencies and percentage. We used Fisher exact test, chi-squares test. $p<0.05$ was considered significant. Statistical analyses were performed with the SPSS statistical package.

Results: A total of 313 patients were enrolled into the study: 145 women and 168 men. In the group, 182 had Crohn's disease (CD), 120 had ulcerative colitis (UC) and 11 with IBDU (unclassified IBD). Most participants had disease duration over 8 years, received biological treatment, corti-

coids or/and immunosuppressive therapy. Amongst respondents 17% (31) of patients with CD, 25.8% (31) with UC were overweight and 10.5% (19) with CD and 15.8% (19) with UC were obese (p= 0.017). We found that 16.3% of all respondents were smokers (79.6% (144) CD, 90.8% (109) UC and 72.7%(8); p 0.053) and 33.9% declared to consume alcohol (39.4%(71) CD, 26.9%(32) UC and 18.2%(2) IBDU; p 0.045). 25.4% were exposed to UV radiation, only 18.8% of them used sunblock. 58.8% (67) of patients with CD, 35.8% (19) and UC receiving immunosuppressants did regular laboratory tests regularly (p= 0.02). 41.4% (46) of UC, 27.1% (49) of CD and 70.0%(7) IBDU declared not to do any dermatological control (p =0.013). 77% of patients had abdominal ultrasound done. Out of 52.9% of patients who had colonoscopy recommended, only 27.3% had it performed (16.9%(30) with CD vs . 43.1%(50) with UC p< 0 .001). Most of examinations were ordered by gastroenterologists. Female patients had regular breast control (CD 78.6% (66), UC 91.2%(52) and 50% (2) IBDU p 0.034) and 93.8% (76) had gynaecological examination. 80.2% of patients knew about HPV but most declared not to be vaccinated. 17.9% of patients had urological control, but most had no important pathology detected.

Conclusion: According to our study, many patients are still exposed to risk factors, such as obesity, smoking or little physical activity, which are modifiable. Systematic control especially dermatological check-ups should be recommended. Additionally, not only gastrologists but also other specialists and GPs should remind patients about regular checkups. Primary prevention, such as HPV vaccinations, should be reminded to all patients.

CIRCULATING CELL-FREE DNA AND MITOCHONDRIAL DNA PREDICT DISEASE ACTIVITY IN PAEDIATRIC-ONSET INFLAMMATORY BOWEL DISEASE

D. Wands[1,2], S.-Y. Lau[2], S. Chuah[2], R. Hall[2], R. Whelan[2], L. Fischer[2], R. Kalla[2], P. Cartlidge[2], B. Drury[2], G.R. Jones[2], D.C. Wilson[1], G.-T. Ho[2]

Introduction: Paediatric-onset inflammatory bowel disease (PIBD) is a distinct phenotype with more aggressive and extensive gut inflammation at diagnosis in comparison to adult-onset IBD.[1] Disease activity in paediatric IBD is typically monitored using a combination of clinical, endoscopic, and laboratory parameters. Circulating cell-free DNA (cfDNA) and mitochondrial DNA (mtDNA) are damage-associated molecular patterns (DAMPS) released into the bloodstream during tissue damage and cell death and can be detected in peripheral blood samples. There is a growing interest in the use of cfDNA and mtDNA as potential non-invasive biomarkers for disease activity. Recent studies have suggested that levels of cfDNA and mtDNA may correlate with disease activity in adult IBD[2] but their utility in paediatric populations, where mitochondrial dysfunction is strongly implicated,[3] remains largely unexplored. This study aims to present initial data on the potential use of cfDNA and mtDNA as biomarkers for disease activity in paediatric-onset IBD.

Aims & Methods: GI-DAMPs/MUSIC is an ongoing cross-sectional and longitudinal multi-centre translational research study in Scotland (2020 – 2025) with a primary aim of investigating the inflammatory mechanisms of IBD with a focus on multi-omics, immune- and microbiome-profiling aligned to careful clinical prospective follow-up. We measured circulating cfDNA and mtDNA, using mtDNA-specific *ND2* gene dPCR, in the peripheral blood of patients diagnosed under 17 years (A1 phenotype)[4] and correlated this with detailed phenotypic data, clinical disease activity scores and standard biomarkers.

Results: 24 patients, out of a total GI-DAMPS cohort of 338, were A1 phenotype and included in the analysis (14/24 (58%) male, 23 Crohn's disease (CD), 1 Ulcerative colitis (UC)) with a median (IQR) age at diagnosis of 13 (11.5-15 years). Patients with highly active disease had higher levels of cfDNA levels compared to those in remission (median 0.435 (0.246-0.700 ng/µl) vs 0.123 (0.066-0.160 ng/µl), p=0.005). mtDNA levels were also significantly higher in those with highly active disease compared to those in remission (median 363.6 (135.2-639.6 copies/µl) vs 96.4 (78.2-129.8 copies/µl), p=0.024). cfDNA was moderately correlated with total white cell count (Pearson correlation, r=0.41, p=0.48) and negatively correlated with haemoglobin (r=-0.42, p=0.41), though these correlations were not seen with mtDNA (all p=>0.05).

Conclusion: In conclusion, our initial data demonstrate that the levels of circulating cell-free DNA (cfDNA) and mitochondrial DNA (mtDNA) in the blood are potentially valuable biomarkers for differentiating disease activity in paediatric IBD. These findings suggest that measuring cfDNA and mtDNA levels could provide a non-invasive method for monitoring disease activity in young patients with IBD, enabling early detection of disease flare-ups and facilitating prompt intervention. Further investigation is needed to validate these results and determine the clinical utility of these biomarkers in the management of paediatric IBD.

A SPECIFIC MICROBIOTA SIGNATURE IS ASSOCIATED TO IMMUNOTHERAPY-RELATED COLITIS AS ASSESSED BY A MACHINE LEARNING APPROACH – A COMPARATIVE STUDY WITH INFLAMMATORY BOWEL DISEASES AND HEALTHY CONTROLS

B. Barberio[1], I. Patuzzi[2], S. Facchin[3], M. De Ruvo[4], A. Dal Maso[4], S. Frega[4], B. Simionati[5], F. Zingone[6], L. Bonanno[4], E.V. Savarino[7]

Introduction: Immuno-mediated colitis is one of the most common gastrointestinal side effects associated with immune checkpoint inhibitors (ICIs). ICIs-colitis shares with inflammatory bowel disease (IBD), including both Crohn's Disease (CD) and Ulcerative Colitis (UC), the clinical presentation, macroscopic, microscopic, and serological findings, making challenging the differentiation between the two conditions. The gut microbiota has been suggested as an important driver in the pathogenesis of ICIs-colitis as well as in the pathogenesis of IBD.

We aimed to assess whether a specific microbiota profile, as measured by a machine learning approach, can be associated with ICIs-colitis and whether it differs from the one assessed in patients with IBD and in healthy controls (HCs).

Aims & Methods: In this prospective pilot study, consecutive patients with ICIs-colitis, patients with IBD and HCs were enrolled. Stool samples were collected for fecal microbiota assessment analysis by 16S rRNA gene sequencing approach. The raw reads underwent a filtering procedure performed within QIIME2 analysis framework (version 2022.8). Alpha diversity was evaluated on rarefied counts (Richness, Shannon, and Pielou indices; rarefaction level: 31,556), while beta diversity was calculated on normalized counts (Bray-Curtis, Jaccard, Canberra, Weighted and Unweighted Unifrac; counts normalized with GMPR). The diversity analysis was conducted in R (version 4.1.0). A permutational analysis of variance (PERMANOVA) test on Bay-Curtis dissimilarity was used to test for differences in the microbiota composition between disease status groups (vegan and ecole packages). The MaAsLin2 package was then used to perform differential abundance analysis at all taxonomic levels. Supervised and unsupervised machine learning algorithms were applied.

Results: Nineteen patients with ICIs-colitis, 40 patients with UC (20 active and 20 inactive), 34 with CD (14 active and 20 inactive) and 36 HC were enrolled. Alpha diversity was not significantly different between ICIs-colitis and HCs (p=0.94), while it was statistically significant between IBD and HCs (p=0.02) and between IBD and ICIs-colitis (p=0.03). At phylum levels, we found high levels of Tenericutes in HCs and high levels of Proteobacteria in ICIs-colitis. Moreover, we found high levels of Actinobacteria in IBD compared to the other group. Interestingly, at genus levels, we found very high levels of Enhydrobacters in ICIs-colitis compared to patients with IBD. While at species levels, high levels of Bifidobacterium longum in patients with UC were observed. A specific microbiota profile was found for each group (IBD, ICIs, HC) and was confirmed with sparse partial least squares discriminant analysis, a machine learning-supervised approach. The latter allowed us to observe a perfect class prediction and group separation using the complete information (full Operational Taxonomic Unit table), with a minimal loss in performance when using only 5% of features.

Conclusion: A machine learning approach to 16S rRNA data identifies a bacterial signature characterizing ICIs-colitis from IBD and HCs. Future research will clarify whether such microbiota profiling is useful for prediction, early diagnosis and management of patients with ICIs-colitis.

Contact E-Mail Address: amer.lamis47@gmail.com

Introduction: The clinical assessment of patients diagnosed with inflammatory bowel disease remains the gold standard for the medical follow up. For each patient, the calculation of multiple scores are required to estimate the clinical severity (CDAI or the complete form of the Mayo score (CF-MS) or the patient's quality of life (for example, IBQD and CUCQ). These scores are time consuming and seldom used in clinical practice.

Aims & Methods: The primary objective of this study is to establish a short questionnaire for patients diagnosed with IBD, easily applicable in clinical practice, that assembles the disease activity and the quality of life.

This is a prospective study where 52 patients diagnosed with IBD filled in a new questionnaire including 58 items (revolving around the disease activity and the quality of life), the IBDQ-32, CDAI, and the complete form of the Mayo. Principal component analysis allowed to identify 8 domains. The reliability analysis permitted to reduce the questionnaire to 22 items, then, classified in terms of clinical severity and quality of life (QOLQ). Spearman correlation between each domain, the IBDQ-32, CDAI, CF-MS, and the new 22-items questionnaire is established. The clinical severity and QOLQ compared to IBDQ, CF-MS and CDAI were further assessed using a binary logistic regression.

	V/s	Cut-off	AUROC	Cohen's Kappa
QOL (46)	IBDQ	14	0.818	0.46
Clinical severity- Crohn (56)	CDAI	19	0.834	0.608
Clinical severity- UC (56)	CF-MS	10	0.748	0.548
Total (91)	IBDQ	24	0.866	0.644
Total – Crohn (91)	CDAI	34	0.838	0.51
Total – UC (91)	CF-MS	25	0.726	0.451

()= maximum score.

Results: Fifty-two patients 33 (63.5%) and 19 (36.5%) with Crohn's disease and UC respectively had a mean age of 41.3 ± 16.3, mean CDAI is 99 ± 107, and CF-MS is 2.88 ± 2.29. Our score was divided into two categories regrouping the 8 identified domains: clinical severity included domains related to physical activity, bowel urgency, bloating, abdominal pain, extra digestive symptoms. QOLQ included daily activities limitation, bowel urgency, satisfaction, patient's health compared to others. A Spearman correlation showed that the IBDQ is inversely correlated to the quality of life in Crohn's disease (rho= -0.486, p= 0.004) and UC (rho= -0.467, p= 0.044). In addition, the CDAI is correlated to the clinical severity (rho= 0.712, p < 0.0001). In UC, the CF-MS is also correlated to the clinical severity (rho= 0.671, p= 0.002). Then, the cut-off of each section (QOLQ and clinical severity) defining the clinical remission was identified using the AUROC. The agreement between the two variables studied was specified using the Cohen's Kappa.

Conclusion: This study showed that this new 22-items questionnaire is a short and reliable clinical assessment method for clinical and quality related uses. Further studies on a larger scale are required to validate it for a more generalizable use.

Introduction: Patients with inflammatory bowel disease (IBD) have increasedrisk to develop bacterial enteric infections (Clostridium difficile infection [CDI] and non-CDI). Thus, when hospitalized due to IBD flare, they often undergo assessment for enteric infection.
Our study aimed to assess the impact of enteric infections on hospitalized patients with IBD on the disease course, morbidity, and mortality.
Aims & Methods: In our retrospective study, we included patients hospitalized due to IBD exacerbation who were further stratified in those with enteric infection (Clostridium difficile infection (CDI) and non-CDI) and those without infections.
We collected demographic and clinical data including disease location and behavior, previous treatments and surgery, comorbidities, medications for IBD, symptoms at the time of admission at the emergency department (ED), number and type of blood and stool tests for enteric infections, CRP levels, therapies during hospitalization and after discharge, post discharge related hospitalization, post discharge surgery, post discharge mortality. Continuous variables are reported as median and IQR (interquartile range [25th percentile, 75th percentile]) while categorical ones as counts and percents.
Similarity between distributions is tested using the Kolmogorov-Smirnov test. Pearson's Chi Squared (with Yate's continuity correction) and Fisher's exact test are used for categorical variables, while Wilcoxon rank sum test (with continuity correction) it is used for continuous ones. Statistical analysis was performed using R (v. 4.2.2 - 2022).
Results: We included 267 patients hospitalized due to IBD exacerbation with a concomitant enteric infections and 89 IBD patients without. At baseline characteristics, IBD patients with enteric infections had longer median times of hospitalization than those without (10vs 6 days, p<0.001), and they presented higher CRP levels (36 vs 17, p<0.001).
Post-discharge, 29/89 (32.6%) and 57/267 (21.3%) of patients with and without enteric infections, respectively, were readmitted to ED for a flare (p=0.04). Moreover, infected patients had higher steroid dependency after discharge (p=0.003) compared to those without enteric infection.
Post-discharge, we did not find any difference in biological therapy optimization between the two groups (p=0.07). We then stratified IBD patients with infections in two sub-groups: patients with CDI (n=19) and patients with non-CDI (n=70). We found a statistically significant difference in IBD related re-hospitalization between the two groups (0% in CDI vs 22.9% in non-CDI, p=0.02).
Conclusion: Our findings suggest that enteric infections in IBD patients play an important role on complications like hospitalization and steroid dependency. Early detection, appropriate management, and prevention strategies are crucial to avoid their deleterious outcomes.

ASSESSMENT OF FACTORS ASSOCIATED WITH CUMULATIVE BOWEL DAMAGE IN SURGICALLY NAÏVE PATIENTS USING LEMANN INDEX AND GLOBAL MARIA INDEX IN CROHN'S DISEASE

V. Domislovic[1], K. Hrabric Sonje[2], M. Brinar[1], S. Cukovic-Cavka[1], N. Turk[1], D. Grgic[1], A. Barisic[1], M. Jelakovic[1], M. Prutki[2], Z. Krznaric[1]
[1]University Hospital Centre Zagreb, Department of Gastroenterology and Hepatology, Zagreb, Croatia, [2]University Hospital Centre Zagreb, Clinical Department of Diagnostic and Interventional Radiology, Zagreb, Croatia

Contact E-Mail Address: viktor.domislovic@gmail.com
Introduction: The Lémann index (LI) is a unique tool that measures cumulative bowel damage in Crohn's disease (CD) and is composed of surgical procedures and severity and extent of bowel lesions according to endoscopy and MR enterography (MRE). (1) Since there is a significant contribution of previous surgery in LI calculation, our aim of this study is to investigate factors associated with cumulative bowel damage using LI in both total population and surgically naïve patients.
Aims & Methods: In this cross-sectional study, LI was calculated evaluating 20 small bowel, 7 large bowel and 3 upper GI segments. For each segment bowel resections, inflammatory, stricturing or penetrating lesions were considered using MRE and upper and lower endoscopy. Global MaRIA (gMaRIA) index was calculated using following parameters on 6 bowel segments on MRE: bowel wall thickness, ulcers, edema, and relative contrast enhancement. Longstanding disease was defined as ≥10-year duration. Disease activity was defined as CRP>5 or HBI≥5. Extent and disease behavior were assessed using Montreal classification. Predictors were analyzed using multivariate logistic regression adjusted for confounders (age, gender, BMI, smoking status, CRP, disease behavior and extension, biological therapy, gMaRIA score, and HBI).
Results: This study included 320 CD patients [age 36 (24-46), 54.6% males, disease duration 7.2 (1-14) years, BMI 21.3 (17.4-24.8) kg/m2]. There were 142 (44.4%) surgically naïve and 128 (40%) patients with longstanding disease. In total population, higher LI values were observed among those with longstanding disease (10.31 vs 5.35 years, p<0.001), patients treated with biological therapy (9.7 vs. 6.4, p=0.005) and prior surgery (11.81 vs. 1.62, p<0.005). There was no difference in LI according to activity (p=0.921) and smoking status (p=0.336). Multivariate analysis on total population revealed independent predictors of elevated LI which were BMI (β=-0.268, p<0.02), disease duration (β=0.120, p=0.041) and prior surgery (β=5.42, p<0.001). Hence, separate multivariate analysis was performed on surgically naïve which revealed following predictors of LI (other than surgery): current smoking (β=1.14, p=0.010), perianal disease (β=1.39, p=0.02) and gMaRIA score (β=0.093, p<0.001). Diagnostic accuracy of LI in surgically naive patients in defining active disease was lower [AUC 0.74 (95%CI 0.64-0.85)] compared to gMaRIA [AUC 0.81 (95%CI 0.72-0.9)].
Conclusion: Prior surgery has significant impact on LI giving highest scores for resected segments. Positive predictors of cumulative bowel damage in surgically naïve patients were smoking, perianal disease, and radiological

activity (gMaRIA), while in total population longer disease duration, BMI and prior surgery. There are several important contributing variables on cumulative bowel damage which were revealed after removing previously operated patients, which would otherwise remain unrecognized. This risk factors in CD could stratify patients at high risk for complicated course of disease.

Introduction: Recent research has shown that there is considerable interest in studying inflammatory bowel diseases (IBD) due to the potential for dietary interventions to be used as a therapeutic approach for their onset and progression. Evidence suggests that Western-style diets, with high intake of processed foods, food additives, red meat, and animal fat, have been associated with an increased risk of IBD.

Aims & Methods: The purpose of this study is to evaluate the link between an anti-inflammatory exclusion diet and the maintenance of IBD remission, as well as to assess the potential therapeutic advantages of this dietary approach in preserving IBD remission.

The inclusion and exclusion criteria were applied to a total of 189 individuals with IBD, with 21 individuals not meeting the criteria. Therefore, 168 eligible patients were enrolled in the study and allocated to either an exclusion diet or a regular diet, based on their personal preference.

Results: A cohort of 84 adult patients with inflammatory bowel disease (IBD) was recruited for the study. The cohort included 47.6% males, with 44 patients having ulcerative colitis (UC) and 40 having Crohn's disease (CD). The intervention group received an exclusion diet consisting of the removal of red and processed meat, fried foods, high-lactose foods, fast food, white bread, sweetened drinks, and vegetable oils rich in omega-6 for a period of 1 year. An equivalent number of IBD patients with similar demographics and disease types formed the control group. The exclusion diet was well tolerated, with 90% of participants adhering to it frequently or always.

The study demonstrated that the clinical response was maintained in 80 patients (95.2%) in the intervention group, which was significantly higher than the 72 patients (85.7%) in the control group (p-value=0.036). Although not statistically significant, fecal calprotectin was higher in the control group than in the intervention group at the one-year follow-up interval. Additional information is provided in Table 1.

Parameter	All patients (168)	Exclusion diet (n=84)	Control (n=84)	p-value*
Sex (male)	80(47.6)	40 (47.6)	40 (47.6)	1.000
Age (years)	41.5 (18-77)	43.5 (23-77)	39.5 (18-72)	0.371
Immunosuppressive treatment Azathioprine Methotrexate	30 (17.9) 4 (2.4)	10 (11.9) 2 (2.4)	20(23.9) 2 (2.4)	0.083
Biologic treatment Infliximab Adalimumab Vedolizumab Ustekinumab Tofacitinib	48(28.6) 44 (26.2) 32 (19.1) 8 (4.8) 4 (2.4)	22 (26.2) 24 (28.6) 10 (11.9) 4 (4.8) 2 (2.4)	26 (31) 20 (23.8) 22 (26.2) 4 (4.8) 2 (2.4)	0.033
Combo therapy	30 (17.9)	10 (11.9)	20 (23.9)	0.069
Other IBD treatment	28 (16.7)	20 (23.8)	8 (9.5)	0.022
Initial fecal calprotectin >300 mcg/g	34 (20.2)	18 (21.4)	16 (19)	0.443
Fecal calprotectin>300 mcg/g after one year	22 (13.1)	8 (9.5)	14 (16.7)	0.171
Clinical remission after one year	152 (90.5)	80 (95.2)	72 (85.7)	0.036

Conclusion: Patients who adhere to an exclusion diet have the chance of a significantly higher rate of maintenance of clinical remission (95% versus 86% in the control group). A trend toward improvement in inflammation tests was observed in the intervention group, confirming once again that Western-style diet is an important etiological factor in IBD. Therefore, it is recommended that the exclusion, anti-inflammatory diet be presented to all patients diagnosed with IBD as a potential intervention.

PREVALENCE OF GASTROINTESTINAL SYMPTOMS, QUALITY OF LIFE, VISCERAL HYPERSENSITIVITY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE IN DEEP REMISSION

A. Trikola[1], K. Mousourakis[2], G. Karamanolis[3], N. Viazis[2]
[1]Naval Hospital of Athens, Gastrointestinal Department, Athens, Greece, [2]Evangelismos General Hospital, Gastrointestinal Department, Athens, Greece, [3]Athens Medical School, Gastrointestinal Department, Ampelokoipi, Greece

Contact E-Mail Address: artemis.trikola@yahoo.gr

Introduction: Patients with inflammatory bowel disease (IBD) may present with persisting gastrointestinal symptoms, despite clinical, biochemical and endoscopic remission. Disorders of the gut-brain interaction may coexist, resulting in hypervigilance and visceral hypersensitivity, thus affecting the quality of life of these patients. Failure to identify the origin and assess the reported symptoms may result in unnecessary treatment escalation.

The aim of this study is to describe the prevalence of gastrointestinal symptoms and visceral hypersensitivity and the quality of life in patients with IBD in deep remission.

Aims & Methods: We analyzed data from consecutive patients with either Crohn's disease (CD) or ulcerative colitis (UC), who remained under deep remission for at least 6 months. Remission was defined as absence of clinical, biochemical and endoscopic features of active disease.

We collected demographics, disease characteristics, symptom severity (via Patient Assessment of gastrointestinal disorders (PAGI-SYM), quality of life (via Patients assessment of gastrointestinal disorders- PAGI-QoL), psychological features including anxiety/depression (Hospital Anxiety and Depression Scale (HADS) and GI-specific anxiety (Visceral Sensitivity Index (VSI).

Results: A total of 69 patients, of whom 50.8% with CD and 49.2% with UC under deep remission (43.2% females, mean age 41.29 +/-14.87) were recruited. All applied questionnaires displayed excellent reliability analysis (Cronbach's alpha was 0.922 for PAGI-SYM, 0.962 for PAGI-QOL, 0.909 for VSI, and 0.848 for HADS respectively). Patients with CD and UC expressed similar gastrointestinal symptoms, as reflected by PAGI-SYM, with the exception of the loss of appetite, where patients with CD experience more severe symptoms than patients with UC (p=0.03). Moreover, the two groups displayed similar outcomes in VSI. Both patients with UC and CD in remission scored normally in HADS, although high on the anxiety score scale (mean anxiety scale 6.25+/- 3.5 and depression scale 4.47 +/- 3.31). However, a total of 36% and 24% of patients score abnormal in anxiety and depression scales respectively.

Conclusion: In this retrospective cohort, we found similar expression of gastrointestinal symptoms, quality of life, visceral hypersensitivity, and anxiety and depression scores in patients with UC and CD in deep remission. However, almost one-third of patients have persisting symptoms, affecting their QoL. A holistic approach is of paramount importance in patients with IBD, targeting both inflammatory and neuro-sensitivity pathways.

Introduction: Patients with inflammatory bowel disease (IBD) have an increased risk of developing intestinal and extra-intestinal cancers. Specific therapies used to control inflammation in IBD may have a different impact on cancer risk. However, there are no long-term studies investigating cancer risk in patients with IBD.

Aims & Methods: In the present study we aimed to quantify the overall risk for of developing cancer and to identify specific risk factors for the occurrence of intestinal and extra-intestinal cancers in 560 consecutive patients with Crohn's disease (CD, N=310) or ulcerative colitis (UC, N=250) referred to our outpatient department between January 2021 and February 2022. Demographic data, smoking status, alcohol consumption, age at IBD diagnosis, disease location and course, therapies, and cancer development after IBD diagnosis were recorded. Odds ratios (OR) were estimated by logistic regression analysis. Standardized Incidence Ratios (SIRs) were estimated compared with the general population.

Results: During a median follow-up interval or time of 10 years (range 1-26 years), 6.6% of patients (37/550, female 65 %, mean age 51 years) developed cancer (SIR 1.94, 95%CI 1.4-2.6). The most common cancers were colorectal (12.3%), skin (8.2%), and breast cancer (7.2%). Female patients had an increased risk for all cancers (SIR 3.11, 95%CI 2.06-4.3), melanoma (SIR 5.6, 95%CI 1.14-16.2) and colorectal cancer (SIR 7.59, 95%CI 3-15.4). Male patients had an increased risk of lymphoma (SIR 26.15, 95%CI 3.2-95.7). Younger age at diagnosis of CD (A1 Montreal classification, OR 37.9, 95%CI 10-14), immunosuppressive monotherapy (OR 5.5, 95%CI 2.65- 11) or in combination with anti-TNFα (OR 9.9, 95%CI 3.3-29.09) were associated with an increased risk of cancer in the study population.

Conclusion: We have identified subgroups of IBD patients who would particularly benefit from screening programs. Our findings need to be validated in independent cohorts.

Disclosure: Nothing to disclose.

Introduction: The distinction between intestinal tuberculosis (IT) and Crohn's disease (CD) is difficult because of the numerous clinical, endoscopic and histological similarities between these two diseases, essentially in the ileo-cecal localization, which poses a problem of positive diagnosis and therefore of therapeutic management of these patients. The diagnosis of IT can be easy when it is associated with a pulmonary or peritoneal localization, more difficult when it is isolated.

The aim of our work is to show the interest of quantiferon in the differential diagnosis between these two pathologies.

Aims & Methods: This is a retrospective, descriptive monocentric study conducted over a period of 15 years from January 2007 to July 2022. 666 cases of CD were identified including 189 patients with ileocecal localization and during the same period 53 cases of TI were included. All our patients had an endoscopic evaluation with biopsies, an entero-CT scan and a phthisiological check-up. We included all patients with ileocolitis having chronic transit disorders.

Results: The average age of our patients was 39 years for IT and 32 years for CD. The sex ratio F/H=1.4 for IT and F/H=1.2 for CD.

The circumstances of discovery were dominated by chronic abdominal pain, then diarrhea and finally subocclusive syndrome in 46.5% (n=88), 38.6% (n=73) and 15.8% (n=30) respectively in patients with a retained diagnosis of CD, and by abdominal pain, chronic diarrhea and finally constipation and/or subocclusive syndrome in 41.5% (n=22), 39.6% (n=21) and 22.6% (n=12) of the patients diagnosed with IT respectively.

Quantiferon was performed in 79 patients and was positive in 35.4% of patients (n=28) with CD and 64.5% of those with TI (n=51). ASCA was performed in 63 patients and was positive in 60% (n=38) and negative in 40% (n=25) of patients.

In cases where ASCA was positive/Qantiferon negative, the sensitivity, specificity, positive predictive value and negative predictive value for the diagnosis of CD were 80%, 98%, 93% and 50%, respectively.

Conclusion: Quantiferon has an important contribution in the differential diagnosis between IT and CD, the association with ASCA allows to refine the diagnosis between these two entities for a better therapeutic management.

Disclosure: Nothing to disclose.

Introduction: Transmural healing (TH) is a relevant target of biologic therapy in Crohn's disease (CD). Despite stable clinical remission, a proportion of patients (pts) under long term anti-TNF shows an increased bowel wall thickening (BWT). The causes of this are not clear.

Aims & Methods: This study aims to determine factors correlated with failure to reach TH despite long standing clinical remission with anti-TNF in CD.

This prospective study recruited a consecutive series of CD patients under adalimumab (ADA) or infliximab (IFX) in clinical remission since ≥1 year. Patients without clinical and sonographic assessment or increased BWT when starting biologic therapy, were excluded.

At enrollment the following parameters were collected: BMI, smoking, age at diagnosis, duration of CD, CD behavior and location, previous surgery, duration of clinical remission, previous use and duration of anti-TNF therapy, and concomitant immunomodulators. All pts underwent therapeutic drug monitoring (TDM) of ADA or IFX trough serum levels and intestinal ultrasound (IUS). TDM were assessed using a commercial assay, using therapeutic TL concentration >5mg/mL for IFX, and >7.5ug/mL for ADA and results were grouped as inferior to, up to thrice and more than thrice the normal value. IUS assessments, including those at the start of therapy, were performed by 2 expert sonographers (>10000 IUS). BWT at IUS was classified as: transmural healing (TH, BWT ≤3mm), transmural response (TR, BWT<25% of baseline) and no response (NR, BWT>4.5mm and no TR). Univariate analysis was performed and variables with $p<0.3$ entered a multivariate binary logistic regression analysis to identify those independently associated with the outcomes of interest (TH, TR, NR).

Results: 68 pts were included, 49 men with mean age of 32.2yrs, mean disease duration of 12.4yrs and remission duration of 4.1yrs. 18 pts were on IFX and 50 ADA, with a mean duration of therapy of 3.6 yrs. 36 pts (52.9%) showed anti-TNF TL below the normal threshold. 22 pts (38.4%) showed TH, 32 (47.1%) TR and 26 (38.2%) no response to treatment.

TH correlated with inflammatory CD phenotype (p 0.002), duration of remission (p 0.01), high TL of ADA (p 0.02), lower baseline BWT (0.0005) and absence of strictures at IUS after therapy (p 0.03). At multivariate analysis TH significantly correlated with BMI (p 0.01) and lower baseline BWT (CI95% -1.12 -0.1, p 0.01).

TR correlated with inflammatory phenotype (p 0.01), higher serum TL of ADA (p 0.001) and IFX (p 0.04) and overall with higher drug levels (p 0.01) and absence of strictures after therapy (p 0.04). At multivariate analysis TR correlated with shorter CD duration (CI95% -1.75 -0.13, p 0.02), higher drug levels (CI95% 0.03 0.22, p 0.01) and non stricturing phenotype (CI95% -2.85 -0.31, p 0.01)

NR was correlated with stricturing phenotype (p 0.007), lower serum TL of ADA (p 0.005) and IFX (p 0.04) and overall with lower levels of anti-TNF (p 0.005), greater baseline BWT (p 0.001) and stricture after therapy (p 0.002). At multivariate analysis NR correlated with lower BMI (CI95% -0.52 -0.09, p 0.004), lower drug levels (CI95% -0.32 -0.04, p 0.01), higher BWT at baseline (CI95% 0.11 1.21, p 0.02) and stricturing phenotype (CI95% 1.16 5.27, p 0.002).

Conclusion: Persistence of increased BWT in CD patients in stable clinical remission under biologic therapy is multifactorial and seems mainly due to sub-therapeutic TL of anti-TNF and development of strictures. High BWT when starting treatment, low BMI, development of strictures during treatment, disease duration and lower TL of anti-TNF alpha are key factors of the behavior of BWT and in reaching TH.

A LOW FAT, HIGH FIBER DIETARY INTERVENTION LEADS TO CHANGES IN SERUM PROTEOMIC PATTERNS IN CROHN'S DISEASE PATIENTS COMPARED TO HOUSEHOLD CONTROLS

H. Hazime[1], M.A. Quintero[1], L. Garces[1,1], O. Damas[1], C. Mengarelli[1], I. Fernandez[1], N. Solis[1], R. Killian[1], P. Mendygral[1], M. Ortega[1], D. Kerman[1], A. Deshpande[1], S. Proksell[1], I. Barrera[1], M. Abreu[1]

Contact E-Mail Address: mabreu1@med.miami.edu

Introduction: Crohn's disease (CD) is an inflammatory bowel disease (IBD) characterized by chronic inflammation and dysbiosis. Current pharmacologic-based treatment strategies have improved the course of CD but adverse effects and resistance call for exploring non-pharmacologic options. Diet plays a pivotal role in the development and progression of CD and recent studies highlight the feasibility and effectiveness of specific diet interventions in improving CD symptoms. However, little is known about the degree to which diet-modulation impacts biological responses in CD. To that end, we conducted a patient preference study to test a low fat, high fiber (LF/HF) diet in CD patients.

Aims & Methods: Here, we used unbiased serum proteomic screening to interrogate the systemic impact of short-term (8-week) catered dietary intervention on circulating protein levels in CD patients and healthy household controls (HHC) receiving identical diets. Serum samples were obtained from 10 CD patients and matched HHC enrolled in our LF/HF catered diet intervention study (NCT04213729) at baseline and 8-weeks following the diet. Quantitative proteome analysis was done using the SOMAscan assay (SomaLogic). Biological pathway and network analyses were performed.

Results: At baselined, CD patients had increased levels of the pro-inflammatory proteins serum amyloid A-1 (SAA1) and C-reactive protein (CRP) and increased levels of fibrinogen and Fibrinogen-like protein 1 (FGL1) compared with HHC. The immunomodulatory proteins C-type lectin domain family 12 member A (CLEC12A) and immunoglobulin A (IgA) were also elevated in CD patients compared to HHCs. In the same comparison, CD patients had reduced levels of Transcobalamin-2 (TCN2), the protein responsible for B-12 transport, and Alcohol dehydrogenase 1C (ADH1C), a protein recently highlighted for its immune-regulating role in IBD. After 8 weeks of catered LF/HF diet, CD patients had marked decrease of CRP, fibrinogen, FGL1, CLEC12A and an upregulation in ADH1C. In both CD patients and HHC, our data at the 8-week timepoint compared to baseline show a significant downregulation in the adipocyte-derived protein leptin and the Complement component 1 Q subcomponent-binding protein (C1QBP) which plays a role in impairing goblet cell formation IBD. We also observed a marked downward trend in the levels of SAA1 and CRP at the 8-week time point in CD patients and an upregulation in Ras-related

protein (Rab-21) and (Rab-7), which are important in intestinal epithelium maintenance. Lastly, pathway analysis revealed a significant enrichment in pathways associated with amino acid and fatty acid metabolism, endothelial cell development, and cellular response to DNA damage following 8 weeks of LF/HF diet intervention in CD patients.

Baseline: HHC Vs.CD		After diet: HHC Vs. CD		CD: baseline Vs. after diet	
Decreased in CD	Increased in CD	Improved after diet (decreased in CD)	Improved after diet (increase in CD)	Increased after diet	Decreased after diet
TCN2 (6)	SAA1 (-1.9)	SAA1 (-1.6)	ADH1C (0.053)	RAB21 (0.96)	SAA1 (-0.6)
ADH1C (0.82)	CRP (-1.1)	CRP (0.14)		RAB7A(0.91)	CRP (-0.4)
	Fibrinogen (-0.5)	Fibrinogen (0.067)			Leptin (-0.72)
	FGL1 (-0.97)	FGL1 (-0.14)			C1QBP (-0.34)
	CLEC12A (-0.39)	IgA (-0.43)			
	IgA (-0.67)	CLEC12A (-0.13)			

Table. Summary of major proteins altered out of 7,500 proteins identified in each comparison (fold change).

Conclusion: Overall, our results suggest that catering a diet high in fiber and low in fat for 8 weeks is enough to lead to distinct protein level modulations suggestive of improved immune function, mucosal healing, and inflammatory status. These strategies can lead to identification of novel targets of diet responses in CD.

DEEP LEARNING AND MINIMALLY INVASIVE CROHN'S DISEASE INFLAMMATORY ACTIVITY ASSESSMENT: DEVELOPMENT OF A PAN ENDOSCOPY CONVOLUTIONAL NEURAL NETWORK

J. Afonso[1], M.J. Mascarenhas Saraiva[1], P. Cardoso[1], T. Ribeiro[1], F. Mendes[1], M. Martins[1], A.P. Andrade[1], H. Cardoso[1], J. Ferreira[2], G. Macedo[1]
[1]Centro Hospitalar S. João, Gastroenterology Department, Porto, Portugal, [2]Faculdade de Engenharia da Universidade do Porto, Porto, Portugal

Contact E-Mail Address: joaoafonso28@gmail.com
Introduction: Capsule endoscopy (CE) is a valuable tool for assessing inflammation in patients with Crohn's disease (CD). The current standard for evaluating inflammation are validated scores like Lewis score (LS), Capsule Endoscopy Crohn's Disease Activity Index (CECDAI) and ELIAKIM score and laboratory values. Recent advances in artificial intelligence (AI) have made it possible to automatically select the most relevant frames in capsule endoscopy.
Aims & Methods: In this study, our objective was to develop an automated scoring system using CE images to objectively grade inflammation. Panenteric CE videos (PillCam Crohn's) performed in CD patients between 09/2020 and 01/2023 were retrospectively reviewed and LS, CECDAI and ELIAKIM scores calculated. We developed a convolutional neural network based automated score consisting in the percentage of positive frames selected by the algorithm (for small bowel and colon separately). We correlated clinical data and the validated scores with the artificial intelligence generated score (AIS).
Results: A total of 61 patients were included. The median SL was 225 [0-6,06], CECDAI was 6 [0-33], ELIAKIM was 4 [0-38] and SB_AIS was 0.5659 [0-29.45]. We found a strong correlation between SB_AIS and LS, CECDAI and ELIAKIM scores (Pearson's r= 0.751, r=0.707, r= 0.655, p = 0.001). We found a strong correlation between SL and ELIAKIM (r= 0,768, p = 0.001) and very strong correlation between CECDAI and SL scores (r= 0,854, p = 0.001) and CECDAI and ELIAKIM (r= 0,827, p = 0.001).
Conclusion: Our study showed that the AI-generated score had a strong correlation with validated scores, indicating that it could serve as an objective and efficient method for evaluating inflammation in CD patients. As a pre-proof study, our findings provide a promising basis for future reffining a CE score that can accurately correlate with prognostic factors and aid in the management and treatment of CD patients.
Disclosure: Nothing to disclose.

Contact E-Mail Address: sahar.hamza137@gmail.com
Introduction: The enhancement of the quality of life (QoL) of patients with inflammatory bowel disease (IBD) has become a major therapeutic target in the management of this disease. Sexuality is one of its main determinants. However, in Tunisia, there is little data on sexual dysfunction (SD) and fertility among IBD patients.
Aims & Methods: The aim of this study was to determine the incidence and the factors associated with SD during IBD. We conducted a cross-sectional study including patients with IBD followed at the Gastroenterology Department of Charles Nicole Hospital between July and December 2020. Sexual function was assessed by the Female Sexual Function Index (FSFI) score in women and by the International Index of Erectile Function (IIEF) in men. Scores assessing patients 'overall QoL were calculated: Hospital anxiety and depression scale (HADS), Fatigue Severity Scale (FSS), and Short Inflammatory Bowel Disease Questionnaire (S-IBDQ). All patients gave oral informed consent before answering the questionnaires.
Results: A total of 65 patients were included of whom 72.3% had CD and 27.7% had UC, with a mean age of 47.58±10.18 years and sex ratio (M/F) of 0.44.
SD was found in 73.3% of women according to the FSFI and in 15% of men according to the IIEF-15. Erectile dysfunction (ED) was observed in 40% of patients based on the IIEF-5.
Female gender was a significant factor of SD (p<0.001; OR 15.6; CI [3.9-62.8]).
An analytical statistical study was conducted, showing factors associated with SD in the female patient group only.
Our study showed that the factors associated with the presence of female SD were age (p=0.018), absence of professional activity (p=0.034), length of marriage (p=0.022), presence of probable or overt depression (p=0.01), fatigue (p=0.042), impaired QoL judged by the S-IBDQ (p=0, 042), the four domains of the S-IBDQ (bowel symptoms (p=0.04), general signs (p=0.011), emotional domain (p=0.004), social domain (p=0.013)), IBD-disk score (p=0.007), and IBD-disk domains (sexual activity (p<0.001), emotion (p=0.001), energy (p=0.016), and joint pain (p=0.015)).
There were no factors that appeared to be associated with male SD. Meanwhile, we found a statistically significant association between men's perception of impaired sexuality due to IBD and the presence of ED (p=0.004; OR=33; CI [2.4-443.6]).
In multivariate analysis, the factors independently associated with female SD were the duration of marriage (p=0.018; OR 3.58; CI [1.43-7.83]), the presence of suspected or overt depression (p<0.001; OR 12.6; CI [1.82-72.52]) and fatigue (p=0.032; OR 11.8; CI [1.61-96.7]).

Conclusion: Our study shows that sexual disorders are frequent in IBD patients, especially in women. A multidisciplinary management involving gastroenterologists, psychologists, and sexologists is sometimes necessary in these young patients, in order to improve their QoL.

Disclosure: Nothing to disclose.

Contact E-Mail Address: a_buisson@hotmail.fr

Introduction: The STRIDE 2 recommendations consider achievement of both clinical remission (no rectal bleeding and normalization of stool frequency), and endoscopic remission as the best therapeutic target. Despite the negative impact of bowel urgency on patients' quality of life, this symptom, which is frequently observed in UC patients, has not been taken into account by a such definition.

Aims & Methods: In this large multicenter cohort, we aimed to assess whether the persistence of bowel urgency after induction therapy is independently associated with the risk of treatment discontinuation due to active UC, colectomy, and a lower likelihood of being in clinical, endoscopic or histological remission.

From a multicenter retrospective study, we included consecutive UC adult patients previously exposed to at least one anti-TNF agent, with partial Mayo score (pMS) > 2, who started biologics or small molecules between January 2019 and June 2022. Bowel urgency was defined as a binary criterion based on the SCCAI definition. The primary endpoint was the time to drug discontinuation due to active UC. Secondary endpoints were the time to relapse, the time to colectomy as well as steroid-free clinical remission (pMS ≤ 2) (CFREM), endoscopic remission (CFREM + Mayo endoscopic score (MES) ≤ 1), and mucosal healing (CFREM + MES ≤ 1 + histological remission *i.e.* Nancy index ≤ 1) at last follow-up.

Results: Among 473 patients with UC, 270 were assessed for bowel urgency after induction therapy (between W14 and week 16) (mean age 43.0 ± 17.0 years-old, median UC duration 6 [3-11] years, female gender = 54.0%, pancolitis = 45.9%). The median follow-up was 14 [8-22] months. The rate of CFREM after induction therapy was 54.4% (147/270) while 21.5% (58/270) had remaining bowel urgencies after induction therapy. Among the 147 patients achieving remission after induction therapy, 12 presented with persistent bowel urgencies (8.2%). In contrast, 62.6% (77/123) of the patients with no CFREM after induction therapy did not have any bowel urgency. The agreements between bowel urgency and absence of CFREM (67.0%, kappa-coefficient = 0.30 ± 0.05), rectal bleeding (75.2%, kappa-coefficient = 0.33 ± 0.06) or normalization of stools frequency (67.9%, kappa-coefficient = 0.35 ± 0.05) were mild. Among the patients with persistent bowel urgency after induction therapy, only 3.7% of the patients had MES = 0 while 85.2% had MES ≥ 2. In multivariable analyses including CFREM at week 16, persistence of bowel urgency after induction therapy was independently associated with the time to drug discontinuation (HR = 2.0 [1.1-3.5], p = 0.016) and colectomy (HR = 4.4 [2.3-8.4], p < 0.001) as well as absence of mucosal healing (OR = 5.0 [1.1-24.8], p = 0.046) at last follow-up. A trend was also observed regarding the association between remaining bowel urgency after induction therapy and no CFREM (OR = 6.1 [0.8-48.0], p = 0.085) or absence of endoscopic remission (OR = 2.4 [0.9-6.1], p = 0.077) at last follow-up.

Conclusion: Persistence of bowel urgency despite clinical remission is associated with higher risk of drug discontinuation due to active UC, colectomy and lower likelihood of mucosal healing. Bowel urgency should be implemented into international guidelines to define clinical remission in patients with UC.

GENDER-SPECIFIC DIFFERENCES IN GASTROINTESTINAL SYMPTOMS AMONG PEDIATRIC PATIENTS WITH INFLAMMATORY BOWEL DISEASES AND COELIAC DISEASES ASSESSED WITH THE VALIDATED PSAGIS SCALE

B. Majcher[1], K. Hammer[1], U. Anwar[2], H. Kogler[1], A. Vécsei[1], J. Hammer[2]

Introduction: Gender-specific differences in adult patients with immune mediated diseases like inflammatory bowel diseases (IBD) or coeliac diseases are increasingly recognised (1). In paediatric patients, gender differences in the incidence of IBD have been identified in a pooled analysis of population-based studies (2). However, gastrointestinal (GI) symptoms associated with paediatric IBD or coeliac disease and possible gender differences in GI symptoms have not been systematically studied.

Aims & Methods: Our aim was to utilise the newly developed, validated paediatric Structured Assessment of Gastrointestinal Symptoms (pSAGIS) scale to systematically assess GI symptoms in children with Crohn's disease, ulcerative colitis, and coeliac disease by gender in an paediatric gastrointestinal outpatient clinic.

The pSAGIS is a patient-reported outcome measure (PROM) that consists of 21 GI-related questions and assesses the type and five severity grades of symptoms.

pSAGIS scales were completed by patients or their caregivers attending the GI outpatient unit of St. Anna Children's Hospital, Vienna, Austria between the years 2016 and 2020. The diagnoses of patients were established on clinical terms after a complete examination deemed clinically necessary. Based on pSAGIS, an overall GI-symptom score was calculated as the sum of each individual symptom score for patients with Crohn's disease, ulcerative colitis and coeliac disease, and symptom scores were compared between female and male patients. In addition, GI symptoms were summarised in five symptom groups (abdominal pain, dyspepsia, diarrhea, constipation, dysphagia/nausea). Data are given as mean ± standard deviation (SD), a p-value <0.05 was considered significant.

Results: From 3344 collected pSAGIS questionnaires 12.9% (n=430) were completed by children diagnosed with Crohn's disease (71.9% male, 28.1% female), 9.0% (n=302) with ulcerative colitis (57.0% male, 43.0% female), and 24.7% (n=827) with coeliac disease (36.4% male, 63.6% female). In patients with Crohn's disease the overall GI-symptom score was significantly higher among female patients comparing to male patients (7.3±10,1 vs. 2. 8±4,2, p<0.001) while in patients with ulcerative colitis overall symptom scores were higher in male than in female patients (5.6±8.5 vs 2.9±5.9; p=0.002). The table shows scores of symptom groups in patients with Crohn's disease and ulcerative colitis. The overall GI symptom score was low in patients with coeliac disease, and no significant differences were found between male and female coeliac patients (3.1±4.6 vs. 3.9±6.4, p=0,064).

	Crohn's disease			Ulcerative colitis		
	male	female	p-value	male	female	p-value
abdominal pain	1.0±2.1	2.6±3.8	<0.0001	1.7±2.7	1.3±2.9	0.1692
dyspepsia	0.9±1.5	2.7±4.7	<0.0001	1.5±2.6	0.4±1.2	<0.0001
diarrhea	0.5±1.1	0.8±1.7	0.0247	1.8±3.0	0.6±1.7	<0.0001
constipation	0.2±0.6	0.4±1.0	0.0042	0.2±0.6	0.4±0.8	0.0771
dysphagia/nausea	0.3±0.8	0.8±1.4	<0.0001	0.4±1.2	0.2±0.9	0.3156
	Mean symptom score ± SD			Mean symptom score ± SD		

Table.

Conclusion: Gender specific symptoms and symptom burden exist in paediatric patients with Crohn's disease and ulcerative colitis. These gender differences may affect time to diagnosis, initiation of treatment and adherence to treatment and need further investigation. The pSAGIS is an easy adjunct to gastrointestinal history taking and allows a valid and systematic symptom assessment in a paediatric outpatient clinic.

FAECAL CALPROTECTIN TO PREDICT THE RISK OF RELAPSE IN PATIENTS WITH ULCERATIVE COLITIS IN CLINICAL REMISSION AND ENDOSCOPIC MAYO SCORE 0 OR 1: RESULTS OF THE CALPRODICT-UC STUDY

A. Buisson[1], A. Doublet[1], C. Carpentier[1], R. Minet-Quinard[1], B. Pereira[1]

[1]CHU Estaing Clermont-Ferrand, IBD Unit, Clermont-Ferrand, France

Contact E-Mail Address: a_buisson@hotmail.fr

Introduction: In ulcerative colitis (UC), the current therapeutic target is to achieve endoscopic remission defined as a Mayo endoscopic score (MES) 0. However, differentiating MES 0 and 1 remains difficult in daily practice.

Aims & Methods: In this study, we aimed to evaluate faecal calprotectin (FCal) as a predictor of relapse in patients with UC in clinical remission with MES 0 and 1.

In this monocenter retrospective study, we included all adult patients with UC in clinical remission (partial mayo score ≤ 2) and MES 0 or 1, who had FCal testing within the month before endoscopy, without therapeutic intervention between calprotectin assay and endoscopy.

The primary endpoint was clinical relapse (partial Mayo score > 2 including at least one subscore among rectal bleeding or stools frequency > 1) leading to therapeutic escalation or treatment discontinuation.

The analyzes were carried out according to the Kaplan-Meier method using univariate and then multivariable models (Cox model). The results were expressed as a hazard ratio (HR) with 95% confidence interval.

Results: Overall, 362 patients were included with 47.5 (172/362) and 52.5% (190/362) of patients with MES at 0 and 1, respectively. The median level of FCal was 48 µg/g [14-157] with 25.4% (92/362) of patients with a FCal level > 150 µg/g. Among MES 0-patients, 28 (7.7%) and 144 (39.8%) had FCal respectively above and below the threshold of 150µg/g while 64 (17.7%) and 126 (34.8%) MES 1-patients had calprotectin levels respectively higher and less than 150 µg/g. The median follow-up was 13.6 months [5.4-36.1]. During follow-up, 49 patients (13.5%)experienced a relapse and 36 patients (10.0%) had to discontinue the current medication. MES 1 was associated with a higher risk of relapse (HR = 1.85[0.98-3.50], p=0.056) or treatment discontinuation than MES 0 (HR=3.02[1.36 – 6.73], p=0.007).

FCal value > 150 µg/g was associated with an increased risk of relapse (HR=3.15[1.72 – 5.75], p<0.001) or treatment discontinuation (HR=2.85[1.44–5.66], p=0.003) compared to lower values. MES 0 patients with FCal < 150 µg/g had a reduced risk of relapse compared to those with MES 0 and FCal > 150 (HR = 3.16[1.08 – 9.27], p=0.035), and MES 1 and FCal > 150 (HR=4.01 [1.84 – 8.96], p=0.001). Among MES 1 patients, those with FCal < 150 had a lower risk of relapse than those with higher values (p=0.01).

Regarding the risk of treatment discontinuation for relapse, MES 0 patients with FCal < 150 had a lower risk than those with MES 0 with FCal > 150 (HR=5.80[1.45 -23.23], p=0.013), MES 1 with FCal < 150 (HR=4.11[1.34-12.63], p=0.013) and MES 1 with FCal > 150 (HR = 7.20[2.31 -22.44], p=0.001).

Conclusion: FCal could be helpful to predict the risk of relapse among the patients in clinical remission with MES 0 and 1.

VIDEO CAPSULE ENDOSCOPY MAY DETECT ACTIVE SMALL BOWEL CROHN'S DISEASE REQUIRING CHANGE OF TREATMENT DESPITE UNREMARKABLE ILEO-COLONIC ANASTOMOSIS

T. Thurm[1], N. Zmora[1,2], A. Hirsch[1], L. Deutsch (Mlynarsky)[1], N. Maharshak[1]
[1]Tel Aviv Medical Center, affiliated with Sackler School of Medicine, Department of Gastroenterology and Hepatology, Tel-Aviv, Israel, [2]Weizmann Institute of Science, Immunology Department, Rehovot, Israel

Introduction: Previous studies have shown benefit in performing video capsule endoscopy (VCE) in Crohn's disease (CD) diagnosis, especially in cases of an unremarkable ileo-colonoscopy, however data on the role of VCE in postsurgical follow-up of CD patients is lacking.
Aims & Methods: Our aim was to evaluate CD endoscopic activity in the small bowel (SB) of patients presenting with disease remission at the ileo-colonic anastomosis.
We retrospectively obtained data on patients with CD older than 18 years of age, who underwent ileo-colonoscopy between the dates 1/10/2012 through 31/09/2022. Patients in whom VCE was performed within 8 months of ileo-colonoscopy were eligible for analysis. Lewis and Rutgeerts scores were calculated based on VCE images and endoscopy reports, respectively. Disease remission was deemed as Rutgeerts score of i0-i1 at the ileo-colonic anastomosis, and Lewis score (LS) of<135 on VCE.
Results: A total of 1,334 ileo-colonoscopies were performed in CD patients with ileo-colonic anastomosis during the study period, of whom 31 patients (male gender 58.06%; mean age 41.77±14.19 years) were referred to VCE within 8 months of ileo-colonoscopy, (median 124.81 days). Twenty patients exhibited endoscopic remission at the anastomosis, 3 of them failed passage of a patency capsule and 17 successfully completed VCE. Only 5 patients (29.4%) had a normal LS, while 12 (70.6%) exhibited an active SB disease (LS≥135, mean 791.3±1254.9). Patients with a discrepancy between the two scores, were characterized by a shorter disease duration (P=0.011) and showed a trend towards a shorter time since surgery (P=0.06). No correlation was found between SB disease activity and concurrent medical therapy (P=0.898). Treatment modification was applied in 7 patients (41.2%) and was associated with a higher LS (biserial correlation coefficient 0.51, P=0.037).
Conclusion: Endoscopic remission at the ileo-colonic anastomosis is not an accurate indicator for CD remission in the SB, especially in a new-onset disease and soon after the surgery. VCE has an added value to ileo-colonoscopy in postsurgical follow-up and treatment adjustment in patients with CD.
Disclosure: Nothing to disclose.

Introduction: Crohn's disease (CD) is a chronic inflammatory condition that leads to cumulative structural bowel damage. The Lémann Index is a validated tool that can be a useful for monitoring the progression of the disease and evaluating the effectiveness of different therapies. Recent data have shown a range of biomarkers and endoscopic findings preceding the diagnosis of CD.
Aims & Methods: Our aim was to describe the most frequent cross-sectional findings in asymptomatic patients with an incidental diagnosis of CD and to evaluate the progression of bowel damage from a preclinical stage until the symptomatic onset of the disease. Patients with an incidental diagnosis of CD during the colorectal cancer screening programme were included. Only patients with available MRI enterography were included. They were compared 1:1 to controls matched by disease extent from an inception cohort of patients with CD diagnosed after symptomatic onset of the disease. All cross-sectional examinations were centrally-read by one experienced radiologist, performing a descriptive analysis of the main radiological findings and calculation of Lémann score on both cohorts. Descriptive statistics were used along with comparisons with chi-square tests and Mann-Whitney analysis.
Results: A total of 38 patients were included: 19 cases with preclinical CD and 19 matched-controls (age 55 years (IQR, 54-62) vs 49 years (IQR, 45-58); 53% vs 42% male; 74% vs 53% non-smokers, respectively). CD location was 53% L1, 21% L2 and 26% L3; and CD behaviour was B1 in 74% vs 79%; B2 in 26% vs 16%; and none vs 5%, among cases and controls, respectively.
The most frequent transmural findings on MRI were contrast enhancement and wall thickening (79% respectively), followed by oedema (42%), while among extraintestinal findings they were lymphadenopathy (68%) and increased vascularity (42%). Among patients with strictures, controls showed a higher rate of preestenotic dilation (100% vs 0%, p=0.01).
Bowel damage assessment revealed no statistically significant differences in the Lémann index between preclinical CD and controls (p=0.95). However, we observed that cases had statistically significant higher scores in the colonic/rectum score (p=0.014). We found no differences in the Lémann index between preclinical CD patients who subsenquently developed symptoms (median LI 1.0 [IQR, 0.3-2.0]) and those who did not (1.1 [IQR, 0.68-2.65], respectively, p=0.71) or with controls (1.3 [IQR, 0.0-3.1], respectively, p=0.96).
Conclusion: Patients with preclinical CD demonstrate similar findings on MRI enterography and they have the same degree of bowel damage as new-onset symptomatic CD. Close monitoring should be recommended based on these findings.

Contact E-Mail Address: margideb@gmail.com

Introduction: The diagnosis of Crohn's Disease (CD) is based on a combination of clinical symptoms, laboratory tests, endoscopy and imaging data. Imaging technique use, including ultrasonography, computed tomography (CT) and magnetic resonance enterography (MRE), have been increasing in recent years. Transabdominal ultrasound is non-invasive, does not use ionizing radiation and is easily accepted by patients. In particular, in Small Intestine Contrast Ultrasonography (SICUS) the ingestion of a macrogol solution as oral contrast medium may optimize image quality and increase sensitivity and diagnostic accuracy in detecting lesions of the small intestine.

Aims & Methods: We aimed to evaluate diagnostic performance of SICUS for CD. A literature search was performed and updated in February 2023. We selected only studies in which SICUS was compared to a technique allowing the assessment of whole gastrointestinal tract such as MRE, CT scan or surgical evaluation. The end-point was to estimate the pooled weighted sensitivity, specificity, likelihood ratio for positive and negative test (PLR and NLR, respectively) and diagnostic odd ratio (DOR) of SICUS. Summary receiver operating characteristic curves (SROC) were drawn and pooled areas under the curve (AUC) were calculated. A random effect model was followed in all analyses. We assessed heterogeneity using the χ^2 test and, if statistically significant, the I^2 statistic was computed. The data were expressed as proportions/percentages, and 95% confidence intervals (CI) were calculated. The MetaDisc software version 1.4 was used.

Results: Five studies were included in the analysis. Overall, 325 patients with CD were recruited. SICUS showed a pooled sensitivity for diagnosis of 95% (95% CI 89-99%) a specificity of 77% (95% CI 60-90%), and the AUC of SROC curve was 0.94. Presence of strictures was examined in 94 patients within all studies. SICUS demonstrated a pooled sensitivity of 78% (95% CI 63-88%) and a specificity of 96% (95% CI 85-99%), with AUC = 0.93. For abscesses, SICUS demonstrated a pooled sensitivity of 100% (95% CI 59-100%) and a specificity of 90% (95% CI 74-98%). Fistulae were evaluated in 55 patients overall across three studies. SICUS showed a pooled sensitivity of 77% (95% CI 46-95%) and a specificity of 92% (95% CI 75-99%). Three studies investigated the presence of pre-stenotic luminal dilation in 61 patients. We found a pooled sensitivity of 100% (95% CI 80-100%) a specificity of 80% (95% CI 65-90%) and the AUC of SROC curve was 0.91.

Conclusion: SICUS has excellent diagnostic performance compared to gold standard, despite some situations (stenosis and fistulae) show suboptimal diagnostic effectiveness.

Disclosure: Nothing to disclose.

Introduction: Transmural remission in Crohn's disease (CD) has been associated with improved long-term clinical outcomes including reduced hospitalization, surgery, escalation of treatment, and a decrease in clinical relapse over endoscopic remission alone. Albeit transmural remission rate (TRR) in CD patients treated with anti-TNF drugs in first line has been well explored, data on TRR using vedolizumab (VDZ) or ustekinumab (UST) as second-line therapy for CD are still limited.

Aims & Methods: The aim of this study was to evaluate the TRR in CD patients in maintenance treatment, comparing adalimumab (ADA) in first line with VDZ/UST in second line. From 2018 to 2022 we performed a real world observational longitudinal study evaluating the TRR in all consecutive CD patients in a 2-years maintenance treatment with ADA in first line compared with those treated by VDZ or UST in second line. HBI, fecal calprotectin (FC), SES-CD, and bowel wall thickness (BWT) at ultrasound were analyzed in all patients at the baseline (T0) and after 2 years of maintenance treatment (T1). Clinical remission was defined when HBI was <4. Endoscopic remission was defined when SES-CD was <2. Transmural remission was defined when BWT was <3 mm at a "per-patient" analysis. In accordance with recent literature, laboratory remission was defined when FC was <94 ug/gr.

Results: One hundred and sixty-one CD patients (78 ADA, 41 VDZ, 42 UST) were included in the study. At T1, transmural remission rate was recorded in 39.7% of CD patients treated in first line with ADA, and in 17.1% and 21.4% for VDZ and UST, respectively, in second line (ADA vs VDZ/UST: p<0.05; VDZ vs UST: p 0.6). Endoscopic remission rate was 50% for patients treated in first line with ADA, and 31.7% and 35.7% for second line VDZ and UST, respectively (ADA vs VDZ/UST: p<0.05; VDZ vs UST: p 0.7). Laboratory remission rate was 53.8% for patients treated in first line with ADA, and 29.3% and 35.7% for VDZ and UST in second line, respectively (ADA vs VDZ/UST: p<0.05; VDZ vs UST: p 0.5). Clinical remission rate was 58.9% for patients treated in first line with ADA, and 43.9% and 47.6% for second line VDZ and UST, respectively (ADA vs VDZ/UST: p=0.09; VDZ vs UST: p=0.2).

Conclusion: Our findings showed that in CD patients in maintenance treatment with biologics, ADA in first line showed a higher TRR compared with VDZ/UST in second line. Moreover, VDZ and UST showed similar TRR and other outcomes when used in second line.

INTESTINAL ULTRASOUND – COLITIS SEVERITY INDEX (IUS-CSI): VALIDATION OF AN INTESTINAL ULTRASOUND-BASED SCORE FOR ASSESSING DISEASE ACTIVITY IN ULCERATIVE COLITIS

K.V. Nagarajan[1], R.B. Mallappa[1], A. Yelsangikar[1], A. Nagar[1], R. Agarwal[1], N. Bhat[1]
[1]Aster CMI Hospital, Gastroenterology, Bangalore, India

Contact E-Mail Address: kayal.doc@gmail.com

Introduction: Endoscopic scoring systems like Mayo endoscopic score (MES) is the gold standard for the assessment of disease activity in patients with ulcerative colitis. Intestinal ultrasound (IUS) is an attractive tool for assessing Ulcerative colitis (UC) disease activity. A novel IUS Score for UC was proposed by us in 2019 using simple IUS parameters which correlated well with MES.

Aims & Methods: Aims: We aim to internally validate our Intestinal Ultra-Sound – Colitis Severity Index (IUS-CSI) scoring system.

Methods: Consecutive patients with UC undergoing colonoscopy for diagnosis, screening, or flare of symptoms were included in the study. These patients were evaluated with IUS within 1 week of their colonoscopy. The colon was divided into segments – sigmoid, left, transverse, and right colon. Rectum was excluded from the study. Endoscopic disease activity was graded using MES for each colonic segment. IUS-CSI score was calculated for each colonic segment using Bowel wall thickness (BWT), Colour doppler signal score (CDS) and bowel wall stratification (BWS). The correlation of IUS-CSI with MES for that segment was studied.

IUS-CSI	Score
BWT	
< 3.0 mm	0
3.1 - 5.0 mm	2
> 5.1mm	4
BWS	
Present	0
Absent	4
CDS	
No/ minimal uptake	2
Short stretches	4
Long stretches	6

IUS-CSI	MES Score
< 4	0/1
5-8	2
> 9	3

Results: 45 consecutive patients with UC who underwent colonoscopy were included in the study. IUS was performed in 42 patients; 3 patients could not be evaluated in view of thick abdominal wall. Total of 168 colonic segments were assessed both by colonoscopy and IUS. 32 colonic segments had MES 0, 28 segments had MES 1, 92 segments had MES 2 and 16 segments had MES 3.

Mean BWT for MES 0, 1, 2 and 3 were 2.1mm, 2.5mm, 3.4mm and 5.1mm respectively. Of all the IUS parameters, BWT and CDS had consistent correlation with MES (p=<0.001).

The IUS-CSI was calculated for each colonic segment and correlated with the MES for that segment. A linear positive correlation was seen between IUS-CSI & MES for each colonic segment using Pearson's correlation coefficient (r) and is as follows: Sigmoid colon r= 0.88(0.79,0.93), left colon r= 0.85(0.74,0.92), transverse colon r=0.89(0.8,0.94) and right colon r=0.79(0.64,0.88). The IUS-CSI for sigmoid colon correlated with the overall MES (r =0.83; p = 0.0001).

Conclusion: IUS-CSI has an excellent correlation with MES. IUS-CSI assessment of the sigmoid colon correlates best with overall endoscopic activity. IUS-CSI scoring system with intestinal ultrasound can be used to assess disease activity in UC non-invasively.

Introduction: The role of adipose tissue in IBD is yet to be fully elucidated. Adipose tissue is distributed into two main compartments ; Visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT). Previous studies suggest that VAT may be a predictor of disease progression particularly in Crohn's disease (CD)(1). VAT:SAT ratio, and not BMI, has been associated with a structuring CD phenotype, faecal calprotectin and quality of life (2).

In previous studies, visceral obesity has been defined as a VAT area of 100cm^2 as well as VAT:SAT 40% (3-4). We sought to investigate the difference in fat composition of patients with IBD using computed tomography (CT).

Aims & Methods: Patients with IBD were selected randomly from an IBD database in our centre. Age and gender matched controls were selected for comparison.

Using TeraRecon software, we retrospectively analyzed CT results to obtain the following parameters; VAT Area (cm^2), SAT Area (cm^2), VAT:SAT Ratio (VAT/VAT+SAT - %) and Waist Circumference (WC) (cm). Measurements were taken at the level of the umbilicus (L3). Data was also collected retrospectively from outpatient clinic letters, previous biopsy reports and endoscopy reports. Statistical analysis was preformed using Minitab.

Results: A random sample of 480 patients were identified. 279 of these patients were excluded, leaving 201 patients which were analysed.

The majority of this cohort were female (n=102). The mean age was 43. 122 patients had CD and 79 patients had Ulcerative colitis (UC). At the time of imaging, 95 patients were on biologics with a further 29 patients progressing onto biologics later in their treatment. Visceral obesity (40% VAT:SAT) was found in 31.8% of patients. 46.8% of patients had VAT 100cm^2. Male gender accounted for 17.27% more VAT:SAT in comparison to female gender (p =0.000). VAT showed a strong correlation with WC (r =0.809).

No significant difference was found in fat composition or WC between a sample of patients with IBD and their controls.

Patients with UC had 5.2% more VAT:SAT compared to patients with CD (*p=0.036*). Males had a 17.3% higher VAT:SAT (*p=0.000*). There was no significant differences noted between those on biologics vs. non-biologic treatments. However, those taking thiopurines (6-Mercaptopurine (6-MP)/ Azathioprine) had 5.6% lower VAT:SAT compared to those not (*p=0.038*). Combination therapy (thiopurine + Biologic) had 9.02% more VAT:SAT than those on thiopurine monotherapy *(p=0.058*).

Binary logistic regression models were used to identify factors associated with markers of disease severity (surgery, multiple surgeries and multiple biologic use). Age was found to be a significant associated factor with multiple surgeries (coeff 0.0641) (p=0.001).

Conclusion: Visceral obesity was found in at least 30% of patients in this IBD cohort. This was in comparison to 44%of the age-gender matched control group.

We report no significant difference in body fat composition or WC in age and gender matched controls and a random sample of patients with IBD. Rising obesity levels in the community may account for this. However, in this cohort, patients with UC had a higher % VAT:SAT compared to those with CD. Regarding treatment, thiopurine monotherapy was associated with lower %VAT:SAT. This may suggest that combination therapy may be required in those with higher %VAT:SAT to treat a more aggressive disease course.

Age is a known risk factor for a more severe disease course in IBD. This was in keeping with our model.

Of note, WC showed a strong correlation with VAT. This may be a more acceptable alternative for monitoring VAT rather than CT imaging.

Introduction: Ileocolonoscopy and Rutgeerts endoscopic score remains the gold standard to evaluate post-operative recurrence (POR) in Crohn's disease (CD) patients (1).

Intestinal ultrasound (IUS) is proposed as a non-invasive alternative to ileocolonoscopy for the diagnosis of POR, with a sensitivity of 94% and specificity of 84% (2). There are several IUS scores that evaluate CD disease activity such as SUS-CD (validated), IBUS-SAS and Simple US Score, which have not yet been studied in the diagnosis of POR.

Aims & Methods: The aim of this study is to assess whether IUS parameters and ultrasound scores correlate with endoscopy in the diagnosis of POR. A unicentric retrospective study was performed. There were included patients with CD with both an ileocolonoscopy and intestinal ultrasound performed for the detection of POR, the time between tests was less than 6 months and there was no therapeutic change between tests.

Endoscopic POR was evaluated with Rutgeers score (RS), considering POR RS ≥i2b. In IUS, were used: Simple US Score, SUS-CD and IBUS-SAS.

Results: 103 patients were included, the Montreal classification was: A1 n=6 (5.8%), A2 n=78 (75.7%), A3 n=18 (17.5%), L1 n=54 (52.4%), L2 n=2 (1.9%), L3 n=47 (50.6%), B1 n=10 (9.7%), B2 n=49 (47.6%) and B3 n=44 (42.7%).

30 patients (29.1%) had no endoscopic POR, 22 (21.4%) had RS i2a, 12 (11.6%) RS i2b and 39 (37.9%) had severe POR (RS i3-i4). The mean wall thickness measured by IUS in patients without endoscopic POR was 2.7 mm (SD +/- 1.3) versus 5.0 (SD +/- 1.7) in patients with RS ≥i2b (p 0.001). Hyperemia (Limberg >1) was present in 60 patients (82.2%) with RS ≥i2a vs in 4 patients (13.3%) without endoscopic POR (p 0.001). Both hyperemia and wall thickness had a sensitivity of 89.0% and specificity of 76.7% in the diagnosis of POR.

The mean values for IUS scores were: Simple US Score 5.5 (SD +/- 3.1), SUS-CD 2.1 (SD +/- 1.8) and IBUS-SAS 32.9 (SD +/- 26.3). There weren't statistical differences between IUS scores in patients with RS <i2b and ≥i2b. Simple US Score had an area under the ROC curve (AUC) of 51%, IBUS-SAS presented an AUC of 48.4% and SUS-CD of 48.5%.

Conclusion: In our experience wall thickness and hyperemia are useful parameters to diagnosis POR, however IUS scores (IBUS-SAS, SUS-CD and Simple US Score) are less reliable. In the future new scores adapted to POR may be needed.

THE IMPACT OF POINT-OF-CARE INTESTINAL ULTRASOUND IN INFLAMMATORY BOWEL DISEASE PATIENTS

W.L. Tan[1,2], E. Barr[1,2], E. Khoo[1,2,3], R. Fernandes[1,2,3], H. Pham[2,3], Y.-K. An[1,2,3], J. Begun[1,2,3]

Introduction: Intestinal Ultrasound (IUS) is an accurate, non-invasive technique to monitor disease activity and guide treatment decisions in inflammatory bowel disease (IBD). It has gained popularity as a point-of-care (POC) modality due to its tolerability and ease-of-use and reproducibility of results.

Aims & Methods: This study aims to assess the impact of POC IUS in daily clinical management of IBD. We conducted a single-centre retrospective cohort study of IBD patients who were evaluated with POC IUS between September 2022 and March 2023. Ultrasound data were retrieved including ultrasound reports, static images. and cine loop with doppler activity. Clinical data were retrieved from the electronic medical record. Descrip-

tive statistics were used to evaluate characteristics of the study population. Chi-squared tests and logistic regression were used for categorical outcomes.

Results: A total of 210 IUS examinations were included in patients with Crohn's disease (n=118, 56%), ulcerative colitis (n=90, 43%) and IBD-unclassified (n=2, 1%). The median age was 35.6years and the median disease duration was 7.0years. Fifty percent of IUS (n=105) was performed on asymptomatic patients as part of routine care; twenty-five percent (n=53) was for symptomatic patients; and twenty-three percent (n=49) was a follow-up imaging to assess response to a change in therapy. A change in management following IUS was recorded in 117 cases (55.7%).

For routine examinations (n=105), 22.9% (n=24) were abnormal, seven (7%) were referred for urgent endoscopy, thirty-five cases (33.3%) changed therapy, twenty (19%) initiated new therapy and four (4%) optimised existing therapy. Among symptomatic patients who underwent IUS (n=53), a change of medication was documented in 89% (n=47), endoscopy performed after examinations in 15% (n=8), 23% (n=12) were prescribed laxatives and 2% (n=1) were admitted to hospital.

Abnormal IUS and change in medication following IUS was higher in symptomatic than asymptomatic patients (54.7% vs 23.1%, p<0.001 and 54.7% vs 12.0%, p<0.001, respectively). Faecal calprotectin (n=105) (p=0.03) and magnetic resonance imaging (n=8) (p=0.06) results within a month prior to IUS were directly correlated with bowel wall thickness >3mm on IUS. Nineteen endoscopies were done within 1 month after examinations, which was also positively correlated with IUS result (p=0.01).

Conclusion: Our real-world study showed that POC IUS plays a role in 'treat-to-target' strategy in patient-management decisions, especially among symptomatic patients, allowing rapid treatment decisions. In addition to other objective markers of disease, including faecal calprotectin, POC IUS has the potential to reduce the need for more invasive endoscopic assessment of disease activity.

Disclosure: None.

REPRODUCIBILITY OF DISEASE EXTENT ON MR ENTEROGRAPHY AND RELATIONSHIP WITH RESPONSE TO ANTI-TNF-A THERAPY IN SMALL BOWEL CROHN'S DISEASE: CLINICAL UTILITY OF A NOVEL INTEGRATED RADIOLOGY REPORTING WORKFLOW

H. Fitzke[1,2,3], S. Rahman[4], A. Bhagwanani[5], J. Holmes[1,2], A. Bard[6], D. Prezzi[7], G. Bhatnagar[5,1,6], S. Taylor[1,2]

Introduction: Consistent reporting of disease activity and extent on MR enterography (MRE) is essential for 'treat-to-target' management of Crohn's disease (CD) [1]. The simplified magnetic resonance index of activity (sMaRIA) is a fast and reliable tool for assessing disease activity in research settings [2] but clinical use is limited. In contrast, the length of affected bowel is often reported as it is important for surgical planning. Until recently, limited image analysis tools meant that disease length could only be estimated within ±5cm [3].

We assessed the clinical utility of an integrated radiology reporting workflow combining sMaRIA and disease length measurements for clinical follow-up of SBCD patients on anti-TNF-α therapy.

Aims & Methods: Our primary aim was to assess the relationship between change (Δ) in sMaRIA score and Δ length of the most severe segment (mSS) with patients' clinical response to anti-TNF-α therapy for SBCD. Our secondary aim was to investigate inter-reader agreement for disease extent and mSS length. Two consultant GI radiologists (R1 & R2) blinded to clinical data reviewed pre- and post-therapy MREs acquired between 2006-2014 [4]. They used a cloud-based workflow (EntrolyticsTM, Motilent, London, UK) to report the number of SB disease segments (>3cm considered distinct) and the location, sMaRIA score and length of the mSS. Clinical 'Response' was based on a physician's global assessment as 'Responder' Δ ≤ -1; or ‚Non-responder' Δ ≥ 0 on a 4-point scale. Baseline and Δ post therapy were summarised for 'Responders' and 'Non-responders' as median [Q1;Q3] and differences assessed using the Wilcox test. Inter-reader agreement was quantified as % agreement on the number and location of disease segments and Bland-Altman bias (95% CI) ± coefficient of repeatability.

Results: Of 30 patients included in the primary analysis (57% male; age 25 [22;46]), 67% responded to anti-TNF-α therapy. The interval between scans for 'Responders' was 1.0 years [0.5; 1.7] compared to 'Non-responders' 2.4 [1.6; 3.3] (p = 0.09). According to R1, there was no difference in segmental sMaRIA score or disease length at baseline or Δ following therapy between groups (Table 1).

	Non-responder	Responder	p-value
sMaRIA (baseline)	2.5 [2;3]	3 [2;3]	0.31
Δ sMaRIA (follow-up)	-0.5 [-1;0]	-1 [-1;0]	0.66
Length, cm (baseline)	15 [8;29]	11 [6;17]	0.40
Δ Length, cm (follow-up)	-1 [-3;4]	-0.4 [-7;1]	0.50

Table 1.

R2 agreed on mSS location in 78% and number of individual disease sites in 41% of patients. According to both R1 & R2, the location of mSS changed in 10% patients. After excluding 4 patients with extremely long disease (>25cm), the mean difference at baseline was 0.6 cm (95% CI: -4.3 to 5.5) ± 23.9 cm and follow-up 1.1 cm (95% CI: -4.2 to 2.0) ± 15.1 cm. Inter-reader agreement for the Δ length following therapy was -1.72 cm (95% CI: -6.5 to 3.1) ± 23.4 cm.

Conclusion: Assessment of the most severely affected segment alone was not sufficient to detect response to anti-TNF-α therapy as there was no difference in Δ sMaRIA score or Δ length between 'Non-responders' compared to 'Responders'. Radiologists agreed on the mSS location in a high proportion of cases compared to the number of disease sites. There was no systematic bias in the measurement of disease length, but the coefficient of repeatability was high compared to clinically relevant ranges of 0-5cm; 5-15cm and 15cm [3]. This should be considered when using global scores that are based on the sum of multiple segments and/or include disease length (e.g. sMaRIA, MEGS).

Introduction: Endoscopy is the method of choice for detecting gastrointestinal diseases and colorectal cancer in humans. Computer-aided analysis of colonoscopy videos is helpful for the diagnosis and severity assessment of the disease. However, a large number of images captured during colonoscopy are uninformative, so the detection and removal of these non-informative frames is an important first step towards automated images analysis.

Aims & Methods: 15 colonoscopy videos of IBD patients were collected. An algorithm for automatic identification of non-informative frames in colonoscopy videos using ResNext101 network were developed. An innovative method of expert scoring and labeling "non-informative frames" was established. Four experts scored each original image for score 0 (informative) or score 1 (non-informative). All images were assigned a score from 0 to 4. After scoring, the final label of a frame with a score greater than or equal to the noninformative threshold score is non-informative. Accuracy, sensitivity, specificity and other metrics were calculated to evaluate the performance of the model in distinguishing informative frames from non-informative frames.

Results: A total of 9589 frames were extracted from the videos. 7945 frames were used as the training set, 764 frames were used as the validation set, and 880 frames for the test set. When the non-informative threshold was set to 4, the accuracy, sensitivity and specificity of the model for detecting non-informative frames could reach 93%, 84.8% and 95.7%, respectively. When the threshold was set to 3, the model reached 90.8%, 82.8% and 95.8%, respectively. When the threshold was set to 2, the above indicators could reach 88%, 91.2% and 81.4%, respectively. When the threshold was set to 1, the above indicators could reach 93.9%, 95.7% and 82.4%, respectively.

Conclusion: The proposed automatic and accurate non-informative frame detection system is essential for further colonoscopy video analysis. Doctors can choose different non-information frame thresholds according to different clinical application scenarios. Accurate detection and removal of non-informative frames can effectively improve the accuracy of disease severity assessment and reduce computational cost.

Contact E-Mail Address: kaoutarchahi@gmail.com

Introduction: Hepatobiliary disease is one of the most common extra-intestinal manifestations of chronic inflammatory bowel disease (IBD), but the prevalence of liver disease in IBD patients remains poorly understood and may be underestimated due to the use of invasive methods such as liver biopsy for diagnosis. Ultrasound pulse elastometry (FibroScan®) is a direct, non-invasive and effective physical approach to assess liver fibrosis.

Aims & Methods: The objective of the study is to assess the prevalence of liver fibrosis in IBD patients using ultrasound pulse elastometry (FibroScan®).

This prospective study included 56 patients with chronic inflammatory bowel disease, epidemiological, clinical and therapeutic data were collected. Liver elasticity was assessed by ultrasound pulse elastometry (FibroScan®) performed by a single physician. The cutoff value for significant liver fibrosis was F ≥2: 8 kPa.

Results: In this study, 56 patients were included, 22 men and 34 women with a sex ratio M/F of 0.6, the mean age was 32.9 years old, 43 patients had CROHN disease, 13 patients had UC. The mean duration of disease progression was 4.7 years. The mean value of liver stiffness was 7 kPa. The median IQR was 0.7 with an average success rate of 100%. 80.3% of patients had a fibrosis value < F2, and 19.6% of patients had a fibrosis value > F2. There were no differences in liver stiffness (LS) depending on type of IBD. Age and female sex, however, were independently associated with a higher LS.

Conclusion: This study confirms the relatively high prevalence of fibrosis in IBD patients, there were no differences in liver stiffness (LS) depending on type of IBD or BMI. Age and female sex, however, were independently associated with a higher LS. , Fibroscan is a non-invasive and efficient technique, which can be potentially useful for evaluation and follow-up of liver fibrosis in IBD patients.

Disclosure: Nothing to disclose.

Contact E-Mail Address: maria.kalogi32@gmail.com

Introduction: The Inflammatory Bowel Disease (IBD) Disk represents a self-administered questionnaire that can facilitate, in real time, assessment of IBD related disability, and IBD-related daily life burden[1,2]. Surrogate markers of IBD activity tend to associate with increased disability. Intestinal ultrasound (IUS) is a non-invasive tool that can objectively and accurately define disease activity and complications in IBD patients.

Aims & Methods: The aim of our study was to investigate the correlation between IBD-Disk and IUS in IBD patients. We performed a cross-sectional study that included formally diagnosed IBD patients who underwent IUS and subsequently completed the IBD-Disk questionnaire. Active disease on IUS was defined as bowel wall thickness (BWT) >3 mm at the most affected bowel segment. The overall IBD-Disk score was calculated as the sum of its 10 components, ranging from 0 to 100 (best score: 0, worst score: 100). We explored the correlation between IBD-Disk and its components with IUS. We additionally investigated the correlation of IBD-related daily life burden with IUS. (IBD-Disk total score > 40: high IBD related daily life burden vs IBD-Disk total score ≤ 40: low IBD related daily life burden[2]).

PATIENT CHARACTERISTICS	CROHN'S DISEASE n= 42	ULCERATIVE COLITIS n= 27
SEX	18 males/ 24 females	12 males/ 15 females
AGE [median, IQR]	34 [23.8-44.8]	40 [32-55]
AGE AT FIRST DIAGNOSIS (Montreal Classification)	A1:10 A2:31 A3:1	<40 years: 19 >40 years: 8
DISEASE DISTRIBUTION (Montreal Classification)	L1:24, L2:4, L3:14, L4:1	E1:1 E2:19 E3:12

OPERATED PATIENTS	n =11	n=0
CLINICAL ACTIVITY SCORES	HBI <5: 26 5-7: 12 8-16: 4 >16: 0	PARTIAL MAYO SCORE < 2: 6 2-4: 8 5-6: 6 7-9: 7
CURRENT TREATMENT	Biologics/JAK Inhibitors (IFX, ADA, VEDO, UST): 38 IMM (AZA, MTX): 2 Corticosteroids: 1 5-ASA: 0 No TRT: 2	Biologics/JAK Inhibitors (IFX, ADA, VEDO, UST, TOFA): 19 IMM (AZA, MTX): 1 Corticosteroids: 3 5-ASA: 7 No TRT: 0

HBI: Harvey Bradshaw Index, IFX: Infliximab, ADA: Adalimumab, VEDO: Vedolizumab, UST: Ustekinumab, TOFA: Tofacitinib, IMM: Immunomodulators, AZA: Azathioprine, MTX: Methotrexate, 5-ASA: 5-Aminosalicylates, TRT: Treatment

Table 1: Patients characteristics.

Results: We included 69 patients (Table 1), who underwent IUS for disease monitoring (56.5%) and symptoms suggestive of disease flare (43.5%). Median IBD-Disk total score in our cohort was 48 (IQR 19-56.5). Median IBD-Disk total score was 52 (IQR 47-58.5) in IUS active vs 16 (IQR 6-23) in IUS inactive patients (p<0.001). The area under the ROC curve of IBD-Disk total score in predicting IUS activity was 0.909 (95% C.I: 0.819-0.99, p<0.001). IBD-Disk score >33 predicted disease activity in IUS with 93.5% sensitivity and 91.3% specificity. We observed a moderate correlation between IBD-Disk score and BWT (ρ=0.554, p<0.001) as well as between IBD-Disk score and C-reactive protein (ρ=0.686, p<0.001). Among the components of the IBD-Disk, 7/10 (abdominal pain, regulating defecation, education/work, sleep, energy, sexual function and interpersonal interactions) manifested a moderate correlation with BWT. IBD-Disk score > 40 was found in 40/46 (87%) of IUS active and 2/23 (8.7%) of IUS inactive patients, while IBD-Disk score ≤ 40 was found in 6/46 (13%) of IUS active and 21/23 (91.3%) of IUS inactive patients respectively (p<0.001). Median BWT was 2.1 mm (IQR 1.6-2.9) in patients with IBD-Disk score ≤ 40 and 6 mm (IQR 4.8-6.8) in patients with IBD-Disk score > 40 (p<0.001).

Conclusion: IBD-Disk displayed a significant correlation with IUS evidence of disease activity in IBD patients. Active disease in IUS was significantly correlated with a high IBD-related daily life burden as expressed by IBD-Disk total score > 40. IBD-Disk could be used in clinical practice to evaluate disease activity and severity in IBD patients.

Contact E-Mail Address: Iyad.Naim@nottingham.ac.uk

Introduction: In Crohn's disease (CD), 10% of patients present with fibrostenosis with a further 10% progressing from inflammatory to a fibrostenotic disease behaviour over 7 years[1]. The prevalence of CD fibrostenosis is >20%[2]. 40% of fibrostenotic CD patients need surgery at 5 years compared to ~10% with inflammatory disease[2]. Fibrotic tissues exhibit excessive accumulation of collagen type 1 and 3, with amide protons in the collagen backbone showing potential for quantification using MT imaging [3].

GI-Seg by Motilent is a tool that uses advanced image analysis algorithms to segment the gastrointestinal tract in MRI scans. The software creates a three-dimensional model of the GI tract, allowing clinicians to visualize and analyse the structure and volume of the organs in detail. GI-Seg is designed to save clinicians time and increase the accuracy of their diagnoses by automating the segmentation process, which can be a time-consuming and error-prone task when done manually.

Aims & Methods: The primary objective of this study is to undertake biological validation of the candidate MRI measures as independent imaging biomarkers of histological fibrosis with the primary outcome being the

correlation between MRI measures and histological fibrosis measures. Patients with CD histological diagnosis and in need of surgical resection for stenosis attended a one-hour 3T MRI scanning session within 12 weeks prior to their intestinal resection surgery.

After the surgical resection, consecutive sections were cut in the sample and scored by a specialized gastrointestinal pathologist for inflammation, fibrosis, and muscular hypertrophy. A global score was derived for these variables for each individual bowel wall layer and for the whole bowel wall.

An expert radiologist with the help of the histopathologist located the strictures on the magnetisation transfer (MT) and T2 weighted scans. Z-spectrum quantification involved fitting z-spectra to a three-pool model using the Levenberg-Marquardt algorithm, with voxel-wise mapping of the fitted parameters. The GI-seg tool was also used to generate a 3D model of the stricture on T2 weighted scans measuring bowel wall volume and mean signal intensity of each stricture.

Pearson correlation coefficient was used to quantify the correlation between the variables.

Results: A total of 8 CD (19 strictures) patients were recruited. Strictures were identified in histopathology and located on the in-vivo T2 weighted and MT scans by the radiologist. Out of the 8 patients, 6 were used for Z-spectrum quantification. Bowel wall volumes in mm^3 and Mean signal intensity were calculated using the GI-seg tool.

MT Z- spectrum amplitude fit showed a high correlation with global fibrosis ($r(10) = .775$, $p = .008$), and inflammation scores ($r(10) = .824$, $p = .003$). Mean T2 signal intensity measured using GI-Seg highly correlated with global fibrosis scores ($r(19) = .617$, $p = .005$) , global inflammation scores ($r(19) = .692$, $p = .001$) and MT Z- spectrum amplitude fit ($r(10) = .941$, $p < .001$).

The volume of each stricture showed a moderate correlation to global fibrosis scores ($r(19) = .383$, $p = .106$), global inflammation scores ($r(19) = .425$, $p = .069$) and muscular hyperplasia ($r(19) = .404$, $p = .086$).

Conclusion: This study reveals a strong correlation between mean T2 signal intensity and global fibrosis, muscular hyperplasia, and inflammation scores in CD strictures. The GI-seg tool accurately measured bowel wall volume and signal intensity, indicating potential as independent imaging biomarkers for fibrosis, inflammation, in CD strictures.

Introduction:

Crohn's disease (CD) is a chronic, auto-immune, inflammatory condition affecting the digestive tract. Accurate evaluation of CD activity is crucial to ongoing treatment monitoring. Magnetic resonance enterography (MRE) is used to characterise disease behaviour, but its interpretation remains subjective. There are validated MRE activity scores available, such as the simplified magnetic resonance enterography index (sMARIA), but they often fail to capture early treatment response. Much current evaluation is based on an isolated 2D evaluation of a subjectively-chosen area of diseased bowel rather than assessing the full disease volume; even in this limited context, reductions in bowel wall thickness are associated with treatment response. It is believed that segmentation of abnormal bowel volume may allow more objective, quantitative assessment for tracking disease activity and treatment response. This is not feasible without automation due to constraints on clinician's time.

To address this issue, we developed a segmentation protocol and semi-automated pipeline for use on coronal T2-weighted MRI, routinely acquired during Crohn's monitoring.

Aims & Methods: Imaging data from patients with confirmed CD from the METRIC / METRIC EF trials [1,2] were collected from 6 different hospitals. Abnormal bowel segments, identified based on pre-existing clinical information, had centrelines drawn by expert radiologists on coronal T2-weighted noncontrast MRI. Volumetric segmentation was performed based on these by a technician or radiologist. All annotations were performed on Entrolytics® (Motilent Ltd, UK).

Patients were randomly split to train, validation and test at project start. The train set (60 segments, 49 patients) was used for explicit optimisation (parameter fitting). The validation set (20 segments, 18 patients) was used for interim performance quantification. The test set (37 segments, 34 patients) was held out during development. To examine inter-reader agreement, N=18 cases from the VIGOR++ [3] study were annotated with centrelines drawn through the Terminal Ileum, and segmentation performed independently by two readers in isolation, from the same centreline.

The algorithm uses k-means clustering to divide images into partitions, which are characterised using a custom feature set. The fraction of their voxels contributing to the segmentation is predicted by a trained Random Forest Regressor.

We quantify agreement for bowel wall segmentations based on the same centreline, using three standard metrics for segmentation quality: Dice score, symmetric Hausdorff distance and mean contour distance. We compare agreement between readers with agreement between algorithm and human readers using the Kolmogorov-Smirnov test.

Results: Between human readers (N=18), levels of agreement are moderate (mean Dice score = 0.603, Symmetric Hausdorff Distance = 13.1mm, Mean Contour Distance = 1.30mm). Between algorithm and human (N=37), levels of agreement are comparable (mean Dice score = 0.521, Symmetric Hausdorff Distance = 15.1mm, Mean Contour Distance = 2.28mm). Difference in Dice scores between these two distributions cannot be detected (K-S statistic = 0.285, p = 0.230). Difference in SHD cannot be detected (K-S statistic = 0.339, p = 0.099). Differences in MCD can be detected (K-S statistic = 0.697, $p = 4.51\times10^{-6}$).

Conclusion: Our semi-automated algorithm agrees with humans at a similar level to inter-reader agreement. This algorithm will be embedded within a web-based platform in order to further aid researchers and clinicians in deriving quantitative imaging biomarkers.

Contact E-Mail Address: h.e.fitzke@qmul.ac.uk

Introduction: Crohn's disease is routinely monitored via Magnetic Resonance Enterography (MRE), requiring patients to drink large volumes of hyperosmolar oral contrast to distend the bowel. This is poorly tolerated and associated with lower gastrointestinal symptoms up to 48 hours after the scan [1].

The use of most contrast agents (e.g. mannitol) for MRE is 'off label' and there is little consensus on the volume, timing or concentration or agent used [2].

Aims & Methods: This study assesses the impact of modifying the oral contrast protocol used in routine MRE on diagnostic quality of images and reported symptoms. Full standard prep (1.6L of 1.67% Mannitol over 60mins, FSP) was compared with a Modified Reduced prep (0.6L of 1.67% Mannitol over 60mins, with 0.3L nutrient drink, MRP) and a Reduced Prep (1.0L of 1.67% mannitol over 45 mins, RP). These were given to healthy volunteers (age 18-55, BMI 18-35, with no MRI contraindications) fasted for 4 hours prior to the scan, which was performed on a Philips 3T scanner for 40mins. Volunteers were asked to rate their cramps and diarrhoea on a scale from 1 to 100 before the drink and after the scan. Images were reviewed by a blinded radiologist, ranking them for diagnostic quality from 0 (very poor distension) to 4 (excellent distension) and lumen diameter in the terminal ileum (TI).

All statistical comparisons were performed using Paired Wilcox tests with Holm correction for multiple comparisons were used to assess FSP vs MRP, and FSP vs RP, separately.

Results: Sixteen healthy volunteers were recruited: median age 29 (IQR: 28 - 31); 29% female. Immediately following imaging, reported severity of cramps was found to be similar between FSP (9.5 IQR: 1 - 37) and RP (1.0 IQR: 1 - 19, p = 1.0); and reduced in MRP (1 IQR: 1 - 4, p = 0.045).

Severity of diarrhoea was rated high with FSP (6 IQR: 4.25 - 7) and substantially reduced with MRP (1 IQR: 1 - 2, p=0.017), with a trend for RP (3 IQR: 1.25 - 4, p=0.068). Distension quality was equivalent with a median of 2 ‚Fair' in FSP and 3 'Good' in RP groups (p=0.149).

However, it was worse in MRP with a median of 1 ‚Poor' (p=0.015). TI diameter was equivalent (p=0.149) between FSP (18 mm IQR: 17 - 20) and RP (19 mm IQR: 18 - 21) and lower in MRP (15 mm IQR: 11 - 19, p = 0.015).

Conclusion: The modified reduced prep (MRP) was associated with reduced cramp and diarrhoea severity compared to full standard prep (FSP), but also reduced distension quality. Using the reduced prep (RP), diarrhoea symptoms improced, but with no reduction in image quality. The findings suggest that modifying the MRE protocol may improve patient tolerance, particularly in Crohn's disease patients who require frequent monitoring.

MRI FACTORS ASSOCIATED WITH RELAPSE FOLLOWING DISCONTINUATION OF BIOLOGIC MEDICATION IN CROHN'S DISEASE

J. Pakpoor[1], H. Fitzke[2], M. Hameed[1], T. Glover[3], J. Holmes[2], W. Blad[4], L. Whitley[4], S. Taylor[5]

[1]University College London Hospital NHS Trust, Radiology, London, United Kingdom, [2]University College London, Centre for Medical Imaging, London, United Kingdom, [3]St Mark's and Northwick Park Hospitals, Radiology, London, United Kingdom, [4]University College London Hospital NHS Trust, Gastroenterology, London, United Kingdom, [5]University College London - Centre for Medical Imaging, University College London, Centre for Medical Imaging, London, United Kingdom

Contact E-Mail Address: h.e.fitzke@qmul.ac.uk

Introduction: The decision to stop biologic medication in Crohn's Disease (CD) in apparent clinical remission is challenging. We investigated MR enterography (MRE) observations associated with future relapse.

Aims & Methods: 49 CD patients discontinuing biologics due to clinical remission and undergoing MRE within 12-months prior, or 1-month after, were identified. Two blinded radiologists subjectively assessed small bowel disease presence/activity and disease length, wall-thickness, fat-wrapping [1] and sMARIA score [2]. ‚Relapse' status was assigned based on full clinical records including patient symptoms, biochemistry, imaging and drug prescription. Per-patient analysis was performed using the most severely affected segment and groups were compared with Chi-Square and Wilcox test.

Results: Mean patient age was 30.1 (SD: 13.0, 19 female). Median follow-up was 55 months (6-110). Twenty-five (51%) had disease relapse (DR) and 24 (49%) no relapse (NDR). Sixteen of 24 (67%) and 15/25 (60%) of the NDR and DR respectively still had small bowel disease present on MRE prior to biologic cessation. This was subjectively deemed active in 10/15 (66%) DR vs just 5/16 (31%) of NDR. One patient was excluded from the quantitative analysis due to image artifacts. Maximum wall thickness in the most severely affected segment was the only MRE observation associated with subsequent relapse (Table 1).

		Relapse?		Difference
		No (N = 24)	Yes (N = 24)	p-value
Number of SB disease segments	0	8 (33%)	9 (38%)	0.88
	1	16 (67%)	13 (54%)	
	>1	0 (0%)	2 (8%)	
Maximum wall thickness, mm		5.4 [3.4; 6.6]	7.3 [6; 9.6]	0.01
Length of abnormal segment, cm		8 [6; 13]	14 [5; 23]	0.49
Segmental sMaRIA score		1 [1; 2]	1 [1; 2]	0.39
Fat wrap	Absent	13 (54%)	8 (33%)	0.11
	Present	4 (17%)	10 (42%)	

Table 1.

Conclusion: Simple presence or absence of residual small bowel abnormality does not in itself predict future relapse. However, in those with residual disease, simple bowel wall thickness is greater in those who relapse and may be a simple tool to guide the decision to discontinue biologic medication.

CONTRAST-ENHANCED ULTRASOUND DISTINGUISHES INFLAMMATORY FROM NON-INFLAMMATORY STENOSIS IN CROHN'S DISEASE: FIRST RESULTS FROM THE STRICTURE STUDY

F. de Voogd[1], A. Mookhoek[2], K. Beek[3], K. Van Rijn[3], M. Pruijt[1], C. Teichert[1], J. Van der Bilt[4], C. Buskens[4], W.A. Bemelman[4], J. Stoker[3], G.R. D'Haens[1], K.B. Gecse[1]

Contact E-Mail Address: f.a.devoogd@amsterdamumc.nl

Introduction: Stenotic complications affect 30%-50% of patients with Crohn's disease (CD)[1]. There is currently no imaging modality to identify stricture composition, which would allow early targeted (anti-inflammatory vs surgical) treatment. Intestinal ultrasound (IUS) and its advanced modalities (contrast-enhanced and elastography) have the potential for transmural disease evaluation. The aim of the STRICTURE study was to investigate (advanced) IUS and MRI techniques to distinguish between inflammatory- (IP) and non-inflammatory predominant phenotypes (non-IP) of stricturing CD.

Aims & Methods: In this prospective, longitudinal study, consecutive patients with small bowel stricturing CD undergoing surgery were included. Patients were eligible if they had a non-passable stricture during endoscopy in the small bowel or at the valve/anastomosis and/or a stricture at cross-sectional imaging (IUS or MRE) with a bowel wall thickness (BWT) >3.0 mm in combination with narrowing of the lumen <1.0 cm or a prestenotic dilation (lumen width ≥2.5 cm)[3]. Clinical scores (Harvey-Bradshaw index and Crohn's Disease Obstructive Score[4]) and biochemical parameters were collected. All patients underwent conventional IUS (B-mode/colour Doppler signal)[5], CEUS and SWE and cine-loops were scored by one rater. After surgery, histological slides were retrieved at the same distance from the valve/anastomosis as measurements were made on IUS. Subsequently, a blinded expert pathologist scored all slides as [1] inflammatory (IP; BWT based on inflammatory infiltrates and edema according to the Nancy score), [2] fibrotic (FP; BWT based on structural changes due to fibrosis, adipose tissue and/or muscular hypertrophy[6]) or [3] mixed phenotype (MP; BWT with inflammatory and fibrotic aspects but no predominant phenotype). FP and MP were both classified as non-IP.

Results: A total of 36 patients (female: 58%, age: 42 ± 18 years) with a mean BWT of 6.7 ± 1.7 mm were included. Median time between IUS and surgery was 14 [3-50] days. A total of 7 patients had an IP, 18 a FP and 11 a MP. For the conventional IUS parameters, loss of bowel wall stratification was more frequently found in IP strictures (OR: 7.87 [1.24-50.00], p=0.029). Clinical, biochemical, other conventional IUS parameters, length of the

stricture (13 [8-18] cm vs 10.5 [7.5-17.5] cm) and width of the prestenotic dilation (2.70 [1.70-2.80] cm) vs 2.30 [1.75-3.35] cm) were not significantly different between patients with IP and non-IP. However, CEUS, including wash-in and wash-out parameters, were significantly higher in IP versus non-IP strictures (Table 1).

When excluding MP strictures, CEUS was the only modality that could distinguish between IP and FP. SWE inversely correlated with CEUS (Table 1) but did not differentiate between IP and non-IP (33.30 [26.00-44.80] kPa vs 43.49 [28.30-54.00] kPa, p=0.48) or IP and FP (33.30 [26.00-44.80] kPa vs 41.23 [24.36-48.60 kPa, p=0.95).

CEUS parameter in decibel	Inflammatory phenotype	Non-inflammatory phenotype (fibrosis and mixed)	Signi-ficance	Cut-off value (AUC/sens/spec)	SWE correlation
Peak enhancement (median [IQR])	31.6 [31.0-35.7]	29.38 [27.29-31.50]	p=0.014	31.0 (0.8/86%/69%)	ρ=-0.36, p=0.04
Wash-in area under the curve (median [IQR])	39.4 [38.3-41.5]	36.09 [32.27-38.26]	p=0.005	38.2 (0.84/86%/77%)	ρ=-0.32, p=0.08
Wash-in perfusion index (median [IQR])	29.6 [29.3-33.7]	27.63 [25.40-29.64]	p=0.016	29.2 (0.8/86%/69%)	ρ=-0.37, p=0.04
Wash-out area under the curve (median [IQR])	43.1 [41.3-45.1]	38.90 [36.50-41.85]	p=0.016	41.8 (0.8/71%/77%)	ρ=-0.37, p=0.04
Wash-in and Wash-out area under curve (median [IQR])	44.3 [43.1-46.7]	40.74 [38.23-43.54]	p=0.008	43.0 (0.82/86%/69%)	ρ=-0.36, p=0.05

Conclusion: CEUS accurately distinguishes predominant inflammatory from not-predominant inflammatory strictures in CD and inversely correlates with SWE. CEUS, could be of additional value in this specific population to select patients most suitable for anti-inflammatory treatment. Reproducibility of advanced IUS techniques is under investigation.

Contact E-Mail Address: shankar.kumar@nhs.net

Introduction: Accurate evaluation of Crohn's disease (CD) activity is crucial to optimise and monitor treatment. Magnetic resonance enterography (MRE) has an important role in characterising disease behaviour, but its interpretation remains subjective. Currently available validated MRE activity scores such as the simplified magnetic resonance enterography index (sMARIA) often fail to capture early treatment response; changes in constituent parameters may lag behind clinical improvements by several months.

Furthermore, current evaluation is based on an isolated 2D assessment of subjectively the worst area of diseased bowel rather than assessing the full disease volume.

Nonetheless, reductions in bowel wall thickness are associated with treatment response, but are subjective, and small reductions may not be detected reliably.

We hypothesised that disease volume may be a more responsive imaging biomarker for disease response than conventional MRE scores.

Aims & Methods: This study aimed to evaluate the technical feasibility and clinical utility of volumetric measurement of terminal ileal (TI) CD on MRE compared to an endoscopic reference standard, and sMARIA activity score. We also assessed whether volumetric changes in disease burden measured on MRE are responsive to changes induced by biologic therapy.

Patients with CD proven by histopathological analysis who prospectively underwent both MRE and ileocolonoscopy scored with Crohn's Disease Endoscopic Index of Severity (CDEIS) within 1 month were included.

A board-certified abdominal radiologist placed a centreline through the lumen of the TI that defined the length of diseased bowel on the T2-weighted non-fat saturated sequence. Centrelines were used as the basis for manual segmentations of the involved bowel wall performed independently by two board-certified abdominal radiologists. If there was no disease apparent on MRE, 5 cm of "normal" bowel wall was segmented. The mean volume of disease was compared to CDEIS and sMARIA. Inter-observer agreement for segmentation was assessed using Bland-Altman analysis.

We also examined a group of patients with CD who had been treated with biologics, undergone paired pre- and post- treatment MRE, and classified as treatment responders by their treating gastroenterologist based on all available clinical data (global physician assessment). We compared the volumetric burden of CD on their pre- and post- biologic treatment MRE.

Results: Thirty patients (median age of 29 (IQR 24, 34) years, 18 females) with available MRE and endoscopy were included. The mean difference of volume of disease between the 2 readers was -3.0 cm^3 (limits of agreement -21.8, 15.9). The median of the mean volume of disease in those with endoscopically active terminal ileal CD (CDEIS ≥ 3, n = 15) was 20.9 cm^3 (IQR 11.3, 44.0) compared to 5.7 cm^3 (2.9, 9.8) with no active CD on endoscopy (n = 15). The median of the mean volume of disease of patients with active CD by sMARIA (>= 1) (n = 23) was 15.0 cm^3 (8.7, 44.0) compared to 2.85 cm^3 (2.6, 3.1) for those with inactive CD.

In a further group of 6 clinically responding patients, the median volume of disease on the pre-treatment scan was 28.5 cm^3 (26.4, 31.3) and 11 cm^3 (4.8, 16.6) on the post-treatment scan, with a median percentage difference of -110% (-147%, -51%).

Conclusion: Volumetric measurement of CD burden on MRE is a feasible method, relates to the endoscopic burden of disease, and is sensitive to changes induced by biologics. This represents a novel, objective biomarker using MRE for assessing disease activity and treatment response in CD, worthy of further validation.

Introduction: Transmural healing (TH) has been proposed as a therapeutic target in Crohn's Disease (CD) with studies showing a better prognosis than endoscopic healing (EH). However, EH is not always accompanied by TH and vice versa.

Aims & Methods: We aimed to evaluate the endoscopic and radiological factors associated with the discordance between EH and TH, the impact of earlier biological initiation on this mismatch and the long-term effect on prognosis. Multicentric retrospective study in patients with CD under biologic therapy who had a baseline computed tomography enterography (CTE) or magnetic resonance enterography (MRE) before therapy initiation and a follow-up ileocolonoscopy and MRE at 12±6 months. EH was defined as an SES-CD<3 or absence of ulcers and TH as the complete normalization of mural and extra-mural inflammation. All radiologic examinations were reviewed by expert radiologists after a consensus and the analysis was performed by inflamed intestinal segments using the McNemar's test. The impact of the time of biological therapy initiation was assessed using logistic regression. After 5 years of follow-up, we assessed for the presence of long-term bowel damage defined as the need for intestinal resection or progression in disease phenotype (presence of new stenosis or fistula or worsening of previously existing stenosis or fistula).

Results: 84 patients were included (52% females) with a median age at diagnosis of 27 yo (IQR 22-37). Half had ileocolonic involvement, 42% isolated ileal disease and 8% colonic disease; most had inflammatory phenotype before treatment (51%) and a median disease duration of 15 months (IQR 4-84). Almost half of the patients (49%, n=41) achieved EH and of those 63% (n=26) did not achieve TH; 23% (n=19) attained TH, of whom 21% (n=4) did not achieve EH. Most of the patients who achieved EH but not TH had persistent disease in the small bowel when compared to the large bowel (88.5% vs 11.5%, p<0.01). Among patients who achieved EH, 71 intestinal segments with signs of inflammation before treatment initiation were analysed. Only the presence of a stricture had a non-significant variation with therapy when compared with the baseline assessment (Table 1). Among the endoscopic variations in patients who achieved TH, only the presence of endoscopic stenosis did not achieve a significant variation and remained persistent (Table 1). There were no differences according to the time of initiation of biological therapy. The persistence of a radiological stricture in patients with EH was associated with long-term bowel damage (13% vs 67%, p=0.02).

Variables	Pre-treatment (0 months)	Post-treatment (12±6 meses)	p-value	% of segments in endoscopic remission with persistent lesions in MRE
Increased bowel wall thickness >3mm	68/71 (96%)	29/71 (41%)	<0.01	29/68 (43%)
Increased contrast enhancement	69/71 (97%)	28/71 (39%)	<0.01	28/69 (41%)
Perienteric stranding	34/71 (48%)	9/71 (13%)	<0.01	8/34 (24%)
Stricture	12/71 (17%)	11/71 (16%)	0.65	9/12 (75%)
Penetrating lesions	11/71 (15%)	3/71 (4%)	0.01	3/11 (27%)
Variables	Pre-treatment (0 months)	Post-treatment (12±6 meses)	p-value	% persistent endoscopic lesions in patients with TH
Deep ulcers	8/14 (57%)	2/19 (11%)	<0.01	1/8 (12.5%)
Large ulcers	6/13 (46%)	1/19 (5%)	0.01	0/6 (0%)
Stricture	3/13 (23%)	2/19 (11%)	0.32	2/3 (67%)

Table 1 – Persistent radiological and endoscopic lesions in patients with EH and TH, respectively.

Conclusion: In patients with CD who achieved EH, the persistence of radiological lesions is frequent and does not seem to be modified by earlier biological therapy. The persistence of a radiological stricture is associated with long-term bowel damage. The evaluation of the endoscopic changes in patients with TH was limited by the small sample size.

INTESTINAL ULTRASONOGRAPHY AS AN ALTERNATIVE TO FAECAL CALPROTECTIN TO MONITOR PATIENTS WITH CROHN'S DISEASE: EXPERIENCE FROM A NOVICE ULTRASONOGRAPHIST (FUSION STUDY)

K. Mathieu[1], B. Pereira[1], A. Buisson[1]
[1]*CHU Estaing Clermont-Ferrand, IBD Unit, Clermont-Ferrand, France*

Contact E-Mail Address: a_buisson@hotmail.fr

Introduction: While faecal calprotectin (Fcal) is now recommended, the positioning of intestinal ultrasonography (IUS) is still unknown to monitor patients with CD.

Aims & Methods: We aimed to assess the agreement between IUS and Fcal to detect active CD and to compare these two monitoring tools to determine the need of therapeutic escalation. We also compared the acceptability between IUS and Fcal and evaluated the potential learning curve of a novice ultrasonographist.

In this cross-sectional prospective study, we consecutively included CD patients ≥ 18 years-old with concomitant IUS and Fcal testing within 7 days. IUS was performed by a novice ultrasonographist.

The endpoints were 1) the agreement between IUS and Fcal (> 150 µg/g) to detect active CD and 2) the need for therapeutic escalation. Active CD per US was defined as one among the following lesions: abnormal bowel thickness (> 3 mm), abnormal vascular pattern (colour Doppler signal > 1), or loss of bowel wall layer stratification or mesenteric fat wrapping). The need for therapeutic escalation was based on the judgement of an experienced IBD physician blinded from the IUS results. Acceptability by the patients was assessed by an acceptability numerical scale ranging from 0 to 10 (10 = perfect acceptability).

Results: Among 66 patients undergoing IUS, 56 patients had also Fcal testing (adherence rate = 84.5%). The agreement between IUS and Fcal to detect an active CD was 80.4 % (κ-coefficient=0.536±0.127). Fcal, IUS or both had respectively the following positive predictive values (76.9% [54.0–99.8], 70.0% [49.9–90.1], and 81.8% [59.0–100.0]) and negative predictive values (81.4% [69.8–93.0], 88.9% [78.6–99.2], and 80.0% [68.3–91.7]) to detect active CD requiring therapeutic escalation.

Using a 10 points-acceptability numerical scale, IUS presented with a better acceptability than Fcal (9.5 ± 1.2 vs 8.0 ± 2.3, p < 0.0001). As expected, the duration of IUS procedure decreased over time (correlation coefficient = - 0.54, p = 0.001) and ranged from 40 to 15 minutes. Of note, this duration plateaued between 15 and 20 minutes-long from the 24th procedure. In contrast, the agreement between IUS and faecal calprotectin, as well as the performances of IUS to identify the need for therapeutic escalation did not change over time.

Conclusion: IUS and faecal calprotectin do not give the same information and could be complementary to monitor patient with CD. The implementation of IUS in IBD centers seems to be quickly feasible.

Disclosure: Nothing to disclose.

HUMORAL RESPONSE TO SARS-COV-2 VACCINATION AMONG PATIENTS WITH INFLAMMATORY BOWEL DISEASE RECEIVING IMMUNOSSUPRESSIVE MEDICATIONS

M. Pereira[1]
[1]*Universidade do Estado do Rio de Janeir, Gastroenterology, Rio de Janeiro, Brazil*

Contact E-Mail Address: mlcosta16@gmail.com

Introduction: Patients with inflammatory bowel disease (IBD) frequently use immunosuppressants and immunobiologicals for maintenance treatment. The humoral responsiveness to COVID-19 vaccines in this group of patients using this drugs is still not fully understood, as the need for more vaccine boosters.

Aims & Methods: Our study aims to evaluate the humoral response to different types of vaccines against SARS-Cov-2 in this population, as well as to compare this response with the healthy population. Patients with IBD enrolled at the Policlinic Piquet Carneiro (UERJ) were prospectively followed with serial blood collection between July 2021 and July 2022. Samples were screened to determine antibody titers, and patients were stratified by demographic and clinical characteristics, naturally occurring infection, vaccination schemes, and IBD medications.

Anti-spike IgG antibody titers against the SARS-Cov-2 were determined by ELISA before and one month after the two doses of different vaccination schemes in patients with IBD, regularly followed-up at the outpatient unit. The results were compared with those of a healthy control group during the same period.

Results: In the IBD group (46 individuals), mean antibody titers were 430.3 AU/ml pre-vaccination and 8038.4 AU/ml after the two vaccine doses. In comparison, in the control group (92 individuals), mean antibody titers were 90.5 AU/ml pre-vaccination and 7697.5 AU/ml after the two doses. In both groups, there was a significant increase in the titer of antibodies after the two vaccine doses (p<0.001). When comparing antibody titers one month after the 2nd dose, there was no difference between the two groups (p=0.731).

On the other hand, in the IBD group, there was a difference between the vaccination schemes, with higher titers in those who received Pfizer, as well as in younger patients (p<0.005) and in those with previous natural COVID-19 infection (p<0.012).

Diagnosis of Crohn's disease or ulcerative colitis, sex, race, smoking status, clinical variables related to disease localization, extension, behavior, clinical activity, and type of medical therapy did not significantly affect the immune response to vaccines.

Conclusion: The use of immunosuppressants and immunobiologicals does not affect the overall humoral response to the COVID-19 vaccination among patients with IBD. Nevertheless, specific vaccine schemes, age, and previous COVID-19 infection significantly affect antibody titers.

Introduction: Patients with immune mediated inflammatory diseases (IMIDs) on immunosuppressive therapies have attenuated vaccine responses (1-3) and are prone to severe infections. Knowledge of COVID-19 outcome following vaccine and hybrid immunity, and identification of protective anti-Spike antibody concentrations are important to further develop vaccine strategies in this vulnerable patient group.
Aims & Methods: In this prospective observational study, adult patients with IMID on immunosuppressive therapies were followed from February 15, 2021, to February 15, 2023. Throughout the study, patients and controls reported data regarding COVID-19, COVID-19 related hospital admissions were recorded from The Norwegian Patient Registry. Anti-Spike antibodies were assessed 2-4 weeks following vaccination and COVID-19. The objectives of this study were to investigate the outcomes of COVID-19 in a large cohort of IMID patients compared to healthy controls, and to identify any associations between anti-Spike antibody concentrations and disease course.
Results: Of 2250 IMID patients included in the study, a total of 1729 with a documented COVID-19 history were included in the present analyses (305 Crohn's disease, 215 ulcerative colitis, 648 rheumatoid arthritis, 272 psoriatic arthritis, and 289 spondyloarthritis) (median age 54 years (IQR 42-64), 971 (56 %) females). Of the patients, 1080 of 1729 (62%) used anti-TNF treatment (65% monotherapy, 35% combination therapy).
1140 (66%) of patients and 236 of 350 (67%) healthy controls (HC) reported COVID-19, the majority (85%) within the Omicron era. COVID-19 reinfection was reported in in 141 (12%) patients and 32 (14%) HC (p=0.66). Compared to hybrid immunity (COVID-19 after three vaccine doses), the risk of COVID-19 was six times higher following vaccine series only (HR 5.9, (95% CI [4.45, 7.80]), p<0.001). Anti-Spike antibody concentrations <8000 BAU/ml were predictive of COVID-19 after three (HR 1.5 (95% CI [1.14, 1.90]), p=0.003) and four vaccine doses (HR 1.4 (95% CI [1.13, 1.83]), p=0.003), and in hybrid immunity (HR 2.6 (95% CI [1.32, 5.13]), p=0.006). In the entire cohort, the median anti-Spike antibody concentration after the 2nd vaccine dose was 2823 BAU/ml (IQR 999-6199), after the 3rd dose 6529 BAU/ml (IQR 2325-10140), after the 4th dose 7624 BAU/ml (3809-12751) and following hybrid immunity 23506 BAU/ml (11423, 37007). Hospitalisation due to COVID-19 (severe disease) occurred in 22 (2%) patients, 9 (41%) before any vaccination, and none of HC. Four patients were admitted to intensive care. Prior to hospitalisation, the median anti-Spike antibody concentration was 444 BAU/ml (IQR 31-1634). Patients with severe disease were older than non-hospitalised (median age 61 years (IQR 48-74) vs. 54 (42-64), p=0.04) and had a higher frequency of comorbidities (19/22 (86%) vs. 474/1118 (42%), p=0.02). No COVID-19 related deaths occurred.
Prolonged COVID-19 (symptoms >14 days) were reported by 201 (18%) patients compared to 29 (12%) HC (p=0.09). The risk of prolonged disease was higher in the vaccine group compared to the hybrid group (HR 8.5 (95 % CI [3.84, 18.90]), p<0.001).
Conclusion: IMID patients and healthy controls had a comparable occurrence of COVID-19, prolonged disease and reinfection. However, severe disease developed only in the patient group. Hybrid immunity protects against COVID-19 and prolonged disease. A high anti-Spike antibody concentration protects against COVID-19, supporting the role of repeated vaccination in IMID patients on immune-suppressive therapy.

FACILITATING EQUITABLE IBD CARE TRUST-WIDE: A NEED FOR TREATMENT TARGETS IN IBD?

H. Gordon[1], M. Hentges[2], S. Gnanasampanthan[1], A. Ibarra[1], I. O'Shea[1], F. Ronquillo[1], S. Utulu[1], F. Vlachou[1], N. Jawad[1]

Contact E-Mail Address: max.hentges@nhs.net

Introduction: Timely biological therapy in IBD is associated with reduced disease progression, especially in CD (Berg et al 2019). However, there are no clear UK standards detailing the timescale in which IBD care should be delivered. We evaluated the time between initial consideration of therapy and first dose in a district general hospital and tertiary referral centre in Barts Health NHS Trust.

Aims & Methods: Details of patients receiving biologics for IBD at Newham (NUH) and Royal London Hospital (RLH) (between 2018 – 2022) were obtained from infusion clinics; electronic records were reviewed for the 50 most recent referrals. The following information was collected: demographics, phenotype, drug, first documentation of consideration of biologic, completion of funding application, onset of therapy.

Results: Demographics:

NUH: Age (median(IQR)) = 43.5(30.3 – 50.56) Gender (F:M) = 26:24, CD:UC = 34:16, Biologic: infliximab:vedolizumab:ustekinumab:adalimumab: 29:5:11:5, First biologic: n=34

RLH: Age (median(IQR)) = 31.6 (24.6 – 41.1) Gender (F:M) = 27:23 CD:UC = 23:27, Biologic: infliximab:vedolizumab:ustekinumab:adalimumab: 34:12:3:1, First biologic: n=25

There was substantially longer (median (IQR)) time between initial consideration of therapy and first dose delivered at NUH (94.5 days (44 – 174)) compared with RLH (35.5 days (23.75 – 69), p<0.01). However, time from completion of funding application to first dose did not differ significantly between sites (43.5 days (30.3 – 50.6) vs 31.6 days (24.6 – 41.1), p=0.42). In patients receiving first biologic, there was a trend towards a longer time since diagnosis at NUH (3.2 years (1.0 – 9.1) vs 1.7 years (0.5 – 4.3), p=0.08).

Conclusion: Patients treated in a tertiary referral centre started biologics sooner after consideration, and earlier in disease course. This does not appear due to availability of infusion services, but due to time to complete initial investigations and finalise escalation. This may reflect differences in service set-up; in particular, NUH manages IBD care with a single IBD nurse, and fewer options for fast-track clinic follow up. A clear UK IBD standards framework identifying recommended time frames for establishing biologics is indicated, to ensure equity in care across tertiary and DGH settings.

Introduction: Patients with chronic inflammatory diseases (CID) have an increased risk for contracting infections. For patients with inflammatory bowel diseases (IBD), European Crohn's and Colitis Organization (ECCO) provides guidelines for vaccination against vaccine-preventable diseases.

Aims & Methods: To assess the knowledge and awareness of common vaccinations and extent of immunization among patients with CID in Denmark, Finland, Norway, Sweden (Nordics), and to identify gaps between the existing ECCO guidelines and current practice as experienced by patients.

A structured anonymous online survey for patients with CID (IBD, rheumatological disease (RD) and dermatological diseases (DD)) was conducted in 2022. The survey was answered by 1748 respondents (IBD n=543, RD n=1031, DD n=563).

Results: Among respondents, 89% were female, 58% had disease duration >10 years, and majority had ongoing systemic immunosuppressive treatment (IT) (65%). Most of the IBD (66%) and RD (59%) patients and minority of DD patients (38%) were treated in specialised care.

Forty-nine percent stated their healthcare professional (HCP) did not inform them about increased risk of infection – however, 55% believed they are somewhat or much more likely to suffer from infections than those without CID or treatment.

In total, 68% considered it important to get vaccinated due to their CID or treatment (RD (74%), IBD (61,3%), DD (57%)). This despite that 63% stated they had not received any information regarding vaccinations at the start of their treatment, 44% considered the information on vaccinations related to their CID and treatment was difficult to find and 71% would like to receive more information.

Commonly recommended vaccinations in all disease groups vs. IBD were COVID-19 (66% vs. 67%), influenza vaccination (IV) (63% vs. 62%) and pneumococcal vaccination (PV) (45% vs. 44%). Comparing respondents ≥65 and <65 years in all disease groups, a difference was observed in how often IV (71% vs. 57%) and PV (57% vs. 38%) were recommended.

Only 22% had their vaccination status checked *before* initiating treatment; lowest in DD (16%) and highest in RD (25%). Moreover, 64% (IBD 66%, RD 57%, DD 71%) did not have vaccination status assessed regularly. Eighty-six percent did not receive a vaccination plan in relation to their CID and treatment and 43% were dissatisfied with the follow-up of vaccination status. Respondents of ≥65 years were more satisfied than those <65 years (34% vs. 25% very satisfied) and respondents with RD were more satisfied than those with IBD or DD (33% vs. 25% vs. 20%).

The vaccination rate among patients with IBD *before* start with IT was highest for IV (40%) (COVID-19 18%, PV 29%, Herpes zoster vaccine (HZV) 0%). No major differences between disease groups were observed except for COVID-19 vaccination, which was received by 30% of all patients.

The vaccination rate among patients with IBD *while on* IT was highest for COVID-19 (82%) (PV 43%, IV 70%, HZV 1%). No major differences between disease groups were observed in HZV (1%) but PV, IV and COVID-19 vaccines were received by 37%, 62% and 74% of all the CID patients, respectively.

Conclusion: This Nordic survey provides insights on patients' information needs and sources, and own experiences related to recommendations on vaccinations in relation to their CID and IT. The results confirm a gap between the ECCO guidelines and patients' expectations, and demonstrate a need for increased vaccination rate for common vaccinations and awareness among patients and HCP regarding ECCO guidelines in patients with IBD.

Introduction: Tofacitinib is an oral janus kinase inhibitor (JAK) approved for patients with moderate to severe ulcerative colitis (UC) and either inadequate response or loss of response or intolerance to conventional or biologic therapy. The 5-year and 10-year cumulative risk of colectomy in UC is 10%–15%.[1] Due to the increasing number of anti tumor necrosis factor (TNF)-alfa non responders, tofacitinib seems a valuable therapeutic alternative. This study aims to assess the effectiveness of tofacitinib in preventing colectomy in patients with moderate-to-severe UC refractory to anti TNF-alfa agents.

Aims & Methods: We performed an observational retrospective and prospective multicenter study in five Italian IBD referral units including adult patients with confirmed diagnosis of moderate-to-severe UC (defined by a total Mayo score ≥ 6), treated with tofacitinib because of response failure or intolerance to anti TNF-alfa agents. Primary aim was the effectiveness of tofacitinib in preventing colectomy during a follow-up of 52 weeks. Secondary aims were: survival without colectomy, survival without tofacitinib discontinuation, clinical remission (defined as Mayo partial score ≤ 2) at week 8, 24 and 52, endoscopic remission (defined as Mayo endoscopic score ≤ 1) and steroid-free clinical remission (Mayo Partial score ≤ 2 without steroid) at week 52; adverse events (AE) to tofacitinib. Descriptive statistics and Kaplan Meier analyses of survival were performed.

Results: From January 2021 to October 2022 45 patients were included. During the follow-up, 6 patients (13%) underwent colectomy and all of them before week 24. Survival without colectomy and survival without tofacitinib discontinuation are represented in Figs.1-2. Clinical remission was reached by 17 patients (37.7%) at week 8, by 20 (44.4%) at week 24, and by 22 patients (48.8%) at week 52. Among the 11 patients with an endoscopic evaluation available after completing 52-week treatment, 9 (82%) achieved endoscopic remission. At week 52, 22 patients (49%) maintained steroid-free clinical remission. In eighteen patients (40%) tofacitinib was interrupted, because of failure in 15 and because of a severe AE in 3. AE occurred in 9 patients (20%), but in 3 only (6.7%) were severe and entailed treatment interruption.

Conclusion: These data confirm effectiveness and safety of tofacitinib in preventing colectomy in moderate-to-severe UC refractory to anti TNF-alfa agents.

EFFICACY AND SAFETY OF PROACTIVE DRUG MONITORING IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE DURING MAINTENANCE TREATMENT WITH ANTI-TNF AGENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

N. Manceñido Marcos[1], B. Novella Arribas[2], G. Mora Navarro[2], F. Rodríguez Salvanés[2], P. Loeches Belinchón[2], J. Gisbert[3]

Contact E-Mail Address: nmancenido@gmail.com

Introduction: Proactive therapeutic drug monitoring (TDM) has been suggested to improve outcomes in patients with inflammatory bowel disease (IBD) treated with anti-tumour necrosis factor (anti-TNFα) therapy. A systematic review and a meta-analysis of the literature was conducted to assess treatment efficacy and safety, and a systematic review to compare the cost-effectiveness of proactive TDM versus conventional management during maintenance treatment with anti-TNFα.

Aims & Methods: A search was conducted of MEDLINE, EMBASE, and the Cochrane Library up to January 2022. The primary outcome was the ability to maintain clinical remission at 12 months. The certainty of evidence was determined using the GRADE approach.

Results: Nine studies were identified: one systematic review, six randomised clinical trials, and two cohort studies (for safety evaluation). The analysis of the clinical trials showed no superior efficacy of proactive TDM [relative risk 1.16; 95% confidence interval (CI): 0.98–1.37, n=528; I^2=55%]. In contrast, the analysis of the cohort studies and systematic review revealed that proactive TDM could improve the durability of anti-TNFα treatment [odds ratio (OR) 0.12; 95%CI: 0.05–0.27; n=390; I^2=45%), prevent acute infusion reactions (OR 0.21; 95%CI: 0.05–0.82; n=390; I^2=0%), decrease adverse events (OR 0.38; 95%CI: 0.15–0.98; n=390; I^2=14%), and reduce the probability of surgery, at lower economical expenditure.

Conclusion: The analysed evidence did not confirm the superiority of proactive TDM of anti-TNFα agents over conventional management. Therefore, proactive TDM should not be recommended for the management of IBD patients receiving maintenance anti-TNFα treatment.

Contact E-Mail Address: s.schreiber@mucosa.de

Introduction: CT-P13 subcutaneous (SC) infliximab formulation demonstrated superiority over placebo in maintenance therapy in Crohn's disease (CD)[1] and Ulcerative Colitis (UC)[2] patients in two parallel 54 weeks studies (LIBERTY-CD and LIBERTY-UC).

We performed a post-hoc subgroup analysis comparing patients treated with CT-P13 SC with and without combination immunosuppressants (IS) at baseline in CD and UC.

Aims & Methods: Patients with moderately to severely active CD and UC who responded at W10 to CT-P13 intravenous infliximab 5mg/kg (Weeks 0, 2 and 6) were randomized (2:1) to receive CT-P13 SC 120 mg (CT-P13 SC) or placebo every 2 weeks until W54 as maintenance therapy. IS (azathioprine [AZA], 6-mercaptopurine [6-MP], or methotrexate [MTX]) were allowed if patients maintained stable doses at least 8 weeks prior to W0, and stable doses were maintained up to W54.

Results: 231 CD and 294 UC patients were randomized to receive CT-P13 SC maintenance therapy. Among them, 71 (30.7%) and 65 (22.1%) patients received CT-P13 SC with IS in CD and UC, respectively (In CD; 63, 4 and 4 patients of AZA, 6-MP, MTX, respectively, In UC; 63, 2 and 0 patients of AZA, 6-MP, MTX, respectively). There were no statistically significant differences in all of the efficacy outcomes between monotherapy and combination therapy groups at W54 in both studies (Table 1). A trend is seen for higher rates of corticosteroid-free remission with combination therapy in both CD and UC patients.

No statistically significant differences were seen between monotherapy and combination therapy groups in the maintenance period in incidences of treatment-emergent adverse event (TEAE), systemic injection reactions (SIR) in combined analysis of CD and UC patients (TEAE 68.0% vs 74.3% [p=0.1989], SIR 3.3% vs 1.4% [p=0.3743], respectively).

A significantly lower incidence of infection was seen with monotherapy during the maintenance period in combined analysis of both studies (26.9 % monotherapy vs 36.4% combination therapy [p=0.0400]). In the combined analysis of both studies, the serious infections were reported for 10 (2.5%) patients in the monotherapy and 3 (2.1%) patients in the combination therapy.

In combined analysis of CD and UC patients, rate of anti-drug antibody [ADA] positive conversion up to W54 was statistically lower in combination therapy group (70.2% monotherapy vs 47.8% combination therapy [p<0.0001]).

CT-P13 SC 120mg in LIBERTY-CD				CT-P13 SC 120mg in LIBERTY-UC			
n (%)	Monotherapy (N=160)	Combination therapy (N=71)	P-value[a]	n (%)	Monotherapy (N=229)	Combination therapy (N=65)	P-value[a]

Clinical remission (alternative definition)[f]	89 (55.6)	42 (59.2)	0.5647	-	-	-	-
Endoscopic remission[g]	55 (34.4)	25 (35.2)	0.8439	-	-	-	-

[a] The nominal p-value was obtained from Cochran-Mantel-Haenszel test
[b] Clinical remission at Week 54, defined as an absolute Crohn's disease activity index (CDAI) score of <150 points
[c] Endoscopic response at Week 54, defined as a 50% decrease in Simplified endoscopic activity score for Crohn's disease (SES-CD) score from the baseline value
[d] Clinical response at Week 54, defined as a decrease in CDAI score of 100 points or more from the baseline value
[e] Corticosteroid-free remission at Week 54, defined as being in clinical remission (by an absolute CDAI score of <150) in addition to not receiving any corticosteroids for at least 8 weeks prior to Week 54, among the patients who used oral corticosteroids at baseline
[f] Clinical remission at Week 54, defined as Stool frequency subscore of 0 or 1 point, rectal bleeding subscore 0 point, and endoscopic subscore 0 or 1 point
[g] Endoscopic remission at Week 54, defined as an absolute SES-CD score of ≤4 and at least 2-point reduction from the baseline value with no sub-score of >1
[h] Clinical remission at Week 54, defined as modified Mayo score with stool frequency subscore of 0 or 1 point, rectal bleeding subscore 0 point, and endoscopic subscore 0 or 1 point
[i] Endoscopic-histologic mucosal improvement at Week 54, defined as absolute endoscopic subscore of 0 or 1 point from modified Mayo score and an absolute Robarts Histopathology Index (RHI) score of 3 points or less with an accompanying lamina propria neutrophils and neutrophils in epithelium subscore of 0 point
[j] Clinical response at Week 54, defined as decrease in modified Mayo score from baseline of at least 2 points and at least 30%, with an accompanying decrease in the rectal bleeding subscore of at least 1 point or an absolute rectal bleeding subscore of 0 or 1 point
[k] Corticosteroid-free remission at Week 54, defined as being in clinical remission (by modified Mayo score) in addition to not requiring any treatment with corticosteroid for at least 8 weeks at Week 54, among the patients who used oral corticosteroids at baseline

Table 1. Proportion of patients achieving efficacy outcomes at W54

Conclusion: No statistical differences in efficacy outcomes at W54 were observed between monotherapy and combination therapy in CD and UC patients. Concomitant IS use was associated with less ADA formation, whereas more infections are seen for combination therapy during maintenance period in CD and UC patients. The overall safety profile during maintenance period was otherwise comparable between monotherapy and combination therapy in CD and UC patients. This post-hoc analysis suggests limited benefit of concomitant IS with CT-P13 SC but a higher infection risk. Notably, patients were not randomized according to IS use nor were the studies 'powered' to demonstrate differences.

TREATMENT DISCONTINUATION FOR BIOSIMILAR VERSUS ORIGINATOR IN INFLIXIMAB INITIATORS

M. Birck[1], L. Lukusa[1], H. Singh[2], W. Afif[3], N. Narula[4], Y. Leung[5], S. Bernatsky[1]
[1]Research Institute of the McGill University Health Centre, Montreal, Canada, [2]University of Manitoba, Winnipeg, Canada, [3]McGill University Health Center, Gastroenterology, Montreal, Canada, [4]McMaster University, Medicine, Hamilton, Canada, [5]University of British Columbia, Medicine, Vancouver, Canada

Contact E-Mail Address: waqqas.afif@mcgill.ca

Introduction: Infliximab biosimilars (INF-B) to treat inflammatory arthritis and inflammatory bowel disease have been on the North American markets since 2014. However, relatively few evaluations of real-world patterns of use and discontinuation have been conducted.

Aims & Methods: We aimed to compare discontinuation among initiators of INF-B and INF-O in the context of provincial public health insurance in Canada.

We analyzed claims data from provincial public drug plans across Canada (except Quebec) from the National Prescription Drug Utilization Information System. We studied infliximab-naïve patients (≥18 years) with at least 1 infliximab infusion from January 2015-December 2019. Discontinuation was defined as a ≥ 90-day gap between infusions without restarting therapy until the end of follow-up. We used Cox regression to compare time to discontinuation. We adjusted for age, sex, prior use of biologic/systemic steroids, province, and calendar year.

Results: We studied 7,220 infliximab-naïve individuals (28.3% initiating INF-B), of whom 51.9% were women. Subjects had a mean age of 45.5 years (standard deviation 18.4). Most resided in Ontario (33.9%), British Columbia (26.9%) and Alberta (15.4%). During follow-up, 325 individuals (15.9%) initiating INF-B and 1,222 (23.6%) initiating INF-O discontinued therapy completely. Comparing INF-B to INF-O, there was no clear difference in discontinuation rate (adjusted hazard ratio, 1.09; 95% confidence interval 0.95-1.24). Older age independently predicted discontinuation: the higher discontinuation in Ontario may, in part, represent demographics (Ontario's public drug plan covers seniors only) or other factors.

Variables	HR (95% CI)	
	Unadjusted	Adjusted*
Female (biological sex)	1.031 (0.933, 1.139)	1.032 (0.934, 1.140)
Age at INF initiation (years)	1.001 (0.998, 1.004)	1.000 (0.997, 1.003)
Biosimilar	1.050 (0.927, 1.189)	1.076 (0.940, 1.232)
Corticosteroids prior to initiation	0.824 (0.717, 0.947)	0.886 (0.762, 1.031)
Biologic prior to initiation	0.924 (0.751, 1.138)	0.994 (0.795, 1.244)
Ontario province	1.308 (1.179, 1.450)	1.293 (1.161, 1.439)
Calendar year ≥2018	0.881 (0.777, 1.000)	0.831 (0.726, 0.952)

* Adjusted for all variables shown.

Table 1. Unadjusted and adjusted hazard ratio (HR) for discontinuation of infliximab (INF)

Conclusion: Canadian public drug plan beneficiaries initiating INF-B and INF-O had similar rates of discontinuation in this 5-year analysis. Limitations of claims data include the lack of information on the decision to prescribe and discontinue INF-B vs. INF-O, as well as the inability to control for factors not found in administrative data (e.g., race/ethnicity).

Contact E-Mail Address: lvuitton@chu-besancon.fr

Introduction: Tofacitinib is an oral small molecule Janus kinase inhibitor for the treatment of ulcerative colitis.

Aims & Methods: This post hoc analysis aimed to 1) identify baseline factors associated with symptomatic remission at Week 8 in patients who received tofacitinib 10 mg twice daily (BID) in OCTAVE Induction 1&2 (NCT01465763; NCT01458951),[1] and 2) compare the efficacy of tofacitinib 5 and 10 mg BID after 52 weeks of maintenance treatment in OCTAVE Sustain (NCT01458574)[1] in patients who achieved symptomatic remission at maintenance baseline (ie after 8 weeks of induction therapy) vs those who did not. Logistic regression analysis was performed for symptomatic remission as the dependent variable, with each induction baseline predictor as an independent covariate. The proportions of patients in remission, corticosteroid-free remission (CSFR) and sustained CSFR at Week 52 were summarised in those who were symptomatic remitters vs non-remitters at maintenance baseline.

Results: Prior tumour necrosis factor inhibitor exposure or failure was associated with lower odds of achieving symptomatic remission at Week 8 of induction studies (odds ratio [OR] 0.44, 95% confidence interval [CI] 0.25, 0.77; OR 0.42, 95% CI 0.23, 0.75; respectively). Baseline total Mayo score (<9 vs ≥9) and lower stool frequency (2 vs 3) and endoscopic subscore (2 vs 3) were associated with higher odds of achieving symptomatic remission at Week 8 of induction studies (OR 2.82, 95% CI 1.63, 4.88; OR 3.04, 95% CI 1.63, 5.65; OR 2.86, 95% CI 1.65, 4.97; respectively). A numerically higher proportion of maintenance baseline symptomatic remitters vs non-remitters achieved remission at Week 52 (47.1% vs 34.2%; all tofacitinib doses). No differences were seen between maintenance baseline symptomatic remitters and non-remitters at Week 52 (all tofacitinib doses) in terms of achievement of CSFR (26.9 vs 26.3%, respectively) and sustained CSFR (41.2% vs 41.0%, respectively; Table).

Outcome at Week 52 of OCTAVE Sustain	Maintenance treatment		
	Tofacitinib 5 mg BID	Tofacitinib 10 mg BID	All tofacitinib doses
Remission, n/N (%)			
Symptomatic remission status at Week 8 of OCTAVE Induction 1&2:			
Yes[b]	14/36 (38.9)	18/32 (56.3)	32/68 (47.1)
No	41/134 (30.6)	51/135 (37.8)	92/269 (34.2)
CSFR, n/N (%)[c]			
Symptomatic remission status at Week 8 of OCTAVE Induction 1&2:			
Yes[b]	4/16 (25.0)	3/10 (30.0)	7/26 (26.9)
No	19/72 (26.4)	16/61 (26.2)	35/133 (26.3)
Sustained CSFR, n/N (%)[d]			
Symptomatic remission status at Week 8 of OCTAVE Induction 1&2:			
Yes[b]	11/36 (30.6)	17/32 (53.1)	28/68 (41.2)
No	9/21 (42.9)	7/18 (38.9)	16/39 (41.0)

[a]Only patients receiving tofacitinib 10 mg BID who achieved a clinical response (a decrease from induction study baseline total Mayo score of ≥3 points and ≥30%, plus a decrease in rectal bleeding subscore of ≥1 point or an absolute rectal bleeding subscore of 0 or 1) in OCTAVE Induction 1&2, and were re-randomised to receive tofacitinib 5 or 10 mg BID in OCTAVE Sustain, were included in this analysis

[b]Symptomatic remission was defined as a total Mayo score of ≤2 with no individual subscore >1, and both rectal bleeding and stool frequency subscores of 0 at the end of OCTAVE Induction 1&2

[c]Includes patients who were receiving corticosteroids at OCTAVE Sustain baseline. CSFR at Week 52 was defined as a total Mayo score of ≤2 with no individual subscore >1, and a rectal bleeding subscore of 0 (based on centrally read endoscopic subscores), in addition to not requiring any treatment with corticosteroids for at least 4 weeks prior to the Week 52 visit

[d]Includes patients who were in remission at OCTAVE Sustain study baseline. Sustained CSFR was defined as CSFR (based on centrally read endoscopic subscores) at both Week 24 and Week 52 of OCTAVE Sustain

BID, twice daily; CSFR, corticosteroid-free remission; N, number of patients in each treatment subgroup; n, number of patients with specified endpoint

Table. Proportion of responders in remission endpoints at Week 52 of OCTAVE Sustain, by maintenance treatment group and symptomatic remission status at Week 8 of OCTAVE Induction 1&2[a,b]

Conclusion: A numerically higher proportion of patients who were symptomatic remitters vs non-remitters after 8 weeks of induction therapy with tofacitinib achieved remission at Week 52 of OCTAVE Sustain, but those who did not achieve symptomatic remission after 8 weeks of induction treatment could still achieve efficacy endpoints with both tofacitinib maintenance doses at Week 52.

AN INDIRECT COMPARISON OF ADALIMUMAB AND AZATHIOPRINE IN THE MANAGEMENT OF STEROID DEPENDENT INFLAMMATORY BOWEL DISEASE: A SINGLE CENTER REAL WORLD STUDY

M. Saladino[1], R. Randazzo[1], R. Ajovalasit[1], P. Melatti[1], F.M. Di Giorgio,[2], L.M. Amato[1], S. Muscarella[1], D. Brinch[1], C. Celsa[1], C. Camma[1], M. Cappello[1]

Contact E-Mail Address: marica.cappello61@gmail.com

Introduction: Anti-TNF alfa and Azathioprine (AZA) are treatments of choice in the setting of steroid-dependent Inflammatory Bowel Disease (IBD). Thanks to its low cost (with the advent of biosimilars),manageability and lack of immunogenicity Adalimumab (ADA) is the most used anti-TNF. Comparative data between ADA and AZA are scanty.

Aims & Methods: The aim of this study was to compare ADA and AZA in terms of efficacy, safety and persistence in treatment in patients with steroid dependent IBD naive to biologics and/or immunosuppresive therapy. A retrospective-prospective observational study was conducted on consecutive IBD-patients in follow up in our tertiary referral center, who started ADA or AZA between 01/2016 and 01/2022. A minimum follow up of 12 weeks was required. Drug choice was upon clinical judgement.

Primary outcome was clinical remission at week 12, 36, 60 and 84, assessed by HBI for CD and p-Mayo score for UC. Secondary outcomes were probability of persistence in treatment and safety.

Results: 100 patients were enrolled (54 CD, 46 UC), The two treatment groups showed similar baseline characteristics regarding age, sex, familial predisposition, smoking, previous surgery, and concomitant therapies. The use of systemic steroids at week 0 was documented in 25/48 (52,1%) of patients who started ADA and in 18/52 (28,9%) patients on AZA (p=0,079). The results on primary outcome are described in the table below.

In CD both treatments showed similar effectiveness, while patients affected by UC had a significant higher rate of clinical remission when treated with AZA. Six adverse events were registered in the ADA group, 13 AE occurred in the AZA group (p=0,113). Overall retention rate was 38/48 (79,2%) for ADA and 29/52 (55,7%) for AZA (p=0,013).

The cumulative probabilities of persistence in treatment was similar in the two groups (p=0,554), but after 84 week a higher trend to treatment discontinuation was observed with AZA. According to IBD type, treatment persistence with ADA was higher in patients with CD (p=0,007) with a retention rate of 92,9% for ADA versus 42,3% for AZA (P<0,001); while in UC the cumulative probability of persistence in treatment was higher for patients treated with AZA (p=0,016) with a retention rate of 69,2% versus 60% for ADA (p=0,519).

CLINICAL REMISSION	CD ADA	CD AZA	P-VALUE	UC ADA	UC AZA	P-VALUE
W12	20/28 (71,43%)	20/26 (76,92%)	0,648	13/20 (65%)	22/26 (84,61%)	0,126
W36	22/26 (84,62%)	20/22 (90,9%)	0,516	5/15 (33,33%)	20/21 (95,23%)	<0,001
W60	20/22 (90,9%)	17/19 (89,47%)	0,878	0/1	16/16	<0,001
W84	15/17 (88,23%)	13/14 (92,85%)	0,670	-	13/13	

Table.

Conclusion: Our results show good effectiveness, in terms of clinical remission, in patients with CD in both treatment groups, although ADA has a significant higher probability of persistence in treatment. In UC, AZA group have significant better effectiveness and higher retention rate compared to ADA, while the cumulative probability of persistence in treatment is not statistically significant.

These findings suggest the need of a different therapeutic approach in steroid-dependent CD and UC; in particular AZA should be preferred to ADA in patients with UC. In CD both treatments represent a valuable therapeutic option, but ADA may guarantee a better persistence in treatment. These data need to be confirmed in larger series.

THE LONG-TERM EFFECT ON SURGERY-FREE SURVIVAL OF BIOLOGICAL COMPARED TO CONVENTIONAL THERAPY IN CROHN'S DISEASE IN REAL WORLD-DATA: A PROPENSITY-SCORE MATCHED STUDY

M. Valvano[1], A. Vinci[2], M. Ameli[1], N. Cesaro[1], S. Frassino[1], A. Viscido[1], S. Necozione[3], G. Latella[1]

Contact E-Mail Address: valvano.marco@libero.it

Introduction: The introduction of biological drugs has led to great expectations and growing optimism in the possibility that this new therapeutic strategy could favourably change the natural history of Inflammatory Bowel Disease (IBD) and in particular that it could lead to a significant reduction in surgery in the short and long term. The evaluation of the incidence of intestinal resection after the introduction of biological therapy is very complex and subject to several potential bias, the most prominent being the shift in IBD management over the last few decades.

Aims & Methods: This study aims to assess the impact of biological versus conventional therapy on surgery-free survival time (from the diagnosis to the first bowel resection) and on the overall risk of surgery in patients with Crohn's disease (CD) who were never with the surgical option.

This is a retrospective, double-arm study including CD patients treated with either biological or conventional therapy (mesalamine, immunomodulators, antibiotics, or steroids). All CD patients admitted at the GI Unit of the S. Salvatore Hospital (L'Aquila, Italy) and treated with biological therapy since 1998 were included in the biological arm. Data concerning the CD patients receiving a conventional therapy were retrospectively collected from our database. These patients were divided into a pre-1998 and post-1998 group (pre and post biologic era, respectively). Our primary outcome was the evaluation of the surgery-free survival since CD diagnosis to the first bowel resection. Surgery-free time and event incidence rates were calculated and compared among all groups, both in the original population and in the propensity-matched population.

Results: 203 CD patients (49 biological, 93 conventional post-1998, 61 conventional pre-1998) were included in the study. Kaplan-Mayer survivorship estimate shows that patients in the biological arm had a longer surgery-free survival compared to those in the conventional arm (p=0.03). However, after propensity matching analysis, no significant difference was found in surgery-free survival (p=0.3). A sub-group analysis showed shorter surgery-free survival in patients on conventional therapy in the pre-biologic era only (p=0.02) while no significative difference was found between the biologic and conventional post-biologic groups (p=0.15).

Conclusion: This study shows that the introduction of biological therapy had only a slight impact on the occurrence of surgery in CD patients over a long observation period. Despite the milder disease, patients in the conventional group in the biologic era had the same surgery-free survival compared to patients in biological therapy. Nevertheless, biological therapy appears to delay the first intestinal resection. However, the cumulative incidence of first intestinal resection between patients who underwent biological or conventional therapy ends up being similar considering a very long period.

Disclosure: None.

TARGETING IMPROVED TREG SELECTIVITY WITH THE IL-2 MUTEIN EFAVALEUKIN ALFA: RATIONALE FOR IL-2 THERAPY IN ULCERATIVE COLITIS

F. Firoozbakht[1], N. Sarkar[2], K. Gorski[2], N. Tchao[2]

[1]Amgen Inc., Thousand Oaks, United States, [2]Amgen Inc., South San Francisco, United States

Contact E-Mail Address: ffiroozb@amgen.com

Introduction: Targeting interleukin (IL)-2 and its ability to expand regulatory T cells (Treg) represents a novel therapeutic mechanism for the treatment of ulcerative colitis (UC). Low-dose recombinant IL-2 (aldesleukin) has shown disease-modifying activity in UC in early clinical studies.[1,2] However, low dose IL-2 has a small selectivity window for Treg over conventional CD4+ T cells (Tcon) and natural killer (NK) cells, with the potential for inflammatory cell expansion and adverse events (AE) related to low selectivity. Efavaleukin alfa is an IL-2 mutein Fc fusion protein with a mutation that decreases binding to IL-2Rβ and increases dependence on IL-2Rα (CD25), which is expressed constitutively at high levels on Treg.

Here we evaluated the selectivity of efavaleukin alfa for Treg expansion, using data from preclinical[3] and phase 1 (NCT03451422)[4] studies to support the biologic rationale for a phase 2 clinical study of efavaleukin alfa in UC patients.

Aims & Methods: In vitro activity and selectivity were assessed according to levels of phosphorylated STAT5 (pSTAT5) and proliferation of Treg, Tcon, and NK cells in primary human peripheral blood mononuclear cells (PBMC) cultured with increased doses of efavaleukin alfa or aldesleukin. The in vivo effects on body temperature, C-reactive protein (CRP), proinflammatory cytokine production, and peripheral blood Treg, Tcon, and NK cell numbers were evaluated in cynomolgus monkeys after escalating single SC doses of efavaleukin alfa or 5 consecutive daily SC doses of aldesleukin.

Safety, tolerability, and pharmacodynamics of efavaleukin alfa vs placebo were evaluated in a single-dose phase 1a study in healthy subjects and in a multiple ascending dose phase 1b study in patients with systemic lupus erythematosus (SLE).

Results: In human PBMC cultures, efavaleukin alfa led to a more selective Treg response (pSTAT5 and proliferation) than aldesleukin, with lower levels of IL-2 signaling observed in non-Treg (Tcon and NK) cells and proliferation of inflammatory cells only observed at higher doses of efavaleukin alfa vs aldesleukin. Dose-dependent expansion of FoxP3+ Treg in aldesleukin-treated cynomolgus monkeys was accompanied by increased body temperature and levels of CRP and IL-6. However, efavaleukin alfa stimulated Treg expansion with no increases in IL-6 and without significant effects on body temperature or CRP except at the highest dose, suggesting an increased therapeutic window compared with aldesleukin.

In phase 1 studies, peak Treg expansion was observed at 8 days post-dose, and mean Treg levels remained above baseline through the end of the follow-up period. The mean peak increases in FoxP3+ Treg were 4.7-fold above baseline after a single dose administered to healthy subjects and 17.4-fold above baseline after multiple doses in SLE patients. In contrast, there were minimal changes in fold-change of Tcon, CD8+ T

cells, B cells, or NK cells with efavaleukin alfa. In phase 1 studies, the most common AEs were mild-moderate (grade 1-2) injection site reactions, and no dose-limiting toxicities, treatment-related serious AEs, or deaths were reported.

Conclusion: Efavaleukin alfa is a novel IL-2 therapy that has an increased therapeutic window compared with aldesleukin. Preclinical and phase 1 results with efavaleukin alfa demonstrated highly selective expansion of Treg with minimal effects on pro-inflammatory immune cells. These findings support the rationale and design of an ongoing phase 2b study investigating the safety and efficacy of efavaleukin alfa induction therapy in patients with moderate to severe active UC (NCT04987307).

Introduction: Inflammatory bowel disease (IBD) represents a cluster of chronic systemic intestinal disturbances that comprise Crohn's disease (CD) and ulcerative colitis. It has been shown that the transcription factor peroxisome proliferator activated receptor-gamma (PPAR-α) exerts its anti-inflammatory action by negatively influencing the expression and activity of inflammatory transcription factor called NF-kb. In the absence of (PPAR-α) gene, IBD pathologies are exacerbated. (1)

We have previously shown that the polyphenolic extract from maqui fruit decreased reactive oxygen species (ROS) in a dose-dependent manner and its administration in an experimental animal model of CD significatively ameliorated the clinical course of the disease and intestinal inflammation.

Aims & Methods: We explored whether maqui extract had an anti-inflammatory role through modulating PPAR-α expression in epithelial cells and macrophage cells from colon tissue. Male Balb/c mice 12-14 weeks old which were exposed to 2,4,6-trinitrobenzene sulfonic acid (TNBS) via intracolonic administration and were randomly assigned in 4 groups (n=6) as follows: i) Control Group (EtOH 50%) ii) Crohn's Disease Group (100 mg/kg of TNBS plus EtOH 50%), iii) Curative Group (maqui at 50mg/kg for 4 days after TNBS induction), iv) Preventive Group (maqui at 50mg/kg 7 days prior TNBS and 4 days after induction).

Results: In the epithelial cells, TNBS induced a slight decrease of PPAR-α expression when we compared with the control group. Notably, this difference did not reach statistical significance. The administration of maqui extract did not alter epithelial PPAR-α level. Similar PPAR-α staining intensity and expression was showed either for curative or preventive groups remained like the control group.

In terms of specific macrophage PPAR-α levels, a stronger positive staining and intensity was observed in the CD mice when compared to the controls. However, this difference was not significant. Similarly, an increase in PPAR-α staining intensity and PPAR-α positive macrophages was also observed in mice that received curative maqui treatment, whereas colons from mice receiving maqui extract as a preventive treatment yielded a significative PPAR-α staining.

Conclusion: Maqui extract treatment elicit an anti-inflammatory action by increasing the expression of PPAR-α in immune cells during the earlier phase of the disease. These data support the preventive effect of polyphenols from maqui extract and its potential antiinflammatory effect in IBD.

Contact E-Mail Address: marla.dubinsky@mssm.edu

Introduction: Ozanimod is an oral sphingosine 1-phosphate (S1P) receptor 1 and 5 modulator approved in multiple countries for the treatment of adults with moderately to severely active ulcerative colitis (UC) and relapsing multiple sclerosis (RMS). Ozanimod is also being studied in the treatment of Crohn's disease (CD). S1P receptors are involved in vascular formation during embryogenesis, and prescribing information for S1P receptor modulators, such as ozanimod, contain recommendations for effective contraception use as well as general statements about potential fetal risk based on data from preclinical studies.

Aims & Methods: The objective of this analysis was to review pregnancy outcomes during ozanimod use in the clinical development program in all studies in which patients with UC, CD, or RMS or healthy volunteers received ozanimod. Within studies in the ozanimod clinical development program, female patients of childbearing potential were required to use effective contraception while receiving ozanimod and for up to 3 months after discontinuing the drug; treatment discontinuation was required when pregnancy was confirmed. Pregnancy outcomes in the ozanimod clinical development program were assessed through November 19, 2022.

Results: In ozanimod clinical trials, 78 patient pregnancies occurred: 14 in those with UC, 6 in those with CD, 57 in those with RMS (there were 58

outcomes due to twins), and 1 in a healthy volunteer (Table). All patient pregnancy exposures to ozanimod occurred during the first trimester. Patients discontinued study medication promptly after pregnancy was confirmed, except for those who elected pregnancy termination and remained on study medication. The incidence of spontaneous abortion in clinical trial patients was 15%. The preterm birth rate was 10% of all live births. Outcomes in patients with UC included 7 live births (no congenital abnormalities or premature births), 3 spontaneous early losses, and 4 elective terminations (Table). No teratogenicity was observed in patients with ozanimod exposure during early pregnancy.

	UC	CD	RMS	Healthy volunteer	Total
Pregnancies	14	6	57[a]	1	78
Live birth without congenital anomaly	7	2	28	0	37
Live birth with congenital anomaly	0	0	1[b]	0	1
Premature birth	0	0	4	0	4
Ongoing	0	1	5	0	6
Spontaneous early losses	3	1	8[c]	0	12
Elective termination	4	0	10	1	15
No information	0	2	2	0	4

[a]58 outcomes due to twins. [b]Duplex kidney. [c]A twin pregnancy led to 1 early loss and 1 live birth.

Table. Pregnancy outcomes during the ozanimod clinical development program by patient population.

Conclusion: Pregnancy should be avoided in patients receiving ozanimod and for 3 months after discontinuing ozanimod. Clinical experience with ozanimod during pregnancy is limited. In this small cohort of patients, there has been no increased incidence of fetal abnormalities or adverse pregnancy outcomes seen with ozanimod exposure in early pregnancy.

REINITIATION OF OZANIMOD AFTER DOSE INTERRUPTION: ASSESSMENT OF EFFECT ON HEART RATE

P. Zhang[1], M. Syto[1], S. Walker[1], G. Tirucherai[1], B. Murthy[1], D. Tatosian[1]

[1]Bristol Myers Squibb, Princeton, United States

Contact E-Mail Address: Peijin.Zhang@bms.com

Introduction: Ozanimod (OZA), a selective sphingosine 1-phosphate (S1P) receptor 1 and 5 modulator, is approved in multiple countries for the treatment of adults with moderately to severely active ulcerative colitis and relapsing multiple sclerosis. Treatment with OZA and other S1P receptor modulators has been associated with bradycardia likely due to the pharmacologic effect of $S1P_1$ receptors on heart rate (HR). Thus, dose titration with OZA is implemented to mitigate this risk.

Aims & Methods: This randomized, double-blind, placebo (PBO)–controlled, adaptive phase 1 study evaluated the effects of OZA reinitiation on HR. OZA was reinitiated at a maintenance dose of 0.92 mg (equivalent to OZA HCl 1 mg) after different washout intervals relative to dose escalation in healthy adults. Participants were randomized to receive once-daily OZA (dose titration: 0.23 mg for Days 1–4, 0.46 mg for Days 5–7, and 0.92 mg thereafter) or PBO for 28 days in Period 1, followed by a washout of 3, 7, or 14 days, and then treatment reinitiation with a single dose of either OZA 0.92 mg or PBO in Period 2. The changes at Period 2 Day 1 from Period 1 Day 1 (CFP1) in the HR_{Nadir} from 0–12 hours postdose were compared between OZA/OZA and PBO/PBO groups after each washout interval and were analyzed using an ANCOVA model with fixed effects for treatment, Period 1 Day 1 HR_{Nadir} (0–12 hours), sex, and treatment × Period 1 Day 1 HR_{Nadir} (0–12 hours); least squares (LS) mean differences between OZA/OZA and PBO/PBO with 90% CI were calculated. The maximum reductions in hourly HR using the change from predose HR minimum value from 0–12 hours relative to dosing on the corresponding day of interest (CFP_{min} HR) and time to HR_{Nadir} were compared between combined OZA (OZA/OZA and OZA/PBO; n=51) and PBO/PBO participants. Safety was also assessed.

Results: Of 64 healthy adults who completed the study, 15, 16, and 15 received OZA/OZA and completed the 3-, 7-, and 14-day washout intervals, respectively; 18 individuals received PBO/PBO (6 in each washout period; they were combined for all washout interval comparisons). LS mean CFP1 Day 1 HR_{Nadir} changes were generally similar between OZA/OZA and PBO/PBO groups at each washout interval: 3 days = 3.51 vs 1.73 beats per minute (bpm), 7 days = 0.85 vs 1.87 bpm, and 14 days = 0.27 vs 1.81 bpm, respectively. The CFP1 Day 1 HR_{Nadir} LS mean differences between OZA/OZA and PBO/PBO (90% CI) at each washout interval were 3 days = 1.78 bpm (–1.76 to 5.32), 7 days = –1.02 bpm (–3.88 to 1.85), and 14 days = –1.54 bpm (–4.20 to 1.11). During the OZA dose escalation, CFP_{min} HR changes ranged from –11.90 to –8.70 bpm for OZA (combined) and from –9.45 to –7.79 bpm for PBO/PBO. Predose HR values for OZA (combined) on Days 5 and 8 were ~5 bpm lower than on Day 1. Postdose CFP_{min} HR changes were similar between Days 5 and 8 for OZA (combined), which were ~3 bpm lower than on Day 1. Median time to HR_{Nadir} was similar between OZA (combined; 4 hours) and PBO/PBO (3–4 hours). Repeated dosing of OZA for 28 days (including the 7-day dose escalation) and reinitiation of OZA 0.92 mg after all washout intervals was generally safe and well tolerated in healthy participants.

Conclusion: Overall, reinitiation of OZA at the maintenance dose of 0.92 mg once daily after dose interruption of 3, 7, or 14 consecutive days was not associated with meaningful changes in HR. OZA can be safely reinitiated at the maintenance dose without repeating dose titration within 14 days of drug discontinuation.

TOFACITINIB RELATED CANCER RISK: RESULTS FROM A SYSTEMATIC REVIEW WITH META-ANALYSIS

M. Vernero[1], C. Bezzio[2], D.G. Ribaldone[3], E. Alimenti[4], E. Bugianesi[5], G. Manes[6], S. Saibeni[6]
[1]University of Turin, Department of Medical Sciences, Turin, Italy, [2]ASST Rhiodense Hospital, Gastroenterology Division, Rho (MI), Italy, [3]University of Turin, Department of Medical Sciences, Division of Gastroenterology, Turin, Italy, [4]University of Pavia, Department of Medical Sciences, Pavia, Italy, [5]AOU Città della Salute e della Scienza University of Torino, Medical Sciences, Torino, Italy, [6]ASST Rhodense, Gastroenterology Unit, Rho, Italy

Contact E-Mail Address: martavernero@gmail.com

Introduction: Tofacitinib is a relatively novel therapy for immune-mediated inflammatory diseases, including rheumatoid arthritis, psoriatic arthritis, and ulcerative colitis. It is a small-molecule drug that exerts its effects by inhibiting Janus kinases. Recently, concerns have been raised about the drug's safety in terms of cardiovascular side effects and cancer risk.

Aims & Methods: This meta-analysis determined the risk of cancer in patients treated with tofacitinib for different clinical indications, compared to both a placebo and other therapies. We searched PubMed (accessed on november 1st 2022) for original articles regarding tofacitinib's cancer risk when used for rheumatoid arthritis, ulcerative colitis, Crohn's disease, psoriatic arthritis, and ankylosing spondylitis.

Results: Of the 2047 initial records, 22 articles describing 26 controlled studies (including 22 randomized controlled trials) were selected. In the comparison between tofacitinib and any control treatment, the relative risk (RR) for any cancer was 1.06 (95% CI, 0.86–1.31; p = 0.95). In separate comparisons between tofacitinib and either a placebo or biological therapy, no difference was found in the overall cancer risk (vs. placebo, RR = 1.04; 95% CI, 0.44–2.48; p = 0.95; vs. biological drugs, RR = 1.06; 95% CI, 0.86–1.31; p = 0.58). When tofacitinib was compared to tumor necrosis factor (TNF) inhibitors, the overall cancer RR was 1.40 (95% CI, 1.06–2.08; p = 0.02). Similarly, significant results were obtained for all cancers, except for non-melanoma skin cancer (RR = 1.47; 95% CI, 1.05–2.06; p = 0.03), and for this skin cancer alone (RR = 1.30; 95% CI, 0.22–5.83; p = 0.88).

Conclusion: In conclusion, no difference in the overall cancer risk was found between tofacitinib and either a placebo or biological drugs, while a slightly higher risk was found in patients treated with tofacitinib than anti-TNF agents. Further studies are needed to better define the cancer risk of tofacitinib therapy.

Disclosure: Nothing to disclose.

Introduction: C-reactive protein (CRP) and fecal calprotectin (FeCal) are non-invasive inflammatory biomarkers used to assess disease activity in UC. The Phase 3 QUASAR induction study evaluated the efficacy and safety of guselkumab (GUS), an IL-23 p19 subunit antagonist, in patients (pts) with moderately to severely active UC.

Here, we analyze the effect of GUS treatment on CRP and FeCal through Week (Wk) 12 in pts with elevated CRP and/or FeCal.

Aims & Methods: Pts with a modified Mayo score of 5-9 and a Mayo endoscopy subscore ≥2 at baseline (BL) were randomized 3:2 to receive either GUS 200mg IV or placebo (PBO) IV at Wks0, 4, and 8. CRP and FeCal were assessed at BL, Wk4, Wk8 (for CRP only), and Wk12.

Results: A total of 701 pts were evaluated and approximately 50% of randomized pts had a history of inadequate response/intolerance to advanced therapies (ADT) for UC; 47.4% of these pts had inadequate response/intolerance to ≥2 ADT classes. Median BL concentrations of CRP and FeCal were similar between the GUS-treated and PBO-treated pts (4.34 vs 3.83mg/L and 1651 vs 1606mg/kg, respectively).

Among pts with elevated CRP and/or FeCal at BL, greater reductions in CRP and FeCal were observed at the earliest timepoint assessed (Wk4) with GUS and continued through Wk12 compared with PBO (Table).

At BL, 248 GUS-treated pts and 160 PBO-treated pts had elevated CRP (>3mg/L); the proportions were similar between treatment groups (58.9% vs 57.1%, respectively). Among these pts, median change from BL in CRP concentration (mg/L) at Wk12 for the GUS and PBO cohorts were -3.99 and -0.51mg/L, respectively (nominal p<0.001); the proportions of pts achieving 50% and 75% reduction in CRP levels (or ≤3mg/L) at Wk12 were higher for GUS-treated pts than those receiving PBO (59.7% vs 28.1% and 47.2% vs 19.4%, respectively; both nominal p<0.001).

Similarly, a higher proportion of GUS-treated pts achieved CRP≤3mg/L at Wk12 than PBO-treated pts (40.3% vs 16.3%, nominal p<0.001).

At BL, 333 GUS-treated pts and 225 PBO-treated pts had elevated FeCal (>250mg/kg); the proportions were similar between treatment groups (79.1% vs 80.4%, respectively).

Median change from BL in FeCal concentration (mg/kg) for pts with elevated FeCal at BL at Wk12 were -800 and -86mg/kg for the GUS and PBO cohorts, respectively (nominal p<0.001); the proportions of pts achieving 50% and 75% reduction in FeCal levels (or ≤250 mg/kg) at Wk12 were higher for GUS-treated pts than those receiving PBO (51.1% vs 33.8% and 41.4% vs 23.6%, respectively; both nominal p<0.001).

A larger percentage of pts treated with GUS achieved FeCal≤250mg/kg at Wk12 than pts treated with PBO (29.4% vs 17.3%, nominal p<0.001).

	Placebo IV	Guselkumab 200 mg IV
CRP (mg/L)		
Baseline, N	160	248

Wk 12, N	201	293
Median change from baseline [IQR]	-86 [-1254; 504]	-800 [-2532; 0]***

****Nominal P≤0.001.* Patients who had a prohibited change in UC medication, an ostomy or colectomy, or discontinued study agent due to lack of efficacy or an AE of worsening of UC or other reasons except for COVID-19 related reasons (excluding COVID-19 infection) or regional crisis in Russia and Ukraine prior to the designated timepoint had their baseline value carried forward from the time of the event onward. The p-values of treatment comparison were based on the mixed-effect model repeated measures with CRP and FeCal values being log-transformed.

Table. Change from baseline in CRP and FeCal through Week 12 among patients with elevated CRP (>3mg/L) or FeCal (>250mg/kg) at baseline.

Conclusion: In this phase 3 induction study, pts with moderately to severely active UC and elevated inflammatory markers treated with GUS 200mg IV induction showed greater improvement from BL in both CRP and FeCal levels compared with PBO. Differences were observed as early as the first assessments at Wk4 and continued through Wk12.

IMPACT OF OZANIMOD (OZA) ON C-REACTIVE PROTEIN (CRP) LEVELS AND THE ASSOCIATION WITH OZA EFFICACY IN PATIENTS (PTS) WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS (UC): RESULTS FROM THE PHASE 3 TRUE NORTH (TN) STUDY

S. Harris[1], R. Maddux[1], C. Wu[1], Y. Hu[1], A. Petersen[1], D.T. Rubin[2]

[1]Bristol Myers Squibb, Princeton, United States, [2]University of Chicago Medicine, Inflammatory Bowel Disease Center, Chicago, United States

Contact E-Mail Address: sarah.harris@bms.com

Introduction: OZA is approved in multiple countries for treatment of moderately to severely active UC in adults. In the phase 3 TN study, OZA was efficacious for up to 52 wk in pts with moderately to severely active UC. CRP is a widely used serum indicator of inflammation and prognosis in inflammatory bowel disease.

Aims & Methods: The effect of OZA on CRP levels and the association of CRP levels with OZA efficacy were assessed in all TN pts. During the 10-wk induction period, pts in Cohort 1 were randomized to OZA 0.92 mg or placebo (PBO) or received open-label OZA 0.92 mg in Cohort 2. Pts with clinical response to OZA at Week (W) 10 were rerandomized to OZA or PBO for maintenance through W52. Serum CRP levels were assessed at baseline (BL) through W52.

Disease activity scores (rectal bleeding subscore [RBS], stool frequency subscore, Physician's Global Assessment subscore, endoscopy subscore, and partial and total Mayo scores) were assessed at BL and W10. Efficacy endpoints (clinical remission, clinical response, endoscopic improvement, mucosal healing, and histologic remission) were assessed at W10. Associations of CRP levels with disease activity and efficacy endpoints were assessed using Spearman's correlation and logistic regression, respectively.

Results: 645 pts were randomized to OZA (n=429) or PBO (n=216) and 367 pts received open-label OZA for 10 wk; 230 and 227 OZA-treated pts who responded were rerandomized to OZA and PBO, respectively, for maintenance through W52 (69 PBO-treated pts who responded continued on PBO). Pts on OZA showed reductions from BL in CRP levels at W10, which was significant vs PBO (P<0.001, both cohorts) (Table).

Reductions in CRP levels were significantly greater in pts with vs without clinical response at W10 in all treatment groups (P<0.001, all groups) (Table).

Significantly greater reductions in CRP levels occurred with OZA vs PBO at W10 regardless of prior biologic or anti–tumor necrosis factor exposure (P<0.05, all groups). Reductions in CRP levels were maintained through W52; pts who continued OZA had similar reductions at W52 as pts who switched to PBO (Table).

Decreases in CRP levels in W52 responders were maintained through W52 of treatment, while W52 nonresponder CRP levels started to rise following induction toward BL values (Table).

BL CRP levels were significantly positively correlated with most BL disease activity scores (Spearman's *rho* 0.2–0.3, P<0.05, all scores) except RBS. BL CRP levels and change in CRP levels at W5 were prognostic for W10 response. Higher BL CRP levels were associated with lower endoscopic improvement, mucosal healing, and histologic remission at W10 and greater reductions in CRP levels at W5 were associated with better clinical response at W10, independent of treatment.

Change in CRP levels at W10 was significantly positively correlated with change in most disease activity scores at W10 with OZA and PBO (Spearman's *rho* 0.1–0.3, P<0.05, all scores in both groups) except endoscopy with PBO.

	Induction (Week 10)			Maintenance (Week 52)	
	PBO (C1) (n=216)	OZA (C1) (n=429)	OZA (C2) (n=367)	OZA/PBO (n=227)	OZA/OZA (n=230)
All pts	–1.2 (–13.3, 12.7) n=192	–26.8 (–33.3, –19.8) n=407	–25.7 (–32.7, –18.1) n=336	–19.9 (–30.9, –7.1) n=125	–23.5 (–32.7, –13.0) n=181
Responders[a]	–39.9 (–52.5, –24.0) n=55	–45.9 (–52.2, –38.9) n=204	–40.4 (–47.5, –32.3) n=189	–33.1 (–44.1, –20.0) n=91	–30.9 (–40.4, –20.0) n=135

[a]Responders are pts who achieved clinical response at W10 for the induction period and at W52 for the maintenance period. [b]Nonresponders are pts who did not achieve clinical response at W10 for the induction period and at W52 for the maintenance period.
C1, Cohort 1; C2, Cohort 2.

Table. Adjusted mean percent change from BL in CRP levels (95% CI)

Conclusion: In moderately to severely active UC pts, OZA led to reductions in CRP levels. Higher BL CRP levels were associated with worse disease outcomes and greater reductions in CRP levels were associated with better disease outcomes regardless of treatment, supporting CRP levels as a prognostic biomarker for UC.

IMPACT OF OZANIMOD (OZA) ON INTERLEUKIN-17A (IL-17A) LEVELS AND THE ASSOCIATION WITH OZA EFFICACY IN PATIENTS (PTS) WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS (UC): RESULTS FROM THE PHASE 3 TRUE NORTH (TN) STUDY

S. Harris[1], R. Maddux[1], C. Wu[1], Y. Hu[1], A. Petersen[1], S. Vermeire[2]
[1]Bristol Myers Squibb, Princeton, United States, [2]University of Leuven, Leuven, Belgium

Contact E-Mail Address: sarah.harris@bms.com

Introduction: OZA is a sphingosine 1-phosphate receptor modulator approved for the treatment of moderately to severely active UC. In the phase 3 TN study, OZA was efficacious for up to 52 wk with a favorable safety profile. IL-17A, a proinflammatory cytokine, sustains the release of other inflammatory mediators and is associated with inflammatory bowel disease.

Aims & Methods: This analysis assessed the effect of OZA on IL-17A levels and the association of IL-17A levels with OZA efficacy during TN. During the 10-wk induction period, pts in Cohort 1 were randomized to OZA 0.92 mg or placebo (PBO) and pts in Cohort 2 received open-label OZA 0.92 mg. Pts with clinical response to OZA at Week (W) 10 were rerandomized to OZA or PBO for maintenance through W52. IL-17A levels were assessed at baseline, W10, and W52.

Disease activity scores (rectal bleeding and stool frequency subscores, Physician's Global Assessment subscore, endoscopy subscore, and partial and total Mayo scores) were assessed at baseline and W10. Efficacy endpoints (clinical remission, clinical response, endoscopic improvement, mucosal healing, and histologic remission) were assessed at W10 and W52. Associations of IL-17A levels with disease activity and efficacy endpoints were assessed using Spearman's correlation and logistic regression, respectively.

Results: In all, 645 pts were randomized to OZA (n=429) or PBO (n=216) and 367 pts received open-label OZA; 230 and 227 OZA-treated pts were rerandomized to OZA and PBO, respectively, for maintenance. Pts on OZA demonstrated reductions from baseline in IL-17A at W10, which was significant vs PBO (P<0.001, both cohorts) (Table). IL-17A reductions were significantly greater in pts with vs without clinical response at W10 in all OZA and PBO treatment groups (P<0.01, all groups) (Table). Significantly greater IL-17A reductions occurred with OZA vs PBO at W10 regardless of prior biologic or anti–tumor necrosis factor exposure (P<0.001, all groups). IL-17A reductions were maintained through W52; pts who continued OZA had significantly greater IL-17A reductions at W52 vs pts who switched to PBO (P<0.001) (Table). IL-17A reductions were significantly greater in pts with vs without clinical response at W52 (P<0.001, OZA and PBO groups) (Table). Baseline IL-17A levels were significantly correlated with all baseline disease activity scores (Spearman's *rho* 0.1–0.2, P<0.05, all scores), but were not associated with treatment responses at W10. Change in IL-17A from baseline to W10 was significantly correlated with change in all disease activity scores at W10 with OZA and PBO (Spearman's *rho* 0.2–0.4, P<0.05, all scores in both groups).

Furthermore, greater reductions from baseline to W10 in IL-17A was significantly associated with higher probability of achieving clinical remission, clinical response, endoscopic improvement, and mucosal healing at W52 (P<0.05, all endpoints) in pts on continuous OZA through W52.

IL-17A adjusted mean percent change from baseline (95% CI)	Induction (W10)			Maintenance (W52)	
	C1: PBO (n=216)	C1: OZA (n=429)	C2: OZA (n=367)	OZA/PBO (n=227)	OZA/OZA (n=230)
All pts	–10.5 (–18.1, –2.2) n=159	–33.5 (–37.5, –29.3) n=340	–40.3 (–44.0, –36.4) n=294	–37.5 (–43.6, –30.7) n=112	–50.7 (–54.9, –46.1) n=152
Responders[a]	–27.8 (–38.0, –15.9) n=47	–46.6 (–50.6, –42.2) n=177	–46.6 (–50.6, –42.2) n=175	–44.1 (–50.3, –37.2) n=80	–55.8 (–60.0, –51.3) n=113

[a]Responders are pts who achieved clinical response at W10 for the induction period and at W52 for the maintenance period. [b]Nonresponders are pts who did not achieve clinical response at W10 for the induction period and at W52 for the maintenance period.
C1, Cohort 1; C2, Cohort 2.

Table. Change from baseline in IL-17A at W10 and W52

Conclusion: OZA led to IL-17A reductions, indicative of decreases in inflammatory responses. Higher baseline IL-17A was associated with higher baseline disease activity, and greater reductions in IL-17A were associated with better short- and long-term disease outcomes. These data support IL-17A as a good disease marker for UC.

HEALTHCARE RESOURCE UTILIZATION AND TREATMENT USAGE AMONG FLARING AND NON-FLARING PATIENTS WITH ULCERATIVE COLITIS – A REAL-WORLD GLOBAL STUDY

A. Dignass[1], I. Redondo[2], P. Streit[3], S. Hartz[4], H. Knight[5], S. Barlow[5], N. Harvey[5], T. Hunter Gibble[6]
[1]Agaplesion Markus Krankenhaus, Medizinische Klinik I, Frankfurt/Main, Germany, [2]Eli Lilly and Company, Lisbon, Portugal, [3]Eli Lilly and Company, Vernier, Switzerland, [4]Eli Lilly and Company, Bracknell, United Kingdom, [5]Adelphi Real World, Bollington, United Kingdom, [6]Eli Lilly and Company, Indianapolis, United States

Contact E-Mail Address: axel.dignass@agaplesion.de

Introduction: Despite increasing treatment opportunities for ulcerative colitis (UC), patients often suffer acute periods of increased disease severity. Since little is known regarding how healthcare resource utilization (HCRU) and drug dosing differ between flaring and non-flaring patients in a real-world clinical setting, we aimed to assess these differences.

Aims & Methods: Data were extracted from the Adelphi UC Disease Specific Programme, a point-in-time survey of gastroenterologists and patients conducted in France, Germany, Italy, Spain, the United Kingdom, and the United States from January 2020 - March 2021. Gastroenterologists provided clinical characteristics, treatment history and HCRU for their next 5-7 consulting UC patients with a history of moderate-severe disease. Patients were categorized based on whether they had experienced a flare in the last 12 months, and compared using Fisher's exact, t-test and Mann-Whitney tests. Two subgroups were analysed separately to explore drug dosing patterns for flaring and non-flaring patients; those on targeted therapies (TT; biologics, Janus kinase inhibitors) who had been receiving their therapy for ≥12 months and those who were currently receiving corticosteroids.

Results: This study included 2,019 patients; 968 (47.9%) were reported by their gastroenterologist to have flared in the last 12 months, while 1,051 (52.1%) had no flares. While age and sex were similar across the patient subgroups, flaring patients had a shorter disease duration (p=0.05) and greater disease extension (p<0.01) than non-flaring patients (Table 1).

	Not flared in the last 12 months (n=1,051)	Flared in the last 12 months (n=968)	p-value
Age, mean (SD)	40.4 (14.4)	40.1 (14.3)	0.63
Sex, Male, n (%)	576 (54.8)	511 (52.8)	0.37
Ethnicity, White/ Caucasian, n (%)	939 (89.3)	826 (85.3)	<0.01
Disease duration, years Mean (SD)	n=956 5.3 (6.2)	n=924 4.7 (5.6)	0.05
Total number of consultations in the last 12 months Mean (SD)	n=740 5.3 (4.6)	n=767 7.2 (6.2)	<0.01
Number of hospitalizations in the last 12 months Mean (SD)	n=947 0.1 (0.9)	n=892 0.4 (0.8)	<0.01
Has the patient received corticosteroids in the last 12 months? Yes, n (%)	146 (13.9)	381 (39.4)	<0.01
During the course of the current regimen, has the corticosteroid dose changed? Escalated, n (%) Not escalated, n (%)	n=90 5 (5.6) 85 (94.4)	n=274 27 (9.9) 247 (90.2)	0.28
During the maintenance phase, has the dose of targeted therapy changed? Escalated, n (%) Not escalated, n (%)	n=436 51 (11.7) 385 (88.3)	n=171 44 (25.7) 127 (74.3)	<0.01

Table 1. Gastroenterologist-reported patient demographics, clinical characteristics, healthcare resource utilization, and treatment usage.

Differences were seen across all HCRU measures with a greater number of consultations (7.2 vs 5.3), hospitalizations (0.4 vs 0.1), biopsies, endoscopies, stool and blood tests in the last 12 months for flaring patients compared to non-flaring patients (all p<0.01).

A higher proportion of flaring patients had received corticosteroids in the last 12 months compared to non-flaring patients (39.4% vs 13.9%, p<0.01), and among those currently receiving corticosteroids, 9.9% of flaring patients had their corticosteroid dose escalated vs 5.6% of non-flaring patients (p=0.28).

Of those patients receiving their current TT for ≥12 months, 25.7% of flaring patients had their TT dose escalated compared to 11.7% of non-flaring patients (p<0.01).

Conclusion: Almost half of patients with UC in our cohort had experienced a flare within the last 12 months. These patients had greater HCRU, increased corticosteroid use, and those on TT were more likely to receive escalated drug doses, highlighting the need for additional treatment options to target disease control, entailing the potential for a reduced burden of flares on UC patients and healthcare systems.

THE ADDITION OF BOWEL URGENCY IMPROVEMENT TO THE ACHIEVEMENT OF CLINICAL RESPONSE AND REMISSION WAS ASSOCIATED WITH BETTER QUALITY OF LIFE IN PATIENTS WITH ULCERATIVE COLITIS FROM MIRIKIZUMAB PHASE 3 TRIALS

D.T. Rubin[1], J. Wu[2], S.K. Baygani[2], N. Morris[2], T. Hunter Gibble[2], S. Schreiber[3]
[1]University of Chicago Medicine, Chicago, United States, [2]Eli Lilly and Company, Indianapolis, United States, [3]University Hospital Schleswig-Holstein, Department of Internal Medicine I, Kiel, Germany

Contact E-Mail Address: drubin@uchicago.edu

Introduction: Mirikizumab (miri), an anti-IL-23p19 antibody, demonstrated efficacy and safety in patients with moderately-to-severely active ulcerative colitis (UC) in the Phase 3 LUCENT-1 induction[1] (NCT03518086) and LUCENT-2 maintenance[2] (NCT03524092) trials. Bowel urgency (BU) remission and clinically meaningful improvement (CMI) are associated with clinical response and remission.[3]

This analysis evaluated if the addition of BU improvement to the achievement of clinical response or remission was associated with better quality of life (QoL).

Aims & Methods: In LUCENT-1, patients were randomized 3:1 to miri 300mg intravenous or placebo every four weeks. Miri-treated patients achieving clinical response to miri at week 12 (W12) were re-randomized 2:1 to subcutaneous miri 200mg or placebo Q4W for 40 weeks in LUCENT-2 (continuous treatment up to W52). Clinical remission is based on the modified Mayo Score (MMS) and was defined as: stool frequency subscore = 0 or 1 with a ≥1-point decrease from baseline; rectal bleeding (RB) subscore = 0; endoscopic subscore = 0 or 1.

Clinical response was defined as ≥2-point and ≥30% decrease in the MMS from baseline, and RB = 0 or 1, or ≥1-point decrease from baseline. Patients' QoL was measured using the Inflammatory Bowel Disease Questionnaire (IBDQ): IBDQ response (≥16-point improvement from baseline in IBDQ total score) and IBDQ remission (IBDQ total score ≥ 170; higher scores indicating better disease specific QoL).[4,5] BU was assessed using the Urgency Numeric Rating Scale (UNRS), an 11-point scale ranging from 0 ("no urgency") to 10 ("worst possible urgency"), with both BU CMI (≥3-point change) and BU remission (UNRS score of 0 or 1), measured in patients with a baseline UNRS of ≥3.[6]

The association between BU improvement (CMI or remission) and IBDQ (response or remission) was evaluated using the chi-square test of association among patients with baseline UNRS ≥3 who achieved clinical response. This analysis was repeated among patients who achieved clinical remission.

Results: Among patients achieving clinical response, a significantly higher proportion achieved IBDQ response and IBDQ remission when they also achieved BU CMI or BU remission compared with those who did not both at W12 and W52 (p<0.005) (Table 1). Among patients who achieved clinical remission, achievement of BU CMI was significantly associated with IBDQ response (p<0.005) but not IBDQ remission, and achievement of BU remission was significantly associated with IBDQ remission (p<0.005) but not IBDQ response at W12; achieving BU remission was significantly associated with better IBDQ response and IBDQ remission at week 52 (p<0.05).

	IBDQ Response (W12), p-value*		IBDQ Remission (W12), p-value*		IBDQ Response (W52), p-value*		IBDQ Remission (W52), p-value*	
Clinical Response + BU CMI	368 (91.54%)		291 (72.39%)		261 (95.26%)		233 (85.04%)	
Clinical Response - BU CMI	165 (71.74%)	<.0001	126 (54.78%)	<.0001	71 (83.53%)	0.0003	59 (69.41%)	0.0012

Clinical Remission -BU Remission	123 (88.49%)	0.3587	92 (66.19%)	<.0001	83 (92.22%)	0.0074	70 (77.78%)	0.0003

Note: Data is represented as n (%). *Used the chi-square test of association. P-values less than 0.05 are bolded.

Table 1. Association of Clinical Remission and Response with achievement of Bowel Urgency Remission and CMI on IBDQ Response/Remission in patients with UC at W12 and W52 of Continuous Treatment

Conclusion: Among patients with UC from miri phase 3 trials, the additional improvement of BU (CMI or remission) to the achievement of clinical response or remission was associated with greater QoL assessed by IBDQ response and remission.

ADHERENCE TO AZATHIOPRINE AND MERCAPTOPURINE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M. Thorpe[1], J. Phillips[1,2], A. Archer[1,2], K. Arnold[3], A. Coles-Driver[3], J. Tyrrell-Price[1]

[1]University Hospitals Bristol and Weston NHS Foundation Trust, Department of Gastroenterology, Bristol, United Kingdom, [2]University of Bristol, Population Health Sciences, Bristol, United Kingdom, [3]Bristol South Gloucestershire North Somerset Integrated Care Board, Bristol, United Kingdom

Contact E-Mail Address: jennifer.g.brazier@gmail.com

Introduction: Azathioprine and mercaptopurine are commonly used to treat Inflammatory Bowel Disease (IBD), with around 6 in 10 patients being prescribed them at some point. Adherence to treatment is important to maintain disease control, prevent flare ups, reduce the need for steroids and improve wellbeing. A good response to treatment may delay or negate the need to escalate treatment to Biologic medications or surgery. Despite this, treatment non-adherence is a common problem among patients with chronic diseases, averaging at around 50%. In IBD specifically, the data varies widely, but non-adherence to oral therapy has been reported to be as high as 72%.

Aims & Methods: The aim of this study was to determine the adherence to azathioprine and mercaptopurine in IBD patients across the Bristol, North Somerset, South Gloucestershire Integrated Care Board (BNSSG ICB). Primary care records were searched to identify all patients with IBD prescribed azathioprine or mercaptopurine. Demographic data as well as data on disease type, length of treatment and co-prescription with a Biologic treatment was collected. Medication adherence was determined by GP records of pharmacy refill data.

Results: A total of 1313 patients were identified as having IBD and a current prescription for azathioprine or mercaptopurine, from 78 GP surgeries (98% of surgeries within the BNSSG ICB). 154 patients were excluded as they had been on azathioprine for less than 1 year. 59% of the 1159 included patients had Crohn's disease. 360 patients (31%) were on combination therapy with a Biologic medication. 324 patients (28%) were found to be non-adherent with their medication based on prescription refill data suggesting that they do not have an adequate supply of medication.

Conclusion: Our data suggests that adherence to the immunosuppressant medications azathioprine and mercaptopurine in patients with IBD is comparable or slightly better than in other chronic diseases. However,

pharmacy refill data is an indirect measure of medication adherence so adherence may have been overestimated. There remains a substantial proportion of patients who are not adhering to treatment, which is likely to be associated with poorer outcomes.

FIRST CLINICAL EXPERIENCE OF ORAL FERRIC MALTOL TREATMENT IN PREGNANT WOMEN WITH INFLAMMATORY BOWEL DISEASE AND IRON DEFICIENCY ANAEMIA

S. Howaldt[1], A. Schüller[1]
[1]HaFCED e.K., Hamburg, Germany

Contact E-Mail Address: howaldt@hafced.de

Introduction: Iron deficiency (ID) and iron deficiency anaemia (IDA) are common complications of inflammatory bowel diseases (IBD). Ferric maltol is an oral iron therapy which increased haemoglobin within 12 weeks and sustainably improved the quality of life in patients with IBD and IDA. [1,2] While IDA is also frequently associated with pregnancy [3], there is no available data on the efficacy and safety of ferric maltol in pregnancy or in pregnant women with ID/IDA.

Aims & Methods: This study documented the first known clinical experience of ferric maltol in pregnant women with IBD and either ID or IDA. Retrospective clinical data from January 2017 to February 2023 in the MVZ Immunology database included pregnant patients with a confirmed diagnosis of IBD and treatment with ferric maltol during their pregnancy. The following patient data were collected: haematological parameters [haemoglobin (Hb), transferrin saturation level (TSAT), soluble transferrin receptor (stfR), ferritin], biomarkers for intestinal inflammation (calprotectin) and safety data. Descriptive results are reported here.

Results: A total of 27 female IBD patients with ID/IDA were included in this analysis, 11 with ulcerative colitis and 16 with Crohn's disease. The mean age was 35.9 years. A total of 29 pregnancies were treated with ferric maltol therapy (two patients had two pregnancies during this period). Prescriptions started after a mean of month 5 of pregnancy. In the course of most pregnancies, dosing was one capsule daily, as patients tended to have mild anemia. The number of prescribed boxes (56 capsules of ferric maltol: one capsule twice a day) per pregnancy was 1 in 82.8% [24/29], 2 in 13.8% [4/29], and 3 in 3.4% [1/29]. Nine cases with Hb < 11g/dl did take two capsules per day. After FM therapy, mean Hb levels increased from 11.3 to 12.36 g/dl (4-7 months), mean stfR levels increased from 1.2 to 1.5 mg/l, and mean ferritin levels increased from 27.2 to 30.0 ng/l, while mean TSAT decreased slightly from 17% to 15.4% (Table).

	Before FM	After FM
Hb (g/dl), Mean	11.3	12.3
Hb (g/dl), Median	11.3	12.6
TSAT (%), Mean	17	15.4
TSAT (%), Median	13	12.5
stfR (mg/l), Mean	1.2	1.5
stfR (mg/l), Median	1.0	1.2
Ferritin ng/ml, Mean	27.2	30.0
Ferritin ng/ml, Median	9.0	16.5

Table.

Two patients developed side effects: One had new onset of abdominal pain shortly after starting, one had abdominal pain and increased meteorism. Both patients discontinued ferric maltol treatment and complaints then stopped. At the time of the current analysis, all 27 completed pregnancies proceeded without complications and ended with healthy neonatal infants without abnormalities. Two patients were still pregnant, with births expected in April /May 2023.

Conclusion: These first clinical data on the use of ferric maltol in pregnancy suggest that ferric maltol appears to have a favourable safety profile with few side effects for pregnant patients with IBD and ID/IDA.

THE ADDITION OF BOWEL URGENCY IMPROVEMENT TO THE ACHIEVEMENT OF CLINICAL RESPONSE OR REMISSION WAS ASSOCIATED WITH BETTER WORK PRODUCTIVITY IN PATIENTS WITH ULCERATIVE COLITIS FROM MIRIKIZUMAB PHASE 3 TRIALS

D.T. Rubin[1], J. Wu[2], B. Park[2], S.K. Baygani[2], N. Morris[2], T. Hunter Gibble[2], S. Schreiber[3]
[1]University of Chicago Medicine, Chicago, United States, [2]Eli Lilly and Company, Indianapolis, United States, [3]University Hospital Schleswig-Holstein, Department of Internal Medicine I, Kiel, Germany

Contact E-Mail Address: drubin@uchicago.edu

Introduction: Mirikizumab (miri), an anti-IL-23p19 antibody, demonstrated efficacy and safety in patients with moderately-to-severely active ulcerative colitis (UC) in LUCENT Phase 3 trials.[1,2]

Bowel urgency (BU) clinically meaningful improvement (CMI) and BU remission were associated with clinical response and remission and also contributed to the improvement in Work Productivity and Activity Impairment Questionnaire UC (WPAI:UC) scores.[3,4]

This analysis evaluated if the addition of BU improvement to clinical response or remission was associated with better work productivity.

Aims & Methods: In LUCENT-1 (NCT03518086), patients were randomized 3:1 to induction miri 300mg intravenous or placebo every four weeks (Q4W). Patients who achieved clinical response to miri at week 12 (W12) were re-randomized 2:1 to maintenance subcutaneous injection of miri 200mg or placebo Q4W for 40 weeks in LUCENT-2 [52 weeks (W52) continuous treatment] (NCT03524092). Clinical response and remission were assessed along with change from baseline in WPAI:UC domain scores (activity impairment, absenteeism, presenteeism, and overall work impairment).[5] BU was assessed using the Urgency Numeric Rating Scale (UNRS), an 11-point scale ranging from 0 ("no urgency") to 10 ("worst possible urgency"), with both BU CMI (≥3-point change) and BU remission (UNRS score of 0 or 1), measured in patients with a baseline UNRS of ≥3.[6] The association between BU (CMI or remission) with the change of WPAI:UC was evaluated using analysis of variance among patients with baseline UNRS ≥3 who achieved clinical response. This analysis was repeated among patients who achieved clinical remission.

Results: The addition of BU CMI was positively associated with reduction of activity impairment, presenteeism, and overall work impairment in patients who achieved clinical response or remission at both W12 and W52 ($p<0.005$) (Table 1). Achieving clinical response and BU remission was significantly associated with greater reduction of activity impairment,

2: W12: 225, 122, 122, 122; W52: 84, 56, 56, 56.
3: W12: 188, 114, 114, 114; W52: 180, 106, 106, 106.
4: W12: 433, 228, 228, 228; W52: 176, 110, 110, 110.
5: W12: 167, 100, 100, 100; W52: 173, 106, 106, 106.
6: W12: 59, 31, 31, 31; W52: 41, 28, 28, 28.
7: W12: 89, 56, 56, 56; W52: 126, 79, 79, 79.
8: W12: 137, 75, 75, 75; W52: 88, 55, 55, 55.

BL = Baseline; BU = Bowel Urgency; CMI= Clinical Meaningful Improvement; SD: standard deviation; W12: week 12; W52: week 52. Clinical remission: stool frequency subscore = 0 or 1 with a ≥1-point decrease from baseline; rectal bleeding (RB) subscore = 0; and endoscopic subscore = 0 or 1. Clinical response: ≥2-point and ≥30% decrease in the modified Mayo Score from baseline, and RB = 0 or 1, or ≥1-point decrease from baseline.

*Evaluated using ANOVA (Analysis of variance) model including BU CMI (yes/no) or BU remission (yes/no). P-values less than 0.05 are bolded.

PP0774 TABLE 1. Association of Clinical Remission/Response with achievement of Bowel Urgency Remission/CMI on Change from Baseline of WPAI:UC Domain Scores in Patients with UC at W12 and W52 of Continuous Treatment.

presenteeism, and overall work impairment compared to patients with clinical remission only at both W12 and W52 (p<0.01). The combined improvement of achieving both clinical remission and BU remission was significantly associated with higher reduction in activity impairment at W12 (-36.1% vs -27.3%; p=0.0147) and overall work impairment at W52 (-39.9% vs -29.8%; p=0.0394). Patients who achieved both clinical response or clinical remission and BU CMI or BU remission did not show a significant difference in absenteeism compared to those who achieved clinical response or remission alone.

Conclusion: Among patients with UC from miri phase 3 trials, the addition of BU (CMI or remission) to the achievement of clinical response or remission was associated with reduction of WPAI:UC scores: activity impairment, presenteeism, and overall work impairment.

GOOD DRUG SUSTAINABILITY IN INFLAMMATORY BOWEL DISEASE PATIENTS IN CLINICAL REMISSION ON THIOPURINE MONOTHERAPY

H. Bouhlel[1], S. Mrabet[2], R. Harbi[1], I. Akkari[1], H. Sboui[1], A. Derbel[1], E. Ben Jazia[1]
[1]Farhat Hached Hospital, Gastroenterologie, Sousse, Tunisia, [2]Farhat Hached University Hospital, Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: hajerbouhlel92@gmail.com

Introduction: Immunomodulator monotherapy is an important component in the treatment of inflammatory bowel disease (IBD). However, there is conflicting litterature about thiopurines maintaining long-term remission in patients with active IBD.The aim of this study is to determine the durable clinical remission rate in adults with Crohn's disease (CD) or ulcerative colitis (UC) on thiopurine monotherapy.

Aims & Methods: We performed a retrospective analysis of adult patients diagnosed from 2004 to 2016,. We included IBD patients who initiated thiopurine monotherapy and were in remission for at least 3 years, with a minimum follow-up period of 7 years. The Mayo score (MS) and Crohn disease activity index (CDAI) were used to assess disease activity in UC and CD patients, respectively. The primary endpoint was sustained clinical remission on thiopurines at 7 years of follow-up . This included patients who had not relapsed or discontinued the drug due to side effects. The secondary endpoint was clinical relapse over the follow-up period, which was defined as CDAI > 150 in CD and MS > 3 in UC.

Results: We evaluated 94 patients (52 female, 41 male sex ratio H/F = 0,7 mean age 35.9 ± 15 years) .Among our patients 12 were smoking, 52 among our patients were diagnosed with Crohn's disease (CD), 38 ulcerative colitis (UC), 4 inclassed IBD. Among our patients 43 (45.7%) were treated with azathioprine monotherapy . At 7 years of follow up, 29 patients (67%) remained in clinical remission on thiopurine monotherapy. Three patients presented complications such as deep collection in two cases and ileal stenosis in one case. Eleven patients (25%) stopped treatment for haematological toxicity in 8 cases, liver toxicity in two cases and digestive intolerance in one case.

Conclusion: This analysis demonstrates that there is good sustainability of clinical remission in IBD patients on thiopurine monotherapy. However, this treatment was poorly tolerated by the quarter of patients.

Disclosure: Nothing to disclose.

PP0776

DEVELOPMENT OF A CARE BUNDLE FOR MANAGING ACUTE SEVERE COLITIS ON THE ACUTE MEDICAL TAKE - A QUALITY IMPROVEMENT PROJECT

D.E. Rangedara[1], P. Prakash[2]
[1]Prince Charles Hospital, Gastroenterology, Merthyr Tydfil, United Kingdom, [2]Grange University Hospital, Gastroenterology, Cwmbran, United Kingdom

Contact E-Mail Address: edwardrangedara@hotmail.co.uk

Introduction: Acute Severe Colitis (ASC) is a relatively common presentation to hospital which is associated with a high morbidity and mortality and requires aggressive and competent treatment. Initial assessment and management is typically performed by a non-gastroenterologist who may have had limited experience managing this subset of patients. The aim of this project was to create a care bundle for managing ASC for use on the acute medical take across Cwm Taf Morgannwg University Health Board, Wales to provide standardised care for these patients which would improve confidence and knowledge of the junior doctors treating them and in turn improve patient care.

Aims & Methods: An electronic questionnaire would be sent to a variety of junior doctors at different stages in their training who all work on the acute medical take to assess their confidence and knowledge in managing patients with ASC on the acute take and assess whether the project would be a worthwhile idea. The care bundle would then be developed and implemented and a second questionnaire would then be sent to see if it would achieve improved confidence and knowledge, ultimately providing standardised care and inevitably better patient outcomes.

Results: We received 25 responses to our initial questionnaire from junior doctors who work on the acute medical take. 20% of our respondees had never managed a patient with ASC before and 60% did not feel confident managing patients with ASC. 24% did not know exactly what drugs to administer/avoid and 28% would not feel comfortable identifying a toxic megacolon on an Abdominal X-Ray. 100% of responses thought the project would have a positive impact on the standard of care and outcomes for these patients as well as improve confidence and knowledge of the assessing doctors on the medical take.

After implementation of the care bundle, a second questionnaire was sent which received 19 responses from junior doctors who work on the acute medical take. 100% of respondees felt the care bundle gave them increased confidence and knowledge in managing patients with ASC and that it would improve patient outcomes and overall care.

Conclusion: Our project has shown an ASC care bundle can improve confidence, knowledge and training for junior doctors who encounter such patients on the acute medical take. By providing a framework for implementing best medical practice and standardised care, patient outcomes, satisfaction and overall care will inevitably be better.

Introduction: Not all patients with ulcerative colitis (UC) respond initially to treatment with biologic agents, and predicting their efficacy prior to treatment is difficult. Vedolizumab, a humanized monoclonal antibody against alpha 4 beta 7 (α4β7) integrin, suppresses immune cell migration by blocking the interaction between α4β7 integrin and mucosal addressin cell adhesion molecule 1, and is used to treat patients with UC with moderate-to-severe activity. Reports about histological features that predict vedolizumab efficacy are scarce.

Aims & Methods: We evaluated the infiltration of inflammatory cells in the colonic mucosa prior to the induction of vedolizumab and examined the association between histological features and vedolizumab efficacy.

This was a multicenter, retrospective study. Patients with UC who were treated with vedolizumab between November 2018 and April 2021 were enrolled in this study. All eligible patients had moderate-to-severe disease activity at the time of the initial treatment with vedolizumab. Biopsy specimens taken from the colonic mucosa prior to vedolizumab induction were used, and the areas positively stained for CD4, CD68, and CD45 per

unit area of the lamina propria were calculated. Clinical and histological features were compared between those with and without remission at week 22, and the factors associated with clinical outcomes were identified.

Results: A total of 42 patients were included in this study. 17 (40.5%) patients achieved clinical remission at week 22. Significantly more CD4+ cells were found in the colonic mucosal tissues of patients with remission than in those without remission (odds ratio [OR]=1.44, P=0.014). In contrast, the CD68-positive area and the CD45-positive were not significantly different between the two groups. The concomitant use of corticosteroids and high Mayo scores had a negative association with the vedolizumab response (OR=0.11, P=0.008 and OR=0.50, P=0.009, respectively).

Conclusion: A high CD4+ infiltration in the colonic mucosa was associated with remission after vedolizumab treatment. Histological evaluation for CD4+ cell infiltration may be helpful in selecting patients who can benefit from vedolizumab.

Disclosure: Nothing to disclose.

OUTCOMES OF VEDOLIZUMAB DOSE INTENSIFICATION: RESULTS FROM AN ASIAN INFLAMMATORY BOWEL DISEASE (IBD) COHORT STUDY

S.W. Tay[1], M. Tan[1], Y.Y. Tan[1], W.P.W. Chan[1]
[1]*Singapore General Hospital, Department of Gastroenterology and Hepatology, Singapore, Singapore*

Contact E-Mail Address: shuwen.tay@mohh.com.sg

Introduction: Vedolizumab (VDZ) is a monoclonal antibody approved for use in both Crohn's Disease (CD) and Ulcerative Colitis (UC). Some patients treated with VDZ have suboptimal disease response to induction and 8-weekly maintenance dosing. Dose intensification (DI) by shortening the dosing interval is a strategy used to improve response to treatment. This study aims to identify factors associated with DI in an Asian cohort of IBD patients.

Aims & Methods: This was a retrospective cohort study performed in a single tertiary center in Singapore. Patients who received VDZ between Sept 2016 to Sept 2022 were identified from a prospectively maintained registry. Patient demographics, disease phenotype, treatment history and biochemical parameters were retrieved. Factors predictive of requiring DI were analysed. Statistical analysis was performed using SPSS v23.0.

Results: A total of 69 IBD patients who received VDZ were identified. Mean age was 57.1 years (SD=20.1). Males made up 63.1% of the cohort, with 3 patients (4.6%) being active smokers. Thirty-nine patients (60.0%) had prior exposure to immunomodulators, 32 patients (49.2%) had prior anti-tumour necrosis factor-alpha inhibitor exposure, 5 patients (7.7%) had prior ustekinumab exposure. None of the patients had prior exposure to small molecules.

A total of 4 patients (6.2%) had prior exposure to 2 biologic agents, 30 patients (45.2%) had prior exposure to 1 biologic agent, and 31 patients (47.7%) were biologic-naïve. Disease duration prior to VDZ use was 8.4 years (SD=8.0). VDZ treatment duration was 24.4 months (SD=19.2).

A total of 25 patients (10 CD, 15 UC) underwent DI. Time from induction to DI was 384.4 days (SD=301.2). Gender, active smoking status, age of diagnosis, previous treatment or biologic exposure, higher pre-induction C-reactive protein and stool calprotectin did not predict for need for DI. (Figure 1)

Four patients achieved clinical remission post induction but subsequently required DI. Fourteen patients underwent DI to Q6W dosing and 11 patients received Q4W dosing. Patient demographics are shown in Figure 2a. Outcomes of DI at 52-weeks post DI is shown in Figure 2b. Eight patients (32.0%) achieved treatment endpoints of corticosteroid-free remission (n=2), biochemical remission (n=2) and endoscopic remission (n=4). Mean duration on VDZ with DI in CD was 9.9months (SD=9.1), and 35.9months (SD=19.9) in UC.

Ten patients were switched to another biologic. Five (2 UC, 3 CD) patients required surgery despite DI. One patient had recurrent *Clostridium difficile* infections while on VDZ. [illegible]ere no other complications or hospitalizations associated with DI.

Conclusion: This is the first VDZ DI study in Asia. One third of patients who receive VDZ required DI, of which a third achieved remission by week 52. Some Asian patients with IBD may require DI to achieve remission.

Disclosure: Nothing to disclose.

EFFECTIVENESS OF PARTIAL ENTERAL NUTRITION TO TREAT ADULTS WITH CROHN'S DISEASE WHO LOST RESPONSE TO BIOLOGICAL THERAPY

O.M. Nardone[1], G. Calabrese[2], A. La Mantia[2], G. Fierro[2], A. Testa[2], A. Rispo[2], L. Alfonsi[2], F. Pasanisi[2], F. Castiglione[2]
[1]*University of Naples Federico II, Public Health, Naples, Italy,*
[2]*University of Naples Federico II, Clinical Medicine and Surgery, Naples, Italy*

Contact E-Mail Address: Olga.nardone@libero.it

Introduction: Partial enteral nutrition (PEN) is a consolidated treatment in children with Crohn's disease (CD). However, the benefit of PEN is not well-established for adults with CD. Hence, we aimed to assess the effectiveness of PEN in combination with biological therapy on transmural response/remission and clinical outcomes in adults with CD who lost response to biologics.

Aims & Methods: We performed a single-centre retrospective observational study by including patients who received PEN due to loss of response to biologics. The primary endpoint was the transmural response/remission rate at six months. We defined transmural remission as bowel wall thickness ≤3 mm, while transmural response as a decrease in BWT≥25%. Secondary endpoints included clinical remission, defined as Harvey Bradshaw Index<5, and selected clinical outcomes such as surgery, hospitalisations, and therapy change at six months. Patients were considered adherent when they completed PEN for 6-8 weeks as required for induction of remission, whereas they were not adherent when they stopped or did not tolerate it.

Results: Forty-two patients,25 males (59,5%) with a mean age of 36,1 ±15,6yo and a mean disease duration of 138,0 ±113,1 months, were enrolled.14 patients completed PEN at eight weeks, with a rate of adherence of 33,3%. While 16(38.1%) patients stopped the treatment for intolerance and maintained only biological therapy, 12(28.6%) underwent surgery before six months follow-up. At six months, patients treated with PEN+biologic had a transmural response of 64,9% compared to 25% treated only with biologics (p=0.03). In both groups, no patients achieved transmural remission.

Nevertheless, clinical remission was obtained in 9 (64,3%) patients treated with PEN+biologic compared to 4 (25%) with biologic (p=0.03). Three patients (18.7%) underwent surgery, all intolerant to PEN. Patients who interrupted PEN and maintained biologics had a higher rate of 56,2% of dose escalation/interval and 68,7% changed therapy at six months compared to 7,1% and 14,2% respectively treated with PEN+biologic(p<0.05) [Table 1].

	PEN + Biologic (n=14)	Biologic therapy (n=16)	p-value
HBI	4,8 (±2,1)	7,1 (±2,5)	0,01
FC (µg/g)	335,5 (±651,9)	405,4 (±611,8)	0,76
CRP (mg/L)	7,4 (±6,4)	10,1 (±10,1)	0,40
BMI (kg/m^2)	20,5 (±1,8)	19,7 (±2,2)	0,27
Clinical remission	9 (64,3%)	4 (25,0%)	< 0,05
Transmural response	9 (64,3%)	4 (25,0%)	< 0,05
Surgery	0	3 (18,7%)	0,14
Dose/interval escalation	1 (7,1%)	9 (56,2%)	< 0,05
Swap/switch of therapy	2 (14,2%)	11 (68,7%)	< 0,05

Table 1.

In multivariate analysis, multiple treatment failures were associated with adherence to PEN(OR=1,583; CI=1,06-2,36;p<0.05).

Conclusion: For patients who lost response to biological therapy, the addition of PEN was associated with transmural response and clinical remission. Multiple failures to biologics were associated with adherence to PEN. Therefore, it should be considered in difficult-to-treat patients.

Disclosure: None to declare.

PP0780

PREDICTORS OF RELAPSE IN CASES OF ULCERATIVE COLITIS THAT ACHIEVED MUCOSAL HEALING WITH BIOLOGICS

T. Toyokawa[1], J. Horii[1], I. Fujita[1]
[1]*National Hospital Organization Fukuyama Medical Center, Gastroenterology, Fukuyama, Japan*

Contact E-Mail Address: toyotatu@kmail.plala.or.jp

Introduction: Biologics are useful for the treatment of moderate to severe ulcerative colitis (UC) and can achieve mucosal healing (MH). Many papers have reported that relapse can be prevented by targeting MH. However, recurrences of UC is possible even in cases that MH was once obtained.

Aims & Methods: In this study, we investigated cases of relapse after MH was achieved with biologics, aiming to determine the predictors of recurrences.

Forty-five patients who were successfully treated with biologics (including Tofacitinib) at our hospital and confirmed MH were stratified into those who relapsed during the course of treatment and those who did not. Patient background (age, gender, extent of inflammation, severity, disease type, pre-treatment history, time to biologics introduction, Mayo Endoscopic Score (MES), smoking history), and clinical data (leukocyte count, hemoglobin level, albumin level, CRP level) at the time of biologics introduction were compared. For statistical analysis, χ-square and Mann-Whitney *U* tests were used for univariate analysis and logistic regression analysis was used for multivariate analysis, with $p < 0.05$ as a significant difference.

Results: Of the 45 eligible patients, 21 (47 %) relapsed during follow-up after the introduction of biologics (mean 28.6 months, range 8-95 months). Univariate analysis of the patients stratified into 21 patients with relapse and 24 patients without relapse showed that MES at the introduction of biologics was 3 (71 % vs. 29 %, $p = 0.0047$) and that those with history of smoking were significantly more frequent in the relapse group (8.3 % vs. 43 %, $p = 0.0072$). In addition, the relapse group had slightly higher CRP levels (mean 4.4 mg/dl vs. 2.3 mg/dl, $p = 0.184$), younger age (mean 39 vs 46 years, $p = 0.10$), severe disease activity (mild: moderate: severe 3: 19: 2 vs. 3: 11: 7, $p = 0.094$), and history of tacrolimus use (9.5 % vs 0 %, $p = 0.12$), although the differences were not significant. A multivariate analysis on these factors showed that MES 3 (OR 9.21, 95 % CI 1.18-72.0, $p = 0.034$) and smoking history (OR 25.2, 95 % CI 1.20-529.0, $p = 0.038$) were independent predictors of relapse.

Conclusion: In the present study conducted at our hospital, nearly half of the patients had relapsed even when MH was achieved with the use of biologics for UC. Furthermore, the severity of the endoscopic findings at the introduction of biologics was an important predictor of recurrence. In other words, patients with severe endoscopic findings at the time of introduction of biologics should be treated keeping in mind the high risk of relapse, even if MH is achieved. This fact is considered very important for the introduction of biologics with UC patients in future and the construction of treatment a strategy after the introduction.

Disclosure: Nothing to disclose.

Contact E-Mail Address: drmaris@otenet.gr

Introduction: The management of patients with inflammatory bowel disease (IBD) during the coronavirus disease 2019 (COVID-19) pandemic has been a challenge, as immunosuppressant therapies comprise the cornerstone of IBD treatment and social distancing is recommended to diminish the virus spread. The aim of this study is to investigate the impact of COVID-19 on the therapeutic decisions and management of patients with IBD.

Aims & Methods: Records from patients diagnosed with ulcerative colitis (UC), Crohn's disease (CD) and unclassified-IBD (IBD-u), under follow-up by a single IBD center, were retrospectively screened from March 2020 to May 2021. Primary and secondary outcomes were predetermined to be changes in therapeutic decisions and monitoring respectively, during the pandemic.

Results: A total of 201 patients were included in the study [125 (62%) UC, 69 (34%) CD and 7 (3%) IBD-U]. Patients with UC were treated with 5-aminosalicylic acid [(5-ASA), 89], infliximab [(IFX), 21], combination therapy with 5-ASA and azathioprine (AZA), (11) and adalimumab [(ADA), 4)]. To avoid hospital environment, two patients under IFX (10%) switched to subcutaneous home-infusions with ADA and in eight patients treated with IFX (38%), infusion intervals increased to ten weeks (drug holiday). No complications were observed. Patients with CD were treated with IFX (39), ADA (12), vedolizumab (8), AZA (4), combination therapy with AZA or methotrexate (4) and ustekinumab (2). To avoid hospital environment, two patients under IFX (5%) switched to subcutaneous home-infusions with ADA and in 12 patients treated with IFX (30%), infusion intervals increased to ten weeks (drug holiday). One patient in clinical remission discontinued IFX and received AZA. Although a significant number of outpatient visits, endoscopic procedures and non-urgent surgeries were postponed, two patients with CD (IFX) required emergency surgery which was performed without delay. Patients' monitoring was carried out through telemedicine (remote monitoring, intangible prescription and drug home delivery).

Conclusion: The vast majority of patients treated with biologics did not discontinue maintenance therapy and a significant number extended intravenous infusion intervals. The setting of this critical and unprecedented situation has led to significant changes in decision making in IBD management, based on patients' preferences aiming an efficient and safer care.

Introduction: Increased blood pressure (BP) and hypertension are known adverse effects of sphingosine 1-phosphate ($S1P)_{1,4,5}$ receptor modulators. Etrasimod is an investigational, oral, once-daily, selective $S1P_{1,4,5}$ receptor modulator in development for the treatment of moderately to severely active ulcerative colitis (UC).

Aims & Methods: We assessed the impact of etrasimod on BP and hypertension development among patients (pts) in the etrasimod UC clinical programme. Pivotal (placebo [PBO]-controlled phase [p]3 [NCT03945188; NCT03996369] studies) and All UC (PBO-controlled plus open-label extension [OLE]; p2 [NCT02447302], p3 and OLE [NCT03950232 and NCT04176588, data snapshot Jan 31, 2022; NCT02536404] studies) cohort data were analysed. BP was assessed at each visit and at 2 and 4 weeks (wks) post-treatment cessation. Proportions and exposure-adjusted incidence rates (EAIRs; pts with AEs divided by the total pt-years [PY] at risk for AEs, per 1 PY) of treatment-emergent Hypertension (Medical Dictionary for Regulatory Activities preferred term [PT]) AEs among pts receiving etrasimod (2 mg once daily; both cohorts) or PBO (Pivotal UC cohort) were assessed.

Characteristics of pts with Hypertension AEs that met sponsor-designated events of interest (SDEI) criteria (related to hypertension associated with sustained increases in BP [systolic/diastolic: ≥ 160/100 mmHg], or requiring new or increased antihypertensive therapy) were analysed descriptively.

Results: In the Pivotal and All UC cohorts, 11/527 (2.1%; EAIR, 0.04; PBO: 2/260 [0.8%; EAIR, 0.02]) and 20/942 (2.1%; EAIR, 0.03) etrasimod-treated pts had PT Hypertension, respectively; none led to study treatment discontinuation. In the All UC cohort, 19/942 (2.0%; EAIR, 0.02) etrasimod-treated pts had hypertension-related SDEIs.

Of these events, 6 were in pts with hypertension history; none were serious or led to treatment discontinuation; 6 resolved (5 with intervention), 8 were resolving/unknown outcome and 5 were unresolved. Etrasimod-treated pts had minimal changes in BP over time (All UC cohort, mean change in systolic/diastolic BP at Wk52: 2.9/1.2 mmHg, respectively; Table). In the All UC cohort, at Wk104, no etrasimod-treated pts had a systolic/diastolic BP > 160/100 mmHg, respectively.

Time point	Pivotal UC cohort				Time point	All UC cohort	
	Systolic BP, mmHg		Diastolic BP, mmHg			Systolic BP, mmHg	Diastolic BP, mmHg
	Etrasimod 2 mg QD (N=527)	PBO (N=260)	Etrasimod 2 mg QD (N=527)	PBO (N=260)		Etrasimod 2 mg QD (N=942)	
Baseline[a], mean (SD) [etrasimod, n=527; PBO, n=260]	120.7 (12.50)	121.3 (13.08)	75.8 (8.53)	77.2 (9.56)	Baseline[a], mean (SD) [n=942]	119.6 (12.89)	75.6 (8.57)
Change at Wk12, mean (SD) [etrasimod, n=474; PBO, n=231]	2.0 (11.17)	-1.4 (10.68)	1.6 (8.08)	-0.4 (8.07)	Change at Wk12, mean (SD) [n=821]	2.1 (10.78)	1.7 (8.01)
Change at Wk52, mean (SD) [etrasimod, n=162; PBO, n=44]	2.2 (11.08)	1.3 (9.16)	0.4 (8.47)	-0.8 (8.52)	Change at Wk52, mean (SD) [n=246]	2.9 (10.39)	1.2 (8.36)
Change at Wk78/ Wk104[b], mean (SD) [N/A]	-	-	-	-	Change at Wk78/ Wk104, mean (SD) [Wk78, n=147; Wk104, n=29]	1.9 (10.65)/ -0.7 (13.54)	1.1 (8.05)/ 0.8 (7.40)
Change at 2-/4-wk follow-up visit[c], mean (SD) [2-wk: etrasimod, n=39; PBO, n=6; 4-wk: etrasimod, n=36; PBO, n=10]	0.2 (10.66)/ -0.4 (11.47)	6.7 (10.61)/ 8.1 (8.18)	1.6 (7.99)/ 0.2 (10.40)	3.2 (3.71)/ 3.0 (7.12)	Change at 2-/4-wk follow-up visit[c], mean (SD) [2-wk; n=203; 4-wk, n=105]	2.6 (13.73)/ 1.9 (12.43)	1.3 (8.74)/ 1.4 (9.18)

Pivotal UC cohort comprised patients from the placebo-controlled p3 ELEVATE UC 52 (NCT03945188) and p3 ELEVATE UC 12 (NCT03996369) studies. All UC cohort comprised patients from the p2 OASIS (NCT02447302), p2 OASIS OLE (NCT02536404 [completed Nov 01, 2018]), p3 ELEVATE UC 52 (NCT03945188), p3 ELEVATE UC 12 (NCT03996369) and p3 ELEVATE UC OLE (NCT03950232 [data snapshot Jan 31, 2022]) studies, and the open-label phase of the p3 study NCT04176588 (data snapshot Jan 31, 2022)

[a]Baseline is defined, by study treatment group received, as the last non-missing measurement taken on or prior to the study treatment group start date

[b]Wk78 and 104 data are not provided for the Pivotal UC cohort as only data up to Wk52 of ELEVATE UC 52 are included for pts in this cohort

[c]Pts who did not participate in the OLE study had 2-wk and 4-wk follow-up visits after their last treatment administration

BP, blood pressure; N, total number of patients; n, number of patients with evaluable data at a visit; N/A, not applicable; OLE, open-label extension;
p, phase; pts, patients; PBO, placebo; QD, once daily; SD, standard deviation; UC, ulcerative colitis; wk, week

Table. Change from baseline in BP over time among pts in the etrasimod UC clinical programme (Pivotal and All UC cohorts).

Conclusion: Hypertension events were infrequent among etrasimod-treated pts. No clinically meaningful changes in BP with etrasimod 2 mg over time or following treatment discontinuation were observed up to 2 years. Data interpretations are limited by small pt numbers.

A SINGLE CENTRE AUDIT REVIEWING THE PRACTICE OF ACUTE SEVERE ULCERATIVE COLITIS (ASUC) MANAGEMENT USING CALCINEURIN INHIBITOR AND BIOLOGICAL THERAPY. ARE THEY SHOWING GOOD OUTCOME AND SUCCESS IN AVOIDING COLECTOMY AT 30 DAYS AND 1 YEAR MARK?

R. Hill[1], M.H. Kamarul Bahrin[1], M. Qizalbash[1], M.F.A. Baig[1]
[1]Nottingham University Hospital, Gastroenterology, Nottingham, United Kingdom

Contact E-Mail Address: dr_aq@hotmail.com

Introduction: Up to 30% of patients inflicted with acute severe ulcerative colitis (ASUC) requires an urgent colectomy during their inpatient stay[1], despite use of corticosteroid therapy. In younger population cohort, of which Ulcerative Colitis (UC) is fairly prevalent, the idea of having a colectomy with stoma formation does not constitute an ideal physical image, hence many prefer to be managed conservatively through medical therapy. The two options licensed for this purpose are infliximab and ciclosporin[2].

Aims & Methods: Our audit aims to look at the use of infliximab and ciclosporin to manage an ASUC and whether they result in long term remission and significant colon retention rate at 30 days and 1 year mark.

We carried out a retrospective audit on 74 patients who received said therapies between 2021 to 2022 for ASUC. Subsequently we calculated the number of patients who required re-admission with flare-ups, the colon retention rate at 30 days and 1 year post therapy initiation, as well as the 30 days and 1 year mortality rate as a direct or indirect result of said therapies (we defined this as evidence of clinically immunosuppressive state leading to severe sepsis).

Results: There are only 6 patients in total (8.69%) who were given ciclosporin to treat an ASUC episode as compared to infliximab, which forms the majority of the population (68 patients). All of them were commenced in an inpatient setting . On top of that, they failed to improve despite this and subsequently required a form of rescue colectomy. Of these, 5 required ciclosporin as the second line treatment following failed primary therapy with infliximab, going by the recommendation by the BSG Guideline.

Among those who were prescribed infliximab, 32 (47.1%) requires initiation as inpatient (IP) as compared to 36 (52.9%) who commenced in an outpatient (OP) setting. Among those who requires IP initiation, we saw there is 84.4% complete colon retention rate at 1 year mark and 6.25% colon retention rate lasting less than 30 days and more than 30 days but less than 1 year respectively. 1 patient died within 1 year of receiving the scheduled infliximab therapy as a result of overwhelming chest sepsis, which may or may not be related to this. Most patients successfully avoided further flare up at 1 year mark post infliximab initiation (78.1%).

Further focusing onto infliximab therapy initiation as IP, 14 patients were co-prescribed purine analogues as compared to 18 who were not. All these 14 patients successfully avoided colectomy at 1 year mark as compared to 14 out 18 patients from the other group.

Accelerated infliximab therapy was trialled in 2 IP cases and they both demonstrated complete colon retention at 1 year mark, though we acknowledge that our data is too small to make any conclusive statement for or against this regime.

Rescue therapy	Total number of patients included	Further episode of flare up			Colectomy			Death		
		None	within 30 days	within 1 year	None	within 30 days	within 1 year	None	within 30 days	within 1 year
Ciclosporin	6	6	0	0	0	6	0	5	0	1
Infliximab IP	32	25	4	5	27	2	2	32	0	0
infliximab OP	36	36	0	0	36	0	0	35	0	1

Conclusion: In summary, our data on colon retention rate, the survival rate and the need for re-admission demonstrated a strong case to advocate for biological therapy as a mean to avoid colectomy and re-admission in those with ASUC. The rate of colectomy in the calcineurin inhibitor group is high but we must note that their ASUC severity is higher as they failed to respond to the 1st line treatment to begin with. No difference in outcome was seen in the accelerated regime group, but co-prescription of purine analogues appears to be protective.

Introduction: Etrasimod is an investigational, oral, once-daily, selective sphingosine 1-phosphate $(S1P)_{1,4,5}$ receptor modulator in development for the treatment of moderately to severely active ulcerative colitis (UC). Prior analyses demonstrated etrasimod efficacy in UC[1] and greater improvement from baseline in Inflammatory Bowel Disease Questionnaire (IBDQ) total score and domains vs placebo (PBO).[2]

Aims & Methods: This post hoc subgroup analysis examined the effect of prior and concomitant therapies on IBDQ scores in the phase 3 ELEVATE UC clinical programme. In ELEVATE UC 52 (NCT03945188) and ELEVATE UC 12 (NCT03996369), eligible patients (pts) with modified Mayo scores of 4–9 completed the 32-item IBDQ at Weeks (Wks)12 (both trials) and 52 (ELEVATE UC 52). In this analysis, pts were stratified by prior biologic/Janus kinase inhibitor (bio/JAKi) and baseline corticosteroid (CS) use. Least squares (LS) mean change from baseline in IBDQ total and domain scores were compared for etrasimod vs PBO (data as observed). Proportions of pts with IBDQ remission (total score ≥ 170) were analysed (nonresponder imputation).

Results: Among all randomised patients, there were 304/433 and 236/354 pts without prior bio/JAKi use and 298/433 and 255/354 pts without baseline CS use in ELEVATE UC 52 and ELEVATE UC 12, respectively. Overall, mean baseline IBDQ total scores were similar in pts with and without prior bio/JAKi or baseline CS use. At Wks12 (both trials) and 52 (ELEVATE UC 52), LS mean change from baseline in IBDQ total and domain scores was higher ($p<0.05$) for etrasimod vs PBO in pts without prior bio/JAKi and pts without baseline CS use (Table). IBDQ remission was generally achieved by significantly higher proportions of pts receiving etrasimod vs PBO regardless of prior bio/JAKi or baseline CS use at Wk52 (prior bio/JAKi use: No, 46.8% vs 21.2% [$p<0.001$] and Yes, 25.0% vs 11.1% [$p=0.043$]; baseline CS use: No, 41.3% vs 15.7% [$p<0.001$] and Yes, 38.7% vs 23.8% [$p=0.087$]).

Conclusion: Pts receiving etrasimod had improvements in IBDQ total score and in all 4 domains at Wk12, maintained at Wk52. Significant differences were shown in these outcomes with etrasimod vs PBO in pts without prior bio/JAKi and without baseline CS use. IBDQ remission was generally achieved by higher proportions of pts without vs with prior bio/JAKi or without vs with baseline CS use.

The IBDQ evaluates disease-related quality of life using 32 items examined with 4 domains: bowel symptoms (score range, 10–70), systemic symptoms (score range, 5–35), emotional health (score range, 12–84) and social function (score range, 5–35). For the total score (range, 32–224) and each domain, a higher score indicates a better quality of life
Responses after intercurrent events and missing responses were considered as nonresponses

Introduction: Targeting mitochondrial function and oxidative stress is successful in animal models of IBD. NLRX1 is a mitochondrial associated protein upregulating mitochondrial metabolism: It reduces oxidative stress and decreases pro-inflammatory cell differentiation and cytokine release. NX-13 is a first-in-class, orally active, once-daily, gut-selective NLRX1 agonist with low systemic exposure in development for Ulcerative Colitis (UC). In three mouse models of IBD, NX-13 effectively activated NLRX1 to reduce inflammatory responses and disease severity.

In two phase 1 studies (56 healthy subjects; 38 UC patients) NX-13 was well tolerated. Low systemic drug exposure relative to stool levels suggested a gut-selective drug distribution. Phase 1B topline results were reported previously[1].

We now present data demonstrating target engagement and downstream effects consistent with the preclinical mechanism of action (MOA).

Aims & Methods: In this double-blind phase 1B trial, 36 patients with active UC (Total Mayo Score 4-10; Mayo endoscopic subscore 2-3) were randomly assigned to NX-13 250mg Immediate Release (IR), 500mg IR, 500mg Delayed Release (DR) or Placebo to be taken QD for 4 weeks. We report pharmacodynamic results based on expression of NLRX1 and downstream immunometabolic markers in colonic tissue samples collected at screening and week 4 of treatment. NLRX1 protein levels were measured by immunohistochemistry scored by a blinded pathologist, and immunometabolic markers were measured by qRT-PCR.

Results: All NX-13 treated groups showed target engagement through mean positive increases in NLRX1 expression versus placebo at week 4, with more pronounced upregulation observed in responding patients (Table 1A). Gene expression profiles after 4 weeks of treatment showed upregulation of the mitochondrial metabolism gene *MT-ND3,* with downstream reductions in *HIF1α* and *NLRP3* in the NX-13 IR groups but not in the placebo group (Table 1B).

NX-13 250mg IR dosed patients also displayed downstream decreases in *IL-17α* and *IL-1β* gene expression, and the 500mg IR group showed reduction in IL-1β. Changes in NLRX1 expression and immunometabolic markers correlated with clinical response to NX-13 and were numerically greater in responding IR-dosed patients compared to non-responding patients (Table 1).

A. Immunohisto-chemistry	Definition	Subgroup	Placebo (n=2)		NX-13 250mg IR (n=8)		NX-13 500mg IR (n=8)		NX-13 500mg DR (n=8)	
NLRX1 Composite Score Change from Baseline	Mean (Standard Error) of 4-point score accounting for NLRX1 intensity and number of positive cells in the epithelium and lamina propria	Responder	n/a	n/a	0.54	(0.36)	2.58	(0.46)	1.42	(0.68)
		Non-responder	-0.38	(0.38)	0.25	(0.25)	1.35	(0.84)	0.7	(0.76)
B. Gene Expression	Definition		Placebo (n=1)		NX-13 250mg IR (n=7)		NX-13 500mg IR (n=6)		NX-13 500mg DR (n=5)	
MT-ND3	Median (Interquartile Range) fold change over baseline expression	Responder	(n/a)	(n/a)	1.37	(1.2-1.54)	1.52	(1.14-1.90)	n/a	n/a
		Non-responder	0.71	(n/a)	0.86	(0.45-1.28)	1.04	(0.96-1.14)	0.76	(0.34-1.68)
HIF1α		Responder	(n/a)	(n/a)	0.74	(0.53-0.81)	0.83	(0.80-0.86)	n/a	n/a
		Non-responder	1.06	(n/a)	2.18	(1.07-3.29)	0.95	(0.55-1.5)	1.11	(0.69-2.50)
NLRP3		Responder	(n/a)	(n/a)	0.65	(0.58-0.88)	0.59	(0.56-0.62)	n/a	n/a
		Non-responder	1.26	(n/a)	1.89	(1.28-2.50)	0.92	(0.30-2.04)	1.35	(0.64-2.34)

PP0785 Table.

Conclusion: Treatment with NX-13 induced upregulation of its target, NLRX1, as well as downstream immunometabolic signaling consistent with preclinical MOA studies. Most importantly, target engagement parallels clinical benefit. This novel mechanism of action warrants further study and is currently being evaluated in a phase 2 proof of concept study (NCT05785715).

Introduction: Our study aimed to retrospectively analyze the clinical efficacy of the double intravenous induction treatment of Ustekinumab (UST) in patients with complex perianal fistulizing Crohn's disease (PFCD).

Aims & Methods: From January 2022 to March 2023, a total of 60 complex PFCD patients were included by retrieving the clinical database of the Second Affiliated Hospital of Wenzhou Medical University. They received sufficient intravenous infusion of UST (6mg/kg) at weeks 0, 8 and subcutaneous injection of 90mg UST very 8 weeks for maintenance treatment. Perianal Disease Activity Index (PDAI) and Van Assche Index (VAI) were used to evaluate anal fistula outcome events, while Harvey Bradshaw Index (HBI) and Simplified Endoscopic Score of Crohn's disease (SES-CD) were employed to assess intestinal outcome events. We also evaluated the normalization rates of C-reactive protein (CRP≤5.0mg/L) and erythrocyte sedimentation rate (male ESR≤15mm/h, female ESR≤20mm/h), as well as the improvement of several nutritional indicators, including serum albumin (Alb), and hemoglobin (Hb).

Results: Compared with weeks 0, 8, and 16, respectively, the average PDAI score was significantly decreased at week 24 (all P<0.001). The clinical response rates of anal fistula at weeks 8, 16, and 24 were 41.67%, 55.00%, and 63.33%, respectively; the clinical remission rates of anal fistula were 21.67%, 31.67%, and 43.33%, respectively. Compared to week 0, the median VAI score was significantly reduced at week 24 (P<0.001). At week 24, the partial response rate and fistula healing rate of anal fistula imaging were 45.00% and 38.33%, respectively. Compared with weeks 0, 8, and 16, respectively, the median HBI score was significantly decreased at week 24 (all P<0.001). The intestinal clinical response rates at weeks 8, 16, and 24 were 53.33%, 70.00%, and 83.33%, respectively, while the intestinal

clinical remission rates were 41.67%, 61.67%, and 75.00%, respectively. Compared to week 0, the median SES-CD score was significantly reduced at week 24 (P<0.001). At week 24, the endoscopic response rate and endoscopic remission rate were 73.73% and 45.00%, respectively. Compared with weeks 0, 8, and 16, respectively, the median levels of CRP and ESR were significantly decreased at week 24 (all P<0.001). At weeks 8, 16, and 24, the normalization rates of CRP were 51.67%, 73.33%, and 78.33%, respectively, while the normalization rates of ESR were 43.33%, 58.33%, and 75.00%, respectively. Compared to week 0, the average levels of serum Alb (P=0.002) and Hb (P=0.048) were increased at week 24. At week 24, the endoscopic response rate was higher in the patients receiving first-line UST treatment than in those patients receiving non first-line UST treatment (P=0.013).

Conclusion: The double intravenous induction treatment of UST could effectively improve the clinical efficacy in complex PFCD patients. In addition, the efficacy of first-line UST in treating complex PFCD patients was better than that of non first-line UST treatment.

Disclosure: Nothing to disclose.

Introduction: Infant outcomes are favourable post in-utero exposure to thiopurines (TP), with no increase in infant infections or adverse growth and developmental outcomes[1-2]. However, infant thrombocytosis, anaemia, lymphopenia and liver function derangement have been observed in small studies[1,3,4]. We aimed to identify the frequency of and associations with these abnormalities in TP exposed infants and determine the clinical impact.

Aims & Methods: Infants born to participants in the multi-centre prospective PICCOLO-X study receiving TP were compared to infants exposed to biologic monotherapy (BM) in-utero. TP metabolites (6-thiogaunine (TGN) and 6-methylmercaptopurine (MMP)), liver function tests (LFT) and full blood examination (FBE) were taken from cord blood at delivery, and repeated at 6 weeks (6W). Abnormal parameters were repeated thereafter until normalization and infants reviewed by a paediatric gastroenterologist. Infants are followed for 2 years. TGN and MMP levels were assessed using high performance liquid chromatography. The lower limit for detection was 15 for TGN and 100pmol/8 x 10^8 RBCs for MMP. Age specific biochemical and haematological reference ranges were used.

Results: 78 TP and 52 BM infants (IFX 5, ADA 9, 23 UST and 15 VDZ) were included. Delivery outcomes were equivalent between the groups. TGN and MMP were undetectable at delivery in 6/55 and 47/55 respectively, and all tested cleared both at 6W (n=44). The median delivery infant:maternal TGN and MMP ratios were 0.38 (IQR 0.24-0.50, n=49) and 0.18 (0.05-0.45, n=8). Thrombocytosis was seen in 80% (62/77) of all infants at 6W and 77% (49/64) at 3 months (3M). Elevated ALT was seen in >50% of infants at 3M and 6 months (6M), and anaemia in 12% (8/67) at delivery. There was no increased risk of thrombocytosis or transaminitis in TP exposed infants vs controls (Table). Maternal TP shunting (RR 2.06, 95% CI 1.33-3.18, p<0.01) and MMP (coef. 0.03, 0.02) at delivery and preceding infection (RR 1.65, 1.01-2.70, 0.05) were associated with increasing ALT at 6W, as were preceding infection and elevated ALT (1.25, 1.14-1.37, <0.01) and ALP (1.89, 1.49-2.40, <0.01) at 3M. Vaccination prior to bloods increased the risk of elevated ALP at 6W (1.87, 1.11-3.13, 0.02). Neutropenia risk was increased in those with preceding infection (1.94, 1.05-3.59, 0.04) and vaccination (6.33, 1.09-36.83, <0.04) at 3M. Neutropenia at 6W was associated with an increased risk of infection at 3M (4.89, 1.64-14.57, <0.01). Maternal CRP in trimester 2 was associated with increasing ALT at 6W (coef. 0.7, 95% CI 0.4-1.0, p<0.01), 3M (1.6, 1.2-2.1, <0.01) and 6M (1.6, 1.2-2.0, <0.01), as was maternal calprotectin in trimester 3 and infant 6W platelets (0.08, 0.02-1.5, <0.01). There was no increased risk of infection, chronic disease, allergy or growth <10^{th} percentile in TP vs BM exposed infants at 6W, 3M and 6M.

Infant outcome	Time-point	Thiopurines (%, n)	Biologic monotherapy (%,n)	Relative risk (95%) p, univariate binary regression	Adjusted coefficient (95%CI) p, Ordinary multivariate linear regression
Thrombocytosis/ Platelet count	6 weeks	80.7 (42/52)	80 (20/25)	1.01 (0.80 – 1.28) 0.93	38.3 (-330.2-406.7) 0.76
	6 months	59.5 (22/37)	62.5 (10/16)	0.95 (0.60-1.51) 0.83	360.8 (-370.8-1092.4) 0.24
Neutropaenia/ neutrophil count	3 months	2.94 (1/33)	26.3 (5/19)	0.11 (0.01-0.89) 0.04	1.82 (-4.02-7.67) 0.39
Elevated ALT/ ALT level	6 weeks	51.9 (28/54)	50 (13/26)	1.04 (0.65-1.65) 0.88	14.3 (-66.2-94.8) 0.67
	6 months	18.2 (6/33)	7.14 (1/14)	2.55 (0.37-19.24) 0.37	22.7 (-599.1-644.5) 0.89
Elevated ALP/ALP count	3 months	12.5 (5/40)	40 (8/20)	0.3 (0.11-0.83) 0.02	-71.9 (-317.1-173.3) 0.46
Anaemia/ Haemaglobin	Delivery	11.7 (6/51)	12.5 (2/16)	0.94 (0.21-4.21) 0.94	-36.5 (-91.7-18.3 0.2

Conclusion: Abnormal biochemical and haematologic outcomes were seen in infants born to women with IBD, but not more commonly in those exposed to TP in-utero, and with favourable clinical outcomes. Abnormalities were associated antenatal maternal inflammation, altered maternal thiopurine metabolism and preceding infant infection and vaccination.

Introduction: Etrasimod is an investigational, oral, once-daily, selective sphingosine 1-phosphate $(S1P)_{1,4,5}$ receptor modulator in development for the treatment of moderately to severely active ulcerative colitis (UC).

Aims & Methods: We report efficacy and safety of etrasimod in patients (pts) with/without concomitant corticosteroid (CS) use at baseline (BL) of the ELEVATE UC phase 3 trials. In ELEVATE UC 52 (NCT03945188) and ELEVATE UC 12 (NCT03996369), pts with moderately to severely active UC were randomised 2:1 to once-daily etrasimod 2 mg or placebo (PBO). ELEVATE UC 52 used a treat-through design with a 12-week (wk) induction period followed by a 40-wk maintenance period. ELEVATE UC 12 had a 12-wk induction period. At entry, pts were permitted to receive oral concomitant CS (prednisone [≤ 20 mg/day], budesonide [≤ 9 mg/day], or equivalent]) if on a stable dose for ≥ 4 wks prior to screening endoscopy; from Wk 12 CS tapering was recommended. Primary and secondary efficacy endpoints (defined in Table) and safety were assessed by BL concomitant CS status.

Results: In ELEVATE UC 52, 32.2% (93/289) and 29.2% (42/144) of etrasimod- and PBO-treated pts, respectively, were receiving CS at BL. In ELEVATE UC 12, 27.3% (65/238) and 29.3% (34/116) of etrasimod- and PBO-treated pts were receiving CS at BL.

Among pts receiving CS at BL in ELEVATE UC 52, a higher proportion of etrasimod- vs PBO-treated pts achieved the endpoint of clinical remission (CR) at Wk 12 ($p<0.05$) and Wk 52 ($p<0.001$); this was also observed in pts not receiving CS at BL ($p<0.001$ at Wks 12 and 52; Table). In ELEVATE UC 12, a higher observed proportion of etrasimod- vs PBO-treated pts receiving CS at BL achieved CR at Wk 12 ($p>0.05$); a significant difference was observed in pts not receiving CS at BL ($p<0.01$).

In both studies, similar results were observed across all secondary endpoints, with greater differences between etrasimod and PBO seen in pts not receiving CS at BL (Table). Across both ELEVATE trials, there were fewer

Data in bold indicate significant *p* values. All data shown refer to the full analysis set (MMS 4–9) with CS at baseline (CS at BL) or no CS at baseline (no-CS at BL)

[a]Clinical remission, the primary efficacy endpoint, was defined as SFS=0 (or =1 with a ≥ 1-point decrease from baseline), RBS=0, and ES ≤ 1 (excluding friability)

[b]Percentages are based on N, the number of patients in the subgroup in the analysis set by treatment, patients missing an assessment at the specified analysis visit are considered non-responders

[c]Difference is for etrasimod minus placebo and is based on estimated common risk difference using the Mantel-Haenszel weights; *p*-value is 2-sided to test the hypothesis of the risk difference being 0

[d]Endoscopic improvement (key secondary efficacy endpoint) was defined as an ES ≤ 1 (excluding friability)

[e]Symptomatic remission (key secondary efficacy endpoint) was defined as SFS=0 (or =1 with a ≥ 1-point decrease from baseline) and RBS=0

[f]Endoscopic improvement , histological remission (key secondary efficacy endpoint) was defined as ES ≤ 1 (excluding friability) with histologic remission measured by a Geboes Index score < 2.0

[g]Clinical response (other secondary efficacy endpoint) was defined as a ≥ 2-point and ≥ 30% decrease from baseline in MMS, and a ≥ 1-point decrease from baseline in RBS or an absolute RBS ≤ 1

BL, baseline; CI, confidence interval; CS, corticosteroid; ES, endoscopic subscore; Etra, etrasimod; MMS, modified Mayo score; N, the number of patients in the subgroup in the analysis set by treatment; n, number of responding patients; PBO, placebo; RBS, rectal-bleeding subscore; SFS, stool-frequency subscore; UC ulcerative colitis

PP0788 Table. Efficacy at Wk 12 and Wk 52 in patients with and without CS use at baseline in the ELEVATE UC 52 and UC 12 phase 3 trials.

serious adverse events and serious infections in the etrasimod arm in pts with CS at BL, than in those without CS at BL. In the PBO arms, the opposite was true.

Conclusion: Regardless of concomitant CS use at BL, etrasimod generally demonstrated efficacy at Wks 12 and 52, with greater treatment effect seen in pts without CS use at BL. No additional safety signal was apparent when etrasimod was initiated in combination with CS compared to without CS.

Introduction: Etrasimod is an investigational, once-daily (QD), oral, selective sphingosine 1-phosphate $(S1P)_{1,4,5}$ receptor modulator in development to treat immune-mediated inflammatory disorders. CULTIVATE (NCT04173273) is a seamless phase 2/3 trial comprising 5 substudies designed to evaluate the efficacy, safety and tolerability of etrasimod in patients with moderately to severely active Crohn's disease (CD).

Aims & Methods: Here, we report the induction data from the first substudy (Substudy A). Substudy A was a phase 2, randomised, double-blind study using a 14-week induction period followed by a 52-week extension period. Adults (18–80 years) with moderately to severely active CD and an inadequate response, loss of response or intolerance to ≥1 conventional or advanced treatments for CD were randomised 1:1 to etrasimod 2 or 3 mg QD. Patients were stratified by baseline biologic failure status and oral corticosteroid use. The primary efficacy endpoint was achievement of endoscopic response (defined as endoscopic remission [SES-CD ≤4 and ≥2-point reduction from baseline with no subscore >1] or ≥50% decrease in SES-CD score) at Week 14. Secondary/exploratory endpoints included achievement of endoscopic remission, clinical remission (CDAI <150) and IBDQ remission (IBDQ ≥170), at Week 14. Outcomes were analysed in the full analysis set (all randomised patients treated with ≥1 dose of etrasimod) using non-responder imputation or observed data.

Results: Of 83 patients randomised to either etrasimod 2 or 3 mg QD, 32/42 (76.2%) and 36/41 (87.8%) completed Week 14, respectively. Overall, 21.4% and 9.8% of patients receiving etrasimod 2 and 3 mg QD, respectively, achieved the primary endpoint of endoscopic response, 14.3% and

7.3% achieved endoscopic remission, 31.0% and 43.9% achieved clinical remission, and 33.3% and 40.0% achieved IBDQ remission at Week 14. Most TEAEs were mild or moderate. The incidence of serious TEAEs (4.8% and 2.4%) and TEAEs leading to discontinuation (4.8% and 7.3%) was low with etrasimod 2 and 3 mg QD, respectively (Table). Two patients randomized to etrasimod 3 mg QD experienced second-degree atrioventricular block type I TEAEs (one patient during 2-mg titration).

Baseline demographics and clinical characteristics	Etrasimod 2 mg QD (N=42)	Etrasimod 3 mg QD (N=41)
Age, mean (SD), years	38.3 (12.6)	40.8 (14.0)
Female, n (%)	22 (52.4)	19 (46.3)
Extent of CD, n (%)		
Ileal disease	7 (16.7)	12 (29.3)

First-degree AV block	1 (2.4)[g]	1 (2.4)[h]
Second-degree AV block, Mobitz type I	0	2 (4.9)[h,i]
Hypertension	1 (2.4)	0

[a]Endoscopic response is defined as endoscopic remission or ≥50% decrease in SES-CD score (non-responder imputation)
[b]Endoscopic remission is defined as SES-CD ≤4 and ≥2-point reduction from baseline with no subscore >1 (non-responder imputation)
[c]Clinical remission is defined as CDAI <150 (non-responder imputation)
[d]IBDQ remission is defined as IBDQ ≥170 (as observed)
[e]Subjects assigned to the 3 mg QD group received etrasimod 2 mg QD during the first week
[f]MedDRA version 24.1 System Organ Class and Preferred Terms. Opportunistic infections were identified using SMQ Opportunistic infection (narrow scope)
[g]One patient randomised to the 2 mg group had an asymptomatic first-degree AV block on Day 1
[h]One patient in the 3 mg group had both an asymptomatic second-degree AV block type I (on day 7 following 3-mg dose escalation) and an asymptomatic first-degree AV block (second week)
[i]One patient in the 3 mg group had a symptomatic second-degree AV block type I (during 2-mg titration)
AV, atrioventricular; CD, Crohn's disease; CDAI, Crohn's Disease Activity Index; CTCAE, Common Terminology Criteria for Adverse Events version 5; IBDQ, Inflammatory Bowel Disease Questionnaire; MedDRA, Medical Dictionary for Regulatory Activities; N, total number of patients; n, number of patients with evaluable data within each category; QD, once daily; SD, standard deviation; SES-CD, Simple Endoscopic Score for Crohn's Disease; SMQ, Standardised MedDRA Queries; TEAE, treatment-emergent adverse event

Table. Baseline demographics and clinical characteristics, proportions of patients achieving endoscopic remission, endoscopic response, and clinical remission at Week 14 (full analysis set), and overall summary of safety data (safety set).

Conclusion: Data from this substudy of patients with moderately to severely active CD suggest endoscopic and clinical improvement with both etrasimod 2 and 3 mg QD. However, the small sample size and lack of a placebo arm limit the ability to draw conclusions about efficacy, including comparison between the etrasimod 2 and 3 mg groups. Both doses were well tolerated, and safety was consistent with other etrasimod clinical programmes. Data from the extension phase of Substudy A and the placebo-controlled, dose-ranging phase 2b Substudy 1 are forthcoming.

THE EFFECTIVENESS AND SAFENESS OF ALLOGENEIC MESENCHYMAL STROMAL CELLS OF BONE MARROW IN PATIENTS WITH REFRACTORY CROHN'S DISEASE - 10 YEARS OF OBSERVATION

O. Knyazev[1,2], A. Kagramanova[1], A. Lishchinskaya[1], A. Parfenov[1]
[1]Moscow Clinical Scientific Center named after A.S. Loginov, IBD, Moscow, Russia, [2]State Scientific Centre of Coloproctology named after A.N. Ryzhyh, Moscow, Russia

Contact E-Mail Address: kagramanova@me.com

Introduction: Crohn's disease (CD) is a chronic inflammatory disease of the gastrointestinal tract with recurrent nature of the flow. The frequency of exacerbations is approximately 20-25% at 1 year and 75% for 3 years. If the remission lasted less than 12 months, there is a 65% chance that the aggravation comes in the next 18 months. For the duration of remission for 12 months or more the likelihood of an explosion in the next 18 months is reduced to 20%.

Aims & Methods: To evaluate the influence of culture of allogeneic mesenchymal stromal cells (MSCs) of bone marrow for the duration of remission in patients with refractory CD.

Materials and Methods. The first group of patients with CD (n=30) received MSCs, the dose of prednisone was not more than 20 mg/day. The second group of patients (n=30) received standard anti-inflammatory drug therapy of 5-aminosalicylic acid (5-ASA) and glucocorticosteroids (GCS). Age of patients ranged from 19 to 49 years (Me-36 years). The disease was of moderate and high activity, length of damage - ileokolit, ileitis and colitis, the observation time ranged from 68 to 118 months. Clinical activity was assessed by the Crohn's disease activity index (CDAI). The culture of allogeneic MSCs injected drip at 2.5 million per 1 kg of body weight (0-1-26-52 weeks and twice a year).

Results: CDAI in the 1-st group was 242,6±11,7 points, in the 2-nd 240,9±12,9 points (p=0,83), CRP levels in 1-st group was 29,3±6.4 mg/l, the 2-nd - 27,8±4,8 (p=0,47). After 1 year of follow-CDAI in 1-st group was 70,0±11,0 points, in the 2-nd - 133,8±22,2 points (p<0,001), CRP levels in 1-st group was 6,36±1,5 mg/l, in the 2-nd - 12,2±2,9 (p<0,001). After 5 years - the CDAI in 1-st group - 120,0±22,3 points, in the 2-nd - 208,7±17,6 points (p<0,001), CRP levels in 1-st group - 11,3±2,6 mg/l, in the 2-nd - 15,5±2,4 (p<0,001). After 10 years - the CDAI in 1-st group - 126,0±23,8 points, in the 2-nd - 248,7±14,6 points (p<0,001), CRP levels in 1-st group was 12, 3±2,8 mg/l, in the 2-nd - 19,5±3,1 (p <0,001). In the first group of patients in remission after 1, 5 and 10 years was kept at 70%, 46.7% and 43.3%, respectively. In the second group of patients at 1, 5 and 10 year remission was maintained at 36.6%, 6.67% and 6.67%, respectively.

Conclusion: Transplantation of MSCs contributes to longer-term clinical and endoscopic remission in patients with refractory Crohn's disease compared with therapy with corticosteroids.

Disclosure: Nothing to disclose.

Introduction: To compare the efficacy of therapy mesenchymal stromal cells (MSCs), bone marrow, and the standard anti-inflammatory therapy in the extra-intestinal manifestations (sacroiliitis and ankylosing spondylitis) in patients with Crohn's disease (CD).

Aims & Methods: 34 CD patients with extraintestinal manifestations (ankylosing spondylitis and sacroiliitis, are not related to the activity of Crohn's disease) were divided into two groups. The first group of patients aged 18 to 58 years (Me-34) (n=16) received MSCs culture scheme (0-1-2-3, then every 26 weeks). The second group of patients with CD (n=18) aged 20 to 60 years old (Me-28) received standard anti-inflammatory therapy with glucocorticosteroids (GCS) and immunosuppressive (IS). Evaluation of efficacy was conducted on the level of activity of inflammation (CRP, thrombocytosis) and ankylosing spondylitis activity index (BASDAI) were performed at 12, 25 and 52 weeks of therapy.

Results: Among the patients in Group 1 reduction in the activity of the AS after 12 weeks of observation occurred in 4/16 patients (25.9%). In group 2, a decrease in activity of the AS occurred in 5/18 (27.7%) (p=0.83).

After 26 weeks in patients (group 1) receiving MSCs, reducing the activity of the AS occurred in 10/16 (62.5%). In group 2, a decrease in activity of the AS occurred in 5/18 (27.7%) (p=0.044).

After 52 weeks in group 1 patients the minimal activity of the AS persisted in 10/16 (62.5%) patients with CD. In group 2, there was increased activity of the AS in one patient 4/18 (22.2%) (p=0.042).

Conclusion: MSCs transplantation can reduce the activity of the AS associated with Crohn's disease compared to standard anti-inflammatory GCS/IS therapy.

Disclosure: Nothing to disclose.

Introduction: The predictors of sustainability of biologic drugs in paediatric patients with Crohn's disease (CD) remain unknown.

Aims & Methods: We aimed to evaluate the predictors of sustainability of biologic drugs for paediatric patients with Crohn's disease (CD). The Czech National Prospective Registry of Biologic and Targeted Therapy of Inflammatory Bowel Disease (CREdIT) was used to identify the biologic treatment courses in paediatric patients with CD. Mixed-effects Cox models and propensity score analyses were used to identify associations between predefined predictors and treatment sustainability.

Results: Among the 558 observations of 473 paediatric CD patients, 264 were treated with adalimumab (47%), 240 with infliximab (43%), 41 with ustekinumab (7%), and 13 with vedolizumab (2%). On multivariable analysis, patients treated with infliximab had a higher risk of discontinuation than those treated with adalimumab (HR=0.640, 95%CI 0.412-0.993) in the whole group, as well as among patients who received first-line treatment (HR=0.575, 95%CI 0.360-0.919). Propensity-score analysis also showed lower sustainability (HR=0.563, 95%CI 1.159-2.725) and a shorter time to escalation (HR=0.095, 95%CI 0.044-0.202) with infliximab as compared to adalimumab. The time since diagnosis (HR=0.828, 95%CI 0.762-0.901) and baseline haemoglobin level (HR=1.019, 95%CI 1.006-1.033) were also predictors of sustainability. In patients receiving infliximab, baseline immunosuppressive therapy prolonged sustainability (HR=2.976, 95%CI 1.342-6.579).

Conclusion: Given the results suggesting shorter sustainability, the need for earlier intensification and thus higher drug exposure, and the greater need for immunosuppression with infliximab than with adalimumab, the choice of these drugs cannot be considered completely equitable. Furthermore, it should be emphasised that the initiation of biological therapy should not be delayed.

References: Given the results suggesting shorter sustainability, the need for earlier intensification and thus higher drug exposure, and the greater need for immunosuppression with infliximab than with adalimumab, the choice of these drugs cannot be considered completely equitable. Furthermore, it should be emphasised that the initiation of biological therapy should not be delayed.

Introduction: The effectiveness of fecal microbiota transplantation (FMT) in Ulcerative colitis (UC) remains unclear, with significant differences in protocols and procedures among clinical trials (1).

Aims & Methods: This study aimed to investigate the feasibility and effectiveness of a FMT protocol with close infusions in patients with active UC, also exploring the microbial modulation underlying its therapeutic efficacy.

In this prospective cohort study, subjects with mild-to-moderately active UC received three consecutive fecal infusions by colonoscopy, at baseline, T1 (2 weeks) and T2 (6 weeks) respectively. Faeces were collected by the donor on the day of the infusion and processed within 6 hours. A control population with the same baseline features undergoing Infliximab treatment was enrolled.

Primary outcomes were the number of adverse events and the compliance rate. Secondary outcomes were: clinical remission; clinical response; endoscopic remission; microbial differences.

Results: Nineteen patients with mild-to-moderately active UC were enrolled.

During the protocol, 2 patients dropped out because of disease worsening and 1 patients dropped out because of hospitalization due to nephrolithiasis.

Clinical response was obtained in 6 of 16 patients at week-2 (PP=37%; ITT=31%), in 8 of 16 at week-6 (PP=50%; ITT=42%), and in 9 at week-12 (PP=56%; ITT=47%). Clinical response was maintained in 8 patients at week 24 (PP=50%; ITT=42%). Clinical remission was achieved in 4 subjects at week-2, in 5 at week-6 (PP=31%; ITT=26%), and in 5 at week-12 (PP=31%; ITT=26%). Endoscopic remission at week 12 was reached in 6 patients (PP=37%; ITT=31%). In the control population, 13 of 19 patients achieved clinical response at week 6 and 10 of 19 patients maintained clinical response after 6 months.

During the time course, the microbiota richness was higher in responders compared with the non-responders. *Peptostreptococcus*, *Lactobacillus* and *Veillonella* were higher in non-responders while *Parabacteroides*, *Bacteroides*, *Faecalibacterium* and *Akkermansia* were higher in responders in all time points.

Conclusion: Serial FMT infusions appear to be feasible, safe, and able to provide a considerable clinical and microbial response in UC patients. In particular, the comparison with patients under biologic therapy suggests a potential role in maintaining clinical response or enhancing maintenance. Gut microbiota profiling highlighted the role of specific intestinal bacteria in predicting both negative and positive response to FMT.

Introduction: Subcutaneous (SC) Infliximab (IFX) is non-inferior to intravenous (IV) IFX, for maintenance of remission in inflammatory bowel disease (IBD) (1). There are limited data on factors affecting the decisions of patients who choose SC administration of biologics (2, 3). Our centre offered suitable patients SC IFX from November 2022.

Aims & Methods: (1) Determine disease-related, economic, social and personal factors that affect the decision of a patient with IBD to transition from IV to SC administration of IFX.

(2) Assess effects of SC administration on pharmacokinetics and disease control. Participants completed a questionnaire on their IBD history, personal and financial circumstances, and reasons for electing or declining to transition. Clinical and biochemical data were retrieved from the electronic patient record (EPR). A bivariable logistic regression model was used to determine factors associated with electing to transition.

Results: 144 patients were offered the opportunity to transition during the study period. 80 (55.5%) agreed to transition, 64 (44.5%) declined. 101 patients (70.1%) agreed to participate in the study. 59.4% were male, 67.3% had Crohn's disease. Age ranged was 18-82 (median 41) years. Infusion frequency was every 4 (9.8%), 6 (22.8%), 7 (2.0%), or 8 weeks (65.4%). 76% were employed/self-employed, 41.6% had a medical card and 44.6% had private health insurance. Median (IQR) travel time was 90 mins (40, 130). 48 patients (47.5%) reported that they missed school/work for their infusions. At baseline, median (IQR) laboratory results were CRP 1.2mg/L (0.6, 2.7), IFX trough 7.4mg/mL (4.9, 11.8), faecal calprotectin 39 mg/g (10, 98), IBD-Control 14 (13, 16). 8 weeks after first SC dose, median (IQR) results (n=36) were CRP 1.1mg/L (0.8, 2.0) IFX trough 17.8mg/mL (12.5, 21.4), IBD-Control 16 (14, 16). The strongest reasons to transition (% agree/ strongly agree on five-point Likert) were, "I want to transition because it will…"

(1) reduce my travel time (94.5%),

(2) fit my work/life balance better (87.3%) and

(3) reduce my time away from work/school (74.5%). The strongest reasons against transition were,

(1)I would miss having my bloods checked regularly (84.8%),

(2) I feel safer attending the infusion unit (80.4%),

(3) I would not be able to voice concerns about my treatment as easily (80.4%) and

(4) I would miss regular contact with a healthcare professional (69.6%). Table 1 shows results of binary logistic regression used to determine factors associated with the likelihood of electing to transition.

Variable	OR	p
Age (years)	1.01	0.06
Sex (male = 1)	0.82	0.70
IBD Type (CD = 1)	0.65	0.46
Medical Card	2.88	0.13
Health Insurance	0.33	0.05
Drug Payment Scheme	4.99	0.03
Travel Time	1.01	0.22
IBD Control	1.01	0.85
Missing School/Work for Infusion	3.78	0.04

Conclusion: SC IFX is safe, effective and well-tolerated by those who choose to transition. It is attractive to many patients, because attending for IV infusions can interrupt their employment, education and family life, but cost is a significant barrier for some patients. IBD teams must be adequately resourced to assure patients who transition that they will continue to have ready access to high-quality medical care and disease monitoring. Discrepancies in healthcare markets may provide a perverse incentive to continue receiving IV biologic, for those who would prefer SC.

Introduction: In the UNIFI study of ustekinumab (UST) for ulcerative colitis (UC), patients (pts) who achieved both histologic and endoscopic improvement of the mucosa (histo-endoscopic mucosal improvement [HEMI]) after induction with UST followed by maintenance had higher rates of clinical remission at 1 year and symptomatic remission at 3 years than those with histologic or endoscopic improvement alone.[1,2]

Here we present long-term outcomes for pts who achieved symptomatic remission after induction with intravenous (IV) UST with or without HEMI.

Aims & Methods: In UNIFI, pts were randomised to IV UST (130 mg or ~6 mg/kg/body weight) or placebo (PBO). Patients who were in clinical response 8 weeks (w) following IV induction with UST were randomized to subcutaneous (SC) UST 90 mg q12w or q8w or SC PBO maintenance. At the discretion of the investigator, enrolment in this long-term extension study was optional for pts who completed 44w on maintenance. HEMI was defined as having both histologic improvement (<5% neutrophils in the epithelium, no crypt destruction, and no erosions, ulcerations, or granulations) and endoscopic improvement (Mayo endoscopic subscore of 0 or 1). Symptomatic remission was defined as a stool frequency subscore of 0 or 1 and a rectal bleeding subscore of 0. Efficacy 8w after IV induction was categorized as 1) disease clearance (achieving both HEMI and symptomatic remission), 2) symptomatic remission without HEMI, or 3) neither symptomatic remission nor HEMI. Time to treatment failure (UC-related surgery or hospitalization, adverse event of UC, or discontinuation of study agent due to an adverse event of worsening UC or lack of efficacy) was compared between cohorts by using a log-rank test.

Results: Eight weeks after IV induction, 79 pts achieved disease clearance, 142 pts achieved symptomatic remission but not HEMI, and 82 pts did not achieve symptomatic remission nor HEMI. Proportions of pts in symptomatic remission were highest for those who were in disease clearance after induction through 200 weeks (~4 years) of UST treatment (Table). The time to treatment failure was longer in pts with disease clearance than pts in symptomatic remission without HEMI (p=0.004), and in pts in symptomatic remission without HEMI than pts with neither symptomatic remission nor HEMI (p=0.043).

Conclusion: Patients with disease clearance 8w after IV induction had greater long-term symptomatic remission outcomes and longer time to treatment failure than those with symptomatic remission without HEMI or those with neither symptomatic remission nor HEMI after induction.

	Disease clearance	Symptomatic remission without HEMI	Neither symptomatic remission nor HEMI
Number of pts	79	142	82
Week 44			
Symptomatic remission	63 (79.7%)	98 (69.0%)	35 (42.7%)
CS-free symptomatic remission	60 (75.9%)	97 (68.3%)	34 (41.5%)
Week 92			
Symptomatic remission	63 (79.7%)	100 (70.4%)	41 (50.0%)
CS-free Symptomatic remission	60 (75.9%)	98 (69.0%)	39 (47.6%)
Week 152			
Symptomatic remission	60 (75.9%)	78 (54.9%)	32 (39.0%)
CS-free Symptomatic remission	57 (72.2%)	76 (53.5%)	31 (37.8%)
Week 200			
Symptomatic remission	58 (73.4%)	76 (53.5%)	37 (45.1%)
CS-free Symptomatic remission	56 (70.9%)	74 (52.1%)	35 (42.7%)

CS=corticosteroid; HEMI=histo-endoscopic mucosal improvement; IV=intravenous; SC=subcutaneous.

Table: Symptomatic remission through 4 years in pts receiving SC maintenance ustekinumab among those with disease clearance, symptomatic remission without HEMI, or neither symptomatic remission nor HEMI 8 weeks after IV ustekinumab induction.

DFL23806, A SELECTIVE AGONIST OF GPR120, DISPLAYS UNIQUE PHARMACOLOGICAL POTENTIAL AND INHIBITS ACUTE AND CHRONIC COLITIS IN MURINE MODELS

R. Cypriano Dutra[1], G. Bianchini[1], R. Novelli[1], P.G. Amendola[1], S. Carty[1], G. Cremonesi[1], A. Aramini[1]

Introduction: No single pharmacological approach is currently available for the treatment of inflammatory bowel disease (IBD) in active and maintenance stages. As evidence is growing on the immuno-modulatory activities of the G-protein coupled receptor GPR120 and on its role in modulating the pathophysiology of IBD, its potential as a therapeutic target for this disease is worthy of exploration.

Aims & Methods: Herein, we have developed DFL23806, a new GPR120 selective small molecule agonist, and propose it as a potential therapeutic approach for IBD. We employed our in-house proprietary Exscalate platform for molecular docking simulations to define the site and mode of binding of the compound with the receptor and used *in vitro* studies and *in vivo* models (murine dextran sodium sulfate (DSS)-induced acute and chronic colitis and 2,4,6-trinitrobenzene sulfonic acid (TNBS)-induced chronic colitis models) to characterize the mechanism of action of our molecule and evaluate its therapeutic effects.

Results: DFL23806 is a selective agonist of human and mouse GPR120 that can activate both the G-protein dependent and independent signaling (β-arrestin pathway) of the receptor. DFL23806 has been designed to have high metabolic stability and reach the ileum and colon at optimal concentrations that allow for the activation of GPR120 while, notably, delaying its internalization.

This can lead to prolonged periods of signal transduction compared to other commercially available GPR120 agonists and amplification of signaling effects. *In vivo*, intrarectal treatment with DFL23806 exerted consistent immunomodulatory action in DSS-induced acute colitis in mice.

Moreover, oral treatment with DFL23806 significantly inhibited both DSS- and TNBS-induced chronic colonic inflammation and fibrosis by improving the disease activity index, endoscopic score, and reducing body weight loss and colonic tissue damage. Interestingly, DFL23806 treatment also modulated the composition of microbiota, inhibiting the concentration of pathogenic bacteria, and rescued intestinal dysbiosis induced by TNBS.

Conclusion: These results suggest that the stimulation of GPR120 could be an effective strategy for managing colitis, and that DFL23806 has great potential as a therapeutic for the treatment of IBD.

Disclosure: The authors are employees of Dompé farmaceutici s.p.a., Italy. The company has interests in the development of GPR120 selective agonist for the treatment of IBD and metabolic diseases.

Introduction: Due to lack of published data on ustekinumab (UST) use in Greece, we aimed to generate local real-world evidence (RWE) on UST treatment persistence and clinical outcomes [including patient-reported outcomes (PROs)] in patients with Crohn's Disease (CD).

Aims & Methods: REASSURE is an ongoing, non-interventional, 24-month prospective study of adult (18-80 years old) patients with CD, who commenced therapy with UST as 1st, 2nd or 3rd biologic therapy as per approved label in Greece. Harvey-Bradshaw Index (HBI) and PROs are collected by routine assessments at baseline (start of UST) and every 6 months thereafter. PROs include the Inflammatory Bowel Disease Questionnaire (IBDQ), the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) Scale, and the Work Productivity and Activity Impairment Questionnaire in CD (WPAI:CD). Interim analysis was performed when all enrolled patients completed 1 year of follow-up.

Results: Between April 2019 and March 2022, 169 eligible patients [median (Interquartile range, IQR) age at baseline: 45 (35.0-54.0) years; bio-naïve: 35.5%; employed: 43.8%] were enrolled in 19 gastroenterology clinics and completed 1-year of follow-up. The median time from CD diagnosis to UST initiation was 7.0 (1.8-13.0) years.

The 12-month persistence rate was 84.0% (95% Confidence Interval: 78.5-89.5%). Over a median treatment duration of 12.3 months, a median of 7.0 (6.0 - 8.0) intravenous (IV) and subcutaneous (SC) injections were received. At 12 months, 14.2% (24/169) of patients discontinued UST (mean duration of 6.3 months) due to lack/loss of efficacy (10/24), safety issues (8/24), loss to follow-up (3/24), patient's decision (2/24) and death (1/24; unrelated to UST).

The baseline median values for total HBI (8.0), IBDQ (166.0), FACIT-F (33.0), WPAI:CD work productivity loss (30.0), and activity impairment scores (35.0) significantly improved (p<0.01) at 12 months, with median changes of -4.0, 17.1, 4.0, -10.0, and 10.0, respectively, among paired observations.

Similar improvements were noted in the subgroups per treatment line. The UST-related adverse events (AE) and serious AE rates were 18.3% (31/169) and 4.7% (8/169) respectively. Baseline data and 12-month outcomes are shown in Table 1.

Conclusion: These data provide evidence for high persistence rate of UST in patients with CD in a real-world setting in Greece and demonstrate favorable effects on disease activity and PROs, accompanied by a predictable safety profile.

Introduction: Infliximab is an important treatment option in the management of inflammatory bowel disease (IBD). It has traditionally been administered as an intravenous(IV) infusion but is now available as a subcutaneous (SC) injection. There is limited real world data around SC infliximab use and drug levels. In Ireland, IV medications are paid for from the hospital budget and SC medications are paid for from the community health budget.
Aims & Methods: This study aims to assess the trough levels of infliximab when given in SC formulation compared to IV formulation, to assess faecal calprotectin pre and post switching drug route, to assess patient's attitudes to SC therapy and to examine the cost savings associated with switching to SC infliximab. Proactive therapeutic drug levels are routinely performed in our clinic and we routinely offer SC switch to patients on IV infliximab. Patients currently receiving infliximab were identified using the departmental IBD database. Inclusion and exclusion criteria were applied. Infliximab trough levels from when the patient was receiving IV infliximab were compared to the most recent trough level while using SC infliximab. Response to SC infliximab was assessed using faecal calprotectin. Health related quality of life was also measured using the IBD Disk Questionnaire. A subset of patients completed a questionnaire about attitudes to SC therapy. The financial cost of providing IV infliximab to each patient was assessed.
Results: In total 103 patients receiving SC infliximab for >3 months were identified. 0 were excluded. 55 (53%) were female and 48 (47%) were male. The median age was 39 (19-79). 57 (55%) had Crohn's disease (CD), 46 (45%) had ulcerative colitis (UC). Infliximab trough levels improved by an average of 14.98ug/mL (188.6%) after switching to SC (P<0.05). Faecal calprotectin fell by an average of 74.45ug/g (-18.8%) after switching from IV to SC formulation (P<0.05). Average IBD disk score while on SC infliximab was 36.96/100 reflecting that the included patients have ongoing disease activity. The IBD disk score correlated with faecal calprotectin r 0.22 (P<0.05). In a subset of patients surveyed, 90% (n=10) preferred SC to IV infliximab. Switching from IV to SC infliximab for the 103 patients included in this study has saved our department 523,137 euro per annum. There are also significant savings in terms of infusion suite capacity. In total our unit saves 670 infusion suite appointments per year due to these patients switching to SC therapy.
Conclusion: Switching from IV to SC Infliximab is not associated with a deterioration in infliximab drug levels or faecal calprotectin levels. Switching from IV to SC infliximab saved significant amounts of money for our hospital budget and has improved our infusion suite capacity. Patients expressed a preference for SC administration over IV. In summary switching from IV to SC infliximab may be considered for patients with Crohn's disease and ulcerative colitis.
Disclosure: Nothing to disclose.

Introduction: Ustekinumab (UST) is a monoclonal antibody against the p40 subunit, common to IL-12 and IL-23 and was approved recently for the treatment of moderate to severe ulcerative colitis (UC).
Aims & Methods: The aim of this ongoing study is to report and analyze data from a large cohort of Greek patients with UC, who receive treatment with UST. We collected data from patients with UC from 14 Greek hospitals who commenced treatment with UST and evaluated their clinical response at week 16. Clinical response was defined as 50% reduction in the UC PRO2 values at week 16 compared to the values before treatment (baseline).
Results: Herein, we report the clinical outcomes at week 16, following the completion of induction regimen (i.v. loading 6mg/kg plus 1st 90mg sc injection at week 8). The demographics and disease characteristics of the first 101 enrolled patients are shown in Table 1. The majority of patients (70, 70%) commenced treatment with UST due to active disease despite previous treatments. Seventy-six patients (76%) had been exposed to at least one biologic agent, most commonly anti-TNFs (54%). Thirty-eight (38%) and 29 (29%) patients were exposed to one and two biologics, respectively. Sixteen patients (16%) had previously received both infliximab (IFX) and vedolizumab (VDZ). Corticosteroids (50%) and mesalazine

(5-ASA, 68%) were the most common concomitant treatments. UST was discontinued in 4 patients due to no response. A total of 79 patients have reached the 16th week time-point, out of whom 61 have enough data to be analyzed. Analysis of the patients who had active disease at induction (total number with adequate data: 50) showed that clinical response was achieved in 36 (72%) and clinical steroid-free remission in 23 (46%) patients. In multiple logistic analysis concomitant use of 5-ASA was associated with a higher probability of clinical response at week 16 (*P*=0.009), while hemoglobin >13.1g/dL (*P*=0.047), and age >60 years (*P*=0.059) were associated with a lower probability of response. Seven patients were receiving concomitant corticosteroids at week 16.

Sex (n, %)		Male 67 (66)	
Age (mean, SD)		51 (17.5) years	
Disease duration (mean, range)		10.5 (0.5-39) years	
Montreal classification [N=93(%)]	E1	E2	E3
	3 (3)	41 (44)	49 (53)
Family history [n,(%)]		9 (9)	
Extraintestinal manifestation [n,(%)]		33 (33)	
Full MAYO score [n=93, mean (SD)]		7.1 (2.9)	
UCEIS [n=80, mean (SD)]		4.9 (2.0)	

Table 1. Patients' characteristics with moderate-severe UC who received UST [N=101].

Conclusion: In a real world clinical setting, UST was mostly used as a 2nd or 3rd line treatment for moderate to severe UC. At the end of induction treatment, the majority of patients showed clinical response and almost half were in steroid-free remission. Positive predictive factors of response to UST included the concomitant use of 5-ASA, while Hb >13.1 g/dl and age >60 years were associated with lack of response.

Introduction: Inflammatory bowel disease (IBD), ulcerative colitis (UC) and Crohn's disease (CD), is a group of chronic inflammatory disorders. Biologics are indicated for patients failing conventional maintenance therapy with moderate to severe activity. Different routes of administration, intravenous (IV), subcutaneous (SC) or oral have been approved. For chronic diseases such as IBD, some patients may prefer self-administered SC dosing to IV dosing as a less time-intensive and more convenient treatment option. This study aims to assess acceptance, safety and satisfaction of transition from IV to SC administration of Infliximab (IFX) and Vedolizumab (VDZ) in cohort of patients with IBD.

Aims & Methods: The transition from IV to SC administration was proposed to 91 patients. All patients were given two questionnaire: (a) before the switch, surveyed on the impact of the IV administration on their life and (b) 8 weeks after the switch focused on the level of satisfaction and onset of adverse event (AE). Data on medical history and treatment was collected from electronic health records.

Results: Overall, 91 patients were enrolled for switching from IV to SC therapy. All patients filled the first questionnaire. The IV therapy did not or minimally burden on patients' life in 71% and 15 patients (16%) refused the transition. The main reasons why patients preferred to stay on IV administration were the fear of reducing follow-up visits with IBD staff and the fear of doing the therapy outside the hospital. On the other hand, 76 patients accepted and 8 weeks after the transition they completed the second questionnaire. of these 76, 39 CD and 51 male, 41 (53%) were treated with VDZ and the majority of patients (53%) were at the first line of treatment. Most of patients (67%) did not experience any difficulties in handling the device but "only" the 65% respected the correct time-table of administration. 20% of patients report at least one AE, the most common were erythema, swelling and pain in the injection site. Only the 5% should switch back to IV treament. 8 patients (10%) were switched back to IV administration due to AEs and 1 swaped to Ustekinumab.

Conclusion: In this cohort of IBD patients, we found a good acceptance rate (83.5%). The vast majority of patients (95%) was satisfied of transition from IV to SC. Moreover, we reported a good safety profile of SC therapy, AEs were mostly self-limited and local.

Disclosure: Nothing to disclose.

Introduction: Vedolizumab (VDZ) is a gut-selective anti–lymphocyte trafficking drug used to treat ulcerative colitis and Crohn's disease (CD), lifelong conditions with unknown aetiology. In the POLONEZ II study, we evaluated the real-world effectiveness, including patient-reported outcomes (PROs), and safety of VDZ therapy in patients with CD treated in the National Drug Programme in Poland. Previously, we reported interim results at week (wk) 14.[1]

Aims & Methods: We describe long-term outcomes after 54 wks of VDZ treatment. POLONEZ II was a multicentre, observational, prospective study in patients with moderately to severely active CD eligible for reimbursed treatment with VDZ in 10 centres in Poland between April 2020 and November 2021. The primary endpoints at wk 54 were clinical response (≥70-point reduction in the Crohn's Disease Activity Index [CDAI] and >25% versus wk 14), remission rate (CDAI ≤150) and steroid-free remission (CDAI ≤150 in patients with steroid use at baseline but not at the time of assessment). Secondary endpoints at wk 54 included changes from baseline in PROs: quality of life (QoL; Inflammatory Bowel Disease Questionnaire [IBDQ]) and fatigue (Inflammatory Bowel Disease-Fatigue Self-assessment Scale [IBD-F]). Safety outcomes included adverse events (AEs) coded from Medical Dictionary for Regulatory Activities (v25.0).

Results: A total of 98 patients (55 men; mean [standard deviation] age: 35.1 [12.2] years) with CD were enrolled in the study. At wk 54, 63 (64.3%) patients had continued VDZ treatment. Primary reason for discontinuation was lack or loss of response (n=23/35, 65.7%). The most common disease location was ileocolonic (n=71/98, 72.4%), and 67.3% (n=66/98) of patients had received previous biologic therapy. At wk 54, clinical response was observed in 63.3% (n=62/98), clinical remission in 48% (n=47/98) and steroid-free remission in 36% (n=18/50) of patients (Table 1). The median CDAI score significantly decreased from 336.5 at baseline to 110.0 (P<0.001) at wk 54. Of the responders with corticosteroid dose reduction, 73.3% (n=22/30) of patients had a 100% reduction in dose at wk 54 (corticosteroid-free). At wk 54, median changes from baseline scores on the IBDQ (total and all subscales) were statistically significant (P<0.001) and maintained from wk 14. Significant improvements were maintained from wk 14 in IBD-F fatigue severity and frequency (P<0.05) and fatigue impact on daily activities (P<0.001).

Overall, 11 (11.2%) patients experienced 15 non-serious AEs (none VDZ-related) and 6 (6.1%) patients experienced 9 serious AEs (one VDZ-related). One (1.0%) patient experienced rash as a VDZ-related serious AE (1.3 per 100 patient-years).

Crohn's Disease Activity Index (CDAI) outcome	Week 14	Week 54	Durability [Response/remission/ steroid-free remission that was maintained from week 14–54]	95% Confidence interval for durability
Clinical response, N (%) Overall, N=98	90 (91.8)	62 (63.3)	62 (68.9)	58.1, 78.0
Bionaive, n=32	29 (90.6)	21 (65.6)	21 (72.4)	52.5, 86.6
Bioexposed, n=66	61 (92.4)	41 (62.1)	41 (67.2)	53.9, 78.4
Biofailure, n=35	33 (94.3)	21 (60.0)	21 (63.6)	45.1, 79.0
Clinical remission, N (%) Overall, N=98	62 (63.3)	47 (48.0)	39 (62.9)	49.7, 74.6
Bionaive, n=32	21 (65.6)	17 (53.1)	14 (66.7)	43.1, 84.5
Bioexposed, n=66	41 (62.1)	30 (45.5)	25 (61.0)	44.5, 75.4
Biofailure, n=35	21 (60.0)	17 (48.6)	14 (66.7)	43.1, 84.5
Steroid-free remission, N (%) Overall, N=50	15 (30.0)	18 (36.0)	8 (53.3)	27.4, 77.7

Table 1. Clinical response and remission at week 54 (full analysis set)

Conclusion: The results elucidate the real-world use of VDZ in patients with moderately to severely active CD treated for 54 wks in the Polish National Drug Programme. VDZ was effective in maintaining clinical remission in approximately half of the patients, with benefits on disease activity and PROs (QoL and fatigue) and was generally well tolerated.

Introduction: Inflammatory bowel diseases (IBD) may impact the daily life in affected patients in various dimensions including quality of life and work productivity. Suboptimal disease management and limited efficacy of available treatment options can cause inadequate disease control (IDC) resulting in disease progression and negative long-term outcomes. Here, we aim to assess the rates of IDC in daily clinical practice and the related economic burden.

Aims & Methods: IBD-PODCAST is a global cross-sectional, multicenter, non-interventional study assessing signs of residual disease activity according to STRIDE II-criteria[1] in patients with ulcerative colitis (UC) or Crohn's disease (CD). Analysis included patient- and physician-reported measures as well as retrospectively assessed components of the medical record of the last 12 months. In accordance with the recent STRIDE-II recommendations[1], pre-defined indicators ('red flags') of IDC were assessed incl. clinical parameters, biomarkers, endoscopy and imaging studies and patient questionnaires such as the Short Inflammatory Bowel Disease Questionnaire (SIBDQ) and the Work Productivity and Activity Impairment Questionnaire (WPAI)). In addition, reported Health care resource utilization (HCRU) was assessed.

Results: From 04/2022 to 11/2022, 438 patients with IBD (UC: n=228; CD: n=210) were included at 21 German IBD centers. Parameters of IDC were identified in 43.8% (92/210) CD patients and in 39.9% (91/228) UC patients. More specifically, impaired quality of life (SIBDQ <50) was identified as the most common indicator of IDC, followed by steroid overuse and failure to achieve clinically meaningful improvement (>50% reduction of symptoms since therapy initiation) across both indications. Patients with IDC showed substantial impairments in WPAI such as work time missed (CD: 13.4% IDC vs. 2.6% ADC (adequate disease control) and UC: 10.5% IDC vs. 3.0% ADC). HCRU was substantially increased in the IDC group reflected by increased ER visits, hospitalization and surgery rates.

HCRU	Crohn's Disease (N=210)		Ulcerative Colitis (N=228)	
	IDC (N=92)	ADC (N=118)	IDC (N=91)	ADC (N=137)
Number of patients with ≥1 ER visits, n (%)	6 (6.5%)	2 (1.7%)	2 (2.2%)	1 (0.7%)
Number of patients with ≥1 hospitalization, n (%)	9 (9.8%)	5 (4.2%)	3 (3.3%)	2 (1.5%)
Number of patients with ≥1 surgery, n (%)	7 (7.6%)	4 (3.4%)	2 (2.2%)	1 (0.7%)

Table 1. HCRU in patients with IBD according to disease control status

Conclusion: In a substantial proportion of patients with IBD, inadequate disease control was associated with impaired quality of life, lower work productivity and more frequent health care utilization. Our data underlines the continued need for improved disease management and more treatment options in IBD patients.

IN PATIENTS WITH CROHN'S DISEASE MONITORING OF USTEKINUMAB LEVELS DURING INDUCTION CAN IDENTIFY EARLY INADEQUATE RESPONSE

A. Mínguez Sabater[1], G. Bastida[1], V. Argumánez Tello[1], I. Terol Chafer[1], M. Iborra[1], M. Aguas[1], I. Moret[2], E. Cerrillo Bataller[1], A. Garrido[1], L. Tortosa[2], P. Nos Mateu[1]

Contact E-Mail Address: alejandromsab11@gmail.com

Introduction: Ustekinumab (UST), an inhibitor of the p40 subunit of interleukins 12 and 23, is approved for the treatment of moderate and severe Crohn disease (CD) but a significant number of patients either partially respond or do not benefit at all. Therapeutic drug monitoring can be used to optimize the efficacy of biological drugs by ensuring adequate exposure to these drugs.

Aims & Methods: The aim of our research was to identify the relationship between serum concentrations of UST during the induction and biochemical remission at week 16 in patients with CD.

All CD patients treated with UST included in a local database were identified. Only patients with a fecal calprotectin (FCP) > 250 mg/g were selected. All patients were treated with an initial intravenous induction therapy of UST, followed by subcutaneous maintenance therapy. Disease activity was assessed retrospectively by clinical (Harvey–Bradshaw Index [HBI]) and biochemical parameters (FCP; C-reactive protein (CRP) and Albumin) at Week 0, Week 4, week 8 and week 16. UST trough levels were measured at 4, 8 and 16 weeks using a commercially available validated enzyme-linked immunosorbent assay (ELISA).

Main outcome was biochemical remission, defined by a decreased of calprotectin levels more than 80% or an absolute value less than 200 mg/g at week 16.

Results: Seventy-six patients were included. Patients' Characteristics at baseline are listed in table 1. Median [IQR] HBI was 5,5 [3-8] at the beginning of treatment. Evolution of biochemical parameters throughout induction is showed in table 2.

At the end of the induction phase (week 16), HBI, CRP and FCP decreased significantly from baseline. At this moment HBI was less than 2 in 51% of patients. FCP was available in 63 patients. Biochemical remission was observed in 26/63 (41,3%) patients. Median [IQR] UST serum concentrations were 20,9 µg/mL [13,7–26,3] at w4, 10,1 µg/mL [3,5–7,4] at w8 and 4,1 µg/mL [1,4–3,9] at w16. Quartile analysis demonstrated that 100% and 66% with an UST serum concentration in the highest quartile [Q4], at w4 and w8, achieved a biochemical remission by w16 [$p = 0.05$ and $p < 0,02$ respectively]. The area under the receiving operating characteristic curve (AUROC) of UST levels to predict biochemical remission at week 4 and week 8 were 0,84 $CI_{95\%}$ (0,62-1) and 0,74 $CI_{95\%}$ (0,57-0,91) respectively.

Conclusion: Serum concentrations of UST at week 4 and 8 after intravenous infusion could be used to stratify patients according to the probability of achieving remission. This measurements during induction could be used to optimize treatment of CD.

Introduction: Patients with IBD often have related anxiety and depression which may negatively impact disease activity and have been consistently highlighted as an unmet need by patient groups. Timely access to psychiatric and psychological support can be difficult and costly.

We investigated the effectiveness of a novel cognitive behavioural therapy (CBT) program delivered by a trained mental health nurse in place of a formal psychologist.

Aims & Methods: A retrospective review of all CBT referrals made for adult patents between Sep 2019 – Dec 2022 in a tertiary IBD Centre. Referrals were from IBD Consultants, senior medical Trainees, IBD Nurses and a liaison psychiatrist. Patients are offered high-intensity CBT for up to 8 consecutive weeks as per local protocol of a minimum 4 sessions. The CBT took place virtually; over the phone or video call via MS Teams. Patients who completed at least 4 sessions of CBT were included in this review.

Our primary measure was to assess if there was an improvement in mental health using CORE-10, a brief validated psychometric questionnaire, completed at the start and end of therapy. A score of greater than 11 was an indicator of psychological distress, and a reduction of 6 points is clinically meaningful[i].

Results: 96 patients were referred to the inflammatory bowel disease CBT service. Of those 47 patients went on to complete at least 4 sessions of CBT, with an average age of 33. 91% of referrals were for either anxiety or depression. With other cited indications including; anger management, PTSD and functional pain.

15 patients (32%) had UC, 31 patients (66%) had Crohn's disease and 1 patient had indeterminate colitis. The majority of patients had 8 sessions of CBT of which all were completed virtually. The average disease duration was least 8 years at the time of referral.

26 (55%) of patients were on biologics at the time of initiating CBT, with 23% patient of patients referred having undergone at least one surgery prior to referral. Physician global assessment at the initiation of CBT showed 25 (56%) patients were in clinical remission. 21 (45%) patients were in clinical remission following their course of CBT.

Following the completed CBT sessions 37 patients had some improvement in their CORE-10 score with a mean reduction for all patients of 7.6. 20 patients had a CORE-10 reduction of at least 6. 33 patients (70%) had a CORE10 score of >11 at baseline, indicating significant psychological distress. Of the 33 patients with an initial score >11, 20 patients 61% showed reliable clinical improvement.

10 patients (21%) referred for CBT showed, either an increase (8 patients) or no change (2 patients) in their CORE10 score following at least 4 sessions of CBT.

Conclusion: Studies have consistently demonstrated a high burden of anxiety amongst patients with IBD which can have a detrimental effect on quality of life and disease outcomes. CBT delivered by a trained mental health nurse is an effective and relatively low-cost intervention for patients with IBD, delivering beneficial treatment outcomes, and maintaining good levels of engagement; including those with a severe phenotype of disease.

CBT did not significantly influence disease activity as measured by physician global assessment.

Introduction: Ustekinumab has been recently approved for the treatment of moderately to severe ulcerative colitis (UC). Data from the UNIFI clinical trial are encouraging; nevertheless, real-world assessment is needed.
Aims & Methods: We assess the effectiveness, safety and pharmacokinetics of ustekinumab in a cohort of refractory UC patients.
Multicentre and observational study of UC patients who received ustekinumab for active disease. Values for Partial Mayo Score (PMS), endoscopic activity, C reactive protein (CRP) and faecal calprotectin (FC) were recorded at baseline and at weeks 8, 24 and 52 weeks and at 18 and 24 months when was possible. Demographic and clinical data, previous treatments, adverse events (AEs), surgeries and hospitalizations were documented. Possible predictors of response were examined.
Results: Two patients only received the first IV dose. During follow-up, 58 patients (54%) required interval reduction (every 4 weeks (76%) and every 6 weeks (24%)) after a median of 22.3 weeks [11.6, 41.2]. Intravenous reinduction doses were administered to 20 (18.5%) after 27.7 weeks [6.64, 56.3]. Three patients required a maintenance therapy with IV administration. The clinical remission (PMS≤ 2) rates were 39.6%, 41%, 51% at 8, 24 and 52 weeks, respectively, and 61%, and 57.7% at 18 and 24 months, respectively. FC levels returned to normal (<250 µg/g) in the 39.6%, 41%, 51%, 61%, 58% of the patients at weeks 8, 24 and 52 and at 18 and 24 months respectively. CRP returned to normal (<3 mg/L) in the 79%, 75%, 76.5%, 71% and 70% of the patients at weeks 8, 24 and 52 and at 18 and 24 months respectively.
Fewer previous anti-TNF agents and the loss of response to anti-TNF were associated with clinical response and with normalization of FC respectively. No variables at baseline (body mass index, serum albumin, and lymphocytes count) were associated with ustekinumab through levels. Of the 17 patients with endoscopy before and after treatment, 6 were in remission and 3 with mild activity. The AEs were recorded in 5 (4.6%) patients, 12 (11%) were hospitalized and 9 (8.3%) had surgery. A total of 23 patients (21%) discontinued ustekinumab over time, the persistence rates were 98%, 91%, 83% and 81% at 8, 24, 48 and 96 weeks respectively.
Conclusion: This is the first study to show the real-world long-term effectiveness, persistence, endoscopic improvement and safety of ustekinumab in a cohort of highly refractory UC patients. The clinical remission preceded the FC normalization. Ustekinumab through levels and their pharmacokinetic require further investigations.
Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel disease (IBD) commonly affects female patients of reproductive age, making the interaction between fertility, pregnancy and IBD an important issue in disease management. The effect of disease activity on the outcome of pregnancy and its impact on neonatal growth is a field of intense research. Close follow-up of pregnant IBD patients by a multidisciplinary team improves maternal and neonatal outcomes.

Aims & Methods: A national retrospective study of pregnancies in women with IBD between 2010-2020 was carried out in 22 IBD reference centers in Greece. Patient characteristics such as disease profile, type of treatment, and disease activity during gestation were analyzed in correlation to the method of delivery, pregnancy outcomes, as well as breastfeeding and offspring health.

Results: Two-hundred and twenty-three pregnancies in 175 IBD patients were registered in the study. 122 with Crohn's disease (CD). Median age during diagnosis was 25.6 years (12-44) with median disease duration of 7.4 years (0-23). One-hundred and twenty-nine patients (58%) were recorded during their first pregnancy. Early pregnancy termination was reported by 48 patients (22%). Pregnancy as a result of *in vitro* fertilization (IVF) occurred in 15 cases (6.7%). At the beginning of gestation 165 patients (74%) were under treatment: 48 with anti-TNF agents (29%), 43 with azathioprine (26%), 101 with 5-aminosalicylic acid formulations (61%) and 12 with steroids (7%). We recorded 49 cases of IBD flares (22%) during pregnancy. Two-thirds of them (n=30) were in remission at the onset of the pregnancy. Almost half of them (n=22) required corticosteroid treatment. Patients with ulcerative colitis (UC) were in greater risk of disease flare during pregnancy (p<0.001). All but 3 pregnancies (99.1%) resulted in uncomplicated delivery. In 147 cases (67.1%) *cesarean* delivery was performed. Two late fetal deaths (0.9%) were reported, both in patients with continuously active disease since the beginning of pregnancy. After delivery, 75 patients (34%) presented with a disease flare, which was associated with active disease at the beginning of pregnancy (p <0.001).

Mean age of diagnosis (years)	**25.6 (12-44)**

Table 1. Demographics and characteristics of the cohort

Conclusion: The majority of female, Greek IBD patients, had a favorable pregnancy outcome. Active inflammation during gestation and UC diagnosis were associated with a negative impact on pregnancy outcomes. The results of this study are in favor of the continuation of IBD treatment during pregnancy.

This study was funded by a research grant 2020EOMIFNEmp1 from the Hellenic Group for the Study of IBD (EOMIFNE)

Introduction: Predicting and monitoring methotrexate (MTX) responses in patients with Crohn's disease (CD) is presently not possible. Measurement of MTX-polyglutamates (MTX-PGs) in red blood cells (RBC) might enable therapeutic drug monitoring (TDM) as shown in other immune-mediated inflammatory diseases. Our aims were to assess the relation between MTX-PGs and treatment response, and to identify predictors of response in CD patients treated with MTX.

Aims & Methods: In a multicenter prospective cohort study, CD patients starting subcutaneously (s.c.) MTX without biologics were included and followed for one year. At baseline, clinical and biochemical parameters were recorded. 8,12, 24, and 52 weeks after start of therapy or when dropping out, blood samples were collected and individual MTX-PG levels ($MTX\text{-}PG_1$ - $MTX\text{-}PG_5$) were assessed in RBCs using mass spectometry. Primary outcome was either s.c. MTX discontinuation or initiation of step-up therapy due to disease activity or toxicity. MTX-PGs were analysed in an extended Cox model, and corrected for prednisone (at start) and budesonide. Secondary outcomes included biochemical disease activity, measured with fecal calprotectin (FCP).

Results: Eighty CD patients enrolled (mean age 55±13y, 35% male) with a median FCP of 268 µg/g (IQR 73-480). After one year 21 patients were still on MTX sc monotherapy. Twenty-one patients stopped MTX because of disease activity, 29 because of toxicity, and four because of a combination of both reasons (5 patients censored: ended study participation or stopped MTX because of undefined reasons).

$MTX\text{-}PG_3$ was the most abundant MTX-PG species with a median concentration of 51 nmol/L RBC (IQR 37-62) at week 12. A higher $MTX\text{-}PG_3$ concentration was associated with a higher rate of MTX drug survival (HR 0.86:for every 10 nmol/L increase in $MTX\text{-}PG_3$ the rate of MTX discontinuation decreased with 14%, 95%CI 0.75-0.99), lower FCP (β -3.7, SE 1.3) as well as biochemical response (FCP < 250, OR 1.1, 95% CI 1.0-1.3).

A higher HBI at baseline was associated with an increased rate of s.c. MTX monotherapy discontinuation (HR 1.08, 95% CI 1.02-1.16). Predictors of discontinuation due to disease activity (cause specific hazards) were male sex (3.83, 1.62-9.05), baseline eGFR (1.06, 1.02-1.09), baseline HBI (1.12, 1.02-1.23) and baseline plasma folate (0.94, 0.88-0.99). Sex and plasma folate were not correlated with HBI. No toxicity-specific predictors for stopping MTX could be identified.

Conclusion: RBC $MTX\text{-}PG_3$ concentrations are related to better MTX drug-survival and decreased biochemical disease activity. Therefore, the measurement of RBC $MTX\text{-}PG_3$ holds potential as a tool for TDM. Lower plasma folate at baseline and male sex are predictors for MTX-specific failure in the first year.

Disclosure: Nothing to disclose.

IMPLICATIONS OF TIOGUANINE DOSING IN IBD PATIENTS WITH A TPMT DEFICIENCY

Introduction: Tioguanine is metabolised by less enzymatic steps compared to azathioprine and mercaptopurine, without generating 6-methylmercaptopurine ribonucleotides. However, thiopurine S-methyl transferase (TPMT) plays a role in early toxicity in all thiopurines. We aimed to describe the hazards and opportunities of tioguanine use in inflammatory bowel disease (IBD) patients with aberrant TPMT metabolism and propose preventative measures to safely prescribe tioguanine in these patients.

Aims & Methods: In this retrospective cohort study, all determined *TPMT* genotypes (2016 – 2021) were evaluated for aberrant metabolism (*i.e.* intermediate and poor TPMT metabolisers). Subsequently, all IBD patients on tioguanine with aberrant *TPMT* genotypes were evaluated for tioguanine dosages, adverse drug events, lab abnormalities, treatment duration and effectiveness.

Results: *TPMT* genotypes were determined in 485 patients of whom 50 (10.3%) and 4 patients (0.8%) were intermediate and poor metabolisers, respectively. Of these patients, 12 intermediate and 4 poor TPMT metabolisers had been prescribed tioguanine in varying doses. In one poor TPMT metaboliser, tioguanine 10 mg/day induced delayed pancytopenia. In general, reduced tioguanine dosages of 5 mg/day for intermediate TPMT metabolisers, and 10 mg two-weekly for poor TPMT metabolisers, resulted in a safe, long-term treatment strategy.

Conclusion: Diminished or absent TPMT enzyme activity was related with a pharmacokinetic shift of tioguanine metabolism which is associated with relatively late occurring myelotoxicity in patients on standard tioguanine dose. However, in strongly reduced dose regimens with strict therapeutic drug and safety monitoring, tioguanine treatment remained a safe and effective option in IBD patients with dysfunctional TPMT.

Disclosure: The authors disclose no conflicts of interest with respect to this manuscript.

ECONOMIC BURDEN OF SUBOPTIMAL TREATMENT WITH CORTICOSTEROID OVERUSE FOR ULCERATIVE COLITIS

S. Horst[1], K.A. Betts[2], X. Nie[2], S.Y. Gao[2], D. Paul[3]
[1]Vanderbilt Inflammatory Bowel Disease Clinic, Nashville, United States, [2]Analysis Group, Inc., Los Angeles, United States, [3]Bristol Myers Squibb, Princeton, United States

Introduction: Conventional therapy is recommended for the treatment of mild-to-moderate ulcerative colitis (UC); however, patients (pts) are often unable to maintain durable responses and may be suboptimally treated with the overuse of corticosteroids (CS). Some studies on advanced therapies have reported pts achieving CS-free remission, which may benefit pts with UC. This study characterizes CS overuse and the associated economic burden.

Aims & Methods: Data were extracted from the IBM MarketScan Commercial and Medicare Supplemental Databases (January 1, 2014–March 31, 2021) for pts (age ≥18 years) with ≥2 UC diagnoses (≥90 days apart) who received first-line (1L) conventional therapy and had continuous enrollment for 6 months before and 4 years after treatment initiation, respectively. Conventional therapy included aminosalicylates (5-ASA), immunomodulators (IM), CS monotherapy, and CS combination therapy. CS overuse was identified if pts had an episode of receiving CS for a continuous period of >90 days or ≥2 episodes within 1 year. For pts with CS overuse, the index date was defined as the earlier of the 91st day of a CS episode or the initiation date of the second CS episode within 1 year. For pts without CS overuse, the index date was defined as 12 months after the initiation of 1L conventional therapy. All-cause healthcare resource use (HCRU) and costs incurred in terms of per pt per year (PPPY) were evaluated for pts with and without CS overuse at baseline (6 months before the index date) and during the follow-up period (from the index date to the end of 4 years after initiation of 1L).

Results: Overall, 4004 pts were included. Of these, 1820 (45.5%) pts had CS overuse. Median time from 1L treatment initiation to CS overuse was 9.4 (interquartile range, 4.5–23.0) months. Pts with CS overuse were less likely to receive mesalamine monotherapy in 1L (28.1% vs 56.7%) (Table). For pts with and without CS overuse, the baseline mean PPPY medical costs were $15,942 and $5964 ($P$<0.001), and total mean drug costs were $6051 and $6970, respectively ($P$<0.001). During the follow-up period, pts with CS overuse had higher inpatient (24.6% vs 14.2%; P<0.001) and emergency room visits (59.0% vs 50.5%; P<0.001) than those without; for pts with and without CS overuse, total mean medical costs were $10,418 and $4922 ($P$<0.001), and total mean drug costs were $9951 and $5923 ($P$<0.001), respectively.

	Pts with CS overuse (N=1820)	Pts without CS overuse (N=2184)
Age, mean ± standard deviation, years	47.7 ± 13.1	46.4 ± 12.5
Female, n (%)	1040 (57.1)	1171 (53.6)
Conventional therapies received in 1L, n (%)		
Mesalamine	511 (28.1)	1239 (56.7)
CS	780 (42.9)	393 (18.0)
CS + mesalamine	359 (19.7)	244 (11.2)
IM	10 (0.5)	36 (1.6)
IM + mesalamine	4 (0.2)	22 (1.0)
Other regimens[a]	156 (8.6)	250 (11.4)

[a]Balsalazide monotherapy, olsalazine monotherapy, and combinations of CS, IM, and 5-ASA.

Table. Pt characteristics and treatment use.

Conclusion: Approximately half of pts with UC had overused CS while being treated with conventional therapies. In these pts, all-cause HCRU during follow-up, and costs at baseline (except for drug costs) and during follow-up were significantly higher compared with those without CS overuse, suggesting a need for other more effective therapies to be considered for the treatment of these pts. Pts with UC currently treated with prolonged CS courses may benefit from early use of advanced therapies, which are associated with the induction of CS-free remission.

Introduction:

Upadacitinib, an oral, selective, and reversible Janus kinase inhibitor (JAKi), vedolizumab (VEDO), an α4β7 integrin monoclonal antibody, ustekinumab (UST), an IL-12/23 inhibitor, and tofacitinib (TOFA), a pan JAKi, are all approved therapies for patients with moderately to severely active ulcerative colitis (UC). Evidence on their comparative efficacy and safety during maintenance are lacking.

Aims & Methods: Separate placebo (PBO)-anchored matching-adjusted indirect comparisons (MAIC) of the efficacy and safety of UPA vs VEDO, UST, and TOFA during maintenance were conducted. Induction responders were rerandomized in the phase 3 maintenance studies to oral UPA 15 or 30 mg once daily or PBO in U-ACHIEVE, VEDO 300 mg intravenous or PBO in GEMINI-1, UST 90 mg subcutaneous or PBO in UNIFI, and oral TOFA 5 mg twice daily or PBO in OCTAVE Sustain. Efficacy outcomes at maintenance weeks 44(UST)/46(VEDO)/52(UPA/ TOFA) were adjusted by the likelihood of induction clinical response to assess treat-through efficacy in the intent-to-treat population. Outcomes included clinical response (decrease in Full Mayo score [FMS] ≥3 points and ≥30% and decrease in rectal bleeding score [RBS] of ≥1 or an absolute RBS of 0 or 1), clinical remission (FMS ≤2 with no subscore >1, plus RBS of 0 for UPA vs TOFA [remission]), and endoscopic improvement (EI, endoscopic subscore 0 or 1). Safety outcomes included adverse events (AEs), serious AEs (SAEs), and AEs leading to discontinuation (except for UPA vs VEDO). Select baseline characteristics from the UPA trial were weighted to match the VEDO, UST, or TOFA trials, separately. Numbers needed to treat or harm (NNT or NNH) were calculated as the inverse of the difference in proportions of patients demonstrating each outcome between UPA and VEDO, UST, or TOFA to assess benefit-risk.

Results: Greater proportions of patients receiving UPA 15 mg vs VEDO demonstrated clinical response, clinical remission, and EI (difference in proportions>0; $p<0.05$) and achieved clinical response and EI with UPA vs TOFA ($p<0.05$). Significantly greater proportions of patients receiving UPA 30 mg vs VEDO, UST, or TOFA demonstrated all efficacy outcomes (difference in proportions>0; $p<0.05$), with NNTs <8.7. Difference in proportions of AEs, SAEs, and AEs leading to discontinuation were small and not statistically different between both doses of UPA and the studied comparator therapies.

Conclusion: After 1 year of maintenance, greater clinical efficacy and similar safety was observed with UPA vs VEDO, UST, or TOFA in patients with active UC, suggesting a favourable benefit-risk profile of UPA vs other advanced therapies. Differences in trial design, such as variable timing of rerandomization and dosages and assessment times, and endpoint definitions may persist and impact responder profiles.

[a]For efficacy outcomes, treat-through results are calculated as: (induction MAIC response rate) x (maintenance MAIC efficacy rate). Standard errors were calculated as square root of the variance for product of two independent variables (i.e., induction MAIC response rate and maintenance MAIC efficacy rate). [b]UPA data are individual patient-level results while VEDO, UST, or TOFA data are aggregated published results. Core baseline characteristics used in the weighting included age, gender, extent and duration of disease, total Mayo score, and prior UC medication/biologic usage. [c]Difference in proportions between advanced therapies (UPA arms vs comparators) are shown in bold; otherwise, differences are shown vs placebo. [d]Positive (negative) NNTs denote greater (lower) efficacy of UPA vs comparator, and positive (negative) NNHs denote greater (lower) safety risk of UPA vs comparator. [e]Broad safety outcomes are included because they were collected consistently across clinical trials. [f]Data were not available in the VEDO GEMINI-1 maintenance phase 3 trial. *P*-value equals *<0.05, **≤0.01, ***<0.001. AEs, adverse events; EI, endoscopic improvement; N/A, not applicable; NNH, number needed to harm; NNT, number needed to treat; PBO, placebo; SAEs, serious adverse events; UPA15, upadacitinib 15 mg; UPA30, upadacitinib 30 mg; UST90, ustekinumab 90 mg; TOFA5, tofacitinib 5 mg; VEDO300, vedolizumab 300 mg.

MAINTENANCE THERAPY AFTER AN EPISODE OF STEROID-RESPONSIVE ACUTE SEVERE ULCERATIVE COLITIS: WHAT IS THE BEST STRATEGY?

Introduction: Althouth the advances in treatment of inflammatory bowel disease, the best maintenance therapy after steroid-responsive acute severe ulcerative colitis (ASUC) is still controversial.

Aims & Methods: Our goal was to compare the outcomes of starting different treatment regimens in patients with steroid-responsive ASUC. We did a retrospective single-centre cohort study including all patients hospitalized with ASUC, between 2014-2022, who responded to steroids according to Oxford Criteria. Patients were divided in two groups according to the maintenance treatment after ASUC episode - 5-ASA/immunomodulator (IMM) or biological therapy. Short (<1 year) and long-term (>1 year) outcomes after ASUC hospitalization were assessed. The primary outcome was a composite outcome defined by proximal disease extension, therapy escalation (including steroids), new hospitalization or colectomy.

Results: 32 steroid-responsive patients were included, 31% were male. Baseline characteristics are shown in Table 1.

Overall, 28% of patients were discharged with 5-ASA/IMM and 72% with biologics (infliximab, vedolizumab, golimumab). During a median follow up of 3 years (IQR 1.7-4.9), 50% of patients needed a new course of steroids, 3% presented proximal disease extension, 53% needed therapy escalation, 31% required a new hospitalization and 16% underwent colectomy. Regarding the composite outcomes, no differences were found between the two groups in short-term outcomes.

In long-term-outcomes, patients treated with biologics had a lower rate of events, comparing with patients treated with 5ASA/IMM (67% vs 17%, p=0,013), and a trend towards to a longer time without events (log-rank p=0,093).

Baseline characteristics	5-ASA/IMM (n=9)	Biologic (n=23)	p-value
Clinical and demographic characterization			
Age at diagnosis, y (mean ± SD)	38±19	41±19	0.660
Disease extension at diagnosis, n (%) E1 | E2 | E3	1 (11) | 3 (33) | 5 (56)	2 (9) | 7 (30) | 14 (61)	0.957
Need of steroids before this hospitalization, n (%)	1 (11)	13 (57)	0.044
Previous medication, n (%)			
Aminosalicylates	4 (44)	19 (83)	0.075
IMMs	0 (0)	5 (22)	0.288
Biologic	0 (0)	6 (26)	0.150
ASUC hospitalization characterization			
Endoscopic severity, n (%) Mayo 2 | Mayo 3	6 (67) | 3 (33)	7 (30) | 16 (70)	0.109
Hospitalization duration, days (median, IQR)	7 (6-9)	10 (8-14)	0.022
Steroids response, n (%)			
Complete	7 (78)	7 (30)	0.022
Incomplete	2 (22)	16 (70)	

IMMs – Immunomodulators; IQR – Interquartile range; SD – Standard deviation; UC – Ulcerative colitis; y – Years.

Table 1. Baseline and hospitalization characterization, accordingly to maintenance therapeutic regimen after steroid-responsive ASUC episode.

Conclusion: In our cohort, no differences were found in short-term outcomes. However, in long-term outcomes, patients treated with biologic had a lower rate of events and a trend towards to a longer time without events, suggesting this may be a better strategy. Our sample size and the low number of patients on 5-ASA/IMM limit our conclusions, further studies with larger sample size and longer follow-up are needed.

Disclosure: Nothing to disclose.

Introduction: The efficacy and safety of upadacitinib (UPA), an oral, reversible Janus kinase (JAK) inhibitor approved for the treatment of moderately to severely active Crohn's disease (CD),[1,2] has been demonstrated in two phase 3 induction studies (U-EXCEL, NCT03345849[3]; U-EXCEED, NCT03345836[4]) and a phase 3 maintenance study (U-ENDURE, NCT03345823[5]). An association between shorter disease duration and improved outcomes has been shown in post hoc analyses of clinical trial data with other advanced CD therapies.[6,7]

We therefore conducted a post hoc analysis of data from these phase 3 UPA studies to assess the potential impact of CD duration on UPA efficacy.

Aims & Methods: Patients in the induction studies were randomized 2:1 to receive UPA 45 mg (UPA45) or placebo (PBO) once daily for 12 weeks.[2,3] Patients achieving clinical response per stool frequency and/or abdominal pain score (SF/APS) criteria were re-randomized 1:1:1 in the maintenance study to UPA 30 mg (UPA30), UPA 15 mg (UPA15), or PBO once-daily for 52 weeks.[4] Efficacy was evaluated in patient subgroups stratified by CD duration at baseline (< 2 years, 2–5 years, >5–10 years, and >10 years). Endpoints evaluated at week 12 (induction) and week 52 (maintenance) included achievement of clinical remission (per average daily very soft/liquid SF/APS and per Crohn's Disease Activity Index [CDAI]), normalization of fecal calprotectin and high-sensitivity C-reactive protein levels for patients with elevated baseline levels, endoscopic response, endoscopic remission, and mucosal healing.

Results: Baseline patient and disease characteristics were generally similar across CD duration subgroups during induction (N = 1021). UPA45 demonstrated nominally greater improvement vs PBO in efficacy endpoints across most CD duration subgroups at week 12 (Table). UPA45-treated patients with a shorter disease duration had numerically greater endoscopic improvement vs patients with longer disease duration, and nominally greater endoscopic improvement vs patients receiving PBO at week 12 (Table).

Endpoint by CD duration at baseline, % (n/N)	Induction, Week 12 (U-EXCEL and U-EXCEED, pooled)		Maintenance, Week 52 (U-ENDURE)

APS, abdominal pain score; CD, Crohn's disease; CDAI, Crohn's disease activity index; FCP, fecal calprotectin; hs-CRP, high-sensitivity C-reactive protein; PBO, placebo; QD, once daily; SES-CD, Simple Endoscopic Score for Crohn's Disease; SF, stool frequency; UPA, upadacitinib; y, years.
[a]Average daily SF ≤ 2.8 and average daily APS ≤ 1.0, and both not greater than baseline.
[b]CDAI < 150.
[c]FCP normalization to ≤ 250 mg/kg among patients with elevated baseline levels.
[d]hs-CRP normalization to ≤ 5 mg/L, among patients with elevated baseline levels.
[e]Decrease in SES-CD > 50% from baseline (or for patient with a baseline SES-CD of 4, ³ 2-point reduction from baseline) .
[f]SES-CD ≤ 4 and ³ 2-point reduction from baseline and no subscore > 1 in any individual variable.
[g]SES-CD ulcerated surface subscore of 0.
*$P \leq .05$; **$P \leq .01$; ***$P \leq .001$ vs PBO. All P-values are nominal and not multiplicity adjusted.

Table. Efficacy Outcomes by Baseline CD Duration During Induction and Maintenance Studies.

Further, the clinical remission rate per CDAI at week 12 was numerically higher with UPA45 vs PBO in patients with CD duration < 2 years, and was nominally higher vs PBO in other CD duration subgroups (Table). Consistent with induction outcomes, UPA30 and UPA15 demonstrated nominally or numerically greater improvement in efficacy endpoints vs PBO regardless of disease duration at week 52 (Table); there was also a general trend towards greater improvements in efficacy outcomes in patients with a shorter disease duration.

Conclusion: Regardless of disease duration, UPA demonstrated positive clinical and endoscopic outcomes in patients with moderately to severely active CD. Achievement of endoscopic endpoints was numerically higher in patients with shorter vs longer duration of CD, suggesting initiation of UPA earlier in the disease course may lead to better outcomes for patients.

Introduction: Intestinal fibrosis is a common complication of inflammatory bowel diseases (IBD) characterized by increased production of extracellular matrix and crosslinking enzymes by intestinal mesenchymal cells. The advanced process of fibrosis leads to strictures often requiring surgical treatment. Therefore new methods of treatment of intestinal fibrosis are sought with endocannabinoid system (ES) as a potential therapeutic target. Cannabinoid receptors 1 and 2 (CB1 and CB2, respectively) are classic receptors of the ES involved in the regulation of the intestinal mucosa inflammation and permeability. Studies show that the regulation of ES activity can affect the process of fibrosis in various preclinical models of fibrosis.

Aims & Methods: The primary purpose of the study was to evaluate the effect of selective CB1 agonist, WIN 55, 212-2 (WIN) on expression of fibrosis regulatory proteins: alpha smooth muscle Actin 2 (Acta2), Collagen I (Coll), Fibronectin 2 (Fn2) and SMAD family member 3 (Smad3) in a mice model of Dextran sulfate sodium (DSS)-induced intestinal fibrosis. Moreover, the expression of the named proteins in colonic samples of patients with ulcerative colitis (UC) and healthy controls (HC) was compared.

Chronic colitis and fibrosis in mice model were induced by oral administration of 1.5% DSS in rotation with tap water for 3 weeks in three cycles. WIN was administrated starting from day 10th and continued every other day until day 77th, control mice were administered with saline. The mice were sacrificed on day 78th, their colon was excised and samples were taken for molecular analysis. Colonic samples from patients with UC and HC were collected and frozen for further exploration. The expression of genes encoding Acta2, Smad3, Col1, Fn2 in mouse and human material was assessed by Real Time RT-PCR. Statistical analysis was conducted using Student's t-test to compare means of expressed molecules.

Results: We found lower relative expression of genes encoding assessed fibrosis regulatory proteins in mice treated with WIN than in inflamed mice: 4698±2323 vs. 9656±6032 for ACTA2, 4774±1073 vs 8510±2906 for COL1, 20993±7280 vs. 52148±17877 for FN1 and 373±31 vs. 478±77 for SMAD3. In human samples we noticed higher relative mean expression level of COL1 and SMAD3 in patients with UC compared to 7 HC 37422±6554 vs. 23816±2681 and 2134±261 vs. 1593±255, respectively.

Conclusion: We observed a decrease in relative expression of FN1, ACTA2, COL1, SMAD3 in samples from mice treated with CB1 agonist compared to inflamed mice. Also, a difference in expression of these proteins were found in intestinal samples from UC patients compared to HC, indicating a contribution of these molecules to intestinal fibrosis. Our results show that regulation of ECS activity play role in the inhibition of the intestinal fibrosis in IBD and appears as a potential therapeutic target in patients at high risk of developing strictures.

EFFECTS OF THE MONASH POUCH DIET ON VOLATILE ORGANIC COMPOUNDS (VOC) IN THE POUCH LUMEN IN PATIENTS WITH AN ILEOANAL POUCH

Z. Ardalan[1], K. Green[2], M. Sparrow[1], P.R. Gibson[1], C.S.J. Probert[2], C.K. Yao[1]

[1]Monash University & Alfred Hospital, Department of Gastroenterology, Melbourne, Australia, [2]University of Liverpool, Department of Molecular and Clinical Cancer Medicine, Liverpool, United Kingdom

Contact E-Mail Address: chu.yao@monash.edu

Introduction: The Monash Pouch diet is a multi-prong diet strategy that theoretically targets 'correction' of the microbial metabolic activities, namely excessive sulphide reduction and protein fermentation in the pouch. The diet has previously been shown to be a feasible, highly tolerated and acceptable diet to patients with an ileoanal pouch with signals for clinical improvements[1].

Aims & Methods: The study aimed to assess the effects of the 5-week dietary intervention on the pouch microenvironment via volatile organic metabolites in patients with an ileoanal pouch. In a pilot, open-label study, patients with an ileoanal pouch for ulcerative colitis received dietary advice on a Monash Pouch diet for 5 weeks. They were instructed to restrict osmotically active carbohydrates, total and animal protein, sulphate/sulphite preservatives and carrageenan while increasing oligosaccharide intake. Faecal samples were collected at baseline and at the end of the 5-week intervention and analysed for VOCs using gas-chromatography-mass spectrometry. Changes in VOC were compared particularly for bacterial fermentative metabolites. Results were analysed using Metaboanalyst (version 5.0) and metabolites of interest were defined by paired fold-change analysis.

Results: Eleven patients (6 men, mean age 55 years) completed the dietary intervention and provided faecal samples. Average number of VOCs detected between baseline and post-diet intervention (53 (9) vs 55 (7); p=0.59; paired t-test) were not significantly different. At baseline, percentage occurrence of protein fermentation metabolite was the highest for phenols (9/11, 81%) whereas the branched-chain fatty acids, 2- and 3-methylbutanoic acid (isovalerate) (45% and 64% respectively) and 2-methylpropanoic acid (isobutyrate) (54%), were detected. No volatile sulphur compounds

were detected. The dietary intervention saw no significant changes in ethanoate (acetate) (p=0.88), propanoate (propionate) (p=0.44), butanoic (butyrate) (p=0.57) or any of protein fermentation metabolites (p>0.15). Fold-change analysis identified six important features that were altered from pre- to post-intervention. Ethyl-2-methylbutanoate (fold change: 4.07; Log_2 2.03), 3-isothiocyanatoprop-1-ene (2.01; Log_2 1.01) increased whilst pentane-2,3-dione (0.48; Log_2 -1.07), propanal (0.49; Log_2 -1.02) and 7-methyl-3-methylideneocta-1,6-diene (0.49; Log_2-1.02) decreased. Of the known bacterial fermentation metabolites, there was a trend for changes in intake of animal protein to correlate with changes in 3-methylbutanoic acid(r=0.57; p=0.07) and a significant correlation between fibre intake and propanoic acid (r=-0.66; p=0.03).

Conclusion: VOC analysis of ileal effluent has provided signals that protein fermentation may not be prominent (low concentrations of metabolites associated with protein fermentation) and that the Monash Pouch diet paradoxically shifted pouch microbial fermentation towards increased proteolytic activities (increased ethyl-2-methylbutanoate), suggesting the dietary strategy may require modification. However, given the small sample size of this cohort, these results should be interpreted with caution and the fold-change data be regarded as clues to VOCs that may be significant in a larger cohort of ileoanal UC pouch patients.

IS USTEKINUMAB EFFECTIVE IN CROHN'S DISEASE PATIENTS WITH PARADOXICAL SKIN REACTIONS CAUSED BY TUMOR NECROSIS FACTOR-ALPHA INHIBITORS?

S. Hosomi[1], K. Fujimoto[1], Y. Kobayashi[1], R. Nakata[1], Y. Nishida[1], M. Ominami[1], S. Fukunaga[1], K. Otani[1], N. Kamata[1], F. Tanaka[1], Y. Nagami[1], K. Taira[1], Y. Fujiwara[1]

[1]Osaka Metropolitan University Graduate School of Medicine, Gastroenterology, Osaka, Japan

Introduction: Ustekinumab (UST) is becoming widely used as a therapeutic option for Crohn's disease (CD) as a biologic agent with a novel mechanism of interleukin (IL)-12/23 inhibition, which is expected to have therapeutic effects on pathology involving factors other than tumor necrosis factor (TNF)-α.

In this study, we investigated the effect of UST on skin lesions and the rate of subsequent continuous maintenance treatment of CD with skin lesions that appeared as a paradoxical reaction to TNF-α inhibitor (TNFi).

Aims & Methods: Fifty-four patients with CD who were introduced UST as 2nd or 3rd Bio at our hospital from June 2017 to September 2020 were retrospectively enrolled in the study. We defined treatment discontinuation as hospitalization, surgery, or treatment change due to CD exacerbation. The cumulative continuous maintenance dose rate was calculated by the Kaplan-Meier method.

Results: Of the 54 patients, 10 had skin lesions as a paradoxical reaction to the previous TNFi. Eight patients were males, and 2 were females. The median (interquartile range) values for each were: age, 35.4 (32.9–39.2) year-old; disease duration, 13.4 (6.4–18.1) years; Harvey-Bradshaw Index (HBI), 3 (1–5.5); CRP, 0.22 (0.04–0.38) mg/dL, Alb 3.95 (3.6–4.4) g/dL. Infliximab in 4 patients and adalimumab in 6 patients were used as the last TNFi. Of the 10 patients in the group with the paradoxical reaction, 4 (50%; 2 psoriasiform eruptions, 2 folliculitis, and 1 palmoplantar pustulosis) achieved complete response of skin lesions, 5 (50%; 2 psoriasiform eruptions and 2 exacerbations of atopic dermatitis) achieved partial response. After 1 year of UST induction, the cumulative continuous treatment rate was 56.3% in the group with no paradoxical reaction and 70% in the group with paradoxical reaction, and there was no statistical difference between the two groups (Log-rank; P = 0.349). A univariate Cox regression analysis also showed that the clinical history of skin paradoxical response was not associated with UST sustained efficacy (Table).

Risk factors	Reference	HR(95%CI)	P value
Gender, Female	Male	0.97 (0.39-2.42)	0.95
Disease duration(yr)		0.99 (0.95-1.03)	0.53
Disease behavior, B2	B1	0.23 (0.07-0.73)	0.013
Disease behavior, B3	B1	0.14 (0.04-0.50)	0.0025
Perianal disease, Yes	No	0.51 (0.24-1.09)	0.082
Harvey–Bradshaw index at induction		1.05 (0.97-1.13)	0.27
Bio exposure, Double	Single	1.29 (0.6-2.76)	0.51
Concomitant IM, Yes	No	1.36 (0.62-2.98)	0.44
Skin paradoxical reaction, Yes	No	0.60 (0.21-1.76)	0.35

Conclusion: UST was highly effective in treating skin lesions as a paradoxical reaction to TNFi (90% partial or complete response). The cumulative continuous treatment rate after induction of UST was comparable to that of the group without paradoxical skin reaction, indicating that UST is useful for treating CD with paradoxical skin reaction to TNFi.

INFLUENCE OF VITAMIN D SUPPLEMENTATION ON THE CLINICAL EFFICACY OF USTEKINUMAB IN PATIENTS WITH CROHN'S DISEASE: A RETROSPECTIVE ANALYSIS

S. Rao[1], Y. Jiang[1], S. Cao[1], D. Lin[1], H. Wu[1]

[1]The Second Affiliated Hospital Wen Zhou Medical University Dept. of Gastroenterology, Wenzhou, China

Contact E-Mail Address: 993661568@qq.com

Introduction: It is uncertain whether vitamin D supplementation contributes to improving the outcomes of patients with Crohn's disease (CD). Our study aimed to retrospectively analyze the influence of vitamin D supplementation on the clinical efficacy of Ustekinumab (UST) in Chinese CD patients.

Aims & Methods: A total of 71 patients with moderately to severely active CD were included, who received UST as first-line treatment from May 2021 to February 2023. Harvey Bradshaw Index (HBI) was applied to evaluate disease activity of CD patients. Simplified Endoscopic Score for Crohn's Disease (SES-CD) was employed to assess intestinal inflammation in CD patients. According to whether or not take vitamin D supplementation

(400IU/day) simultaneously in the course of UST treatment, the patients were divided into supplementary group (n=40) and non-supplementary group (n=31). The main end points were the differences of clinical remission rate (HBI≤4 scores) and mucosal healing rate (SES-CD≤2 scores) between supplementary group and non-supplementary group at week 24. The secondary end points were the differences of clinical response rate (the decrease of HBI score was more than 3 scores than week 0) and biochemical remission rate (CRP≤5mg/L) between supplementary group and non-supplementary group at week 8.

Results: At week 8, the average level of serum 25-hydroxyvitamin D [25(OH)D] was elevated in supplementary group compared with its baseline level [(17.18±5.46)μg/L *vs* (13.71±7.73)μg/L, *P*<0.001]. Compared with non-supplementary group, the average HBI score [(5.71±1.88) *vs* (8.34±2.27), *P*<0.001] and median CRP level [10.83(21.07, 3.95)mg/L *vs* 16.17(35.48, 6.91)mg/L, *P*=0.001] were significantly decreased in supplementary group. Both of the clinical response rate and biochemical remission rate were higher in supplementary group than in non-supplementary group (63.41% *vs* 46.67%, *P*=0.036; 43.90% *vs* 13.33%, *P*=0.001, respectively). At week 24, the average level of serum 25(OH)D continued to be increased in supplementary group compared with its baseline level [(24.73±8.34)μg/L *vs* (13.71±7.73)μg/L, *P*<0.001]. The declines of average HBI score [(4.90±1.45) *vs* (2.33±0.59), *P*<0.001] and SES-CD score [(2.97±1.41) *vs* (4.33±3.20), *P*=0.037] were more significant in supplementary group than in non-supplementary group. Both of the clinical remission rate and endoscopic mucosal healing rate were significantly higher in supplementary group than in non-supplementary group (58.53% *vs* 36.67%, *P*=0.001; 60.97% *vs* 30.00%, *P*=0.003, respectively). According to the baseline level of serum 25(OH)D, 71 CD patients were divided into vitamin D deficiency group[25(OH)D<20μg/L, n=42] and non-deficiency group[25(OH)D≥20μg/L, n=29]. The further analysis for vitamin D deficiency group showed that the clinical remission rate and mucosal healing rate were higher the patients receiving vitamin D supplementation treatment than those not receiving vitamin D supplementation treatment (58.62% *vs* 38.46%, *P*<0.001; 51.72% *vs* 30.77%, *P*<0.001, respectively).

Conclusion: Vitamin D supplementation may contribute to improving the clinical efficacy in CD patients receiving UST as first-line treatment, especially suitable for those patients with vitamin D deficiency.

EFFICACY OF ANTI-TUMOR NECROSIS FACTOR ALPHA THERAPY IN INTESTINAL BEHÇET'S DISEASE

J. Kim[1], J. Park[1], J. Cheon[1], S. Park[1], T. Kim[1]

[1]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, South Korea

Contact E-Mail Address: greatjanet93@gmail.com

Introduction: Intestinal Behçet's disease (BD) is a rare chronic intestinal vasculitic disorder and it is often refractory to conventional therapies such as corticosteroids and immunomodulators. We aimed to assess the efficacy and tolerability of anti-tumor necrosis factor alpha (TNF α) in intestinal BD.

Aims & Methods: We retrospectively reviewed 667 patients with intestinal BD registered at the Inflammatory Bowel Disease Clinic of Severance Hospital, Seoul, Korea. Response rates of anti-TNF α treatment, predictive factors of sustained response and relapse were analyzed.

Results: A total of 46 patients with refractory moderate to severe intestinal BD were selected for the anti-TNF α therapy. According to the intention-to-treat (ITT) principle, clinical remission rates were 8.7%, 21.7%, 6.5%, and 8.7%, clinical response rates were 76.1%, 71.7%, 39.1%, and 26.1%, and biological response rates were 60.9%, 60.9%, 39.1%, and 26.1%, respectively. According to the per-protocol (PP) principle, clinical remission rates were 8.7%, 25.6%, 13.0%, and 28.6%, clinical response rates were 76.1%, 84.6%, 78.3%, and 85.7%, and biological response rates were 60.9%, 71.8%, 78.2%, and 85.7%, respectively. Previous corticosteroid use more than 20 mg per day (HR: 4.781) and multiple number of ulcers (HR: 8.599) were more likely to have relapse of intestinal BD, and clinical response at 1 month (HR: 0.189) was associated with lowering the relapse. One patient had severe sepsis, 1 patient was diagnosed pneumonia and herpes zoster, and 1 patient experienced otitis externa.

Conclusion: Anti-TNF α therapy could be a useful therapeutic option for refractory intestinal BD with an acceptable efficacy and tolerability profiles.

Introduction: Inflammatory Bowel Diseases (IBD) patients are associated to a higher risk of developing colonic dysplasia and colorectal cancer due to long-standing colonic inflammation and immunosuppressant therapies. They seem to have also a higher risk of developing extra-intestinal

PP0818 Table 1: Type and frequency of Malignancies and characteristics of the patients.

malignancies, such as cholangiocarcinoma, skin cancer, and others. Different studies have been conducted to assess whether a correlation exists between IBD, medical treatments and cancers, but the results are controversial.

Aims & Methods: Our study aimed to evaluate the risk factors of malignancies in our IBD patients, particularly considering the medication history.

In this single-center retrospective study, IBD patients with a history of at least one malignancy post-IBD diagnosis followed at the Gastroenterology Unit of Azienda Ospedale Università Padova were enrolled (***cases***). Demographics and clinical data, including medication information, were collected before and at the time of malignancy diagnosis. A group of IBD patients, matched by sex and age, without a malignancy history were also included (***controls***), considering the medications taken before and at the time of the last visit for comparison.

Results: Among 2213 IBD patients followed at our center (1212 males, 1040 CD, and 1173 UC), 153 cases (80 UC and 73 CD, 46.4% males, mean age at diagnosis: 38.4±14.7) and 50 sex and matched controls were included (30 UC and 20 CD, 52% males, mean age at diagnosis: 38.9±0.8). Twelve patients had two malignancies, and 2 had three. For the scope of our study, we considered only the first tumor. Results are shown in the Table 1.

The mean time from IBD diagnosis to the first tumor was 15 years (SD 10.5). Considering malignancies, the most frequent in our population were breast cancer (27/1001 females, 2.7%), colorectal cancer (23/2213, 1%), melanoma (24/2213, 1.1%), and non-melanoma skin cancer (15/2213, 0.7%). Patients with colon cancer were younger at the time of IBD diagnosis (31.0±15.8 vs. 38.9±0.8), while patients with prostate and urinary cancer (11/2213, 0.5%) were older compared to controls (49.6±13.7 vs. 38.9±0.8). A lower percentage of patients with colon (13%), breast (4%), and prostate cancers (9.1%) had taken biological therapy before cancer occurrence, as compared to controls (44%, p<0.01).

Finally, we observed a significantly higher number of melanoma and breast cancer patients taking azathioprine (AZA) at the time of cancer diagnosis for more than 4 years. No difference in terms of duration of AZA and biological therapies before cancer diagnosis was observed.

Conclusion: Our study found that biological therapy was not associated to malignancies, while azathioprine use was associated with breast and melanoma cancers. A younger age at diagnosis was associated with colon cancer, while an older age with prostate and urinary cancers.

Disclosure: Nothing to disclose.

SYSTEMATIC REVIEW AND META-ANALYSIS: PSYCHOLOGICAL THERAPIES ARE ASSOCIATED WITH SHORT-TERM IMPROVEMENTS IN PSYCHOLOGICAL HEALTH IN INFLAMMATORY BOWEL DISEASE

C. Riggott[1,2], A. Mikocka-Walus[3], D.J. Gracie[1,2], A.C. Ford[1,2]
[1]Leeds Gastroenterology Institute, St. James's University Hospital, Leeds, United Kingdom, [2]Leeds Institute of Medical Research St. James's, University of Leeds, Leeds, United Kingdom, [3]Deakin University, School of Psychology, Melbourne, Australia

Contact E-Mail Address: christyriggott@doctors.org.uk

Introduction: Psychological co-morbidity, including anxiety and depression, is highly prevalent in inflammatory bowel disease (IBD), and associated with worse disease outcomes and increased healthcare utilization. This complex relationship likely arises due to gut-brain axis communication. Treatments targeting this pathway, including psychological therapies, may provide a means of improving psychological health in IBD. However, randomised control trials (RCTs) examining effect of psychological therapies in IBD are conflicting, and a previous meta-analysis demonstrated only short-term improvements in quality of life.

Aims & Methods: To assess whether psychological therapies positively impact psychological health of patients with IBD, we updated our previous systematic review and meta-analysis. RCTs examining the effects of psychological therapies vs. control in adults with IBD were identified by searching MEDLINE, EMBASE, EMBASE Classic, PsychINFO, and the Cochrane central register of controlled trials. Two investigators assessed eligibility of potential studies and extracted data from eligible studies

independently. Continuous outcomes assessed included the effect of psychological therapies on measures of psychological health, including depression, anxiety, stress, and quality of life scores. Where data were available, outcomes were assessed both upon completion of therapy, and again at the final point of follow-up. The effect of psychological therapies was summarised using a standardised mean difference (SMD) with 95% confidence intervals (CIs).

Results: In total 25 RCTs were included, reporting data from 2,227 patients with IBD. Nine studies examined effects of psychological therapies in specific populations, including patients with reduced quality of life, elevated stress scores, fatigue, or presence of depressive symptoms. The remaining studies were conducted in unselected patients. In four RCTs, for patients with clinically active IBD, upon completion of treatment, quality of life scores were significantly higher in patients assigned to psychological therapies (SMD = 0.68; 95% CI 0.09 to 1.26, *p*=0.02), but there was no improvement in anxiety scores (SMD = -1.04; 95% CI -2.46 to 0.39). The effects of psychological therapies for patients with quiescent disease in 21 RCTs are summarized in table 1; psychological therapies led to significantly lower anxiety, depression, and stress scores, and significantly higher quality of life scores at treatment completion. This benefit persisted to final follow-up in trials for depression scores. Effect was strongest with third wave therapies, and in RCTs recruiting selected patients.

	Number of patients	Summary Statistic for Effect of Psychological Therapies (95% confidence interval)	p value for the difference
Anxiety scores (SMD)			
At completion of therapy	1088	-0.23 (-0.36 to -0.09)	<0.001
At final point of follow-up	700	-0.17 (-0.34 to 0.01)	0.06
Depression scores (SMD)			
At completion of therapy	1189	-0.26 (-0.38 to -0.15)	<0.001
At final point of follow-up	856	-0.16 (-0.30 to -0.03)	0.02
Stress scores (SMD)			
At completion of therapy	813	-0.22 (-0.42 to -0.03)	0.03
At final point of follow-up	551	-0.18 (-0.40 to 0.04)	0.11
Quality of life scores (SMD)			
At completion of therapy	1080	0.31 (0.16 to 0.46)	<0.001
At final point of follow-up	773	0.13 (-0.02 to 0.29)	0.08

Table 1- Effect of Psychological Therapy on measures of psychological health in patients with quiescent IBD.

Conclusion: Psychological therapies exert short-term benefits on all aspects of psychological health for patients with quiescent IBD and improve quality of life in patients with clinically active disease. Future RCTs should examine the effects of these therapies in selected groups of patients with evidence of psychological distress, where benefit is likely to be greatest.

Contact E-Mail Address: gkokkot@gmail.com

Introduction: Ustekinumab is a monoclonal antibody that targets the p-40 subunit of the interleukins IL-12 and IL-23 and is used to treat moderate to severe Crohn's disease.

Aims & Methods: The present study aims to capture the experience of a tertiary center regarding the use of ustekinumab in patients with Crohn's disease in clinical practice [real-world] settings. This is a retrospective cohort study. Demographic and disease-related data on the day of ustekinumab initiation were collected. Study primary endpoint of the study was the persistence of treatment at the end of the first year without the administration of corticosteroids (cs-free). Secondary endpoints were the persistence of treatment at the end of the first, second and fourth year with and without the need for corticosteroids. The statistical program SPSS-23 was used for the analysis.

Results: In total, 99 patients have been registered until this point [women, 52.5%; mean age 42 years, SD=16; median disease duration=6 years IQR=1.5-11;A1/A2/A3, 6.1/65.7/28.3%; L1/L2/L3/L4, 58.6/7.1/34.3/12.1%; B1/B2/B3, 51.5/30.3/18.2%; perianal disease 26%]. Among study participants, 68.7% reported history of exposure to at least one biologic agent and 35.4% had undergone a CD-related surgery. At ustekinumab initiation 6.1% were receiving concomitant azathioprine, 4% methotrexate and 32.3%corticosteroids. 75.8% (75/99) continue ustekinumab with a median duration of administration of 14.5 months (range=0.5-66). Cs-free persistence in one-year was observed in 70.1% (54/77), cs-free persistence in two-years in 59.2% (29/49), and cs-free persistence in four-years in 45% (9/20). Simple persistence in one-, two- and four-years was observed in 84.4% (65/77), 61.2% (30/49) and 55% (11/20) respectively. Seven patients (9.3%) required intensification (90mg subcutaneously every 4 weeks) and one (1.3%) required reinduction (one-time weight-adjusted intravenous administration) due to loss of response. Patients that achieved cs-free persistence in one year were associated with higher persistence in two- and four-years compared with those who received corticosteroids during the first year of ustekinumab administration (*P*<0.001). Patients with a history of CD-related surgery achieved higher percentages of persistence (*P*<0.05). In univariate logistic regression, cs-free persistence in one-year was found to be associated with Harvey-Bradshaw Index [HBI] (OR=0.81, *P*=0.025), CRP [mg/L] (OR=0.96, *P*=0.059), history of CD-related surgery (OR=3.52, *P*=0.041), and neutrophils>5820/μL (OR=0.19, *P*=0.021). In multivariate logistic regression, cs-free persistence in one-year was found only to be negatively associated with HBI (OR=0.44, 95%CI: 0.24-0.81, *P*=0.008). No serious infection or malignancy has been observed.

Conclusion: Our analysis showed that patients with Crohn's disease achieved high rates of persistence on ustekinumab without the need of corticosteroids administration up to 4 years after the initiation of treatment. Patients with more severe diasease at drug initiation experienced lower persistence. Long-term administration of ustekinumab is not associated with any new safety concerns.

PP0821

EFFICACY OF INTRAVENOUS FERRIC CARBOXYMALTOSE TREATMENT IS INDEPENDENT FROM DISEASE ACTIVITY AND DOES NOT REQUIRE THERAPY OPTIMISATION IN CASE OF SILENT IBD WITH IDA – A PROSPECTIVE STUDY

T. Molnár[1], T. Resál[1], P. Bacsur[1], A. Balint[1], B. Farkas[1], A. Fabian[1], R. Bor[1], M. Rutka[1], S. Zoltán[1], K. Farkas[1]
[1]*University of Szeged, Department of Medicine, Szeged, Hungary*

Contact E-Mail Address: molnar.tamas@med.u-szeged.hu

Introduction: Anaemia and iron deficiency (IDA) in inflammatory bowel disease (IBD) usually suggests an underlying inflammatory activity at some degree. In case of inflammation, oral iron supplementation is mostly ineffective, or even it could worse symptoms. In contrast, ferric-carboxymaltose appears to be effective and safe independently from underlying disease activity so far.

Aims & Methods: Our aim was to prospectively investigate the short- and long term efficacy of ferric carboxymaltose regarding to disease activity and whether dose optimisation of IBD treatment (as a T2T approach) is necessary with iv iron supplementation in case of IDA observed in patients with remission. We included patients in our prospective study based on the IDA criteria defined by the ECCO guideline. Patients were divided into two groups according to the disease status (active/remission). Active disease was defined by CRP ≥10 mg/l or by clinical activity scores CDAI ≥150 in Crohn's disease and pMayo ≥2 in ulcerative colitis. Patients in the active group (A) received iv. iron with therapy modification. Patients in the remission group were further divided into two subgroups: patients in group R1 received iron supplementation alone, while patients in the R2 group had therapy optimisation in addition to iron supplementation. Ferric-carboxymaltose was administered at the first visit according the body weight and haemoglobin level. From that time, laboratory parameters and clinical activities were measured in every two month throughout the 6 months' follow-up period. Primary outcome was defined as the normalisation of haemoglobin levels or an increase of at least 20 g/l.

Results: In total, 73 patients were involved (mean age 40.4 years; male/female ratio 51/19; CD/UC 46/16), 27 patients in group A, and 23-23 in groups R1 and R2, respectively. Primary outcomes achieved at week 8, 16 and 24 did not differ between groups. Haemoglobin level increased significantly in all groups ($p<0.001$), in addition, no difference was observed between patients in the active and remission groups. Increase in haemoglobin levels did not differed in R1 and R2 subgroups. Ferritin and serum iron levels and transferrin saturation increased in all groups ($p<0.05$), without any difference observed between the groups. No adverse event was observed.

Conclusion: Based on our results, ferric-carboximaltose is an effective and safe therapeutic method in the treatment of IDA. Our results suggest, that iv. ferric-carboxymaltose is equally effective in active and inactive IBD. Based on our results, iv. iron supplementation is efficient in remission without treatment modification, however, due to the pathomechanism of IDA, treatment modification should be considered in every case.

KG, Berlin, Germany,* [5]*Institut Dr. Schauerte GmbH, Munich, Germany*

Contact E-Mail Address: Hermann.Schulze@agaplesion.de

Introduction: Vedolizumab (VDZ) is a gut-selective anti-lymphocyte trafficking agent and is approved for treating patients with moderate to severe active UC (ulcerative colitis) and CD (Crohn's disease) intravenously (IV) or subcutaneously (SC).

The LISTEN II study determines patient characteristics and effectiveness in VDZ-treated patients in clinical routine with focus on patient reported outcomes (PROs).

Aims & Methods: LISTEN II is a multicentre, prospective, non-interventional study in Germany. Adult patients with UC or CD who either initiate VDZ IV or switch from IV to SC formulation, are enrolled. Data on patient characteristics, modalities of VDZ use and disease activity (pMayo and HBI) are followed up quarterly for up to one year per routine care.

Electronic assessments of PROs are recorded weekly via a study-specific app (ePRO). Here, interim data up to 6 months follow-up are presented.

Results: Data of 242 UC (52% female, mean age 41 years) and 149 CD patients (60% female, mean age 40 years) were included in this analysis. VDZ treatment was newly initiated IV (start) in 206 UC and 127 CD patients and switched from IV to SC application (switch) by 36 UC and 22 CD patients at baseline.

After 6-month's treatment, total mean pMayo score decreased in UC start-patients from 5.0±2.1 to 2.1±2.0 and remained at 1.0±1.3 in switch-patients. In CD-start patients HBI score decreased from 5.6±4.2 to 2.9±3.5 and from 3.0±3.5 to 2.5±2.9 in switch-patients.

The ePRO was initially used by 74% of UC and 73% of CD patients. The mean age was 39 years and the majority (84%) had newly started VDZ treatment. The initial high willingness to ePRO use declined to approx. 40% usage within the second quarter and to 30% during further follow-up. When looking at sustained usage per patient (percentage of patients who completed at least one question of ≥80% of all questionnaires available to them), 62% of UC and 55% of CD patients were sustained ePRO users. Most of UC patients (82%) and CD patients (88%) used a support program for the first time.

ePRO users with UC more frequently reported high burden of disease at study inclusion compared to those with CD (55% versus 25%; high burden of disease defined for UC as pMayo >4 and CD as HBI >7), with a mean pMayo score of 4.4±2.5 for UC and mean HBI score of 5.3±4.2 for CD patients.

Overall, mean scores for ePRO symptoms declined within the follow-up period from baseline to 6 months. The absolute decline was most pronounced for symptoms impact on work productivity (3.9 to 1.9 points) in UC patients and sick leave (1.2 to 0.6 points) for CD patients (Table).

UC patients Symptoms (Score range)	General wellbeing (0-4)	Impact on work productivity (0-10)	Sick leave (days per week) (0-7)	Rectal bleeding (0-3)
Baseline mean (SD)	N=180 1.7 (0.9)	N=171 3.9 (3.0)	N=177 1.1 (2.3)	N=175 1.3 (1.2)
3 Month mean (SD)	N=115 1.3 (0.8)	N=111 2.3 (2.6)	N=111 0.4 (1.5)	N=111 0.5 (0.9)
6 Month mean (SD)	N=78 1.2 (0.6)	N=76 1.9 (2.2)	N=76 0.2 (1.0)	N=76 0.3 (0.6)
CD patients Symptoms (Score range)	General wellbeing (0-4)	Impact on work productivity (0-4)	Sick leave (days per week) (0-7)	Abdominal pain (0-4)
Baseline mean (SD)	N=107 1.7 (0.9)	N=106 1.6 (1.1)	N=104 1.2 (2.5)	N=107 1.7 (1.1)
3 Month mean (SD)	N=70 1.5 (0.7)	N=70 1.1 (1.0)	N=69 1.0 (2.3)	N=70 1.2 (0.9)
6 Month mean (SD)	N=41 1.4 (0.7)	N=41 1.1 (1.0)	N=40 0.6 (1.9)	N=41 1.1 (0.7)

Table: ePRO progression of UC and CD patients

Conclusion: LISTEN II real-world data support the effectiveness of VDZ treatment in UC and CD patients. Patients, newly starting VDZ IV showed a decrease in disease activity under VDZ treatment, while for patients switching from existing VDZ IV to SC maintained therapeutic effectiveness was observed. UC and CD patients reported a steady improvement of relevant symptoms under VDZ treatment using the ePRO, however app adherence declined to 30% during follow-up.

HYDROGEN GAS INHALATION IMPROVED INTESTINAL MICROBIOTA IN ULCERATIVE COLITIS: A RANDOMIZED DOUBLE-BLIND PLACEBO-CONTROLLED TRIAL

T. Maruyama[1], D. Ishikawa[1,2], K. Nomura[1], M. Haraikawa[1], R. Odakura[1], M. Omori[1], K. Haga[1], T. Shibuya[1], A. Nagahara[1,2]

Introduction: Recently, the dysbiosis of intestinal microbiota has been identified as a cause of ulcerative colitis (UC). We have reported that controlling the intestinal microbiota influences the efficacy of antibiotic-fecal microbiota transplantation (A-FMT) for UC. Hydrogen (H_2) has a cytoprotective function by removing active oxygen from cells, and it was reported that H_2 water maintained the balance of the intestinal microbiota and suppressed the progression in UC model mice.

Aims & Methods: In this study, we investigated changes in the intestinal microbiota, therapeutic effects, and safety of H_2 gas inhalation in UC patients.

We included active UC patients who participated in the clinical study "A randomized, double-blind, parallel-group study of hydrogen gas inhalation for ulcerative colitis" (UMIN000042017) between October 2020 and August 2021. Eligible participants are at least 20 years old and have been diagnosed with active UC {Lichtiger's Clinical Activity Index (CAI) of 3 to 10 and Mayo endoscopic subscores (MES) ≥ of 1}. 10 participants with UC were registered and were assigned to either the H_2 inhalation group or the air inhalation group. The H_2-producing machine (Jobs-α) was developed to generate 5-6% H_2 gas in 4 L/min mixed air by electrolysis. The placebo air machine was also developed and uses an air pump to generate 4 L/min of air. All participants will inhale the gas 4 hours every day for 8 weeks, and they are checked the inhalation time of the machine.

Patients are assessed the changes in the partial Mayo Score and CAI scores from baseline to the 8th weeks while checking for adverse events, and defined "remission" when their Mayo score improved to less than 2 points at 8 weeks after inhalation. The intestinal microbiota was analyzed by 16S rRNA sequencing of stool samples before and after inhalation.

Results: 10 patients (4 males and 6 females, age 38.1±8.9 years, disease duration 9.4±9.6 years, Mayo score 4.8±1.4, MES 1.2±0.4) participated in the study, and the total inhalation time was 225.6±100.0 hours. In the H_2 group, the Mayo score decreased from 4.6±1.4 to 3.0±1.3, and the remission induction rate was 3 out of 5 patients. In the placebo group, the Mayo score decreased from 5.0±1.4 to 3.8±1.5 ($p = 0.59$), and the remission induction rate was 1 out of 5 cases ($p = 0.24$). There were no adverse events due to inhalation. Analysis of the intestinal microbiota showed that the Chao1 index, a measure of alpha diversity and species richness, tended to be more diverse after H_2 inhalation ($p = 0.12$). Principal coordinate analysis was performed to compare differences in bacterial composition between H_2 group and placebo group. β-diversity tended to differ after inhalation from before in the H_2 group (ANOSIM, $p = 0.35$). The proportion of intestinal microbiota was compared between before and after H_2 inhalation. In the placebo group, the change of intestinal microbiota was not observed, wearers, in the H_2 group, Gordonibacter increased ($p = 0.07$), Clostridium ramosum ($p = 0.07$) and Schalia odontolytica ($p = 0.09$) decreased, and Gordonibacter pamelaeae ($p = 0.07$) increased, resulting in improvement the diversity of intestinal microbiota.

Conclusion: There are some limitations the small number of cases and a single-center clinical trial. H_2 inhalation increase the diversity of the intestinal microbiota and may have a possibility to lead to a therapeutic option of UC.

SWITCHING FROM INTRAVENOUS TO SUBCUTANEOUS INFLIXIMAB FORMULATION DETERMINES A REDUCTION OF ANTIDRUG ANTIBODY LEVELS

N. Piazza O Sed[1], M.C. Maregatti[2,1], T. Pessarelli[2,1], F. Conforti[1], D. Noviello[2,1], C. Molteni[2], C. Amoroso[1], M. Muia[1], M. Fraquelli[1], M. Vecchi[2,1], F. Caprioli[2,1]

Introduction: Higher infliximab (IFX) trough levels (TL) are associated with better disease control in patients with inflammatory bowel diseases (IBD) treated with this drug. [1,2,3] Still, reduced TL and anti drug antibodies (ADAs) can be found in a proportion of patients receiving IFX therapy despite being in clinical and endoscopic remission.

An increase in infliximab TL has recently been reported after switching from intravenous (IV) to subcutaneous (SC) formulation. [4] Whether the increase of IFX levels observed after switching to SC formulation is associated with the reduction of ADAs has not been investigated yet.

Aims & Methods: This is a preliminary report from a prospective multicentre cohort study on IBD patients in deep remission switching from IV to SC IFX. Clinical and biochemical remission rates, iInfliximab TL and ADAs were assessed over a period of 12 months at specific time points (T0-T3-T6-T12). Variations of IFX levels and ADAs as compared with baseline were assessed over time.

Results: Data from 36 IBD patients (61% Crohn's disease, 39% ulcerative colitis, mean disease duration 9.17 years +/- 6.87, mean infliximab therapy at switch 5.61 years +/- 3.5), switched to subcutaneous IFX from May 2022 to April 2023, are reported. Mean follow-up time was 212.13 days (+/- 122.87, range 28-357 days). All patients remained in clinical remission at the end of follow-up. Median baseline IFX levels were 10.77 ug/ml (range 0.2-41.8 ug/m). A statistically significant increase in IFX median drug levels was observed three and six months after switching (37.9 ug/ml, range 0.2-51 ug/ml; p value <0.00001 and 35.75 ug/ml, range 9.6-51 ug/ml p value <0.00001) respectively. Seven patients (30%) had presence of ADAs at baseline, associated with reduced median TL (0.2 ug/ml, range 0.2-0,97). In this group, median infliximab TL increased after the switch (13.24 ug/ml at six months), which was associated in 42% of them with a significant reduction of ADAs over time.

Conclusion: Our preliminary data confirm a statistically significant increase in IFX levels after switching from IV to SC formulation over time despite the presence of ADAs. In patients with presence of ADA at baseline, switching to subcutaneous infliximab could lead to a significant reduction of their levels.

Introduction: Acute severe flares occur in 15% of patients with ulcerative colitis (UC). Intravenous corticosteroids induce clinical remission in up to 50-60% of cases. Infliximab (IFX) and cyclosporin (CsA) are the only evi-

dence-based alternatives to colectomy in steroid-refractory acute severe UC (SRASUC), with a similar efficacy. It has been suggested that a more aggressive induction regimen of IFX might decrease the rate of colectomy.
Aims & Methods: To evaluate the short and mid-term outcomes of patients with SRASUC treated with IFX regarding the used induction regimen.
Methods: Retrospective, observational study including adult patients included in the ENEIDA registry supported by GETECCU, treated with IFX (at least two doses) due to SRASUC and available follow-up of at least 3 months or until colectomy or death. Dates and dosing of the first three IFX infusions, dose-escalation or treatment discontinuation, colectomy and date were collected. Induction regimens were grouped as follows: CONVENTIONAL (IFX 5mg/kg at 0, 2 and 6 weeks), ESCALATED (any of the first three infusions >5mg/kg) and ACCELERATED (second infusion administered before 11 days of the first one, or third infusion administered before 21 days of the second one).
Results: A total of 339 patients were included, 59% with extensive UC and 34% previously exposed to thiopurines. At the time of the first IFX infusion, median partial Mayo score was 7 (IQR, 6-8), median Mayo endoscopic subscore 3 (IQR, 2-3) and median C-reactive protein 49 mg/L (IQR, 18-99). IFX was started after a median of 7 days (IQR, 6-8) on iv steroids, with concomitant thiopurines in 51% of the cases. The induction regimen was conventional in 207 patients (61%), escalated in 81 (24%), and accelerated in 99 (29%), although 48 (14%) used escalated and accelerated regimens together. Partial Mayo score, Mayo endoscopic subscore and C-reactive protein levels at the time of the first IFX infusion were not significantly different between those patients following conventional regimen and those who did not; baseline serum albumin levels (29.9±0.7 vs 32.3±0.9 g/L; P=0.002) and prior exposure to thiopurines (38.2% vs 25.9%; P=0.022) were significantly lower in patients who followed escalated or accelerated regimens. One hundred and thirty-three patients (39%) discontinued IFX within the first year due to failure (no response or partial response) in 72 (21%), adverse event in 45 (13%), complete remission in 9 (3%) and patient's willingness in 5 (2%).
The colectomy rate at 30 days, 90 days and 12 months in the whole series was 6%, 8% and 13%, respectively. Patients who followed a full conventional regimen had significantly lower rates of colectomy at 30 (1.5% vs 12.9%; p<0.0001), 90 days (3.9% vs 15.2%; p<0.0001) and 1 year (9.6% vs 20.9%; p=0.004). In the logistic regression analysis, following a conventional induction regimen was the only protective factor of colectomy at 30 (OR 0.08 95%CI 0.02-0.36) and 90 days (OR 0.19 95%CI 0.07-0.54).
No differences were observed among conventional and intensified induction regimens in terms of steroid reintroduction and IFX discontinuation within the first year.
Conclusion: In clinical practice, accelerated and/or escalated induction regimens of IFX are used in almost half of the patients with SRASUC. Accelerated and escalated induction regimens were associated with significantly higher rates of colectomy at one and three months. Therefore, no benefit of using these modified induction regimens was found on the basis of current clinical practice decision-making criteria.

Introduction: Subcutaneous (SC) infliximab (IFX) is effective in maintaining biochemical, clinical and endoscopic remission rates [1,2,3] in inflammatory bowel disease (IBD) patients. Moreover, it has an excellent safety profile, particularly for immunological issues. Intestinal ultrasound (IUS) is a non-invasive and reliable tool that is currently gaining popularity for IBD monitoring. [4]
Transmural healing is considered a desirable long-term treatment endpoint, especially in Crohn's disease (CD). [5]
Whether switching from intravenous (IV) to SC IFX is effective in maintaining transmural remission in IBD is still not known.
Aims & Methods: This is a preliminary report from a prospective multicentre cohort study on both ulcerative colitis (UC) and CD patients treated with IFX. Patients on IV-IFX treatment for at least one year, on clinical, endoscopic and transmural remission were judged to be eligible for switching to SC-IFX. Patients were prospectively followed-up with clinical and biochemical parameters (fecal calprotectin, FC; C-reactive protein, CRP) over a period of 12 months at specific time points (baseline, 3, 6 and 12 months). Therapeutic drug monitoring was evaluated with trough levels and anti-drug antibodies. IUS was performed at baseline and every six months, during which bowel wall thickness (BWT) at terminal ileum (cut-off 3 mm), and at each colonic segment (cut-off 4 mm) was assessed. Limberg score for vascularization, and presence of mesenteric activation, lymphadenopathy and abdominal effusion were assessed. Clinical, biochemical, transmural remission rates and safety profile were prospectively evaluated.
Results: Thirty-six IBD patients were enrolled: males 72%, age 41.7 (± 13.14), 61% with CD. Perianal disease was present in 66% of CD patients. Mean disease duration was 9.1 ± 6.7 years, and patients had been receiving IFX therapy for a mean time of 5.88 ± 3.77 years. All patients showed normal BWT and vascularization (Limberg score <= 1) at baseline.
Median bowel wall thickness was 2.2 (IQR 1.6-2.6) mm for ileum; 2.0 (IQR 1.7-2.5) mm for right colon; 2.2 (IQR 2.0-3.0) mm transverse; left colon 2.7 (IQR 2.0-3.0) mm. Lymphadenopathy was reported in 4 patients (11.1%) and a mild abdominal effusion in 1 patient (2.7%). Mean follow-up time was 212.13 ± SD 122.87 days (range 28-357 days). All patients maintained IUS transmural remission with a median bowel wall thickness of 2.8 (IQR 2.2-3.0) mm for ileum; 2.6 (IQR 2.2-2.8) mm for right colon; 2.5 (IQR 2.0-2.8) mm transverse; left colon 3.6 (IQR 3.2-4.0) mm and a Limberg score <=1; abdominal effusion documented in a patient at baseline resolved by week 24. No statistically significant increase in FC levels (median FC 43 ug/g at T0, IQR 34-108 ug/g; median FC 26 ug/g at T6, IQR 18-48 ug/g; p >0.05), nor in CRP were observed. In only 3 (8.3%) patients a transitory increase in FC (FC > 250 ug/g) was observed, unrelated to IUS or endoscopic activity. No patients discontinued therapy with SC-IFX, treatment was overall well tolerated: six mild infective events, two mild cutaneous injection reaction were observed, with no patient developing severe adverse events (SAEs) during the study period. To date all patients are still in clinical remission, including perianal disease, on treatment with SC-IFX.

Conclusion: Switching from IV to SC infliximab in a selected cohort of IBD patients is safe and effective in maintaining clinical, biochemical and transmural remission. IUS is a useful, non-invasive and low-cost tool for periodic disease assessment.

Introduction: Upadacitinib (UPA) is an oral, reversible Janus kinase inhibitor that demonstrated efficacy compared with placebo (PBO) in 2 double-blind, multicenter induction studies, U-EXCEED (NCT03345836) and U-EXCEL (NCT03345849), and 1 maintenance study, U-ENDURE.[1-3] UPA is approved for patients with moderately to severely active Crohn's disease (CD).[4,5] This post hoc analysis evaluated the efficacy and safety of UPA in the induction treatment of East Asian patients in U-EXCEED and U-EXCEL.

Aims & Methods: In U-EXCEL and U-EXCEED, patients with CD were randomized 2:1 to receive UPA 45 mg or PBO once daily (QD) for 12 weeks. Clinical remission per average daily very soft or liquid stool frequency (SF) ≤ 2.8 and average daily abdominal pain score (APS) ≤ 1.0 and neither greater than baseline; clinical remission per CD Activity Index (CDAI) < 150; clinical response (CR-100, decrease of ≥ 100 in CDAI from baseline); endoscopic response (decrease in Simple Endoscopic Score for CD [SES-CD] > 50% from baseline); endoscopic remission (SES-CD ≤ 4 and at least 2-point reduction from baseline, and no subscore > 1 in any individual variable); and absence of draining fistulas through 12 weeks were evaluated. Nonresponder imputation incorporating multiple imputation to handle missing data due to COVID-19 was used.

Results: Of the 1021 patients enrolled in U-EXCEL and U-EXCEED, 204 were included in this analysis of East Asian patients; patient demographics and baseline disease characteristics were similar for the UPA 45 mg and PBO treatment groups (Table). A greater proportion of patients treated with UPA achieved clinical remission vs PBO (SF/APS: 62.5% vs 20.6%; nominal $P < .0001$; CDAI: 50.7% vs 20.6%; nominal $P < .0001$) at week 12. At week 2, CR-100 was achieved by 33.8% vs 7.6% of patients receiving UPA and PBO, respectively. Similarly, a greater proportion of patients treated with UPA achieved endoscopic outcomes vs PBO at week 12 (endoscopic response: 61.8% vs 10.3%; nominal $P < .0001$; endoscopic remission: 27.9% vs 5.9%; nominal $P < .0001$). In patients taking corticosteroids for CD at baseline, 57.1% receiving UPA discontinued corticosteroid use and achieved clinical remission per CDAI vs 20.0% of patients receiving PBO (nominal $P < .0001$). Among patients with draining fistulas at baseline, 28.6% of patients receiving UPA vs 0% of patients receiving PBO had no draining of their fistulas at week 12. The rate of adverse events (AEs) in the UPA group was comparable to that of patients receiving PBO (69.9% vs 70.6%). AEs leading to study discontinuation occurred in 5.9% and 4.4% of patients, and severe AEs in 10.3% and 13.2% of patients in the UPA and PBO groups, respectively. There were no treatment-emergent deaths in either group. AEs of special interest (including serious infections, opportunistic infections, and herpes zoster) occurred at similar rates regardless of treatment group; no malignancies, adjudicated major cardiovascular events, or venous thromboembolic events were reported.

Baseline Characteristics[a]	PBO (n = 68)	UPA 45 mg (n = 136)
Demographics		
Age (years), mean (SD)	33.1 (9.7)	32.7 (10.6)
Female, n (%)	24 (35.3)	50 (36.8)
Disease Characteristics		
Disease duration (years), mean (SD)	5.9 (3.8)	6.4 (6.1)
Corticosteroid use, n (%)	20 (29.4)	49 (36.0)
Prior biologic failures, n (%)		
0	16 (23.5)	30 (22.1)
1	35 (51.5)	71 (52.2)
2	14 (20.6)	28 (20.6)
≥3	3 (4.4)	7 (5.1)
CDAI, mean (SD)	280.8 (82.7)	284.8 (79.0)
SES-CD, mean (SD)	15.6 (6.5)	16.8 (7.8)
Average daily SF, mean (SD)	4.3 (2.4)	4.2 (2.0)
Average daily APS, mean (SD)	1.7 (0.7)	1.7 (0.8)
hs-CRP, median (range)	11.3 (0.2–94.1)	15.0 (0.2–144.0)
FCP, median (range)	1908 (30–18,191)	2361 (31–28,800)
Draining fistulas, n (%)	5 (7.4)	14 (10.3)

APS, abdominal pain score; CDAI, Crohn's Disease Activity Index; hs-CRP, high-sensitivity C-reactive protein; PBO, placebo; SES-CD, Simple Endoscopic Score for Crohn's Disease; SF, stool frequency, UPA, upadacitinib.

[a]The East Asian subpopulation consisted of patients in China, Japan, Korea, Malaysia, and Taiwan; patients from Hong Kong and Singapore would also be included in this analysis, but none enrolled.

Table. Baseline Disease Characteristics.

Conclusion: East Asian patients with moderately to severely active CD treated with UPA 45 mg achieved clinical and endoscopic outcomes at higher rates than did patients receiving PBO, with a tolerable safety profile.

Introduction: The efficacy and safety of upadacitinib (UPA), an oral reversible Janus kinase inhibitor, were demonstrated for patients with Crohn's disease (CD) in three phase 3 randomized, controlled, double-blind clinical trials: U-EXCEL (NCT03345849), U-EXCEED (NCT03345836), and U-ENDURE (NCT03345823).[1–3] UPA is approved for the treatment of moderately to severely active CD.[4,5] The STRIDE-II CD treat-to-target guidelines recommend using composite clinical and endoscopic treatment targets to improve patient outcomes.[6] We assess the efficacy of UPA in patients with moderately to severely active CD using stringent, composite efficacy endpoints.

Aims & Methods: In two phase 3 induction studies, U-EXCEL and U-EXCEED, patients were randomized 2:1 to receive once-daily UPA 45 mg or placebo (PBO) for 12 weeks. Those who achieved a clinical response (≥30% decrease in average daily very soft or liquid stool frequency [SF] and/or ≥30% decrease in average daily abdominal pain score [APS] and both not worse than baseline) to UPA were re-randomized 1:1:1 to receive UPA 15 mg, UPA 30 mg, or PBO in the 52-week U-ENDURE maintenance study. Five composite clinical and endoscopic endpoints were assessed at weeks 12 of induction and 52 of maintenance therapy: (1) enhanced clinical response (per very soft/liquid SF and APS) and endoscopic response; (2) clinical response (CR-100) and endoscopic response; (3) clinical remission per CD Activity Index (CDAI) and endoscopic response; (4) SF/APS clinical remission and endoscopic remission; and (5) CDAI clinical remission and endoscopic remission. Treatment group differences were compared using the Cochran-Mantel-Haenszel test, adjusted for stratification factors. Analyses used nonresponder imputation while incorporating multiple imputation to handle missing data due to COVID-19.

Results: A greater proportion of patients receiving UPA 45 mg vs PBO achieved stringent clinical and endoscopic endpoints at week 12: enhanced clinical response and endoscopic response (33.7 vs 6.1%); CR-100 and endoscopic response (27.8 vs 5.2%); CDAI clinical remission and endoscopic response (24.7 vs 5.2%); SF/APS clinical remission and endoscopic remission (15.7 vs 3.5%); and CDAI clinical remission and endoscopic re-

mission (15.0 vs 3.7%; for all comparisons, nominal *P* values ≤ .001; Table). At week 52, a greater proportion of patients who received UPA 15 mg or UPA 30 mg achieved stringent clinical and endoscopic endpoints vs patients in the PBO group (Table). Composite endpoint achievement rates were numerically greater with UPA 30 mg than with UPA 15 mg (Table). The safety of UPA in CD was previously reported.[1–3]

	Induction Week 12		Maintenance Week 52		
Stringent Endpoint	UPA 45 mg n = 674	PBO n = 347	UPA 30 mg n = 168	UPA a mg n = 169	PBO n = 165

APS, abdominal pain score; CDAI, Crohn's Disease Activity Index; CR-100, clinical response; NRI-C, nonresponder imputation incorporating multiple imputation for data missing due to COVID-19; PBO, placebo; SES-CD, Simplified Endoscopic Score for Crohn's Disease; SF, stool frequency; UPA, upadacitinib.

Data are reported using NRI-C.*P* values compare UPA treatment groups to the respective PBO group. *P* values were nominal and not multiplicity adjusted.

*$P \leq .05$; **$P \leq .01$; ***$P \leq .001$.

[a] ≥ 60% decrease in average daily very soft or liquid SF and/or ≥ 35% decrease in average daily APS from baseline and both not greater than baseline, or SF/APS clinical remission

[b] Decrease in SES-CD > 50% from induction baseline; for patients with an SES-CD of 4 at induction baseline, ≥ 2-point reduction from induction baseline.

[c] Adjusted risk difference is calculated based on the Cochran-Mantel-Haenszel test.

[d] Decrease of ≥ 100 points in CDAI from baseline.

[e] CDAI < 150.

[f] Average daily soft or liquid SF ≤ 2.8 AND average daily APS ≤ 1.0 and both not greater than baseline.

[g] SES-CD ≤ 4 and ≥ 2-point reduction from baseline and no subscore > 1 in any individual variable.

Table. Achievement of Stringent Efficacy Endpoints With Upadacitinib Induction and Maintenance Therapy.

Conclusion: In both induction and maintenance studies, patients receiving UPA had greater achievement of stringent efficacy endpoints vs patients who received PBO. UPA 30 mg demonstrated numerically greater clinical and endoscopic efficacy vs UPA 15 mg. The largest differences between UPA and PBO treatment groups occurred for the enhanced clinical response and endoscopic response endpoint.

ACUTE SEVERE ULCERATIVE COLITIS: ULCERATIVE COLITIS VERSUS CROHN'S DISEASE

W. Khemiri[1], N. Ben Mustapha[2], N. Ben Safta[1], S. Laabidi[1], M. Serghini[1], M. Fekih[1], A. Labidi[1], J. Boubaker[1]

Contact E-Mail Address: Khemiri.wafa00@gmail.com

Introduction: Severe acute ulcerative colitis (ASUC) is a life-threatening medical emergency of colonic inflammatory bowel disease (IBD), most often in ulcerative colitis (UC) but also in Crohn's disease (CD).

Aims & Methods: The aim of our study was to compare the epidemioclinical and evolutionary profiles of ASUC in UC and in CD.

We conducted a retrospective, descriptive and comparative study including patients who presented with ASUC over a 10-year period [January 2010 - December 2019]. The diagnosis of ASUC was established on Truelove and Witts criteria and supported by endoscopic findings. Group 1 included patients with UC and group 2 included patients with CD. Patients followed for CD with anoperineal manifestations or upper gastrointestinal tract involvement were excluded. Data were entered and analyzed by SPSS software version 26.

Results: We included 71 patients with a sex ratio M/F of 0.65. The mean age at diagnosis of IBD was 31.08 years with extremes ranging from 12 to 58 years. Twenty-one percent of the patients had a body mass index greater than 25kg/m2. Thirty-three patients had UC, while 38 patients had CD. Patients in group 2 had a significantly lower mean age of occurrence of ASUC (30.84 vs. 37.33 years; p=0.02). The two groups were comparable for sex(p=0.62), smoking (p=0.71) and family history of IBD (p=0.94). ASUC was inaugural in 36.6% of the patients with no difference between the 2 groups (p=0.3). Twenty-six patients in group 1 were previously on treatment (p=0.03), mainly with Pentasa. For the diagnosis of ASUC, the median number of bloody stools was 7 with no difference between the 2 groups (p=0.56). The mean CRP level was significantly higher in group 2 (121mg/l vs 74.49mg/l;p=0.004). Severity signs on endoscopy were similar between the 2 groups (p=0.17). There was also no difference in the presence of colonic infection between the 2 groups (p=0.66). The response to the first line treatment with corticosteroids was found in 61.2% (n=38) and was significantly higher in group 2 (p=0.02). The mean number of bloody stools was significantly lower in group 2 at day 3 and day 5 of the treatment (p=0.003 and p=0.005 respectively). The decrease in mean CRP level at day 3 and day 5 of the treatment was comparable between the 2 groups (p=0.15 and p=0.12 respectively). Thus, the use of second-line therapy was more important in group 1 (p=0.017). There was no difference between the 2 groups regarding the occurrence of complications during the course of the disease, mainly colectasia, perforation and digestive bleeding (p=1, p=0.13 and p=1 respectively). Surgical treatment was required in 26.7% of the patients (n=19) without a difference between the 2 groups (p=0.53). It was significantly associated with an early occurrence of the ASUC (p=0.009), the need for second-line treatment (p<0.001) and the number of bloody stools at day 3 and day 5 of the follow-up (p<0.001 and p<0.001 respectively). There was no difference between the 2 groups regarding the occurrence of postoperative complications, mainly abscess (p=1) and rectal stump inflammation (p=0.6). The occurrence of a second ASUC under maintenance treatment was more important in group 1 without a significant difference (37.5 vs 14.7% p=0,08).

Conclusion: ASUC is the most severe complication of colonic IBD and is prone to an overall outcome independent of the type of the underlying IBD.

Disclosure: Nothing to disclose.

PREDICTORS OF ENDOSCOPIC AND HISTOLOGIC RESPONSE AFTER FIRST-LINE BIOLOGIC THERAPY IN ULCERATIVE COLITIS

K. Jo[1], C.H. Lee[1], H.J. Lee[1], J.P. Im[1], B.G. Kim[1], J.S. Kim[1], S.-J. Koh[1]

Introduction: Ulcerative colitis (UC) is increasing in prevalence and incidence in Korea, and each patient shows a different course and treatment response. Since the 2000s, biologics have been developed and treatment options have diversified. Biologics and small-molecule therapeutics for immunological targets are currently under research and development. In the past, the goal was clinical improvement, including symptoms, but now endoscopic mucosal healing and, furthermore, the continuation of histological remission are gradually suggested. Accordingly, the purpose of this study was to identify clinical factors that could predict histological remission in patients receiving a first-line biologic agent, as well as confirm the patient's response to treatment and prognosis.

Aims & Methods: We retrospectively analyzed the medical records of 440 patients who had been diagnosed with UC and exposed to biologics for the first time in our hospital without using biologics at other hospitals between January 01, 2010 and December 31, 2022. Patients who did not undergo pre- and post-exposure endoscopy and biopsy or whose follow-up was discontinued were excluded. Clinical characteristics, blood tests, endoscopic findings, and pathological examination results of a total of 72 patients were collected. Endoscopic response was defined as a decrease in the Mayo Endoscopic Subscore (MES) compared to the score before the first exposure to the biological agent. Histological remission was defined as the result of no cryptitis, no crypt abscess, or no inflammatory cells observed on histological examination, and histological response was defined as remission in patients previously observed with active inflammation.

Results: The ratio of males to females was 53:19, and the median age at the time of diagnosis was 41 years. The average Mayo score at the time of diagnosis was 7.2, and the group with a histological response was 6.0, showing a statistically significant difference. The average albumin was 3.88 and was 4.06 in the histological response group, with a statistically significant difference. The median time to exposure to the first biologic was 1520 days. A colectomy was performed in three cases. Biologics were started with infliximab in 46.7% of patients, followed by adalimumab and vedolizumab in 22.7% and 21.3%, respectively. There was no statistical correlation between histological response and each biologic agent.

MES before exposure to biological agents was 50% in 2 and 44.4% in 3, but there was no statistical difference between each group. Multivariate logistic regression analysis was performed to identify predictors of endoscopic and histological responses after the first exposure to biological agents. As a result, it was confirmed that the Mayo score, ESR, and albumin had a causal relationship with the endoscopic response, respectively, and the odds ratio was 0.781, 1.051, and 3.319, respectively (p-value 0.044, 0.007,

0.049). In addition, it was confirmed that the Mayo score had a causal relationship with the histological response with an odds ratio of 0.796 (p-value 0.046).

Conclusion: This study confirmed that disease activity before treatment was a predictor of histological remission in UC patients using first-line biologics. It was confirmed that the histological response as well as the endoscopic response were well induced when the disease activity was low. Therefore, early escalation to biologics before the patient's condition worsens may be the basis for improving the overall prognosis.

REAL-WORLD EVIDENCE DATA WAREHOUSE FOR POOLED ANALYSES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES IN GERMANY: THE "UMBRELLA-IBD REGISTRY" OF THE COMPETENCE NETWORK IBD

B. Bokemeyer[1,2,3], S. Plachta-Danielzik[3], T. Wenske[3], E. Gilman[3], F. Tran[2], A. Bokemeyer[4], S. Schreiber[2,3]

Contact E-Mail Address: bernd.bokemeyer@t-online.de

Introduction: Head-to-head (H2H) comparisons of biologics and small molecules in randomised clinical trials (RCTs) are considered the gold standard in inflammatory bowel disease (IBD). However, comparative real-world evidence (RWE) registry studies can provide important additional knowledge. Our aim is to perform a range of such H2H RWE studies, including subgroup analyses, to examine different treatments in patients with IBD. To do so, we draw upon data from a large data warehouse (UMBRELLA-IBD), which pools data from all eight prospective RWE registries in the Competence Network IBD. All patients were recruited to each registry in a similar manner.

Aims&Methods: Pooled analyses have a range of important methodological and logistical requirements, all of which are met in the eight prospective RWE registries that feed data into the UMBRELLA-IBD data warehouse: (1) The prospectively collected data are highly homogeneous, with each registry using similar inclusion and exclusion criteria, and the analyses of registry data using similar outcome parameters; (2) The quality of the data is high, and the data are comparable due to comprehensive remote and onsite monitoring; (3) The advanced statistical methods used to compensate for the absence of randomisation include propensity score adjustment with inverse probability of treatment weighting (IPTW) and are applied similarly in each analysis (Table 1). In concordance with a priori protocols, data and parameters from the eight Competence Network IBD registries were checked for consistency, merged and then migrated to a common server. Additionally, a data validation plan (DVP) was created to process all data, with individual items being adapted by appropriate recoding for the pooled evaluation.

Results:

In the new UMBRELLA-IBD data warehouse of the Competence Network IBD, prospectively recorded data from a total of 6,689 IBD patients in eight registry studies in Germany are available for a planned pooled analysis (Table 1), albeit with some patients potentially having been recruited to more than one of these studies. As of 31 March 2023, 35% of the patients included in the data warehouse are biologic-naïve and started their first biologic/small molecule treatment at recruitment. Prospectively documented one-year records are available for 75% of patients, and supplementary biomaterials have been collected in 40% of patients. Recruitment and follow-up are ongoing in some registries.

Prospective RWE registries in the Competence Network IBD	Patients with IBD	Study duration	Bio-naïve patients	Pts. with short course of disease	CD/UC	Biomaterials in (%) of patients	Month 12 visit documented
BioCrohn	1,530	2008 - 2018	393	677 (< 3 years)	CD	85%	1,216
BioColitis	883	2013 - 2021	238	447 (< 2 years)	UC	51%	666
Run-CD	901	2017 - 2024	301	-	CD	30%	802
VEDO-IBD	1,284	2017 - 2022	824	150 (< 2 years)	CD/UC	51%	937
IBD-Inception Registry	140	2016 - 2019		140 (< 1 year)	CD/UC	-	110
RUN-UC	507	2020 -2024	238	-	UC	-	387
FilgoColitis	162	2022 - 2025	22	-	UC	-	28
TARGET	1,282	2019 - ongoing	308	-	CD/UC	-	861
IBD patients included in total*	6,689	2008 - today	2,324	1414	CD/UC		5,007

Table 1: IBD patients in the prospective registries of the Competence Network IBD at a glance: Umbrella-IBD (as of 31 March 2023)
* Some patients may be recruited in more than one study

Conclusion: The large UMBRELLA-IBD RWE data warehouse from eight different prospective Competence Network IBD registries is a promising initiative for conducting further comparative studies that will provide important evidence in addition to that from existing RCTs in IBD patients.

Introduction: Inflammatory Bowel Diseases (IBD) are multifactorial diseases, including Ulcerative Colitis (UC) and Crohn's Disease (CD).

Up to 50% of IBD patients show a primary or secondary non-response to standard biological therapy. Therefore, Randomized Clinical Trials (RCTs) represent a significant therapeutic opportunity for them.

Aims & Methods: This study aims to compare the clinical characteristics of "real-life" IBD patients of our tertiary IBD centre to "trial patients" and to identify novel therapeutic targets from real-life populations to be considered for RCTs. We prospectively enrolled consecutive patients who started biologic therapy from August 2019 to August 2020 at Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Rome. We divided patients into three sub-groups: (1) "real-life" patients, patients treated according to clinical practice with standard biologic therapy that did not meet the inclusion and exclusion criteria for RCTs, (2) patients "real-life suitable for trial", potentially eligible in RCTs, but treated with standard of care, and (3) "trial" patients". Trial patients were treated with drugs from 14 phases 2b and 3 studies actively recruiting in our centre.

Results: We enrolled 134 patients: 72 with UC and 62 with CD. "Real-life" patients were 41 in UC and 38 in CD, "real-life suitable for trial" were 6 in UC and 14 in CD, and "trial" were 25 in UC and 10 in CD.

According to the existing inclusion and exclusion criteria, the study showed that only 43% of UC patients and 39% of CD were suitable for a potential enrollment in RCTs. However, only 16% of CD was finally enrolled in RCTs. At the enrollment, UC patients were excluded due to topical therapy use, cancer, recent *Clostridium difficile* infection or laboratory abnormalities. In contrast, CD patients were excluded mainly for a low CDAI but also due to complications of the disease that might require surgery, previous total or subtotal colectomy or major abdominal surgery in the previous six months. Both "trial" UC and CD patients showed more extraintestinal manifestations of disease, especially the articular ones ($p<0,05$). Moreover, "trial" patients presented, both in CD and UC, a higher significant concomitant use of systemic corticosteroids at the dose < or = 20mg/die ($p < 0,05$). Percentages of patients treated previously with other biological drugs were superior in "trial" patients compared to "real-life" in UC (88% vs 29%); instead, in CD, there was no significant difference (60% vs 45%).

We observed different baseline clinical disease activity scores in CD: the mean HBI of "real-life" patients was 4.8, and the mean HBI of "trial" patients was 9.1.

In addition, patients enrolled in RCTs waited longer before accessing the proposed biological therapy.

Conclusion: This study highlights some differences between clinical practice and research, particularly regarding the criteria for starting biological therapy in CD.

Firstly, "trial patients" presented more complex diseases, significantly impacting their clinical status.

Furthermore, RCTs use clinical scores (CDAI) as determinants for enrollment and decision-making, although endoscopy and radiological imaging are more widely used in clinical practice for decision making.

These differences could cover the actual effectiveness of a new drug compared to the theoretical efficacy derived from registration RCTs.

Therefore, we believe that new therapeutic targets, such as mucosal or histological healing in UC and transmural healing or new radiological scores in CD, should be considered and perhaps used in RCTs.

Disclosure: Nothing to disclose.

Introduction: It remains questionable whether vitamin D supplementation contributes to remission in patients with ulcerative colitis (UC).Our study aimed to investigate the influence of vitamin D supplementation on the efficacy of Vedolizumab in Chinese UC patients.

Aims & Methods: A total of 91 patients with active UC (Mayo clinical score ≥3) were collected in this study, who were bio-naïve and prescribed with Vedolizumab treatment for 22 weeks. Disease activity was assessed by Mayo clinical score and Mayo endoscopic score (MES) was used to evaluate intestinal inflammation. Patients were subsequently divided into supplementation group and non- supplementation group. Supplementation group patients were assigned to took oral vitamin D 400 IU/d within 3 days after the first Vedolizumab injection and continued during the follow-up period. The primary outcomes included clinical response rate, clinical remission rate, mucosal healing rate at week 22 as well as the change of CRP, ESR and faecal calprotectin during follow-up. The secondary endpoint was the expression profiles of Th-cell-related cytokines at week 22.

Results: At week 22, supplementation group showed a greater decline rate of CRP (93.54[80.00, 97.33] *vs* 52.22[-26.62, 83.93]%, P<0.001), ESR (75.00[51.67, 87.65] *vs* 32.69[-8.62, 76.96]%, P<0.001) and faecal calprotectin (60.94[34.63, 76.35] *vs* 25.66[17.99, 54.81]%, P<0.001) than non-supplementary group patients did. What's more, the clinical response rate, clinical remission rate, and mucosal healing rate were higher in supplementation group than in non-supplementation group (81.63 *vs* 57.14%, P=0.011; 67.35 *vs* 40.48%, P=0.010; 73.47 *vs* 52.38%, P=0.037, respectively). Among 91 enrolled patients, 30 patients (16 in supplementation group) quantitatively analyzed serum cytokines levels at baseline and week 22. In supplementary group, serum IL-6 level decreased at week 22 compared with its baseline value (4.28 ± 0.42 *vs* 5.21 ± 0.64 pg/mL, P < 0.001), while the serum IL-10 level at week 22 had a remarkable increase from baseline (4.87 [4.58, 5.74] *vs* 4.25 [3.53, 4.53] pg/mL, P = 0.003).

Conclusion: Vitamin D supplementation might relieve intestinal inflammation and improve VDZ efficacy in UC patients via down-regulating IL-6 and up-regulating IL-10.

Introduction: Filgotinib (FIL) is a once-daily, oral, Janus kinase 1 preferential inhibitor approved for the treatment of ulcerative colitis (UC). Previous analyses of data from the phase 2b/3 SELECTION trial (NCT02914522) demonstrated that FIL 200 mg (FIL200) improved health-related quality of life (HRQoL) and led to comprehensive disease control (comprising clinical, biomarker, HRQoL and endoscopic improvements) in patients with UC.[1]

Aims & Methods: We evaluated individual Inflammatory Bowel Disease Questionnaire (IBDQ) item data from SELECTION to assess which items drive the benefits of FIL treatment. In SELECTION, adults with moderately to severely active UC were randomized 2:2:1 to receive FIL200, FIL 100 mg or PBO once daily for 11 weeks in Induction Studies A and B (biologic-naive and -experienced patients, respectively). Patients who responded to FIL were rerandomized 2:1 to continue their induction FIL dose in the 47-week Maintenance Study. In this *post hoc* analysis, standardized effect sizes (SES) were calculated to evaluate the relative magnitude of the difference in mean scores of individual IBDQ items at week 10 (W10) between FIL200 versus PBO-treated patients, and at week 58 (W58) between patients who continued FIL200 treatment (FIL200→FIL200) versus those who were rerandomized to PBO (FIL200→PBO). SES were also calculated for the mean change in score of individual IBDQ items from baseline to W10, and from maintenance baseline to W58. SES were categorized by Cohen's thresholds ('trivial' [<0.2]; 'small' [≥0.2–<0.5]; 'moderate' [≥0.5–<0.8]; and 'large' [≥0.8]). A last observation carried forward imputation approach was used for missing data.

Results: At W10, patients treated with FIL200 overall (n=506) had improvements in all individual IBDQ items versus those treated with PBO (n=277) and had moderate to large increases from baseline (SES ≥0.5) in all individual IBDQ items. The IBDQ items with the five largest SES for FIL200 versus PBO at W10 (analysed by induction study), and for FIL200→FIL200 (n=199) versus FIL200→PBO (n=98) at W58 are summarized in the Table. FIL200 treatment consistently resulted in the largest benefits in items related to pain ('abdominal pain' and 'abdominal cramps'), ability to engage socially ('satisfied with life', 'depressed or discouraged', 'social engagement' and 'problems with activities') and bowel urgency ('loose bowel movements' and 'finding a washroom') versus PBO at W10, and versus FIL200→PBO at W58

Conclusion: FIL200 treatment provides improvements in HRQoL versus PBO, with large SES seen for most IBDQ items, and the greatest improvements in items related to pain, social engagement and bowel urgency over 58 weeks. This analysis reveals the specific IBDQ items that drive the

FIL200 group – end of induction (W10)									
Biologic-naive (n=245)					Biologic-experienced (n=261)				
IBDQ items	W10 score, mean (SD)	SES vs PBO	Change in mean score from baseline, mean (SD)	SES vs baseline	IBDQ item	W10 score, mean (SD)	SES vs PBO	Change in mean score from baseline, mean (SD)	SES vs baseline
Social engagement	5.8 (1.4)	0.62	1.8 (1.9)	0.82	Loose bowel movements	4.1 (1.9)	0.72	1.9 (1.9)	0.88
Satisfied with life	4.6 (1.2)	0.62	1.3 (1.5)	0.73	Problems with activities	4.7 (1.8)	0.64	1.9 (1.9)	0.89
Depressed or discouraged	5.4 (1.3)	0.58	1.6 (1.7)	0.78	Abdominal pain	5.1 (1.6)	0.63	1.6 (1.6)	1.02
Abdominal cramps	5.5 (1.4)	0.56	1.8 (1.6)	0.99	Bowel movement frequency	5.2 (1.9)	0.62	2.2 (2.1)	0.83
Felt angry[a]	5.6 (1.3)	0.55	1.6 (1.7)	0.81	Rectal bleeding	5.0 (2.0)	0.62	2.6 (2.1)	1.01

FIL200→FIL200 group (n=199) – end of maintenance (W58)				
IBDQ item	W58 score, mean (SD)	SES vs FIL200→PBO	Change in mean score from maintenance baseline, mean (SD)	SES vs maintenance baseline
Bowel movement frequency	6.3 (1.4)	0.57	0.4 (1.6)	0.19
Rectal bleeding	6.3 (1.4)	0.55	0.2 (1.6)	0.10
Abdominal cramps	6.2 (1.1)	0.47	0.5 (1.4)	0.28
Problems with activities	6.0 (1.3)	0.44	0.6 (1.4)	0.42
Finding a washroom	6.1 (1.4)	0.41	0.4 (1.4)	0.27

[a]The items ‚felt angry' and ‚irritable' had the same SES versus PBO; however, ‚felt angry' had the larger change in mean score from baseline.
SES for comparison with PBO/FIL200→PBO was calculated as follows: mean differences/pooled SD.
SES for comparison with baseline was calculated as follows: mean change from baseline/(SD/√(2*(1−*r*))).
SES were categorized by Cohen's thresholds (‚trivial' [<0.2], ‚small' [≥0.2–<0.5], ‚moderate' [≥0.5–<0.8] and ‚large' [≥0.8]).
FIL200→FIL200 treatment group = patients who responded to FIL200 during induction and were rerandomized to continue FIL200 during maintenance.
FIL200→PBO treatment group = patients who responded to FIL200 during induction and were rerandomized to PBO during maintenance.
FIL200, filgotinib 200 mg; IBDQ, Inflammatory Bowel Disease Questionnaire; PBO, placebo; *r*, Pearson correlation coefficient; SD, standard deviation; SES, standardized effect size; W10, week 10; W58, week 58.

PP0834 Table. Top five individual IBDQ item scores ranked by SES for FIL200 versus PBO groups at W10 and FIL200→FIL200 versus FIL200→PBO groups at W58.

benefits to HRQoL of FIL and adds further evidence to that showing that FIL contributes to restoration of health through comprehensive disease control for patients with UC.[1]

Introduction: The advent of new therapeutic agents might change the management of acute severe ulcerative colitis (ASUC) by reducing the risk of colectomy and thereby changing the natural history of the disease. Thus, the effectiveness and safety of sequential treatment should be elucidated in patients admitted for ASUC. The main aim was to evaluate colectomy-free survival in patients with ASUC refractory to intravenous corticosteroids who failed to infliximab (IFX) or ciclosporin (CyA) and received a second-line (2L) therapy. The secondary aims were to evaluate the short- and long-term effectiveness and to assess the safety of this strategy.

Aims & Methods: Multicentre study of patients admitted with ASUC refractory to corticosteroids who received a 2L therapy after failing either CyA or IFX during the same hospitalisation. Clinical activity was classified based on partial Mayo score and Lichtiger activity index. Patients who stopped

the 2L therapy due to disease activity or adverse events were considered failures. Patients were followed-up until colectomy or one year after 2L initiation. Predictors of short-term colectomy-free survival were assessed by logistic regression analysis, while long-term was evaluated by Kaplan-Meier curves and Cox regression models.

Results: A total of 78 patients from 24 European centres were included. As first-line therapy (after failing corticosteroids), IFX was administered to 32 patients, and CyA to 46. The median age at hospital admission was 35 years (IQR 26-47), and 42 (54%) were men. The prescribed therapy after IFX failure was: CyA in 17, tofacitinib in 13, and ustekinumab (UST) in two patients. After CyA failure, IFX was prescribed in 45 patients, and UST in one. At last study visit, 26 patients (33%) were still under the 2L therapy (IFX in 15, CyA in two, tofacitinib in two, and UST in one).

A total of 29 patients (37%) underwent colectomy during the follow-up; the majority of them (93%) within the first eight weeks. Median time to colectomy after starting the 2L therapy was 14 days (IQR 3-23). The main indication of colectomy was primary non-response in 23 patient (79%). In multivariate analysis, older age at hospital admission (OR 1.1, 95%CI 1.0-1.1), the use of CyA as rescue therapy (OR 8.0, 95%CI 1.3-48), and severe disease (vs. moderate) before the rescue therapy initiation (OR 8.7, 95%CI: 2.0-38) were associated with the likelihood of colectomy.

A total of 31 patients (44%) at week 12 and 18 (30%) at week 52 achieved clinical remission under the 2L therapy; 39 patients (55%) at week 12 and 20 patients (33%) at week 52 reached clinical response (including remission). Corticosteroid-free clinical remission was maintained in 26% and 19% of patients at week 12 and at week 52, respectively. Clinical relapse was observed in 43 patients (55%); of them, six patients (14%) intensified the therapy and five (83%) regained response.

25 patients (32%) had adverse events (AE); 14 had serious AE. Resolution with no sequelae was observed in 20 patients (80%). Infections were the most frequent AE, reported in 12 patients (15%), followed by infusion reactions in five (6%). No differences in AEs between the 2L therapies prescribed were observed. There were two deaths: one due to cerebral thrombophlebitis and another due to bacteriemia after colectomy, both when CyA was the therapy prescribed.

Conclusion: A 2L salvage therapy avoids colectomy in a considerable percentage of patients admitted by ASUC and therefore it can be considered after IFX or CyA failure. The individual therapeutic approach must be discussed with patients due to the risk of serious AE

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are chronic inflammatory diseases of digestive tract, and anti-inflammatory drugs, such as vedolizumab, have central role in their treatment. Intravenous form of vedolizumab is approved for induction and maintenance of remission in patients with CD and UC. Recently, subcutaneous form of vedolizumab was approved as a maintenance therapy after the induction with, at least, two intravenous doses.

Aims & Methods: The aim of this study was to show how the switch from intravenous to subcutaneous vedolizumab in a real-life setting in inflammatory bowel disease (IBD) patients on stable maintenance therapy affects vedolizumab serum concentration and clinical outcomes. IBD patients treated with intravenous vedolizumab and planned to switch to subcutaneous vedolizumab at the Department of Gastroenterology and Hepatology in the University Hospital Centre Osijek were included in the study. Patients were in remission at the time of transition (based on clinical symptoms, fecal calprotectin level or endoscopy scores).

Data on vedolizumab serum trough concentration and clinical outcomes (remission rate, fecal calprotectin level, clinical scores, hospitalization rate, rate of surgical procedures, change of therapy, and adverse events) were collected prior to and after the switch from intravenous to subcutaneous vedolizumab.

Results: In total, 31 patients, 17 with CD and 14 with UC, were included in final analysis. Median follow up was 12 months (interquartile range, IQR 9-12). Median duration of therapy with intravenous vedolizumab prior to switch was 14 months (IQR 6-32). Mean serum trough concentration of intravenous vedolizumab was significantly lower than mean serum trough concentration of subcutaneous vedolizumab (25.62 mg/L±14.29 vs. 34.93±14.59 mg/L; p=0.002). This rise in vedolizumab serum concentration after the switch to subcutaneous drug, was more evident in CD (Δ11.8 mg/L) than in UC (Δ5.79 mg/L) patients. There was no significant difference between fecal calprotectin level in all patients, as well as fecal calprotectin and Harvey–Bradshaw index in CD patients prior to or after the transition to subcutaneous vedolizumab. In UC patients, fecal calprotectin and Partial Mayo score were significantly higher (p= 0.011 and p=0.018, respectively) after the switch to subcutaneous vedolizumab, although this difference was not clinically significant.

There was a significant difference in remission rate before and after the transition to subcutaneous vedolizumab in all patients (100% vs 71%; p=0.004), and in UC patients (100% vs. 57.1%; p=0.031). During the follow up, one (3.2%) CD patient was hospitalized and had a surgical procedure due to IBD. In 7 (22.6%) patients, the therapy was discontinued during the follow-up period with a median of 8 months.

In all patients, therapy was discontinued due to loss of response. In total, 27 adverse events were reported by 17 patients, and the most common adverse event was COVID-19. One serious adverse event was reported (a patient was hospitalized for subileus).

Conclusion: Despite the rise in serum vedolizumab trough concentration after the switch from intravenous to subcutaneous vedolizumab, total remission rate was significantly lower in all patients and in the subgroup of UC patients. No new safety signals were observed in patients after the switch to subcutaneous vedolizumab.

BIOMARKER OF CORTICOSTEROID THERAPY FOR MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS

H. Machida[1], T. Nishimoto[1], A. Hoshimoto[1], J. Omori[1], N. Akimoto[1], A. Tatsuguchi[1], K. Iwakiri[1]

[1]Nippon Medical School, Department of Gastroenterology, Tokyo, Japan

Contact E-Mail Address: s13-089mh@nms.ac.jp

Introduction: Ulcerative colitis (UC) is characterized by chronic immune mediated inflammation of the colon and rectum. Prednisolone (PSL) is a common treatment for patients with moderate to severe active UC, but its effect varies among patients, including resistance, response, and dependence. In addition, the longer PSL therapy continues, the greater the concern regarding drug-related side effects. Currently, new immunomodulatory therapies are being developed for the treatment of UC, like carotegrast methyl, a drug showing promise in the treatment of patients with moderate UC refractory to 5-aminosalicylic acid (5-ASA).

Thus, the clinical benefit of being able to predict whether certain patients would benefit from PSL therapy prior to administration cannot be overestimated.

Aims & Methods: We compared the clinical characteristics of patients with steroid-resistant (SR) and steroid-non-resistant (SNR) UC and retrospectively evaluated for biomarkers that could predict the efficacy of PSL prior to administration in patients with moderate to severe active UC who failed to respond to 5-ASA.

We enrolled 92 UC patients presenting at Nippon Medical School Hospital with a history of PSL administration prior to March 2022. The patients were divided into two groups, SR patients and NSR patients, and their clinical characteristics were determined according to medical records.

Results: Clinical characteristics of UC patients were as follows: the median age, 48±17 years; height 166±9.2 cm, and weight, 58±14 kg; including 57 males to 35 females. The most common distribution of disease type was the total colitis (63%), followed by left-sided colitis (32%), and proctitis (5%). Complete SR was observed in 15 patients (16%), with remaining 77 patients (84%) classified as SNR. There was no significant difference found in Mayo Endoscopic Score, first dose of PSL, number of hospitalizations, number of relapses, percentage of patients with total-colitis type, or duration of PSL treatment between the SR group and the SNR group. The non-remission rate, defined as failure to achieve mucosal healing, was significantly higher in the SR group (66%) than in the SNR group (36%) (P=0.03). The proportion of patients treated with azathioprine was significantly higher in the SNR group (40%) than in the SR group (39%). The proportion of patients treated with biologics or small molecular compounds was significantly higher in the SR group (40%) than in the SNR group (22%) (P=0.03).

We then compared haematological biomarkers from blood samples obtained prior to PSL administration between the two groups. There was no significant difference in WBC counts, hemoglobin values, serum albumin concentrations, CRP values, and ESR between the two groups. However, eosinophil (both total count number and ratio to white blood cell count) was significantly higher in the SNR group than in the SR group (P=0.02). Neutrophil-lymphocyte ratio tended to be higher in the SNR group than in the SR group (P=0.059). Histological examination revealed that infiltrated eosinophil counts in rectal mucosa biopsied by endoscopy was significantly higher in the SNR group than in the SR group.

Conclusion: Both eosinophil ratios in the blood and rectal mucosa, and neutrophil-lymphocyte ratios in the blood may be potential biomarkers for steroid responsiveness prior to administration.

PP0838

INVESTIGATING THE EVOLUTION OF THE TREATMENT ALGORITHM OF ULCERATIVE COLITIS PATIENTS

P. Robinson[1], D. Baldock[1]
[1]*Ipsos, Healthcare Syndicated, London, United Kingdom*

Contact E-Mail Address: denise.baldock@ipsos.com

Introduction: To examine the evolution of the ulcerative colitis (UC) treatment pathway in advanced therapy (AT) naïve and later line EU4+UK patients over time, as well as identifying how treatment goals may have changed.

Aims & Methods: A multi-centre online medical chart review study of patients with UC was conducted between Jan – Mar 2018, Jul – Sep 2020 and Jan – Mar 2023, among EU4+UK (UK, FR, DE, IT & ES) gastroenterologists practicing across hospital and private practices. Recruited physicians were screened for duration of practice in their specialty and caseload. Respondents completed patient record forms of their next 4 UC patients seen following receipt of the survey.

Results: The total number of sampled gastroenterologists recruited in this survey and reported UC patients are in Table 1.

Timepoint	Q1 2018	Q3 2020	Q1 2023
Surveyed gastroenterologists	207	211	220
Reported UC patients	816	844	880

Table 1: Sampled physician and reported patient sample size

Between Q1'18 – Q3'20 - Q1'23 the percentage usage of total adalimumab volume in reported UC patients dropped (30% vs 15% vs 13%, respectively), as well as the proportion of these patients reported as first line adalimumab patients (90% vs 88% vs 87%, respectively). In addition, the proportion of reported patients who experienced a switch from one TNF to another also drops between Q1'18 – Q3'20 (14% vs 10%, respectively). Conversely, the proportion of reported UC patients receiving a non-TNF therapy increases over time (12% vs 29% vs 43%, respectively); specifically, the proportion of reported non-TNF first line patients increased (5% vs 12% vs 25%, respectively). Switches from non-TNFs to TNFs increased between Q1'18 – Q3'20 (8% vs 11%, respectively). The proportion of the overall sample occupied by first line patients decreased between Q1'18 – Q3'20 (84% vs 77%, respectively).

Conclusion: In this study cohort, use of adalimumab molecule decreases over time, seemingly in favour of non-TNF therapies, as more products become available in the gastroenterology landscape. This trend is seen across both the overall market and at first line of therapy, suggesting a move away from use of the more 'traditional' therapies in general, as well as more frequently choosing a non-TNF as a first line option. The increasing proportion of non-TNF 1st line patients, as well as the increasing proportion of those switching from non-TNFs to TNFs, suggests an increasing proclivity to use non-TNF products earlier in the treatment algorithm. TNF cycling also decreases, suggesting an increased tendency to use non-TNF products. This, along with the decreasing proportion of the sample occupied by first line patients, could indicate an increased propensity by gastroenterologists to switch patients between therapies sooner. Further investigation using comparator cohort is warranted to further investigate impact of increasing numbers of approved UC treatment options.

Disclosure: Nothing to disclose.

PP0839

ASSESSING THE EVOLVING NUANCES OF JAK INHIBITOR PRESCRIPTION IN ULCERATIVE COLITIS (UC) PATIENTS

M. Thoo[1], P. Robinson[2], D. Baldock[2]
[1]*Ipsos, Healthcare Syndicated, Kuala Lumpur, Malaysia,* [2]*Ipsos, Healthcare Syndicated, London, United Kingdom*

Contact E-Mail Address: denise.baldock@ipsos.com

Introduction: Targeted oral therapies offer advanced therapy options with convenient administration and different mechanism of actions to existing biologic therapies to treat ulcerative colitis (UC). The objective of this study was to assess the evolution of Janus Kinase inhibitor (JAKi) usage in UC patients, highlighting any nuances in treating different patient types.

Aims & Methods: A multi-centre online medical chart review study of patients with UC was conducted between Jul – Sep 2019, 2021, and 2022 among UK, FR, DE, IT & ES gastroenterologists practicing across hospital and private practices. Physicians were screened for practice duration and patient volume. Charts of patients prescribed with JAKis were included in the analysis.

Results: The total number of sampled gastroenterologists recruited in this survey and collective total of reported UC patients treated with JAKi therapy are

- Q3 2019: 206 gastroenterologists reporting 127 patients
- Q3 2021: 203 gastroenterologists reporting 87 patients
- Q3 2022: 206 gastroenterologists reporting 100 patients

Looking at reported JAKi-receiving UC patient characteristics, the mean age became progressively younger over time (2019: 40yrs, 2021: 38yrs, 2022: 36yrs) and the proportion of JAKi patients recorded as male also increased between 2019 to 2021 (2019: 65%, 2021: 62%, 2022: 75%). Reported JAKi patients recorded without any additional comorbidities also increased in proportion of the sample from 2019 (2019: 39%, 2021: 58%, 2022: 65%).

The mean recorded calprotectin level of reported JAKi-receiving UC patients increased over time (calprotectin mean – 2019: 204, 2021: 250, 2022: 341). When analysing reasons that prompted sampled gastroenterologists to choose JAKis for the UC patients, 'rapid symptomatic control' and 'pain reduction' were the most frequently cited reasons for every time point.

Timepoint	Q3 2019	Q3 2021	Q3 2022
% cited with ‚rapid symptomatic control'	22.0%	28.7%	36.0%
% cited with ‚pain reduction'	7.1%	10.3%	13.0%
% cited with ‚can be used as monotherapy'	37.8%	43.7%	26.0%

Table 1: Cited reasons for JAKi usage in reported UC patients (% patients)

'Can be used as monotherapy' was cited less as a reason for choosing JAKi in 2022 vs 2019. This aligns with reported JAKi monotherapy usage decreased over the same timeframe (% reported patients receiving JAKi as monotherapy – 2019: 76%, 2021: 72%, 2022: 55%), whilst reported JAKi combination usage with 5-ASA increased (% reported patients receiving JAKi as combination with 5-ASA – 2019: 8%, 2021: 16%, 2022: 30%).

Conclusion: In this study cohort, there is evidence of evolving nuances in JAKi usage among gastroenterologists in their UC patients over time. This may be partly influenced by clinical data release and regulatory influences over this timescale. Further investigation using comparator cohort is warranted.

Disclosure: Nothing to disclose.

PP0840

LONG-TERM OUTCOMES OF ORAL ANTIBIOTICS COMBINATION THERAPY FOR INDUCTION AND MAINTENANCE OF ULCERATIVE COLITIS

Y. Nishikawa[1], N. Sato[1], T. Ohkusa[1]
[1]*Juntendo University, Department of Microbiota Research, Bunkyo-ku, Japan*

Contact E-Mail Address: ohkusa@juntendo.ac.jp

Introduction: Ulcerative colitis (UC) is a chronic inflammatory bowel disease. The long-term maintenance of the disease is an important key of the treatment, as patients experience repetitive exacerbation. Dysbiosis of the gut microbiota is observed among UC patients and modifying their gut microbiota is recently attracting attention as one of the therapeutic targets. In our past study, *Fusobacterium varium* was observed on the mucosa of UC patients with high frequency. Based on this, we developed an antibiotic combination therapy (ATM therapy), which was expected to have sensitivity to *F. varium*. The regimen of our prior studies showed decent effectiveness for induction and maintenance on active UC patients.

Aims & Methods: In this study, we aim to investigate the long-term effectiveness of ATM therapy on a larger cohort.

A prospective open-label trial was undertaken. Patients were eligible if they were 18 years of age or above, and had an established diagnosis of UC based on endoscopic, clinical and histological feature. Exclusion criteria were penicillin allergy, administration of antibiotics agents within 2 weeks of study entry, ongoing biologic therapy, pregnancy, cancer and other serious comorbid illness. Patients who had stool pathogens were also excluded. A combination of oral amoxicillin (1500mg), tetracycline (1500mg) and metronidazole (750mg) was administered to patients daily for 2 weeks in addition to their conventional medication. Clinical assessment was performed using the Mayo score before treatment and at 0, 3, 6, 9 and 12 months. Endoscopic evaluation was performed using the Mayo score before treatment and at 3 and 12 months. The primary endpoint was the response rate at 3 months after the completion of ATM therapy. The secondary endpoints were the remission rate at 3 months, both remission and response rate at completion and 1 year after the ATM therapy. All adverse events were recorded.

Results: The data from 311 active UC patients were analysed. The compliance rate was 95.7%. The response rate and remission rate were 75.2% and 30.9% at completion, 62.7% and 29.6% at 3 months, 35.4% and 24.4% at 12 months, respectively. In the patient group with severe disease activity, the response rate tended to be high and was statistically higher at 6 months (p=0.0299). Regarding steroid dependent, resistant and disease extent, the response rate showed no statistical difference at any follow-up points. Adverse events were reported in 60.8% of participants. The most frequent adverse events were diarrhea (19.0%) and fever (14.8%). No life-threatening adverse event was observed and all the symptoms disappeared immediately after the discontinuation or the completement of the therapy.

Conclusion: 2 weeks administration of ATM therapy induces response and remission of UC and maintains the symptom for long-term. The ATM therapy would be considered as one of the easy and convenient therapeutic choices for both induction and maintenance of the disease.

Disclosure: Nothing to disclose.

ANTI-TNF AGENTS AND VEDOLIZUMAB HAVE SIMILAR SAFETY AS FIRST-LINE BIOLOGIC TREATMENT OF ELDERLY PATIENTS WITH ULCERATIVE COLITIS

N. Nachmias Peiser[1], T. Thurm[2], N.A. Cohen[2], A. Hirsch[2], Y. Ron[2], N. Maharshak[2]
[1]*Tel Aviv Sourasky Medical Center, Internal Medicine Department D, Tel Aviv, Israel,* [2]*Tel Aviv Sourasky Medical Center, Department of Gastroenterology and Liver Diseases, Tel Aviv, Israel*

Contact E-Mail Address: noy.na87@gmail.com

Introduction: The prevalence of ulcerative colitis (UC) in elderly patients is rising and is associated with aging-related challenges such as functional reserve decline, compromised immune responses, and comorbidities. Anti-TNF agents and vedolizumab are effective therapies for UC but may also be associated with increased risk in elderly patients. Therefore, it is challenging to choose a first-line biologic therapy (FLBT) and data regarding FLBT for the aging population are scarce.

Aims & Methods: Our aim was to compare the safety, and persistence on drug of elderly patients with UC treated with anti-TNF agents compared to vedolizumab as first-line therapy.

This was a retrospective, single tertiary center study, including all patients with UC who initiated their FLBT at age≥60 years, between 1/1/2010 to 31/12/202. Clinical and demographic data were extracted and adverse events occurring within 52 weeks of treatment initiation were recorded.

Results: A total of 264 patients with UC aged ≥60 years were screened,62 patients were included in the final analysis [35 males (56.4%), age 68.9±7.0 years, disease duration 12.1±13.1 years]. Anti-TNF was the FLBT for 33 patients (53.2%) and vedolizumab for 29 patients (46.8%). Disease duration, gender, smoking status, concomitant exposure to steroids, concomitant use of IMM were comparable between the groups. Patients treated with an anti-TNF had a significantly lower CCI (4.9±1.86vs. 3.7±2.0, p=0.017) and more severe endoscopic disease (2.5±0.8 vs. 2.2±0.6, p=0.009) **(**Table **1)**.

	Anti TNF (n=33)	Vedolizumab(n=29)	
Male gender (%)	18 (54.45)	17 (58.62)	0.801
Disease duration (y)	10.45±10.55	13.93±15.47	0.301
Steroids(%)	18(54.5)	14(48.2)	0.696
IMM(%)	9(27.2)	2(6.8%)	0.194
Mayo score	2.53±0.8	2.26±0.6	0.009
CCI	3.75±2.01	4.96±1.86	0.017
SCCAI	8.2±3.4	7.2±3.4	0.614
^CRP(mg\L)	8.1 [1.27-18.10]	10.9 [2.55-37.75]	0.466
^Calprotectin(µg/g)	1392.5 [389.00-2750.00]	618.0 [281.75-1100.75]	0.367

*Anti TNF group included 21 patients on infliximab and 12 patients on Adalimumab; Plus-minus values are means ±SD, 5-ASA=5 aminosalicylic acid, IMM=immunomodulators(methotrexate, azathioprine,6-mercaptopurine),y=years
^CRP and calprotectin are calculated as medians with IQR in [ ].

Table 1: Characteristics of study cohort.

Overall, at 52 weeks of follow-up, 6 patients had an adverse event. 4 patients suffered from infections:1 patient treated with Anti-TNF had severe pneumonia and needed hospitalization, 2 patients treated with vedolizumab had CMV infection and needed treatment cessation until resolution of CMV and another patient treated with vedolizumab, with known metastatic disease (CCI=10), died due to sepsis (week 17). No de-novo or recurrent malignancy were observed. One patient on vedolizumab had a skin rash treated with antihistamines and did not require treatment cessation, another patient on infliximab stopped treatment due to anaphylaxis. There

were similar rates of hospitalizations between the cohorts (39.4% vs.17.2%, respectively, p=0.230). In terms of treatment persistence, median time on anti-TNF was similar to that on vedolizumab (32.00 weeks [20.00-80.57, n=13] vs 45.07 weeks [24.39-155.60, n=28] (p=0.324), respectively).
Conclusion: Anti-TNF and vedolizumab are equally safe as first-line biologic therapy among elderly patients with UC indicating that other factors may guide therapy selection in this patient population. Further prospective and larger studies are needed to fortify our findings.
Disclosure: Nothing to disclose.

THE EFFECTS OF QINGCHANG WENZHONG DECOCTION ON TISSUE-RESIDENT MEMORY CD4+T CELLS IN MICE WITH ULCERATIVE COLITIS

M. Wang[1], Y. Yuan[1], X. Lu[1], W. Zhang[1], Y. Yun[1], Y. Xing[1], J. Li[1], T. Mao[1]
[1]Beijing University of Chinese Medicine / Dongfang Hospital, Beijing, China

Contact E-Mail Address: 547446830@qq.com
Introduction: Ulcerative colitis (UC) is a difficult-to-treat gastrointestinal disease, but its etiology and pathogenesis have not been clarified. An increasing number of studies have shown that the development and recurrence of UC are closely related to immune memory dysfunction. Our team's previous clinical and animal experiments have suggested that the treatment of UC with the Qingchang Wenzhong Decoction (QCWZD) is effective and can regulate intestinal mucosal immunity, but the exact mechanism is not yet clear. In this study, tissue-resident memory $CD4^+T$ cells ($CD4^+T_{RM}$ cells) were used as the entry point to further investigate the immunological mechanism of the QCWZD for the treatment of UC.
Aims & Methods: To explore the regulatory effect of QCWZD on $CD4^+T_{RM}$ cells in mice with DSS-induced colitis. This study aims to provide a new theoretical basis for the treatment of UC. Female C57BL/6 mice were randomly divided into control group, model group, QCWZD low-dose group, QCWZD medium-dose group, QCWZD high-dose group. Mice in control group were fed and watered freely throughout the whole process. Model group and doses group of QCWZD were used to replicate the UC model by freely drinking 2.5 % dextran sulfate sodium (DSS) (w/v) solution for 7 days. At the same time, model group was given deionized water gavage, and each dose group of QCWZD were given the corresponding concentration of QCWZD intervention for 1 week (Fig1 A). During this period, the mice were observed daily for general condition, weight measurement, detection of fecal occult blood, recording of fecal properties. The proportion of $CD4^+T_{RM}$ cells was performed with flow cytometry and the expression levels of proteins in related signaling pathways was assessed.
Results: Our findings demonstrated that DSS intervention resulted in colon inflammation with clinical changes, while QCWZD appreciably reversed these phenomenon, as evidenced by retarded body weight loss, recovery of rectal bleeding and diarrhea, decreased disease activity index scores (Fig1 B-C). Moreover, the proportion of $CD4^+T_{RM}$ cells in the lamina propria of mice in the DSS group were significantly higher than those in the Control group, while the $CD4^+T_{RM}$ cells proportion was significantly reduced after the intervention with the QCWZD (Fig1 D-E). Mechanistically, the results from RT-qPCR analysis of the colonic tissue showed that QCWZD could significantly reduce the expression of glucose transporter protein *Glut1/2/4* mRNA (Fig2 F-H), as well as the levels of key enzyme genes of glycolytic pathway (*HK2, PKM2, G6PC, LDHA* mRNA) (Fig2 I-J), suggesting that QCWZD had an inhibitory effect on glycolytic metabolism in colitis mice. We further found that the mRNA expressions of colon *LepR* and *HIF-1α* mRNA were significantly downregulated in QCWZD-treated mice (Fig2 M-N). These results demonstrated that QCWZD regulated the glycolytic metabolism of $CD4^+T_{RM}$ cells by inhibiting the activity of LepR/HIF-1α signaling axis.
Conclusion: The results from our current study demonstrated that orally administrated QCWZD regulates $CD4^+T_{RM}$ cells immune homeostasis through the modulation of glycolytic metabolism, and hold the therapeutic potential for immunology-targeted strategy in the treatment of UC.

COMPARISON OF REAL-WORLD TREATMENT PERSISTENCE AND SAFETY OF VEDOLIZUMAB AND ANTI-TUMOR NECROSIS FACTOR-ALPHA TREATMENT IN BIOLOGIC-NAÏVE PATIENTS WITH CROHN'S DISEASE: SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

A. Armuzzi[1], P. Biedermann[2], R.J. Brown[3], M. Neuhold[2], S. Wisseh[4], S. Schreiber[5]

Contact E-Mail Address: alessandro.armuzzi@hunimed.eu
Introduction: Vedolizumab (VDZ), a gut-selective anti-lymphocyte trafficking agent, was approved for the treatment of moderate-to-severe Crohn's disease (CD) in Europe and the USA in 2014. We conducted a systematic literature review and meta-analysis of studies reporting real-world effectiveness of VDZ in patients with CD. Here we describe treatment persistence in biologic-naïve patients with CD treated with VDZ compared with anti-tumor necrosis factor-alpha (TNFα) treatment at 12 and 24 months to address the gap of long-term data available on patients with CD.
Aims & Methods: Systematic literature reviews were performed using MEDLINE, MEDLINE In-Process, Embase, Cochrane Library, clinicaltrials.gov, and the World Health Organization International Clinical Trials Registry Platform to identify relevant studies published from May 2014 to July 2022. In addition, if the congress abstracts were not indexed in Embase, key congresses from 2015 to July 2022 were hand searched. Data from adults (aged ≥ 18 years) with CD treated with VDZ in observational/real-world studies were extracted for meta-analysis. The analysis was conducted using the DerSimonian-Laird random-effects method to obtain weighted mean rates (percentage of patients) and the corresponding 95% confidence interval (CI) for each treatment persistence or serious adverse event (SAE) as performed for a meta-analysis published in 2018.[1]
Results: Overall, data from 78 studies of 30 158 patients with CD had at least one outcome of interest for analysis. Four and three studies of 7082 and 5040 patients with CD, respectively, reported the rate of treatment persistence in biologic-naïve patients treated with VDZ versus anti-TNFα treatment at 12 and 24 months. The rate of treatment persistence was higher with VDZ (83.8% [95% CI 71.4–96.1]) compared with anti-TNFα treatment (75.3% [69.9–80.7]) at 12 months. Similarly, the rate of treatment persistence was higher with VDZ (70.4% [95% CI 61.3–79.6]) compared with anti-TNFα treatment (64.5% [56.9–72.2]) at 24 months. Two

studies of 491 and 86 biologic-naïve patients with CD treated with VDZ versus anti-TNFα treatment reported SAEs. In a retrospective study, safety outcomes were followed from treatment initiation up to five half-lives post-treatment discontinuation; 8.3% treated with VDZ experienced SAEs compared with 19.0% with anti-TNFα treatment.[2] In an additional retrospective study that reported SAEs within the first 12 months of treatment; the rate of SAEs was comparable between patients treated with VDZ (18.2%) and anti-TNFα treatment (17.0%).[3] Among these patients, only those receiving anti-TNFα treatment experienced drug-induced SAEs (3.8%; pancreatitis and systemic lupus erythematosus).[3]

Conclusion: This meta-analysis of real-world studies demonstrated higher rates of long-term treatment persistence and suggests that VDZ may have a favorable safety profile compared with anti-TNFα treatment in biologic-naïve patients with CD.

Introduction: Ulcerative colitis (UC) is a chronic, relapsing, nonspecific inflammatory bowel disease (IBD). Cucurbitacin B (CuB) is a naturally occurring compound primarily found in plants of the Cucurbitaceae and Cruciferae families. CuB has been shown to have a wide range of pharmacological activities, including anti-inflammatory, antioxidant, antiviral, hypoglycemic, hepatoprotective, neuroprotective, and anti-cancer effects. However, there is a paucity of reports providing direct evidence of the efficacy of CuB in ameliorating colitis in mice.

Aims & Methods: This study aimed to explore the therapeutic effect and underlying molecular mechanisms of CuB on dextran sulfate sodium (DSS)-induced UC mice and lipopolysaccharide (LPS)-induced RAW264.7 cells. The protective effect of CuB on DSS-induced UC was evaluated by assessing weight loss, disease activity index (DAI) score, spleen index, colon length shortening, myeloperoxidase (MPO) activity, and pathological changes. The levels of inflammatory cytokines were detected by ELISA and RT-PCR analysis. The expressions of tight junction (TJ) proteins like ZO-1, Occludin, and the target proteins in the mitogen-activated protein kinase (MAPK) and nuclear factor-kappa B (NF-κB) were determined by western blotting analysis.

Results: CuB significantly attenuated the symptoms of UC and suppressed colon MPO activity. In addition, CuB could significantly increase the expression of TJs in UC mice. Meanwhile, CuB treatment reduced the levels of inflammatory cytokines and inhibited the phosphorylation of MAPK and NF-κB signaling pathways in UC mice and in LPS-induced RAW264.7 cells.

Conclusion: In summary, our study demonstrated that CuB ameliorated DSS-induced UC by inhibiting the inflammatory response and maintaining the intestinal barrier function via modulation of the MAPK/NF-κB pathways. These results suggest that CuB could be a promising candidate for UC therapy.

UPREGULATED TISSUE FACTOR IN COLONIC MESENCHYMAL CELLS IN ACTIVE ULCERATIVE COLITIS IS ASSOCIATED WITH SEVERE AND RESISTANT TO TREATMENT DISEASE, BUT TOFACITINIB HAS NO EFFECT ON IT

I. Drygiannakis[1], N. Tzenaki[1], E. Archontoulaki[2], E. Filidou[3], L. Kandilogiannakis[3], N. Dovrolis[3], G. Kefaloyiannis[4], V. Valatas[1], G. Kolios[3], I. Koutroubakis[1]

Introduction: Tissue factor (TF) on cell membranes initiates blood clotting upon vessel trauma and exposure of subendothelial cells to blood flow. The risk of thromboembolic events is increased in patients with ulcerative colitis (UC). Tofacitinib, a JAK1 & 3 inhibitor, recently introduced in UC therapeutics, may further increase the risk[1].

Aims & Methods: To delineate thrombosis pathophysiology in this context, TF expression in primary human colonic mesenchymal cells (PHCMC) of patients with active UC was correlated with clinical, biochemical and endoscopic data. We then treated those PHCMC with tofacitinib, with or without cytokines to better mimic the *in vivo* milieu they are exposed to. PHCMC were isolated and set to *ex vivo* culture from endoscopic biopsies of the inflamed mucosa of 10 UC patients with an endoscopic Mayo score ≥ 2 were treated with each one of all major T helper (Th)1 (TNF-α, IFN-ɣ), Th2 (IL-4, IL-13) or T regulatory (Treg; TGF-β, IL-10) cytokines with or without tofacitinib. Cells were lysed, RNA was isolated and reverse-transcribed to cDNA. *TF* and *RPL4* (housekeeping) cDNAs were quantified as C_T cycles with real-time, reverse-transcription PCR. Wilcoxon and Mann-Whitney U tests were used to compare *TF* $\Delta\Delta C_T$ for paired or unpaired values, respectively, and Spearman's rho to correlate *TF* $\Delta\Delta C_T$ with scale clinical variables and continuous laboratory values.

Results: Increased *TF* mRNA abundance in PHCMC was associated with increased partial Mayo score (Spearman's rho 0.661, $p < 0.044$), reduced serum albumin (Spearman's rho -0.723, $p < 0.05$) and more severe endo-

scopic lesions (endoscopic Mayo score 3). No association with CRP was found (p > 0.999). Cells originating from UC patients of an endoscopic Mayo score 3 expressed 20 times more *TF* than those from an endoscopic Mayo score 2 (p < 0.017). Furthermore, PHCMC from difficult-to-treat patients, defined as requiring > 1 biologics, expressed 9 times more *TF* than those from patients requiring ≤ 1 biologics.

Interestingly, treatment of PHMC with tofacitinib did not upregulate *TF*. PHCMC expressed receptors and responded to treatment with all major Th1 (TNF-α, IFN-ɣ), Th2 (IL-4, IL-13) or Treg (TGF-β, IL-10) cytokines by further upregulating *TF* by 5.5-7.5 times (p 0.001 - 0.035). IL-13 had the maximal effect. Even when tofacitinib was added together with the aforementioned cytokines, it did not further upregulate *TF*. Instead, it tended to partially inhibit their effects; for example, it decreased upregulation of *TF* by IL-13 by 40%.

Conclusion: The expression of *TF* mRNA in active UC is significantly associated with clinically and endoscopically severe disease and resistance to treatment. Tofacitinib *per se* does not increase *TF*. Instead, it may limit the upregulating effect of pro-inflammatory cytokines.

Introduction: Early surgical intervention in Crohn's disease (CD) with inflammatory (B1) phenotype has been shown to be equally successful compared to biologic treatment in the LIR!C study. A recent work by PREDICT IBD group reconfirmed these findings.

On the other hand, the prospective multicenter CREOLE study demonstrated long term (>4 years) surgery free survival in stricturing (B2) CD in over 50% of patients, treated with medical and endoscopic therapy. These conflicting findings complicate decision making in the individual patient, and data on conservative management of penetrating CD is lacking.

Aims & Methods: To compare long term outcomes between the early surgery and conservative treatment approach in patients presenting with penetrating (B3) CD.

This was a retrospective, single tertiary center study, including adult CD patients hospitalized with penetrating abdominal CD, between 1/8/2010 to 30/6/2018.

Demographic and clinical data including medical treatment, hospitalization duration, medical and surgical treatments during hospitalization and subsequent hospitalizations and treatments were collected from hospital records. Patients were divided into 2 groups:

1. Early surgery (<12 weeks from index hospitalization), and;
2. Conservative treatment.

Multivariable logistic regression model adjusted for age, sex and smoking status was used for statistical analysis.

Results: A total of 43 CD patients [21 male (48.8%), age 37.9±15.1 years, disease duration 14.1±12.0 years] were hospitalized during the study period for first presentation of penetrating CD [14 (32.6%) with a sinus tract and 29 (67.4%) with an abscess]. Twenty-three patients (53.5%) underwent early surgery (69.5% of whom manifested with abscesses), and the rest were managed non-surgically.

Both groups were similar in terms of CD Montreal classification, smoking status, and type of penetrating complication. Follow up duration was comparable (median 5.2±2.3 years vs 5.3±2.3 years for early surgery vs conservative treatment, respectively, p=0.855).

Exposure to biologics, immunomodulators and glucocorticoids was comparable between the groups before and after index hospitalization.

During the follow up after discharge from the index hospitalization, patients in the surgical group had significantly lower incidence rates of recurrent abscesses (45% vs 4.5%, odds-ratio (OR) 0.04, 95% confidence interval (CI) 0.003-0.40, p=0.006), need for recurrent courses of antibiotics (55.0% vs 14.3%, OR 0.09, 95% CI 0.02-0.53, p=0.07) and recurrent hospitalizations (70.0% vs 39.1%, OR 0.16, 95% CI=0.03-0.72, p=0.017). Two patients (8.7%) in the early surgery group underwent abdominal surgery during follow-up compared to six patients (30.0%) of the conservative treatment group (OR 0.11, 95% CI 0.01-0.92, p=0.04).

Conclusion: In CD patients hospitalized with a penetrating complication, early surgery resulted in significantly less adverse long-term outcomes, such as recurrent abscesses, need for antibiotic treatment, hospitalizations, and surgeries than patients managed conservatively over a median follow up period of 5 years.

Disclosure: Nothing to disclose.

Introduction: The Janus kinase inhibitor (JAKi) upadacitinib (UPA) is approved for the treatment of moderate-to-severe ulcerative colitis (UC). However, safety warnings from the US Food and Drug Administration and the European Medicines Agency recommend caution when using JAKis in certain at-risk patients. These drug-class warnings are based on data from the ORAL Surveillance (OS) study, a safety outcomes trial comparing risk of cardiovascular (CV) events with the JAKi tofacitinib plus methotrexate vs a tumor necrosis factor inhibitor (TNFi) plus methotrexate in patients with rheumatoid arthritis (RA) who were ≥50 years of age with ≥1 CV risk factor.[1] An OS study post hoc analysis observed higher major adverse CV event risk with tofacitinib vs TNFi in patients with RA plus a history of atherosclerotic CV disease (ASCVD).[2] CV risk profiles may be different for patients with UC vs RA.

Aims & Methods: This analysis aimed to describe the CV risk profile for patients with UC relative to the CV risk profile for patients with RA included in the OS study. Patients with UC enrolled in the placebo-controlled UPA U-ACHIEVE and U-ACCOMPLISH induction trials[3] were evaluated for the OS study inclusion criteria (age ≥50 years, ≥1 CV risk factor [CV event history, hypertension, diabetes mellitus, smoking/tobacco use, and high-density lipoprotein cholesterol <1.034 mmol/L]). In addition, history of coronary artery disease or ASCVD and 10-year CV disease risk for patients with UC with no prior CV disease were estimated using the American College of Cardiology ASCVD risk score calculation.

Results: Overall, 268/1097 (24.4%) patients with UC met the OS criteria and 624 (56.9%) had ≥1 CV risk factor, regardless of age. Few patients with UC (30; 2.7%) had a history of ASCVD, in contrast to the RA population (640/4362; 14.7%). The distribution of 10-year ASCVD risk scores for patients with UC was similar between the placebo and UPA treatment arms, but markedly different from patients with RA (Table). Most patients with UC were categorized as low risk (938; 85.5%), with another 52 (4.7%) categorized as borderline risk, 51 (4.6%) as intermediate risk, and 26 (2.4%) as high risk.

	Patient Population[a]				
	Ulcerative Colitis		Rheumatoid Arthritis[2]		
ASCVD risk[b], n (%)	Placebo N = 378	UPA 45 mg N = 719	TOFA 5 mg N = 1455	TOFA 10 mg N = 1456	TNFi N = 1451
HxASCVD	10 (2.6)	20 (2.8)	204 (14)	222 (15)	214 (15)
High (≥20%)	6 (1.6)	20 (2.8)	258 (18)	289 (20)	278 (19)
Intermediate (≥7.5% to <20%)	19 (5.0)	32 (4.5)	472 (32)	490 (34)	483 (33)
Borderline (≥5% to <7.5%)	13 (3.4)	39 (5.4)	198 (14)	169 (12)	153 (11)
Low (<5%)	330 (87.3)	608 (84.6)	306 (21)	268 (18)	308 (21)

[a]In the rheumatoid arthritis population, the 10-year risk scores were multiplied by 1.5 prior to the derivation of risk categories; in ulcerative colitis, no multiplier was used. [b]ASCVD risk score was calculated based on the following factors: patient age, sex, race, systolic blood pressure, total cholesterol, HDL, history of diabetes [Y/N] or smoking [Y/N], and hypertension treatment [Y/N]). ASCVD, atherosclerotic cardiovascular disease; HxASCVD, history of ASCVD; TNFi, tumor necrosis factor inhibitors, TOFA, tofacitinib; UPA, upadacitinib

Table.

Conclusion: The majority of patients in the UC trials had low estimated CV risk, while the majority of patients with RA included in the OS study were at intermediate or high CV risk. Caution should be used when extrapolating adverse events data from patients with RA to risk discussions for patients with UC.

Introduction: Tofacitinib is indicated for the treatment of adult patients with moderately to severely active ulcerative colitis (UC). The recommended induction scheme is 10 mg twice daily (BID) for at least 8 weeks followed by a maintenance dose of 5 mg BID. However, some patients re-

quire 10mg bid, for 16 weeks at the induction phase. Our study aimed to assess the demographics and disease characteristics of such patients and their outcome at 24 weeks.

Aims & Methods: This was a multicenter, retrospective, observational study which included patients with moderate to severe UC, who received induction therapy with Tofacitinib 10mg bid for a 16-week period. Data were collected between July 2018 and November 2022. The primary objective was disease outcome, defined as clinical remission and/or the need of steroids. Secondary outcomes were treatment withdrawal, treatment de-escalation and adverse events.

Results: In total 31 patients, are currently enrolled in our study, from 10 IBD centres [males: 51.6%, mean age at study entry: 40.0 years, median disease duration: 7 years]. Patient demographic and clinical characteristics at baseline are shown in table 1. Four patients (12.9%) discontinued treatment before week 24, due to inadequate response. De-escalation of dosing to 5mg bid tofacitinib was attempted in 13 of 27 patients (48.1%) and was successful in 7 patients (53.8%) who maintained clinical response until week 24 of the study. Of the other 6 out of 13 patients, 6 patients received again the higher dose (10 mg bid) and regained response and only one patient discontinued treatment. Overall, 85.7% (6/7) of the patients who received tofacitinib 5mg bid and 66.7% (14/21) who received 10mg bid at 24 weeks, had received more than one biologic prior to tofacitinib (*P*=0.34). At week 24, the partial Mayo score was available in 26 patients; 13 patients were in steroid-free clinical remission (pMayo <2). Twelve patients had mild active disease (pMayo 2-4) and 9 of them had stopped steroids. No major adverse events were observed during the entire observation period.

Age [years; mean (±SD)]		41.0 (±13.6)
Sex [N (%)]	Male	16 (51.6)
BMI [kg/m^2; median (IQR)]		26.8 (23.7 – 28.6)
Smokers [N (%)]	Never/Current/Prior	23 (74.2)/ 3 (9.7)/ 5 (16.1)
Previous treatment [N (%)]	Systemic corticosteroids	25 (80.6)
	Thiopurines/ Methotrexate	16 (51.6)/ 2 (6.5)
	Biologics	26 (83.9)
pMayo score [N (%)]	2-4/ 5-7/ >7	9 (29.0)/ 14 (45.2)/ 8 (25.8)
EndoMayo score [N (%)]	2/3	10 (32.3) / 18 (58.1)

Table 1. Demographic and clinical characteristics of patients (N=31).

Conclusion: In a real-world setting, a 24-week treatment with tofacitinib 10mg BID is safe and the majority of patients achieve clinical remission and manage to stop steroids. De-escalation at 5mg bid is successful in more than half of them. We prospectively follow up our cohort to investigate whether these preliminary results will be confirmed for a longer period.

Disclosure: Nothing to disclose.

THE COMPARATIVE EFFECTIVENESS OF ANTI-TNF IN BIO-NAÏVE AND BIO-EXPERIENCED PATIENTS WITH IBD: RESULTS FROM A REAL-WORLD EXPERIENCE AT A BELGIAN TERTIARY CENTRE

L. Deroo[1], L. Suarez-Lopez[2], M. Truyens[1,3], J. Geldof[1], S. Akhayad[1], G. Dewitte[1], E. Glorieus[1,3], T. Lobaton[1,3]

Contact E-Mail Address: liesbeth.deroo@ugent.be

Introduction: As the therapeutic armamentarium for inflammatory bowel disease (IBD) is rapidly expanding, it is of increasing importance to optimize treatment sequencing. However, head-to-head trials comparing efficacy of tumor necrosis factor alpha inhibitors (anti-TNF) in bio-naïve and bio-experienced patients (not compared to placebo), are scarce.

Aims & Methods: Aim: To compare the effectiveness of anti-TNF (infliximab and adalimumab) in bio-naïve versus bio-experienced IBD patients in a real world setting.

Methods: A retrospective monocentric study was performed in IBD patients treated with anti-TNF at a Belgian University Hospital, from January 2018 to June 2021 with follow-up until December 2021.

Primary endpoints considering efficacy after induction and after 1 year of therapy were: clinical response (CRp) and remission (CRm), biochemical response (BRp) and remission (BRm) and endoscopic response (ERp) and remission (ERm).

Secondary endpoint was treatment survival during follow-up. For assessment of risk factors influencing efficacy and treatment survival, a multivariate logistic regression and Cox regression model were applied.

Results: A total of 114 patients were treated with anti-TNF, 57 bio-naïve and 57 bio-experienced. At baseline, significantly more bio-experienced patients had moderate to severe comorbidities (12.3% (5/57) vs. 0% (0/57), P=0.013) and longer disease duration (4 vs. 1 year, P<0.001).

Montreal classification for location in Crohn's disease (CD) was significantly different (P=0.024), as there were less patients with L3 and more patients with L4 in bio-naïve vs. bio-experienced patients. After induction of therapy, no difference could be found for CRp and CRm for both groups (P=0.364 and P=1.000 respectively).

Bio-naïve patients had a significantly higher BRp (87.8% (43/49) vs. 68.6% (35/51), P=0.021). Multiple logistic regression showed a significant higher BRp rate for patients treated for CD vs. UC (aOR 3.17 95% CI[1.03-9.78], P=0.045). Same results were found for BRm (87.8% (43/49) and 64.7% (33/51) for bio-naïve vs. bio-experienced, P=0.007).

Multiple logistic regression showed a significant higher BRm in bio-naïve patients (aOR 3.72 [1.21-11.48], P=0.022) and in patients treated for CD vs. UC (aOR 3.48 [1.14-10.60], P=0.028). ERp (P=0.377) and ERm (P=0.707) were not significantly different.

After 1 year, no difference could be found for CRp (P=0.126). Significant more bio-naïve patients reached CRm (78.2% (43/55) and 60.4% (32/53), P=0.045). Multiple logistic regression could not withheld this difference after adjustment. No significant difference was seen for BRp (P=0.954) and BRm (P=0.367). More bio-naïve patients reached ERp (81.3% (26/32) vs. 54.1% (20/37), P=0.017). Multiple logistic regression showed a just not significant higher ERp rate in bio-naïve patients (aOR 4.99 [1.00-24.86], P=0.050). Age had a significant influence on ERp (aOR 0.93 [0.874-0.996], P=0.039). No difference could be found for ERm (P=0.227). Regarding treatment survival using Cox regression model, no significant difference could be found for both groups (aHR 1.54 [0.71-3.32], P=0.273).

Conclusion: In general, in this tertiary real world cohort of patients with IBD, the effectiveness of anti-TNF did not differ significantly between bio-naïve and bio-experienced patients.

Disclosure: Nothing to disclose.

Introduction: Ustekinumab (UST) and adalimumab (ADA) are approved for the treatment of Crohn's disease (CD); however, comparative data assessing the mechanism of action (MoA) of Interleukin (IL)-12/23p40 (UST) and TNFα (ADA) blockade in CD are limited. The SEAVUE study (NCT03464136) prospectively compared the safety and efficacy of both treatments in a randomized, double-blind, treat-through design.

The objective of this study is to assess key inflammatory mediators in CD associated with the MoA of UST and ADA in the context of a head-to-head comparator study.

Aims & Methods: Biologic-naïve patients with moderately to severely active CD received either UST (n=191; approximately 6 mg/kg intravenously on day 0, then 90 mg subcutaneously [SC] once every 8 weeks (WK)) or ADA (n=195; 160 mg on day 0, 80 mg at 2 WKs, then 40 mg SC once every 2 WKs through WK56). Serum was collected at WKs 0, 16, and 52 and assessed with a broad inflammatory panel (Olink 92 analyte) and a targeted custom IL-22 immunoassay.

Differences in temporally expressed proteins for each treatment arm were determined with a minimum fold change (≥1.2) using a linear model accounting for subject as a random effect. Normalized values for each treatment group were compared with healthy control sera (n=40). Treatment groups were further subdivided by patient reported outcomes (PRO) and endoscopic response status at WK52.

Results: Of the 93 analytes, 79 passed quality control thresholds. UST and ADA induced distinct serum inflammatory profiles at both induction WK16 and maintenance WK52, notable shifts are described here. UST inhibited interferon gamma (IFNɣ), IL-22, OSM, CXCL9 and IL-6 at WK16 and WK52 compared to baseline ($p<0.05$). ADA inhibited IFNɣ, OSM, IL-6, CXCL10, CXCL11, CCL3, CCL23, and TNFRSF9 at WK16 and WK 52 compared to baseline ($p<0.05$). Sub-group analysis revealed both UST and ADA significantly reduced IFNɣ at WK16 and WK52 in endoscopic responders ($p<0.05$). UST suppressed IL-22 in both endoscopic responders and non-responders at WK16 (31% and 20%, respectively) and WK52 (41% and 25%, respectively) while ADA had no impact on IL-22 at Wk16 and elevated IL-22 levels in endoscopic non-responders at WK52 ($p<0.05$). In UST patients, a reduction of IFNɣ significantly correlated with an improvement in the fatigue component of the PROMIS-29 (>5 point decrease). ADA reduced IFNɣ only in responders ($p<0.05$) with no correlation to fatigue and more broadly suppressed of chemokines. Inflammatory chemokines CXCL11 and CCL23 were elevated at baseline and significantly reduced at WK16 and WK52 by both UST and ADA ($p<0.05$). CCL4 and CXCL10 were not elevated at baseline or impacted by UST but were reduced by ADA relative to control sera ($p<0.05$).

Conclusion: These data demonstrate differential systemic inflammatory mediators associated with UST and ADA treatment in biologic-naïve patients with moderately to severely active CD as observed in the SEAVUE active comparator study. The magnitude of reduction of IFNɣ was linked to endoscopic response and improvement in fatigue. Suppression of IL-22 by UST is consistent with inhibition of IL-12/23p40.

While ADA reduced IFNɣ only in endoscopic responders, it did not reduce IL-22 and exhibited a broader anti-inflammatory effect via chemokine level decrease that was not associated with endoscopic response. Long-term treatment data are necessary to understand the association of therapeutic MoA with treatment retention and PRO.

FILGOTINIB FOR THE TREATMENT OF MODERATE TO SEVERE ULCERATIVE COLITIS: AN EARLY REAL-WORLD UK TERTIARY CENTRE EXPERIENCE

R. Hall[1], A. Agorogianni[1], S. Kalyanji[1], F. Donovan[1], K. Patel[1], S. Honap[1,2]

[1]St George's University Hospital NHS Foundation Trust, London, United Kingdom, [2]King's College London, School of Immunology and Microbial Sciences, London, United Kingdom

Contact E-Mail Address: richard_hall@live.co.uk

Introduction: Filgotinib is an oral Janus kinase 1 selective inhibitor licensed for the treatment of moderate to severe ulcerative colitis (UC) following the successful UC-SELECTION registration trials.[1] However, no real-world data have been published since filgotinib first received marketing authorisation in November 2021.

Aims & Methods: The aim of this study was to assess the short-term safety and effectiveness of filgotinib for the treatment of UC. The primary outcome was post-induction clinical remission, defined as a Simple Clinical Colitis Activity Index (SCCAI) of ≤2. A retrospective, observational cohort study was conducted at a tertiary IBD referral centre using prospectively maintained records between August 2022 and February 2023. Clinical disease activity was assessed at baseline and following induction at week 10 using paired SCCAI scores, faecal calprotectin (FCAL), and C-reactive protein (CRP). Quality of life was assessed using the IBD-Control questionnaire. Non-responder imputation was used for analyses.

Results: Thirty-four patients were initiated on filgotinib during the study period, with post-induction outcome data available for 32 patients; 56% male, median age 38 (IQR range 26–53), 41% with prior biologic and/or tofacitinib exposure. Patients were treated for a median duration of 20 weeks (IQR 13–25) with treatment persistence of 69% at the time of analysis; eight patients were switched to alternative treatments due to non-response and two patients underwent colectomy.

At the end of induction, nine patients (28%) were in clinical remission; all patients were corticosteroid-free. Median SCCAI decreased significantly from a baseline of 7 (IQR 4-10) to 1 (IQR 0-6) at week 10, p<0.01, n=25. Median FCAL fell numerically from a baseline of 464 mcg/g (IQR 183-1245) to 125mcg/g (IQR 30-502) following induction, p=0.06, n=20.

There was no significant change in CRP, haemoglobin, serum albumin, or lipid profile components following induction. There was a significant improvement in pre- and post-treatment quality of life scores from a median of 5 (IQR 2-9) to 16 (IQR 4-16), p<0.01.

Thirteen patients described a mild self-resolving coryzal illness, sore throat, or headaches during treatment. There was one reported case of oral herpes simplex infection requiring treatment interruption. There were no serious adverse events.

Conclusion: Filgotinib was well tolerated and clinically effective in the short term with improvements in quality of life but larger prospective cohorts with longer follow up are needed.

Introduction: Real-world studies on vedolizumab (VDZ) are often limited by small sample size and short follow-up; furthermore, there is still only limited knowledge regarding predictors of response. Our study aims to evaluate the long-term effectiveness and safety of VDZ, and to apply a machine learning (ML)-based algorithm to identify predictors of both outcomes.

Aims & Methods: The Long-term Italian VDZ Effectiveness (LIVE) study included CD and UC patients (pts) started on VDZ from 04/2016 to 06/2017 at 47 centers of the Italian Group for the study of IBD. Pts were prospectively followed-up to 06/2019. The primary endpoint was steroid-free clinical

remission (SFCR) at 12 months (mo). Secondary endpoints included persistence and safety. An eXplainable Artificial Intelligence (XAI) model (XGBoost) was applied to identify the main baseline clinical predictor of SFCR at 12 months and of the development of adverse events (AEs).

Results: We enrolled 1111 pts (564 CD, 547 UC). At baseline, mean age and disease duration were 47.7 (±16) and 11.8 (±9) years; 256 (23%) pts were bionaïve. SFCR (clinical remission + no steroid therapy in previous 3 mo) was reported in 193 (34.3%) and 178 (31.6%) CD pts, and in 205 (37.8%) and 215 (39,7%) UC pts, at 12 and 24 mo. Notably, a nearly significant increase in the rates of SFCR was observed from 14 weeks to 6 mo (27.1% *vs.* 35.7%, p=0.051) in the CD cohort; similarly, a significant increase in the rates of SFCR between 14 weeks and 6 mo (28.0% *vs.* 35.6%, p=0.008) was recorded in UC patients. From 6 months onwards, a substantial stability was observed in both cohorts. Overall, 488 (44.2%) patients suspended vedolizumab during the observation: 261 (46.4%) CD and 227 (41.9%) UC patients. Cumulative treatment persistence at 12 and 24 mo was 73.3% and 67.3%. Median vedolizumab therapy duration was 98.7 (14.0-117.1) and 102.2 (14.0-117.4) weeks for patients with CD and UC, respectively (p=ns). Vedolizumab ineffectiveness was the cause of treatment discontinuation in 399 (81.8%) patients: specifically, 79 (16.2%) primary failures and 320 (65.6%) secondary failures. A significantly longer persistence was observed among bionaïve compared to bioexperienced CD pts (p=0.02), but not in UC. In the entire cohort, 318 AEs were experienced by 308 patients, with an incident rate of 0.14 AE per patient-year; infections were the most common (120, 38.0%). AEs caused 61 (20.0%) patients to withdraw from vedolizumab treatment. The trained ML algorithm was used to predict 12 mo-SFCR and the development of AEs. To minimize the bias introduced by the imbalanced dataset, a data augmentation technique (Synthetic Minority Over-sampling Technique, SMOTE) was introduced. The predictive model's accuracy (F1 score) was 0.85 for both outcomes. To explore the relations between the variables for the predicted outcome, Shapley Additive exPlanations (SHAP) was adopted. Previous exposure to anti-TNFα, female sex, more severe baseline clinical activity and baseline steroid therapy at baseline were the most important drivers of predicting no SFCR at 12 months. In regard to safety, fewer comorbidities and baseline corticosteroid therapy were the most important features associated with no development of AEs.

Conclusion: About 1/3 of VDZ-treated pts achieved 12 mo-SFCR. With ML, we identified the most important predictors of SFCR and of the development of AEs: in that regard, XAI is a promising tool in precision medicine, as it helps reconcile sophisticated models with the biological explainability of data.

ACHIEVEMENT OF LONG-TERM TREATMENT GOALS WITH UPADACITINIB IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS: A POST-HOC ANALYSIS OF INDUCTION AND MAINTENANCE PHASE 3 TRIALS

J. Panes[1], R. Panaccione[2], M.C. Dubinsky[3], Y. Ishiguro[4], J. Tran[5,6], D. Ilo[6], J. Eccleston[6], Y. Sanchez Gonzalez[6], B.G. Feagan[7]

Contact E-Mail Address: julian.panes@gmail.com

Introduction: Per the STRIDE II consensus, mucosal healing and normalization of quality of life are considered long-term treatment goals in ulcerative colitis (UC). Results from Phase 2/3 induction and maintenance trials (U-ACHIEVE and U-ACCOMPLISH) showed that patients with moderately to severely active UC treated with upadacitinib (UPA) had significant improvements in these outcomes individually.

However, there is a need to understand better the extent to which patients treated with UPA can achieve both treatment goals jointly within one year of maintenance therapy.

Aims & Methods: In the U-ACHIEVE and U-ACCOMPLISH trials, patients with a clinical response after 8-week induction treatment with UPA 45 mg QD were re-randomized 1:1:1 to UPA 15 mg QD, UPA 30 mg QD or placebo (PBO) QD. Long-term treatment goals were determined based on the percentage of patients who achieved the composite endpoint of endoscopic remission (ER), complete symptom resolution (CSR), and Inflammatory Bowel Disease Questionnaire (IBDQ) remission at the end of induction week 8 and maintenance week 52. ER was defined as an endoscopic score of 0; CSR as stool frequency subscore ≤1, rectal bleeding subscore of 0, no bowel urgency, no abdominal pain; and IBDQ remission as IBDQ total score ≥170.

The response rate between PBO and UPA was calculated using the Cochran-Mantel-Haenszel test, adjusting for baseline characteristics. The percentage of patients who maintained vs achieved ER+CSR+IBDQ remission during maintenance week 52 was also calculated.

Results: At induction week 8, a significantly greater percentage of patients treated with UPA 45 mg achieved ER+CSR+IBDQ remission vs PBO (6.4% vs 0.9%, respectively, p<0.001, Table).

At maintenance week 52, the percentage of induction responders who achieved ER+CSR+IBDQ remission reached 18.3% with UPA 30 mg and 13.1% with UPA 15 mg vs 4.5% with PBO (p<0.001).

Of the patients who achieved ER+CSR+IBDQ remission by week 0 of maintenance, 42.1% (8/19), 23.5% (4/17), and 22.2% (4/18) in the UPA 30 mg, UPA 15 mg, and PBO groups, respectively, sustained the composite endpoint at week 52.

Among patients who did not achieve this composite endpoint by week 0 of maintenance, 16.2% (35/214), 12.3% (26/208), and 2.9% (6/205) in the UPA 30 mg, UPA 15 mg, and PBO groups, respectively, achieved it at week 52.

Conclusion: Results of this post hoc analysis indicate that the rigorous, long-term treatment goals of ER+CSR+IBDQ remission can be achieved with UPA in some patients with moderately to severely active UC by week 8 of induction. By maintenance week 52, nearly one in five patients treated with UPA 30 mg and approximately one in eight patients treated with UPA

15 mg achieved the stringent target. Sustained maintenance treatment with UPA results in an increasing proportion of patients achieving or maintaining these long-term goals of treatment after only one year.

	Responder, n/N (%)	Adjusted rate diff[a], % (95% CI)
Induction week 8		
PBO	3/328 (0.9)	5.5 (3.3, 7.7)*
UPA 45 mg QD	42/660 (6.4)	
Maintenance week 52[b]		
PBO	10/223 (4.5)	
UPA 15 mg QD	30/225 (13.1)	8.5 (3.4, 13.7)*
UPA 30 mg QD	43/233 (18.3)	13.7 (8.1, 19.3)*

*p ≤ 0.001 for UPA vs PBO.
[a]At week 8, the adjusted response rate between PBO and UPA 45 mg was calculated using the Cochran-Mantel-Haenszel (CMH) test adjusting for baseline corticosteroid use, Adapted Mayo score, and inadequate response to biologic (Bio-IR) status. At week 52, the rate difference between PBO and UPA 30 mg and 15 mg was calculated using CMH adjusted for Bio-IR status at induction baseline, and clinical remission status and corticosteroid use at week 0 of maintenance. Calculations were based on non-responder imputation incorporating multiple imputation to handle missing data due to COVID-19 or non-responder imputation if there were no missing data due to COVID-19. [b]The maintenance study population comprises patients who achieved clinical response after UPA 45 mg QD 8-week induction treatment in the Phase 2 and 3 programs and were enrolled in the 52-week maintenance treatment period. CI, confidence intervals; IBDQ, Inflammatory Bowel Disease Questionnaire (IBDQ), PBO, placebo; QD, once daily; UPA, upadacitinib.

Table. Percentage of patients who achieved composite endpoint of endoscopic remission and complete symptom resolution and IBDQ remission at week 8 of induction and week 52 of maintenance.

THE COMPARATIVE EFFECTIVENESS OF VEDOLIZUMAB AND TNF INHIBITORS IN BIO-NAÏVE PATIENTS WITH IBD: RESULTS FROM A REAL-WORLD EXPERIENCE AT A BELGIAN TERTIARY CENTRE

L. Deroo[1], L. Suarez-Lopez[2], M. Truyens[1,3], J. Geldof[1], S. Akhayad[1], G. Dewitte[1], E. Glorieus[1,3], T. Lobaton[1,3]
[1]Ghent University Hospital, Gastroenterology and Hepatology, Ghent, Belgium, [2]University Hospital of Santiago of Compostela, Gastroenterology, Health Research institute (IDIS), Santiago de Compostela, Spain, [3]Ghent University Hospital, IBD Research Unit - Gastro-Enterology, Department of Internal Medicine and Paediatrics, Ghent, Belgium

Contact E-Mail Address: liesbeth.deroo@ugent.be

Introduction: The therapeutic armamentarium for inflammatory bowel disease (IBD) is rapidly increasing recent years with newer therapies such as vedolizumab (VDZ). Their effectiveness has already been demonstrated against placebo, but head-to-head trials compared to tumour necrosis factor alpha inhibitors (anti-TNF) are scarce.
Aims & Methods: Aim: To compare the effectiveness of VDZ versus anti-TNF in bio-naïve IBD patients in a real world setting.
Methods: A retrospective monocentric study was performed in IBD patients treated with VDZ and anti-TNF at a Belgian University Hospital, from January 2018 to June 2021 with follow-up until December 2021. Primary endpoints considering efficacy after induction and after 1 year of therapy were: clinical response (CRp) and remission (CRm), biochemical response (BRp) and remission (BRm) and endoscopic response (ERp) and remission (ERm). Secondary endpoint was treatment survival during follow-up. For assessment of risk factors influencing efficacy and treatment survival, a multivariate logistic regression and Cox regression model were applied. Propensity scores for VDZ vs. anti-TNF were weighted for age at start biological, IBD type, perianal disease activity, disease duration and previous IBD-related intestinal resection.
Results: In total, 42 patients received VDZ and 57 anti-TNF. At baseline, the VDZ group had an older median age (38 vs. 31 years, P=0.024), longer disease duration (P=0.017) and more moderate to severe comorbidities (21.4% (9/42) vs. 0% (0/57), P<0.001). In the anti-TNF group, percentage of CD patients was higher (77.2% (44/57) vs. 57.1% (24/42),P=0.034), patients had more upper GI, penetrating or stricturing disease (P=0.013 for location and P=0.004 for behavior), perianal disease (P=0.034) and used more immunomodulators (IMM) during treatment (52.6% (30/57) vs. 16.7% (7/42), P<0.001). After treatment induction, CRp (P=0.311) and CRm (P=0.216) rate was not significantly different. The anti-TNF group had a significantly higher BRp rate compared to the VDZ group (87.8% (43/49) *vs.* (23/34), P=0.026). After adjusting for propensity score, age, IBD type, systemic corticosteroid (CS) or IMM use, the higher rate of BRp remained (aOR 3.83 [1.01-14.60], P=0.049).
Similar results were found for BRm (87.8% (43/49) vs. 67.6% (23/34), P=0.026). After adjustment for the same confounders, the higher rate of BRm in the anti-TNF group remained (aOR 3.83 [1.01-14.60], P=0.049). No significant difference was seen for ERp (P=1.000) and ERm (P=0.338). After 1 year, univariate analysis showed no significant difference for CRp (P=0.736) and CRm (P=0.404), nor for BRp (P=0.907) and BRm (0.890) or

for ERp (P=0.163) and ERm (P=0.533). Treatment survival using Cox regression model with adjustment for propensity and IMM or CS use, showed no significant longer treatment duration for anti-TNF compared to VDZ (aHR 0.947 [0.36-2.49], P=0.913).

Conclusion: In this tertiary real-world cohort of bio-naïve patients with IBD, anti-TNF and VDZ showed a similar efficacy, with an advantage of anti-TNF regarding onset of action.

Disclosure: Nothing to disclose.

Introduction: Biosimilars are used for the treatment of inflammatory bowel disease (IBD). However, data on the switch from one biosimilar to another still lack. We aimed to study, in an IBD cohort, the effects of the CT-P13-to-SB2-switch, in terms of effectiveness, safety, psychological implications, pharmacokinetic and inflammatory marker levels.

Aims & Methods: Consecutive CT-P13-to-SB2-switched IBD patients were enrolled and prospectively followed-up for 12 months (mo). Patient-reported outcomes (PROs) were employed: specific PRO-2 for CD and UC, IBD-Disability Index (IBD-DI), Functional Assessment of Chronic Illness Therapy Fatigue (FACIT), Short-IBD-Questionnaire (SIBDQ). Psychometric tests were administered to assess the psychological impact of the switch: Hospital Anxiety and Depression Scale (HADS), Perceived Stress Scale (PSS), Believes About Medicine (BMQ). C-reactive protein (CRP) levels, concomitant steroid use, and adverse events of interest (AEIs) were recorded. Serum samples were obtained before and after the switch to measure: infliximab (IFX) and anti-IFX trough levels (TLs), and cytokine (TNF-α, IL-6, IL-8, IL-17A, IL22) concentrations.

Results: We enrolled 119 (73 CD, 46 UC). Median age was 40 years (IQR:27-52), median disease duration 9 years (IQR:4-16). Median duration of pre-switch infliximab was 45 mo (IQR:24.5-75.5); 50 (42.0%) patients had previously received infliximab originator-to-CT-P13 switch (median CT-P13 duration: 28 mo, IQR:27-29). In UC, mean stool frequency scores were 0.2±0.5, 0.4±0.8, 0.7±1.5, 0.2±0.5, and mean rectal bleeding scores were 0.1±0.4, 0.1±0.4, 0.4±0.8, 0.0±0.0, at baseline, 2, 6 and 12 mo (p=ns for all). In CD, mean stool frequency scores were 1.9±2.0, 2.1±2.2, 1.8±1.9, 1.5±1.8(p=ns for all), and mean abdominal pain scores were 0.5±0.7, 0.4±0.6, 0.3±0.6, 0.2±0.5 (p=ns for all, expect baseline vs.12 mo p=0.01) at baseline, 2, 6 and 12 mo. Patients in SFCR were 100 (84.0%) at baseline, 97 (81.5%) at 2 mo (p=ns vs baseline), 86 (72.3%) at 6 mo (p=0.03 vs baseline) and 90 (75.6%) at 12 mo (p=ns vs baseline). Mean CRP levels were constantly <5mg/L (3.4±8.0, 3.2±5.8, 2.4±4.0, 2.2±5.7, at baseline, 2, 6 and 12 mo, p=ns for all). No significant changes in psychometric assessments were observed during follow-up in regard to: HADS (10.3±6.8 at baseline, 10.6±8.1 at 2 mo, 11.3±8.1 at 6 mo), PSS (14.3±7.8, 15.7±8.8, 14.9±8.1), IBD-DI (-0.7±4.6, -1.3±5.9, 9.0±4.7), FACIT (42.2±8.9, 40.6±10.8, 41.8±8.6), SIBDQ (55.2±11.4, 54.1±11.8, 56.7±10.7), BMQ-S1-SS1 (18.0±3.4, 18.0±2.3, 17.5±2.9), BMQ-S1-SS2 (15.3±2.6, 15.4±2.0, 15.1±1.9), BMQ-S2-SS1 (9.8±3.2, 9.3±2.6, 9.5±2.7), BMQ-S2-SS2 (8.7±2.9, 8.6±3.0, 9.0±2.7). AEIs were observed in 43(36.1%) patients, most commonly infections (17) and arthralgias (15); 3 cancer diagnoses and 2 infusion reactions were recorded. Pre- and post-switch median IFX TLs remained stable (4.07 vs 4.86 µg/mL, p=ns). Anti-IFX antibodies were detected in 5.1% and 2.5% of patients before and after the switch, respectively; de novo antibody formation was observed in one patient after the switch. The median concentration of TNF-α (9.77 vs 9.16 pg/mL, p=ns), IL-8 (9.04 vs 10.10 pg/mL, p=ns) and IL-22 (5.52 vs 6.43, p=ns) remained stable; conversely, a significant increase was observed in IL-6 (1.20 vs 1.73 pg/mL, p=0.01) and IL-17A (0.72 vs 1.08 pg/mL, p=0.02) median concentrations.

Conclusion: Switching from CT-P13 to SB2 can be considered safe, does not significantly affect treatment effectiveness nor drug pharmacokinetic, and is seemingly not associated with major negative psychological implications.

Contact E-Mail Address: liesbeth.deroo@ugent.be

Introduction: As the therapeutic armamentarium for inflammatory bowel diseases (IBD) is rapidly expanding, it is of increasing importance to optimize treatment sequencing. However, head-to-head trials comparing efficacy of vedolizumab (VDZ) in bio-naïve versus bio-experienced patients are scarce.

Aims & Methods: Aim: To compare the effectiveness of VDZ in bio-naïve versus bio-experienced patients with IBD in a real world setting.

Methods: A retrospective monocentric study was performed in IBD patients treated with VDZ at a Belgian University Hospital, from January 2018 to June 2021 with follow-up until December 2021. Primary endpoints considering efficacy after induction and after 1 year of therapy were: clinical response (CRp) and remission (CRm), biochemical response (BRp) and remission (BRm) and endoscopic response (ERp) and remission (ERm). Secondary endpoint was treatment survival during follow-up. For assessment of risk factors influencing efficacy and treatment survival, a multi-

variate logistic regression and Cox regression model (CRM) were applied.

Results: A total of 84 patients were treated with VDZ, 42 bio-naïve and 42 bio-experienced. At baseline, significantly more bio-experienced patients had prior intestinal resection (IR) (40.5% (17/42) vs. 16.7% (7/42), P=0.016), used an immunomodulator (IMM) (35.7% (15/42) vs. 16.7% (7/42), P=0.047) and had a longer disease duration (12.5 vs. 3.5 years, P<0.001). Bio-naïve patients had more moderate to severe comorbidities (21.4% (9/42) vs. 2.4% (1/42), P=0.007). After VDZ induction, CRp rate was higher in bio-naïve patients (60.9% (39/42) vs 39.1% (25/42), P<0.001).

Multiple logistic regression analyses revealed that bio-naïve patients had a higher chance reaching CRp (aOR 14.69, 95%CI [3.12-69.14], P<0.001) (table). CRm was reached in 35.7% bio-naïve and 19% bio-experienced patients (P=0.087). No significant difference in BRp (P=0.932) or BRm (P=0.730) rate was found . A significantly higher ERp rate was seen in bio-naïve patients (90.3% (28/31) vs. 66.7% (18/27), P=0.027). Multiple logistic regression analyses showed a trend towards higher ERp rate in bio-naïve patients (aOR 4.65, [0.99-21.84], P= 0.051) (table).

No significant difference was seen for ERm (32.3 % (10/31) vs. 11.1% (3/27), P=0.054). After 1 year of VDZ, CRp was significantly higher in bio-naïve patients (82.9% (34/41) vs. 62.5% (25/40), P=0.039). Multiple logistic regression analyses showed no significant difference between both groups. Univariate analyses showed significantly higher CRm rate in bio-naïve patients (70.7% (29/41) vs. 37.5% (15/40), P=0.003).

After adjustment for age, disease duration, IMM use and prior IR, this difference was no longer significant. Patients without prior IR had significantly higher odds of reaching CRm (aOR 4.33,[1.13-16.59], P=0.032). No significant difference was seen for BRp (P=0.443) and BRm (P=0.313), nor for ERp (P=0.184) or ERm (P=0.061) in univariate analyses. Cox regression analysis showed significantly longer treatment survival in bio-naïve patients (aHR 2.32, [1.03-5.23], P=0.043).

	Clinical response after induction		Endoscopic response after induction	
Multivariate regression model	aOR [95% CI]	P-value	aOR [95% CI] P-value	P-value
VDZ in bio-naïve patients (vs. bio-experienced patients)	14.69 [3.12-69.14]	P<0.001	4.65 [0.99-21.84]	P=0.051
Age (years)	1.00 [0.96-1.04]	P=0.954	1.01 [0.96-1.06]	P=0.998
Ever IMM use during treatment (yes)	1.22 [0.30-4.97]	P=0.783	3.48 [0.38-32.33]	P=0.273
Disease duration (years)	1.08 [0.99-1.18]	P=0.095	1.00 [0.91-1.10]	P=0.998
Prior intestinal resection (yes)	0.52 [0.11-2.49]	P=0.417	1.04 [0.13-8.34]	P=0.968

Conclusion: In this tertiary real-world cohort of patients treated with VDZ, overall, a better efficacy was seen in bio-naïve compared to bio-experienced patients.

Disclosure: Nothing to disclose.

PP0857

SAFETY OF VEDOLIZUMAB, USTEKINUMAB AND TNF INHIBITORS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A RETROSPECTIVE MONOCENTRIC COHORT STUDY

L. Deroo[1], L. Suarez-Lopez[2], M. Truyens[1,3], J. Geldof[1], S. Akhayad[1], G. Dewitte[1], E. Glorieus[1,3], T. Lobaton[1,3]

[1]Ghent University Hospital, Gastroenterology and Hepatology, Ghent, Belgium, [2]University Hospital of Santiago of Compostela, Gastroenterology, Health Research Institute (IDIS), Santiago de Compostela, Spain, [3]Ghent University Hospital, IBD Research Unit - Gastro-Enterology, Department of Internal Medicine and Paediatrics, Ghent, Belgium

Contact E-Mail Address: liesbeth.deroo@ugent.be

Introduction: New biologics such as vedolizumab (VDZ) and ustekinumab (UST) have expanded the therapeutic armamentarium for inflammatory bowel diseases (IBD) over the past decade. Head-to-head trials comparing safety to tumor necrosis factor alpha inhibitors (anti-TNF) are limited. Data on safety of biologic sequencing remains scarce.

Aims & Methods: Aim: To assess the impact of different biologics and previous treatments on the incidence of severe adverse events (SAE) in a real-world tertiary IBD patient cohort.

Methods: A retrospective monocentric study was performed at the Ghent University Hospital. Patients starting anti-TNF, VDZ or UST from January 2018 to June 2021 with follow-up until December 2021 were included. SAE were defined as intestinal resection (IR), IBD-inflammation related hospitalization (IBD-hosp), IBD-treatment related hospitalization (e.g. infections) (treat-hosp), malignancy and death. Cox regression analysis was used to explore risk factors (RF) of SAE.

Results: In total 267 patients were included: 84 on VDZ, 69 UST, 60 infliximab (IFX) and 54 adalimumab (ADM). At baseline a significant difference was found between biologic groups for age (younger in IFX and ADM - P=0.001), IBD type (Crohn's disease (CD): VDZ 51.2%, UST 73.9%, IFX 70%, ADM 77.8% - P=0.003), CRP (in mg/L, med, IQR - VDZ: 5[1.6-12.4], UST: 8.5[2.8-19.3], IFX: 13 [1.87-31.8], ADM:3.2[1-8.1] - P<0.001) and calprotectin (in µg/g, med, IQR) (VDZ: 579 [175- 1801], UST: 707 [244-2889], IFX: 652 [65-2449], ADM 200 [43.7-789] - P=0.021)). Perianal CD rate was higher in anti-TNF and UST patients (P=0.003) and prior disease duration differed significantly (VDZ: 9years, UST10y, IFX 2y,ADM 3.5y - P<0.001)). Concomitant immunomodulator (IMM) use was higher in the IFX group (81.7% vs 25% for all other groups P<0.001)) and corticosteroid (CS) use differed among treatment groups (VDZ 78.6%, UST 68.1%, IFX 70%, ADM 55.6% (P=0.041)). Number of prior biologics was higher in the UST group (P<0.001).

No significant difference in SAE rate could be found between different biologics (UST 37.7%, IFX 33.3%, VDZ 23.8%, ADM 22.2% - P=0.148). Cox regression revealed age ≥60years (aHR 2.00, 95%CI 1.11-3.60, P=0.020) and higher number of previous biologics (aHR 1.29, 95%CI 1.03-1.60, P=0.024) as independent RF for SAE. Considering SAEs types, IR rate was not significantly different between biologic groups (VDZ 4.8%, UST 15.9%, IFX 8.3%, ADM 5.6% - P=0.096). Cox regression revealed previous IMM use as an independent RF for IR (aHR 4.26, 95%CI 1.62-11.19, P=0.003). No significant difference was found between biologics considering IBD-hosp (VDZ 15.5%, UST 30.4%, IFX 21.7%, ADM 14.8% – P=0.087). Higher number of previous biologics was an independent RF for IBD-hosp (aHR 1.32, 95%CI 1.02-1.71, P=0.036). Treat-hosp rate was not significantly different between biologic groups (VDZ 7.1%, UST 10.1%, IFX 6.7%, ADM 5.6% – P=0.811). Age ≥60years was found to be an independent RF of treat-hosp (aHR 4.93, 95%CI 1.91-12.76, P=0.001). Six patients developed malignancy (3 VDZ: colorectal carcinoma, melanoma, low grade appendix neoplasia; 2 IFX: cervix CIN3, gastric adenocarcinoma; 1 ADM: basal cell carcinoma). One patient died due to progressive melanoma while on VDZ.

Conclusion: In this tertiary real-world IBD patient cohort, no influence of type of biologic on the SAE rate could be found. Elderly age (≥60 years) and higher number of previous biologics were an independent RF for SAEs.
Disclosure: Nothing to disclose.

Contact E-Mail Address: christopher.ma@ucalgary.ca
Introduction: Crohn's disease (CD) clinical trials have evolved from evaluating symptoms to including endoscopic outcomes as coprimary endpoints, as was done in clinical trials of upadacitinib (UPA), an oral, reversible Janus kinase inhibitor, and ustekinumab (UST), an anti-interleukin 12/23. Endoscopic healing has been recommended as a long-term treatment target by the Selecting Therapeutic Targets in Inflammatory Bowel Disease (STRIDE) initiative.
Aims & Methods: The objective of this study is to conduct a placebo (PBO)-anchored matching-adjusted indirect comparison (MAIC) of endoscopic outcomes between UPA and UST among patients with moderately to severely active CD. Data from phase 3 UPA trials (NCT: 03105128, 03104413, 03105102) and an UST endoscopy substudy (NCT: 01369329, 01369342, 01369355) from the phase 3 UNITI/IM-UNITI program were used. For induction, patients (pts) received UPA 45mg once daily (QD) for 12 weeks (wks), UST 6mg/kg intravenously, or PBO. For maintenance, pts received UPA 15mg or 30mg QD, subcutaneous UST 90mg every 8 (Q8W) or 12 wks (Q12W), or PBO. Individual pt level data from the UPA trials included pts with baseline (BL) CD Activity Index between 220-450 and excluded pts with prior UST or vedolizumab exposure or missing data due to COVID. Induction BL characteristics identified as treatment-effect modifiers, including disease duration, location, and phenotype, median c-reactive protein, prior biologic failure, and mean Simple Endoscopic Score for CD (SES-CD), were weighted to match those reported in the UST endoscopy substudy for both induction and maintenance. Endoscopic outcomes were evaluated after induction (Wk 12 UPA, Wk 8 UST) and maintenance (Wk 52 UPA, Wk 44 UST). Endoscopic outcomes included endoscopic response (reduction of ≥50% from induction BL in SES-CD) and remission (total SES-CD ≤2), mucosal healing (present with ulceration in at least 1 ileocolonic segment at induction BL) and change in SES-CD score from induction BL.
Results: The effective sample sizes for induction MAICs were 207 UPA and 155 UST pts and ranged from 16–53 (UPA) and 17–46 (UST) for maintenance MAICs. A significantly (P<0.05) greater proportion of UPA vs UST pts achieved endoscopic response and remission, mucosal healing, and had a larger reduction from BL in mean SES-CD score at the end of induction; PBO-adjusted treatment differences were 26.3%, 9.9%, 13.0%, and –3.7 points, respectively. Endoscopic remission rates at the end of maintenance were numerically higher for UPA 30mg vs UST 90mg (Q8W+Q12W). PBO-adjusted rate differences in endoscopic response and mucosal healing between UPA 30mg and UST Q12W were significant (35.5% and 39.0%, respectively; p<0.05); other outcomes (UPA 15mg vs UST) were comparable.
Conclusion: Greater proportions of pts on UPA vs UST achieved endoscopic outcomes at the end of induction for pts with moderately to severely active CD. Although sample sizes during maintenance were limited, these MAICs show endoscopic outcomes are achieved in a numerically higher proportion of pts treated with UPA 30mg vs. UST, while outcomes are comparable with UPA 15mg vs UST.

Outcome[a]	N or ESS	Rate[b]	Rate Difference (95% CI) UPA or UST vs PBO	Rate Difference (95% CI) UPA vs UST
Induction

Introduction: Biologic therapies are associated with an increased risk for adverse events such as infections and malignancies. This is of particular importance in elderly patients with inflammatory bowel disease (IBD).

Aims & Methods: The aim of this study was to compare the efficacy and safety of different biologic therapies between IBD patients aged over 60 years and younger patients.All adult patients with IBD treated with biologic agents from 2010 to 2022 in the sole tertiary referral center for inflammatory bowel disease in central Greece were screened for eligibility and their electronic medical records were retrospectively reviewed. Data collected included the socio-demographic and clinical characteristics of the study population, endoscopy reports as well as information regarding treatment compliance and drug sustainability. Adverse events (AEs) and serious AEs were also recorded. Patients with incomplete information were excluded from the analysis.

Results: 267 IBD patients were screened for eligibility and 187 were included. The majority (65%) of the patients had Crohn's disease. Of all patients, 47.8% received infliximab, 18% adalimumab, 18% vedolizumab, and 16% ustekinumab. The median duration of biologic treatments was 10 years. Parallel steroid therapy was required in 70% at baseline, 35% at 3 months, 18 % at 6 months, and 5% at 12 months from treatment onset. The efficacy of biologic therapies did not differ significantly between patients aged > 60 years and younger patients. Kaplan-Meyer analysis did not show statistical differences or trends in drug sustainability (P > 0.05), time to an adverse event (P >0.05), and infection rates (P >0.05) among the different classes of biologic agents compared. The most common AEs leading to drug discontinuation were loss of response and local injection site reactions. After adjusting for differences in baseline characteristics between the two age groups, no significant differences in drug sustainability and the need for treatment optimization were found between elderly and younger patients (p >0.05).

Conclusion: Available biologic therapies were characterized by comparable efficacy, sustainability, and safety among elder and younger patients, hardening the preferential selection among the available biologic agents for the elderly. More real-world evidence is required to make treatment recommendations.

Introduction: Mirikizumab [(miri), a p19-directed IL-23 antibody] has been shown to be effective in patients with moderately to severely active ulcerative colitis (UC) in Phase 3, randomised, double-blind, placebo-controlled trials (LUCENT-1 NCT03518086; LUCENT-2 NCT03524092).[1] Given the importance of understanding treat-to-target strategies, the relationship between improved histologic and endoscopic endpoints and improvement of the inflammatory biomarkers faecal calprotectin (fCal) and C-reactive protein (CRP) was studied within miri-treated patients enrolled in the programme.

Aims & Methods: This analysis focused on miri-treated patients (n=868) from the induction study receiving intravenous (IV) every 4 weeks (Q4W) until week (W)12 and miri induction responders at week W12, who were rerandomised for the maintenance period, receiving subcutaneous miri (n=365) Q4W up to W52. The relationship between achieving histologic-endoscopic mucosal improvement (HEMI), histologic-endoscopic mucosal remission (HEMR) (definitions in Tables) and improvement of fCal (≤250µg/g) and CRP (≤6mg/L) levels at W12 and W52 was explored using Fisher's exact tests.

Relationship between mirikizumab treated patients achieving HEMI and HEMR at end of induction (W12) and normalised faecal calprotectin and C-reactive protein values				Relationship between mirikizumab responder patients rerandomised to mirikizumab achieving HEMI and HEMR at end of maintenance (W52) and normalised faecal calprotectin and C-reactive protein values			
Mirikizumab treated patients (N=868)				Mirikizumab induction responder patients rerandomised to mirikizumab (n=365)			
End of induction-Week 12	Patients achieving HEMI (n=235)	Patients not achieving HEMI (n=633)	p-value	End of maintenance-Week 52	Patients achieving HEMI (n=174)	Patients not achieving HEMI (n=191)	p-value
% fCal ≤ 250µg/g	179 (76.2%)	138 (21.8%)	<0.001	% fCal≤250µg/g	129 (74.1%)	62 (32.5%)	<0.001
% CRP ≤ 6mg/L	208 (88.5%)	460 (72.7%)	<0.001	% CRP≤6mg/L	153 (87.9%)	117 (61.3%)	<0.001
End of induction-Week 12	Patients achieving HEMR (n=193)	Patients not achieving HEMR (n=675)	p-value	End of maintenance-Week 52	Patients achieving HEMR (n=158)	Patients not achieving HEMR (n=207)	p-value
% fCal ≤ 250µg/g	153 (79.3%)	164 (24.3%)	<0.001	% fCal≤250µg/g	121 (76.6%)	70 (33.8%)	<0.001
% CRP ≤ 6mg/L	173 (89.6%)	495 (73.3%)	<0.001	% CRP≤6mg/L	139 (88.0%)	131 (63.3%)	<0.001

Abbreviations: CRP=C-reactive protein; fCal=faecal calprotectin; HEMI=Histologic-endoscopic mucosal improvement defined as Mayo Endoscopic Subscore (ES)=0 or 1 (excluding friability) and Geboes≤3.1; HEMR Histologic-endoscopic mucosal remission defined as ES=0 or 1 (excluding friability) + Geboes≤2b; N=patient population; n=patient subpopulation; W=week

Results: At W12, a significantly higher percentage of miri-treated patients achieving HEMI (n=235/868) had normalised fCal and CRP values (76.2% and 88.5%), compared to miri-treated patients who did not achieve HEMI (n=633/868) (21.8% and 72.7%, both p<0.001; Table). Similarly, a higher

proportion of patients achieving HEMR (n=193/868) had normalised fCal and CRP values (79.3% and 89.6%), compared to those who did not achieve HEMR (n=675/868) (24.3% and 73.3%, both p<0.001; Table). At W52, a significantly higher percentage of the miri induction responder patients rerandomised to miri achieving HEMI (174/365) had normalised fCal and CRP values (74.1% and 87.9%), compared to patients not achieving HEMI (191/365) (32.5% and 61.3%; both p<0.001).

Similarly, at W52, a higher proportion of patients achieving HEMR (n=158/365) had normalised fCal and CRP values (76.6% and 88.0%), *versus* patients not achieving HEMR (n=207/365) (33.8% and 63.3%; both p<0.001, Table).

Conclusion: At both W12 and W52, patients treated with miri who achieved HEMI or HEMR showed statistically significant improvements in fCal and CRP levels. This suggests that CRP and fCal may be useful markers of histology and endoscopy outcomes after induction and maintenance with miri.

Introduction: Fatigue is commonly reported by Crohn's Disease patients even in the absence of disease activity.

Other possible causative factors need to be determined in order to successfully address this problem, which significantly affects patients' lives even when treatment targets have been achieved.

Sarcopenia and Depression are also common in Crohn's Disease and possibly related to fatigue.

Aims & Methods: Consecutive patients with Crohn's Disease who came to the infusion center to receive maintenance intravenous infliximab treatment were included. All participants had to be in full clinical (HBI <5), biological (C-RP < 0.5 mg/dL and/or fecal calprotectin <100 μg/mg) , endoscopic (SES-CD 0-2), or enterographic remission in the past 6 months.

Anthropometric measurements (Weight, Height, Body Mass Index, Circumcenter waist, hips, gastrocnemius, Waist to Hip Ratio), Body Composition Measurements (Body Fat, Total Body Water, Body Fat Mass Index, Lean Body Mass), Physical Activity Tests (Handgrip Strength test, 6-meter Walk Test, One Leg Standing test, 30-second Chair Stand test) and Questionnaires related to Sarcopenia (Lawton Instrumental Activities of Daily Living Scale-LIADLS, Activities Daily Living Scale-ADLS, Dixon's Diet Score-DASH, Mini Nutritional Assessment-MNA, Mediterranean Diet Serving Score MDSS, the Mind Diet Score-MDS) were conducted.

We used the Functional Assessment of Chronic Illness Therapy-Fatigue scale (FACIT-F) to measure fatigue. We used the Hamilton Depression Rating Scale (HAM-D) to assess for depression. Linear regression analysis was used to assess the impact of sarcopenia and depression on fatigue.

Results: A total of 39 patients were included: mean age 38.6 years, mean body weight 80 Kg, median disease duration 9 years, female 22 (56,%), male 17 (44%).
We included patients with ileal disease (48%), perianal disease (28%), stomas (8%), extraintestinal manifestations (12%), on second or third biologic therapy (56%), smokers (10%).
Median C-RP was 0.13 mg/dL and median albumin was 4.5 g/dL.
Sarcopenia was almost non existent by all measures: Indicatively, Median Max Hand Grip was 25.7 (range 10.8-57.4).
Median FACIT-F was 45 (range 7-52).
Median HAM-D was 4 (range 0-25).
There was no correlation between FACIT-F and Sarcopenia (Max Hand Grip): p=0,280, β coefficient = 0,159.
There was a correlation between FACIT-F and HAM-D: p<0,001, β coefficient = -1,576.
Interestingly there was also a correlation between HAM-D and max Hand Grip: p=0,029, β coefficient = -0,804.
Conclusion: We found expectantly low (though not in all patients) estimates of sarcopenia, fatigue and depression in this selected group of Crohn's Disease patients in complete remission receiving intravenous infliximab.
Fatigue could not be attributed to sarcopenia. On the contrary depression seemed to be one of the main determinants of fatigue.
Multidisciplinary care of fatigue should include psychological evaluation and possible intervention.
Further research in the field of fatigue related to Inflammatory Bowel Disease is needed.
Disclosure: Nothing to disclose.

PREDICTIVE FACTORS ASSOCIATED WITH LONG-TERM SURVIVAL OF ANTI-TNF AGENTS IN THE MANAGEMENT OF CROHN'S DISEASE

K. Argyriou[1], A. Manolakis[1], C. Kateri[1], S. Kyriakidis[1], T. Bektsis[1], E. Tsakiridou[2], A. Kaltsa[1], A.N. Kapsoritakis[1]

Contact E-Mail Address: kosnar2@yahoo.gr
Introduction: Tumor necrosis factor (TNF) inhibitor therapies (anti-TNFs) are routinely used for the management of Crohn's disease (CD) in patients with moderate to severe disease activity. However, approximately 30% of patients discontinue anti-TNF treatment due to inefficacy or adverse events.
Aims & Methods: This study analyzed the long-term anti-TNFα drug survival in a cohort of patients with CD from central Greece aiming to find potential predictive factors that are associated with increased survival of anti-TNF agents. All adult patients with CD treated with anti-TNF agents including infliximab (IFX) ή adalimumab (ADA) from 2012 to 2022 in the sole tertiary referral center for inflammatory bowel disease in central Greece were screened for eligibility and their electronic medical records were reviewed retrospectively. Data collected included the socio-demographic and clinical characteristics of our population as well as specific information regarding anti-TNF treatment survival, concomitant treatment modalities, treatment compliance, adverse events, and the need for treatment optimization. Parametric and non-parametric statistical tests were used for the description of the study population.
To evaluate the survival of anti-TNF agents, a Kaplan-Meier survival curve was performed whereas the influence of population characteristics on the survival of anti-TNF agents was assessed with linear regression. Patients with incomplete data were excluded from the analysis.
Results: 193 patients were screened for eligibility and 123 were finally included. Over the study period, 68% and 71% of the population treated with IFX and ADA required treatment optimization. The majority of the population (>60%) received anti-TNF as a 1-st line treatment. At 1 year, the probability of retaining anti-TNFs was>75% with no significant differences being recorded between IFX and ADA whereas the percentage of patients who remained on the same treatment at 5 years gradually reduced to 23% and 35% respectively.
Among the population characteristics, the increased disease duration at the onset of treatment was the sole factor that was positively associated with increased survival to both anti-TNFs ([standardized beta: .545, t: 3.690, p: < .001 95,0% Confidence Interval: 1.580-5.511 for ADA], [standardized beta: .479, t:5.119, p: <.001 95,0% Confidence Interval: 1.738-3.952 for IFX]), whereas the development of antibodies (standardized beta: .247, t: 2.639, p: < .01 95,0% Confidence Interval: 3.682-26.312) and the early need for treatment optimization (standardized beta: .203, t: 2.128, p: < .037 95,0% Confidence Interval: 1.373-41.358), defined as the need for treatment optimization within the first year, were the sole factors that were associated with reduced survival of IFX.
Conclusion: Treatment survival with anti-TNF agents decreases in CD patients over time. A trend for increased long-term survival was recorded for ADA over IFX. Among CD patients, the increased disease duration at treatment onset was found to be associated with increased treatment survival irrespective of the type of anti-TNF agents that was selected. Immunogenicity and the need for early treatment optimization were the sole factors that were associated with reduced treatment survival among CD patients receiving IFX.

Introduction: Several therapeutic options are now available for the treatment of moderate-to-severe ulcerative colitis (UC): pivotal trials have reported efficacy and safety of anti-TNF-α, Vedolizumab (VDZ), Ustekinumab (USTE) and Tofacitinib (TOFA) but comparative data are scanty and only one head to head trial (Varsity trial) is available. Network meta-analysis from Singh et al. demonstrated that TOFA and USTE are the best options in anti-TNF exposed patients. Real-worlds studies are discrepant most reporting similar efficacy of second-line drugs. Thus, the optimal sequence of therapeutic choices is still unclear.

Aims & Methods: Our aim was to analyze comparative efficacy of VDZ, TOFA and USTE in a homogeneous cohort of UC patients in a real life setting. We report data of a retrospective-prospective study conducted between 2020 and 2023 in our tertiary referral center. The primary outcome (PO) was clinical response (assessed by partial Mayo score). Secondary outcomes were: steroid-free remission (SFR), adverse events (AEs), time and reasons for treatment discontinuation, surgery and hospitalization rate. All outcomes were investigated at 8 weeks and at the end of follow-up (FU). At the end of FU another secondary outcome was therapy optimization. All data were analysed using the Medcalc program.

Results: 73 patients (65,75% males, mean age 55 yrs) with moderate-to-severe UC were included, mostly (84%) anti-TNF experienced, treated with TOFA (27,4%), USTE (26%) or VDZ (46.6%). Average FU was 11 months. TOFA showed a significant higher clinical response rate at week 8 (80% vs 58,8% VDZ and 42,1% USTE; p = 0,016) while there were no significant differences at the end of FU. SFR rate didn't reach the statistical significance at week 8 and at the end of FU (55% TOFA, 58,8% VDZ and 47,37% UST). 4 patients experienced AEs: 2 paresthesias and 1 mild AST/ALT elevation in the TOFA group; 1 fever of unknowkn origin (FUO) in the USTE group. Treatment discontinuation rate didn't show significant differences. All discontinuations were for treatment failure except the patient with FUO. All the other AEs showed spontaneous resolution. None of the patients was submitted to surgery or hospitalized. Optimisation rate at the end of FU was higher in the VDZ group (50% vs 25% TOFA and 15,8% USTE ; p value (VDZ vs UST 0,009; VDZ vs TOFA 0,05).

Conclusion: TOFA was more effective at wk 8 in comparison with USTE in agreement with previous studies which have documented an increased speed of action of JaK-inhibitors. In the long run efficacy results are similar, thus not confirming superiority of TOFA and USTE as compared to VDZ observed in other studies and reported by national and European guidelines. Treatment optimization was more frequently required with VDZ. Further head-to-head trials and real-world studies are needed to investigate the comparative efficacy of second-line therapeutic agents after anti-TNF failure.

Disclosure: Nothing to disclose.

Introduction: Long-term VDZ outcomes in real-world cohorts have mostly focussed on 1-year follow-up, with the longest reporting outcomes at 2-years. However, most of these studies include biologic exposed patients and also report limited data on objective markers of inflammation.

Aims & Methods: We performed a retrospective, observational, cohort study. All adult UC/IBDU patients who ever received VDZ complete induction from 2014 to December 2021 were included. Baseline phenotype and follow-up data were collected via review of electronic medical records.

The primary outcome of this study was VDZ persistence.

Secondary outcomes included: clinical (partial Mayo <2), biochemical (CRP <5 gr/L) and faecal biomarker (faecal calprotectin <250 µgr/gr) remission at 1,3 and 5 years; hospitalisation, steroid prescription, surgical rates; predictors of VDZ persistence; and serious adverse events.

Results: We included 290 patients (UC n=271 [93.4%], IBDU n=19 [6.6%]), median time on VDZ 27.6 months (IQR 14.4-43.2). VDZ persistence at first year was 80.7%, 64.4% at two years, 56.5% at 3 years, 49.5% at 4 years, 47.9% at 5 years and 41.5% at 6 years. Median time to discontinuation was 14.1 months (IQR 7.0-23.3 months).

Reasons for drug discontinuation: 51(17.6%) primary non-response, 63 (21.7%) secondary loss of response [8 (2.8%) during the first year; 33 (11.4%) between the first and second year; 13 (4.5%) between the second and third year; 5 (1.7%) between the third and fourth year and 4 (1.4%) over the fourth year], 9 (3.1%) adverse event, 4 (1.4%) remission and 6 (2.1%) other reasons.

Multivariable Cox Regression model found previous exposure to one biologic/small molecule (HR 1.52, 95% CI 1.03-2.22, p=0.033); two or more biologic/small molecule (HR 2.37, 95% CI1.37-4.09, p=0.002), steroid at baseline (HR 1.57, 95%CI 1.08-2.29, p=0.019), left-side colitis (HR 2.80, 95% CI 1.11-7.09, p=0.029), extensive colitis (HR 3.32, 95%CI 1.34-8.21, p=0.010) and disease duration ≥ 10 years (HR 0.60, 95%CI 0.43-0.86) were independent predictors for VDZ persistence (Table 1).

Clinical, biochemical and faecal biomarker remission at year 1 were 171/226 (75.7%), 157/217 (72.4%) and 127/181 (70.2%); at year 3, 83/92 (90.2%), 78/91 (85.7%) and 52/59 (88.1%) and at year 5, 23/25 (92%), 23/26 (88.5%) and 15/17 (88.2%) respectively. During follow-up, steroid prescription was needed in 98 (33.8%), hospitalization 45 (15.5%) and surgery 10 (3.4%). Serious adverse events were 1.2 per 100 patient-year follow-up.

Variable	Univariable Cox Regression			Multivariable Cox Regression		
	Hazard Ratio	95% CI	p	Hazard Ratio	95% CI	p

- Two or more	2.26	1.31-3.88	0.003	2.37	1.37-4.09	0.002
Concomitant steroids at baseline	1.67	1.16-2.42	0.006	1.57	1.08-2.29	0.019
Partial Mayo ≥ 2 at baseline	1.81	1.11-2.94	0.017			

Conclusion: VDZ effectiveness is durable and its persistence is influenced by disease duration, previous exposure to biologics/small molecules, disease extension and steroids at baseline. Long-term VDZ safety is confirmed in our study.

JAK INHIBITORS FOR THE TREATMENT OF INFLAMMATORY BOWEL DISEASE: RESULTS OF AN INTERNATIONAL SURVEY OF PERCEPTIONS, ATTITUDES, AND CLINICAL PRACTICE

S. Honap[1,2], P. Irving[2,3], M. Samaan[3]

Introduction: Janus kinase inhibitors (JAKi) are small molecule drugs with demonstrated efficacy in inflammatory bowel disease (IBD). However, widespread utilisation may be hindered by safety concerns.

Aims & Methods: The aim of this study was to assess the risk-benefit perceptions, attitudes, and clinical practices of those using JAKi to treat IBD. A prospective, cross-sectional study was conducted using a 23-item electronic survey, which was distributed to ECCO members and delegates of the 18th Congress of ECCO, 2023, held in Copenhagen, Denmark.

Results: There were 385 respondents from 48 countries; 72% were based in tertiary referral centres and 50% were gastroenterologists with ≥10 years' experience. JAKi were rarely used first line (8%) but were commonly used outside market authorisation (31%). Many (17%) were unconfident discussing JAKi risk-benefit profile and 7% had never prescribed JAKi despite consulting >100 unique IBD patients/year. If venous thromboembolism risks were present, 15% preferentially referred for surgery than initiate JAKi; 21% would do this even if the patient was already anticoagulated. IBD subspecialists with full GI accreditation were less likely to refer to surgery over JAKi initiation, OR 0.40 (95% CI 0.17-0.85) p=0.02. For patients relapsing on dose-reduction, 8% would switch treatment rather than dose-escalate. Conversely, 45% felt that cardiovascular safety concerns from post-marketing studies were irrelevant to IBD. Despite lack of detailed, long-term safety data, safety profiles of novel JAK1-selective drugs were perceived to be favourable to tofacitinib by most (62%).

Conclusion: The study provides unique insights from an international cohort of experienced IBD clinicians and indicates that while clinical practice appears to be in keeping with international guidance, a significant minority remain deterred by safety concerns.

THE ROLE OF CHEST X-RAYS WHEN SCREENING FOR LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE BEFORE STARTING BIOLOGIC TREATMENT

S.B. Christiansen[1], M.A. Ainsworth[1]
[1]Odense University Hospital, Gastroenterology, Odense, Denmark

Contact E-Mail Address: sebch17@student.sdu.dk

Introduction: The use of biologics has improved the outcome for patients with inflammatory bowel disease (IBD) treatment. However, most biologics, particular TNF inhibitors, can reactivate latent tuberculosis infections (LTBI). (1)
It is therefore common practice to screen patients for tuberculosis (TB) before initiating biologic treatment. The value of chest X-ray (CXR) as a screening instrument for latent tuberculosis is contested. This, some guidelines recommend always using CXR in addition to an immunological assay test like a QuantiFERON-TB (QFT) test, while others recommend CXR be used under certain conditions, only, such as in immunocompromised patients or if the immunological assay produces a positive result. (2)

Aims & Methods: The primary objective of the present study was to investigate if a chest X-ray identifies patients with latent tuberculosis who are not identified with a QuantiFERON-TB test when screening for latent tuberculosis infection before starting biologic treatment in inflammatory bowel disease patients.
A secondary objective was to identify possible patient characteristics which could increase the necessity for a chest X-ray when screening.
This study was a single center, retrospective cohort study of all IBD patients at the Department of Medical Gastroenterology at Odense University Hospital in Denmark who initiated biologic treatment between Oct. 2017 to Oct. 2022.
The primary outcome of interest in this study was the test results for the QFT test and the CXR. Secondary outcomes of interest were patient characteristics thought to influence either the strength of the QFT test or the likelihood of a patient having LTBI.
The test results were compiled and presented together in a 3x2 table. The total number of patients who received a negative QFT test result, but a TB suspect CXR would represent the number of patients who would be of increased risk of LTBI reactivation when starting biologic treatment without a CXR.

Results: The population studied was low risk for TB and had few risk factors for having false negative QFT results except for concurrent glucocorticoid treatment and inflammatory activity. None of the 8 TB cases present in the population were identified based solely on a suspect chest X-ray (see table). Since no patients had a negative QFT combined with suspect CXR, patient characteristics associated with such an outcome could not be identified.

	TB suspect CXR	Non-suspect CXR
Positive QFT test	1	7
Negative QFT test	0	494
Inconclusive QFT test	0	18

TB=tuberculosis QFT=QuantiFERON CXR=Chest X-ray

Conclusion: This results indicate that the benefits of supplementing a QFT test with a CXR are limited and is unlikely to outweigh the cost of patient test-burden, radiation exposure, and economic resources when screening for LTBI in a low endemic population.
While it remains likely that imaging still plays an important role in certain subgroups of patients with higher TB incidence, no characteristics could be identified in this study due to the low-endemic nature of the study population.

SAFETY AND EFFECTIVENESS OF COMBINING BIOLOGICS AND SMALL MOLECULES IN THE TREATMENT OF INFLAMMATORY BOWEL DISEASE: AN UPDATED SYSTEMATIC REVIEW WITH METANALYSIS

P.F. da Silva Mesquita[1], A. Ponte[1,1], M.M. Estevinho[1], J.P. Laranjeira Correia[1], A. Rodrigues[1], A.P. Silva[1], J.C. Silva[1,1], A.C.R.C. Gomes[1], T. Freitas[1]
[1]Centro Hospitalar de Vila Nova de Gaia- Espinho, Department of Gastrenterology, Vila Nova de Gaia, Portugal

Contact E-Mail Address: pedro.filipe.silva.mesquita@gmail.com
Introduction: The number of patients with inflammatory bowel disease (IBD) refractory to different biologic classes and small molecules is growing. Combining mechanisms of action seems to be the key to breaking the therapeutical ceiling; however, the available evidence is still limited and of low quality.
Aims & Methods: We conducted a systematic review and meta-analysis to summarize the available data on the safety and effectiveness of different combinations of biologics and small molecules in Crohn's disease, ulcerative colitis, and indeterminate colitis.
Through a systematic search of multiple electronic databases until March 1, 2023, we included studies with two or more patients on dual biologic therapy or in combination with small molecules due to active intestinal disease.
We reported effectiveness as pooled rates of clinical and endoscopic response and remission. Safety was assessed as pooled rates of adverse events and serious adverse events for each combination. The quality of evidence was rated according to the Critical Appraisal Skills Programme checklist.
Results: We included 28 studies - 2 randomized controlled trials and 26 observational studies - with 499 patients on 7 different combinations (Anti-TNF + Vedolizumab/Ustekinumab/Tofacitinib/Natalizumab/Goselkumab or Vedolizumab + Ustekinumab/Tofacitinib). The most common was tumor Anti-TNF & anti-integrins (n=96).
In patients mostly refractory to monotherapy due to active intestinal disease, combination therapy resulted in pooled clinical and endoscopic remission rates of 48% (CI 0.44-0.52) and 32% (CI 0.26-0.39), respectively. Pooled clinical and endoscopic response rates were 76% (CI 0.65-0.85) and 52% (CI 0.46-0.58), respectively.
Pooled serious adverse event rates (SAE) were 9% (CI 0.06-0.11), with Anti-TNF + Ustekinumab (n=19)/Natalizumab (n=52) and Ustekinumab + Tofacitinib (n=22), being the safest options with no registered SAE.
Heterogeneity was significant only for pooled rates of adverse events. The certainty of the evidence was low due to the nature and inconsistencies between the included studies.
Most of the studies failed to report the outcomes based on the disease subtype and specify which biological agent was used when an anti-TNF was part of the combination. Only one study had a control arm with monotherapy.
Conclusion: Combining Biologics and Small Molecules appears safe and possibly effective in patients with IBD. New trials with higher-quality data will be detrimental to generalizing access to this approach.

CELLULAR AND MOLECULAR IMPACT OF THE MELANOCORTIN RECEPTOR AGONIST PL8177 IN DEXTRAN SULFATE SODIUM–INDUCED COLITIS IN RATS

P. Kayne[1], P. Dhingra[1], A. Obr[1], C. Spana[1], J. Dodd[1]
[1]Palatin Technologies, Inc., Cranbury, United States

Contact E-Mail Address: pkayne@palatin.com
Introduction: The melanocortin 1 receptor (MC1R)–specific agonist PL8177 and its main metabolite PL8435 have demonstrated MC1R binding affinity and functional activity that mirrors that of α-melanocyte–stimulating hormone, which has been shown to be effective in reducing inflammation in numerous experimental models. This study investigates the effects of PL8177 on inflammation, cell population composition, and gene and protein expression in colons from a dextran sulfate sodium (DSS)–induced rat model of colitis. The objective is to determine the effectiveness of PL8177 in this model and to characterize its underlying mechanism of action.
Aims & Methods: Male Wistar rats received 5% DSS in drinking water for 3 days to induce colitis (each group n=6). Rats in the sham group received drinking water only. The other groups received vehicle control (placebo)–filled capsules; PL8177-filled capsules at 20, 50, and 100 µg per animal (by oral gavage); or oral mesalazine (positive control). At termination on day 8, 24 hours after the last dose, colon tissues were harvested, dissected, and snap frozen with liquid nitrogen. Colon samples were analyzed for cytokine levels, single nuclei RNA-seq, and data-independent acquisition tandem mass spectrometry. Colitis was assessed by a disease activity index (diarrhea and rectal bleeding), colon length shortening, colon weight gain, and histopathological assessment. The total colitis index was used to assess inflammatory damage.
Results: Colitis was induced in rats treated with DSS. Treatment with oral PL8177 50 µg showed a significant (P<0.05) improvement in colon weight (53% reduction), stool consistency, and fecal occult blood score compared to vehicle. There was a significant (P<0.05) improvement in the total colitis index for the PL8177 100-µg group vs vehicle control group. All PL8177 cohorts showed greater improvement in the total colitis index compared to the mesalazine-treated cohort. PL8177 50 µg showed a significant (P<0.05) improvement in colon weight (53% reduction), whereas mesalazine treatment was associated with a marked reduction in colon length, but only moderate improvement (35%) in colon weight. Single nuclei

RNA-seq analysis showed that after oral PL8177 100 µg treatment, relative cell populations and key gene expression levels were closer to those of healthy controls. A subclustering analysis revealed significant differences between the PL8177 100-µg and vehicle populations. Although both showed the presence of macrophages, those present in vehicle-treated colons were primarily M1 macrophages that are involved in inflammation. In the PL8177 100 µg–treated colons, macrophages were primarily M2, which are pro-resolution. Proteomic analysis showed that the colons of PL8177-treated rats are more similar to sham colons than to vehicle colons.

Additionally, after treatment with PL8177, a protein known to promote intestinal homeostasis and a blood-based biomarker protein showed expression similar to that seen in the sham group, a result not seen in vehicle-treated colons.

Conclusion: In a rat model, oral PL8177 treatment of colonic inflammation showed significant improvement in anatomical markers of colitis vs the vehicle and mesalazine control groups, supporting the aim of treating inflammatory bowel disease (IBD) in humans. Transcriptomics and proteomics data show that oral PL8177 treatment causes diseased colons to move toward the healthy state and to resolve inflammation. Resolving inflammation—rather than blocking it—provides the possibility of efficacy coupled with safety in treating IBD.

Introduction: Ulcerative colitis (UC) represents the widespread inflammatory bowel disease (IBD) affecting millions of patients worldwide. UC usually begins at the onset of adulthood and progresses across the patient's lifetime. Snail mucus has many hidden activities; many of them have been discovered in recent years. Scientific researchers have demonstrated that mucus-derivate drugs can be used in many therapies.

For example, it is used in creams to ease skin abrasions and scars, to cure respiratory diseases and heartburn, and at last, scientists discovered unexpected and previously unknown properties.

At the beginning of the twentieth century, a new interest in gastropods has grown up for their possible employment in medicine and industries.

Aims & Methods: This study aimed to investigate the possible therapeutic effect of mucus extracted from helix pomica snail in an experimental ulcerative colitis model induced by dextran sulphate sodium. Twenty-four mice were included and categorized into four groups.

The 1st group acted as a normal control group, whereas the 2nd group acted as a pathological control group and ingested dextran sulphate sodium in drinking water.

The 3rd Group was treated orally with sulfasalazine and then ingested dextran sulphate sodium in drinking water.

The 4th group was treated orally with helix pomatia mucus and then ingested dextran sulphate sodium in drinking water. After seven days, the animals were euthanized, and the intestinal specimens were collected for pathological and biochemical assessment.

Results: Our results showed an improvement in histopathology with regression of the intestinal lesions in the 4th group compared to the pathological control group. The levels of nuclear-kappa B, and IL-1B decreased significantly after using helix pomatia mucus.

Conclusion: Helix pomatia mucus could be a potential therapy to protect against experimentally induced ulcerative colitis.

Disclosure: Nothing to disclose.

DATA IN A TERTIARY HOSPITAL ON SWITCHING FROM AN INTENSIFIED AND NON INTENSIFIED REGIMEN OF INTRAVENOUS VEDOLIZUMAB TO A SUBCUTANEOUS IN ADULTS WITH INFLAMMATORY BOWEL DISEASE

L. Andrés Pascual[1], L. Arias García[1], R.M. Saiz Chumillas[1], I. Chivato Martín-Falquina[1], B. Sicilia Aladren[1]
[1]Hospital Universitario de Burgos, Burgos, Spain

Contact E-Mail Address: laura.4cn50910@gmail.com

Introduction: Vedolizumab is a humanised monoclonal antibody whose mechanism of action is inhibition of the α4β7 integrin of T leukocytes. It is indicated for moderate or severe flare of inflammatory bowel disease. Subcutaneous (SC) vedolizumab, a new formulation recently approved, is a major advantage for patients for home administration.

Aims & Methods: Analyse the percentage of clinical and biochemical remission in patients on treatment with intravenous (IV) vedolizumab after switching to SC vedolizumab. In addition, the relationship between a treatment with intensified IV vedolizumab and subsequent drug levels versus patients without intensification.

Single-center, descriptive, observational, and retrospective study of a cohort of all of 19 patients diagnosed with ulcerative colitis (UC) and crohn disease (CD) teatred with IV vedolizumab in January 2022, who underwent a switch to SC vedolizumab. Analyse of clinical and analytical parameters (faecal calprotectin (FC), concomitant treatment, vedolizumab levels during follow-up, need for intensified intravenous treatment, ocurrence of adverse effects or loss of response) in patients on IV vedolizumab treatment and subsequent switch to SC vedolizumab with follow-up during weeks 4, 12, and 24.

Results: Ten patients (22.6%) were diagnosed with UC and 9 patients (47.3%) with CD. The baseline characteristics of the patients are described in table 1. 68% of patients were exposed to anti-TNF when initiating IV Vedolizumab due to loss of response, and 15,7% had been exposed to >1 anti-TNF. 31% (6 patients) were naive to Anti-TNF, 4 patients (21%) IV vedolizumab was started as the first line of treatment due to the increased risk of infections and a previous history of neoplasia and in 2 patients with CD (10.5%) vedolizumab was started as prevention of recurrence. Up to 8 patients (42.1%) were on an intensified IV vedolizumab prior to switching to SC vedolizumab. Biochemical remission (FC < 150 µg/g) was achieved in 14 patients (77.7%) at week 24 of follow-up. All 19 patients (100%) achieved clinical remission. It was noted that biochemical remission was not achieved in up to 50% of patients on the intensified regimen with IV vedolizumab. Mean baseline intravenous vedolizumab levels were 12.1 µg/ml. After switching to SC vedolizumab, the mean levels were 13.1 µg/ml at week 4, 19.9 µg/ml at week 12 and 22.9 µg/ml at week 24 **(p= 0.001).** There was no statistically significant difference in biochemical remission between patients who received an intensive IV vedolizumab regimen and those who did not. One adverse event (paraesthesia) was described in one patient (5.2%) in relation to IV vedolizumab.

Age (years) median (IQR)	60 (38-71)
Sex (male) n (%)	12 (63.1%)
Inflammatory bowel disease: Ulcerative colitis/Crohn disease n (%)	10 (52.6%) / 9 (47.3%)
Reason for starting iv VDZ	
Anti-TNF naive, n (%)	4 (21%)
Failure to first Anti-TNF/ Failure to second Anti-TNF, n (%)	10 (52.6 %) / 3 (15.7%)
Recurrence prevention, n (%)	2 (10.5%)
Concomitant treatments	
Topical salicylates/ Another Biologic (ustekinumab), n (%)	7 (36.8 %) / 1 (5.2%)
Current intensification when switched, n (%)	8 (42.1 %)

Table 1. Baseline characteristics.

Conclusion: 78% of patients after switching from IV vedolizumab to SC vedolizumab, reached clinical and biochemical remission at 6 months of follow-up. In addition, vedolizumab levels increased progressiively after switching IV vedolizumab to SC treatment. These findings confirm that SC vedolizumab is a good therapeutic option for long-term maintenance.

Introduction: Anti-tumour necrosis factor-alpha (anti-TNF-alpha) therapy is an effective treatment for the management of Crohn's disease (CD). However, treatment failure is common.

Aims & Methods: The aim of this study was to identify predictors of anti-TNF-alpha therapy failure.

Retrospective single-center study including anti-TNF-alpha naïve patients with CD, who started on intravenous infliximab, between January 2019 and December 2021. Biochemical parameters included erythrocyte sedimentation rate (ESR), c-reactive protein (CRP), faecal calprotectin, infliximab serum concentrations and the presence of antibodies to infliximab (ATI). Anti-TNF-alpha therapy failure was defined as the development of ATI at 6 and 12 months, absence of clinical response at 6 months, absence of clinical remission or of objective response at 12 months. Clinical response was defined as a reduction in Harvey-Bradshaw index (HBI) of ≥ 3 points comparing with initial value or HBI < 5 points if initial HBI ≥ 7 points and clinical remission as HBI ≤ 4 points. Objective response was assessed by endoscopic studies, defined by improvement of mucosal inflammation and absence of deep ulcerations, or imaging, defined as improvement in bowel wall thickness, inflammatory fat, mural blood flow and hyperenhancement.

Results: A total of 53 CD patients were included, 30 were female (56.6%), with a mean age at the beginning of treatment of 39 ± 2 years. Considering the Montreal classification, 31 patients had ileal disease (58.5%), 7 colonic (13.2%) and 15 ileocolonic disease (28.3%); 22 patients had nonstricturing, nonpenetrating disease (41.5%), 22 stricturing (41.5%) and 9 penetrating disease (17.0%). Eleven patients had perianal disease (20.8%). A total of 26 patients (49.1%) were treated with combination of anti-TNF-alpha and immunomodulatory therapy (thiopurine or methotrexate). Anti-TNF-alpha therapy failure occurred in 21 patients (39.6%). At 6 months, the development of ATI occurred in 6 patients (11.3%) and absence of clinical response in 9 patients (17.0%). At 12 months, absence of clinical remission was seen in 13.6% of patients and absence of objective response in 27.0% of patients.

At 6 months, the development of ATI was significantly higher in patients with lower infliximab serum concentrations at week 14 (with antibodies 5.9±3.2 µg/mL vs without 14.3±7.7 µg/mL, p<0.001). Additionally, the development of ATI was significantly higher in patients with a higher initial value of ESR (with antibodies median 35 vs without median 13, p=0.045). The infliximab serum concentrations at week 14 (AUC 0.828; p=0.009; sensitivity 0.833 and specificity 0.404 for values ≤11.6) and the initial value of ESR (AUC 0.754; p=0.045; sensitivity 0.833 and specificity 0.468 for values ≥15) had very good and good discriminative capacity, respectively, in predicting the development of ATI. No statistically significant differences were found in initial values of CRP and faecal calprotectin, between both groups. Moreover, the other definers of anti-TNF-alpha therapy failure were not associated with the combination with immunomodulatory therapy, infliximab serum concentrations at week 14 or initial values of ESR, CRP and faecal calprotectin.

Conclusion: Infliximab serum concentration after induction therapy is the most important factor in the development of ATI, influencing treatment response, regardless of the combination of anti-TNF-alpha therapy with immunomodulatory therapy. A higher initial value of ESR can also predict the development of ATI.

Disclosure: Nothing to disclose.

Introduction: A previous meta-analysis in Crohn's disease (CD) patients suggested lower discontinuation rates due to lack of efficacy in infliximab (IFX) compared to vedolizumab (VDZ) during a one-year maintenance phase.[1] This study aims to compare the discontinuation rates due to lack of efficacy between VDZ and IFX by adding the one-year clinical results of "A Randomized, Placebo-Controlled, Double-Blind, Phase 3 Study to Evaluate the Efficacy and Safety of the Subcutaneous Injection of CT-P13 (CT-P13 SC) as Maintenance Therapy in Patients With Moderately to Severely Active Crohn's Disease (LIBERTY-CD; NCT03945019)".[2]

Aims & Methods: Discontinuation rates due to lack of efficacy during the one-year maintenance phase were compared between the treatments. Using a random-effect model, pooled discontinuation rates were reported as forest plots with 95% confidence intervals (CI). The heterogeneity between studies was examined. A sensitivity analysis was conducted among patients who responded to induction therapy. Statistical analyses were performed using MetaProp in R (version 4.2.2).

Results: Four randomized controlled trials (RCTs) (NCT02883452, NOR-SWITCH, PLANETCD, and LIBERTY-CD) on IFX and two RCTs (GEMINI 2 and VISIBLE 2) on VDZ in patients with CD were included for the analysis (IFX: N=659, VDZ: N=995). Pooled discontinuation rates due to lack of efficacy during the one-year maintenance phase were significantly lower in patients who were treated with IFX (0.05 [95%CI: 0.00-0.09], heterogeneity: I^2=86%) compared to those treated with VDZ (0.37 [95%CI: 0.26-0.48], heterogeneity: I^2=93%) (Table 1).

A sensitivity analysis was performed after excluding non-responders to induction therapy which resulted in slightly lower rates of discontinuation due to lack of efficacy in VDZ (0.32 [95% CI: 0.27-0.37], heterogeneity: I^2=48%). However, the significant difference was maintained (Table 1).

Treatment	Study[a]	Route	Dosing	Events	Total	Proportion (95% CI)	Weight	Random effect model	Heterogeneity I^2 (P-value)
IFX	NCT02883452	SC	Q2W	3	28	0.11 (0.02–0.28)	9.1%	0.05 (0.00–0.09)	86% (p<0.01)
	NCT02883452	IV	Q8W	0	25	0.00 (0.00–0.14)	19.0%		
	PLANET CD	IV	Q8W	23	220	0.10 (0.07–0.15)	21.6%		
	NOR-SWITCH	IV	Q8W	1	155	0.01 (0.00– 0.04)	26.3%		
	LIBERTY-CD	SC	Q2W	12	231	0.05 (0.03–0.09)	24.0%		
VDZ	GEMINI 2	IV	Q4W[a]	48	154	0.31 (0.24–0.39)	24.4%	0.37 (0.26–0.48)	93% (p<0.01)
	GEMINI 2	IV	Q4W[b]	208	412	0.50 (0.46–0.55)	25.9%		
	GEMINI 2	IV	Q8W	58	154	0.38 (0.30–0.46)	24.2%		
	VISILE 2	SC	Q2W	78	275	0.28 (0.23–0.34)	25.6%		
VDZ (excl. primary non-responder)	GEMINI 2	IV	Q4W	48	154	0.31 (0.24-0.39)	30.2%	0.32 (0.27–0.37)	48% (p=0.15)
	GEMINI 2	IV	Q8W	58	154	0.38 (0.30-0.46)	28.7%		
	VISIBLE 2	SC	Q2W	78	275	0.28 (0.23-0.34)	41.1%		

a: responders at week 6; b: non-responders at week 6; CI, confidence interval; IFX, infliximab; IV, intravenous; Q*n*W, every *n* weeks; SC, subcutaneous; VDZ, vedolizumab

Table 1. Discontinuation rates due to lack of efficacy during the one-year maintenance phase.

Conclusion: Consistent with previous findings, IFX showed significantly lower rates of discontinuation due to lack of efficacy during the one-year maintenance compared to VDZ. In the sensitivity analysis that excluded non-responders to induction therapy in VDZ studies, the significant difference between treatments was maintained.

EXPOSURE TO ANTI-TNFA AGENT IS ASSOCIATED WITH THE DEVELOPMENT OF AUTOIMMUNE DISEASE IN INFLAMMATORY BOWEL DISEASE: A POPULATION-BASED CASE-CONTROL STUDY

S.J. Oh[1], C.K. Lee[1], H.J. Kim[1], J.E. Kim[1]

[1]Kyung Hee University Hospital, Gastroenterology, Seoul, South Korea

Contact E-Mail Address: linus204@naver.com

Introduction: Autoimmune-related phenomena appearing after anti-TNFα agent use are increasingly being reported. However, the precise pathogenesis has not been elucidated, and there is little evidence to establish a clear cause-effect relationship. Therefore, we evaluate whether exposure to anti-TNF agents is associated with the development of autoimmune diseases in patients with inflammatory bowel disease (IBD).

Aims & Methods: This population-based case-control study investigated all IBD patients identified from 2004 to 2018 using the Korean National Health Insurance Service (NHIS) database. IBD patients with diagnostic codes for autoimmune disease (central nervous system (CNS) event, psoriasis, interstitial lung disease (ILD), lupus or systemic vasculitis) was

included as case in the study. Each case was matched to a control patient with IBD without the presence of autoimmune disease based on index date, age, sex, and subtype and diagnosis year of IBD. Incidence estimates were established by using the earliest claim data with diagnostic codes for autoimmune disease as the index date. Association with TNF inhibitor was evaluated with conditional logistic regression. Subgroup analyses were performed according to the type of autoimmune disease, and we also stratified anti-TNFα agent exposure according to drug type, cumulative frequency, and duration.

Results: During the study period, a total of 515,707 incident IBD patients (ulcerative colitis, 314,824; Crohn's disease, 180,669) were included. We identified 45,430 cases of autoimmune disease and 470,277 unmatched controls. Of this total, more than two-thirds (68%) were over the age of 40 and median of IBD duration until diagnosis of autoimmune disease was 5.75 years. The proportion of cases with overall autoimmune disease who received treatment with anti-TNFα agents (3.2%) was higher than that of controls (2.4%). Exposure to anti-TNFα agents after IBD diagnosis significantly increased overall autoimmune disease risk by approximately 1.35, and the elevated risk was maintained even after adjusting for multiple confounding factors (adjusted odds ratio [AOR], 1.43; 95% CI, 1.35–1.51). Logistic regression analysis was also performed after matching and revealed that use of anti-TNF agents increases the risk of autoimmune disease compared to never use especially in psoriasis and lupus. In addition, the cumulative effect of anti-TNF agents, which increases the risk of autoimmune disease according to frequency, was confirmed (P_{trend} <0.0001).

	Simple logistic regression			Multiple logistic regression			Matching		
	OR	CI	P-value	OR	CI	P-value	OR	CI	P-value
Overall	1.35	1.28–1.42	<.001	1.43	1.35–1.51	<.001	1.86	1.70–2.04	<.001
CNS	1.08	0.91–1.26	0.386	1.03	0.87–1.22	0.722	1.056	0.89–1.26	0.540
ILD	1.13	0.97–1.31	0.111	1.12	0.96–1.31	0.144	1.15	0.98–1.35	0.082
Psoriasis	1.33	1.24–1.42	<.001	1.41	1.31–1.51	<.001	1.53	1.40–1.67	<.001
Lupus	2.15	1.89–2.44	<.001	2.56	2.24–2.93	<.001	2.21	1.92–2.54	<.001
Vasculitis	1.25	0.94–1.66	0.127	1.32	0.98–1.76	0.066	1.19	0.88–1.62	0.297

Conclusion: This study found that exposure to anti-TNFα in patients with IBD appeared to be associated with increased risk of autoimmune disease especially psoriasis and lupus. It is presumed that inhibition of inflammatory cascade by anti-TNF agents induces other unexpected immune responses. Therefore, clinicians should be aware of the risks and benefits of theses agents and take appropriate measures to minimize potential adverse effects.

DUAL THERAPY WITH CAROTEGRAST (AJM300: ORAL A4 INTEGRIN ANTAGONIST) AND BIOLOGICS FOR REFRACTORY ULCERATIVE COLITIS

T. Fujii[1], S. Hibiya[1], H. Shimizu[1], A. Kawamoto[1], K. Takenaka[1], E. Saito[1], M. Nagahori[1], K. Ohtsuka[1], R. Okamoto[1]
[1]*Tokyo Medical and Dental University, Gastroenterology and Hepatology, Tokyo, Japan*

Contact E-Mail Address: tfujii.gast@tmd.ac.jp

Introduction: A diverse variety of biologics and *small molecule*s have been developed for the treatment of refractory ulcerative colitis; however, it is still reported that 10% of these patients will undergo surgery within a decade for inadequate induction and maintenance of remission due to reasons such as drug ineffectiveness, loss of response, and side effects. Dual therapy using a combination of biologics has been attempted for rheumatoid arthritis with lack of success, owing to insufficient efficacy and increase in side effects.

In inflammatory bowel disease, biologics have been developed against adhesion molecules, which are considered to have high intestinal selectivity and safety, with potential for safe co-administration with other drugs. Carotegrast (AJM300), an oral α4 integrin antagonist, has been developed and approved as a novel therapy for ulcerative colitis, however there have been no reports so far on the dual use of carotegrast with other biologics.

Aims & Methods: We investigated the efficacy and safety of carotegrast in combination with other biologics in treating refractory ulcerative colitis. Six patients (3 males, median age 27 years) who underwent dual therapy with carotegrast and another biologic (4 cases of ustekinumab and 2 cases of infliximab) for treatment refractory ulcerative colitis at the Advanced Clinical Center for Inflammatory Bowel Diseases, Tokyo Medical and Dental University after May 2022 were included, Patient background, short-term efficacy, and safety profile were investigated.

Results: The median pMayo at induction was 5.0 (3-6). 50% of patients were steroid-refractory, 50% were steroid-dependent. 5 patients had inadequate or no response to previous biologics and 1 patient had a loss of response to biologics. The median time between the last dose of biologic and the start of carotegrast was 14.5 days, and the mean duration of carotegrast administration was 38.8 days. Carotegrast was discontinued in one patient due to epigastric pain.

All 5 patients who were eligible for continued treatment achieved pMayo0 at 2 weeks, and also maintained pMayo0 at the end of the 6-8 week treatment period, and were placed on maintenance therapy with biologics. No side effects other than epigastric pain were observed.

Conclusion: Dual therapy with carotegerast and another biologic may be effective and safe in ulcerative colitis patients with biologics failure.

Disclosure: Nothing to disclose.

PP0875

VITAMIN D DEFICIENCY IS ASSOCIATED WITH POOR DISEASE OUTCOME UNDER ANTI-TNF THERAPY IN CHILDREN WITH IBD

A. Yerushalmy Feler[1], Y. Manor[1], S. Cohen[1]
[1]*Tel Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel Aviv University, Pediatric Gastroenterology Institute, Tel Aviv, Israel*

Contact E-Mail Address: anaty11@yahoo.com

Introduction: Deficiency of serum 25-hydroxyvitamin D [25(OH)D] was associated with decreased short-term response to anti-tumor necrosis factor-alpha (TNFα) agents in adults with inflammatory bowel disease (IBD). Data on the long-term outcome of pediatric IBD with 25(OH)D deficiency under anti-TNFα therapy are scarce.

The aim of this study was to evaluate the relation between serum 25(OH)D levels and the long-term outcome of pediatric IBD under anti-TNFα therapy.

Aims & Methods: Children (<18 years) with IBD that were treated with anti-TNFα agents, and had 25(OH)D levels measured at the initiation of therapy and at least 12 months of follow up under this therapy were included. Demographic, clinical and laboratory data were retrospectively collected. IBD activity was measured by Pediatric Crohn's Disease Activity Index (PCDAI) or Pediatric ulcerative colitis activity index (PUCAI). IBD outcomes were defined as clinical response (reduction of PCDAI > 12.5 or PUCAI > 20 points), clinical remission (PCDAI or PUCAI < 10 points), laboratory remission (C-reactive protein < 5 mg/L and fecal calprotectin < 150 mcg/g), IBD exacerbation (relapse of clinical symptoms accompanied with an elevation above 10 points in the PCDAI or the PUCAI), IBD-related hospitalization, surgery and durability of therapy. Vitamin D deficiency was defined as serum 25(OH)D levels < 30 ng/ml.

Results: Of 530 children with IBD, 150 were treated with anti-TNFα agents and 84 [58 Crohn's disease, 26 ulcerative colitis, median age 15.2 (12.8-16.5) years] met the inclusion criteria. Their median 25(OH)D level was 23 (16.3-29.6) ng/ml, and 65 (77.4%) were 25(OH)D-deficient. 25(OH)D levels above 30 ng/ml were significantly associated with clinical response [HR=4 (1.43-11.11), P=0.008], clinical remission [HR=4.62 (2.56-8.33), P<0.001] and laboratory remission [HR=6.34 (3.39-11.84), P<0.001). Disease exacerbation, IBD-related hospitalization and surgery were non-significantly more prevalent among 25(OH)D-deficient children (12.2% vs. 5.3%, 13.8% vs. 0, 3.1% vs. 0, respectively, P=NS). While anti-TNFα trough levels were similar between 25(OH)D-deficient and non-deficient children, intensification of anti-TNFα therapy was more prevalent among 25(OH)D-deficient children (64.6% vs. 21.1%, P<0.001), as was discontinuation of anti-TNFα therapy (32.3% vs. 10.5%, P=0.061). In a multivariate analysis that included age, sex, IBD type, disease duration and anti-TNFα trough levels, 25(OH)D levels above 30 ng/ml were significantly associated with clinical response and remission [HR=3.92 (1.52-10.08), P=0.005 and HR=5.23 (1.88-14.55), P=0.002, respectively].

Conclusion: Deficiency of serum 25(OH)D is an independent predictor to poor IBD outcome under anti-TNFα therapy in children with IBD. Prospective studies are needed to determine whether supplementation of vitamin D can improve IBD outcome under anti-TNFα therapy.

Disclosure: Nothing to disclose.

PP0876

AN AUSTRALIAN STUDY OF EXCLUSIVE ENTERAL NUTRITION FOR MANAGEMENT OF ACTIVE SEVERE INFLAMMATORY BOWEL DISEASE FOCUSING ON EFFICACY AND PATIENT REPORTED PERSPECTIVE

S. Rouse[1], S. Riccardi[2], L. Bown[2], K. Curin[1], J. Petrunic[1], N. McGuinn[1], S. Vogrin[3], E. Chow[1]

[1]Western Health, Gastroenterology, Melbourne, Australia, [2]Western Health, Dietetics, Melbourne, Australia, [3]Western Health, Statistics, Melbourne, Australia

Contact E-Mail Address: sarah.eaton268@gmail.com

Introduction: Exclusive enteral nutrition (EEN) is a well-established first line therapy in paediatric Crohn's disease and is as effective as corticosteroids but without the harmful adverse effects (1; 2; 3). EEN is an emerging therapeutic option in adult Inflammatory Bowel Disease (IBD), however there are concerns about poor tolerability and compliance. The Western Health IBD team has been using EEN in adult IBD patients with active severe disease.

The study aims to examine the tolerability, compliance and efficacy of EEN and provide a unique insight into the patient perspective.

Aims & Methods: Patients with IBD, either Crohn's Disease (CD) or Ulcerative Colitis (UC) who initiated EEN at Western Health, Australia between 1/12/2020 and 30/3/2023 were included in the study. The standard course of EEN consists of exclusive consumption of an oral nutrition supplement and water for at least 4 weeks. A retrospective audit of patients' basic demographic data, disease phenotype and clinical outcomes was conducted. Fisher's exact test was used to assess differences between the cohort who completed ≥4 weeks of EEN and those who did not. Comparison of patients' clinical outcomes pre- and post-EEN was conducted with the Wilcox signed-rank test to assess efficacy of EEN. Patients were invited to participate in an online survey regarding their compliance and views of EEN efficacy and tolerability.

Results: 24 IBD patients with active disease were included; 21 with CD and 3 with pan UC. There were 16 males and the median age was 44.5 (IQR 35.5) years old. 10 patients had fistulising CD, 13 had stricturing disease and 8 had perianal disease. 7 patients reported previous surgical intervention. At time of initiation of EEN, 12 patients were on corticosteroids and 14 were on biologic therapy. 17 out of 24 patients who started EEN completed ≥ 4 weeks of therapy.

Fisher's exact tests for age, sex, smoking history, concurrent steroid use, CDAI or faecal calprotectin did not reveal statistically significant associations (p<0.05) with patients' ability to complete ≥4 weeks of EEN.

The Wilcox signed-rank test showed a statistically significant reduction in the median Crohn's Disease Activity Index (CDAI), albumin and haemoglobin in CD patients. Median reduction in CDAI was 137 (n=14,z=3.296,p=<0.001). Median improvement of albumin was 5g/L (n=16,z=2.67,p=0.008), median improvement of haemoglobin was 8g/L (n=16,z=-2.304,p=0.021). In the small UC cohort, there was no change in Partial Mayo Scores before and after EEN.

Patient perspective surveys were completed by 11 of the 19 invited patients. 7 patients reported that the EEN diet was successful in achieving their goal and they would repeat the diet if it was recommended. Patient goals included delaying surgery, avoiding steroids and improving symptoms. Overall satisfaction was measured with a linear analogue scale, the median score was 8 (IQR 5.5). Compliance analysis revealed 6 patients reported never straying from the EEN diet, 4 patients consumed non-recommended food or drink once or twice in the time period and 1 patient did this roughly once per week.

Conclusion: Our small single centre study provides supportive evidence that EEN is effective and well tolerated in adult IBD patients. 70% of patients completed at least 4 weeks of EEN. There is a statistically significant improvement in CD patient clinical outcomes. There was a high level of patient satisfaction, as well as high patient compliance. In the future, this form of dietary intervention could be more widely accepted in management of IBD patients with moderate to severe disease.

RELATIONSHIP BETWEEN DIETARY PATTERNS AND MENTAL HEALTH IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

H. Nadeem[1], S. Gold[2], M. Yousuf[3], B. Chiew[3], L. Taylor[3], M. Raman[3]

[1]University of Calgary, Internal Medicine, Calgary, Canada, [2]Icahn School of Medicine at Mount Sinai, Division of Gastroenterology, New York, United States, [3]University of Calgary, Division of Gastroenterology, Calgary, Canada

Contact E-Mail Address: Huznadeem123@gmail.com

Introduction: Pro-inflammatory diets have been associated with increased depression and anxiety in general populations. Patients with inflammatory bowel disease (IBD) have higher rates of depression and anxiety as compared to the healthy population. Whether the dietary patterns impact mental health outcomes in patients with IBD remains unclear.

Aims & Methods: This study was performed as part of a randomized controlled trial (RCT) designed to identify the impact of a dietary intervention in ulcerative colitis (UC). The goal of this sub-study was to determine if there is a relationship between mental health and dietary patterns in patients with UC utilizing baseline data from the RCT. Patients over the age of

18 years with UC either in clinical remission or with active disease were recruited in Calgary, Alberta. Clinical and demographic data were collected including IBD activity utilizing the partial Mayo score. At enrollment, all patients completed a validated 24-hour dietary recall questionnaire, the Patient Health Questionnaire-8 (PHQ) to assess for depression and the General Anxiety Disorder-7 (GAD) to evaluate for anxiety. In addition, serum and intestinal inflammatory markers (c-reactive protein [CRP]) and stool calprotectin were collected at the time of enrollment. Utilizing this information, the healthy eating index (HEI) and Mediterranean Diet Score (MDS) were calculated. A higher HEI score indicates greater adherence to a general healthy eating pattern while a higher MDS is suggestive of adherence to a Mediterranean diet. Bivariate comparisons were made using Chi-squared and student t-tests. Multivariable regression was also performed controlling for potential confounders.

Results: In total, 30 patients were recruited for this study; 16(53%) were male with a mean age of 38.6 years (standard deviation [SD] =12.0). At the time of enrollment, 12(40%) patients were on corticosteroids for treatment of their UC, 8(27%) were on a biologic, and 5(17%) on an immunomodulator. The mean partial Mayo score in the cohort was 4.5 (SD=3.6, range 0-11) and 13(43%) had a fecal calprotectin greater than 250 µg/g. Among participants, the mean PHQ score was 6.6 (13 with no depression, 8 with mild depression, 4 with moderate, 3 with moderate/severe and no one with severe depression). The mean GAD score was 5.0 (15 with no anxiety, 9 with mild anxiety, 3 with moderate anxiety and none with severe anxiety). In this study, the mean total MDS was 4.8 (SD =1.6, range 1-8) and mean total HEI was 69.0 (SD=9.1, range 53-85). When controlling for age, sex, body mass index, disease activity and corticosteroid use, severity of depression (p=0.03, 95% Confidence interval [CI] -.26 to -.01) and anxiety (p=0.02 95%CI -.34 to -.03) was inversely correlated with total MDS. Of interest, similar associations were not seen with the HEI.

Conclusion: The impact of diet and nutrition on mental health illness is increasingly being recognized in patients with IBD. Patients with UC in this study who had a lower prevalence of anxiety and depression were more likely to be eating a Mediterranean style diet. In contrast, there was no significant association between mental health disease and HEI, suggesting that the Mediterranean diet score is potentially identifying different dietary behaviors. Future studies to establish causality are necessary to better elucidate these relationships.

Contact E-Mail Address: s.schreiber@mucosa.de

Introduction: Bowel urgency is increasingly being recognized as an impactful symptom in patients with ulcerative colitis (UC)[1]. However, limited information is available regarding its potential association with other patient reported outcomes. We assessed the association of bowel urgency clinically meaningful improvement (CMI) or bowel urgency remission with Inflammatory Bowel Disease Questionnaire (IBDQ) scores whilst adjusting for the potential confounding effects of stool frequency (SF) and rectal bleeding (RB) remission using data from LUCENT-1 (NCT03518086) and LUCENT-2 (NCT03524092) phase 3 trials.

Aims & Methods: Bowel urgency severity was assessed by the Urgency Numeric Rating Scale (UNRS) (0=no urgency to 10=worst possible urgency). Bowel urgency CMI was defined as ≥3-point decrease in UNRS compared to baseline and bowel urgency remission was defined as UNRS of 0 or 1.[2] IBDQ scores (range: 32–224) were calculated; higher scores indicate better quality of life. Mediation analyses were performed to examine the relative association between direct effects of bowel urgency CMI and bowel urgency remission (separate predictors) and IBDQ scores while adjusting for the potential confounding effects of SF remission and RB remission (mediators). Analyses were treatment agnostic and combined patients from mirikizumab and placebo groups from LUCENT-1 (N=1162) and LUCENT-2 (N=544) trials at Week (W) 12 and 40 (W52 of continuous treatment).

Results: At W12 and W52, bowel urgency remission directly accounted for 44.8% and 32.5% improvement in IBDQ total score, respectively; 22.7% and 39.1% of improvement was mediated by RB remission and 32.5% and 28.4% by SF remission, respectively. At W12, bowel urgency remission resulted in the largest proportion of improvement in each of the IBDQ domain subscores, whereas at W52, RB remission had a greater confounding effect. At W12 and W52, bowel urgency CMI accounted for 70% and 57.3% improvement in IBDQ total score, respectively; 12.8% and 25.6% of effects were mediated by RB remission and 17.2% and 17.1% by SF remission, respectively. Bowel urgency CMI accounted for the largest proportion of association with improvement in each of the IBDQ domain subscores at both W12 and W52.

Conclusion: Improvements in IBDQ scores were primarily ascribed to bowel urgency remission and bowel urgency CMI relative to RB remission and SF remission, particularly at W12, in patients with moderately-to-severely active UC. These findings suggest that bowel urgency is a critical and independent symptom that considerably impacts patients' quality of life.

RELATIVE ASSOCIATION OF BOWEL URGENCY CLINICALLY MEANINGFUL IMPROVEMENT AND BOWEL URGENCY REMISSION VS STOOL FREQUENCY REMISSION AND RECTAL BLEEDING REMISSION WITH IMPROVEMENT IN WPAI SCORES IN PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS: AN ANALYSIS FROM LUCENT-1 AND LUCENT-2

B.E. Sands[1], B.G. Feagan[2], T. Hunter Gibble[3], A. Keohane[3], W.J. Eastman[3], K. Traxler[3], S. Schreiber[4], V. Jairath[5], A. Armuzzi[6]

Introduction: Bowel urgency is increasingly recognized as a common and impactful symptom in patients with Ulcerative Colitis (UC)[1]. However, there are limited data exploring the relationship of bowel urgency with work productivity. We examined the relative association of bowel urgency clinically meaningful improvement (CMI) and bowel urgency remission with Work Productivity and Activity Impairment (WPAI) scores in the presence of rectal bleeding (RB) remission and stool frequency (SF) remission as potential confounding variables using data from LUCENT-1 (NCT03518086) and LUCENT-2 (NCT03524092) phase 3 trials.

Aims & Methods: Bowel urgency severity was assessed using the Urgency Numeric Rating Scale (UNRS; 0=no urgency to 10=worst possible urgency). Bowel urgency CMI is a ≥3-point decrease and bowel urgency remission is a UNRS score of 0 or 1[2]. WPAI scores (absenteeism, presenteeism, and work productivity loss in employed patients, and activity impairment in all patients) were measured using a 6-item questionnaire; higher scores indicate greater impairment and less productivity. Mediation analyses were performed to separately examine the relative association between the direct effect of bowel urgency CMI and bowel urgency remission (predictor) and WPAI scores while adjusting for the potential confounding effects of RB remission and SF remission (mediator). Analyses were treatment agnostic and combined patients from mirikizumab and placebo groups from LUCENT-1 (N=1162) and LUCENT-2 (N=544) trials.

Results: At week (W)12 and W52, the direct effect of bowel urgency remission accounted for 43%–49% and 27%–57% of the improvement in all WPAI domain scores except absenteeism, respectively. The association values greater than 100% at W12 and W52 (153% and 148%, respectively) reflect the critical importance of SF remission in the improvement of absenteeism score. Bowel urgency CMI resulted in the largest proportion of improvement in WPAI domain scores (except absenteeism) at W12 (71%–74%) and W52 (66%–78%). Bowel urgency CMI accounted for 68% and 239% of the improvement in absenteeism scores at W12 and W52, respectively. At W52, 750% of the effect was mediated by RB remission.

Conclusion: Improvement in work productivity and regular activities were primarily ascribed to bowel urgency remission or bowel urgency CMI relative to RB remission and SF remission in patients with moderately-to-severely active UC. These findings suggest that bowel urgency is a critical and independent symptom that considerably impacts patients' productivity.

Introduction: In contrast to ulcerative colitis (UC), the impact of bowel urgency (BU) in patients with moderate-to-severe Crohn's disease (CD) is unclear. The Communicating Needs and Features of IBD Experiences (CONFIDE) survey aims to understand the experience and impact of symptoms on lives of patients with UC or CD worldwide (United States [US], Europe [EU], and Japan). This survey also explores the communication gaps between healthcare professionals (HCPs) and patients. Previously reported CONFIDE data suggested that BU was the second most reported symptom among US and EU5 (France, Germany, Italy, Spain, and UK) patients with moderate-to-severe UC.[1] Persistent BU was reported in 46% US and 28% EU5 patients receiving advanced therapies for UC and 45% US and 37% EU5 patients reported wearing diapers/pads/protection at least once every week.[1] Here, we present patient and HCP perspectives on the experiences and impact of CD-related symptoms.

Aims & Methods: Online, quantitative, cross-sectional surveys were conducted separately among HCPs and patients with CD from US and EU5 between May and October 2021. Moderate-to-severe CD was defined using criteria based on previous treatment, steroid use, and/or hospitalization. Data are presented as descriptive statistics.

Results: Surveys were completed by 215 US (male [M]=55%, mean age 41 years) and 547 EU5 (M=55%, mean age 38 years) patients. Of these, 58% US and 63% EU5 patients were receiving advanced therapies (biologic/novel oral) and 66% and 63% were receiving steroids at the time of survey completion, respectively. Most patients in the US (61%) and EU5 (62%) reported moderate CD, followed by severe (25% and 10%), and mild CD (14% and 28%).

In both US and EU5 populations, top three symptoms currently (past month) experienced by patients were diarrhoea (US: 55%, EU5: 55%), BU (US: 42%, EU5: 38%), and increased stool frequency (US: 40%, EU5: 37%). Among the patients receiving advanced therapies (US: 58%, EU5: 63%), 46% US and 39% EU5 patients experienced BU and 27% US and 19% EU5 patients reported fistula-related symptoms around the anus/rectum. Of the patients who had experienced BU, only 40% US and 27% EU5 patients were completely comfortable discussing BU with their HCPs and only 27% US and 23% EU5 patients felt comfortable discussing BU-related accidents. Embarrassment was the most common reason for discomfort associated with discussing BU (US: 73%, EU5: 64%) and BU-related accidents (US: 72%, EU5: 66%) with HCPs.

A total of 200 US (M=78%) and 503 EU5 (M=71%) HCPs completed the surveys, of which 92% were gastroenterologists or specialists in internal medicine and 7% were non-physicians. According to HCPs, the top three patient-reported symptoms were diarrhoea (US: 67%, EU5: 66%), blood in

stool (US: 44%, EU5: 24%), and increased stool frequency (US: 32%, EU5: 28%). BU was reported among the top three symptoms only by 19% US and 16% EU5 HCPs. Many HCPs (US: 34%, EU5: 40%) reported not proactively discussing BU, with the most common reason being that they "expect the patient to bring this up if this is an issue" (US: 34%, EU5: 42.0%).

Conclusion: Similar to the findings in UC patients[1], bowel urgency was the second most reported symptom among patients with CD, but not among the HCP-perceived top three symptoms. A large proportion of patients with moderate-to-severe CD receiving advanced therapies continued to experience bowel urgency. These results indicate a communication gap between HCPs and patients with CD, highlighting the underappreciation of the impacts of bowel urgency on patients' daily lives.

UTILITY OF VEDOLIZUMAB CLINICAL DECISION SUPPORT TOOL IN PREDICTION OF BIO-NAIVE CROHN'S DISEASE PATIENTS OUTCOMES TREATED WITH ADALIMUMAB OR USTEKINUMAB

V. Tomasic[1], A. Biscanin[1,2], P. Cacic[1], L. Palac[2], Z. Dorosulic[1], D. Kralj[1], F. Babic[1], D. Ogresta Kordej[1], D. Hrabar[1,2]

Contact E-Mail Address: tomasicvedran@gmail.com

Introduction: Vedolizumab Clinical Decision Support Tool (V-CDST) identifies Crohn's disease (CD) patients most likely to benefit from vedolizumab administration. Real world data are needed to assess whether V-CDST is drug specific or can be applicable for other biologic CD agents. Aim of this study is to evaluate ability of the 5-variable V-CDST (5V-CDST) and new modified 3-variable V-CDST (3V-CDST) to predict effectiveness of adalimumab (ADA) or ustekinumab (UST) treatment for bio-naive CD patients.

Aims & Methods: A single center, noninterventional retrospective cohort review study was performed on real-life data of adult bio-naive CD patients who were treated with adalimumab (160/80 mg SC at BL/W2, then 40 mg SC every 2 Ws) or ustekinumab (6 mg/kg IV at BL then 90mg SC every 12 Ws) for a minimum of 6 months. Routine clinical, biochemical (CRP, serum albumin, fecal calprotectin - FC), and endoscopic (Simple Endoscopic Score for Crohn's disease – SES-CD; Rutgeerts score) findings were assessed according to STRIDE-II recommendations.

Treatment effectiveness was defined as FC <250 mcg/g, and/or SES-CD ≤3/ Rutgeerts score ≤i2b, and/or no need for steroids, treatment escalation, switching biologics, and CD-related surgery. 5V-CDST score >19/3V-CDST score >3 were associated with high probability of treatment response and 5V-CDST score ≤19/3V-CDST score ≤3 with low probability of treatment response. Participants' characteristics were assessed using descriptive statistics. Normal distribution was assessed using Kolmogorov-Smirnov and Shapiro-Wilk tests.

Categorical variables were analyzed using the Chi-square and Fisher exact test. Binary logistic regression was carried out in order to assess the predictive capacity of 5V-CDST/3V-CDST.

Results: Total of 69 patients (53.3% females; smokers 25%) were included; 48 received ADA (median age 31.5 years), and 21 received UST (median age 52 years). Poor discriminative and predictive performance for the both 5V-CDST and 3V-CDST was observed both in the ADA and UST treated patients; there was no statisticaly significant difference between 5V-CDST and biochemical remission (ADA p=1; UST p=0.6), 3V-CDST and biochemical remission (ADA p=1; UST p=0.08), 5V-CDST and steroid-free remission (ADA p=0.36; UST p=0.28), 3V-CDST and steroid-free remission (ADA p=0.7; UST p=1), 5V-CDST and endoscopic remission (ADA p=0.36; UST p=0.6), 3V-CDST and endoscopic remission (ADA p=0.7; UST p=1), 5V-

CDST and combination of steroid-free + biochemical + endoscopic remission (ADA p=0.18; UST p=0.46), 3V-CDST and combination of steroid-free + biochemical + endoscopic remission (ADA p=0.6; UST p=0.3), 5V-CDST and treatment escalation (ADA p=0.75; UST p=1), 5V-CDST and switching biologics (ADA p=0.33; UST p=1), 3V-CDST and switching biologics (ADA p=0.3; UST p=1), and 5V-CDST and CD-related surgery (ADA p=0.5 vs UST p=1). 3V-CDST in ADA group can discriminate patients with high probability for CD-related surgery; patients with 3V-CDST ≤3 are 48 times more likely to undergo operation compared to those with higher 3V-CDST (p<0.01; OR: 48). Same performance was not detected in UST group (p=0.2)

Conclusion: Regarding our cohort the 5V-CDST and 3V-CDST do not have a predictive capacity to identify groups of bio-naive CD patients which could benefit from administration of ADA or UST.

Disclosure: Nothing to disclose.

EFFICACY AND SAFETY OF GRANULOCYTOAPHERESIS IN THE TREATMENT OF STEROID-DEPENDENT AND STEROID-REFRACTORY INFLAMMATORY BOWEL DISEASE

N.D. Salazar Parada[1], M. Algara San Nicolas[1], A. Suárez-Saro Fernández[1], A. Masedo[1], C. Yela San Bernardino[1], C. Begoña[1], P. Martínez Montiel[1], I. Fernández Vázquez[1]
[1]*Hospital Universitario 12 de Octubre, Gastroenterology and Hepatology, Madrid, Spain*

Contact E-Mail Address: nnspdaniel@hotmail.com

Introduction: Despite the importance of granulocytoapheresis (GCA) in the treatment of inflammatory bowel disease (IBD), its effectiveness in steroid-dependent and steroid-refractory IBD has not been widely evaluated, the approaches are heterogeneous and data on efficacy and safety remain limited in our population.

Aims & Methods: This study aims to assess the effectiveness of GCA for induction of remission and maintenance in patients with steroid-dependent and steroid-refractory IBD in the real-world practice.

Retrospective cohort of patients with steroid-dependent and steroid-refractory colonic IBD, in which GCA was used as induction of remission and maintenance treatment between January-2015 to January-2023. We analyze demographics, disease characteristics, prior exposure including biologic agents. The success of GCA was defined on a decrease of at least 3 points in the True-love score for Ulcerative Colitis (UC) and a decrease of at least 100 points in the CDAI for Crohn Disease (CD).

To analyze predictive factors of treatment success we performed a univariate and multivariable analysis.

Results: 49 patients were included. 5 cycles of apheresis were performed in the first 3 weeks as induction and at least 10 cycles of apheresis as maintenance in the next 6 months.

75 % (37 / 49) had UC, 86.4 % (32 / 37) were steroid-refractory while 13.6 % (5 / 37) steroid-dependent, 54 % (20 / 37) male; median age 60 ± 10.5 years with a mean of 10.5 years from diagnosis. 67.7 % (25 / 37) had received at least 1 biological treatment in the past, 43.5 % (17 / 39) ≥ 2 biological. After induction, 75 % (28 / 37) responded to treatment, 62 % (23 / 37) continued with maintenance therapy of which 67 % (15 / 23) responding. Mean PCR and calprotectin were 3,16 mg / dl and 2038 mg / dl before treatment, 1.45 mg / dl and 1025 mg / dl after induction, 1.15 mg / dl and 900 mg / dl after maintenance, respectively.

25 % (12 / 49) had CD, 50 % (6/12) male; median age 62 ± 9.8 years, 75 % (9 / 12) steroid-refractory and 25 % (3 / 12) steroid-dependent, with a mean of 9 years from diagnosis, 67.7 % had received at least one biological treatment in the past. After induction, 58 % (7 / 12) responded, 80 % (10 / 12) continued with maintenance with 50 % (5 / 10) responding. Mean CRP and calprotectin were 3.16 mg / dl and 3645 mg / dl before treatment, 1.7 mg / dl and 2473 mg / dl after induction, 1.14 mg / dl and 623 mg / dl after maintenance.

Factors such as smoking, extent of disease, longer disease course and lack of response to previous treatments, were not significantly related to response in either induction or maintenance.

No patient had major adverse events recorded.

Conclusion: GCA appears to be safe and effective for inducing and maintaining clinical remission in patients with IBD, especially in patients with UC. No significant differences were found in disease extension, duration or lack of response to previous treatments.

Disclosure: Nothing to disclose.

PP0883

EARLY REAL WORLD EXPERIENCE OF FILGOTINIB FOR TREATMENT OF MODERATE-SEVERE ULCERATIVE COLITIS

R. Campbell[1], E. Brownson[1], J. Macdonald[1], J.P. Seenan[1]
[1]*Queen Elizabeth University Hospital, Gastroenterology, Glasgow, United Kingdom*

Contact E-Mail Address: emily.brownson@ggc.scot.nhs.uk

Introduction: Filgotinib is a selective JAK1 inhibitor recently licensed for use in moderate-severe Ulcerative Colitis (UC)[1].

Aims & Methods: We sought to review outcomes for patients commenced on Filgotinib for UC in the Glasgow South Sector IBD Service. Patients were identified using the local IBD Biologics Database. Electronic patient records were reviewed for demographics, previous treatment, and outcomes since commencing Filgotinib.

Results: 28 patients were commenced on filgotinib between July 2022 and February 2023. 21.4% were female and 78.6% male with a median age of 38y. By Montreal classification, 3.6% were classified as E1, 64.3% as E2 and 32.1% as E3. 50% of patients were biologic naïve with 71.4% on concomitant treatment with aminosalicylate. Median follow-up was 4 months.

78.6% (22/28) reported improvement in their symptoms with only 21.4% (6/28) experiencing side effects (SEs). 64.3% in the biologic-naïve group found subjective improvement in symptoms with 85.7% noting improvement in the biologic-experienced group. SEs included infections (3), Increase in cholesterol/triglycerides (2) and subjective worsening of low mood (1).

17 Patients had pre and post-treatment Faecal calprotectin (FC) available. Of those patients, 70.6% had an improvement with an overall reduction in median FC level from 1567 to 203 across the group. This reduction did not reach statistical significance.

7/28 patients required a course of rescue steroids after starting treatment. No patients required IP admission since commencing treatment. 5/28 were considered to have a primary non-response to Filgotinib. Of these, 4 were switched to alternative advanced therapies and 1 awaits surgery.

Conclusion: Filgotinib appears a safe and effective treatment in moderate-severe UC for both biologic-naïve and experienced patients. Its oral route of administration and quick onset mechanism of action make it an appealing choice. Further real-world data is required with larger patient cohorts to establish its true utility in routine clinical practice.

Introduction: Recently, a subcutaneous formulation of biosimilar infliximab (CT-P13) (SC-IFX) has been approved for inflammatory bowel disease (IBD). The aims of this study were to evaluate efficacy, safety, pharmacokinetics and patient experience following a switching to SC-IFX in patients who are in clinical remission on IV-IFX maintenance treatment.

Aims & Methods: Multicentre, descriptive, and observational study including Crohn's disease (CD) and ulcerative colitis (UC) patients who were going to be changed from IV-IFX to SC-IFX on the ENEIDA registry (a large, prospectively maintained database of the Spanish Working Group in IBD–GETECCU). All patients were on clinical and biological remission at least 24 weeks before changing. Demographic and disease data, clinical activity (Harvey-Bradshaw index for CD and mayo index for UC), analytical data (C reactive protein (CRP) and fecal calprotectin (FC), as well as trough levels were collected at baseline, at 12 and 24 weeks.

Results: One hundred and fifty-five patients were included: 54 UC (35%) and 91 (65%) CD; 44% women and 56% men; age 45.5 years (32-55). IV-IFX was mainly administered due to active disease (72%) and perianal disease (7%) and during 32 months [range 14-56]. Pre-switch, 78 (50.3%) were on 8-weekly dosing of IV-IFX, 77 (49.7%) were with intensification dose and the half (50.3%) were on concomitant immunomodulatory therapy. SC-IFX was mainly switching by COVID-19 pandemic (60%), to increase through levels (15%) or patient request (25%). The majority of patients (140, 90%) remained with standard dose, 8 (5%) required dose intensification (120 mg weekly in 4 and 240 mg every 2 weeks in 4) and 7 (4.5%) had successful de-escalation (120 mg every 3 weeks in 4 and 120 mg every 4 weeks in 3). Clinical indices, CRP levels and FC remained unchanged. Median SC-IFX levels significantly increased from baseline of 4.5 µg/dl [range 2.6-9.2] to 14 µg/dl [range 9.5-16.2] at week 12 and 13.2 µg/dl [range 10.4-19.7] at week 24. No factors (immunossupresor, body mass index, disease location) were associated with the increase of IFX trough levels. During 24 weeks of follow-up, 16 of the 78 patients (20.5%) stopped immunosuppressant treatment. The adverse events were recorded in 9 patients (5.8%), 4 (2.6%) were hospitalized and 4 (2.6%) had surgery (one of them for perianal disease). Nine patients (5.8%) stopped SC-IFX (1 primary failure, 2 loss of response, 4 adverse events, 1 voluntarily, and 1 surgery).

Conclusion: The switch from IV to SC IFX maintains clinical remission safely in IBD patients, offers higher drug levels and a good patient acceptance. However, the significance of higher drug levels with SC-IFX requires further exploration.

Disclosure: Nothing to disclose.

Introduction: Perianal Crohn´s disease(PCD) have a substantial negative impact on quality of life and implies poor long-term prognosis. Anti-tumor necrosis factor(antiTNF) therapy remain as the treatment of choice, although only infliximab has improved fistula closure rates in randomized controlled trials.

However, achieving permanent fistula closure remains a major challenge for physicians. For this reason, treatment optimization based on antiTNF serum levels has been evaluated, usually based on clinical response.

Aims & Methods: Our aim is to evaluate the relation between antiTNF serum concentrations at induction(w2 and 6), including infliximab and adalimumab, and clinical and radiological outcomes at w24 and w52 after initiation of the biologic therapy.

We conducted a single tertiary center, retrospective, cohort study including 65patients with an established diagnosis of PCD according to usual criteria(clinical, analytical, endoscopic) treated with antiTNF because of perianal activity.

Variables related to their PCD such as phenotype, location, treatment, type of fistulas according to AGA classification and proctitis presence were collected.

Regarding treatment, we collected antiTNF type(original/biosimilar) and serum levels at week 2,6,24 and 52, concomitant treatment and setons presence.

We defined clinical response as the absence of drainage on physical examination without a seton and clinical remission as the absence of external fistula openings.

Radiological response was defined as the absence of hypersignal T2 or gadolinium enhancement, absence of abscess or proctitis in pelvic MRI.

Results: 65patients were included, whose baseline characteristics are shown in Table1. None of the demographic nor disease characteristics collected were statistically significant related to clinical or radiological response at w24 or w52.

Taking into account the clinical response at w52, IFX mean levels at w2 were 25.8µg/mL(SD 4.1) in non responders and 30.9µg/mL(SD 14) in responders(p=0.39). At w6 they were 17.2µg/mL(SD 12.2) and 19.4µg/mL(SD 13.8) respectively(p=0.7). ADA mean levels at w2 were 13.3µg/mL(SD 7.7) in non responders and 14µg/mL(SD 6.3) in responders(p=0.87). At w6 they were 10.1µg/mL(SD 3.3) and 12µg/mL(SD 6.1) respectively(p=0.59).

For radiological response at w52 IFX mean levels at w2 were 27µg/mL(SD 15.3) in non responders and 32.7µg/mL(SD 14.5) in responders(p=0.45). At w6 the mean levels were 15.9µg/mL(SD 6.7) and 23.7µg/mL(SD 14.8) respectively(p=0.27). In ADA group the mean levels at w2 were 14.8µg/mL(SD 7.6) in responders and only one patient did not respond. At w6 ADA mean levels were 12.3µg/mL(SD 5.9) in non responders and 12.7µg/mL(SD 6.2) in responders(p=0.94).

We also observed that an early response at w24 was related with a long-term response at w52, 89.9% of the patients who responded at w52, had already responded at w24.

Age (yr), mean (SD)	**46.28(14.62)**
Male/female (%male)	30/35(46,2%)
Location,N(%)	
L1	10(15.4%)
L2	32(49.2%)
L3	23(35.4%)
Behavior,N(%)	
B1	35(53.84%)
B2	12(18.46%)
B3	18(27.7%)
Fistula,N(%)	
Simple	12(18.5%)
Complex	53(81.5%)
Seton,N(%)	
Never	12(18,5%)
Removed	34(52,3%)
Still placed	19(29.2%)
Previous treatment,N(%)	
Thiopurines	
Corticosteroids	61(93.8%)
Biological drugs	29(44.6%)
	23(35.4%)
AntiTNF,N(%)	
Infliximab/biosimilar	10(15.4%)/22(33.8%)
Adalimumab/biosimilar	26(40%)/7(10.8%)

Conclusion: In our study we observed that almost 90% of the patients who had an early response also responded at w52, so trying to achieve an early response should be an aim in clinical practice.

Despite the limited number of patients, our study shows a trend in the relationship between higher antiTNF levels and clinical and radiological response rates.

Disclosure: Nothing to disclose.

Introduction: Biological therapy in IBD patients is one of the cornerstones of treatment. For patients with loss of response while on maintenance therapy, options for dose escalation with the same agent are used to avoid switching targets, and this is done through a reinduction and dose intensification. While dose escalation is standard treatment with anti-TNF agents, current data on the efficacy of dose optimisation with ustekinumab in real life is limited.

Aims & Methods: The aim of the study is to assess the efficacy of dose optimisation (reinduction and intensification) therapy with Ustekinumab and to identify prognostic factors associated with clinical response. We performed a retrospective cohort study of patients that received dose optimisation with ustekinumab between January 2016 to July 2022. Demographic and clinical characteristics were obtained from the medical records. To assess for prognostic factors, responders and non-responders were compared using logistic regression analysis.

Results: A total of 94 patients were on ustekinumab treatment, and from these, 32 (30%) patients required dose optimisation during follow-up. The characteristics of patients included are summarized in Table 1. In 16 (50%) patients dose optimization was performed due to lack of response during the induction with Ustekinumab, the other 16 patients (50%) were intensified due to secondary failure. There were 15 (46.9%) patients in whom intravenous reinduction was performed prior to intensification. Three types of intensification were performed: 90mg subcutaneous every 4 weeks, 90mg subcutaneous every 6 weeks or 130mg intravenous every 4 weeks.

In 23 (72%) patients clinical remission was obtained after dose optimisation and were considered responders for logistic regression analysis. Extraintestinal manifestations (p=0.03) and secondary failure to Ustekinumab (p=0.049) were associated with a better response. No significant differences were observed between the type of intensification, the fact that they received prior reinduction or other demographic characteristics.

	n = 32
Gender (% women)	18 (56,2%)
Smokers (%)	8 (25%)
Disease type (%)	
Crohn's disease	27 (84,4%)
Ulcerative colitis	5 (15,6%)
Disease extension:	
Crohn's disease (L1-L2-L3-L4)	L1 12(37,5%), L2 3 (9,4%), L3 9 (28,1%), L4 3 (9,4%)
Ulcerative colitis (E2-E3)	E2 1 (3,1%), E3 4 (12,5%)
Behaviour in Crohn's disease (B1-B2-B3)	B1 9 (28,1%), B2 7 (21,9%), B3 9 (28,1%), B2+3 2 (6,3%)
Surgery (%)	10 (31,3%)
Perianal disease (%)	14 (43,8%)
Extraintestinal manifestations (%)	15 (46,9%)
Previous treatments (%)	
Naive	4 (2,5%)
Immunosupressor	19 (59,4%)
Biologic	28 (87,5%)
Only intensification	17 (53,1%)
Reinduction + intensification	15 (46,9%)
Reason for reinduction + intensification	
Primary failure	16 (50%)
Secondary failure	16 (50%)
Type intensification	
90mg sc /4 weeks	17 (53,3%)
90mg sc /6 weeks	5 (15,6%)
130mg iv /4 weeks	10 (31,3%)

Table 1. Demographic data and prognostic factors of the cohort.

Conclusion: Dose optimization with ustekinumab is useful in clinical practice with a good response rate, specially in patients with secondary failure.

Introduction: Biologic drugs are key in the current treatment of patients with inflammatory bowel disease (IBD). Identifying patients at high risk of primary non-response or loss of response is key to individualize treatment

Aims & Methods: Aim: To identify risk factors associated with primary nonresponse, loss of response and adverse effects to the first biologic drug used in patients with IBD.

Methoids: Single-centre retrospective cohort study including all consecutive patients with IBD naïve to biologic treatment who have started biologic treatment from 2000 to January 2022. A minimum follow-up of 6 months from the start of the biologic was required. Only the first biologic used in each patient was evaluated. HLA-DQA1 genotyping was done in all patients. Primary response rate was assessed at 24 weeks. Regression analyses were used to assess risk factors. The possible risk factors evaluated were sex, HLADQA1 genotype, smoking at diagnosis, body mass index, age at diagnosis, disease type, location, extent and phenotype disease according to Montreal classification, type biologic drug, disease severity at biologic initiation (Mayo index and Harvey Bradshaw index), combotherapy (≥ 6 months), and history of IBD resective surgery.

Results: A total of 421 patients were included, 290 with Crohn's disease and 131 with Ulcerative Colitis. 51.1% were male. The mean age at biologic initiation was 39 years. The most commonly used biologic was infliximab (IFX) (50.1%), followed by adalimumab (ADA) (46.8%). 46.1% carried HLADQA1*05 allele/s and 24.2% carried HLADQA1*03 allele/s. Almost half of the patients (47.7%) were treated with combotherapy (biologic + inmmunomodulator). The primary response rate was high: 84.8% (IFX 82.5%, ADA 87.8%). The loss of response rate was 33.3% (IFX 29.9%, ADA 35.5%), with a mean time of 5 years. Adverse effects occurred in 22.1% of patients (IFX 28.9%, ADA 16.2%). In multivariate analysis, carrying HLADQA1*05 allele was the only factor of all evaluated that was associated with an increased risk of loss of response [Odds Ratio: 1.83 (1.16-2.87), p=0.009], while carrying an HLADQA1*03 allele was protective for loss of response [Odds ratio: 0.37 (0.15- 0.89), p=0.026]. Female sex [Odds ratio: 1.61 (1.04-2.49), p=0.032)], the use of infliximab [Odds ratio: 2.00 (1.28-3.14), p=0.003] and the use of higher than standard doses in the IFX induction regimen [Odds Ratio: 3.28 (1.10-9.81), p=0.034] were identified as risk factors for the development of adverse effects.

Conclusion: 1) Our results support that carrying HLADQA1*05 increases the risk of secondary loss of response to anti-TNF drugs and suggest that carrying HLADQA1*03 decreases this risk.

2) Female sex is an independent risk factor for the development of adverse effects to anti-TNF drugs.

3) Infliximab is the biologic drug with the highest rate of adverse effects and the use of higher than standard doses during induction is associated with an increased risk of adverse effects.

Disclosure: Nothing to disclose.

MACHINE LEARNING APPROACH TO PREDICT TREATMENT OUTCOMES OF ANTI-TUMOR NECROSIS FACTOR -A ANTIBODY AGENTS FOR PATIENTS WITH CROHN'S DISEASE

Y. Mamiya[1], T. Taida[1], H. Nakazawa[1], Y. Oyama[1], C. Goto[1], R. Horio[1], A. Kurosugi[1], T. Kaneko[1], M. Sonoda[1], N. Akizue[1], Y. Ohta[1], K. Okimoto[1], K. Saito[1], T. Matsumura[1], J. Kato[1], N. Kato[1]
[1]Chiba University Hospital, Gastroenterology, Chiba, Japan

Contact E-Mail Address: yukiyo0311@icloud.com

Introduction: The number of patients with inflammatory bowel diseases continues to increase, and several biologic therapies can be used. However, there have yet been few useful biomarkers for drug selection in clinical practice, resulting in difficulty to optimize treatment with biologics. Recently, the usefulness of machine learning approach to predict treatment outcomes has been reported in the fields of several gastrointestinal diseases. Here, we applied machine learning approach to predict treatment outcomes of anti-tumor necrosis factor (TNF)-α antibody agents in patients with Crohn's disease (CD). In addition, the clinical variables that weighed significantly for anti-TNF-α antibody agents selection for patients with CD were identified.

Aims & Methods: Consecutive CD patients who had been treated with anti-TNF-α antibody agents in Chiba University Hospital from July 2004 to March 2022 were analyzed. Medical information including age, gender, medical history, disease type, treatment history, endoscopic findings, and blood test findings at the start of biological agents administration was collected. These variables were applied to machine learning approach, and the primary outcome was to predict primary failure of anti-TNFα antibody agents. Then, factors related to the poor outcome with anti-TNFα antibody agents were identified. The used machine learning system was LightGBM, a gradient boosting method. The constructed model performance was assessed through the area under the curve (AUC) with specificity and sensitivity. The SHapley Additive exPlanations (SHAP) were implemented for each predictive factor for evaluation of the impact on primary failure of anti-TNFα antibody agents.

Results: Total 232 CD patients who were treated with anti-TNF-α antibody agents at the hospital were analyzed. Of these, 29 patients failed in remission induction with anti-TNFα antibody agents. The constructed model with LightGBM was showed high prediction performance with AUC of 0.94 (sensitivity: 1.00 and specificity: 0.88).

The SHAP value showed that several variables were correlated with primary failure; platelet count (0.045), current medical treatment with thiopurine (0.025) and elemental diet (-0.008), surgical history (0.011), and disease duration (0.019).

Conclusion: Machine learning approach using clinical parameters alone could construct a predictive model of primary failure of anti-TNF-α antibody agents in CD patients with high accuracy. Platelet count, current medical treatment with thiopurine hand elemental diet, surgical history and disease duration were correlated with the primary failure, among which platelet count appeared to affect the most to the primary failure.

CORTICOSTEROID-FREE REMISSION IN ANTI-TNF FAILED CROHN'S DISEASE PATIENTS TREATED WITH VEDOLIZUMAB AS SECOND-LINE BIOLOGIC THERAPY: A REAL WORLD DATA REVIEW

C. Agboton[1], D. Lindner[2]
[1]*Takeda, Cambridge, United States,* [2]*Takeda, Zurich, Switzerland*

Contact E-Mail Address: christian.agboton@takeda.com

Introduction: Clinical response to vedolizumab has been reported as being significantly lower in patients exposed to anti-TNFs [1,2]. However, in most countries anti-TNFs remain the de facto first biologic therapies for patients with Crohn's disease (CD). After failure of a first Anti-TNF drug, change of class of therapy is increasingly recommended in lieu of a second anti-TNF [3]. Using corticosteroid-free (CSF) remission as the main clinical outcome, we collected data on vedolizumab used as second biologic in CD patients who failed anti-TNF therapies.

Aims & Methods: PubMed and Embase were searched for real world data from cohorts of adult patients with at least 95% of exposure to anti-TNFs, at least 6 months of data, direct access to patients data (no claims database), and CSF remissions (no cumulative data) were selected. Additionally, the use rates of corticosteroids and other concomitant medications at baseline were extracted.

Results: A total of 10 studies met the search requirements, with patient numbers ranging from N=45 to N=161. One author from the Netherlands reported twice on the same registry, only one dataset was retained to avoid counting patients twice. Clinical remission was defined as either a Harvey Bradshaw index of less than or equal to 4 (8 studies) or as a Crohn's disease activity index score <150 without resort to surgery (1 study). Across studies, the rates of corticosteroid use at baseline varied from 15.5% in a 2017 French cohort to 51.0% in a 2018 US study. Rates of CSF remission at 6 months were not related to baseline corticosteroid use and ranged from 15.3% in a 2020 UK report to 58.2% in a 2021 French cohort.

On average, CSF remission at 6 months was achieved in 37.1%, (95% CI 33.6 - 40.5%) of TNF failed CD patients treated with vedolizumab as second line biological therapy [Table]. Clinical remission rates at 6 months were generally higher, but at 1 year, clinical remission and CSF remission rates were almost identical in most cohorts, highlighting the importance of achieving early CSF remission.

Conclusion: Despite anti-TNF failure, a significant proportion of CD patients may respond to vedolizumab and achieve CSF remission, regardless of the baseline use of concomitant corticosteroids. This benefit is established within 6 months after induction.

COMBINATION THERAPY WITH BIOLOGICS AND SMALL MOLECULES IN REFRACTORY INFLAMMATORY BOWEL DISEASE (IBD): A SINGLE TERTIARY-CENTRE EXPERIENCE

A. Bhakta[1], S. Kalyanji Mehta[1], F. Donovan[1], K.V. Patel[1], A. Poullis[1]
[1]St George's University Hospitals NHS Foundation Trust, Gastroenterology, London, United Kingdom

Contact E-Mail Address: aaron.bhakta@nhs.net

Introduction: There are a growing number of drugs approved for IBD. Despite this, there remains a subset of patients with IBD who do not respond to conventional medical treatment, which can result in significant morbidity and detrimentally impact quality of life. In these refractory cases, biologics or small molecules may be combined and the aim was to report the experience of IBD patients treated with such combination therapies in our tertiary-centre.

Aims & Methods: This was a retrospective single-centre cohort study evaluating adult IBD patients receiving combination therapy, which was defined as either two biologics or one biologic and a small molecule simultaneously. All patients received combination therapy to treat refractory IBD. Baseline patient characteristics, IBD phenotype and combinations used were reported. Response to combination therapy was based on overall evaluation, comprising clinical, biochemical, endoscopic and radiological measures, where appropriate. Steroid use during combination therapy was documented. Safety outcomes were recorded for each patient and included infection, development of cancer and hospitalisation. Worsening of IBD was not included as an adverse event as this was not felt to be directly related to combination therapy.

Results: We identified 13 patients (all with Crohn's disease) that were treated with combination therapy. One patient received two combinations. Combinations included: Vedolizumab and Adalimumab (n=3), Ustekinumab and Adalimumab (n=5), Ustekinumab and Infliximab (n=1), Vedolizumab and Infliximab (n=2), Upadacitinib and Vedolizumab (n=1), Upadacitinib and Infliximab (n=1), Vedolizumab and Ustekinumab (n=1). The median duration of combination therapy was 182 days (interquartile range 277) and duration of follow up was 11.4 patient years. Response to combination therapy was observed in 9 of the 13 patients (69%), with a steroid-free response in 7 patients (54%). Three patients (23%) had worsening of their IBD and in 1 patient (8%) combination therapy was started too recently to be able to meaningfully measure response. During follow up, one patient on Infliximab and Upadacitinib required hospitalisation for active luminal symptoms and developed mild nosocomial COVID-19 infection, but he was also receiving steroids concomitantly and had previously received Methotrexate earlier on during the period of combination therapy. The same patient also required intestinal surgery for medically refractory IBD during the hospital admission. No other patients developed adverse events during follow up. Combination therapy is currently being continued in 10 out of 13 patients (77%).

Conclusion: In this small cohort, combination therapy led to improvement in IBD in the majority of patients. Those that had worsening of their IBD whilst on combination therapy all had complex, multi-focal Crohn's disease, including the one patient who required surgery. Only one patient (8%) developed an adverse event. Combination therapy was shown in our single-centre experience to be a successful way to treat refractory IBD in high-risk phenotypes and is likely to be the future of treating these groups of patients. Two of our patients were treated with Upadacitinib as part of their combination therapy, which is a newly approved small molecule for IBD. Additional studies on different combinations of biologics and small molecules are needed, especially with more IBD drugs on the horizon.

Introduction: Tofacitinib is an oral small molecule Janus kinase inhibitor for the treatment of ulcerative colitis (UC). Histological outcomes and the immune landscape were assessed in an UC patient cohort at baseline and after 8 weeks tofacitinib.

Aims & Methods: In this prospective study, 40 patients with moderate to severely active UC received tofacitinib 10 mg twice daily for 8 weeks. Clinical, endoscopic and histological outcomes were assessed at baseline and week 8 and colon biopsies were stained for JAK1-3, Tyrosine kinase 2 (TYK2) and Signal transducer and activator of transcription (STAT) 1-6 total protein expression using immunohistochemistry (IHC). Histological remission was defined as a Robarts Histopathology Index (RHI) ≤3 points without mucosal neutrophils and histological response as 50% decrease in RHI compared to baseline. Response was defined as histological remission and endoscopic Mayo score (EMS) ≤1 (histo-endoscopic mucosal improvement). Biopsies were scored by a blinded pathologist. Whole slide images with multiple biopsies per patients were stained using IHC, analyzed using automated cell detection (QuPath) and quantified in percentages by dividing the number of positive stained cells by the total number of cells on the slide. Outcomes were compared between responders and non-responders (*NR*).

Results: Out of 40 patients, 26 (65%) had severe endoscopic disease (EMS 3) with a median RHI of 14. Thirty-one patients (78%) had failed prior anti-Tumor Necrosis Factor (anti-TNF) agents and 18 (55%) failed vedolizumab. At week 8, 23 patients (58%) achieved histological remission, 34 (85%) histological response and 15 (38%) histo-endoscopic mucosal improvement. A significant decline in RHI compared to baseline was observed after 8 weeks both in responders (14 vs 0, $p<0.001$) and *NR* (15 vs 6, $p=0.002$). In the entire cohort, total STAT1 ($p<0.001$), STAT3 ($p=0.002$) and STAT5 ($p=0.026$) expression significantly decreased after 8 weeks treatment compared to baseline, which was not different between responders and NR (Table). However, responders to tofacitinib expressed significantly lower total STAT1 levels compared to NR at 8 weeks ($p<0.001$). Likewise, JAK2 ($p=0.008$) and total STAT2 expression ($p=0.004$) were significantly lower in responders compared to *NR* at 8 weeks, although no significant decrease compared to baseline was observed. A trend towards lower baseline JAK1, JAK2 and total STAT4 expression and higher total STAT6 expression was seen in responders compared to *NR*.

	Responders Baseline	NR Baseline	p-value Baseline Responders vs NR	Responders Week 8	NR Week 8	p-value Week 8 Responders vs NR
JAK1, *median % [IQR]*	6.2 [1.1-12.1]	13.7 [6.9-17.6]	0.113	8.4 [5.2-13.1]	9.7 [5.6-13.6]	0.811
JAK2, *median % [IQR]*	0.4 [0.1-2.1]	2.7 [0.1-7.7]	0.125	0.2 [0.1-1.7]	1.8 [0.6-8.6]	0.008
TYK2, *median % [IQR]*	13.3 [1.3-27.6]	10.0 [5.5-25.4]	0.761	11.9 [7.4-15.4]	17.5 [10.3-26.6]	0.156

STAT2, *median % [IQR]*	0.3 [0.1-1.7]	0.7 [0.2-1.8]	0.393	0.3 [0.1-0.6]	0.8 [0.4-2.6]	0.004
STAT3, *median % [IQR]*	0.3 [0.0-6.7]	0.8 [0.1-6.6]	0.361	0.0 [0.0-0.2]	0.1 [0.0-1.0]**	0.106
STAT4, *median % [IQR]*	0.9 [0.3-2.4]	1.9 [0.4-3.3]	0.315	1.2 [0.5-3.2]	2.1 [1.4-3.9]	0.175
STAT5, *median % [IQR]*	0.1 [0.0-1.1]	0.2 [0.2-1.3]	0.235	0.0 [0.0-0.3]	0.2 [0.0-0.9	0.159
STAT6, *median % [IQR]*	23.6 [4.2-28.8]	17.4 [7.6-32.1]	0.455	14.1 [5.3-45.7]	22.1 [10.9-32.5]	0.472

*Table legend: IQR, interquartile range; * statistically significant decrease after 8 weeks compared to baseline in responders; ** statistically significant decrease after 8 weeks compared to baseline in NR.*

Conclusion: Tofacitinib resulted in histological response in the majority of UC patients and led to a substantial decline of total STAT1, STAT3 and STAT5 expression both in responders and *NR*. Yet, after 8 weeks significantly lower total STAT1 levels were observed in responders compared to *NR*. Responders tended to express lower JAK1, JAK2 and total STAT4 and higher total STAT6 levels at baseline.

Disclosure: This study was funded and supported by Pfizer.

PP0892

LONG-TERM UPREGULATION OF MIR-124 IN BLOOD AND RECTAL BIOPSIES OF PATIENTS WITH MODERATE-TO-SEVERE ULCERATIVE COLITIS RECEIVING OBEFAZIMOD 50 MG DAILY FOR 96-WEEKS

J. Santo[1], A. Flatres[1], P. Gineste[2], D. Scherrer[1], J. Nitcheu[2], S. Sloan[2], H.J. Ehrlich[2], B.E. Sands[3], S. Vermeire[4]

Contact E-Mail Address: julien.santo@abivax.com

Introduction: Obefazimod is an oral small molecule that has demonstrated long-term efficacy and safety in patients with moderate-to-severe ulcerative colitis (UC) (1,2). Obefazimod is known to modulate inflammation by upregulating a specific anti-inflammatory micro-RNA (miR-124) (3). We examined the long-term effects of obefazimod on miR-124 in blood and rectal biopsies of patients enrolled in a 96-week maintenance study.

Aims & Methods: Patients received placebo or obefazimod 25mg, 50mg or 100mg once daily (od) during a 16-week induction phase and, irrespective of their clinical response, could enter an open-label 96-week maintenance phase with obefazimod 50mg od. Absolute quantification (QuantaSoft Pro) of the miR-124 copy number was performed at baseline, weeks 48 and 96 by using droplet digital PCR technology on 115 whole blood samples and 508 rectal biopsy samples. An ANOVA was performed including treatment, time, the interaction between treatment and time, the baseline value as fixed factor and time as repeated effect.

Results: A daily treatment with obefazimod 50 mg significantly upregulated miR-124 over time in blood and rectal tissue at weeks 48 and 96 (p<0.001 vs. baseline). The miR-124 upregulation was observed in all patients, including those previously receiving placebo during the induction phase.

Treatment during the induction phase	*Time*	Rectal tissue *Median fold change from baseline*	Blood *Median fold change from baseline*
Obefazimod 100 mg	W48	4.8 †	128.2 †
	W96	7.4 †	188.3 †
Obefazimod 50 mg	W48	5.8 †	230.1 †
	W96	10.3 †	244.4 †
Obefazimod 25 mg	W48	4.5 †	308.8 †
	W96	8.5 †	128.5 †
Placebo	W48	4.8 †	237.0 †
	W96	7.5 †	396.8 †

†: p<0.001 vs. baseline ; each timepoint (W48 and W96) is compared to the baseline using a Dunnett adjustment.

Table: Upregulated miR-124 in rectal tissue and blood of patients receiving obefazimod 50 mg during the maintenance phase

Conclusion: The 96-week efficacy of obefazimod 50mg od in patients with moderate-to-severe UC is associated with a maintained increase in miR-124 expression in blood and rectal tissue.

Contact E-Mail Address: cwi1118@yuhs.ac

Introduction: The role of early immunomodulator or biologic agent treatment on clinical outcomes in inflammatory bowel disease (IBD) has emerged in the era of precision medicine. We aimed to analyze the impact of early use of immunomodulator or biologic treatment on clinical outcomes of intestinal Behçet's disease (BD).

Aims & Methods: Of 780 patients with intestinal BD, 342 patients received immunomodulator and 114 patients received biologic treatments between 1997 and 2021 at Severance Hospital, Seoul, South Korea. We compared the cumulative rates of intestinal-BD related hospitalization, emergency room visit, biologics use, and surgery between early treatment group and late treatment group.

		Immunomodulator use		Biologics use	
		Late use (N=179)	Early use (N=163)	Late use (N=81)	Early use (N=33)
Hospitalization	Event	125 (69.8%)	109 (66.9%)	67 (82.7%)	25 (75.8%)
	Multivariable-adjusted HR (95% CI)[a]	Referent	2.029 (1.528-2.712)**	Referent	2.923 (1.754-4.870)**
Emergency room visit	Event	93 (52.0%)	84 (51.5%)	56 (69.1%)	22 (66.7%)
	Multivariable-adjusted HR (95% CI)[a]	Referent	2.018 (1.435-2.838)**	Referent	2.878 (1.674-4.948)**
Intestinal BD-related surgery	Event	88 (49.2%)	41 (25.2%)	48 (59.3%)	10 (30.3%)
	Multivariable-adjusted HR (95% CI)[a]	Referent	0.614 (0.416-0.904)**	Referent	0.775 (0.383-1.568)
Biologics use	Event	44 (24.6%)	49 (30.2%)		
	Multivariable-adjusted HR (95% CI)[a]	Referent	1.891 (1.182-3.027)**		

[a] Multivariable model adjusted for the age at diagnosis, sex, health insurance, smoking, appendectomy history, family history of IBD, marriage status, DAIBD score at diagnosis, systemic BD, number of ulcers, shape of ulcers, size of ulcer, depth of ulcers, type of ulcers, and laboratory findings at diagnosis.
*$p < 0.10$, **$p < 0.05$
HR, hazard ratio; CI, confidence interval; BD, Behçet's disease; IBD, inflammatory bowel disease; DAIBD, disease activity index for intestinal Behçet's disease.

Results: 179 patients (22.9%) received late immunomodulator therapy after 1 year from diagnosis, and 163 patients (20.9%) received early immunomodulator therapy within 1 year. Age, disease activity index for intestinal BD (DAIBD) score, systemic BD rate, C-reactive protein (CRP) at diagnosis were significantly higher in the early immunomodulatory group than in the late immunomodulatory group.

In a Cox regression multivariate analysis, the early immunomodulator group was positively associated with future hospitalization (HR: 2.029, 95% CI: 1.518-2.712, *p* value<0.001), emergency room visit (HR: 2.018, 95% CI 1.435-2.838, *p* value<0.001), biologics use (HR: 1.891, 95% CI: 1.182-3.027, *p* value=0.008), but was negatively associated with future surgery (HR: 0.614, 95% CI: 0.416-0.904, *p* value=0.014). 81 patients (10.4%) received late biologic agent therapy after 1 year from diagnosis, and 33 patients (4.2%) received early biologic agent therapy within 1 year. Systemic BD rate at diagnosis was significantly higher in the early biologics group than in the late biologics group. In a Cox regression multivariate analysis, the early biologics group was positively associated with future hospitalization (HR: 2.923, 95% CI: 1.754-4.870, *p* value<0.001), emergency room visit (HR: 2.878, 95% CI: 1.674-4.948, *p* value<0.001), but early biologic agent therapy was not associated with future surgery (HR: 0.775, 95% CI: 0.383-1.568, *p* value=0.479).

Conclusion: Intestinal BD patients who took immunomodulator or biological agents at an earlier time had severe disease activity at diagnosis, but were less likely to undergo future surgery, the most important prognostic index of this disease, than those who took later.

Disclosure: Nothing to disclose.

EXAMINING THE ROLE OF FAECAL MICROBIOTA TRANSPLANTATION (FMT) TO INDUCE REMISSION IN RESISTANT ULCERATIVE PROCTITIS (UP)

S. Raja[1], R. Bryant[1], S. Costello[2], C.K. Rayner[3]
[1]The Queen Elizabeth Hospital, Department of Gastroenterology, Woodville South, Australia, [2]The Queen Elizabeth Hospital, Department of Gastroenterology, Adelaide, Australia, [3]Royal Adelaide Hospital, Dept. of Medicine, Adelaide, Australia

Contact E-Mail Address: sreecanth.raja@sa.gov.au

Introduction: Refractory ulcerative proctitis (UP) represents a clinical conundrum, often necessitating systemic therapy for localised disease. Faecal microbiota transplant (FMT) has proven efficacy for remission induction ulcerative colitis, yet has not been evaluated in UP.

Aims & Methods: Aims: To undertake a prospective open-label study examining the safety and efficacy of Faecal Microbiota Transplant (FMT) enema therapy for management of resistant ulcerative proctitis (UP).

Methods: Patients with mild-moderately active UP (total Mayo score 3-10 with endoscopic Mayo subscore ≥ 1) resistant to 5-Aminosalicylates (5-ASA) were prospectively enrolled. After an initial conditioning phase of vancomycin therapy and dietary education, participants received six anaerobically prepared single donor FMT retention enemas over an eight-week period. The primary end point was clinical and endoscopic remission (total Mayo score ≤2) at 8 weeks. Secondary endpoints included safety, histological remission and patient reported outcomes (Inflammatory Bowel Disease Questionnaire). Disease activity assessments including clinical, endoscopic, histological and quality of life measures were performed at week 0 and week 8 to assess response to FMT therapy. Systematic adverse event reporting was completed at each study visit.

Results: Among 30 participants enrolled (mean age 41 years, 17 (57%) women) , 26 completed the study protocol. Clinical and endoscopic remission was achieved in 10 patients (33.3%).

Serious adverse events necessitating study withdrawal occurred in 3 enrolled patients due to flare of UP (n=2) and *Clostridioides difficile (C. difficile)* colitis (n=1).

Conclusion: FMT enema therapy was well tolerated and demonstrated efficacy in inducing clinical and endoscopic remission in resistant UK. The role of antibiotic preconditioning of recipients and choice of antibiotic therapy remains unclear. Further controlled studies in this area are warranted.

Contact E-Mail Address: mabreu1@med.miami.edu

Introduction: Crohn's disease (CD) can lead to inflammation of the intestinal tract and may be complicated by strictures[1]. Patients want diet-based approaches to therapy but relatively few prospective diet studies have been conducted with high rates of adherence.

Aims & Methods: We conducted a patient preference study NCT04213729 to test a high fiber(17gm/1000 calories for fiber), low fat(20-25% calories from fat) diet in CD patients. In the current study, we asked whether patients changed their symptoms following the catered diet intervention and whether the CD-related phenotype impacted the response to diet. Patients chose to receive diet counseling alone (group 1), catered food for 8 weeks (group 2), or catered food for a patient and a household member as well as participate in Dyadic Psychosocial Support (DPS)sessions (group 3).DPS sessions incorporated psychoeducational components that combined didactic and behavioral procedures. High fiber catered foods consisted of soluble and insoluble fibers as well as fermentable fibers such as fructans and galactooligosaccharides, etc. Detailed demographic, clinical, anthropomorphic, quality of life, biochemical and food knowledge data were collected at baseline and week 8. A total of 73 patients and 24 household controls were enrolled.

Results: At baseline,60-80%of CD patients were in remission based on PRO2 score (stool frequency≤ 1.5, abdominal pain ≤1)and Harvey Bradshaw index<5. On average, CD patients consumed a diet with less than 9gm/1000 calories of fiber and >40% fat at baseline. All three CD groups were well-matched at baseline with the household controls consuming also less fiber. Patients receiving the catered food had a high rate of adherence to the diet(80%)at week 8; patients receiving diet counseling alone had 5%adherence to a low-fat diet and 10%adherence to a high-fiber diet at week 8. Serum amyloid A(SSA), CRP, and fecal calprotectin were low at baseline and remained low. Catered meals improved values of fecal calprotectin or SAA in the subset of patients that had elevated levels of these biomarkers. Group 3 received DPS sessions for the CD patient and household control and had significantly improved nutrition literacy (score average:70.6,p=0.000636)while groups 1 and 2 averaged 57 and 57.1, respectively. Food-related quality of life(FRQoL 29)scores were significantly improved for those participants that received diet and DPS. FRQoL average increased from 82.1 to 107(p=0.000541).29% had B2 fibro-stenotic disease and received high-fiber catered food. This subset of patients had a decrease in stool frequency and no increase in abdominal pain symptoms. The mean number of bowel movements and pain scores improved or did not change.

Gender		Age at diagnosis (mean)	25 (9-58)	Inflammatory Outcomes	At screening	At week 8	General Nutrition Knowledge Questionnaire	At screening	At week 8

Race		Ileum + colon	41 (56%)	CRP (mg/L)	3.5 (sd 7.8)	2.7 (sd 3.8)	Group 2	70.9 (sd 22.7)	87.5 (sd 28.8)
White	68 (90%)	Colon	4 (5%)	Fibrostenotic B2 Subgroup	At screening	At week 8	Group 3	82.1 (sd 23.8)	107 (sd 29.1) *p=0.000541
Black	1 (1.3%)	Current use of immuno-modulators	9 (12%)	Stool Frequency	4.9 (sd7.6)	4.8 (sd 8.6)			
History of G.I surgeries	29 (39%)	Current use of Biologics	61 (81%)	Abdominal Pain	1 (range 0-3)	0.6 (sd 0.7)			

Conclusion: CD patients even those in remission, have very low consumption of fruits and vegetables. We show that even patients with B2 phenotype CD can tolerate 8 weeks of high fiber, low-fat diet without worsening of symptoms. One time diet counseling was not able to change diet behavior. Catering meals offers an effective way to control dietary intake in CD clinical trials. Psychology interventions for the CD patient and household improved food-related quality of life and nutritional literacy.

Introduction: Tofacitinib (TOF) is an effective treatment for ulcerative colitis (UC). However, compared with biologics, it is associated with a higher incidence of herpes zoster and malignant tumors, and it is contraindicated in pregnant women. Therefore, TOF is used in the second line or later for patients with UC in whom remission cannot be induced or maintained by biologics. However, patients might elect to discontinue TOF because of malignant disease or the desire to become pregnant.

However, the risk of UC recurrence is high if TOF is discontinued. TOF and ustekinumab (UST) have similar mechanisms of action involving the JAK pathway[1)]. The inflammatory cytokines suppressed by these drugs partially overlap[2)].

Aims & Methods: The aim of this study was to investigate the efficacy and safety of active switching to UST as an alternative to TOF withdrawal. Four patients were included, and the following patient information was recorded: age, gender, duration of disease, disease severity, steroid resistance/

dependence, duration of biologic and TOF use before the active switch, reason for the active switch, observation period after the active switch, remission therapy after the active switch, side effects of UST, and outcomes.
Results: Age at diagnosis (median)(months):35–64(49), Males/Females: 0/4, Disease duration(median)(months):85–227(150),Disease severity: severe/moderate: 0/4, Steroid : resistance/dependence: 0/4.

Duration of biologics and tofacitinib before active switch(months)	
case1	IFX(3)→TOF(24)
case2	IFX(53)→ADA(40)→GLM(2)→Seitai(herbal medicine)(25)→TOF(20)
case3	ADA(6)→GLM(22)→VED(4)→TOF(24)
case4	GLM(3)→TOF(22)
Reason for active switch	malignant disease (3) desire to become pregnant:1
Observation period after active switch(median) (months)	4-23(14)
Maintenence therapy :5ASA/AZA	4/0
Side effect of UST	none
Outcome: relapse/remission	0/4

IFX:infliximab, TOF:tofacitinib, ADA:adalimumab, GLM:golimumab, VED:vedlizumab

Table.

As illustrated in the Table, TOF was used in the second- to fifth-line setting approximately 2 years before an active switch to UST. Treatment with 5ASA alone to maintain remission was performed in all patients, and no cases of relapse, UST-related side effects, or treatment discontinuation were observed. The pregnant patient is currently progressing with her pregnancy smoothly, and she is scheduled to give birth in July 2023.
Conclusion: For patients who require TOF withdrawal, it is possible to safely and effectively maintain remission via an active switch to UST.

LIPIDOMIC ANALYSIS OF FAECES FROM PATIENTS WITH ULCERATIVE COLITIS UNDERGOING FAECAL MICROBIOTA TRANSPLANTATION PREDICTS TREATMENT RESPONSE

F. Zwezerijnen-Jiwa[1,2,3], S. Maneta-Stavrakaki[1], P. Paizs[1], M. Jitsumura[4], M. Hitchings[5], Z. Takats[1], J. Kinross[1], D. Harris[5]

Introduction: Faecal microbiota transplantation (FMT) may induce remission in patients with ulcerative colitis (UC), however the mechanisms through which this occurs are unknown. Lipids mediate inflammation and contribute to the pathophysiology of inflammatory bowel diseases. We therefore hypothesise that the faecal lipidome mediates treatment response in UC patients undergoing FMT.
Aims & Methods: We aimed to investigate the faecal lipidome using ambient mass spectrometry to identify metabolites that mediate treatment response. Patients were recruited from a single-centre, single-blinded randomised controlled trial consisting of 18 treatment-naïve UC patients (ISRCTN58082603). All patients were pre-treated with antibiotics and underwent bowel lavage. Patients were divided into three intervention groups: 1) A single FMT enema (n=7) 2), five consecutive FMTs enema's within five days (n=7) and 3) a control group given antibiotics and bowel lavage only (n=4). Fresh faecal samples were taken before and one-, four-, eight- and twelve weeks after FMT treatment. Response was evaluated as endoscopic remission or a drop of ≥2 points in the partial Mayo score. High-throughput laser assisted-rapid evaporative ionization mass spectrometry (LA-REIMS) set-up (Xevo G2-S QT of mass spectrometer (Waters Corporation)) as an approach for shotgun lipidomics was used. After pre-processing of the LA-REIMS data, univariate and multivariate statistics were performed using Metaboanalyst 5.0 and an in-house developed bioinformatic pipeline to build predictive models of response using leave-one-patient-out cross-validation.
Results: From 18 patients with a median age of 42 (range 18-70), male 7 (39%), 6/14 patients in the FMT intervention and 2 patients in the control group demonstrated an endoscopic response. The metabolic variance based on Partial Least-Squares Discriminant Analysis between FMT treatment and control group at baseline was not significant (R2=0.39, Q2=0.32 and diagnostic accuracy of 0.84). However, responders and non-responders demonstrated a different pre-treatment faecal lipidomic profile (R2=0.78, Q2=0.66 and diagnostic accuracy of 0.93). This persisted 12 weeks after FMT treatment (R2=0.96, Q2=0.92 and diagnostic accuracy of 1.0). Within group metabolic variances of the lipidome were also visible. For example, the pre- and post-intervention faecal lipidome discretely varied in those UC patients who responded to FMT (R2=0.63, Q2=0.52 and diagnostic accuracy of 0.92). Interestingly, a moderate variance was also seen in the control group before and after treatment with only antibiotics and bowel lavage (R2=0.87, Q2=0.78 and diagnostic accuracy of 0.98). Univariate analysis demonstrated fatty acids and glycerophospholipids explained much of this variance and they were statistically different between responders and non-responders to FMT treatment (FDR adjusted p<0.05). Tentative metabolite identification of the *m/z* values in statistical-

ly important metabolites suggested that cholesterol sulfate (465.304 *m/z*), pantothenic acid (218.102 *m/z*, vitamin B5) were statistically more likely to be excreted in patients who responded to an intervention, although they do not mediate inflammation per se.

Conclusion: FMT sustainably modifies the faecal lipidome in UC patients that respond to FMT, suggesting a role for the lipidome in driving remission. However, influenced by both donor and host's faecal lipid metabolism. Future and ongoing work involve time-series analyses of significant metabolites during different time points in the course of the treatment.

Introduction: The development of anti-TNF agents has brought major advances in the treatment of ulcerative colitis (UC), however, many patients still require the use of 2nd-, 3rd-, or even 4th-line biologicals or small molecules.

Aims & Methods: We conducted a retrospective, multicentre study with the inclusion of UC patients who failed anti-TNF therapy due to primary non-response (PNR) or loss of response (LOR), and received sequential biological treatment for moderate-to-severe disease activity or for acute, severe exacerbation (ASUC).

The primary aim was to evaluate and compare the effectiveness of 2nd-, 3rd-, or 4th-line biological or small molecule therapies after anti-TNF failure. Treatment effectiveness was determined by persistence and colectomy-free survival. Logistic regression analysis was performed to identify the predictive value of demographic factors, clinical, endoscopic, and laboratory parameters for colectomy.

Results: To date, 454 UC patients have been included. The median follow-up time was 57.7 months (IQR: 92.9-33.3). The indication for the 1th-line anti-TNF therapy was chronic, refractory UC in 307(67.6%) and ASUC in 147(32.4%) patients. The rate of PNR, as reason for treatment discontinuation progressively increased in accordance with the lines of sequential treatment (23.1%/31.7%/36.2%/45.0%), however, the incidence of LOR did not show a definite tendency among the various therapeutic lines (50.0%/56.1%/58.0%/40.0%). A significant difference with treatment persistence was seen among the most frequently used biologicals and small molecules following anti-TNF failure *(Table 1.)*.

Ustekinumab (UST) had superior persistence compared to vedolizumab (VDZ) and tofacitinib (TOFA) at 3, 6, 12 and 24 months, regardless of the number of previous anti-TNFs. The overall colectomy rate was 15.6%, mostly due to chronic, refractory UC (61.9%). The probability of colectomy-free survival was 97.2%, 93.3% and 91.2% at 1, 2 and 3 years, respectively. Cyclosporine use during the course of the disease proved to be protective against colectomy (OR: 2.88, 95% CI: 1.447-5.733, *p*=0.0026). Pancolitis (OR: 3.24, 95% CI: 1.604-6.562, *p*=0.0012) appeared to be predictive for colectomy. Following anti-TNF failure, the incidence of colectomy was shown to be significantly lower with 2nd-line UST (n=3 (5.8%), *p*=0.0422) than with VDZ (n=57 (16.8%)) or TOFA (n=11 (20.4%)).

Treatment persistence after anti-TNF failure	n (%)	Median (Q1, Q3)	3 months (%)	6 months (%)	12 months (%)	24 months (%)	36 months (%)
VDZ	340 (76.2%)	30.5 (9.6, NA)	94.9%	86.8%	67.5%	52.5%	47.0%
UST	52 (11.7%)	26 (21.5, NA)	98.0%	95.9%	87.4%	79.9%	72.6%
TOFA	54 (12.1%)	20.8 (4.1, NA)	75.0%	70.6%	57.1%	49.7%	49.7%
Difference among treatments (logrank p-value)			<0.0001	0.0006	0.0068	0.0273	0.1105

Table 1. Treatment persistence among the most frequently used biologicals and small molecules following anti-TNF failure.

Conclusion: According to the preliminary results of this ongoing cohort, sequential therapy was effective in avoiding colectomy in 84.4% of the patients and even after multiple lines of treatment we could expect a relatively low rate of colectomy. UST, as a 2nd-line therapy after anti-TNF failure, was significantly superior, both in terms of persistence and colectomy-free survival, compared to VDZ or TOFA. Cyclosporine use reduced the risk of colectomy, while pancolitis was seen to be a predictive factor for surgery. Further analysis are being performed to identify factors that influence the efficacy of non-TNF agents and to clarify their role in the subsequent therapeutic lines.

Introduction: Current data suggests that biosimilar is safe and effective for patients with inflammatory bowel disease (IBD).[1-2] However, the drug discontinuation and nocebo effect after switching from originator to biosimilar have increased over time. [3]

Aims & Methods: We aimed to evaluate clinical efficacy, biomarkers activity, therapeutic drug monitoring (TDM) adverse events (AEs), and nocebo effect in IBD patients who underwent biosimilar switch. A prospective observational study of consecutive IBD patients who underwent non-medical biosimilar switch at McGill University Health Centre, Montreal, Canada, between April 1, 2022 – March 31, 2023. The patients were follow-up until 24 weeks following the switch. Disease activity, biomarkers, TDM and AEs including nocebo effect were captured at 8 weeks before switch, at time of the switch (baseline), 12 and 24 weeks after the switch.

Results: A total of 210 patients were included [81.4% were Crohn's disease (CD), median age at inclusion: 42 years (IQR 29-61)]. There was no significant difference in the rates of clinical remission at week 8 before the switch, baseline, week 12, and 24 after the switch; 89.0%, 93.4%, 86.3% and 90.8%, p=0.129. The rates of sustained clinical remission at week 12 and week 24 after switching were 79.4% and 69.6% respectively. The proportion of patients remaining in biomarkers remission was not significantly different at week 8 before the switch, baseline, week 12, and 24 after the switch; CRP: 81.3%/ 74.7%/ 81.2%/ 73.0%, p=0.343; Fecal calprotectin: 78.3%/ 74.5%/ 71.7%/ 76.3%, p=0.829. The rates of maintaining in therapeutic level (84.7%/ 83.9%/ 83.0%/ 85.3%, p=0.597) and prevalence of positive anti-drug antibodies remained unchanged before and after the switch. Nocebo effect was observed in 13.3% and 4.3% of patients discontinued biosimilar therapy. Main results of the study outcomes in IBD patients following Biosimilar switch is shown in Table 1.

Outcomes monitoring, n (%)	8 weeks before the switch	At switch (baseline)	Week 12 after switch	Week 24 after switch	p-value
Clinical remission	187/210 (89.0%)	184/197 (93.4%)	164/190 (86.3%)	167/184 (90.8%)	0.129
Steroid-free clinical remission	185/210 (88.1%)	181/197 (91.8%)	163/190 (85.8%)	166/184 (90.2%)	0.113
IBD flare	NA	6/184 (3.3%)	14/167 (8.4%)	10/161 (6.2%)	0.121
CRP remission	113/139 (81.3%)	59/79 (74.7%)	69/85 (81.2%)	73/100 (73.0%)	0.343
Fecal calprotectin remission	65/83 (78.3%)	41/55 (74.5%)	43/60 (71.7%)	58/76 (76.3%)	0.829
Maintaining in therapeutic level	72/85 (84.7%)	47/56 (83.9%)	88/106 (83.0%)	99/116 (85.3%)	0.597
Adalimumab anti-drug Ab positive	0/44 (0%)	0/28 (0%)	2/49 (4.1%)	2/50 (4.0%)	0.345
Infliximab anti-drug Ab positive	1/41 (2.4%)	0/28 (0%)	1/57 (1.8%)	2/66 (3.0%)	0.616
Nocebo effect	NA	9 (4.3%)	13 (6.4%)	6 (3.0%)	NS

Table 1.

Conclusion: Despite a significant number of early nocebo complaints within the first 6 months after the biosimilar switch, no significant changes were found in clinical efficacy, biomarkers, therapeutic drug level, and anti-drug antibodies.

FISTULIZING CROHN'S DISEASE (EXCLUDING ANO-PEINEAL LESIONS): MEDICAL OR SURGICAL TREATMENT

F.Z. El Hajoubi[1], S. Mechhor[1], M. Cherkaoui Malki[1], H. El Bacha[1], N. Benzzoubeir[1], I. Errabih[1]

Introduction: Crohn's disease is an inflammatory enterocolitis, characterised by chronic transmural involvement that can be complicated by enterocutaneous, intestinal, enterovesical and rectovaginal fistulae. Diagnosis is relatively easy thanks to the development of imaging examinations, particularly entero-MRI. However, the therapeutic management of fistulising forms of Crohn's disease, although most often involving surgery, remains controversial in the literature.

Aims & Methods: In this study we report on the clinical, radiological, therapeutic and evolutionary aspects of fistulising Crohn's disease.

This is a retrospective descriptive and analytical study, spanning 10 years from January 2012 to July 2022, including 740 patients with proven Crohn's disease. Factors studied were age, sex, type of fistula, medical and surgical treatment, evolution and follow-up. Patients with fistulising Crohn's disease with ano-perineal lesions were excluded from this study. SPSS 20.0 software was used for statistical analysis, the Chi-square test was used to compare categorical variables.

Results: Of a total of 740 cases of Crohn's disease, 108 patients had a fistulising form excluding ano-perineal lesions, a rate of 14.6%. 19% (n=141) had a fistulising form with ano-perineal lesions, 42.1% (n=311) had a stenosing form and 24.2% (n=179) had an inflammatory form. The mean age of our patients was 37.7 years +/- 11.3. Sex ratio was 1.34 with a female predominance. The location of the fistulas was dominated by intestinal fistulas in 59% (n=64) of cases, followed by enterocutaneous fistulas in 29.6% (n=32), then enterovesical fistulas in 10% (n=11) and rectovaginal fistulas in 0.9% (n=1). Medical treatment with immunosuppressants was initiated in 20 cases (18.5%) of intestinal fistulas, 5 cases (4.6%) of enterocutaneous fistulas and 1 case (0.9%) of rectovaginal fistulas. 6.5% of patients (n=7) were put on biotherapy. Surgical treatment was indicated immediately in 52% of cases (n=56) and after failure of medical treatment in 14.8% (n=16) of cases.

Fistula closure after medical treatment was observed in two patients with an ileal location of the disease (14.3%), in one patient (9.1%) with a colonic location, and in 5 patients (7.5%) with an ileocolic location: this difference was statistically significant $p < 0.001$.

In the case of internal fistulas, 39 (32%) patients closed after treatment, while external fistulas closed in 22 (1.8%) patients and only 9 (0.7%) patients with both internal and external fistulas had fistula closure, a difference that was statistically significant $p<0.001$.

Fistulas closed in 4 (57.1%) patients after initiation of biotherapy versus 3 patients on immunosuppressants and did not close in any patient in whom no therapy was initiated, this difference was statistically significant $p<0.0001$.

Conclusion: Fistulizing Crohn's disease poses a problem of medical-surgical management. In this study, we note that surgical treatment is ultimately indicated in the majority of cases of Crohn's fistulas. Anti-TNF drugs can lead to fistula closure; however, this treatment is not yet readily available to patients due to lack of resources.

Disclosure: none conflict of interest

PRA023 IMPROVED HEALTH-RELATED QUALITY OF LIFE AS MEASURED BY IBDQ-32 IN A PHASE 2 TRIAL FROM PATIENTS WITH MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS

L. Peyrin-Biroulet[1], B.E. Sands[2], S. Danese[3], D.T. Rubin[4], D. Nguyen[5], Q. Dinh[5], A. Melnyk[5], B. Dong[5], C. Ma[6], T. Ritter[7], R. Panaccione[8]

Introduction: PRA023 is a humanized monoclonal antibody against tumor necrosis factor–like cytokine 1A (TL1A), a key pro-inflammatory cytokine and pro-fibrosis regulator, in development for inflammatory bowel diseases. In a phase 2 double-blind, placebo-controlled study (ARTEMIS-UC) assessing the efficacy and safety of PRA023 induction treatment in adults with moderately to severely active ulcerative colitis (UC), a significantly greater proportion of patients who received PRA023 achieved the primary endpoint of clinical remission after 12 weeks. This post hoc analysis assessed the impact of PRA023 on health-related quality of life using the Inflammatory Bowel Disease Questionnaire (IBDQ-32).

Aims & Methods: Adults with a modified Mayo score of 4 to 9, centrally read endoscopy subscore of ≥2, rectal bleeding subscore of ≥1, and history of insufficient response, loss of response, and/or intolerance to conventional and/or advanced therapies (≤4 advanced agents from ≤3 classes allowed) were stratified by prior biologic exposure and genetic-based diagnostic status and randomized 1:1 to placebo or intravenous PRA023 (1000 mg on day 1, and 500 mg at weeks 2, 6, and 10). IBDQ outcomes measures include: IBDQ response (score of ≥16-point from baseline), IBDQ remission (total score ≥170), and mean change from baseline in total and domain scores after 12 weeks of induction therapy. Score changes from baseline were compared among treatment groups, and the impact of prior advanced therapy exposure on IBDQ remission was assessed. Higher scores represent better quality of life.

Results: Of the 135 patients in the study, 60/67 (89.6%) in the placebo arm and 68/68 (100%) in the PRA023 arm completed the 12-week induction period. Baseline characteristics were similar between the treatment groups. Significantly greater proportions of patients in the PRA023 group achieved IBDQ response (82.4% PRA023 vs 49.3% placebo, Δ33.1%, p<0.0001) and IBDQ remission (51.5% PRA023 vs 19.4% placebo, Δ32.1%, p=0.0001) at week 12. Prior advanced therapy use did not affect the placebo-adjusted proportion of patients experiencing IBDQ remission in those who received PRA023 (Δ34.4% vs Δ30.0%, respectively, for prior and no prior advanced therapy). The total IBDQ score and all IBDQ domain subscores (bowel symptoms, systemic symptoms, emotional function, and social function) were significantly improved after 12 weeks of PRA023 induction treatment compared to placebo (Table 1).

IBDQ outcomes	Placebo	PRA023	% Difference vs placebo (95% CI)	P value
IBDQ response (%, n/N)†‡	49.3 (33/67)	82.4 (56/68)	33.1 (17.2–46.8)	<0.0001
IBDQ remission (%, n/N)‡	19.4 (13/67)	51.5 (35/68)	32.1 (16.0–45.9)	0.0001
-Prior advanced therapy	18.8 (6/32)	53.1 (17/32)	34.4 (10.9–53.1)	-

Introduction: Recently, subcutaneous vedolizumab formulation has been approved for the treatment of Inflammatory Bowel Disease. Data from randomized controlled trials on Crohn disease and ulcerative colitis report that subcutaneous vedolizumab formulation efficacy and safety were comparable to intravenous one.

Aims & Methods: The aim of our study was thus to evaluate the safety and the effectiveness of switching from intravenous to subcutaneous vedolizumab in inflammatory bowel disease patients in clinical remission.

In this prospective cohort study, we collected data on patients afferent to our center from September 2021 to April 2022. Baseline demographic characteristics, 12- and 24-weeks follow-up clinical activity and C-reactive protein levels, and adverse events were recorded. The primary endpoint was to assess combined steroid-free clinical remission plus biochemical remission at week 24.

Results: 93 patients (43 Crohn disease, 50 ulcerative colitis) switched from intravenous to subcutaneous vedolizumab therapy after a median duration of intravenous treatment of 36 months [IQR 16-52]. Of note, 53.7% were previously anti-TNFα exposed and 41.9% were naive to biologics and immunosuppressors. Most of patients (94.6%) were on every 8-weeks maintenance therapy. At baseline, 80 patients (86%) were in combined remission; 93.5% of patients and 91,4% of patients reached the 12-weeks and 24-weeks follow up visit respectively. At week 24, 89.2% (n=74) patients maintained combined steroid-free clinical remission plus biochemical remission from baseline. Overall, 25 adverse events out of 23 patients were reported, mostly SARS-CoV-2 infections and injection site reactions, with further 4 recurrence episodes. Twelve patients (12.9%) discontinued subcutaneous and restarted intravenous vedolizumab.

Conclusion: Switching from intravenous to subcutaneous vedolizumab can be considered a reasonably safe and effective treatment in maintaining remission in inflammatory bowel disease patients at a 24-weeks

follow-up. Additionally, this might slash healthcare costs. However, larger scale real-life studies with long-term follow-ups are needed.

Disclosure: Conflicts of interest: Daniela Pugliese received speaker fees and/or advisory board fees from AbbVie, Janssen, MSD, Pfizer and Takeda. Introduction: Infections are one of the main side effects faced by patients treated with biological agents.

Aims & Methods: Objective: We aimed to determine the rates of bacterial infections among Inflammatory Bowel Disease (IBD) patients treated with biological agents in a real-life setting.

Methods: Retrospective study based on the Clalit healthcare nationwide database, which included all patients diagnosed with IBD between 1999 and 2022. Data on bacterial infections were collected for patients treated with a biologic agent (Anti_TNF, Vedolizumab and Ustekinumab) and were compared to all other IBD patients during the corresponding timeframe.

Data regarding demographics, bacterial infection events, and mortality were collected. Data were collected using the MdClone platform from the largest Health Maintenance Organization, "Clalit" in Israel.

Results: 5523 IBD patients treated with Anti-TNF were compared to 29,598 patients not treated with Anti-TNF. Patients treated with Anti-TNF were younger, age 35.62±14.29 compared to 47.06±19.49 years. Anti-TNF patients had higher rates of respiratory tract infection (36.2% vs 31.2%), genitourinary system infection, 26.7% vs 23.7%, gastrointestinal tract infection (31.8% vs 21.6%), skin infection (22.5% vs 14.3%) and Ear, Nose, throat infection (31.5% vs 24.2%).

2220 patients treated with Vedolizumab compared to 35,100 not treated with Vedolizumab, patients treated with Vedolizumab had higher rates of bacterial infections, respiratory tract infection (13.5 vs 5.1%, p<0.001), genitourinary system infection, (9.7% vs 3.8%, p<0.001) gastrointestinal tract infection (12.6% vs 3.5%, p<0.001), skin infection (8.4% vs 3%, p<0.001) and Ear, Nose, throat infection (11% vs 4.4%, p<0.001).

In addition, risk of bacterial infection was higher among 940 patients treated with Ustekinumab than those not treated with Ustekinumab.

Conclusion: Significantly increased risk found among IBD patients treated with biologic agents; clinicians should consider the increased susceptibility to bacterial infections when deciding which biological agent to prescribe to their asthma patients

Disclosure: Nothing to disclose.

PROACTIVE THERAPEUTIC DRUG MONITORING FOR INFLIXIMAB MAY REDUCE STEROID EXPOSURE IN IBD

S. Shields[1,2], A. Dunlop[3], J.P. Seenan[1,2], J. Macdonald[1,2]
[1]Queen Elizabeth University Hospital, Gastroenterology, Glasgow, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom, [3]Queen Elizabeth University Hospital, Biochemistry, Glasgow, United Kingdom

Contact E-Mail Address: stephanie.shields3@nhs.scot

Introduction: Therapeutic Drug Monitoring (TDM), measuring serum drug levels (DL) and antibodies, is an established tool to optimise the efficacy of anti-TNF medicines in the treatment of patients with inflammatory bowel disease (IBD) via adaptation of drug frequency and dose. TDM is generally performed in proactive (pTDM) or reactive (rTDM) strategies. In rTDM, DLs are performed when disease relapses or flare occurs. In pTDM, DLs are measured routinely as part of ongoing clinical review to enable manipulation of drug dosing to achieve DLs within specified therapeutic ranges.[1,2,3] While TDM testing is recommended in clinical practice guidelines, there is a lack of data demonstrating the impact of TDM on clinically meaningful outcomes and it is unclear whether the type of testing strategy employed is important . Reducing excessive steroid exposure for these patients remains an important clinical outcome in the UK .[4]

Aims & Methods: The aim of this study was to assess the impact of pTDM and rTDM on steroid exposure for our local, Infliximab (IFX) treated, IBD population.

Patient data was identified using the West of Scotland NHS Safe Haven. Patients with IBD, treated with IFX, and undergoing TDM were included and allocated to a pTDM or rTDM group based on the clinical indication of first TDM test. DL and prednisolone exposure data were extracted and reviewed from January 2018-December 2019. Annual steroid excess was defined as 2 or more steroid prescriptions in 12 months.[1] SPSS was used to perform a Chi-squared and Mann-Whitney U tests.

Results: 197 patients were included (pTDM:172, rTDM:25). 210 corresponding DLs were available. The median pTDM DL was 5.35ug/ml, and 5.25ug/ml in the rTDM group. No difference was seen in DLs between the 2 groups (p=0.828). 91/197 (46.2%) were exposed to steroids in the 2 year period, 63/197 (31.9%) in excess. 17/25 (68%) of rTDM patients were exposed to steroid compared to 74/172 (43%) in the pTDM group (p=0.19). 14/25 (56%) of rTDM patients were exposed to steroid in excess compared to 49/172 (28.5%) in the pTDM group (p=0.006).

Conclusion: In this retrospective cohort steroid exposure and excess was lower in patients undergoing pTDM compared to rTDM. Further work exploring the factors influencing this observation, in larger, prospective studies is required to fully understand the impact of TDM on patient care. The relationship between TDM and other clinical outcomes, including hospital admissions, is underway in this cohort.

Contact E-Mail Address: joanareves94@gmail.com

Introduction: Anti-TNF drugs are highly effective for treating Inflammatory Bowel Disease (IBD) but have a high chance of loss of response, particularly due to immunogenicity. Using immunomodulators (IMM) can partly overcome this. The HLA-DQA105 polymorphism was identified as a predictor of anti-infliximab antibodies (AIA).

However, the impact of this polymorphism in real-world studies and its association with other factors related to the development of immunogenicity needs to be established.

Aims & Methods: We aim to study the association of the polymorphism HLA-DQA1*05 with the development of AIA in a real-life cohort of patients with IBD.

We conducted a retrospective cohort study including adult patients with Crohn's Disease (CD) and Ulcerative Colitis (UC) who were or have been taking infliximab (IFX) with a minimum follow-up of 6 months. DNA amplification and sequencing by Sanger methodology were used to identify the presence of the HLA-DQA1*05 polymorphism. The presence of AIA was evaluated through ELISA, and IFX trough levels (IFX TL) were assessed by a point-of-care methodology.

A Cox regression analysis was performed to assess the impact of the polymorphism on the time until the development of AIA and its association with other relevant factors (use of concomitant IMM, body mass index, gender, IFX TL, baseline albumin and type of disease - CD vs UC).

Results: We included 115 patients (76% CD and 24% UC) of whom 60% were male with a median age at diagnosis of 30 years old (IQR 20-42). Almost half of the patients (52%) started combination therapy with IMM. Thirty patients (26%) developed AIA, with no significant difference between patients with CD and UC (23% vs 36%, p=0.2). The median time until the development of AIA was 8 (IQR 5-16) months. During follow-up, 34% had a primary or secondary loss of response; 37% stopped IFX and 21% had adverse effects.

The prevalence of the polymorphism was 70.4%. Among patients who developed AIA, there was no difference between HLA-DQA1*05 carriers and non-carriers (21% vs 38%, p=0.06). However, there was a significant difference in the concomitant use of IMM, which was lower in the group of patients who developed AIA (13% vs 40%, p<0.01). Half of the patients needed to optimize IFX dosing and there were no differences among polymorphism carriers and non-carriers (48% vs 53%p=0.6). Patients who developed AIA had significantly lower median IFX TL when compared to patients without AIA (0.4, IQR 0.35-1.4 vs 7.4, IQR 3.4-13.5, p<0.001).

There was no difference in the median IFX TL according to the presence of the polymorphism (p=0.8). The risk of developing AIA was similar between HLA-DQA1*05 carriers and non-carriers (HR 0.8, 95%CI 0.4-1.6, p=0.4) even after adjusting for the other risk factors associated with immunogenicity (HR 0.5, 95%CI 0.1-1.9, p=0.3). No differences were found according to the type of disease. Patients with the HLA-DQA1*05 polymorphism and who were using a concomitant IMM had the lowest risk of developing AIA, which was significantly lower when compared to patients who carried the polymorphism and were not taking the IMM (HR 0.2, 95%CI 0.04-0.9, p=0.03).

Conclusion: In this Portuguese cohort of IBD patients, the HLA-DQA105 polymorphism was highly prevalent and did not influence the development of AIA. Further real-world studies with larger sample sizes are needed to determine the utility of this polymorphism as a predictor of AIA.

USTEKINUMAB TREATMENT IN CROHN'S DISEASE AND ULCERATIVE COLITIS: A REAL-WORLD COMPARISON BETWEEN ITS EFFECTIVENESS AND SAFETY IN THIS TWO POPULATIONS

L. Bertin[1], B. Barberio[1], G. Semprucci[1], F. Zingone[1], E.V. Savarino[1]

[1]University of Padua, Division of Gastroenterology, Dept. of Surgery, Oncology and Gastroenterology, Padua, Italy

Contact E-Mail Address: luluisa92@gmail.com

Introduction: Ustekinumab is an effective treatment for patients with Crohn's disease (CD) and Ulcerative Colitis (UC). Real-world effectiveness and safety studies are warranted especially in the bio-experienced inflammatory bowel disease (IBD) population and in patients with UC vs CD, where the evidence is still limited.

Aims & Methods: The aim of our study was to assess clinical, biochemical and endoscopic remission as well as the safety profile of Ustekinumab at week 52. All consecutive moderate-to-severe IBD patients who started Ustekinumab from 01/01/2019 to 01/12/2022 were included. We collected demographic and clinical data, including disease location and behavior, previous treatments, previous surgery, concomitant medications. In addition, data on partial Mayo (p-Mayo) Score, Harvey-Bradshaw Index (HBI), C Reactive Protein, fecal calprotectin were collected. Serious infections and adverse events were defined as those requiring hospitalization or treatment discontinuation. Continuous and categorical variables were expressed as mean with standard deviation (SD) and frequency with percentages respectively. Comparisons among variables were conducted using one-way ANOVA and Chi-square. Overall 1-year persistence on Ustekinumab was estimated using the Kaplan-Meier method. All data analyses were performed with SPSS Version 29.0 statistic software package.

Results: Overall, 131 IBD (84 with CD and 47 with UC) adult patients were enrolled. Among the patients included, all CD patients and 89.4% (42/47) UC patients were bio-experienced; most of them had previous anti-TNF therapy (98% CD patients; 83% UC patients). Forty-one CD patients (49%) had undergone bowel resective surgery. At week 52, 53% of CD patients and 50% of UC patients obtained a clinical response (p=0,000); 37.3% of CD patients and 16.6% UC were in steroid-free clinical remission (p=0,02). In addition, 51.6% CD patients and 20% of UC patients reached biochemical remission (p=0,28), while 29.5% CD patients and 20% UC patients obtained an endoscopic remission (p=0,000). A total of 15 adverse events occurred during follow-up in both groups, of which the majority were infectious (9/15) and 4 were classified as serious adverse events. At 12 months, treatment persistence with Ustekinumab was 84.5% in CD patients and 87.2% in UC.

Conclusion: Ustekinumab was an effective therapy in both patients with CD and UC. However UC patients had better clinical, endoscopic and biochemical outcomes. Ustekinumab is safe and well-tolerated. Infections were the most frequent adverse events.
Disclosure: Nothing to disclose.

Contact E-Mail Address: Norma.alfieri@outlook.com
Introduction: In Crohn's disease (CD) a symptomatic luminal stricture occurs in up to 20% of patients at the diagnosis and in more than 50% during lifetime (1,2). Endoscopic balloon dilatation (EBD) or surgical procedures are the currently available treatments (3,4). However, a considerable percentage of patients often require further surgery for post-operative CD recurrence (5). A consequent increased burden of short bowel syndrome is warranted. The combination of biological therapy with EBD could potentially reduce this risk.
Aims & Methods: The aim of our study was to evaluate the efficacy of EBD combined with biologic therapy in symptomatic gastrointestinal strictures in CD's patients. We conducted a retrospective study including consecutive CD patients who underwent EBD for low bowel strictures from December 2015 until November 2022 at our tertiary IBD Center. Clinical strictures recurrence, needs for steroids and for surgery due to CD stenosis relapse were the primary outcomes evaluated during a follow-up period of six and twelve months. Chi-square and univariate statistical analyses were used when appropriate.
Results: A total of 52 patients treated with EBD with an overall number of 55 strictures were included. In the study population, 14 patients (27%) were smoker, the mean age was of 46,8 (18-77) years; the median of disease duration was 9 (0-42) years. Thirty-nine patients (75%) were in active treatment with biologic therapy at the moment of EBD. Twenty-three patients (44%) underwent EBD for anastomotic stricture, 8 (15%) for ileal stricture, 11 (21%) for ileocecal valve stricture, 5 (6%) for anal stricture and 4 (8%) for colic stricture. Three patients (6%) underwent EBD for multifocal bowel stenosis. Twenty-two (42%) patients had increased CRP value, 40 patients (77%) had evidence of moderate or severe endoscopic disease activity and 42 (81%) patients showed ulcerative lesions at stricture site. EBD was performed by 8-10, 12-15 or 15-18 mm dilation balloon. Technical success was reported in 60% of procedures and no adverse events were registered.
After 6 months from EBD, at univariate analysis, active smoke resulted a risk factor for clinical stricture recurrence (OR 10,25; IC 1,350 to 135,4; p value = 0,022) and for subsequent surgery (OR 10,25; IC 1,350 to 135,4; p value = 0,022). Moreover, increased CRP at the time of dilatation resulted a risk factor for need of steroids (OR 14,63; IC 2,69 to 71,50; p value = 0,0006). Concomitant biologic therapy and presence of ulcerative lesions did not show significative correlation with considered outcomes.
After 12 months from EBD, concomitant biologic therapy resulted a protective factor for prevention of surgery (OR 0,061; IC 0,005 to 0,502; p value = 0,0047), while anastomotic strictures were associated with a lower risk of sub-occlusion events than ileal stenosis (OR 0,07; IC 0,005 to 0,651; p value = 0,015). Increased CRP at the time of EBD, ulcerative lesions at the stricture site and active smoke were not significantly correlated with the considered outcome.
Conclusion: Our results suggest that in patients with CD undergoing EBD for bowel CD stricture, concomitant biological therapy reduces the risk of surgery for CD stenosis recurrence. Further prospective and controlled studies are underway to confirm these observations.

THIOPURINES IN CROHN'S DISEASE: DO THEY STILL HAVE A PLACE AS MONOTHERAPY IN REAL LIFE?

S. Dilal[1], H. El Bacha[2], M. Cherkaoui Malki[3], S. Mechhor[4], M. Konso[1], N. Benzzoubeir[1], I. Errabih[5]
[1]University Hospital Center Ibn Sina, Medicine B, Rabat, Morocco, [2]Hopital Ibn Sina / Universite Mohamed V / Faculte de Medecine, Gastroenterologie et Hepatologie, Rabat, Morocco, [3]University Hospital Ibn Sina, Gastroenteroly B, Rabat, Morocco, [4]Ibn Sina Hospital, Medicine B, Rabat, Morocco, [5]Ibn Sina University Hospital, Médecine B, Rabat, Morocco

Contact E-Mail Address: drsaradilal@gmail.com
Introduction: Thiopurines (TP) (azathioprine AZA, and 6 mercaptopurine 6MP) are immunosuppressive drugs (IS) used in the treatment of chronic inflammatory bowel diseases (IBD), particularly Crohn's disease (CD). The aim of our work is to see if they still have an indication in monotherapy, in the era of biotherapies and small molecules.
Aims & Methods: This is a retrospective analytical study conducted at the Hepato-Gastroenterology and Proctology Department "Medicine B" from January 2012 to July 2022. 740 patients were followed for CD during this

period. 407 patients were put on TP. Age, sex, different characteristics of CD, indication for and type of TP treatment, and course of treatment were collected from all patients. SPSS 20.0 software was used for statistical analysis. The khi-2 test was used to compare categorical variables. The binary logistic regression model was used for multivariate analysis.

Results: There were 375 patients followed up for CD on TP monotherapy (92.13%) and 32 on combination therapy (7.86%). The sex ratio was F/H=1.5. The average age was 39.8 years (15-72). The location was ileal in 69 patients (16.95%), colonic in 78 patients (19.16%), ileocolic in 257 patients (63.14%), 6 patients (1.47%) had upper gastrointestinal tract involvement of CD and 3 patients (0.73%) had anal CD. 99 patients (24.32%) had anoperineal lesions (APL).

The phenotype was stenosing in 47 cases (11.54%), fistulizing in 159 cases (39%), stenosing and fistulizing in 60 cases (14.74%) and inflammatory in 141 cases (34.64%). The type of TP used was AZA in 299 patients (73.46%) and 6MP in 108 patients (26.53%). TP was indicated as maintenance treatment in 270 cases (66.33%), as monotherapy in the absence of biotherapy (which was not available before 2016) in fistulizing forms in 105 cases (25.8%), and in case of cortico-dependency in 32 cases (7.86%).

Clinical remission was obtained with monotherapy in 326 cases (86.93%) and with combotherapy in 24 cases (75%), this difference is statistically non-significant *p=0.08*. Mucosal healing was noted with monotherapy in 124 cases (33%) in patients who performed a control endoscopy, and with combotherapy in 15 cases (46.87%), this difference is statistically not significant *p=0.07*.

CRP was negatived in monotherapy in 149 patients (39.73%) and in combination therapy in 27 patients (84.37%), this difference is statistically significant *p<0.001*. Fecal calprotectin was not always available. Among the patients who had it performed (65: 15.97%), it was negative in 18 cases (41.86%) in monotherapy and 3 cases (13.63%) in combination therapy. This difference is statistically significant *p=0.015*.

Metabolite dosing was also rarely available. In cases where this was done (43 cases: 10.56%), 6-TGN was in the therapeutic range only in 14 cases (32.55%) and in 36 cases (83.72%) for 6-MMP, requiring therapeutic adjustment.

In multivariate analysis and adjusting for the different confounding parameters, it was found that only the combination therapy was a predictive factor for mucosal healing [OR=1.8; [0.8 - 3.9]; *p=0.01*].

Conclusion: The results of this study show that TPs still have a place in the therapeutic arsenal of CD, but that their combination with biotherapy allows more clinical and biological remission and especially mucosal healing.

Disclosure: Nothing to disclose.

PP0909

EFFICACY AND SAFETY OF SWITCHING FROM INTRAVENOUS VEDOLIZUMAB TO SUBCUTANEOUS APPLICATION IN PATIENTS WITH IBD IN CLINICAL REMISSION

B. Moser[1], L. Schoeler[1], A. Schirbel[1], C. Jochum[1]
[1]*Charité – Universitätsmedizin Berlin, Berlin, Germany*

Contact E-Mail Address: benjamin.moser@charite.de

Introduction: The subcutaneous use of vedolizumab (VDZ) has been approved for the treatment of inflammatory bowel diseases for a few years and is becoming increasingly established. Regarding the safety and effectiveness of the switch to subcutaneous application, only few real-world data is available so far.

Aims & Methods: The study investigates the efficacy and safety after switching to the subcutaneous administration in direct comparison with continuation of the intravenous administration of VDZ.

The work retrospectively analyzes the data of patients of a tertiary care center in Germany who were treated with VDZ in the period 01/2020-06/2021. Two groups were compared: group 1 (sc-group) represents patients who were switched to subcutaneous application, group 2 (iv-group) patients who continued intravenous use. Patients who had received at least four intravenous doses of VDZ and were in clinical remission at baseline were included. Efficacy and safety were compared at 3-6 months and at 9-12 months. The primary endpoint was the presence of clinical remission, as measured by the Partial Mayo Score (remission < 2) for ulcerative colitis (UC) and the Short Crohn's Disease Activity Index (remission < 150) for Crohn's disease (CD).

Results: A total of 78 patients were retrospectively analyzed, including 37 patients in the sc-group (66.7% UC; 33.3% CD) and 41 patients in the iv-group (72.5% UC; 27.5% CD).

After 3-6 months 85.4% were in remission in the iv-group and 81.1% in the sc-group, and after 9-12 months 82.9% in the iv-group and 74.2% in the sc-group. Non-inferiority of subcutaneous administration could not be demonstrated with a pre-defined non-inferiority margin of +-10% and a 95% confidence interval.

Discontinuation of therapy occurred in 6 patients (16.2%) in the sc-group and in 2 patients (5%) in the iv-group. In 3 patients (8.1%) of the sc-group, therapy was discontinued due to the local reaction at the injection site. Beyond that, there were no differences between the two groups in terms of safety and tolerability.

Conclusion: In this cohort of patients in clinical remission under intravenous VDZ, the switch to subcutaneous application of VDZ could not meet the criteria of non-inferiority in terms of efficacy compared with continued intravenous use. Further studies are needed to evaluate the long-term effectiveness and safety of subcutaneous VDZ therapy.

Disclosure: Nothing to disclose.

MANAGEMENT OF METASTATIC CUTANEOUS CROHN'S DISEASE USING USTEKINUMAB: A SINGLE CENTRE STUDY

H. Aleman-Gonzalez[1], E. Whitehead[1], J. Turnbull[1], S. Sebastian[1]
[1]*Hull University Teaching Hospitals, Kingston upon Hull, United Kingdom*

Contact E-Mail Address: alemangonzalezhaidee@hotmail.es

Introduction: Metastatic Crohn's disease (MCD), also known as cutaneous Crohn's disease is one of the rarest cutaneous lesions in IBD. It is defined by granulomatous lesions infiltrating the skin that are discontinuous from the affected GI tract. In most occasions, MCD occurs parallel to the course of a well-establish GI disease, but occasionally it can precede the GI manifestations from months to years. Studies addressing the therapeutic approach to MCD are limited. Ustekinumab is licenced for Crohn`s disease and also for skin disorders including psoriasis. We report our experience in managing MCD in a tertiary IBD centre.

Aims & Methods: This is a single centre retrospective review of biopsy proven cutaneous Crohn's disease. Patient details obtained from patient records included demographic data, previous failure to biologics and/or IMS, response and time to response to Ustekinumab and therapeutic drug monitoring.

Results: A retrospective review of patients with cutaneous Crohn's disease was performed. All patients had undergone a skin biopsy for histologically confirmation. Ten patients were included (Males: Females 5:5). Median age was 53 years (IQR 24-67). The most common location was the perianal area often preceded by a surgical wound from a proctectomy and 2 patients had peristomal skin affected. Ninety- percent of patients had failed antiTNF therapy and 6 out of 10 had failed to both Infliximab and

Adalimumab, one of them had also lost response to Vedolizumab. All patients received ustekinumab with median follow up since initiation of 45 months (IQR 27-60). All patients noticed improvement since initiation of Ustekinumab with a median time to response of 10 weeks (IQR 4-28). Four out of 10 patients achieved a complete healing of the skin lesions while rest of patients reported a partial response. Most patients had therapeutic or supratherapeutic Ustekinumab level ranging from 2 to 6 mg/L. Dose escalation was done in 8 patients.

Conclusion: Metastatic Crohn's disease is a rather uncommon entity with different clinical manifestations. Our series report satisfactory response to ustekinumab in MCD. Larger studies are required to confirm these findings.

Disclosure: Nothing to disclose.

EFFECTIVENESS, SAFETY AND INCREMENTAL COSTS OF PROACTIVE THERAPEUTIC DRUG MONITORING OF INFLIXIMAB IN A REAL-LIFE COHORT OF INFLAMMATORY BOWEL DISEASE PATIENTS

Z. Zelinkova[1], B. Kadleckova[1], A. Lipovska[1], D. Podmanicky[2]
[1]Nemocnica Bory - Penta Hospitals, Department of Gastroenterology, Bratislava, Slovakia, [2]Nemocnica Bory - Penta Hospitals, Department of Surgery, Bratislava, Slovakia

Contact E-Mail Address: zdetkova@yahoo.co.uk

Introduction: The use of infliximab (IFX) is limited by low treatment persistence. Proactive therapeutic drug monitoring (pTDM) has been shown to increase the treatment persistence in inflammatory bowel disease (IBD) patients but the real-life data evaluating effectiveness, safety and costs of this approach are scarce.

Aims & Methods: The aim of this study was to assess survival on treatment, safety and costs of pTDM of IFX in the treatment IBD.

IBD patients who started IFX in a referral centre using pTDM between January 2018 and March 2021 were included. The main outcomes were treatment persistence, adverse events and incremental costs of pTDM.

IFX trough levels were assessed in the week 14 and subsequently every six months by commercially available ELISA kit (Ridascreen R-Biopharm) and the intensification of treatment the cut-off of 3µg/ml was used.

Costs related to the measurements of levels and the costs of intensified treatment were calculated. The costs of pTDM were compared costs of a modelled cohort using reactive TDM (rTDM) based on the data from the same cohort. The model used arbitrarily determined intensification regimen to 5mg/kg of IFX every 4 weeks in pharmacokinetically determined clinical or endoscopic loss of response. The calculation was performed for the first year of treatment.

Results: Overall, 99 patients with IBD were included (58 men – 59%; mean age 39,96 years, minimum-maximum, 20-73 years; 64% patients with Crohn´disease; mean disease duration 103 months, minimum – maximum, 8-402 months).

The treatment was intensified in 57 patients (58%). Overall treatment survival with pTDM was 87% at 6 months, 77% at one year, 66% at two years and 60% at both, the third and fourth year of treatment. There were no differences between patients on conventional regimen vs. intensified regimen with regards to adverse events.

The costs related to pTDM in this cohort of 99 patients were € 90 306,56 while the costs of the modelled cohort using rTDM were € 24 846,30. The overall incremental costs were thus € 65 460,26 with mean costs per patient for the first year of treatment of € 661,21.

Conclusion: Proactive TDM of IFX results in a steady 60% treatment persistence beyond the second year of treatment with no impact on the safety. In the context of this solid treatment persistence, the incremental costs related to proactive TDM seem negligible when considering the costs of alternative biologicals used in case of loss of response to IFX.

Disclosure: Nothing to disclose.

NOVEL DIGITAL HEALTH TOOLS IMPROVE CLINICAL OUTCOMES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: PRELIMINARY RESULTS

L. Taylor[1], M. Yousuf[1], V. Rajagopalan[1], P. Tandon[2], M. Raman[1]
[1]University of Calgary, Cumming School of Medicine, Calgary, Canada, [2]University of Alberta, Medicine, Edmonton, Canada

Contact E-Mail Address: mkothand@ucalgary.ca

Introduction: Inflammatory bowel disease (IBD) management faces significant care gaps, particularly in areas such as diet and mental health support. Digital health applications provide remote support to patients with IBD to improve health, however few digital applications have published evidence of efficacy.

Aims & Methods: The purpose of this randomized controlled trial (RCT) was to identify if use of the LyfeMD digital health platform results in significant changes in health behaviours among patients in remission with Crohn's Disease (CD) and Ulcerative Colitis (UC). LyfeMD is an integrated digital and human platform designed to improve physical and mental health. Patients over the age of 18 with UC or CD in remission were recruited in Calgary, Alberta. Participants were randomly assigned to the LyfeMD intervention (n=10) or the standard care control (n=10) group. The intervention group was given access to the LyfeMD mobile app for 8 weeks and assigned a health coach. Self-reported validated measures were collected at baseline and week 8 including demographics, leisure-time physical activity (LTPA), stress score (SS), depression and anxiety risk, sleep, screen-time outside of work, and sitting time. Diet intake was collected using 2 consecutive 24-hour recalls (ASA-24) at baseline and week 12. Intake data was used to calculate the healthy eating index (HEI). Independent and paired sample t-tests were used to identify significant differences between and within groups.

Results: Twenty people were recruited for this study (N=10 per group); 65% were female, with a mean age of 45.3 years (standard deviation) [SD] =9.9). Mean body mass index was 28.1kg/m2 (7.0) and 80% of the participants had CD. After 8 weeks the intervention group showed significant improvements in risk of anxiety (mean = -1.9/21 [2.3]) screen time (mean = -7.2/168 hours/week [11.3]), sitting hours (-10.6/168 hours/week, [12.9], and overall well-being (mean = +12.5/100 [21.2]) ($p<0.05$). At week 12 the intervention group also showed significant improvements in both overall diet quality (mean = +12.2/100 [16.6]) and moderation scores (mean= +5.6/50 [5.0]). Between the groups we see significant differences for both sitting time and for the moderation component of the HEI ($p<0.05$).

Conclusion: The LyfeMD digital health platform is a safe option for patients with IBD, providing accessible lifestyle therapy thus, reducing current gaps in the healthcare system. Future studies should focus on an increased sample size and targeting remote populations where this program may be even more valuable to healthcare providers and patients.

Disclosure: Lorian Taylor, Puneeta Tandon and Maitreyi Raman are co-founders of LyfeMD. Vidya Rajagopalan at the time of this study worked for the University of Calgary and presently works for LyfeMD.

PP0913

REAL-WORLD COMPARISON OF EFFECTIVENESS BETWEEN USTEKINUMAB AND A SECOND ANTI-TNF AGENT IN PATIENTS WITH SYMPTOMATIC STENOSING CROHN'S DISEASE AFTER FAILURE OF A FIRST ANTI-TNF AGENT: RESULTS OF THE USTEKNOSIS STUDY

A. Buisson[1], A. Jammet[1], B. Pereira[1], M. Fumery[2]
[1]CHU Estaing Clermont-Ferrand, IBD Unit, Clermont-Ferrand, France, [2]Amiens University Hospital, Gastroenterology, Amiens, France

Contact E-Mail Address: a_buisson@hotmail.fr

Introduction: While surgery was considered as the reference for stricturing Crohn's disease (CD), anti-TNF agents are now the first-line treatment thanks to the CREOLE study. However, there is no data about efficacy after anti-TNF failure.

Aims & Methods: We aimed to compare the effectiveness of ustekinumab and a second anti-TNF agent after failure of a first anti-TNF in symptomatic stricturing Crohn's disease (CD).

In this multicenter study, we retrospectively included all adult patients with CD treated with ustekinumab or anti-TNF for symptomatic stricture (confirmed on imaging or endoscopy) after prior exposure ≥ one anti-TNF for the current stricture, without surgery between the failure of the last anti-TNF and the study.

The primary endpoint was clinical remission (composite endpoint) at 6 months defined as no pain, no vomiting, no food restriction, no sub-occlusive episode, no steroid, no surgery or discontinuation of treatment.

The long-term endpoints were discontinuation of treatment for failure, bowel damage progression and surgery. The comparisons were performed after using propensity score analysis adjusted on potential confounders.

Results: Overall, 70 patients were analyzed, including 34 in the ustekinumab group and 36 in the anti-TNF group (29 on infliximab and 7 on adalimumab). The two groups were similar for age (38.5 vs 37.6 years), CD duration (12.2 vs 13.5 years), female gender (41.2% vs 51.8%), CD location (p=0.43) and CD phenotype (p=0.38).

Concomitant immunosuppressant was observed in 63.9% with an anti-TNF versus 8.8% with ustekinumab. The number (p=0.56) and the length (p=0.10) of stricture were also similar. The proportion of patients ≥ 2 prior biologics was higher in the ustekinumab group (41.2% vs 8.3%; p=0.001). The rate of primary failure to anti-TNF agent was comparable (16.7% vs 20.6%).

After adjustment based on propensity scores, the rate of clinical remission at 6 months was 73.9% and 42.7% (p = 0.24), under ustekinumab and anti-TNF, respectively. The predictive factors of remission in patients receiving ustekinumab were prior bowel resection (p=0.001) and length of stricture < 12 cm (p=0.042), while no predictor was found in those treated with anti-TNF agent.

The risk of treatment discontinuation for failure (HR =2.86 [1.33-6.15]; p=0.008) or bowel damage progression (HR=3.90 [1.64-9.24]; p=0.003) were significantly greater in patients receiving another anti-TNF agent compared to those on ustekinumab.

We did not observe any significant difference concerning the risk of surgery (HR=2.60 [0.70-9.61]; p=0.15).

Conclusion: Ustekinumab seems to be more effective than a 2nd anti-TNF to treat symptomatic stricturing CD after failure of a first anti-TNF. However, these data need to be confirmed by independent prospective data.

SWITCHING FROM INTRA-VENOUS TO SC INFLIXIMAB IS SAFE AND FEASIBLE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE SUFFERING FROM OBESITY: A POST-HOC ANALYSIS OF THE REMSWITCH STUDY

A. Buisson[1], M. Nachury[2], B. Pereira[1], M. Fumery[3]
[1]CHU Estaing Clermont-Ferrand, IBD Unit, Clermont-Ferrand, France, [2]CHRU Lille, Gastroenterology, Lille, France, [3]Amiens University Hospital, Gastroenterology Department, Amiens, France

Contact E-Mail Address: a_buisson@hotmail.fr

Introduction: The REMSWITCH study recently demonstrated that switching from IV to SC IFX is feasible and well-accepted leading to a low risk of relapse in patients with IBD. Because the doses of IV infliximab depend on the weight of the patients contrary to SC infliximab, whether the switch is also feasible in IBD patients suffering from obesity remains questionable.

Aims & Methods: We assessed the clinical and pharmacological evolution after switching from IV to SC IFX in IBD patients suffering from obesity to evaluate the feasibility of the switch in this specific population.

During the REMSWITCH study, all IBD patients in clinical remission (CDAI < 150 or partial Mayo score ≤ 2) were consecutively included in 3 IBD centers and were switched to SC IFX 120mg/2 weeks (wk) (regardless of IV dose) at the theoretical day of IV infusion (visit 0 = V0) and were followed every 4 to 8 weeks according to the initial IV regimen for 6 months. Obesity was defined as a body mass index (BMI) > 30 kg/m^2.

Results: Among the 130 patients enrolled in the REMSWITCH study, 21 suffered from obesity including 6 patients (28.6%) with BMI > 35 kg/m^2. Among them, 8 patients (38.1%), 8 patients (38.1%), 4 patients (19.0%) and one patient (4.8%) were treated with IV infliximab at a dose of 5mg/kg/8wk, 10 mg/kg/8wk, 10mg/kg/6 wk and 10mg/kg/4 wk, respectively.

The rate of clinical relapse leading to therapeutic escalation was 14.3% (3/21) in patients suffering from obesity including 16.7% (1/6) in those with BMI > 35 kg/m^2 compared to 17.4 % (19/109) in patients with BMI < 30 kg/m^2 (p = 0.92).

In 109 patients with BMI < 30 kg/m^2, clinical relapse leading to therapeutic escalation was observed in 17.4% including 12.2%, 6.3%, 14.3% and 64.3% in patients treated with 5mg/kg/8wk, 10 mg/kg/8wk, 10mg/kg/6 wk and 10mg/kg/4 wk, respectively. Dose increase (240 mg/2 wk) induced clinical remission in 77.7% of relapsers.

Among the 21 patients suffering from obesity, clinical relapse leading to therapeutic escalation was observed in 14.3% including 0.0%, 12.5%, 25.0% and 100.0% in patients treated with 5mg/kg/8wk, 10 mg/kg/8wk, 10mg/kg/6 wk and 10mg/kg/4 wk, respectively (p= 0.05). Dose increase (240 mg/2 wk) induced clinical remission in 100.0% of relapsers.

Among the subgroup of IBD patients suffering from obesity, infliximab trough levels (TL) were significantly higher after switching from IV to SC IFX: 6.8 ±4.6 vs 12.4 ±4.8 (p=0.011). TL increased in patients receiving 5 mg/kg/8 wk (3.6 ± 2.1 vs 14.7 ±5.7; p<0.0001) or 10 mg/kg/8 wk (7.8 ±4.2 vs 10.8 ±3.1; p=0.042) but remained stable in those treated with 10 mg/kg/6 wk or 10 mg/kg/4 wk (10.7 ±5.7 vs 9.7±2.7; p=1.0). No patient suffering from obesity developed anti-IFX antibodies. In multivariable analysis, contrary to 10 mg/kg every 4 weeks regimen (odds ratio, 12.4; 95% confidence interval, 1.6–98.4; P [.017) and fecal calprotectin >250 mg/g at baseline (odds ratio, 5.4; 95% confidence interval, 1.1–27.6; p = 0.042), obesity did not influence the risk of relapse.

Obese patients' acceptability was better with SC injections compared to IV infusions (10pts-acceptability numerical scale = 8.6 ±1.5 vs 7.3 ±1.7; p<0.05).

Conclusion: Switching from IV to SC IFX is feasible and well-accepted leading to a low risk of relapse in patients with IBD suffering from obesity.

Introduction: Thiopurines are one of the major drugs for inflammatory bowel disease. In Asian individuals, the SNP p.Arg139Cys in exon 3 of *NUDT15* is associated with leucopenia and hair loss.

Aims & Methods: The aims of this study are to evaluate the long-term effects of *NUDT15* on clinical outcomes.

The patients (ulcerative colitis130, Crohn's disease 55 cases) were divided into the mutant and the wild group of *NUDT15*, and the daily dosage of thiopurines and the effect of the mutation on hospitalization and surgery were investigated.

Results: Compared to the mutant group (n = 48), the daily thiopurine dosage increased in the wild group (n = 137)(p = 0.024). The time to dose reduction and discontinuation of thiopurine was significantly shorter in the mutant group, respectively (p < 0.001, p = 0.039). The mutant group tended to have more hospitalizations (p = 0.067), and surgeries were significantly more frequent (p = 0.028). In ulcerative colitis, thiopurine discontinuation was associated with hospitalization and surgery, respectively (p = 0.003, HR 2.87, 95% CI 1.44 - 5.71, p = 0.036, HR 5.45, 95% CI 1.12 - 26.5). In Crohn's disease, the presence of SNPs was associated with hospitalization (p = 0.019, HR 3.68, 95% CI 1.24-10.97) and surgery (p = 0.036, HR 6.81, 95% CI 1.14 - 40.86).

Conclusion: In ulcerative colitis, it is important to continue thiopurine with fine-tuning of the dosage to avoid hospitalization and surgery. In Crohn's disease, a direct association between the *NUDT15* SNP and hospitalization and surgery was demonstrated.

Introduction: Granulocyte–monocyte apheresis (GMA) selectively removes activated leukocytes and immune mediators, and it has shown to be safe and effective in treating ulcerative colitis (UC). Previous reports have also described its combination with biologics.

Aims & Methods: The aim of our study was to evaluate the efficacy and safety of combining GMA after primary non-response (PNR) or loss of response (LOR) to tofacitinib (TOFA) in patients with UC. A retrospective, multicentre study was performed in 7 IBD Units, including all patients with refractory UC who received combined plus GMA and TOFA. The number of GMA sessions, its frequency, filtered blood volume and length of each session were compiled, along with the clinical data. Efficacy was assessed 1 and 6 months after finishing GMA by partial Mayo score, CRP and faecal calprotectin. Data regarding TOFA intensification, need for new immunomodulators/biologics and colectomy were also compiled. Descriptive statistics and non-parametric tests were used in the statistical analysis.

Results: Twelve patients with UC were included (median 46 years [IQR, 37-58]; 67% female; 67% E3; 75% non-smokers). Patients were receiving TOFA 10 mg bid (75%), 5 mg bid (16%), or 15 mg bid (8%), with 33% receiving steroids at baseline. All patients had prior exposure to anti-TNF agents, 42% to vedolizumab and 8% ustekinumab. Median baseline Mayo score was 7 (IQR, 5-7), median CRP of 11 mg/L (IQR, 5-32) and faecal calprotectin 800 mg/kg (IQ, 715-2,094). GMA was started mostly after PNR (73%), and the median number of GMA sessions was 11 (IQR, 3-20) and 50% received maintenance GMA. Partial Mayo score significantly decreased 1 month after the last GMA session (p=0.027). Four patients (36%) were switched to a new therapy and no patient required colectomy during follow-up. All patients under steroids at baseline were able to stop them. No patient reported adverse events related to the combination therapy.
Conclusion: Combination of GMA with TOFA can be an effective and safe therapy in selected cases of UC after PNR or LOR to this drug.
Disclosure: Nothing to disclose.

Introduction: Although significant progress has been made in medical treatments for Crohn's disease, most patients still require surgery, with about 70% undergoing surgery at least once in their lifetime. Therefore, postoperative management presents a major challenge.
Aims & Methods: This study aimed to identify predictive factors for postoperative morbidity in surgical cases of Crohn's disease. We performed a retrospective study on patients with Crohn's disease who underwent intestinal resection in the general surgery and gastroenterology department of our Hospital. Cases with surgeries indicated for perianal lesions of Crohn's disease were excluded. The study collected cases over a 7-year period, from January 2011 to December 2017.
Postoperative morbidity was defined by the occurrence of specific and/or nonspecific complications after surgery, with early morbidity defined as within 1 month after surgery and late morbidity beyond this period. We analyzed the data using SPSS software version 22, with significance set at $p < 0.05$.
Results: Fifty-five patients with Crohn's disease were included, with a mean age of 34.3 years (range 17-68 years). Thirty-four patients were men (61.8%) and 21 were women (38.2%), resulting in a male-to-female ratio of 1.61. Active smoking was reported in 11 patients (20%). Surgery was performed as an emergency admission in 21 patients (38.2%) for acute appendicitis syndrome, intestinal obstruction, intra-abdominal collection with septic shock, or ileal perforation in 7 (33.3%), 10 (47.6%), 2 (9.5%), and 2 (9.5%) cases, respectively.
Among the remaining 34 patients, elective surgery was performed after failure of medical treatment (n = 20), contraindication to immunosuppressive treatment (n = 10), or for an enterovesical or enterocutaneous fistula (n = 7). The surgical approach was classical in 38 patients (69.1%) and laparoscopic in 17 patients (30.9%). Ileocecal resection was the most common operative procedure (n = 40). The mean follow-up period was 45 months (range 16-72 months). Early postoperative morbidity occurred in six patients (10.9%) with anastomotic leak in three cases complicated by septic shock and fatal outcome, right iliac fossa abscess in two cases, and cutaneous fistula in one case, with a mean delay of 18 days. Thirteen patients (23.63%) developed late complications, including incisional hernia in one case, intestinal occlusion on scarred flanges in one case, and recurrent disease symptoms in eleven cases after a mean delay of 9 months. In multivariate analysis, age >40 years (p = 0.01 OR = 4.6), ASA score >1 (p = 0.02 OR = 3), emergency surgery (p = 0.001; OR = 11), discovery of an abscess during surgery (p = 0.02 OR = 4.7), and classical surgical approach (p = 0.04 OR = 2) were found to be predictive factors for postoperative morbidity.
Conclusion: Surgery-related morbidity is a significant concern in the management of Crohn's disease and is influenced by several factors, including patient characteristics, timing and approach of surgery, and disease progression. Understanding these factors is essential for improving the management of patients with Crohn's disease who are frequently operated.
Disclosure: Nothing to disclose.

LOW CROHN'S DISEASE POST-OPERATIVE ENDOSCOPIC RECURRENCE RATES AT 1 YEAR: A 20-YEAR EXPERIENCE IN SINGAPORE

W.H.J. Leong[1], C.K. Tan[2], F. Teh[2], M. Tan[1]
[1]Singapore General Hospital, Gastroenterology and Hepatology, Singapore, Singapore, [2]Changi General Hospital, Gastroenterology and Hepatology, Singapore, Singapore

Introduction: Despite significant advances in medical treatment options for patients with Crohn's disease (CD), up to 30% still require bowel surgery within the first decade after diagnosis[1].
Endoscopic post-operative recurrence is not uncommon with rates up to 70% recurrence at 1 year.[2,3,4]
Most studies regarding endoscopic recurrence (ER) in CD were performed with non-Asians. We aimed to describe our cohort of CD patients to ascertain the number of patients who had ER within 1 year after index bowel resection and assess the factors associated with ER.
Aims & Methods: We performed a retrospective cohort study across 2 tertiary hospitals in Singapore. We identified adult patients with CD who had undergone an index bowel resection for CD between January 2000 to December 2021 with subsequent endoscopy within 6-12 months of surgery. Patients were stratified as high risk; defined as ≥1 of the following – active smoking, penetrating disease at index surgery or perianal disease. Data on disease characteristics, prior treatment, indication and type of surgery, and post operative prophylaxis was collected. ER was defined by Rutgeerts score of ≥i2. Analysis was done with SPSS v23.0.
Results: After screening 41 patients, we identified 26 patients who met the inclusion criteria. The baseline characteristics are detailed in Table 1. The majority were male (77%), with a median age of 31 years and had ileocolonic disease (L3) (69%). 9 (35%) had penetrating disease (B3). 11 (42%) patients were biologic experienced, indicating an overall therapy-refractory population. The most common indications for resection were stricturing CD (38%) and persistent inflammation (27%). Median disease duration to surgery was 553 days. 58% were classified as high risk with this group representing a more treatment experienced group with nearly half exposed to biologics prior to resection. 42% of patients received post-operative prophylaxis of either an immunomodulator or a biologic. A higher proportion of patients in the high-risk group received biologics as post-operative prophylaxis compared to the low-risk group (20% vs 9%).
The overall ER rate was 15%. Significantly, no patients on prophylaxis in either the high or low-risk groups developed recurrence. In patients without prophylaxis, the overall ER rate was 27%. This occurred in 33% in the high-risk group and 17% in the low-risk group.

		Median (IQR), n (%) Total (n=26)
Age (yr)		31 (34-39)
Gender	Male	20 (77)
	Female	6 (23)
Disease Location	L1, Ileal	5 (19)
	L2, Colonic	3 (12)
	L3, Ileocolonic	18 (69)
Disease Behaviour	B1, Non-stricturing, non-penetrating	7 (27)
	B2, Stricturing	10 (38)
	B3, Penetrating	9 (35)
	Perianal Disease	4 (15)
Treatment Prior to Surgery	Immunomodulator	15 (58)
	Biologic	11 (42)
Indication for Surgery	Stricture	10 (38)
	Abscess	3 (12)
	Perforation	2 (8)
	Inflammation	7 (27)
	Others	4 (15)
Postoperative Recurrence Risk Stratification	High	15 (58)
	Low	11 (42)
Postoperative Prophylaxis	EITHER Biologic or Immunomodulator	11 (42)
Postoperative Endoscopic Recurrence	All	4 (15)
	Patients who received postoperative prophylaxis (n=11)	0
	Patients who did not receive post operative prophylaxis (n=15)	4 (27)

Table 1: Baseline Characteristics and Endoscopic Recurrence

Conclusion: Postoperative ER within 1 year in patients without postoperative prophylaxis was 27% in our cohort. Postoperative prophylaxis with either immunomodulators or biologics shows a trend towards preventing postoperative ER within 1 year in both high and low risk patients.

Introduction: Electrical stimulation of the cervical vagus nerve (VNS) activates the inflammatory reflex to reduce inflammation and ameliorate disease in subjects with therapy-refractoryCrohn's disease (CD) (D'Haens et.al., under review). Considering the surgical implantation of a neurostimulator, we hypothesized that using a transcutaneous device to stimulate the auricular cutaneous branch of the vagus nerve (taVNS), could be used as a preoperative screening test. Should taVNS activate the inflammatory reflex, the blood cytokine response to an ex vivo endotoxin challenge would decrease (Koopman et.al., PNAS 2016; 113(29): 8284). The objective was to explore whether a noninvasive taVNS procedure could be used preoperatively to identify which patients would ultimately respond clinically to VNS administered via an implanted device.

Aims & Methods: This describes an exploratory substudy within an open label study of patients with moderately to highly active CD. The patients (17 enrolled, 13 male, 35 years [range 21-62], CDAI±SEM= 306±15) previously failed biological treatment (i.e TNF antagonists, vedolizumab). At screening, a baseline blood sample was drawn and incubated (37 °C, 24 hours) in a standardized and validated culture system containing endotoxin (TruCulture, RBM). A taVNS device (Cerbomed), approved for the treatment of epilepsy, depression, and pain, was fitted to the left ear and stimulated for 5 minutes at an intensity that provided sensation that was "noticeable but not painful." Additional blood samples were drawn at 1 and 4 hours post-stimulation and incubated, as described above. Plasma cytokine levels (TNF, IL-1b, IL-6) were quantitated (MSD). Following successful screening, implantation of a VNS device (Cyberonics) was performed. Daily VNS treatment was initiated after 2-weeks postoperative recovery and continued to week 16. Change from baseline levels of bioassay cytokines was compared between those patients who achieved a CDAI-100 response (responders) and patients who did not achieve a CDAI-100 response at week 16 (non-responders). Differences between groups were assessed by t-test.

Results: 13 patients consented and took part in the exploratory sub-study. Of these, 8 patients were responders to VNS therapy at week 16 and 5 were non-responders. Of the responders, approximately half had decreased or no change in bioassay cytokine levels at both 1 and 4 hours and approximately half had increased or minimal change in cytokine levels. Similarly, of the non-responders, approximately half had decreased or no change in bioassay cytokine levels at both 1 and 4 hours and approximately half

had increased or minimal change in cytokine levels. There was no significant difference at 1 or 4 hours between the change from baseline bioassay levels of TNF, IL-1b, or IL-6 in the responders compared to the non-responders (p>0.4).

Conclusion: No differences were observed in bioassay cytokines following taVNS that can be predictive of an individual patient's clinical response to VNS at week 16. This may be due to the taVNS device not consistently activating the correct nerve fibers, a disconnect between the ability of taVNS and VNS to activate the inflammatory reflex and affect inflammation in CD patients, or the relatively high concentration of endotoxin used within the validated bioassay. Use of a noninvasive test to predict clinical response to an implanted vagus nerve stimulation device would be useful. However, data using taVNS have not yet validated the clinical utility of this screening approach.

Introduction: Resection rates for patients with Crohn's disease (CD) have decreased over the past decades. Despite this trend, studies indicate that the rates of re-resections remain close to 30% over a 20-year period (1). There are still several unresolved questions related to risk factors, disease progression, treatment response and monitoring.

Aims & Methods: We aimed to investigate the association of clinical risk factors, disease course related to intestinal resection and risk of re-resection. Using surgical procedure and diagnosis codes within the electronic health record system and the Danish National Patient Register, we established a population-based cohort with all CD patients who underwent a primary intestinal resection between 2010 and 2020 in a region of Denmark with a background population of 2.730.000 (46% of the Danish population). Individual patient data with clinical characteristics, disease course, medical treatments, type of surgical procedures and complications as well as imaging and endoscopies were collected in a REDcap database. To characterize the cohort, we used nonparametric statistics including median, interquartile range (IQR), and percentages.

Results: A total of 939 patients had a resection performed within the study period of which 633 received a primary resection with a follow-up of 118 months (IQR: 69-170). Of those, 617 (97,5%) had a full dataset available for analysis (Table 1). Median age at diagnosis was 28 years (IQR: 21-44), and 222 (36%) were smokers.

Distribution of disease location at diagnosis were L1 ileal 271 (44%), L2 colonic 70 (11%), L3 ileocolonic 264 (43%), L4 upper GI 10 (2%), with disease phenotype B1 non-stricturing/penetrating 172 (28%), B2 stricturing 317 (51%), B3 penetrating 79 (13%), and perianal 23 (4%). A total of 317 (51%) received corticosteroids within the first year of diagnosis. Prior to the first resection 329 (53%) patients received immunomodulators and 300 (49%) biologics. Postoperative readmission-rate within 30 days was 19% across the cohort.

A total of 2019 colonoscopies (SES-CD and Rutgeerts score) and 3217 imaging examinations were registered. Median number of months from first to second, second to third, and third to fourth resection were 12 (IQR: 6-41), 22 (IQR: 7-49), and 28 (IQR 7.5-53.5) respectively.

	Resection 1 n (%)	Resection 2 n (%)	Resection 3 n (%)	Resection 4 n (%)
Number of resections	617	149 (25)	31 (5)	5(1)
Corticosteroids use after resection	168 (27)	42 (28)	6 (19)	0
Immunomodulators started post-resection	354 (57)	64 (43)	16 (52)	3 (60)
Biologics started post-resection	245 (40)	76 (51)	22 (70)	3 (60)
Acute resection (< 24h)	75 (12)	22 (15)	2 (6)	1 (20)
CD-surgery related readmission (≤30 d)	120 (19)	21 (14)	3 (10)	4 (80)
Laparoscopic resection	343 (56)	67 (45)	10 (32)	2 (40)
Primary anastomosis	470 (76)	114 (77)	18 (58)	3 (60)
Anastomotic leak	22 (5)	10 (9)	1 (6)	0

Table 1. Basic characteristics for primary and re-resections including medical and surgical specifications.

Conclusion: The initial analysis of this population-based cohort demonstrates that despite high biological therapy exposure before first resection and onwards, one fourth of patients will need additional resections within ten years. Despite their young age, patients undergoing intestinal resections have a high risk of complications, with one in five needing readmissions within 30 days. We are currently analyzing the role of prophylactic vs. on-demand biologics, post-surgery imaging results, and other factors for risk of flare/resection and risk-factors of post-surgery morbidity in this cohort.

SACRAL NERVE STIMULATION INHIBITS THE MAPK/NF-KB SIGNALING PATHWAY AND PROMOTES TREG -TH1/TH17 CELL BALANCE AND SELF-RENEWAL OF ENTERIC NERVOUS SYSTEM IN TNBS-INDUCED INFLAMMATION IN RATS

Y. Meng[1], J. Chen[2]
[1]Guangdong Provincial Key Laboratory of Gastroenterology, Nanfang Hospital, Department of Gastroenterology, Guangzhou, China, [2]Johns Hopkins University School of Medicine, Division of Gastroenterology and Hepatology, Baltimore, United States

Contact E-Mail Address: 1031294787@qq.com

Introduction: 2,4,6-trinitrobenzene sulfonic acid (TNBS) is known to induce inflammation through triggering the MAPK/NF-κB pathway and activation of T helper cells. Sacral nerve stimulation (SNS) was reported to exert an anti-inflammatory effect on TNBS-induced colitis.
The aim was to investigate whether the SNS anti-inflammatory effect was mediated via the MAPK/NF-κB pathway and/or balancing Th1/17-Treg cells. We also explored if SNS could alter self-renewal of neurons in myenteric plexus.

Aims & Methods: Forty male SD rats were implanted wire electrodes unilaterally at sacral nerve (S3). 7 days later, the rats were administrated with TNBS intra-rectally. 5 days later, 20 of them were treated with SNS 1 hour daily for 10 days and the other 20 rats were treated with sham-SNS (same setting but SNS at 0mA). Additional 20 rats were injected with saline(as controls). Various inflammatory proteins and cells were assessed.

Results: 1) compared to sham-SNS, SNS significantly decreased DAI (area under the curve: 64.3±3.8 vs. 49.5±3.2, P<0.01), macroscopic scores (5.85±0.9 vs. 2.55±0.6, P=0.03) and microscopic scores (4.6±1.1 vs. 2.7±0.8, P=0.04) and normalized the colon length;
2) in colon tissues, compared with sham-SNS, SNS reduced the percentage of Th1 cells (8.87%±2.32% to 5.40%±1.39%, P=0.04) and Th17 cells (12.35%±1.61% to 9.75%±1.17%, P=0.04) but increased Treg cells (15.73%±2.81% to 20.15%±2.24%,P=0.03);
3) SNS reduced the phosphorylation of MAPKs compared to Sham-SNS (p-ERK/ERK: 22.5%, P=0.03; p-JNK/JNK: 25.6%, P=0.04) and prevented the nuclear translocation of NF-κB p65 by 40.7% (P=0.02);
4) choline acetyltransferase (ChAT) neurons were decreased by TNBS but reversed by SNS (19.06% ± 2.07% to 25.68%±3.56%, P=0.02). Nitric oxide synthase (NOS) neurons was increased by TNBS but decreased by SNS (17.21% ±1.27% to 13.34%±1.63%, P=0.03).

Conclusion: SNS is effective in inhibiting colon inflammation through the inhibition of the MAPK/NF-κB pathway, balancing of Th1/Th17-Treg cells, and also improving the LMMP neuronal self-renewal and regeneration.

Disclosure: Nothing.

Introduction: Crohn's disease (CD) is characterized by recurrent flares of intestinal inflammation that can affect any segment of the digestive tract. Frequently, transmural inflammation can lead to serious intraabdominal complications that may eventually require surgical intervention. Surgery in CD is not curative and almost 25% of patients will need multiple interventions. The mesentery might be involved in CD pathogenesis by modulating local hormonal and immunologic processes, which is why surgical techniques involving the mesentery have recently drawn attention. Certain studies reported that removing the mesentery during intestinal resection might improve the postoperative outcome, but the results are controversial.

Aims & Methods: Our main aim was to evaluate the effectiveness of performing extended mesenteric excision (EME) in preventing postoperative CD recurrence (POR) compared with limited mesenteric excision (LME). Second, we investigated the role of EME on overall postoperative complications, as compared to LME. We conducted our study according to a pre-registered protocol in PROSPERO (CRD42022371789). Studies that reported short- and long-term outcomes of CD patients who underwent intestinal resection with EME compared with LME were considered eligible. A systematic search was performed in five databases (Pubmed, Embase, Cochrane, Scopus, Web of Science) from inception until 9th November 2022. Pooled odds ratios (ORs) with a 95% confidence interval (CI) were calculated using the random-effects model. The risk of bias was assessed with the Risk of Bias in Non-randomized Studies of Interventions (ROBINS-I) tool. We evaluated the certainty of evidence according to the recommendations proposed by the Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) Working Group.

Results: During the systematic search, 7201 records were retrieved. After the duplicate removal and selection process, we included six papers that reported data from five studies. The meta-analysis was performed with data pooled from three retrospective cohort studies, of which two included patients with ileocolic resections and one with colorectal resections. These studies analyzed 516 patients, of which 304 underwent EME and 212 LME.

Our results showed a non-significant lower rate of surgical recurrence in the EME group compared with LME (OR 0.3; 95% CI: 0.02-3.73). Regarding overall postoperative complications, performing EME was also associated with non-significant lower odds (OR 0.78; 95% CI: 0.33-1.82). The certainty of the evidence for the meta-analysis outcomes was very low and low, respectively. Concerns were raised by the moderate level of bias and, more importantly, by the inconsistency and imprecision of the results.

Conclusion: Our meta-analysis indicated a trend towards lower rates of POR in patients who underwent intestinal resections with EME compared with LME. However, results are to be interpreted cautiously due to the statistical non-significance and the low quality of evidence. Considering overall postoperative complication rates, performing intestinal resections with EME appears to be a safe procedure compared with LME. Results from ongoing randomized controlled trials and further high-quality studies are needed to determine the role of mesentery resections in CD surgery.

ADHERENCE TO GUIDELINES AFTER ILEOCOLONIC RESECTION FOR CROHN'S DISEASE: AN AUSTRALIAN EXPERIENCE

A. Haig[1,2], D. Shukla[1], M. Bhullar[1], J. Edwards[1], N. Ishaq[1], L. Willmann[1], D. Subhaharan[1], P. Kakkadasam Ramaswamy[1], W. Mohsen[1]

[1]Gold Coast University Hospital, Gastroenterology and Hepatology, Gold Coast, Australia, [2]Griffith University, School of Medicine and Dentistry, Southport, Australia

Contact E-Mail Address: adam.haig@gmail.com

Introduction: In recent years Ileo-colic resection (ICR) has emerged as an effective treatment option for patients with ileal or ileo-caecal Crohn's disease (CD). Prophylactic treatment, including thiopurines and TNF-alpha inhibitors, have demonstrated efficacy in altering the disease course and reducing postoperative recurrence (POR). Consequently, the European Crohn's and Colitis Organization (ECCO) published guidelines in 2016 and 2018 with consensus statements regarding postoperative care, and recommends risk-stratification for POR and prescription of prophylactic treatment to high-risk individuals. Existing data indicate suboptimal adherence to these guidelines, potentially leading to increased healthcare costs.

Aims & Methods: There is a scarcity of data on post-operative care patterns from Australia and this study aimed to evaluate guideline adherence in an Australian tertiary centre. Patients who underwent an ileocolonic resection and primary anastomosis for CD between 2017 and 2021 were retrospectively analysed. Patients with 12-month follow-up data available were included. Adherence to three specific guideline aspects: (1) prophylactic therapy prescription in high-risk patients, (2) colonoscopy within 12 months of ICR, and (3) documentation of a Rutgeerts' score at colonoscopy, were evaluated. High-risk patients were defined as those with one or more of the following risk factors for recurrence: postoperative smoking, prior CD-related intestinal resection, presence of penetrating or perianal disease, or presence of granulomas in the resection specimen.

Results: A total of 59 patients met inclusion criteria. Patient demographic data and risk factors for POR are shown in table 1. 36 (61%) underwent colonoscopy within 12 months, and 54 (92%) had a colonoscopy during the follow-up period (median 248 days, range 61 – 1764 days). A Rutgeerts' score was documented in 26/54 (48%) patients who underwent colonoscopy. Of the 50 patients with at least one risk factor for recurrence, 38 (76%) received appropriate prophylactic therapy. Risk factors for the 12 patients not appropriately prescribed prophylactic therapy included granulomata (n = 7), penetrating disease (n = 4), smoking (n = 3), prior resection (n = 2) and perianal disease (n = 1). Five of these patients had two risk factors for recurrence. In only 11 of 59 patients (19%) were all three guideline criteria satisfied.

Age - median (IQR)	45 (23)
Presence of risk factors for recurrence - n (%)	
Prior intestinal resection	18 (31)
Postoperative smoking	19 (17)
Presence of penetrating disease	26 (44)
Presence of granulomata in resection specimen	23 (39)
Perianal disease	9 (15)
Extensive involvement (> 50cm)	3 (5)
Any risk factor for recurrence	50 (85)

Table 1. Patient characteristics and risk factors for recurrence

Conclusion: This study revealed suboptimal adherence to the ECCO guidelines in the studied Australian cohort, particularly in documenting Rutgeerts' score and performing colonoscopy within 12 months. It also suggests that the presence of granulomata in the resection specimen is an underrecognized risk factor for POR. The findings highlight a need for quality improvement initiatives to enhance guideline awareness and adherence among gastroenterologists.

Disclosure: Nothing to disclose.

THE TREATMENT AND TREATMENT OUTCOMES OF POUCHITIS IN PATIENTS WITH ULCERATIVE COLITIS FOLLOWING IPAA – A DANISH POPULATION-BASED COHORT STUDY

B. Lo[1,2], R. Bergstrøm[1,2], E. Toft[1,2], O. Bulut[1,2], J. Burisch[1,2]
[1]Copenhagen University Hospital – Amager and Hvidovre, Gastrounit, Medical Section, Hvidovre, Denmark, [2]Copenhagen University Hospital – Amager and Hvidovre, Copenhagen Center for Inflammatory Bowel Disease in Children, Adolescents and Adults, Hvidovre, Denmark

Contact E-Mail Address: rosalina.bergstroem.moelbaek.01@regionh.dk

Introduction: Ulcerative colitis (UC), a chronic inflammatory bowel disease, may require surgical intervention such as colectomy. Post-colectomy, an ileal pouch-anal anastomosis (IPAA) offers an alternative to a permanent ostomy. However, up to 50% of patients with an IPAA will experience pouchitis, which can cause symptoms similar to UC. More robust data is needed to establish effective treatments and assess their real-world effectiveness, especially in population-based cohorts.

Aims & Methods: The aim was to investigate the choice of treatments for pouchitis, their effectiveness, and pouch failure rates in UC patients who underwent IPAA at Copenhagen University Hospital Hvidovre between 11th November 1993 and 26th April 2021. Patients were screened through electronic medical records. Antibiotic treatment responses were defined as antibiotic dependent (needing 4+ courses/year), antibiotic refractory (courses of antibiotics lasting >28 days), and antibiotic responsive (not meeting the other criteria). Continuous or pro necessitate treatments were considered refractory (29 days), while courses without a stop date and no new symptoms were deemed responsive (14 days).

Results: A total of 239 UC patients underwent IPAA. After excluding 6 patients who did not receive ileostomy reversal, 233 were analysed with a median follow-up of 8.36 (IQR: 4.33–11.16) years. 529 pouchitis treatment courses were prescribed to 118 (50.64%) of the UC patients, with 474 (89.6%) being antibiotics. Ciprofloxacin and metronidazole were the most common prescribed antibiotics, while adalimumab and infliximab were the most common used biologics. The median duration of antibiotic treatment was 11 (IQR: 9-19 days) days.

Two-thirds of antibiotic courses were responsive, while one-third were refractory or dependent. This corresponded to, 46.4% of the 233 patients being antibiotic responsive, 14.6% dependent, and 16.3% refractory.

Survival rates for responsive, refractory, and dependent pouchitis treatments were as follows:

For responsive treatments, survival rates were 0.84 at 6 months, 0.77 at 12 months, 0.65 at 24 months, 0.56 at 60 months, and 0.49 at 120 months.

For refractory treatments, survival rates were 0.98 at 6 months, 0.97 at 12 months, 0.95 at 24 months, 0.89 at 60 months, and 0.80 at 120 months.

For dependent treatments, survival rates were 0.97 at 6 months, 0.94 at 12 months, 0.91 at 24 months, 0.86 at 60 months, and 0.83 at 120 months.

Pouch failure occurred in 13.8% (32) of patients. These patients experienced 36 pouch failures, where 12 (33.33%) were due to acute and chronic sepsis, 19 (52.78%) were caused by poor function for mechanical or functional reasons, 3 (8.33%) resulted from mucosal inflammation (pouchitis), and 2 (5.56%) were attributed to neoplastic transformation. Prior to pouch failure, 50.8% of the 32 patients had at least 1 responsive episode of pouchitis, 21.9% had dependent pouchitis, and 18.8% had refractory pouchitis.

Conclusion: This study provides insights into pouchitis treatment strategies, their effectiveness, and failure rates in UC patients who undergoes IPAA. The majority of pouchitis treatments were antibiotics, with ciprofloxacin and metronidazole being the most common. Antibiotic responsiveness varied among patients, with pouch failure observed in 13.8% of cases. These findings contribute to a better understanding of pouchitis management in real-world settings, emphasizing the need for further research to optimize treatment strategies and improve patient outcomes.

INCIDENCE AND DISEASE COURSE OF POUCHITIS IN PATIENTS WITH ULCERATIVE COLITIS AND AN ILEAL POUCH-ANAL ANASTOMOSIS (IPAA)– A DANISH POPULATION-BASED COHORT STUDY

B. Lo[1,2], R. Bergstrøm[1,2], E. Toft[1,2], O. Bulut[1,2], J. Burisch[1,2]
[1]Copenhagen University Hospital – Amager and Hvidovre, Gastrounit, Medical Section, Hvidovre, Denmark, [2]Copenhagen University Hospital – Amager and Hvidovre, Copenhagen Center for Inflammatory Bowel Disease in Children, Adolescents and Adults, Hvidovre, Denmark

Contact E-Mail Address: rosalina.bergstroem.moelbaek.01@regionh.dk

Introduction: Ulcerative colitis (UC) is a chronic inflammatory bowel disease affecting the colon and rectum. In some cases, surgical intervention such as colectomy may be necessary. Following colectomy, the creation of an ileal pouch-anal anastomosis (IPAA) provides an alternative to permanent ostomy. However, pouchitis is a well-recognized complication of IPAA, causing inflammation and symptoms similar to those of ulcerative colitis. Despite its frequency, there remains a paucity of reliable data on the incidence and long-term disease course of pouchitis, especially from population-based cohorts

Aims & Methods: We aim to investigate the incidence and disease course pouchitis in UC patients who've underwent an IPAA between 11th November 1993 and 26th April 2021 at Copenhagen University Hospital Hvidovre, Gastrounit. Due to centralization of IPAA, the department covers approx. 46 % of the Danish population. All patients were manually screened through their electronic medical record. All events of pouchitis and the duration was registered.

Results: In total, 239 UC patients had ileal pouch-anal anastomosis (IPAA) performed between 11th November 1993 and 26th April 2021. However, 6 patients did not have their relieving ileostomy put back and their constructed pouch taken into usage and were therefore excluded from the analysis. The median follow-up time was 8.36 years (IQR: 4.33 – 11.16) for the 233 patients. During the observation period, a total of 122 (52.36 %)

UC patients, experienced 421 events of pouchitis ranging from 1-25 episodes per patient. Of the 421 events, 329 (78.15 %) were defined as acute (≤ 28 days) and 92 (21.85 %) as chronic pouchitis (>28 days). Looking at the frequency of the flares, 311 (73.87 %) of these could be categorised as episodic pouchitis (<3 episodes per year) and 110 (26.13 %) as relapsing pouchitis (≥3 episodes per year). The episodes of relapsing pouchitis were distributed among 31 patients (26.19 %). The mean time from IPAA construction to the first episode of pouchtitis was 27.24 (SD: 36.20) months. The mean length of each episode of pouchitis until remission was 25.69 (SD: 59.70) days. While the time between each pouchitis episode was a mean of 373.53 (SD: 620.14) days.

The survival rate, referring to time to pouchitis, at 6 months, 1,2,5, and 10 years are shown in table 1.

	0	6	12	24	60	120
Episodic	100%	88%	76%	64%	52%	44%
Relapsing	100%	100%	96%	92%	90%	86%

Conclusion: This study highlights the high incidence of pouchitis in UC patients who have undergone an IPAA. Approximately half of the patients experienced at least one episode of pouchitis. The time from IPAA construction to the first episode of pouchitis was around 2 years, with a mean duration of each episode being around 3 weeks. The frequency of relapsing pouchitis was seen in a quarter of the patients. These findings emphasize the importance of identifying preventive and therapeutic strategies for pouchitis in this patient population to improve long-term outcomes.

PROPHYLAXIS OF POST-OPERATIVE RELAPSE IN PATIENTS WITH CROHN'S DISEASE; INDICATIONS AND PRACTICE

R. Paiman[1], Z.A. Butt[1], M.A. Ainsworth[1]
[1]Odense University Hospital, Gastroenterology, Odense, Denmark

Contact E-Mail Address: Rangeena.Paiman2@rsyd.dk

Introduction: Lifetime risk of surgery in Crohn's disease (CD) is substantial. In order to reduce risk of recurrence after surgery, initiation of medical prophylaxis based on assessment of risk of relapse is generally recommended (1) although specific criteria for risk assessment is debatable (2).

Aims & Methods: Aims: The objectives were to assess adherence to guideline recommendations as regards post-operative prophylaxis and to evaluate efficacy of profylaxis.

Methods: Population-based, single-center prospective study of all CD patients undergoing intestinal resection between February 1st, 2017, and January 31st, 2022. Based on medical records,patients were classified as either high or low risk of relapse. Treatment received and outcome of treatment was registered and correlated to known prognostic factors such as smoking status, age, previous surgical resection.

Results: A total of 216 patients were included in the study, out of which 104 and 112 were in the high and low-risk groups, respectively. Only 61% of the patients in the high-risk group received post-operative prophylaxis (POP). There was no significant difference in relapse rates between those who received POP and those who did not. Forty-two out of 63 patients (67%, CI: 55-78) who received post-operative prophylaxis, experienced either clinical, endoscopic and/or MR-relapse while the numbers were 22/41 (53%, CI: 38-69, *p=0.218*) for those who did not receive any.

Seventy-four out of 112 (66%) of patients in the low risk group received POP in spite of being low risk. Also in this group, there was no significant difference in relapse rates between patients receiving POP (66%, CI: 55-77) and those not receiving POP (47%, CI: 31-63, p=*0.067).*

Relapse risk in patients not receiving POP was only numerically but non-significantly smaller for low risk patients (47%) compared to high risk patients (54%).

Conclusion: Adherence to recommendations for POP in CD was relatively low. In patients not receiving POP, risk of relapse was not statistically significantly higher in high risk patients compared to low risk patients. Compared to patients not receiving POP, patients who received POP (irrespective of low or high presumed risk) did not seem to benefit in terms of reduced risk of relapse. These finding question the clinical usefulness and predictive capacity of the current risk stratification as well as currently used medications for POP

Introduction: Despite new therapeutic strategies, substantial proportion of patients with ulcerative colitis (UC) undergo colectomy at some point. Restorative proctocolectomy with ileal pouch ano anastomosis (IPAA) is regarded as intervention of choice in these patients. However, the disease conversion to Crohn's disease (CD) is reported in up to one third of these patients who necessitate immune suppressive treatment after IPAA. Considering the life-long need for immune suppressive therapy in these patients, ileo-rectal anastomosis (IRA) would represent a good alternative to IPAA in this specific group of patients. Todate, no data are available to predict the UC-CD conversion. One of the possibility to reduce the risk of performing IPAA in patients developing CD in pouch is to use the modified two-stage proctocolectomy approach and identify patients who develop CD endoscopically between colectomy and the restoration of continuity.

Aims & Methods: The aim of the present study was to assess the UC-CD conversion rate identified prior IPAA via ileoscopy.

All patients with UC operated in one tertiary IBD center between 2016 and 2021 were identified in medical records. The main outcome was CD detected at ileoscopy between the first stage operation, i.e. total colectomy with terminal ileostomy and the restoration of continuity either via IPAA or IRA. The ileoscopy was performed between three to six months after colectomy. The secondary outcome was the rate of conversion to CD after IPAA or IRA.

Results: Sixty patients underwent total colectomy (mean age 41 years, range 22-77; 62% were men); seven patients were lost to follow-up, finally the data from 53 patients were analysed. The majority of these patients (36 - 68%) underwent colectomy for therapy resistent chronically active UC, 9 (17%) patients for acute severe UC, 2 patients had benign colonic stenosis, 5 had high-grade dysplasia or colorectal cancer detected at surveillance colonoscopy and one patient had extensive pseudopolyposis.

All resection specimen were reviewed and no histopathological features of CD were found. Three out of the 53 (6%) ileoscopically assessed patients prior IPAA or IRA were diagnosed with CD in prestomal terminal ileum. During the further follow-up, additional 4 patients developped CD, two after IPAA, one with definitive ileostomy in prestomal ileum and one in neoterminal ileum after IRA.

In total 7 out of 53 patients in this cohort developped CD (13%). Using the two stage approach with ileoscopy between colectomy and restoration of continuity, three out of these seven patients with CD convertion in this cohort were detected prior the decision on the type of second-stage operation.

Conclusion: The conversion from ulcerative colitis to Crohn`s disease occurs in a significant proportion of IBD patients after colectomy. Ileoscopy performed between the two stages of restorative proctolectomy is helpfull in detecting these patients and guiding the decision on the type of surgical intervention to restore continuity.

TRANSANAL VERSUS CONVENTIONAL ILEAL POUCH-ANAL ANASTOMOSIS IN ULCERATIVE COLITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF COMPARATIVE STUDIES

M. Elhadi[1], T. Khaled[1]
[1]*University of Tripoli, Faculty of Medicien, Tripoli, Libya*

Contact E-Mail Address: muhammed.elhadi.uot@gmail.com

Introduction: Ulcerative colitis (UC) is a chronic inflammatory bowel disease affecting the colon and rectum. Surgical intervention is often required in cases of medically refractory disease, dysplasia, or colorectal cancer. Restorative proctocolectomy with ileal pouch-anal anastomosis (IPAA) is the preferred surgical procedure for these patients. The transanal approach to IPAA has emerged as a minimally invasive alternative to conventional surgery. However, the safety, efficacy, and long-term outcomes of transanal IPAA remain unclear.

Aims & Methods: This systematic review and meta-analysis aimed to assess the safety, efficacy, and long-term outcomes of transanal ileal pouch-anal anastomosis in adult patients with ulcerative colitis and compare it with the conventional approach. A comprehensive literature search was conducted using PubMed, EMBASE, and the Cochrane Library from inception to October 2022. Comparative studies were included for adult patients with UC who underwent transanal IPAA versus conventional IPAA. Outcomes analyzed included anastomotic leak, major and minor complications, using relative risk (RR). Meta-analysis was performed using R 4.0.3 and its packages metafor and meta.

Results: Our search identified 4 comparative studies, including a total of 858 patients (338 transanal and 520 conventional IPAA). The meta-analysis showed no significant differences in anastomotic leak (pooled RR 1.72, 95% confidence interval [CI] 0.77-3.79, I2=3%), minor complications (pooled RR 0.97, 95% CI 0.68-1.37, I2=75%), or major complications (pooled RR 0.81, 95% CI 0.52-1.27, I2=56%) between the two groups.

Conclusion: This systematic review and meta-analysis suggest that transanal ileal pouch-anal anastomosis is a safe and effective alternative to conventional IPAA for patients with ulcerative colitis, with similar rates of complications. More high-quality RCTs are needed to confirm these findings and to further evaluate the long-term outcomes of this procedure.

Disclosure: Nothing to disclose.

AESTHETIC BENEFIT OF ILEO-CAECAL RESECTION FOR CROHN'S DISEASE BY SINGLE TROCAR VERSUS CONVENTIONAL LAPAROSCOPY

A. Antier[1], A. Challine[1], M. Collard[1], C. debove[1], N. Chafai[1], J. Lefevre[1], Y. Parc[1]
[1]*Hopital Saint-Antoine General and Digestive Surgery, Paris, France*

Contact E-Mail Address: lefevre.jeremie@gmail.com

Introduction: Studies evaluating the single incision laparoscopy (SIL) found an identical rate of postoperative complications and duration of hospitalization, with a probable aesthetic benefit compared to multi-trocar laparoscopy (MTL). The difference of a peri-umbilical or trans-umbilical incision has not been assessed in this young population.

Aims & Methods: The aim of this study was to compare the aesthetic result after ileocecal resection (ICR) for Crohn's by SIL or MTL.

All ileocecal resection with anastomosis (2012-2020) were retrospectively included. The aesthetic result was evaluated by the Body Image Questionnaire. A case-control study was carried out by matching on: age, sex, BMI, smoking, surgical history, surgical indication, corticosteroid therapy and associated procedure.

Results: 206 patients (SIL=65; MTL=141) were included. Overall morbidity was 37.4% (severe morbidity=5.3%), with no difference between the groups. 124 patients (71%) responded to the questionnaire (mean follow-up: 4.7 years).

Body image was identical in both groups but the aesthetic scale was better in the SIL group (21.1 vs. 18.4, p<0.001). In the SIL group, body image was better in patients who had a trans-umbilical versus periumbilical incision (5.2 versus 6.4, p=0.04), the aesthetic scale was identical regardless of the incision.

After matching (SIL=37; MTL=37), body image remained identical in the two groups and the aesthetic scale remained better in the SIL group (21.1 vs. 19.3, p=0.03). The factors associated with a very good aesthetic result were the SIL and the absence of a history of abdominal surgery in univariate and in multivariate the SIL (OR=2.30[1.01-5.28], p=0.05).

Conclusion: The SIL for an ICR for Crohn's allows a better aesthetic result compared to the MTL, especially after trans-umbilical incision.

Disclosure: Nothing to disclose.

ISOLATED ANASTOMOTIC LINE ULCERATIONS ARE ASSOCIATED WITH A HIGHER RISK OF POSTOPERATIVE RECURRENCE IN PATIENTS WITH CROHN'S DISEASE UNDERGOING ILEOCECAL RESECTION AND A DIFFERENTIAL MUCOSA-ASSOCIATED MICROBIOME COMPOSITION

P. Olivera[1], C. Hernandez-Rocha[1], K. Borowski[1], W. Turpin[1], H. Leibovitzh[1], R. Milgrom[1], J. Stempak[1], S.-H. Lee[1], M.S. Silverberg[1], IBD Genetics Consortium
[1]*Mount Sinai Hospital, Zane Cohen Centre for Digestive Diseases, Lunenfeld-Tanenbaum Research Institute, Toronto, Canada*

Contact E-Mail Address: poliverasendra@gmail.com

Introduction: Anastomotic ulcers are a common finding in Crohn's disease (CD) patients undergoing ileocolonic resection (ICR). The clinical significance of these lesions remains debated, as some studies have suggested that they may be associated with a higher risk of postoperative recurrence (POR), while others have not found a significant association. Also, the pathogenesis of anastomotic ulcers is poorly understood.

Aims & Methods: We aimed to assess the risk of CD postoperative recurrence (POR) after ICR in patients with and without isolated anastomotic ulcers among those with otherwise healthy neo-terminal ileum (TI). Also, we aimed to assess the mucosa-associated microbiome composition on either side of the anastomosis.

CD patients undergoing ICR were prospectively recruited as part of the multicenter NIDDK Inflammatory Bowel Disease Genetics Consortium CD Ileal Post-Op Study. In this analysis, we included subjects recruited at Mount Sinai Hospital Toronto without any ulcerations in the neo-TI (simple endoscopic score for CD ≤2) at the first postoperative colonoscopy (FC). Patients with ulcerations limited to the anastomotic line were classified as modified Rutgeerts score (mRS) i2a, whereas those without any ulceration as i0. Biopsies were taken on both sides of the anastomosis at FC, and the mucosa-associated microbiome was assessed by sequencing the 16S rRNA gene. POR was retrospectively defined as a composite of clinical recurrence (symptomatic worsening with objective evidence of inflammation within 6 months of symptom onset), change in CD-related therapy, endoscopic balloon dilation, or intestinal resection. We used Cox proportional hazards models to assess the risk of POR since FC. Alpha and beta diversity were analyzed at the ileal and colonic sides of the anastomosis using the *phyloseq* package. Differential abundance analysis between groups was performed employing *MaAsLin2*. False discovery rate of q<0.2 was considered significant.

Results: Sixty patients were included. Median age was 32.5 years [IQR 26-40.5], 53.3% were female, median disease duration was 9 years [IQR 2-15.5], median time from surgery to FC was 198 days [IQR 172-262], median follow-up was 4.2 years [IRQ 2.6-6.6]. 34 (56.7%) were mRS i0 group, and 26 (43.3%) were mRS i2a group. There were no significant differences in Montreal classification, smoking status, previous resection, biologic or non-biologic medication use at FC.

In multivariate analysis, mRS i2a was associated with a higher risk of POR after adjusting for previous surgical resection, penetrating behavior, and biologic use at FC (adjusted HR 5.15, 95% CI 2.24-11.87, p= 0.00012).

There were no differences in alpha or beta diversity on either side of the anastomosis. In the neo-TI, after adjusting for age, sex, and biologic use at FC, the genera *Lachnospiraceae NK4A136* (p=0.004, q=0.17) and *Klebsiella* (p=0.005, q=0.17) were more abundant in i0 and i2a, respectively. On the colonic side, the genera *Fusobacterium* (p=0.0012, q=0.038) and *Lachnospira* (p=0.01, q=0.15) were more abundant in i2a.

Conclusion: In CD patients with otherwise healthy neo-TI, we found a significantly higher risk of POR in those with anastomotic ulcerations. We found a differential microbiome composition on both sides of the anastomosis, suggesting putative taxa to be related to these lesions.

Introduction: Although the prognostic significance of cellular components of the immune system has been investigated in several solid neoplasms and is well established, the role of plasma cells in the tumor microenvironment has been neglected and only recently these cells are increasingly being appreciated as key players in the tumor microenvironment.

Aims & Methods: The purpose of our study is to explore the contribution of plasma cells to the immune microenvironment of colorectal adenocarcinomas and describe their correlation with prognosis.

In our study, a total of 108 patients with colorectal adenocarcinoma were included [68 men/40 women, median age (IQR): 70 (64-76) years, I-IV stage (AJCC/TNM 8th edition)] who underwent surgical resection between January 2004 to May 2008. Histological slides and paraffin blocks were retrieved from the archives of the Department of Pathology, Attikon University Hospital.

Tissue microarrays (TMAs) of 2 mm diameter were constructed with representative areas from the center and periphery of the tumor. Immunohistochemical stains were performed on TMAs to detect the presence of plasma cells (CD138) and cells of adaptive immunity (CD3, CD4, CD8, CD20). Tertiary lymphoid structures (TLS) were assessed on hematoxylin-eosin-stained slides.

Depending on the number of plasma cells, the cases were classified into the following categories: absence of plasma cells or presence of rare single cells, presence of rare small aggregates (>5 cells/aggregation), presence of frequent aggregates, presence of large aggregates or sheets of plasma cells. Clinical and pathologic information was acquired from hospital medical records including patient's outcome and survival.

Results: Increased number of plasma cells (presence of frequent aggregates, presence of large aggregates or sheets of plasma cells) was observed in 70 cases (65%), while absence or rare aggregates of plasma cells was demonstrated 38 cases (35 %). The presence of large aggregates or sheets of plasma cells in the tumor was significantly associated with the presence of TLS (p=0.004) and tumor infiltration by increased numbers of CD3$^+$, CD8$^+$ T, and CD20$^+$ B lymphocytes compared with the absence of plasma cells or the presence of rare single plasma cells (p=0.025, p=0.012, p=0.001, respectively).

Moreover, it was reported that the presence of an increased number of plasma cells compared with the absence of plasma cells in the center of the tumor is significantly correlated to a more favorable prognosis (77 vs 47 months; p=0.047; p<0.05).

Conclusion: In patients with colorectal adenocarcinoma, the presence of high densities of plasma cells in the tumor bed may be associated with increased adaptive immune cell populations in the tumor environment, as well as with longer patient's survival. Consequently, a careful evaluation of plasma cells and a better understanding of their role in the tumor microenvironment of colorectal cancer seems to be crucial in order to design efficient immunotherapeutic strategies.

IMMUNOHISTOCHEMICAL STUDY OF MYC ONCOGENE EXPRESSION IN COLORECTAL ADENOCARCINOMAS AND CORRELATION WITH CELLULAR COMPONENTS OF ADAPTIVE IMMUNITY IN THE TUMOR MICROENVIRONMENT

K. Dimopoulou[1], I. Lappas[2], A. Spathis[2], A. Athanasiadou[2], C. Papamichail[2], E. Lumani[2], T. Argyropoulos[3], I. Panayiotides[2], P. Foukas[2]

Contact E-Mail Address: conu_med@hotmail.com

Introduction: The *MYC* oncogene plays a pivotal role in variable cellular functions including proliferation, differentiation, metabolism, protein synthesis, survival and apoptosis, while it is also considered a crucial regulator of tumor immune microenvironment.

Aims & Methods: The purpose of our research is the evaluation of the immunohistochemical expression of MYC protein in primary colorectal adenocarcinomas and its correlation with prognosis, as well as with the qualitative and quantitative characteristics of the immune microenvironment.

In our study, a total of 94 patients with colorectal adenocarcinoma were included [59 men/35 women, median age (IQR): 71 (44-88) years, I-IV stage (AJCC/TNM 8th edition)] who underwent surgical resection between January 2004 to May 2008. Histological slides and paraffin blocks were retrieved from the archives of the Department of Pathology, Attikon University Hospital. Tissue microarrays (TMAs) of 2 mm diameter were constructed with representative areas from the center and the periphery of the tumor. Immunohistochemical stains were performed on TMAs to detect the expression of MYC and Ki67 (proliferation index) by neoplastic cells and the presence of adaptive immunity (CD3, CD4, CD8, CD20) cells. MYC immunostaining in >20% of neoplastic cells was scored as positive (over-expressed). Clinical and pathologic information was acquired from hospital medical records including patient's outcome and survival.

Results: MYC over-expression (>20%) in the center and periphery of the tumor was observed in 59 patients (63%) and is significantly associated with tumor infiltration by increased number of CD3+, CD4+, CD8+ T and CD20+ B lymphocytes as well as with an increased index of cell proliferation Ki-

67 (p<0.001). In addition, positive MYC expression in the tumor periphery is significantly correlated with longer overall survival compared to cases with weak MYC expression (70 vs 48,5 months; p=0.046; p<0.05).

Conclusion: In patients with colorectal adenocarcinoma, increased MYC expression by neoplastic cells is associated with increased densities of adaptive immune cells in the tumor microenvironment. In addition, it is associated with a favorable prognosis, possibly through a more effective antitumor immune response. Consequently, the expression of MYC might be a useful predicting indicator of anti-tumor immunity status and patient's prognosis.

Introduction: Mastocytosis is a heterogeneous disorder characterized by abnormal mast cell proliferation in one or more organs that induces cutaneous and/or systemic symptoms. While gastrointestinal (GI) symptoms are frequently reported (prevalence ~60%), no surrogate markers have been investigated yet.

Aims & Methods: This study aimed to explore disease-specific markers and their link to gastrointestinal symptoms in mastocytosis. Plasma samples were collected from patients with mastocytosis, including patients with cutaneous mastocytosis (CM), indolent systemic mastocytosis (ISM), and Advanced SM (AdvSM). The presence of GI symptoms was registered. Patients with polycythemia vera (PCV), a stem cell disorder characterized by sludging of blood, were included as controls. In total, 276 systemic proteins were analyzed by Proximity Extension Assay using the OLINK Target 96 Cardiovascular II and III, and Immune response panels. Relative protein concentrations, expressed in NPX ($\log_2$ Normalized Protein eXpression), were analyzed using Principal Component Analysis (PCA), linear regression of protein adjusted values (for age and sex) and the Boruta algorithm (based on random forest) in R. Mann-Whitney U test, false discovery rate and Spearman correlation were applied for univariate analyses (GraphPad Prism 9).

Results: A PCA based on the systemic proteomic profile (SProtP, n=275 detected proteins) of mastocytosis patients revealed 1 cluster of CM (n=15) and ISM (n=81) patients that separated away from AdvSM (n=12) patients. A separate PCA confirmed the ISM and AdvSM centroid distance (p<0.001). Feature selection with boruta confirmed 29 markers to be relevant for the outcome ISM (vs AdvSM), the majority found in low levels such as the Interleukin 1 Receptor Type 1 (IL-1RT1) (FDR-adjusted p value (q)<0.001), and inhibitory receptor Lymphocyte Activating 3 (LAG3) (q<0.01). Both ISM and AdvSM groups showed a distinct SProtP against PCV patients, respectively, in separate PCAs (p<0.001). For the outcome ISM (vs PCV), high levels of the mast cell mediator Tryptase α/β 1 (TPSAB1) (q<0.0001) and Mast Cell Immunoglobulin Like Receptor 1 (MILR1) (q<0.0001) and low levels of Fibroblast Growth Factor 2 (FGF2) (q<0.0001) were confirmed among the 27 relevant markers. For the outcome AdvSM (vs PCV), 25 relevant markers were found in high levels, including MILR1 (q<0.001), IL-1RT1 (q<0.0001), and Granulin Precursor (GRN) (q<0.0001).

Upper and/or lower GI manifestations were often reported within the mastocytosis group: 53.3% (n=8) CM, 73.1% (n=57) ISM, and 58.3% (n=7) AdvSM. ISM patients that reported GI manifestations (/GI+) showed higher levels of MILR1 (4.3 (3.9-5.0) vs 4.07 (3.4-4.3), p<0.01) and Transferrin Receptor protein 1 (TR) (4.9 (4.3-5.3) vs 4.36 (4.0-4.9), p<0.05) than patients without GI symptoms (GR-). In contrast, AdvSM/GI+ patients weakly tended to show higher NPX values than patients GI- manifestations (p>0.05). In addition, plasma TPSAB1 levels of ISM/GI+ patients correlated with MILR1 levels (r=0.45; 95%CI (0.2-0.6), p<0.001), while in patients with ISM/GI- TPSAB1 correlated moderately with FGF2 (r=0.6; 95%CI (0.2-0.8), p<0.01). No correlations were found between the top confirmed markers and TPSAB1 in AdvSM, regardless of the presence of GI symptoms.

Conclusion: Distinct systemic proteomic profiles, and specific plasma markers, of ISM and AdvSM patients support different disease mechanisms. While some of these markers might be associated with the presence of GI symptoms, further investigations are needed.

FECAL CALPROTECTIN AMONG OTHER PREDICTORS IN EVALUATION OF PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

A.M. Mahros[1], E. El Shenawy[1], M. Hussien Ahmed[1]

[1]Kafr El Sheikh University, Gastroentrology, Hepatology and Infectious Disease, Kafr Elsheikh, Egypt

Contact E-Mail Address: dr.mm63@yahoo.com

Introduction: Familial Mediterranean fever (FMF) is auto-inflammatory disease presented by repeated episodes of fever and serositis. intestinal inflammation is a sub-clinical process occur during FMF attacks[1]. Fecal calprotectin is a simple tool for assessment of the intestinal inflammation[2].

Aims & Methods: The aim was to assess the fecal calprotectin as new marker of FMF and predictor of response to colchicine.

Methods: We included patients diagnosed with FMF according to the Yalçınkaya criteria and confirmed by PCR for the gene in our outpatient clinic at Kafrelsheikh University Hospital between May 2020 and May 2022. Patients subjected to history taking, clinical and laboratory evaluation. We excluded patients with other causes of raised FC such as those who took NSAID or known to have IBD. The fecal Calprotectin was measured and level more than 50 µg/g were considered abnormal.

Results: we included 158 patients. Among them 102 patients were females, and 56 were males. Largest number of patients was diagnosed at age of twenties. Only 5 patients were diagnosed at fifties. 72 (45.57%) patients had more than 6 attacks. Attacks last in 73.42% of patients for less than 48 hours. About 60.76% patients had negative parent consanguinity and 18.99% patients had history of abdominal surgery. 130 patients had heterozygous mutation; 28 patients had homozygous mutations confirmed by PCR. Fecal calprotectin level at time of diagnosis between the two groups. Heterozygous group level was 69.92 ± 30.92 while Homozygous was 158.21 ± 47.33. the cut off value of Calprotectin level was 100 pg/ml had 96.40% sensitivity and 96.60% Specificity Calprotectin level have negative correlation with Colchicine dose needed.

Conclusion: Our result suggests faecal Calprotectin can by used among as predictors of FMF attacks and indictor for adequate colchicine response. fecal calprotectin levels may be used to screen severity intestinal inflammation in Homozygous and heterozygous.

TISSUE-NONSPECIFIC ALKALINE PHOSPHATASE (TNAP) ALTERS SYSTEMIC INFLAMMATION IN CECAL SLURRY-INDUCED SEPSIS

A. Seguí-Pérez[1], M. Tena-Garitaonaindia[1], D. Ceacero-Heras[1], Á. Jiménez-Ortas[1], G. Ruiz-Henares[2], J.L. Millán[3], F. Sánchez de Medina[2], O. Martínez-Augustin[1]

Contact E-Mail Address: mireiatena@ugr.es

Introduction: Sepsis is defined as organic dysfunction related to a disordered response to infection. Alkaline phosphatases catalyze the hydrolysis of phosphate groups from different substrates, such as bacterial lipopolysaccharide (LPS), an important mediator in the pathophysiology of sepsis (1). Different studies have confirmed that intestinal alkaline phosphatase (IAP) reduces intestinal permeability, intestinal inflammation, bacterial translocation and, as a consequence, systemic inflammation (2, 3). However, several studies have demonstrated the importance of the tissue-nonspecific alkaline phosphatase (TNAP) isoenzyme in inflammatory processes (4).

Aims & Methods: We aimed to investigate the effect of TNAP in polymicrobial sepsis induced by cecal slurry (CS) injection using TNAP heterozygous mice ($TNAP^{+/-}$) and an inhibitor of TNAP (SBI-425). Mice underwent intraperitoneal injection of 1 mg CS/kg and were sacrificed after 24 h. Body weight loss and mice behavioral outcomes were determined. LPS level in plasma was determined. In addition, permeability to oral fluorescein isothiocyanate-dextran 4 kD (FITC) was assessed. Finally, RNA extraction and RT-qPCR were carried out for gene expression analysis.

Results: CS-induced sepsis resulted in dramatic weight loss and a significant impact on mice behavioral outcomes, with no differences between groups. The polymicrobial infection was associated to high presence of LPS in septic mice plasma, which triggered a systemic inflammatory response. Namely, sepsis caused intestinal barrier defect (higher concentration of FITC-dextran in plasma) and increased inflammatory cytokines in the colon. In this context, TNAP haplodeficiency or inhibition diminished the expression of certain inflammatory markers (*S100a8* and *Cxcl1*, the latter only in heterozygous mice). The same dampening of inflammatory marker expression was observed in the liver, kidney and particularly in the lung (*Cxcl1*, *Cxcl2*, *Il6* and *Il10*). SBI-425 had a less pronounced effect at this level.

Conclusion: These preliminary results show that TNAP haplodeficiency or inhibition modulate CS-induced sepsis, resulting in attenuated inflammatory response.

Introduction: Mast cells are the primary cells that cause acute and chronic colitis due to irradiation causing radiation-induced colitis (RIC). Herein, we investigated whether pre-treatment with tranilast, mast cell inhibitor, could alleviate RIC.

Aims & Methods: A total of 23 Sprague Dawley (SD) rats were randomly divided into three groups control (n=5, C), irradiation group (n=9, RG), and tranilast pre-treated irradiation group (n=9, TG). Tranilast (100 mg/kg) was administered with meal for 10 d to TG, then Gamma ray (20 gray single dose) was irradiated to the pelvis of RG and TG. Ten weeks after irradiation, the rats were euthanized. Rectal tissue samples were stained and the total inflammation score (TIS) and mast cell count were assessed histopathologically. Expression of MUC2, MUC5AC and matrix metalloproteinase (MMP)-9 were also assessed immunohistochemically

Results: Either TIS or some components of TIS including epithelial atypia, vascular sclerosis and colitis cystica profunda, were significantly higher in RG than in TG (p=0.02, 0.038, 0.025, 0.01, respectively). The median number of infiltrating mast cells was significantly higher in the RG (27.5±18.40)) than in TG (6.0±6.02) (P=0.034). Quantitatively, the number of MMP-9-positive cells was significantly higher in the RG (23.67±19.00) than in the TG (10.25±8.45) ($p<0.05$).

Conclusion: TIS and MMP9 exhibited strong associations (correlation coefficient r=0.6, $p<0.05$) Immunohistochemically, mucin-lake of CCP showed MUC2 positivity only but was negative for MUC5AC. Conclusively, tranilast pretreatment in RIC shows an anti-inflammatory effect on the RIC with reducing mast cell infiltration and MMP expression

Disclosure: Nothing to disclose.

Introduction: Sepsis is defined as an organic dysfunction that threatens the life of patients due to an abnormally regulated response to infection [1]. The initial phase of sepsis is dominated by an increased production of proinflammatory cytokines, which leads to augmented capillary permeability, extravasation, hypercoagulability and myelopoiesis. One of the main sources of infection in sepsis is believed to be the intestinal microbiota via traslocation through the mucosa to the bloodstream. Systemic inflammation weakens intestinal barrier function (IBF) in animal models, resulting in increased bacterial traslocation [2].

Even if the management of sepsis has advanced in the last decades, mortality is still high and there is room for improvement. Thus, the search for effective treatments is clearly justified. Glucocorticoids (GC) constitute a therapeutic modality in sepsis, but they have only shown moderate benefit. This may be accounted for by the harmful effects of GCs on IBF, which may facilitate translocation of luminal microorganisms and molecules. Besides, GC treatment impairs epithelial healing in experimental colitis in mice [3]. Previous results of our research group have shown that mice with induced deletion of the GC receptor (GR) in intestinal epithelial cells (i.e. NR3C1$^{\Delta IEC}$ mice) are protected against dextran sulphate sodium (DSS)-induced colitis [4].

Aims & Methods: Our aim is to understand the role of the intestinal epithelial GR and its involvement in IBF regulation in experimental sepsis, with the ultimate goal of improving the management of sepsis with GCs.

The cecal ligation and puncture (CLP) model of sepsis was applied to WT C57BL/6J and NR3C1$^{\Delta IEC}$ mice. Caecum-exposed mice were used as control (sham). Mice were sacrificed 24 hours after surgery. Four hours before sacrifice, mice were administered 4 kD FITC-dextran, a fluorescent marker of permeability. Colon, jejunum, adrenes, kidney and liver RT-qPCRs were performed as well as determination of corticosterone plasma levels.

Results: After 24 h, CLP mice exhibited hypoglycemia and splenomegaly with elevated corticosterone plasma levels, which were associated to increased *Cyp11a1* in the adrenes. Of note, both parameters were less pronounced in KO mice. Intestinal barrier function was weakened, as indicated by downregulation of *Tjp1* and increased FITC-dextran plasma levels, which were similar in WT and KO mice. A modest increase in inflammatory markers was noted in the colon and jejunum. However, KO mice exhibited dampened inflammatory response in the colon, with lower expression of inflammatory markers such as *S100a8* and *S100a9*, but not in the jejunum. Similarly, the colonic expression of *Cyp11a1* and *Lrh1*, involved in local steroidogenesis, was lower in CLP mice, regardless of genotype. WT but not KO mice showed an increased in of tissue non-specific alkaline phosphatase (TNAP) in liver, an enzyme involved in detoxification of phosphorylated molecules such as bacterial lipopolysaccharide, but lower expression of *Tsc22d3,* whose role is described to be protective against sepsis [5]. Inflammation markers were also augmented in the lung and kidney.

Conclusion: In the early stages of the CLP model of sepsis the colon and jejunum are inflamed, and epithelial deletion of the glucocorticoid receptor appears to modulate colonic inflammation, but not barrier function or systemic status.

DEPLETION OF BUTYRATE-PRODUCING MICROBES OF THE FIRMICUTES PREDICTS NONRESPONSE TO FMT THERAPY IN PATIENTS WITH RECURRENT *CLOSTRIDIUM DIFFICILE* INFECTION

H. Tian[1], X. Wang[1], Q. Chen[1], H. Qin[1]

[1]Tenth People's Hospital of Tongji University, Department of Colorectal Disease, Shanghai, China

Contact E-Mail Address: baiyi_nanjing@163.com

Introduction: Nearly 10% of *Clostridium difficile* infection (CDI) patients do not respond to fecal microbiota transplantation (FMT) treatment. Conducting clinical FMT studies to reveal microbiome characteristics of FMT-refractory patients is crucial for devising precise treatments for CDI, especially recurrent CDI (rCDI).

Aims & Methods: Twenty-three rCDI patients with parallel clinical baselines were recruited for FMT. Ten FMT donors meeting strict health standards were screened out from thousands of healthy people, and 171 stool samples were collected as healthy controls. Fecal samples were collected from 4 donors continuously for 25 weeks to evaluate the impact of microbiota fluctuation on FMT application.

Results: Seven of 23 patients didn't respond to FMT treatment. The microbiome characteristics of non-remission patients showed significantly reduced α-diversity indexes. Butyrate-producing bacteria of the Firmicutes, including *Bifidobacterium*, *Christensenellaceae_R_7_group*, *Ruminococcaceae_unclassified*, *Veillonella*, *Coprococcus_2*, *Fusicatenibacter*, *Oscillospira*, and *Roseburia*, were almost completely depleted before treatment. *Burkholderiales_unclassified*, *Coprococcus_2*, and *Oscillospira* failed to colonize patient guts before and after treatment. Patients with good prognosis were characterized by a high relative abundance of *Veillonella* before treatment relative to its general depletion in patients with poor prognosis. Genera interactions in lower effectiveness FMT donors were more similar to those in non-remission patients, and *Burkholderiales_unclassified*, *Coprococcus_2*, and *Oscillospira* were frequently depleted in these donors. Older patients were not conducive to the colonization of *Veillonella*, consistent with their poor prognosis after FMT. rCDI patients with Crohn's disease were only found in the non-remission group.

Conclusion: rCDI patients with poor prognosis from FMT have characteristics unfavorable to Firmicutes butyrate-producing microbe colonization.

ASSOCIATION OF FECAL SHORT-CHAIN FATTY ACID LEVELS WITH CONSTIPATION SEVERITY IN SLOW TRANSIT CONSTIPATION

T. Yu[1], Y. Tang[1]
[1]The First Affiliated Hospital with Nanjing Medical University, Gastroenterology, Nanjing, China

Contact E-Mail Address: njmuyt@163.com

Introduction: Intestinal short-chain fatty acids (SCFAs) are significantly reduced in patients with constipation, and changes in distal colon transport function are related to fecal SCFAs content.

Aims & Methods: We aimed to identify the content of microbial metabolites SCFAs in feces of patients with slow transit constipation (STC), and its relationship with the severity of constipation and the quality of life. All Participants (patients with STC and controls) were included in the Gastroenterology outpatient Department and physical examination Center of First Affiliated Hospital of Nanjing Medical University from August 2021 to January 2022. Fecal samples of the two groups were collected and fecal supernatant was isolated. The nature and concentration of SCFAs in feces of the two groups were determined by gas chromatography-mass spectrometry (GC-MS), the differences of SCFAs and its diagnostic value for STC were analyzed. Questionnaires were conducted in patients with STC, including Constipation Scoring System (CSS), Patient Assessment of Constipation Symptoms questionnaire (PAC-SYM), and Patient Assessment of Constipation Quality of Life questionnaire (PAC-QOL), to analyze the correlation between fecal SCFAs level and the severity of constipation or the quality of life in patients with STC.

Results: A total of 32 patients were included (STC group[n=16], control group[n=16]). The total SCFAs content in STC group was lower than that in healthy control group (475.85±251.68 vs 639.77±213.97, P=0.056). The contents of acetic acid and propionic acid were significantly decreased (149.06±88.54 vs 261.33±109.75, 100.60±60.62 vs 157.34±66.37, P <0.05). Isobutyric acid and isovaleric acid increased (27.21±15.06 vs 18.16±8.65, 31.78±18.81 vs 16.90±10.05, P<0.05). Acetic acid and propionic acid were the main components of SCFAs, and there were significant differences between STC group and healthy control group. The ROC curve showed that the AUC of acetic acid and propionic acid were 0.79 and 0.74, respectively. At acetic acid concentrations of 252.21 ug/ml, the specificity and sensitivity to distinguish heathy people from STC was 93.7% and 56.3%. Total SCFAs, acetic acid, and propionic acid concentrations in STC patients' fecal supervenient were negatively correlated with CSS (r=-0.751,-0.618, all P<0.05), but not with PAC-SYM scores and PAC-QOL scores.

Conclusion: The content of SCFAs in fecal supernatant of STC patients was decreased, and the content of acetic acid and propionic acid was significantly decreased. The contents of acetic acid and propionic acid were negatively correlated with the severity of constipation, and could be used as an indicator to evaluate the diagnosis and severity of constipation. Distinguishing patients with STC with SCFAs alteration may guide the individualized treatment of STC.

Disclosure: Nothing to disclose.

Introduction: Despite advancements in treatment strategies, cardiovascular diseases continue to be a leading cause of death worldwide and persist as a major public health concern. Therefore, it is important to seek new potential therapeutic targets. The gut microbiome is suggested to play a role in the development of coronary artery disease (CAD). Studies have shown different microbiome compositions in patients with CAD (Gao, Kwun), however, it is not yet completely understood whether these dysbiosis signatures are causative for CAD or are a consequence of the disease.

Aims & Methods: In this study, we aimed to investigate whether dysbiosis signatures of CAD are already present in individuals at risk. We conducted a cross-sectional study using shotgun metagenomic sequencing to analyze 411 fecal samples from individuals with low (n=130), intermediate (n=130), and high (n=125) cardiovascular risk, as well as those with ST-elevation myocardial infarction (STEMI) (n=26). Cardiovascular risk was calculated by using the Framingham score. We analyzed alpha and beta diversity in the gut microbiome, as well as the differential abundance of species and functional pathways among the groups.

Results: We identified 8 species and 49 pathways to be differently abundant among the different groups. These findings included an increase of *Collinsella stercoris* abundance with increasing cardiovascular risk (STEMI vs risk groups; coefficient = 1.75, FDR = 0.005), and reduced abundance of *Bacteroides vulgatus* and *Bacteroides uniformis* in the STEMI group compared to the risk groups (respectively; coefficient = -2.28, FDR = 0.013 and coefficient = -1.35, FDR = 0.019). Differential abundance analysis of the pathways identified four upregulated pathways linked to starch biosynthesis and phenolic compound degradation in the STEMI group compared to groups with lower risk. All other differently abundant pathways were decreased in the STEMI group in contrast to other groups. These pathways were associated with many processes such as nucleotide biosynthesis, fatty acid and lipid biosynthesis, and carbohydrate biosynthesis. We did not find significant trends in Shannon diversity and beta diversity.

Conclusion: Our study revealed that specific species and pathways were differently abundant in STEMI patients compared to groups with varying cardiovascular risk. These species are promising candidates for further investigation to improve our understanding of their role in CAD. Our study underscores the need for experimental studies, using culturomics and intervention trials, to gain further insights into the directional and causal relationships of specific gut microbial species in CAD.

Contact E-Mail Address: chinheesong@gmail.com

Introduction: Ninjurin1 (Ninj1), a transmembrane protein, has been implicated in exhibiting dual roles, both pro-inflammatory and anti-inflammatory, in the pathogenesis of inflammatory diseases.

Aims & Methods: The objective of this study was to examine the involvement of Ninj1 in the development of colitis-associated colon tumor, as well as its potential association with sex hormones. Male and female mice, both wild-type (WT) and Ninj1 knockout (KO), that were treated with azoxymethane (AOM) and dextran sulfate sodium (DSS), were sacrificed at week 2 and 13 after AOM injection, with or without additional treatment of 17β-estradiol (E2) or testosterone propionate (TP). Clinical symptoms, histological severity of colitis, the levels of inflammatory mediators, and tumor number in the colon from the mice were evaluated.

Results: In male mice, the scores of disease activity index (DAI) and colonic epithelial damage and the ELISA levels of IL-6 and IL-1β increased by AOM/DSS treatment were significantly decreased by E2 treatment in WT group (Table). Compared to WT, the scores and the ELISA levels increased by AOM/DSS treatment were lower in the Ninj1 KO group, and the inhibitory effect of E2 was also attenuated in the Ninj1 KO group.

Interestingly, a large tumor number exceeding 2 mm in size generated from a distal colon was also significantly lower in the Ninj1 KO group than in the WT group, and the inhibitory effect of E2 was also attenuated in Ninj1 KO group (Table). In female mice, DAI and damage scores increased by AOM/DSS treatment were lower in Ninj1 KO group than in WTs (Table). However, the effect of TP supplementation only showed a tendency to increase scores in both the WT and Ninj1 KO groups. In female mice, there was no difference in the larger tumor number generated by AOM/DSS treatment between WT and Ninj1 KO, but the tumor promoting effect of TP was significantly increased in the Ninj1 KO group (Table).

Interestingly, the tumor-promoting effect of TP showed a significant increase in the KO group than in the WT in proximal colon in female mice.

		Proximal colon	Distal colon	Whole colon
WT male	Con. *vs.* AOM/DSS	-	* (increase)	* (increase)
	AOM/DSS *vs.* AOM/DSS+E2	-	* (decrease)	* (decrease)
Ninj1 KO male	Con. *vs.* AOM/DSS	* (increase)	* (increase)	* (increase)
	AOM/DSS *vs.* AOM/DSS+E2	-	-	* (decrease)
WT female	Con. *vs.* AOM/DSS	* (increase)	* (increase)	* (increase)
	AOM/DSS *vs.* AOM/DSS+TP	-	-	-
Ninj1 KO female	Con. *vs.* AOM/DSS	* (increase)	* (increase)	* (increase)
	AOM/DSS *vs.* AOM/DSS+TP	* (increase)	* (increase)	* (increase)

*, $P < 0.05$; WT, wild-type; Ninj1, ninjurin1; KO, knockout; Con., control; AOM/DSS, azoxymethane/dextran sulfate sodium; E2, 17β-estradiol; TP, testosterone propionate.

Table. Summary of occurrence tumors by colon location.

Conclusion: In terms of inflammation or tumor development, the effect of Ninj1 KO was stronger in males than in females. In particular, the suppressive effect of E2 was weakened in the Ninj1 KO group, while the promoting effect of TP was strengthened in the Ninj1 KO group.

Taken together Ninj1 look like to promote colorectal tumorigenesis in in males, which was opposite to that of estrogen. Investigation of its underlying mechanism of Ninj1 is undergoing by molecular experiments.

EFFECT OF PROBIOTIC (VIVOMIXX) ON GUT MICROBIOME AND SHORT CHAIN FATTY ACIDS IN HEALTHY ASIAN VOLUNTEERS - A PILOT EXPLORATORY RANDOMIZED CONTROLLED TRIAL

S.H.K. Koo[1], Y.B. Tan[1], C.K. Tan[1], F.M. Manejero[1], S.W.D. Ang[1], T.-L. Ang[1]
[1]Changi General Hospital, Singapore, Singapore

Contact E-Mail Address: tanyubin89@gmail.com

Introduction: Gut dysbiosis is implicated in various gastrointestinal and metabolic diseases. Probiotics is known to have favorable effects on gut microbiota and the production of essential short chain fatty acids (SCFA), albeit with inconsistent findings. The effects of bowel cleansing on the intestinal microbiota have been characterized, however the impact of administering probiotics following a colonic lavage on the intestinal microbiota has not been studied. Rifaximin has also been shown inconsistently in studies to affect the gut microbiome. In addition, treatment with probiotic for a duration of 4 weeks was demonstrated to modulate intestinal bacterial taxa in healthy adults.

This pilot study examined the effects of a probiotic (vivomixx), with and without pre-treatment with colonic lavage or rifaximin, on the gut microbiome, SCFA and its recovery.

Aims & Methods: This is a single centre, exploratory randomized controlled study on healthy Asian adult volunteers. Participants were randomized equally to four study groups: (A) Colonic lavage using polyethylene glycol (PEG), followed by 4 weeks of vivomixx; (B) Colonic lavage, followed by 4 weeks of placebo; (C) 4 weeks of vivomixx; and (D) 2 weeks of rifaximin, followed by 4 weeks of vivomixx. Stool samples were collected at baseline, 4 weeks and 8 weeks after the administration of vivomixx or placebo.

Additionally, Group A, B and D had stools collected before and after administration of PEG (Group A, B) or rifaximin (Group D). All stools were subjected to 16S rRNA sequencing for microbiome and SCFA analysis by gas chromatography mass spectrometry.

Results: A total of 32 participants were recruited, 1 in Group C dropped out after the first visit, leaving 31 in the final analysis. All three exposure elements – PEG, rifaximin and vivomixx resulted in large microbiome composition changes. Exposure of PEG also resulted in significant changes to SCFA concentrations. Pre-treatment with colonic lavage deterred engraftment as evidenced by the smaller increase in abundance of *Bifidobacterium* in Group A and B as compared to those without PEG (Group C). There was apparent selective engraftment of *Lactobacillus* after rifaximin treatment (Group D) and this was also shown in the SCFA analysis where the concentrations of Acetic, Butyric and Propionic acids, which are byproducts of *Lactobacillus* increased after Rifaximin treatment prior to vivomixx. This increase seems sustained at 8 weeks. There was also a trend of sustained vivomixx effects on gut microbiome at 4 weeks after stopping the probiotic.

Conclusion: Vivomixx demonstrated favorable impact on gut microbiome composition but its impact on SCFA in this study was minimal. Rifaximin however, has been shown to increase SCFA concentrations and this increase was sustained 8 weeks after probiotics was given. The data provide valuable insights for designing future trials. The modulation of gut microbiome and SCFA is a potential treatment target in diseases associated with gut dysbiosis.

Introduction: Gut microbiome is supposed to influence on both digestive and distant organs including brain, muscle and skin. Skin, the largest organ of our body parts, protects our inner body as a physical barrier; thus, it is important to maintain its better condition and to prevent various skin diseases.

The influence of gut microbiota on skin has been of great interest in public, yet the mechanism remains unclear in science, supposedly under the complex interaction between skin microbiome, inner body condition including gut microbiome, and outer environment. Today, some positive functions of oral probiotics on skin condition are reported such as skin hydration and anti-inflammation, although the effects have been studied only recently. Among them, Bifidobacterium is one of the most studied bacteria on skin function and its anti-inflammatory and/or photoprotective effects are suggested in both mice and humans.

Aims & Methods: In this study, we aim to investigate the effect of oral *B. breve* M-16V on the facial skin surface in human.

In a randomized double-blind placebo-controlled trial, 120 adult east Asian women aged 30-79 years with no undergoing clinical treatment on face skin were enrolled. Participants received *Bifidobacterium breve* M-16V ($1´10^{10}$ CFU) or placebo twice daily for 12 weeks. Facial skin condition was evaluated objectively by dermatologist and Canfield VISIA evolution, at baseline, 4 weeks, 8 weeks and 12 weeks.

The condition was also rated subjectively by participants themselves at each check point. Daily lifestyle including diet, sleep and exercise was stated on questionnaire and participants were asked not to change their lifestyle during the study. The primary outcome was the total VISIA score at each check point. All the objective and subjective skin scores were also analysed.

Results: The data of 120 participants (59 probiotic, 61 placebo) were collected from September 2021 to January 2022 in Tokyo, Japan. The absolute count of brown spots significantly decreased at week4 in probiotic group (p=0.011) while it worsened in placebo group at week12 (p=0.001). The count from the baseline showed statistical improvement in probiotic group than placebo at week4 (p=0.008) and week 8 (p=0.030). The feature score of brown spots also showed improvement in probiotic group at week4 (p=0.001) and week8 (p=0.05), and the change from the baseline at week4 was better than placebo (p=0.011). The feature score of wrinkles worsened in both groups throughout the study. The subjective evaluation of skin moisture, wrinkles and bowel movement improved in probiotic group at week12.

Subjective evaluation of overall skin condition improved in both groups. The mean total VISIA score was tended small in probiotic group at week12 (-0.025) but did not show statistical difference (p=0.38). Adverse events were seen in 37.3% of the participants.

There were no serious adverse events during the trial. The major adverse events were dermatological problems such as folliculitis (13.6% in probiotics and 11.5% in placebo), the common cold symptoms (10.2% in probiotics and 11.5% in placebo) and digestive symptoms including diarrhea (10.2% in probiotics and 9.8% in placebo). The frequency of adverse events was not statistically different between both groups.

Conclusion: Oral intake of *B. breve* M-16V appears to benefit skin condition by improving facial skin brown spots and bowel movement. It may also improve facial wrinkles and moisture.

Disclosure: Nothing to disclose.

THE CLINICAL SYMPTOMS AND INTESTINAL FLORA OF TIBET PATIENTS DIFFERS FROM HAN WITH IBS

H. Huan[1], C. Liu[1], L. Hu[1]
[1]Hospital of Chengdu Office of People's Government of Tibetan Autonomous Region, Chengdu, China

Contact E-Mail Address: 1276613141@qq.com

Introduction: Irritable bowel syndrome (IBS) is characterized by abdominal pain or distension with the disorder of bowel habit and stool. It is believed that the changes of gut microbiota may play a major role in the occurrence and development of IBS. T

o date, few studies have focused on the clinical features and intestinal flora of IBS in the Tibetan population.

Aims & Methods: In this study, we aimed to compared the difference between the Tibets and Hans of IBS patients. This prospective single-center randomized controlled trial was designed and conducted in the Department of Gastroenterology, Hospital of Chengdu Office of People's Government of Tibetan Autonomous Region, PR China. The study was approved by the Medical Ethics Committee (approval number: (2018) study No. 20). Patients meeting inclusion and exclusion criteria were grouped by their race to the Tibet group and the Han group. All enrolled patients were received conventional management. Besides, a simplified GSRS-based questionnaire, including five dimensions of IBS-related symptoms, was used to assess the severity of IBS. The stool samples of all participants were collected for the analysis of gut microbiota by the 16sRNA Illumina sequencing analysis.

Results: From August 2018 to January 2019, a total of 45 patients with IBS admitted to the were recruited in this study, including 20 Han and 25 Tibetan, aged from 27 to 74 years old. The baseline data for the two groups were comparable. No significant difference was found in the total symptom score of the simplified GSRS-based questionnaire between the Han and Tibetan groups. But the symptom components varied in each dimension. According to symptom questionnaire, there was no significant difference in pain-related symptoms such as abdominal pain (13.93% *vs* 13.64%), pain frequency (13.43% *vs* 12.88%) and defecation pain (12.94% *vs* 11.36%) between the Tibetan and Han patients. However, it should be noted that Tibetans with IBS are more likely to suffer from bloating, and the proportion is significantly higher than that of the Han population(17.41% *vs* 9.09%, $p<0.001$).

Moreover, shift of gut microbiota were showed between two groups. At the phylum level, the Tibet group had a significantly higher proportion of Bacteroidetes than the Han group (38.16±28.15% *vs* 17.28±13.72%, $p=0.015$). In total, 20 taxa were significantly different between the Tibet and the Han group and the top-10 representative taxa. There was a significant negative correlation between genus Blautia and bloating scores (*Pearson* r = -0.33, $p=0.025$).

Conclusion: The characteristics of Tibet patients differs from Han with IBS, not only in the clinical symptoms, but also in the characteristics of intestinal flora. Tibetans with IBS are more prone to bloating, which might due to the gut microbiota. The genus Blautia might play a role in this mechanism.

Disclosure: Nothing to disclose.

THE CHARACTERISTICS OF *STRONGYLOIDES STERCORALIS* INFECTION: A SINGLE-CENTER EXPERIENCE IN VIETNAM

C. Nguyen[1], H. Huu Bui[1], N. Le[1], L. Dang[1], D. Bui[1]
[1]University Medical Center Ho Chi Minh City, Gastroenterology, Ho Chi Minh, Vietnam

Contact E-Mail Address: chuong.nd1@umc.edu.vn

Introduction: *Strongyloides stercoralis*, a soil-transmitted nematode, is one of the most overlooked tropical diseases. The infection is known to cause a potentially fatal syndrome in immunosuppressed individuals. Despite increased global awareness of Strongyloidiasis, data on this infectious disease is still lacking in Vietnam.

Aims & Methods: This retrospective study was carried out to describe the clinical and laboratory characteristics of strongyloidiasis cases in University Medical Center Ho Chi Minh City to aid in early diagnosis.

The data of patients who were admitted to the Gastroenterology Department of University Medical Center Ho Chi Minh City from January 2018 to December 2022 were examined. The diagnosis of Strongyloidiasis relies on identifying larvae in stool and/or the positive of the serologic test without prior treatment. The following information was collected: clinical manifestation, laboratory test, abdominal imaging, treatment course, and follow-up.

Results: A total of 163 patients who satisfied the inclusion criteria were retrospectively reviewed. Their median age was 68 (23-97) and male was predominant (73%). Abdominal pain (63.2%), nausea (50.3%), diarrhea (46%), and fatigue (76.7%) were the four most common symptoms. The immunocompromised state appears to be the risk factor for strongyloidiasis, with 64.4% of cases. Of which, long-term steroids use was the most prominent (23.3%). More than half of the cases (50.% and 57.1%, respectively) had hypereosinophilia and hypoalbuminemia. Severe hyponatremia is also a notable feature, accounting for nearly one-fifth of all cases (17.3%). In terms of imaging, signs and symptoms are nonspecific, including ascites, bowel dilation, or obstruction. Larvae were found in the stool in two-thirds of the cases (66%) and the serologic test was positive in 74.7% of the cases. Chronic strongyloidiasis accounted for the vast majority of cases (92.6%), with hyperinfection syndrome and disseminated strongyloidiasis accounting for a minor proportion (1.2% and 6.2%, respectively). A significant decrease in the eosinophil counts from baseline to one week after treatment (22.9% of cases), when median values were within the normal range. Except in 17 out of 163 cases (10.4%), the response to ivermectin was excellent.

Conclusion: Strongyloidiasis should be suspected in patients who are immunocompromised, have multiple chronic diseases, have gastrointestinal symptoms, eosinophilia and/or hypoalbuminemia.

Introduction: The gut microbiome plays a significant role in the development, progression, and treatment of various gastrointestinal (GI) diseases. However, analyzing the microbiome remains a time-consuming challenge, mainly due to the lack of validated methodologies that can extract DNA and RNA simultaneously. This study aimed to determine the impact of storage conditions and nucleic acid extraction protocols on the recovery and integrity of microbial genetic material from stool samples.

Aims & Methods: Stool samples from seven healthy individuals were stored under different conditions: in conventional stool collection tubes at room temperature (condition A); or in collection tubes with DNA stabilizer (INVITEK) at room temperature (condition B), at -20°C (condition C), or at -80°C (condition D). For DNA and RNA extraction, the Chemagic DNA Stool Extraction kit (Perkin Elmer) was used.

Although this kit was only validated for DNA extraction, modifications to the standard protocol were made to achieve RNA extraction. The yield and purity of both DNA and RNA were evaluated using the Nanodrop2000. The applicability of the kit for RNA extraction was ultimately assessed using 16s rRNA sequencing and whole viral genome sequencing (Illumina MiSeq).

Results: Collecting stool samples in tubes containing DNA stabilizer and keeping them frozen allowed for higher yields (mean DNA and RNA concentrations of 70±52 and 51±42ng/µl, respectively, for samples at -80°C vs. 61±41 and 50±45ng/µl at -20°C), with good purity. Conversely, significantly lower concentrations were obtained for samples at room temperature, particularly if tubes without stabilizer were used. Perkin Elmer's extraction kit successfully extracted DNA and RNA independently of RNase treatment, although higher yields were obtained without RNase (mean RNA concentrations of 150±123 vs. 51±42ng/µl). Whole genome sequencing confirmed the ability to extract and categorize viral material.

Nucleic acid	Condition	Nucleic acid	A260	A280	A260/280	A260/230
DNA	A	19.70 ± 9.15 ng/µl	0.81 ± 0.30	0.45 ± 0.16	1.54 ± 0.21	2.01 ± 0.55
	B	46.30 ± 20.17 ng/µl	1.12 ± 0.27	0.55 ± 0.16	1.84 ± 0.11	2.31 ± 0.69
	C	61.30 ± 41.10 ng/µl	1.47 ± 0.93	0.80 ± 0.41	1.78 ± 0.08	2.62 ± 0.62

Introduction: Recurrent urinary tract infections (rUTIs) affect up to 25% of women worldwide[1], with risk of antibiotic-related side effects and multidrug resistance. Several gut pathobionts, mainly Enterobacteriaceae, are responsible for nearly 90% of all UTIs, and gut microbiome imbalance has recently appeared as a main pathogenic pathway of UTIs[2]. Untargeted probiotics have provided conflicting results in this setting,[3-5] and current evidence does not support their use.[6] Gut microbiome testing are emerging as a promising diagnostic tool to target microbiome and offer a personalized therapeutic strategy, but their real value is unknown.
Aims & Methods: Our aim is to evaluate whether targeting gut microbiome is an effective strategy to prevent rUTIs derived from gut pathobionts.
In this pilot study, we included consecutive patients with rUTIs derived from gut pathobionts referring at our outpatient microbiome clinic in 2022. All patients underwent a commercially available stool microbiome testing (XMICROGem from XBIOGem) based on 16S rRNA analysis, performed as already described[7]. Then, patients received a targeted therapy based on results of the gut microbiome testing, with the aim of restoring a balanced microbiota. Non-adsorbable antibiotics were used to downregulate pathobionts' abundance, while prebiotics and probiotics were given to boost the abundance of specific taxa and/or to compete with pathobionts. Patients were followed up at least 12 weeks after the end of therapy.
We collected the following data of patients: age, gender, presence of gastrointestinal (GI) symptoms (assessed with GSRS), taxa responsible of UTIs; specific characteristics of gut microbiome (alpha diversity, abundance of Enterobacteriaceae, Escherichia, Klebsiella, Bifidobacteria, Akkermansia, and short-chain fatty acid producers including Lachnospiraceae, Faecalibacterium, Roseburia, Butyrivibrio); specific therapies given after testing, including non-adsorbable antibiotics, prebiotics, and probiotic strains. The primary outcome was the recurrence of UTIs, and the secondary outcome was gastrointestinal symptoms, at 12-week follow-up.
Results: Twelve patients were enrolled in the study period (n= 11 females, mean age 40 years). Of them, 11 (92%) presented with GI symptoms (67% with bloating, 50% with constipation, 50% with abdominal pain, 42% with dyspepsia, 17% with diarrhea). rUTIs were caused by *E. coli* in 11 patients and *E. faecalis* in one patient. The gut microbiome testing showed a decrease of alpha diversity in two patients (17%), of Akkermansia in eight patients (67%) and of SCFA-producers in seven patients (58%), as well as increased Proteobacteria in seven patients (58%). Moreover, Bacteroidetes were increased in four patients (33%) while Firmicutes were decreased in two patients (17%). Ten patients underwent rifaximin (83%) and two paromomycin (17%). *E. coli Nissle 1917* was used in seven patients (58%), five in combination with an *Enterococcus faecium-based* strain,one in combination with *Lactobacillus crispatus* M247, and one in combination with both. Multi-strains probiotics were used in 7 patients (58%). Prebiotics were administered in seven patients. At 12-week follow-up, nine patients (75%) were free from new episodes of UTIs, and eight patients (73%) experienced an improvement of GI symptoms.
Conclusion: A precision medicine strategy based on gut microbiome testing may be a promising approach to treat rUTIs and ameliorate associated GI symptoms. Well designed, randomized and larger studies are needed to confirm our preliminary findings.

Introduction: Gut microbiome alterations are known to be one of the pathogenic pathways of irritable bowel syndrome (IBS), mainly in its post-infectious form (PI-IBS) [1]. To date, untargeted therapeutic approaches have obtained conflicting results in patients with PI-IBS [2,3]

Gut microbiome testing are emerging as a promising diagnostic tool to target microbiota and offer a personalized therapeutic strategy, but their real value is still unknown.

Aims & Methods: Our aim is to evaluate whether a personalized approach based on gut microbiome testing is an effective strategy for PI-IBS.

In this pilot study, we included consecutive patients with PI-IBS, diagnosed according to the Rome IV guidelines[4], referring at our outpatient microbiome clinic in 2022.

All patients underwent a commercially available stool microbiome testing (XMICROGem from XBIOGem) based on 16S rRNA analysis and performed as already described[5]. Then, patients received a targeted therapy based on results of the gut microbiome testing, with the aim of restoring balance among the bacterial subpopulations of the gut microbiota. Non-adsorbable antibiotics were used to downregulate the abundance of pathobionts, while prebiotics and probiotics were given to boost the abundance of specific taxa and/or to compete with gut pathobionts. Patients were followed up to 12 weeks after the end of therapy.

We collected the following data of patients: age, gender, presence of gastrointestinal (GI) symptoms (assessed with the GSRS); specific characteristics of gut microbiome (alpha diversity, abundance of Proteobacteria, Firmicutes, Bacteroidetes, Bifidobacteria, Lactobacilli, Akkermansia, and short-chain fatty acid producers including Lachnospiraceae, Faecalibacterium, Roseburia, Butyrivibrio); specific therapy given after testing, including non-adsorbable antibiotics, prebiotics, and probiotic strains. The primary outcome was the resolution of at list one symptom, while secondary outcomes were the resolution of more than one (if present) and all of them at 12 weeks.

Results: Thirteen patients were enrolled in the study period (8 males, 5 females, mean age 31 years-old). Of them, 9 (69%) had IBS-D and 4 (31%) IBS-C. Nine patients (69%) had bloating, and 10 (71%) had abdominal pain at baseline. At gut microbiome testing: three (23%) patients presented with low alpha diversity, three (23%) with high abundance of Proteobacteria, five (38%) of Firmicutes. Seven (54%) patients presented with low abundance of SCFA-producing bacteria, eight (62%) of Akkermansia and nine (69%) of Bifidobacteria.

Patients were treated with the following non-adsorbable antibiotics: rifaximin in nine (69%) patients, and paromomicin in four (31%) patients. The following prebiotics and probiotic strains were used after antibiotics: multispecies probiotics in five patients (38%), Bifidobacterium-based probiotics in five patients (38%), Lactobacillus-based probiotics in eight patients (54%), and *Escherichia coli* Nissle 1917 in 2 (15%) patients; inulin and psyllium were used in nine (69%) patients.

At 12-week follow-up, 12 patients (93%) experienced an improvement of symptoms, with five of them (38%) experiencing a total remission of symptoms.

Conclusion: A precision medicine approach based on gut microbiome testing may be a promising strategy to treat PI-IBS. Well designed, randomized and larger studies are needed to confirm our preliminary findings.

Contact E-Mail Address: sevandrea96@gmail.com
Introduction: Clostridioides difficile infection is a major challenge for healthcare systems. Inflammatory bowel disease (IBD), including ulcerative colitis (UC) and Crohn's disease, is a risk factor for primary and recurrent CDI (rCDI). Moreover, CDI itself often worsens the clinical picture of IBD, increasing the risk of complications. Fecal microbiota transplantation (FMT) is a highly effective treatment for rCDI, but data from patients with IBD and CDI are limited and often referred to mixed cohorts.
Aims & Methods: We aimed to report outcomes from a cohort of patients with UC treated with FMT for rCDI superinfection.
In a retrospective, single-centre cohort study we evaluated characteristics and outcomes of patients with UC who received FMT for rCDI. The primary outcome was negative C. difficile toxin 8 weeks after FMT.
Results: Thirty-five patients were included in the analysis. Sixteen patients were cured after single FMT, while 19 patients received repeat FMT. Overall, FMT cured rCDI in 32 patients (91%), and repeat FMT was significantly associated with sustained cure of CDI compared with single FMT (84% vs 50%, p= 0.018). Twenty-four patients (69%) experienced remission or an amelioration of UC activity. Serious adverse events were not observed.
Conclusion: In our cohort of patients with UC, FMT was highly effective in curing rCDI without severe adverse events, and repeat FMT was significantly associated with CDI cure. Most patients also experienced remission or amelioration of UC activity after FMT. Our findings suggest that a sequential FMT protocol may be used routinely in patients with UC and rCDI.

LARGE QUESTIONNAIRE STUDY IDENTIFYING POSITIVE PREDICTORS FOR INTESTINAL METHANOGEN OVERGROWTH

M. Otterstad[1], J. Haworth[1], S. Treadway[1], N. Boyle[2], A.R. Hobson[1]
[1]Functional Gut Clinic, Manchester, United Kingdom, [2]RefluxUK, London, United Kingdom

Contact E-Mail Address: jordan@functionalgutdiagnostics.com
Introduction: Intestinal methanogen overgrowth (IMO) is characterized by colonization of methanogenic species in the gastrointestinal tract and elevated breath methane levels, which are associated with constipation. It can be diagnosed with a simple, non-invasive hydrogen and methane breath test (HMBT). We wanted to determine if IMO is associated with any other symptoms, medications or medical conditions.
Aims & Methods: A large questionnaire-based study was conducted in over 1000 patients of which 731 patients underwent a lactulose HMBT. The 26-item questionnaire included questions about medical history and symptoms, and we used this to identify positive predictors for IMO. Patients were considered positive for IMO if any of the breath samples provided had a concentration of ≥10 ppm methane. Samples were analysed using gas chromatography and statistical significance of associations and predictors were calculated using chi square and logistic regression, respectively.
Results: 232 patients were positive for IMO on HMBT. There was a positive association for constipation (P < 0.001) and negative association for diarrhoea (P = 0.002). Excessive methane was associated with stools that appear fatty/greasy and/or tend float (P < 0.001) where 75% of patients with IMO reported this. 22 patients in this cohort had inflammatory bowel disease (IBD) of which 91% tested negative for methane (P = 0.020).
Conclusion: This large questionnaire study has provided further evidence that excessive breath methane production is associated with constipation and inversely associated with diarrhoea and IBD. We have also shown that excess methane may also lead to fatty/greasy stools that can float. HMBT plays an important role to identify IMO in patients with constipation.

ABC SCORE FOR LOWER GASTROINTESTINAL HAEMORRHAGE: DOES IT TELL US MORE THAN ONE-MONTH SURVIVAL?

M. Jacunski[1], A. Mehta[1], F. Moroni[1], S. Siddhi[1]
[1]Aberdeen Royal Infirmary, Digestive Disorders, Aberdeen, United Kingdom

Contact E-Mail Address: mark.jacunski@nhs.scot
Introduction: The management of acute lower gastrointestinal bleeding (LGIB) is based on clinical acumen and local protocols that are not underpinned by validated scoring systems. The ABC score is validated to predict 30-day survival in LGIB but not to predict need for therapeutic intervention. Therefore, we retrospectively reviewed the clinical course of inpatients with LGIB at the Aberdeen Royal Infirmary (ARI) to evaluate ABC score performance in decision-making in a period before and during the COVID-19 pandemic as a part of a natural experiment.
Aims & Methods: Consecutive unscheduled admissions to ARI in the 10 months before and after 31/03/2020 with discharge summaries coded with lower or unspecified GIB that warranted investigation or management were identified by electronic patient record search. Patient demographics, investigations, and outcome were analysed with statistical testing by chi-squared and Wilcoxon rank sum tests. General linear models were created within R using a random selection of 80% of the cohort to "train" the model, using the remaining 20% as "validation" of model performance.
Results: The search identified 273 admissions (257 unique patients): 138 (51%) in the pre-pandemic period and 135 (49%) in the pandemic period. There were no significant differences in sex, age, ABC score, or length of stay between these two periods. ABC score was associated with decreased 30-day survival, though most patients with a high ABC score nonetheless survived. Patients with an intermediate ABC score were most likely to be admitted to critical care and those with a low ABC score had the shortest length of stay. ABC score performed very well in predicting 30-day survival (area under the curve [AUC] = 0.97), but not in predicting LGI endoscopy, computed tomography mesenteric angiograms, or deferment to outpatient investigations. Likewise, ABC score did not accurately predict admission to critical care. Half of patients with a high ABC score of 8 or more (15 out of 30) were qualitatively described as too frail for invasive procedures such as endoscopy.
Conclusion: The ABC score to predict 30-day survival in patients with LGIB was very accurate in our retrospective cohort of patients admitted to the ARI, both before and after the start of the COVID-19 pandemic. However, the ABC score was relatively ineffectual in predicting investigations, man-

agement, and critical care admission. Higher ABC scores were generally garnered by frailer patients, reflecting the large proportion of points relating to chronic conditions. Accordingly, these are patients in whom invasive management strategies are often not appropriate. Due to limitations in our data, we were unable to compare the performance of the ABC score relative to other scoring systems. The ABC score is unlikely to contribute to clinical decision making in the initial management of LGIB. Therefore, further large-scale studies are required to provide an evidence basis to guide admission to critical care and urgent intervention.

DO WE NEED EMERGENCY COLONOSCOPY FOR ACUTE DIVERTICULUM BLEEDING?

M. Tanaka[1], T. Nakashima[1], Y. Okishio[1], S. Kawashima[1], T. Yonemitsu[1], S. Tamura[1], K. Ueda[1], S. Kato[1]

[1]Wakayama Medical University, Emergency and Critical Care, Wakayama City, Japan

Contact E-Mail Address: a2mb1061@yahoo.co.jp

Introduction: It has been reported that diverticulum hemorrhage has a high spontaneous hemostasis rate of 70 to 90% and rarely leads to hemorrhagic shock, so emergency colonoscopy is not widely performed. However, there is a report that the identification rate of stigmata of recent hemorrhage increases with early colonoscopy administration, so we have performed many emergency colonoscopy within 24 hours after the ER visit.

Aims & Methods: We retrospectively examined 68 cases of diverticulum bleeding who visited our hospital from April 2011 to October 2016; 38 cases in the emergency group who underwent colonoscopy within 24 hours and 30 cases in the elective group who underwent colonoscopy after 24 hours.

Results: The age was 73 ± 11 in the emergency group and 72 ± 12 in the elective group. The blood Hb concentration at the first ER visit was 10.0 ± 3.0 g / dL in the emergency group and 10.5 ± 2.4 in the elective group, showing no significant difference. There were no significant differences in blood pressure or pulse rate at the first ER visit. The oral antiplatelet drug use was 39% in the emergency group, which was higher than that in the elective group 23%, but there was no significant difference in the oral anticoagulant and NSAIDS use. The length of hospital stay was 8.0 ± 6.1 days in the emergency group, 8.0 ± 4.6 days in the elective group, and the blood transfusion rate was 53% in the emergency group and 46% in the elective group, showing no significant differences. A significant difference was observed in the rate of identifying bleeding sources. In 26% of the emergency group and 10% of the elective group, stigmata of recent hemorrhage was identified and hemostatic treatment was performed ($p<0.05$). No major complications such as intestine perforation was observed in the two group.

Conclusion: Emergency colonoscopy for diverticulum bleeding does not reduce blood transfusion during hospital stay, but it identifies bleeding sources and may lead to effective treatment.

Disclosure: Nothing to disclose.

Introduction: Colonic diverticular bleeding (CDB) is the most common cause of acute lower gastrointestinal bleeding (ALGIB) and often requires blood transfusion. There are several studies regarding the use of restrictive blood transfusion for acute upper gastrointestinal bleeding, but there is only one previous study regarding the use of restrictive blood transfusion for ALGIB [1]. Therefore, the efficacy of restrictive blood transfusion for CDB remains unclear.

Aims & Methods: This study sought to elucidate the association between the restrictive blood transfusion strategy and the clinical outcomes in patients with CDB. We retrospectively analyzed 475 patients who were urgently hospitalized for CBD and received blood transfusions at two facilities between November 2013 and December 2021. Transfusion strategy was defined as the restrictive group when patients received transfusion for hemoglobin (Hb) ≤ 7 g/dl, and the liberal group when patients received for Hb > 7 g/dl. The hemoglobin cut-off value for restrictive blood transfusion was determined based on a prior randomized clinical trial regarding UGIB [2]. Rebleeding within 30-days, mortality within 30-days, and composite outcome within 30-days were evaluated. The composite outcome comprised the following endpoints: rebleeding, need for surgery or IVR for hemostasis, and mortality within 30 days. We also investigated medical costs during hospitalization. Logistic regression analysis was performed to calculate the odds ratios (OR) with 95% confidence interval (CI) to analyze associations between restrictive transfusion strategy and outcomes.

Results: Of 475 patients, 184 (38.7%) (124 males, 60 females, mean age 76.5±11.5 years) patients received blood transfusion. The mean hemoglobin levels at the time of transfusion in the restrictive and liberal groups were 6.3±0.6 g/dl and 8.2±1.2 g/dl, In the restrictive and liberal group, rebleeding within 30-days was 53.9% and 45.3% ($P = 0.24$), the mortality within 30-days was 1.1% and 0% ($P = 0.30$), the composite outcome within 30-days was 56.1% and 52.6% ($P = 0.63$), respectively. After adjusting for potential confounders, multivariate analysis revealed that restrictive transfusion strategy not associated with decreased rebleeding risk within 30-days, ($P = 0.42$; odds ratio [OR], 1.3), whereas endoscopic hemostasis significantly associated with decreased rebleeding risk ($P < 0.01$; OR 0.2). There was no statistically significant difference in total medical costs between the two groups ($P = 0.68$).

Conclusion: There were no statistically significant differences in rebleeding within 30-days, mortality within 30-days, and compositeoutcome within 30-days between the restrictive and liberal blood transfusion strategies. Restrictive blood transfusion may be a reasonable therapeutic strategy for patients with CDB, except for patients in which shock status cannot be withdrawn. However, further evidence is needed to advocated the efficacy of restrictive transfusion strategies for lower gastrointestinal bleeding.

Introduction: Colonic diverticular bleeding (CDB) is the most common cause of acute lower gastrointestinal bleeding (ALGIB). In a recent Japanese multicenter retrospective cohort study, 63.6% of patients with ALGIB were ultimately diagnosed with CDB [1]. It has also been reported that CDB in ALGIB is reportedly more severe than in other entities [2, 3]. However, few reports have demonstrated the efficacy and safety of bowel preparation for patients undergoing urgent colonoscopy.
Aims & Methods: We aim to clarify choice a of bowel preparation for urgent colonoscopy in patients with colonic diverticular bleeding. In a multicenter retrospective cohort study at 10 institutions, we analyzed the endoscopic findings and clinical course of patients diagnosed with CDB who underwent urgent colonoscopy within 24 hours after admission. Bowel preparation consisted of oral consumption of 1 to 2 L of polyethylene glycol lavage (PEL); enemas were not used. We compared those CDB patients who underwent PEL (PEL group) with a control group who did not undergo PEL (non-PEL group) before and after propensity score matching. For the matching, we selected variables known at the time of hospital admission (i.e. age, sex, comorbidities, medications, performance status, and laboratory data). The primary endpoint of the study was length of hospital stay, and secondary endpoints included blood transfusion requirements, rebleeding rates, endoscopic findings, and complications.
Results: 242 patients were enrolled in this study. The median age was 76 years, and 60.7% of patients were men (n = 147). Approximately half of the patients underwent bowel preparation with PEL prior to urgent colonoscopy (n = 129). We compared with clinical findings between the PEL and non-PEL groups. The length of hospital stay was shorter in the PEL group (8.0 ± 5.1 days vs 10.9 ± 5.8 days; mean ± SD; $P < 0.001$). Further, the PEL group was significantly younger (72.2 ± 12.1 vs 75.4 ± 13.1; mean ± SD; $P = 0.036$), had fewer patients with hypertension (62.0% vs 75.2%; $P = 0.027$) and malignant neoplasm (1.6% vs 10.6%; $P = 0.002$), and had better performance statuses (86.1% vs 76.1%; $P = 0.047$). Patients in the PEL group received fewer blood transfusions (25.6% vs 44.3%; $P = 0.002$), had a higher rate of cecal completion (88.3% vs 49.6%; $P < 0.001$), and shorter endoscopic observation times (20.8 ± 16.2 min vs 29.9 ± 24.8 min; mean ± SD; $P = 0.006$). After propensity score matching, there were 91 patients each in PEL group and in non-PEL group. PEL group had a significantly shorter hospital stay (7.9 ± 4.6 days vs 10.7 ± 5.8 days; mean ± SD; $P < 0.001$), a higher cecum completion rate (87.8% vs 48.3%; $P < 0.001$), and a shorter endoscopic observation time (20.7 ± 16.8 min vs 28.9 ± 24.1 min; mean ± SD; $P = 0.031$) than non-PEL group. There were no significant differences in blood transfusion requirements, rebleeding rates, identification of SRH, need for endoscopic hemostatic treatment, or complication rates.
Conclusion: In patients with CDB, urgent colonoscopy under PEL resulted in shorter hospital stays, higher cecal completion rates, and shorter endoscopic observation time in urgent colonoscopy. The safety of urgent colonoscopy with PEL was comparable to colonoscopy without PEL. These results suggest that PEL is preferrable for urgent colonoscopy in patients with CDB.

Introduction: Recurrence of colonic diverticular bleeding (CDB) can occur both in the short term and long term. The right and left sides of the colon are embryologically and hemodynamically different; thus, different rebleeding rates are expected depending on whether the diverticula are located in the right or left side of the colon. However, only few reports have specifically investigated the difference in CDB rebleeding rates between the right-sided and left-sided diverticula.
Aims & Methods: We aimed to compare the rebleeding rates in CDB between cases with right-sided and left-sided diverticula. Among the patients who underwent colonoscopy (CS) for hematochezia, and were admitted to our hospital between February 2009 and January 2022, 275 consecutive CDB patients (182 men and 93 women, mean age: 71 years) were included in the study, after excluding patients with diverticula in both sides of the colon. The diagnosis of CDB was made by CS, and the location of the diverticula was evaluated using CS and computed tomography. The right-sided group (n=167) was defined as patients with diverticula only in the right colon, and the left-sided group (n=108) was defined as patients with diverticula only in the left colon. Endoscopic treatment was indicated when stigmata of recent hemorrhage was identified during colonoscopic examination. Rebleeding was defined as significant amounts of fresh,

bloody, or wine-colored stool after discharge. The cumulative rebleeding rate after discharge was compared in both groups by the Kaplan–Meier curve, using the log-rank test. The hazard ratios adjusted for age, sex, body mass index (BMI), and background factors were calculated using the Cox proportional hazards model.

Results: A total of 119 definitive CDB cases and 156 presumptive CDB cases were included in this study. Cases that underwent surgical resection of the colon during follow-up were not included in the study. Endoscopic treatment was performed in 118 patients. The median follow-up after discharge was 26 months (interquartile range: 4–55 months), and rebleeding occurred in 75 patients (27%). Cumulative rebleeding rates in the right-sided group over 1, 3, and 5 years were 18%, 26%, and 38%, while those in the left-sided group were 13%, 15%, and 23%, respectively, with significantly more rebleeding observed in the right-sided group (P = 0.002). The hazard ratio, adjusted for age, sex, BMI, and background factors, namely, alcohol consumption, performance status, white blood cell count on admission, heart failure, non-steroidal anti-inflammatory drug use, low-dose aspirin use, and endoscopic treatment, was 1.87 (95% confidence interval: 1.04–3.36).

Conclusion: After discharge from the hospital, CDB from the right-sided colon is more likely to recur than that from the left-sided colon.

Disclosure: Nothing to disclose.

Introduction: Although the recommended method of an initial examination of hematochezia is colonoscopy, computed-enhanced CT (CECT) is an appealing diagnostic modality for the same disorder, because it has a superior ability of detecting active bleeding and it is widely available, fast, and minimally invasive. In many centers, CECT has already become an established method for characterizing the location of hematochezia. However, its impact on clinical courses of patients with colon diverticular bleeding is fully known. We conducted this study to assess them on the basis of single-center experience in Japan.

Aims & Methods: Consecutive 370 patients with colon diverticular bleeding from April 2002 to January 2023 were enrolled. Diagnosis of colon diverticular bleeding was based on total colonoscopy. Patients were divided into two groups who underwent initial examinations via CECT and colonoscopy.

Patient attributes, clinical data, and outcomes (length of hospital stay, re-bleeding rate, blood transfusion units and 30 days survival rate) were retrospectively analyzed. The patient characteristics and outcomes were compared between two groups using $\chi 2$ test or Fisher's exact test.

Results: 279 patients were men (75.4%). The average age was 70.0(30-94) years old. Initial CECT was performed to 204 patients (Group A) (54.9%) and remaining 166(group B).

Patients in group A were more likely to have cerebrovascular disorder.

Findings for other characteristics were similar between two groups.

In Group A, CECT revealed extravasation in 110 patients (53.9%).

Emergent colonoscopy was performed in 118 patients (extravasation positive 100: negative 18) and found bleeding point in 46 patients (extravasation positive 43: negative 3).

In Group B, emergent colonoscopy was performed in 70 patients and found bleeding point in 19(27.1%) patients.

Patients in group A required more blood transfusion units than group B significantly (3.36 ± 6.28 units in group A vs. 1.53 ± 2.96 units in Group B, p=0.001).

No significant difference was observed in terms of length of hospital stay (10.64 ± 7.11 days in group A vs.9.95 ± 5.37 days in Group B ,p=0.32) , recurrent bleeding rate (23.6 % in group A vs. 23.4 % in Group B, OR 1.016 ,p=1) , and 30 days survival rate (99.5% in Group A vs. 100 % in Group B, OR 1.005 ,p=1)

Conclusion: Emergent colonoscopy, subsequent to initial CECT which revealed extravasation, can detect bleeding point more efficiently in patients with colon diverticular bleeding. But, CECT did not improve clinical outcomes of these patients in this study.

SEVERE COVID-19 IS ASSOCIATED WITH RISK OF LOWER GASTROINTESTINAL BLEEDING

S. Hibiya[1], T. Fujii[1], T. Fujii[2], K. Ohtsuka[1], R. Okamoto[1]

[1]Tokyo Medical and Dental University, Gastroenterology and Hepatology, Tokyo, Japan, [2]Tokyo Metropolitan Hiroo Hospital, Tokyo, Japan

Contact E-Mail Address: shibiya.gast@tmd.ac.jp

Introduction: Patients with the coronavirus disease 2019 (COVID-19) develop venous thromboembolism, resulting in a poor prognosis. Therefore, thromboprophylaxis is important for treatment, but anticoagulation is a risk for gastrointestinal bleeding. Gastrointestinal bleeding has been reported to occur in 2% to 13% of COVID-19 hospitalized patients[1], but few reports have examined the association between COVID-19 and gastrointestinal bleeding.

Aims & Methods: This study aimed to identify gastrointestinal bleeding risk factors in COVID-19 patients. A multicenter, retrospective cohort study was conducted in patients admitted with a diagnosis of COVID-19 between January 2020 and December 2021 in Japan. Thirteen hospitals around Tokyo area participated in this study. The severity of COVID-19 was classified in this study according to the NIH severity classification, Cases below moderate were classified as not severe in this study. We collected information on the background factors (gender, age, severity of COVID-19, medical history, medication at admission, treatment details) and presence of gastrointestinal bleeding during hospitalization. A multivariable logistic regression analysis model was adjusted to evaluate the association between background confounding factors and presence of gastrointestinal bleeding. Multivariate analysis was also performed separately for upper and lower gastrointestinal bleeding. Additionally, we evaluated the association between post-hospitalization treatment and gastrointestinal bleeding using descriptive statistics.

Results: 12,044 patients were included in the analysis. 4165 (34.6 %) were severe COVID-19 patients, and 1257 (10.4%) were critical COVID-19 patients. 103 (0.9 %) had gastrointestinal bleeding, of which 60 (0.5 %) were diagnosed with upper gastrointestinal bleeding and 45 (0.4%) with lower gastrointestinal bleeding. Two patients had both upper and lower gastrointestinal bleeding. Multivariate analysis showed that COVID-19 severe group had a significantly higher risk of gastrointestinal bleeding than COVID-19 not severe group (odds ratio (OR) 2.8, 95% confidence interval (CI): 1.3-5.7), and COVID-19 critical group also had a significantly higher risk of gastrointestinal bleeding (OR 22.0, 95% CI: 11.2-43.0). The risk of upper gastrointestinal bleeding was significantly higher in the critical group (OR 16.9, 95% CI: 7.5-37.8), but the severe group did not have a significantly in-

creased risk (OR 1.6 , 95% CI: 0.6-4.1). On the other hand, the risk of lower gastrointestinal bleeding was significantly higher in the severe group (OR 6.0, 95% CI: 1.7-21.3) and in the critical group (OR 35.5, 95% CI: 10.5-120.4) compared to the not severe group, suggesting that COVID-19 severe group was associated with lower gastrointestinal bleeding risk but not associated with upper gastrointestinal bleeding. No significant association was found between gastrointestinal bleeding and post-hospitalization anticoagulation in the COVID-19 severe group.

Conclusion: COVID-19 severity was considered a significant risk for gastrointestinal bleeding in hospitalized patients. The COVID-19 severe group is at risk for lower gastrointestinal bleeding even without the use of anticoagulants after hospitalization. Patients with severe or critical COVID-19 should be treated with caution, as they are at higher risk for complications of gastrointestinal bleeding, especially lower gastrointestinal bleeding.

VALIDATION OF OUR NEW PROTOCOL FOR COLONIC DIVERTICULAR HEMORRHAGE FOR ADJUSTING THE TIMING OF EMERGENCY ENDOSCOPIC PROCEDURES

Y. Shimazu[1], N. Akimoto[1], J. Omori[1], A. Tatsuguchi[1], A. Hoshimoto[1], T. Nishimoto[1], O. Goto[1], K. Iwakiri[1]
[1]Nippon Medical School, Graduate School of Medicine, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: Yuge0stripe@gmail.com

Introduction: Although the number of patients with diverticular hemorrhage in the colon has been increasing in recent years, it remains controversial whether emergency colonoscopy is effective for patient outcomes. We developed a new protocol to avoid emergency colonoscopic procedures at night (22:00-05:00), in which colonoscopy were performed within 8, 12, or 24 hours after the patient's arrival, as determined by the presence or absence of extravasation on contrast-enhanced computerized tomography and history of shock at the time of arrival. We have been applying the new protocol for lower gastrointestinal bleeding since the end of 2021. In addition, the endoscopic band ligation method has beenstandardized as the first choice for hemostasis when stigmata of recent hemorrhage (SRH) was identified. The purpose of this study was to verify the effectiveness of the new protocol.

Aims & Methods: Among patients diagnosed as diverticular hemorrhage at Nippon Medical School Hospital, we evaluated clinical outcomes including SRH identification rate, the rebleeding rate after 30 days of hemostasis, the period of hospitalization, and the rate for the hemostasis method after identifying SRH. Each clinical outcome factor afterapplying the protocol (January 2022 to December 2022) was compared with those before the protocol was established (January 2020 to December 2021). The chi-square or Fisher's exact test was used to compare categorical variables. Mann-Whitney U test was used to compare continuous variables.

Results: Among 93 cases diagnosed as diverticular hemorrhage during the new protocol was in operation, 79 cases followed the protocol and 74 cases underwent endoscopy. Among 191 cases diagnosed as diverticular hemorrhage before new protocol was in operation, 175 cases underwent endoscopy. After the new protocol was in operation, the number of emergency endoscopies at night (22 pm - 5 am) tended to decrease (before, 7.4% vs. after, 4.1%; P=0.41) although the difference was not significant. Both the SRH identification rate (before, 18.3% vs. after, 17.6%; P = 0.90) and the rebleeding rate after 30 days of hemostasis (8.0% vs. 6.8%; P = 0.74) was comparable between two groups. The period of hospitalization was significantly shortened by 1 day after the new protocol was in operation (P = 0.02). The rate for the hemostasis method after identifying SRH using clip/EBL was 8.4%/13% before the new protocol compared with 7.5%/9.7% after the new protocol.

Conclusion: Even when emergency colonoscopic procedures for colonic diverticular hemorrhage were not performed during nighttime whenever possible according to the protocol, similar clinical outcomes were observed by setting up detailed protocols according to the different situations.

There are no different patient outcomes observed even when emergency colonoscopic procedures for colonic diverticular hemorrhage were not performed during nighttime.

Our new protocol has validity to avoid nighttime colonoscopy as much as possible.

Disclosure: Nothing to disclose.

EVALUATION OF THE INTRODUCTION OF FAECAL IMMUNOCHEMICAL TESTING (FIT) FOR PATIENTS WITH RECTAL BLEEDING IN NOTTINGHAM

S. Man[1], A.J. Morton[1,2], D.J. Humes[1,2], A. Banerjea[2]
[1]University of Nottingham, Nottingham, United Kingdom, [2]Nottingham University Hospital NHS Trust, Nottingham, United Kingdom

Contact E-Mail Address: david.humes@nottingham.ac.uk

Introduction: Quantitative faecal immunochemical testing (FIT) is used in primary care to triage symptomatic patients for two-week-wait (TWW) colorectal cancer (CRC) referral, advised for use in all symptoms by specialty associations. FIT may effectively rule out CRC in FIT negative patients with rectal bleeding, with the potential to reduce endoscopy demand for patients with very low risk of CRC. Nottingham incorporated FIT (OC Sensor) into the TWW CRC diagnosis pathways for patients with rectal bleeding in November 2021. General Practitioners were advised to complete TWW referral for FIT ≥10 µgHb/g faeces (≥4 in the presence of anaemia or thrombocytosis).

Aims & Methods: Evaluate the demographics, investigations and early outcomes of the patients completing a FIT for rectal bleeding and compare to a reference group of TWW patients with rectal bleeding prior to the implementation of FIT.

Patients with rectal bleeding undertaking FIT after its introduction in this pathway (November 2021 to July 2022) had data collected in the Trust Enterprise Data Warehouse, allowing the formation of aggregate data (FIT group). Demographic, endoscopy, and cancer diagnosis was recorded with linkage to trust endoscopy and histology databases. A database of patients with rectal bleeding referred on a TWW pathway prior to the introduction of FIT (November 2017 to August 2019) was used as a comparison (pre-FIT group). In the pre-FIT group, investigation/outcome data was entered directly into the database by the nursing team managing referrals.

Results: 2490 patients undertook a FIT for rectal bleeding after its introduction into the pathway, with 1497 patients in the reference pre-FIT group. There were more females in the FIT group than pre-FIT group (52.6% vs 48.9% respectively). The median age was lower in the FIT group (58 years vs 63.2 years). 75% of patients with rectal bleeding undertaking FIT had a negative (<10 µgHb/g faeces) FIT, 4% a value 10-19.9 µgHb/g faeces, 8% 20-99.9 µgHb/g faeces and 12.4% ≥100 µgHb/g faeces.

65.6% of patients with a FIT ≥ 10 µgHb/g faeces underwent endoscopy, compared to 81.2% in the pre-FIT group. The proportion of patients having endoscopy increased with rising FIT result (50% at a result 10-19.9µgHb/g faeces, 74.2% ≥100 µgHb/g faeces). 13.3% of patients with a FIT <10 µgHb/g faeces underwent endoscopy.

24 (3.9%) of patients with a FIT ≥10 μgHb/g faeces had histological diagnosis of CRC. There were no diagnoses of CRC in FIT <10 μgHb/g faeces. 10 extra-colonic cancers were diagnosed in the FIT group (0.4%), all FIT <10 μgHb/g faeces. 93 (6.2%) of the pre-FIT group had a histological diagnosis of CRC, 9 (0.6%) had a diagnosis of extra-colonic cancer.

Conclusion: FIT's role in rectal bleeding remains unclear. In the limited follow-up of this study FIT appears to rule out CRC – 75% of patients returned a result <10 μgHb/g faeces and no CRC was found in these patients. However, CRC detection rates were almost 60% higher pre-FIT than in the FIT positive group; this may be explained by FIT being used for lower risk patients or the limited follow-up. Even in rectal bleeding a negative FIT may signpost towards extracolonic cancer, all found in FIT <10, suggesting appropriate investigations are required for these patients with low risk of CRC. Longer-term follow-up is required to assess whether any CRCs have been missed in "FIT-negative" patients to gauge the effectiveness of FIT for rectal bleeding and impact on endoscopy demand.

Disclosure: Nothing to disclose.

CLINICAL CHARACTERISTICS OF ACUTE HEMORRHAGIC RECTAL ULCER

A. Hoshimoto[1], J. Omori[1], R. Inoue[1], T. Nishimoto[1], N. Akimoto[1], A. Tatsuguchi[1], K. Iwakiri[1]

[1]Nippon Medical School, Graduate School of Medicine, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: a-hoshimoto@nms.ac.jp

Introduction: Acute hemorrhagic rectal ulcer (AHRU) is one of the most common diseases in elderly patients with underlying medical conditions and often results in serious outcomes. Although AHRU is a potentially life-threatening disease, its characteristics and clinical course are not fully elucidated.

Aims & Methods: We aimed to clarify the clinical characteristics of patients with acute hemorrhagic rectal ulcer. We enrolled consecutive 68 AHRU patients admitting to Nippon Medical School Hospital from September 2015 to December 2022, and their clinical characteristics and outcomes were determined according to medical records retrospectively.

Results: Clinical characteristics of AHRU patients were as follows: mean age 79; including 33 males and 35 females.

31 patients (46%) had a performance status (PS) of 3 or more. Comorbidities were cardiovascular disease in 24 patients, chronic renal failure (eGFR<30 for more than 3 months) in 12 patients, cerebrovascular disease in 14 patients, chronic hepatitis and cirrhosis in 2 patients, hypertension in 33 patients, diabetes in 22 patients, and dyslipidemia in 21 patients. Medications were antiplatelet agents in 27 patients, anticoagulants in 18 patients, NSAIDs in 7 patients, and steroids in 6 patients. 24 of 68 patients (38%) underwent endoscopic hemostasis (clip in 15 cases, hemostatic forceps in 9 cases, and combined clip and HSE injection in 1 case), interventional radiology in 1 case, and transanal suture in 4 cases. Rebleeding was observed in 16 of 68 patients (24%). Rebleeding after endoscopic hemostasis was observed in 7 of 24 patients (29%), of which 3 patients performed emergency colonoscopy after rebleeding. Of the 68 patients who required blood transfusion during hospitalization, 50 patients (74%) had a mean transfusion volume of 10.6 units (2-50). 13 (19%) of the 68 patients died during hospitalization due to exacerbation of their comorbidities.

Conclusion: AHRU was more common in elderly patients with comorbidities and lowered PS. Patients with AHRU who was required for endoscopic hemostasis was associated with frequent rebleeding, and some patients were led to severe outcome due to their complications or exacerbation of comorbidities. Therefore, management of patients with AHRU should focus on not only controlling the local bleeding but also managing their comorbidities and complications.

Disclosure: Nothing to disclose.

TRANSCATHETER ANGIOGRAPHY AND VASCULAR EMBOLIZATION IN COLONIC DIVERTICULAR BLEEDING

J. Omori[1], A. Hoshimoto[1], T. Nishimoto[1], N. Akimoto[1], A. Tatsuguchi[1], S. Fujimori[1], K. Iwakiri[1]

[1]Nippon Medical School, Graduate School of Medicine, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: 67trocadero@nms.ac.jp

Introduction: Although transcatheter arterial embolization (TAE) has been reported to be effective for colonic diverticular bleeding, the patient outcomes of TAE have not been fully elucidated. The present study was conducted to investigate the patient characteristics and outcomes of TAE for colonic diverticular bleeding.

Aims & Methods: We enrolled 50 patients who were performed transcatheter angiography among 294 patients diagnosed as colonic diverticular bleeding by colonoscopy and abdominal CT, and were required for hospitalization from August 2012 to January 2021. Their clinical characteristics and outcomes of TAE were determined according to medical records retrospectively.

Results: The mean age of all 50 patients (44 males and 6 females) was 68 (45-86) years. History of cardiovascular disease in 15 patients, cerebrovascular disease in 7, renal disease in 4, hepatic disease in 5, hypertension in 27, diabetes mellitus in 5, and dyslipidemia in 10. The reasons for transcatheter angiography were rebleeding after colonoscopy in 21 cases (42%), shock vital in 13 cases (26%), extravasation on CT in 4 cases (8%), difficulty in stopping bleeding by endoscopy in 4 cases (8%), and rebleeding after angiography in 7 cases (14%). TAE was performed in 30 of 50 patients (60%). 7 of 50 patients (14%) were performed transcatheter angiography twice, of which 3 patients successfully performed TAE on the second time, 2 patients successfully performed TAE both times. The reasons for unsuccessful TAE were all negative extravasation on transcatheter angiography, and there were no cases in which TAE was technically impossible. In a comparison of 30 successful TAE cases and 20 unsuccessful TAE cases, the mean time from the appearance of hematochezia to transcatheter angiography (9.8 vs. 12.75 h; P=0.413), the rate of extravasation on CT before transcatheter angiography (56% vs. 45%; P=0.419) were not significantly different between the two groups. On the other hand, the rate of early rebleeding within 30 days was significantly lower in patients with successful TAE (13% vs. 60%, P = 0.001).

Conclusion: In cases of colonic diverticular bleeding, transcatheter angiography can be safely performed even when the patient's circulation is unstable. Moreover, the early rebleeding rate was significantly reduced in cases of successful TAE. However, the early rebleeding rate was high in patients who did not receive successful TAE, this should be considered as a future subject.

Disclosure: Nothing to disclose.

PP0964

LONG-TERM TREATMENT OF PATIENTS WITH SCREEN-DETECTED COLORECTAL CANCER IS LESS STRENUOUS - A RETROSPECTIVE COHORT STUDY

J. Dressler[1], S.H. Njor[2,3], M. Rasmussen[1], L.N. Jørgensen[4,5]
[1]Bispebjerg Hospital, Digestive Disease Center, Copenhagen NV, Denmark, [2]Randers Regional Hospital, Research Clinic for Cancer Screening, Randers, Denmark, [3]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark, [4]Bispebjerg Hospital, Digestive Disease Center, København NV, Denmark, [5]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Contact E-Mail Address: jannie.dressler@regionh.dk

Introduction: Colorectal cancer (CRC) screening has been implemented in numerous countries within the last two decades[1]. There is strong evidence that CRC screening leads to enhanced disease free- and overall survival[2–6]. However, there is to the best of our knowledge no studies investigating the effects of CRC screening on treatment in a long-term perspective.

Aims & Methods: The objective of this study was to investigate the effects of the Danish national CRC screening program on long-term treatment and health care contacts for patients diagnosed with CRC.This nationwide retrospective cohort study evaluated surgical- and oncological outpatient visits, treatments with chemo- and radiotherapy, health care contacts and hospitalization for patients with CRC during the first two years after diagnosis comparing patients with and without screen-detected CRC. The population consisted of Danish residents aged 50-75 years and diagnosed with CRC between January 1rst 2014 and March 31rst 2018. Data was collected from national healthcare registers .Duration of hospitalization were analyzed using a multivariate general linear model, metastasectomies and emergency surgeries were analyzed using a multivariate generalized linear model and data on oncological treatments were analyzed using a multivariate Poisson regression. Moreover, analyzes were stratified into UICC stages and adjusted for sex, 5-year age groups, type of cancer (colonic/rectal), and Charlson Comorbidity Index score to reduce healthy user bias.

Results: We included 4,708 and 7,332 patients with screen-detected CRC (SD-CRC) and non-screen-detected CRC (NSD-CRC), respectively. SD-CRC was associated with 38% reduced hospitalization. In a UICC-stratified analysis, hospitalization was shorter in the SD-CRC group across all UICC-stages. The rate of emergency surgery was significantly lower (RR=0.34, 95%-CI:0.28-0.41) in the SD-CRC group. There was no difference between the groups in rates of surgery for lung and liver metastasis. Lower number of oncological outpatient visits (RR=0.35, 95%-CI:0.33-0.37), treatment with chemotherapy (RR=0.57, 95%-CI:0.56-0.59) and radiotherapy (RR=0.50, 95%-CI:0.49-0.52) were found for patients with SD-CRC. UICC-stratified analyses revealed that these differences were consistent for all UICC stages, except for a significantly higher rate of treatment with chemotherapy in SD-CRC UICC stage IV. Overall, there was no difference between the two populations in number of contacts with primary healthcare providers. However, a UICC-stratified analysis revealed significantly fewer contacts with primary healthcare providers for patients with SD-CRC UICC I and III.

Conclusion: Compared with NSD-CRC, SD-CRC was associated with shorter hospitalization, less emergency surgery, and reduced oncological treatment within two years after diagnosis.

Introduction: Colorectal cancer's (CRC) incidence above 50 years old has been decreasing globally in the last decades, but its incidence in patients below 50 years old (early-onset colorectal cancer, EO-CRC) has been increasing, for reasons not yet fully understood.

Aims & Methods: A unicentric cohort study was conducted in a tertiary centre, including all patients admitted for a first diagnosis of CRC and evaluated by the Multidisciplinary Colorectal Cancer Group from 01.01.2017 until 31.12.2018. Patients with a previous diagnosis of a Hereditary Colorectal Cancer Syndrome were excluded.

Results: A total of 438 patients were included, 58.2% males, with a mean age at diagnosis of 67.7±11.1 years old. Mean follow-up time was 41.49 months. There were 25 EO-CRC patients (5.7%), 17 males (68%), mean age 43.1±6.0 years old.

Globally, 32.4% of the patients were current or past smokers, 18.5% had previous non-colorectal cancer, 7.5% and 3.4% were previously exposed to immunosuppressive drugs or abdominal/pelvic radiotherapy, respectively. The majority presented with normal(29.7%) to high Body Max Index (39.7%), median 25.6 (IQR:22.6-28.4) Kg/m^2. The most common CRC location was the rectum (42.9%) and 56.1% were stage I or II (AJCC 8th edition).

In the univariate analysis, a significant association was found between EO-CRC and: smoking status (past or current smokers 52% in EO-CRC vs. 31.2% in older cases p=0.009); lymphovascular invasion (40.0% in EO-CRC vs. 17.4% in over 50, p=0.018)

No significant differences were found for histological subtype (p=0.447), perineural invasion (p=0.474), or tumor stage at diagnosis, although a relevant proportion of the younger patients had metastatic disease at diagnosis (28.0% vs. 12.8%, p=0.064).

Immunohistochemistry for mismatch-repair proteins showed loss of expression of at least one protein in 1/18 EO-CRC patients and 22/179 of older patients (p=0.728).

From the EO-CRC patients, 16 were evaluated in the Familial Cancer Clinic and 14 underwent germline mutation analysis: 13 patients had inconclusive results, one of them presented a *MUTYH* heterozygote mutation and another was diagnosed with *MUTYH*-associated Polyposis (composed heterozygote mutation).

Conclusion: Colorectal cancer showed distinctive features in the younger population, with a higher prevalence of lymphovascular invasion and, possibly, a higher incidence of metastatic disease at diagnosis. Smoking had a significant association with CRC, especially in this younger population. Whether this means there is a biological difference is not yet clear. More evidence is needed in order to clarify EO-CRC aetiology and to develop screening and improve management strategies.

Introduction: It is known that there are sex differences in the characteristics of colorectal cancer (CRC), such as incidence and prognosis. However, there is still a lack of understanding on the underlying mechanisms of its sex difference.

Aims & Methods: The aim of this study was to investigate the correlation between the clinicopathological features and the molecular characteristics of CRC depending on sex. 1,068 patients diagnosed with CRC and treated (surgery, chemotherapy or supportive care) at Seoul National University Bundang Hospital were prospectively enrolled. Basic characteristics such as sex, age, and social history, clinical characteristics such as tumor location, stage, and survival were analyzed. In addition, molecular expressions of microsatellite instability (MSI), oncogenes including K-ras, N-ras and H-ras, and DNA mismatch repair genes including MLH-1, MSH-2, MSH-6 and PMS-2 were also investigated.

Results: There were 630 males and 438 females, with a sex ratio of 1.5:1. Risk behaviors for cancer occurrence, such as drinking and smoking, were much more common in males ($p < 0.001$, respectively). In females, right colon cancer was more frequent than in males ($p = 0.022$), which seems to be associated with the loss of MLH-1 ($p < 0.001$) and PMS-2 expression ($p = 0.003$) (Table). In multivariate regression analyses, older age ($p = 0.001$), lower BMI ($p < 0.001$), presence of symptoms ($p = 0.048$), advanced cancer stage ($p < 0.001$) and mutation of BRAF ($p = 0.030$) were significant risk factors for disease-related death. Females showed better overall survival ($p = 0.031$) as well as disease-specific survival than males ($p = 0.088$), and this difference was most pronounced in age 40-69 group (overall survival $p = 0.024$; disease-specific survival $p = 0.104$, respectively), while not evident in the younger and older age groups (Table).

		Total (N=1,068)	Male (%) (n=630)	Female (%) (n=438)	p-value
Age		64.11 ± 12.69	64.04 ± 12.55	64.21 ± 12.91	0.830
BMI (n=1,047)		23.22 ± 3.44	23.33 ± 3.32	23.06 ± 3.60	0.214
Tumor location	Rt. colon	308 (28.8)	163 (25.9)	145 (33.1)	0.022
	Lt. colon	386 (36.2)	244 (38.7)	142 (32.4)	
	Rectum	374 (35.0)	223 (35.4)	151 (34.5)	
MLH1 (n=735)	No	43 (5.9)	14 (3.2)		<0.001
	Yes	692 (94.1)	417 (96.8)		
PMS2 (n=719)	No	46 (6.4)	17 (4.1)		0.003
	Yes	673 (93.6)	401 (95.9)		

Table. (A-C) Overall and (D-F) cancer-specific survival according to sex and age.

Conclusion: Colorectal cancer shows sex differences in various characteristics including incidence, tumor location and prognosis, which might be originated from sex hormone and molecular characteristics.

Introduction: Familial adenomatous polyposis (FAP) is a dominantly inherited disorder that predisposes to colorectal cancer. However, after the introduction of prophylactic colectomy and endoscopic surveillance, as well as genetic screening of first-degree family members, the risk of CRC has decreased dramatically with subsequent prolonged expected life expectancy[1] Current guidelines solely aim at preventing cancer, which has been the focus for decades.[2-3] From a patient perspective, mental aspects of the disease, which might decrease quality of life may be equally important. However, knowledge and focus on mental well-being in FAP patients is limited. If FAP patients are at increased risk of mental stress and ultimately of developing psychiatric disorders, a potential possibility of early intervention is missed. The Danish Polyposis Register has for over 40 years included data from all Danish FAP patients. Consequently, the register is free of referral and selection bias. We aimed this study at estimating the impact on educational level and risk of psychiatric disorders in a nationwide cohort of patients with FAP compared to a matched background population.

Aims & Methods: Known Danish FAP patients by April 2021 were identified from the Danish Polyposis Register and paired with four matched controls based on matched on sex, birth year, and zip code at birth. Using national registries, educational status, psychiatric contacts or diagnoses, and need for antidepressants, anxiolytics, or antipsychotics were compared be-

tween FAP patients and controls. Follow-up of patients started on the date of their first being identified as having FAP or on 1st January 1996, whichever came last. Follow-up ended on the date of any of the listed outcomes, emigration, death, loss to follow-up or the end of the study on 1st January 2020, whichever came first. Relative risk for any of the listed outcomes was quantified by hazard ratios (HR); these were estimated using Cox proportional hazards regression, with age as the underlying timescale, and used the variables of exposure status, year of outcome, sex, cancer, and education for the multiple regression model. Cancer was included as a time-varying covariate in the Cox proportional hazards regressions.

Results: The analysis included 445 FAP patients and 1,538 controls. The highest attained education was significantly lower for FAP patients (p<0.001). When comparing FAP patients and controls and adjusting for cancer diagnosis, an increased risk was observed for a psychiatric contact (1.69, CI 95%, 1.25–2.29, p<0.001), any psychiatric prescription (1.39, CI 95%, 1.17–1.66, p<0.001), receiving a psychiatric diagnosis (1.64, CI 95%, 1.19–2.26, p=0.002), as well as facing any psychiatric event (HR 1.55, CI 95%, 1.32–1.83, p<0.001). An increased risk was specifically seen for affective (1.76, CI 95%, 1.09–2.83, p=002) and behavioral disorders (2.01, CI 95%, 1.10–3.69, p=0.02) as well as prescription of antidepressants (1.59, CI 95%, 1.24–2.03, p<0.001) and antipsychotics (1.85, CI 95%, 1.26–2.70, p=0.002). For FAP patients, the median age for affective and behavioral disorders was 32.7 years (range 15.0–73.6 years) and 14.7 years (range 5.5–47.7 years), respectively, which did not differ from controls.

Conclusion: Compared to controls, FAP patients have a significantly reduced educational level and an increased risk of developing affective and behavioural disorders with increased needs for antidepressants and antipsychotics. This calls for further exploratory and interventional trials.

Introduction: In recent years, the number of early-onset CRC (EO-CRC) diagnosed at the age of less than 50 years has been increasing. Previous studies suggest that EO-CRC may have higher malignant potentials and a worse prognosis than late-onset CRC. However, the reason why EO-CRC is regarded as aggressive cancer and result in delayed diagnosis remains unclear. We thought that both the lack of appropriate opportunities for screening or medical examination and the bias that was caused owing to being analyzed altogether regarding the different clinical stages could af-

fect worse prognosis of EO-CRC. In this study, we focused on T1 cancer to highlight the essential features of EO-CRC to minimize the bias caused by the time of diagnosis.

Aims & Methods: This study is a secondary analysis of the main JSCCR (The Japanese Society for Cancer of the Colon and Rectum) project, "International joint research on lymph node metastasis in CRC". Utilizing 4673 T1 CRC cases treated between July 2009 and December 2016 at 27 facilities belonging to JSCCR, we divided the patients into 5 groups according to age at the diagnosis: 49 years or younger, 50–59 years, 60–69 years, 70–79 years, and 80 years or older. To analyze the clinicopathological features including sex, tumor location, macroscopic type, tumor size, histology, submucosal invasion depth, lymphatic/venous invasion, tumor budding, lymph node metastasis, and treatment methods, the Spearman's correlation test was used. The difference of disease-free survival (DFS) between early-onset and later-onset CRC was also examined using log-rank test and Kaplan–Meier method.

Results: The cases of EO-CRC were 349 (7.5%). Among age groups, the proportion of rectum (from 49 years or younger to 80 years or older;44.1%, 42.0%, 36.6%, 29.0%, and 12.0%, respectively; P <0.05), protruded type (62.2%, 59.1%, 54.9%, 48.4%, 45.9%; P <0.05), and frequency of lymph node metastasis (10.0%, 7%, 8.0%, 7.0%, 4.6%; P <0.05) were decreased as the age group increased. In terms of sex, the proportion of male tends to decrease as the age group increased (57.9%, 60.8%, 63.5%, 57.0%, 52.7%, respectively; P <0.05). No significant differences were found among the five age groups for tumor size, histology, submucosal invasion depth, vascular invasion, tumor budding, recurrence rate, and treatment. No significant difference was observed regarding DFS between the two groups (5-year DFS; 98.7% for EO-CRC and 94.3% for late-onset CRC).

Conclusion: This study showed that the frequency of lymph node metastasis of T1 CRC decreased according to the increase of age at diagnosis, suggesting that EO-CRC may have a greater biological malignant potential compared to late-onset CRC.

As far as we know, this is also the first study to report that "protruded type" would be one of the features of EO-CRC. Although no difference was observed as for DFS between two groups, it was plausible considering that only T1 stage CRC was enrolled in this study. Further studies are warranted to evaluate the clinicopathological features characterizing early stage EO-CRC.

ADVANCED NEOPLASIA AT COLONOSCOPY IN THE YEAR IN INDIVIDUALS WITH HIGH RISK INJURIES IN SUCCESSIVE ROUNDS OF THE POPULATION SCREENING PROGRAM

M. Biarnes Martinez[1], X. Bessa Caserras[1], L. Ilzarbe Sanchez[2], L. Carot[1], C. Barrufet[3], M. González-Vivó[1], C. Alvarez Urturi[1]
[1]Hospital Del Mar, Gastroenterology, Barcelona, Spain, [2]Hospital Del Mar, Dept. of Digestology, Barcelona, Spain, [3]Hospital Del Mar, Barcelona, Spain

Contact E-Mail Address: l.carot.lc@gmail.com

Introduction: There is no evidence on the best surveillance strategy in individuals with high-risk lesions (sessile adenomas ≥20mm and/or number of adenomas ≥10). The Catalan Society of Digestology recommends a surveillance colonoscopy per year for this group.

Aims & Methods: The aim was to evaluate the findings of this colonoscopy in order to assess its usefulness.

Retrospective analysis of the surveillance colonoscopy per year performed in individuals with high-risk lesions from the 3rd, 4th and 5th rounds of the program of population screening Ciutat Vella-Sant Martí of Barcelona.

Results: 179 individuals were identified, of which 12 were excluded due to lack of data. 40.1% were women and 61.7% were over 60 years old. Among the total of 167 individuals, 87 (52.1%) met criteria for size, 63 (37.7%) for multiplicity and 17 (10.2%) met both. Lesions ≥20 mm were resected in fragments in 46.2% of cases. In 67 cases, more than one baseline colonoscopy was required (46.9%), to review the polypectomy base for fragmented lesions or to complete the polypectomy. 143 (85.6%) individuals underwent surveillance colonoscopy (mean time: 14.7±7.2 months).

No predictors of non-surveillance in the year were found. Colonoscopy at one year was normal in 54 (37.8%) cases, non-advanced lesions (adenomas/serrated) in 66 (46.2%) cases, advanced lesions in 22 (15.4%) cases and one case was detected of CRC (0.7%). Globally, the prevalence of advanced neoplasia (AN) was 16.1%.

The presence of AN was not associated with age, sex, round, or basal faecal hemoglobin, but with multiplicity (23.1% vs 6.7, p<0.05, in multiplicity group vs lesion group ≥ 20mm, respectively), regardless of the number of baseline colonoscopies. In the group of lesions ≥20mm resected in fragment with review colonoscopy at 4-6 months, no cases of AN were detected per year.

Conclusion: The prevalence of AN per year in individuals with high-risk lesions is considerable, and seems associated with basal multiplicity. In individuals with lesions ≥20mm with a normal follow-up colonoscopy, prolonged surveillance could be considered.

Disclosure: Nothing to disclose.

Contact E-Mail Address: lasse.pedersen@rn.dk

Introduction: The adenoma detection rate (ADR) is widely recognized as a quality indicator in colonoscopy based colorectal cancer (CRC) screening. ADR has been shown to be inversely associated with the risk of post colonoscopy colorectal cancer (PCCRC).[1,2]

A wide variation on the ADR among endoscopy units has been observed in the Danish fecal immunochemical based colonoscopy screening programme since the initiation in 2014. The ADR varied from 39% to 67% among endoscopist units from 2014-2017.[3]

Aims & Methods: To investigate the association between ADR and the risk of PCCRC using multivariable Poisson regression. Endoscopy units were grouped in quartiles based on the ADR. PCCRC was defined as a colorectal occurred 6-36 months after the initial screening colonoscopy. The Danish colorectal cancer screening registry (from 2014-2017) and the Danish Cancer registry (from 2014-2020) were used to identify colonoscopies, screening detected CRCs and PCCRCs.

Results: The study covered 80,374 colonoscopies (performed at 20 endoscopy units), 4,829 screening detected CRCs and 356 PCCRCs. Mean ADR in quartile 1 (lowest) was 41.0%, range [38.8-44.3], quartile 2: 48.3% [46.2-50.0], quartile 3: 52.2% [50.2-53.6] and quartile 4: 60.0% [54.1-67.0]. The proportion of PCCRCs (of all CRC) declined from 8.8% in quartile 1 to 4.8% in quartile 4.

Results from the multivariable Poisson regression analysis (outcome = PCCRC, predictors = age, sex, ADR) are shown in Table 1. The analysis found increased risk for PCCRC among females and a falling risk of PCCRC with higher ADR quartile.

	Relative risk	95% CI	p-value
Sex (%)			
Male	1 (Reference)		
Female	1.25	(1.02; 1.54)	0.03
ADR (%)			
Quartile 1: 41.0 [38.8-44.3]	1 (Reference)		
Quartile 2: 48.3 [46.2-50.0]	0.89	(0.68; 1.18)	0.43
Quartile 3: 52.2 [50.2-53.6]	0.72	(0.54; 0.95)	0.02
Quartile 4: 60.0 [54.1-67.0]	0.55	(0.40; 0.74)	< 0.01

**Age groups were not significant and omitted due to abstract table limitations.*

*Table 1: Multivariable poisson regression analysis for PCCRC**

Scatter plots of mean ADR (for each quartile) and relative risk suggest a linear relationship, indicating that a 1 percentage point increase in ADR lowers the risk of PCCRC by 2.5%.

Conclusion: PCCRC is an important colonoscopy quality performance indicator, however the need for years of follow-up and large-scale data limits the use as an indicator for current colonoscopy performance. ADR is a viable alternative. The latest Danish colonoscopy screening report from 2021 still shows a wide variation in ADR highlighting the need for attention to colonoscopy performance in order to increase the efficacy of the CRC screening program.[4]

Contact E-Mail Address: e.breekveldt@erasmusmc.nl

Introduction: Screen-detected colorectal cancers (CRCs) are often treated less invasively than stage-matched non-screen-detected CRCs, but the reasons for this are not fully understood. This study aimed to describe the treatment of stage I CRCs detected within and outside the CRC screening program in the Netherlands and to identify factors associated with treatment on population level.

Aims & Methods: Data from the Netherlands Cancer Registry of all stage I CRCs diagnosed between January 1, 2008 and December 31, 2020 were analyzed, comparing patient, tumor and treatment characteristics of screen-detected and non-screen-detected stage I CRCs. Multivariable logistic regression analyses were used to assess the association between treatment (local excision only vs. surgical oncologic resection) and patient and tumor characteristics, stratified for T-stage and tumor location.

	T1 colon cancers	T1 rectal cancers
	OR (95% CI)	*OR (95% CI)*
Sex		
Male	1	1
Female	1.03 (0.91-1.18)	1.26 (1.03-1.55)
Age category		
55-59 years	1	1
60-64 years	1.21 (0.98-1.51)	1.01 (0.72-1.43)
65-69 years	1.12 (0.91-1.37)	1.15 (0.83-1.59)
70-74 years	0.92 (0.74-1.13)	0.84 (0.60-1.17)
75-79 years	0.75 (0.60-0.94)	1.10 (0.76-1.59)
LVI		
No	1	1
Yes	3.15 (2.61-3.81)	1.55 (1.17-2.03)
Location		
Left	1	N/A
Right	4.20 (3.61-4.90)	N/A
Tumor differentiation		
Grade 1	1	1
Grade 2	1.58 (1.06-2.35)	1.32 (0.69-2.68)
Grade 3	6.96 (3.63-12.85)	3.19 (1.26-8.43)
Detection		
Screening	1	1
No screening	2.19 (1.93-2.49)	1.29 (1.05-1.59)

Table 1. Multivariable logistic regression analyses for the association between treatment and patient- and tumor characteristics with model a) T1 colon cancers and b) T1 rectal cancers.
Abbreviations: LVI: lymphovascular invasion. OR: odds ratio. CI: confidence interval.

Results: Screen-detected stage I CRCs were relatively more often T1 than T2 compared to non-screen detected stage I CRCs (66.9% versus 53.3%, p <0.0001). When only considering T1 tumors, both screen-detected colon and rectal cancers were more often treated with local excision only than non-screen detected T1 cancers (OR 2.19, 95%CI 1.93-2.49 and OR 1.29, 95%CI 1.05-1.59, respectively), adjusted for sex, tumor location, lymphovascular invasion (LVI) status and tumor differentiation (Table 1).

Conclusion: Less invasive treatment of screen-detected stage I CRC is partly explained by the higher rate of T1 compared with non-screen-detected stage I CRC. Those with T1 stage I CRCs were also more likely to undergo less invasive treatment if they were detected by screening, after adjusting for risk factors such as LVI and tumor differentiation.

Introduction: Testicular cancer (TC) survivors treated with platinum-based chemotherapy have an increased risk for developing secondary colorectal cancer (CRC) [1]. Colonoscopy surveillance is offered to other high-risk survivors to reduce CRC incidence and mortality. We aimed to assess the yield of colonoscopy in TC survivors.

[1] Groot HJ, Lubberts S, de Wit R, Witjes JA, Martijn Kerst J, de Jong IJ, et al. Risk of Solid Cancer After Treatment of Testicular Germ Cell Cancer in the Platinum Era. J Clin Oncol. 2018;36:2504–13. Available from: https://doi.org/10.1200/JCO.2017.

Aims & Methods: We conducted a prospective multicenter primary colonoscopy screening study in four Dutch hospitals. The yield of colorectal neoplasia among TC survivors was assessed at primary colonoscopy. Neoplasia was defined as adenomas, serrated polyps (SPs), advanced adenomas (AAs; high-grade dysplasia, ≥25% villous component, or ≥10mm diameter), advanced serrated polyps (ASPs; dysplasia or ≥10mm diameter), or CRC. Advanced neoplasia (AN) was defined as AA, ASP, or CRC. Yield of colonoscopy was compared to matched average-risk American males that underwent primary screening colonoscopy (n=24.193) and using a propensity score matched analysis, adjusted for age, smoking status, alcohol consumption and body mass index.

Results: A total of 137 TC survivors underwent colonoscopy. Median age was 50 years among TC survivors (IQR 43-57) vs. 55 years (IQR 51-62) in American controls. The prevalence of any neoplasia and AN was higher in TC survivors compared to age-matched American controls (Table 1). Using propensity score matching the difference in the prevalence of AN between TC survivors and American controls was even larger (8.7% vs. 1.7%; p<0.0001).

Most advanced lesion, n (%)	CATCHER	NHCR	p value
Total	137	24,193	<0.0001
No lesions	63 (46.0)	15,615 (64.5)	
Adenomas and/or SPs	62 (40.8)	7,249 (30.0)	
Advanced neoplasia	12 (8.8)	1,329 (5.5)	
30-39 year olds			0.4
No lesions	12 (70.6)	197 (81.1)	
Adenomas and/or SPs	4 (23.5)	39 (16.0)	
Advanced neoplasia	1 (5.9)	7 (2.9)	
40-49 year olds			<0.001
No lesions	27 (51.9)	873 (74.7)	
Adenomas and/or SPs	22 (42.3)	238 (20.4)	
Advanced neoplasia	3 (5.8)	58 (5.0)	
50-59 year olds			<0.001
No lesions	16 (37.2)	8,713 (64.4)	
Adenomas and/or SPs	23 (53.5)	4,101 (30.3)	
Advanced neoplasia	4 (9.3)	721 (5.3)	
60-69 year olds			0.01
No lesions	8 (34.8)	4,870 (63.4)	
Adenomas and/or SPs	13 (56.5)	2,383 (31.0)	
Advanced neoplasia	2 (8.7)	434 (5.6)	
70-80 year olds			-
No lesions	0	962 (61.7)	
Adenomas and/or SPs	0	488 (31.3)	
Advanced neoplasia	2	109 (7.0)	

Table 1. Distribution of most advanced lesions in the CATCHER cohort vs. the NHCR (control) cohort, stratified per age category. Abbreviations: SP: serrated polyp. NHCR: New Hampshire Colonoscopy Registry.

Conclusion: TC survivors treated with platinum-based chemotherapy had a higher incidence of any neoplasia and AN compared with age-matched controls, which was underscored by the propensity score matching analysis. These results support our hypothesis that platinum-based chemotherapy increases the risk of developing colorectal neoplasia in TC survivors, emphasizing the importance of participation in CRC screening and clear risk communication.

Contact E-Mail Address: y.kishida@scchr.jp

Introduction: Colorectal cancer (CRC) can be divided into screen-detected and non-screen-detected CRC. Furthermore, based on the interval between CRC detection and a previous screening or examination, CRC can be classified into several groups, including interval cancer and post-colonoscopy CRC. The proportion and characteristics of each CRC need to be clarified to understand the usefulness and limitations of CRC screening; however, they have not been fully elucidated. Particularly, little data is available on interval cancer under the annual fecal immunochemical test (FIT) screening.

Aims & Methods: We aimed to examine the proportions and characteristics of CRC with different detection histories by conducting a multicenter prospective study in Japan ("C-DETECT study"). Consecutive adult patients with CRC were prospectively enrolled in four hub hospitals of cancer treatment. CRC detection methods and intervals from previous examinations were assessed using a questionnaire. Since the population-based CRC screening using an annual FIT is performed in Japan, FIT-interval cancer was defined as CRC detected within 1 year following a previous negative FIT. Three-year post-colonoscopy CRC (PCCRC-3yr), which was defined as CRC detected within 3 years after the previous colonoscopy with negative CRC, was also investigated. Differences in the lesion and patient characteristics were compared for patients with the following CRC using the chi-squared test: i) screen-detected and non-screen-detected CRC; ii) (a) FIT-interval cancer, (b) PCCRC-3yr, (c) CRC detected within 1 year after a positive FIT with noncompliance to colonoscopy, and (d) CRC other than (a), (b), and (c).

Results: Of 1,241 CRC patients (1064 with invasive and 177 with intramucosal CRC), 475 (38.3%) had screen-detected and 766 (61.7%) had non-screen-detected CRCs. Non-screen detected CRCs showed significantly higher proportions of presence of ≥T2 invasion, metastasis, worse histology (poorly differentiated adenocarcinoma, signet-ring cell, or mucinous carcinoma) and left-sided CRCs than screen-detected CRC (82.1% vs 52.8% (P<0.01); 52.0% vs 26.7% (P<0.01); 18.7% vs 11.4% (P<0.01); 71.1% vs 61.7% (P<0.01), respectively). FIT-interval cancer (a), PCCRC-3yr (b), and CRC detected within 1 year after a positive FIT with noncompliance to colonoscopy (c) accounted for 4.5%, 7.0%, and 3.9% of all CRCs, respectively, and for 3.9%, 5.4%, and 4.3% of invasive CRCs, respectively. The comparison among these three types (a, b, c) and the other (d) demonstrated a significant difference in the proportions of ≥T2 invasion ((a) 58.9%, (b) 44.8%, (c) 87.5%, and (d) 73.0%, respectively (P<0.01)), metastasis ((a) 33.9%, (b) 21.8%, (c) 54.2%, and (d) 43.9%, respectively (P<0.01)), right-sided CRC ((a) 42.9%, (b) 40.2%, (c) 18.8%, and (d) 28.6%, respectively (P<0.01)), and female patients ((a) 53.6%, (b) 49.4%, (c) 27.1%, and (d) 41.6% respectively (P=0.02)).

Conclusion: Non-screen-detected CRC accounted for a large proportion of patients and demonstrated advanced characteristics in terms of invasion depth and metastasis, as well as CRC detected shortly after a positive FIT with no colonoscopy. These findings emphasize the importance of screening and colonoscopy compliance following a positive FIT.

Notably, FIT-interval cancer and PCCRC-3yr existed in non-negligible proportions even under the annual FIT screening system and were characterized by higher proportions of a right-sided location and female. This novel finding suggests that these two types of CRCs may have different biological features from the others.

Disclosure: Nothing to disclose.

PREVALENCE OF ANAL HR-HPV INFECTION AND ABNORMAL CYTOHISTOLOGY IN MSM USING PREP COMPARED TO MSM LIVING WITH HIV

M. Surmont[1], M. Verheyden[2], J. Gutermuth[2], S. Sahebali[3], S. Allard[4]

[1]UZ Brussel, Department of Gastroenterology-Hepatology, Jette, Belgium, [2]UZ Brussel, Department of Dermatology and Venereology, Jette, Belgium, [3]UZ Brussel, Department of Pathology, Jette, Belgium, [4]UZ Brussel, Department of Internal Medicine and Infectious Diseases, Jette, Belgium

Contact E-Mail Address: magalimarie@hotmail.com

Introduction: Persistent high-risk Human Papillomavirus (HR-HPV) infection can lead to an anal high-grade squamous intraepithelial lesion (HSIL), the precursor lesion to anal squamous cell carcinoma (SCC).

HR-HPV prevalence is higher in men who have sex with men living with HIV (MSMLWH) than in HIV-negative MSM, respectively 74% and 37-41% (1,2). The use of Pre-Exposure Prophylaxis (PrEP) in HIV-negative MSM to prevent HIV contraction created a new Sexual Minority Group among MSM, i.e. MSM using PrEP. The aim of this study was to determine the prevalence of anal HR-HPV infection and abnormal anal cytohistology in MSM using PrEP and MSMLWH. Preliminary data are reported here and final results are expected in coming months.

Aims & Methods: MSM using PrEP and MSMLWH were enrolled in this mono-centric study during consultations at the S-clinic and the HIV-reference centre respectively. Patient characteristics, sexual behavior and demographics were collected using a questionnaire, completed on the day of the anal swab testing. Patients with HR-HPV infection, abnormal cytology or both were subsequently sent for High Resolution Anoscopy (HRA).

Results: At present, we enrolled 150 MSM using PrEP and 107 MSMLWH. Quality of anal swabs was sufficient in respectively 95% (n=143) and 81% (n=87). HR-HPV prevalence in MSM using PrEP was comparable with HR-HPV prevalence in MSMLWH; respectively 74% (n=106) and 75% (n=65) tested positive for at least one HR-HPV (p=1.000). No significant difference in abnormal cytology was seen; 53% (n=76) of MSM using PrEP and 58% (n=51) of MSMLWH had either ASC-US, ASC-H, LSIL or HSIL (p=0.6). Until today, 58 MSM using PrEP and 31 MSMLWH underwent HRA. Biopsies were

performed in 43 MSM using PrEP and 25 MSMLWH. Preliminary results on histology of lesions show presence of anal HSIL in 19% (n=11) and 32% (n=10) respectively (p= 0.706).

Conclusion: MSM using PrEP have a similar risk of HR-HPV infection and abnormal anal cytohistology as MSMLWH, which is higher than what has been reported in HIV-negative MSM not using PrEP (1). ANCHOR showed that treating anal HSIL reduces the incidence of anal SCC in people living with HIV (3), but the risk of progression to anal cancer and thus the need for screening and treatment is to be investigated in this immunocompetent population of MSM using PrEP.

Introduction: Screening by fecal immunochemical test (FIT) reduces colon cancer (CC) mortality and incidence, yet its efficiency may vary depending upon tumor location and recipient demographics. We addressed the modifications of left and right CC epidemiology following screening adoption.

Aims & Methods: To address the differences between left and right CC, we analyzed by Joinpoint, robust and logistic regression models the data of Parma County tumor registry, comprising 6697 incident cases above 50 years of age in the period 1994-2018 and recording screening adherence since the start in 2005.

Results: Adjusted standardized rates of left-CC declined significantly within screening age (50-69 years) (male annual percent changes [APC] -8.38; p<.001; female APC -13.1; p=.007), as well above it (male APC-4.97; p=.001; female APC -3.96; p=.003). The incidence of right-CC did not decline in screening age and increased above (male APC, 1.91%; p=0.001; female APC, 2.23%; p<0.001). Robust regression confirmed that left-CC decreased irrespectively of sex and age (all p<.001, but for elder males, p=.03), pointing to significant increase of right-CC across sexes and ages (all p£.006).

In multivariable regression models, as compared left-CC the risk of right-CC almost doubled in the 7thdecade (Odds Ratio 1.89, 95%CI 1.43-2.44; p=.001), was higher for females (OR 1.40; 95%CI 1.27-1.54; p<.001) and after screening adoption (OR 1.44, 95%CI 1.27-1.54; p<.001).

In sex specific models, the probability of right-CC in females increased from 65 years of age (OR 1.80, 95%CI 1.18-2.75; p=.007) and in males from 75 years (OR 1.58, 95% CI 1.09-2.27; p=.015).

Due to the unequal distribution of right-CC, the rate of interval cancers over screen detected ones was significantly different between males (78/315; 25%) and females (93/200; 46.5%; p=.0004).

Independently from screening participation, right-CC in females brought an increased risk only of stage II (OR 1.43, 95%CI 1.06-1.92; p=.017) while in males it also enhanced the risks of stage III (OR 1.54, 95%CI 1.17-2.02; p=0.002), and IV (OR 1.47, 95%CI 1.06-2.03; p=.02) cancers.

At Cox modeling, right-CC carried a lower risk of death in females than in males (HR 0.77, 95%CI 0.67-0.89; p<.001), independently from tumor stage and screening status.

Conclusion: The screening reduced only the incidence of left-CC, while that of right-CC raised with aging, primarily and earlier in females. Right-CC progression in males carried a higher risk of death. Unimodal administration of FIT was followed by increasing burden of right-CC, advocating awareness on its specific development and progression by sex and age.

Disclosure: Nothing to disclose.

RISK FACTORS OF RECTAL NEUROENDOCRINE TUMOR IN A LARGE POPULATION BASED COHORT

S.U. Kim[1], S.Y. Nam[1], S.W. Jeon[1]

[1]School of Medicine, Kyungpook National University, Internal Medicine, Daegu, South Korea

Contact E-Mail Address: galilei511@naver.com

Introduction: Risk factors for rectal neuroendocrine tumor (NET) has not been reported in a cohort setting, even if their association was reported in a cross sectional study. We investigated sex-specific risk factors of rectal NET in a population-based cohort.

Aims & Methods: This is a population-based cohort study. Cancer and NET-free individuals who underwent general health examination during 2010 at the Korean National Health Insurance Service were enrolled and followed through 2017. Many epidemiologic factors and lipid were evaluated. Adjusted hazard ratios (aHR) and 95% confidence intervals (CI) determined by Cox regression analysis were used to investigate risk of NET.

Results: Rectal NET was newly detected in 2339 of 5.522 million individuals. In adjusted analysis, male sex (HR, 1.32; 95% CI, 1.17-1.48), current smoker (HR, 1.19), past smoker (HR,1.14), and obesity (HR, 1.462; 95% CI, 1.01-2.11 in BMI >=30) increased the risk of rectal NET. Frequent alcohol consumption increased the risk of rectal NET with dose dependent manner (HR, 1.36 in 1/week, 1.47 in 2-3/week, 1.54 in 4-5/week, 1.16 in >=6/week). In men, current smoker, past smoker, frequent alcohol consumption, and obesity (HR, 2.51; 95% CI, 1.41-4.45 in BMI >=30) increased the risk of NET. In women, past smoker (HR, 1.65), frequent drinker, and previous hysterectomy history (HR, 1.54; 95% CI, 1.16-2.03) increased the risk of rectal NET. Younger age was associated with rectal NET risk in both men and women.

Conclusion: Younger age, smoking, frequent alcohol consumption increased the risk of rectal NET in both men and women, whereas obesity markedly increased rectal NET in men but not in women. In women, previous hysterectomy history increased the risk of rectal NET.

INTERVAL COLORECTAL CANCERS IN THE CZECH REPUBLIC

S. Suchanek[1], O. Ngo[2,3], M. Ambrozova[3], K. Hejcmanova[2,3], R. Chloupkova[2,3], T. Grega[1], O. Majek[2,3], L. Dušek[2,3], M. Zavoral[1]
[1]Military University Hospital, Department of Internal Medicine and Department of Gastrointestinal Oncology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [3]Institute of Health Information and Statistics of the Czech Republic, Prague, Czech Republic

Contact E-Mail Address: stepan.suchanek@uvn.cz

Introduction: The organized, population-based National Colorectal Cancer (CRC) Screening Program in the Czech Republic is focused on asymptomatic individuals aged over 50. There are two methods available. Fecal occult blood test (FOBT) is offered by general practitioners annually at ages 50 – 54 and biennially at age ≥ 55 (followed by FOBT+ colonoscopy, if positive). And screening colonoscopy from age 50, repeated in 10 years interval, if negative. Both, FOBT+ colonoscopy and screening colonoscopy are considered preventive colonoscopies. FOBT performed in the laboratory is designated as diagnostic FOBT. Interval cancer is defined as a malignity diagnosed after an index exam (preventive, diagnostic, or therapeutic) in which no cancer is detected, and before the date of the next recommended exam.

Aims & Methods: The analysis included men and women of age ≥ 55 diagnosed with their first colorectal cancer in the period 2016-2020 (data source: National Cancer Registry). For those patients, the search of examinations in the National Registry of Reimbursed Health Services was performed focused on procedures in the period 0.5-5.5 years (depending on the type of examination; FOBT till 2.5 years, colonoscopy till 5.5 years) before the time of the cancer diagnosis: FOBT (screening and diagnostic), FOBT+colonoscopy and screening colonoscopy marked as preventive colonoscopy, diagnostic colonoscopy. As therapy, the endoscopic polypectomy, mucosal resection, and submucosal dissection performed within 6 months of the mentioned examinations were considered.

Results: There were colorectal cancers in 30,723 patients found (Table 1), with 13,816 cancers in stages III and IV (45.0%). The majority of the patients (64.4%) did not undergo any observed procedure. 20.3% of patients had negative FOBT, so, they were considered as patients with interval cancer. Preventive colonoscopies were accompanied by a low rate of interval cancers (0.9%).

Procedures in patients with colorectal cancer	All stages No. (%)	Advanced stages (II and IV) No. (%)
Preventive colonoscopy with therapy	354 (1.2%)	126 (0.9%)
Preventive colonoscopy without therapy	289 (0.9%)	123 (0.9%)
Screening FOBT positive with diagnostic colonoscopy	279 (0.9%)	72 (0.5%)
Screening FOBT positive without any diagnostic colonoscopy	1,073 (3.5%)	447 (3.2%)
Screening FOBT negative	6,228 (20.3%)	2,769 (20.0%)
Diagnostic colonoscopy	2197 (7.2%)	879 (6.4%)
Diagnostic FOBT	509 (1.7%)	223 (1.6%)
No examination	19,794 (64.4%)	9,177 (66.4%)
Total	30,723	13,816

Conclusion: The highest number of colorectal cancers was found in patients with no procedures related to CRC incidence and mortality reduction (preventive, diagnostic, or therapeutic). Approximately 20% of people with colorectal cancers had interval carcinoma (after negative screening FOBT) which could be caused by the inappropriate setting of FOBT examination or low sensitivity of FOBT. The higher proportion of cancers after negative screening FOBT might be also caused by the fold higher number of procedures FOBT performed.

ADHERENCE TO THE HUNGARIAN POPULATION-BASED COLORECTAL SCREENING PROGRAM AND POTENTIAL INFLUENCING DEMOGRAPHIC FACTORS

A. Fabian[1], R. Bor[1], B. Vasas[2], Z. Bosze[1], M. Szűcs[3], T. Tóth[1], A. Balint[1], P. Bacsur[1], K. Farkas[1], T. Resál[1], M. Rutka[1], T. Molnár[1], Z. Szepes[1]
[1]University of Szeged, Szent-Györgyi Albert Medical School, Department of Internal Medicine, Szeged, Hungary, [2]University of Szeged, Department of Pathology, Szeged, Hungary, [3]University of Szeged, Department of Medical Physics and Informatics, Szeged, Hungary

Contact E-Mail Address: fabiananna9@gmail.com

Introduction: Participation in colorectal cancer (CRC) screening programs significantly vary with 36–71% fecal occult blood test (FOBT) uptake rates, and compliance with referral for colonoscopy ranging 64–92% in Europe. The Hungarian population-based colorectal cancer (CRC) screening program (EFOP-1.8.1-VEKOP-15-2016-00001) was launched in 2019 among asymptomatic individuals between the ages of 50 and 70 with average risk of CRC.

Aims & Methods: The aim of this study was to assess the adherence to Hungarian population-based CRC screening program (EFOP-1.8.1-VEKOP-15-2016-00001), and to determine influencing demographic factors. This observational, non-interventional cohort study retrospectively analyzed participation data of the Hungarian population-based CRC screening program between 2019 and 2022, prospectively collected in National Public Health Institute's registry.

Data were analyzed as that of 13/02/2023. Gender and type of residence (municipality, town, city with county rights, and capital) were investigated as demographic parameters potentially influencing adherence rates with logistic regression.

Results: Of 1,819,664 invited individuals, 377,552 returned the screening kit, resulting in 20.8% adherence to FOBT. 36,995 individuals (9.8%) had non-negative results. 20,902 individuals (56.5%) were reported to undergo screening colonoscopy.

Adherence rates to FOBT decreased over the years since the initiation of the screening program: yearly rates for returning screening kits from 2019 to 2022 were 32.1%, 24.8%, 18.8%, and 14.1%, respectively. In contrast, adherence rates to screening colonoscopy showed less variation over the years (58.9%, 52.7%, 52.3%, 55.62% from 2019 to 2022). Average kit returning time over the years was as follows: 99.2±0.2 days, 66.6±0.3 days, 56.0±0.5 days, and 68.0±0.1 days, from 2019 to 2022, respectively.

Over the years, colonoscopy was performed following the FOBT results after an average of 85.5±0.9 days, 93.8±1.5 days, 56.6±2.0 days, and 52.8±0.4 days. Female gender was associated with higher adherence to returning screening kits (22.4% vs. 18.8%).

Attendance rates at screening colonoscopies were 57.2% for males and 55.5% for females. Screening kits were returned by 19.1% of individuals living in municipalities, 20.5% of those living in towns, 23.5% of those living in cities with county rights and 19.8% of those living in the capital.

Attendance rates at colonoscopy according to type of residence were the following: 57.8% for individuals from municipalities, 53.9% for those from towns, 60.3% for those from cities with county rights, and only 50.2% for those from the capital. Adherence rates to FOBT tests were significantly influenced by both gender and type of residence, while attendance rates at screening colonoscopy was only influenced by type of residence.

Conclusion: Adherence rates to Hungarian CRC screening program are somewhat lower than in other European countries. Although adherence rates to FOBT gradually decreased since the initiation of the CRC screening program, adherence rates to screening colonoscopy remained stable. Socio-demographic factors influence screening adherence.

IMPACT OF A COLORECTAL CANCER SCREENING PROGRAM IN THE SOUTHWESTERN OLTENIA REGION

A.G. Bocioaga[1], C.T. Streba[1], C.N. Oancea[1], T. Ciurea[1], D.I. Gheonea[1]

[1]University of Medicine and Pharmacy of Craiova, Research Center of Gastroenterology and Hepatology, Craiova, Romania

Contact E-Mail Address: alexandra.bocioaga@yahoo.com

Introduction: Colorectal cancer (CRC) is one of the most commonly diagnosed types of cancer worldwide, ranking as the third most common neoplasia and the second leading cause of cancer-related deaths according to Global Cancer Statistics 2020 [1].

In Romania, CRC has the highest incidence rate, as reported by the Globocan platform in 2020, although the mortality rate follows global trends. The growing incidence of colorectal cancer poses a significant challenge to the global healthcare system [2].

Aims & Methods: Our aims are to assess and demonstrate the importance and value of a CRC screening program in early diagnosis among individuals aged 50 to 75 years in the southwestern of Oltenia, Romania. We prospectively enrolled apparently healthy individuals between 50 and 75 years old in a CRC prevention program at the University of Medicine and Pharmacy of Craiova, in the southwestern Oltenia region. The ongoing program started in November 2020.

Exclusion criteria included individuals already enrolled in a screening program for CRC, with a personal history of colonic polyps, colorectal cancer, or inflammatory bowel diseases and individuals with a family history of inherited syndromes linked with CRC**.** Patients were identified based on the lists provided by participating general practitioners.

All provided informed consent and completed a questionnaire regarding symptoms and family history of CRC. Based on their responses, patients were either offered a fecal immunochemical test (FIT) followed by colonoscopy in case of a positive result or were directly referred for colonoscopy. Those with negative results were instructed to repeat the test in two years.

Results: Until 24 April 2023 we enrolled 44,714 individuals (18,415 male, 41.18%). Of these, 38,610 (86.34%) received FITs, of whom 2,426 (6.28%) had a positive finding and 49 were directly referred for colonoscopy based on their questionnaire answers. We performed 1,262 colonoscopies, also having 1,004 refusals (41.38% of positive FITs) and 209 (8.61%) in waiting. Percentage of positive FIT tests correlated with older age ($p<0.05$). The chance of a positive colonoscopy finding correlated with the FIT value ($p<0.05$) and older age ($p<0.05$), while not being linked to either gender or provenance.

We did not find lesions in 400 subjects (31.7% negative colonoscopies). In total, we found 2,092 significant lesions in 862 patients: 100 tumors and 1,992 polyps.

Conclusion: We provided here the first results of a large-scale CRC screening program in the Southwestern region of Romania, proving the importance of a coherent early detection strategy in the successful management of digestive malignancies. The high rate of colonoscopy refusals shows the need for an awareness campaign involving all medical and allied health personnel.

LONG-TERM COLORECTAL CANCER INCIDENCE, UNPERTURBED BY SURVEILLANCE, AMONG PEOPLE WITH NO POLYPS OR LOW-RISK POLYPS: AN ANALYSIS OF DATA FROM THE UK FLEXIBLE SIGMOIDOSCOPY SCREENING TRIAL

E.C. Robbins[1], K. Wooldrage[1], B.P. Saunders[2], A.J. Cross[1]

[1]Imperial College London, Cancer Screening & Prevention Research Group, London, United Kingdom, [2]St. Mark’s Hospital, Wolfson Unit for Endoscopy, London, United Kingdom

Contact E-Mail Address: e.robbins@imperial.ac.uk

Introduction: Existing data on long-term colorectal cancer (CRC) incidence after polyp removal has limitations. Colonoscopy surveillance is frequently performed post-polypectomy, altering CRC incidence, but this is often not adequately addressed in analyses.

Additionally, numbers of CRC cases are often insufficient for precise estimates or subgroup analyses.

Aims & Methods: Our aim was to examine long-term CRC incidence, unperturbed by surveillance, in patients who had no polyps or low-risk polyps at endoscopic screening, by anatomic subsite. In the UK Flexible Sigmoidoscopy Screening Trial, ~41,000 participants had a once-only flexible sigmoidoscopy screen and were followed-up for a median of 21 years. This analysis includes participants who had no polyps or low-risk polyps found in the distal colon or rectum at screening, with polypectomy when needed. Only 0.5% had a baseline colonoscopy and 0.2% had colonoscopy surveillance. Participants with low-risk polyps were those with <3 adenomas <10mm with tubular histology and low-grade dysplasia and/or hyperplastic polyps <10mm. Outcomes were incident CRC by anatomic subsite (distal, proximal). Time-to-event data were censored at any first surveillance colonoscopy.

Cox regression compared incidence between those with no polyps and those with low-risk polyps, adjusted for age, sex, and baseline characteristics independently associated with CRC incidence. Standardised incidence ratios compared incidence to that in the general population (England, 2005).

Results: Of 37,911 participants in the analysis, 29,810 (79%) had no polyps and 8,101 (21%) had low-risk polyps. Compared to those with no polyps, distal and proximal cancer incidence was higher in those with low-risk polyps. Compared to the general population, distal cancer incidence was lower in those with no polyps and in those with low-risk polyps. Compared to the general population, proximal cancer incidence was not significantly different in those with no polyps but was higher in those with low-risk polyps (Table 1).

Subsite	Group	Number of cases	Incidence rate per 100,000 person-years (95%CI)	Multivariable hazard ratio (95%CI)	p-value[a]	Standardised incidence ratio (95%CI)[b]
Distal	No polyps	184	32 (28-37)	1	0.01	0.27 (0.23-0.31)
	Low-risk	66	45 (35-57)	1.46 (1.09-1.94)		0.33 (0.26-0.42)
Proximal	No polyps	366	65 (58-72)	1	<0.001	0.91 (0.82-1.01)
	Low-risk	170	115 (99-134)	1.81 (1.50-2.18)		1.57 (1.34-1.82)

CI: confidence interval.
[a]Calculated with the likelihood ratio test.
[b]Calculated by dividing observed by expected numbers of cancer cases, presented with exact Poisson 95%CIs.

Table 1. Colorectal cancer incidence and age-sex-standardised incidence ratios, by polyp group and anatomic subsite.

Conclusion: After flexible sigmoidoscopy screening, with no colonoscopy surveillance, the risk of distal cancer among those with no polyps or low-risk polyps was substantially lower than in the general population; however, among those with low-risk polyps, the risk of proximal cancer was higher than in the general population. Participants with distal low-risk polyps at baseline appear to have had a propensity for synchronous and/or metachronous proximal neoplasia and might have benefited from a baseline or surveillance colonoscopy.

DIAPH3 IS UPREGULATED THROUGH M1A METHYLATION, AND PROMOTES THE INVASIVENESS OF COLORECTAL CANCER VIA TARGETING KRT19

M. Xue[1], S. Mi[1]
[1]The Second Affiliated Hospital, School of Medicine, Zhejiang University, Gastroenterology, Hangzhou, China

Contact E-Mail Address: xuemeng@zju.edu.cn
Introduction: In recent years, emphasis has been shifted on to understanding the role of N1-methyladenosine (m1A) in tumor progression. While little is known about its regulatory effect on mRNA and its role in metastatic colorectal cancer (CRC).
Aims & Methods: We performed methylated RNA immunoprecipitation sequencing with tumor tissues and tumor-adjacent normal tissues from three CRC patients to determine the profile of m1A methylation in CRC. Expression of Diaphanous-related formin 3 (DIAPH3) and its correlation with clinicopathological characteristics of CRC were evaluated using immunohistochemistry and online datasets. The role of DIAPH3 in the migration and invasion of CRC cells was evaluated by wound healing and transwell assays. Besides, the downstream targets of DIAPH3 were screened by mass spectrometry analysis. By co-transfecting DIAPH3 siRNA and Keratin 19 (KRT19) ectopic plasmid in CRC cells, the role of DIAPH3-KRT19 signaling axis was confirmed.
Results: The mRNA level of DIAHP3 and its m1A modification were increased simultaneously in CRC. Besides, high expression of DIAPH3 in CRC tissues was significantly associated with metastasis, and tended to progress to an advanced stage. After knocking down the expression of DIAPH3, the migration and invasion capabilities of CRC cells suffered notable decline, which can be rescued by overexpressing KRT19. Besides, the degradation of KRT19 might be regulated by DIAPH3 in a proteasome-dependent pathway.
Conclusion: DIAPH3 mRNA was upregulated in CRC cells through m1A methylation. Targeting DIAPH3 results in suppressed migration and invasion of CRC cells, potentially through proteasome-dependent degradation of downstream KRT19.
Disclosure: Nothing to disclose.

Introduction: Colorectal cancer (CRC) is one of the leading causes of cancer-related mortality and morbidity worldwide. Its tumor microenvironment is composed of a complex interplay of various monocytes, dendritic cells, macrophages and T-cells. Among them, there are various subtypes of T-cells, each of which plays a very important role and has been reported to be associated with prognosis in various cancers. In CRC, there are many reports on the association between CD8+ T-cells and Foxp3+ T-cells and prognosis. However, these are all reports mainly focused on advanced cancers. No studies on T-cells focused on early-stage CRC have been reported to date. Among early-stage CRC, submucosal deep invasive (T1b) CRC has a lymph node metastasis rate of about 10%.
Although submucosal invasion depth, vascular invasion, histologic grade, or budding grade are known to be pathological risk factors of lymph node metastasis, there have been no reports evaluating the relationship between tumor microenvironment and lymph node metastasis.
Therefore, in this study, we aimed to investigate the characteristics of T-cells according to the degree of CRC invasion and the association between T-cells and the risk of lymph node metastasis in T1b CRC.
Aims & Methods: Initially, 60 patients with colorectal neoplasia [20 with intramucosal neoplasia (IM group); 20 with submucosal invasive CRC (SM group); and 20 with advanced cancer (AD group)] treated at Hiroshima University Hospital from January 2011 to December 2015 were randomly selected. We examined changes in T-cells with tumor invasion. Next, 84 patients with T1b CRC who underwent initial surgical resection with lymph node dissection or additional surgical resection with lymph node dissection after endoscopic resection at Hiroshima University Hospital from March 2013 to July 2019 were selected.
We examined the relationship between T-cells and lymph node metastasis in T1b CRC. For all specimens, the phenotype and number of T-cells were evaluated using the triple immunofluorescence method of CD4 (helper T-cell marker), CD8 (killer T-cell marker), and Foxp3 (regulatory T-cell marker). We counted T-cells by subtype in the center (CT) and the invasive front (IF) of the tumor and examined their association with lymph node metastasis.
Results: In the IM group, there was no significant difference in the number of any subtype between CT and IF, while in the SM and AD groups, all subtypes were more numerous in IF than CT. They were also predominantly more numerous as the degree of tumor invasion with IM, SM, and AD. The high number of Foxp3 in IF and the high ratio of Foxp3/CD4 and Foxp3/CD8 were positively correlated with lymph node metastasis.
Conclusion: High Foxp3 counts and high Foxp3/CD4 and high Foxp3/CD8 ratios in IF of T1b CRC may help predict lymph node metastasis.
Disclosure: The authors have no conflicts of interest or financial ties to disclose.

Introduction: Colorectal cancer(CRC) is the third most common cancer in the world and the fourth most common cause of cancer death. Its incidence has continued to increase in recent years. MicroRNAs (miRNAs) are the most studied non-coding RNAs. In the process of tumorigenesis and development, miRNA plays an important role as an inhibitor or proto-oncogene of tumors, which makes miRNAs extremely attractive targets for new treatment methods of tumors. microRNA-derived protein (MidP619) is highly specific and highly expressed in most tumors, but expressed low in normal cells. The downregulation of MidP619 hinders the proliferation and metastasis of various tumor cell lines.

The results of this study reveal for the first time the important role of miRNA at the 3' end, confirm a novel protein translation mode, and elucidate its important role in tumorigenesis and development through relevant experiments.

Aims & Methods: The expression of MidP619 in CRC and non-cancerous tissue was detected by immunohistochemical staining. CO-IP and protein mass spectrometry were used to identify MidP619 and its associated interaction proteins, and bioinformatics analysis was performed on their interaction protein data. After overexpression of MidP619 by protein mass spectrometry analysis and proteomics-related bioinformatics, the relevant protein components and their changes were studied. Transwell assay was used to study tumor invasion and migration; CCK-8 analysis to study tumor metabolic capacity; Edu was used to analyze tumor cell proliferation; Tumor migration ability was detected by wound healing assay; Colony formation experiments were used to identify tumor colony formation. A series of in vivo experiments were conducted to help reveal the mechanisms of MidP169 in colorectal cancer.

Results: MidP169 expression was markedly higher in CRC tissues than in non-tumour tissues. Through protein interaction and protein mass spectrometry, the interaction between MidP619 and angiogenesis-related proteins ANXA2, ANXA1 and PARVA was verified. The MidP619 overexpression in the colorectal cancer cell line was found that it had an important role in the occurrence and development of tumors through proteomic verification. Through overexpression and knockout of MidP619, Transwell, CCK-8, Edu, wound healing and colony formation experiments, it was verified that MidP619 plays an important role in the proliferation, migration and invasion ability of CRC cells. Western blot experiments preliminarily verified that MidP619 may play an important role in tumor epithelial-mesenchymal transformation (EMT) or tumor angiogenesis.

Finally, overexpression of MidP169 increased the malignancy of the tumor and angiogenesis-related treatments inhibited tumour growth in a xenograft mouse model.

Conclusion: Through the study of MidP619 in CRC, it has been confirmed that MidP619 is widely involved in the proliferation, invasion, migration, metabolism, angiogenesis and other factors leading to increased malignancy of colorectal cancer at the cellular, animal and clinical levels. Through interaction proteins and proteomics experiments, the interacting proteins of MidP619 and the related pathways involved in them were discovered. It provides more evidence for the protein translated by the new model of MidP to play a role in the body, especially tumors.

Disclosure: Nothing to disclose.

ROOT-CAUSE ANALYSIS OF POST-COLONOSCOPY COLORECTAL CANCER PATIENTS IN A LARGE TERTIARY ISRAELI MEDICAL CENTER

I. Ghersin[1], M. Postnikov[2], Y. Gorelik[1], B.G. Silverman[3], A. Klein[1,4], A.A. Flugelman[5,4], E.E. Half[1,4]
[1]Rambam Health Care Campus, Gastroenterology, Haifa, Israel, [2]Rambam Health Care Campus, Internal Medicine B, Haifa, Israel, [3]Israel Center for Disease Control, Ministry of Health, Israel National Cancer Registry, Ramat Gan, Israel, [4]Technion - Israel Institute of Technology, Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel, [5]Rambam Health Care Campus, Preventive Medicine Center, Haifa, Israel

Contact E-Mail Address: eohalf@gmail.com

Introduction: Post-colonoscopy colorectal cancer (PCCRC) is defined by the World Endoscopy Organization (WEO) as CRC recorded between 6 to 48 months after a negative colonoscopy. Previously described causes for PCCRC include missed lesions, inadequate bowel preparation, unresected lesions and incomplete resection. Causes of PCCRC in Israel have not been described.

Aims & Methods: Using the root-cause algorithm proposed by the WEO, we aimed to investigate plausible explanations for PCCRCs in a tertiary center in Israel.

We extracted data on all colonoscopies performed in the Department of Gastroenterology at Rambam Health Care Campus between 2001-2021. Data were crossed-linked with the Israeli cancer registry to identify all patients who received a first-time diagnosis of CRC. All patients who received a diagnosis of CRC after an index negative colonoscopy at our institution were considered as possible PCCRC cases.

For all possible PCCRC cases individual electronic medical records (EMRs) were reviewed by a physician to assure PCCRC status. Patients not meeting the WEO definition of PCCRC, those without sufficient information on clinical, endoscopy and/or pathology findings to confirm the PCCRC status, those with histology other than colorectal adenocarcinoma, and patients with appendiceal cancers were excluded.

For PCCRC cases we applied the WEO algorithm to categorize explanations for PCCRC as follow:

A. Possible missed lesion, prior examination adequate;

B. Possible missed lesion, prior examination inadequate;

C. Detected lesion, not resected; or

D. Likely incomplete resection of previously identified lesion.

Results: Out of 220 cases of possible PCCRC, 130 did not meet the WEO definition for PCCRC, and 57 were excluded due to missing data (n=49), incompatible histology (n=7) or appendiceal location (n=1). Thirty three cases meeting the WEO definition of PCCRC were analyzed. Average patient age at diagnosis was 65.4 years. Six patients (18.2%) had a positive family history of CRC. Four patients (12.1%) had a prior diagnosis of inflammatory bowel disease. Thirty of 33 (91%) index colonoscopies were complete (cecal intubation reported). The most common tumor locations were the rectum (6/33, 18.2%) and cecum (5/33, 15.1%).

We identified 14 category A PCCRCs (42.4%); 16 category B PCCRCs (48.5%); 3 category C PCCRCs (9.1%); and 4 category D PCCRC (12.1%). Among them 4 patients (12.1%) could be categorized into more than one group. When further analyzing the cause of each case, we found that in 18 of 33 cases (54.5%) altogether there was miscommunication between the endoscopist and the patient or the endoscopist and the primary referral physician regarding the post colonoscopy recommendations.

Conclusion: As previously reported, most PCCRCs in our cohort originated from possible missed lesions in the setting of inadequate examinations. As such most of these cases could have been avoided by repeating colonoscopy. We had the advantage of further studying individual cases, and

we can determine that over half of PCCRCs can be avoided by improving the communication process between the endoscopist, the referring physician, and the patient. These findings highlight the importance of communication in the prevention of PCCRCs.

Disclosure: Nothing to disclose.

OPTIMAL GLYCEMIC CONTROL AND VARIABILITY INDEPENDENTLY DECREASES COLORECTAL CANCER DEVELOPMENT: A TERRITORY-WIDE STUDY OF 171,270 PATIENTS WITH DIABETES MELLITUS

X. Mao[1], K.S. Cheung[1], J.T. Tan[1], L.-Y. Mak[1], C.H. Lee[1], C.L. Chiang[2], R.W.H. Hui[1], H.M. Cheng[1], M.-F. Yuen[1], W.K. Leung[1], W.-K. Seto[1]
[1]The University of Hong Kong, Department of Medicine, Hong Kong, Hong Kong, [2]The University of Hong Kong, Clinical Oncology, Hong Kong, Hong Kong

Contact E-Mail Address: mongolhorse2002@gmail.com

Introduction: Diabetes mellitus (DM) is an independent risk factor for colorectal cancer (CRC). Glycemic control and variability are the main components of glycemic homeostasis. We aim to identify the association of glycemic control and variability with CRC development in individuals with DM.

Aims & Methods: Patients with DM diagnosed between 2005 and 2013 were followed up till 2020 (CRC or death occurrence) via a territory-wide electronic healthcare registry from Asia. We excluded age <18 years, those with human immunodeficiency virus, inflammatory bowel disease, insufficient HbA1c measurements, and prior diagnosed CRC. We identified DM following the American Diabetes Association criteria with at least two abnormal tests of hemoglobin A1c (HbA1c) ≥6.5% or fasting plasma glucose ≥7 mmol/L; antidiabetic medication use; or International Classification of Diseases Ninth Revision (ICD-9).

An initial three-year lead-in period from the DM diagnosis date was applied to evaluate glycemic control and variability: optimal glycemic control was regarded as mean HbA1c <7% from at least two measurements; lower glycemic variability was regarded as measurements of <25% quantile, including standard deviation (SD), coefficient of variation, and average successive variability. Cox regression models with inverse probability of treatment weighting (IPTW) of study characteristics were used to calculate hazard ratios (HRs) of CRC with optimal glycemic control.

Results: During a median follow-up of 6.7 (interquartile: 5.3-8.7) years, 2,231 (1.3%) of 171,270 patients with DM (mean [SD] age: 61.7 [11.7] years; male: 90,441 [52.8%]) developed CRC. Patient characteristics were well balanced after IPTW (all standardized mean differences <0.01). The 12-year cumulative incidence of CRC was 2.2% (95%CI 2.0%-2.4%) and 2.7% (95%CI 2.5%-3.0%) in optimal and suboptimal glycemic control respectively with an HR of 0.83 (95%CI 0.76-0.90). The association was validated in sensitivity analyses (HRs: 0.79-0.88) and consistent across subgroups regardless of at-risk age (40-75 years), obesity, smoking status, aspirin use, and diabetes-related comorbidity (HRs: 0.73-0.86). CRC risk increased incrementally with HbA1c increases beyond ≥7% in the multivariate Cox regression model, from an adjusted HR of 1.31 (95%CI 1.17-1.48) for HbA1c 7.0%-7.5%, to 1.36 (95%CI, 1.16-1.59) for HbA1c 7.5%-<8.0%, to 1.47 (95%CI, 1.20-1.80) for HbA1c 8.0%-<8.5%.

The beneficial effects of glycemic control were limited to the left colon (HR 0.82, 95%CI 0.71-0.94) and rectum (HR 0.81, 95%CI 0.68-0.96) but not to the right colon (HR 0.92, 95%CI 0.75-1.11). Among those who had colonoscopy during the study period (n=14,399), optimal glycemic control was associated with lower CRC risk in patients with (HR 0.78, 95%CI 0.67-0.92) and without (HR 0.85, 95%CI 0.73-0.98) adenomas. Lower vs. higher glycemic variability yielded consistent associations for CRC risk (HRs: 0.81-0.85; All P <0.001). Optimal glycemic control had no association with adenoma (HR 1.01, 95%CI, 0.96-1.07) and advanced adenoma (HR 0.98, 95%CI 0.87-1.10) development.

Conclusion: Optimal glycemic control was independently associated with reduced CRC development in patients with DM, while the worsening of glycemic control was associated with an incrementally increased cancer risk. Our study findings can aid CRC risk stratification of among patients with DM.

Introduction: Colorectal Cancer (CRC) is the third most common cancer worldwide. Only scant data is known regarding specific ethnicities and minorities. The Arab population in Israel is about 20% of the population; the Arab population in Israel has unique historical, social, and cultural characteristics. The Arab society in Israel has undergone major and rapid changes in lifestyle in the last five decades, from agricultural to urban society, with changes in nutrition, a high rate of smoking among men, a low rate of physical activity, and a high rate of consanguinity, which affect the health of the population.

Aims & Methods: We aimed to investigate the general characteristic, comorbidities, and all cause-mortality of CRC among the Arab population compared to the Jewish population.

CRC patients, according to ICD-10 codes were retrospectively included between the years 1999 and 2021. Data regarding demographics, age at diagnosis, comorbidities, and mortality were collected. Data were retrieved using the MdClone platform from the largest Health Maintenance Organization, "Clalit" in Israel. The risk factors and comorbidities were compared between young patients (≤50 years) compared to the other patients.

Results: 61,679 CRC patients were included in the present study, 4891 (7.9%) of Arab ethnicity and 56,788 of Jewish ethnicity. Age at diagnosis is significantly younger Among Arab (62.5±14 vs 70.8±13 years, p<0.001), with a higher males proportion of 51.3% vs 49.2%, p=0,005). 21.3% of the Arab CRC patients were diagnosed at age 50 or younger, compared to 8% of Jewish patients, p<0.001. Significant differences were found in family history of CRC and smoking (3.6% vs 6.2%, 34.9% vs 30%, respectively. Higher rates of diabetes mellitus and obesity were found among Arab patients (37.6% vs 27.5%, and 36% vs 21.4%, p<0.001), while lower rates of ischemic heart disease, hypertension and chronic kidney disease (9.7% vs 12.6%, 45.6% vs 53.7% and 8.1% vs 10.3%, p<0.001, respectively.

All-cause mortality was lower among patients of Arab ethnicity (49.6% vs 60.8%, p<0.001) with younger age at death (70.9±14.5 vs 79.8±11.8, p<0.001).

Conclusion: Disparities in risk factors, comorbidities, and all-cause mortality were found in different ethnic groups; special consideration is needed for specific ethnicities and minorities according to the colon cancer characteristics.

Introduction: This study aimed to build up prognosis model and discover novel prognostic biomarkers for colon adenocarcinoma (COAD) based on ferroptosis-related lncRNA analysis.

Aims & Methods: The RNA-sequencing data and clinical information were obtained from TCGA database. Ferroptosis-related genes used were downloaded from the GSEA database. We screened ferroptosis-related lncRNAs with correlation coefficient >0.3 and P <0.001. Firstly, the prognostic value of ferroptosis-related lncRNAs with P < 0.05 was assessed by univariate Cox regression. Then, the results were submitted to Least Absolute Shrinkage and Selection Operator (LASSO) regression. Eventually, the results of LASSO were incorporated into a multivariate Cox model in order to calculate risk scores. We developed a risk score formula for predicting overall survival (OS), based on a linear combination of ferroptosis-related lncRNAs expression levels multiplied with a regression coefficient. According to the median risk score, patients were divided into high-risk and low-risk groups. K-M method and log-rank test were applied to draw the survival curve of highly and lowly expressed prognostic ferroptosis-related lncRNAs. Cox regression was utilized to build up an independent prognostic model. The index of concordance (C-index), calibration curves, and receiver operating characteristic (ROC) curves were applied to assess the accuracy of the model. The clinical data were included in multivariate Cox regression in order to confirm whether the risk score was an independent indicator for the prognosis.

Results: An eight-lncRNAs signature was built up, 7 lncRNAs (ZEB1-AS1, AL354993.2, LINC02381, AP001505.1, NCK1-DT, CD27-AS1, AC068580.3) predicted a poor prognosis, and SNHG16 predicted a good prognosis. The formula of the risk score calculation: risk score = (0.557*ZEB1-AS1) + (0.199*AL354993.2) + (0.183*LINC02381) + (0.079*AP001505.1) + (0.279*NCK1-DT) + (0.107*CD27-AS1) + (0.532* AC068580.3 – (0.138* SNHG16). The low-risk group had longer OS than the high-risk group (P<0.001, log-rank test), so the risk score might be related to the OS of COAD patients. According to the forest map, the hazard ratios of risk score in univariate and multivariate Cox regression analyses were 1.354 (95% CI: 1.228-1.494, P <0.001) and 1.343 (95%CI = 1.202 -1.500, P <0.001), respectively. Either in univariate or multivariate analysis, the risk score was of independent significance for prognosis. The AUC of ROC curve in 3-years survival was 0.737 and 0.785 in 5-years survival. According to the multivariate factor ROC curves, besides risk score, age and TNM stage also had a good ability to predict overall survival, while gender had a weak ability. Next, risk score, age T, M, N and stage were included into the nomogram. As indicated in the nomogram, risk score and stage were the largest contributors to OS of COAD patients. The risk score increased with stage, demonstrating that this ferroptosis-related lncRNA signature could predict the clinical progression of COAD. We divided the clinical sample data into three groups to obtain the calibration diagram, showing that the OS predicted by the model was in a good agreement with the observed clinically. The C-index of the prognostic model was 0.795 (se=0.028).

Conclusion: A signature based on eight ferroptosis-related lncRNAs is efficient in predicting the prognosis of patients with COAD. The eight lncRNAs may be novel prognostic and therapeutic biomarkers for COAD. The specific mechanism of how ferroptosis-related lncRNAs affects tumor biological behavior remains to be researched.

Disclosure: Nothing to disclose.

Contact E-Mail Address: cheungjustinct@gmail.com

Introduction: Ranking 3rd in the most diagnosed cancer and 2nd in the leading cause of cancer deaths globally, colorectal carcinoma (CRC) is characterized by the nuanced multi-step carcinogenesis in which it acquires the hallmarks of cancer. Metastatic CRC (mCRC), which majorly appears in an advanced stage, has only a 12% 5-year survival. Notably, immediate resection of mCRC is rare, and the lack of operability motivates the further uncovering of carcinogenic mechanisms to broaden our therapeutic options. Our group has directed our focus on alternative splicing event which is frequently reported to be hijacked in cancer. By long-read sequencing in CRC organoids, we identified a novel isoform of citrate synthase (CS) with unprecedented exon-skipping (ΔCS) apart from the full-length isoform (CS-WT). Being the rate-limiting enzyme of the tricarboxylic acid cycle, differentially expressed ΔCS in CRC might be explanatory to metabolic reprogramming phenotype and may serve as a potential target of therapeutic intervention.

Aims & Methods: We validated the sequencing results in normal colonic (n=5), primary CRC (pCRC, n=10), and mCRC organoids (n=3), and in-house patient tumor and adjacent normal tissue pairs (n=97) by RT-qPCR. We performed survival analyses with progression-free survival, disease-free survival, and overall survival using all stages, late-stage, and early-stage stratification to explore the clinical relevance of ΔCS. We then proceeded into in vitro experimental validation in CRC cell lines, and in vivo tail-vein injection in NSG mice for investigating the biological phenomena. We also inspected the molecular mechanism to explain the oncogenic phenomena by focusing on the potential structural effects and enzymatic activity upon exon-skipping in ΔCS.

Results: An in-frame spliced CS transcript unreported in RefSeq and GENECODE was found upregulated in patient-derived pCRC organoids over normal organoids, and mCRC organoids have the highest ΔCS expression among the 3 groups. The clinical relevance of ΔCS was proven by 97 pairs of human CRC tissues, demonstrating a significant overexpression over non-tumoral colonic tissues (Paired student's t-test, p<0.001). Tumor-to-adjacent normal (T/AN) ratio analysis indicated that 80.4% of patients showed increased expression of ΔCS in tumor tissues. A significant association was observed between high ΔCS expression and recurrence (Fisher's exact test, p<0.01). Kaplan-Meier analyses, stratified by median expression, were performed and the high ΔCS expression group was found associated with lower survival rates when compared to the low ΔCS group in both PFS (Log-rank test, p<0.01) and DFS (p<0.005). We further separated groups by cancer stages and found that high ΔCS expression leads to worse survival outcomes in stage III & IV patients, indicating the metastatic feature associated with this isoform (OS: p<0.005; PFS: p<0.005).

Moreover, ΔCS silencing (shΔCS) demonstrated a more profound inhibition of cell proliferation compared with CS-WT knock-down (shCS-WT) and control. shΔCS groups also showed a significant increase in apoptosis cell counts. Overexpression of ΔCS showed enhanced migration ability in vitro and in vivo. The dimerization effect by ΔCS leads to enhanced CS activity, and metabolic shift to amino acids synthesis was found by GC-MS profiling.

Conclusion: Unannotated ΔCS isoform is explanatory to clinically important metastatic phenotype in CRC through metabolic alteration.

Disclosure: Nothing to disclose.

Introduction: Colorectal cancer (CRC) is the 3rd most common cancer worldwide. Approximately 85% of CRC develop on a background of Wnt/β-catenin signalling impairment. Familial adenomatous polyposis (FAP), caused by inherited APC gene mutations (part of the β-catenin destruction complex), is characterized by the development of hundreds to thousands adenomatous polyps. FAP patients have up to 100% risk of developing CRC during their lifetime. The Wnt/β-catenin together with the PI3K/mTOR signalling control the self-renewal and homeostasis of intestinal stem cells and are frequently deregulated in CRC therefore representing attractive targets for chemoprevention and treatment [1], [2].

It has been shown that each pathway may be deregulated by an altered composition of the gut microbiota [3], [4], which plays an important role in the onset, development and progression of CRC thus representing potential target for prevention and potentially biomarkers for the early detection of deranged Wnt/β-catenin-driven lesions [5].

Aims & Methods: The aim of the study was to identify potential targets for the prevention and early detection of CRC in the setting of Wnt/β-catenin disruption.

Transcriptional and translational levels of Wnt/β-catenin and PI3K/mTOR pathways were evaluated by RT-qPCR and immunohistochemical analysis, respectively, in FAP adenomas (n=17 patients) and in sporadic CRC tissues (tumor stages I-III; n=15 patients). In FAP adenomas germline and somatic *APC* mutations were confirmed by Sanger and Targeted Next Generation Sequencing. The composition of oral, fecal and mucosal-associated microbiota was sequenced by the bacterial 16S rRNA gene. Non-diseased Faecal Immunochemical Testing positive subjects (FIT+; n=17) were included as control group.

Results: We found increased expressions of *AXIN2* and *cMYC*, downstream targets of Wnt/β-catenin, in FAP adenomas. The activation status of PI3K/mTOR was confirmed by an increase of *RPS6* gene and pS6R protein expression, indicating that germline and somatic *APC* mutations of FAP adenomas induce an activation of both pathways.

On the other hand, compared to FAP adenomas, a higher expression of *AXIN2, cMYC* and cytosolic and nuclear β-catenin was found in CRC, while no changes were detected in pS6R, suggesting that the hyperactivation of Wnt/β-catenin in sporadic CRC contributes to the impairment of mTOR signalling. Importantly, we analyzed the microbiome composition in FAP and CRC settings.

The oral microbiota of FAP was significantly enriched of Proteobacteria ($p<0.01$), which decreased in FAP adenomatous mucosal samples compared to FIT+ and CRC. In contrast, Firmicutes showed an opposite trend in FAP patients, with a decrease in the oral composition ($p<0.01$) and an increase in the adenomatous mucosa ($p<0.05$).

Interestingly, a significant decrease of the CRC-protective phylum Actinobacteria was found in oral and adenomas microbiota of FAP patients compared to FIT+.

In contrast, CRC fecal microbiota was enriched of Proteobacteria and a higher abundance of the well-known cancer associated families Fusobacteriaceae, Clostridiaceae and Gemellaceae was found in CRC mucosal samples compared to FIT+.

Conclusion: These findings reveal new insights into the role of Wnt/β-catenin and PI3K/mTOR pathways in influencing the homeostasis of precancerous CRC lesions.

Moreover, by defining different microbial signatures in FAP patients, these results will contribute to the enhancement of non-invasive screening tools for the early detection of WNT signalling-driven colorectal cancers.

Introduction: Angiogenesis is a hallmark of cancer[1] and it plays a critical role in tumor development, especially in the proliferation and progression of colorectal cancer (CRC)[2,3].

Indeed, tumor vasculature prompts tumor growth and metastasis since it not only provides nutrients and oxygen for the rapid proliferation of cancer cells as well as a route for metastatization, but also affects the infiltration of immune cells to the tumor site. Thus, the targeting of angiogenesis has become an attractive strategy against various human malignancies, including CRC[4]. In fact, tumor-associated vessels are leaky and poorly efficient due to the dismantlement of the basement membrane and the loss of pericytes, thus preventing proficient drug delivery to the tumor[5].

In this context, we demonstrated that Multimerin-2, an extracellular matrix glycoprotein deposited along the blood vessels in juxtaposition between endothelial cells and pericytes, mural cells fundamental in vessels stabilization, is key in the maintenance of vascular homoeostasis[6].

However, the effects of this molecule on pericytes biology and its putative impact on the immune cells' recruitment are still poorly understood.

Aims & Methods: Immunohistochemistry analysis on colorectal cancer patients' biopsies revealed that colon cancer associated vessels display a downregulated expression of Multimerin-2. Thus, we aimed to verify the extent of pericyte recruitment by Multimerin-2-devoid vessels in a colon cancer model and to evaluate how Multimerin-2 loss affects the surrounding tumor microenvironment.

Human umbilical vein endothelial cells (HUVEC) and Human brain vascular pericytes (HBVP) were used as *in vitro* models for proliferation, functional assays, transcriptomic and proteomics analyses. *Wild type* and *Multimerin-2*$^{-/-}$ C57BL/6 mice were subcutaneously injected with the syngeneic colon cancer MC-38 cells and the tumor sections were analysed by immunofluorescence analyses. Animals were then treated with cisplatin six hours prior sacrificing to evaluate the drug delivery.

Results: We demonstrated that Multimerin-2 affects pericytes migration, adhesion, and proliferation. MC-38 xenografts from *Multimerin-2*$^{-/-}$ mice displayed lower number of pericytes along the vessels as well as increased hypoxia, likely due to vascular inefficiency. The delivery of drug to the tumors was impaired as assessed by the analysis of cisplatin DNA adducts, following the treatment with the chemotherapy drug.

Importantly, tumors from *Multimerin-2*$^{-/-}$ mice also displayed an altered CD68^{+} cells infiltrate, suggesting that Multimerin-2 loss can affect macrophages recruitment to the tumor site. These results are in agreement with the finding that Multimerin-2 devoid endothelium was more permissive for the migration of the monocytic cell line THP-1. Finally, the loss of Multimerin-2 also associates with the expression of cytokines involved in macrophages recruitment.

Conclusion: In conclusion, loss of Multimerin-2 in CRC associates with poor pericyte recruitment, compromised delivery of drugs to the tumor, and an altered immune response. Our results suggest that Multimerin-2 expression could represent a promising marker to predict the efficacy of immunotherapy and the outcome of CRC patients.

A COMBINATION OF RAPAMYCIN, Ω3-PUFA DOCOSAHEXAENOIC ACID AND EPIGALLOCATECHIN-3-GALLATE FOR THE SIMULTANEOUS SUPPRESSION OF PI3K/MTOR PATHWAY AND WNT/B-CATENIN SIGNALLING IN COLORECTAL CARCINOGENESIS

C. Alquati[1], F.J. Di Paola[1], A. Bernardi[1], A. Prossomariti[1], G. Piazzi[1], G. Calafato[1], F. Buttitta[1], D. Cuicchi[2], G. Poggioli[1,2], L. Ricciardiello[1,2]

Introduction: The Wnt/β-catenin signalling is frequently deregulated in colorectal cancer (CRC); indeed, germ-line (as found in familial adenomatous polyposis – FAP) or somatic loss of function of the *APC* gene represent crucial events in CRC onset. Importantly the PI3K/mTOR pathway is frequently impaired in CRC development and closely involved together with Wnt/β-catenin signalling in self-renewal and homeostasis of intestinal stem cells (1,2). Numerous inhibitors of Wnt/β-catenin and PI3K/mTOR pathways have been proposed as potential anti-cancer treatments (3,4), but long-term exposure often fails due to toxicity or the acquisition of resistance, usually associated with the activation of the non-inhibited pathway due to their mutual regulation (5).

Aims & Methods: The aim of the study was to evaluate the effect of a combination (RDE) of Rapamycin, ω3-PUFA Docosahexaenoic Acid (DHA) and epigallocatechin-3-gallate (EGCG) on PI3K/mTOR and Wnt/β-catenin pathways, in order to define an effective combinatorial approach for CRC prevention through simultaneous suppression of both pathways.

For this purpose RDE was tested for 24 or 48 hours (in cell lines and intestinal organoids, respectively) in selected different genetic backgrounds: (i) *APC*-mutated settings consisting of cell lines SW480 and HT-29, and intestinal organoids from four FAP patients morphologically normal-appearing mucosa (NM); (ii) non-*APC*-mutated CRC settings comprising HCT116 (*CTNNB1 mutated*) cell line and sporadic CRC organoids (CRC1: *TP53 mutated*; CRC2: *PI3KCA and TP53 mutated*); HEK293STF cell line and three healthy patients NM-derived organoids as non-mutated settings (iii). We evaluated cells and organoids viability, markers of intestinal stemness (*LGR5*) and differentiation (*KRT20*), and we analyzed the expression of target genes and effector proteins of the Wnt/β-catenin and PI3K/mTOR pathways by RT-qPCR and Western-blot.

Results: We found that RDE strongly inhibited PI3K/mTOR by downregulating the protein expression of phospho-P70S6K and phospho-S6R in all tested genetic backgrounds. FAP NM organoids responded to RDE similarly to HEK293STF cell line and the healthy organoids, with increased translocation of β-catenin into the nucleus. In contrast, in the *APC*-mutated SW480 and HT-29 cell lines, RDE inactivated the Wnt/β-catenin pathway, inhibiting β-catenin nuclear translocation despite the downregulation of APC and AXIN1. These findings were replicated in HCT116 cell line, that also showed reduced cell viability and induction of apoptosis. On the other hand, in non-*APC*-mutated CRC organoids, RDE showed a mild downregulation of Wnt/β-catenin pathway. Importantly, RDE significantly suppressed *LGR5* and induced *KRT20* gene expression. Finally, independently from the genetic backgrounds, exposing organoids to RDE led to increased expression of *c-MYC*.

Conclusion: We found that the dual inhibition of PI3K/mTOR and Wnt/β-catenin pathways by RDE is influenced by genetic backgrounds. Our approach was effective in CRC cell lines and in organoids by affecting markers of intestinal stemness and tissue differentiation, suggesting a potential therapeutic approach for both preventive and therapeutic strategies against CRC.

Introduction: Colorectal cancer is one of the most frequent malignant tumors worldwide. With increasing use of prognostic biomarkers, molecularly stratified treatment of colorectal cancer is improving in clinical practice. However, identifying stable and easily detectable biomarkers for clinical use remains a challenge. Among these biomarkers, epigenetic changes, especially DNA methylation, are the most promising candidates for clinical practice. Prominent examples of such methylation markers are SEPTIN9, the Secretin Receptor (SCTR), and Engrailed Homeobox 1 (EN1). The methylation preferentially affects CpG islands within promoter regions of these genes. Aberrant methylation of CpG islands in the promoter region can be associated with the silencing of tumor suppressor genes and promotes tumorigenesis and tumor growth.

Aims & Methods: Our goal is to develop an innovative diagnostic tool for the reliable detection of malignant colon tissue based on the recognition of specific methylation patterns. This reporter system will detect hypermethylated genetic regions in vivo using luminescence. Suitable biomarkers for this approach will be identified by methylation profiling of colorectal carcinoma cell lines as well as organoids from patients with colorectal cancer.

Our reporter system consists of two constructs. The first construct, the key element of which is the methyl-binding domain of Methyl-CpG-binding domain protein 1 (MBD1), recognizes hypermethylated CpG islands that are frequently located within the promoter region.

The second construct can bind with high specificity to the genomic region of interest via the sgRNA of a deadCas9. When the two components combine in close proximity, a SplitTEV protease induces the newly developed flipNluc luciferase.

The emitted luminescence signal then detects the tumor in a highly specific manner and can be quantified. In addition, whole-genome bisulfite sequencing on colon carcinoma cell lines HCT116 and CaCo2 and organoids from colon biopsies were used to identify additional specific hypermethylated regions. The raw data was analyzed bioinformatically using Bismark and the R package DSS.

Results: We verified the functionality of our new assay by assessing the induction of the newly developed flipNLuc luciferase by the TEV protease. We detected a significant increase in luminescence, confirming the functionality of the luciferase. Thereafter, we validated the reporter system by analyzing the methylation marker genes EN1 and SCTR, which are typically hypermethylated in colorectal carcinoma. In particular, significantly increased luminescence was measured compared to the unmethylated housekeeping genes GAPDH and GPI. To optimize the sensitivity and specificity of our new detection system, additional genes with differentially methylated regions were identified during bioinformatic analysis of the sequencing data. Currently, we are adapting our reporter system to these newly identified genes to validate their potential role as new specific biomarkers.

Conclusion: Reliable DNA methylation biomarkers for clinical practice in the diagnosis of colorectal cancer are still limited. The developed method allows the highly specific identification of malignant tissue based on the detection of hypermethylated CpG islands. Furthermore, our method can be used for targeted screening for new methylation markers. By replacing the sgRNAs of deadCas9, our newly developed method is not limited to the detection of colon tumors and can be adapted to the diagnosis of other tumor entities.

Introduction: Liver steatosis represents the hepatic manifestation of increased adiposopathy, whose pathogenetic features have been proposed as tumorigenic triggers, specifically in colorectal cancer (CRC) [1]. Fatty liver diagnosis challenges clinicians since it is clinically silent and may be complicated with liver fibrosis. Since liver biopsy is not feasible in all patients, non-invasive and point-of-care indexes have been proposed to detect liver steatosis and fibrosis [2].

Aims & Methods: We performed a retrospective analysis among 1145 metabolic subjects to reveal any condition that may predict and concur to CRC development during a 8-years period. Anthropometric and bio humoral parameters were recorded at time zero. Non-invasive liver fibrosis scores were calculated as follows: AAR=AST/ALT; FIB-4=(age x AST)/(platelet count x √ALT); mFIB-4=(10 x age x AST)/(platelet count x ALT); Forns=7.811-3.131 x ln(platelet count) +0.781 x ln(GGT) + 3.467 x ln(age) - 0.014 x (total cholesterol); APRI= AST/Upper limit of normal values x 100/platelet count; AARPRI=AST/ALT/platelet count x 150. Comparisons were carried out by Student-T test (p-value <0.05 was considered significant) and ROC analysis was performed to assess cut-off values. Chi-square test was used to calculate the associated Odds Ratio (OR) with 95% confidence interval (CI).

Results: During a 8 years period, 28 patients (2.4%) developed CRC. No association between CRC development and visceral and general obesity was detected, while fasting plasma glucose was significantly higher and Vitamin D was significantly lower in patients who later were diagnosed with CRC, compared to those who did not develop cancer. We found that all

non-invasive liver fibrosis scores significantly identified CRC-developer at time 0 (see Table). In ROC analysis, these scores also showed good sensitivity and specificity in predicting colon cancer (AAR AUC= 0.59, sensitivity 44% and specificity 78%; FIB-4 AUC= 0.74, sensitivity 84% and specificity 57%; mFIB-4 AUC=0.69, sensitivity 80% and specificity 53%; Forns AUC= 0.67, sensitivity 73% and specificity 54%; APRI AUC= 0.63, sensitivity 57% and specificity 75%; AARPRI AUC =0.64, sensitivity 44% and specificity 83%). We then calculated ORs for values above the ROC cut-offs finding that higher FIB-4 was associated with a 6-fold increased risk of developing CRC (95% CI=2.2-16.5), while mFIB-4 showed a OR=3.6 (95% CI=1.4-8.7), Forns OR was 3.1 (95% CI=1.3-7.9), APRI OR was 3.2 (95% CI=1.4-6.9) and AARPRI OR was 3 (95% CI=1.3-6.4).

	No Cancer (n=1117) mean ± SD	Colon cancer (n=28) mean ± SD	p-value
Fasting glucose (mg/dL)	100.8±29.1	119.5±49.8	0.0011
25-OH Vitamin D (pg/mL)	22.8±11.2	16.3±7.8	0.0099
AAR	0.8±0.3	1±0.5	0.0064
FIB-4	1.1±0.7	1.8±1	<0.0001
mFIB-4	2.2±1.5	3.3±2.3	0.0004
Forns	5.3±1.8	6.3±1.3	0.0039
APRI	0.3±0.2	0.5±0.4	0.0003
AARPRI	0.6±0.3	0.8±0.5	0.0011

Conclusion: These findings support the hypothesis that liver steatosis and fibrosis may play a role in the clinical background of CRC and bring to light the fascinating possibility of a reversed gut-liver axis communication in the pathogenesis of CRC. Thus, the use of non-invasive scores of liver fibrosis may be helpful to predict the risk of CRC and serve as novel prognostic factors for prevention and therapeutic strategies.

A CIRCULAR RNA GENERATED FROM *LRBA* SUPPRESSED COLORECTAL CANCER PROGRESSION THROUGH HSPA8-MEDIATED AUTOPHAGY

B. Xia[1], J. Wang[1], J. Yang[1]

[1]West China Hospital of Sichuan University, Chengdu, China

Contact E-Mail Address: xbh0715@163.com

Introduction: Circular RNAs (circRNAs) are a class of singlestranded, covalently closed RNA molecules that are formed by precursor mRNA back-splicing or skipping events of thousands of genes in eukaryotes. CircRNAs play an essential role in the initiation and progression of human cancers by participating in the regulation of one or several cancer hallmarks.

Aims & Methods: In our study, we aimed to reveal the functions and mechanisms of circRNAs in colorectal cancer (CRC) progression. High-throughput RNA sequencing (RNA-seq) was performed to assess RNA expression profiles in 10 paires of CRC tumor tissues and matched adjacent peritumor tissues, then the expression level of top five dysregulated circRNAs were tested in CRC cancer cell lines. The circLRBA with concordant alteration in RNA-seq data and cell lines was validated in tumor and corresponding adjacent tissues (85 pairs) from a CRC cohort by qRT-PCR analysis followed by correlation and prognosis analysis between circLRBA and clinical characteristics. Sanger sequencing, RNase R and Actinomycin D assays were used to verify the ring structure of circLRBA. Nuclear-cytoplasmic separation experiment and the fluorescence in situ hybridization (FISH) were performed to show the cellular location of circLRBA.

Functional experiments, including CCK8 assay, colony formation assay, transwell assay, 3D multicellular tumor spheroid invasion assay and orthotopic-injected CRC cell line-derived xenograft (CDX) mouse models, were performed by using circLRBA overexpression and knockdown cell lines to investigate the effects of circLRBA on CRC progression in vitro and in vivo. Mechanistically, RNA-sequencing was used to reveal the dysregulated genes followed by circLRBA overexpression. Bioinformatic analysis was used to predict the possible downstream pathways.

Furthermore, Biotin-labeled RNA pulldown and RNA immunoprecipitation (RIP) assays were carried out to identify the proteins directly interacting with circLRBA.

Results: Totally 853 differentially expressed circRNAs were identified, including 778 down-regulated and 75 up-regulated circRNAs. We identified a circular RNA generated from the *LRBA* gene, designated circLRBA, that was significantly down-regulated in CRC tissues and associated with unfavorable clinicopathological parameters.

CircLRBA was dominantly distributed in the cytoplasm in several CRC cell lines. Gain- and loss-of-function experiments suggested that circLRBA could inhibit CRC cell proliferation, metastasis and apoptosis in vitro and in vivo. RNA-seq of circLRBA-overexpressing cells and the controls revealed that these dysregulated genes were significantly enriched in pathways of malignant neoplasm of colon stage IV (*DisGeNET* database), protein localization to endoplastic reticulum and lysosomal lumen (*Gene Ontology* analyse).

Furthermore, RNA pulldown and RIP assays validated that circLRBA directly binds to the HSPA8 protein, which is an essential chaperone for mediating cell autophagy by translocating proteins containing the KFERQ-like motif in their amino acid sequence to undergo lysosomal degradation.

Conclusion: Our study uncovered a novel *LRBA* gene-generated circRNA with a tumor suppression function. CircLRBA probably inhibited CRC progression by chaperone-mediated autophagy (CMA) through interacting with HSPA8. However, further exploration is needed to reveal the substrate protein of HSPA8 and its effects on CRC. CircLRBA is expected to be a new therapeutic target for CRC patients in the future.

Disclosure: No conflict of interest.

Introduction: Immune checkpoint blockade (ICB) for treatment of colorectal cancer (CRC) has been approved for clinical use since 2017. However, the approval of PD-L1 inhibitor for CRC has been encumbered by the lack of durable clinical benefits. Increasing evidence from other cancer types support that PD-L1 expression correlates to the efficacy of ICB and tumor PD-L1 is essential for ICB-mediated tumor cytotoxicity [1-3]. Concomitantly, many studies have also demonstrated the infrequent expression of PD-L1 in CRC cells [4, 5], thereby alluding to the possibility of low/absent PD-L1 expression as a primary obstacle to ICB efficacy.

Aims & Methods: Given the integral role of tumour microenvironment (TME) in shaping the tumour's natural history, we sought to elucidate the role of tumour stroma in regulating CRC PD-L1 expression. To this end, we aim to rescue tumor PD-L1 and assess its utility in ICB-mediated anti-tumour immunity.

To explore the role of different cell types in the TME on CRC PD-L1 expression, cocultures between major cell compartments of the TME and CRC cell lines were performed. Further various omics approaches were utilised to characterise the crosstalk between CRC and stromal cells that saw significant suppression of CRC PD-L1 expression.

Results: Myeloid cells are able to exert a significant suppression of PD-L1 expression in CRC and this suppression is regulated at a post-transcriptional level. The underlying mechanism is orchestrated by CRC metabolic shift from glycolysis to oxidative phosphorylation in response to harsh metabolic competition within the TME.

Conclusion: We have identified potential cellular compartment of the TME and mechanisms which may explain, in part, low/absent CRC PD-L1 expression. This can thus serve to evaluate appropriate external manipulations that can alleviate CRC PD-L1 suppression and explore the possibility of combinatory therapy with anti-PD-L1 ICB to improve its clinical efficacy and durability.

Introduction: Colorectal polyposis, characterized by more than 10 adenomas, indicates a higher risk of malignancy and necessitates more frequent screening and genetic assessment. However, there are still a large number of polyposis patients with negative genetic test results. This study aimed to explore the risk genetic variants associated with non-hereditary colorectal polyposis through a genome-wide association study (GWAS).

Aims & Methods: Among patients who underwent colonoscopy at a single referral university hospital from January 2012 to September 2021, a total of 638 patients with 10 or more biopsy-proven cumulative polyps on colonoscopies and without genetic mutations or family history related to colorectal polyposis were included in this study. For the control group, a total of 7087 people who underwent colonoscopy for the purpose of health check-up at the Korea Medical Institute and were normal at least twice in a row were included. To find susceptible loci to non-hereditary colorectal polyposis, GWAS was performed and a genome-wide p-value threshold of 5×10^{-7} was set to assess statistical significance.

We compared the genetic differences between two groups of patients with non-hereditary colorectal polyposis: those with 10 or more polyp recurrences observed during follow-up colonoscopies and those without such recurrences. We utilized SNPs that were identified as risk variants for non-hereditary colorectal polyposis in this GWAS. For each SNP, we defined the risk allele as the allele associated with increased risk of non-hereditary colorectal polyposis as identified in this GWAS. Genotypes were coded as 0, 1, or 2 based on the number of risk alleles identified at each SNP. We used a polytomous logistic regression model to identify SNPs that significantly increased the risk of polyp recurrence compared to the group without recurrence. Results of all regression analyses were adjusted for age, sex, BMI, smoking history, alcohol consumption history, family history of cancer, history of cancer other than colorectal cancer, comorbidities, and history of medication use.

Results: A total of 71 risk variants were discovered, which were new single-nucleotide polymorphisms (SNPs) not found in previous GWAS associated with colorectal cancer and polyp (Figure 1). 5 genes (UPF3A, BICRA, CBWD6, PDE4DIP, ABCC4) nearest or overlapped with 7 SNPs (rs566295755, rs2770288, rs1012003, rs201270202, rs71264659, rs1699813, rs149368557) previously reported directly or indirectly related to the development of colorectal cancer were proven to be risk variants significantly associated with non-hereditary colorectal polyposis. In addition, two new genes (CNTN4, CNTNAP3B) that have not previously been reported to be associated with colorectal cancer or polyp were newly identified.

The SNP rs149368557 was identified as being significantly associated with an increased risk of polyp recurrence in non-polyposis hereditary colorectal cancer (p-value: 0.049, odds ratio: 2.991, 95% confidence interval: 1.006–8.899).

Conclusion: In this study, we found 71 novel risk variants associated with non-hereditary colorectal polyposis. The SNP rs149368557 was identified as being significantly associated with an increased risk of polyp recurrence in non-hereditary colorectal polyposis. The risk variants and genes discovered in this study might be utilized as novel targets to prevent colorectal cancer in the future.

EXPLORING THE POTENTIAL OF METFORMIN AND CELECOXIB AS NEW ADJUVANT THERAPY FOR COLORECTAL CANCER

H. Rahimi Kolour[1]

[1]Research Institute for Gastroenterology and Liver Diseases, Shahid Beheshti University of Medical Sciences, Basic and Molecular Epidemiology of Gastrointestinal Disorders Research Center, Tehran, Iran

Contact E-Mail Address: Hanimrahimi94@yahoo.com

Introduction: Colorectal cancer (CRC) is a global health concern, with high mortality rates and limited success in early detection and effective treatment of metastatic disease. While conventional treatments such as surgery, chemotherapy, and radiation therapy have shown some success, there is still a need for new and more effective treatment options. Repurposing existing drugs for cancer treatment has gained increasing attention due to its cost-effective nature and the availability of a large number of approved drugs with established safety profiles.

In this study, we investigate the potential of using metformin and celecoxib as adjuvant agents for CRC treatment. Both drugs have been shown to have anti-cancer properties and are well-established for the treatment of other conditions. By analyzing gene expression data sets for these drugs and performing *in vitro* assays, we aim to evaluate their effectiveness as combination therapy and explore the underlying mechanisms of action.

Aims & Methods: Gene expression data sets for these drugs were obtained from the GEO database (GSE11237 and GSE67342) and analyzed using the R Limma package. Fold-change (FC; value > 1) and p-value ≤ 0.05 are considered as DEG selection criteria. MTT assay, apoptosis, and cell cycle analysis will be performed to evaluate the cytotoxic effect of these drugs on CaCO2 and SW48 cell lines. Furthermore, to assess the expression of the candidate genes identified in the *in-silico* phase, we will perform real-time PCR analysis.

Results: After performing gene expression analysis using the R Limma package, we found that only one gene, *ID1*, was identified as commonly expressed in both datasets. STRING server was used to find the intermediate network between *ID1* and other human genes. Finally, the resulting gene network was determined by using Gephi software. Based on this, three modules were obtained. The genes in the module containing *ID1* are *MYOD1*, *SMAD4*, *SMAD9*, *SMAD5*, and *TCF3*. Among the resulting genes, considering that *ID1* is a hub gene and the functional pathway of this gene is TGFB. We selected the *SMAD4* gene, which plays a role in this pathway, as a companion gene to determine the expression level of these two genes in treatment with both drugs.

Our results suggest a potential functional role for *ID1* in the cellular response to treatment with the drugs metformin and celecoxib in CRC.

Conclusion: In conclusion, our study provides evidence that the combination therapy of metformin and celecoxib may have the potential as adjuvant therapy for CRC. These findings contribute to the understanding of the molecular mechanisms underlying the therapeutic effects of these drugs in CRC and provide a basis for the development of new adjuvant therapies that could improve patient outcomes and reduce healthcare costs.

Disclosure: Nothing to disclose.

P53 - A NOVEL REGULATOR OF PERIPHERAL TOLERANCE AND IMMUNE EVASION IN COLORECTAL CARCINOMA

K. Neumeyer[1], D. Tümen[1], E. Aschenbrenner[1], C. Kunst[1], A. Kandulski[1], K. Guelow[1], M. Müller-Schilling[1]

[1]University Hospital Regensburg, Department of Internal Medicine I, Gastroenterology, Hepatology, Endocrinology, Rheumatology and, Infectious Diseases, Regensburg, Germany

Contact E-Mail Address: katja.neumeyer@stud.uni-regensburg.de

Introduction: Tumor-related peripheral tolerance is responsible for the limited ability of the immune system to control tumor growth. In addition to the known functions of p53 as a tumor suppressor, there is increasing evidence that p53 also regulates innate and adaptive immune responses. Wild-type p53 affects the innate immune system by modulating macrophage function via the induction of cytokine expression, thereby sharpening the immune system to suppress tumorigenesis. When p53 is mutated or deleted, as is the case in many tumors, macrophages are not attracted to the tumor and immune evasion occurs.

In addition to soluble factors that activate innate immunity, the glycerophospholipid phosphatidylserine also plays a key role in peripheral tolerance. This lipid is localized on the inner side of the plasma membrane facing the cell matrix.

The exposure of phosphatidylserine to the outside of the cell, e.g. during apoptosis, causes the induction of peripheral tolerance and helps to suppress inflammation. The localization of phosphatidylserine is regulated by the flippase complex.

Here, we demonstrate for the first time that p53 exerts a direct influence on the composition of the plasma membrane and can control immune responses by regulation of flippase protein expression. When p53 is deleted or mutated, phosphatidylserine is externalized and tolerance towards the tumor is induced.

Aims & Methods: We generated stable HCT116 cell lines using CRISPR/Cas9 that have either a complete knock-out of p53 or knock-out of the DNA-binding domain of p53. We assessed exposure of phosphatidylserine and induction of cell death by flow cytometry and determined the metabolic activity of the cells by measuring NAD(P)H and ATP.

In addition, the expression of flippase subunits was analyzed by Western blot and quantitative PCR. Comparative transcriptome analysis of wild-type and p53 knock-out cells was performed by next-generation sequencing to further investigate the regulation of phosphatidylserine exposure.

Results: Following the knock-out of p53 or deletion of the p53 DNA-binding domain, we detected a translocation of phosphatidylserine to the outer side of the plasma membrane. Of importance, cells with knock-out of the p53 DNA-binding domain, as well as cells with complete p53 knock-out, remained metabolically active. Proliferation was comparable to wild-type cells. Thus, cell death can be excluded as the underlying mechanism of phosphatidylserine externalization.

Subsequently, the expression of essential flippase subunits was examined. We observed a downregulation of the protein expression of ATP11A and ATP11C subunits in p53 knock-out cells. This explains why there is an increased phosphatidylserine exposure in these cells and how tumors with p53 deletions may evade the immune system.

Moreover, transcriptome analysis revealed that genes upregulated in p53 knock-out cells are mainly induced by interferons, demonstrating involvement of the immune system.

Conclusion: Here we report a novel function of p53 as an immunomodulator. In addition to its tumor suppressor properties, p53 regulates plasma membrane composition. Deletion of p53 or its DNA-binding domain, as frequently observed in malignant tumors, leads to the downregulation of essential flippase subunits and thus, to the externalization of phosphatidylserine. In this way, peripheral tolerance can be induced and the malignant tumor can escape the immune system. Thus, we describe a novel function of p53 in mediating peripheral tolerance in malignant tumors.

Disclosure: Nothing to disclose.

THE SODIUM CHANNEL SUBUNIT SCNN1B SUPPRESSES COLORECTAL TUMORIGENESIS VIA MODULATION OF THE GUT MICROBIOTA AND IMMUNE MICROENVIRONMENT

Y. Qian[1], C.C. Wong[2]

[1]Shenzhen University General Hospital, Gastroenterology and Hepatology, Shenzhen, China, [2]The Chinese University of Hong Kong, Medicine and Therapeutics, Shatin, Hong Kong

Contact E-Mail Address: chichun.wong@cuhk.edu.hk

Introduction: We previously demonstrated that SCNN1B is a potential tumor suppressor in colorectal cancer (CRC), however, its role in the tumor microenvironment is largely unknown. In this study, we have constructed a conditional, colon specific SCNN1B knockout mouse model, and investigated the effects of SCNN1B knockout on colorectal tumorigenesis, and the associated alterations in the gut microbiome and tumor immune microenvironment.

Aims & Methods: Conditional SCNN1B knockout mouse was established, and then crossed to CDX2-CreERT2 mouse to generate colon specific SCNN1B knockout mouse model. To knockout SCNN1B, mice were injected with tamoxifen (100mg/kg, i.p., 6 times). After SCNN1B knockout, the mice were subjected to the Azoxymethane (AOM)/Dextran Sodium Sulfate (DSS)-induced colorectal tumorigenesis. Gut barrier function was determined by FITC-dextran permeability assay. Mucosal and fecal microbiota in SCNN1B knockout mice and control mice were determined by 16S rRNA sequencing and shot gun metagenomic sequencing, respectively. The tumor immune cell infiltration was determined by flow cytometry.

Results: Colon-specific SCNN1B knockout mice were successfully constructed. Compared to wildtype controls, SCNN1B knockout significantly increased tumor number ($P<0.05$) and load ($P<0.05$) in colon. Notably, gut permeability was increased in SCNN1B knockout mice, as evidenced by increased levels of circulation FITC-dextran in the gut permeability assays. Analysis of the mucosal microbiota revealed that knockout of SCNN1B led to decreased microbial diversity according to alpha- and beta-diversities as compared to wildtype counterparts, suggesting that knockout of SCNN1B promoted gut dysbiosis. SCNN1B knockout mice were enriched in the bacterial genera of Lawsonibacter, Duncaniella, and Desulfovibrionaceae, together with the depletion of Geosporobacter. In terms of microbial function, SCNN1B knockout mice microbiota was enriched in dark sulphur oxidation activity, which is frequently associated with pathogenic processes. Meanwhile, flow cytometry demonstrated the loss of SCNN1B promoted immunosuppression, characterized by increased infiltration of myeloid-derived suppressor cells (MDSCs) and decreased CD8+ T cell activation.

Conclusion: SCNN1B functions as a tumor suppressor in CRC. Colon specific knockout of SCNN1B in mice dysregulated gut microbiota and impaired antitumor immune response, which might contribute to the pathogenesis of CRC.

Disclosure: Nothing to disclose.

RECTAL CHROMATIN NANO-ARCHITECTURE AND MICRORNAS AS A MARKER OF FIELD CARCINOGENESIS: IMPLICATIONS FOR RISK STRATIFICATION FOR COLORECTAL CANCER SCREENING

H. Roy[1], A.S. Chang[2], S. Prabhala[2], A. Daneshkhah[2], M. Dela Cruz[1], H. Subramanian[2], V. Backman[2]

[1]Baylor College of Medicine, Houston, United States, [2]Northwestern University, Evanston, United States

Contact E-Mail Address: hemant.roy@bcm.edu

Introduction: Colonoscopy is highly effective yet inefficient at colorectal cancer (CRC) prevention with a prevalence of target (advanced adenomas) of only about 8%. Thus, finding a modality to risk-stratify for colonoscopy would be of public health implications One approach is to leverage field carcinogenesis, the concept that the gene/environmental interaction that predispose to neoplastic lesions are diffuse and thus rectal mucosa can predict risk of proximal neoplasia (1).

Given the diffuse molecular alterations, our group has focused on transcriptional assessment through chromatin nano-architecture. While epigenetics such as methylation, histone acetylation etc will be reflected in chromatin nano-architecture, microRNAs (mIRs) provide an independent impact on gene expression. We, therefore, wanted to test whether chromatin + miR markers from the rectum would predict concomitant adenomas.

Aims & Methods: Chromatin Nano-architecture: We used a novel nanoscale optics technology, partial wave spectroscopic microscopy (PWS) which enables us to go quantify chromatin heterogeneity through pixel-to-pixel variability in refractive indices (2). The calculated marker correlated with fractal dimension (*D*).

Human Studies: We recruited patients undergoing screening/surveillance colonoscopy with IRB consent. Following colonoscopy 6 biopsies of endoscopically normal rectum. We had 104 controls and 53 advanced adenoma patients for these studies. Advanced adenomas were defined as size >10mm, >25% villous features or high grade dysplasia. Controls were those without adenomas/carcinomas.

miR: We used RT-PCR with internal controls. We used literature to identify 4 candidates miRs and used the delta delta approach to compute fold change of miR expression (case versus control).

Results: We analyzed D from the rectal biopsies with PWS from our clinical dataset and observed excellent diagnostic performance of area under receiver operator characteristic curve (AUC) of = 0.85 for those with and without advanced adenomas sensitivity = 0.74, specificity = 0.83.

The potential of our biomarker is also evaluated via combining with epigenetic regulators microRNAs (miR) in an independent pilot study. Evaluating the 4 oncomiRs in 20 human rectal biopsies (10 control, 10 advanced adenoma) had increased expressions in patients harboring advanced adenomas (fold changes were miR137=3.4, miR92a=5.97, miR-135b-5p=174 and miR361-5p=2.01).

With our PWS marker, the elevation of miR-92a, miR-135b-5p, and D was synergistic for discriminating patients with vs. without advanced adenomas to 0.9 increase in AUC compared to D alone. AUC) = 0.90, sensitivity = 0.88, specificity = 0.85.

Conclusion: We demonstrate, for the first time, that the chromatin nano-architectural parameter, D had excellent performance for identifying patients screen relevant neoplasia elsewhere in the colon. Furthermore, adding several miR markers to provide a more comprehensive epigenetic profile was synergistic diagnostics with D. Future studies will employ more miRs and combine with artificial intelligence to further improve the already strong performance for potential clinical impact.

Introduction: Inflammation is a recognized hallmark of colorectal cancer (CRC), contributing to its development and progression. Therefore, targeting cancer-associated inflammation may offer new avenues for cancer treatment. Anti-inflammatory drugs currently used for the treatment of patients with CRC show many adverse side effects that prompted researchers to propose the specialized pro-resolving mediators (SPMs), derived from omega-3 polyunsaturated fatty acids, as promoters of resolution of cancer-associated inflammation.

We previously demonstrated that the endothelial Major Facilitator Superfamily Domain-containing 2A (MFSD2A) promotes the resolution of chronic intestinal inflammation by overseeing the release of SPMs.

Aims & Methods: Considering the direct connection between inflammation and cancer development that mutually impact on each other, we hypothesize that defective MFSD2A-dependent pathways in endothelial cells may fail to resolve tumor-associated intestinal inflammation, thus promoting CRC development, growth and metastasization. Therefore, enhancing the expression of MFSD2A in the vascular compartment may counteract CRC-associated inflammation, ultimately resulting in anticancer effects.

Based on these premises, our project aims to identify the MFSD2A-dependent pathways responsible for the resolution of tumor-associated intestinal inflammation, paving the way for a new avenue for the treatment of CRC.

To test our hypothesis, we derived Human Intestinal Microvascular endothelial cells (HIMEC) from surgical specimens of CRC patients and healthy subjects. We evaluated the biological effects of MFSD2A overexpression in CRC and healthy HIMEC in terms of transcriptomic and lipidomic profiles. To better elucidate how the enhancement of MFSD2A expression *in vitro* shapes cancer cell growth, we performed co-colture experiments with HIMEC and human epithelial adenocarcinoma cell line (Caco2).

Results: To test our hypothesis, we performed a transcriptomic analysis on HIMEC. Besides the increased levels of MFSD2A transcript in CRC by comparison with the healthy, this analysis pointed out the activation of the resolution phase-related biological processes in CRC as compared to the healthy, proposing the endothelium as a player also in CRC pathogenesis.

Furthermore, by lipidomics, CRC HIMEC displayed increased release of SPMs and reduced levels of the pro-inflammatory lipids by comparison with the healthy control cells. Interestingly, upon MFSD2A silencing, CRC HIMEC switched to a pro-inflammatory phenotype, characterized by the activation of pro-inflammatory biological processes and the increased release of pro-inflammatory lipids. Notably, the enhancement of MFSD2A expression *in vitro* reduces cancer cell growth.

Conclusion: These data suggested that MFSD2A might contrast the tumor-associated inflammation and ensure the correct balance between pro-inflammatory and pro-resolving milieu, offering novel insights into the development of innovative therapies suitable for CRC patient management.

Introduction: Colorectal cancer (CRC) results from the combination of genetic alterations and environmental risk factors. Several evidences indicate that the diet may have a role in prevention and progression of CRC, but more research is needed to clarify the heterogeneity of dietary associations with CRC.

Aims & Methods: We aim at dissecting the role of diet on CRC progression exploiting the patient-derived tumor xenograft (PDX) model, implanting subcutaneously human CRCs at different staging into immunodeficient mice, and feeding with control normal diet (ND) and classical western diet (WD). Tumor phenotype, transcriptomic, genetic and metabolomic were analyzed. Statistical analysis was performed using machine learning and Mann Whitney t test.

Results: The response to WD was heterogeneous among all generated PDXs. Only one out of three showed a greater growth in mice fed with WD. Particularly, WD induced transcriptomic perturbations of several genes related to epigenetic regulations and tumor progression, remodeling tumor microenvironment, promoting mucin secretion, mitochondria dysfunction and metabolic reprogramming. Interestingly, the three PDXs responded to the same WD with a distinct metabolomic profile that was validated

through the machine learning. With whole exome sequencing, PDXs did not share the same somatic cancer mutations that could play a key role in conditioning response to a specific diet. Consistently, the same heterogeneous response to WD in tumor growth was observed in xenografts generated with CRC cell lines. To strictly mimics human diet, we tested in comparison to classic WD, humanized WD diet that displayed a different tumor behavior. The analysis of patient derived organoids developed from PDX fed with humanized diets revealed that the altered metabolic reprogramming acquired *in vivo* is also maintained *in vitro* in absence of any stimulus, suggesting a metabolic memory of cancer cells.

Conclusion: Specific CRC somatic mutations, modifying several signaling pathway and tumor metabolism promote tumor growth and progression, and could be predictive of a response to a specific diet. In this scenario, PDX could be considered as a suitable approach to study the response to the diet and to provide a screening of different diets in order to create a dietary guidance for CRC patients.

Introduction: Colorectal cancer (CRC) is a global health problem with high incidence and mortality rates. Although the incidence has decreased with the use of screening tests, the mortality rate is approximately 1,6 – 2,0 % per year. Recent studies have shown a steady increase in the incidence of early onset (<50 years) CRC compared to that of patients >50 years of age. Early-onset CRC cancer is reported to have a more progressive course and may have a genetic and epigenetic background. In this study, we aimed to investigate the disease characteristics and risk factors for colorectal cancer in patients <50 years old and compare with patients over 50 years of age.

Aims & Methods: Patients younger than 50 years, diagnosed with colorectal adenocarcinoma and followed in our hospitals' gastroenterology, oncology, or general surgery departments between January/2009 and June/2022 were included in this retrospective study. A total of 6102 patients' files were examined. Among these, 1166 were under the age of 50, whilst 4936 were 50 years and older. Patients younger than 18 years, who had a previous history of CRC, a known familial CRC syndrome, who had synchronous tumors at the time of diagnosis or had in situ CRC were not included in the study. After applying the exclusion criteria, 989 patients were included in the under-50 age group. The comparison group consisted of 1009 patients randomly selected from a group of 4000 patients aged 50 years or older. Patients were divided into Group A (<50 years) and Group B (≥ 50 years) according to the age at diagnosis. Patients' demographic characteristics, body mass index, history of cigarette smoking and alcohol use, presenting symptoms, history of H. pylori infection, co-morbidities and medications were recorded from the files. Tumour characteristics, localization, size, TNM stage, and treatment methods were also analyzed and the relationship with each other was examined comparatively.

Results: The results of 1998 patients included in the study are shown in Table 1. TNM stages and the duration of symptoms before the diagnosis were similar between the groups but the rate of stage 1 disease was higher in group B. The rates of metastatic disease and rectal cancer were higher in Group A, but statistically non-significant. Abdominal pain was significantly more frequent in Group A, while anemia was significantly more common in Group B. Patients in Group A had higher rates of IBD, family history of CRC, mucinous adenocarcinoma, poorly differentiated tumor, higher histological grade and higher microsatellite instability (MSI-H). Although perineural and lymphatic invasion rates were similar, vascular invasion was higher in group B.

Variables	Group A (n)	Group B (n)	p value
Body Mass Index ≥30 kg/m^2	110	198	p<0.01
Family history of CRC	137	130	p<0.05
History of Inflammatory Bowel Disease	16	7	p<0.01
Tumor grade-1	104	151	p<0.01
Mucinous adenocarcinoma	131	90	p<0.01
Poor differentiation	165	96	p<0.01
High histologic grade	116	65	p<0.01
Presence of vascular invasion	277	412	p<0.01
MSI-H	58	29	p<0.01

Table1. Comparison of Patients in Group A and Group B

Conclusion: Our study revealed that Early-onset CRC is more frequently diagnosed at the metastatic stage, is characterized by a more common presence of mucinous cells, poorly differentiated histology, and microsatellite instability.

CROSS-SECTIONAL INVESTIGATION OF THE DISTRIBUTION CHARACTERISTICS AND PROGNOSTIC SIGNIFICANCE OF LATERAL LYMPH NODES IN PATIENTS WITH RECTAL CANCER

Y. Zhang[1], X. Yang[1], X. Deng[1], W. Meng[1], Z. Wang[1]

[1]West China Hospital, Sichuan University, Colorectal Cancer Center, Department of General Surgery, Chengdu, China

Contact E-Mail Address: Doctorzhang415@163.com

Introduction: Information about the distribution characteristics and prognostic significance of lateral lymph nodes (LLNs) on primary computed tomography (CT) scan in rectal cancer patients is lacking.

Aims & Methods: Between January 2013 and December 2016, patients with pathologically-proved rectal cancer and pretreatment abdominal enhanced CT in our department were screened.

We firstly redivided LLNs into 7 categories based on their locations. Then, the number and distribution of all measurable LLNs and the characteristics of the largest LLN in each lateral compartment were recorded. Furthermore, we investigated the long-term outcomes in patients with different LLNs characteristics and LLN risk scoring.

Results: A total of 572 patients were enrolled in this study. About 80% of patients had measurable LLNs. Most patients developed measurable LLNs in the obturator cranial compartment and a total of 231 (40.38%) patients and 281 (49.13%) patients had left and right obturator cranial LNs, respectively. The proportion of patients with left and right distal internal iliac LNs was 8.57% and 16.61%, respectively, and patients with left and right extended distal internal iliac LNs was 6.64% and 8.22%, respectively. We found the largest LLN short-axis diameter with 3-5 mm and 5-7 mm accounted for the most in every single compartment. The proportion of patients with the largest LLN short-axis diameter with 3-5 mm and 5-7 mm in the left obturator cranial compartment was 64.5% and 16%, respectively,

and in the right obturator cranial compartment was 55.2% and 24.9%, respectively. In the whole cohort, there were 20 (4.4%) patients with >10 mm LLN, 52 (11.3%) patients with 7-10 mm LLN, 158 (34.4%) patients with 5-7 mm LLN, 206 (44.9%) patients with 3-5 mm LLN, 23 (5.0%) patients with 0-3 mm LLN. LLNs in the left proximal internal iliac compartment and the left distal internal iliac compartment had the largest short-axis diameter (5.42 ± 2.94) and long-axis diameter (8.47 ± 11.34), respectively. LLNs in the left obturator caudal compartment had both the shortest short-axis (3.85 ± 2.18) and long-axis diameter (5.47 ± 2.99), respectively. Lateral local recurrence (LLR) was observed in 20 patients, which accounted for 83.3% of the local recurrence (LR). Patients with LLN short-axis diameter > 10 mm had the worst 5-year OS (18.5%), which was comparable with that in patients with simultaneous distant metastasis (SDM, 8.5%). With regard to local recurrence-free survival (LRFS) and lateral local recurrence-free survival (LLRFS), patients with LLN short-axis diameter > 10 mm had the worst 5-year LRFS (35.7%) and LLRFS (35.7%). We used the largest LLN characteristics on CT scan to stratify the risk of LLNM (considering short-axis diameter, morphology, border and appearance). Patients with LLN risk scoring ≥ 2 had a worse prognosis than those with LLN risk scoring < 2, while better than those with SDM.

Conclusion: Our study comprehensively descripted the distribution characteristics and prognostic significance of LLNs. Our results confirmed that LLR is the main locoregional recurrence pattern. In addition, most rectal cancer patients have measurable LLNs. However, these patients with enlarged LLNs still have a significant better prognosis than patients with distant metastasis, which indicated the potential value of locoregional treatment for enlarged LLNs. Well-designed studies with larger sample size are required to prove our results.

HIGH-RISK POLYPS AND COLORECTAL CANCER IN PATIENTS WITH HEREDITARY DIFFUSE GASTRIC CANCER

S. Ventura[1], J. Chaves[2], A.C. Vasconcelos[2], R. Ortigão[2], M. Dinis-Ribeiro[2], C. Lopes Brandão[2]

[1]Centro Hospitalar Tondela-Viseu, Department of Gastroenterology, Viseu, Portugal, [2]Ipo Porto, Porto, Portugal

Contact E-Mail Address: sofiasantosventura@gmail.com

Introduction: CDH1 gene mutations are associated with gastric and breast cancer. The risk of colorectal cancer may be increased in the presence of this mutation, although evidence is scarce.

Aims & Methods: Aims: To assess the presence of high-risk colorectal polyps (polyp with ≥10mm or with high-grade dysplasia, ≥5 adenomas, any serrated polyp ≥10mm or with dysplasia) and colorectal cancer in patients on surveillance program with mutation in CDH1 gene.

Methods: Retrospective study in patients with CDH1 gene mutation followed in a family risk appointment in a tertiary care hospital.

Results: Data from 36 patients with a mean age of 44.22±14.77 years, 20 males, with a mean follow-up of 5.5 years. Twenty-seven patients had family history of gastric cancer and 9 of gastric and breast cancer; twelve patients had never undergone colonoscopy (age ≤ 40 years). Of the 24 patients who had already undergone at least one colonoscopy, 12 (50%) never removed polyps. Only 4 patients had high-risk polyps (age 30, 52, 59 and 77 years) and no patient presented with colorectal cancer during follow-up.

Conclusion: Although this is a small sample, our study revealed a low percentage of patients with hereditary diffuse gastric cancer with high-risk colorectal polyps (and only one patient with a high-risk polyp aged <50 years) and no patients with colorectal cancer, similar to a population without a CDH1 mutation. Further studies with larger sample sizes are needed to clarify the impact of CDH1 mutation on colorectal cancer.

Disclosure: Nothing to disclose.

Contact E-Mail Address: tshimura@med.nagoya-cu.ac.jp

Introduction: Since currently utilized screening tools including fecal immunochemical test and serum tumor markers cannot reveal sufficient diagnostic powers for colorectal cancer (CRC) due to their low sensitivities. It is thus hopeful to discover non-invasive diagnostic biomarkers for CRC. Urine is one of the most attractive samples for mass-screening because of the non-invasiveness and easy handling. We have previously reported many types of urinary biomarkers for gastrointestinal malignancies.

Aims & Methods: We conducted the current study to discover and establish urinary protein biomarkers that enables early detection of CRC. Among 475 patients including 299 healthy controls (HCs) and 175 stage 0-III CRC patients, age- and sex-matched 373 patients were enrolled in this case-control study. A whole cohort was randomly divided into the discovery cohort (n=32), training cohort (n=220) and validation cohort (n=111). In the discovery cohort, we have performed the isobaric tags for relative

and absolute quantitation (iTRAQ) -coupled liquid chromatography-mass spectrometry (LC-MS) to identify urinary protein biomarker candidates. After that, the urinary protein biomarkers were established with ELISA in the training cohort. Finally, the established biomarkers were validated with ELISA in the independent validation cohort.

Results: In the discovery cohort, we identified 78 urinary proteins with aberrant expression between HCs and CRC patients. Among them, urinary levels of 11 proteins were significantly higher in the CRC patients than in the HCs, and 4 urinary proteins were independent biomarkers on the multivariate analysis in the training cohort. In the validation cohort, these urinary proteins also showed significantly higher levels in the CRC patients than in the HCs. Of these urinary biomarkers, DPEP1 and TFF1 were top two urinary protein biomarkers for the diagnosis of CRC, and the combination biomarker panel using these two proteins showed an excellent AUC of 0.870 with 94.3% sensitivity and 63.4% specificity for the diagnosis of stage 0-III CRC. Notably, this combination biomarker panel could distinguish stage 0-I CRC that are curable with endoscopic resection, with an AUC of 0.852, 93.8% sensitivity and 61.6% specificity.

Conclusion: The established novel urinary biomarker panel provides a promising method for early detection of CRC with completely non-invasive manner.

Disclosure: Nothing to disclose.

Contact E-Mail Address: hardik.hr@gmail.com

Introduction: An accurate optical diagnosis [1,2] of colorectal polyps could make colonoscopy more cost-effective and reduce the risks of polypectomy. In a few recent retrospective studies, it was shown that artificial intelligence (AI) could be used to find and classify colorectal polyps. Many of these studies were based on still endoscopic images or video recordings rather than their application in real-time colonoscopy procedures. We conducted an open-label, non-randomized, prospective, single-center study with the aim to validate the performance of a novel state-of-the-art Artificial Intelligence (AI) model for colorectal lesion detection during routine diagnostic colonoscopy and evaluate its feasibility in daily endoscopy.

Aims & Methods: The study is a prospective, non-randomized, single-center clinical evaluation of the real-time performance of the deep learning AI model for colorectal lesion detection in colonoscopy procedures. Under white light and NBI, the primary endoscopist did the colonoscopies with high-definition endoscopes (EVIS-EXERA 290 video system, Olympus Optical, Tokyo, Japan). All of the polyps were marked for size (measured with biopsy forceps), location, and shape based on the Paris classification, and then they were either removed or a biopsy sample was taken for histologic analysis. (Fig. 1). The main goal of this study was to figure out the "adenoma miss rate," which is the number of patients whose adenomas were missed by the endoscopists but found by the AI and then confirmed by the endoscopists on re-examination (and, as a gold standard, by histological examination). The mean and the total number of missed lesions were analyzed.

Results: Totally, 81 lesions were detected and removed from the 42 subjects, out of the n=200 colonoscopies done in March 2023. Of the 81 lesions removed from subjects, 78 (96.3%) lesions were examined, including 27 (33.3%) neoplastic lesions and 47 (60.5%) non-neoplastic lesions, and the other 3 (3.7%) lesions were not examined after snaring. As for finding lesions, the AI module found 81 of them (100%), while endoscopists found 61 of them (75.3%). Of the 20 lesions missed by the endoscopists, 5 (38.5%) were missed in the transverse colon, which was the section with the highest missing rate. Based on final histology, there were 4 (14.8%) missed neoplastic lesions and 15 (30.6%) missed non-neoplastic lesions. One missed lesion was not examined. An AI-based detection system found all the lesions. According to the power analysis, the estimated sensitivity was above 95% (with an alpha value of 0.05 and a power of 80%).

Pathology	All Lesions	Lesions Missed by Endoscopist	Missing Rate
Neoplastic	27	4	14.8%
Non-Neoplastic	49	15	30.6%
Not Available	5	1	20.0%
Total	81	20	24.7%

Table: Pathology distribution of colonic lesions with the missing rate of each class.

Conclusion: Optical diagnosis using computer-aided diagnostic systems has a potential role in predicting the presence of polyps. The diagnostic performance of CAD seems to be better than that of endoscopy for colon polyp detection. With recent breakthroughs in artificial intelligence, interest in CAD is gaining traction as a novel approach to improving the quality of colonoscopies. We anticipate that each of these hurdles will likely be overcome during the next several years, which will open the door to the clinical application of CAD in colonoscopy. Large-scale use of this technology can be useful in community practice and service.

MANAGEMENT OF EARLY ONSET COLORECTAL CANCER

M. Abu Talib[1], R. Solares[1], D. Kamali[1]

[1]Darlington Memorial Hospital, Darlington, United Kingdom

Contact E-Mail Address: maztalib@hotmail.com

Introduction: Incidence of early onset colorectal cancer (EOCRC,defined as under the age of 50) is rising globally. In the UK, this has tripled between 1990-2014. The National Bowel Cancer Audit 2021 (NBOCA) report in conjunction with Royal College of Surgeons of England (RCSE) found EOCRC often present as an emergency with more advanced disease. Bases on their initial findings, they hypothesize that EOCRC receive more aggressive treatment modalities with poorer prognosis. We aimed to compare our experience of EOCRC in a district general hospital with an annual 300 colorectal cancer resections with the NBOCA findings.

Aims & Methods: Retrospective observation of EOCRC between 2018–2022 in emergency and elective setting.

Results: 97 patients with a male preponderance (72:25). Mean number of cases per year was 19.4. Age range was 21 to 49 years; mean age at the time of diagnosis 37.6. 45% presented as emergencies. 50%were ASA 2,

32% ASA 1, 18% ASA 3/4. All patients received treatment. 36% underwent resection of primary malignancy and chemotherapy; 27% had resection, chemotherapy and excision of metastates; 4% resection and excision of metastates; 20% chemotherapy only. 7% patients did not have resection but underwent emergency/elective defunctioning or stenting. Majority of tumours were in the left colon (33), 24 in right colon, 6 neuroendocrine caecal cancers, 24 rectal cancers. 10% had synchronous cancers. At time of diagnosis, 32% had distant metastates. 35%staged as T4, 38% T3, 15% T2, 11% T1. 40% staged as N2, 38% N1, 19% N0. 7% had recurrence within 5 years (3 T3, 3 T4,1 T2). Mortality within 5 years was 16% (8 T4, 7 T3, 1 T2).
Conclusion: Our experience has shown that similarly to NBOCA, EOCRC are more likely to present as an emergency, with more advanced T stage and nodal disease with left sided cancers. Unlike NBOCA, we did not find a significant annual increase in its incidence and there was a strong male preponderance. This will guide our clinical assessments of patient seen in both emergency and elective setting to consider EOCRC as a diagnosis and to offer them for more aggressive and early treatment.

ADDITIONAL 30-SECOND OBSERVATION OF THE RIGHT-SIDED COLON FOR MISSED POLYP DETECTION WITH TEXTURE AND COLOR ENHANCEMENT IMAGING COMPARED TO NARROW BAND IMAGING: A RANDOMIZED TRIAL

N. Yoshida[1], Y. Inagaki[2], Y. Inada[3], O. Dohi[4], R. Hirose[1], K. Inoue[1], Y. Itoh[1]
[1]Kyoto Prefectural University of Medicine, Molecular Gastroenterology and Hepatology, Kyoto, Japan, [2]Nishizin Hospital, Kyoto, Japan, [3]Kyoto First Red Cross Hospital, Kyoto, Japan, [4]Kyoto Prefectural University of Medicine, Gastroenterology and Hepatology, Kyoto, Japan

Contact E-Mail Address: naohisa@koto.kpu-m.ac.jp
Introduction: The efficacy of texture and color enhancement imaging (TXI) is a new observational mode in the novel light-emitting diode (LED) endoscopic system (EVIS-X1) for polyp detection. However, the efficacy of TXI has not been examined well.
Aims & Methods: We aimed to evaluate the non-inferiority of the additional 30-second (Add-30-s) observation of the right-sided colon (cecum/ascending colon) with TXI compared to narrow band imaging (NBI) for detecting missed polyps. We enrolled 381 patients ≥40 years old who underwent colonoscopy from September 2021 to June 2022 in three institutions and randomly assigned them to either the TXI or NBI groups. The right-sided colon was first observed with white light imaging (WLI) in both groups. Secondly, after re-insertion from hepatic flexure to the cecum, the right-sided colon was observed with Add-30-s observation of either TXI or NBI. The primary endpoint was to examine the non-inferiority of TXI to NBI using the mean number of adenomas and sessile serrated lesions (SSL) per patient (MASP). The secondary ones were to examine adenoma detection rate (ADR), adenoma, and SSL detection rates (ASDR), and polyp detection rates (PDR) in both groups.
Results: The TXI and NBI groups consisted of 177 and 181 patients, respectively. Regarding the Add-30-s observation using TXI and NBI, the mean polyp sizes (mm) were 3.8±3.2 and 2.9±2.5, (p=0.04), the ratios of cecal location were 14.3% and 34.3% (p<0.01), and the ratios of polypoid morphology were 66.1% and 62.9% (p=0.49), respectively. The MAPs/MASPs/MAPPs were 0.23/0.29/0.32 and 0.24/0.30/0.35 in the TXI and NBI groups, respectively (p=0.83/0.87/0.59). Regarding MASP of TXI and NBI as the primary endpoint of this study, between-group difference of 1.0%, 95% CI -0·38 to 20·04), indicating non-inferiority (p<0.001). MAP and MAPP were also significantly non-inferior between the two groups. The increases in the ADR, ASDR, and PDR in the TXI/NBI groups were 10.2%/10.5% (p=0.81), 13.0%/12.7% (p=0.71), and 15.3%/13.8% (p=0.71), respectively. The MAPs in the first WLI observation and the first+second observation were 0.49 and 0.71 (p=0.02) in the TXI group (p=0.02) and 0.42 and 0.66 (p=0.01) in the NBI group, respectively. The MASPs in the first WLI observation and the first+second observation were 0.58 and 0.86 (p=0.02) in the TXI group and 0.46 and 0.76 (p<0.01) in the NBI group, respectively. There were no significant differences in the ADR, ASDR, and PDR between the first observation and the first+second observation in both the TXI and NBI groups.
Conclusion: Regarding add-30-s observation of the right-sided colon, TXI was non-inferior to NBI. Add-30-s observation with either NBI or TXI could increase the ADR by 10%.

Introduction: Volatile organic compounds (VOCs) form a specific chemical profile that can be used to detect the colorectal cancer-related changes in human metabolism and thereby, to diagnose this type of cancer even at an early stage.
Aims & Methods: The aim of this study was to characterize the volatile chemical patterns associated with cancer and normal tissues obtained from colorectal cancer patients and identify potential volatile biomarkers of colorectal cancer. In total 50 paired tissue samples were analyzed. Volatiles released by the tissue samples were captured using solid phase microextraction (HS-SPME) and next identified and quantified using gas chromatography with mass spectrometric detection (GC-MS).
A Wilcoxon signed-rank test was used to compare the emissions of VOCs from cancer and non-cancerous tissues and p<0.05 was taken as significant threshold.
Results: A total of 163 compounds were found in the headspace of the tissue samples. Amongst these, 149 VOCs were identified in cancer tissues and 147 in non-cancerous ones. 138 volatiles were found in both types of tissues. The predominant chemical classes in both tissues are hydrocarbons (25%) and alcohols (15%). These are followed by aldehydes, ketones and aromatics. Only 40 VOCs (27%) exhibited incidence higher than 50% in cancerous tissues. In case of healthy tissue this number amounted to 44 (30%). 11 volatiles occurred in at least 90% of both types of samples and thereby can be considered as omnipresent. 15 VOCs showed consistent differences in their headspace concentrations above samples under study. Of these, 4 compounds were found to have increased emissions from

the cancer tissue, and the other 11 showed the reduced release from this type of samples. The species emitted in higher amounts by cancerous tissue comprised 1-propanol, pyridine, isoprene and methyl thiolacetate ($p<0.05$).

Conclusion: The results of this study confirm that the chemical fingerprint formed by volatiles in colorectal tissue is altered by colorectal cancer. These VOCs - 1-propanol, pyridine, isoprene, methyl thiolacetate were found to be the most promising biomarker candidates for detecting colorectal cancer.

Disclosure: Nothing to disclose.

Introduction: The risk factors for synchronous lymph node metastasis (LNM) in pT1 colorectal cancer (CRC) are submucosal invasion depth (≥1000μm), lymphovascular involvement (LVI), poorly differentiated components (por), and tumor budding (BD). On the other hand, in pedunculated lesions with invasion confined to the head of the polyp, the incidence of LNM and recurrence have been reported to be very low (0-2.4% and 0%, respectively).[1,2] However, the robust evidence has been limited.

Aims & Methods: This retrospective study aimed to compare the incidence of LNM and recurrence between the head and stalk invasion groups, based on submucosal invasion assessment using Haggitt Level 2 (HL2; the junction line between normal and neoplastic epithelium), and to evaluate the impact of LNM/recurrence risk factors in pedunculated pT1 CRC.

Patients with pedunculated pT1 CRC treated by endoscopic or surgical resection in our hospital between January 2010 and December 2021 were included. Those with multiple invasive CRCs, synchronous advanced cancer in other organs, and familial adenomatous polyposis were excluded. The submucosal invasion was classified into two groups, head invasion (above HL2) and stalk invasion (beyond HL2). Clinicopathological characteristics, incidence of LMN, and recurrence rate were analyzed between patients with head and stalk invasion.

Results: The study included 66 patients with 66 lesions. The median age was 67 years, and 52 patients (78.8%) were male. The median tumor size was 20mm, and the location was as follows: 4 lesions (6.1%) in the right colon and 62 lesions (93.9%) in the left colon. There were 40 head invasion and 26 stalk invasion lesions. There were no significant differences between the two groups for LVI (17.5% vs 26.9%), por (2.5% vs 7.5%), and BD (5.0% vs 7.7%). Surgical resection was performed more frequently in the stalk invasion group (20% vs 77%, $P < 0.01$). Synchronous LNM was observed in 2 patients in the head invasion group (5.0%, 95% confidence interval [CI] 0.6-16.9), and 1 patient in the stalk invasion group (3.8%, 95%CI 0.1-19.6) ($P = 1$). Recurrence was observed in 1 patient in the head invasion group (2.5%, 95%CI 0.1-13.2), and 1 patient in the stalk invasion group (3.8%, 95%CI 0.1-19.6) ($P = 1$), both of them were distant metastasis. In patients without LVI, por, nor BD, there was no LMN in either group, but recurrence was observed in 1/32 patients in the head invasion group (3.1%, 95%CI 0-17.1), and 1/16 patients in the stalk invasion group (6.3%, 95%CI 0-30.3) ($P = 0.61$). The patient with recurrence in the head invasion group without LVI/por/BD revealed multiple liver metastases one year after endoscopic resection, and he received chemotherapy but died of colon cancer one and a half years after recurrence.

Conclusion: In pedunculated pT1 CRC, synchronous LNM and recurrence were observed in the head invasion group, with no significant difference from the stalk invasion group. Among cases without LVI/por/BD, there was no LNM but recurrence was observed in both of head and stalk invasion groups. Contrary to the previous reports, head invasion was not a completely LNM/recurrence-free condition, so endoscopic resection alone cannot be considered curative.

REDUCED EXPRESSION OF SMOC1 IS ASSOCIATED WITH PROGRESSION OF COLORECTAL TRADITIONAL SERRATED ADENOMAS AND CONVENTIONAL ADENOMAS

Introduction: Colorectal serrated lesions (SLs) include hyperplastic polyp (HP), traditional serrated adenoma (TSA) and sessile serrated lesion (SSL). Aberrant DNA methylation is prevalent in colorectal SLs. We previously reported that SMOC1 (SPARC-related molecular calcium-binding 1) was frequently methylated and silenced in TSAs as well as in high-grade adenomas and colorectal cancers (CRCs) but was rarely methylated and silenced in SSLs. [1] However, the expression of SMOC1 in colorectal lesions, including SLs, has not yet been studied in detail.

Aims & Methods: To evaluate the potential of SMOC1 as a biomarker for diagnosis of SLs and risk prediction in colorectal tumors, we aimed to characterize the expression of SMOC1 in colorectal lesions. Specimens of colorectal lesions (n = 199) and adjacent normal colorectal tissues (n = 112) were collected from 173 patients who underwent endoscopic or surgical resection. Colorectal lesions were randomly divided into two groups: a training set and a validation set. SMOC1 expression was analyzed by immunohistochemistry. A rabbit anti-SMOC1 polyclonal antibody (1:1000 dilution, C-20; Sigma-Aldrich) was used for immunohistochemical staining. The intensity of SMOC1 staining was graded as strong (3), moderate (2), weak (1) or negative (0). The proportions of positively stained tumor cells were assigned a value of 0 to 10. Because neoplasm heterogeneity caused varying degrees of immunoreactivity in the slides, we used the sum of each intensity × proportion as an immunohistochemistry (IHC) score (e.g., intensity × proportion = (3) × 5 + (2) × 3 + (1) × 1 + (0) × 1 = IHC score 22; maximum score = 30) to improve accuracy. When TSAs had both flat and protruding components, SMOC1 expression was evaluated in the protrud-

ing component. Thereafter, levels of SMOC1 expression were compared between flat and protruding components in order to evaluate its involvement in the progression of TSAs. All slides were independently evaluated by gastrointestinal pathologists who were blinded to the clinical data.

Results: Histology of the 199 colorectal lesions was as follows: HP, n = 26; SSL, n = 50; SSL with dysplasia (SSLD)/SSL with early invasive cancer (EIC), n = 14; TSA, n = 51; TSA with high grade dysplasia (HGD)/EIC, n = 3; low grade adenoma, n = 17; high grade adenoma, n = 14; HGD, n = 16; EIC, n = 8. Mean IHC scores in normal colonic tissues and colorectal lesions in the training set were as follows: normal colon, 24.2; HP, 21.6; SSL, 24.8; SSLD/SSL with EIC, 17.5; TSA, 7.3; low grade adenoma, 21.4; high grade adenoma, 11.7; HGD, 12.1; EIC, 10.9. These results suggest that SMOC1 is abundantly expressed in normal colon, HPs, SSLs and low grade adenomas, whereas it is significantly downregulated in TSAs, high grade adenomas, HGDs and EICs ($p < 0.05$). Mean IHC scores for colorectal lesions in the validation set were as follows: HP, 17.7; SSL, 22.8; SSLD/SSL with EIC, 11.5; TSA, 3.1; TSA with HGD/EIC, 4.7. Again, we observed abundant expression of SMOC1 in HPs and SSLs, whereas it was significantly downregulated in TSAs and TSAs with HGD/EIC ($p < 0.05$). Among TSAs that contained both flat and protruding components, levels of SMOC1 expression were significantly lower in the protruding components both the training set ($p < 0.001$) and the validation set ($p < 0.05$).

Conclusion: Our results suggest that reduced expression of SMOC1 is associated with progression of TSAs and conventional adenomas and that SMOC1 may be a diagnostic marker of SLs as well as a predictive marker of colorectal tumors at high risk of developing into cancer.

THE USEFULNESS OF *FUSOBACTERIUM NUCLEATUM* MEASUREMENT IN STOOL FOR COLORECTAL CANCER SCREENING

T. Higurashi[1], S. Tamura[1], N. Misawa[1], T. Yoshihara[1], T. Matsuura[1], A. Nakajima[1]

Introduction: Over the world, fecal occult blood testing (FOBT) is used as a colorectal cancer (CRC) screening method for middle age and older age, but there are problems such as sensitivity/specificity issues, low participation rates in primary and secondary screenings, and that the incidence/mortality rates of CRC are still high. *Fusobacterium nucleatum* (*Fn*) has been reported to be frequently detected in the feces of CRC patients in recent years, and it has been reported that screening sensitivity can be increased by combining it with *Fn* PCR testing. However, due to the cost and technical complexity of PCR, it has not yet been widely used in clinical practice. In this study, we developed a simple method using ELISA to measure antibodies against FadA expressed by *Fn* and evaluated its usefulness.

Aims & Methods: We evaluated FOBT, *Fn* PCR quantification, and *Fn* (ELISA) in 41 individuals diagnosed with CRC from April 2020 to December 2022 and 41 healthy volunteers without CRC. Subgroup analysis was also performed in CRC patients at each stage.

Results: The correlation coefficient between *Fn* PCR quantification and *Fn* (ELISA) was good at $r=0.722$, $p<0.001$. FOBT alone had a sensitivity of 61% and a specificity of 100%. In *Fn* ELISA, when cut off#1 was set to maximize the AUC in ROC, the sensitivity and specificity were 76% and 78%, respectively, and when combined with FOBT, the sensitivity was 90% and the specificity was 78%. In screening, high specificity is required, so we set cut off#2 *Fn* ELISA to achieve a specificity of 93% and performed analysis. When combined with FOBT, the sensitivity was 73% and the specificity was 93%. When targeting advanced cancer of stage II or higher, the sensitivity by combining FOBT and *Fn* ELISA was 100% at cut off#1 and 79% at cut off#2, while for early cancer, the sensitivity was 76% at cut off#1 and 59% at cut off#2, both of which were better than the sensitivity of FOBT alone.

Conclusion: By combining *Fn* measurement using ELISA with FOBT, it was possible to increase the diagnostic sensitivity and reduce false negatives compared to FOBT alone. There are challenges such as setting appropriate cut-off values for use in screening, but measuring *Fn* in addition to FOBT may improve screening accuracy and increase the participation rate in secondary screening, and in the future, we would like to evaluate its effectiveness even in populations with low prior probability of screening participation.

LYNCH SYNDROME: MMR VARIANT OF UNCERTAIN SIGNIFICANCE , FREQUENCY AND CLINICAL CHARACTERISTICS, PRELIMINARY DATA

M. Casella[1], L. Sanchez-Mete[2], A. Martayan[3], M. Coppola[2], V.A.M. Stigliano[2]

[1]Università La Sapienza di Roma, Gastroenterology and Digestive Endoscopy, Roma, Italy, [2]IFO, Gastroenterology and Digestive Endoscopy, Roma, Italy, [3]IFO, Clinical Pathology, Roma, Italy

Contact E-Mail Address: marta.casella1@gmail.com

Introduction: The most common inherited cancer syndrome that increases individual risk for colon cancer is Lynch syndrome. It is caused by Mismatch Repair deficiency due to a germline pathogenetic variant of MMR gene (MLH1, MSH2, MSH6, PMS2, EPCAM) . The introduction of multigene testing has improved and speeded up the diagnosis but has also increased the chance of finding a variant of uncertain significance (VUS) for a clinical point of view. The clinical features and management of these cases is still not clearly defined.

The aim of the present study was to determine the frequency of VUS in patients with clinical suspicion of Lynch syndrome and to define their clinical characteristic compared with Lynch affected.

Aims & Methods: Patients referred to the Centre of reference for hereditary colorectal cancer syndromes of our institution, who performed multigene testing from 2017 to 2022 for suspicion of Lynch syndrome, were retrospectively evaluated. Demographics, clinical data and oncological family history were recorded.

Genetic analysis of probands was performed using Next Generation Sequencing technology. Variant classification was performed according to the InSiGHT database (https://www.insight-group.org/variants/databases) or the the InSiGHT Variant Interpretation Committee (VIC) MMR gene variant classification criteria.

Patients were divided into three groups according to the results of genetic testing: pathogenetic variant (Lynch syndrome affected, LS), Variant of uncertain significance (VUS) or a negative result.

Results: 172 patients were enrolled for the study (53M; 119F), mean age at diagnosis 47.2 years (range 26-78 years). Genetic analysis detected a LS (7 MLH1, 8 MSH2, 6 MSH6, 3 PMS2) in 24/172 (13.9%), a VUS (5 MLH1, 8 MSH2, 9 MSH6, 2 PMS2) in 24/172 (13.9%) cases and a negative test in 124 patients (72.1 %). Clinical features showed a colorectal cancer (CRC) in 20/24 (83.3%) LS; 14/24 (58%) VUS pts and 61/124 (49%) negative pts; an endometrial cancer in 6/20 (25%) LS; 7/14 (29%) VUS; 49/61 (39.5%) negative test pts (p. 0.007, significant at $p<0.05$). Multiple primary cancers

were present in 11/20 LS(45.8%) ; 5/14 (20.8%) of VUS ; 23/61 (18.5%) of negative test pts. A family history of cancer fulfilling Amsterdam I or II criteria was present in 37.5% in either LS or VUS pts and in 15.3% of negative test pts.

Conclusion: Multigene testing increases the likelihood of detecting a VUS in patients with suspicion of hereditary syndromes. Because of uncertainity of its pathologenic role, oncological surveillance for target organs is undefined, guidelines are lacking and this is of particular concern for psysicians . In the present study, emerged some different clinical features between LS and MMR VUS patients: female gender was prevalent in VUS and negative test groups, a colo-rectal cancer and multiple primary cancers were significantly more represented in LS; Amsterdam criteria were predominant in LS and VUS groups. These preliminary data suggest that the VUS group has peculiar clinical features that in addition to segregation analysis and functional assays, could help to predict /support variant pathogenicity or benignity and subsequent clinical management.

Contact E-Mail Address: matsumura919@yahoo.co.jp

Introduction: In early-stage colorectal cancer (CRC), distinguishing CRC with deep invasion is crucial in determining subsequent treatments. However, diagnosis remains difficult. Recently, we have developed and reported a computer-aided diagnostic (CAD) system to diagnose CRC with deep invasion, using only non-magnified white light imaging.1) This study aimed to compare the diagnostic accuracy of CAD for early-stage CRC with that obtained in a prospective study using magnified narrow-band imaging endoscopy (M-NBI) and dye-based magnified chromoendoscopy (MCE).2)

Aims & Methods: Among 1173 lesions registered in a multicenter prospective study, 1428 images of 162 early-stage CRC cases (125 Tis CRCs, 16 T1a CRCs and 21 T1b CRCs) registered at our hospital were included. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy rate of the CAD system for diagnosing T1b (depth of invasion ≥1000 μm) CRC were all calculated, and compared with those of M-NBI and MCE diagnoses. Optical diagnoses by M-NBI and MCE were performed by experts in real time.

Results: The sensitivity, specificity, PPV, NPV, and accuracy rate of CAD were 57.1%, 85.8%, 37.5%, 93.1%, and 82.1%, respectively. Whereas those of M-NBI were 71.4%, 93.6%, 62.5%, 95.7%, and 90.2%, respectively, and those of MCE were 85.7%, 91.5%, 60.0%, 97.7%, and 90.7%, respectively. The overall accuracy rate of CAD was significantly lower than those of M-NBI and MCE diagnoses. However, the accuracy rates for depressed lesions (IIa, IIa+IIc) were 87.5% for M-NBI, 81.3% for MCE, and 87.5% for CAD, and for polypoid lesions (Ip, Is) were 83.1% for M-NBI, 84.5% for MCE, and 76.1% for CAD, indicating that the accuracy rates of CAD were similar to those of M-NBI and MCE diagnoses in these cases.

Conclusion: CAD using non-magnified white light imaging is useful for the diagnosis of deep invasive cancer in depressed or polypoidal early-stage CRCs.

Introduction: As we know colorectal cancer is one of the most common types of cancers. Nowadays there are various invasive and non-invasive methods to diagnose this cancer. Detection using molecular markers at an early stages(stages1-2) is a convenient method.The aim of this study is to evaluate the frequency of GRASP gene promoter methylation in colorectal cancerous lesion compared to the surrounding healthy tissue.

Aims & Methods: This cross-sectional study was carried out on 100 patients with early-stage colorectal cancer between 2019-2022. DNA from samples of colorectal cancer tissue and healthy tissue around the tumor were extracted by FFPE (formalin-fixed paraffin embedded) method. Endonuclease resistance DNA methylation was measured and the frequency of GRASP gene promoter in both samples was calculated and compared.

Results: Methylation of GRASP gene promoter in colorectal cancer tissue increased significantly in early stages compared to healthy surrounding tissue. Methylation of GRASP gene promoter in cancer samples was (70.47 %, $P < 0.0001$) compared with healthy tissue samples (38.08 %, $P < 0.0001$).

Conclusion: The results showed that the frequency of GRASP gene promoter methylation in colorectal cancer tissue is significantly higher than the surrounding healthy tissue.

HARNESSING LANGUAGE MODELS FOR STREAMLINED POST-COLONOSCOPY PATIENT MANAGEMENT: A NOVEL APPROACH

Y. Gorelik[1], I. Ghersin[1], I. Maza[1], A. Klein[1]
[1]*Rambam Health Care Campus, Gastroenterology Institute, Haifa, Israel*

Contact E-Mail Address: yurigorelik@gmail.com

Introduction: ChatGPT is a large language model with applications in numerous fields, including medicine[1,2]. Post-colonoscopy surveillance is crucial in colorectal cancer prevention, but adherence to guidelines remains low[3,4]. This study aims to evaluate ChatGPT's ability to streamline post-colonoscopy patient management by processing endoscopy and pathology results and providing guideline-based recommendations and patient summaries.

Aims & Methods: A proof of concept pilot study was conducted with 20 clinical scenarios prepared by a gastroenterologist, covering various recommendations from society guidelines. Scenarios were prompted to ChatGPT as structured endoscopy reports and free text clinical notes. Two senior gastroenterologists evaluated ChatGPT's responses, marking them as correct or incorrect. Fleiss' Kappa coefficient was calculated to evaluate inter-rater agreement, and accuracy was assessed in terms of concordance with guidelines.

Results: Of the 20 scenarios, 90% (18/20) of ChatGPT's responses adhered to guidelines. In 17/20 (85%) cases, both endoscopists marked the responses as correct and adherent to guidelines. Inter-rater agreement was very good, with a Fleiss' kappa coefficient of 0.84 ($p<0.01$). ChatGPT interpreted free text clinical notes similarly to structured endoscopic responses in 19/20 scenarios (95%). The model composed concise, easily understandable patient letters with comprehensive advice on maintaining a healthy lifestyle.

Conclusion: ChatGPT shows potential in providing accurate post-colonoscopy surveillance recommendations, which could aid healthcare providers in decision-making and improve guideline adherence. However, limitations include inherent randomness in responses, and the possibility of incorrect recommendations. Future prospective research is essential for exploring the integration of ChatGPT or similar language models into electronic health record systems and evaluating their effectiveness as decision support tools and means of enhancing patient communication.

Introduction: There are three main concepts in colorectal carcinogenesis. The first is the well-known "adenoma-carcinoma sequence", while the second is the "saw-tooth lesion pathway". In this concept, serrated lesions transform into early carcinomas. The third concept is the "de novo" pathway, in which early carcinomas can develop even in the absence of an adenoma. In this pathway, the cancer is thought to arise directly from the normal epithelium, rather than from an adenoma, and the cancer tends to progress at a faster rate and with a higher grade of malignancy. For diagnosing colorectal cancer, magnified endoscopy, specifically the Pit pattern classification, has proved to be useful. Recently, the endoscopic examination (EC classification) has been developed, and now not only structural atypia but also cellular atypia can be observed in vivo.

In this study, we aimed to clarify the endoscopic characteristics of colorectal cancer and demonstrate the usefulness of pit pattern classification and EC classification. Our study focused mainly on colorectal cancer that is considered to arise through the "de novo" pathway.
