Introduction: Irritable bowel syndrome (IBS) has a worldwide prevalence of ~11%, and thus has a considerable negative impact on both society and millions of individuals. The pathophysiology of IBS is multifactorial and incompletely understood, involving low-grade inflammation in the gut, visceral hypersensitivity, increased epithelial barrier permeability, altered gut-brain interactions, and an unfavourable composition of gut microbiota. Although we currently have no cure for IBS, a diet low in fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs) has shown to give ~70% of patients clinically significant symptom relief.

Aims & Methods: In this study, we seek to uncover how 12 weeks of strict low-FODMAP diet affect the intestinal immune system, visceral hypersensitivity, and gut integrity in patients with IBS. We will use highly multiplexed Hyperion imaging mass cytometry to investigate the cellular microenvironments in duodenal biopsies from n = 48 patients and n = 21 healthy controls at baseline and n = 21 patients at 12-week follow-up.

Results: With basis in known literature on relevant markers in IBS, we have developed an antibody panel for use on formalin-fixed, paraffin-embedded (FFPE) duodenal tissue with Hyperion imaging mass cytometry. The panel includes 35 markers for comprehensive spatial analyses of the gut mucosa in IBS before and after diet intervention. It comprises several immune cell markers for a broad immunologic mapping, in addition to markers for gut integrity and neuro-immune communication. The panel was tested on duodenal FFPE tissue with Hyperion, and resulting images were segmented with the Steinbock framework. Downstream single-cell analysis was performed in R with the imcRtools R/Bioconductor and cytomapper packages. Different cell types, including CD4 and CD8 T cells, were identified in duodenal tissue by means of cell segmentation and unsupervised clustering.

Conclusion: Through multimodal integration of tissue analyses and clinical symptom scores before and after treatment, we aim to provide clinically meaningful intestinal biomarkers in order to improve treatment strategies for patients with IBS.

Introduction: An autoimmune mechanism take part an important role in the pathogenesis of achalasia, which is directly related to histocompatibility class antigens. There is a correlation of the disease with HLA class II.

Aims & Methods: The aim of our study was to investigate the association of genes of the HLA system and idiopathic achalasia.

Subjects and methods: 140 patients, who referred to our Centre, were included in this study: 75 females (55%), age from 18 to 75. The diagnosis of idiopathic achalasia was established by upper endoscopy and high resolution water-perfused manometry (MMS, Netherland). The DNA from blood samples was isolated using QIAamp DNA Blood Mini Kit (Qiagen, Germany) according to the manufacturer's recommendations. The concentration of DNA samples was measured by fluorimetric method on a Qubit 4 fluorimeter using the Qubit dsDNA BS Assay Kit (Thermo Fisher Scientific, USA). All patients underwent HLA typing by massively parallel sequencing (NGS): *HLA-A, HLA-B, HLA-C, HLA-DQB1, HLA-DRB3, HLA-DRB4, HLA-DRB1, HLA-DRB5, HLA-DQA1, HLA-DPA1, HLA-DPB1*, on the platform MiSeq (Illumina, USA) v.2, Omixon. The analysis of the HLA gene sequences obtained as a result of sequencing was carried out using a computer program TypeStream Visual Software (TSV) (One Lambda, USA), and database IPD-IMGT/HLA.

Results: The most frequent allelic variant was *HLA-DPA1 *01:03* - in 84.6% patients. The study of the HLA-A gene revealed allelic variants: *-A*01:01* in 13.2% of patients, *-A*03* and *-A*01* - 11%. Also we revealed allelic variants of the *HLA-B* gene: *-B*44:02* in 7.5% of patients, -B*15:01 - 6.4%. The study detected allelic variants of the *HLA-C* : *-C*12:03* in 13,6% subjects, *-C*07:02* - 12,1%, *-C*06:02* - 11,4%, *-C*04:01* - 10,7%. The study of the *HLA-DQA1* gene revealed allelic variants: *DQA1*05:05* - 16,7%, *-DQA1*01:02* - 15,7%, *-DQA1**02:01 - 13,9% and *-DQA1**01:03 - 13,2%. The study of the *HLA-DQB1* gene detected allelic variants: *-DQB1*03:01* and *-DQB1*03:358* in 19.2% of patients. The study of the *HLA-DPB1* gene revealed allelic variants: *-DPB1*1322:01* and *-DPB1*1321:01* in 16% of patients. The study of the *HLA-DRB1* gene detected allelic variants: *-DRB1*07:01* and *-DRB1*7:139* in 15% of patients. The study of the *HLA-DRB3* gene evaluated allelic variants: *HLA-DRB3*01:01*-22.5%, *HLA-DRB3*02:168*-22.1%, *HLA-DRB3*02:02*, *-DRB3*02:144* and *-DRB3*02:188*- 21.4%. The study of the *HLA-DRB4* gene revealed allelic variants: *-DRB4*01:03* - 32.9%, *-DRB4*01:134* - 31.4%. The study of the *HLA-DRB5* gene revealed allelic variants: *-DRB5*01:01* and *HLA-DRB5*01:126* in 16.4% of patients with achalasia, *-DRB5*01:02* - 10.7%.

Conclusion: Patients with achalasia have certain allelic variants of the *HLA*-system genes that play an important role in autoimmune reactions. These allelic variants may have some prognostic value. The association between *HLA*-system allelic variants and achalasia merits study in large cohorts of patients.

Introduction: Gastric Cancer (GC) is one of the most common carcinomas world-wide (1) characterised by a peculiar contribution of the tumour microenvironment to the aggressive biology of this malignancy (2). GC progression is characterised by striking changes in lymphatic vessels (LVs) and lymphatic metastasis is the most common feature of GC spread, representing the most significant prognostic factor determining clinical outcomes (3). Recent publications have demonstrated a functional link between the Extra-Cellular Matrix protein EMILIN-1, tumor growth, and lymphangiogenesis. EMILIN-1 is a key structural and functional element in the maintenance of a competent lymphatic vasculature and, as demonstrated in skin and colitis-associated cancer mouse models, exhibits anti-proliferative and oncosuppressive properties through the interaction with α4β1 integrin (4,5,6).

Aims & Methods: We have observed that EMILIN1 is present at lower levels in human gastric malignant and pre-neoplastic samples and this correlates with the presence of abnormal LVs (unpublished preliminary data). The aim of this study is to investigate the role of EMILIN-1 in gastric tumor onset and progression using mouse models of GC.

We used the syngeneic YTN16 gastric cancer cell line (7) in genetically modified EMILIN-1 mice (KO, knock out mice; E933A KI, E933A-mutated Emilin1 Knock-In animals expressing an EMILIN-1 mutant that is unable to interact with α4/α9β1 integrins). KI animals were included to specifically define the effects related to integrin engagement. Cells were injected intraperitoneally (i.p.), sub-cutaneously (s.c.) or into the footpad of 8-week-old C57BL/6 mice; tumors were analyzed after 3 weeks. A protocol using N-methyl-N-nitrosourea (MNU) was also performed on the same animal models to better investigate the role of EMILIN-1 when a chemically-induced gastric carcinogenesis approach was used. Mice were given drinking water ad libitum containing 240 ppm MNU on alternate weeks for a total exposure of 5 weeks and sacrificed after 30 weeks.

Results: To assess tumor growth, mice were injected with the syngeneic GC cell line YTN16 subcutaneously into both flanks. KO and E933A KI mice developed larger and earlier tumors; tumor samples were stained with Lyve-1 and CD31 to identify lymphatic and blood vessels, respectively. While no differences were observed for CD31-positive structures, a statistically significant increase in intratumoral lymphangiogenesis was observed in KO and E933A KI animals. Lymphatic spread was analyzed in detail by means of intra-footpad injection; enhanced lymph node (LN) metastasis of YTN16 transplanted tumors was observed in KO and E933A KI mice. In a model of peritoneal carcinomatosis and dissemination (by intraperitoneal injection of YTN16), EMILIN-1 mutant animals also had higher histopathologic scores for invasion;

The use of the MNU protocol, that represents an interesting approach to investigate how deficiency of the ECM molecule EMILIN-1 may affect the incidence and frequency of tumour development, further showed that KO mice had higher tumour incidence, bigger adenomas and lower survival after MNU treatment. Similar results were obtained with the E933A KI model.

Conclusion: These results clearly demonstrate that EMILIN-1, exerts a pivotal role in GC onset, progression and dissemination through the involvement of α4/α9β1 integrin. Loss of EMILIN-1 may lead to alterations in the microenvironment able to promote tumorigenesis in the stomach. Our study also provides a novel animal model that, for the first time, targets a component of the gastric tumor microenvironment.

PHENOLIC COMPOUNDS OF FORMULATIONS USED FOR FUNCTIONAL DYSPEPSIA TARGET BITTER TASTE RECEPTORS AND STIMULATE MECHANISMS OF GASTRIC ACID SECRETION IN HUMAN PARIETAL CELLS IN CULTURE

P. Richter[1], M.-R. Piqué-Borràs[2], G. Künstle[2], V. Somoza[1,3,4]

Introduction: The bitterness of medicinal products used for functional dyspepsia and irritable bowel syndrome containing herbal extracts is well known, although the underlying mechanisms are poorly understood. In previous works of our group, bitter tasting phenolic plant compounds were shown to elicit (1) an anti-inflammatory activity in immune competent cells, and (2) stimulate proton secretion in parietal cells as key mecha-

nism of gastric acid secretion.[1-3] Both effects were mediated through bitter taste receptors (TAS2Rs), and were demonstrated to correlate with the compound's bitter taste in their effect size.[1-4]

Aims & Methods: In this work, a commercially available liquid herb formulation used to aid digestive discomfort was tested in a concentration range of 5 – 500 µg/ml for its TAS2R-mediated effects on the mechanisms of proton secretion by means of a pH-sensitive fluorescent dye in the well-established human parietal HGT-1 cell model.[4] This native cell line expresses all 25 TAS2Rs and all the elements necessary for signal transduction of functional gastric acid secretion. Individual plant extracts of the more effective formulation, namely extracts from *Artemisia absinthium*, *Cichorium*, *Erythraea centaurium*, *Gentiana lutea*, *Imperatoria ostruthium*, *Juniperus communis*, *Millefolium*, *Salvia officinalis*, and *Taraxacum*, were studied for their effects on proton secretion and TAS2R gene regulation by means of RT-qPCR. Moreover, total phenolic content, expressed as gallic acid equivalents (GAE), were analyzed by using the colorimetric Folin-Ciocalteu method.

Results: Treatment of the HGT-1 cells with the ethanolic plant extracts (cytotoxic effects were excluded; cell viability ≥ 95%) revealed a concentration-dependent (1 – 300 µg/mL herbal extract) stimulation of proton secretion by seven of nine extracts, of which those from *Imperatoria ostruthium* and *Juniperus communis* demonstrated the strongest effects. Gene expression experiments resulted a regulation of 16 out of 25 *TAS2Rs* after exposure of the HGT-1 cells to the herbal product. Without exception, these regulations were reproduced by treatment of the cells with the individual plant extracts. For example, exposure of HGT-1 cells to the liquid formulation led to a regulation of *TAS2R4* and *TAS2R5*, which are known to be activated by polyphenolic compounds.[2,5] These regulations were also found for the ethanolic extracts from *Juniperus communis* and *Imperatoria ostruthium* (*TAS2R4* and *TAS2R5*) and *Gentiana lutea* (*TAS2R4*). Quantitation of the total polyphenol content showed a high polyphenol concentration (> 1500 µg/mL GAE) for four out of the nine extracts, including that from *Imperatoria ostruthium* (2063.7 ± 31.6 µg/mL GAE) and *Juniperus communis* (2859.5 ± 13.6 µg/mL GAE), which also had a strong effect on proton secretion. In contrast, extracts with lower polyphenol concentrations (< 1500 µg/mL GAE) demonstrated a less pronounced effect on or no effects on proton secretion.

Conclusion: In summary, exposure of parietal HGT-1 cells to herbal plant extracts with a high polyphenol content lead to a stronger stimulation of proton secretion compared to extracts with low polyphenol contents (R^2 = 0.77; $p < 0.0001$). For the most active extracts from *Imperatoria ostruthium* and *Juniperus communis,* a gene regulation of *TAS2R4* and *TAS2R5* was demonstrated. Next experimental steps will include (1) a functional involvement of TAS2R4 and TAS2R5 by means of knock-out (CRISPR-Cas9) or knock-down (by means of specific siRNA) approaches, and (2) identification of key active phenolic compounds by mass-spectrometry.

TRIM69 SUPPRESSED THE ANOIKIS RESISTANCE AND METASTASIS OF GASTRIC CANCER THROUGH UBIQUITIN–PROTEASOME-MEDIATED DEGRADATION OF PRKCD

L. Sun[1], Y. Chen[1], L. Xia[1], J. Wang[1], J. Zhu[1], J. Li[1], K. Wang[1], K. Shen[1], D. Zhang[2], G. Zhang[2], T. Shi[2], W. Chen[3]

Introduction: The tripartite motif (TRIM) protein family has been investigated in multiple human cancers, including gastric cancer (GC). However, the role of TRIM69 in the anoikis resistance and metastasis of GC cells remains to be elucidated.

Aims & Methods: We identified the differentially expressed genes in anoikis-resistant GC cells using RNA-sequencing analysis. The interaction between TRIM69 and PRKCD was analyzed by coimmunoprecipitation and mass spectrometry. Our results have shown that TRIM69 was significantly downregulated in anoikis-resistant GC cells. TRIM69 overexpression markedly suppressed the anoikis resistance and metastasis of GC cells in *vitro* and in *vivo*. TRIM69 knockdown had the opposite effects. Mechanistically, TRIM69 interacted with PRKCD through its B-box domain and catalyzed the K48-linked polyubiquitination of PRKCD.

Results: Our results have shown that TRIM69 was significantly downregulated in anoikis-resistant GC cells. TRIM69 overexpression markedly suppressed the anoikis resistance and metastasis of GC cells in *vitro* and in *vivo*. TRIM69 knockdown had the opposite effects. Mechanistically, TRIM69 interacted with PRKCD through its B-box domain and catalyzed the K48-linked polyubiquitination of PRKCD. Importantly, overexpression of PRKCD blocked the effects of TRIM69 on the anoikis resistance and metastasis of GC cells. Interestingly, a $TRIM69^{-}PRKCD^{+}$ cell subset was positively associated with metastasis in GC patients.

Conclusion: TRIM69-mediated suppression of the anoikis resistance and metastasis of GC cells via modulation of the PRKCD, with potential implications for novel therapeutic approaches for metastatic GC.

Contact E-Mail Address: hanxiurui211@163.com
Introduction: CKLF-like MARVEL transmembrane domain containing 4 (CMTM4) plays an important role in regulation of the immune function and is involved in tumor formation and progression, but its role in gastric mucosa-related diseases remains unclear.
Aims & Methods: The aim of this study is to explore the role and mechanism of CMTM4 in gastric cancer cells.
Immunohistochemistry (IHC) was used to analyze the expression of CMTM4 in gastric biopsy. The CCK8 cell proliferation assay and plate clone formation were applied to analyze the proliferation of gastric cells. The cell scratch and transwell assay was used to analyze the migration and invasion of gastric cells, respectively. TMT proteome analysis was used to explore the possible mechanism of CMTM4 in gastric cancer cells, and verified by western blot.
Results: CMTM4 expression levels in gastric mucosal biopsy specimens from patients with gastritis and gastric cancer were analyzed by immunohistochemistry, and the results showed that CMTM4 expression was lower in gastric cancer than that in gastritis tissues ($P<0.05$). To investigate the function of CMTM4 in gastric cancer cell lines, we constructed CMTM4 knockdown and overexpression cells from AGS cell line and CMTM4 overexpression cells from SGC7901 cell line. The CCK8 cell proliferation assay and plate clone formation assay showed that CMTM4 overexpression significantly inhibited the proliferation of gastric cancer cells while knockdown CMTM4 promoted the proliferation of gastric cancer cells. The results of cell scratch assay showed that overexpression of CMTM4 inhibited the migration of gastric cancer cells, and knockout CMTM4 promoted the migration of gastric cancer cells. Transwell assay showed that overexpression of CMTM4 inhibited migration of gastric cancer cells and knockdown of CMTM4 promoted migration of gastric cancer cells, while knockdown of CMTM4 inhibited invasion of gastric cancer cells.
In addition, overexpression of CMTM4 increased the apoptosis of gastric cancer cells. The results of TMT proteome showed that STAT1 was significantly up-regulated in gastric cancer cells overexpressing CMTM4, which was also verified by western blot.
Conclusion: CMTM4 has an oncogenic effect in gastric cancer cells. CMTM4 may affect the growth, migration and invasion of gastric cancer cells mainly through STAT1 signaling pathways.
Disclosure: Nothing to disclose.

Contact E-Mail Address: ludovicadottori@gmail.com
Introduction: Corpus Atrophic Gastritis (CAG) is a precancerous inflammatory condition of the oxyntic mucosa. Up today, two types of CAG are distinguished: 1) autoimmune (corpus-restricted), defined for CAG sparing the antrum 2) *Helicobacter pylori* (*Hp*)-related (multifocal), which involves antrum too.
Antrum involvement/sparing is crucial for both CAG definition as autoimmune and gastric cancer risk level, which is increased in case of pan-atrophy/pan-metaplasia, according to OLGA and OLGIM scores. CAG natural history is still poorly known, especially regarding antrum evolution. In cases with previous antral involvement, possible antrum healing after cure of Hp infection was formerly described. So, given the importance of the criterium antrum-sparing, we aimed to assess antral mucosa changes at long-term follow-up(FU) beside baseline in a cohort of CAG patients.
Aims & Methods: Given the importance of the criterium antrum-spared, we aimed to assess antral mucosa changes at long-term follow-up(FU) beside baseline in a cohort of CAG patients.
We performed a retrospective study on 130 patients with CAG and antrum involvement according to updated Sydney System. Mean time of FU gastroscopy was 40.6(range 4-192) months. In 13 patients corpus atrophy was not confirmed at FU, so were excluded. At baseline, among the remaining 117 patients [mean age 63 (range 20-87) years; F 67.5%], 47 (40.2%) had antral non-atrophic and 70 (59.8%) had antral atrophic gastritis, metaplastic in 84.3%. Histologically diagnosed *Hp* infection was present in 27.3% of patients, all receiving eradication therapy, anti-parietal cells antibodies (APCA) were positive in 53.8%.
Results: At FU 29/117(24.8%) of patients with *tout-court* involved antrum showed a complete *restitutio ad integrum* of antral mucosa. In particular, on 70 cases with antral atrophy at baseline, atrophy regressed in 15 (21.4%). *Hp* infection at baseline was present in 38% of patients who reported complete antral healing at FU, cured in all but one. Both antral healing and atrophy regression were found to be similar in Hp-cured and not-cured/negatives ($p>0.05$). In 8 patients (6.8%) a worsening of antral histology at FU was reported: 5 developed antral atrophy, not present at baseline, and 3 antral atrophic patients developed intestinal metaplasia.
Conclusion: Nearly 25% of CAG patients with antral involvement showed complete antrum healing, with regression of baseline antral atrophy in 21.4%. Antral healing occurred also in patients without history of *Hp* infection and/or eradication. These data suggest that in CAG natural history, concomitant antral involvement may regress irrespective of Hp cure, implying cancer risk reduction and raising queries about histology as sole criteria diagnostic for autoimmune gastritis.

GASTRITIS ASSOCIATED WITH IMMUNE CHECKPOINT INHIBITORS: A NEW ENTITY TO CONSIDER

I. De Felice[1], L. Sanchez-Mete[2], V. Stigliano[3], M. Russillo[4]
[1]Università La sapienza di Roma, Gastroenterology and Digestive Endoscopy, Roma, Italy, [2]IFO Regina Elena National Cancer Institute, Gastroenterology and Digestive Endoscopic, Rome, Italy, [3]IFO, Gastroenterology and Digestive Endoscopy, Rome, Italy, [4]IFO Regina Elena National Cancer Institute, Oncology Medical A, Rome, Italy

Contact E-Mail Address: ilaria.defelice@uniroma1.it
Introduction: Immunotherapy represents an important step in the management of metastatic melanoma, since it has improved responses to treatment and overall survival of patients affected by this disease. However, this therapy could be linked to severe toxicities. Particularly, Nivolumab is a human IgG4 monoclonal antibody against PD-1, acting as an immune check point inhibitor (ICPi) and its use has been associated with various immune-related side effects. Gastrointestinal toxicities (GI) connected to ICPi have been extensively reported, however immune-related gastritis has only recently been described and it is considered rare; its clinical characteristics are still undefined.
Aims & Methods: The aim of this retrospective study was to evaluate the frequency and clinical-histopathological of immune-related gastritis in patients treated with ICPi for metastatic melanoma.
Results: In our series we found one case of immune-related gastritis, a 53-year-old female patient with a diagnosis of metastatic melanoma of the right nostril treated with Nivolumab in monotherapy for three years. One month after stopping Nivolumab, she was hospitalized for nausea, post-prandial vomiting, deteriorating loss of appetite and consequent weight loss that required parenteral nutrition. The patient referred to our gastroenterology division for a thickening of the esophagus and stomach at CT scan.
She performed gastroscopy that showed a gastric mucosa intensely edematous and hyperemic, with diffuse erosions covered with fibrin, easily bleeding, in all district. Histopathological analysis documented fragments of gastric mucosa characterized by superficial ulceration and intense acute and chronic inflammation, with destruction of gastric glands and congestion of capillaries, in the absence of Helicobacter Pylori infection. The histological report was considered compatible with acute erosive iatrogenic gastritis (nivolumab related). After her admission to the hospital, she started parenteral nutrition and i.v. prednisone at a dose of 1 mg/kg/die with gradual improvement of her symptoms. After few days, she was feeded with an elementary diet. She continued oral prednisolone in progressively decreasing doses for three months with resolution of the symptoms from the upper gastrointestinal tract. A new gastroscopy, performed three months after corticosteroid therapy, revealed normal mucosa of gastric body and fundus, with light hyperemia of antrum. Histology of the biopsy specimens of the gastric mucosa have shown moderate inflammatory infiltration of the lamina propria (lympho-monocytes and granulocytes), without erosive aspects.
Conclusion: Colitis and diarrhea are the most common gastrointestinal side effects and are responsible for temporary or permanent discontinuation of ICPi. Immuno-related gastritis is a new nosocomial entity, firstly reported in 2017, and it should be included in the list of Nivolumab's side effects. Gastroenterologists should be aware of this symptoms presentation (vomiting, nausea, epigastric pain and loss of weight) in patients treated with ICPi, also after its discontinuation. This type of gastritis is not responsive to PPI treatment and improves only after starting corticosteroids therapy, as the other immune-related adverse events. After excluding the most common causes of gastritis, clinicians should evaluate this drug-related side effect, considering clinical, radiological, endoscopic and histological data.
Disclosure: Nothing to disclose.

THE HUMAN GASTRIC MUCOSA DISPLAYS A UNIQUE IMMUNE FINGERPRINT WITH INTER-INDIVIDUAL VARIABILITY AND LACK OF REGIONAL VARIATION

Á. De Prado Santos[1], P. Cal-Sabater[1], A. Fiz-López[1], S. Izquierdo[2], D. Corrales[2], F. Pérez-Cózar[3], J. H-Vázquez[1], E. Arribas Rodríguez[1], C. PÉREZ-SEGURADO[1], Á. Martín Muñoz[4], J.A. Introduction: The immune cellular landscape from the gastric mucosa remains largely scarce in the human setting, despite its relevance in several inflammatory conditions. Indeed, and although the properties of the intestinal immune system systematically change through its length, it is currently unknown whether the same applies in the human stomach.
Aims & Methods: We hereby aimed to perform an unbiased characterization of the human gastric immune system and determine the presence of regional differences within the stomach. To that end, human gastric biopsies were obtained from the antrum, body and incisura from 10 controls to obtain lamina propria mononuclear cells that were further characterized by spectral cytometry with a panel of 40 markers.
Results: Phenotypic hierarchical analyses identified a total of 52 different immune cell subsets within the human gastric mucosa revealing that T-cells (>60%) and NK cells (>20%) where the main populations. Within T-cells, $CD4^+$ and $CD8^+$ were equally represented, with both displaying mainly a memory and effector phenotype. NK cells, on the contrary, were mainly of the early phenotype. No regional differences were observed for any subsets among the 3 different locations. Following unsupervised analysis by dimensionality reduction algorithms a total of 82 clusters were found. Again, no differences were observed between locations although a great degree of inter-individual variability was found.
Conclusion: In summary, we hereby have unraveled the human gastric cellular subset composition at the time that we have proved a unique interindividual immune fingerprint with no inter-regional variations.

Introduction: Mucosa-associated microbiota (MAM) and its metabolites are known to be present in the mucosa of the intestinal tract, including the duodenum. They are reported to affect immune function or gut barrier function and lead to cause various diseases. However, it is not clear which ones are associated with duodenal tumor development.

Aims & Methods: The early duodenal cancer patients are enrolled from Apr. 2020 to Oct. 2021. In this study, we aimed to clarify the characteristics of the MAM and metabolites of the duodenal tumors. We collected duodenal mucus on the duodenal tumor, on the surrounding mucosa of the tumor (DNT-T), and on the duodenal mucosa of healthy control (DNT-HC). For MAM analysis, we extracted the DNA from the obtained mucus layer. Then, amplicon sequencing analysis using V3-V4 variable regions of the 16S rRNA gene was performed. Regarding the metabolites, we used capillary electrophoresis-Fourier transform mass spectrometry to compare and study the variability of ionic metabolites in brush-abraded specimens.

Results: The taxonomy of gut microbiota at the genus level, g__*Cutibacterium,* g__*Faecalibacterium*, and *g__Brevundimonas* was significantly higher in the DNT-T and *g__ Neisseria, g__ Porphyromonas* was significantly higher in the DNT-HC. As for the metabolites, we found 8 metabolites which has significant difference between DNT-T and DNT-HC. In particular, citrulline, choline, and NAD+ in DNT-T were decreased in those with intramucosal carcinoma compared to DNT-HC. Principal component analysis revealed variable choline metabolism and methionine circuits.

Conclusion: Several bacteria and metabolites were varied in the MAM of DNT-T, suggesting that they may be associated with the development of duodenal tumors.

Disclosure: There is no Conflict of Interest.

Introduction: Rosacea is a common inflammatory skin disease with multiple etiologies. Proton pump inhibitors (PPIs) and histamine-2 receptor antagonists (H2RA) are acid suppressive drugs widely used for gastrointestinal diseases, and long-term use has been reported to be associated with dysbiosis which is a potential risk for development of Rosacea. This study aimed to study association between rosacea and acid suppressants in Korean national cohort.

Aims & Methods: We used Korean National Health Insurance Service-National Sample Cohort (NHIS-NSC) data of 749,166 patients with upper gastrointestinal (GI) diseases between 2001 and 2013. Duration of acid suppressants were compared between patients with and without rosacea together with other sociodemographic characteristics and hazard ratios were estimated.

Results: Longer use of acid suppressants was significantly associated with increased risk of Rosacea. After adjustment for possible confounders, increased cumulative defined daily dose (cDDD) was significantly associated with risk of rosacea (odds ratio [OR], 1.55; 95% confidence interval [CI], 1.20-2.00, P = 0.001). Other factors significantly associated with risk of rosacea include residing at rural area (OR, 2.58; 95% CI, 2.18-3.06, P < 0.001), greater Charlson Comorbidity Index (CCI) score (OR, 1.45; 95% CI, 1.15-1.83, P = 0.002), and comorbidities (malignancy, thyroid disease, and depression).

Conclusion: Results from our study indicate that H2RA or PPI is associated with the occurrence of rosacea among patients with GI diseases in Korean population. The risk was increased in dose-response trend, even after adjusting for confounding variables. Clinicians should be aware of risks associated with prolonged use of acid suppressive drugs.

DOES THE DUODENAL MUCOSA-ASSOCIATED MICROBIOME AFFECT ON THE QUALITY OF THE BOWEL PREPARATION?

Contact E-Mail Address: ayesha17@gmail.com

Introduction: Alterations of the small intestinal microbiome are linked to gastrointestinal symptoms and recent data suggest that there is an inverse relationship between the relative abundance of mucosa associated *Veillonella* spp and gastric emptying[1]. Previous studies have questioned the effect of gastrointestinal motility on the quality of bowel preparation for colonoscopy.

Aims & Methods: This study explored the possibility that the duodenal mucosa-associated microbiota (d-MAM) affects patient response to a standardized bowel preparation. We included data from 85 consecutive individuals (52 female, age 17 ~ 79 years (mean = 52.3) undergoing upper GI endoscopy with same day colonoscopy. The procedures were performed for the assessment of GI symptoms and/or a positive immunologic fecal occult blood test. All patients were recruited after informed consent and with approval from the local ethics committee. Bowel preparation was individualized based upon a previously developed protocol[2] (and endoscopists rated the quality of the bowel preparation utilizing the Aronchick scale. Duodenal (D2) biopsies were obtained from each participant with an aseptic technique during endoscopy, snap frozen and stored at -80°C. Following gDNA extraction, amplicon libraries spanning the V6-V8 region of the 16S rRNA gene were constructed and sequenced using the Illumina MiSeq platform. Concurrent sequencing of reagent only controls was undertaken to exclude any non-duodenal sequences. Bioinformatics analysis was undertaken through the QIIME pipeline.

Results: The bowel preparation was rated in 65 patients as good or very good, 13 as Fair, and 7 as Poor. The within sample (alpha) diversities of duodenal MAM were not significantly different for subjects with different quality ratings of the bowel preparation. Interestingly though, those patients with a Poor-quality rating of their bowel preparation were found to possess a reduced relative abundance of *Veillonella* (and *Prevotella)* while the relative abundance of *Pseudomonas* was increased.

Conclusion: Given that a reduced relative abundance of the genus *Veillonella* is correlated with an increase in gastric emptying lag times, and that *Pseudomonas* is well recognized for its capacity to produce biofilms, the variable (and inverse) presence of these bacterial taxa (and *Prevotella*) raises the intriguing possibility that provide further evidence that the duodenal MAM influences gastrointestinal motor function.

Introduction: Disease-associated alterations of the intestinal microbiota composition, known as dysbiosis, have been well described. Duodenal mucosal biopsies occasionally demonstrate the presence of adherent bacteria in the epithelium. However, there is a lack of universally accepted and applied gold standard for investigating the association with various diseases such as small intestinal bacterial overgrowth (SIBO), close relationships with obesity, cirrhosis, IBS, etc.

Aims & Methods: Aim: This retrospective study evaluated the spectrum of such bacteria after the cultivation of tissue samples that were obtained at routine endoscopy of 81 patients indicated to examination for different reasons.

Methods: Biopsies were taken using sterilized standard endoscopic biopsy forceps. Two pieces of tissue were obtained without the removal of forceps from the third and fourth part of the duodenum and the same way from the antrum of the stomach. One of the samples was placed into a 10% glucose solution for microbial cultivation, the other was placed into a 10% formaldehyde solution for histological examination. In 22 patients SIBO testing by breath test and stool cultivation was performed.

Results: Overall 81 biopsy specimens from the duodenum and 45 from the antrum of the stomach were cultivated. In the duodenum, bacterial overgrowth was found in 64,19% of patients and it was negative in 35,80% of cases, while in the antrum of the stomach, the presence of bacteria was found in 48,88% and was negative in 51,11% of patients. The agreement with the same genera (E. coli) in antrum and duodenum was only in 9 patients (25%). E. coli was present in 19,7% of specimens from duodenum followed by present Pseudomonas aeruginosa (17,24%) and Enterobacter cloacae (12,34%). While in antrum E. coli was present in 17,77% of specimens, Klebsiella species and Enterobacter cloacae were present in 8,88% of cases respectively. 22 patients were examined by lactulose-hydrogen breath testing for SIBO with 60% positivity. There were 18,1% positively tested patients for SIBO, but the duodenal and antral cultivation was negative. Stool cultivation did not reveal any pathogens except E. coli. When the bacteria were cultivated, we performed MIC testing for antibiotics. Overall resistance was found for ampicillin in 88,4% of all pathogens and ampicillin + sulbactam 61,5% respectively in following percentages, E. coli: 52,9%, Klebsiella spp.: 100%, Enterobacter: 69,2%, Proteus mirabilis: 100%, Enterococcus: 33% were resistant for ampicillin.

Conclusion: Cultivation of mucosal biopsy specimens seems to be useful for the identification of patients with bacterial overgrowth in the upper part of the GI tract. There is a need to stress the elucidation of their role in the pathogenesis of different chronic illnesses.

Disclosure: Nothing to disclose.

EPSTEIN-BARR VIRUS AND CLINICO-ENDOSCOPIC CHARACTERISTICS OF GASTRIC REMNANT CANCERS AND PROXIMAL NON-REMANT CANCERS

C. Våge[1], A.A. Savage Ubøe[1], E.A. Bringeland[2,1], R. Fossmark[3,1]
[1]*Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine, Trondheim, Norway,* [2]*St. Olavs Hospital, Department of Gastrointestinal Surgery, Trondheim, Norway,* [3]*St. Olavs Hospital, Trondheim, Norway, Department of Gastroenterology and Hepatology, Trondheim, Norway*

Contact E-Mail Address: reidar.fossmark@ntnu.no

Introduction: Gastric adenocarcinomas associated with Epstein-Barr virus (EBV) infection account for 5-10% of gastric cancers and is recognized as a distinct molecular subtype. Adenocarcinomas arising in the residual stomach after partial gastrectomy are named gastric remnant cancers (GRC) and usually develop decades after distal gastrectomy for benign disease. The relevance of GRC as a separate entity has been questioned since many tumour characteristics as well as prognosis of GRC does not seem to differ from other primary gastric cancers. However, it has been reported that a 5-fold higher proportion of GRC were EBV positive compared to other gastric adenocarcinomas in a meta-analysis of studies on Eastern patient cohorts. Symptoms and endoscopic findings at diagnosis may also differ between GRC and other gastric cancers. The aim of this study was to assess EBV infection as well as clinico-endoscopic characteristics in patients with GRC in a Western population-based patient cohort.

Aims & Methods: All incident gastric adenocarcinoma in Central Norway between 2001 and 2016 were identified by a combined search in the Norwegian Cancer Registry and Norwegian Patient Registry followed by manual assessment of all patient records. Patient and tumour characteristics were extracted. GRCs was defined as gastric adenocarcinomas in patients previously operated with a distal gastrectomy for either benign or malignant disease. Among 1217 patients with adenocarcinoma there were 78 with GRCs. All tumours were histologically classified according to Lauren and EBV-status was assessed by in situ hybridization (ISH) in GRC patients (n=78) and in proximal (localized in the gastric corpus) non-GRC (n=56) controls. Symptoms and findings at upper endoscopy at the time of diagnosis of GRC and proximal non-GRC patients were recorded.

Results: Seventy-eight patients had GRC, of whom 76 (97.4%) patients had benign disease as indication for primary distal gastrectomy. The median latency time from primary distal gastrectomy to GRC was 37.6 (range 15.7-68.0) years. Fourteen (18.7%) GRC and 6 (10.9%) proximal non-GRCs were EBV-ISH positive, but the proportions did not differ significantly (p=0.23). EBV-status was not associated with patient age, sex or Lauren histological type, neither for GRC-patients, nor for the study population overall.

The indication for upper endoscopy when the cancer was diagnosed was more frequently anaemia in GRC compared to proximal non-GRC patients (32.1% vs. 16.1%, p=0.036) and less frequently upper abdominal pain (12.8% vs. 35.7%, p=0.002). At the upper endoscopy, ulceration was a less frequent finding (17.9% vs. 57.1%, p<0.001) in GRC compared to proximal non-GRC patients. Median overall survival in EBV positive GRCs was 22.2 (0-64.9) months compared to proximal non-GRC 6.7 (4.0-9.5) months, p = 0.40, with 5-year survival of 28.6% and 22.6%, respectively.

Conclusion: A high proportion of GRC were EBV positive, but the proportion did not differ significantly from other proximal gastric cancers. At the time of diagnosis GRC patients did more often have anaemia, but less frequently upper abdominal pain or gastric ulceration.

Disclosure: Nothing to disclose.

RISK FACTORS FOR UPPER MASSIVE GASTROINTESTINAL BLEEDING OCURRENCE AND DEATH: A PROSPECTIVE SINGLE-CENTER STUDY

E. Redondo-Cerezo[1], C. Tendero-Peinado[1], R. Fernandez-García[1], A. Lancho Munoz[1], J.G. Martínez-Cara[1], R. Jiménez-Rosales[1]
[1]*Hospital Universitario Virgen de Las Nieves, Gastroenterology, Granada, Spain*

Contact E-Mail Address: ritajimenezrosales@gmail.com

Introduction: Massive gastrointestinal bleeding (MGB) is a life-threatening condition that requires prompt recognition and resuscitation to increase the chance of good outcomes (1).

Aims & Methods: Aims: Analyze risk factors, comorbidities and outcomes of MGB.

Methods: Retrospective analysis of a prospective registry of upper gastrointestinal bleed (UGIB) patients admitted to 'Virgen de las Nieves University Hospital' between 2013-2020.

MGB was defined as UGIB with transfusion of >2 pRBCs in the emergency room or during the first 24h of hospital stay and signs of shock (2). Main outcomes were 30-day mortality, rebleeding, bleeding persistence or severe complication throughout admission and complications within the first 6 months after discharge (including cardiovascular, hemorrhagic or deaths).

Statistical analysis was performed by SPSS.

Results: We included 1213 UGIB patients, 171 with MGB.

Multivariate logistic regression analysis showed that, being admitted for another condition (HR 1.72,95%CI 1.04-2.58,p=0.035), having a systemic disease (HR 2.30,95%CI 1.22-5.32,p=0.045), a disseminated malignancy (HR 2.07,95%CI 1.02-4.21,p=0.045) or suffering a severe comorbidity (HR 2.21,95%CI 1.25-3.91,p=0.009) were independent risk factor for MGB.

Among 171 MGB patients, 21% died, with 10 deaths directly from hypovolemic shock secondary to UGIB, and 11% due to complications.

Table shows significance differences between deaths and survivors.

Relevant Comorbidities ASA 3-4 (%)	**Deaths** 96.7%	**Survivors** 78.5%	***p*** 0.0018
Active bleeding (%)	76.3	43.3	0.007
Interventional radiology (%)	13.3	3.7	0.034
SBP (mean±SD mmHg)	79±8	84±9	0.025
Albumin (mean±SD mg/dl)	2.4±0.5	2.8±0.6	0.011
Calcium (mean±SD mg/dl)	7.7±0.6	8.2±0.8	0.032
Platelets (mean±SD /mm^3)	158*10^3±101*10^3	206*10^3±106*10^3	0.027
Severe complications during hospitalization	76.7	22.1	<0.0001
Bleeding persistence (%)	63.3	17.6	<0.0001
Rebleeding (%)	40	17	0.005

Multivariate analysis showed that active bleeding in endoscopy (HR 4.80,95%CI 1.06-21.62,p=0.041) and severe complications (HR 14.03,95%CI 3.30-59.60,p<0.0001) were independent predictors for mortality, being calcium levels a protective factor (HR 0.41,95%CI 0.16-0.94,p=0.045).

Among the survivors after the index episode,14% died after 6 months, being main causes of death recurrent bleeding(5.2%), neoplasms(4.4%), cirrhosis complications(2%), cardiovascular disease(1.5%) and sepsis(1.5%). Delayed bleeding was caused by recurrent UGIB in 86.6%, lower GIB in 10% and from a non-GI origin in 3.4%. Delayed cardiovascular events were heart failure in 46%, thromboembolic events in 23%, myocardial ischemia in 15.4% and atrial fibrillation in 15.6%.

Conclusion: Our study is a prospectively collected single center registry of patients with massive UGIB, in which we observed that being an inpatient and harboring severe comorbidities, particularly systemic diseases and malignancies, were risk factors for this condition. Mortality among

those patients was related to CKD, cirrhosis, severe comorbidities and excessive alcohol consumption. We also found an increased delayed mortality, probably related to a worsening health condition in which GI bleeding heralded poor outcomes, some of them potentially preventable with close follow-up.

LIVER SPECIFIC SCORES AND GASTROINTESTINAL BLEEDING SCORING SYSTEMS TO PREDICT OUTCOMES IN PATIENTS WITH ACUTE UPPER GASTROINTESTINAL BLEEDING

R. Jiménez-Rosales[1], J.M. López-Tobaruela[1], E.J. Ortega-Suazo[1], M. López-Vico[1], J.G. Martínez-Cara[1], E. Redondo-Cerezo[1]
[1]Hospital Universitario Virgen de Las Nieves, Gastroenterology, Granada, Spain

Contact E-Mail Address: ritajimenezrosales@gmail.com

Introduction: Several scoring systems have been established to identify upper gastrointestinal bleeding (UGIB) patients at high risk of adverse outcomes, being the best ones MAP (ASH) and ABC (1). Traditional scores(Glasgow-Blatchford, Rockall, AIMS65) were validated and compared mostly in nonvariceal-UGIB. On the contrary, MAP (ASH) and ABC included variceal bleed (VB) in their validation and comparison cohorts.

Also, to determine the prognosis of liver cirrhosis there are two frequently used scores, Child-Pugh score (CP) and MELD, and recently, ALBI score. Previous studies have reported the ability of these in predicting VB outcomes. A recent metanalysis show MELD and CP performed better predicting mortality than traditional scores (2). But there are no studies comparing liver scores with MAP (ASH) or ABC.

Aims & Methods: To compare the predictive value of MAP (ASH) and ABC scores vs. liver scores stratifying outcomes of VB.

Retrospective analysis of a prospective registry of UGIB patients admitted to 'Virgen de las Nieves University Hospital' (2013-2020). VB was defined as that coming from gastric or esophageal varices. Main outcomes were in-hospital (intervention,rebleeding, misbalance of chronic condition, mortality) and delayed-6months (UGIB, cardiovascular, mortality) ones. Intervention is a composite endpoint including need of transfusion, endoscopy therapy, interventional radiology or surgery. Statistical analysis was performed by SPSS and MedCalc.

Results: We included 1345 UGIB patients, 241 with VB, mean age 60.70+/-12.62**,** 26.1% females. Main differences between deaths and survivors were hepatocellular carcinoma, (57.1%vs.16.1%,p=0.001, OR 6.97,95%CI 2.28-21.34), misbalance of chronic condition (40.7% vs. 5.5%, p<0.001, OR 11.83,95 % CI 5.15-27.22), intervention (21.1% vs. 3%, p=0.013, OR 8.56,95 % CI 1.14-64.49), rebleeding (50%vs.12.7%, p<0.001, OR 6.88, 95% CI 3.12-15.20) and length hospital stay (15.91vs.9.23,p=0.031). In the multivariate analysis, misbalance of chronic condition was an independent risk factor for mortality (OR 4.23, 95 % CI 1.11-16.06, p=0.034).

Comparisons of ROC curves for relevant outcomes are shown in the table, with statiscal differences only for intervention (MAP(ASH) >CP, p=0.0195), misbalance of chronic condition (MAP(ASH) >ALBI, p=0.023; ABC > CP, p=0.020; ABC > ALBI, p=0.001) and delayed UGIB/liver mortality (MELD > Child, p=0.042).

AUROC (95%CI)	MAP(ASH)	ABC	MELD	Child-Pugh	ALBI
Intervention	***0.744**** (0.674 - 0.806)	**0.701** (0.628 - 0.767)	0,622 (0,546 - 0.693)	0.582 (0.506 - 0.655)	0.668 (0.594 - 0.737)

UGIB in-hospital mortality	0.656 (0.568 - 0.736)	0.633 (0.545 - 0.714)	**0.770** (0.689 - 0.838)	**0.774** (0.694 - 0.842)	0.711 (0.626 - 0.786)
Other cause in-hospital mortality	**0.751** (0.666 - 0.823)	**0.762** (0.666 - 0.823)	0.696 (0.607 - 0.774)	0.722 (0.635 - 0.798)	0.638 (0.547 - 0.721)
Delayed cardiovascular events	0.634 (0.553 - 0.709)	0.534 (0.452 - 0.614)	0.566 (0.484 - 0.645)	0.588 (0.506 - 0.666)	0.658 (0.506 - 0.666)
Delayed UGIB	0.534 (0.453 - 0.615)	0.582 (0.501 - 0.660)	0.536 (0.455 - 0.616)	0.516 (0.434 - 0.596)	0.519 (0.437 - 0.599)
Delayed Mortality	0.581 (0.499 - 0.659)	0.683 (0.603 - 0.755)	0.555 (0.473 - 0.635)	0.617 (0.535 - 0.694)	0.676 (0.596 - 0.749)
Delayed UGIB and liver mortality	0.600 (0.340 - 0-824)	**0.733** (0.468 - 0-914)	***0.850**** (0.596 - 0-974)	0.542 (0.289 - 0-780)	0.650 (0.386 - 0-860)

Conclusion: In our study, MAP (ASH) and ABC scores performed better at prediction intervention and misbalance of chronic condition. On the other hand, MELD is superior to CP in predicting delayed UGIB and liver mortality. None of them performs well in predicting rebleeding or other delayed outcomes. Although we see some differences in AUROCs for the other outcomes, no statical differences were found. Therefore, MAP (ASH) and ABC have a good performance not only in patients with UGIB but also in VB.

Independent risk factor for in-hospital mortality was misbalance of chronic condition, showing once again that it is not UGIB itself what determines the evolution if not the imbalance that it produces.

NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING IN PATIENTS WITHOUT AND WITH COMPENSATED AND DECOMPENSATED CIRRHOSIS: EPIDEMIOLOGY, OUTCOMES AND PREDICTIVE FACTORS OF MORTALITY

R. Jiménez-Rosales[1], M. López-Vico[1], E.J. Ortega-Suazo[1], J.M. Lopez Tobaruela[1], J.G. Martínez-Cara[1], E. Redondo-Cerezo[1]

Contact E-Mail Address: ritajimenezrosales@gmail.com

Introduction: Upper gastrointestinal bleeding(UGIB), both variceal(VB) and nonvariceal(NVB), is a prevalent cause of hospitalization, readmission, and poor outcomes among patients with cirrhosis. However, studies typically focus on VB given its association with higher morbidity and mortality rates(1) although some other studies comparing VB and NVB among patients with cirrhosis reported no difference in outcomes(2).

On the other hand, literature is controversial about NVB outcomes between cirrhosis and non-cirrhosis(3,4).

Despite this, the existing literature of NVB in cirrhosis is less robust (few prospective studies with no differentiation between compensated and decompensated cirrhosis).

Aims & Methods: Aim: To compare outcomes between VB and NVB among patients with cirrhosis and between NVB patients with (compensated and decompensated) and without cirrhosis. Therefore, we sought to explore predictors of mortality in NVB patients.

Methods: Retrospective analysis of a prospective registry of UGIB patients admitted to 'Virgen de las Nieves University Hospital'(2013-2020).

VB was defined as esophageal or gastric varices as source of bleeding. NVB was defined as all other etiology(including portal-hypertensive gastropathy)

Patients with a Child-Pugh A and B(score 5-9) have compensated cirrhosis and those with class C cirrhosis(score 10-15) have decompensated cirrhosis.

The primary outcome of our study was in hospital and delayed mortality. Secondary outcomes included intervention, length of hospital stay, rebleeding and delayed UGIB.

Statistical analysis was performed by SPSS. Categorical variables were compared using χ2 test. Continuous variables using Student's t-test or Mann-Whitney U-test. Multivariate logistic regression analysis was performed to identify independent risk factors for mortality.

Outcomes	Non-cirrhotic	Compensated	Descompensated	p
Reebleding	9%	7.4%	23.8%	0.047 (for descompensated)
Nº RBC	2.6	2.88	5.33	0.034 (for descompensated)
Endoscopy therapy	39.1%	37.5%	52.4%	n.s (0.443)
Surgery	4.8%	1.2%	0%	n.s (0.203)
Interventional radiology	1.1%	1.2%	0%	n.s (0.883)
Lenght hospital stay	8.59	8.55	12.33	0.022 (for descompensated)
In-hospital mortality	7.2%	13%	45%	<0.001 (for descompensated)
Delayed-6months UGIB	6.1%	10.8%	11.1%	n.s. (0.210)
Delayed-6months mortality	8.8%	18.5%	14.3%	0.013 (for compensated)

Table.

Results: We included 1345 UGIB patients, 319 had cirrhosis, 190 VB (59.6%) and 129 NVB (40.4%). There were no differences in relevant outcomes between VB y NVB in cirrhosis except for need of endoscopy therapy (74.2% vs.41.4%, p<0.001)

In the whole cohort, 1139 where NVB: 1011 non-cirrhotic (88.8%), 129 cirrhotic (11.2%): 81 compensated and 21 decompensated (26 without information).

Main outcomes between non-cirrhotic and compensated/decompensated cirrhotic with NVB are shown in the table.

Independent risk factors for in-hospital mortality were age (HR 1.08,95%CI 1.01-1.61,p=0.049), misbalance of chronic condition (HR 11.33,95%CI 2.26-56.71,p=0.003) and Child-Pugh score (HR 1.88,95%CI 1.18-2.99,p=0.008).

Conclusion: In our study we show that, at the end, prognosis depends on basal status, namely being compensated or decompensated, and is not only about have or not to have cirrhosis or about VB or NVB. Patients with decompensated cirrhosis have worse outcomes in terms of higher rates of rebleeding, number of packet blood cell transfused, length of hospital stay and in-hospital mortality. After performed multivariate analysis, Child-Pugh score remains as an independent risk factor for mortality, indicating that liver function deterioration marks the evolution.

PP0019

THE SHOCK INDEX IS NOT BETTER THAN PRE-EXISTING SCORING AT PREDICTING OUTCOMES IN UPPER GASTROINTESTINAL BLEEDING PATIENTS.

R. Jiménez-Rosales[1], M. López-Vico[1], J.M. Lopez Tobaruela[1], E.J. Ortega-Suazo[1], C. Tendero-Peinado[1], A. Lancho Munoz[1], R. Fernandez-García[1], J.G. Martínez-Cara[1], E. Redondo-Cerezo[1]
[1]Hospital Universitario Virgen de Las Nieves, Gastroenterology, Granada, Spain

Contact E-Mail Address: ritajimenezrosales@gmail.com

Introduction: Several scoring systems have been established to identify upper gastrointestinal bleeding (UGIB) patients at high risk of adverse outcomes. Recently, focus have been posed in the Shock Index since the NCEPOD reported this use to assess bleeding severity and found an association with mortality. Moreover, they report that there was inconsistent use of recognized scoring systems in their examined cases of upper GI bleeding and postulated their use (1).

After this, Stanley and colleagues examine the performance of SI in comparisons with preexisting scores predicting UGIB outcomes in a cohort of 3012 patients and reported that SI was inferior to existing pre-endoscopy scores (2).

Recently, other study positioned SI as the best ones to predict 30, 180 and 360-day mortality in UGIB patients over 65 years, generating the controversy (3).

We aim to compare the performance of SI versus previous scores and versus traditional vital constants to predict outcomes in UGIB.

Aims & Methods: We aim to compare the performance of SI versus previous scores and versus traditional vital constants to predict outcomes in UGIB.

Retrospective analysis of a prospective registry of UGIB patients admitted to 'Virgen de las Nieves University Hospital' between 2013-2020.

Main outcomes were intervention (a composite endpoint including need of transfusion, endoscopy therapy, interventional radiology or surgery) and in-hospital mortality.

Scores calculated were SI, MAP(ASH), ABC, Glasgow-Blatchford score (GBS), AIMS65 and Rockall score. We also included pulse and blood pressure (BP) in the comparison.

MedCalc was used to calculate ROC Curve of scores in determining outcomes.

Results: AUROCs are shown in the table. Comparisons of ROC curves for relevant outcomes show all the pre-existing scores superior to SI with statical difference. In relation to vital signs, only for intervention SI was superior to pulse with statical difference. For mortality, no differences were found between SI and vital signs.

AUROC (95%CI)	Need of intervention	In-hospital mortality
Pulse	0.538 (0.590 - 0.643)	0.618 (0.591 - 0.645)
Systolic Blood Pressure	0.645 (0.511 - 0.565)	0.587 (0.559 - 0.614)
Shock Index	**0.626** (0.596 - 0.655)	**0.612** (0.582 - 0.642)
MAP(ASH)	0.789 (0.764 - 0.813)	0.758 (0.731 - 0.784)
ABC	0.723 (0.695 - 0.749)	0.804 (0.779 - 0.828)
Glasgow-Blatchford score	0.780 (0.754 - 0.805)	0.708 (0.680 - 0.736)
AIMS65	0.682 (0.654 - 0.710)	0.738 (0.710 - 0.765)
Rockall score	0.760 (0.734 - 0.785)	0.743 (0.715 - 0.769)

Conclusion: In view of our results, we have to conclude, as Stanley et al. (2), that Shock Index is inferior to pre-existing scores in predicting outcomes in UGIB. In comparison to vital signs Shock Index not offer any advantages with the exception to pulse for intervention.

Therefore, we maintain our previous recommendation (4) to use MAP(ASH), or failing that ABC, for predicting intervention and mortality in UGIB since it is easier to calculate with an excellent performance.

ANALYSIS OF IN-HOSPITAL AND DELAYED CARDIOVASCULAR COMPLICATIONS AFTER ACUTE UPPER GASTROINTESTINAL BLEEDING

R. Jiménez-Rosales[1], A. Lancho Munoz[1], R. Fernandez-García[1], C. Tendero-Peinado[1], J.G. Martínez-Cara[1], E. Redondo-Cerezo[1]

[1]*Hospital Universitario Virgen de Las Nieves, Gastroenterology, Granada, Spain*

Introduction: Acute upper gastrointestinal bleeding (AUGIB) is a common, life-threatening clinical emergency with considerable morbidity and mortality. It is postulated that AUGIB can lead to hypotension and hypoperfusion of the vital organs. In response to these changes, the body activates its compensatory mechanism deriving in higher levels of oxidative stress, inflammation, hypercoagulable state and vascular endothelial injury. All these put these patients in a higher risk of myocardial injury (MI), which may lead to increased mortality in AUGIB patients (1,2).

However, older studies show similar mortality rates for those with AUGIB who develop MI (3,4).

Moreover, general abnormalities caused by AUGIB might well have delayed consequences with a significant impact on mortality (5).

Aims & Methods: To analyze the risk factors for in-hospital (ACVC) and delayed (DCVC) cardiovascular complications after AUGIB.

Retrospective analysis of a prospective registry of UGIB patients admitted to 'Virgen de las Nieves University Hospital' (2013-2020). Main outcomes were ACVC (including stroke, lung embolism, myocardial injury and heart failure) and DCVC-6months (including coronary syndrome, thromboembolic event, heart failure and arrhythmia). Statistical analysis was performed by SPSS.

ACVC	With	Without	HR (95%CI)	p
Age	76.39	64.23	1.45 (1.10 - 2.33)	0.043
COPD	30.4%	10.1%	3.87 (1.56 - 9.59)	0.007
Coronary disease	34.8%	9.6%	5.02 (2.10 - 12.07)	0.001
Stroke	17.4%	5.8%	3.40 (1.13 - 10.25)	0.045
High blood pressure	69.6%	43.7%	2.95 (1.20 - 7.21)	0.018
Antiplatelets	39.1%	20.3%	2.52 (1.08 - 5.88)	0.037
Urea at admission (mg/dL)	147.17	86.51	4.85 (1.75 - 11.23)	0.010
Active bleeding	56.5%	27.5%	3.43 (1.49-7.90)	0.004
Need for intervention	91.3%	73.7%	4.62 (1.70 - 12.52)	0.047
Reebleeding	26.1%	9.9%	3.23 (1.25 - 8.33)	0.023
Lenght hospital stay	16.96	8.97	5.23 (2.34 - 14.53)	0.015
Inpatient	34.8%	15.2%	2.97 (1.24 - 7.10)	0.018
In-hospital mortality	36.4%	10%	5.15 (2.12 - 12.52)	0.001
DCVC	**With**	**Without**	**HR (95%CI)**	**p**
Age	74.46	63.67	1.56 (1.15 - 2.46)	0.035
COPD	19%	9.8%	2.16 (1.19 - 3.91)	0.020
Cronic Kidney Disease	29.1%	13.7%	2.59 (1.55 – 4.33)	0.001
Heart Failure	39.2%	8.2%	7.25 (4.41 - 11. 93)	<0.001
Coronary disease	22.8%	9.4%	2.85 (1.63 - 5.00)	0.001
Atrial fibrilation	49.4%	15.8%	5.18 (3.24 - 8.28)	0.001
Valvular disease	37%	7.3%	7.45 (3.20 - 17.31)	< 0.001
Stroke	15.2%	5.1%	3.35 (1.72 - 6.53)	0.001
High blood pressure	55.7%	43.5%	1.63 (1.03 - 2.58)	0.046
Anticoaugulants	49.4%	18.9%	4.18 (2.62 - 6.65)	<0.001
Urea at admission (mg/dL)	113.94	83.36	3.47 (1.83 - 6.25)	< 0.001
Delayed bleeding	40.5%	12.9%	4.58 (2.83 - 7.42)	< 0.001
Delayed mortality	23.1%	6.5%	4.34 (2.44 - 7.72)	< 0.001

Table. Differences between patients with and without ACVC and DCVC.

Results: We included 1345 AUGIB patients, mean age 64.44 +/- 16.19, 32.3% females, 23 with ACVC (1.7%), 8 of these patients died. 79 develop DCVC (5.9%), 18 of these patients died.

Independent risk factor for ACVC were age (HR 1.08, 95%CI 1.03-1.15, p=0.003), previous coronary disease (HR 2.98, 95%CI 1.05-9.48, p=0.045), urea (HR 1.007, 95%CI 1.002-1.013, p=0.011) and rebleeding (HR 3.85, CI95% 1.17-2.71, p= 0.027).

Independent risk factor for DCVC was previous heart failure (HR 5.92, 95%CI 2.17-16.17, p=0.001).

Conclusion: Patients with AUGIB who develop in-hospital cardiovascular events are older, have more comorbidities, more severe bleeding and worse outcomes. The independent risk factors for AUGIB induced cardiovascular event identified are age, previous coronary disease, urea and rebleeding. In the same way, patients with delayed cardiovascular event are older, have more comorbidities and worse delayed outcomes. The independent risk factor for AUGIB induced delayed cardiovascular event identified is previous heart failure.

Introduction: Upper gastrointestinal bleeding (UGIB) remains one of the major emergencies. However, predicting the presence and degree of UGIB before endoscopy is still inaccurate. Therefore, the development of an accurate and non-invasive method is required. The purpose of this study was to discover potential metabolic biomarkers for UGIB using an in vitro digestion model, liquid chromatography-mass spectrometry (LC-MS) and gas chromatography-mass spectrometry (GC-MS).

Aims & Methods: Blood samples from 30 healthy volunteers were collected. To simulate UGIB , blood samples underwent either simulated gastric phase in vitro digestion (Blood + simulated gastric fluid (SGF)) or both simulated gastric and intestinal phase (Blood + SGF + simulated intestinal fluid (SIF)). Using untargeted metabolomics approaches with LC-MS and GC-MS metabolomic profiles and volatile organic compounds (VOC) profiles of digested blood were analyzed. Compounds that distinguish between undigested blood and digested blood were sorted out to screen potential biomarkers for UGIB.

Results: From the LC-MS analysis of the undigested blood (Control) and digested blood; blood that was digested with SGF (Blood + SGF) and blood that was digested with both SIF and SGF (Blood + SGF + SIF), a total of 47 metabolites were identified. The levels of 42 (7 from Blood + SGF and 37 from Blood + SGF + SIF) metabolites had significantly higher levels ($p < 0.05$, $Log2(FC) > 2$) in the digested blood as compared to the Control.

By analyzing extracted VOCs respectively in Control groups and metabolized samples(Blood+SGF and Blood + SGF + SIF) through GC-MS, 16 compounds were identified as statistically significant. Among them, three compounds appeared at higher levels in the Blood + SGF than the Control($p<0.05$, $Log2(FC) > 2$). In addition, three compounds showed higher levels in the Blood + SGF + SIF than the Control.

Conclusion: With metabolomic approaches, we have detected 63 statistically significant compounds (47 compounds by LC-MS, 16 compounds by GC-MS). Specific features with the considerable possibilities to be biomarkers for UGIB were found. Through in-depth understanding of metabolic pathways and further investigation in clinical settings, discovered features could be utilized to diagnose UGIB in an accurate and non-invasive manner.

Introduction: Non-variceal upper gastrointestinal bleeding (NVUGIB) is a common gastroenterological emergency associated with significant morbidity and mortality [1-3]. Upper gastrointestinal endoscopy is currently recommended as the gold standard modality for both diagnosis and treatment [4]. As historically played a limited role in the diagnosis of acute NVUGIB, multidetector-row computed tomography angiography (MDCTA) is emerging as a promising tool in the diagnosis of NVUGIB, especially for severe cases [5-6]. However, to date, evidence concerning the role of MDCTA in the NVUGIB diagnosis is still lacking.

Aims & Methods: The purpose of this study was to retrospectively investigate the diagnostic performance of emergent MDCTA performed prior to any diagnostic modality or following urgent upper endoscopy to identify the status, the site and the underlying etiology of severe NVUGIB. Institutional databases were reviewed in order to identify severe acute NVUGIB patients who were admitted to our bleeding unit and were referred for emergent MDCTA prior to any hemostatic treatment (<3 hours) or following (<3 hours) endoscopy, between December 2019 and October 2022. The study aim was to evaluate the diagnostic performance of MDCTA to detect the status, the site and the etiology of severe NVUGIB with endoscopy, digital subtraction angiography, surgery, pathology or a combination of them as reference standards.

Results: A total of 68 patients (38 men, median age 69 years [range 25–96]) were enrolled. The overall MDCTA sensitivity, specificity, and accuracy to diagnose bleeding status were 77.8% (95% CI: 65.5-87.3), 40% (95% CI: 5.3-85.3), and 75% (95% CI: 63.0-84.7), respectively (Table 1).

	Active (n = 40)	Recent (n = 26)	Non-active and non-recent (n = 2)	Total (n = 68)
TP	29	20	-	49
TN	-	-	2	2
FP	0	3	-	3
FN	11	3	0	14
Sensitivity (95% CI)	72.5 (56.1-85.4)	87.0 (66.4-97.2)	-	77.8 (65.5-87.3)
Specificity (95% CI)	-	-	100 (15.81-100)	40.0 (5.3-85.3)
PPV (95% CI)	100 (88.1-100)	87.0 (66.4-97.2)	-	94.2 (84.1-98.8)
NPV (95% CI)	-	-	100 (15.81-100)	12.5 (1.55-38.4)
Accuracy (95% CI)	-	-	-	75 (63.0-84.7)

TP, true positive; TN, true negative; FP, false positive; FN, false negative; CI, confidence interval; PPV, positive predictive value; NPV, negative predictive value.

Table 1. The diagnostic performance of MDCTA in detecting bleeding status.

Finally, the overall MDCTA sensitivity to identify the bleeding site and the bleeding etiology were 92.4% (95% CI: 83.2-97.5) and 79% (95% CI: 66.8-88.3), respectively.

Conclusion: MDCTA seems to be a feasible and effective modality in detecting the site, the status and the etiology of severe acute NVUGIB. It may play a crucial role in the management of selected cases of NVUGIB, especially those clinically severe and/or secondary to rare and extraordinary rare sources, effectively guiding timing and type of treatment. However, further large prospective studies are needed to clarify the role of MDCTA in the diagnostic process of acute NVUGIB.

THE EFFECTS OF *BIFIDOBACTERIUM BREVE*, BIF195 ON NON-STEROIDAL ANTI-INFLAMMATORY DRUG-INDUCED GASTROINTESTINAL INJURY – THE INFLUENCE OF DOSE

S. Engel[1], A. Damholt[1], F. Shanahan[2,3,4], M. Buckley[5], E. Quigley[6]

[1]Chr. Hansen A/S, Human Health, Scientific Affairs, Hoersholm, Denmark, [2]Cork University Hospital, Wilton, Cork, Ireland, [3]University College Cork, Department of Medicine, Cork, Ireland, [4]University College Cork, APC Microbiome, Cork, Ireland, [5]Mercy University Hospital, Cork, Ireland, [6]Houston Methodist Hospital & Weill Conell Medical College, Division of Gastroenterology and Hepatology, Houston, United States

Contact E-Mail Address: dksaen@chr-hansen.com

Introduction: Use of Non-steroidal anti-inflammatory drugs (NSAIDS) is associated with gastrointestinal (GI) injury with the degree of damage depending on dose, duration of treatment, concomitant medication, and patient risk profile(Goldstein & Cryer, 2015; Lanza et al., 1999, 2018; Yeomans et al., 2018).

Aims & Methods: Previously, we have reported that the probiotic strain *Bifidobacterium breve,* Bif195 (DSM 33360) at doses of $50x10^9$ and $100x10^9$ CFU/day alleviated aspirin-induced mucosal injury in the small intestine(Mortensen et al., 2019) and the stomach(Damholt et al., 2021), respectively.

Here, we report results from an additional randomized controlled double-blind trial (RCT) of Bif195 in a lower dose on NSAID-induced mucosal injury. Although the trials were not directly comparable in design, they provid-

ed an opportunity to evaluate the effect of different doses of Bif195. In this study the NSAID was ibuprofen given in a dose of 800 mg/day for 6 weeks. Video Capsule Endoscopy was used to assess small-intestinal damage and to calculate Lewis score throughout the study(Gralnek et al., 2008).

Results: A total of 160 subjects (63% women) were included in the full analysis set (randomized, consumed at least one dose of trial product and with available efficacy data for the primary endpoint) with mean ± SD body mass index of 26.8 ± 6.1 kg/m^2 and age of 27.3 ± 5.5 years. There were no effects of the Bif195 intervention on any of the primary and secondary endpoints. Low-dose Bif195 did not reduce ibuprofen-induced damage in the small intestine compared to placebo as evaluated by Lewis score (AUC, mean ± SEM 2358 ± 137 vs 2208 ± 123, p=0.474). It is noteworthy that the degree of damage associated with ibuprofen was markedly lower than that associated with aspirin in an earlier study (AUC, mean ± SEM 4351 ± 574)(Mortensen et al., 2019). Bif195 was well-tolerated, and no treatment-related adverse events were recorded. We conclude that the lower level of damage induced by ibuprofen compared to aspirin in combination with low dose Bif195, might have had an impact on the ability of the trial to identify an effect.

Conclusion: In summary, of three individual RCTs examining the effects of Bif195 on aspirin- and ibuprofen-induced gut mucosal injury, two showed benefits while one employing a lower dose of Bif195 in individuals exposed to ibuprofen failed to show benefit. While these studies suggest that the effects of Bif195 may be dose related this should be interpreted with caution due to the differences in injurious agent and trial design. The trial was registered at Clinicaltrials.gov: NCT04447924.

Introduction: A decline in Activities of Daily Living and cognitive function due to long hospital stays is a problem among elderly patients. Recently, it has been reported that the lower nutritional status in elderly patients correlates stays with long hospital stays for correlates of various diseases. Although there are several score systems to predict the need for intervention or prognosis in bleeding peptic ulcer (BPU) patients, the association between nutritional status and length of stay in elderly BPU patients has not been fully investigated.

The subjective global assessment (SGA) is applied for one of the nutritional assessment tools in the present study. SGA is a simple nutritional status scale that can be performed only by interview tools and physical examination.

Aims & Methods: This study aims to investigate whether the nutritional status of elderly BPU patients at admission affects the length of hospitalization. We retrospectively reviewed the electrical health record of BPU patients who were 66 years old or older from April 2018 to December 2022. The patients were categorized into two groups according to the median length of hospitalization (9 days); the short-term hospitalization group (S group), and the long-term hospitalization group (L group).

The definition of S group and L group were patients 9 days or less of the length of hospitalization, and 10 days or more of the length of hospitalization respectively.

The univariate analysis evaluated the following factors: age, sex, albumin level (ALB), body mass index (BMI), and SGA. Multiple logistic regression analysis was performed, where the presence of long hospital stays were the objective variable, and age, gender, ALB, BMI, and SGA as explanatory variables. ALB, BMI, and SGA were based on data from the first day of admission by the BPU. SGA was calculated by trained nurses on the first day of admission. Fisher's exact test was used for gender in the comparison of the S and L groups. Logistic regression analysis was used to analyze the data for continuous variables.

Multivariate logistic regression analysis using all variables was constructed to calculate odds ratios (ORs) and 95% confidence intervals (CI). All tests were two-sided, and P<0.05 was considered to be statistically significant.

Results: Of the 111 patients, 63 were in the S group and 48 in the L group. The median length of hospital stay (range) was 7 (3-9) days in the S group and 15 (10-76) days in the L group. The median age (range) was 78 (66-93) years old in the S group and 81 (66-95) years old in the L group. The male/female ratio was 39/24 for the S group and 26/22 for the L group.

The median (range) of nutritional status as S/L group was ALB(mg/dL): 3.2(1.8-4.1)/2.8(1.8-4.2), BMI kg/m^2: 22.33(13.56-46.6)/21.04(14.7-30.7), SGA: 11(6-14)/9(4-14).In univariate analysis, older age (p=0.0190), ALB (p=0.0019), and SGA (p=0.0002) were significantly associated with long hospital stays.

In multivariate analysis, only SGA (odds ratio 0.69, 95% Cl 0.55-0.87, p=0.0014) was associated with longer hospital stays, whereas ALB (odds ratio 0.44, 95% Cl 0.19-1.04, p=0.0556) and BMI(odds ratio 1.05, 95% Cl 0.95-1.16, p=0.3412) were not associated with longer hospital stays.

Conclusion: SGA can be a useful predictor of long hospital stay in elderly BPU patients.

Introduction: Emergency department overcrowding is an important health problem all over the world, because it increases the risk of mortality. The causes of overcrowding are different like aging population and increase in chronic diseases. Several solutions have been proposed, such as the establishment of the short stay unit for conditions that can't be managed at home, but require treatment or hospitalation for up to 72 hours. Several studies show how short stay Unit can significantly reduce hospital length of stay or reduce mortality for certain conditions, such as chronic obstructive pulmonary disease or heart failure, head injury or pyelonephritis. Among the pathologies proposed for short stay unit are non-variceal upper gastro-intestinal bleeding but currently there are no studies addressing the safety and efficacy of short stay unit in the management of non-variceal upper gastrointestinal bleeding.
Aims & Methods: Aim of our study is evaluate the efficacy of short stay unit in decreasing the requirement of hospitalization, hospital length of stay, hospital readmission and mortality in non-variceal upper gastrointestinal bleeding, compared with admission to the regular ward. This was a retrospective, single-centre observational study. Medical records of patients who presented to the Emergency Department with non-variceal upper gastrointestinal bleeding, April 1, 2021, and September 30, 2022, were analysed. The study population includes patients aged >18 years, of either sex, presenting to the Emergency Department acute blood loss from the upper gastro-intestinal tract.
The population was divided into two groups: patients admitted to an ordinary inpatient ward (control) and patients treated at short stay unit (intervention). Clinical and medical history data were assembled for both groups.
The hospital length of stay was the primary outcome.
Secondary outcomes were time to endoscopy, number of blood units transfused, readmission to the hospital at 30 days and in-hospital mortality.
Results: The analysis included 120 patients with a mean age of 70 years, 54% of whom were men. Sixty patients admitted to SSU. Patients admitted to the medical ward had a higher mean age and a higher likelihood of having a history of cerebrovascular disease or active cancer. The Glasgow-Blatchford score, used to assess bleeding risk, mortality and hospital readmission, were similar in the two groups of study. Multivariate analysis, after adjustment for confoundersit, establish that the only factor independently associated with reduced time in hospital (LOS) was admission to short stay unit ($p<0.0001$).
Admission to short stay unit was independently and significantly associated with shorter time to endoscopy ($p<0.001$). The only other factor associated with a shorter time to endoscopy was creatinine level ($p=0.05$), while home treatment with proton pump inhibitors was associated with a longer time to endoscopy. Hospital length of stay, time to endoscopy, number of patients of requiring transfusions and number of units of blood transfused were significantly lower in patients admitted to short stay unit, than in the control group.
Conclusion: The results of the study show that management of non-variceal upper gastrointestinal bleeding in short stay unit can significantly reduce the time required for endoscopy, the hospital length of stay and number of transfused blood units, without increasing mortality and hospital readmission. Treatment of non-variceal in short stay unit may help to reduce emergency department overcrowding, but multicentred randomized controlled trials are needed to confirm these data.
Disclosure: Nothing to disclose.

Introduction: Despite lack of evidence, patients are kept nil by mouth for 48 to 96 hours after upper gastrointestinal bleeding (UGIB) due to fear of rebleeding. However, many trials have demonstrated the benefits of early nutrition after UGIB. We conducted a meta-analysis of randomized controlled trials to evaluate the safety and outcomes of early nutrition compared to delayed nutrition after UGIB.
Aims & Methods: The protocol was registered on PROSPERO in advance (CRD42022372306). Five databases (PubMed, Embase, CENTRAL, Scopus, and Web of Science) were searched on the 10th of November 2022 to identify randomized controlled trials that met our eligibility criteria. In-hospital and 30-day outcomes were pooled separately. Mortality rate, rebleeding rate, and length of hospital stay were the primary outcomes. The pooled risk ratio (RR), mean difference (MD), and the corresponding 95% confidence interval (CI) were calculated using a random effects model.
Results: A total of 10 trials with 1,051 patients were included in the analysis. Comparing the two groups, 7-day mortality showed no significant difference (RR=1.23, CI: 0.72 - 2.10), while there was a clear tendency for a decrease in 30-day mortality in the early nutrition group (RR=0.57, CI: 0.31 – 1.04). As for 7-day and 30-day rebleeding, there was no statistically

significant difference between the two groups (RR=1.05, CI: 0.63 – 1.74 and RR=1.16, CI: 0.59 – 2.26, respectively). In addition, our analysis showed that the early nutrition group needed a reduced length of hospital stay compared to the delayed nutrition group (MD= - 1.22, CI: -2.43 to -0.01).

Conclusion: Compared with delayed nutrition, early nutrition appears to be a safe intervention and could reduce the length of hospital stay without increasing the risk of complications regarding rebleeding or mortality after upper gastrointestinal bleeding.

Disclosure: Nothing to disclose.

Introduction: In the context of proper proton pump inhibitors (PPI) use, over-prescription is commonly criticized. Conversely, few studies have assessed the consequences of not prescribing PPIs in patients with a recognized indication for prophylactic treatment.

This study aims to compare, in a cohort of patients with upper gastrointestinal bleeding (UGB), those with and without PPI at bleeding onset and in particular patients who are considered at high risk for UGB.

Aims & Methods: We undertook a post-hoc analysis of data from a prospective multicenter observational study (1) conducted in 46 French medical centers, which included all consecutive UGB cases that occurred between November 2017 and October 2018. Data about patients' demographics, clinical, endoscopic and prognostic features were collected.

First, we explored bleeding etiology in patients with and without PPI at the time of bleeding. Then, we calculated the rate of prophylactic PPI prescription in patients having an UGB related to peptic ulcer disease (PUD) and notably in those considered at higher risk of bleeding according to international guidelines (2, 3).

In patients who had peptic ulcer bleeding, we compared those with and without PPI upon bleeding onset, in terms of baseline demographics and bleeding severity. We then analyzed the predictors of severe UGB defined by a Glasgow Blatchford score (GBS)≥11. We included PPI prophylaxis in our analysis to determine its role in reducing bleeding severity.

Results: A total of 2,498 patients with UGB were included, of whom 777 (31%) were on PPI at the time of bleeding. UGB related to PUD was significantly less prevalent in patients with PPI than in those without PPI (28% vs 46%, respectively; p< 0.0001).

No difference was observed in the frequency of bleeding related to portal hypertension nor to esophagitis between the two groups (P=0.64 and 0.26, respectively) whereas hemorrhagic angiodysplasias were more common in the group with PPI (p<0.0001).

Of the 893 patients who had UGB related to PUD, only 21.5% were on PPI. These patients, compared to those without PPI, were older (74 vs 69 years; p<0.0001) and had more comorbidities (defined by a Charlson score≥3) (p<0.0001), notably at cardiovascular level. Ulcer was more likely to be located in the stomach in patients with PPI and in the duodenum in those without PPI (p=0.002). Helicobacter Pylori prevalence and Forrest classification were comparable in both groups (p=0.11 and 0.18, respectively). There was no statistically significant difference in terms of severity measured by mean GBS, blood transfusions or 6-week mortality and rebleeding rates (p>0.05).

In patients at high risk for UGB, we noted an under-prescription of PPI prophylaxis (Table 1). Independent predictors for severe bleeding according to multivariate analysis were the following: age≥65years (p=0.001), in-hospital bleeding (p=0.012), Charlson score≥3 (p<0.0001) and dual anti-platelets use (p=0.031). The absence of PPI prophylaxis did not affect bleeding severity (p=0.5).

	PUD-related UGB	High Risk patients	PPI-prescription rate
NSAIDS	112	74	20%
AP	312	122	35%
OAC	178	89	34%
Dual-AP	46	16	50%
OAC+AP	50	7	29%

NSAIDS: non-steroidal anti-inflammatory drugs, AP: anti-platelets, OAC: oral anti-coagulants, PUD: peptic ulcer disease, UGB: upper gastrointestinal bleeding, PPI: proton pump inhibitor, * Risk stratification according to European Society of Cardiologist (2) and American college of Gastroenterology guidelines (3).

*Table 1: PPI prescription rates in high risk patients**

Conclusion: In this cohort of patients with UGB, peptic ulcer bleeding occurred less frequently in patients on PPI. However, PPI treatment did not affect bleeding severity which was mainly determined by patients' age and comorbidities. Most importantly, we noted a significant under-prescription of prophylactic PPI in high-risk groups having a well-recognized indication for gastric protection. This finding must be highlighted when discussing proper prescribing practices.

Introduction: Variceal bleeding is a common and life-threatening complication of liver cirrhosis, with endoscopic therapy being an important treatment modality [1].

There are several endoscopic techniques available for the management of variceal bleeding, including band ligation, sclerotherapy, tissue adhesives, and endoscopic ultrasound-guided variceal obturation (EUS-VO) [2].

Aims & Methods: This meta-analysis aimed to compare the efficacy and safety of different endoscopic modalities for the prevention and management of variceal bleeding in patients with liver cirrhosis. A systematic literature search was conducted in several databases, including PubMed, Embase, and Cochrane Library, from inception to September 2022.

Randomized controlled trials, cohort studies, and case-control studies that compared different endoscopic modalities for the management of variceal bleeding in patients with liver cirrhosis were included.

The primary outcomes of interest were initial hemostasis rates, rebleeding rates, and adverse events.

Results: A total of 15 studies (n = 1,742) met the inclusion criteria and were included in the meta-analysis. The pooled results showed that band ligation was associated with lower rebleeding rates compared to sclerotherapy (OR 0.59, 95% CI 0.44-0.79, p = 0.001), while sclerotherapy was associated with a higher risk of adverse events (OR 3.21, 95% CI 1.69-6.11, p < 0.001).

Tissue adhesives, such as N-butyl-2-cyanoacrylate, were associated with higher initial hemostasis rates compared to other endoscopic therapies (OR 1.82, 95% CI 1.30-2.55, p = 0.001) and lower rebleeding rates (OR 0.39, 95% CI 0.20-0.77, p = 0.006). EUS-VO was associated with higher initial hemostasis rates (OR 1.93, 95% CI 1.08-3.43, p = 0.027) and lower rebleeding rates (OR 0.43, 95% CI 0.26-0.71, p = 0.001) compared to traditional endoscopic therapies.

Conclusion: Our meta-analysis suggests that band ligation and tissue adhesives may be superior to sclerotherapy for the prevention and management of variceal bleeding in patients with liver cirrhosis. EUS-VO may be a promising alternative to traditional endoscopic therapies, although further studies are needed to confirm its efficacy and safety. The choice of endoscopic technique should be individualized based on patient factors and physician expertise.

Introduction: Delayed bleeding is a rare but important major adverse event (mAE) after endoscopic submucosal tunneling procedures (ESTP), which is scarcely reported.

We aimed to characterize the clinical characteristics of delayed bleeding and provide better management of this mAE.

Aims & Methods: From August 2010 to October 2022, we reviewed 3,852 patients with achalasia receiving peroral endoscopic myotomy (POEM) and 1,937 patients with upper GI tumors receiving submucosal tunneling endoscopic resection (STER). Among these, records of 22 patients (15 POEM, 7 STER) with delayed bleeding were collected. Clinical characteristics, treatment, and outcomes of delayed bleeding were analyzed.

Results: The mean age was 43.6 years. Ten patients (45.5%) were intratunnel bleeding, seven (31.8%) were intratunnel bleeding accompanied by mucosal bleeding, and 5 (22.7%) were mucosal bleeding.

The most common accompanied symptoms were hematemesis, fever, and melena. The most common accompanied mAEs were fistula, pulmonary inflammation, and pleural effusion with atelectasis. The mean duration from ESTP to endoscopic intervention was 5.3±4.9 days. Active bleeding was identified in 21 patients (95.5%).

The bleeding was successfully controlled by electrocoagulation (19 cases), endoscopic clipping (6 cases), and Sengstaken-Blakemore tube insertion (3 cases) and no patient required surgical intervention. The mean hemostatic procedure duration was 61.8±45.8 minutes. The mean post-bleeding hospital stay was 10.0±6.2 days.

A brief meta-analysis of previous studies showed the pooled estimate delayed bleeding rare after POEM, STER, and G-POEM was 0.4%.

Conclusion: Delayed bleeding is uncommon and could be effectively managed by timely emergency endoscopic procedures without requiring subsequent surgical interventions.

RESTRICTIVE TRANSFUSION IS NON-INFERIOR TO LIBERAL TRANSFUSION IN UPPER GASTROINTESTINAL BLEEDING: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS

Introduction: Starting the blood supplementation at a higher haemoglobin threshold (Hgb <90-100 g/L) in upper gastrointestinal bleeding (UGIB) can lead to severe consequences due to volume overload. Previous studies have already shown the benefits of restrictive transfusion (Hgb <70-80 g/L). However, the optimal transfusion threshold and how restrictive transfusion affects short- and long-term outcomes after UGIB remained unanswered.

Aims & Methods: We aimed to assess the efficacy and safety of restrictive compared to liberal transfusion strategies in the GIB population, assessing the source of bleeding and transfusion thresholds separately. We searched PubMed, CENTRAL, Embase, and Web of Science for randomised controlled trials on 15.01.2022 without restrictions. Studies comparing lower to higher RBC transfusion thresholds after GIB were eligible. We used the random effect model and calculated pooled mean differences (MD), risk ratios (RR) and proportions with 95% confidence intervals (CI) to calculate the overall effect size.

Results: The search yielded 3955 hits. All seven eligible studies reported on the upper GIB population. Restrictive transfusion did not increase the in-hospital- (RR:0.94; CI:0.46,1.94) and 30-day mortality (RR:0.68; CI:0.48,0.97). In-hospital- and 28 to 45-day rebleeding rate was also not higher with the restrictive modality (RR:0.67; CI:0.30,1.50; RR:0.75; CI:0.49,1.16, respectively). Results of individual studies showed a lower rate of transfusion reactions and post-transfusion intervention if the transfusion was started at a lower threshold. A haemoglobin threshold >80g/L may result in a higher untoward outcome rate.

Conclusion: In summary, restrictive transfusion proved non-inferior to liberal transfusion regarding all investigated clinical endpoints. The optimal restrictive transfusion threshold should be further investigated.

Introduction: Gastrointestinal (GI) hemorrhage remains the most common emergency in digestive endoscopy. However, its management is often tricky given the different etiopathogenic and clinical profiles associated with it. There is a tendency to believe that GI bleeding is often more detrimental in patients on anti-platelet aggregation and/or anticoagulation because of the altered physiological hemostasis and the risk of flare-up of the underlying disease justifying their use.

Aims & Methods: The aim of our study was to investigate the epidemiological, clinical profile and outcomes of gastrointestinal bleeding occurring in this particular context. We conducted a retrospective comparative study including patients hospitalized for GI bleeding between 2015 and 2023. Patients were divided into two groups according to whether they were on antithrombotic therapy (platelet and/or oral anticoagulation) (G1) or not (G2).

We have excluded patients with portal hypertension related bleeding and patients with inherited *blood disorders*. Clinico-biological, therapeutic data and outcomes were collected and compared between the two groups.

Results: Of the 91 patients enrolled with a sex-ratio of 1.84, 52 were on anti-platelet agents and/or oral anticoagulants. The mean age was significantly higher in patients under anti-thrombotic treatment (G1: 70 vs G2: 56 years, p<0.0001). The two groups were comparable in terms of gender, systolic blood pressure, hemoglobin levels.

However, G1 patient showed higher levels of CRP (G1: 38.8 vs G2: 25.86 mg/dl, p=0.04) and plasma urea (G1: 12,8 vs G2: 9,3 mmol/l, p=0.02). The main cause of bleeding in both groups was peptic ulcer disease.

Nevertheless, lower GI bleeding was significantly more frequent in the first group (p=0.03), with the main etiology in this context being diverticular hemorrhage (p=0.01). There was no significant difference in the number of red blood cells (RBCs) transfused, the time taken to perform GI endoscopy, the use of a particular endoscopic hemostasis technique and the number of sessions required to control the bleeding between the two groups.

Patients under anti-thrombotic therapy were significantly more likely to be explored by colonoscopy (p=0.01), to have longer mean hospital stay (G1: 8 vs G2: 5 days, p=0.03), without any increase in hemodynamic disorders or infectious complications.

Similarly, there was no increase in the need for catecholamines, intensive care unit admission or in mortality rates noted in G1 patients (p >0.05). Finally, the rate of distant bleeding recurrence was slightly similar in the two groups (G1: 13,4 vs G2: 17,9 %, p> 0.05)

Conclusion: Although the occurrence of digestive bleeding is a severe adverse event in patients undergoing antithrombotic therapy due to a precarious underlying condition, there were no major differences regarding outcomes when compared with patients without anti-thrombotic therapy.

This reflects a better knowledge of the guidelines regulating the use of these drugs with a better assessment of the bleeding/clotting balance and the improvement of endoscopic hemostasis management.

Introduction: Upper gastrointestinal bleeding (UGIB) is one of the most common emergencies experienced by physicians. Peptic ulcer disease is the most common cause of UGIB, being responsible for 31% to 67% of all cases. Available endoscopic techniques for the treatment of UGIB include epinephrine injection treatment, thermal coagulation, hemostatic clips, fibrin sealant, argon plasma coagulation, and a combination of epinephrine injection with another treatment modality. However, there is no clear evidence as to which method is best and should constitute the modality of choice.
Our aim was to compare the efficacy of hot forceps (HF) versus hemoclips (HC) in patients with non-variceal upper gastrointestinal bleeding (UGIB).
Aims & Methods: We conducted a retrospective study between June 2017 and June 2019. Primary hemostasis rates, recurrent bleeding, emergency surgery requirements, transfusion requirements, 30-day mortality, bleeding-related deaths, duration of hospital stay, and cost were compared between the two groups.
In all cases, diluted adrenaline (1:10.000) was injected into four quadrants of the ulcer and/or lesion before HF or HC. The dose of epinephrine was decided at the endoscopist's discretion but did not exceed 2.5 mL in any location, or a total dosage of 10 mL.
Electrocautery coagulation was performed using monopolar single-use HF with the following settings: 80W, effect 4, and soft coagulation mode.
The electrocautery current was applied for 1 to 2 seconds by gently touching the four sites immediately surrounding the ulcer with the closed tip of the hemostatic forceps.
The center of the vessel was subsequently coagulated, as described above. A device with an arm length of 7.5 mm and a jaw angle of 135° was employed in endoscopic HC therapy. This was applied using a rotatable clip-fixing device and repeated until hemostasis was achieved. HC, argon plasma coagulation, and sclerotherapy with polidocanol modalities were used when hemostasis could not be achieved by HF, respectively.
Results: A total of 217 consecutive patients underwent endoscopy for preliminary diagnosis of UGIB between June 2017 and June 2019. Of those, 115 patients were excluded due to causes other than peptic ulcer disease or no need for therapeutic intervention. The remaining 102 patients were divided between HF (n=65) and HC (n=37) groups. Demographic data of the patients are presented in Table-1.
The initial hemostasis success rates were 96.6% (57/65) in the HF group and 91.7% (33/37) in the HC group (p= 0.277). The incidence of early recurrent bleeding was 2.0% (2/65) in the HF group and 2.7% (1/37) in the HC group (p=0,154). HF is also found to be much more cost-effective than HC ($113.6 in the HC group vs $17.9 in the HF group, p=0.001).
No significant differences were observed between the groups regarding duration of hospital stay, mortality, or surgery requirements (p> 0.05). Detailed information about procedure-related parameters is presented in Table-2.
Conclusion: In this retrospective analysis, our findings showed that HF may be superior to HC in terms of cost, and procedure time in non-variceal UGIB patients. Prospective studies with larger cohorts are needed to support these findings.

MITIGATING THE NEED FOR PATIENT TRANSPORT BY TREATING UPPER GASTROINTESTINAL BLEEDINGS IN ICU-SETTINGS WITH A SINGLE-USE THERAPEUTIC GASTROSCOPE

C. Borja[1], A. Engelbrecht Kristensen[2], R. Vinther Russell[2]
[1]Ambu, Market Access, Ballerup, Denmark, [2]Ambu, Ballerup, Denmark

Contact E-Mail Address: cibr@ambu.com
Introduction: Globally healthcare systems and healthcare professionals (HCP) are under increasing pressure, in particular due to the growing shortage of healthcare workers.[1]
Reducing the intra-hospital patient transportation could potentially free up HCP resources**.** Intra-hospital transport can further be associated to patient risks due to unexpected events during the transfer[2] specifically, transportation of clinical ill patients which have been significantly correlated with adverse events.[3]
Additionally, nurses perceive intra-hospital transport as a cause of stress and increased workload.[4]
When transferring critical patients there are several parameters to consider, the electromedical equipment, stability condition and the short time to extract information of the patient to continue with a safe and suitable transfer.[5]
The current study investigates the potential benefits of having single-use therapeutical gastroscopes, needed equipment and utilities available in the intensive care unit (ICU), to treat ICU admitted patients presenting an upper gastrointestinal bleed (UGIB).
Aims & Methods: Between January 2021 and October 2022, an anonymous survey was distributed across 8 countries (Australia, France, Germany, Italy, Spain, United Kingdom, United States of America and Japan). The survey was distributed through M3 Global Research. The main target of the survey were gastroenterologists and gastrointestinal surgeons, from public hospitals, public university hospitals, private hospitals, private clinics, screening centers and ambulatory surgery centers (ASC). Data was collected through Survey Exact and analyzed in Excel.
Results: 341 answers from gastrointestinal surgeons and gastroenterologists were collected. 3% of ICU patients present an UGIB during admission. Presently, 45% of patients with UGIB are treated in the ICU, 24% of patients are currently transported to the operating room (OR) and 31% to the endoscopy unit (EU). The average time used transporting patients from the ICU is 21min and 22min to the OR and EU, respectively. 5 to 6 HCP are needed to transport an UGIB patient from ICU to OR/EU.

Physicians assumed that 46% CI [42.1;49.9%] of currently transported ICU patients could avoid being transported if single-use therapeutical gastroscopes were available in the ICU and the UGIB management was equally efficient in the ICU as in the OR or EU, meaning 75% of UGIB patients could be managed in the ICU compared to current handling.

Conclusion: The risk and resources associated to intra hospital transport of critical ill patients with UGIB could be reduced in 46% if therapeutical gastroscopes, needed equipment and utilities are available in the ICU.

Thereafter, the portability and availability of the single-use therapeutical gastroscope in this scenario, could allow faster attention to the patient in need, free up time, workload and stress of HCP and other staff which are currently involved in the transport and handling of patients with UGIB from ICU.

Introduction: The last UK audit of the management of acute upper gastrointestinal bleeding (AUGIB) was conducted in 2007.[1] We report patient characteristics, investigations, treatments, and clinical outcomes from an interim analysis of the 2022 UK audit.

Aims & Methods: Prospective multi-centre observational study of adults (≥16 years) presenting in or to UK hospitals with AUGIB between 3 May and 2 July 2022.

Results: Data on the first 2881 patients (median age 70yr) from 158 participating hospitals are reported. New admissions with AUGIB (n=2205) were younger than inpatients developing AUGIB (median age 68 vs 75 yrs, respectively) with fewer comorbidities (63% vs 79%, respectively). At presentation, 17%(490/2881) had chronic liver disease (CLD), 28% (n=815) a history of alcohol excess, 7% (n=294) were taking non-steroidal anti-inflammatory drugs (NSAID) and 44%(n=1268) antiplatelets or anticoagulants. 80% (n=2315) patients had an inpatient endoscopy; 32%(742/2315) had peptic ulcer disease (PUD), 9% (212/2315) had a variceal bleed, and 27% (622/2315) received endoscopic therapy.

Reasons for no endoscopy (n=566) were: 47%(n=265) not clinically indicated/25%(n=139) outpatient procedure /18%(n=102) not for active treatment /6%(n=37) self-discharged /0.5%(n=3) transferred to other hospital /5%(n=28) death. 9%(202/2315) had evidence of further bleeding after index endoscopy. 0.6%(n=19) underwent surgery, 3%(n=72) had interventional radiology (IR) and 47%(n=1367) were transfused ≥1 packed red blood cells (PRC); 4%(n=113) platelets; and 5%(n=137) fresh frozen plasma (FFP) for AUGIB. Median length of stay (LOS) was 5 days. In-hospital mortality was 8.2%(n=636); 5.3% in new admissions and 19% in inpatients. Comparisons with the full 2007 audit are presented in table 1.

	2007 (n=6750)	2022 (n=2881, interim results of first patients)
Median age	68 yr (IQR 49-81)	70 yr (IQR 54-81)
Any comorbidity	50%	66%
Medications		
NSAID	11%	7%
Antiplatelets	33%	21%
Anticoagulants	13%	29%
Other		
Alcohol excess	26%	28%
CLD	9%	17%
Inpatient endoscopy	74%	80%
PUD	36%	32%
Variceal bleed	11%	9%
Use of endoscopic therapy	24%	27%
Further bleeding after index endoscopy	13%	9%
Surgery	1.9%	0.6%
IR	1.2%	2.5%
Transfusion ≥1 unit		
PRC	43%	47%
Platelets	2.8%	4%
FFP	7%	5%
Median LOS	5 days (IQR 2-12)	5 days (IQR 3-10)
In-hospital mortality	10%	8.2%

Table 1.

Conclusion: Despite an older and more co-morbid population, there is an indication of reduced recurrent bleeding, need for surgery and in-hospital mortality for AUGIB since 2007. This improvement may correlate with improved management and better endoscopic therapy.

Introduction: Acute upper gastrointestinal bleeding (AUGIB) is a common medical emergency. We compare the characteristics and management of variceal vs non-variceal causes of AUGIB in the 2022 UK audit.

Aims & Methods: Prospective multi-centre observational study of adults (>16 years) presenting in or to UK hospitals with AUGIB between 3 May and 2 July 2022.

Results: In this interim analysis, endoscopy was performed for 2315 of the first 2881 patients and a cause identified in 1542. Those identified with varices (14%, 212/1542) were younger than those with non-variceal AUGIB (median age 57 vs 70 yr, respectively).

For varices, sites included: 87%(185/212) oesophageal; 18%(38/212) gastric; 3% (7/212) duodenal. 43% (92/212) were on non-selective beta-blocker prophylaxis on admission; 32%(68/212) had a history of previous AUGIB and 24% (50/212) were on a variceal band ligation programme. 69%(147/212) had stigmata of recent bleeding; 75%(160/212) received endotherapy: 62%(132/212) had variceal therapy (banding – 124, glue or thrombin injection – 11) and 6% (12/212) required a Sengstaken tube. 4% (8/212) underwent TIPSS and 58% (123/212) were discharged on a non-selective beta-blocker.

For those with non-variceal causes, findings included: 58%(777/1330) peptic ulcer disease; 26%(353/1330) oesophagitis; 5%(69/1330) portal hypertensive gastropathy; 7%(96/1330) malignancy and 28%(369/1330) others. 38% (506/1330) had stigmata of recent bleeding; 34% (447/1330) received endotherapy: 13% (176/1330) had a single modality and 20% (271/1330) ≥1 modality. Different modalities included: 23% (105/447) thermal device; 60% (270/447) adrenaline injection; 48% (215/447) haemostatic clips; 24% (109/447) haemostatic powders or gel; 14% (64/447) argon plasma coagulation and 8% (37/447) others .

Outcomes for patients with variceal vs non-variceal cause of bleeding are shown (Table 1).

Outcome	Variceal (n=212)	Non-variceal (n=1330)	p- value
Median age	57 (IQR 49-68)	70 (IQR 55-80)	<0.05
Pre-endoscopy treatment			
Proton pump inhibitors	69%	81%	<0.05
Terlipressin	61%	NA	-
Antibiotics	56%	NA	-
Intubation for endoscopy	30%	6%	<0.05
Transfer to HDU or ITU	16%	6%	<0.05
Endoscopy outcomes			
Stigmata of recent bleed	69%	38%	<0.05
Endotherapy	75%	34%	<0.05
Further bleeding after Index endoscopy	14%	9%	<0.05
IR	3.7%	2.8%	0.47
Surgery	0%	1%	0.14
Transfusion >1 unit			
Packed red cells	64%	54%	<0.05
Fresh frozen plasma	17%	4%	<0.05
Platelets	14%	3%	<0.05
Median LOS	7 days (IQR 4-12)	5 days (IQR 3-11)	<0.05
In-hospital mortality	9.4%	7.2%	0.25

Table 1.

Conclusion: Patients with variceal bleeding were younger, with higher therapeutic and transfusion requirements, re-bleeding rates and length of stay. Mortality was not significantly different to non-variceal bleeding.
Disclosure: Nothing to disclose.

Contact E-Mail Address: benhayoun.yassamin@gmail.com
Introduction: Upper gastrointestinal bleeding (UGIB) is one of the main potentially life-threatening emergencies encountered in gastroenterology that requires prompt management. For this reason, numerous prognostic scores have been developed to predict the level of risk in patients. However, there are few studies in the literature comparing these scores.
Aims & Methods: The main objective of this study was to compare the performance of the pre-endoscopic scores Glasgow-Blatchford Score (GBS), Rockall Score (pRS), and quick Sequential Organ Failure Assessment (qSOFA) in predicting the severity of UGIB according to predefined criteria. Methods: This is a retrospective descriptive and analytical study of 102 patients who presented with upper gastrointestinal bleeding at the International University Hospital Cheikh Khalifa over a period of 1 year between October 2021 and October 2022. Scores were calculated for each patient with complete medical records. The data was analyzed using the Jamovi 2.2.5 software. The accuracy of each risk score in predicting clinical criteria was evaluated by the area under the receiver operating characteristic curve (AUROC). A p-value less than 0.05 was considered statistically significant.
Results: The included patients had a mean age of 57.1 years with a slight female predominance (53.9%). GBS was found to be **more predictive** of the risk of admission to the Intensive care Unit (ICU) and the need for blood transfusion than pRS and qSOFA with an AUROC of 0.914 for these two criteria. GBS was also more predictive of the risk of therapeutic intervention (AUROC 0.882) compared to pRS (AUROC 0.788) and qSOFA (AUROC 0.676). Regarding endoscopic intervention, pRS and GBS were equally able to predict this criterion with moderate power (AUROC pRS 0.721) (AUROC GBS 0.747). qSOFA showed no significant performance, especially in its preferred domain of admission to the ICU (AUROC 0.735) (Table). None of the 3 scores was able to predict the need for surgical intervention.

	Variable	AUC (95% CI)	Cut-off value	Specificity	Sensitivity	PPV	NPV
Need for Intensive Care Unit	GBS	0,914	>10	81,82%	88,89%	72,73%	93,1%
	pRS	0,843	> 3	71,21%	86,11%	62%	90,38%
	qSOFA	0,735	> 1	80,3%	66,67%	64,86%	81,54%
Need for blood transfusion	GBS	0,914	> 10	85,25%	85,37%	79,55%	89,66%
	pRS	0,769	> 3	67,21%	67,21%	60%	78,85%
	qSOFA	0,687	> 1	78,69%	78,69%	64,86%	73,85%
Endoscopic intervention	GBS	0.747	> 8	60,00%	81,08%	53,57%	84,78%
	pRS	0.721	> 2	56,92%	86,49%	53,33%	88,1%
	qSOFA	0.615	> 1	72,31%	51,35%	51,35%	72,31%

Table: Comparison of AUC, sensitivity, specificity, PPV and NPV along with cut-off value of Glasgow-Blatchford Score, pre-Rockall, and Quick-Sofa scores to predict the clinical outcomes.

Conclusion: At the end of this study, the use of GBS and pRS in daily clinical practice in emergency departments is strongly recommended to predict the need for therapeutic intervention, hospitalization, or re-bleeding episodes. However, it would be interesting to study the usefulness of these prognostic scores, especially qSOFA, through larger prospective studies.

OPTIMAL THRESHOLD FOR RESTRICTIVE TRANSFUSION AFTER ACUTE GASTROINTESTINAL BLEEDING: INSIGHTS FROM THE HUNGARIAN GASTROINTESTINAL BLEEDING REGISTRY

B. Teutsch[1,2], Z. Abonyi Tóth[1], O. Ferencz[1], N. Vörhendi[2], O.A. Simon[2], E. Boros[2], D. Palinkas[1,3], L. Frim[2], E. Tari[1,4], P. Kalló[2], P. Hegyi[1,2,4], R. Hágendorn[2,5], I. Szabó[2,5], B. Eross[1,2,4]

Introduction: Gastrointestinal bleeding is among the most common indications for red blood cell (RBC) transfusion. According to current guidelines, restrictive RBC transfusion initiated at a lower haemoglobin (Hgb) level (<70-80 g/L) is non-inferior to liberal strategy (<90-100 g/L) regarding mortality and rebleeding. Moreover, it results in a lower rate of adverse events and decreases hospital expenses. However, the published randomised controlled trials are not using a unified definition for the restrictive modality.

Aims & Methods: Our analysis aims to assess the efficacy of restrictive transfusion by comparing different Hgb thresholds. Patients enrolled in the Hungarian Gastrointestinal Bleeding Registry who received RBC transfusion during hospitalisation were found eligible. The transfused group was divided into subgroups based on their lowest Hgb level during hospitalisation: ≤60 g/L (group 1), 61-70 g/L (group 2), 71-80 g/L (group 3), ≥80 g/L (group 4). Patients with recurrent bleeding were excluded. The outcomes examined included in-hospital mortality, the need for surgical intervention, intensive care therapy, and length of hospital stay. When comparing the groups, group 2 was used as the reference. Adjusted odds ratios (aOR) were calculated using binominal logistic regression, while the ANOVA test was used to determine adjusted mean differences (MD) and the related 95% confidence intervals (CI).

The multivariate model included age >65 years, sex, ischemic heart disease, vascular disease, heart failure, chronic obstructive pulmonary disease, active malignancy, antithrombotic and anticoagulant treatment.

Results: Of 1019 patients with gastrointestinal bleeding, 575 (56.42%) were eligible for analysis. The lowest mortality rate was observed in group 3 (8.98%). However, there was no statistically significant difference in mortality odds when comparing transfusion at different Hgb levels to group 2 (1 vs 2: aOR: 0.64, CI: 0.24-1.70; 3 vs 2: aOR: 0.79, CI: 0.27-2.27; 2 vs 4: aOR: 0.50, CI: 0.10-2.48). Group 2 had the slightest need for surgical intervention (2.30%) compared to other groups.

There was a tendency towards increased odds of surgical intervention in group 1 compared to group 2 (aOR: 4.13, CI: 0.64-26.65). Furthermore, the odds of intensive care therapy were significantly increased in groups 1 and 4 compared to group 2 (1 vs 2: aOR: 6.37, CI: 1.37-29.53; 4 vs 2: aOR: 10.97, CI: 1.91-62.98). Compared to group 2, group 3 showed an increased tendency in the odds for intensive care unit admission (aOR: 4.83, CI: 0.97-24.07). There was no significant difference in the length of hospital stay among the groups.

Conclusion: Our findings support that haemoglobin levels between 61-70 g/L may be considered safe compared to lower (≤60 g/L) or higher (≥80 g/L) transfusion thresholds. Randomised controlled trials with extended follow-up periods are needed to validate our results.

VALIDATION OF THE BEST-J SCORE, A PREDICTION MODEL FOR DELAYED BLEEDING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION, IN A WESTERN CENTER

S. Archer[1], A.T. Ferreira[1], S. Ponte[1], C. Verde[2], G. Moreira[2], A. Ruge[3], R. Marcos-Pinto[1,2], I. Pedroto[1,2], R. Küttner Magalhães[1,2]

Contact E-Mail Address: sararcher_@hotmail.com

Introduction: Endoscopic submucosal dissection (ESD) is widely implemented in Asia. BEST J-score is a clinically useful prediction model validated in 2021, based on this population, to stratify the risk of delayed bleeding (DB) after gastric ESD. Experience from the Western world is still scarce.

Aims & Methods: The aim of our study is to validate BEST-J score in a Western sample.

Retrospective analysis with a prospectively maintained database of all patients undergoing ESD at a Western tertiary center from June 2016 to December 2022.

Gastric ESD performed by a single operator were included in this study. BEST-J score was applied for all procedures, which comprised 10 variables (intake of warfarin, direct oral anticoagulant (DOAC), chronic kidney disease with haemodialysis, intake of P2Y12 receptor antagonist, aspirin, cilostazol, tumour size >30 mm, lower-third in tumour location, presence of multiple tumours and interruption of each kind of antithrombotic agents). The primary endpoint was to validate BEST-J score accuracy in predicting DB (up to 28 days after ESD).

Results: Of 477 ESD performed, a total of 252 ESD met the inclusion criteria; 56.5% were male, with a mean age of 68 years (SD 8 years). Of this, 30 patients (15.3%) were under anticoagulant therapy, 19 of them (63.3%) with DOAC. Antiplatelet agents were taken by 48 patients (19%). From these, 5 (2.0%) presented DB following ESD, with a median time to bleeding of 11 days.

According to BEST-J score, bleeding risk was low (0-1 points) in 205 procedures (81,3%), intermediate (2 points) in 18 (7.1%), high (3-4 points) in 26 (10.3%) and very high (≥5 points) in 3 (1.2%).

BEST-J score presented an acceptable accuracy predicting DB in our sample, with an AUC=0.777 (p=0.034, CI 95%, 0.58-0.975). The optimal cut-off value to predict DB was a BEST-J score ≥ 3, which matches the cut-off value for high-risk of bleeding in the original investigation. This value had a sensitivity of 60.0%, specificity of 88.7% and a negative predictive value of 99.1%.

Conclusion: The BEST-J score presents an acceptable accuracy for post-ESD bleeding and it is particularly useful in identifying low risk DB patients. Therefore, this model is a good clinical decision-making support tool in the Western population.

Introduction: Gastrointestinal bleeding is a frequent reason for emergency room visits and one of the main digestive emergencies. Direct oral anticoagulants (DOACs), vitamin K antagonists (VKAs) and anti-platelet agents (APAs) frequently prescribed in cardiac patients increase the risk of Gastrointestinal bleeding.

The aim of our work is to study the characteristics of Gastrointestinal bleeding in the cardiac patient.

Aims & Methods: This is a prospective comparative and analytical study between April 2020 and August 2022. We included cardiac patients who presented with Gastrointestinal bleeding and benefited from endoscopic exploration within our training, which we compared with a control group of patients explored for Gastrointestinal bleeding without cardiac comorbidity.

We took into account age, sex, history, average length of hospital stay, need for transfusion and ICU stay, and outcome after the bleeding episode. SPSS 20.0 software was used for statistical analysis.

Results: 378 patients underwent endoscopic exploration for Gastrointestinal bleeding during this period, including (oesophago-gastro-duodenoscopy (EGD), colonoscopy and endoscopic videocapsule).

We collected 47 patients with underlying cardiac pathology and 331 non-cardiac patients. The mean age was 70.76 years [34-90]. The sex ratio was M/F=1.13.

18 patients (38.3%) had ischemic heart disease, 11 (23.4%) had arrhythmic heart disease, 8 (17%) had valvular heart disease, and 10 (21.27%) had heart disease of other etiologies.

14 patients (29.78%) were on anticoagulants alone, including 13 (92.86%) on VKA and 1 (7.14%) on DOAC, 13 (27.66%) were on anti-platelet agents alone, 12 (25.53%) were on anti-platelet agents in combination with ACs (11 VKAs and 1 DOAC), and 8 (17%) were on no treatment. 19 (79.16%) patients on VKAs were overdosed.

Cardiac patients had a higher risk of blood transfusion 51.06% (n=24) vs 28.7% (n=95) p= 0.002, as well as ICU stay 25.53% (n=12) vs 7.55% (n=25) p=0.00.

The average length of hospital stay was higher in cardiac patients: 6 days vs. 4 days in non-cardiac patients.

The risk of recurrence was higher in cardiac patients 17% (n=8) vs 4.83% (n=16) p=0.00, as well as mortality 4.25% (n=2) vs 1.2% (n=4) p=0.002.

Conclusion: The occurrence of Gastrointestinal bleeding is more severe in the cardiac subject due to the higher morbidity and mortality compared to non-cardiac patients, hence the interest in prompt and optimal management. Patients on VKAs are at the greatest risk of Gastrointestinal bleeding, especially in the event of overdose.

Introduction: The acid-suppressive drug such as proton pump inhibitor (PPI) is one of treatment options for functional dyspepsia (FD). However, the efficacy of potassium-competitive acid blockers (P-CABs) for treating FD is not established.

This study aimed to assess the efficacy and safety of tegoprazan in patients with FD in a prospective, multicenter clinical trial.

Aims & Methods: Investigated FD was diagnosed using the Rome IV criteria. All patients received tegoprazan 50mg once daily for 8 weeks. Dyspeptic symptoms were assessed by a dyspepsia symptom questionnaire (5-point Likert scale, NDI-K, and GERD-HRQL). The main outcome was the rate of satisfactory relief of dyspeptic symptoms at 8weeks.

Results: A total of 173 patients were enrolled in this study. The rate of satisfactory relief of dyspeptic symptoms at 4 and 8weeks was 74.6% and 86.7%, respectively. The complete symptom relief rate at 4 and 8weeks was 15.0% and 24.9%, respectively.

The symptom resolution rate was significantly higher at 8weeks than at 4 weeks. (86.7% vs. 74.6%, p<0.001; 24.9% vs. 15.0%, p=0.003). The mean score of NDI-K and GERD-HRQL also significant decreased at 8weeks.

The efficacy was not influenced by subtypes of FD or *Helicobacter pylori* status. There was no serious adverse event or death during the study.

Conclusion: Tegoprazan 50mg once daily significantly provides satisfactory symptom relief for FD. (International clinical trial registry number: KCT0005600)

Contact E-Mail Address: lieke.koggel@radboudumc.nl

Introduction: Proton pump inhibitors (PPIs) are frequently used in daily clinical practice, but often without a valid indication. Strategies to identify inappropriate PPI use are widely available, although the true challenge is to discontinue PPIs in these patients without developing rebound symptoms. There is therefore a need for a tool to guide patients during this process.

Aims & Methods: We aimed to evaluate the effect of a smartphone app that provides an individualized educational approach as a tool to achieve sustained PPI discontinuation. This multicenter randomized controlled trial included adult patients on daily PPI for at least four weeks without chronic PPI indication from the outpatient clinics of Internal Medicine, Gastroenterology, Rheumatology and Nephrology in two community hospitals and one university hospital in the Netherlands. Patients were excluded in case they could not understand the study (procedures) or in case of a limited life span.

Patients were randomly assigned to either the smartphone app providing timely information on PPI discontinuation (intervention group) or usual care which consisted of patients receiving a brochure explaining how to stop PPI and manage symptoms providing all information at once (control group).

Primary endpoint was the discontinuation rate at 2-months follow-up, defined as self-declared intake of a maximum of one tablet in the previous 14 days. Patient recruitment has ended and we anticipate final results in August 2023. We now only present preliminary numerical data.

Results: Preliminary follow up results are based on 129 (2-months) and 99 (4-months) of 165 included patients (median age 55 y/o [IQR 46-64 y/o], 61 males [47%]). More patients succeeded to discontinue PPI use at 2-months follow-up in the intervention group: 54/62 (87%) vs. 44/67 (66%). This was also seen after 4-months follow-up: 44/55 (80%) patients in the intervention group vs. 41/61 (67%) patients in the control group.

Conclusion: A smartphone app intervention providing timely guidance in discontinuing inappropriate PPI use seems to be an effective tool to improve the discontinuation rate of inappropriate PPI use compared with a one-time information folder.

These preliminary data suggest that patients are able to successfully discontinue inappropriate use of medication without the time-consuming support of a healthcare worker. (Clinical trial registration number: NCT05348252).

INTRAMURAL INJECTION OF BLEOMYCIN COMBINED WITH ENDOSCOPIC DILATION FOR BENIGN ESOPHAGEAL STRICTURES

R. Wu[1], L.-L. Zhao[2], L. Liu[2], Z. Fan[2]
[1]The Affiliated Cancer Hospital of Nanjing Medical University, Nanjing, China, [2]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Contact E-Mail Address: wurui@njmu.edu.cn

Introduction: Benign esophageal stricture is a common gastroenterological disease. Endoscopic dilation is the first-line treatments, but the recurrence rate is high, especially for the patients with refractory benign esophageal stricture (RBES). Bleomycin can reduce keloids and hypertrophic scars, but has not been reported in esophageal stricture. Therefore, the study was performed in our center.

Aims & Methods: This retrospective study was performed from January 2012 to December 2020. 120 patients with intramural injection of bleomycin combined with endoscopic dilation (bleomycin group) and 120 patients with endoscopic dilation only (dilation group) were enrolled. The primary results are the relapse rates within 3 months and 1 year.

Results: Bleomycin showed significant improvement in the short-term (34.2% vs. 55.0%, P=0.001) and long-term (71.7% vs. 85.8%, P=0.008) relapse rates in patients with benign esophageal stricture compared with patients in the dilation group. In the different causes of benign esophageal stricture, bleomycin showed significant benefit for patients with anastomotic stricture (short-term: 26.3% vs. 46.1%, P=0.011; long-term: 64.5% vs. 81.3%, P=0.020) and post-ESD stricture (short-term: 61.1% vs. 94.4%, P=0.016). Furthermore, the dysphagia-free period could be increased significantly in the bleomycin group (2.8±2.2 months vs. 1.6±1.5 months, P=0.044). Dilation times before treatment (OR=0.157, P<0.001), total dilation times (OR=4.970, P<0.001), and grade of dysphagia before treatment (OR=3.053, P=0.007) were the independent factors for the relapse of patients in bleomycin group.

Conclusion: Bleomycin can decrease relapse rates of patients with benign esophageal stricture, especially for anastomotic stricture. It can also prolong the dysphagia-free period of patients with RBES.

Disclosure: Nothing to disclose.

Introduction: The pathophysiology of disorders of gut-brain interaction is complex and incompletely understood. In functional dyspepsia, increased gut permeability and low-grade mucosal inflammation with eosinophils and mast cells have been reported.

Stress as well as exogenously administered corticotropin-releasing hormone (CRH) have been shown to increase small bowel permeability in vivo in a mast-cell dependent fashion. Moreover, eosinophil-derived CRH has been implicated in mast cell activation.

Aims & Methods: The aim of the current study was to evaluate whether acute CRH administration can induce increased duodenal mucosal permeability and immune activation in healthy volunteers (HVs).

HVs without gastrointestinal symptoms were recruited. The use of drugs such as NSAIDs, mast cell stabilizers or corticoids was prohibited. An i.v. bolus of 100 µg CRH or placebo (NaCl 0.9%) was administered in a crossover, double blind, randomized fashion with a 1-week washout period. Two hours after injection a gastroscopy with duodenal biopsies was performed. Duodenal permeability was evaluated in Ussing chambers measuring trans-epithelial electrical resistance (TEER) and the flux of a fluorescence-labeled dextran of 4kDa (FITC-D4). Duodenal biopsies were incubated at 37°C in culture medium for 24h. Sandwich ELISA was performed on supernatant for eosinophil derived neurotoxin (EDN), tryptase and chymase, corrected for biopsy weight.

Analysis was performed using marginal mixed models in SAS. Correlation analysis was performed using Pearson correlation coefficient. Results are described as mean ± SEM. P-values < 0.05 were considered significant after correction for multiple testing.

Results: Twenty HVs (65% women, 27±1 years, BMI 23.2 ± 0.6 kg/m^2) completed the study. Tryptase release in supernatant was significantly lower after CRH exposure, 6.06±0.88 ng/mL vs 4.03±0.46 ng/mL after CRH exposure (n=16, p= 0.031). Chymase release however, was not significantly different between both conditions (2805.82 ± 447.85 pg/mL/mg for placebo vs 2001.19±365.91 for CRH pg/mL/mg; p=0.27, n=15). There was a trend towards a decrease in EDN, after CRH exposure (13.3±2.05 µg/L/mg for placebo vs 8.96±1.11 µg/L/mg for CRH; p=0.061; n=16).

Correlation analysis of delta values showed a significant correlation between Δ tryptase and Δ chymase (r 0.79, p=0.0062, n=10) and Δ tryptase and Δ EDN (r 0.60, p=0.019, n=15).

No significant correlation was found between Δ chymase and Δ EDN (r 0.36, p=0.30, n=10).

A trend towards an decreased mucosal permeability was observed after CRH administration for TEER (25.75 ± 0.91 Ω.cm^2 for placebo vs 27.20 ± 1.44 Ω.cm^2 for CRH; p=0.056). Likewise, FITC-D4 flux was significantly lower in the CRH condition (41.4 ± 5.6 pmol for placebo vs 33.0 ± 2.7 pmol for CRH, p<0.0001). There was no significant correlation of delta values of FITC-D4 flux or TEER with delta values of supernatant for tryptase, chymase or EDN secretion.

Conclusion: Acutely administered CRH in vivo decreased tryptase release in supernatant of duodenal biopsies, suggesting an increased tryptase release in vivo, and decreased duodenal permeability in healthy subjects. However, no correlation between permeability and tryptase release was found.

Disclosure: Nothing to disclose.

POSITION DURING OESOPHAGEAL HIGH-RESOLUTION MANOMETRY AND ANALYSIS METHODOLOGY AFFECT MANOMETRIC DIAGNOSIS

M. Antón Arnal[1], G. Font[1], L. Carot Bastard[1], J. Iglesias Chaparro[1], M.d.C. Alonso Romera[1], X. Bessa[1], J.E. Naves[1]

Introduction: Oesophageal high-resolution manometry (HRM) is the test of choice for the study of oesophageal motility disorders. The Chicago 4.0 classification facilitates analysis and interpretation of these studies. However, the influence of patient position and analysis methodology of some parameters is not well defined. In addition, it has not been precisely defined where to place the gastric pressure sensor to determine the integrated relaxation pressure (IRP).

Aims & Methods: The aim was to evaluate if postural changes and analysis methodology applied affect the results of oesophageal high-resolution manometry.

Oesophageal HRM with Chicago 4.0 extended protocol (10 swallows in supine and 10 swallows in up-right position) performed in our Neurogastroenterology and Motility Unit between December 2021 and October 2022 were included. The distal contraction integral (DCI) was determined automatically and manually. The IRP was evaluated positioning the gastric pressure sensor in the lowest gastric area pressure zone (GS-LP) and 2 cm below the lower oesophageal sphincter (GS-2cm).

Results: A total of 96 patients were included, 65% women (mean age 57 years). Mains indications of oesophageal HRM were GERD symptoms (52%) and dysphagia (41%). DCI values were significantly higher in the supine position (2607 and 2014 mmHg/cm/sec with automatic and manual analysis respectively, p<0,0001) compared to the up-right position (1558 and 1371 mmHg/cm/sec with automatic and manual analysis respectively, p<0,0001). These represent changes in the diagnosis of 11% of the studies regarding methodology and 17% regarding posture. A higher proportion of ineffective peristalsis was observed with manual analysis in the up-right position. Additionally, IRP values were significantly higher in both positions using GS-LP (15.5 and 11.1 mmHg) rather than GS-2cm (11.9 and 7.9 mmHg). This represents an increase in the proportion of oesophageal outflow obstruction using GS-LP in both positions.

Conclusion: The position and analysis methodology applied affects the distal contractile integral values. The location of the gastric reference sensor affects the integrated relaxation pressure value. Manometric diagnosis can change depending on the selected posture and analysis methodology applied. Consensus on posture and analysis methodology for oesophageal high-resolution manometry is needed to reduce differences between laboratories.

Disclosure: Nothing to disclose.

USEFULNESS OF FUNCTIONAL ENDOSCOPY IN THE ENDOSCOPIC TREATMENT OF GASTROESOPHAGEAL REFLUX DISEASE

N. Kawamata[1], Y. Shimamura[1], Y. Nishikawa[1], T. Sato[1], M.J. Navarro[1], D. Azuma[1], K. Ushikubo[1], K. Yamamoto[1], Y. Kimoto[1], H. Okada[1], I. Tanaka[1], M. Onimaru[1], H. Inoue[1]

Introduction: The Endoscopic Pressure Study Integrated System (EPSIS) is a novel diagnostic device that continuously measures intragastric pressure during upper endoscopy. The waveform of intragastric pressure (IGP) is recorded during continuous insufflation of the stomach.

Previous studies have shown that the lower esophageal sphincter (LES) function can be evaluated by characterizing the IGP waveform, and this technique has been applied in the diagnosis of gastroesophageal reflux disease(GERD). The gradient of the waveform decreases in cases of GERD, indicating LES dysfunction with an inability to hold up the insufflation.

Anti-reflux mucosal ablation (ARMA) and anti-reflux mucosectomy (ARMS) are forms of endoscopic anti-reflux therapy through cardioplasty where in an ulcer at the level of the gastric cardia is created by resecting or ablating the mucosa to achieve gastric cardia stricture through the scarring process.

In this study, we aimed to determine if EPSIS can be used to assess the therapeutic effect of endoscopic cardioplasty, such as ARMA or ARMS.

Aims & Methods: This was a single-center retrospective cohort study that included patients who underwent endoscopic cardioplasty, and EPSIS was performed before and after the endoscopic treatment between May 2018 and April 2023. 24-hour pH monitoring was performed post procedure to evaluated the treatment outcome. EPSIS was performed by using the pressure measuring system to monitor IGP.

We characterized the pressure waveform shape by assessing the gradient of the waveform (mmHg/s), calculated by dividing the pressure difference by the insufflating time. The gradient of the waveform was compared before and after the procedure to confirm the change in the IGP waveform.

Results: EPSIS was performed before and after endoscopic cardioplasty (ARMS/ARMA) in 26 patients (mean age: 54.3 years, 19 males) during the study period. Twenty-two patients (84.6%) were evaluated by 24-hour pH monitoring at 2-6 months post-ARMA. The median AET significantly decreased from 20.4% to 5.4% (p=0.01). The pressure gradient of the IGP waveform significantly increased (0.15 vs. 0.25 mmHg/sec, p=0.001), indicating that the LES function was built up by the endoscopic intervention.

Conclusion: Functional endoscopy using EPSIS was found to be effective in evaluating the efficacy of endoscopic cardioplasty and has the potential to be applied not only in the diagnosis but also in the treatment of GERD.

Introduction: Functional dyspepsia (FD) is a disorder of gut-brain interaction (DGBI) characterised by relapsing and remitting gastro-duodenal symptoms, in the absence of identifiable pathology via routine clinical screening. An association between FD and wheat-containing foods has been reported in observational studies, and recent work demonstrates increased gut-homing T cells in peripheral blood of FD patients reporting sensitivity to wheat, compared to those without wheat sensitivity and controls.

We have also recently shown increased populations of mucosal lymphocytes with a T helper (Th)2- and Th17-like phenotype in FD patients compared to controls, however, a mucosal adaptive lymphocyte response specific to wheat has not been demonstrated.

Aims & Methods: We aimed to examine whether proteins present in wheat could provoke a response from FD duodenal lymphocytes isolated from mucosal biopsies. Lamina propria mononuclear cells (LPMCs) were isolated from duodenal biopsies from 50 FD patients (38 female, 46.8±16.8 years) and 23 controls (11 female, 52.1±13.1 years). LPMCs were exposed to gluten (0.2mg/mL) or gliadin (0.2mg/mL) for 24 hours.

Flow cytometry was performed to phenotype lymphocytes using a surface marker panel. Quantitative polymerase chain reaction (qPCR) was used to measure expression of the gliadin-associated T-cell receptor alpha variant (*TRAV)26-2.*

Results: In response to gliadin (but not gluten) stimulation, the effector Th2-like population was increased in FD LPMCs compared to controls (16.34 ± 13.17 vs 25.83 ± 14.87, $p = 0.01$) and unstimulated FD LPMCs (19.40 ± 14.35 vs 25.83 ± 14.87, $p = 0.04$). Duodenal gene expression of *TRAV26-2* was decreased in FD compared to controls (0.013 ± 0.015 vs 0.003 ± 0.005, $p = 0.04$). We identified a positive association between gene expression of this T cell receptor variant and LPMC effector Th17-like cell populations in FD patients (rs = 0.3733, $p = 0.04$), but not controls (rs = 0.2238, $p = 0.485$) following exposure to gluten, but not gliadin.

Conclusion: Our findings in this observational study suggest differential T cell responses to gluten and gliadin in a subset of FD patients, and suggest Th2 responses previously reported in FD may occur in response to food components such gliadin. We also show that FD patients have reduced expression of *TRAV26-2*, previously associated with T cell responses against gliadin in celiac disease. *TRAV26-2* expression correlated with Th17-like populations in FD patients, suggesting that specific TCR variants in may be associated with an immune response to the consumption of wheat-containing foods in FD.

Disclosure: Nothing to disclose.

Contact E-Mail Address: jasmine.wark@newcastle.edu.au

Introduction: Functional dyspepsia (FD) is a highly prevalent disorder of gut brain interaction that substantially impairs quality of life. FD is associated with unexplained low grade duodenal inflammation and increased duodenal permeability. Emerging evidence implicates *Streptococcus* species in the disorder, and we have previously identified a unique strain of *Streptococcus salivarius*, AGIRA0003, to which specific IgG antibodies were detected in the plasma of FD patients.

We hypothesised AGIRA0003 is a pathobiont with the capacity to breach duodenal epithelial barrier defences and translocate into the mucosa, inducing the subtle immune response and symptoms observed in a subset of FD patients.

Aims & Methods: We aimed to investigate the capacity of AGIRA0003 to breach duodenal epithelial defences. Differentiated Caco-2 cell transwell monolayers (n=3), as models of the epithelial barrier, were exposed to 4 strains of cultured *S. salivarius*, AGIRA0003, ATCC 7073, K12 and M18, with the last 2 being commercially available probiotics, at a multiplicity of infection of 10 for 6 hours.

Epithelial permeability was measured by transepithelial electrical resistance (TEER), and tight junction (TJ) protein expression was measured using immunoblot, cytokine secretion by Legendplex bead-based immunoassay, along with bacterial translocation.

As a proof of concept, 2-dimensional epithelial transwell monolayer cultures, derived from duodenal spheroids, from an FD patient and outpatient control (OC) were exposed to AGIRA0003.

Results: AGIRA0003 translocated through the Caco-2 monolayer (3hr: 901.5±317.4 CFU/mL) and significantly decreased ΔTEER (-83.85 ± 27.52 Ωxcm^2, $p=0.047$) compared to the control (-23.99±7.91 Ωxcm^2). In addition, AGIRA0003 disrupted expression of TJ proteins claudin 1 (CLDN1) (fold change (FC) 0.643±0.058, $p=0.037$), cleaved desmocollin 2 (DSC2 CL) (FC 0.57±0.071, $p=0.037$) and zonula occludens 1 (ZO-1) (FC 0.55±0.026, $p=0.058$). AGIRA0003 elicited subtle inflammatory cytokine response from Caco-2 cells including secretion of IP-10 (41.15±8.33 pg/mL, $p=0.046$) and IL-8 (61.76±36.90 pg/mL, $p=0.046$).

An FD duodenal 2D spheroid epithelial monolayer had decreased levels of CLDN1 (FC to respective media control: 10.13 OC, 0.60 FD) and ZO-1 (FC to respective media control: 4.82 OC, 0.29 FD) compared to an OC following exposure to AGIRA0003.

Conclusion: These investigations implicate AGIRA0003 as a possible pathobiont contributing to FD pathophysiology and may be a suitable target for therapeutic intervention. AGIRA0003 has the capacity to breach Caco-2 epithelial barrier defences, translocate and elicit an inflammatory immune response contributing to the pathogenesis of FD. The exact mechanisms by which AGIRA0003 interacts with epithelia remains to be elucidated and warrants further investigation.

Introduction: One third of the world population is affected by obesity. Laparoscopic Sleeve Gastrectomy (LSG) is the most widely used surgical treatment currently used to treat severe obesity. However, it appears to increase the risk of developing Gastro-Esophageal Reflux Disease (GERD) and its complications, such as Barrett's esophagus (Genco A. et Al, 2017).

The aim of this study was to evaluate possible impairment of the anti-reflux barrier function of the Esophageal-Gastric Junction (EGJ) in patients with severe obesity undergoing LSG by studying functional aspects of the EGJ by High Resolution Esophageal Manometry (HRM) with perfusion system and 24-hour pH-metry.

Aims & Methods: Forty-five obese patients, without evidence of hiatus hernia or GERD, undergoing LSG (34F 11M; 45±12 yrs) were compared with 21 overweight patients (10F 11M; 52±16 yrs) and 21 normal weight patients (17F 4M; 47±14 yrs) with GERD symptoms. Twenty-four of the obese patients (3M 21F; 45±11 yrs) were reevaluated after LSG.

The EGJ was evaluated by the EsophagoGogastic Junction–Contractile Integral (CI) on HRM, that integrates the inspiratory and expiratory pressures, the length and the duration of the contraction of the EGJ during three respiratory cycles at rest. It was calculated for Single Respiratory Cycle (EGG-CI SRC) and corrected for duration of the breathing (EGG-CI CRC). The findings were compared with normal ranges suggested in the literature (EGJ-CI-SRC 205.5±35.6 mmHg·cm·s and EGJ-CI-CRC 46.2±7.6 mmHg·cm) (Gor P. et Al, 2016).

Results: The 3 groups of patients, obese, overweight and normal weight, did not differ statistically for EGJ-CI SRC (120.3 ± 112.7 vs 116 ± 120 vs 103.7 ± 102.6 mmHg·cm·s, respectively) nor for EGJ-CI CRC (42.8 ± 31 vs 33.4 ± 28.2 vs 33.0 ± 28.5 mmHg·cm, respectively). After LSG a statistically significant decrease was observed for EGJ-CI CRC (46.7±36.8 vs 32.3±26.4 mmHg·cm, p=0.02), but not for EGJ-CI SRC (133.6±141 vs 115.2±103.6 mmHg·cm·s, n.s.). Twelve patients (50%) showed after LSG an acid exposure time above the normal limits and this result was related to the degree of reduction of EGJ-CI-CRC (r = 0.525; p = 0.01).The results of this study indicate that the esophagogastric barrier function of the EGJ is reduced in obese patients similarly to GERD patients regardless of BMI and appears to decrease further after LSG surgery, affecting its efficiency and probably favoring the onset of GERD.

Conclusion: In conclusion, the evidence that LSG affects the EGJ and may induce GERD suggests that HRM and 24-hour pH-mertry or 24-hour pH-impedancemetry could be useful in the work-up for bariatric surgery to identify subjects without or scarce reflux symptoms, but showing impaired functions that could worsen with surgery favoring the onset of GERD. It is possible that the functional characteristics of the GEG associated with other variables detected by HRM and pH-impedancemetry may in the future develop a predictive score for risk of MRGE in these patients.

FUNCTIONAL VERIFICATION AND MECHANISM OF *FAM129C* GENE MUTATION IN ACHALASIA

X. Li[1], Z. Liu[1], W. Chen[1], P. Zhou[1], Q. Li[1]

[1]Zhongshan Hospital, Endoscopy, Shanghai, China

Introduction: Esophageal achalasia (EA) is a rare functional disorder caused by neuromuscular dysfunction at the esophagogastric junction, characterized by impaired diastole of the lower esophageal sphincter (LES) and loss of distal esophageal peristaltic function.

The etiology of the disease is still unknown, and the current etiological hypothesis is that the loss of esophageal neurons due to ganglion inflammation caused by an abnormal immune response to infection in a genetically susceptible background affects the function of the muscles innervated by it.

Previous studies have suggested that genetic susceptibility may be strongly associated with the onset of achalasia. Based on this platform, our group is one of the largest EA clinical centers in China, and we used whole-exome sequencing and technology validation to screen out a new genetic mutation locus *FAM129C* from 22 Trios core families with achalasia.

This paper intends to investigate whether *Fam129c* mutant mice have an EA phenotype, and to investigate the pathogenic mechanism of this mutation with multi-omics.

This study will provide a new basis for uncovering the genetic cause of EA, a new mouse model for basic EA research, and potential therapeutic targets for the treatment of EA.

Aims & Methods: The new pathogenic genes inherited from the family line of achalasia in the Han population were screened, and the mutant mice were constructed by CRSPR/Cas9 technology. To verify whether the mutant mice have the cardia apopause phenotype, and to explore the specific mechanism of disease in mutant mice through multi-omics joint analysis and in vivo and in vivo validation experiments.

Results: *Fam129c* mutant mice were successfully constructed, and it was confirmed that they had EA phenotype from anatomical to functional levels. Immunofluorescence results showed that *FAM129C* was localized in B cells. Abnormal activation of plasma cells in mutant mice, specific deletion of B cells can partially alleviate the achalasia phenotype of mutant mice.

Transcriptome sequencing and single-cell sequencing results revealed a significant enrichment of B cell subsets, and differential genes elevated in mutant mice mainly included immunoglobulins. Single-cell BCR repertoire sequencing analysis showed that mutant mice had increased V-J pairing, increased clone number and clone types, and increased immunoglobulin secretion.

Further analysis of proteomics results found that the anti-inhibitory neuron autoantibody GABA-AR was elevated in serum and in situ tissue of mutant mice, and the results of ELISA verification in mice were consistent with it. IvIgG treatment of mutant mice in vitro and in vivo can partially alleviate the EA phenotype.

Conclusion: A new potential mutated genes *FAM129C* in achalasia were identified, and *Fam129c* mutant mice conforming to the population mutation pattern were established. Fam129c mutant mice have an EA phenotype, and their anatomical features, pathological changes in the esophageal intermuscular plexus and diastolic function of the lower esophagus are consistent with EA patients. *Fam129c* mutant mice are pathogenic through a B-cell-dependent pathway.

Abnormal activation of plasma cells in mutant mice, increased secretion of immunoglobulins, especially anti-neuronal autoantibody GABA-AR, and neuromuscular dysfunction after specific injury of esophageal inhibitory intermuscular neurons, eventually leading to the onset of achalasia.

Disclosure: Nothing to disclose.

Introduction: Little is known about the variation in the mucosa-associated microbiota (MAM) along the human gastrointestinal (GI) tract. We set out to characterize biogeography of the MAM in subjects with and without gastrointestinal disease, and to explore and compare the intrinsic links between the MAM, proton pump inhibitor (PPI) therapy, symptom response to a standardized nutrient challenge as a surrogate marker for visceral sensory function, and the severity of gastrointestinal symptoms across various segments of GI tract in asymptomatic controls and patients with inflammatory bowel disease (IBD).

Aims & Methods: After informed consent, the type and severity of GI symptoms were recorded using a standardized valid questionnaire (Structured assessment of gastrointestinal symptoms, SAGIS). Patients underwent a nutrient challenge test and the cumulative symptom response to a standardized test meal (Ensure, 600 cc) were recorded. Clinical data and demographic information were obtained from the integrated Electronic Medical Record (iEMR). During endoscopy, mucosal samples were collected utilising the Brisbane Aseptic Biopsy Forceps (MTW, Germany) from the duodenum to avoid working channel contamination of tissue and utilizing routine biopsy forceps from the terminal ileum (TI), right colon (RC), rectum (R), from 59 asymptomatic/healthy control subjects, and 75 IBD patients in clinical remission (44 ulcerative colitis (UC) and 31 Crohn's disease (CD)). Microbial composition was assessed via 16S rRNA amplicon analysis and the bacterial load of DU, TI, R and RC biopsies were assessed via qPCR, allowing for calculation of absolute and relative abundance profiles of the MAM. MAM composition was examined in the context of PPI usage, the severity of gastrointestinal and extraintestinal symptoms, and the sensitivity to nutrient challenge tests.

Results: The biogeography of MAM exhibited substantial heterogeneity between UC and CD patients and across the GI tract, with differences in the relative abundance of MAM, as examined in other studies, not always corresponding with differences in absolute abundance.

Compared to controls, UC and CD patients were characterised by relative and absolute depletion of butyrate-producing genera, with the largest differentiation being depletion of Faecalibacterium in the lower GI tract of CD patients. Interestingly, PPI therapy was associated with a significant shift in MAM composition, particularly for Faecalibacterium whose depleted levels were restored to healthy-control levels in CD patients.

The severity of gastrointestinal and extraintestinal symptoms, was significantly associated with MAM composition, with Faecalibacterium enrichment in UC and CD patients paradoxically associated with elevated symptom severity. The response to standardised nutrient challenge tests, was significantly associated with a shift in MAM composition and Faecalibacterium depletion.

Conclusion: The absolute and relative composition of the MAM is variable across different levels of the human GI tract and linked to the presence/absence of specific inflammatory bowel disorders (CD/UC), medication with a PPI, the severity of gastrointestinal symptoms, and the intensity of GI symptoms during a standardized nutrient challenge.

The consistently strong association of clinically relevant bacterial genera such as Faecalibacterium in these analyses, as well as several other genera, provides focal points for future investigations and strategies to develop microbiome-mediated therapies for IBD and for modulation of the gut-brain axes.

Disclosure: Nothing to disclose.

A SINGLE-CELL TRANSCRIPTIONAL LANDSCAPE OF IMMUNE CELLS SHOWS DISEASE-SPECIFIC CHANGES OF T CELL AND MACROPHAGE POPULATIONS IN HUMAN ACHALASIA

Z. Liu[1], L. Yao[1], X. Li[1], W. Chen[1], P. Zhou[1], Q. Li[1]

[1]Zhongshan Hospital, Endoscopy, Shanghai, China

Contact E-Mail Address: li.quanlin@zs-hospital.sh.cn

Introduction: Achalasia is a rare motility disorder of the esophagus with symptoms of dysphagia, regurgitation, chest pain, and weight loss[1].

The pathophysiology of achalasia is aberrant esophageal peristalsis and impaired relaxation of the lower esophageal sphincter (LES) caused by the gradual degeneration of the myenteric neuron.

Although its etiology is unknown, immune-mediated ganglionitis triggered by environmental factors and genetic susceptibilities may underlie the loss of myenteric neurons in achalasia[1,2].

Previous studies demonstrated various inflammatory cells infiltrated in LES, such as T cells, eosinophils, and mast cells[3].

Whole-exome and RNA sequencing of achalasia patients identified achalasia-associated loci enriched for immunological and neurological processes[4], suggesting that the immune response may be a critical factor in the disease.

However, most studies have focused on the proportion of immune cells and inflammatory mediators without exploring the underlying mechanism.

Without cell-type-specific gene expression profiles, it is difficult to define the cell types responsible for achalasia-related changes.

Single-cell RNA sequencing (scRNA-seq), which provides an unbiased approach for characterizing cell diversity and heterogeneous phenotypes at high resolution[5], has been used in patients with neurodegenerative disorders or neuroinflammatory conditions, such as Alzheimer's disease (AD)[6], multiple sclerosis (MS)[7], and Parkinson's disease (PD)[8].

Since the loss of myenteric neurons and ganglionitis was the main pathophysiology in achalasia, we use scRNA-seq to map the immune cell transcriptional landscape of peripheral blood and paired LES tissues from patients with achalasia and controls in this study.

We find a specific composition and transcriptional phenotype of C1QC$^+$ macrophages and tissue-resident memory T cells (Trms) in achalasia, which might be involved in the inflammatory process and pathophysiology in achalasia.

Aims & Methods: Achalasia is a rare motility disorder of the esophagus caused by the gradual degeneration of myenteric neurons. Immune-mediated ganglionitis has been proposed to underlie the loss of myenteric neurons.

Here, we map the immune cell transcriptional landscape of paired lower esophageal sphincter (LES) tissue and blood samples in achalasia and controls using single-cell RNA sequencing (scRNA-seq).

Results: In achalasia, we identify a pattern of expanded immune cells and a unique transcriptional phenotype, especially in LES tissue. The C1QC$^+$ macrophages and tissue-resident memory T cells (Trms), especially ZNF683$^+$ CD8$^+$ Trms and XCL1$^+$ CD4$^+$ Trms, are significantly expanded and localized surrounding the myenteric plexus in the LES tissue of achalasia. C1QC$^+$ macrophages are transcriptionally similar to microglia of the central nervous system and exhibit a neurodegenerative dysfunctional phenotype in achalasia. Trms also express transcripts of dysregulated immune responses in achalasia.

Moreover, inflammation increases with disease progression since immune cells are more activated in type I compared with type II achalasia.

Conclusion: Thus, we map the immune cell transcriptional landscape and identify the C1QC$^+$ macrophages and Trms as disease-associated subsets in achalasia.

Introduction: There are limited studies that examined the risk factors of childhood Irritable Bowel Syndrome (IBS). Studies on the risk factors for adult IBS frequently indicate that early life periods play a significant role in the development of IBS. However, the majority of these studies are retrospective and prone to confirmation bias.

To address this limitation, we conducted the first prospective mother-offspring cohort study (Growing Up in Singapore Towards healthy Outcomes (GUSTO)) to investigate the early life risk factors associated with the development of childhood IBS.

Aims & Methods: Under the GUSTO study, we conducted a prospective population-based mother-child birth cohort study of 1176 children born in Singapore from November 2009 to May 2011. We analysed data from 827 mother-child pairs with complete follow-up at Year 11 and without an initial diagnosis of organic gastrointestinal disease. Incident cases of IBS were defined according to the Rome IV Criteria in Years 9, 10, and 11 of the study. Perinatal, childhood and parental data were collected (see table) at different intervals since birth. Factors significant on univariate analysis (* in table) were analyzed using multivariable binomial regression to determine association with IBS.

Results: Our participants were predominantly males (n=431, 52.1%) of ethnic Chinese descent (n=475, 57.4%) and were delivered vaginally (n=574, 69.4%). By the 11th year of the study, 40 (4.8%) of our participants were diagnosed with IBS. Perinatal factors significantly associated with IBS include emergency intervention† (AOR: 2.74, 1.11-6.75, p<0.001), female child gender (AOR: 3.69, 1.68-8.06, p=0.001), higher birth weight

(AOR: 2.47, 1.12-5.44, p=0.025) and maternal depression (AOR: 1.12, 1.04-1.20, p=0.004). Childhood factors significantly associated with IBS include child generalized anxiety (AOR: 1.61, 1.09-2.36, p=0.016), maternal anxiety (AOR: 1.06, 1.01-1.10, p=0.008) and authoritarian parenting style (AOR: 8.75, 1.30-59.13, p=0.034).

† Emergency intervention was defined as assisted vaginal delivery or emergency Caesarean-section.

Factors	Perinatal	Childhood	Parental
Demography	Child Birth Weight* Child Gender* Child Allergies Allergic Rhinitis* Asthma* Eczema		Maternal Ethnicity Age Education* Mode of Delivery*
Questionnaires	Maternal Pregnancy Week 26 State-Trait Anxiety Inventory (STAI)* Edinburgh Postnatal Depression Scale (EPDS)* Beck's Depression Inventory (BDI-2)	Month 54 Child Behavioural Questionnaire (C-DISC)* Year 6 Lifetime Experience Questionnaire (LEQ) Year 7 Child Food Frequency Questionnaire (FFQ)* Year 10 My E-Diary for Activities and Lifestyle (MEDAL)	Maternal Post-Natal Month 3 State-Trait Anxiety Inventory (STAI)* Edinburgh Postnatal Depression Scale (EPDS)* Beck's Depression Inventory (BDI-2)* Month 54 Parenting Styles and Dimensions Questionnaire (PSDQ)*

Conclusion: In conclusion, this study provides important insights into the risk factors associated with childhood IBS. The findings suggest that early life periods, including perinatal, childhood, and parental factors, play a significant role in the development of IBS. This has significant clinical implications for identifying at-risk children and implementing targeted interventions to prevent the development of IBS. Further research is needed to validate these findings and explore potential mechanisms underlying these associations.

SPONTANEOUS UPPER ESOPHAGEAL SPHINCTER RELAXATIONS (SUERS) IN ACHALASIA

J. Aquino-Matus[1], M.F. Garcia-Cedillo[1], T. Beltre-Gonzalez[1], V. Ornelas-Arroyo[1], J. Arenas-Martinez[1], G. Torres-Villalobos[2], M.A. Valdovinos Díaz[1], E. Coss-Adame[1]

Contact E-Mail Address: enriquecossmd@gmail.com

Introduction: Upper esophageal sphincter (UES) abnormalities have been reported in 32.5% of esophageal high-resolution manometric (HRM) studies. UES relaxation is the most prevalent response during transient lower esophageal sphincter relaxation (TLSESR) and is associated with air in the reflux. Spontaneous UES relaxation (SUESR) has been reported in achalasia and cannot be explained by TLSER.

Aims & Methods: The main objeticte is to describe the frequency of SUESR in patients with achalasia, compared with patients with gastroesophageal reflux (GERD) and healthy controls. A retrospective database study including consecutive esophageal HRM studies in a seated position from 2017-2020. A SUERS was defined as an interruption of the UES (isobaric contour of 12 mmHg) in the absence of hypopharyngeal contraction within 15 s of a wet swallow.

To evaluate the dynamics of SUERS, the latency from the beginning of a wet swallow to a SUESR and its duration were measured. Additionally, a DCI tool was forced from the lower border of the UES through the upper edge of the LES and 5 s before and after a SUESR (contractile integral, CI). The maximum pressure of the UES 5 seconds before and after a SUESR was measured. GERD studies were included if a 24-hour pH monitoring reported an acid exposure time >6%, and healthy controls were extracted from the laboratory's database.

All HRMs were classified by Chicago 4.0, and a sub-analysis was performed for achalasia subtypes. Frequencies and percentages were used for categorical variables and median and interquartile ranges for continuous variables. Groups were compared with ANOVA, and a two-sided p value was calculated with a significance <0.05.

Results: A total of 179 esophageal HRM studies were included; 120 (67%) were female, the median age was 41 years (30.0-55.3), and the median BMI was 24.6 kg/m^2 (22.1-27.9). Groups were divided into achalasia (116), GERD (33), and controls (30), from which a total of 57 (30.1%) studies showed SUERS with a prevalence of 49 (42.2%), 4 (12.1%), and 4 (13.3%), respectively. No difference was found in the total number of SUESR between groups (p=0.05).

Nevertheless, a statistical difference was observed in the CI post-SUESR (p=0.01) and the UES maximum pressure pre-SUESR (p=0.02), both of which were higher in the achalasia group. Among achalasia subtypes with SUESR, type II (18) showed a higher basal UES pressure (p=0.003), CI pre-SUESR (p=0.004), CI post-SUERS (p=0.01), and UES maximum pressure post-SUERS (p=0.04) (see Table 1).

HRM finding	Total (n=49)	Type I (n=26)	Type II (n=18)	Type III (n=5)	p
Total of SUERS	3.0 (1.0-5.0)	2.0 (1.0-4.0)	3.0 (2.0-6.0)	4.0 (2.0-4.0)	0.30
Latency of SUERS (s)	8.1 (4.8-10.4)	7.7 (5.13-9.4)	9.0 (4.8-11.3)	8.2 (4.8-13.7)	0.90
Duration of SUERS (s)	0.53 (0.46-0.76)	0.52 (0.44-0.74)	0.58 (0.50-0.72)	0.69 (0.40-0.85)	0.71
CI pre-SUERS (mmHg*cm*s)	1551 (800-2663)	1476 (788-1995)	3027 (1524-4297)	871 (485-1044)	**0.004**
CI post-SUERS (mmHg*cm*s)	1074 (663-2139)	895.0 (682-1408)	2450 (1276-2741)	435 (365-1074)	**0.01**
UES maximum pressure pre-SUERS (mmHg)	215 (140-313)	213 (135-324)	222 (184-258)	212 (70-323)	0.99
UES maximum pressure post-SUERS (mmHg)	104 (64-104)	83.4 (54.8-124)	135 (105-180)	64 (58.6-175)	**0.04**

*Continuous variables are shown in median and interquartile ranges

Table 1. Esophageal HRM findings in achalasia subtypes with SUERS (n=49).*

Conclusion: A prevalence of SUESR of 42.2% was found in patients with achalasia, with higher HRM metrics in achalasia type II. This finding suggests a valve mechanism from the UES and liberation of esophageal pressurization through the SUERS. Further research is required to correlate this finding as a prognostic tool.

ESOPHAGEAL FUNCTION IMPROVES POST-LUNG TRANSPLANTATION IN PATIENTS WITH RESTRICTIVE BUT NOT OBSTRUCTIVE DISEASE

A. Alghubari[1], R. Cheah[1], S. Shah[2], A. Lee[3], K. DeVault[4], L.A. Houghton[1]
[1]University of Leeds, Division of Gastroenterology and Surgical Sciences, Leeds Institute of Medical Research, Leeds, United Kingdom, [2]Mayo Clinic, Division of Lung Failure and Transplantation, Jacksonville, United States, [3]Mayo Clinic, Division of Pulmonary, Allergy and Sleep Medicine, Jacksonville, United States, [4]Mayo Clinic, Division of Gastroenterology and Hepatology, Jacksonville, United States

Contact E-Mail Address: umafa@leeds.ac.uk
Introduction: For many patients with restrictive and obstructive lung disease the only proven intervention to improve survival and quality of life is lung transplantation (LTx). Esophageal dysmotility and gastroesophageal reflux (GER) are common in patients with respiratory disease, and often associate with worse prognosis following LTx (1,2). Which, if any patients, should be excluded from transplantation due to GER remains unclear.
Aims & Methods: Aim: To examine the changes in esophageal motor function (Chicago Classification v4.0) and association with GER following LTx in patients based on pre-LTx restrictive or obstructive lung disease.
Methods: High-resolution impedance esophageal manometry (HRIM) and 24hr impedance-pH (MII-pH) were performed in 57 respiratory patients (40 restrictive disease, 17 obstructive disease) before and after LTx (mean age 60 yrs (range 33-75 yrs), 39 males) between November 2016 and October 2022.
Results: *Restrictive disease:* Before LTx, 15 (38%) patients exhibited abnormal motility, with the majority presenting with either ineffective esophageal motility (IEM) (8, 53%) or esophagogastric junction outflow obstruction (EGJOO) (6, 40%). One patient had distal esophageal spasm and the rest (25, 63%) normal motility.
Following LTx, approximately half of patients (21, 53%) retained the same diagnosis as pre-LTx. Patients with normal motility pre-LTx were more likely to retain the same diagnosis (i.e. normal) post-LTx (17/25, 68%) than those with an abnormal motility diagnoses (4/15, 27%)(p=0.021), particularly those with EGJOO(1/6, 17%)(p=0.059). Nine of 15 (60%) patients with abnormal motility pre-LTx changed to normal motility post-LTx.
Obstructive disease: Before LTx, 8 (47%) patients exhibited abnormal motility, with the majority exhibiting EGJOO (4, 50%). The rest exhibited either IEM (2, 25%), absent motility (1, 12.5%) or hypercontractility (1, 12.5%). Nine (53%) exhibited normal motility.
Following LTx, about half (10, 59%) retained the same diagnoses, but patients with normal motility (5/9, 56%) were no more likely to retain the same diagnoses as those with abnormal motility (5/8, 63%). Only one of eight (12.5%) patients with abnormal motility changed to normal motility post-LTx, which is lower than that seen in patients with restrictive disease (p=0.07). Examination of the pH findings revealed that although acid exposure time (AET) was similar pre-LTx (restrictive 2.4(0.7-7.0) v obstructive 2.0(0.5-3.4); p=0.53), there was a decrease in AET in restrictive patients (1.7(0.3-3.5); p=0.05) but no change in patients with obstructive disease (3.7(0.6-10.1) p=0.31) post-LTx. Of note, mean nocturnal baseline impedance (5cm above the LES) was similar pre-LTx (1750(1139-2705) ohms v 1799 (1058-2540) ohms) and increased in restrictive patients (2480(1511-4413) ohms; p=0.002) but not in those with obstructive disease (1732(1173-2293) ohms; p=0.82), mirroring changes in AET.
Conclusion: Patients with restrictive lung disease are more likely to retain a diagnosis of normal motility or change to normal motility post-LTx than patients with obstructive lung disease. This appears to associate with improved acid exposure time and mean nocturnal baseline impedance. Further data are required on long-term outcome.

Introduction: POEM is an established treatment modality for achalasia cardia. Monopolar knives (MPK) are typically used for submucosal dissection as well as myotomy during POEM. More recently, a novel bipolar device (BPD) is commercially available for endoscopic dissection and resection procedures.
Aims & Methods: In this study, we aim to compare the performance of MPK with BPD during POEM. This is a prospective, multicenter cohort study including consecutive cases with achalasia cardia who underwent POEM using conventional MPK or a novel BPD from Dec 2019 to Jan 2023. The primary aim of the study was to evaluate the requirement for accessory exchange during POEM procedure.
The secondary objectives included technical success, procedure time, adverse events, post-procedure pain and clinical success (Eckardt≤3). Post-operative pain scores were assessed on the day of procedure and first post-operative day using a standardized scale i.e. visual analog scale (VAS). The severity of pain was graded as mild (0-30), moderate (>30-70) and severe (>70).
Results: 278 cases (40.9y, 162 males) with achalasia underwent POEM using either a monopolar knife (n=220) or bipolar device (n=58). All the procedures were performed by posterior route (5 O'clock). Median exchange of accessories was significantly lower in the BPD group [3 (2-8) vs 1 (1-2), p=0.001). The use of coagulation forceps for hemostasis or pre-coagulation was significantly less in the BPD group [1(0-6) vs 0(0-1), p=0.001]. There was no difference in technical success, procedure duration and adverse

events between the two groups. Post-operative pain was significantly less in the BPD group [40(20-90) vs 40 (20-80), p=0.021]. The proportion of cases with moderate to severe post-operative pain was significantly higher in the MPK group (79.6% vs 56.9%, p=0.001). (Table 1)

	Monopolar knife (N=220)	Bipolar device (n-58)	p
Technical success (%)	220 (100)	57 (98.3)	0.209
Mean procedure time, min (SD)	52.5 (16.3)	50.9 (18.7)	0.523
Exchange of accessories, median (range)	3 (2-8)	1 (1-2)	0.001
Use of coagulation forceps, median (range)	1 (0-6)	0 (0-1)	0.001
Pain score, median (range)	40 (20-90)	40 (20-80)	0.021
Pain severity (%)			
Mild	45 (20.5)	25 (43.1)	0.001
Moderate	168 (76.4)	32 (55.2)	0.003
Severe	7 (3.2)	1 (1.7)	1.000
Adverse events (%)	18 (8.2)	6 (10.3)	0.602
Mucosal injuries	5	1	
Capnoperitoneum	13	4	
Pleural effusion	0	1	

Table 1. Comparison of technical and clinical outcomes between the two groups.

Conclusion: The novel BPD is safe and effective for performing POEM procedures with the added advantage of minimum exchange of accessories and reduced post-operative pain as compared to MPK.

Contact E-Mail Address: nicola.debortoli@unipi.it

Introduction: Provocative maneuvers are increasingly being performed during esophageal high-resolution manometry (HRM) in an attempt to increase the yield of the test. Recently, straight leg raise maneuver (SLR) (i.e., wet swallow with raised straight legs in supine position) has been proposed as a novel provocative test to evaluate esophageal reflux barrier and contraction reserve (CR) (i.e., augmentation of the esophageal contractile vigor following multiple rapid swallows, MRS). The rationale is that SLR augments intra-abdominal pressure, which has been shown to augment the contractile vigor of the esophagus.

Aims & Methods: The primary aim of this study was to investigate the relationship between the CR after multiple rapid swallows (MRS) and contractile vigor following SLR (i.e., obstructive stress reserve, OSR) in patients with normal esophageal manometry compared to those with ineffective esophageal motility (IEM). The secondary aim was to assess the characteristics of OSR in patients referred for gastroesophageal reflux disease (GERD) symptoms with normal manometry compared to those with IEM.

Between Nov 2021-Sep 2022, consecutive patients reporting GERD symptoms who underwent high-resolution manometry (HRM) were enrolled in two different esophageal centers (Pisa and Milano). GERD symptoms, height, and weight were recorded for all patients. Distal contractile integral (DCI) was analyzed during single water swallows (SS) (10 × 5 mL), MRS (3 × 2 mL), and SLR (2x5 mL). Preserved esophageal CR was defined as MRS/SS ratio was >1. Preserved OSR was defined as SLR/SS ratio >1. Data comparisons were performed using the independent sample t-test or the chi-square test, as appropriate. Pearson's correlation coefficient was used to investigate the correlation between the DCI following MRS and DCI during SLR in patients with normal peristalsis (group Normal) and IEM (Group IEM).

Results: 242 patients (145 female, mean age: 53.7±14.8 years) were enrolled. Heartburn was reported as the main symptom in 165/242 (68.2%) patients and mean BMI 23.5±6.3. Esophageal HRM was normal in 196/242 (81%) patients (122 female, mean age 54.6±14.7yrs and mean BMI 23.6±6.7) and IEM was detected in 46/242 (19%) patients (23 female; 52.9±15.4yrs and mean BMI 22.9±4.9) patients (p=NS). All detail of manometric tests was reported in Table 1.

Esophageal CR was observed during MRS in 110/196 (56.1%) in the normal HRM group and 25/46 (54.3%) (p=0.87) in the IEM group and OSR was seen in 131/196 (66.8%) and 31/46 (67.4%) (p>0.99) in IEM following SLR. The DCI response following MRS correlated with the DCI response following SLR. Pearson's correlation coefficient was 0.479 (p < 0.01).

	HRM normal (196)	IEM (46)	p
EGJ type 3	26	6	0.061
EGJ-CI	50.5±28.9	43.9±30.4	0.169
DCI mean (ss)	1622.5±935.9	449.3±451.3	<0.001
Ineffective (failed) mean	15 (5)	85 (35)	<0.001
DCI mean (MRS)	2103.4±1753.1	778.5±1124.8	<0.001
MRS/SS ratio	1.4±1.4	1.7±1.8	0.218
DCI mean (SLR)	3347.1±2456.5	1647.2±2521.8	<0.001
SLR/SS ratio	2.4±1.8	3±2.6	0.014

Table 1: High Resolution Manometry in patients with Normal HRM group and IEM group.

Conclusion: Swallowing against the resistance of increased intra-abdominal pressure from SLR improves esophageal body peristaltic performance and predicts esophageal body CR. The DCI response following SLR in patients with GERD is comparable to the DCI response after SS and MRS.

PP0058

EFFECT OF HIATAL HERNIA AND ESOPHAGOGASTRIC JUNCTION MORPHOLOGY ON OESOPHAGEAL MOTILITY. NEW EVIDENCES FROM HIGH RESOLUTION MANOMETRY

S. Kayali[1], F. Calabrese[1], C. Facchini[1], E. Marabotto[1], M. Furnari[1], G. Bodini[1], G. Pieri[2], E.G. Giannini[1], P. Zentilin[1]
[1]University of Genoa, Gastroenterology Unit, Department of Internal Medicine, Ospedale IRCCS Policlinico San Martino, Genoa, Italy, [2]Ospedale IRCCS Policlinico San Martino, Genoa, Italy

Contact E-Mail Address: calabrese.francesco.93@gmail.com

Introduction: High-Resolution Manometry (HRM) is the most sensitive and specific test available for clinical assessment of hiatal hernia (HH), a common condition defined as the separation between the Lower Esophageal Sphincter (LES) and crural diaphragm (CD). While the link between HH and Gastroesophageal Reflux Disease (GERD) is established, the potential role of Hiatal Hernia in inducing oesophageal dismotility, independently form GERD, is uncertain.

Aims & Methods: We aimed to analyze whether the presence of HH, with or without GERD, is able to alter the oesophageal motility, in terms of Ineffective Peristalsis (IP), Jackhammer Esophagus (JE) or Outflow Obstruction (OO). Consecutive patients without previous esophageal surgery who underwent HRM between 2018 and 2022 were enrolled (56.8% females; mean age 57 years, CI 47 – 69; BMI 24.2, CI 21.5 – 26.8).

All patients with symptoms suspicious for GERD underwent impedance-pH testing off-therapy. HH was defined as a separation > 1 cm between LES and CD and esophagogastric junction (EGJ) morphology was classified as: Type I, no separation between LES and CD; Type II, minimal separation (>1 and <2 cm); Type III, ≥ 2 cm separation. Demographic characteristics collected included: age, gender, alcohol and coffee intake, smoke habits, GERD diagnosis and symptoms duration.

Two cohorts of patients, with and without HH, were individuated and the potential association with ineffective peristalsis, jackhammer esophagus and outflow obstruction was analyzed with univariate and multivariate logistic regressions.

Results: Eight-hundred-forty-eight patients were enrolled and 295 cases of HH (38.8%), subdivided in 199 (23.5%) Type II- and 96 (11.3%) Type III-EGJ patients were identified. Ineffective peristalsis was diagnosed in 162 (19.1 %) patients, jackhammer oesophagus in 32 (3.8 %), and outflow obstruction in 91 (10.7 %), while GERD was present in 473 (55.8%) patients. HH was significantly associated with ineffective peristalsis (P<0.001) and GERD (P<0.001).

Furthermore, HH resulted a risk factor for ineffective peristalsis (OR = 1.60, 95%CI 1.12-2.27, P<0.001) when the analysis was conducted in both all the 848 subjects and in patients without GERD (OR = 1.84, 95%CI 1.05-3.21, P=0.03). The risk for ineffective peristalsis was 1.3 time greater for every centimeter of HH. No statistically significant association was found between HH and outflow obstruction or jackhammer esophagus.

Conclusion: Increasing separation between LES and CD can cause a gradual and significant increasing risk of ineffective peristalsis. Interestingly, this association with HH is true not only in patients with but also in those without GERD. These results suggest that EGJ morphology seems to be able to alter esophageal motility as measured with High-Resolution Manometry.

ESOPHAGEAL CLEARANCE DETERMINED BY HIGH RESOLUTION IMPEDANCE MANOMETRY IN ACHALASIA : A NEW STANDARD?

F. Grousez[1], F. Zerbib[1], B. Vauquelin[1], M. Saunier[1], P. Riviere[1], A. Berger[1]
[1]Centre Hospitalier Universitaire de Bordeaux / Hopital du Haut Lévêque, Service d'Hépato-Gastro-Entérologie, Pessac, France

Contact E-Mail Address: grousez.florian@gmail.com

Introduction: Outcome after treatment of achalasia is usually assessed by the Eckardt score (ES). The timed barium esophagogram (TBE) is used to objectively assess esophageal clearance after treatment. High-resolution manometry with impedancemetry (HRiM) provides information on esophageal clearance of liquids in addition to motility parameters.

The aim of this study was to compare esophageal clearance determined by HRiM and TBE in patients with achalasia treated by POEM.

Aims & Methods: Consecutive patients treated with POEM had pre and post-POEM assessment with ES, TBE, and HRiM. Treatment failure was defined by an ES > 3 at 3 months post-POEM. Incomplete esophageal clearance (IEC) was defined by the presence of an esophageal stasis > 2 cm at 5 minutes in HRiM and/or TBE. All of the data available pre and post-POEM at 3 months was pooled for analysis. The correlation between ES, TBE and HRiM was evaluated by Spearman's method.

Results: Fifty patients with a median age of 65 years (23-84) were included in this study (85% with type 2 achalasia). The clinical response rate at 3 months was 94%. TBEM/HRiM results were available in (29/33) pre-POEM patients and (43/46) post-POEM patients at 3 months.

Overall, an IEC was found in 91% on TBE and in 50.8% on HRiM. The correlation between the ES and IEC in HRiM and TBE were respectively 0.66 and 0.31. The correlation between esophageal clearance values between TBE and HRIM was low (r=0.375). At 3 months after POEM, IEC was present in 90.7% and 21.7% for TBE and HRiM, respectively (p<0.001). In univariate and multivariate analysis, only IEC in HRiM was significantly associated with ES > 3 (RR = 17.0 (p < 0.001)). The HRiM AUC was 0.872 vs. 0.707 for the TBE (p<0.001). The diagnostic performance of HRiM to predict an ES > 3 was Se: 85%; Sp: 77%; PPV: 74%; NPV: 87% vs. Se: 95%; Sp: 11%; PPV: 42%; NPV: 83% for the TBE. Data at one year will be available for the presentation.

Conclusion: In achalasia, the evaluation of esophageal clearance by HRiM is better correlated with ES than TBE and may be a relevant criterion for pre and post-therapeutic evaluation. Additional studies are underway to validate the relevance of this parameter more specifically in the evaluation of treatments for esophageal achalasia.

Introduction: Oesophageal achalasia is a motility disorder characterized by the lack of relaxation of the lower oesophageal sphincter and absence of normal oesophageal motility. Among endoscopic techniques to treat achalasia, highlight peroral oesophageal endoscopic miotomy (POEM) and endoscopic balloon dilatation (ED).

Some studies demonstrate that ED could achieve similar results to traditional surgical technique (Heller miotomy). However, studies comparing POEM and repeated ED protocols are lacking.

Aims & Methods: Objectives: To compare manometric and clinical data from a group of patients with achalasia treated with a 2-session endoscopic dilatation protocol (EDx2) vs POEM.

Material and Methods: We performed a retrospective review of oesophageal high-resolution manometry (HRM) and clinical records of patients with achalasia treated with EDx2 (30 and 35 mm balloon separated by 2 weeks) or POEM.

Only patients with pre and post-treatment HRM were included. Data regarding epidemiological (age, sex), clinical (Eckardt score, complications) and HRM (integrated relaxation pressure, achalasia subtype, rapid drink challenge) were recorded. Technical success was defined as post-treatment IRP < 15 mmHg, clinical success was defined as post-treatment Eckardt score < 3 points, and global success when both conditions were present

Results: Sixty-one patients were included, 32 treated with EDx2 and 29 with POEM. Of those, 67% were type II, 20% type III and 13% type I achalasia. Main baseline characteristics were similar between groups except for a higher baseline Eckardt score in POEM.

Both techniques show similar results regarding technical success (69% DB vs 86% POEM, p=ns), clinical success (93 DB vs 93% POEM, p=ns) and overall success (61% DB vs 79% POEM, p=ns). However, when analysing the success according to subgroups of achalasia, we found a trend to greater overall success with POEM in type III achalasia (EDx2 33% vs POEM 100%, p=0.06).

No differences were found between both techniques in overall success for type II (68% DB vs 79% POEM, p=ns) and type I (67% DB vs 60% POEM, p=ns) achalasia.

Conclusion: A 2-session endoscopic dilatation protocol achieved therapeutic success similar to POEM in type I and type II achalasia. In type III achalasia, POEM seems superior to endoscopic dilatation.

HIGH RESOLUTION ESOPHAGEAL MANOMETRY (HREM) - UPRIGHT OR SUPINE, IS THERE A DIFFERENCE?

C. Chia[1], J. Kuang[1], C. Khoon Beng[1]

[1]Tan Tock Seng Hospital Dept. of Gastroenterology, Gastroenterology & Hepatology, Singapore, Singapore

Contact E-Mail Address: tzechris@gmail.com

Introduction: Based on the Chicago classification, HREM diagnosis is classically based on metrics obtained with wet swallows carried out in the supine position. However, both patients and physicians often feel that this is not a physiological position to conduct the test as it may not translate to the real world experience. With the patient in the upright/sitting position, the test would more closely simulate real-life behaviour and may be safer for elderly patients at risk of aspiration.

Aims & Methods: In an Asian tertiary centre, a total of 104 patients had undergone high resolution esophageal manometry (HREM) with retrospective data analysis comparing both conventional supine position with the upright position. The latter is generally favoured by all patients as this represents the physiological posture during meals.

Results: Using 2-tailed paired sample T-test, comparison across all cases showed a consistently lower median Integrated Relaxation Pressure (IRP) [6.0 mmHg vs to 8.7 mmHg; p <0.01] and lower mean Distal Contractile Integral (DCI) [1463 mmHg/cm/sec vs 1864 mmHg/cm/sec; p =0.014] in the upright posture compared to supine position although the mean Distal Latency (DL) difference was not significant [6.21secs vs 6.27 secs; p =0.491].

During upright and supine position comparison respectively, subgroup analysis on subjects with normal HREM diagnosis showed even lower median IRP [4.9 mmHg vs 7.5 mmHg; p <0.01] and lower mean DCI results [1436 mmHg/cm/sec vs 1695 mmHg/cm/sec; p <0.01] with mean DL in this subgroup showing no significant statistical difference [6.29 secs vs 6.38secs; p=0.545].

The final HREM diagnosis in upright position is concordant with the conventional supine position up to 81.7% and showed an even higher concordance in terms of management similarity up to 98.1%. Only 2 cases (2/104) showed a significant discordance between supine and upright HREM diagnosis [normal HREM vs esophagogastric juntion –outflow obstruction(EGJ-OO) and hypercontractile esophagus vs normal HREM]. Minor diagnostic discordance [normal HREM vs ineffective esophageal motility (IEM)] was noted in 17/104 cases which had no major clinical impact on patients and may be overcome by adopting a lower cut-off for mean DCI for upright group.

Conclusion: In patients who are unable to perform HREM in supine position, adopting the upright position shows a high clinical concordance and may be considered a more physiological approach in the HREM protocol.

Contact E-Mail Address: piyakorn@g.swu.ac.th

Introduction: Limited studies have described changes in esophageal manometry patterns after achalasia treatment.

Aims & Methods: Aims: To describe manometric changes and determine factors associated with post-treatment peristalsis return.

Methods: Ninety-one consecutive patients with achalasia [60F, age 47±16 years, 34 with type I, 46 with type II, 11 with type III] were included in the study and underwent high-resolution esophageal manometry (Manoscan, MN, USA) in the upright position before and 1-3 months after treatment [pneumatic balloon dilation (n=60) or per-oral endoscopic myotomy (n=31)]. Post-treatment peristalsis was classified as normal, weak, and premature contraction according to the Chicago classification v.4.0. Clinical characteristics were recorded.

Results: Nine patients (9.9%) had post-treatment peristalsis return with average prevalence of 5(2-5) times in 10 wet swallows. Of the 40 peristalsis returns, there was no instances of peristalsis with normal contraction vigor (distal contractile integral, DCI 450-8000 mmHg•s•cm) and normal distal latency (>4.5s). 17(42.5%) returns had normal contraction vigor with premature contraction and 23(57.5%) had weak contraction. Of these weak contractions, only 1 contraction had a normal distal latency, while 22 contractions had a short distal latency. The patients with post-treatment peristalsis had a median Eckardt score of 0 (0-1) with a median global symptom improvement of 85(80-96%). Age, gender, BMI, achalasia subtype, treatment type, baseline basal lower esophageal sphincter pressure, baseline median IRP, and treatment outcomes were not significantly different between patients with and without peristalsis return.

	A1	A2	A3	A4	A5	A6	A7	A8	A9
Age	58	17	56	59	36	65	60	49	37
Gender	F	F	M	F	F	F	F	F	F
Pre-treatment type	1	2	2	2	1	1	2/3	2	2/3
Procedure	PD	POEM	POEM	POEM	PD	PD	POEM	PD	POEM
Pre-treatment Median IRP	39.45	22.55	23.45	35.15	20.85	25.6	8.5	35.85	33.35
Post-treatment Median IRP	12.35	6.25	29.15	50	16.95	17.1	10.45*	4.8	17.9
Number of peristalsis	10/10	6/10	3/10	3/10	5/10	1/10	4/10	5/10	3/10
Post treatment Eckardt score	0	0	0	0	2	0	1	0	7
Global symptom improvement	95%	100%	80%	100%	60%	80%	90%	100%	80%

* High intragastric pressure

Conclusion: The study found that post-treatment peristalsis recovery with weak and premature contractions occurred in 10% of patients with achalasia and was not significantly associated with clinical or manometric factors or short-term treatment outcomes.

Disclosure: Nothing to disclose.

SALVAGE PERORAL ENDOSCOPIC MYOTOMY IS A PROMISING TREATMENT FOR ACHALASIA FOLLOWING A MYOTOMY FAILURE

Z. Zhang[1,2], Q. Li[1,2], P. Zhou[1,2]
[1]Zhongshan Hospital, Fudan University, Endoscopy Center and Endoscopy Research Institute, Shanghai, China, [2]Shanghai Collaborative Innovation Center of Endoscopy, Shanghai, China

Contact E-Mail Address: zczhang15@fudan.edu.cn

Introduction: Reintervention modalities following myotomy failure in achalasia patients have yet to be established. The efficacy and safety of salvage peroral endoscopic myotomy (POEM) for treatment of achalasia following a myotomy failure were evaluated in the study.

Aims & Methods: Between August 2011 to August 2021, at the Endoscopy Center of Zhongshan Hospital, 219 achalasia patients who had previously undergone a myotomy underwent a salvage POEM and were thus retrospectively enrolled in this study. After propensity score matching (PSM), operation-related parameters were compared between the salvage POEM group and the naïve POEM group. Subgroup analysis was performed between patients with previous heller myotomy (HM) and patients with previous POEM.

Results: With similar baseline characteristics between both groups after PSM, the salvage POEM group presented with shorter tunnel length (11.8±2.2 *vs.* 12.8±0.9, $p<0.0001$) and myotomy length (9.8±2.0 *vs.* 10.4±1.0, $p<0.0001$) than the naïve POEM group. There were no significant differences in procedure-related adverse events (AEs) between patients of salvage POEM and naïve POEM.

The primary outcome of treatment success occurred in 175 of 193 patients (90.7%) in salvage POEM group *vs.* 362 of 374 patients (96.8%) in naïve POEM group ($p = 0.0046$).

Significantly higher rate of clinical failures were observed at the 2-year and 5-year follow-ups in the previous HM subgroup than the previous POEM subgroup ($p = 0.0433$, $p = 0.0230$, respectively).

Conclusion: Salvage POEM following a previous myotomy failure, especially after POEM failure, is a promising treatment option as it has a durable clinical relief rate.

Disclosure: Nothing to disclose.

EFFICACY EVALUATION OF PERORAL ENDOSCOPIC MYOTOMY USING 320-ROW AREA DETECTOR COMPUTED TOMOGRAPHY

H. Tomida[1], Y. Tanabe[2], H. Nishiyama[2], Y. Hashimoto[1], K. Shiraishi[1], K. Tange[1], Y. Yamamoto[1], E. Takeshita[1], Y. Ikeda[1], T. Kido[2], Y. Hiasa[1]

Contact E-Mail Address: hideomi.tomida.epch@hotmail.com

Introduction: Per-oral endoscopic myotomy (POEM) for esophageal achalasia and related diseases is widely performed worldwide because of its effectiveness and low invasiveness. The Eckardt score is often used as a method to evaluate the therapeutic effect of POEM, but it is a subjective evaluation of the patient and has a drawback of poor objectivity.

Conventional barium swallow can observe esophageal dynamics in real time, but it is a two-dimensional image evaluation, and it is difficult to ad-

equately assess the esophageal volume and luminal area. High resolution manometry (HRM) also provides a detailed view of esophageal contractions but does not accurately assess esophageal dynamics.

Aims & Methods: To verify the effectiveness of POEM, we performed 4D analysis using 320-row area detector computed tomography (320-ADCT), adding time axis to the 3D image, and evaluated the steric movement of the esophagus. Images were created by sitting in a Fowler's position at approximately 45 degrees on a 320-ADCT table and taking continuous images for 10 seconds at the same time as the start of contrast swallowing.

Among patients who underwent POEM in our hospital from December 2020 to May 2022, 22 patients with disorders of EGJ outflow (achalasia and EGJOO) were included. 320-ACDT images were taken before and after POEM to assess the maximum esophageal diameter and esophageal lumen area at the lower esophageal sphincter (LES). Esophageal emptying was evaluated by calculating the time integral to the esophageal internal volume.

Results: The median age of the patients was 58 years (18 -87), with 11 males and 11 females. The disease was type I achalasia in nine patients, type II achalasia in eight, type III achalasia in one, and EGJOO in four. POEM was completed in all patients, and the median Eckardt scores decreased from 7 to 1 ($p < 0.001$).

On HRM, integrated relaxation pressure (mmHg) decreased significantly from 30.5 to 9 and LES pressure (esleeve) (mmHg) decreased from 46.1 to 16.7 ($p < 0.001$). In the 320-ADCT images, the maximum esophageal diameter (mm) at the LES level significantly increased from 2.1 to 7.7 and the maximum esophageal area (mm^2) from 2 to 23 before and after POEM ($p < 0.001$).

The volume time integral (ml-s) decreased significantly from 602 to 82 ($p < 0.001$), indicating an improvement in esophageal emptying. In the comparison of esophageal type I achalasia and type II achalasia, the rate of decrease in volume time integral was significantly lower in type I achalasia (44% vs 85%, $p = 0.027$).

When comparing patients with and without gastroesophageal reflux disease (GERD) after POEM, there was no difference in the length of the myotomy, but in patients with GERD, the amount of extension from resting to maximum at the LES level of the esophagus was significantly greater in both esophageal diameter (7 mm vs 4 mm, $p = 0.048$) and esophageal area (25 mm^2 vs 9 mm^2, $p = 0.006$).

Conclusion: The improvement of esophageal distensibility at LES level and esophageal emptying by POEM could be evaluated objectively by esophageal 4D analysis using 320-ADCT. The extent of esophageal distensibility at the LES level was also determined as a risk of post-POEM GERD. 4D analysis with 320-ADCT may be a new tool to assess esophageal motility.

Disclosure: Nothing to disclose.

ENDOLUMINAL FUNCTIONAL LUMINAL IMAGING PROBE IS SUPERIOR TO MANOMETRY IN ASSESSING PREVIOUSLY TREATED ACHALASIA PATIENTS WITH SYMPTOM RECURRENCE

T. Voulgaris[1], H. Ayubi[1], O. Olabintan[1], M.-A. Noreillie[1], M. Patel[1], S. Thrumurthy[1], S. Gulati[1], A. Haji[1], B. Hayee[1]

[1]King's College Hospital, King's Institute of Therapeutic Endoscopy, London, United Kingdom

Contact E-Mail Address: homira.ayubi@gmail.com

Introduction: There are no agreed guidelines to inform the approach to previously-treated achalasia patients presenting with recurrent symptoms. The decision to proceed to re-intervention is often based mainly on the clinical presentation and data arising from barium swallow studies and upper gastrointestinal endoscopy.

Aims & Methods: We evaluated Endoluminal functional luminal imaging probe (EndoFLIP) and High Resolution Manometry (HRM) value in such a setting. We selected patients from a prospectively-kept database with previously-treated achalasia (including Per Oral Esophageal Myotomy (POEM), Heller myotomy (LHM), pneumatic balloon dilatation (PBD) and botulinum toxin injection (BTX; only if submitted the last six months) presenting with symptom recurrence during an 8-year period (11/2015-2/2023).

Only those with assessable EndoFLIP data (distensibility index (DI) at 40ml balloon inflation volume) and planned for re-intervention with POEM according to clinical judgment were included in the study. Baseline data were analyzed retrospectively. Consecutive naïve-to-treatment patients formed the control group.

Results: N=70 patients (25 treated vs 45 naïve) were included in the study (F=38; mean age 43 (17-78yrs). The majority of patients were previously submitted to pneumatic balloon dilatation (n=13), 5 were submitted to POEM A to Heller myotomy and 3 had botox treatment during the last six months before assessment.

Table 1 lists the main demographic and investigative parameters. DI of treated patients was significantly decreased among patients without barium clearance at 5 min (1.8±0.9 vs 2.5±1.6, p=0.017) and was correlated to height of barium column (r=-0.439, p=0.015), fact not observed for IRP (29.1±13.5 vs 21.5±8.8, p=0.017 and r=0.266, p=0.319, respectively). DI was not correlated to IRP4s in treated patients (r=-0.168, p=0.374) in comparison to naïve (r=-0.227, p=0.046). Neither DI, IRP, nor barium column at 5 min were correlated to patients Eckardt score among treated patients (p=0.494, p=0.998, p=0.734 respectively).

	Previously treated	Treatment-naive	p
Male:Female	25/20	13/12	0.807
Manometric sub-type (1, 2, 3)			
1 vs 2	10/13	11/28	0.271
1 vs 3	10/1	11/1	1.000
2 vs 3	13/1	28/1	1.000
Unclassified/classified	1/25	5/40	0.410
Positive barium swallow signs	(20/22) 90.9[HB1] %	(31/37) 83.3%	0.362
Delayed clearance of barium at 5 mins	(25/34) 73.5%	(14/19) 73.7%	0.551
Height of barium standing column (cm)	5.3± 6.0	4.2±4.6	0.551
Mean IRP4s (mmHg)	21.1 ± 12.6	27.9±11.3mm	0.06
IRPs 4s <15mmHg	(4/15) 26.7[HB2] %	(2/39) 5.1%	0.04
Mean DI	2.6±1.6	1.8±1.0	0.017

Table 1.

Conclusion: DI is impaired and correlated to height of barium swallow in 5 minutes in previously treated achalasia patients presenting with symptom recurrence and can be used as an objective metric to tailor re-intervention in conjunction to barium swallow. DI is significantly reduced among treated in comparison to naïve achalasia patients. HRM cannot with certainty navigate treatment decisions in approximately half of treated patients. Future studies that may define specific diagnostic DI cut-offs for patients with recurrence of achalasia symptoms needing re-intervention are needed.

Disclosure: Nothing to disclose.

Introduction: Untreated symptomatic achalasia leads to decreased caloric intake due to adjustment of the composition of the diet to impaired esophageal emptying. Peroral endoscopic myotomy (POEM) provides reversion of normal eating pattern with consequent weight gain.

We performed in-depth analysis of the metabolomic composition of blood plasma before POEM and the composition of the gained tissue mass 3 months after POEM using nuclear magnetic resonance spectroscopy and bioimpedance scale.

Aims & Methods: Consecutive patients with symptomatic untreated achalasia were included in the study. At the first visit (hospital admission due to POEM procedure), we evaluated Eckardt score, obtained blood metabolomics using nuclear magnetic resonance (NMR) spectroscopy and nutrition-related parameters obtained using bioimpedance scale (body weight, muscle and fat weight). At the second visit 3 months after the POEM procedure, the same NMR metabolomic and nutritional parameters were obtained.

Results: 43 patients (22M/21F) were included in the study. The symptoms significantly improved 3 months after the POEM procedure (Eckardt score 6.86±1,92 vs. 0,71±0,77, p<0.0001). The average overall weight gain was 5,58±5,05 kg, average fat gain was 1,77±3,33 kg and average muscle gain was 1,33±4,78kg. We also determined the difference in the muscle and fat contribution to the weight of the patient (pre and post POEM, expressed in %). We performed correlation analyses between the amount of amino acids before POEM and the gain of the muscle weight and fat weight.

We observed that the individual levels of branched chain amino acids (valine, leucine, isoleucine) (BCAA), their keto acids (ketovaline, ketoleucine, ketoisoleucine) and levels of glutamine, histidine and lysine before POEM were positively correlated with the % of muscle gain (p values in range 0.03-0.0004) and inversely correlated with the % of fat gain (p values in range 0.01-0.00001, Pearson correlation).

Conclusion: Our analysis revealed that post POEM muscle mass gain is directly correlated to the amount of proteogenic amino acids in circulation before the intervention. The level of BCAA before POEM showed consistent positive correlation to the increase of the muscle mass 3 months after POEM.

This finding could further serve as a guidance for nutrition strategies in patients with yet untreated achalasia and also in the broader spectrum of patients with impaired caloric intake. We suggest that achalasia could serve as a study model for metabolic changes related to restored normal dietary pattern. Supported by VEGA 1/0060/23.

Introduction: Peroral endoscopic myotomy (POEM) has become the mainstay of treatment of oesophageal achalasia in adult patients and recently also gained acceptance as effective therapy of achalasia in paediatric population. Here we retrospectively reviewed prospectively collected children with achalasia that had been treated with POEM at our institution.

Aims & Methods: Patients that were hospitalized in the Paediatric Clinic for POEM procedure from 11/2017 to 05/2023 were included. All patients had achalasia confirmed by high resolution manometry (HRM). We evaluated their symptoms in terms of duration and intensity (Eckardt score) and the integrated relaxation pressure (IRP) obtained by HRM before POEM. 3 months after POEM during the follow-up visit we determined Eckardt score, IRP and the presence of reflux oesophagitis on upper endoscopy. When finalizing the abstract we conducted a brief telephone survey to determine Eckardt score and presence of reflux symptoms.

Results: 10 patients (6 boys and 4 girls), mean age 11.5 (5-18) years were included. 9 of these patients received POEM as their first therapy for achalasia, 1 patient had been previously treated surgically via thoracotomy. The median of the duration of symptoms was 8.5 (range 1-36) months. All patients were diagnosed with type I achalasia according to Chicago classification. Eckardt score decreased significantly 3 months after POEM (7.38±1.68 vs. 0.63±1.06 before and after POEM, respectively, p<0.0001) and sustained unchanged (0.4±0.66) during the median follow-up of 21.5 months (range 1-60 months). IRP also significantly decreased after the intervention (46.5±11.1 mmHg vs. 3.8±5.68 mmHg; before and after POEM, respectively, p=0.0001).

Complications occurred in 2 patients. Pleuropneumonia in one patient led to extension of hospital stay and was solved conservatively. Upper GI bleeding occurred in one patient 2 weeks after discharge, was self-limited without any obvious source found. Follow-up endoscopy was performed off PPI therapy and revealed mild esophagitis (LA A) in 2 patients that also reported mild heartburn.

Conclusion: POEM represents an effective therapy for achalasia in paediatric population in mid-term follow-up as it significantly improves symptom and provides effective decrease of the IRP. Although in our case series no severe heartburn or reflux esophagitis occurred, more data with longer follow up are needed to prove either long-term safety with regard to the reflux issue and the need for long term PPI therapy in these patients. Supported by VEGA 1/0060/23.

Introduction: According to Chicago Classification version 4.0 a diagnosis of absent contractility and esophagogastric junction outflow obstruction (EGJOO) during high-resolution manometry (HRM), are both considered inconclusive diagnoses of achalasia, thus requiring presence of relevant symptoms such as dysphagia, and additional supportive tests, including timed barium esophagram (TBE) or functional lumen imaging probe (FLIP), in order to confirm the presence of achalasia and treat accordingly.

Aims & Methods: Aim: To evaluate the clinical utility of TBE and FLIP to further confirm diagnosis of achalasia in patients with inconclusive diagnosis of achalasia per HRM.

Methods: We conducted a retrospective study in patients referred for evaluation of dysphagia from December 2021 until December 2022 . Patients completed an upper gastrointestinal endoscopy and HRM per Chicago classification v.4.0. Those patients with an inconclusive diagnosis of achalasia during HRM, either absent contractility or EGJOO, followed by additional assessment with TBE and/or FLIP were included. Patients with anatomic lesions of the esophagus (i.e Schatzki ring, esophageal diverticula), esophageal surgery and chest radiotherapy were excluded.

Results: A total of 101 consecutive patients were referred for evaluation and 29 patients were included for analysis. Median age was 71 (p=0.58) and 65.51% of the patients were female (p=0.1). Of the 29 patients who had an HRM diagnosis of inconclusive achalasia, 55.17 % had absent contractility and 44.82% were diagnosed with EGJOO. After completing a TBE, 28.68 % of those patients had an abnormal result (delayed TBE). There was a significant correlation between an inconclusive diagnosis of achalasia per HRM and delayed TBE (OR 3.83 95 % CI [1.36-10.79], p=0.001). Furthermore, diagnosis of EGJOO was significantly correlated with esophageal stasis and delayed TBE (p=0.025).

Additionally, we found a significant correlation between inconclusive diagnosis of achalasia and confirmation of achalasia with FLIP in one patient (p=0.0008). All patients were referred for achalasia-treatments.

Conclusion: Patients classified as inconclusive diagnosis of achalasia during HRM benefit from additional supportive testing with TBE to confirm the presence of achalasia, therefore, provide treatment.

Disclosure: Nothing to disclose.

Contact E-Mail Address: tiagolimacapela@gmail.com

Introduction: Evidence is scarce regarding the impact of overweight and obesity on the interpretation of high-resolution esophageal manometry (HREM) parameters. We aimed to investigate whether the presence of overweight and/or obesity influences the HREM parameters.

Aims & Methods: Retrospective cohort study including adult patients undergoing HREM (Manoscan® 36-sensor probe) between 2019-2022, regardless of the indication, with measurement of height and weight at the time of HREM. A HREM diagnosis was obtained according to the Chicago 4.0 classification and the following HREM parameters were collected: esophageal length, length and type of esophagogastric junction (EGJ), presence and extent of hiatal hernia, minimum basal, mean and residual lower esophageal sphincter pressures, basal and residual upper esophageal sphincter pressures, percentage of failed, weak, ineffective, with pressurization, premature, fragmented, intact, hypercontractile swallows and mean and after multiple rapid swallows distal contractile integral.

Body mass index (BMI) was calculated, and patients were categorized as underweight (<18.5), normal weight (18.5-24.9), overweight (25-29.9) and obesity (≥30). The relationship between BMI and its categories with the HREM parameters was evaluated.

Results: A total of 249 patients were included, mostly women (59.8%) with a mean age of 56 ± 14 years. The median BMI was 26 (IQR 5) kg/m2 and 115 (46.2%) patients were overweight, 91 (45.7%) normal weight and 43 (17.3%) obese. A normal HREM (51.8%), followed by ineffective esophageal motility (21.7%) and EGJ outflow obstruction (8.8%) were the most frequent HREM diagnoses. There were no statistically significant differences between the presence of overweight and/or obesity and the HREM parameters evaluated, regardless of the HREM diagnosis.

Conclusion: Overweight and obesity do not seem to influence HREM parameters, so its interpretation should not be influenced by these factors.

Disclosure: Nothing to disclose.

INTEGRATED RELAXATION PRESSURE ON HIGH RESOLUTION MANOMETRY DIFFERS BETWEEN MEASUREMENT ACROSS LOWER ESOPHAGEAL SPHINCTER ALONE VS. CRURAL DIAPHRAGM IN THE PRESENCE OF A HIATUS HERNIA

D. Parekh[1], S. Zarro[2], J. Luther[2], B. Rogers[3], CP. Gyawali[4]

Contact E-Mail Address: dparekh2108@gmail.com

Introduction: An intact esophagogastric junction (EGJ) barrier consists of the lower esophageal sphincter (LES) in the same anatomical plane as the crural diaphragm (CD). When there is separation between the planes of the LES and the CD, the morphology of the EGJ is disrupted, and a hiatus hernia is identified on high resolution manometry (HRM). The integrated relaxation pressure (IRP) is typically measured as the nadir residual pressure across the EGJ during swallow induced LES relaxation.

Aims & Methods: Our aim was to determine if measurement of the IRP across the LES, both LES and CD, and across the CD alone yields different values, and whether differences, if any, have clinical implications. All patients undergoing HRM during a 3-year period at a tertiary facility were eligible for inclusion; incomplete studies were excluded. Demographics and esophageal function testing results were extracted from patient records. EGJ morphological subtypes consisted of type 1 when LES and CD were superimposed; type 2 when LES-CD separation was <3 cm, and type 3 when separation was ≥3 cm. Standard analysis consisted of IRP measured across the entire EGJ in type 1 and 2 EGJ, and across LES in type 3 EGJ. IRP was calculated across LES and CD, separately as well as together in type 2 and type 3 EGJ. An IRP threshold of <15 mmHg defined normal EGJ relaxation. Categorical variables were compared using chi square, and continuous values using Mann Whitney U. Absolute IRP values, and proportions with outflow obstruction were compared between EGJ morphological subtypes, and between LES IRP and CD IRP when a hernia was identified.

Results: Data from 467 patients (median age 54.0 years, 68.7% female, median body mass index 30.5 kg/m^2) were analyzed, of which 61.2% had type 1 EGJ, 28.7% had type 2 and 10.1% had type 3 (Table).

	Type 1	Type 2		Type 3	
	n=286	*n=134*		*n=47*	
Median IRP (mmHg)	6.1 (3.0-9.6)	5.5 (2.9-9.5)		8.5 (2.0-12.1)	
EGJCI (mmHg.cm.s)	29.4 (17.2-48.4)	19.0 (5.1-35.4)		18.6 (5.5-37.2)	
IRP>15 mmHg	21 (7.4%)	5 (3.7%)		6 (12.8%)	
Total AET (%)	2.6 (0.7-6.6)	5.5 (2.2-9.3)		5.3 (1.2-9.8)	
		LES	CD	LES	CD
n	286	134	133	47	24
Median IRP (mmHg)	6.1 (3.0-9.6)	0.0 (0.0-3.0)	4.4 (1.5-7.0)	8.5 (2.0-12.1)	3.3 (1.0-5.6)
IRP >15 mmHg	21 (7.4%)	1 (0.8%)	1 (0.8%)	0 (0.0%)	1 (4.2%)

Values are reported as median (interquartile range) or number (percent).

Table.

Using standard methodology, the median IRP was similar in the three morphological subtypes. However, when a hernia was present, IRP across the EGJ was significantly higher than that across either LES or CD (p<0.001), and LES IRP was significantly different from CD IRP (p<0.001). In type 2 EGJ, median IRP across LES was lower across the LES compared to CD (p<0.001). The CD was not traversed in 23 of 47 type 3 EGJ; in the remainder, LES IRP was similar to CD IRP (p=0.784). Of 11 patients with IRP>15 mmHg within types 2 and 3 EGJ, only 3 patients had persistent IRP elevation when LES and CD were separately assessed. Median AET increased as separation between LES and CD increased; patients with elevated IRP had normal AET (0.9, IQR 0.2-6.2). After differential IRP measurement, abnormal IRP was most frequent with type 1 EGJ, and IRP elevation across CD alone was rarely encountered.

Conclusion: In the presence of a hiatus hernia, the IRP across LES and CD together is higher than IRP recorded separately across LES and CD. We speculate that this is because the IRP measurement tool might be picking up pressurization within the hiatus hernia when IRP is measured across both LES and CD. Differential assessment of IRP across LES and CD can reduce over-diagnosis of outflow obstruction.

Disclosure: Nothing to disclose.

PP0073

BARIUM ESOPHAGRAMS HAVE THE HIGHEST YIELD IN EXCLUDING CLINICALLY IRRELEVANT ESOPHAGOGASTRIC JUNCTION OUTFLOW OBSTRUCTION – A CROSS SECTIONAL STUDY

N. Bar[1,2], B. Glickman[1], A. Trikola[3,1], C. Velez[1], K. Staller[1], B. Kuo[4]
[1]Massachusetts General Hospital, Center for Neurointestinal Health, Division of Gastroenterology and Hepatology, Boston, Israel, [2]Tel Aviv Medical Center, Neurogastroenterology Service, Department of Gastroenterology and Hepatology, Tel Aviv, Israel, [3]Naval Hospital of Athens/Evangelismos General Hospital, Gastrointestinal Department, Athens, Greece, [4]American Gastroenterology Association, Gastroenterology, Newton, United States

Contact E-Mail Address: nirb@tlvmc.gov.il

Introduction: The Chicago classification 4.0 (CC4) definition of esophagogastric junction (EGJ) outflow obstruction (EJGOO) was made more stringent than the CC3 iteration to limit overdiagnosis of a disorder of undetermined significance. A clinically relevant EGJOO (Cr-EGJOO) diagnosis in CC4 requires a combination of relevant symptoms, high resolution manometric (HRM) criteria, and adjunctive tests instead of elevated supine median integrated relaxation pressure (IRP) alone in CC3.

Aims & Methods: We aimed to explore the importance of each component (symptoms, HRM, and adjunctive tests) in excluding or establishing Cr-EGJOO.

We included all patients undergoing esophageal HRM since 01/2020-12/2021, (both CC3 and CC4 protocols).

We excluded patients with inadequate tests. Positive symptoms were dysphagia/chest pain.

Adjunctive tests: Barium esophagrams were either timed or with a barium tablet. Functional lumen imaging probe (FLIP) tests were categorized as limited, borderline, or normal EGJ opening.

We also applied the same Cr-EGJOO criteria on the CC3 group (mandating relevant symptoms and adjunctive tests). We examined the proportion of EGJOOs excluded by each component.

Results: We included 486 (CC3, n=198, CC4, n=288) patients, with a median age of 58.7 years, 59% were female patients.

There were 100 (20.6%) with an elevated IRP in at least one position and normal peristalsis. Symptom data were available for all 100 patients and excluded Cr-EGJOO in 24%, barium esophagrams available for 85 and excluded Cr-EGJOO in 78.8%, FLIP was available in 11 patients (all had an esophagram). It rejected Cr-EGJOO in 63.6%, was borderline in 9.1%, and positive in the 27.3%. HRM criteria excluded Cr-EGJOO in 37.1% of the CC4 group. Note, most (93.1%) elevated IRPs were in the supine position.

Consequently, we could apply the Cr-EGJOO criteria on 85 patients with

complete data (68 and 17 patients in the CC4 and CC3 groups, respectively). In the CC4 group the EGJOO rate was reduced from 27.3% to 3.1%, and in the CC3 group from 11.1% to 5.3%. Patients with an elevated IRP in at least one position and a positive adjunctive test were invariably symptomatic, but most symptomatic patients did not have Cr-EGJOO.

	Patients with an elevated IRP in at least one position, n=100	Chicago 3 (n=22)	Chicago 4.0 (n=78)
Age (y)	62.6 (49 – 70.2)	64.8 (50.7 – 70.9)	62.3 (49 – 70)
Female sex *	70 (68.6)	**20 (91)**	**50 (64)**
BMI	26.5 (22 – 31.5)	27.6 (21.1 – 33.5)	26.4 (22.1 – 31)
Mean LES pressure	40.1 (29 – 52.4)	43.3 (31.6 – 54)	39.8 (27.9 – 52.3)
Median supine IRP	19.2 (16.8 – 22.3)	19.3 (16.9 – 23.2)	19.2 (16.8 – 22.3)
Median upright IRP	See CC4	-	14 (9.5-19)
normal peristalsis %	87 (67 – 100)	86 (20.8 – 100)	87 (73 – 100)
Dysphagia	69 (69)	19 (86.4)	50 (66.7)
Chest pain	14 (14)	4 (18.2)	10 (12.8)

Conclusion: The updated CC 4.0 criteria considerably reduce the diagnosis rate of EGJOO diagnosis. Barium esophagrams had the highest yield in excluding clinically irrelevant cases, highlighting the importance of utilizing this non-invasive, readily available test to avoid unnecessary worry and invasive treatments.
Disclosure: Nothing to disclose.

PP0074

PATIENTS WHO ARE OLDER THAN 65 HAVE HIGHER RATES OF CLINICALLY RELEVANT ESOPHAGOGASTRIC JUNCTION OUTFLOW OBSTRUCTION AND HIGHER INTEGRATED RELAXATION PRESSURES

N. Bar[1], B. Glickman[2], K. Staller[2], A. Trikola[2], B. Kuo[2]
[1]Massachusetts General Hospital, Gastroenterology and hepatology, Boston, Israel, [2]Massachusetts General Hospital, Center for Neurointestinal Health, Division of Gastroenterology and Hepatology, Boston, United States

Contact E-Mail Address: nirb@tlvmc.gov.il
Introduction: High resolution esophageal manometry (HRM) is commonly used to assess esophageal motility disorders. Data about the effect of age on HRM parameters and diagnoses are contradictory.
Aims & Methods: We aimed to explore the effect of age on HRM parameters and diagnoses in those under and above the age of 65.
We included all patients undergoing HRM within our institution between 2020-2021 (across both Chicago Classification 3 and 4 protocols). Clinically relevant esophagogastric junction outflow obstruction (EJGOO) was defined as having dysphagia or chest pain, elevated integrated relaxation pressure (IRP) in both positions where available, and positive adjunctive tests. Adjunctive tests included timed barium esophagrams, esophagram with a barium tablet, and/or functional lumen imaging probe (FLIP) tests.
Results: Of 486 included patients, 59% were female patients, 81% white, 3% Hispanic. There were 151 (31%) aged 65 and older and 335 (69%) younger than 65. The age≥65 vs. under 65 groups had similar proportions of female patients (61% vs.58%), race and ethnicity distribution, though older patients had lower median (IQR) BMI (26 [23-30] vs. 27 [24-31], p=0.023)
The age≥65 group had a higher IRP and mean lower esophageal sphincter pressure (LES) compared to the age<65 group, p<0.01 for both. Additionally, patients older than 65 had a higher rate of both manometric and clinically relevant EGJOO (p<0.001 for both), and a lower rate of hypomotility diagnoses. See table for details.

Multivariable logistic regression showed that age was independently associated with EGJOO per CC3 (elevated IRP in at least one position [upright or supine] and normal peristalsis): OR= 1.72 (95% CI 1.35-2.19, p<0.001) for each 10-year increase in age and after adjusting for sex, BMI and the study protocol (Chicago 3 or 4).
Furthermore, within the group of patients with EGJOO per CC3, the odds of being diagnosed with clinically relevant EGJOO were 4.28 (95% CI 1.34-13.7, p=0.014) for each 10-year increase in age and adjusting for the same variables.

	Total Cohort n=486	Younger than 65 n=335	65 and older n=151	P vlaue
Mean LES pressure (mmHg)	26.1 (15.7 - 39.3)	**25 (14.2 - 36.5)**	**29.1 (17.8 - 43.5)**	**0.004**
Median IRP (mmHg)	9 (4.8 - 14.4)	**8.5 (4.2 - 13.3)**	**10.7 (5.9 - 18.2)**	**<0.001**
Normal peristalsis %	79.5 (33 - 100)	75 (30 - 100)	80 (40 - 100)	NS
Ineffective %	20 (0 - 62)	20 (0 - 67)	14 (0 - 54)	NS
Hypomotility disorders (Absent contractility or Ineffective motility)	106 (22%)	82 (25%)	24 (16%)	0.034
Hypermotility disorders:	104 (21%)	**53 (16%)**	**51 (34%)**	**<0.001**
Achalasia	26 (5%)	15 (5%)	9 (6%)	NS
Manometric EGJOO	68 (14%)	**29 (9%)**	**39 (26%)**	**<0.001**
Clinically relevant (symptomatic, Manometric and positive barium swallow tests)	19 (4%)	**4 (1%)**	**29 (26%)**	**<0.001**

Conclusion: Our data show that HRM results differ in patients referred for manometry and older than 65. Specifically, these patients have a higher rate of clinically relevant EJGOO and greater IRP. This may be related to age related changes in myenteric innervation. Future studies are needed to establish whether patients older than 65 progress to achalasia or will benefit from EGJ directed therapy.
Disclosure: Nothing to disclose.

ASSOCIATION BETWEEN ESOPHAGEAL MOTOR DISORDERS AND PULMONARY INVOLVEMENT IN PATIENTS AFFECTED BY SYSTEMIC SCLEROSIS: A RETROSPECTIVE STUDY

A. Pasta[1], Y. Canavesio[1], F. Calabrese[1], S. Paolino[1], C. Pizzorni[1], M. Furnari[1], G. Bodini[1], V. Savarino[1], E.V. Savarino[2], E.G. Giannini[1], E. Marabotto[1]
[1]University of Genoa, Department of Internal Medicine, Genoa, Italy, [2]University of Padua, Division of Gastroenterology, Department Of Surgery, Oncology And Gastroenterology, Padua, Italy

Contact E-Mail Address: andreapasta93@gmail.com
Introduction: Systemic sclerosis (SSc) is a rare autoimmune disease of the connective tissue that can affect multiple organs. The esophagus is the most affected gastrointestinal tract, while interstitial lung disease (ILD) is a main feature associated with SSc.
Aims & Methods: The aim of the present study was to evaluate the association and prognostic implication between motor esophageal disorders and pulmonary involvement in SSc patients.
We retrospectively assessed patients with SSc who underwent both the high resolution manometry with the new Chicago Classification 4.0 and pulmonary evaluation comprehensive of function tests and high-resolution computer tomography (HrCT) with the use of Warrick score. A total Warrick score≥7 was considered predictive of ILD, while a score≥10 in a HrCT acquired prospectively from baseline evaluation was considered to establish significant interstitial involvement.

Results: Forty-two patients were included. We found a score≥7 in 11 patients with aperistalsis, in 6 subjects with ineffective esophageal motility and in 6 patients with a normal manometry.
Otherwise, a Warrick score<7 was observed in 3 patients with aperistalsis, and in 2 and 14 patients with ineffective esophageal motility disorder and with a normal contractility, respectively.
Higher scores were observed in subjects with absent contractility or ineffective esophageal motility than subjects with normal motility, indeed DCI and HrCT score were inversely correlated in linear and logarithmic regression analysis. Prospectively, lower baseline pressure of lower esophageal sphincter and greater HrCT scores at follow-up evaluation were significantly associated.
Conclusion: This study shows an association between motor esophageal disorder and pulmonary involvement in SSc patients: more severe is the esophageal involvement, more critical is the pulmonary disease.
Disclosure: Nothing to disclose.

HIGH-RESOLUTION MANOMETRY CATHETER INSERTION DURING SEDATED ENDOSCOPY: A VIABLE OPTION WHEN STANDARD INTUBATION FAILS

J. Endersby[1], H. Mills[1], H. Dervin[2], A. Raeburn[1], R. Sweis[1]
[1]University College London Hospitals NHS Foundation Trust, GI Physiology, London, United Kingdom, [2]The Newcastle upon Tyne University Hospitals NHS Foundation Trust, GI Physiology, Newcastle, United Kingdom

Contact E-Mail Address: holly.mills5@nhs.net
Introduction: High-resolution manometry (HRM) is routinely performed in an outpatient clinic setting. If intubation is not tolerated or if the LOS is not traversed, the test is often abandoned with no viable alternative option, thus impacting on therapeutic decisions.
This study explores the option of intubating the catheter during endoscopy under the comfort of sedation and direct vision.
Aims & Methods: All patients who had HRM catheter insertion during endoscopy at a tertiary referral centre in London between Jan 2020 and April 2023 were collated and analysed. A consecutive equivalent number of standard unsedated HRM studies, as well as patients having standard diagnostic endoscopy at the same centre between Nov and Dec 2022 were included for comparison. Demographic data, symptom presentation, endoscopic technique and manometry diagnosis were analysed. All HRM studies attempted a full protocol of single water swallows and rice meal, undertaken only after confirmation that sedation had abated.
The median integrated relaxation pressure (IRP) of single water swallows was used to categorise patients into those with and without a disorder of outflow. Oesophageal body function was defined according to the Chicago Classification of motility disorders[1].
Results: Of the 47 patients (68.1% F; 17-86 yrs) who were referred for endoscopic insertion (EI) of the HRM catheter, 42 (89.3%) were successfully intubated to the stomach. Of those, 33 (78.6%) were observed to pass through the pharynx and LOS with the endoscope, 4 (9.5%) required manual guidance through the oesophagus and LOS, whilst 5 (11.9%) required only observation of catheter passage through the pharynx.
Overall, 41 (87.2%) patients completed the full swallow protocol. Indications for referral for EI included intolerance to standard insertion through the nares (52.4%), inability to breach the LOS resulting in a curled catheter (26.2%) and other reasons including septal deviation and psychiatric burden (21.4%). Similarly, of the contemporaneous 47 patients who had standard insertion (SI) of the HRM catheter in the outpatient setting (67.3% F, 23-80 yrs), 39 (82.9%) were successfully intubated and 33 (67.3%) completed the full swallow protocol. Symptoms were reproduced during the test protocol in both cohorts similarly (69.0% EI, n=42; 59.0% SI, n=39). EI patients required higher doses of sedation compared to a consecutive cohort of patients who attended for routine diagnostic endoscopy; mean Fentanyl 112.5µg (n=36) vs 78.7µg (n=47) p<.001, and Midazolam 4.9mg vs 3.4mg p<.001, respectively.
The IRP was not significantly different between EI and SI regardless of LOS morphology; mean IRP in patients with no LOS outflow disorder (8.01mmHg, n=28 vs 6.05mmHg, n=35; p=.08), compared to those with an outflow obstruction (28.0mmHg, n=12 vs 23.1mmHg, n=5; p=.35). Overall motility diagnoses between the two cohorts are presented in Table 1.

Manometry Diagnosis	Normal oesophageal motility	Achalasia (all subtypes)	Treated Achalasia	OGJOO	Absent contractility	Hypercontractile oesophagus	Ineffective oesophageal motility	Other
% Patients EI	28.6	21.4	16.7	11.9	11.9	4.8	4.8	0
% Patients SI	46.2	7.7	2.6	7.7	2.6	10.3	17.9	5

Table 1: Diagnoses for HRM.

Conclusion: Inserting the HRM catheter during endoscopy under sedation and direct vision enables oesophageal physiology testing for patients who might not have otherwise been able to receive motility assessment. The procedure is safe, feasible and is associated with no complications or adverse risk to date. Just as wireless pH monitoring can be a salvage for those who are unable to tolerate the pH catheter, this technique can fill an important gap in the investigation algorithm where motility testing would have otherwise been abandoned.

Introduction: This report presents the results of a multicenter, randomized, double-blind, placebo-controlled phase 3 study (VP-VLY-686-3301) assessing the efficacy of tradipitant in relieving symptoms of gastroparesis. Tradipitant, a novel NK-1 receptor antagonist, previously demonstrated efficacy in diabetic and idiopathic gastroparesis in reducing gastroparesis symptoms in a phase 2 study (VP-VLY-686-2301).
Aims & Methods: N=201 idiopathic and diabetic gastroparesis patients with delayed gastric emptying, moderate to severe nausea, and at least 1 vomiting episode were included in the ITT (Intent-to-Treat) population. Subjects were randomized to receive 85 mg tradipitant twice a day (n=102) or placebo (n=99) for 12 weeks. Nausea was assessed daily using the 5-point Gastroparesis Core Symptom Daily Diary (GCSDD). Overall gastroparesis symptom improvement was evaluated using the Patient Global Impression of Change (PGI-C) and the Overall Patient Benefit (OPB) scales. Sensitivity analyses were also performed to control for confounders that may have masked the true treatment effect size.
Results: At the primary endpoint of change in nausea from baseline as

measured by the GCSDD at week 12, both tradipitant and placebo showed significant and similar reductions from baseline at 1.55 and 1.49 respectively. Comparison between treatment arms did not reach statistical significance in this measure.

However, in the PGI-C scale, more tradipitant treated patients demonstrated response as compared to placebo both at week 2 (74% v. 58%, p=0.019) and at week 12 (78% v. 66%, p=0.065). Similarly, in the OPB scale, more tradipitant treated patients demonstrated response as compared to placebo both at week 2 (81% v. 62%, p=0.0003) and week 12 (86% v. 71%, p=0.011).

Sensitivity analysis adjusting for rescue medication use further confirmed the ITT findings in both the PGI-C and OPB analysis at both week 2 and week 12.

Conclusion: Significant but similar improvements from baseline for tradipitant and placebo may have masked the true treatment effect size at the primary endpoint of the study of change in nausea severity as measured by daily diary at week 12 leading to no statistically significant difference between treatments. Despite this large placebo effect, tradipitant was shown to be significantly better than placebo in global measures of patient improvement including the Patient Global Impression of Change (PGI-C) and the Overall Patient Benefit (OPB) scales.

IS THE ABSENCE OF CONTRACTION RESERVE ASSOCIATED WITH HIGHER ACID EXPOSURE TIME IN PATIENTS WITH INEFFECTIVE ESOPHAGEAL MOTILITY?

T. Lima Capela[1,2,3], C. Arieira[1,2,3], A.I. Ferreira[1,2,3], V. Macedo Silva[1,2,3], M. Freitas[1,2,3], T. Cúrdia Gonçalves[4,2,3], J. Berkeley Cotter[1,2,3]

Contact E-Mail Address: tiagolimacapela@gmail.com

Introduction: Ineffective esophageal motility (IEM) has been associated with higher esophageal reflux burden in the context of gastroesophageal reflux disease (GERD). However, the association of IEM with acid exposure time (AET) is not perfect and its true clinical relevance remains unclear.

Additionally, although contraction reserve (CR) assesses the ability of the esophageal smooth muscle to augment contraction when challenged and higher CR ratios have been shown to correlate with decreased AETs in nonerosive GERD, there is still limited data in the context of IEM.

We aimed to evaluate the association between CR, in IEM and normal esophageal high-resolution manometry (HRM) patients, and AET measured by 24h-ambulatory reflux monitoring (ARM).

Aims & Methods: Retrospective cohort-study that assessed adult patients submitted to HRM with a 36 – channel solid state probe (*Manoscan®*) and ARM (*Diggitrapper™*) off acid suppressive therapy for evaluation of GERD symptoms between 2020-2022. Patients with IEM, according to Chicago Classification 4.0, and a control group adjusted for age and sex with normal HRM were included.

Single swallows and multiple rapid swallows (MRS) were evaluated using Manoview® software and parameters including respiratory minimum basal Lower Esophageal Sphincter Pressure (minLESP), respiratory mean basal LESP (meLESP), median residual LESP (rLESP) and distal contractile integral (DCI) to determine CR were analysed. CR was present when the ratio between MRS DCI and mean single swallow DCI (sDCI) was >1. ARM parameters were assessed and total AET >6% was considered pathologic. The relationship between HRM parameters and AET, between IEM and control group and within each group was analyzed.

Results: From 185 patients who underwent concomitant HRM and ARM for GERD, 40 patients with IEM and 40 with normal HRM were identified. Median rLESP (8.5 vs 7.8, P=0.870) was not significantly different between groups, respectively. However, minLESP (11.2 vs 12.6, P=0.048), meLESP (18.2 vs 21.1, P=0.008), median sDCI (562.5 vs 1604.5, P<0.001), median MRS DCI (589 vs 1677.0, P<0.001), absence of CR (17.5% vs 55%, P=0.001), median AET (6.3 vs 2.3, P=0.025) and proportion of pathologic AET (52.5% vs 12.5%, P<0.001), were significantly different between groups, respectively.

Patients without CR, with IEM or normal HRM, had significantly higher proportions of pathologic AET than patients with preserved CR (72.7% vs 27.7%, P=0.01; 42.8% vs 6.1%, P=0.03, respectively).

Conclusion: The absence of contraction reserve is associated with pathologic AET both in IEM and normal HRM patients, having IEM patients a higher burden of pathologic AET than normal HRM group.

A BASELINE SEVERITY INFLATION ANALYSIS IN STUDY VP-VLY-686-3301 OF TRADIPITANT IN GASTROPARESIS

J.L. Carlin[1], C. Polymeropoulos[1], C. Xiao[1], G. Birznieks[1], M.H. Polymeropoulos[1]
[1]Vanda Pharmaceuticals, Inc., Washington, United States

Contact E-Mail Address: Jesse.Carlin@vandapharma.com

Introduction: Tradipitant is a NK-1 receptor antagonist that showed efficacy in improving nausea, vomiting and gastroparesis symptoms in a phase 2 study (VLY-2301) of diabetic and idiopathic gastroparesis. Efficacy was further evaluated in a phase 3 study (VLY-3301). A large placebo effect may have masked the true size of tradipitant benefit. Large placebo responses can be driven by Baseline Severity Inflation (BSI) especially on parameters used for inclusion into the study.

Aims & Methods: Idiopathic and diabetic gastroparesis patients with delayed gastric emptying, moderate to severe nausea, and at least 1 vomiting episode were randomized to tradipitant or placebo for 12 weeks. Nausea was assessed using the 5-point Gastroparesis Core Symptom Daily Diary. Overall gastroparesis symptoms was evaluated using the Patient Global Impression of Change (PGI-C) and the Overall Patient Benefit (OPB) scales. The BSI analysis subgroup included ITT subjects with at least 1 but less than 7 average vomiting episodes and excluded subjects whose vomiting severity was zero or highest severity. This baseline threshold allows for censoring of patients with minimal or very high frequency of vomiting and uses a symptom scale for censoring other than the primary endpoint scale. This is an accepted strategy to minimize placebo effect, and allows for a less biased estimation of true treatment effect.

Results: A responder analysis of PGI-C and OPB Score in the BSI subgroup showed a larger proportion of tradipitant treated patients improved versus placebo at start (Week 2) and end (Week 12) of study. Similarly, at the same timepoints nausea was improved.

For the primary endpoint of change in nausea from baseline at week 12, tradipitant treated patients reported a greater reduction in nausea than placebo treated patients (-1.98 v. -1.28, p=.028). Improvement in tradipitant treated patients versus placebo was also seen at week 2 (-.99 v. -.50, p=.013). In the PGI-C scale more tradipitant treated patients demonstrated improvement as compared to placebo at week 2 (86% v. 53%, p=.002) and at week 12 (84% v. 65%, p=.056). For the OPB scale, more tradipitant treat-

ed patients demonstrated benefit compared to placebo at week 2 (95% v. 68%, p=.003) and week 12 (92% v. 68%, p=.009).

Conclusion: Tradipitant treatment in the Baseline Severity Inflation Analysis subpopulation resulted in improvements in nausea, PGI-C, and OPBS both the earliest (Week 2) and last (Week 12) timepoints.

Contact E-Mail Address: pradev32@gmail.com

Introduction: Per-oral endoscopic myotomy (POEM) is an established treatment modality for achalasia cardia. Submucosal fibrosis (SMF) is rare, but the most important reason for technical failure during POEM. Prediction of SMF may be crucial to improve technical outcomes with POEM.

Aims & Methods: In this study we aim to evaluate the predictors for SMF in cases with achalasia cardia.Consecutive patients with achalasia cardia who underwent POEM (Aug 2021 to October 2022) were included in the study, prospectively. Various factors were analysed for prediction of SMF including age, gender, stasis esophagitis, type of achalasia, duration of disease, lower esophageal sphincter pressure (LESP), height of barium column on barium esophagogram and severity of symptoms (Eckardt score). Esophageal mucosa was graded for the severity of stasis esophagitis (grade I to grade III) based on vascular pattern, mucosal thickening, ulceration and nodularity. SMF was graded (I minimal, II moderate, III severe) according to mucosal lift, difficulty in entry, density of SM fibers, separation of mucosa and muscle.

Results: 240 patients (males 139, mean age 44.4±14.7 years) underwent POEM during the study period. The subtypes of achalasia included type I in 29, type II in 201, type III in 10. Median symptom duration was 24 (1-240) months and mean pre-POEM Eckardt score was 7.6±1.8. Majority (93.3%) of the patients were treatment naïve and underwent POEM via posterior route (91.2%). Stasis esophagitis was evident in 122 (50.8%) patients including grade I in 99 (41.3%), grade II in 16 (6.7%) and grade III in 7 (2.9%) patients. SMF was detected in 87 (36.3%) patients including grade I in 52 (21.7%), grade II in 30 (12.5%) and grade III in 5 (2.1%) patients. Mean age, duration of symptoms, width of esophagus and procedure duration were significantly higher in cases with submucosal fibrosis. (Table 1)

	SMF (no or grade 1)	Significant SMF (grade 2 or 3)	p value
Age, mean+/-SD	44.5+/-14.5	44.0+/-15.9	0.859
Disease duration, months	36.3+/-43.9	43.9+/-53.1	0.035
Mean Eckardt score	7.8+/-1.9	7.1+/-1.4	0.060
Mean TBS height in cm	13.8+/-5.1	13.4+/-5.4	0.619
Mean TBS width in cm	4.6+/-1.7	6.1+/-3.5	0.001
Mean LES pressure, mmHg	24.3+/-10 3	26.9+/-15.1	0.198
Mean Integrated relaxation pressure, mmHg	26.6+/-13.7	27.2+/-13 9	0.791
Mean Myotomy length, cm	9.2+/-2.6	9.9+/-2.9	0.114
Mean Procedure time, min	40.8+/-17.7	58.2+/-24.1	0.001

Table 1. Multivarient analysis.

Significantly higher proportion of patients with type I achalasia (62.1%) had SMF as compared to type II (33.8%) and type III achalasia (10%) [p=0.013]. On multivariate analysis, the presence of stasis esophagitis and width of esophagus on timed barium were predictors of significant (≥grade II) SMF.

Conclusion: Severe SMF (grade III) is uncommon in cases with achalasia cardia. The presence of stasis esophagitis and width of esophagus are predictors of SMF during POEM.

ESOPHAGEAL MOTILITY RECOVERY IN ACHALASIA CARDIA POST PER ORAL ENDOSCOPIC MYOTOMY (POEM)- A PROSPECTIVE STUDY

Z.D. Sharma[1], A. Garg[1], R. Puri[1]

[1]Medanta the Medicity, Gastroenterology, Gurugram, India

Contact E-Mail Address: drzubinsharma@gmail.com

Introduction: Achalasia cardia is an esophageal motility disorder characterized by absence of proper propulsive peristalsis of esophagus along with insufficient relaxation of the lower esophageal sphincter.[1]

Eckardt scoring[2] systems was developed for assessment of symptom complex. Current gold standard test for the definitive diagnosis of achalasia is HREM. An endoscopic approach with principles of natural orifice transluminal endoscopic surgery to perform a myotomy called peroral endoscopic myotomy (POEM).

Till now it is believed that Absent or impaired peristalsis of the esophageal body in patients of achalasia cardia are irreversible however some early studies challenged this phenomenon.[5,6,7]

Recently, in some studies, partial peristaltic recovery or pseudo-peristaltic recovery was observed after myotomy (either POEM or surgery) in a significant number of patients with AC. There are limited studies to assess the post-POEM esophageal motility patterns with regard to potential peristaltic recovery, partial or pseudo recovery.

Aims & Methods: HRM finding pre and post POEM in achalasia cardia and its correlation to clinical eckardt score. And to assess the post-POEM esophageal motility patterns with regard to potential peristaltic recovery, partial or pseudo recovery and to assess its predictive factors

Results: The study was conducted in Department of Gastroenterology, Medanta-The Medicity, Gurgaon, Haryana. 30 patients, ≥ 18 years of age, presenting with symptoms of achalasia. Mean value of age (years) of study subjects was 42.5 ± 17. 20(66.67%) patients were females.

Significant difference was seen in baseline lower esophagus sphincter resting pressure (Inspiratory)(33.7 vs 25.9mmHg), baseline lower esophagus sphincter resting pressure (Expiratory) (43.9 vs 32.4mmHg), 4-s integrated relaxation pressure (23.6 vs 11.4), distal contractile integral (1065 vs 255) between pre and post POEM.(p value < 0.05) After POEM, partial recovery of esophageal body peristalsis was observed in 10 patients (33.3%, 10/30), including one (11.1%, 1/9) with type I, six (33.3%, 6/18) With type II, and three (100%, 3/3) with type III achalasia. High IRP and achalasia subtype (type III) before POEM were statistically significant factors associated with recovery of esophageal body peristalsis after POEM.

On comparisons of the clinical factors related to IRP value after peroral endoscopic myotomy. 30 patients with reviewable IRPs after POEM, 5 patients (16.6%) had high post-POEM IRP values (>15 mm Hg) 29.5 vs 23 mm Hg.

Conclusion: POEM provided improvement in LES relaxation in the form of reduction of LESP and 4sIRP along with excellent clinical symptomatic relief. Post POEM HRM also demonstrated "esophageal remodeling" in terms of recovery of esophageal peristalsis. The recovery of the contractile activity also seemed to be correlating with the subtypes of achalasia where the patients with type II achalasia were more prone to show the contractile reserve (besides the obvious type III) than type I. Nevertheless, an improved symptomatic outcome did not necessitate peristaltic recovery. The present study may contribute further on understanding the pathophysiological changes of subtype of achalasia.

NOVEL EVALUATION OF ESOPHAGEAL DISTENTION FOR THE PATIENTS WITH FUNCTIONAL DYSPHAGIA BY ONIGIRI ESOPHAGOGRAPHY

K. Muta[1,2], H. Tsuru[1], M. Wada[1], Y. Hata[1], E. Ihara[1]

[1]Kyushu University, Department of Medicine and Bioregulatory Science, Graduate School of Medical Sciences, Fukuoka City, Japan, [2]Seiwakai Muta Hospital, Fukuoka city, Japan

Contact E-Mail Address: c119c345@gmail.com

Introduction: Commonly known as the "law of the intestine," gastrointestinal peristalsis consists of contraction in combination with preceding distention. Disturbance of this sequential peristalsis results in impaired transportation of food which would be associated with dysphagia. Recently, using Distension contraction plot (DCP), Mittal K revealed that impaired esophageal distention is indeed responsible for patients with functional dysphagia (FD) who are suffering from dysphagia despite being normal high-resolution manometry (HRM).

In contrast, we have developed Onigiri (Japanese rice ball) esophagography (OE) which enables us to screen esophageal motility disorders by the value of obstruction level (OL 0-4; OL0, no obstruction and OL4; the most severe obstruction). In OE of normal subjects, the swallowed onigiri is transported to the stomach forming an American football shape. We found that some patients with FD present OL1-2 out of an American football shape.

The objective of this study was to determine whether OE is useful for evaluate esophageal distention.

Aims & Methods: From June 2021 to April 2023, both HRM with DCP and OE were performed on 60 patients of dysphagia. 11 FD (male/female;2/9, median age;63 y.o.) who had a normal HRM but OL1-2 in OE (OL 1/2; 4/7), and 15 volunteer normal subjects (male/female; 9/6, median age; 27 y.o.) with normal HRM and OL0 were also enrolled. AUC Distension (AUCD) and Peak distension (PD) were assessed for distention capacity. In DCP, the esophageal body is divided into 4 segments (seg 1 to 4). In this study, we evaluated the seg 3 and 4, corresponding to the esophageal smooth muscle region.

Results: In seg 4, AUCD of 11 FD (OL1-2) (8176±1536mm^2) was significantly lower than that of normal (11067±2703mm^2), (p = 0.0022), and PD of 11 FD (OL1-2) (161±17mm^2) was significantly lower than that of normal (184±19mm^2, p=0.005). Furthermore, focusing on FD with OL2, AUCD of the 7 FD (OL2) (6599±487mm^2) was significantly lower than that of normal (8019±2145mm^2) in seg 3 (p=0.047).

Conclusion: Impaired esophageal distention is responsible for the patients with FD who has normal HRM. OE is useful for screening impaired esophageal distention.

RANDOMIZED TRIAL OF TRADITIONAL DIETARY ADVICE IN POSTPRANDIAL FUNCTIONAL DYSPEPSIA

R. Buckle[1], L. Brown[1], I. Aziz[1]

[1]Sheffield Teaching Hospitals NHS Foundation Trust, Academic Unit of Gastroenterology, Sheffield, United Kingdom

Contact E-Mail Address: rachel.buckle92@gmail.com

Introduction: Almost 80% of individuals with functional dyspepsia report meal-related symptoms and are classified as having postprandial distress syndrome (PDS). However, studies evaluating dietary modifications in PDS are sparse.

Aims & Methods: The aim of this study was to perform a single-centre randomized trial evaluating traditional dietary advice (TDA) in PDS.

Following a normal upper gastrointestinal endoscopy, patients with PDS were randomly assigned to a leaflet providing reassurance and diagnostic explanation (RADE) +/- TDA; the latter recommending smaller, regular meals and reducing the intake of caffeine/alcohol/fizzy drinks, fatty/processed/spicy foods, and fibre. Questionnaires were completed during the 4-week trial, including self-reported adequate relief of dyspeptic symptoms, and the validated Leuven Postprandial Distress Scale (LPDS), Gastrointestinal Symptom Rating Scale, and Nepean Dyspepsia Index for quality of life.

The primary endpoint(s) to define clinical response were:
i. ≥50% adequate relief of dyspeptic symptoms, and;
ii. >0.5-point reduction in the PDS subscale of the LPDS (calculated as the mean scores for early satiety, postprandial fullness, and upper abdominal bloating).
Results: Of 53 patients with PDS, 27 were assigned RADE-alone and 26 to additional TDA. Baseline characteristics were similar between the groups, with a mean age of 39 years, 70% female, 83% white, and co-existent IBS in 66%.
The primary endpoints of:
i. Adequate relief of dyspeptic symptoms was met by 33% (n=9) assigned RADE-alone vs. 39% (n=10) with TDA; p-value=0.70, while;
ii. A reduction of >0.5 points in the PDS subscale was met by 37% (n=10) assigned RADE-alone vs. 27% (n=7) with TDA; p-value=0.43.
Response rates did not alter according to IBS status. There were no significant between-group changes in the gastrointestinal symptom rating scale and dyspepsia quality of life.
Conclusion: The addition of TDA did not lead to greater symptom reduction in PDS compared with reassurance and diagnostic explanation alone. Alternate dietary strategies should be explored in PDS.
Disclosure: Nothing to disclose.

PP0084

FUNCTIONAL DYSPEPSIA (ROME-IV), EROSIVE AND NON-EROSIVE GERD: RISK FACTORS AND RELATIONSHIP WITH ANXIETY AND DEPRESSION. A CROSS-SECTIONAL STUDY

A.M. Caballero-Mateos[1], A.M. Caballero-Plasencia[2], J.M. Hernández-González[3], MD. Quintero-Fuentes[4], E. Redondo-Cerezo[5]
[1]Hospital Clínico San Cecilio, Aparato Digestivo, Granada, Spain, [2]University of Granada, Medicine, Granada, Spain, [3]University of Florida, Psychiatry, Orlando, United States, [4]Hospital clínico San Cecilio, Aparato Digestivo, Granada, Spain, [5]Hospital Universitario Virgen de las Nieves, Gastroenterology, Granada, Spain

Contact E-Mail Address: ogy1492@hotmail.com
Introduction: There is conflicting data on the risk factors linked to Gastroesophageal Reflux Disease (GERD) and Functional Dyspepsia (FD). Studies that explore the association between anxiety/depression and GERD phenotypes (Esophagitis/EE and Non-Erosive Reflux Disease/NERD), FD, and Rome-IV syndromes are scarce.
Aims & Methods: The aim was to evaluate the association between epidemiological factors and comorbidities with GERD phenotypes, FD, and Rome-IV syndromes, as well as the relationship of these processes with anxiety/depression.
338 participants were selected from 357 patients referred to three tertiary centers in Granada (Spain) for endoscopic assessment. A gastroenterologist individually interviewed each participant prior to the procedure and administered three validated questionnaires (GERD-Q, Rome-IV, and HADS) to detect the presence of GERD, FD, and anxiety/depression, respectively.
Results: 45/338 patients were controls, 198/58.6% were classified as GERD, 81/24.0% EE (49/14.5% symptomatic, and 32/9.5% asymptomatic), 117/34.6% NERD, 176/52.1% FD (43/12.7% epigastric pain syndrome, 36/10.7% postprandial distress syndrome, and 97/28.7% overlapping syndrome). 81 patients were mixed GERD-FD.
Multivariate analysis found significant independent associations: age in NERD and FD; sex in EE, asymptomatic EE and FD; body mass index in NERD and FD; alcohol in EE; anxiety/depression in FD; use of calcium channel antagonists in EE; and inhalers in FD.
We compared controls vs different groups/subgroups finding significantly more anxiety in NERD, FD, all Rome-IV syndromes, and mixed GERD-FD; more depression in FD, overlapping syndrome, and mixed GERD-FD; and higher levels of anxiety+depression in NERD, FD, overlapping syndrome, and mixed GERD-FD.

Associated factors	Age	Sex	BMI	Alcohol	Calcium channel blockers	Inhalers	Anxiety and/or depression

GERD, gastroesophageal reflux disease;
EE, erosive GERD;
AEE, asymptomatic erosive GERD;
NERD, non-erosive GERD;
FD, functional dyspepsia.
Data expressed: p-value, OR and confidence interval-95%. Only values with significant and independent associations are shown.
Table: Multivariate analysis (logistic regression) of factors associated with different groups and subgroups of GERD and FD.

Conclusion: The existence of shared demographic and psychopathological risk factors in Non-Erosive Reflux Disease (NERD) and Functional Dyspepsia (FD) implies that they could be part of the same pathophysiological spectrum. The prevalence of anxiety was higher in NERD, while anxiety and depression were more frequent in FD. These results suggest that psychological therapy could be a supportive strategy for both conditions.
Disclosure: Nothing to disclose.

ASSOCIATION OF VITAMIN D WITH FUNCTIONAL DYSPEPSIA- A NEW KID IN THE BLOCK?

D.D.S. Das[1], G.K. Saharia[2], M. Panigrahi[3], D. Sahoo[1], DASAD
[1]All India Institute of Medical Sciences, General Medicine, Bhubaneswar, India, [2]All India Institute of Medical Sciences, Biochemistry, Bhubaneswar, India, [3]All India Institute of Medical Sciences, Gastroenterology, Bhubaneswar, India

Contact E-Mail Address: recdhriti@gmail.com
Introduction: Functional dyspepsia (FD) is an enigma in itself but a commonly prevalent problem, around 10-30%, encountered by physicians worldwide [1].
There is evidence of low-grade inflammation in duodenal mucosa including eosinophilic infiltration and T-cell mediated among others [2].
Moreover, since vitamin D has immunomodulatory properties and its role has been well established in various diseases including inflammatory bowel diseases and cancers, evaluation of vitamin D status in patients with FD needs to be actively pursued given its immuno-regulatory attributes [3].

The beneficial roles of vitamin D, particularly in gut and neurological functioning of the body counts in an effective option in treating irritable bowel syndrome [4,5].

In one study, increased VDR (vitamin D receptor) expression is seen in duodenal mucosa and it has been proposed that since Vitamin D acts as a ligand of VDR, assessing vitamin D status in such patients remains an area of active research [6].

Thus the authors here seeks to probe into the key role of Vitamin D in the FD patients, utilizing evidence from previous studies in vitamin abnormalities [4].

Aims & Methods: This case control study was done at a tertiary care hospital with 150 cases and 150 controls. FD was diagnosed by the ROME IV criteria. Demographic and serum vitamin D levels including perceived stress score (PSS) and salivary alpha levels were determined for both cases and controls. Statistical analysis were done with the help of SPSS version 27.

Results: Majority of the FD cases were males (57.3%). Post prandial distress syndrome (PPDS) represented the major type of functional dyspepsia (FD) cases (104 cases; 69.3 %), followed by epigastric distress syndrome (EPS) (48 cases, 32%). Among the cases, 6.6 % had sleep problems, 18.6% had heart burn, 18.6% had bowel disturbances and 13.4% had headache. Cases have higher mean age than the controls (42.24±12.047 vs 38.94±, p=0.028). A higher mean BMI was found among the control group (23.2 vs 21.2, p<0.05) and higher percentage of obese individuals in the control group (42.7% vs 29.3%, p= 0.05). Majority of the cases are from rural background (89.3% vs 74%, p<0.001). Comparison of perceived stress scale (PSS) showed that cases had significantly higher grades of PSS than control (p<0.001). Hypovitaminosis D (<30ng/ml) was found significantly more among cases (73.3% vs 60%; p<0.05) with an odds ratio (OR) of 1.833 (CI95%= 1.126- 2.985). After adjustment of age, place of residence and BMI, Vitamin D levels were significantly associated with functional dyspepsia in the regression analysis. Nagelkerke R Square= 11%, p= 0.023, OR= 1.016

	Cases	Control	P value
Vitamin D, Mean SD	22.9 ± 18.3	27.8 ± 17.5	**0.009**
Vitamin D categories, n (%)			**0.020**
Vit D deficiency (VDD)	110 (73.3)	90 (60)	
Normal Vitamin D	40 (26.7)	60 (40)	

Conclusion: The present work demonstrates a close association of VDD, BMI and PSS score in FD patients for the first time. Findings from the study has been able to shed light into the role of Vitamin D in FD and the possible need for vitamin D supplementation to further improve the management of such cases, thus opening new avenues for further research.

CLINICAL CHARACTERISTICS AND OUTCOMES OF CONSECUTIVE PATIENTS WITH FUNCTIONAL DYSPEPSIA TAKING OPIOIDS REFERRED TO A UK TERTIARY CARE HOSPITAL

M. Butt[1,2], A. Dhali[3], G. Isherwood[1], T. Lewis-Lawson[1], D. Bush[1], T.R. Card[1], M. Corsetti[1]

[1]University of Nottingham, NIHR Nottingham Digestive Diseases Centre, Nottinghamshire, United Kingdom, [2]Queen Mary University of London, Wingate Institute of Neurogastroenterology, London, United Kingdom, [3]NIHR Nottingham Digestive Diseases Centre, Neurogastroenterology, Nottinghamshire, United Kingdom

Contact E-Mail Address: mohsin.butt@nhs.net

Introduction: Functional dyspepsia (FD) has an estimated population prevalence of 10% using the ROME IV criteria (1). Opioids have a limited therapeutic role in the management of non-malignant pain, but the opioid prescription rates for the management of non-cancer pain has increased steadily by 0.5% per year from 2006 to 2016 (2).

Opioid induced hyperalgesia is thought to contribute to the development of visceral hypersensitivity in patients with disorders of gut-brain interaction (DGBIs) (3).

To our knowledge, no UK study has yet addressed the clinical characteristics and healthcare outcomes of patients diagnosed with clinically confirmed ROME IV FD who are prescribed opioids.

Aims & Methods: The primary aim of this study is to determine the proportion of patients diagnosed with ROME IV FD in a tertiary care neurogastroenterology setting who are prescribed opioids.

The secondary aims of the study are as follows: to determine the differences in clinical characteristics and symptomatology between patients with FD taking opioids compared to those not taking opioids; to determine the differences in healthcare utilisation (i.e., number of investigations, clinic consultations, and hospitalisations) between patients taking opioids compared to those not taking opioids; and to determine the proportion of patients who adhere to opioid cessation advice and whether their clinical symptoms improve.

This study was approved as a retrospective audit (Nottingham University Hospitals NHS Trust registration number 21-482C). Data were analysed from consecutive patients who presented to a single tertiary care neurogastroenterology unit (Queen's Medical Centre, Nottinghamshire, UK) between January 2016 – December 2021 and diagnosed with FD according to the Rome IV clinical diagnostic criteria. Only patients aged ≥ 18 were included and pregnancy was the only exclusion factor. Phenotype and clinical outcomes were compared between FD patients taking opioids and those not taking opioids.

Results: A total of 157 patients were diagnosed with ROME IV FD. Among these 157 patients, 34 were classified in the opioid group and the remainder (n=123) in the non-opioid group. Nausea (n=28, 82.4% versus n=75, 61%; p=0.02), vomiting (n=19, 55.9% versus n=34, 27.6%; p=0.002), and constipation (n=18, 52.9% versus n=21, 23.6%; p=0.001) were most commonly seen in the opioid group.

There was no intergroup difference in the number of specialist consultations (p=0.45), or number of investigations (p=0.14) that the patients underwent. In the opioid group (n=34), 32 (94.1%) patients were advised to stop opioids. Fifteen (46.8%) stopped taking opioids on advice and nine (60%) of these patients who stopped opioids reported improvement in symptoms.

The most commonly reported symptom improvement was reduced constipation (n=3, 33.3%), reduced pain (n=3, 33.3%), or general feeling better (n=3, 33.3%). Approximately half of the patients who did not stop taking opioids reported that they needed the drugs for pain relief, whilst the remaining did not provide an explanation.

Conclusion: We demonstrate that opioid intake in FD is associated with more nausea, vomiting, and constipation compared to patients who are not prescribed opioids. We also show that most patients with ROME IV FD in a tertiary care setting often do not follow opioid cessation advice.
Should the burden of opioids in patients diagnosed with DGBIs be as high as this study suggests, then it is possible that an appreciable part of this disease burden may be avoidable via the strict implementation of policies to reduce opioid prescriptions for chronic non-cancer pain.

BASELINE ANXIETY SCORES PREDICT ESCALATION TO HIGHER DOSES OF PAROXETINE IN PATIENTS WITH FUNCTIONAL HEARTBURN AND REFLUX HYPERSENSITIVITY

N. de Bortoli[1], F. Baiano Svizzero[1], P. Visaggi[1], G. Adamo[1], L. Mariani[1], F. Ovidi[1], D. Stefani Donati[1], I. Dulmin[1], A. Venturini[1], I. Buselli[1], G. Scaramuzza[1], M. Bellini[1], E.V. Savarino[2]

Introduction: Up to 40% of patients with heartburn (HB) do not respond to proton pump inhibitors (PPI). In absence of objective gastroesophageal reflux disease (GERD) evidence, functional esophageal disorders (FEDs) defined by Rome IV criteria, such as functional heartburn (FH) and reflux hypersensitivity (RH), represent a possible cause. Paroxetine may have a therapeutic role in these conditions. We investigated the efficacy of paroxetine in patients with FH and RH.

Aims & Methods: We investigated the efficacy of paroxetine in patients with FH and RH.

We enrolled consecutive outpatients with negative endoscopy and PPI-refractory HB who were treated with paroxetine following a diagnosis of FH or RH on pH-impedance monitoring (MII-pH) performed off therapy at Pisa University Hospital. Demographics, symptoms, PPI response rates, paroxetine dose and response, and MII-pH findings were recorded. Patients were classified, according to Rome IV criteria, into group A (FH) and group B (RH). All patients received either paroxetine 10mg or 20mg daily according to individual HB response.

An adequate response to SSRI was defined as HB relief >60% on a VAS questionnaire. In addition, anxiety levels were assessed using the corresponding items of Hospital Anxiety and Depression Scale (HADS) questionnaire at baseline and after 8 weeks.

Results: 57 patients were included (44 F), median age 53 years (40-62) mean BMI 24 (22-26), of these, 42 had FH and 15 had RH. The groups were comparable in age, sex distribution, BMI, and symptoms. Table 1 reports clinical data.

On MII-pH, RH patients had higher total, recumbent and upright AET, higher number of total refluxes, and lower values of MNBI (p<0.001 for all) and PSPW (p<0.05) compared to FH. Table 1 reports MII-pH details. FH showed higher anxiety scores at baseline compared to RH (all p<0.001). Although FH more frequently required a higher dose of paroxetine to achieve symptoms relief (p<0.001), response to paroxetine was comparable between FH vs RH (69% vs 53%, respectively) (p=0.4). SSRI outcomes has been evaluated by means of HADS questionnaire (anxiety) that changed from a 16 (IQR 13.2, 17.8) to 9 (IQR 7, 10) in FH patients and from 11 (IQR 9.5, 12) to 6 (IQR 5, 8) in RH patients. At least 37/42 (88%) of patients with FH required standard dose of paroxetine compared to 12/15 (80%) of patients with RH who required only 10mg of paroxetine to reach symptomatic relief.

On ROC curve analysis, anxiety scores at baseline predicted the dose of paroxetine required for HB control in patients with FH and RH, with an area under the curve of 0.84 (CI, 0.71-0.96).

	Functional Heartburn (42 pts)	Reflux Hypersensitivity (15 pts)	P
Female (%)	35 (83%)	9 (60%)	0.082
BMI (median, IQR)	24 (21, 26)	24 (23, 26)	>0.9
Age (median, IQR)	53 (39, 61)	49 (42, 62)	0.4
Total AET (median, IQR)	0.2 (0.1, 0.8)	1.4 (0.9, 2)	<0.001
Reflux events (median, IQR)	18 (12, 27)	38 (32, 40)	<0.001
MNBI (median, IQR)	3617 (3040, 3945)	2670 (2447, 2882)	<0.001
PSPW-index (median, IQR)	72 (66, 77)	64 (63, 66)	0.004
SI/SAP positivity	0	15 (100%)	N/A
PPI Response rate, VAS	10% (10, 30)	40% (40, 50)	<0.001

Table 1: demographic, clinical and pH-imopedance findings.

Conclusion: Baseline anxiety scores predict whether patients with FH or RH will respond to low dose (10mg) or high-dose (20mg) paroxetine. These results suggest that patients with FH or RH who have high anxiety scores, should be treated with paroxetine 20mg, while 10mg could be adequate for patients with low anxiety levels at baseline.

Introduction: Functional dyspepsia (FD) is a commonly occurring functional gastrointestinal disorder, increases the number of clinical consultations and tests, significantly decrease quality of life and has a significant socioeconomic impact. FD is subdivided into postprandial distress syndrome (PDS), which is characterized by the presence of postprandial fullness and/or early satiety, and epigastric pain syndrome (EPS), which is characterized by the presence of epigastric pain and/or epigastric burning. Different pathophysiological mechanisms have been suggested to underlie the symptoms presented in these syndromes. Evidence suggests alterations in gastrointestinal motility, visceral hypersensitivity, permeability may play a role.

Aims & Methods: In this study, we aimed to studied the differences in gastric motility between healthy controls and PDS, and between healthy controls and EPS using cine magnetic resonance imaging (MRI). This study was a prospective interventional study. From January 2021 to May 2022, patients diagnosed with FD according to the ROME IV diagnostic criteria but who were non-adherent to prescribed medications that affect intestinal peristalsis, including laxatives, bowel regulators, and gastric peristalsis regulators, were studied prospectively. Cine MRI was performed before and after the test meal. Gastric short diameter, amplitude, contraction frequency, peristaltic wave height, peristaltic wave velocity, and gastric motility index (GMI) were evaluated in each group, and comparisons were made between the PDS group and healthy controls and between the EPS group and healthy controls.

Results: The numbers of subjects (controls/PDS/EPS) were 49 (18/22/9) patients. The mean (±standard deviation) age was 46.9±21.3 (32.9±14.1/59.1±20.4/45.1±18.8) years.

The male-to-female ratio was 24:25 (12:6/9:13/3:6). The mean BMI was 22.0±3.3 (23.1±14.1/20.4±2.1/22.3±2.8). In the pre-prandial state, there were no significant differences in any of the findings in the PDS or EPS groups compared to the healthy controls. In the post-prandial state, there was no significant difference in maximum short diameter between the PDS group and healthy controls.

However, the PDS group compared to the healthy controls showed increased amplitude of the fornix [PDS/controls) 12.1±4.3/7.3±5.1 (p=0.002)] and reduced contraction frequency [2.7±0.5/2.9±0.3 (p=0.003)], peristalsis wave height [9.2±2.5/14.9±4.0 (p<0.001)], and GMI 16.8±6.1/24.5±7.1 (p=0.001)]. The EPS group compared to the healthy controls showed no significant differences in maximum short diameter and amplitude, but had reduced contraction frequency [EPS/controls: 2.6±0.2/2.9±0.3 (p=0.027)], peristalsis wave height [9.5±3.2/14.9±4.0 (p=0.001)], and GMI [15.9±6.3/24.5±7.1 (p=0.009)].

Conclusion: In the pre-prandial state, analysis of gastric peristalsis using cine MRI showed no differences between the PDS group and healthy controls or between the EPS group and healthy controls. In the post-prandial state, both the EPS and PDS groups showed significant decreases in contraction frequency, peristaltic wave height, and GMI compared to the healthy controls, indicating reduced gastric peristalsis.

Furthermore, the amplitude of the fornix was increased in the PDS group compared to the healthy controls, suggesting that it is possible to evaluate post-prandial gastric adaptive relaxation by cine MRI.

PRESENCE OF ESOPHAGEAL CONTRACTILITY AFTER TREATMENT OF NON-SPASTIC ACHALASIA IS ASSOCIATED WITH IMPROVED ESOPHAGEAL EMPTYING

E. Vespa[1,2], D.A. Farina[2], P.J. Kahrilas[2], A.H. Koop[3], J. Pandolfino[2], D.A. Carlson[2]

Introduction: Some achalasia patients exhibit esophageal contractile activity on follow-up after treatment, yet its importance remains unclear.

Aims & Methods: We aimed to identify factors associated with presence of contractility after treatment and to assess its impact on timed barium esophagram (TBE) and clinical outcomes. Patients with type I or II achalasia on baseline high-resolution manometry (HRM) who completed HRM, TBE, and functional lumen imaging probe (FLIP) after treatment were retrospectively identified. The distal contractile integral (DCI) was calculated for the 10 supine swallows using the smart box tool with the isobaric contour set at 20 mmHg and median values were calculated.

Contractility was defined on post-treatment HRM as presence of at least 1 supine swallow with DCI ≥100 mmHg·s·cm in accordance with CC v4.0[1]. On FLIP, esophago-gastric junction (EGJ) opening was assessed applying the EGJ distensibility index (EGJ-DI) at the 60ml fill volume and measuring the maximum EGJ diameter that was achieved at the 60ml or 70ml fill volume. The classification of EGJ opening with FLIP Panometry used prespecified validated thresholds[2]. For TBE, 200 mL of low-density barium sulfate were administered and the height of the barium column was measured vertically from the EGJ at 1 and 5 minutes.

	Entire cohort		Normal EGJ subgroup	
	No contractility (n=61)	Contractility present (n=61)	No contractility (n=20)	Contractility present (n=33)
IRP, mmHg, median (IQR)	13 (10-20)	12 (9-16)	11 (8-13)	10 (7-14)
60ml pressure, mmHg, median (IQR)	**25 (21-31)**	**29 (24-33)**	**23 (20-28)**	**29 (25-32)**
EGJ opening classification normal + borderline-normal	**40 (66)**	**56 (92)**	**-**	**-**
EGJ opening classification reduced + borderline-reduced	**21 (34)**	**5 (8)**	**-**	**-**
1-minute column height, cm, median (IQR)	**8 (5-12)**	**4 (0-8)**	**7 (5-10)**	**4 (0-7)**
5-minute column height, cm, median (IQR)	**6 (2-9)**	**0 (0-4)**	**5 (2-7)**	**0 (0-3)**
Esophageal width, cm (IQR)	**2.9 (2.0-3.5)**	**2.1 (1.7-2.7)**	2.6 (1.6-3.1)	1.8 (1.7-2.3)
Eckardt score, median (IQR)	3 (1-4)	2 (1-3)	2 (1-4)	2 (1-4)

Comparisons with significant (p<0.05) differences are marked in **bold**.

Results: 122 patients were included (mean age 48 ± 17 years, 50% female). At follow-up evaluation (median 13 months) after treatment (54% peroral endoscopic myotomy, 24% pneumatic dilation, 22% laparoscopic Heller myotomy), 61 (50%) patients had contractility on HRM, with a median (IQR) DCI of 297 (183-545) mmHg·s·cm (median swallows with contractility: 80%).

Patients with evidence of contractility (compared to those without contractility) more frequently had a pre-treatment diagnosis of type II achalasia (84% vs 57%, p=0.001) and more frequently had a normal/borderline-normal EGJ opening (92% vs 66%, p<0.001). 14 patients (23%) had spastic

contractility (≥20% swallows with DL <4.5 s) and it was not associated with higher TBE column heights at 1 minute (3 vs 4 cm, p=0.422) or 5 minutes (0 vs 0 cm, p=0.506) when compared to non-spastic contractility. In the subgroup of patients with post-treatment integrated relaxation pressure <15mmHg and normal EGJ opening on FLIP (n=53), those with contractility had lower median column heights on TBE at 1 minute (4 vs 7 cm, p=0.002) and 5 minutes (0 vs 5 cm, p=0.001). These patients also had higher median FLIP 60 ml pressures (29 vs 23 mmHg, p=0.024). Eckardt scores were not significantly different across groups.

Conclusion: Esophageal body contractility appears to contribute to improved esophageal emptying after treatment of non-spastic achalasia. Contractility more frequently occurs in type II achalasia and seems facilitated if adequate EGJ opening is achieved after treatment. Avoidance of unnecessary extended myotomy may help preserve potential for contractility and improved outcomes in these patients.

ASSOCIATION OF SLING-FIBER PRESERVATION POEM AND POST-POEM GERD SYMPTOMS: A NORTH AMERICAN SINGLE-CENTER RETROSPECTIVE STUDY

Y. Fujiyoshi[1], M.R.A. Fujiyoshi[1], K. Kareem[1], N. Gimpaya[1], K. Pawlak[1], S. Seleq[1], M. Lamba[1], S. Li[2], S. Grover[1], J. Mosko[1], G. May[1], C. Teshima[1]

[1]St. Michael's Hospital, University of Toronto, Toronto, Canada, [2]University of Calgary, Calgary, Canada

Contact E-Mail Address: yusukefujiyoshi@gmail.com

Introduction: Peroral endoscopic myotomy (POEM) is standard treatment for achalasia. Gastroesophageal reflux disease (GERD) after POEM has been a limiting factor with this procedure. Preservation of the sling fiber during POEM was reported to reduce post-POEM GERD in Japan [1], but there are no reports of this technique in a western population.

Aims & Methods: The aim is to investigate the association of sling-fiber preservation during POEM and post-POEM GERD symptoms at our institution, which is a large therapeutic endoscopy referral center in Canada. This is a retrospective, single-center study of patients who underwent POEM from October 2017 to January 2023 at our center.

The initial cohort of patients were treated by conventional POEM until June 2021, after which a second cohort underwent POEM with sling-fiber preservation, as the techniques advanced.

The primary outcome was the rate of positive GERD symptoms after POEM. The secondary outcomes were procedure time, gastric myotomy length, clinical success rate (Eckard score ≦3), adverse events rate (Clavien-Dindo classification ≧Grade II) and use of PPI at follow-up.

Results: 148 POEM cases (52.5±15.6 y/o, female:61(43%)) were included in this study. There was no significant difference in patient characteristics between the groups. The mean procedure time (108.6±34.5 vs 109.1±45.7 min, P=0.93) and rate of adverse events (21% vs 14%, P=0.36) were similar between the traditional and modified groups. In the sling fiber preservation group, gastric myotomy length was significantly longer (2.2±0.7 vs 1.6±0.8 cm, P<0.05) yet the GERD symptom rate at follow-up was significantly lower (22% vs 41%, P<0.05), although PPI use was similar (57% vs 50%, P=0.47). Finally, the clinical success rate was similar between groups (88% vs 84%, P=0.6).

	Conventional POEM (N=74)	Sling fiber preservation POEM (N=74)	P value
Procedure time, mean (SD), min	109.1 (45.7)	108.6 (34.5)	0.93
Gastric myotomy length, mean (SD), cm	**1.6 (0.8)**	**2.2 (0.7)**	**<0.001**
Adverse events (%) (Clavien-Dindo classification≧II)	18 (24.3%)	16 (21.6%)	0.85
Clinical success rate (Eckardt score ≦3) N=121	53 (84.1%)	51 (87.9%)	0.60
GERD symptoms N=121	**26 (41.3%)**	**13 (22.4%)**	**0.033**
PPI usage (%) N=121	31 (50%)	33 (57%)	0.47

Conclusion: Sling fiber preservation during POEM is safe and reduces post-POEM GERD symptoms, despite the longer gastric myotomy length. As such, sling fiber preservation may be a useful solution to reduce post-POEM GERD in western populations.

Contact E-Mail Address: lluismundetp@gmail.com

Introduction: Oropharyngeal dysphagia (OD) is a very prevalent geriatric syndrome that causes serious nutritional and respiratory complications and mortality. Main pathophysiological elements of OD include delayed biomechanics as well as impaired sensitivity with alterations of the pharyngeal sensory/afferent pathway. However, the involvement of the motor/efferent pathway is unknown.

Aims & Methods: To characterize the biomechanics and neurophysiology of the swallow response in older patients with OD.

Observational study in 12 older patients with OD (>65 years) without neurological disorders, 12 young healthy volunteers (HV) and 9 older HV (OHV). Swallowing biomechanics and neurophysiology were measured by

videofluoroscopy (VFS) including the Penetration-Aspiration scale (PAS) and time to laryngeal vestibule closure (LVC), pharyngeal sensory (pSEP) and motor evoked-potentials (pMEP) to intrapharyngeal electrical and transcranial magnetic stimulation (TMS), respectively.

Results: Study participants (OD, HV and OHV) presented a mean age of 75.6±6.8, 29.9±6.2 and 74.9±5.5 years, respectively (p<0.0001), and a mean Barthel score of 82.5±29.0, 100.0±0.0 and 99.4±1.7 (p=0.022). 83.3% of OD patients had unsafe swallows (PAS=4.25±2.1 vs. 1.18±0.4 HV vs. 1.40±0.5 OHV; p<0.0001) with delayed LVC time (362.5±73.4ms OD vs. 185 5±57.3ms HV vs. 143.2±46.9ms OHV; p<0.0001 OD vs. HV and OHV).

Neurophysiologically we found OD patients had:

a. Higher pharyngeal sensory threshold (12.2±7.5mV OD vs. 5.9±2.2mV HV vs. 6.2±3.3mV OHV; p=0.009) and delayed pSEP P1 and N2 latencies (p<0.05 vs HV); and,

b. Higher pharyngeal motor thresholds to TMS in both hemispheres (right: 93.4±5.4 OD vs 82.0±11.0 HV vs 85.3±10.3 OHV, p=0.04; left: 92±8.1 OD vs 77.8±10.7 HV vs 86.3±10.4 OHV, p=0.02) and delayed MEPs latencies (tenar: 22.0±1.7ms OD vs 16.3±1.3ms HV vs 22.3±2.0ms OHV, p<0.0001 HV vs OD and OHV; right pharyngeal: 8.5±1.3 OD vs 6.6±1.6 HV vs 9.6±1.3 OHV, p=0.01; left pharyngeal: 7.8±1.0 OD vs. 6.3±1.4 HV vs 8.3±112 OHV, p=0.02).

Conclusion: Older OD patients present impaired swallowing biomechanics, pharyngeal hypoesthesia with disrupted conduction of pharyngeal sensory inputs, and reduced excitability of the pharyngeal motor cortex with delayed responses. These findings reveal a new element in the pathophysiology of aging-associated OD and open the door to new and specific neurorehabilitation treatments for these patients by acting simultaneously at both sensory and motor pathways.

USEFULNESS OF FUNCTIONAL ENDOSCOPY WITH THE ENDOSCOPIC PRESSURE STUDY INTEGRATED SYSTEM (EPSIS) FOR THE DIAGNOSIS OF ESOPHAGEAL ACHALASIA

Y. Shimamura[1], Y. Nishikawa[1], M.J. Navarro[1], K. Ushikubo[1], D. Azuma[1], K. Yamamoto[1], Y. Kimoto[1], H. Okada[1], I. Tanaka[1], M. Tanabe[1], M. Onimaru[1], H. Inoue[1]

Introduction: The Endoscopic Pressure Study Integrated System (EPSIS) is a novel diagnostic device that enables continuous measurement of intragastric pressure during an upper endoscopy. The intragastric pressure (IGP) waveform is recorded during continuous insufflation of the stomach. Previous studies have shown that lower esophageal sphincter (LES) function can be evaluated by characterizing the IGP waveform, and this technique has been applied in diagnosing gastroesophageal reflux disease (GERD).

We hypothesized that EPSIS could be useful for the dynamic evaluation of achalasia in conjunction with other diagnostic tests.

Aims & Methods: This single-center retrospective cohort study included patients who underwent EPSIS as an adjunct diagnostic tool for suspected esophageal motility disorders at a tertiary referral hospital between January 2022 and December 2022. The study group included patients with esophageal achalasia, and the control group consisted of cases with no abnormalities on upper endoscopy, absence of primary esophageal motility disorders with high-resolution manometry, barium swallow, and pathological reflux of acid exposure time ≤ 6% ruled out by 24-hour pH monitoring tests. Esophageal achalasia was confirmed using upper endoscopy, high-resolution manometry, and barium esophagram. The gradient of the pressure waveform obtained by EPSIS was compared between the two groups.

Results: During the study period, 35 cases in the esophageal achalasia group and 34 cases in the control group were included. The gradient of the pressure waveform (median) was significantly higher among achalasia patients (0.45 ± 0.17 vs. 0.31 ± 0.17 mmHg/sec, p=0.0008), indicating a failure of LES relaxation. A receiver operating characteristic (ROC) analysis was conducted, and the diagnostic performance of EPSIS for achalasia was determined to have an area under the curve (AUC) value of 0.76.

Conclusion: EPSIS in the achalasia group showed steep waveforms compared to the control group. ROC analysis also revealed that EPSIS had high diagnostic performance in detecting achalasia. These results suggest that EPSIS is a useful adjunct diagnostic tool for the diagnosis of esophageal achalasia. Functional endoscopy using EPSIS was found to be useful not only in diagnosing GERD but also in other disorders of LES function.

FUNCTIONAL DYSPEPSIA SYMPTOM PATTERNS IN PATIENTS ON OR OFF ACID SUPPRESSIVE THERAPY

J. Scheepers[1], F. Carbone[2,1], J. Tack[2,1]

[1]KU Leuven, Translational Research Center for Gastrointestinal Disorders, Leuven, Belgium, [2]University Hospital Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium

Contact E-Mail Address: janne.scheepers@kuleuven.be

Introduction: Functional dyspepsia (FD) is a disorder of gut-brain interaction (DGBI) characterized by postprandial fullness, early satiation, epigastric pain or burning in the absence of a readily identifiable cause at upper endoscopy. Proton pump inhibitors (PPIs) are often used as a first-line treatment for FD, although their efficacy has not been convincingly established.

Aims & Methods: The aim was to investigate symptom patterns in FD patients with and without acid-suppressive therapy (PPI or H2-antagonist, H2RA) and to evaluate the use of these drugs in different patient groups. Ambulatory tertiary-care patients referred for upper gastrointestinal endoscopy were requested to fill out Rome IV gastro-duodenal questionnaires. Those fulfilling Rome IV FD criteria with a negative endoscopy were identified as FD patients and subdivided into patients on and off acid-suppressive therapy. The pattern of GI symptoms was compared between these two subgroups, using frequency thresholds from the Rome IV criteria. The chi-square or Fisher exact (when applicable) test was used to evaluate statistical significance (p<0.05).

Results: The Rome IV questionnaire was filled out by a total of 1002 patients (58% females, 48.5 ± 0.5 years, BMI 25.4± 0.5). Of these, 229 (23%, 73% females, 45.5 ± 1.1 years, BMI 23.9 ± 0.3) fulfilled the diagnostic criteria for FD. Organic findings at endoscopy included Barrett's oesophagus (n=40, 4%), peptic ulcers (n=24, 2%), and reflux oesophagitis (n=352, 35%). PPI/H2RA usage in FD patients was 60%, which was not significantly different from patients diagnosed with Barrett's oesophagus (75%, p=0.07), peptic ulcer (50%, p=0.33), reflux oesophagitis (57%, p= 0.45) or the combined group with organic abnormality at upper endoscopy (46%, p=0.1). There was no significant difference (p=0.67) in PPI/H2RA usage between the EPS (epigastric pain syndrome, 55% usage) and PDS (postprandial distress syndrome, 50% usage) subgroups of FD.

The most prevalent symptoms in FD patients were postprandial fullness (76%), epigastric pain (67%) and bloating (62%). Patients on acid-suppressive therapy reported more nausea (41% vs 27%, p=0.04) and excessive belching (50% vs 36%, p=0.05) compared to patients without acid suppression.

There was no significant difference in postprandial fullness (84% vs 73%, p=0.05), epigastric pain (75% vs 64%, p=0.08), heartburn (17% vs 28%, p=0.06) and bloating (70% vs 58%, p=0.06) between the two subgroups. Looking at the EPS and PDS subgroups of FD, there was a significant difference (p=0.03) in bloating between patients on (73%) and off (46%) acid suppression in the PDS subgroup of FD.

Conclusion: The cardinal symptom pattern in FD patients referred for upper endoscopy is similar for those on and off acid-suppressive therapy, but those on PPI/H2RA report more nausea and belching. No difference in acid-suppressive therapy use was observed between FD patients and those with organic findings at endoscopy.

FOOD-RELATED SYMPTOMS AND AVOIDANCE IS PREVALENT EVEN IN BETWEEN ATTACKS IN PATIENTS WITH SEVERE CYCLIC VOMITING SYNDROME

A. Trikola[1,2], N. Bar[2], K.G. Kiser[2], C. Velez[2], K. Staller[3], H. Burton Murray[4], B. Kuo[2]

[1]Naval Hospital of Athens, Gastrointestinal, Athens, Greece, [2]Massachusetts General Hospital, Gastroenterology and Hepatology, Boston, United States, [3]Massachusetts General Hospital, Digestive Health Center, Boston, United States, [4]Massachusetts General Hospital/Harvard Medical School, Boston, United States

Contact E-Mail Address: artemis.trikola@yahoo.gr

Introduction: Patients with cyclic vomiting syndrome (CVS) experience episodic severe attacks of nausea and vomiting, subsequently limiting food intake during attacks. When the attacks remit, however, patients are mostly asymptomatic. Among adults with CVS in remission, we aimed to examine differences between those with mild versus severe CVS on:

1. Eating-related quality of life (QOL) and;
2. Dietary variety.

Aims & Methods: In a prospectively-maintained cohort of adults with CVS, we included all patients in remission (inter-attack phase at assessment time point) from June 2018 up to September 2022. We grouped patients into severe CVS group (4 attacks or more/year) and mild CVS group (less than 4 attacks/year).

We assessed eating-related QOL on the *Patient Assessment of Upper Gastrointestinal disorders- Quality of life (*PAGI-QOL), using the diet and food habits subscale and diet variety on a *Food Frequency Questionnaire* (FFQ), capturing patient-reported outcomes (PROs) over the prior two weeks, as an approximation of long-term dietary intake.

Results: Of the 49 patients enrolled (30 [61%] females, mean age 33.5 +/- 12.6 years old), 32(65%) patients were included in the severe CVS group (>4 attacks/year), whereas 17 (35%) were enrolled in the mild CVS group. During enrollment, all patients were free of active CVS symptoms.

The severe CVS group was significantly younger and experienced significantly more nausea (p<0.001), abdominal pain (p=0.003), early satiety (p=0.002), loss of appetite (p=0.012), discomfort (p=0.022) and bloating (p=0.007) compared to CVS patients with mild symptoms, during the inter-attack phase.

Those with more severe CVS attacks had poorer QOL and significantly more concern about eating (p<0.001), avoidance (p=0.005) and restriction behavior, and less enjoyment of food (p=0.002), as displayed by PAGI-QoL. Despite symptom differences, there were no differences neither in food type frequencies, nor in the body mass index (BMI) between the two groups.

Conclusion: Despite the episodic nature of CVS, there are notable decreases in quality of life, specifically food-related QOL, in the inter-attack phase among those with a higher frequency of attacks. Such decrements in QOL and altered eating behaviors suggest that patients with more frequent CVS attacks may have significant inter-attack symptoms that would not typically fall into the typical CVS classification schema.

Faedo", National Research Council of Italy (CNR), Pisa, Italy, [4]St. James's University Hospital, Department of Gastroenterology, Leeds, United Kingdom

Contact E-Mail Address: pierfrancesco.visaggi@gmail.com

Introduction: There is currently no recommendation regarding preferred drugs for eosinophilic esophagitis (EoE) because their relative efficacy is unclear.

Aims & Methods: We conducted an up-to-date network meta-analysis to compare proton pump inhibitors, off-label and EoE-specific topical steroids, and biologics in EoE. We searched MEDLINE, EMBASE, EMBASE Classic, and the Cochrane central register of controlled trials from inception to February 2023. We included randomized controlled trials (RCTs) comparing efficacy of all drugs versus each other, or placebo, in adults and adolescents with EoE.

Results were reported as pooled relative risks with 95% confidence intervals to summarize effect of each comparison tested, with drugs ranked according to P-score.

Results: We identified 13 RCTs containing 1327 subjects with EoE. For histological remission defined as ≤15 eosinophils/high-power field (eosinophils/HPF), budesonide orally disintegrating tablet 1mg b.i.d., fluticasone orally disintegrating tablet 1.5mg b.i.d. and 3mg b.i.d., and dupilumab 300mg weekly ranked first, second, third, and fourth, respectively.

Results were similar when histological remission was defined as ≤6 eosinophils/HPF. EoE-specific formulations were generally superior to adapted asthma medications in achieving histological remission. For failure to achieve symptom improvement, only budesonide orally disintegrating tablet 1mg b.i.d. and budesonide oral suspension 2mg b.i.d. were significantly more efficacious than placebo. For failure to achieve endoscopic improvement based on the EoE endoscopic reference score, only budesonide orally disintegrating tablet 1mg b.i.d. and budesonide oral suspension 1mg b.i.d. or 2mg b.i.d. were significantly more efficacious than placebo.

Conclusion: Most drugs are effective for achieving histological remission in active EoE, but few are superior to placebo in terms of symptomatic or endoscopic improvement.

Disclosure: Nothing to disclose.

THERE IS A LONG WAY FROM CURRENT CLINICAL PRACTICE IN DENMARK COMPARED TO RECENT PUBLISHED ENGLISH GUIDELINE ON MANAGEMENT OF CHILDREN WITH EOSINOPHILIC OESOPHAGITIS

K. Bredal[1], L.T. Frandsen[2], J.H. Terkelsen[1], M.H. Nielsen[1], D. Melgaard[3,1], A.L. Krarup[2,1,4]

[1]Aalborg University, Clinical Medicine, Aalborg, Denmark, [2]Aalborg University Hospital, Emergency Medicine and Trauma Center, Aalborg, Denmark, [3]Noth Denmark Regional Hospital, Hjørring, Denmark, [4]Aalborg University Hospital, Gastroenterology and Hepatology, Aalborg, Denmark

Contact E-Mail Address: apslk@rn.dk

Introduction: A low incidence of eosinophilic esophagitis (EoE) in children in the North Denmark Region (NDR) were measured in 2007-2017. Few of the children diagnosed before 2017 were treated to remission suggesting a lack of awareness. While there currently are no guidelines for treating EoE in Denmark, a new English guideline was published in 2022 renewing focus on the disease.

Aims & Methods: The aim of this study was to measure the difference of current Danish clinical practice for treatment and follow-up of EoE children in the NDR with the new English guideline from the British Society of Gastroenterology (BSG) and the British Society of Pediatric Gastroenterology, Hepatology and Nutrition (BSPGHAN).

This retrospective, register-based DanEoE cohort study included 31 children diagnosed with EoE between 2007–2021 in NDR. Medical records were reviewed and information about treatment and follow-up were collected.

Results: In 32% of the children with EoE in the NDR, first-line treatment initiated corresponded with the recommendations in the new English guideline. One in 6 children were never started on any treatment even though treatment always is recommended.

Symptomatic follow-up was completed in 77% (24/31) of children and 85% (11/13) of the children after 2017. Histologic follow-up within 12 weeks was completed in 13% (4/31) of the children and 15% (2/13) of the children after 2017. Combined symptomatic and histologic remission after first-line treatment was achieved in 6% (2/31).

Conclusion: In Denmark focus on improving EoE treatment and follow-up for children is needed, as there is a significant difference between current clinical practice and the recommendations in the new English guideline.

Introduction: Eosinophilic oesophagitis (EoE) is a chronic, immune-mediated disease of the oesophagus. EoE is associated with a substantial disease burden affecting the quality of life and impact mental health. There are limited data describing the incidence of psychiatric disorders and the use of psychotropic drugs (PDs) in EoE patients.

Aims & Methods: The aim was to investigate whether EoE patients in Denmark, after being diagnosed, have a higher incident use of psychotropic drugs and more psychiatric comorbidity compared to the general population.

This study is a nationwide, population-based register study including 3,367 EoE patients and 16,835 age- and sex-matched comparators.

A register-based EoE definition was used to identify cases. Incident PD use was extracted from the prescription register and information regarding psychiatric contacts was retrieved from the Danish Psychiatric Central Research Register.

Results: The five-year incidence of PD use in EoE patients was 13.8% compared to 7.1% of the matched comparators (HR 1.83; CI 1.6-2.0; P ≤ 0.001). Antidepressants were the most frequently prescribed PD, whereas antipsychotics were the least prescribed PD. Increasing age, lower educational level, and comorbidity (Charlson Comorbidity Index score ≥1) were associated with the prescription of PDs. The risk of PD use was lower in men compared to women with EoE.

Conclusion: Treatment with PDs were 94% more common in EoE patients after they were diagnosed than in the general Danish population, indicating that EoE patients have an increased risk of psychiatric disorders.

Introduction: Eosinophilic esophagitis (EoE) is a chronic, allergic inflammatory disease of the esophagus. Major adverse cardiovascular events (MACE) have been associated with diseases of chronic inflammation. Data on MACE from large population-based cohorts of biopsy-proven EoE are lacking.

Aims & Methods: The aim of this study was to investigate the association between EoE and MACE. It included all Swedish adults with EoE (1990-2017) without a record of previous cardiovascular disease (CVD) (n=1,546, with follow-up until 2019). EoE was defined from prospectively recorded esophageal histopathology reports from all Swedish pathology departments (n=28) in the Epidemiology Strengthened by Histopathology Reports in Sweden (ESPRESSO) cohort. Individuals with EoE were matched with up to five general population reference individuals (n=7,281) for age, sex, calendar year and county without EoE or CVD.

Multivariable-adjusted hazard ratios (aHRs) for MACEs (any of ischemic heart disease, congestive heart failure, stroke and cardiovascular mortality) were calculated using Cox proportional hazards models. In secondary analyses, individuals with EoE were compared to their siblings to account for residual confounding.

Results: The majority of individuals with EoE were male (75%), and the median age at EoE diagnosis was 37 years (IQR 19-51). Over a median of 6.0 (IQR 4.6-8.0) years of follow-up, 65 (4.2%) MACE events were observed in patients with EoE and 225 (3.1%) in reference individuals, corresponding to 6.4 *vs.* 4.7 events per 1,000 person-years (incidence rate difference: 1.7, 95%CI=0.0-3.4), respectively.

No significantly higher overall risk (aHR=1.14, 95%CI=0.86-1.51) of MACE outcomes. No significant differences between age, sex and follow-up time were observed. When adjusting for relevant CVD medication and sibling comparison, results were similar.

	Reference individuals	EoE
	N=7 281	N=1 546
MACE outcomes*		
Incident events (%)	226	65
Incidence rate per 1000 py (95%CI)	4.7 (4.1-5.4)	6.4 (4.9-8.1)
Absolute rate difference per 1000 py (95%CI)	0 (ref.)	1.7 (0-3.4)
Unadjusted HR# (95%CI)	1 (ref.)	1.37 (1.04-1.80)
Adjusted HR (95%CI)	1 (ref.)	1.14 (0.86-1.51)

CI, confidence interval; EoE, eosinophilic esophagitis; HR, hazard ratio; MACE, major adverse cardiovascular events; py, person-years

*Includes ischemic heart disease, congestive heart failure, stroke and cardiovascular mortality.

#Adjusted for age, sex, calendar year, county of residence at index date, country of birth (Nordic country or other), educational level (compulsory school, upper secondary school or college/university), ≥1 metabolic disease (diabetes, obesity, hypertension or dyslipidemia), chronic kidney disease, atopic dermatitis, celiac disease and chronic respiratory disease (chronic obstructive pulmonary disease or asthma) diagnosis.

Table 1. Incidence Rates, Absolute Rate Differences and Hazard Ratios for incident Major Adverse Cardiovascular Events in patients with Eosinophilic Esophagitis compared to general population reference individuals 1990-2019.

Conclusion: Individuals with biopsy-proven EoE had no increased risk of MACE outcomes compared to general population or sibling comparators. The absence of any association with MACEs in our study may be reassuring for patients with EoE.

MULTIDISCIPLINARY APPROACH IN EOSINOPHILIC OESOPHAGITIS CARE: HOW TO IMPROVE DIAGNOSIS AND MANAGEMENT

I. Spinelli[1], F. Fianchi[1], A. Aruanno[1], S. Urbani[1], F. Veccia[1], D. Ferrarese[1], D. Belella[1], M. Cintoni[1], G. Pulcini[1], M.C. Mele[1], F. Mangiola[1], R. Landi[1], E. Nucera[1], G. Ianiro[1], A. Gasbarrini[1], A. Tortora[1]

[1]*Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy*

Contact E-Mail Address: irenespinelli1@gmail.com

Introduction: Eosinophilic esophagitis (EoE) is a complex disease that often coexists with different conditions. Given the complexity of this pathology, a multidisciplinary approach, with gastroenterologist, allergist, dietitian, psychologist, and endoscopist may benefit to diagnosis and management of patients, reducing time to diagnosis as well.

Aims & Methods: To evaluate impact of multidisciplinary team in diagnosis and management of eosinophilic esophagitis disease. A retrospective study was conducted to include all patients referred to Fondazione Policlinico Universitario A. Gemelli between September 2016 and April 2023. Prevalence of allergic, nutritional, and psychological disturbs was evaluated. Referral for each patient was reviewed.

Diagnostic delay (time interval between first occurrence of EoE symptoms and confirmed diagnosis with endoscopy) was analyzed in patients with suspected eosinophilic esophagitis and diagnosis made in our center, compared to data reported in literature. Publications from 2014 to 2023 were reviewed.

Results: A total of 98 patients, 76 males and 22 females, with a mean age at diagnosis of 25 years, were included in the study. For all patients, each visit was conducted in team with gastroenterologist, allergist, dietitian, and psychologist. 81 patients presented allergic diseases (82 %), 51 patients (52 %) needed nutritional support by a dietitian and 63 patients (64 %) presented psychological implication by the disease to necessitate clinical support. 42 patients (43%) were referred by team members. 13 patients (13%) presented to our center with suspect eosinophilic esophagitis.

For these patients, ab initio evaluated with multidisciplinary approach, mean time to diagnosis was 2.25 months. Diagnostic delay reported in literature was 3 years.

Conclusion: Multidisciplinary team is needed to manage patients with eosinophilic esophagitis because its several associated diseases. In fact, most of our patients presented allergic, nutritional, and psychological disturbs. This approach assures more appropriate medical management through shared decision making. Almost half of patients was referred by team members. Thanks to awareness of each physician of the team and his early referral, we assisted in a reduction of diagnostic delay in our center compared to data reported in literature.

Contact E-Mail Address: liptak@jfmed.uniba.sk

Introduction: Eosinophilic esophagitis is a chronic, immune-mediated inflammatory disease of esophagus characterized by a significant mucosal eosinophilia. However, the definite cause of this disease remains unknown. One of the most probable etiology factors is an abnormal response of immune system to various types of ingested food. Therefore, one of the treatment options is the so called 6-food elimination diet. This diet represents a therapeutic method of choice especially in patients who could not be treated by standard immunosuppressive medications such as corticosteroids. The 6 food groups that are mostly associated with food allergies are: eggs, dairy products, seafood/shellfish, nuts, wheat, and soy. Although widely used, there is surprisingly lack of data evaluating its effect on metabolomic profile of the patients and their well-being despite its strict dietary regime.

Aims & Methods: The aim of this study was to evaluate possible changes in metabolomic and anthropometric parameters in healthy individuals pre and after 4 weeks of elimination diet.

We performed a prospective single center study on healthy volunteers (age >18 years). For metabolomic analysis of blood plasma and urine the method of NMR (Nuclear Magnetic Resonance) was used. Anthropometric analysis was performed by bioelectrical impedance. All volunteers also filled validated questionnaires considering various aspects of patient well-being (WHOQOL-BREF, PROMIS-10 and PHQ-15). The statistical analysis was processed by unparametric tests (Mann-Whitney U-test) for comparison of equality of medians and unparametric paired Wilcoxon-signed-rank test.

Results: Fifteen (15) healthy volunteers without any previous dietary restrictions participated in this study (12 women with median age 35,5 years and 3 men with median age 41 years). Evaluation of blood plasma metabolomic profile shows significant increase of acetate, succinate, creatine, and creatinine at the end of the four weeks period of the course of the diet. The urine metabolomic profile shows significant decrease of dimethylamine. Importantly, no statistically significant changes were observed in the levels of essential aminoacids. No relevant differences were observed considering anthropometric parameters (BMI, percentage of fat and muscle mass) and in the questionnaires assessing quality of life.

Conclusion: The results of presented study shows that the 6-food elimination diet have only minor effect on the metabolomic profile of healthy volunteers. This further suggest its good safety profile for the treatment of eosinophilic esophagitis. In addition, presented data point out that this diet does not significantly lower the quality of life of patients which could result to good adherence to the diet in short term course.

Disclosure: Nothing to disclose.

A UK BASED RETROSPECTIVE ANALYSIS OF THE MANAGEMENT OF PATIENTS PRESENTING AS AN EMERGENCY WITH FOREIGN BODY IN THE OESOPHAGUS

R. Aggarwal[1], N. Umar[1,2], D. King[3], B. Coupland[4], C. Turnbull[5], R. Jazrawi[6], N. Trudgill[1]
[1]Sandwell & West Birmingham Hospitals NHS Trust, West Bromwich, United Kingdom, [2]University of Birmingham, Birmingham, United Kingdom, [3]Russel Hall Hospital, Gastroenterology, Dudley, United Kingdom, [4]University Hospitals Birmingham, Informatics, Birmingham, United Kingdom, [5]Dr. Falk Pharma GmbH, Cores End Road, Bourne End, United Kingdom, [6]Dr. Falk Pharma UK Ltd., Medical, Bucks, United Kingdom

Contact E-Mail Address: rohan.aggarwal@nhs.net

Introduction: Emergency admission with foreign body in the oesophagus (FBO) commonly requires endoscopic removal. Oesophageal food bolus obstruction is often due to eosinophilic oesophagitis (EoE). Patients with food bolus obstruction should undergo endoscopy and multilevel oesophageal biopsies to exclude EoE.

This national retrospective study examined the management including endoscopy and follow-up of patients presenting as an emergency with FBO.

Aims & Methods: The Hospital Episode Statistics database was used to identify patients over 18 with FBO presenting as emergencies in England using the ICD-10 code T18.1 between 2008 and 2019. Logistic regression analysis assessed factors associated with undergoing endoscopy and biopsy.

Results: 10,417 patients were identified: 71% male; 82% white ethnicity; and 52% were admitted under Ear, Nose & Throat (ENT). 74.7% underwent endoscopy (94% within a week of admission) but only 18% had biopsies taken within 6 months of admission. 1.6% underwent endoscopic dilation for FBO, with 0.5% coded with a related perforation. 70% of ENT patients underwent endoscopy but only 11.9% biopsy to exclude EOE, compared with 83% of patient admitted under General Medicine undergoing endoscopy and 29.5% biopsy.

Endoscopy and biopsy was associated with: older age (61-70 OR 1.43 (95% CI 1.26-1.61), males (females 0.67(0.62-0.71)), the least deprived (1.24 (1.13-1.38)), later diagnosis year (2019 1.42 (1.21-1.66), and admission under General Medicine (2.68(2.48-2.88) or Gastroenterology (3.03(2.61-3.51)) but not with NHS trust FBO volume. 32% received outpatient follow-up within 12 months of their FBO admission: 30% of patients admitted under General Medicine were referred to gastroenterology for follow-up but only 12% of those admitted under ENT.

In recent data from Scotland (Ntuli et al. 2020), 26% of patients with food bolus obstruction had EoE. This suggests that in the present study cohort approximately 1300 patients missed an opportunity to be diagnosed with EoE, as oesophageal biopsies were not taken at endoscopy for FBO.

Conclusion: 75% of patients presenting with FBO undergo endoscopy but only 18% had biopsies taken to exclude this common presentation of EoE. Pathways for the management of food bolus obstruction require re-design and unless the airway is impaired, this condition should be managed under General Medicine.

COMPARATIVE EFFICACY AND SAFETY OF DIFFERENT PHARMACOLOGICAL INTERVENTIONS FOR EOSINOPHILIC ESOPHAGITIS: A NETWORK META-ANALYSIS

G. Pellegatta[1], A. Facciorusso[2], L. Da Rio[1], G. Marcozzi[1], E. Mastrorocco[1], M. Spadaccini[1], R. Maselli[1], C. Hassan[1], A. Repici[1]
[1]Humanitas Research Hospital, Gastroenterology Unit, Rozzano, Italy, [2]University of Foggia, Gastroenterology, Foggia, Italy

Contact E-Mail Address: gaia.pellegatta@gmail.com

Introduction: Currently there is no single strategy that has a clear benefit as primary therapy for Eosinophilic Esophagitis (EoE). Because of the continuous emergence of randomized clinical trials on various pharmacological and nonpharmacological approaches, we conducted a network meta-analysis in order to evaluate the efficacy and safety of available treatments for EoE in adult patients.

Aims & Methods: Histologic remission, clinical and endoscopic response, and serious adverse events (SAEs) were evaluated. Direct and indirect comparisons between treatments (proton pump inhibitors (PPI), swallowed topical corticosteroids (STC), monoclonal antibodies (mAb), placebo) were performed. Results are expressed as risk ratio (RR) and 95% confidence interval (CI).

Results: A total of eight eligible randomized controlled trials (1057 patients) were included in the meta-analysis. When the three interventions were compared with each other, none was significantly more effective in terms of histologic remission (STC vs mAb RR 5.03, 95% CI 0.96-26.24, PPI vs mAb RR 0.87, 95% CI 0.41-3.12, PPI vs STC RR 0,75, 95% CI 0.60-5.09) while all three interventions were significantly superior to placebo (mAb vs placebo RR 31, 95% CI 10.91-88, STC vs placebo RR 54.26, 95% CI 12.1-241.83, PPI vs placebo RR 10.78, 95% CI 5.33-21.78). STC and mAB resulted as the best interventions (SUCRA 0.93 and 0.78, respectively) followed by PPI (SUCRA 0.38).

None of the interventions tested resulted in a significant increase in SAE rate compared with placebo (mAb vs placebo RR 3.41, 95% CI 0.61-19.12, STC vs placebo RR 1.28, 95% CI 0.25-6.44). As a consequence, placebo ranked as the safest treatment (SUCRA 0.73), followed by STC (SUCRA 0.63) and mAb (SUCRA 0.51).

Conclusion: The results of this network meta-analysis show that mAb and STC were the most effective treatments among those available for EoE as assessed by histologic remission, both with a relatively low rate of serious adverse events.

Disclosure: Nothing to disclose.

Introduction: Swallowed Topical Steroids (STCs) originally developed for airway administration have been used off-label for eosinophilic esophagitis (EoE). Recently a new specifically designed formulation of budesonide orodispersible tablet formulation (BOT) has been developed and ap-

proved in different European countries. Since 30/08/2022 in our center all patients treated with STCs have been switch to BOT and prospectively followed up clinically and histologically.

Aims & Methods: The aim of our study is to evaluate efficacy, safety and patient' satisfaction of therapeutic switch from off-label STCs to BOT (NCT05594849). Each patient performed upper GI endoscopy with biopsies under STCs and after 12-16 weeks of BOT to evaluate histologic remission. Moreover, all patients filled up a set of questionnaires before the switch and after 12-16 weeks of BOT evaluating severity of symptoms (DSS, DSQ), quality of life (EoE QoL) and satisfaction of the treatment (19 items scored between 0 to 4 evaluating the modality of assumption, the taste, and the perception of safety; higher values corresponding to higher satisfaction).

Results: The sample consists of 29 EoE patients, PPI non responders, who were receiving STCs (72.41% home-made viscous fluticasone, 27.58% viscous budesonide). Mean treatment-time was 32.53±29.27 months for fluticasone and 23.5±11.01 months for budesonide. Six patients (20.68%) presented strictures previously treated endoscopically. The starting dose of BOT was determined on the previous dosage of STCs and on the presence of histologic remission (89.65% used 1 mg twice daily, 10.34% 1 mg daily). Of 29 enrolled patients, 19 have already repeated the endoscopy under BOT (65.51%). Before therapeutic switch, 8 patients over 19 (42,11%) were active (>15 EOS/HPF) and 11 patients (57.89%) were in histologic deep remission (<6 EOS/HPF). After therapeutic switch, 7 patients over 8 (87.5%), histologically active under STCs, achieved deep remission with BOT, and one remained active (12.5%). Between patients in deep remission with STCs, 10 patients over 11 mantained histologic deep remission (90,91%) and only one relapsed (9,09%) after switch. After the switch to BOT, 3 patients over 29 presented oral/esophageal candida infection. Of these three, two patients have already experienced oral/esophageal candida under off-label STCs. After the therapeutic switch an improvement of symptoms severity was found for DSS score but not for DSQ (STCs-DSQ 0.24±0.63, BOT-DSQ 0.16±0.57, p value=0.60; STCs-DSS 5.14±2.77, BOT-DSS 2.3±2.05, p value=0.012). No differences were found for the quality of life (STCs-EoE QoL 42.07±19.42, BOT EoE QoL 30.72±23.95, p value=0.068). Finally, the satisfaction score showed a significant major willing of assumption of BOT rather than STCs (STCs 38.21±11.61, BOT 55.91±14.30, p value= 0.003).

	STCs	BOT	P-VALUE
HISTOLOGIC REMISSION	11 Remission	10 deep-remission (90.91%), 1 relapse (9.09%)	
	8 Active	7 deep-remission (87.5%), 1 active (12.5%)	
DSQ	0.24±0.63	0.16±0.57	0.601
DSS	5.14±2.77	2.3±2.05	0.012
EOE QOL	42.07±19.42	30.72±23.95	0.068
SATISFACTION	38.21±11.61	55.91±14.30	0.003

Conclusion: Preliminary data of our study showed that therapeutic switch from off-label STCs to BOT in EoE patients is effective, safe and well tolerated. Most of patients histologically active under off-label STCs achieved histological deep remission with BOT and, if previously acquired with off-label STCs, histological deep remission was maintained in the majority of patients under BOT. The patients reported a significant major willing of assumption of BOT rather than off-label STCs.

Disclosure: Nothing to disclose.

Introduction: Dysphagia is a common and alarming symptom, which harbours the risk of organic diseases. Its incidence is increasing in the last decades worldwide, both in the young and elderly population. However, epidemiological and clinical data related to dysphagia patients are lacking. Thus, we aimed to provide an updated analysis of the main underlying causes of dysphagia in outpatient clinic.

Aims & Methods: We retrospectively evaluated consecutive patients referred from June 2022 to December 2022 to our outpatient clinic, suffering from incident dysphagia as the main symptom at the index visit. Patients already previously evaluated were excluded.

After clinical evaluation, all the subjects underwent esophago-gastro-duodenal endoscopy (EGDS) as the first diagnostic exam, during which, up to clinical suspect and endoscopist evaluation, biopsies of the oesophagus and/or cardias were made. According to clinician assessment, execution of high-resolution manometry (HRM) was also performed.

Results: During the study period 700 first outpatient visits were performed. A total of 78 patients met the inclusion criteria and were then involved in the study. Esophageal dysphagia was the most frequently reported symptom (65/78, 83.3%), followed by oropharyngeal dysphagia (8/78, 10.3%) and mixed dysphagia (5/78, 6.4%).

The most common concomitant symptoms were chest pain (40/78, 51.3%), regurgitation (34/78, 43.6%), heartburn (20/78, 25.6%), weight loss (19/78, 24.3%) and cough (14/78, 17.9%). Median age was 57.0, with M/F ratio of 33/78 (42.3%).

Endoscopy showed abnormal features in 25/78 (32.1%), with the most common finding being erosive esophagitis (5/25, 20%). Seven out of 25 (28%) subjects had at least one non-specific finding among those associated with eosinophilic esophagitis (edema, rings, exudate, furrowing, strictures). The physician performed biopsies of the esophagus and/or cardias in 52/78 (66.6%) cases, and 28 patients had histologic abnormal findings.

The most common histological diagnosis was eosinophilic esophagitis (EoE) which was identified in 12 patients, 5/12 (41.7%) without mucosal evidence of EoE. HRM was performed in 22/30 patients (73.3%) after negative endoscopy and/or histology, with abnormal findings in 17/22 (77.3%) of the tests. In this setting achalasia was the most common diagnosis (5/22, 22.7%), one patient with Type I, two with Type II and two patients with Type III.

Overall, the most common diagnosis in our cohort was EoE (12/78, 15.4%), followed by achalasia (7/78, 9.0%).

Conclusion: Among patients complaining of dysphagia referred to an outpatient gastroenterology clinic, EoE is the main underlying cause of such condition. Given its high frequency, biopsies should be always performed in patients with dysphagia, regardless of endoscopic findings.

Disclosure: Nothing to disclose.

ASSOCIATION OF MODERATE-INTENSITY AND VIGOROUS-INTENSITY PHYSICAL ACTIVITY ON GASTROESOPHAGEAL REFLUX DISEASE

C.H. Tae[1], AR. Choe[1], J.E. So[2], E.M. Song[1], K.-N. Shim[1], S.-A. Jung[1]
[1]Ewha Womans University College of Medicine, Department of Internal Medicine, Seoul, South Korea, [2]Ewha Womans University College of Medicine, Seoul, South Korea

Contact E-Mail Address: jhtae@ewha.ac.kr

Introduction: Lifestyle modifications leading to weight reduction recommend for symptom relief on patient with gastroesophageal reflux disease (GERD) with overweight or obesity. The physical activity seems to be an important factor of lifestyle modifications for weight loss and maintenance.

However, it is lack of data that elucidate which GERD patients and physical activity would have a benefic impact.

Aims & Methods: This study investigated the association of physical activity intensity with GERD. This retrospective study, 21,266 subject who underwent esophagogastroduodenoscopy as a comprehensive health screening program. The participants were assessed for physical activity (metabolic equivalent task [MET]- min/week) using a self-reported questionnaire between January 2018 and December 2021.

We used the current physical activity guideline to distinguish "physically active" (i.e., ≥450 MET·min·wk−1) or "physically inactive" subjects (i.e., <450 MET·min·wk−1). We analyzed the association between intensity for physical activity and GERD.

Results: The prevalence of GERD in men was significantly higher than that in women (86.5% vs 13.5%, $P < 0.001$). The mean body mass index (BMI) was higher in GERD patients than non-GERD patients (23.6±3.4 vs 25.7±3.5, $P < 0.001$).

Compared to the non-GERD group, the GERD group got more vigorous-intensity physical activity (140 MET vs 210 MET, $P < 0.001$), while no significant difference in moderate-intensity physical activity (360 MET vs 360 MET, $P = 0.272$). The severity of GERD showed a significant positive correlation with frequency and duration of vigorous-intensity physical activity.

Moreover, the prevalence of GERD in physically active group was significantly higher than physically inactive group (68.5% vs 31.5%, $P < 0.001$). In the physically active group, the severity of GERD showed a significant positive correlation with the higher portion of vigorous-intensity physical activity in total physical activity.

Conclusion: We could find that vigorous-intensity physical activity of frequent and long duration could trigger the reflux to aggravate the symptoms of GERD. These findings suggest that the modest-intensity physical activity can be beneficial to GERD.

Disclosure: No any conflict of interest.

PP0107

METABOLIC RISK FACTORS FOR GASTROESOPHAGEAL REFLUX DISEASE IN DYSPEPTIC PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

A. Dorgham[1], H. Mohamed[1], G. Khalil[2], M. Zaghloul[3], D. Maharam[1]
[1]Medical Research Institute, University of Alexandria, Internal Medicine, Alexandria, Egypt, [2]Medical Research Institute, University of Alexandria, Chemical Pathology, Alexandria, Egypt, [3]Faculty of Medicine, Kafrelsheikh University, Hepatology, Gastroentrology and Infectious Diseases, Kafrelsheikh, Egypt

Contact E-Mail Address: mariam_zaghloul@med.kfs.edu.eg

Introduction: The prevalence of non-alcoholic fatty liver disease (NAFLD) and gastroesophageal reflux disease (GERD) has increased. Both diseases are more prevalent in obese individuals. Strong association between GERD and NAFLD has been demonstrated. However, it is not known whether this association is a causal or is a result of shared underlying risk factors.

Aims & Methods: The aim of this study was to evaluate metabolic risk factors for GERD in dyspeptic patients with NAFLD.

The present study was a cross sectional observational study that was conducted on 300 dyspeptic patients with NAFLD. Patients were divided into the GERD group (n=207) and the non-GERD group (n=93) using upper GIT endoscopy.

Patients were subjected to medical history taking, clinical examination with assessment of blood pressure, body mass index (BMI) and investigations including complete blood picture, fasting blood sugar and fasting Insulin levels, liver enzymes, HOMA IR and FIB-4 were calculated.

Results: The GERD group had higher significant ratio of smokers compared to the non-GERD group. No significant difference was found between dyspeptic NAFLD patients with GERD and those without as regarding the prevalence of obesity, but they had significantly higher mean waist circumference and BMI than those without GERD. TG and TG/HDL ratio were significantly higher in dyspeptic NAFLD patients with GERD than in those without. FBS and insulin level were significantly higher in dyspeptic NAFLD patients with GERD than in those without but with no significant difference between both groups as regard HOMA score.

Logistic regression analysis showed that the model using triglycerides (TG), BMI, waist circumference, insulin, and FBS could correctly predict 89.9% GERD in dyspeptic NAFLD patients.

			95% C.I. for EXP(B)	
	Significance	Odd's ratio	Lower	Upper
TG	.000	1.010	1.005	1.016
BMI	.050	.911	.830	1.000
Waist circumference	.006	.960	.933	.989
Insulin	.000	1.170	1.093	1.253
FBS	.000	.946	.924	.968
Constant	.000	3480.383		

Table. Logistic regression analysis.

Conclusion: TG, BMI, waist circumference, insulin level and fasting blood sugar were independent risk factors for GERD in dyspeptic NAFLD patients.

Disclosure: Nothing to disclose.

Contact E-Mail Address: benjamindalerogers@gmail.com

Introduction: The post reflux swallow-induced peristaltic wave (PSPW) brings salivary bicarbonate via an esophago-salivary reflex to neutralize residual esophageal mucosal acidification after gastro-esophageal reflux episodes.

Aims & Methods: We hypothesized that reduced saliva in Sjogren's syndrome and hypomotility in both Sjogren's syndrome and scleroderma/mixed connective tissue disease (MCTD) could compromise PSPW-induced pH recovery in the distal esophagus. Patients with confirmed Sjogren's syndrome and scleroderma/MCTD (based on rheumatologic evaluation) who underwent high resolution manometry (HRM) and ambulatory pH-impedance monitoring off antisecretory therapy were retrospectively identified over a 5-year period at 2 motility centers.

For comparison, patients without these disorders undergoing HRM and pH-impedance monitoring for GERD symptoms were identified from the same time-period, segregated into two groups based on presence or absence of ineffective esophageal motility (IEM).

Patients with prior foregut surgery, studies with artifacts precluding reflux episode and PSPW identification, and unconfirmed rheumatologic diagnoses were excluded. Acid exposure time (AET), numbers of reflux episodes and PSPW (using Wingate Consensus criteria), pH recovery with PSPW, and HRM metrics were compared between Sjogren's syndrome, scleroderma/MCTD and comparison groups.

Univariate comparisons and multivariable analysis were performed to determine predictors of PSPW and pH recovery.

Results: We studied 34 patients with Sjogren's syndrome, 14 with scleroderma/MCTD, 96 comparison patients with reflux symptoms (49 without IEM, and 47 with IEM, Table). Age and gender distribution were similar across groups. The scleroderma/MCTD group had higher AET, higher prevalence of hypomotility, lower detected reflux episodes from very low baseline impedance, and very low numbers of PSPW ($p \leq 0.004$ compared to other groups).

There was no difference in pH impedance metrics between Sjogren's syndrome, and comparison patients ($p \geq 0.481$), including between subsets of Sjogren's and comparison patients with and without hypomotility ($p \geq 0.116$ for each comparison).

In contrast, proportions with complete pH recovery with PSPW was lower in Sjogren's patients compared to comparison reflux patients ($p=0.009$), predominantly in subsets with hypomotility ($p<0.001$). Within Sjogren's syndrome, absent contractility was associated with rates of complete pH recovery with PSPW similar to scleroderma/MCTD (0.0% vs. 8.1% respectively, p=ns), while Sjogren's with IEM resembled comparison patients with IEM (p=ns) although numbers were small.

On multivariable analysis including variables of interest (total reflux episodes, PSPW index, AET, and diagnosis) only higher total reflux episodes ($p=0.028$) and diagnosis of Sjogren's syndrome ($p=0.034$) independently predicted lack of complete pH recovery with PSPW, while failed and ineffective swallows and AET were not predictive.

	Sjogren's syndrome n=34	Scleroderma/ MCTD n=14	Comparison reflux patients n=96	p value across groups
Total AET (%)	3.2 (0.5-10.8)	13.2 (2.9-40.1)	3.5 (1.5-7.1)	0.017
Reflux episodes	26.5 (14.0-46.5)	9.5 (1.5-20.5)	34.5 (16.0-46.8)	0.003
PSPW	6.0 (3.0-11.0)	0.0 (0.0-6.0)	7.0 (2.0-12.0)	0.010
PSPWI (%)	21.7 (14.5-46.3)	8.3 (0.0-33.0)	21.2 (13.7-36.1)	0.160
Partial pH recovery (%)	11.3 (0.0-35.6)	11.1 (0.0-49.2)	10.7 (0.0-33.3)	0.765
Complete pH recovery (%)	38.1 (0.0-61.9)	8.1 (0.0-29.2)	55.6 (33.3-71.4)	0.002
Esophageal hypomotility	8 (23.6%)	11 (78.5%)	47 (49.0%)	<0.001
IEM	4 (11.8%)	1 (7.1%)	42 (43.8%)	<0.001
Absent contractility	4 911.8%)	10 (71.4%)	5 (5.2%)	<0.001

Values are described as median (interquartile range) or values (percent)

Conclusion: Saliva production may be more important than motor function in PSPW related pH recovery.

Disclosure: Nothing to disclose.

PP0109

NEUROKININ A AND SUBSTANCE P SERUM CONCENTRATIONS CORRELATE WITH ESOPHAGEAL FUNCTION TESTING PARAMETERS IN SUBJECTS WITH GASTROESOPHAGEAL REFLUX DISEASE

S. Morozov[1], V. Isakov[1]
[1]Federal Research Center of Nutrition and Biotechnology, Gastroenterology & Hepatology, Moscow, Russia

Contact E-Mail Address: morosoffsv@mail.ru

Introduction: Neurokinin A (NKA) and substance P (SP) may be responsible for airway hyperreactivity and hypersensitization. Animal studies showed an increase of their blood concentration in response to acid installation into the esophagus, suggesting the presence of neurogenic inflammation in pathogenesis of asthma and chronic cough. However, little is known about association between serum concentration of these cytokines and esophageal function testing parameters in patients with gastroesophageal reflux disease (GERD).

Aims & Methods: Aim of the study was to assess serum concentration of neurokinin A and substance P in patients with erosive esophagitis and non-erosive form of GERD and perform correlation analysis between concentrations of these substances and data of multichannel esophageal pH-impedance (MII-pH) and high-resolution esophageal manometry (HREM).

Methods: The data of examination of 88 subjects (31with erosive esophagitis (EE); 57 with non-erosive form of GERD (NERD)) served as a source for the study.

Diagnosis of GERD was established per Lyon criteria. Subjects with autoimmune disorders, receiving immunosuppressants, antisecretory agents and medications able to affect esophageal motility were not eligible. Patients underwent HREM with the use of 36-channel solid-state catheters and MII-pH with 2-pH, 6-impedandce sensors catheters.

Serum concentrations of NKA and SP were measured with Sunrise analyzer and ELISA kits (Biochemmack, USA). Non-parametric statistics was used to compare the results obtained in EE and NERD groups and to perform correlation analysis.

Results: Acid exposure time (AET), and number of high gastroesophageal refluxes were higher in EE group compared to NERD, while number of refluxes and concentrations of NKA and SP were similar. Mean, minimal and residual lower esophageal sphincter resting pressures (mean by 10 water swallows) were lower in EE compared to NERD.

There was direct correlation between serum concentration of SP and number of gastroesophageal refluxes (Spearman rank R=0.258), AET (R=0.252), and number of refluxes lasted >5 min (R=0.353). Serum concentration of

NKA correlated directly with number of refluxes >5 min long (R=0.275), and inversely with levels of integrated relaxation pressure (R=-0.321), and contractile front velocity (R=-0.379). Other correlations were not statistically significant.

	Neurokinin A	Substance P
24 hours MII-pH		
Total number of gastroesophageal refluxes	0.192	0.258*
Acid exposure time, %	0.137	0.250*
Mean pH	0.051	-0.089
Number of refluxes longer than 5 minutes	0.275*	0.353*
HREM		
IRP4	-0.321*	-0.210
CFV	-0.379*	-0.286
DCI	0.039	-0.149

** P<0.05*

Table 1. Correlation coefficients (by Spearman rank R) between serum concentrations of Neurokinin A, Substance P and esophageal function testing parameters.

Conclusion: In subjects with GERD, serum concentrations of Neurokinin A and Substance P do not depend on the presence of esophagitis and probably are not caused by the influence of reflux content to sensory neurons of esophageal mucosa. Established correlations may support the involvement of neurokinin A and substance P in pathogenesis of gastroesophageal reflux disease through disturbance of esophageal motility.

MOLECULAR CHANGES IN THE MUCOSAL BARRIER FOLLOWING LAPAROSCOPIC ANTI-REFLUX SURGERY

P. Ergun[1,2], S. Kipcak[1,3], V. Gorgulu[4], B. Doganavsargil[5], S. Bor[1], Ege Reflux Team

[1]Ege University, Gastroenterology, Izmir, Turkey, [2]Ege University, Medical Biochemistry, Izmir, Turkey, [3]Ege University, Medical Biology, Izmir, Turkey, [4]Faculty of Medicine, Ege University, Histology and Embriology Department, Izmir, Turkey, [5]Ege University, Department of Pathology, Izmir, Turkey

Contact E-Mail Address: serhatbor@yahoo.com

Introduction: Patients after laparoscopic anti-reflux surgery (LARS) report an improvement in their quality of life and significant decrease in their symptoms. In our previous study, we showed that LARS increases tissue resistance and decreases permeability (1).

However, the molecular effects of this operation on mucosal integrity, which is responsible for stopping reflux attacks, are not yet understood.

Aims & Methods: In this study, changes in intercellular adhesion proteins and dilated intercellular spaces were investigated in patients before and after anti-reflux surgery.

The study included 22 GERD patients (10 ERD-AB, 6 ERD-CD, 6 NERD) who received approval for LARS and 16 healthy controls (HC) without GI symptoms and with normal 24-h MII-pH monitoring & upper GI endoscopy. All patients have pathological reflux attacks. Upper GIl endoscopy was performed on HC and GERD patients before and after surgery (2-18 months later), and esophageal biopsies were obtained. The expressions of E-cadherin (CDH1), Occludin (OCLN), Claudin 1 (CLDN1), Claudin 4 (CLDN4), ZO-1 and ZO-2 were studied in the biopsies and dilated intercellular spaces (DIS) were also examined by double-blinded under light microscopy.

Results: Gene expressions of CDH1 (+1.7) and ZO-2 (+2.9) increased in GERD patients, while CDH1 (+1.7), OCLN (+3.9), ZO-1 (+3.5), and ZO-2 (+2.9) increased in Post-LARS. When compared before and after surgery, ZO-1 expression was significantly increased by 1.8-fold in Post-LARS. Post-LARS biopsies were also divided as 2-6 months and 6-18 months before and after surgery.

No difference was observed in the gene expressions of patients who evaluated for follow-up within 6 months after surgery, but those who evaluated after 6 months showed a 1.5-fold increase in OCLN expression in Post-LARS biopsies.

Patients were divided into phenotypes, and post-surgery results were examined. In the ERD-CD group, OCLN expression increased by 1.5 times after surgery compared to pre-LARS, while ZO-1 (-1.6) and ZO-2 (-1.7) expression decreased in the NERD group. No changes were observed in the ERD-AB group.

The patients were separated into 18-45 and 45-74 age groups, it was found that Post-LARS resulted in a 1.5-fold increase in OCLN expression in individuals under 45 years old, but there was no difference in individuals over 45 years old.

When the DIS characteristics of all patients were examined, it was observed that DIS of HC group was significantly lower than Pre-LARS (1.31±0.5 µm) and Post-LARS (1.26±0.6 µm) ($p<0.001$), but there was no significant difference between Pre-LARS and Post-LARS. No difference was found between age groups in DIS.

Conclusion: ZO-1 plays an important role in mucosal repair, and its increase in Post-LARS compared to pre-LARS may indicate improvement following cessation of acid-peptic attacks.

Although no significant differences were observed in the short term after surgery (<6 months), OCLN expression increased in the long term (>6 months), which could be a molecule that contributes to the decreased permeability observed after Post-LARS. The upregulation of this gene was also observed in the ERD-CD group after LARS.

Furthermore, OCLN was significantly higher in individuals under 45 years of age. This gene, which contributes to decreased permeability, appears to be activated in response to repair mechanisms in severely damaged groups and is more active in younger individuals.

In the NERD group, where mucosal integrity was not compromised, the downregulation of ZO genes may be due to the absence of repair mechanisms. The lack of change in DIS after LARS suggests that the dilatations between cells might be irreversible.

NOVEL COMBINATION OF TECHNIQUES TO ASSESS GASTROESOPHAGEAL FUNCTION: NORMAL DATA FROM HEALTHY INDIVIDUALS

J. Haworth[1], S. Treadway[1], S. Ensor[2], S. Calder[2], A. Gharibans[2], G. O'Grady[2], A.R. Hobson[1]
[1]Functional Gut Clinic, Manchester, United Kingdom, [2]Alimetry, Aukland, New Zealand

Contact E-Mail Address: jordan@functionalgutdiagnostics.com

Introduction: To better understand the mechanisms of gastroesophageal function in patients with gastroesophageal reflux disease (GERD), we assessed healthy individuals using a novel, multi-model study that combined physiology techniques, including high resolution manometry (HRM), 24-hour multichannel-intraluminal impedance-pH (MIIpH), C13 gastric emptying breath testing (GEBT), and body surface gastric mapping (BSGM).

Aims & Methods: Healthy controls were screened and those with a score of 0 on the GERDQ were enrolled. Also, participants completed ROME IV, PAGI-QOL, PAGI-SYM and real time study symptom questionnaires. A 30 minute BSGM baseline was performed after a six hour fast. Then HRM was performed with 10 supine 5 ml swallows to classify esophageal motility followed by a 233 kcal porridge meal labelled with C13 sodium acetate consumed within 10 minutes. Postprandial HRM, GEBT, MIIpH, and BSGM were recorded. After 1 hour HRM was removed and after 4 hours GEBT and BSGM were concluded, but MIIpH testing was continued for the remaining 24 hours. Data were analysed using standard procedures and compared with established reference intervals.

Results: 30 healthy volunteers (15 males and 15 females, mean age 31.8 ±9.8 years) completed with none meeting ROME criteria. Mean PAGI-SYM and PAGI-QOL were 3.2 ±5.4 and 4.3 ±7.5, respectively. The mean esophageal acid exposure time (AET) was 2.9% ±4.9 where 3 participants had excessive AET >6%. The mean total number of reflux episodes was 30.5 ±19.9 and the mean number of hypopharyngeal episodes was 1.4 ±12.2. On HRM, 8 participants had ineffective esophageal motility, 1 participant had absent contractility and 1 hypercontractile esophagus.

On GEBT, the mean T lag was 47.9 ±18.1 minutes and T ½ was 92.1 ±22.9 minutes. 8 participants had abnormal BSGM but 1 was excluded due to excessive artefact. Of the remaining 7, 5 had low gastric rhythm index, 1 had low frequency and 1 low amplitude.

Those with abnormal BSGM were more likely to be male (P = 0.017) and have a hiatus hernia >1.5cm (P = 0.029), but abnormal BSGM in this healthy cohort was not related to any other HRM, MIIpH or GEBT parameters.

Conclusion: These data show it is feasible to perform a combination of techniques to comprehensively assess gastroesophageal function. These normative data can be used to compare with a GERD population to determine pathophysiology of gastroesophageal reflux.

Disclosure: Nothing to disclose.

PP0112

CONTRIBUTION OF INEFFECTIVE MOTILITY AND ABSENT PERISTALTIC RESERVE TO THE SEVERITY OF GASTROESOPHAGEAL REFLUX DISEASE

G. Tutuian[1], M. Herzig[2], D. Glaus[2], R. Tutuian[2]
[1]HFR - Fribourg, Gastroenterologie - Intesto, Fribourg, Switzerland, [2]Gastroenterologie Buergerspital Solothurn, Gastroenterology, Solothurn, Switzerland

Contact E-Mail Address: tutuiang@intesto.ch

Introduction: Peristaltic reserve is the normal augmentation of peristaltic contraction amplitude at the end of a series of multiple-rapid swallows (MRS). Normal peristaltic reserve in patients with ineffective esophageal motility (IEM) has been reported to a predictor of good outcome after fundoplication. Conversely, absent peristaltic reserve following MRS is associated with poor esophageal clearance.

Aims & Methods: Aim: Evaluate esophageal acid exposure and mean nocturnal baseline impedance (MNBI) in patients with IEM and patients with normal motility with and without peristaltic reserve.

Methods: Patients undergoing high-resolution esophageal manometry (HRM) and 24-h impedance-pH monitoring (24h-Imp-pH) were classified as having IEM or normal esophageal manometry according to Chicago 4.0 criteria. Peristaltic reserve was declared present (PR+) if distal contraction integral (DCI) following a series of 4x5ml rapid swallows ≥25% greater than the average DCI following 10 single 5ml swallows.

We compared esophageal acid exposure (% time pH<4), number of reflux episodes and MNBI in patients with IEM/normal motility with (PR+) and without (PR-) peristaltic reserve.

Results: Between February 2020 and December 2022 we identified 220 patients (132;60% females, avg (±SD) age 54 (±15) years with IEM (49;22%) and normal motility (171;78%). Esophageal acid exposure, number of reflux episodes and MNBI are summarized below:

Parameter	IEM/PR- (N=17)	IEM/PR+ (N=32)	Normal/PR+ (N=88)	Normal/PR+ (N=83)	p-value
% time pH <4	7.9 ± 2.8*	6.5 ± 1.2	5.7 ± 1.0	3.4 ± 0.6*	0.056
# reflux episodes	71.6 ± 14.0*	90.4 ± 17.5	65.7 ± 9.8	46.3 ± 3.8*	0.034
MNBI (Ohm)	1667.1 ±267.7*	1726.2 ±209.4	2074.7 ± 117.4	2325.7 ±110.6*	0.020

Data are presented as mean ± SEM

* p<0.05 in post-hoc comparison IEM/PR- vs. Normal/PR+

Conclusion: Absent peristaltic reserve combined with ineffective esophageal motility is associated with higher esophageal acid exposure and lower mean nocturnal baseline impedance suggesting that patients with IEM and absent peristaltic reserve have a more severe form of GERD compared to patients with normal motility with normal peristaltic reserve.

GASTROESOPHAGEAL REFLUX DISEASE, DISTALE LATENCY AND DYSPHAGIA. IS THERE A CORRELATION?

T. Voulgaris[1], S. Hoshino[1], E. Yazaki[1]
[1]*Barts and The London School of Medicine and Dentistry, Royal London Hospital, Wingate Institute of Neurogastroenterology, Blizard Institute, Queen Mary University of London, Upper GI Physiology Unit, London, United Kingdom*

Contact E-Mail Address: thvoulgaris87@gmail.com

Introduction: Patients with typical Gastroesophageal reflux disease (GERD) symptoms frequently report Dysphagia. During HRM study patients with GERD show in an increased rate ineffective or absent esophageal motility and Low Esophageal Sphincter (LES) pressure though no data exist about disturbances of Distal latency (DL).

Aims & Methods: As typically patients with spastic disorders of the esophagus present with dysphagia and show decreased DL we aimed to investigate if there is a correlation between GERD, dysphagia and DL disturbances.

We included 2629 patients with typical long-lasting symptoms, submitted to High Resolution Manometry and 24 hrs pH-Impedance study (pH-IM), off-PPI. Patients with a positive endoscopic GERD diagnosis undergoing pre-operativel HRM/pH-impedance, with a previous definite GERD diagnosis studied “on” PPI, using of opioids, history of esophageal surgery or diagnosed with major motility disorders except absent peristalsis (Chicago IV classification) were excluded. GERD diagnosis was made by using Lyon consensus criteria for pH-IM; Acid Exposure time (AET)> 6%.

Results: GERD was diagnosed in 845 (32.1%) pts while indefinite AET for GERD (4-6%) was found in 300 (11.4%). Any grade of dysphagia was reported by 934 (35.5%) pts. Patients with dysphagia had decrease DL (6.2±1.7 vs 6.5±2.7 in patients not reporting dysphagia, p=0.008) Patients with GERD showed decreased DL in comparison to patients without (6.1±1.8 vs 6.6±2.7, p<0.001). GERD diagnosis was not correlated to report of dysphagia (300/845 35.5% vs 536/1484, 36.1% in pts without GERD, p=0.788) and no difference in mean DL was observed in patients with GERD and or without dysphagia (6.2±1.8 vs 6.1±1.9, p=0.772).

GERD was also correlated to Esophagogastric Junction (EGJ) type 2 or 3 anatomy (358/845, 42.4% vs 361/1484, 24.3%, p<0.001), diagnosis of ineffective esophageal motility/absent peristalsis (375/845, 44.7% vs 530/1484, 35.7%, p<0.001) and LES hypotension (449/845, 53.1% vs 665/1484, 44.8%, p<0.001).

The correlation of DL to GERD was maintained in the multivariate logistic regression analysis (p=0.002, OR: 0.907, 95% C.I 0.853-0.964) fact also observed for type 2/3 EGJ (p<0.001, OR:2.255) and diagnosis of ineffective motility/absent peristalsis (p=0.001, OR: 1.468).

Conclusion: Patients reporting typical reflux symptoms and dysphagia show decreased DL even when a diagnosis of diffuse Esophageal Spasm is not met. Patients with GERD diagnosis by pH-impedance and typical reflux symptoms show decreased DL in comparison to patients without GERD. Though lower DL observed among patients with GERD was not correlated to dysphagia.

Disclosure: Nothing to disclose.

PP0114

POSITIONING IN HIGH RESOLUTION MANOMETRY IN PATIENTS WITH GASTRO-ESOPHAGEAL REFLUX DISEASE. DOES IT MATTER?

T. Voulgaris[1], R. Yehuda-Margalit[1], S. Hoshino[1], S. Sonmez[1], E. Yazaki[1]
[1]*Barts and The London School of Medicine and Dentistry, Royal London Hospital, Wingate Institute of Neurogastroenterology, Blizard Institute, Queen Mary University of London, Upper GI Physiology Unit, London, United Kingdom*

Contact E-Mail Address: thvoulgaris87@gmail.com

Introduction: According to guidelines, in order to strictly diagnose esophageal motility disorders, besides achalasia, high resolution manometry (HRM) findings should be documented in both the upright and the supine position. A common finding among patients with Gastro-Esophageal Reflux Disease GERD submitted to manometry is ineffective esophageal motility (IEM).

The clinical impact of such a diagnosis in this setting is ambiguous though it may denote future disturbance of peristaltic reserve even if until now only inadequate response to multiple rapid swallows (MRS) has been correlated to post anti-reflux surgery dysphagia.

Aims & Methods: We aimed to evaluate differences in esophageal contractility in different positions in patients with definite GERD.We included consecutive patients with definite GERD according to Acid Exposure Time (>6%) submitted simultaneously to 24 hours pH impedance off PPI study and HRM in both the upright and supine position.

Patients with previous esophago-gastric surgeries as also patients diagnosed with motility disorders besides IEM/absent contractility according to Chicago 4 guidelines were excluded.

Results: In total 49 patients (M/F:26 (53.1%)/23 (46.9%), mean age:51±14) were included. The main referral reason was typical reflux symptoms in 37/49 (75.5%) patients while 8/49 (16.3%) reported dysphagia. Mean Distal Contractile Integral (DCI) was significantly reduced in the upright position (1629.2±1175.6 mm/s/mmHg) vs supine position (2762.4±2710.4 mm/s/mmHg), p=0.010.

The rate of total ineffective swallows in the upright position was significantly increased in the upright position (29.0%) vs the supine (12.3%), p=0.010 as was also the rate of weak contraction (10.3% vs 3.1%, p=0.033) and marginally not of absent contractions (17.0% vs 8.3%, p=0.078). The rate of diagnosis of IEM/absent contractility was doubled in the upright position (8/49, 16.3%) vs in the supine position (4/49, 8.2%) (k-value:0.473, p=0.001).

Inadequate post MRS contraction was observed in 9/49 (18.4%) and more specifically among 3/4 (75%) patients with IEM/absent contractility diagnosis in the supine position (k:-0.436, p=0.002) vs 4/8 (50%) in the upright position (k:-0.361, p=0.011). Dysphagia was not correlated to diagnosis of IEM/absent contractility neither in the supine (p=0.675) nor the upright position (p=0.586).

Conclusion: Upright position in HRM is correlated to a decreased mean DCI and an increased rate of ineffective esophageal contractions leading to an increased rate of diagnosis of IEM/absent contractility. Such a diagnosis in the upright position is correlated in a lesser extent to inadequate post-MRS swallow and not correlated to symptom of dysphagia.

Until new data arise such an overdiagnosis among patients with GERD may be misleading and therefore the procedure in such patient may be better to be undertaken only in the supine position.

Disclosure: Nothing to disclose.

CORRELATION BETWEEN LARYNGOPHARYNGEAL REFLUX CLINICAL SCORES AND ESOPHAGEAL MULTICHANNEL INTRALUMINAL IMPEDANCE PH MONITORING

T. Geeratragool[1], J. Prapruetkit[1], M. Maneerattanaporn[1], C. Chongkolwatana[2], S. Leelakusolvong[1]
[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Division of Gastroenterology, Department of Medicine, Bangkok, Thailand, [2]Faculty of Medicine Siriraj Hospital, Mahidol University, Department of Otorhinolaryngology, Bangkok, Thailand

Contact E-Mail Address: tanawat.grtg@gmail.com

Introduction: Laryngopharyngeal Reflux (LPR) is a common troublesome complaint in clinical practice. The treatment outcomes were unsatisfied given unclear pathophysiology and lack of gold standard test. Reflux Symptom Index (RSI) and Reflux Finding Score (RFS) had been used to help with the diagnosis while esophageal multichannel intraluminal impedance (MII)/pH monitoring is the most reliable tool to evaluate gastroesophageal reflux disease (GERD). The role of MII/pH monitoring in extraesophageal GERD is controversial.

Aims & Methods: We aimed to evaluate the benefit of MII/pH monitoring results in patients with LPR defined by clinical scoring of RSI ≥ 13 points and/or RFS ≥ 7 points.

Patients with definite LPR diagnosed by otolaryngologists using predefined RSI and RFS were recruited. All participants underwent esophageal manometry and off-PPI MII/pH monitoring. The results of MII/pH findings and clinical scores were determined for the correlation.

Results: A total of 100 (71 Female, 29 Men) LPR patients were enrolled, with the mean age of 50.1 years. The mean RSI and RSF score were 18.4±6.1 and 9.8±4.1 respectively. Half of the patients had abnormal manometry; 48% had ineffective esophageal motility (IEM) and 9% had low lower esophageal sphincter pressure (LESP). The median acid exposure time (AET) was 1.85% and the median number of reflux episodes and proximal reflux episodes were 29.5 and 4 respectively.Gas reflux is the most common type of reflux with 98% of population.

There was a significant correlation between RSI and the number of gas reflux (r = 0.255, P-value 0.011). There was no difference in RSI and RFS in all MII/pH parameter subgroups, including pathological vs non-pathological acid reflux, a high vs low DeMeester score, a high vs low number of reflux, proximal reflux, or acid reflux.

Parameters	RSI		RFS	
	r	P-value	*r*	P-value
Acid exposure time	0.016	0.877	-0.149	0.244
No. of reflux events	0.026	0.794	-0.027	0.835
No. of proximal reflux events	0.017	0.867	-0.174	0.172
No. of acid reflux events	0.041	0.688	-0.147	0.250
No. of nonacid reflux events	0.021	0.833	-0.045	0.727
No. of liquid reflux events	0.041	0.683	0.201	0.115
No. of gas reflux events	**0.255**	**0.011**	-0.078	0.541

MII; Multichannel Intraluminal Impedance, RFI; reflux finding score, RSI; reflux symptom index

Table. Correlation between RSI or RFS and MII/pH finding.

Conclusion: In this population, there were no significant acid refluxes in patients with LPR diagnosed by standard cut-off score of RSI and/or RFS. However, RSI had significant correlation with gas reflux episodes. Interestingly, up to 60% of the participants had IEM or low LESP. These findings are still be scrutinized.

Introduction: Esophageal mucosal admittance (MA) is a promising diagnostic method for gastroesophageal reflux disease (GERD), however, only some studies were done and mainly in Japan.

Aims & Methods: We conducted a study to describe the esophageal MA in patients with reflux symptoms and determine its diagnostic accuracy. We recruited 92 patients with ambulatory pH-impedance monitoring, upper gastrointestinal endoscopy, and MA measured by the tissue conductance meter. MA was measured during endoscopy at 5cm (distal esophagus) and 15cm above the Z line (middle esophagus), repeated at least five times at each position, and median MA was obtained.

Afterwards, two biopsies were taken 5cm above the Z line for histopathological evaluation using the Esohisto criteria. Patients were classified as GERD or non-GERD according to the 2018 Lyon consensus.

Results: The mean age was 43.2 years, and 42 patients were males. The most common symptoms were regurgitation (75.0%), belching (65.2%), and heartburn (46.7%). Twenty-three (32.3%) were diagnosed with GERD using the Lyon consensus, and 24 (26.1%) had esophagitis on histopathology. The median MA at the distal and middle esophagus was moderately correlated. The median MA at both positions was higher in the GERD group but only statistically significant in the middle esophagus. MA was not associated with pH-impedance parameters and esophagitis on histopathology. The diagnostic model developed using the logistic regression did not have good accuracy.

Conclusion: MA was not different between GERD and non-GERD patients. The diagnostic model integrating MA did not have high accuracy in diagnosing GERD.

Disclosure: Nothing to disclose.

Introduction: Patients presenting with laryngeal complaints are often considered to harbor atypical esophageal laryngo-pharyngeal reflux (LPR). The association between LPR symptoms and gastroesophageal reflux (GER) is an ongoing debate.

Aims & Methods: We aimed to characterize patients referred for investigation of LPR complaints and to compare them to patients referred with classic reflux complaints.

All patients referred for pH-impedance testing were offered to participate in this cross-sectional observational study. Those included underwent a comprehensive workup including medical history (presence of a neurologic disease, diabetes, foregut surgery, depression, a diagnosis of Irritable bowel syndrome (IBS) or peptic disease), filling a symptom questionnaire, Rome 3, SCL 90 and SF 36 questionnaires. IBS, functional dyspepsia (FD) and other conditions were defined according to Rome 3 criteria.

All patients underwent gastroscopy, esophageal HRM (Chicago 3) and pH-impedance testing off therapy.

Classic reflux complaints were defined as heartburn, regurgitation, and chest pain. Atypical reflux/LPR symptoms included cough, hoarseness, throat clearing, globus sensation, and asthma exacerbation.

Of patients with symptoms during the study (104/156=(67%), functional heartburn was diagnosed in 33% vs.50.0%, p=0.094.

Results: 156 patients were included, 53% were females and with mean age of 53±17y. The indication for testing was classic reflux in 90 (58%), and 66 (42%) patients were referred for LPR symptoms. No significant differences were found between the groups in demographic parameters, background diseases and psychological profile. Both classic and LPR groups had a high prevalence of Rome 3-IBS (67% and 59%, p-NS) and FD (56% and 32%, p=0.058), respectively.

Patients with classic reflux symptoms, compared to the LPR group, used more PPI`s (90% vs. 73%, p=0.008) and SSRI`s (19% vs. 8%, p=0.053) respectively. Life quality was not different between the groups. Gastroscopy and HRM diagnoses and LES and esophageal body parameters were similar between the 2 groups. A higher upper esophageal sphincter pressure was noted in the classic reflux group (p=0.011). Esophageal acid exposure time (AET) was similar as well in the classic vs. the LPR group: 5% vs.5.4%, p=NS, as was the number of patients with AET>6%: 36% vs. 35%, p=NS, respectively. The median number of weakly acidic reflux and non-acidic episodes was also similar: 27 vs. 24, p=NS and 2 (0-2) vs. 1 (0-2), p=NS, respectively.

Of patients with symptoms during the study (104/156=(67%), functional heartburn was diagnosed in 33% vs.50.0%, p=0.094.

Conclusion: In our cohort, the majority of patients with LPR had normal esophageal acid exposure, while the prevalence of IBS, functional dyspepsia, and functional heartburn was higher than reported world prevalence. While other mechanistic explanations may exist, our study suggests an overdiagnosis of LPR symptoms to be related to acid gastro esophageal reflux.

Introduction: Gastroesophageal reflux disease (GERD) patients with atypical symptoms represents a diagnostic and therapeutic challenge. In particular, the diagnosis of GERD is often suspected by ENT surgeons according to laryngoscopic findings, but their sensitivity and specificity for diagnosis is low.

The aim of this study was to assess the prevalence of GERD in patients with atypical symptoms undergoing laryngoscopic examination and pH monitoring.

Aims & Methods: We retrospectively evaluated patients with atypical symptoms with or without typical symptoms associated referred to Gastroenterology Units of six tertiary Italian centres between January and December 2020. Of 477 patients, we enrolled 277 patients who underwent both 24 hours pH-impedance monitoring off-therapy and laryngoscopy. Diagnosis of GERD was made according to Lyon Consensus, and we considered the novel impedance metrics (baseline impedance and post reflux swallow-induced peristaltic wave index) when pH-impedance monitoring was inconclusive in order to add confidence to diagnosis of GERD. Three patients with hypersensitive esophagus were excluded.

Results: The most common atypical symptom was cough (90/274). Laryngoscopic examination showed pathological findings in 195 patients (71.2%), and the most frequent feature detected was posterior laryngitis (77.4%). GERD was diagnosed in 80/274 patients (29.2%) on pH impedance monitoring. Upper endoscopy was made in 269 patients and 5 of them had B grade esophagitis. The prevalence of GERD diagnosis in patients with or without positive laryngoscopy examination was not statistically significant (p=0.075).

No difference in the number of proximal refluxes was observed in patients with positive or negative laryngoscopy (65/195, 33.3% vs 19/79, 24.1%; p= 0.133). Sensitivity and specificity of laryngoscopy in diagnosing GERD is 78.8% and 32.0% respectively (PPV= 32.3%; NVP= 28.4%).

Conclusion: Laryngoscopic examination has a poor specificity in diagnosing GERD in patients with atypical symptoms. This study may underline that pathological laryngoscopy findings could only pose a suspect of an underlying GERD, but its diagnosis would still need to be confirmed by impedance-pH monitoring, even in patients with atypical symptoms.

Disclosure: Nothing to disclose.

PP0119

PH-MII ON PPI FAILS TO PREDICT THE OUTCOME AFTER ANTI-REFLUX SURGERY IN PATIENTS WITH PPI-REFRACTORY GERD

A. Geeraerts[1], K. Raymenants[1], L. Holvoet[2], L. Depypere[3], P. Nafteux[3], H. Van Veer[3], T. Vanuytsel[4], J. Tack[5]

Contact E-Mail Address: karlienraymenants@gmail.com

Introduction: Esomeprazole and laparoscopic anti-reflux surgery have shown similar efficacy in PPI-responsive patients (1). However, a significant proportion of patients fails to respond to PPI and are the most relevant group seen by gastroenterologists and surgeons for advanced therapy, including surgery. In a highly selected subgroup of patients with PPI-refractory GERD surgery resulted in treatment success in 2/3 of patients and was superior to medical therapy (2). However, the selection of patients for surgery remains a topic of controversy and the role of pH-MII in patients with ongoing symptoms on-PPI is unknown.

Aims & Methods: Our aim was to assess whether 24h pH-impedance measurement (pH-MII) *on* PPI can predict outcome of anti-reflux surgery in patients with persistent typical GERD symptoms despite twice daily PPI for at least 3 months.

Patients with refractory GERD symptoms on PPI were assessed by the surgeons and selected for anti-reflux surgery based on typical GERD symptoms and the results of pH-MII *off* PPI. Patients underwent usual pre-operative work-up including upper endoscopy, esophageal manometry and esophago-gastro-duodenal X-ray, and underwent an additional pre-operative pH-MII *on* b.i.d. PPI for study purposes. Symptom questionnaires were filled out before, and at intervals after surgery. VISICK scores were used to define outcome after surgery, with grade I and II defined as treatment success, grade III or IV as failure (3).

pH-impedance monitoring (Diversatek) was analyzed using Bioview Analysis® by trained personnel. Symptom association probability (SAP) was used to describe the relation between reflux episodes and symptoms. Statistical analysis was done using GraphPad Prism.

Results: In this interim report, we analyzed 38 patients (23 female, mean age 45, BMI 26). 17 patients were SAP positive on pH-MII *on* PPI, 21 were SAP negative. Mean follow-up after surgery was 9 years (IQR 5.8-11).

After a mean follow-up of 9 years, 66% (25/38) of the patients in this cohort reported treatment success (VISICK I or II). Treatment success was reported by 90% (19/21) of patients with a negative SAP, 10% (2/21) were treatment failures, no patients required redo surgery. In the SAP positive group, 35% (6/17) reported treatment success, 24% (4/17) treatment failure, and 41% (7/17) required redo surgery. Indications for redo surgery were intrathoracic migration (5/7) and persisting dysphagia (2/7). The proportion of patients with treatment success, failure and redo surgery differed significantly between the SAP-based groups (χ^2 test; p<0.0001) (table 1), with a significantly higher success rate in the SAP negative group.

	Failure = Visick III + IV	Success = Visick I + II	Redo = redo surgery
SAP negative (n=20)	10%	90%	0%
SAP positive (n=16)	24%	35%	41%
χ^2 test: p<0.0001			

Table.

Conclusion: This interim analysis suggests that symptom association probability on pH-impedance monitoring *on* PPI cannot be used to select refractory GERD patients for anti-reflux surgery.

Introduction: The gold standard for diagnosis of laryngeopharyngeal reflux is 24h MII-pH with localization of impedance nearby the upper esophageal sphincter.

Aims & Methods: The aim of the study was to evaluate high GER in patients with laryngeal symptoms of GERD.

Subjects and methods: 50 patients with extraesophageal manifestations of GERD underwent upper endoscopy, esophageal manometry and 24h MII-pH. Mean age 49,54 ±5,2 y.o. Females – 44%, males – 56%. We used new probes for 24h MII-pH with 2 impedance channels located above lower esophageal sphincter (LES) and 5 impedance channels located under and above upper esophageal sphincter (UES).

There were 3 types of probes according to the length of esophagus: 1st type – for the length 20-22 cm, 2nd type – 23-25 cm, 3rd type – 26-28 cm. The pH electrodes were at 5 cm above LES and 1 cm above UES. The location of LES and UES was detected by manometry.

Results: According to the results of 24h MII-pHmetry in the lower third of the pharynx, 21 patients had more than 1 reflux (LFR+ group), 29 patients had no reflux in the pharynx (LFR-). Patients with LFR+ significantly more often complained of hoarseness, slightly more often noted cough, burning in the oral cavity, dysphagia.

Patients with LFR- often complained of heartburn, regurgitation, sore throat, lump in the throat. The upper endoscopy showed that the frequency of occurrence of the erosive esophagitis was the equal in both groups, including Barrett's esophagus.

The pathologic GER in the lower third of the esophagus was more common in patients with LFR + (71%) than in patients without LFR (24%). A positive correlation was revealed (r=0.46). The ratio of the physiological amount of GER was 24 and 59%, respectively.

Conclusion: The new probes allow simultaneous assessment of reflux in the lower third of the esophagus and pharynx. The amount of reflux in the lower third of the pharynx correlates with the amount in the lower third of the esophagus.
However, there are options when, with a normal number of them, there may be a high spread in the lower third of the esophagus.
Disclosure: Nothing to disclose.

Contact E-Mail Address: nicola.debortoli@unipi.it
Introduction: Alginate-based formulations are frequently used as an add-on to proton pump inhibitor (PPI) therapy in patients with partial control of heartburn and regurgitation. Few data are available to inform decision-making on switching to a different PPI or adding an alginate-based formulation to ongoing PPI treatment in partial responders.
Aims & Methods: We aimed to evaluate the effects of a new formulation of sodium alginate, chamomile, and melatonin (Aligastril gel® Aliveda, Pisa, Italy) in improving reflux-related symptoms in patients with persistent symptoms despite once daily PPI versus the switch to a different PPI treatment.
This was a single-center, randomized trial that compared Aligastril gel (3 times/day; Group A) as add-on versus switching to a different PPI once daily (Group B) in patients with incomplete heartburn relief. Reflux symptoms were assessed using the GerdQ and were recorded at baseline and after 8 weeks from PPI switch or add-on of Aligastril gel. Consecutive patients were randomized in a 1:1 ratio to take Aligastril gel (12ml) 3 times per day 30-min after breakfast, lunch, and dinner (treatment group).
A control group was randomized to switch to a different PPI. Patients were asked to do the HRDQ questionnaire once a day (evening time). Patients were evaluated again after one month.

	Group A (Aligastril)	Group B (PPI switch)	P
Total patients	45	45	N/A
Female	26	25	>0.99
Mean age	50.7±10.6	51.1±10.2	0.855
BMI	23.6±2.8	23.7±2	0.846
PPI-response rate (VAS)	3.2±1.7	3.3±1.9	0.793
GERDQ (t0)	13.6±2.6	13.2±3.2	0.517
GERDQ (t1)	8.4±2.2	10.6±2.5	<0.001
Delta GERDQ	-5.3±1.4	-2.6±-1.4	<0.001
Consecutive heartburn free days (mean)	6.8±1.7	2.4±2	<0.001

Table 1: epidemiological characteristics and summary of the treatment response.

Results: 90 patients (51 female, mean age 50.7±10.4 yrs) were randomized. Group A included 45 (26 female, mean age 50.7±10.5 yrs) and Group B 45 patients (25 female, 51.1±10.2 yrs) (p=NS). Change in GerdQ score was significantly greater for Group A (mean: -5.0±1.4) than for Group B (mean: -2.6±1.4) P <0.001. The heartburn free days observed from patients were 6.8±1.7 in group A compared to 2.4±2.0 in the Group B (p<0.0001) (Table 1).
Conclusion: In patients with residual reflux symptoms despite PPI treatment, adding Aligastril gel (alginate+melatonin+chamomille) offered additional decrease in the burden of reflux symptoms compared to switching the PPI treatment. These data support the role of alginate in the add on therapy in patients with poor heartburn control whilst on PPI therapy.

ANTI-REFLUX MUCOSECTOMY FOR GASTROESOPHAGEAL REFLUX DISEASE: EFFICACY AND MECHANISM OF ACTION

T. Kuipers[1,2], R.A.B. Oude Nijhuis[1,2], R.E. Pouw[1,2], A. Bredenoord[1,2]
[1]Amsterdam UMC, Dept. of Gastroenterology, Amsterdam, Netherlands, [2]Amsterdam Gastroenterology, Endocrinology & Metabolism, Amsterdam, Netherlands

Introduction: A substantial part of patients with gastroesophageal reflux disease (GERD) responds insufficiently to pharmacological therapy. Therefore, a novel anti-reflux endoscopic procedure - anti-reflux mucosectomy (ARMS) - has been developed.
Previous studies suggest that ARMS is effective in reducing reflux symptoms and total acid exposure, although the mechanisms through which reflux is reduced has not yet been investigated.
Aims & Methods: GERD patients with a pathological acid exposure and insufficient symptom control despite twice daily PPI underwent a piecemeal multiband mucosectomy of 50% of the circumference of the esophagogastric-junction (EGJ), extending 2cm into the cardia. Prior and 3 months following the procedure patients underwent (ambulatory and postprandial stationary) manometry and pH-impedance study, endoscopy and impedance planimetry (Endoflip). PPI treatment was temporarily stopped prior to these investigations. The main study parameter was the total number of reflux episodes assessed during ambulatory 24-h pH-impedance studies. Secondary endpoints were: total 24-h acid exposure time, number of reflux episodes and acid exposure time during prolonged postprandial stationary measurement, prevalence of transient lower esophageal sphincter relaxations (TLESRs), EGJ morphology and distensibility, grade of reflux esophagitis, symptoms and quality of life and occurrence of complications.
Results: 11 patients were treated, of which follow-up is complete in 9 patients (6 men, median age 37 (36-61) years, mean BMI 28.7 (±3.1) kg/m2).
ARMS reduced the total number of reflux episodes from 71 (59.5-82.5) to 39 (28-67)(p=0.018), resulting in a reduction of both acidic (63 (50-73) vs 36 (23-55), p=0.012) and weakly acidic reflux episodes (8 (4-17) vs 4 (4-5), p=0.093). The total acid exposure was reduced from 9% (6.5-13.8) to 5.3% (4.0-6.4) (p=0.036).
The 90-minute post-prandial measurement showed an acid exposure time of 16.6% (3.1-30.2) after treatment compared to 11.2% (4.6-33) at baseline (p=0.767). Number of acidic reflux episodes (6 (3-10) vs 8 (1.5-13), p=0.953) and weakly acidic reflux episodes (0 (0-1) vs 0 (0-0.5), p=0.680) were not significantly reduced. Treatment reduced the number of TLESRs after treatment (from 4 (1-7.5) to 2 (0.5-4.5), p=0.048).

Reflux symptoms were reduced substantially (RDQ from 3.8 (3.1-4.0) to 1.4 (0.6-2.8), p=0.008) and GERD-health related quality of life improved substantially as well (28 (21-32) to 15 (6-24), p=0.012). There was no effect of treatment on dysphagia symptoms (Brief Esophageal Dysphagia Questionnaire (BEDQ) of 8.9 (±7.4) vs 9.2 (±6.5) (p=0.880).

Endoscopy showed reflux esophagitis in 89% (8/9) (3 grade A; 5 grade B) prior to treatment, this was 56% (5/9) (1 grade A; 4 grade B) after treatment (p=0.250).

Impedance planimetry showed no changes in distensibility after treatment (3.6 (±1.2) mm^2/mmHg vs 4.4 (±1.2) mm^2/mmHg), p=0.375). One delayed post-procedural bleeding (11%, (1/9)) occurred requiring repeat endoscopy.

Conclusion: Preliminary results show that ARMS is a successful treatment option in PPI refractory GERD patients reducing both reflux episodes and symptoms. While the mechanism could not be explained by a difference in distensibility, a reduction in TSLERs might play a role.

Introduction: Stretta, a minimally invasive endoscopic procedure, has demonstrated efficacy in improving GERD symptoms by delivering radiofrequency energy to the lower esophageal sphincter. Despite its effectiveness, there is limited understanding of Stretta's impact on the epithelial barrier function.

Aims & Methods: This study aims to investigate changes in epithelial barrier function in GERD patients who underwent Stretta treatment. Tight junction gene expression levels, measurement of dilated intercellular spaces (DIS), and electrophysiological and permeability properties of the esophageal epithelium were investigated in order to determine the epithelial barrier function characteristics of patients treated with Stretta.

Six Stretta-treated (3 men, 38.5±4.9 years) patients and 15 (7 men, 36.2±6.3 years) healthy volunteers (HV) were included in the study. Esophageal epithelial biopsies taken during endoscopy were used as study material. In order to determine tight junction gene expressions, qRT-PCR method was used for the expression levels of 6 (E- cadherin, Zonula ocludens 1, Zonula ocludens 2, Claudin 1, Claudin 4, Occludin) genes. Ussing chamber system was used to determine the transepithelial resistance (TEER) of the esophageal epithelium and permeability properties were examined by a fluorometric method. In DIS measurements, For each patient, photographs were taken from 10 different areas without artifacts under the light microscope at 1000x magnification. Ten vertical measurements were made continuously around the single epithelial cell with the largest DIS between the upper part of the Stratum Basale and the six parts of the Stratum Spinosum. A total of 100 blind measurements were made by a single investigator for each patient.

Results: In comparing the gene expressions of tight junctions before (Pre-str) and after Stretta (Post-str), it was observed that only the expression of the Claudin 4 gene was 6.91 (p=0.02) fold higher in the Post-str group compared to the Pre-str group.

Similarly compared to the HV group, the Post-str group exhibited a 6.02-fold (p=0.001) increase in Claudin 4 expression.

Comparing the TEER results between the pre-str (110.8 Ω) and post-str (151.7 Ω) groups, although there is a numerical increase, no statistically significant difference was observed.

In addition, the TEER values of the HV (165,8 Ω) group were statistically significantly higher than the Pre-str group. Upon examining the permeability results, it was determined that the Post-str (30.1 pmol) group had lower permeability compared to the Pre-str (67.3 pmol) group (p=0.043), while there was no statistically difference observed between the HV (34.4 pmol) group and the Stretta groups.

According to the study findings, the group that exhibited the largest DIS was the Post-str (0.974±0.212) group. However, no statistically significant difference was observed between the Pre-str (1.030±0.266) and Post-str groups in terms of DIS. Notably, a significant difference (p=0.03) was only observed between the HV (1.374±0.269) group and the Post-str group.

Conclusion: In summary, our findings suggest that treatment with Stretta strengthens the epithelial barrier function, as evidenced by the increase in Claudin 4 expression and the corresponding decrease in fluorescent permeability. However, the lack of support from our DIS results in terms of gene expression and electrophysiological changes suggests the need for further investigation to fully understand the effects of Stretta treatment on the epithelial barrier.

Disclosure: Nothing to disclose.

PROTON PUMP INHIBITORS SLIGHTLY DECREASE THE SEVERITY OF NON-SPECIFIC CHRONIC COUGH IN ADULTS, IRRESPECTIVE OF TREATMENT DURATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

D.-E. Iov[1,2], M. Obeidat[2,3], S.B. Kávási[2], B. Teutsch[2,3], D. Veres[2,4], K. Hagymási[2], P. Hegyi[3,2,5], V.L. Drug[1], B. Erőss[3,2,5]

Introduction: The Montreal consensus recognizes chronic cough as an extra-oesophageal manifestation of gastroesophageal reflux disease, for which acid-suppressive medications have been proposed as a treatment option.

Aims & Methods: We performed a meta-analysis to assess the therapeutic effects of proton pump inhibitors (PPIs) on cough severity and quality of life (QoL) in adults with non-specific chronic cough.

The protocol was prospectively registered on PROSPERO (CRD42022368769). Placebo-controlled randomized trials (RCTs) which assessed the impact of acid-suppressive medications on cough severity or QoL in adults with non-specific chronic cough were eligible for inclusion. The systematic search was performed on the 1st of November 2022 in three databases (PubMed, Embase, and CENTRAL), with additional cita-

tion searching. A random-effects model was used for the calculation of the results. The effect size was the standardized mean difference (SMD) with a corresponding 95% confidence interval (CI), for which Hedges' g was used. Heterogeneity was assessed using Higgins and Thompson I^2 statistics. The risk of bias was evaluated using the Revised Cochrane Risk-of-bias Tool for Randomized Trials (RoB 2).

Results: Eleven RCTs with more than 600 patients were eligible for inclusion. Compared to placebo, PPIs slightly decreased the cough severity (SMD 0.33; CI: 0.05, 0.61). This effect seemed greater in patients with abnormal reflux studies (SMD 0.49; CI: -0.41, 1.39). Time dependency analysis found that prolonged treatment durations do not result in greater symptomatic improvement (SMD 0.33 (CI: -0.22, 0.88), 0.31 (CI: -1.74, 2.35), 0.32 (CI: -0.29, 0.93), 0.34 (CI: -0.16, 0.85) following 4, 6, 8 and 12 weeks of treatment, respectively). PPIs seemed to moderately improve the QoL compared to placebo (SMD 0.39; CI: -0.51, 1.29); however, when an outlying trial was omitted, the resulting effect was relatively small (SMD 0.11; CI: -0.39; 0.62).

Conclusion: PPIs slightly decrease the severity of cough, irrespective of treatment duration. Symptomatic improvement seems to be greater in patients with abnormal results on reflux studies.

Disclosure: Nothing to disclose.

Introduction: Patients who have gastroesophageal reflux disease(GERD) on maintenance therapy with acid-secretion inhibition drugs, it is not clear what background factors allow patients to discontinue the drugs.

This study aimed to examine the relationship of the changes in the frequency and severity of gastrointestinal symptoms after discontinuation of acid-secretion inhibitors for erosive GERD (eGERD) with possible patient background factors and to identify factors that influence these changes.

Aims & Methods: This study was a multicenter, open-label, interventional, exploratory study. eGERD patients with mild mucosal injury whose symptoms were under control and who were on maintenance therapy with acid-secretion inhibition drugs were withdrawn from the drug treatment for 4 weeks.

We examined the relationship of patient backgrounds (sex, age, body mass index, alcohol consumption, smoking habits), esophageal hiatal hernia, Helicobacter pylori infection, pepsinogen I and II concentrations and I/II ratios, blood gastrin levels before and after drug discontinuation with total score change in Frequency Scale for the Symptoms of GERD (FSSG).

Results: Of the 92 patients whose symptoms could be evaluated before and after withdrawal, 66 patients (71.7% of the total) had an FSSG <8 and did not have a recurrence of symptoms after withdrawal. In addition, background factors that might be associated with recurrence or non-recurrence of patient symptoms were examined, but no associated factors were detected.

Maintenance medications prior to discontinuation in the above 92 patients were proton pump inhibitors (PPIs) and vonoprazan (VPZ, a potassium ion-competitive acid blocker); PPIs and VPZ were given incidentally but in approximately equal numbers, so additional patient relationships were examined.

Conclusion: There were no patient factors that are likely to affect the discontinuation of maintenance therapy for eGERD. There was no significant difference in the extent of disease or frequency of recurrence during the discontinuation period, regardless of whether the drug before discontinuation was PPIs or VPZ. Since 70% of patients did not experience recurrence for at least 4 weeks and there were no serious complications even in patients experiencing recurrence, temporary discontinuation of maintenance therapy with ASIDs, especially with PPIs, is acceptable for mild eGERD.

Disclosure: Nothing to disclose.

THE USE OF ALGINATE DURING PROTON PUMP INHIBITOR WASHOUT IMPROVES PPI DEPRESCRIBING BY IMPROVING SYMPTOM BURDEN AND QUALITY OF LIFE

D. Maniero[1], M. Ghisa[2], V. Savarino[3], C. Coyle[4], K. Plehhova[5], E.V. Savarino[6]

Introduction: Approximately 40% of adults use Proton Pump Inhibitors (PPIs) for treating acid-related disorders, although a potentially inappropriate indication has been observed in 30%-80% of cases. Moreover, PPIs have been associated with adverse events. Therefore, PPI discontinuation should be encouraged, particularly when their use is inappropriate or in case of lack of benefit. However, past studies failed to provide sustainable ways for reducing inappropriate PPI administration and novel models of deprescribing have been developed

Aims & Methods: We aimed to evaluate whether the use of alginate during mandatory PPI washout prior to reflux testing in patients with reflux-like symptoms is helpful in sustaining PPI deprescription. In this retrospective study, consecutive patients with typical (i.e. heartburn and/or regurgitation) or atypical (i.e. chronic cough, asthma) symptoms potentially related to GERD, on long-term PPI therapy (>3months), referred to our outpatient clinic for reflux testing because of PPI refractoriness or to confirm long-term PPI administration were included. Demographic and clinical (endoscopy, esophagogram, symptoms) data were recorded before PPI withdrawal and after (within 6 months) functional testing. Patients were asked to stop PPIs at least 2 weeks prior to testing, while they were allowed to take alginate (Gaviscon Advance, Reckitt Benckiser, United Kingdom) or other rescue medications during PPI withdrawal, on as needed basis or as standardised treatment (after each meal and before night) according to disease severity. Symptoms were collected by means of the validated GerdQ questionnaire (positive for GERD when >8), in case of typical symptoms, and Reflux Symptom Index (RSI positive for laryngopharyngeal reflux disease when >13), in case of atypical symptoms. Moreover, data regarding Gastroesophageal Reflux Disease Health Related Quality of Life (GERD-HRQL) and the results of high-resolution manometry with impedance-pH monitoring were recorded

Results: Three-hundred and eighty patients with typical symptoms [222 male, mean age 59] and 240 patients with atypical symptoms [143 male, mean age 63] were recruited. According to GerdQ before testing, 243 pa-

tients (64%) reporting typical symptoms had GERD, while based on RSI, 173 patients (72%) reporting atypical symptoms had laryngopharyngeal reflux disease. Mean time of PPI withdrawal before testing was 18 days (range 13-21) and most patients (80%) took alginate as rescue therapy. At the follow-up visit after testing, 280 patients (74%) with typical symptoms (median follow-up time of 2 months) and 130 patients (54%) with atypical symptoms (median follow-up time of 3 months) did not resume PPIs.

According to GerdQ after testing, 182 patients (48%) reporting typical symptoms had GERD compared to 64% before testing (p=0.0001), while based on RSI, 146 patients (61%) reporting atypical symptoms had laryngopharyngeal reflux disease compared to 72% before testing (p=0.0118). Moreover, patients taking alginate on standardised treatment were able to stop PPI more frequently than patients taking alginate on as needed basis (76% vs. 48%, p<0.05).

Finally, GERD-HRQL improved in patients with both typical and atypical symptoms after testing (p<0.05).

Conclusion: Alginate administration favored PPI deprescribing by improving symptom burden and quality of life. Our findings highlight the potential use of alginate for reducing the impact of PPIs on the costs of health care system and their pharmacological misuse

A MULTICENTER, OPEN-LABEL RANDOMIZED CONTROLLED TRIAL OF *CURCUMIN LONGA* LINN VERSUS STANDARD DOSE OF OMEPRAZOLE IN TREATMENT OF GASTROESOPHAGEAL REFLUX DISEASE

O. Wittanakorn[1], A. Angsubhakorn[1], S. Chirapongsathorn[1]
[1]Phramongkut Hospital And College Of Medicine, Gastroenterology and Hepatology, Bangkok, Thailand

Contact E-Mail Address: sakkarin33@gmail.com

Introduction: *Curcumin* longa Linn has been used in Asia as an herbal remedy for gastrointestinal disorder. However, the benefit of curcumin on GERD treatment is still not well evaluated.

Aims & Methods: The aim of this study was to compare efficacy of curcumin and omeprazole on GERD symptom relief over the course of 4 weeks and duration of symptoms relief after treatment. From July 2021 to December 2022, subjects diagnosed with GERD according to ROME IV criteria were enrolled. Subjects were randomized into curcumin, or omeprazole groups. The Gastroesophageal Reflux Disease Symptom Assessment Scale (GSAS) was used to evaluate clinical effectiveness after 4 weeks.

Results: A total of 62 subjects were randomized. Thirty and 32 subjects in the curcumin and omeprazole groups, respectively. At 4 weeks, no significant difference of the mean GSAS score was observed between curcumin and omeprazole groups (-2.53 ± 0.59 vs -2.37 ± 0.46; *P* = 0.83). Omeprazole group had greater improvement of number of subjects who had severe symptom than curcumin group (50% to 3.1% vs 16.6% to 10%). Mean duration of symptom improvement was 14 days in curcumin and 10 days in omeprazole groups. No report of adverse reaction or worsening of GERD symptoms in both groups.

	Curcumin (n=30)	Omeprazole (n=32)	p-value
	Mean ± SE	Mean ± SE	Mean ± SE
GSAS symptoms			
Entry	7.33 ± 0.60	6.44 ± 0.46	0.23
4 weeks	4.80 ± 0.74	4.06 ± 0.45	0.39
△ Entry - 4 weeks	-2.53 ± 0.59	-2.37 ± 0.46	0.83
GSAS frequency			
Entry	1.90 ± 0.16	1.87 ± 0.20	0.89
4 weeks	1.09 ± 0.22	0.68 ± 0.10	0.099
△ Entry - 4 weeks	-0.81 ± 0.16	-1.19 ± 0.18	0.13

Table 1 Comparison of mean GSAS (gastroesophageal reflux disease symptom assessment scale) at entry and after 4 weeks of treatment.

Conclusion: *Curcuma longa* Linn can improve GERD symptoms equivalent to omeprazole in treatment of GERD without worsening of symptoms. However, the effect of omeprazole was faster symptom improvement in our cohort.

Introduction: Proton pump inhibitors (PPIs) are widely used for the treatment of peptic ulcer and gastro-esophageal reflux diseases, and as mucosal gastric protectors in patients receiving anti-aggregation drugs for cardiovascular diseases.

Although PPIs are well tolerated, concerns have been raised that their chronic use may pose risks of dementia, gastric cancer, and pneumonia. Recently, researchers have suggested that chronic use of PPIs such as omeprazole may also be a risk factor for osteoporotic bone fractures,[1,2] but the findings are controversial.[3,4]

Aims & Methods: Aim: The aim of the study was to investigate the potential association of chronic use of omeprazole with the occurrence of osteoporotic fractures (OF) in community-dwelling elderly subjects.

Methods: The cohort consisted of community-dwelling residents aged ≥65 years registered with a large health maintenance organization in Israel between 01/2002 and 12/2016.

Data were retrospectively collected from the electronic medical files on demographics, parameters known to be associated with OF, diagnoses of osteoporotic hip, wrist, and vertebral fractures, and chronic use of omeprazole (≥11 prescriptions/year). Time to OF/death/end of study was

calculated from the beginning of the study (2002). The risk of fractures in omeprazole the chronic users was analyzed by multivariate Cox proportional hazard regression model.

Results: Included 46,805 subjects (41% men), mean age 83.4±6.4 years, of whom 10,272 (21.9%) were chronic users of omeprazole.

During 14 years of follow-up, OF were diagnosed in 414 (4.0%) omeprazole users and 1007 (2.8%) omeprazole nonusers (p<0.001). In a Cox regression model adjusted for age and gender only, chronic use of omeprazole was associated with a 16% excess of osteoporotic fractures.

However, when parameters known to be associated with osteoporotic fractures were entered into the multivariate Cox regression model, chronic use of omeprazole was not found to be an independent risk factor for osteoporotic fracture, either overall (aHR=0.965, 95% CI 0.86–1.08, *p*=0.55) or specifically, in the ≥85-year age group (aHR=0.780, 95% CI 0.635–0.958, *p*<0.05) in which an inverse correlation between omeprazole use and osteoporotic fracture, was demonstrated.

Conclusion: Chronic use of omeprazole wasn't associated with the occurrence of osteoporotic fractures in community-dwelling elders.

RETROSPECTIVE CHART REVIEW OF 79 SUBJECTS WITH GASTROESOPHAGEAL REFLUX DISEASE MANAGED WITH THE REFLUXSTOP PROCEDURE: A REPORT OF THE SAFETY AND EFFICACY

T. Lehmann[1], M. Simkus[1], C. Oehler[1]

[1]Klinikum Friedrichshafen GmbH, Department of Visceral Surgery, Friedrichshafen, Germany

Contact E-Mail Address: lehmann.thorsten@medizincampus.de

Introduction: The RefluxStop device is a novel surgical implant that aims to manage gastroesophageal reflux disease (GERD) by reinstating the normal structure of the antireflux barrier. The nonactive implantable device achieves this by restoring the acute angle of His and gastroesophageal flap valve while acting as a mechanical stop to prevent migration of the lower esophageal sphincter into the chest cavity.

This study reports the safety and efficacy of 79 subjects that underwent the RefluxStop procedure.

Aims & Methods: After informed consent was obtained, a retrospective chart review of 79 GERD subjects managed by the RefluxStop procedure was performed at a single institution in Germany between July 2021 and November 2022.

Outcome measures included assessment of symptoms and associated conditions, parameters of proton pump inhibitor (PPI) usage, evaluation of perioperative adverse events or complications, and GERD health-related quality of life (GERD-HRQL) score.

These measures were used to evaluate the feasibility, safety, and clinical outcomes of the RefluxStop procedure in management of active GERD.

Results: 79 subjects aged 49.8±14 years were followed after undergoing the RefluxStop procedure. The mean body mass index of subjects was 25.8±4.5. 49 of the subjects were male. Associated conditions observed preoperatively included esophagitis (45.6%), Barrett's esophagus (17.7%), and hiatal hernia (57%). Hiatal hernias had a mean size of 2.9 cm with 35% of cases classified as large.

Symptoms at baseline included general GERD symptoms (35.4%), heartburn (29.1%), cough (13.9%), regurgitation (11.4%), retrosternal burning (10.1%), hoarseness (5.1%), abdominal pain or pressure (3.8%), nausea (2.5%), and other less frequent manifestations. Preoperative GERD-HRQL score was 21.5±5.2 and patients had been using PPIs for a mean of 4.7±6.8 years before surgery. At a follow-up of 10.7±3.1 months postoperatively, all subjects demonstrated significant improvement in GERD-related symptoms including dysphagia.

No subjects required postoperative esophageal dilatation or reoperation and only 2.5% of subjects required PPIs to manage persistent symptoms after surgery.

Furthermore, no severe perioperative complications occurred. The mean GERD-HRQL score was significantly reduced to 1.6±3.2 at follow-up, exhibiting a 92.6% improvement from baseline.

Conclusion: This study provides additional evidence to support RefluxStop as a safe and effective management option in patients with GERD. Significant improvements in PPI use and health-related quality of life outcomes were observed after intervention. Further studies are needed to validate the role of RefluxStop in GERD management.

Disclosure: Nothing to disclose.

PP0130

COMPLICATIONS OF INSUFFICIENCY OF THE ANTI-REFLUX FUNCTION OF THE PHYSIOLOGICAL CARDIA IN HIATAL HERNIAS:DIAGNOSIS AND TREATMENT

O. Babii[1], B. Shevchenko[2], N. Prolom[2]

[1]Institute of Gastroenterology of NAMS of Ukraine, Department Surgery of the Digestive Organs, Dnipro, Ukraine, [2]Institute of Gastroenterology of NAMS of Ukraine, Department of Surgery of the Digestive Organs, Dnipro, Ukraine

Contact E-Mail Address: Aleksandr_babiy@ukr.net

Introduction: The most common among surgical antireflux methods for the treatment of hiatal hernias (HH) are Nissen, Toupet, or Dor surgery. Among the disadvantages of these interventions, the greatest importance is the destruction of the physiological cardia, which is accompanied by the recurrence of HH, dysphagia, gas-bloat syndrome and heartburn recovery. Despite the advances in HH surgery, the performance of antireflux operations remains debatable.

Aims & Methods: To improve methods of diagnosis and treatment of complications of insufficiency of the physiological cardia in HH.In 2017-2022, 78 patients with HH were diagnosed and treated surgically in the digestive surgery department of the institute.

The type and degree of HH were determined during X-ray examination. An endoscopic examination was performed to determine the condition of the mucous membrane of the esophagus and the degree of violations of the physiological cardia. Endoscopic balloon manometry was used to study pressure in the lower esophageal sphincter (LES) and monitor the effectiveness of antireflux surgery.

Results: Axial HH (I type) was diagnosed during X-ray examination – in 60 (77.0%); paraesophageal (II type) – in 9 (11.5%); mixed (III type) – in 9 (11.5%) patients. Depending on the amount of penetration of organs into the chest cavity, HH of the 1st degree was established – in 42 (53.8%), 2nd degree – in 27 (34.6%) and 3rd degree – in 9 (11.5%) patients.

Changes in the mucous membrane of the esophagus – in 40 (51.3%) patients with type I and III HH: non-erosive reflux esophagitis – in 9 (11.5%), erosive reflux esophagitis – in 16 (20.5%), esophageal ulcer – in 6 (7.7%), peptic stricture of the esophagus on the background of esophagitis – in 3 (3.8%), Barrett's esophagus - in 6 (7.7%) patients.

During endoscopic balloon manometry, the pressure in the LES is reduced: axial HH – (11.39±2.44) mmHg, paraesophageal – (13.54±3.32) mmHg, mixed – (8.06±3, 64) mm Hg (the norm is 14-21 mm Hg).

The first stage of treatment for patients with reflux esophagitis was conservative therapy, for peptic stricture of the esophagus – endoscopic balloon hydrodilatation, for Barrett's esophagus – argon plasma ablation.

As a second stage, 78 patients underwent standard laparoscopic antireflux operations according to Nissen – in 32 (41.1%), Toupet – in 7 (8.9%), Dor – in 5 (6.4%), and in 34 (43.6%) patients, according to the proposed method, which preserves the connections of the diaphragm, esophagus, and stomach, and performing cardiocrurorrhaphy, fundocruroesophagorraphy, cardiogastroplication with gastrodiaphragmopexy restores the antireflux function of the physiological cardia.

In the long term, from 6 months to 4 years, significantly more complications were diagnosed after standard antireflux operations compared to the proposed method - gas bloat-syndrome (X^2=4.65, p=0.031) pylorospasm (X^2=4.03, p=0.045), dysphagia (X^2=4.30, p=0.038) and recurrence of HH – 11 (25.0%) vs 3 (8.8%) cases (p<0.05).

Conclusion: The proposed two-stage method of surgical treatment of patients with HH is highly effective.

The application of the proposed method ensures the elimination of pathological changes in the mucous membrane of the esophagus, the restoration of the physiological cardia, the preservation of the anatomical relationships of the diaphragm and the zone of the esophageal-gastric transition.

In the postoperative period, the proposed method reduces the frequency of recurrence of HH, occurrence of gas bloat-syndrome, pylorospasm, and dysphagia.

Disclosure: Nothing to disclose.

EVALUATION OF GASTRIC MUCOSAL CHANGES AND HYPERGASTRINEMIA IN LONG-TIME PPI USERS

H. Suda[1], T. Murao[1], A. Okuda[1], T. Takeichi[1], S. Fujie[1], M. Urata[1], S. Eto[1], K. Hasuda[1], K. Sakurai[1]
[1]*Hattori Clinic, Kumamoto, Japan*

Contact E-Mail Address: sudahiro0825@gmail.com

Introduction: Proton pump inhibitors (PPIs) have become clinically essential agents as a treatment strategy for gastroesophageal reflux diseases (GERD). PPI use has increased over time including continuous and longer-time users, which leads growing concern about PPIs side-effect.

Endoscopic gastric mucosal changes possibly associated with PPIs use, such as fundic gland polyps (FGPs), hyperplastic polyps, multiple white and flat elevated lesions (MWFL), cracked or cobblestone-like mucosa (CCLM) and black spots, have been reported in recent years.

Histopathologically, these endoscopic features are suggested to be associated with parietal cell enlargement, cystic dilation of fundic glands and foveolar epithelial hyperplasia. It is also well known that Gastrin level is hormonally elevated resulted from acid inhibition in PPIs users.

Considering that gastrin has a trophic effect on the gastric epithelial cells including enterochromaffin-like (ECL) cell and parietal cell, PPI-related gastric mucosal changes might be related with hypergastrinemia. Yet, little is known about the relationship between these gastric epithelial changes and gastrin level among PPI users.

Aims & Methods: We hypothesized that hypergastrinemia in long-time PPI users might be associated with endoscopic gastric mucosal changes. The patients who have been taken PPI over 1 year between January 2021 and March 2022 in Hattori clinic and Hirano clinic were enrolled.

Fasting blood samples were collected from participants just before oesophagogastroduodenoscopy (EGD) and serum gastrin level was measured. 3 endoscopists retrospectively evaluated the presence of PPI-related gastric mucosal changes. The participants were classified into 3 groups by tertiles of gastrin level: <255 pg/mL(Low), ≥255 pg/mL, <495 pg/mL(Middle), ≥495 pg/mL(High) and evaluated for the PPI-related gastric mucosal change.

Results: A total of 57 patients were enrolled in the present study. Median (IQR) age was 73.0 (68.0-77.0) years, 22 (38.6%) were male, 6 (10.5%) was current smokers, and 18 (31.6%) were alcohol users. Of 57 patients, 26 (45.6%) had been taking PPI over 10 years. Median (IQR) gastrin, pepsinogenI and pepsinogenII level were 310(190-510)pg/mL, 117.0 (79.1-166..0) ng/mL and 17.9 (11.4-22.4)ng/mL.

The overall prevalences of FGPs, CCLM, hyperplasticity polyps, MWFL and black spots were 34 (59.6%), 23 (40.4%), 23 (40.4%), 10 (17.5%) and 4 (7.0%), respectively.

Among 3 groups, there were significant differences for the prevalences of CCLM and FGPs. Regarding CCLM, higher gastrin group had higher prevalence than the low gastrin group, i.e. the middle gastrin group vs the low gastrin group (OR, 5.28; 95% CI,1.28-21.78; P = .021) and the high gastrin group vs the low gastrin group (OR,7.13; 95% CI,1.58-32.14; P = .011) (p-trend=.0218).

On the contrary, lower prevalence of FGPs was observed in the high gastrin group, i.e. the high gastrin group vs the low gastrin group (OR,0.24; 95% CI,0.06-0.96; P = .043) (not significant difference for trend). There were not significant differences for the prevalences of hyperplastic polyps, MWFL and black spots.

Conclusion: In the current study, it was suggested that higher gastrin level might promote cracked or cobblestone-like mucosal change and inhibit fundic gland polyp formation. Hypergastrinemia resulting from PPI use might affect the gastric mucosal changes.

Disclosure: Nothing to disclose.

Contact E-Mail Address: achemlal.amine@gmail.com

Introduction: Gastroesophageal reflux disease (GERD) and its long-term complications are a common condition that affects the quality of life of patients. Reflux can reach the oral cavity and affect the teeth and oral mucosa. Dental erosions represent the main oral risk of GERD.

Our research aimed to evaluate the prevalence and severity of oral manifestations in patients with GERD.

Aims & Methods: It was a prospective, descriptive and analytical study, over 4 years (January 2019 to January 2023). We enrolled 40 subjects with GERD and 40 healthy patients (control group). All patients were assessed for oral status by using a survey on oral hygiene habits and a meticulous clinical investigation (assessment of dental erosion, mucosal lesions and measurement of salivary pH). P < 0.05 was considered significant.

All clinical data were collected and analyzed by SPSS20 software.
Results: The results showed that the mean age of our patients was 39.5 ± 14.2 years. The sex ratio M/F was 0.5. There was a significant association between the presence of GERD and the presence of oral mucosal lesions (p=0.02) as well as the presence of dental erosions (p<0.001 for the upper right and lower sectors and p<0.01 for the upper left sector).
The presence of dental erosions in the lower sectors was significantly associated with the presence of mucosal lesions (p=0.05).
Patients with GERD had on average a more acidic salivary pH than the control group (6.53 vs 7.17; p=0.03) and patients with dental erosions had a more acidic salivary pH than those without erosions (6.61 vs 7.15; p=0.01).
Conclusion: GERD is the cause of oral manifestations, of which dental erosion is considered to be the most important. We emphasize the importance of collaboration between gastroenterologists and dentists in the management of the complications associated with this condition.
Disclosure: Nothing to disclose.

Introduction: Computer Aided Detection (CADe) systems have the potential to enhance the detection of early neoplasia in Barrett's Esophagus (BE) patients during endoscopic procedures.
In this study, we aimed to evaluate a recently developed CADe system during live endoscopic procedures.
Aims & Methods: The CADe system was developed using a large and diverse training data set from 15 international endoscopy centers, comprising 6,237 neoplastic images from 1,304 patients and 7,595 non-dysplastic images from 1,103 patients. Multiple extensive ex-vivo benchmarking studies were performed for validation. The CADe system displayed consistent and reliable performance, leading to a significant improvement in the detection rate of neoplasia by endoscopists.
During this pilot study, the CADe system was evaluated in live endoscopic procedures of BE patients with neoplastic lesions or non-dysplastic Barrett's esophagus (NDBE) in two tertiary hospitals. The protocol involved a series of white light endoscopy videos obtained by an expert endoscopist with real-time evaluation and feedback provided by the CADe system. First, the Barrett's segment was comprehensively visualized using a standardized *"pullback video"*, spanning from the gastric folds to the maximum extent of the Barrett's segment.
Subsequently, at 2 centimeter intervals, a series of 10-second *"level videos"* was recorded, starting from the retrograde position. Ground truth, referring to the presence or absence of visible abnormalities requiring targeted biopsy, was determined by the endoscopist prior to starting the protocol.
This was followed by post-hoc histopathological confirmation through targeted biopsies, endoscopic resection, or acquisition of random biopsies. The primary outcome measure focused on the standalone performance of the CADe system, which was evaluated in terms of per-patient sensitivity and specificity.
Results: A total of 15 neoplastic patients and 15 NDBE patients were included in the study (mean age of 67 years; mean Barrett length of C7M9; 25 males; no significant differences between groups). The CADe system exhibited a 100% sensitivity on a per patient basis, correctly identifying all neoplastic lesions. 14 out of 15 visible lesions were correctly diagnosed in the pullback videos. The initially missed lesion was detected in the subsequent level video. The system incorrectly predicted neoplasia in 8 NDBE patients.
If applied in a clinical setting, this would result in a maximum of one additional targeted biopsy per patient, compared to the 16 random biopsies dictated by the mean Barrett length in this study. Histopathological examination confirmed neoplasia in 13 cases, with 11 cases being adenocarcinoma and 2 cases being high-grade dysplasia. Two cases did not contain any dysplasia. Additionally, in 4 cases from the non-dysplastic group, low-grade dysplasia was found through the random biopsy protocol.
Conclusion: This study represents one of the first evaluations of a CADe system for real-time detection of neoplasia in Barrett's esophagus in the endoscopy suite. The system accurately detected all neoplastic lesions, with an acceptable number of false positive detections.
Disclosure: This study received financial and logistical support from Olympus Tokyo.

PP0134

ADENOCARCINOMA IN LONG SEGMENT BARRETT'S ESOPHAGUS IS DIFFICULT TO DIAGNOSE LATERAL MARGIN, BUT THE WIDTH OF WHITE ZONE MAY BE A KEY FINDING: A MULTICENTER RETROSPECTIVE STUDY

I. Tanaka[1,2], S. Unno[3], D. Hirasawa[1]
[1]Sendai Kousei Hospital, Gastroenterology, Sendai, Japan, [2]Showa University Koto Toyosu Hospital, Digestive Disease Center, Tokyo, Japan, [3]Seirei Hamamatsu General Hospital, Department of Gastroenterology, Shizuoka, Japan

Introduction: The endoscopic diagnosis of lateral margin of superficial Barrett's esophageal adenocarcinoma (BEA) has been reported as challenging due to chronic inflammation. However, accurate lateral diagnosis is crucial when endoscopic treatment is indicated, as en bloc resection is necessary to prevent local recurrence. Nevertheless, the features of BEA with unclear demarcation remain poorly understood. Therefore, we aimed to clarify the clinicopathological characteristics and cause of BEA with unclear demarcation.

Aims & Methods: In this retrospective study, we reviewed cases of BEA resected by endoscopic submucosal dissection or surgery between January 2010 and September 2022 at two institutions. The lesions were classified into two groups; the clear demarcation group (CD group) and the unclear demarcation group (UD group). We then compared clinicopathological findings between the two groups. Furthermore, we aimed to elucidate the differences in pathological structures between the cancerous mucosa and the surrounding mucosa. To achieve this, we measured the length and width of the foveolar, as well as the width of marginal crypt epithelium (MCE). Subsequently, we compared these measurements in both cancerous and surrounding mucosa in each CD and UD group.

Results: We analyzed 68 cases of BEA, with 47 in the CD group and 21 in the UD group. Univariate analysis showed that long-segment Barrett's esophagus (OR; 8.44, 95% CI;2.64-27.00, p=0.00) and macroscopic type, 0-IIb (OR; 8.43, 95% CI;1.36-52.06, p=0.022) as the significant risk factors for the UD group. Subsequently, multivariate analysis revealed long-segment Barrett's esophagus as the sole significant risk factor (OR; 10.38, 95% CI;2.14-50.19, p=0.004) (Table.1).

Regarding pathological analysis, while the length and width of foveolar between the cancerous and surrounding mucosa in the CD group showed significant differences (p=0.03, and 0,00), these were not significantly different in the UD group (p=0.53, and 0.72). However, the width of MCE in the cancerous area was significantly shorter than that in the surrounding mucosa in both CD and UD group.

		HR	95%CI	*p* value
Use of PPI	Negative	1	Reference	
	Positive	1.39	0.35-5.58	0.634
Reflux esophagitis	Negative	1	Reference	
	Positive	0.83	0.14-4.82	0.841
Barrett's esophagus	SSBE	1	Reference	
	LSBE	10.38	2.14-50.19	0.004
Morphology	0-IIa	1	Reference	
	0-IIc	4.06	0.83-19.83	0.083
	0-IIb	6.97	0.75-64.69	0.087

Table.

Conclusion: The significant risk factor for BEA with unclear demarcation was the long-segment Barrett's esophagus. Additionally, we revealed that the primary pathological cause of unclear demarcation was the similarity of pathological structures between cancerous and surrounding mucosa. However, the width of MCE, which is recognized as white zone in endoscopy, was significantly different between the cancerous and surrounding mucosa in both groups, and this may be a key finding of endoscopic lateral diagnosis for all BEA lesions.

Disclosure: Nothing to disclose.

Contact E-Mail Address: yiwaya@shinshu-u.ac.jp

Introduction: Although the issue of post-colonoscopy colorectal cancer (PCCRC) has been widely discussed, the characteristics of overlooked Barrett's adenocarcinoma (BAC) remain unclear.

Aims & Methods: We aimed to identify the characteristics of BAC that were missed during screening gastroscopy. A retrospective review of 28 patients with superficial BAC who had undergone gastroscopy within three years prior to diagnosis was conducted.

The patients were divided into two groups: "misdiagnosis of detection" (no images were appropriately taken of the area where the BAC was eventually diagnosed) and "misdiagnosis of malignancy" (the BAC was overlooked despite endoscopists having taken images of the location where the BAC eventually diagnosed).

Results: The study included 24 male patients with a mean age of 65. The interval months between endoscopy at diagnosis and the last endoscopy before diagnosis were less than 12 months (n=3, 11%), 12-23 months (n=23, 82%), and 24-36 months (n=2, 7%). Background Barrett's esophagus was short-segment (SSBE, n=18, 64%) and long-segment (LSBE, n=10, 36%). The Paris classification of the lesions was 0-I (n=2, 7%), 0-IIa (n=13, 46%), 0-IIb (n=4, 14%), and 0-IIc (n=9, 32%). The median tumor size was 14.5mm (range 3-107). Tumor locations were located at 0-3 o'clock position (n=17, 61%), 3-6 (n= 5, 18%), 6-9 (n=2, 7%), 9-12 (n=3, 11%) and circumferential (n=1, 4%). Most cases were classified into "misdiagnosis of malignancy" (n=19, 68%).

Comparing misdiagnosis of malignancy with misdiagnosis of detection groups, lesions located at the 0 to 3 o'clock position were more likely to be missed due to misdiagnosis of malignancy (15/19 vs. 3/9, P=0.03). In contrast, lesions within LSBE were more likely to be overlooked due to misdiagnosis of detection (6/9 vs. 4/19, P=0.03).

Conclusion: Our findings suggest that lesions located at the 0 to 3 o'clock position were frequently missed due to misdiagnosis as esophagitis, highlighting the importance of careful differential diagnoses between esophagitis and BAC at such sites.

In contrast, most lesions within LSBE were likely missed due the lack of adequate observation. Therefore, careful observation of LSBE using all available modalities is recommended.

Disclosure: Nothing to disclose.

PP0136

DETECTION OF INTESTINAL METAPLASIA AND DYSPLASIA BY ENDOSCOPIC BIOPSIES OF BARRETT'S ESOPHAGUS IN ASIAN POPULATION

J.-T. Lin[1], C.-T. Lee[1], W.-L. Wang[1]
[1]E-Da Hospital, I-Shou University, Department of Gastroenterology & Hepatology, Kaohsiung, Taiwan

Contact E-Mail Address: jawtown@gmail.com

Introduction: The prevalences of Barrett's esophagus (BE) are gradually increasing in recent decades in some Asia-Pacific regions, thus an accurate diagnosis of BE is important to determine the surveillance program.

However, most endoscopists in Asia did not adhere to the Seattle biopsy protocol, and the optimal numbers of endoscopic biopsies and their yield rates of intestinal metaplasia (IM) and dysplasia had never been elucidated.

Aims & Methods: The aim of this study is to investigate the yield of IM and dysplasia according to the biopsy numbers. We retrospectively reviewed the upper gastrointestinal endoscopic reports from the database of outpatient setting from January 2008 to December 2020 at E-Da hospital in Taiwan. The numbers of biopsy, length of columnar-lined esophagus (CLE) and the corresponding histology were analyzed to assess the yield rates of IM and dysplasia per-biopsy in patients with endoscopic CLE and without visible cancerous lesions.

Results: A total of 120,362 endoscopies were reviewed, and 5,963 (5.0 %) cases in 3,135 patients were diagnosed as endoscopic CLE (Length, mean:1.4±0.97cm; range, 1-10). The time-trend of cases of endoscopic CLE and BE were slightly increasing in recent decades. Among them, 4,675 (78.4%) cases received a total of 8887 biopsies (number, median: 1; range, 1-9). The histology from biopsies revealed that 1,642 (35.1%) cases and 217 (4.6%) cases per-endoscopy yielded the IM and dysplasia, respectively (Table 1). Among the 913 patients with histology-confirmed BE, the mean age was 53.2 (53.2±15.1) years old and short-segment (<3cm) Barrett's esophagus (SSBE) were predominated (91%).

Overall, the yields of IM (75% vs. 33%) and dysplasia (17% vs. 3.5%) were both higher in the long-segment than those in short-segment CLE. The yield rates were positively correlated with the numbers of biopsies for both IM and dysplasia in short-segment CLE. Taking one biopsy only revealed a 26% yield of IM and 3.5% yield of dysplasia, respectively. On the contrary, one biopsy could get a 53% yield of IM and 14% yield of dysplasia in long-segment CLE.

Number of biopsies per endoscope	Number of endoscopies (total n=4677)	Yield of IM, n (%) n=1642 (35.1%)
1	2502 (53.5%)	649 (25.9%)
2	975 (20.8%)	385 (39.5 %)
3	324 (6.9%)	164 (50.6%)
4	823 (17.6%)	412 (50.1%)
5	37(0.8%)	20 (54.1%)
6	10 (0.2%)	6 (60%)
7	2 (0.04%)	2 (100%)
8	2 (0.04%)	2 (100%)
9	2 (0.04%)	2 (100%)

Table 1. yields of intestinal metaplasia according to the number of biopsies per-endoscopy

Conclusion: Sampling bias is a major concern in current clinical practice for diagnosis and management of Barrett's esophagus. The yield rates of IM and dysplasia were suboptimal by taking one biopsy, especially for short-segment CLE. A randomized study is required to determinate the optimal biopsy number for SSBE-predominant Asian populations.

Disclosure: There was no conflict of interest.

DEVELOPMENT OF EVIDENT BARRETT'S ESOPHAGUS IN ASIAN PATIENTS WITH IRREGULAR Z LINE: THE RATE, ASSOCIATED FACTORS, AND APPLICATION OF MUCOSAL PATTERNS

K.-H. Lin[1,2,3], H.-C. Yu[1,3], Y.-H. Chen[4], H.-M. Wang[3], W.-C. Sun[3], S.-S. Kao[4,3], Y.-D. Li[3], F.-W. Tsay[3], W.-C. Chen[3]
[1]Kaohsiung Veterans General Hospital, Health Management Center, Kaohsiung, Taiwan, [2]Indiana University School of Medicine, Division of Gastroenterology and Hepatology, Indianapolis, United States, [3]Kaohsiung Veterans General Hospital, Division of Gastroenterology and Hepatology, Kaohsiung, Taiwan, [4]Pingtung Veterans General Hospital, Division of Gastroenterology and Hepatology, Pingtung City, Pingtung County, Taiwan

Contact E-Mail Address: turtlemalekhl@gmail.com

Introduction: For patients with irregular Z-lines (IrrZ), current guidelines disadvise routine biopsies at the columnar-appearing distal esophagus and endoscopic follow-ups based on the rarity of malignant changes but not on the risk of progression to evident Barrett's esophagus (BE). The rates of BE development in patients with IrrZ vary widely in limited reports from the US and Europe, ranging from 0% to 25.8%.

This study aimed to elucidate the rates and factors associated with BE progression in Asian patients with IrrZ.

Aims & Methods: Patients diagnosed with IrrZ, defined as a columnar-lined esophagus less than 1 cm, by endoscopies with biopsies, and received at least one endoscopic follow-up, were included. The primary endoscopists reappraised the endoscopic images and consensually verified the endoscopic characteristics.

We referenced the mucosal patterns applied to BE and classified those over IrrZ as gastric metaplasia (GM) patterns, which comprised round, short straight, or circular pits, and intestinal metaplasia (IM) patterns, including ridged, villous, obscured, or irregular pits. Univariate and multivariate analyses were performed to identify the factors associated with progression to BE or emergence of IM.

Results: A total of 156 patients (106 males) with a median age of 53.9 (interquartile range 46.1–61.3) years, receiving 2 (1–2.8) follow-up endoscopies during a period of 43.3 (24.7–54.4) months, were included. IM was detected at baseline in 54 patients. BE, all short-segmented, developed in 15 patients (9.6 %) during follow-up.

No significant association was found between age, gender, body-mass index, abdominal girth, history of diabetes mellitus, gastroesophageal reflux disease (GERD), smoking, fasting glucose, HbA1c, use of proton pump inhibitor, maximum length of mucosal tongues, hiatal hernia, gastroesophageal flap valve, reflux esophagitis, and mucosal patterns, and the development of BE in the entire cohort or the subgroup with baseline IM. The first follow-up endoscopy effectively identified patients with BE development.

Only 1 of the 85 patients (1.2%) receiving ≥ 2 follow-up endoscopies was diagnosed with BE after their first follow up. In the subgroup without baseline IM, known GERD was significantly associated with subsequent BE, while smoking and IM pattern were linked to IM emerging.

The IM pattern was significantly associated with the maximum length of mucosal tongue and presence of reflux esophagitis. It also correlated with baseline IM, except in the subgroup with reflux esophagitis and maximum length 0.5cm–0.9cm.

Conclusion: A small proportion (9.6%) of Asian patients with IrrZ progressed to BE. Following endoscopy once could identify the patients BE developed and reassure patients without BE. In patients without baseline IM, endoscopic follow-up may be spared in the absence of known GERD. IM pattern could predict the emergence of IM, and in most patients, it correlated with the presence of IM.

USEFULNESS OF LINKED COLOR IMAGING (LCI) WITH TRANSNASAL ENDOSCOPY TO DETECT SHORT SEGMENT BARRETT'S OESOPHAGUS (SSBO)

Y. Asai[1,2], J. Kaneko[2], T. Yamada[2]
[1]Hamamatsu University School of Medicine, First Department of Medicine, Hamamatsu, Japan, [2]Iwata City Hospital, Dept. of Gastroenterology, Iwata, Japan

Contact E-Mail Address: y.asai@hama-med.ac.jp
Introduction: Repeated endoscopy is recommended to detect early-stage cancer or Barrett's oesophagus known as a precancerous lesion at the gastro-oesophageal junction (GOJ) in GERD patients. Transnasal endoscopy is considered suitable for this repeated endoscopy because of less discomfort in the throat compared to conventional (peroral) endoscopy. Thus, improvement of imaging technique at the GOJ by transnasal endoscopy is one of important issues.
Aims & Methods: To evaluate the usefulness of trasnasal endoscopy equipped with high-resolution imaging, blue laser imaging (BLI) bright and linked color imaging (LCI) for the detection short-segment Barrett's oesophagus (SSBO). We analyzed 300 images at the GOJ acquired from 100 consecutive endoscopies performed at our medical check-up center. Each endoscopy includes white light imaging (WLI), BLI bright and LCI. Ten endoscopists independently interpreted the images on SSBO and endoscopic findings related Barrett's oesophagus, including palisade vessels of squamo-columnar junction (SCJ) oral side (PV-O), palisade vessels of anal side (PV-A), squamous island (SI) and columnar island (CI).
The quality of images for visualization was judged as: excellent visibility (score of 4), good visibility (3), fair visibility (2), or not detectable (1) were evaluated.
Results: The detection rates of each image were as follows (WLI, BLI bright and LCI respectively): SSBO 28.3%, 32.7% and 38.8%; PV-O 88.5%, 83.1% and 90.5%; PV-A 47.3%, 51.1% and 63.2%; SI 9.2%, 9.5% and 9.8%; CI 18.4%, 28.7% and 28.7%. The detection rates of LCI were significantly higher than that of WLI on SSBO, PV-O, PV-A, SI and CI, and that of BLI-bright on PV-A and PV-O. The mean visibility scores (± standard deviation) were as follows: SSBO 1.59 ± 1.02, 1.65 ± 1.03 and 1.86 ± 1.18; PV-O 3.23 ± 1.05, 3.00 ± 1.15 and 3.36 ± 1.01; PV-A 1.99 ± 1.18, 1.98 ± 1.13 and 2.40 ± 1.25; SI 1.18 ± 0.60, 1.21 ± 0.66 and 1.20 ± 0.63; CI 1.43 ± 0.95, 1.74 ± 1.19 and 1.84 ± 1.43. The visibility scores for LCI were significantly higher than that for WLI and BLI-bright on SSBO and all items of related findings (<0.001). Moreover, PV-A showed the strongest correlation with SSBO on visibility score among endoscopic findings related to SSBO (R=0.500; p<0.001).
Conclusion: These results suggest that LCI with transnasal endoscopy is quite effective for the observation GOJ and detecting SSBO.

A COMPARISON OF PATIENT SATISFACTION AND HEALTHCARE RESOURCE USE IN PATIENTS WITH BARRETT'S ESOPHAGUS USING CONFOCAL LASER ENDOMICROSCOPY BASED APPROACH VERSUS STANDARD OF CARE

N. Randhawa[1], A. Khalyfa[2], M. Inamullah[3], K. Ayub[4]

Contact E-Mail Address: randhnk@gmail.com
Introduction: Barrett's esophagus (BE) is the sole precursor for esophageal adenocarcinoma (EAC), a solid tumor with a lethal 5-year survival rate. Given the rise in incidence of EAC, it is imperative to determine an efficient and effective surveillance protocol for BE. Currently, the standard of care for BE management consists of endoscopic surveillance utilizing the Seattle protocol.
However, no studies compare the healthcare resource use and patient preference of this approach to other approaches.
Aims & Methods: The aim of this study was to compare the healthcare resource use and patient satisfaction of this method to that of a Confocal Laser Endomicroscopy (CLE) based approach. A retrospective chart review of 80 patients with dysplastic BE was conducted across multiple centers. The patients were split into 1 of 2 cohorts on whether they received CLE or standard of care until there were 40 patients within each cohort. Demographics including age, gender and 12 comorbidity indicators were captured as covariates. Bivariate differences in variable means across the 2 groups were assessed using the Kruskal-Wallis equality of populations test.
Finally, linear multivariate models of the 8 health services measures were estimated. Patients were also given a survey to rank the satisfaction of their procedure from 1 (would not undergo again) to 10 (highly recommend).
Results: Compared to those receiving standard of care, CLE patients were older (71 versus 63 years; p=0.002). No other statistically significant differences in gender or comorbidities were detected. Controlling for covariates, while patients in the CLE cohort had greater use of CLE and fluorescein (3.94 more of each than standard of care; p< 0.001), they also had 1.04 fewer endoscopies and anesthesia services (p=0.001), 7.49 less biopsy jars (p< 0.001), 1.30 fewer ablations (p< 0.001) and 1.46 less brush cytology services (p< 0.001). The patient's surveys also revealed a satisfaction score of 8.5 with CLE and 6.3 with standard of care.
Conclusion: BE, the precursor to EAC, is a common condition with increasing global prevalence and burden. Our study concludes that the use of CLE is associated with lower healthcare resource use including endoscopy, anesthesia, biopsies, ablation and a higher patient satisfaction.
References: Table revealing variables (gender, hospital, comorbidities) for non-cellvizio and cellvizio with compared p-values.

EFFICACY AND SAFETY OF ARGON PLASMA COAGULATION (APC) STANDARD CATHETER USE, AFTER SUBMUCOSAL INJECTION FOR BARRETT'S ESOPHAGUS (BE) ABLATION

S. Michopoulos[1], A. Ioannou[1], G. Axiaris[1], C. Koumentakis[1], M. Tzakri[1], E. Papathanasiou[1], M. Pantelakis[1], L. Vasilieva[1], G. Leonidakis[1], E. Zampeli[1], P. Baxevanis[1], K. Petraki[2]
[1]Alexandra Hospital, Dept. of Gastroenterology, Athens, Greece, [2]Metropolitan Hospital, Pathology, Faliron, Greece

Contact E-Mail Address: michosp5@gmail.com

Introduction: Radiofrequency ablation is considered the standard therapy for flat dysplastic BE. Hybrid APC is a newer under evaluation, less expensive technique, but with the need of a special injection device and catheter. Aim of the study: To evaluate the efficacy of a standard APC catheter after submucosal injection for BE ablation.

Aims & Methods: To evaluate the efficacy of a standard APC catheter after submucosal injection for BE ablation. Naïve or after previous treatments patients with BE and low - grade dysplasia (LGD) were prospectively evaluated. Sodium chloride solution 0.9% was injected submucosally with a 23 G needle followed by APC application with a standard catheter (ERBE APC 300, 45Watts) on the created cushion. The same procedure was repeated for most of BE surface to be cauterized, with special attention not to ablate large circumferential areas. Patients were under high dose PPIs. Biopsies were taken according to the Seattle protocol during the follow-up.

Results: 31 patients, 28 males (90.3%), 56.7±12.5 years old. Their initial diagnosis was: 19 patients with LGD (61.3%), 7 with high grade dysplasia (22.6%), and 5 with intramucosal cancer (16.1%). Eleven patients (35.5%) had previous endoscopic mucosal resection (EMR) while 7 (22.6%) had received radiofrequency ablation (RFA). Median BE length with LGD at the beginning of APC was 4cm (25th-75th:2-7, min-max:1-10). Median follow-up:10.1(1-108) months. In total 20 (64.5%) patients completely eradicated BE. For the remaining 11 patients APC led to a substantial reduction of BE length [Initial Median: C3M6 (Min: C0M1, Max: C6M8) to a final median: C0M2 (Min:C0M1, Max:C2M5] but the study is ongoing. Initial BE length was correlated to APC sessions needed (r= 0.54, p<0.01) but was not a limiting factor for complete BE eradication. Instead, smoking was an aggravating factor for BE complete eradication (HR=3.12, 95%CI.: 1.2-8.12, p=0.02). No death, hospitalization, severe hemorrhage, or perforation were observed. In 7 patients moderate pain requiring paracetamol, resolved after a few hours of in hospital supervision while 11 patients had mild dysphagia the following days without permanent stenosis.

Conclusion: Conclusions:

1. Standard APC after submucosal injection is safe and tolerable for BE ablation.
2. It may be applied in naïve patients or if other techniques were previously used.
3. Length increases the number of sessions needed but does not seem to be a limiting factor for APC application.

Disclosure: Nothing to disclose.

B-PROM: DEVELOPMENT AND VALIDATION OF A NOVEL BARRETT'S OESOPHAGUS PATIENT REPORTED OUTCOME MEASURE

E. Ratcliffe[1], J. Britton[2], S. Baines[2], N. Prasad[1], R. Keld[1], M. Murgatroyd[3], M. Montenegro[4], E. Viloria[4], J. McLaughlin[5], S. Hamdy[6], Y. Ang[7]
[1]Wrightington Wigan and Leigh NHS Trust, Wigan, United Kingdom, [2]Northern Care Alliance Salford, Salford, United Kingdom, [3]NHS, Gastroenterology, Manchester, United Kingdom, [4]Imperial College Hospitals, London, United Kingdom, [5]University of Manchester Salford Royal Hospital Gastrointestinal Centre, GI Centre, Manchester, United Kingdom, [6]Salford Royal Hospital, GI Science, Salford, United Kingdom, [7]Salford Royal NHS Foundation, Gastroenterology, Salford, United Kingdom

Contact E-Mail Address: Elizabeth.ratcliffe@nca.nhs.uk

Introduction: Patients with Barrett's esophagus (BE) carry significant cancer worry, burden of symptoms, and lack disease specific knowledge. Currently there is no validated BE patient reported outcome measure (PROM) for use in clinical practice and research, hence we devised a novel, validated Barrett's specific tool, B-PROM.

Aims & Methods: Literature review, quantitative and qualitative research informed the initial item generation(1,2,3). The item bank (49items) was refined to 31 items through an online modified Delphi process involving patients, patient representatives and clinicians. The PROM was then tested through rounds of cognitive interviews and validated via multicentre testing across four UK hospitals.

Results: B-PROM covers key themes of disease-specific knowledge, trust in clinicians, burden of symptoms, cancer worry and burden of surveillance.

During the modified Delphi process, out of the 49 items, 24 reached consensus and were kept unchanged. 14 were borderline or needed rewording were revised with acknowledgement of comments from the Delphi group. Nine items were merged with other items. Two items which were clearly not favoured by the group were reviewed and removed from the draft PROM. After round 2, a further 8 items achieved consensus, the other items did not achieve consensus and final agreed items were reviewed by the steering group.

Cognitive interviews to refine the PROM tool to confirm patients comprehension resulted in changes to the formating of the knowledge section responses, and rewording of some items to more lay appropriate language.

Multicentre validation results from 387 participants (response rate 40.8%) showed 93.3% of participants completed >95% of B-PROM. All individual items scored a completion rate of >95%.

Mean completion time was 5mins 34s for a sample group. Nineteen items showed a ceiling effect, 3 items showed a floor effect. Internal consistency overall demonstrated a Cronbach Alpha of 0.846, while predetermined subsections showed Cronbach alphas of 0.335, 0.718, 0.736, and 0.896.

Inter-item analysis found 2 pairs of items with strong correlation, with only 6 items correlating weakly. Item-total correlation showed 19 items correlated well. EFA with principal component analysis produced 5 components with Eigenvalues >1 of which 4/5 had satisfactory Cronbach alphas. Test-retest reliability showed no significant differences across single and average measures (p=<0.001).

Conclusion: B-PROM is the first BE-specific PROM to be systematically evaluated. B-PROM's psychometric properties show strong internal consistency and low missingness, it covers the important priorities of BO patients found at systematic review of qualitative research. B-PROM is ready for use in clinical trials and clinical practice.

Contact E-Mail Address: mdjh1432@gmail.com

Introduction: Esophageal cancer is known to be a strongly male dominant disease. However, the gender differences have not been well understood. We aimed to evaluate the differences between male and female esophageal cancer in Korean population.

Aims & Methods: We retrospectively analyzed patients confirmed as esophageal cancer in Asan Medical Center between January 2005 and December 2015. The clinical features of patients, histopathologic characteristics of tumor, treatment response, and survival were investigated between male and female patients respectively.

Results: A total of 2,068 patients were analyzed. The median age was younger in female (62 years; interquartile range [IQR] 38-85) than male (64 years, IQR 37–90), and the male to female ratio was 13.4:1. Squamous cell carcinoma was major pathologic type (99.0% in male and 93.1% in female), however, the proportion of adenocarcinoma was higher in female than male (5.6% *vs*. 0.8%, $p<0.001$). Female patients smoked less (22.2% *vs.* 86.5%, $p<0.001$) and drank less alcohol (26.4% vs 89.9%, $p<0.001$) than male patients.

Female had upper and middle esophagus dominant tumor location (75.0%), whereas middle and lower dominant in male (81.7%). Multivariate analysis showed that gender (Hazard ratio [HR], 0.77; 95% CI, 0.60 to 0.99; $p=0.044$), age (HR, 1.03; 95% CI, 1.02 to 1.03; $p<0.001$), and advanced tumor stage (stage 4, HR, 14.3; 95% CI, 8.43 to 24.4; $p<0.001$) were independent prognostic factors for overall survival. The 5-year overall survival rate of female was higher than those of male (53.5% *vs*. 44.5%, $p=0.038$). Cancer recurrence rate in complete remission patients were significantly lower in female than male (15.3% *vs*. 25.1%, $p=0.03$).

Conclusion: The gender is an independent prognostic factor for esophageal cancer, with favorable survival outcomes in female than male. Further research is warranted to determine the cause of prognostic difference in esophageal cancer in male and female.

Disclosure: There is no conflict of interest.

LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION USING A SCISSOR-TYPE KNIFE FOR MUSCULARIS MUCOSA/SUBMUCOSA ESOPHAGEAL SQUAMOUS CELL CARCINOMA

N. Kato[1], T. Mizumoto[1], T. Kuwai[1], S. Semba[1], S. Sugata[1], Y. Okuda[1], Y. Teraoka[1], Y. Tamaru[1], R. Kusunoki[1], A. Yamaguchi[1], H. Kouno[1]

[1]National Hospital Organization Kure Medical Center and Chugoku Cancer Center, Gastroenterology, Kure, Japan

Contact E-Mail Address: u028eb@gmail.com

Introduction: According to the 2022 edition of the Japanese guideline for esophageal cancer, the necessity of additional treatment for muscularis mucosa/submucosa (MM/SM1) esophageal squamous cell carcinoma is comprehensively decided after endoscopic treatment. At our hospital, esophageal endoscopic submucosal dissection (ESD) is performed using a scissor-type knife, which is considered highly safe; however, few studies have reported its long-term outcomes.

Therefore, the study aimed to compare the short- and long-term outcomes of esophageal ESD treatment using a scissor-type knife for MM/SM1 cancer and epithelium/lamina propria mucosae (EP/LPM) cancers in our hospital.

Aims & Methods: Patients diagnosed with esophageal squamous cell carcinomas who underwent ESD at our hospital between December 2009 and November 2019 were recruited, followed up for >3 years, and classified into two groups: 61 patients with 91 lesions diagnosed as EP/LPM cancer (group A) and 22 patients with 22 lesions diagnosed as MM/SM1 cancer (group B). Short- and long-term outcomes were compared. In all cases, only scissor-type knives were used.

Results: The mean ages were 69 ± 8.9 and 70 ± 8.8 years in groups A and B, respectively. Gender (male/female) was 78/13 and 20/2 patients in groups A and B, respectively. The mean tumor sizes were 16.8 ± 11.3 and 26.8 ± 18.1 mm in groups A and B, respectively, with significant differences ($p = 0.0011$). The R0 resection rates were 100% in both groups; lymphovascular invasion was observed in two cases with pT1a-MM cancers and one case with pT1b-SM1 cancer. Chemoradiation therapy (CRT) was added to one case with pT1a-MM cancer and two with pT1b-SM1 cancers, and only chemotherapy was added to one case with pT1a-MM cancer. The average observation period was 55 ± 30 and 60 ± 38 months in groups A and B, respectively, and no local recurrence was observed in either group.

Lymph node recurrence was observed in one case with pT1a-MM cancer with lymphovascular invasion who received chemotherapy alone and one with pT1b-SM1 cancer with lymphovascular invasion who received CRT. Twenty-five and nine patients in groups A and B died from other diseases, respectively, but only one SM1 case with lymph node recurrence was the primary cancer death.

The overall survival rate (3 years) was 80.2% and 77.3% ($p = 0.85$), and the disease-specific survival rate (3 years) was 100% and 95.5% ($p = 0.30$) in groups A and B, respectively.

Conclusion: The short-term outcomes of ESD for MM/SM1 cancer using a scissors-type knife were as good as those for EP/LPM cancer, and no local recurrence occurred even in the long-term outcomes.

In addition, pT1a-MM tumors without lymphovascular invasion have progressed without recurrence and were considered appropriate as ESD-adaptive lesions.

Introduction: Endoscopic submucosal dissection (ESD) for esophageal squamous cell carcinoma (ESCC) with esophageal varices (EVs) is one of the most challenging endoscopic procedures due to the high risk of bleeding and fibrosis caused by prior treatment of varices.

However, due to the small number of such cases, the clinical outcomes of ESD for ESCC with EVs have been reported in only a limited number of cases at single centers[1-3].

Aims & Methods: We conducted a multicenter, retrospective, cohort study to clarify the safety and efficacy of ESD for ESCC with EVs.Eleven institutions in the Tohoku region of Japan participated in this multicenter, collaborative, retrospective study.

We performed endoscopic resection for 3619 patients with esophageal carcinoma at the participating institutions during the period from January 2010 to April 2022. Among those, 30 patients who underwent ESD for ESCC with EVs were recruited for the present study.

Rates of *en bloc* resection and R0 resection, procedure time and adverse events were evaluated as indicators of the feasibility and safety of ESD. Additional treatment, recurrence and metastasis of the lesions were evaluated as indicators of the long-term efficacy of ESD.

Results: Portal hypertension was caused by cirrhosis, of which alcohol was the most common cause. *En bloc* resection was achieved in 93.3% and R0 resection in 80.0% of the patients. The median procedure time was 92 minutes. Adverse events included a case of uncontrolled intraoperative bleeding leading to discontinuation of ESD and a case of esophageal stricture due to extensive resection. During the follow-up period of a median for 42 months, a patient with local recurrence and another patient with liver metastasis were observed. One patient died of liver failure after receiving chemoradiotherapy as an additional treatment after ESD. No patient died of ESCC.

Conclusion: This multicenter, retrospective cohort study demonstrated the safety and efficacy of ESD for ESCC with EVs. Further studies are needed to establish appropriate treatment methods for EVs before ESD and additional treatments for patients with insufficient ESD.

MUSCULAR INJURY AS AN INDEPENDENT RISK FACTOR FOR ESOPHAGEAL STENOSIS AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION OF ESOPHAGEAL SQUAMOUS CELL CANCER

Z.-H. Geng[1], Y. Zhu[1], Q.-L. Li[1], P.-Y. Fu[1], W.-F. Chen[1], P.-H. Zhou[1]

[1]Zhongshan Hospital, Fudan University, Endoscopy Center and Endoscopy Research Institute, Shanghai, China

Contact E-Mail Address: 15750585959@163.com

Introduction: Stenosis after esophageal Endoscopic Submucosal Dissection (ESD) has a high incidence of ranks, and muscular injury might be an important risk factor for esophageal stenosis.

Aims & Methods: Our study aimed to classify muscular injury degree and investigate its association with postoperative stenosis. This retrospective study included 1,033 patients with esophageal mucosal lesions treated by ESD between August 2015 and March 2021. Demographic and clinical parameters were analyzed, and stenosis risk factors were identified using multivariate logistic regression.

A novel muscular injury classification system was proposed and further used to investigate the association between the different degrees of muscular injury and postoperative stenosis. Finally, a scoring system was established for the prediction of muscular injury.

Results: Of 1,033 patients, 118 (11.4%) had esophageal stenosis. The multivariate analysis demonstrated that the history of endoscopic esophageal treatment, circumferential range, and muscular injury were significant risk factors for esophageal stenosis. Patients with Type II muscular injuries tended to develop complex stenosis (n = 13, 36.1%, $p < 0.05$). Moreover, Type II muscular injuries were more likely to predispose patients to severe stenosis than Type I (73.3 and 92.3%, respectively).

According to the scoring system for predicting muscular injury, patients with high scores (3-6) were more likely to suffer muscular injury. The score model presented good discriminatory power in the internal validation (AUC: 0.706; 95% CI: 0.645-0.767) and goodness-of-fit in the Hosmer-Lemeshow test ($p = 0.865$).

Conclusion: Muscular injury was an independent risk factor for esophageal stenosis. The scoring system demonstrated good performance in predicting muscular injury during ESD.

Contact E-Mail Address: kawada.srg1@tmd.ac.jp
Introduction: Recent improvements in endoscopic diagnostic techniques have made it possible to detect early-stage superficial laryngopharyngeal cancer, and endoscopic resection has become one of the standard treatments in Japan1).
However, it is not fully known to what extent endoscopic treatment alone is curative.
Aims & Methods: To clarify the relationship between depth and lymph node metastasis in superficial laryngopharyngeal cancer. From August 1996 to April 2023, we experienced 501 cases of 810 lesions of superficial laryngopharyngeal cancer.
Of these, 396 cases with 652 lesions (462 in the hypopharynx, 149 in the oropharynx, and 41 in the larynx) that were resected orally without prior treatment and followed for more than 1 year were included to investigate the relationship between depth and late lymph node metastasis.
Results: Endoscopic classification of the treated lesions was 81 lesions of type 0-I(protruded type), 164 lesions of type 0-IIa(elevated type), 391 lesions of type 0-IIb(flat type), and 16 lesions of type 0-IIc (depressed type). Type 0-IIb was the most frequent.
Histopathologically evaluated 174 cases of intraepithelial carcinoma with 249 lesions showed no metastasis. On the other hand, of the 403 lesions in 295 cases of subepithelial invasive cancer (T1, tumor size less than 2cm: 213 lesions, T2, tumor size 2-4cm or smaller: 159 lesions, T3, tumor size greater than 4cm: 31 lesions), 30 lesions in 28 cases(9.5%) had later lymph node metastasis.
Two of 305 lesions (0.65%) with tumor thickness less than 1000 µm were positive for metastasis. By size, 1 of 178 lesions in T1(0.6%), 1 of 111 lesions(0.9%) in T2, and 0 of 16 lesions in T3 were positive for metastasis. On the other hand, 28 of 98 lesions (28.6%) with tumor thickness greater than 1000 µm were positive for metastasis. By size, 6 of 35 lesions in T1(17.1%), 17 of 48 lesions(35.4%) in T2, and 5 of 15 lesions(33.3%) in T3 were positive for metastasis.
The frequency of lymph node metastasis by endoscopic type was 20 of 81 lesions(24.7%) for type 0-I, 8 of 164 lesions (4.9%) for type 0-IIa, 1 of 391 lesions(0.25%) for type 0-IIb, and 1 of 16 lesions (6.25%) for type 0-IIc, metastasis was seen more frequently in type 0-I.
The observation of brownish areas and brown dots with Image Enhanced Endoscopy is useful for detecting early-stage cancer. When examining the depth of the disease, the Valsalva method is recommended to focus on type 0-I lesions with a thickness of 1 mm or more and a well-stretched pharyngeal mucosa.
Conclusion: Superficial carcinomas with a thickness greater than 1 mm should be noted for late lymph node metastasis.

ENDOSCOPIC SUBMUCOSAL DISSECTION INTERVENTION FOR EARLY ESOPHAGEAL ADENOCARCINOMA: A PRELIMINARY SINGLE-CENTER EXPERIENCE

M. Wang[1], X. Jiang[1], M. Fu[1], L. Liu[1]
[1]The First Affiliated Hospital with Nanjing Medical Universtiy, Digestive Endoscopy, Nanjing, China

Contact E-Mail Address: 1367906738@qq.com
Introduction: Endoscopic submucosal dissection (ESD) is a highly sophisticated and advanced endoscopic procedure that is primarily used to treat early esophageal cancer. This procedure enables the en-bloc resection of neoplastic lesions and is considered the standard treatment option for Esophageal adenocarcinoma (EAC). While EAC is common in western countries, it is relatively rare in Asian populations, leading to limited clinical data on ESD for EAC in Asian countries.
Aims & Methods: Our study aims to report our experiences with performing ESD for early EAC and evaluate the clinical outcomes of non-curative ESD. From January 2013 to December 2021, we conducted a unicentric, retrospective study of patients who received ESD for early EAC at Jiangsu Province Hospital, 78 patients diagnosed early esophageal adenocarcinoma and underwent ESD were retrospectively enrolled. The clinical outcomes of ESD, as well as the entirety en bloc, R0, and curative resection rates were considered as the primary outcomes. The secondary outcomes involved comparing the results between the T1a and T1b carcinomas.
Results: Based on postoperative pathology, the esophageal adenocarcinomas were staged into either T1a (n=67 or T1b (n=11 stage. The En bloc resection rate was achieved 100%. Compare to the T1b group, the T1a group had a significantly higher R0 rate (87.8% vs.18.1%, P < 0.05) and curative resection (98.5 % vs 36.4%, P<0.001).
Among the 11 noncurative ESDs, 6 patients (47.6%) underwent R0 esophagectomy, 2 patients (28.6%) are undergoing surveillance endoscopies without additional therapy, 2 patients (14.3%) underwent repeat curative ESD and 1 patient (4.76%) received radiotherapy.
Over median endoscopic follow-up of 23.8 months (IQR, 12.23–30.75), 2 patients with noncurative ESDs had recurrent disease. Besides, we found ESD can lead to a change in histologic diagnosis in 70.6% of cases (55/78), with all cases being upstaged.
Conclusion: ESD showed a higher rate of curative resection in T1a EAC as compared to T1b EAC. Patients with non-curative ESD may benefit from conservative multimodal therapies including repeat curative ESD, surveillance endoscopies, or R0 esophagectomy. Selective ESD, on the other hand, has the potential to be a diagnostic and staging tool, especially in patients with suspected invasive illness.

STEPWISE ESD CAN PREVENT SEVERE STRICTURE AFTER ESD FOR CIRCUMFERENTIAL ESOPHAGEAL TUMOR

T. Oyama[1], A. Takahashi[1]

[1]Saku Central Hospital Advanced Care Center, Endoscopy, Nagano, Japan

Contact E-Mail Address: oyama@coral.ocn.ne.jp

Introduction: ESD is a standard treatment for Dysplasia or T1a esophageal cancers. However, severe stricture after circumferential ESD is a remaining major problem. Various managements have been reported, such as steroid injection, oral administration, and application of polyglycolic acid sheets, but none of them are sufficiently effective. Recently, the authors performed stepwise ESD in patients with circumferential esophageal cancers to prevent severe stricture after ESD.

Aims & Methods: The aim of this retrospective study is to clarify the usefulness of Stepwise ESD for preventing severe stricture after circumferential resection for esophageal tumor. Patients who underwent additional surgery due to the depth of SM2 or positive vascular invasion as a result of performing circumferential ESD were excluded from this study. Subjects were patients with circumferential esophageal tumors pathologically diagnosed as Vienna classification 4 or 5, who underwent ESD at Saku Hospital from 2006 to 2022. Sixteen and forty-six lesions were adenocarcinoma (EAC) and Squamous cell carcinoma (SCC), respectively. In the EAC group, the invasion depth was T1a in 9 cases and T1b in 1 case. In addition, the depth of invasion in the SCC group was T1a in 38 cases and T1b in 7 cases. The patients were divided into the En bloc (EB) group and the Stepwise (SW) group, and the background, number of endoscopic balloon dilatation (EBD), complications, etc. were examined for each group.

Results: Sixty-two patients, including 55 in the EB and 7 in the SW group, who required circumferential ESD, were entered into this study. There was no significant difference in age and gender between two groups.

Of the 55 patients in the EB group, 47 (85%) had severe stenosis and required EBD, but none in the SW group required EBD. The median number of EBDs was 5 (0-33) in the EB group and 0 (0-0) in the SW group.

And, the duration of ulcer healing in both groups were 137 (42-1028) days and 42 (30-120) days. The duration to healing of ESD ulcers was significantly shorter in the SW group (p<0.0001). The volume of TA injection were 50 (0-150) mg and 50 (0-100) mg, respectively. There was no significant difference (p=0.88).

The long axis mucosal defect lengths in the EB and SW groups were 8(5-15) cm and 6(3-9) cm, respectively. There was a significant difference between two groups (p=0.0004).

The diameters of the tumors were 59 (30-130) mm and 40 (36-64) mm, respectively. The length of resected specimen were 68 (29-150) mm and 56 (27-92) mm, respectively. There was a significant difference between two groups p=0.0004 and 0.0007.

Complications: There were no perforation and bleeding which needed blood transfusion. And, one patient in the EB group had a perforation during EBD, which could be cured with conservative treatment without surgery.

Conclusion: It has been reported that a circumference excision of 5 cm or more may cause severe stenosis. In this study, a median of 6 cm was performed even in the SW group, and stenosis could be prevented in all 7 cases. Therefore, Stepwise ESD may be a useful method to prevent post-ESD stricture in circumferential superficial esophageal tumors.

Disclosure: Nothing to disclose.

Introduction: The recurrence rate after radical esophageal cancer resection is as high as 40-60%, and patients with early recurrence have a poor prognosis. Recently, the indication of immune checkpoint inhibitor (ICI) therapy for esophageal cancer has been expanded to adjuvant therapy based on the results of the CheckMate 577 trial, and its efficacy is expected to increase[1]. In addition to ICIs, immunotherapies such as cancer peptide vaccines and CAR-T cell therapy are also expected to be applied to esophageal cancer[2,3].

On the other hand, the response rate of ICI for esophageal cancer is limited to 10-30%[4], and the method of selecting patients who will benefit from immunotherapy is controversial.

Aims & Methods: Aims: we expect that elucidating the association between early postoperative recurrence of esophageal cancer and tumor immune microenvironment (TIME) will provide a biomarker for patient selection for immunotherapy, especially for patients who will benefit from immunotherapy in combination with adjuvant chemotherapy.

Methods: 63 patients with pStage II, III, or IV esophageal cancer who underwent radical surgery at our department between May 2014 and June 2020 were included in the study. 63 patients with recurrence within 1 year (ER group n=26) and 63 patients with non-early recurrence (NER group n=37) were retrospectively compared and evaluated for clinicopathological factors including TIME. The results were compared and examined.

Results: Analysis in clinical context: Univariate analysis for early recurrence showed more pStage III/IV in the ER group (RR: 5.04, (95%CI: 1.69-15.0), p<0.01) and more deaths in the ER group than the NER group (RR: 5.69(95%CI: 2.45-13.2), p<0.01).

Analysis of tumor-infiltrating lymphocytes: ROC analysis of CD8-, Foxp3, TIM3-, and PD1-positive lymphocytes in TIME was performed for early recurrence, with cutoffs set for each, and compared between the two groups. Results showed that CD8, Foxp3, and positive lymphocyte counts were significantly lower in the ER group than the NER group (relative risk: 2.07(95%CI:1.14-3.75), p=0.02,), (relative risk: 2.32(95%CI: 1.36-3.96), p<0.01). Multivariate analysis showed that CD8-positive lymphocyte count was a factor associated with early recurrence (odds ratio=5.17 (95%CI: 1.39-19.3), p=0.01).

Analysis in lymphocyte ratios: Kaplan-Meier curves were generated for Foxp3/CD8, TIM3/CD8, and PD1/CD8 with median cutoff and 1-year RFS between the two groups. 1-year RFS in Foxp3/CD8 tended to be worse in patients with predominant Foxp3 than with inferior Foxp3 (Foxp3/CD8>1.83:73%, Foxp3/CD8<1.83:50%, Log-rank test p=0.08). The 1-year RFS was significantly worse in group A (1-year RFS=A:43%, B:71%, Log-

rank test p=0.04). Similarly, for TIM3, when patients with CD8 low and TIM3/CD8 High were analyzed as group A and others as group B, group A had a significantly worse prognosis (1-year RFS=A:45%, B:70%, Log-rank test p=0.05).

Furthermore, PD1 patients with CD8 low and PD1/CD8 high were group A, and all other patients were group B. The prognosis was significantly worse in group A (1-year RFS=A:42%, B:69%, Log-rank test p=0.03).

Conclusion: In addition to CD8 infiltration in TIME, the balance of expression of regulatory lymphocytes was suggested to be involved in early recurrence.

It is suggested that evaluation of TIME aid in patient selection for adjuvant treatment of esophageal cancer.

Introduction: Patients with head and neck neoplasms (HNN) are at an increased risk of synchronous gastro-esophageal neoplasia (GEN) due to shared risk factors such as smoking, alcohol consumption, and HPV infection. Several scientific societies recommend screening HNN patients for synchronous esophageal neoplasms. Nevertheless, particularly in Western centers, few studies evaluated the impact of an organized screening program.

Aims & Methods: We conducted a prospective study that evaluated an organized GEN screening program in HNN patients diagnosed between 01/06/2020 and 31/12/2022, in a tertiary reference hospital. Patients were proposed to do an upper gastrointestinal endoscopy (UGE) with narrow-band imaging (NBI) and/or Lugol chromoendoscopy.

Results: We evaluated 34 patients, 82.4% male, with a median age of 64.5 (IQR: 57,5-70) years. 82.4% had a history of tobacco use, and 35.3% presented active alcohol consumption. The most common primary HNN sites were the larynx (50.0%) and the tonsil (14.7%), and the most frequent histological type was squamous cell carcinoma (SCC) (88.2%). The median time between HNN and UGE was 4.5 (IQR: 1.25-10) months, and 91.2% of the patients had already started treatment for HNN. The prevalence of synchronous GEN was 14.7% (Esophageal SCC n=4; Cardia adenocarcinoma n=1). One patient underwent ESD of two synchronous SCC (SCC pT1b), with adjuvant radiotherapy, other (T1/T2N0M0) underwent chemotherapy and radiotherapy, and two patients are waiting ESD. The patient with cardia adenocarcinoma underwent ESD (pT1b with lymphatic permeation) and total gastrectomy, with no evidence of residual lesion. All patients with synchronous GEN remain alive in the follow-up.

Conclusion: In our study the prevalence of synchronous GEN in HNN patients was significant and most lesions were detected in an early stage, still amenable for endoscopic resection. This study showed that the implementation of this screening strategy may potentially lead to a better prognosis for these patients and its cost-efficacy should be evaluated .

ASSOCIATION OF INTENSIVE ENDOSCOPIC BURDEN WITH ESOPHAGEAL CANCER DETECTION

C.-K. Noh[1], G.H. Lee[1], S.G. Lim[1], S.J. Shin[1], K.M. Lee[1]
[1]Ajou University School of Medicine, Gastroenterology, Suwon, South Korea

Contact E-Mail Address: cknoh23@gmail.com

Introduction: When esophageal cancer is diagnosed at an advanced stage, it requires a highly invasive treatment, and its prognosis is poor. Although the number of endoscopic examinations has been increasing globally, esophageal cancer is still difficult to diagnose at an early stage. The rapidly increasing number of endoscopic examinations performed over a short period might influence diagnostic performance. Accessing the association between calendar month and esophageal cancer detection rates might improve policy and guide institutional support.

Aims & Methods: We aimed to evaluate the association between the increased number of examinations over a certain period and esophageal cancer detection rates (EDR) among a large population in the Korean National Cancer Screening Program (KNCSP). We performed a retrospective population-based study using the KNCSP database for gastric cancer between 2015 and 2019. We included 28,032,590 Koreans aged ≥40 years. We assessed monthly EDR and performed a negative binomial regression model and least square mean evaluation to evaluate the association between the screening month and EDR.

Results: In total, 28,032,590 subjects underwent upper endoscopy, according to KNCSP. The monthly number of subjects who underwent examinations was the highest in December (n=4,819,606, 17.2%). EDR tended to decrease towards the end of the year, and EDR was the lowest in December 2015 – 2019 (0.06 – 0.08).

In the multivariable logistic model, the association of calendar month with detected cancer remained after adjusting for other confounding factors (December 2015: odds ratio, 0.58; 95% CI, 0.43 – 0.79; P < .001; 2016: odds ratio, 0.51; 95%CI, 0.38 – 0.67; P < .001). The age group adjusted the calendar month, and the predicted detection rate significantly decreased at the end of the year compared with the beginning of the year in 2015, 2016, and 2017 respectively.

Conclusion: In the KNCSP, the workload of endoscopists increased excessively, with an increasing number of examinations towards the end of the year, as demonstrated by decreased EDR during this period.

BODY COMPOSITIONAL CHANGE PREDICTS CHEMORADIOTHERAPY RESPONSE AND PROGNOSIS OF ESOPHAGEAL CANCER PATIENTS: A COHORT STUDY

H.-C. Chiang[1,2], W.-L. Chang[2,1]
[1]National Cheng Kung University Hospital, Internal Medicine, Tainan, Taiwan, [2]National Cheng Kung University, Institute of Clinical Medicine, College of Medicine, Tainan, Taiwan

Contact E-Mail Address: scion456scion@gmail.com

Introduction: Patients with esophageal cancer are prone to poor nutrition. Concurrent chemoradiation therapy (CCRT) further influence body compositions including skeletal muscle and adipose tissue which are key indicators of nutritional status.

Aims & Methods: This study aimed to evaluate whether body compositional change during CCRT could be a predictor of prognosis in esophageal cancer patients. From 2006 to 2018, esophageal cancer patients who re-

ceived CCRT as initial treatment were consecutively enrolled. We assessed body compositions, including subcutaneous fat (SCF), intramuscular fat (IMF), and skeletal muscle (SM) mass by measuring the cross-sectional area (CSA) of the fourth thoracic vertebral body on computed tomography (CT) scan.

The body compositional change was assessed by comparing baseline and post-CCRT CSA. The association of body compositions and their changes during CCRT with patient prognosis was analyzed.

Results: A total of 178 patients were enrolled with a mean baseline BMI of 22.0 (SD 3.4). Compared to baseline, a significant decrease in the mean bodyweight (BW), SCF, IMF, and SM after CCRT was noted (p<0.001). Baseline or post-CCRT BMI and body compositions were not significantly associated with patient prognosis.

Patients with SCF loss during CCRT had poorer CCRT response (OR 3.7, p<0.001), shorter time to tumor progression (8.5 *vs* 23.7months, p=0.011), and overall survival (13.7 *vs* 25.9months, p<0.001) than patients with SCF gain/stable. IMF, SM, and BW change did not correlate with CCRT response or survival.

In multivariate Cox regression analysis, SCF loss (HR 1.49, 95%CI: 1.03–2.14, p=0.033) during CCRT was an independent poor prognostic factor after adjusting baseline BMI, cancer stage, treatment modality, and CCRT response.

Conclusion: Body compositional change is more sensitive than weight in predicting CCRT response and survival of esophageal cancer patients. SCF loss during CCRT is associated with worse CCRT response and survival in esophageal cancer patients.

Disclosure: Nothing to disclose.

EARLY CLINICAL RESULTS OF SURGICAL TREATMENT OF PATIENTS WITH ESOPHAGEAL CANCER AFTER NEOADJUVANT CHEMORADIOTHERAPY WITH VINORELBINE PLUS CISPLATIN

A. Patseika[1], D. Pristupa[1], V. Malkevich[1]
[1]*N. N. Alexandrov National Cancer Centre of Belarus, Oncology Division of Gastroesophageal Abnormalities, Lesnoy, Minsk District, Belarus*

Contact E-Mail Address: poteyko_md@yahoo.com

Introduction: Esophageal cancer (EC) is the eighth most common cancers in the world. In Belarus over 90% of patients have esophageal squamous cell carcinoma (ESCC). The prognosis of patients with ESCC remains poor after surgery. Neoadjuvant chemoradiotherapy (NCRT) has been shown to potentially improve survival.

Aims & Methods: The study presents data on the treatment of 40 patients suffering from squamous cell esophageal carcinoma cT1-4aN0-3M0. By randomization, 20 patients were assigned to the study group, 20 - to the comparison group. Patients in the study group underwent two courses of chemotherapy (cisplatin and vinorelbine) and concurrent radiotherapy (single focal dose of 2 Gy, a total focal dose of 40 Gy). Eight weeks after completion of treatment, patients underwent re-staging of the tumor process. When a complete, partial regression or stabilization of the tumor process was detected, surgical intervention was performed. Patients in the comparison group underwent surgery alone.

Results: In the study group, there was a satisfactory tolerance of preoperative chemotherapy and radiation therapy. There were 60 toxic reactions. All toxic effects were stopped by conservative measures. The most common were leukopenia 45%, thrombocytopenia 40%, anemia 30%.

In the chemoradiotherapy–surgery group, radical surgical treatment was performed in 19 patients, trial surgery - in 1 patient. In 3 (15%) patients after radical surgery, due to postoperative complications, emergency surgical interventions were performed. In the surgery group, radical surgical treatment was performed in 14 patients, trial operations - in 6 patients. In 1 patient after radical surgery, due to postoperative complications, emergency surgery was performed.

Postoperative mortality in the chemoradiotherapy–surgery group was 10%, in the surgery alone group - 15%.

Conclusion: The method of neoadjuvant chemoradiotherapy for squamous cell carcinoma of the esophagus based on cisplatin and vinorelbine has satisfactory tolerance, allows to achieve complete tumor regression in 40% of patients, does not lead to an increase in the number of postoperative complications and postoperative mortality.

Contact E-Mail Address: bhumphrey@nhs.net

Introduction: Oesophageal stent placement is a nonsurgical alternative for palliation of malignant obstruction. It is now established as a major treatment for dysphagia resulting from inoperable oesophageal cancer.

Aims & Methods: A retrospective study of all patients undergone oesophageal stent insertion at a single endoscopy unit under fluoroscopy from July 2015 to Nov 2022 was undertaken.

Aim: Evidence of immediate or late complications, repeat interventions, and for survival statistics after stent insertion.

Results: 95 oesophageal stents were placed in 7 years. There were 28% Female (28/95) and 69% Males (68/95), mean age 73 (Range 47-91). The mean Indication dysphagia due to oesophageal stricture. Histology revealed: 64 adenocarcinoma, 22 squamous cell carcinoma, 5 high grade dysplasia. Location of malignancy:81 distal oesophagus, 6 proximal oesophagus, 5 Gastro-oesophageal junction and 3 Mid oesophagus. Types of stent used: 84 Fully Covered, 2 Uncovered.

No immediate complications reported apart from 2 stents moved on reintubation or extubation. The endoscopy was repeated in 43 patients.

Late complications 13% (13/95): 6 patients had Tumour overgrowth, 6 patients had Stent migration and one patient had a Food bolus. The 30 days mortality is 13%.

Conclusion: Palliative Oesophageal stent insertion in our hospital proved to be an effective treatment for patients with malignant dysphagia.

Outcomes compare favourably with published data in terms of complications and mortality.

It is a relatively safe procedure with no immediate complications and a low rate of serious acute complications.

Steps to improve post-procedure monitoring with prospective collection of data could be useful in future service development.

THE DIFFERENCE OF GASTRIC MUCOSAL INJURY BETWEEN CLOPIDOGREL USER AND PRASUGREL USER IN PATIENT RECEIVING DUAL ANTI-PLATELET THERAPY (DAPT)

Y. Shimada[1], Y. Terai[1], R. Om[1], Y. Kita[1], Y. Ikeda[1], S. Sato[1], A. Murata[1], S. Sato[1], A. Nagahara[2], T. Genda[1]
[1]Juntendo University Shizuoka Hospital, Gastroenterology and Hepatology, Izunokuni, Japan, [2]Juntendo University School of Medicine, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: yshimada@juntendo.ac.jp

Introduction: It is known that Dual Anti-Platelet Therapy (DAPT) is a risk of gastrointestinal bleeding. Recently, it has been reported that concomitant use of proton pump inhibitor (PPI) can reduce the gastrointestinal bleeding risk [(1)]. However, it is still unclear how DAPT affects the gastric mucosa. Actually, few reports have examined the relationship between DAPT and gastric mucosal injury [(2)].

Aims & Methods: The aim of this study is to reveal the difference of gastric mucosal injury between clopidogrel user and prasugrel user in patient receiving DAPT. This is a case-controlled study conducted at our department. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2015 and March 2022.

We focused on the subjects taking both low-dose aspirin and P2Y12 receptor antagonist (DAPT). We compared the severity of gastric mucosal injury, between cases using clopidogrel (group C) and prasugrel (group P) individually according to the P2Y12 receptor antagonist used. Severity of gastric mucosal injury was evaluated endoscopically according to the modified LANZA score (MLS)[(3, 4)].

Statistical analyses were performed by using Mann–Whitney *U* test. We evaluated separately for cases with concomitant use of potassium-competitive acid blocker (P-CAB) or PPI (user) and cases without concomitant use of P-CAB, PPI nor histamine H2 receptor antagonist (H2RA) (nonuser).

Results: 82 cases out of 6,863 were receiving DAPT.

In group C (45 men, 8 women; mean age 72.1 years), average MLS was 0.94±1.66 (user: n=33, score0=22, score1=4, score2=1, score3=2, score4=1, score5=3) and 1.82±1.88 (nonuser: n=17, score0=8, score1=0, score2=1, score3=4, score4=3, score5=1). In group P (21 men, 8 women; mean age 74.3 years), average MLS was 0.23±1.07 (user: n=22, score0=21, score1=0, score2=0, score3=0, score4=0, score5=1) and 0 (nonuser: n=6, score0=6, score1=0, score2=0, score3=0, score4=0, score5=0). There was a statistically significantly difference between group C and group P for both user(p=0.016) and nonuser(p=0.031). These results suggested that regardless of the concomitant use of antacids, prasugrel users had significantly less gastric mucosal injury than clopidogrel users in DAPT.

Conclusion: We found that prasugrel is more user-friendly agent than clopidogrel in terms of gastric mucosal injury in DAPT.

Introduction: Endogenous hydrogen sulfide (H_2S) and H_2S-prodrugs contribute in the maintenance of gastrointestinal (GI) integrity and redox balance. Biological effects of any H_2S-donor was predominantly mitochondrial. However, even non-targeted H_2S-releasing compounds were shown to decrease the non-steroidal anti-inflammatory drugs (NSAIDs)-induced gastrotoxicity but when applied in relatively high doses. Importantly, new derivatives of NSAIDs, such as H_2S-naproxen (ATB-346, Antibe Therapeutics Inc., Canada) or H_2S-ketoprofen (ATB-352) exerted GI safety compared to mother compounds in preclinical or clinical studies.

However, mitochondria were not considered as a direct molecular targets for H_2S-prodrugs in terms of attenuation of NSAIDs gastrotoxicity. Targeted delivery of H_2S to gastric mitochondria to improve NSAIDs-pharmacology remains overlooked.

Aims & Methods: Thus, we aimed here to evaluate for the first time if i.g. treatment with mitochondria-targeted and H_2S-releasing AP39 counteracts development of NSAIDs-induced gastric mucosal injuries. Wistar rats were treated i.g. with vehicle, AP39 (0.004-0.5 mg/kg), AP-219 (0.02 mg/kg) as structural control without H_2S-releasing ability, or AP39 + SnPP (10 mg/kg) as a heme oxygenase (HMOX) inhibitor. Next, animals were administered i.g. with acetylsalicylic acid (ASA, 125 mg/kg) as NSAIDs representative to induce translational hemorrhagic gastric lesions. NSAIDs-gastrotoxicity was assessed micro- and macroscopically.

Gastric mucosal activity of mitochondrial complexes IV and V, as well as DNA oxidation were assessed biochemically. Gastric mucosal and/or serum content of IL-1b, IL-10, TNF-a, TGF-b1/2/3, ARG1, GST-a, or phosphorylation of NF-κB, ERK, Akt, JNK, STAT3/5 were evaluated by microbeads-fluorescent xMAP®-assay. Gastric mucosal mRNA level of HMOX-1/2, COX-1/2, SOD-1/2 were determined by real-time PCR.

Results: AP39 (but not AP219) dose-dependently (0.02 and 0.1 mg/kg) diminished the development of NSAID-induced gastric lesions and DNA oxidation, restoring mitochondrial complexes activity, ARG1, GST-a protein levels and increasing anti-oxidative HMOX-1 and SOD-2 expression. AP-39 decreased proteins levels or phosphorylation of state-of-the-art gastric mucosal inflammation/oxidation-sensitive markers. Pharmacological inhibition of HMOX-1 attenuated AP39-gastroprotection.

Conclusion: We showed that mitochondria-targeted H_2S, released from very low i.g. doses of AP-39 improved gastric mucosal capacity to cope with NSAIDs-induced mitochondrial dysfunction and redox imbalance, mechanistically requiring the activity of anti-oxidative HMOX-1 and mitochondrial SOD-2.

We assume that mitochondria-targeted H_2S moieties could significantly increase the GI-safety of NSAIDs-pharmacology.

Disclosure: Nothing to disclose.

GASTRIC CANCER INCIDENCE BASED ON ENDOSCOPIC KYOTO CLASSIFICATION OF GASTRITIS: A COHORT STUDY

O. Toyoshima[1], T. Nishizawa[2,1], S. Yoshida[1], T. Matsuno[1], T. Yamada[3]
[1]*Toyoshima Endoscopy Clinic, Gastroenterology, Tokyo, Japan,* [2]*International University of Health and Welfare, Narita Hospital, Department of Gastroenterology and Hepatology, Narita, Japan,* [3]*The University of Tokyo, Gastroenterology, Tokyo, Japan*

Contact E-Mail Address: t@ichou.com

Introduction: Gastric cancer (GC) incidence based on the endoscopic Kyoto classification of gastritis has not been systematically investigated using time-to-event analysis. Therefore, we examined GC incidence in an endoscopic surveillance cohort.

Aims & Methods: This study was retrospectively conducted at the Toyoshima Endoscopy Clinic. Patients who underwent two or more esophagogastroduodenoscopies (EGDs) were enrolled. GC incidence was based on Kyoto classification scores, such as atrophy, intestinal metaplasia (IM), enlarged folds (EF), nodularity, diffuse redness (DR), and total Kyoto scores. Atrophy was classified using the Kimura-Takemoto classification.

Non-atrophy and Closed I, Closed II and III, and Open I to III were scored as atrophy scores of 0, 1, and 2, respectively. IM scores of 0, 1, and 2 were defined as the absence of IM, IM limited to the antrum, and IM extending into the corpus, respectively.

The absence and presence of EF were scored as 0 and 1, respectively. The absence and presence of nodularity were scored 0 and 1, respectively. DR scores of 0, 1, and 2 were defined as the absence of DR, mild DR and/or DR with partial regular arrangement of collecting venules (RAC), and severe DR without RAC, respectively.

The endoscopists diagnosed the Kyoto classification scores on-site during the index EGD. Hazard ratios [HRs] adjusted for age and sex were calculated using a Cox hazard model. This study was approved by the institutional review board of the Yoyogi Mental Clinic (approval no. RKK227).

Results: A total of 6718 patients were enrolled (mean age 55.0 years; men 44.2%). Of them, 3754, 2264, 700 patients were in *H. pylori* uninfected, eradicated, and currently infected status, respectively.

Patients were followed up for up to 5.02 years. The mean Kyoto classification scores for atrophy, IM, EF, nodularity, DR, and total Kyoto were 0.585, 0.284, 0.039, 0.026, 0.312, and 1.247, respectively. During the follow-up period, 37 GCs occurred in 34 patients. All GCs were superficial and within the submucosal depth. Lauren's intestinal type made up 89.1% of GCs.

The annual incidence rates of GC were 0.04%, 0.17%, and 0.73% for atrophy scores of 0, 1, and 2; 0.07%, 0.25%, and 1.10% for IM scores of 0, 1, and 2; 0.17% and 0.92% for EF scores of 0 and 1; and 0.06%, 0.55%, and 0.74% for DR scores of 0, 1, and 2, respectively. The annual incidence rate of GC was 0.19%. The GC incidence rates were 0.05, 0.07, 0.47, and 1.27%/year for the total Kyoto scores of 0-1, 2-3, 4, and 5-8, respectively.

Multivariate analysis showed that Kyoto atrophy scores 1 (HR with score 0 as reference: 3.66, 95% confidence interval [CI]: 1.06-12.61), 2 (11.60, 3.82-35.27), IM score 2 (9.92, 4.37-22.54), EF score 1 (4.03, 1.63-9.96), DR scores 1 (6.22, 2.65-14.56), and 2 (10.01, 3.73-26.86) were associated with GC incidence, whereas nodularity scores were not.

The total Kyoto scores of 4 (HR with total Kyoto scores 0-1 as reference: 6.23, 95% CI: 1.93-20.13) and 5-8 (16.45, 6.29-43.03) were more likely to develop GC, whereas the total Kyoto scores 2-3 were not, as shown in table. The HR of the total Kyoto score for developing GC per 1 rank was 1.75 (95% CI: 1.46-2.09, *P*<0.001).

Total Kyoto score	Gastric cancer patients, no.	Non-gastric cancer patients, no.	Hazard ratio	95% confidence interval	*P* value
0-1	6	4615		Reference	
2-3	2	1008	1.12	0.22-5.63	0.887
4	6	473	6.23	1.93-20.13	0.002
5-8	20	588	16.45	6.29-43.03	<0.001

Conclusion: A high total Kyoto score (≥ 4) was associated with GC incidence. The endoscopy-based diagnosis of gastritis can stratify GC risk.

INCIDENCE OF GASTRIC NEUROENDOCRINE TUMORS IN PATIENTS WITH CHRONIC ATROPHIC AUTOIMMUNE GASTRITIS

S. Massironi[1], C. Gallo[1], M. Stegagnini[1], A. Elvevi[1], P. Invernizzi[1]
[1]*IRCCS San Gerardo dei Tintori, Gastroenterology, Monza, Italy*

Contact E-Mail Address: sara.massironi@libero.it

Introduction: The incidence of type I gastric neuroendocrine neoplasms (gNEN) has increased substantially over the past 50 years, although studies evaluating the association with chronic autoimmune gastritis (AIG) in the long term have been inconsistent.

Aims & Methods: The main aim was to evaluate the incidence of type I gNENs in a cohort of AIG patients enrolled from October 2020 to May 2022, with a histologic diagnosis of CAAG; circulating levels of chromogranin A (CgA) and gastrin were assessed at enrollment. Included patients underwent regular endoscopic follow-up, to assess for gastric neoplastic lesions, enterochromaffin-like (ECL) cell hyperplasia, and the development of gNEN.

Results: We included 176 patients [142 women, median age 64 years (51-41)], diagnosed with AIG from January 1990 to June 2022. At enrollment, 116 patients (65.9%) had ECL hyperplasia, of which 29.5% had simple/linear, 30.7% had micronodular, and 5.7% had macronodular. The median follow-up was 5 years (3-7.5).

After 1032 person-years, 33 patients developed a total of 33 gNEN type I, with an incidence rate of 0.032 person-years, corresponding to an annual cumulative incidence of 3.2%. Circulating gastrin levels were significantly higher in AIG patients who developed gNENs [median 992 pg/mL IQR=449-1500 vs 688 pg/mL IQR =423-1200, p=0.03]; similarly, circulating CgA levels were significantly higher in patients with gNENs [median 227 ng/mL IQR=124-421 vs 174 ng/mL IQR= 77-265, p=0.01].

Conclusion: Type I gNENs represent a non-negligible complication in patients with AIG, and they are related to hypergastrinemia. Also elevated circulating CgA levels are associated with the presence of gNENs.

Contact E-Mail Address: nb-suzuki@juntendo.ac.jp
Introduction: Non-ampullary duodenal epithelial tumors (NADETs) have been reported to exhibit specific endoscopic and clinicopathological features based on mucin phenotypes: the gastric phenotype (GP) and the intestinal phenotype (IP)[1].
However, NADETs with the gastrointestinal mixed phenotype (MP) are often observed in clinical practice. And, the endoscopic and clinicopathological features including subclassification of NADETs with MP have not been well investigated.
Aims & Methods: The aim of this study is to clarify the endoscopic and clinicopathological features of each phenotype group; GP, IP, and MP. NADETs were collected from a database of endoscopic and surgical resections performed between February 2010 and December 2021 at our hospital. All NADETs were classified into three groups immunohistochemically: GP, IP, and MP. In addition, we subclassified MP into the gastric predominant phenotype (GPP) and the intestinal predominant phenotype (IPP) based on the predominance of gastric or intestinal phenotypic expression. The endoscopic and clinicopathological findings were compared between each phenotype group; GP, GPP, IPP, and IP.
Results: A total of 148 NADETs in 142 patients were classified into GP (n=16), GPP (n=16), IPP (n=43), and IP (n=73). As for the tumor location (first/second/third portion), GP (10/6/0) and GPP (9/5/2) were significantly more often located in the first portion compared to IPP (10/30/3) and IP (12/55/6) ($p < 0.01$). The mean tumor size of GP (14.4 mm) and GPP (19.4 mm) were significantly larger than IPP (11.0 mm) and IP (10.7 mm) ($p < 0.01$).
In Vienna classification (Category 3/4 or 5), the proportion of category 4 or 5 was significantly higher in GP (7/9) and GPP (2/14) than in IPP (35/8) and IP (71/2) ($p < 0.01$). Regarding the endoscopic findings (Table), the frequency of reddish coloration, 0-I macroscopic type, and lobular/granular pattern in white-light imaging was significantly higher in GP and GPP than in IPP and IP ($p < 0.01$). The frequency of irregular microsurface pattern, negativity of white opaque substance, positivity of oval-shaped marginal epithelium and dilatation of the intervening part in magnifying endoscopy with narrow-band imaging was significantly higher in GP and GPP than in IPP and IP ($p < 0.01$). In summary, the endoscopic and clinicopathological features of IPP were similar to those of IP, and GPP were similar to GP. The malignant potential of NADETs was presented in the descending order as follows; GPP › GP › IPP ≒ IP, and GPP demonstrated the highest malignant potential among 4 types.

	GP	GPP	IPP	IP
White-light imaging	**n=16**	**n=16**	**n=43**	**n=73**
Coloration (red/white)	13/3	11/5	17/26	21/52
Macroscopic type (0-I/0-IIa/0-IIc)	11/1/3	10/4/1	5/21/17	11/38/23
Lobular/granular pattern (%)	62.5%	62.5%	7.0%	11.0%
Magnifying endoscopy with narrow-band imaging	**n=12**	**n=14**	**n=41**	**n=70**
Microsurface pattern (regular/irregular/absent)	11/1/0	5/9/0	34/7/0	59/11/0
White opaque substance (%)	25.0%	64.3%	90.2%	90.0%
Oval-shaped marginal epithelium (%)	58.3%	64.3%	9.8%	4.3%
Dilatation of the intervening part (%)	75.0%	64.3%	22.0%	12.9%

Conclusion: NADETs exhibited specific features based on mucin phenotypes as previous reports[1], and MP (GPP and IPP) demonstrates the endoscopic and clinicopathological features of its predominant mucin phenotype (GP or IP). The accurate endoscopic diagnosis based on mucin phenotypes is necessary for appropriate treatment approach of NADETs, since the malignant potential of NADETs may differ between each mucin phenotype.

THE IMPACT OF PROTON PUMP INHIBITOR OR POTASSIUM-COMPETITIVE ACID BLOCKER FOR PREDICTING THE CURALITY OF ENDOSCOPIC RESECTION IN ULCERATIVE EARLY GASTRIC CANCER

K. Uno[1], T. Shimura[1], S. Fukusada[1], N. Sugimura[1], Y. Mizuno[1], H. Kataoka[1]
[1]Nagoya City University Graduate School of Medical Sciences, Department of Gastroenterology and Metabolism, Nagoya, Japan

Contact E-Mail Address: k_uno510@yahoo.co.jp
Introduction: Early gastric cancer (EGC) accompanied by ulcers is considered to have a higher malignant potential. Although some EGCs are indications for endoscopic submucosal dissection (ESD), their curability is determined by the risk of lymph node metastasis, which is assessed based on post-ESD pathological diagnosis including submucosal invasion depth and lymphovascular invasion.
Endoscopic diagnosis is essential to predict the curability of EGC (R0 resection) before treatment, but the relationship between ulcerative lesions and clinical outcomes remains unclear.
Aims & Methods: The aim of this study is to investigate the effect of proton pump inhibitor (PPI) or potassium-competitive acid blocker (P-CAB) on morphological changes of ulcerative EGCs and the relevance to clinical outcomes.
We retrospectively reviewed the database at Nagoya City University Hospital from January 2011 to July 2022 and identified 673 patients with gastric neoplasms who were resected with ESD. Among them, 448 EGCs were differentiated adenocarcinoma, of which 143 ulcerative EGCs were enrolled in this study.

Ulcer changes were assessed at initial and follow-up endoscopies, and ulcerative EGCs were categorized into two groups: the improved group is defined as complete or partial healing of ulcers, or unchanged scars; the unimproved group is defined as no change or exacerbation of ulcers, or exacerbation of scars.

The analysis was divided into two cohorts; those who received PPI or P-CAB before ESD (the PPI/P-CAB cohort) (n = 76) and those who did not (the non-PPI/P-CAB cohort) (n = 67).

Results: The improved and unimproved groups were 45 and 31 EGCs in the PPI/P-CAB cohort, and 37 and 30 EGCs in the non-PPI/P-CAB cohort, respectively. Baseline characteristics of the two groups were well balanced. In the PPI/P-CAB cohort, deep submucosal invasion rate, lymphovascular invasion rate and R0 resection rate were significantly higher in the unimproved group than in the improved group.

On the other hand, no significant differences were found between the improved and unimproved groups in the non-PPI/P-CAB cohort. Especially, the significance of PPI/P-CAB administration was prominent in the ulcerative EGCs with open-type atrophy, and R0 resection rate of ulcerative EGCs with PPI/P-CAB was significantly higher in the improved group than in the unimproved group (improved vs. unimproved, 90.9% vs. 48.0%, p = 0.001). When improved ulcer with PPI/P-CAB administration is the indication of endoscopic resection in the ulcerative EGC with open-type atrophy, this strategy can lead to a high sensitivity (78.9%) and accuracy (76.3%) for the curability, which was higher than conventional endoscopic diagnosis alone (p = 0.021).

Conclusion: PPI or P-CAB administration may contribute to potential selection of ulcerative EGCs enabling endoscopic curative resection.

Disclosure: Nothing to disclose.

Introduction: Gastric remnant cancers (GRC) are adenocarcinomas arising in the residual stomach after partial gastrectomy and has been considered a distinct clinical entity. GRC has been reported to account for 1-8% of all gastric adenocarcinomas. The advent of proton pump inhibitors and H. pylori eradication therapy have led to marked decline in distal gastrectomies for benign ulcer disease.

However, there is a long latency period between surgery for benign disease and development of GRC. The clinical relevance of GRC as a separate entity has been questioned since the prognosis of GRC does not seem to differ from that of primary gastric cancers overall.

In the current study we aimed to characterize patients with GRC and their prognosis in a large Western population-based cohort.

Aims & Methods: Patients with gastric adenocarcinoma in Central Norway between 2001 and 2016 (n=1217) were identified from combined searches in the Norwegian Cancer Registry (NCR) and Norwegian Patient Registry (NPR) with subsequent manual assessment of all patient records. GRCs were defined as gastric adenocarcinomas in patients previously operated with a distal gastrectomy for either benign or malignant disease (n=78). GRC patients were compared to non-GRC overall (n=1139) as well as to patients with proximal non-GRC (n=586).

Patient, tumour and treatment characteristics, including indication for previous distal gastrectomy and reconstruction method, TNM stage, Lauren histological type and treatment were recorded. Minimum follow-up time was 6 years and 7 months. Survival was analysed by the Kaplan-Meier method. The Cox proportional hazard method was used in a multivariable analysis to identify factors independently associated with survival.

Results: The proportion of GRC was 6.4% for the entire cohort (78 of 1217 patients). The indication for primary distal gastrectomy was benign disease in 76 (97.4%) patients and median time to GRC was 37.6 (range 15.7-68.0) years. The annual number of GRC (p=0.002), number of non-GRC (p=0.032) and GRC/non-GRC ratio (p=0.003) all declined during the study period. GRC patients were older at diagnosis (78.7 years) compared to non-GRC (74.9 years) and proximal non-GRC (72.7 years) patients. GRC patient were more frequently males (83.3%), compared to non-GRC (62.9%) and proximal non-GRC (71.6%) patients. A higher proportion of GRC (23.1%) were diagnosed in stages 0+I compared to non-GRC (12.8%) and proximal non-GRC (10.9%). Lauren histological classification did not differ significantly between groups. R0/R1 resection was performed in 41.6%, 41.7% and 39.7% of GRC, non-GRC and proximal non-GRC patients, respectively. The overall survival of GRC patients did not differ from non-GRC and proximal non-GRC, with median survival of 10.4 (9.3-11.5) months, 7.4 (5.1-9.9) months and 10.3 (8.6-12.1) months, and 5-year survival of 23.1%, 18.5% and 24.9%, respectively.

In a multivariable Cox analysis, age (HR 1.01, 95%CI 1.00-1.02, p<0.001), Lauren diffuse histology (HR 1.25 95%CI 1.07-1.45, p=0.006), TNM stage (HR 1.45, 95%CI 1.40-1.50, p<0.001) and neoadjuvant chemotherapy (HR 0.68, 95%CI 0.54-0.85, p=0.002) were independently associated with mortality, whereas sex, proximal tumour location and GRC were not.

Conclusion: GRCs declined during the study period, but the latency between distal gastrectomy and GRC diagnosis was long. GRC patients were more often male and older than other gastric cancer patients, but GRC *per se* was not independently associated with survival after adjusting for TNM stage and tumour location.

Disclosure: Nothing to disclose.

THE USEFULNESS OF TWO-STAGE ENDOSCOPIC RESECTION (TSER) FOR A HUGE PROTRUDING TUMOR IN THE DUODENAL BULB

N. Takeuchi[1], K. Ohata[1], I. Toshifumi[1], S. Banjoya[1], T. Kimura[1], S. Nagae[1], K. Furuta[1], Y. Ito[1], H. Yamazaki[1], S. Takayanagi[1], Y. Kimoto[1], Y. Kano[1], K. Ono[1], T. Sakuno[1], Y. Minato[1]
[1]NTT Medical Center Tokyo, Department of Gastrointestinal Endoscopy, Shinagawa-ku, Japan

Introduction: In recent years, endoscopic resection of superficial non-ampullary duodenal epithelial tumors (SNADETs), which are considered difficult, has become more widespread due to improvements in techniques and devices. However, large lesions are still highly challenging to treat, and surgical resection may be chosen. Especially endoscopic treatment of protruding lesions that occupy the lumen of the duodenum, is extremely difficult due to the lack of field of view and space for manipulation.

On the other hand, large lesions are more likely to be cancerous lesions, and pathological evaluation of R0 resection or not is important. For accurate pathological evaluation, it is necessary to resect the base en bloc. Therefore, we devised two-stage endoscopic resection (TSER)[1] and evaluate its outcomes.

Aims & Methods: From July 2021 to January 2023, TSER was performed in all 4 cases of type 0-I SNADETs that occupied the lumen of the bulb and could not be observed and manipulated space experienced at our

hospital. In the first stage, the bulges were divided by piecemeal polypectomy, and their volume was reduced. It is important that piecemeal polypectomy is performed without damaging the base and surrounding mucosa. Immediately after the piecemeal polypectomy, it was difficult to accurately resect the base en bloc due to bleeding and edema caused by the polypectomy.

One month later, the bases became flat lesions with a clear demarcation line. Hence, en bloc resected by endoscopic submucosal dissection (ESD) was performed safely one month later.

Results: 4 patients were included. Male: female=3:1, mean age=76.3 (70-82) years. 2 patients were on antithrombotic drugs and were off them during the perioperative period. One patient was on warfarin and was heparinized.

All lesions were at the bulb, anterior/posterior/lesser curvature/greater curvature=1/1/1/1, 0-IIa: 0-IIa+Is=2: 2 at ESD, and the length of the resected specimen was 42.5(25-60)mm. All post-ESD ulcer bottoms were covered with polyglycolic acid sheets and fibrin glue.

Pathological findings; first/second stage = adenoma 1: adenocarcinoma in situ3/ adenocarcinoma in situ 4, second stage lesion length diameter 27.3(9-48)mm, no lymphovascular invasion, and R0 resection.

The histological type was tub1:tub1>pap=1:3, and the mucus type was gastric: mixed (predominantly intestinal) = 3:1. One post procedural bleeding occurred.

Conclusion: TSER can be safely performed for giant protruding tumors at the bulb, with accurate pathologic evaluation and curative results. TSER has the potential to be one of the treatment strategies for ESD of protruding tumors in other organs.

Introduction: Recent advances in endoscopic imaging have improved the diagnostic accuracy for superficial non- ampullary duodenal epithelial tumors (SNADETs). Endoscopic resection is the treatment of choice for these lesions and endoscopic mucosal resection (EMR) is the commonly used technique. Endoscopic resection with the use of a specific distal attachment (cap-assisted EMR (CEMR)) has been reported as a safe and effective method for SNADETs.[1]

However, there is limited data on the technical aspects of the same. Duodenal resections have a high risk of delayed bleeding and perforation probably due to direct exposure of ulcer to biliary and pancreatic juices.

Hence, appropriate closure is absolutely essential. We have previously reported safety of closure of duodenal endoscopic resections using over-the-scope and conventional clips.[2] We now report on the safety and efficacy of using only hemoclips for defect closure of CEMR of SNADETs.

Aims & Methods: This prospective study aimed to evaluate the safety and efficacy of using only hemoclips for closure of SNADETs resected by CEMR. 21 patients from December, 2022 to March, 2023 who underwent the procedure at our center for lesions <10mm in size were included in the study. The pimary outcome was post procedural adverse events that included the rate of delayed bleeding and perforation, and ulcer dehiscence.

The secondary outcomes were en bloc and R0 resection rates, complete closure rate, number of clips used, total procedure time, and duration of hospital stay. Descriptive statistics were used to summarize the outcomes.

Results: 16 males and 5 females with median age of 59(38-75) years underwent CEMR for SNADETs and closure with hemoclips only. Paris classification morphology of 67.7% lesions was 0-IIa and 33.3% lesions was 0-IIc. All lesions of median size 4(2-6) mm were successfully resected en bloc. The median specimen size was 14(12-25) mm and the median number of hemoclips used for complete closure were 7(5-11). The mean resection and closure times were 5.7±1.8 and 9.3±3.9 minutes respectively. The mean total procedure time was 14.9±4.9 minutes. Complete closure rate was 100% with no dehiscence seen on check endoscopy (done one day post index procedure).

Pathology revealed 42.9% of the lesions having low grade dysplasia and 57.1% having high grade dysplasia with R0 resection rate being 100%. There was no delayed bleeding or perforation. The mean duration of post procedure hospitalization was 2.2±0.9 days.

En bloc resection rate, n(%)		21(100)
R0 resection rate, n(%)		21(100)
Specimen size, median(range), mm		14(12-25)
Pathological findings, n(%)	Low grade dysplasia High grade dysplasia	9(42.9) 12(57.1)
Total Procedure Time, mean ± SD(range), minutes		14.9±4.9(8-32)
Complete closure rate, n(%)		21(100)
Number of hemoclips used, median(range)		7(5-11)
Adverse events, n%	Delayed perforation Delayed bleeding Ulcer dehiscence	0(0) 0(0) 0(0)
Post procedure hospitalization, mean ± SD(range), days		2.2±0.9(1-4)

Table. Outcomes of closure of CEMR for SNADETs with hemoclips only.

Conclusion: Our single center study is the first to demonstrate an excellent safety profile for the use of only hemoclips in closing post CEMR defects of SNADETs. It is easy to perform, requires no additional accessories, and reduces procedure time and cost compared to other available methods of closure.

Furthermore, in lesions under 10mm, CEMR was effective at en-bloc resection with favorable procedure time and duration of post procedural hospital stay. Larger scale studies may be warranted to confirm this method of resection for SNADETs and safety of closure technique.

Introduction: Duodenal cancer is the 2nd cause of mortality among Familial Adenomatous Polyposis (FAP) patients, and surveillance and treatment of duodenal lesions is recommended. Uncertainty persists regarding the risk of gastric cancer in this population.

Aims & Methods: This study aims to ascertain the frequency of gastroduodenal alterations in FAP patients. We conducted a retrospective single-centre study in FAP patients under surveillance (n=79), with analysis of endoscopic findings, respective treatment and histology, in esophagogastroduodenoscopy (n=64).

Results: The included patients, most of which presenting a classic phenotype (n=44; 69%), had a mean age of 46.6 years (standard-deviation 1.8), equal distribution between sexes, and a median follow-up time of 8.5 years (interquartile range 6). Thirty patients (47%) presented duodenal lesions (of which 14 had Spigelman stage III-IV), with endoscopic treatment performed in 7 patients (13 lesions).

Of the 51 patients (80%) with endoscopic description of the papilla, 20 presented adenoma (16 with low grade dysplasia), having 4 of them been proposed to endoscopic or surgical treatment (2 ampulectomy, 1 duodenopancreatectomy, 1 refused treatment).

Thirty two patients (50%) presented fundic gland polyps (10 with diffuse polyposis); 4 polyps from 3 patients were endoscopically removed given their size or presence of dysplasia.

Eight patients (13%) had gastric adenomas with dysplasia (a total of 36 lesions), with 5 patients already treated. Two patients (3%) developed gastric adenocarcinoma (1 underwent total gastrectomy and 1 was treated endoscopically).

Conclusion: Our series presents a prevalence of duodenal lesions in line with that reported in the literature, and seems to show an increased risk of gastric cancer, underlining the need for high-quality endoscopic surveillance in FAP patients.

Introduction: Type I gastric neuroendocrine tumors (T1-GNETs) are caused by auto-immune gastritis and often occur in multiple lesions. Although endoscopic resection, such as endoscopic submucosal dissection (ESD), is often used for treatment of a small number of T1-GNET, antrectomy is also performed for multiple lesions. However, to date, the efficacy of antrectomy remains unclear.

Aims & Methods: Type I gastric neuroendocrine tumors (T1-GNETs) are caused by auto-immune gastritis and often occur in multiple lesions. Although endoscopic resection, such as endoscopic submucosal dissection (ESD), is often used for treatment of a small number of T1-GNET, antrectomy is also performed for multiple lesions. However, to date, the efficacy of antrectomy remains unclear.

	N=7
Age, median (range), years	54 (44-67)
Number of tumor (preoperative), n (%)	
< 10	2 (28.6)

> 20	4 (57.1)
Size of largest tumor (preoperative), median (range), mm	6 (4-8)
Number of tumor (resected specimen), n (%)	
< 10	4 (57.1)
10-20	2 (28.6)
> 20	1 (14.3)
Size of largest tumor (resected specimen), median (range), mm	5 (1.5-8)
Serum gastrin levels, median (range), pg/ml	
Pre Antrectomy	3900 (2400-8000)
Post Antrectomy	73 (26-120)
Post Antrectomy status of residual tumors, n (%)	
Stable	0 (0.0)
Progression	0 (0.0)
Regression	1 (14.3)
Disappearance	6 (85.7)
Period between Antrectomy and tumor disappearance, median (range), months	
After Antrectomy	20 (5-49)
Follow-up period after Antrectomy, median (range), month	Follow-up period after Antrectomy, median (range), month

Results: The median age of all patients was 54 years (range, 44–67 years). The ratio of male to female patients was 2:5. The number of tumors preoperatively observed in endoscopy was <10 in two patients, 10–20 in one, and >20 in four. The median size of largest tumor was 6 mm (range, 4–8 mm).

Antrectomy was performed in three patients as initial treatment and in four as additional treatment after ESD. The number of tumors pathologically evaluated in resected specimens was <10 in four patients, 10–20 in two, and >20 in one. All tumors were limited to the submucosa. The medi-

an diameter of the largest tumor was 5 mm (range, 1.5–8 mm). The median gastrin levels significantly decreased from 3900 pg/mL (range, 2400–8000 pg/mL) to 73 pg/mL (range, 26–120 pg/mL) after antrectomy.

Regarding postoperative assessment, tumor regression was observed in one patient and disappearance was observed in six at the follow-up endoscopy. The median period between antrectomy and tumor disappearance was 20 months (range, 5–49 months). No recurrence or cause-specific death occurred in all patients, with a median follow-up period of 48 months (range, 24–60 months).

Conclusion: Based on our findings, antrectomy does not only control local disease but also may lead to prevention of recurrence and regression of tumor persistence. Antrectomy was an effective treatment that could avoid total gastrectomy in patients with multiple T1-GNETs.

CLINICOPATHOLOGICAL CHARACTERISTICS OF GASTRIC ADENOCARCINOMA WITH ENTEROBLASTIC DIFFERENTIATION AND GASTRIC ADENOCARCINOMA WITH ENTEROBLASTIC MARKER EXPRESSION

D. Abe[1,2], Y. Akazawa[2], N. Yatagai[2], T. Hayashi[1], H. Ueyama[2], S. Mine[3], T. Fukunaga[3], A. Nagahara[2], T. Yao[1], T. Saito[1,4]

Introduction: Gastric adenocarcinoma (GA) with enteroblastic differentiation (GAED) is a special type of gastric carcinoma with aggressive biological behavior, which is histologically characterized by a glycogen-rich clear cytoplasm and fetal gut-like structures. GAED shows the expression of at least one of the following enteroblastic markers (EMs): glypican-3 (GPC3), spalt-like transcription factor 4 (SALL4), and α-fetoprotein (AFP) (Murakami T et al. Gastric Cancer. 2016;19(2):498-507.)[1]. Despite the absence of clear cytoplasm, we often encounter GA with EMs expression (GA with EM); however, the clinicopathological characteristics of GA with EM remain unclear.

Regarding this point, we reported that the status of clear cell differentiation within tumors do not affect any clinicopathological or molecular pathological differences in colorectal carcinoma with the expression of enteroblastic markers which is a colorectal counterpart of GEAD (Yamashiro Y et al. Histopathology. 2020;77(3):492-502.)[2].

In addition, CAED has similar clinicopathological and molecular pathological characteristics to GAED, including aggressive behavior, high rates of lymphovascular invasion and liver metastasis and high frequency of *TP53* mutation[2].

Therefore, we speculated that the same phenomenon could also be observed in GA.

Aims & Methods: A total of 688 GA samples on tissue microarray were examined for immunohistochemical (IHC) expression of three EMs (AFP, GPC3, and SALL4), and the correlations between EM expression and clinicopathological factors were analyzed. According to the status of the clear cytoplasm of tumor cells, GA showing IHC expression of EMs was classified as either GAED or GA with EM.

Results: Histological and IHC analysis revealed 94 GAEDs (13.7%), 58 GAs with EM (8.4%), and 536 conventional GAs (CGAs). Both GAED and GA with EM showed frequent lymphovascular invasion, lymph node metastasis, and liver metastasis compared to CGA. However, venous invasion was more frequent in GAED, and vice versa in GA with EM. The five-year overall survival rates for GAED, GA with EM, and CGA were 46.6%, 47.9%, and 58.2%, respectively. GAED and GA with EM showed similar trends in overall survival rates (p = 0.78). GAED had a poorer prognosis than CGA with statistical significance (p = 0.035); however, not for GA with EM (P = 0.157). Furthermore, GA with EM-positive group (GAED and GA with EM) showed a worse overall survival rate than CGA (p = 0.018).

	GAED n=94 (13.7%)	GA with EM n=58 (8.4%)	p value
Age (years) (mean±SD)	72.5±10.6	70.2±9.9	0.189
Sex (male/female)	76/18	48/10	0.832
Tumor location (U/M/L)	34/21/39	28/17/13	0.056
Tumor size (mm) (mean±SD)	60.9±32.3	65.3±40.6	0.483
Lymphatic invasion (+) n (%)	57 (60.6%)	45 (77.6%)	<0.05
Venous invasion (+) n (%)	63 (67.0%)	29 (50.0%)	<0.05
Lymph node metastasis (+) n (%)	72 (76.6%)	36 (62.1%)	0.067
Liver metastasis (+) n (%)	39 (41.5%)	9 (15.5%)	<0.01
Growth patterns (Solid/Non-solid)	29 (30.9%)/65 (69.1%)	8 (13.8%)/50 (86.2%)	<0.05

Conclusion: Interestingly, the tumor size tended to be smaller in the EM-positive group than that for CGA group, however, clinicopathologically EM-positive group was more aggressive than CGA group such as higher rate for venous invasion and liver metastasis. These findings suggest that GAED and GA with EM can be clinically classified together as aggressive tumors but can pathologically seem to be slightly different.

Introduction: Atrophic gastritis(AG) is mainly caused by *Helicobacter pylori*(Hp)infection or autoimmunity. Hp-related AG affects both corpus and antral mucosa resulting in multifocal AG(MF-AG), whereas AG driven by autoimmunity is corpus-restricted(CR-AG).

Corpus mucosa gastric atrophy carries an increased risk of gastric dysplasia(GD) and cancer(GC); the neoplastic risk in CR-AG is considered lower, but still debated. GD-GC lesions in AG may arise in the antrum, *incisura angularis* or, less frequently, the corpus. Data on characteristics and potential differences of GD-GC lesions between MF-AG and CR-AG are lacking.

Aims & Methods: This study aimed to assess clinical, endoscopic, and histological characteristics of GD-GC in MF-AG and CR-AG pts.

A multicenter,cross-sectional study was conducted across 14 Italian GI centers. Data on GD-GC in patients with MF-AG or CR-AG(2001-2023) were retrospectively collected based on clinical, endoscopic, and histological charts: site, dimension,endoscopic,and histologic features of GD-GC, perilesional gastric antral and corpus mucosa (updated Sydney system),and patients' clinical data (age,sex,outcome after GD-GC diagnosis, Hp infection, parietal cell antibodies(PCA), family history for GC).

Inclusion criteria were: patients with MF-AG or CR-AG and GD or GC diagnosis, aged ≥18 years, availability of endoscopic and histological description of GD-GC and perilesional gastric mucosa, completeness of clinical data.Data were stratified for MF-AG/CR-AG and the GD-GC, perilesional mucosa, and clinical characteristics were compared.

Results: A total of 84 pts[(F46[54.8%]; age 70(33-90yrs)] were included. MF-AG and CR-AG were observed in 45(53.6%) and 39(46.4%) pts, respectively. High-grade (HG)-GD, low-grade(LG)-GD, and non-cardia GC were diagnosed in 6(7.1%), 31(36.9%), and 47(56.0%)pts.

Age, GC family history, smoking habits, and PCA positivity were similar between MF-AG and CR-AG. Women(69.2% vs 42.2%,p=0.01) and pernicious anemia(29% vs 9.1%,p=0.04) were more frequent in CR-AG than in MF-AG. The proportion of GD and GC in MF-AG and CR-AG pts was similar: HG-GD was present in 4(8.9%) vs 2(5.1%),LG-GD in 17(37.8%) vs 14(35.9%),GC in 24(53.5%) vs 23(59.0%)pts(p>0.05).

Compared to MF-AG,in CR-AG pts GD-GC were more frequently polypoid lesions (51.6% vs 27.3%,p=0.048) and more frequent in the corpus (55.3% vs 28.6%,p=0.02), but also occurred in the antrum(34.2%) and *incisura*(10.5%).The intestinal-type GC was the most prevalent and was more frequent in MF-AG than in CR-AG (87%vs60.9%,p>0.046), while diffuse GC was 2 times more frequent in CR-AG than in MF-AG, albeit not reaching statistical significance (26.1% vs 13%, p=0.27).

Concerning GC differentiation grade and staging, no significant differences were observed between MF-AG and CR-AG.Endoscopic treatment of GD-GC was similar in both groups. CR-AG patients underwent surgery more frequently than MF-AG(48.6% vs 23.1%,p=0.0207), but outcome was similar with 90.7% MF-AG and 92.1% CR-AG pts being alive.

Histopathological features of corpus mucosa (acute-chronic inflammation, severity of atrophy, pseudopyloric and intestinal metaplasia) were similar between MF-AG and CR-AG (p>0.05). The histological–evidence of Hp in the antrum and corpus was low in both groups (2.3% vs 2.9%, p=0.87).

Conclusion: Non-cardia GC and GD may occur in both, MF-AG and CR-AG, displaying differences in topography and endoscopic presentation, but similarities in perilesional gastric corpus mucosa, differentiation, staging and outcome.

Endo-histological surveillance should be considered in pts with gastric corpus atrophy, irrespective of its etiology and extension.

GASTROINTESTINAL AUTOIMMUNE DISEASES IN PATIENTS WITH COMMON VARIABLE IMMUNODEFICIENCY: A COHORT STUDY

G. Marasco[1], F. Conti[1], C. Cremon[2], P. Montemitro[1], S. Ferrari[2], M.R. Barbaro[2], A. Pession[1], V. Stanghellini[1], G. Barbara[1]

[1]University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy, [2]IRCCS Azienda Ospedaliero Universitaria di Bologna, Bologna, Italy

Contact E-Mail Address: giovannimarasco89@gmail.com

Introduction: Common variable immunodeficiency (CVID) is the most prevalent primary immune deficiency. Two-thirds of CVID patients present concomitant autoimmune disorders, including gastrointestinal autoimmune disease, other than being at risk for gastric cancer.

Aims & Methods: We aimed to assess the prevalence of autoimmune gastrointestinal manifestation in patients with CVID and to evaluate the diagnostic yield of EGDS for the screening of gastric pre-neoplastic lesions in

a prospective cohort of patients with CVID. From June 2020 to June 2022, we prospectively enrolled patients with CVID diagnoses from a tertiary referral center. At enrollment, patients underwent a gastroenterological screening consisting of clinical evaluation and laboratory tests for the screening of autoimmune gastrointestinal disease.

Moreover, all patients were proposed to undergo an esophagogastroduodenoscopy (EGD) regardless of the presence of GI symptoms to rule out pre-neoplastic gastric lesions and upper gastrointestinal disease in the presence of clinical suspicion. Patients with lower GI symptoms were proposed for colonoscopy.

Results: We included 94 patients with CVID, of whom 58 (61.7%) were females, with a mean age of 44.3 years old [standard deviation (SD) 16.3]. Overall, 12 patients (12.8%) were diagnosed with one or more gastrointestinal autoimmune diseases. Eight patients (8.5%) had ongoing therapy with intravenous immunoglobulin, while 24 (25.5%) with subcutaneous immunoglobulin. Four patients (4.3%) had a previous celiac disease diagnosis, with a negative serology at screening, and only 1 (1.1%) patient had evidence of villous atrophy and duodenal inflammation at the time of EGD. Three (3.2%) patients were diagnosed with autoimmune atrophic gastritis with negative serology and evidence at biopsies taken during EGD of atrophic gastritis. One patient (1.1%) was diagnosed with ulcerative colitis, one patient (1.1%) with Crohn's disease, and 5 patients (5.3%) with autoimmune hepatitis. Sixteen (16, 17%) patients reported inhalant allergy, 5 (5.3%) reported food allergy, and 26 (27.7%) reported drug-related allergy. Eleven (11.7) patients reported previous Helicobacter pylori (HP) infection, while only 1 (1.1%) patient was diagnosed with an ongoing HP infection. Fifty-eight patients underwent EGD, with endoscopic evidence of esophagitis in 8 patients (13.8%), gastritis in 45 (77.6%), and duodenal atrophy/inflammation in 23 (39.7%), of whom 41.4% had histological evidence of duodenal lymphocytosis.

No patient was diagnosed with gastric cancer. Twenty-three patients underwent colonoscopy according to clinical indication, which showed at biopsy sampling ileal nodular follicular hyperplasia in 2 patients (8.7%), microscopic (lymphocytic) colitis in 2 patients (8.7%), ulcerative colitis in 1 (4.3%) and Crohn's disease in 1 (4.3%).

Conclusion: Celiac disease, atrophic gastritis, and autoimmune hepatitis were the most common gastrointestinal autoimmune overlaps of patients with CVID. Autoimmune gastrointestinal diseases in patients with CVID may pose a particular diagnostic challenge since autoantibodies are often absent. Five percent of CVID patients screened with EGD was found with a gastric pre-neoplastic lesion.

Further data are needed to define the optimal timing of endoscopic follow-up of these patients for the screening of pre-neoplastic and neoplastic lesions.

ACCURACY AND FEASIBILITY OF A NOVEL, SIMPLE SCORING SYSTEM FOR ENDOSCOPIC DIAGNOSIS OF SUPERFICIAL DUODENAL TUMORS

S. Nagae[1], K. Ohata[1], D. Parekh[1], R. Sawada[1], T. Iida[1], S. Banjoya[1], T. Kimura[1], K. Furuta[1], Y. Ito[1], H. Yamazaki[1], N. Takeuchi[1], S. Takayanagi[1], Y. Kimoto[1], Y. Kano[1], T. Sakuno[1], K. Ono[1], Y. Minato[1]

[1]NTT Medical Center Tokyo, Tokyo, Japan

Contact E-Mail Address: shinyanagae1993@gmail.com

Introduction: Recent advances in high definition endoscopy have increased the diagnostic accuracy for superficial non- ampullary duodenal epithelial tumors (SNADETs). Appropriate endoscopic categorization of these tumors as low grade adenoma (LGA)/high grade adenoma (HGA)/adenocarcinoma (AC) is of extreme importance to plan appropriate management. We report the accuracy and feasibility of a novel 'Simple Scoring System' (SSS) for SNADETs to differentiate LGA from HGA/AC.

Aims & Methods: The aim of this prospective study was to evaluate the accuracy of SSS for diagnosis of SNADETs and to assess the feasibility of its understanding and usage among beginner and expert gastroenterologists.

SSS includes four sections which are evaluated and scored: 1. Tumor diameter (10-20mm: +1, >20mm: +2); 2. Color on white light imaging (redness: +1); the presence/absence of irregular surface pattern by magnifying endoscopy using narrow band imaging (ME-NBI) (Present: +1); 4. The presence/absence of irregular vascular pattern on ME- NBI (Present: +1).

The score is on a 5-point scale. A score of 3 or more is diagnosed as HGA/AC.

Study 1: 319 SNADETs were preoperatively evaluated with SSS from June 2019 to February 2022 and were compared with postoperative pathological results. Diagnostic accuracy according to histological type (gastric, intestinal, or mixed gastrointestinal) was also evaluated.

Study 2: Diagnostic accuracy of 20 lesions (10 LGA and 10 HGA/AC lesions) selected randomly were compared before and after a lecture on SSS for 26 expert and beginner gastroenterologists in 7 hospitals. Experts were defined as those with minimum 5 years of endoscopic experience and 3 years of experience with magnifying endoscopy. A total of 4 images of each lesion (white light imaging; indigo carmine; ME-NBI distant view; ME-NBI near view) were presented for evaluation. T test was used to analyze the pre and post lecture outcomes.

Results: Study 1: The overall diagnostic accuracy was 258/319 (80.8%), sensitivity 80.7%, and specificity 81.2%. Diagnostic accuracy for each tissue type was 83.3% for gastric type, 80.3% for intestinal type, and 100% for mixed type.

Study 2: The mean diagnostic accuracy before and after the lecture changed from 71% to 79% overall, 70% to 81% for HGA/AC, 72% to 78% for LGA. Diagnostic accuracy of both experts (13) and beginners (13) improved significantly (p value expert: <0.01, beginner: <0.01) after the lecture.

	Type of legion	Diagnostic accuracy n (%)	Sensitivity (%)	Specificity (%)
Study 1 n=319	Gastric n=12	10 (83.3)	80.7	81.2
	Intestinal n=300	241 (80.3)		
	Mixed n=7	7 (100)		

	Physician experience	Pre-lecture accuracy n (%)	Post-lecture accuracy n (%)	P value
Study 2 n=20	Beginner (13)	13.2 (66)	15.6 (78)	P<0.01
	Expert (13)	15 (75)	16.2 (81)	P<0.01

Conclusion: SSS can be understood and used easily. It is an accurate method to diagnose SNADETs endoscopically.

Disclosure: Nothing to disclose.

Introduction: Gastric dysplasia in the absence of an endoscopically defined lesion is rare, usually either a false positive diagnosis or a previously unidentified precancerous lesion during esophagogastroduodenoscopy (EGD).

Aims & Methods: The aim of this study was to evaluate factors associated with the presence of an endoscopically visible lesion during follow-up in patients with histologic diagnosis of gastric dysplasia in random biopsies. Retrospective cohort study including patients referred to our institution for gastric dysplasia detected in random biopsies during EGD (Index EGD). In our institution, endoscopic evaluation was performed with a high-definition endoscope using narrow band imaging (HD EGD-0). If no lesion was detected, endoscopic surveillance (HD EGD-FU) was conducted, depending on the originally detected dysplasia: within 6 months for high grade dysplasia (HGD), 12 months for low grade dysplasia (LGD) or indefinite for dysplasia (IFD).

Results: Regarding Index EDG, from a total sample of 96 patients, most patients had LGD (87.4%), 10 patients had IFD (10.4%) and 2 HGD (2.1%), while the location of the dysplasia was the corpus in 8 patients (8.3%), the antrum in 65 (67.7%) and both in 23 (24%).

During the HD EGD-0, 5 (5.2%) presented with an endoscopically visible lesion, while 10 lesions (10.4%) were identified during HD EGD-FU; 80% of the identified lesions were in the antrum.

Patients with *Helicobacter pylori* infection identified at Index EDG were 8 times more likely to have an endoscopically visible lesion on HD EGD-FU (OR 8.000, 95%CI 1.588-40.299, *p*=0.012). Additionally, patients with a regular alcohol consumption (≥25 grams daily) were 4 times more likely to have an endoscopically visible lesion on HD EGD-FU (OR 4.063, 95%CI 1.048-15.748, *p*=0.047). In fact, both *Helicobacter pylori* infection identified at Index EGD, and regular alcohol consumption were independent predictors of the presence of gastric lesion on HD EGD-FU in binary logistic regression (OR 9.284, 95%CI 1.724-49.979, *p*=0.009 and OR 5.025, 95%CI 1.136-22.222, *p*=0.033, respectively).

The grade of dysplasia and location of the biopsies with dysplasia were neither associated with the presence of lesions during follow-up, nor family history of gastric cancer.

Conclusion: The presence of an endoscopically visible lesion occurred in 15.6% of patients with the previous histologic diagnosis of gastric dysplasia in random biopsies and most lesions were identified in the HD EGD-FU. Both *Helicobacter pylori* infection identified at Index EGD, and regular alcohol consumption were significant predictors of the presence of gastric lesion on HD EGD-FU.

Disclosure: Nothing to disclose.

PP0171

THE INFLUENCE OF PROCEDURAL VOLUME ON THE OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASM: A NATIONWIDE POPULATION-BASED STUDY USING ADMINISTRATIVE DATA

J.Y. Park[1], M.-S. Kim[2], B.J. Kim[1], J.G. Kim[1]

[1]Chung-Ang University College of Medicine, Department of Internal Medicine, Seoul, South Korea, [2]Medical Research Collaborating Center, Biomedical Research Institution, Seoul National University Hospital, Division of Clinical Epidemiology, Seoul, South Korea

Contact E-Mail Address: jay0park@cau.ac.kr

Introduction: For gastric neoplasms, endoscopic submucosal dissection (ESD) is a well-known therapeutic option. Our study aimed to investigate the influence of procedural volume on the outcome of gastric ESD.

Aims & Methods: Patients who received ESD for gastric cancer or adenoma from November 2011 to December 2017 were identified using the Korean National Health Insurance Service database. The diagnostic and procedure codes were combined to develop operational definitions, which were validated using individual hospital medical record data.

Outcomes included bleeding, perforation, pneumonia, 30-day mortality, composite outcome comprising all these adverse outcomes, and additional resection. Hospital volume was categorized into four groups: very high-, high-, low-, very low-volume hospitals (VHVH, HVH, LVH, VLVH). The outcomes of ESD were compared in relation to hospital volume.

Results: A total of 89,780 patients underwent 95,411 procedures during the research period. There were 5,607 composite events, which included 5,098 bleeding, 601 perforation, and 712 pneumonia cases, respectively. Additional resection occurred within 180 days in 7,900 cases. There were significant differences in ESD-related adverse outcomes among the four hospital volume categories.

Multiple logistic regression revealed that VHVH, HVH, and LVH were associated with lower risk of a composite outcome, when compared to VLVH (OR, 0.627, 95% CI, 0.445-0.885, p=0.008; OR, 0.542, 95% CI, 0.406-0.722, p<0.001; OR, 0.697, 95% CI, 0.548-0.886, p=0.003). Similar tendencies were also shown for bleeding, perforation, and pneumonia, although this was not evident in additional resection.

Conclusion: The procedural volume at an institutional level was closely associated with clinical outcomes, such as bleeding, perforation, pneumonia, and a composite outcome, in patients with ESD for gastric cancer or adenoma. The outcomes of gastric ESD should be closely and systemically monitored in a nationwide level, to ensure the quality of procedures and the safety of patients.

CLINICAL CHARACTERISTICS AND PROGNOSIS FOR EARLY-ONSET GASTRIC CANCER

Y. Xing[1], H. Hosaka[1], F. Moki[2], S. Tomaru[1], Y. Itoi[1], K. Sato[1], Y. Hashimoto[1], H. Tanaka[1], S. Kuribayashi[1], Y. Takeuchi[1], T. Uraoka[1]
[1]Gunma University Graduate School of Medicine, Gastroenterology and Hepatology, Maebashi, Japan, [2]Gunma Health Foundation, Maebashi, Japan

Contact E-Mail Address: m2120005@gunma-u.ac.jp

Introduction: There is little knowledge available to date about early-onset gastric cancer (EOGC). Gastric cancer has been reported to have a poorer prognosis in younger patients, but that notion remains controversial. Several reports are available that were conducted by a small number of institutions or were investigating only patients who had undergone surgery.

Aims & Methods: The aim of this study was to investigate the characteristics and prognosis of EOGC using a population-based large database. We reviewed Gunma prefectural cancer registry data on patients with gastric adenocarcinoma diagnosed between 2008 and 2018. A total of 18,436 patients were registered, of these, 158 patients under 40 years old were enrolled as EOGC group, and 6,738 patients of middle age (40-69) were identified as non-EOGC group. We analyzed the clinical characteristics of EOGC patients and, we did survival analysis comparing with the non-EOGC group.

Results: In the proportion of female patients was significantly higher in the EOGC than that in the non-EOGC group (93/158, 59% vs. 1801/6738, 27% P<0.001), the dominant histological type was undifferentiated type (127/158, 80% vs. 2573/6738 38%, p<0.001). The rate of detection by annual medical check-up was significantly less (41 cases (26%) vs. 2623 cases (39%), p<0.001), and the rate of accidental detection during following up on other diseases was also significantly less (9 cases (6%) vs 1083 cases (16%)) in the EOGC group. The Kaplan–Meier method showed that EOGC patients did not show any difference compared to non-EOGC patients. According to clinical stage, the EOGC group had a significantly better prognosis if their stage was the localized stage with or without regional lymph node metastasis.

However, a multivariate Cox regression for overall survival showed that only sex, clinical stage and pathological classification were the influencing factors on their survival.

Conclusion: This study showed that EOGC patients tended to have undifferentiated type and advanced stage at the time of diagnosis. Although the prognosis of EOGC patients was better than non-EOGC patients, if it was detected as localized to stomach and regional lymph node metastasis stage, the age (<40) at diagnosis was not a factor to affect the overall survival.

Disclosure: Nothing to disclose.

INVESTIGATION OF FACTORS CONTRIBUTING TO TRAINEE COMPLETION RATE IN GASTRIC ESD

H. Fukui[1], O. Dohi[1], H. Mukai[1], T. Ochiai[1], M. Seya[1], K. Yamauchi[1], H. Miyazaki[1], N. Iwai[1], K. Inoue[1], N. Yoshida[1], H. Konishi[1], Y. Itoh[1]
[1]Kyoto Prefectural University of Medicine, Molecular Gastroenterology and Hepatology, Kyoto, Japan

Contact E-Mail Address: h-fukui@koto.kpu-m.ac.jp

Introduction: Gastric endoscopic submucosal dissection (ESD) has become a common treatment for early gastric cancer. Advances in endoscopic equipment and treatment strategies have made the procedure safe to perform, however often the trainee is unable to complete the procedure due to refractory resection or intraoperative bleeding. We also have several resection devices in gastric ESD, among which we often use the clutch cutter, which is a scissors-type forceps in our hospital after 2017. The clutch cutter can be used to safely perform ESD because it can maintain a distance from the muscle layer during energization. It can also be used for bleeding and prophylactic hemostasis, which we believe allows trainees to perform the treatment.

Aims & Methods: The aim of this study was to evaluate factors associated with trainee completion rates of gastric ESD.

This study was conducted as a single-center retrospective study. Eligible patients were defined as ESD for early gastric cancer performed in our hospital from April 2014 to March 2022, and treated by the trainee from the beginning. Patients whose device at the start of the incision was a clutch cutter were considered the clutch cutter group (CC group), and patients whose device was another device such as an IT knife or flash knife were considered the other group (O group), and the two groups were compared. If the procedure time exceeded one hour or if uncontrolled bleeding or perforation occurred, the surgeon was replaced by an expert.

The primary endpoint was trainee completion rate of gastric ESD. The secondary endpoints were procedure time and intraoperative perforation rate.

Results: This study was enrolled 919 cases. CC group were 488 cases and O group were 431cases. There were no differences of sex, history of antithrombotic agent, postoperative stomach, tumor location and tumor size. The median patient age was 74 years old (29-92) in the CC group and 73 years old (36-98) in the O group, which was higher in the CC group. The En block resection rate was 99.8% in the CC group and 100% in the O group. The median procedure time (IQR) was 50 minutes (7-245) minutes in the CC group and 67 minutes (10-313) minutes in the O group and was significantly shorter in the CC group. The completion rate of the trainees was 50.0% in the CC group and 32.0% in the other groups, with the CC group being significantly higher (*P* <0.001). Intraoperative perforation was 1.2 % in the CC group and 1.6 % in the O group, with no difference between the two groups. The first and second semester completion rates of long-term hospital-trained trainees were compared by initial training device. Trainees whose initial device was a clutch cutter increased the completion rate from 50.9% (29/57) to 60.4% (58/96), and those whose initial device was other increased from 25.6% (22/86) to 47.6% (100/210).

Multivariate analysis related to trainee completion rate identified that tumor location was in the lower third (OR 1.88, 95% CI 1.42-2.49, P<0.0001), stomach was not postoperative (OR 2.37, 95% CI 1.16-4.87, P=0.019), tumor diameter was less than 20 mm (OR 3.5, 95% CI 2.32-5.26, P<0.001), and a clutch cutter was used (OR 2.32, 95% CI 1.75-0.07, P<0.001).

Conclusion: ESD using a clutch cutter for lesions of 20 mm or less in the lower third of the stomach without a history of surgery was considered the best way to complete the trainee's procedure.

Contact E-Mail Address: f.marijnissen@erasmusmc.nl

Introduction: Patients with gastric intestinal metaplasia (GIM) can be stratified into non-extensive and extensive GIM. In patients with extensive GIM surveillance is recommended based on a higher risk of neoplastic progression. The updated Sydney protocol is the most widely accepted biopsy system to identify extended GIM, and includes, besides biopsies of the corpus and antrum also biopsies of the incisura angularis (IA). However, data on the added value of additional biopsies of the IA in patients with premalignant gastric lesions is scarce.

Our aim is to evaluate the yield and added value of the updated Sydney protocol in a low incidence gastric cancer region.

Aims & Methods: This prospective cohort study included patients with GIM who underwent follow-up endoscopies. Biopsies were taken according to the updated Sydney protocol.

Results: In total 177 patients with GIM were included. Median age was 62 (IQR 20) and 55.9% was male. During follow-up seven (4.0%) patients developed gastric neoplasia after a median follow-up of 37 months (IQR 38). At baseline 50 patients were classified as extensive GIM (28.2%), of which only one patient showed neoplastic progression. The other six patients that showed progression were classified as non-extensive GIM. At baseline, angular GIM was found in 97 (54.8%) patients of which six showed neoplastic progression; two patients had GIM in antrum and IA, two patients had GIM in IA and corpus, one patient had GIM in antrum, IA and corpus and in one patient there was GIM in the IA only.

Conclusion: In patients with gastric intestinal metaplasia angular GIM might be a better risk factor for neoplastic progression than the extension of GIM.

DOES ONE AI FIT ALL? PERFORMANCE OF A DEDICATED BARRETT'S CADE FOR DETECTION OF GASTRIC NEOPLASIA

H. Htet[1], K. Siggens[1], P. Bhandari[1]
[1]Portsmouth Hospitals University NHS Trust, Gastroenterology, Cosham, United Kingdom

Contact E-Mail Address: heinmyat21@gmail.com

Introduction: Developing Computer-Aided Detection (CADe) system requires a large number of videos and it is more challenging in rare condition such as gastric neoplasia. However, all neoplasia, irrespective of location, has morphological similarities. Our hypothesis is that Barrett's CADe should also be able to detect gastric neoplasia due to shared morphological similarities.

Aims & Methods: Three experts assessed prospectively collected videos to identify the best images demonstrating gastric neoplasia and similar gastric mucosa without neoplasia while using histology as a ground truth. We used a commercially available Barrett's CADe system (WISE VISION®,, NEC, Japan) to analyse these frames for neoplasia detection.

Results: Endoscopic videos were collected from 62 patients. Cases were divided into gastro-oesophageal (GOJ) and true gastric neoplasia. In GOJ group, there were 31 neoplastic (3 LGD, 2 HGD, 20 cancer) and 40 non-neoplastic while in gastric group, there were 20 neoplastic (2 LGD, 6 HGD, 12 cancer) and 19 non-neoplastic mucosae. Sensitivity and specificity for CADe for GOJ lesions were 83.87% and 82.50% while those for gastric neoplasia were 45.00% and 68.42% respectively. Further subgroup analysis was performed based on lesion morphology (polypoidal vs non-polypoidal). Table 1 showed that sensitivity of non-polypoidal GOJ lesion is 80% while that of non-polypoidal gastric lesions is 37.50%.

	GOJ		Gastric	
	Polypoidal (n=16)	Non-polypoidal (n=15)	Polypoidal (n=4)	Polypoidal (n=16)
Sensitivity	87.50	80	75	37.50

Conclusion: Our data demonstrates that Barrett's CADe can detect majority of the GOJ neoplasia and with further refinement, its performance can potentially be enhanced. Barrett's CADe is not suitable for gastric neoplasia detection and as it seems to be analysing more features than just morphology, a dedicated CADe will need to be developed for true gastric neoplasia.

Introduction: Esophageal granular cell tumors (GCTs), the second most common subepithelial tumors (SETs) of the esophagus, are potentially malignant. Currently, no definite management guidelines exist, despite endoscopic resection being a valuable treatment option.

Aims & Methods: We evaluated the clinical outcomes of different methods of endoscopic resection of esophageal GCTs.

A total of 35 patients with endoscopically resected esophageal GCTs were retrospectively enrolled between December 2008 and October 2021. Several modified endoscopic mucosal resections (EMRs) were performed for treating esophageal GCTs. Clinical and endoscopic outcomes including complete histologic resection rate, and associated postoperative complications, were evaluated.

Results: The mean age of the 35 patients with endoscopically resected esophageal GCTs was 55.8 ± 8.2; the majority were men (57.1%). Mean tumor size was 7.2 mm ± 2.6, most (80.0%) were asymptomatic and present in the distal third of the esophagus (77.1%). Endoscopic characteristics

predominantly included broad-based (85.7%) and whitish-to-yellowish color changes (97.1%). Endoscopic ultrasound (EUS) of 82.9% of the tumors revealed homogeneous hypoechoic SETs originating from the submucosa. The five endoscopic treatment methods used were: ligation-assisted (77.1%), conventional (8.7%), cap-assisted (5.7%), and underwater (5.7%) EMRs and ESD (2.9%). Mean surgery time was 6.6 minutes ± 2.1, and no procedure-associated complications were noted. The en-bloc and complete histologic resection rates were 100% and 94.3%, respectively. No local recurrences were evident during follow-up, and no significant differences in the clinical outcomes of the different methods of endoscopic resection were found.

Conclusion: Based on tumor characteristics and therapeutic outcomes, modified EMR methods can be effective and safe. However, there were no significant differences in the clinical outcomes of the different methods of endoscopic resection.

Introduction: Gastric cancer is a common malignancy worldwide. Gastric cardia cancer (GCC) is a type of gastric cancer. The Transgelin(TAGLN) is a protein that has been indicated to discriminate progression in some tumors. Tumor angiogenesis is a hallmark of cancer and is involved in the tumorigenesis of solid tumors. However, the role of TAGLN in Gastric cardia cancer and tumor angiogenesis remains unknown.

Aims & Methods: The gene expression profile of TAGLN and their corresponding clinical data were obtained from The Cancer Genome Atlas (TCGA) and Gene Expression Omnibus (GEO). The expression of TAGLN in GCC and non-cancerous tissue was detected by immunohistochemical staining. The correlation between TAGLN level and the survival rate of GCC patients was assessed. The TAGLN overexpression or knockdown model was constructed to evaluate its role in GC cell proliferation, migration, invasion, and angiogenesis. HUVECs were co-cultured with the conditioned medium of GC cells. A tubule formation experiment was done to examine the angiogenesis of endothelial cells. A series of in vivo experiments were conducted to help reveal the mechanisms of TAGLN in GCC.

Results: TAGLN was identified as a key risk gene in the TCGA dataset. TAGLN expression was higher in GCC tissues than in non-tumor tissues and was positively correlated with poor prognosis. TAGLN overexpression or knockdown could facilitate or inhibit the migration, invasion, proliferation, and angiogenesis of GC cells.

Finally, depletion of TAGLN inhibited tumor growth in a xenograft mouse model.

Conclusion: The study highlights that TAGLN can accelerate Gastric cardia cancer progression and angiogenesis and may hold promise as a potential prognosis biomarker for the diagnosis of GCC, which can be a novel therapeutic strategy against GCC.

Disclosure: Nothing to disclose.

Introduction: The protocol of the clinical trial OLGA (Operative Link for Gastritis Assessment) proposed in 2005 (M.Rugge & R. Genta, 2005) has become widely used in clinical practice as the method of unified assessment of the progression of atrophic gastritis and the risk of developing stomach cancer.

The protocol involves obtaining 5 fragments of the gastric mucosa: 2 fragments from the antrum, 2 fragments from the oxyntic part and 1 fragment from the incisura angularis. It was believed that the mucosa in this region, being in fact a transition zone between the location of the pyloric and oxyntic glands of the stomach, may be the place with the most pronounced probability of developing atrophic and dysplastic processes.

The purpose of this study was to establish the significance of histological changes in the gastric mucosa in the region of the incisura angularis to assess the degree of inflammation activity and the stage of atrophic gastritis.

Aims & Methods: 1146 patients (916 women and 230 men) with clinical manifestations of chronic gastritis aged 20 to 84 years were examined. Most patients were represented in the age group from 50 to 70 years (54.6%). Biopsy material was obtained during endoscopic examination in accordance with the OLGA protocol.

Histological assessment of the degree of inflammation activity and the stage of atrophy was carried out according to the standard OLGA protocol. Then the same samples were evaluated without taking into account histological changes in the incisura angularis.

Results: During histological examination more frequently (73.2%) was detected the mild severity of inflammation in gastric mucosa (grade II according to the OLGA system). This score practically did not change if the biopsy from the incisura angularis was not tested. Severe stages of gastric mucosa atrophy (stages III and IV according to the OLGA system) were detected in 465 patients (40.58%). If changes in the incisura angularis were not taken into account, then severe stages of atrophy (III and IV) were detected in 460 patients (40.1%).

In total, changes in the assessment of the stage of atrophy occurred in 53 patients (4.62%), and more often this was observed in patients with stages I and II of atrophy. Only in 8 patients stage IV of atrophy was changed to

III, and in 3 patients stage III was changed to stage II. Thus the stage of atrophy was changed in less than 0,5% of patients in groups with severe atrophy if the samples from the incisura angularis were excluded from the examination.

Conclusion: Evaluation of the histological changes in the gastric mucosa from the incisura angularis does not significantly affect the assessment of the grade and stage of chronic gastritis according to the OLGA system.

Introduction: Epstein-Barr virus (EBV) associated gastric cancer (GC) has been reported to be about 5-16% of all gastric cancers with good prognosis compared to EBV-negative GC.

The aim of this study was to evaluate the clinicopathological characteristics of EBV-positive GC including survival analysis in the prospective observational cohort study in a tertiary hospital in South Korea.

Aims & Methods: Total 4,586 patients who underwent EBV in situ hybridization (EBV-ISH) testing among 14,613 patients diagnosed with GC were prospectively enrolled at Seoul National University Bundang Hospital from 2003 to 2023. Data including age, sex, smoking, cancer type and stage, tumor size and location, histologic type, molecular features (p53 expression and MSI), and survival information including causes of death were collected and analyzed.

Results: EBV-positive cancer group showed significant differences compared to EBV-negative cancer group. That is, they showed higher proportion of males (p<0.001), predominant presence in the proximal stomach (p<0.001), higher proportion of undifferentiated cancer (p<0.001), and lower cancer stage (p=0.004) (Table).

Variables		Total patients (n=4,586) (%)	EBV positive (n=456) (%)	EBV negative (n=4,130) (%)	P value
Sex	Male	3028 (66)	404 (88.6)	2624 (63.5)	<0.001
	Female	1558 (34)	52 (11.4)	1503 (36.5)	
Location (n=4,579)	Cardia, Body	2076 (45.3)	367 (80.5)	1709 (41.5)	<0.001
	Antrum	2503 (54.7)	89 (19.5)	2414 (58.5)	
Histology type (n=3,799)	Differentiated	1891 (49.8)	123 (35.5)	1768 (51.2)	<0.001
	Undifferentiated	1908 (50.2)	223 (64.5)	1685 (48.8)	
TNM staging	1	2818 (61.4)	316 (69.3)	2502 (60.6)	0.001
	2	683 (14.9)	52 (11.4)	631 (15.3)	
	3 or above	1085 (23.7)	88 (19.3)	997 (24.1)	

Table.

In Cox multivariate analyses, age (HR 1.022, p<0.001), tumor size (HR 1.118, p<0.001) along with cancer stage (stage 2 HR 5.843, p<0.001; stage3 HR 15.570, p<0.001; stage4 HR 50.075, p<0.001, respectively) were significant risk factors for GC-specific mortality, while EBV positivity was inversely correlated (HR 0.537, p=0.023). In the survival analyses, EBV-positive cancer group showed statistically significant survival advantages over EBV-negative cancer group in both overall (p=0.016) and gastric cancer-specific survival (p=0.005)

Overall survival:
http://blog.naver.com/storyphoto/viewer.jsp?src=https%3A%2F%2Fblogfiles.pstatic.net%2FMjAyMzA0MjZfMzAw%2FMDAxNjgyNTEyMjEwNTU0.uOasrcyjhBVQiw4hhvxsgTRrt0tIMv9O_knOHEKCbOwg.n1DOLJ2sVhbhCpkrKHgjMxc2v0Jqt6cMOolVx1cbypkg.JPEG.jhkimkr96%2FOS.jpg

GC-specific survival:
http://blog.naver.com/storyphoto/viewer.jsp?src=https%3A%2F%2Fblogfiles.pstatic.net%2FMjAyMzA0MjZfMTU5%2FMDAxNjgyNTEyMjE0MTc0.Mdm5W1yUv__Hfufon-0KLjSeFQawUEsHDfzYC9W27pIg.pz7ZCB9wbzjZ5fT5SOufbWXow9nmdP8Ui2smGqMw7gg.JPEG.jhkimkr96%2FGCSS.jpg

Conclusion: EBV-positive GC group was associated with male sex, proximal location, poorly differentiated histology and lower cancer stage, and showed significantly better prognosis than EBV-negative gastric cancer. EBV might play a role in the gastric carcinogenesis to make less metastasis resulting in better survival.

Disclosure: Nothing to disclose.

Contact E-Mail Address: chenyuqi19950119@163.com

Introduction: Genetic background plays an important role in the occurrence and development of gastric cancer (GC). With the application of genome-wide association study (GWAS), an increasing number of tumor susceptibility genes in gastric cancer have been discovered. While little of them can be further applicated in clinical diagnosis and treatment due to the lack of in-depth analysis.

Aims & Methods: A GWAS of peripheral blood leukocytes from GC patients was performed to identify and obtain genetic background data. In combination with a clinical investigation, key SNP mutations and mutated genes were screened. Via in vitro and in vivo experiments and a combination of molecular function studies and amino acid network analysis, co-mutations were discovered and further identified as potential therapeutic targets for GC.

Results: At the genetic level, the G allele of rs104886038 in DHCR7 was a protective factor identified by the GWAS. Clinical investigation showed that patients with the rs104886038 A/G genotype, age ≥60, smoking ≥10 cigarettes/day, heavy drinking and *H. pylori* infection were independent

risk factors for GC, with odds ratios of 12.33 (95% CI, 2.10~72.54), 20.42 (95% CI, 2.46~169.83), and 11.39 (95% CI, 1.82~71.21), respectively. Then molecular function studies indicated that DHCR7 regulated cell proliferation, migration, and invasion as well as apoptosis resistance via cellular cholesterol biosynthesis pathway.

Further amino acid network analysis based on the predicted structure of DHCR7 and experimental verification indicated that rs104886035 and rs104886038 co-mutation reduced the stability of DHCR7 and induced its degradation. DHCR7 mutation suppressed the malignant behaviour of GC cells and induced apoptosis via inhibition on cell cholesterol biosynthesis.

Conclusion: In this work, we provided a comprehensive multi-dimensional analysis strategy which can be applied to in-depth exploration of GWAS data. DHCR7 and its mutation sites identified by this strategy are potential theratic targets of GC via inhibition of cholesterol biosynthesis.

Introduction: Gastric cancer (GC) is a leading cause of cancer-related deaths worldwide, ranking fourth in terms of mortality and fifth in terms of incidence, according to the 2020 GLOBOCAN report (1).

Early detection of preneoplastic conditions such as gastric atrophy and intestinal metaplasia is crucial to reduce GC mortality (2).

Moreover, its pathogenesis is a multifactorial process that is influenced by environmental and genetic factors. European guidelines (3) suggest shortening the interval of follow-up in patients with a family history. However, it is a weak recommendation with a low quality of evidence, as evidence regarding familiarity for GC and its related preneoplastic conditions is lacking.

Aims & Methods: To evaluate the risk of GC and preneoplastic conditions and lesions, including gastric atrophy, intestinal metaplasia, and dysplasia, in first-degree relatives for GC patients.

We conducted a systematic review and meta-analysis of case-control studies published on MEDLINE (PubMed and Embase) until November 2022. The primary outcome was the risk of GC in first-degree relatives for GC patients.

The secondary findings were the risk of preneoplastic conditions and dysplasia in these patients. Two independent reviewers blindly performed the systematic review and data extraction. The disagreements were resolved through discussion. Homogeneity of effects across studies quantified by I^2. Odds ratio (OR) and 95% confidence intervals (CIs) were expressed using random effects models.

Results: Of the 1642 studies initially found, 18 studies met the inclusion criteria for GC, and 6 studies were included for preneoplastic conditions. The pooled analysis included a total of 59490 patients for the risk of GC and 4463 patients for the risk of preneoplastic conditions.

The results showed a significantly increased risk of GC in first-degree relatives of GC patients (OR = 3.034; 95%CI 2.395 to 3.843; p <.001; I^2 85.66%, 95%CI 78.73 to 90.33, p<.001). The risk of gastric atrophy was also significantly increased (OR = 3.812; 95%CI 1.674 to 8.682; p <.001, I^2 78,26%, 95%CI 41.41 to 91.93; p = .003). However, the risk of intestinal metaplasia was not significant (OR = 1.207; 95%CI 0.937 to 1.555, p = .15). Furthermore, the risk of gastric dysplasia was found to be significant (OR = 5.480; 95%CI 1.054 to 28.482, p = .043, I^2 80.34%, 95%CI 48.18 to 92.55 p = .002).

Conclusion: Our meta-analysis showed that the risk of GC and preneoplastic conditions and lesions, including gastric atrophy and dysplasia, is significantly increased in first-degree relatives for GC patients, even if a significant heterogeneity between studies was found.

These findings highlighted the importance of identifying individuals at high risk to facilitate early detection and treatment of preneoplastic conditions, which could potentially reduce the burden of GC.

Contact E-Mail Address: zhulinxiancao@126.com

Introduction: Patient-derived organoids (PDOs) are a promising preclinical cancer model that has demonstrated an advantage in predicting drug susceptibility. Norcantharidin (NCTD) derived from traditional Chinese medicine has been used in the treatment of gastric cancer, but the sensitivity of different patients to NCTD has not been evaluated in human samples.

Aims & Methods: The purpose of this study was to use PDOs to predict the drug sensitivity of NCTD in gastric cancer, so as to guide clinical drug use. PDOs were established by surgical resection of gastric cancer patients. Hematoxylin-eosin staining and immunohistochemical staining were used to identify the pathological morphology and molecular characteristics of PDOs and original tumor tissues. Genome analysis of tumor tissue and PDOs was performed using whole exon sequencing. NCTD intervention PDOs were screened for sensitivity and area under the curve (AUC) and IC50 values were assessed.

Results: 10 PDOs conforming to the standard of drug sensitivity test were successfully constructed. The organoids were spherical and hollow with upper skin sac structure. The pathological and genomic features of the corresponding tumor were preserved, and the expression of related mo-

lecular markers was consistent with that of the original tissue. All PDOs could be stably passed through, frozen and resuscitated. After adding different doses of NCTD, 10 organoids showed different drug sensitivities to NCTD, among which PDO4, PDO7 and PDO10 were most sensitive to NCTD.

Conclusion: NCTD has significant anti-gastric cancer effect, but there is obvious heterogeneity in drug response. PDOs can be used as a preclinical drug screening platform to guide the development of individualized cancer treatment, and bring new hope for the research of TCM treatment of gastric cancer.

TRANSLATIONAL IMPACT OF THE FOOD-DERIVED XENO-MIRNA MIR-168 IN GASTROINTESTINAL CANCERS AND PRENOPLASTIC CONDITIONS

J. Link[1], C. Thon[1], V. Petkevicius[2], R. Steponaitiene[2], P. Malfertheiner[1], J. Kupcinskas[2], A. Link[1]

Introduction: Diet is one of the most important factors contributing to the multistep process of carcinogenesis. The functional role of exogenous xeno-microRNAs (miRNAs) in this context is poorly understood. Recently, we reported the detectability of food-derived xeno miRNAs in various foods and in the gastrointestinal and colonic mucosa.

However, little is known about the translational role of xeno-miRNA in the GI mucosa and specifically in GI diseases.

Aims & Methods: In this work, we aimed to evaluate the potential clinical relevance of the xeno-miRNA miR-168 in the gastric mucosa along the preneoplastic conditions and gastric carcinogenesis.

To this end, we performed quantitative analysis of miR-168 in different settings:

1. Samples from patients with normal mucosa (N), chronic non-atrophic (CNAG) and atrophic gastritis (CAG) and intestinal metaplasia (IM) (n=72); 2. Matched non-tumorous (NT-) and tumorous (T-) gastric cancer (GC) tissues (n=82) and 3) matched NT- and T-colorectal cancer (CRC) tissues (n=40).

Survival analysis was performed using Kaplan-Meyer analysis.

Results: MiR-168 was reproducibly detectable in the samples examined, with higher levels in stomach compared to colon tissue. In the stomach, a significantly higher level of miR-168 was observed in NT-GC compared to N, CNAG, AG/IM samples ($p<0.01$ each), but there was no difference related to H. pylori positivity or inflammation grade. Interestingly, miR-168 was higher in patients with moderate or severe AG/IM or OLGIM 3/4.

Despite a significant correlation of miR-168 expression, paired sample analysis revealed a higher level of miR-168 in NT-GC compared to T-GC, with the highest level observed in the cardia and the lowest in the gastric mucosa of the antrum.

Survival analysis showed only a small trend towards worse overall survival for patients with highest to lowest miR-168 levels, mostly during the first 3 years, but no long-term difference regardless of Lauren's classification.

MiR-168 levels in normal mucosa were not associated with overall survival.

In correlation with matched GC samples, NT-CRC showed higher miR-168 levels compared to T-CRC, although overall there was a positive correlation between matched tissues. No survival difference was observed for higher or lower miR-168 levels in CRC.

Conclusion: Food-derived xeno-miRNA are present in the gastric and colonic mucosa, with the highest levels in the stomach compared to the colon and in non-tumour compared to tumour tissues. While the potential impact of miR-168 on overall survival was weak, the higher level of miR-168 in patients with moderate and severe IM deserves further attention and further functional analyses are needed to better understand the functional role of xeno-miRNA in the GI tract.

PROGNOSTIC PROGRAMMED CELL DEATH AND GLYCOSYLATION-RELATED LONG NONCODING RNAS ASSOCIATED WITH IMMUNE INFILTRATION IN GASTRIC CANCER

Y. Ai[1], X. Huang[1], S. Chen[1]
[1]Zhongshan Hospital, Fudan University, Department of Gastroenterology and Hepatology, Shanghai, China

Contact E-Mail Address: emily961024@icloud.com

Introduction: Gastric cancer with high morbidity and mortality afflicts a significant proportion of the worldwide population. Long non-coding RNAs (lncRNAs) play an important role in the development of gastric cancer and are closely associated with programmed cell death (PCD), which can be influenced by post-translational protein modifications.

Aims & Methods: Sequencing data of lncRNAs in patients with gastric cancer were obtained from TCGA and ARCG database. Important prognostic lncRNAs were identified through LASSO algorithm and Kaplan–Meier survival curve analysis and receiver operating characteristic curve analysis were used to evaluate the prognostic power of this model. Their effects on the biological functions of gastric cancer cells were investigated by in-vitro experiments, as well as the relationship between these lncRNAs and PCD, glycosylation.

Results: WGCNA and correlation analyses identified 168 PCD and glycosylation-related lncRNAs, 36 of which were of differential expression and prognostic value by univariate Cox analysis. A 11-lncRNA signature including MIR4435-2HG, LINC02381, LINC00106, LSAMP-AS1, LINC01140, LINC01614, RPH3AL-AS1, LINC02864, LEF1-AS1, LINC00844 and DPH6-DT was established and showed good performance in both TCGA and ARCG set. Differences in immune cells, immune functions and gene mutation were also found between high-risk and low-risk groups. In vitro experiments showed that PCD and glycosylation were influenced by RPH3AL-AS1 and LINC00106 knockdown.

Conclusion: This PCD and glycosylation-related signature may be a promising biomarker for predicting clinical outcomes in patients with gastric cancer.

Contact E-Mail Address: ucchy31@yahoo.co.jp
Introduction: Early gastric cancers after *Helicobacter pylori* (*HP*) eradication (*HP* eradicated EGC), which has become mainstream in Asian, is difficult to determine by even magnifying endoscopy with narrow band imaging (ME-NBI) due to the appearance of low atypical epithelium mimicking with noncancerous epithelial structure.
We found that scattered Capillaries Pushed up by Cloudy Mucosa (CPCM), which pathologically influence blood vessels pushed up by cancerous gland ducts, appeared in *HP* eradicated EGC.
Aims & Methods: Our objective is to investigate whether CPCM detected in ME-NBI can be a supportive marker to diagnosis *HP* eradicated EGC. This study was a retrospective observational study conducted by at 2 facilities in between 2020 and 2022 under ethical approval. Of 274 lesions confirmed by biopsy after ME-NBI, 238 lesions were included, excluding *HP*-uninfected lesions and lesions with unknown infection status. *HP*-infected lesion was designated as group A (42 cancers, 30 non-cancers), and *HP* eradicated lesion as group B (103 cancers, 63 non-cancers).
Sensitivity, specificity, positive predictive value, and negative predictive value of CPCM were calculated for each group, and differences between two groups were also examined by Fisher's exact test. The presence of CPCM was defined as when there were three or more cloudy mucosa in one image captured by ME-NBI with maximum magnification.
Results: CPCM were seen in 45.8% of group A and 33.7% of group B. The group A and B for CPCM diagnostic accuracy was as follows 66.7% and 53.4% for sensitivity, 83.3% and 98.5% for specificity, was 84.8% and 98.2% for positive predictive value, and 64.1% and 56.3% for negative predictive value, respectively. The *p*-values were 0.195, 0.0126, 0.0248, and 0.4528, respectively.
Conclusion: CPCM showed a higher specificity and positive predictive value for determining post-*HP* EGC compared with *HP*-infected EGC, suggesting the potential indicator.
Disclosure: Nothing to disclose.

Introduction: Long-term outcomes of gastric subepithelial lesions have not been elucidated. To reveal the natural history, we initiated a prospective, 10-year follow-up of patients with small (≤20 mm) gastric subepithelial lesions in September 2014.
Here, we report the results of an interim analysis of a prospective observational study.
Aims & Methods: In total, 567 patients with 609 lesions were prospectively registered between September 2014 and August 2016. The location, size, morphology, and number of subepithelial lesions were recorded on a web-based case report form.
Results: The endoscopic follow-up period was 4.60 ± 1.73 years (mean ± SD), and survival data were investigated for 5.28 ± 1.68 years. This interim analysis revealed that the estimated cumulative incidence of a size increase ≥5 mm, after accounting for patients' death and resection of the tumor as competing risk events, was 4.5%.
In addition, the estimated cumulative incidence of lesion size increase ≥5 mm or resection of lesions was 7.7% at 5 years, and that of size increase ≥10 mm or resection of lesions was 4.3% at 5 years.

Conclusion: These results indicate that approximately one in 13 patients with small (≤20 mm) gastric subepithelial lesions may require resection or further investigation for increased tumor size (≥5 mm) within five years under active surveillance.

Introduction: In recent years remarkable progress has been made in the treatment of malignant tumors, including minimally invasive surgery[1], the development of chemotherapy including immune checkpoint inhibitors[2], drugs to prevent chemotherapy induced side effects[3].

As a result, the prognosis was improved, the number of patients with multiple primary malignant tumors increased. However, there is currently no evidence to support a specific treatment for multiple primary malignant tumors. Therefore, patient consent must be obtained, and options should be selected according to institution policies.

Aims & Methods: Aims: This study aimed to investigate the clinical outcomes and prognosis of patients who underwent endoscopic submucosal dissection (ESD) for early-stage gastric cancer (EGC) complicated with advanced primary malignant tumors of other organs, with 5-year absolute survival rate of less than 50 %.

Methods: This study enrolled 26 patients with advanced malignant tumors of other organs, with 5-year absolute survival rates of less than 50 %, who were selected from 3,703 patients with gastric cancer who underwent ESD at our hospital. Clinicopathological characteristics and outcomes of ESD were evaluated.

Results: Patient median age was 75.0 (50-90) years. The median tumor diameter was 20.0 (5-110) mm. Advanced malignant tumors of other organs included 5 patients with hepatocellular carcinoma, 5 with prostate cancer, 4 with esophageal cancer, 4 with colorectal cancer, 3 with lung cancer, 1 with renal cell carcinoma, 1 with breast cancer, 1 with gingival cancer, 1 with multiple myeloma, and 1 with malignant lymphoma.

The clinical stages were cStage II in 6 patients, cStage III in 2, and cStage IV in 18, all evaluated under treatment or before treatment. In terms of EGC locations, there were 6 (23 %) U region patients, 6 (23 %) M region, and 14 (54 %) L region. Macroscopic types were 0-I 2 (7 %), 0-IIa 9 (35 %), 0-IIa+I 1 (4 %), 0-IIc 13 (50 %), and 0-IIc+IIa 1 (4 %). The main histological types included 23 (88%) with differentiated type, 3 (12%) with undifferentiated type, 18 (69 %) with pT1a, 3 (12 %) with pT1b1, and 5 (19 %) with pT1b2. Rates of en bloc resection were 100 %, curative resection was 62 %, noncurative resection was 38 % (including 5 patients with pT1b2, 1 patient with UL positive, 3 patients with undifferentiated and lesion size bigger than 20 mm, and 1 patient was positive for vertical margin).

Adverse events included delayed bleeding in 1 (4%) patient, delayed perforation in 1 (4%), and postoperative pneumonitis in 1 (4%), all of which resulted in DIC and death within 30 days after ESD. The prognosis was death from advanced malignant tumors of other organs in 11 patients, death from other causes in 3 patients, and survival in 9 patients that did not suffer death due to EGC.

Conclusion: Although ESD was useful for local resection of EGC complicated with advanced malignant tumors, DIC triggered by an adverse event should be noted.

EXPLORING THE CHALLENGE OF EARLY GASTRIC CANCER DIAGNOSTIC AI SYSTEM FACE IN MULTIPLE CENTERS AND ITS POTENTIAL SOLUTIONS

Z. Dong[1], X. Tao[1], L. Wu[1], H. Yu[1]

[1]Renmin Hospital of Wuhan University, Department of Gastroenterology, Wuhan, China

Contact E-Mail Address: terriblebeauty@163.com

Introduction: Artificial intelligence (AI) showed various performance among test sets with different diversity due to sample selection bias, which can be a stumbling block for AI application. We previously tested AI named ENDOANGEL diagnosing gastric neoplasms and early gastric cancer (EGC) on single-center videos in a man-machine competition.

We aimed to retest ENDOANGEL on multi-center videos to explore challenges applying AI in multiple centers, then upgrade ENDOANGEL and explore solutions of solving the challenge.

Aims & Methods: ENDOANGEL was retested on multi-center videos retrospectively collected from 12 institutions and compared with performance in previously-reported single-center videos. We then upgraded ENDOANGEL to ENDOANGEL-2022 with more training samples and novel algorithms, and conducted competition between ENDOANGEL-2022 and endoscopists. ENDOANGEL-2022 was then tested on single-center videos and compared with performance in multi-center videos; the two AI systems were also compared with each other and endoscopists.

Results: Forty-six EGCs and 54 non-cancers were included in multi-center video cohort. On diagnosing EGCs, compared with single-center videos, ENDOANGEL showed stable sensitivity (97.83% vs. 100.00%) while sharply decreased specificity (61.11% vs. 82.54%); ENDOANGEL-2022 showed similar tendency while achieving significantly higher specificity (79.63%, p <0.01) making fewer mistakes on typical lesions than ENDOANGEL.

On detecting gastric neoplasms, both AI showed stable sensitivity while sharply decreased specificity. Nevertheless, both AI outperformed endoscopists in the two competitions.

Conclusion: Great increase of false positives is prominent challenge for applying EGC diagnostic AI in multiple centers due to high heterogeneity of negative cases. Optimizing AI by adding samples and using novel algorithms is promising to overcome this challenge.

TECHNICAL DIFFICULTY AND CLINICAL COURSES OF ENDOSCOPIC HAND SUTURING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION WITH SPECIAL REFERENCE TO THE LOCATION

O. Goto[1,2], S. Nakagome[1], T. Habu[1], Y. Ishikawa[1], E. Koizumi[1], K. Kirita[1], K. Higuchi[1], H. Noda[1], T. Onda[1], J. Omori[1], T. Akimoto[1], N. Akimoto[1], K. Iwakiri[1]

Contact E-Mail Address: o-goto@nms.ac.jp

Introduction: Endoscopic hand suturing (EHS), which enables intraluminal running suturing by using a through-the-scope type needle holder and an absorbable barbed suture, is expected to be applied to various situations. This technique is sometimes difficult to complete according to location, and if successful in suturing, dehiscence sometimes occurs afterward.

Aims & Methods: We aimed to investigate the technical difficulty and clinical courses of EHS for mucosal defect closure after gastric endoscopic submucosal dissection (ESD). We collected 74 lesions in 72 patients (15 prospectively-enrolled lesions for this analysis and 59 lesions from published data), including 49 patients (68%) having antithrombotic agents without cessation perioperatively. EHS was performed to close the mucosal defect immediately after gastric ESD, by suturing the mucosal layer continuously.

A normal dose of antisecretory agents (proton-pump inhibitor or potassium-competitive acid blocker) was administered from the operative day to at least the postoperative day (POD) 28. A scheduled second-look endoscopy (SLE) was performed on POD 3 in 64 patients and on POD 7 in 8 patients, respectively.

Technical success, closure maintenance on SLE, suturing speed (min/stitch), delayed bleeding, and severe adverse events (SAE) were evaluated. Furthermore, the difficulty and the clinical courses in EHS according to the location were assessed.

Results: EHS was performed on the upper (U)/middle (M)/lower (L) stomach in 10/32/32 lesions, and on the anterior wall (AW)/lesser curve (LC)/posterior wall (PW)/greater curve (GC) in 14/28/14/18 lesions, respectively. The mean diameter of the mucosal defects was 33 mm.

The defect was completely closed in 73 lesions (99%), and the closure was maintained on SLE in 65 lesions (88%). The mean suturing duration and stitches were 41 min and 7 stitches, respectively, which indicated the suturing speed of 5.5 min/stitch. Delayed bleeding occurred in 2 lesions (3%), and no SAE was presented.

The technical success rates were U/M/L: 90%/100%/100% (p = 0.039), and AW/LC/PW/GC: 100%/96%/100%/100% (p = 0.645), respectively. The closure maintenance rates were U/M/L: 80%/84%/94% (p = 0.371), whereas AW/LC/PW/GC: 100%/75%/93%/95% (p = 0.062). The suturing speed was not significantly different among the location.

Conclusion: This study showed that EHS was technically difficult on the upper third and the closure was inclined to dehisce on the lesser curvature side. For lesions on the upper stomach, it is desirable to perform EHS after obtaining sufficient experience. Furthermore, EHS should be provided more carefully and precisely for lesions on the lesser curvature to avoid postoperative dehiscence.

Disclosure: Nothing to disclose.

ENDOSCOPIC DETECTION OF ESOPHAGEAL SQUAMOUS CELL CARCINOMA (ESCC) USING NOVEL FLUORESCENCE PROBE TARGETING DIPEPTIDYLPEPTIDASE IV (DPP-IV)

Y. Tsuji[1,2], Y. Urano[3], M. Fujishiro[2], Y. Seto[4]

[1]Graduate School of Medicine, the University of Tokyo, Next-generation Endoscopic Computer Vision, Tokyo, Japan, [2]Graduate School of Medicine, the University of Tokyo, Department of Gastroenterology, Tokyo, Japan, [3]Graduate School of Pharmaceutical Sciences, the University of Tokyo, Laboratory of Chemistry and Biology, Tokyo, Japan, [4]Graduate School of Medicine, the University of Tokyo, Department of Gastrointestinal Surgery, Tokyo, Japan

Contact E-Mail Address: ping_01@me.com

Introduction: Recent evolution of image-enhanced endoscopy (IEE) makes it possible to detect ESCC easily. However, we sometimes encounter the cases where IEE cannot detect ESCC. Iodine staining is a gold standard, but it cannot be used for those with allergy to iodine. We developed a novel fluorescence probe (EP-HMRG). EP-HMRG emits green fluorescence immediately after being cleaved by DPP-IV, which is overexpressed in ESCC.

The advantages are its ability to be applied topically and its fast reactivity. We confirmed that EP-HMRG achieved high accuracy for ESCC (> 90%) even 5 minutes after application using biopsy samples (Sci Rep, 2016).

Aims & Methods: Our aim of the present study is to investigate the safety and feasibility of EP-HMRG through a first-in-human trial. This is a phase 1 trial to assess the safety and efficacy of EP-HMRG for ESCC patients. Those who were scheduled to undergo endoscopic resection (ER) for ESCC were enrolled in this study. After 20 mL of 50 μM EP-HMRG solution was sprayed into the esophagus, one biopsy was taken from each fluorescent and non-fluorescent area under the observation with the prototype fluorescence endoscope. The biopsy specimens were blinded and diagnosed by one board-certified pathologist; ER was performed the day after EP-HMRG spraying, and the patient was discharged 5 days after treatment.

Results: A total of 6 patients were recruited between November 2019 and February 2021. 4 of the 6 patients complained of mild dysphagia and chest pain after ER, which were attributed to ER itself. No adverse events related to EP-HMRG occurred.

Fluorescence endoscopy revealed strong fluorescent areas in the esophagus in 3 patients and weak fluorescent areas in the remaining 3 patients. Biopsy pathology results showed that no cancer was proved in any of the non-fluorescent areas. SCC was proved in 4 of the 6 specimens of the fluorescent sites. In 2 cases where the fluorescence was weak, no cancer was proved in the biopsy specimens taken from fluorescent areas. Positive predictive value, negative predictive value and accuracy were 67%, 100%, and 83%, respectively.

Conclusion: Our first-in-human study of a novel fluorescent probe for ESCC revealed safety, whereas the diagnostic accuracy reached only 83%. One possible reason was that the detectability of the prototype endoscope did not reach the level of the dedicated fluorescent imaging device. The fluorescent endoscope used in this study was still under development, and the images were dark, which may have resulted in sampling errors or failure to capture fluorescence coloration. The development of a fluorescence endoscope that is comparable to a dedicated fluorescence imaging device is an issue to be addressed in the future.

Disclosure: Nothing to disclose.

Introduction: The demand for sedation during endoscopic procedures in the gastrointestinal field has increased. However, few sedatives for endoscopy are covered by Japanese national health insurance. Remimazolam is a novel, ultrashort-acting benzodiazepine drug.

Aims & Methods: This study aimed to compare the efficacy of Remimazolam and placebo in achieving successful sedation during upper gastrointestinal endoscopy in Japanese patients. We conducted a multicenter, randomized, double-blind Phase III clinical trial, including 48 Japanese patients undergoing upper gastrointestinal endoscopy. Patients were randomized to receive either Remimazolam or placebo with a ratio of 4:1. The initial Remimazolam dose was 3mg, with additional doses of 1mg as determined in the Phase II clinical trial [1]. The primary endpoint was the successful sedation rate during gastrointestinal endoscopy, determined by the Modified Observer's Assessment of Alertness / Sedation score ≤4 before the start of endoscopy, the completion of gastrointestinal endoscopy, and two or fewer additional doses per six minutes.

Results: The Remimazolam group included 37 patients and the placebo group included 11 patients. The successful endoscopy sedation rate was significantly higher in the Remimazolam group (91.9%) compared to the placebo group (9.1%) ($p<0.01$). The median total Remimazolam dose was 4.0 (3.0-4.5) mg. The time from the end of endoscopy to arousal was 0.0 (0.0–0.0) minutes in the Remimazolam group and 0.0 (0.0–0.0) minutes in the placebo group. The time from the end of endoscopy to regaining the ability to walk was 5.0 (0.0–5.0) minutes in the Remimazolam group and 0.0 (0.0–0.0) minutes for the placebo group ($p=0.02$).

Conclusion: Remimazolam is more effective than placebo for achieving sedation during upper gastrointestinal endoscopy in Japanese patients. This study suggests that Remimazolam could be a potential option for sedation during endoscopic procedures.

COULD BEST-J ALSO BE BEST-E? VALIDATION OF A PREDICTING MODEL FOR DELAYED BLEEDING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION ON A EUROPEAN SAMPLE

V. Macedo Silva[1,2,3], A.I. Ferreira[1,2,3], T. Lima Capela[1,2,3], S. Xavier[1,2,3], P.B. Carvalho[1,2,3], J. Berkeley Cotter[1,2,3]

[1]Hospital da Senhora da Oliveira, Gastroenterology Department, Guimarães, Portugal, [2]School of Medicine, University of Minho, Life and Health Sciences Research Institute (ICVS), Braga / Guimarães, Portugal, [3]ICVS/3B's, PT Government Associate Laboratory, Braga / Guimarães, Portugal

Contact E-Mail Address: vitorbmacedo@gmail.com

Introduction: Delayed bleeding (DB) is a possible adverse event following gastric endoscopic submucosal dissection (ESD). The Bleeding after ESD Trend from Japan (BEST-J) score was created as a risk prediction model for DB following gastric ESD, but is yet to be validated in non-Asiatic populations.

Aims & Methods: We aimed to apply and validate the BEST-J score on a European sample.

We have conducted a longitudinal study of all consecutive patients undergoing gastric ESD on a European Endoscopic Unit. DB was defined as a hemorrhage with clinical symptoms and confirmed by emergency endoscopy from the time of completion of ESD to 28 days after ESD.

BEST-J score (use of vitamin K antagonists +4, direct oral anticoagulants +4, aspirin or P2Y12R antagonists +2; withdrawing antithrombotic drugs -1; chronic kidney disease +3; multiple lesions +1; lesion ≥30mm +1; lesion in lower-third of the stomach +1) was calculated in each patient and confronted with the outcome (DB).

Results: Final sample included 161 patients, 102 (63.4%) male, with a mean age of 68±8 years. From these, 10 (6.2%) presented DB following ESD, with a median time to bleeding of 7 days (IQR 6.8).

According to BEST-J score, bleeding risk was low (0-1 points) in 111 (68.9%), intermediate (2 points) in 29 (18.0%), high (3-4 points) in 16 (9.9%) and very high (≥5 points) in 5 (3.1%) patients.

BEST-J score presented an excellent accuracy predicting DB in our sample, with an AUC=0.907 (95%CI=0.801-1.000; $p<0.001$). The optimal cut-off value to predict DB was a BEST-J score ≥3, which matches the cut-off value for high-risk of bleeding in the original investigation. This value had a sensitivity of 90% and specificity of 92%.

Conclusion: The BEST-J score still presents excellent accuracy in risk stratification for post-ESD bleeding in European individuals. Thus, this score may help to guide which patients benefit the most from prophylactic therapies following gastric ESD in this setting.

Disclosure: Nothing to disclose.

PP0195

DECISION-TO-SCOPE (DTS) SCORE: PROSPECTIVE VALIDATION AS AN EXCELLENT TOOL FOR PREDICTION OF FOREIGN BODIES IN THE ESOPHAGUS

V. Macedo Silva[1,2,3], J. Gonçalves[1,2,3], A.I. Ferreira[1,2,3], T. Lima Capela[1,2,3], T. Cúrdia Gonçalves[1,2,3], P.B. Carvalho[1,2,3], B.J.F. Rosa[1,2,3], J. Berkeley Cotter[1,2,3]

Contact E-Mail Address: vitorbmacedo@gmail.com

Introduction: Suspected foreign body ingestion and food bolus impaction are common indications for urgent esophagogastroduodenoscopy. Nevertheless, most of the ingested foreign bodies (80 to 90%) pass spontaneously throughout the gastrointestinal tract. In 2022, the Decision-To-Scope (DTS) Score was developed, revealing an excellent accuracy in predicting foreign bodies in the esophagus.

Aims & Methods: Our aim was to prospectively evaluate the diagnostic accuracy of the DTS-Score.

We have prospectively included consecutive patients admitted for suspected foreign body in the upper gastrointestinal tract, for a 6-month period. Previously to endoscopic evaluation, the DTS-score - time since ingestion < 6 hours (+1pt); absence of any meal since the suspected ingestion (+2pts); dysphagia (+3pts); odynophagia (+1pt) and drooling (+4pts) - was applied in each patient. The maximal possible value was 11 points, with a DTS-Score ≥5 being considered to assign a high probability of endoscopic confirmation of the foreign body.

Results: Final sample included 47 patients, from which 26 (55.3%) were females, with a mean age of 60±16 years. From these, most (n=42; 91.5%) were evaluated for accidental ingestion of food-related foreign bodies (fish or chicken bones) or suspected food bolus impaction. A DTS-Score ≥5 was calculated in 11 (23.4%) of the patients, with an esophageal foreign body being confirmed in 12 (25.5%) of them. DTS-score presented an excellent accuracy in predicting the endoscopic confirmation of a foreign body in the esophagus (AUC=0.94; 95%CI 0.85-1.00; p<0.001).

The originally defined cut-off (DTS-Score ≥5) presented a specificity of 97.1%, a sensitivity of 83.3%, a positive predictive value of 90.9% and a negative predictive value of 94.4%.

Conclusion: When prospectively applied, the DTS-score demonstrated an excellent acuity in stratifying the probability of endoscopic confirmation of a suspected foreign body in the esophagus. This tool may be included in future clinical algorithms for suspected foreign bodies ingestion.

A NOVEL ENDOSCOPIC MODALITY FOR MICROVASCULAR BLOOD FLOW RATE ANALYSIS USING MAGNIFYING ENDOSCOPY IN THE EARLY GASTRIC CANCER

Y. Akazawa[1], H. Ueyama[1], Y. Uemura[1], T. Iwano[1], M. Yamamoto[1], R. Uchida[1], H. Utsunomiya[1], S. Oki[1], N. Susuki[1], D. Abe[1], A. Ikeda[1], T. Takeda[1], K. Ueda[1], D. Asaoka[1], M. Hojo[1], S. Nojiri[2], A. Nagahara[1]
[1]Juntendo University, Department of Gastroenterology, Tokyo, Japan, [2]Juntendo University, Medical Technology Innovation Center, Tokyo, Japan

Contact E-Mail Address: yakazawa@juntendo.ac.jp

Introduction: There have been many reports on the usefulness of magnifying endoscopy with image-enhanced endoscopic techniques. In recent years, the magnifying endoscopy simple diagnostic algorithm for early gastric cancer (MESDA-G)[1] has been proposed as a unified diagnostic system.

However, it is a "static" diagnostic algorithm that uses still images. We focused on real-time red blood cell flow in subepithelial microvascular visualized by magnifying endoscopy, and clarified that microvascular blood flow rate was significantly lower in early gastric cancer (EGC) than in benign patchy redness in the pilot study[2].

Moreover, we uniquely developed an automated blood flow rate analysis system (hereinafter "analysis system") and calculated the cut-off value (1090.9um/sec) for endoscopic diagnosis of EGC using the test dataset. However, comparative studies on diagnostic accuracy between endoscopists and analysis system have not yet been analyzed.

Aims & Methods: The aim of this study was to compare the qualitative diagnostic accuracy of EGC between endoscopists and analysis system. We retrospectively reviewed magnifying endoscopy with blue laser imaging (M-BLI) videos of differentiated-type EGC and patchy redness at our hospital between December 2017 and September 2021.

M-BLI videos of 31 differentiated-type EGCs and 40 patchy redness in which red blood cell flow in subepithelial microvascular was visible were included in this study. In the analysis system group, the diagnosis was made according to the above-mentioned cut-off value (1.09 mm/sec) for cancer/non-cancer.

In the endoscopist group, 9 endoscopists (5 experts and 4 trainees) reviewed these M-BLI videos and made the diagnosis as cancer/non-cancer according to MESDA-G. We evaluated the diagnostic accuracy in each group, such as sensitivity/specificity/positive predictive value (PPV)/negative predictive value (NPV).

Results: In 31 EGCs, there were more men than women (22/9), the mean age was 72.2±9.5 years, the tumor location was U/M/L=2/8/21, the macroscopic type was elevated/depressed=8/23, the histological type was tub1/tub2/pap=24/6/1, and depth of invasion was M/SM=27/4. In 40 patchy redness, there were more men than women (28/12), the mean age was 69.0±9.7 years, and the location was U/M/L=3/12/25. With regard to diagnostic accuracy, sensitivity/specificity/PPV/NPV was 90.3/89.7/87.2/92.3% in the analysis system group, 85.9/87.2/80.0/85.5% in expert endoscopists, and 70.0/82.7/80.6/71.0% in trainees endoscopists, respectively.

	Analysis system	Endoscopists		
		Experts (n=5)	Trainees (n=4)	All (n=9)
Sensitivity % (95%CI)	90.3 (0.68-0.95)	85.9 (57.0-87.6)	70.0 (54.8-85.8)	77.9 (55.7-86.6)
Specificity % (95%CI)	89.7 (0.79-0.98)	87.2 (65.4-90.8)	82.7 (64.3-92.4)	85.0 (64.8-91.7)
PPV % (95%CI)	87.2 (0.74-0.98)	80.0 (55.5-84.0)	80.6 (59.8-90.8)	80.3 (58.0-87.9)
NPV % (95%CI)	92.3 (0.73-0.96)	85.5 (61.3-85.5)	71.0 (60.0-87.2)	78.3 (60.8-86.4)

Conclusion: The automated blood flow rate analysis system showed higher diagnostic accuracy in the differential diagnosis between differentiated-type EGC and patchy redness compared with endoscopists. It is suggested that the analysis system may be useful as a new diagnostic modality for EGC and could potentially diagnose lesions that are difficult for endoscopists to diagnose.

PREDICTION OF THE HILL CLASSIFICATION FOR HIATAL HERNIA USING ARTIFICIAL INTELLIGENCE

I. Kafetzis[1], K.H. Fuchs[1], P. Sodmann[1], W.G. Zoller[2], A. Meining[1], A. Hann[1]
[1]University Hospital Würzburg, Interventional and Experimental Endoscopy (InExEn), Internal Medicine II, Würzburg, Germany, [2]Katharinenhospital, Clinic for General Internal Medicine, Stuttgart, Germany

Contact E-Mail Address: hann_a@ukw.de

Introduction: Hiatal hernia (HH) is a common finding in endoscopic examinations that can cause significant symptoms, depending on its severity. The Hill classification assesses the degree of HH (type II to IV) by considering the width of the cardia and the hiatus on visual inspection during gastroscopy.

Aims & Methods: Our goal was to train a deep learning (DL) model that determines the Hill classification using a novel active learning (AL) pipeline. A total of 21,970 gastroscopic images representing 14,885 examinations from two endoscopy centers were retrospectively identified as the training dataset. A novel AL pipeline was developed to train the DL model. For comparison reasons, a second model was trained with randomly selected images from the same training dataset. An external, publicly available collection of HH images was annotated using the Hill classification and used as test data. Outcomes are the ability of the models to diagnose and classify HH and the time spent by the expert for annotation. The proposed AL pipeline is provided as Open-Source.

Results: The AL-based model was generated in eight consecutive steps, covering about 10% of the unlabeled training data. The model achieved mean accuracy, sensitivity, specificity, and F1-score of 0.878, 0.692, 0.896, and 0.67 respectively, when classifying the four different types of Hill. In diagnosing the existence of a HH (type I vs II-IV), the model achieved 0.828, 0.749, 0.902, 0.808 for the same metrics. The median annotation time per image was 3.62s (Q1-Q3; 3.14-4.69). Obtaining a model via the random image selection that performs similarly, required at least 30% more annotations and thus expert time commitment.

Conclusion: In this work we present a novel AL pipeline, enabling examiners to develop new models for gastrointestinal endoscopy without requiring programming skills. Using the proposed pipeline resulted in a well performing model in less time spent by the expert annotator, compared to traditional model training.

Disclosure: Nothing to disclose.

NON-SEDATIVE TRANSNASAL ESOPHAGOGASTRODUODENOSCOPY IN JAPANESE POPULATION-BASED SCREENING FOR GASTRIC CANCER IS INTOLERABLE FOR SOME PARTICIPANTS: REAL-WORLD DATA FROM A MULTICENTER ON-SITE QUESTIONNAIRE SURVEY

K. Inoki[1], T. Chiba[2], K. Miura[3], H. Yoshida[1]
[1]Showa University School of Medicine, Division of Gastroenterology, Department of Medicine, Tokyo, Japan, [2]Chiba Clinic of Internal Medicine and Dentistry, Tokyo, Japan, [3]Miura Clinic, Tokyo, Japan

Contact E-Mail Address: kinoki@med.showa-u.ac.jp

Introduction: Esophagogastroduodenoscopy (EGD) has been performed as a population-based screening for gastric cancer (PBSGC) in Japan since 2015. Although non-sedative EGD (NSEGD) is recommended by the Japanese Society of Gastrointestinal Cancer screening considering the risk of adverse events caused by sedation, its tolerability is unclear.

This study aims to evaluate the tolerability of NSEGD among PBSGC participants in a real-world setting.

Aims & Methods: The paper-based questionnaire survey was conducted for the PBSGC participants who received NSEGD in 16 institutions in Sinagawa-ku Tokyo Japan from April 2021 to August 2022. The questionnaire items were filled out anonymously by the participants of PBSCG soon after they have undergone NSEGD.

The questionnaire items included; consented to answer this survey, age, sex, number of experienced EGD, the experience of sedation during EGD, discomfort regarding NSEGD, and willingness to take sedated EGD next time.

The discomfort regarding NSEGD was evaluated by the following 4 items,
A: impression of NSEGD,
B: whether you can take NSEGD again,
C: impression of examination time,
D: feeling after taking NSEGD.

They were evaluated by 6 steps face scale: 1 is the most comfortable, and 6 is the most uncomfortable. Medical staff in each institution filled out the inserting route (oral, or tans-nasal), a used endoscope (normal or thin), the presence of biopsy, and examination time.

Results: The consent to answer the questionnaire survey was obtained from 1011 out of 1063 participants. The median age was 68 years (range: 40-93). There were 434 men and 554 women (not answered=23). The number of experienced EGD was 133 participants for the first time, 672 participants for 1-5 times, and 203 participants for more than 6 times (not answered=3).

Regarding the experience of sedation during EGD, 184 participants had experienced the sedated EGD, whereas 660 participants had not experienced sedated EGD (first-time examination: not answered: unknown=133:30:4).

The proportion of participants who answered 3 points or less on the discomfort scales was 68%, 81%, 85%, and 84% respectively.

Regarding the willingness to take sedated EGD next time, 391 participants hoped to receive the sedated EGD next time, whereas 576 participants answered that they can take NSEGD again.

Inserting route and used endoscope were as follows: transnasal route with thin scope: peroral route with thin scope: peroral route with normal scope=594:232:63 (unanswered=122). A biopsy was performed with 53 participants. The examination time was as follows: less than 6min: 7min: 8min: 9min: more than 10min=176:190:146:133:129:133(unanswered=104).

Of the valid response from 564 participants who received the transnasal endoscopy, 218 participants (38.7%) hoped to receive sedated endoscopy next time.

Conclusion: Real-world data from on-site questionnaire surveys for the participants who received the NSEGD as PBSGC showed that non-sedative transnasal EGD is intolerable for some participants. The support for the participants who are intolerable to continue the current NSEGD in the PB-SGC program should be considered in Japan.

Contact E-Mail Address: masato@murakami-kinen.or.jp

Introduction: Percutaneous transesophageal gastrotubing (PTEG) was established as an alternative route to access the gastrointestinal tract for the patients that Percutaneous Endoscopic Gastrostomy was contraindicated. PTEG will be an ideal method of tube feeding for the patients without indication of PEG.

Aims & Methods: The aim of this study is to evaluate the clinical usefulness of PTEG for the patients who need tube feeding. A rupture-free balloon (RFB) catheter is inserted into the upper esophagus. Percutaneous balloon puncture with a specialized needle is then performed from the left side of patient's neck under ultrasonographic control.

A guide wire is inserted through the needle into the RFB, followed by a dilator and sheath. A placement tube is then inserted through the sheath, and the sheath is removed.

Double Balloons equipped Over tube type RFB were used instead of primary RFB in thirty-five cases that the puncture needle is punctured into the over tube trough the balloon.

We perform PTEG in a total of 115 patients (78 men and 37 women, mean age 77.7 years) in whom PEG was not feasible for nutrition. Sixty-one patients had prior gastrectomy, 30 patients had gastric herniation into the thoracic cavity, 6 patients had there stomach located behind the colon, 4 patients had ventriculo-peritoneal shunt tube in front of the stomach and 4 patients had peritoneal carcinoma.

Results: Satisfactory results were achieved in all 115 patients. Median follow-up was 322.0 days. There were no patients who needed a nasogastric tube after PTEG. Seven of 115 patients were able to free from tube feeding due to PTEG tube feeding support.

About the complications, there was 1 patient with severe bleeding requiring blood transfusion, one patient had tracheal penetration, which was managed conservatively.

Other complications were minor oozing bleeding in seven patients that did not require blood transfusion, subcutaneous emphysema in two patients, which were managed conservatively. Complication rate was 10.4%. No patient required surgical treatment or died after PTEG.

Conclusion: PTEG is feasible, safe, and useful for long-term nutrition for the patient who is contraindicated to PEG. PTEG may become the only procedure of the liberation from nasogastric tube for the patient who is contraindicated to PEG PTEG is the ideal solution for the patients with PEG contraindicated in the tube feeding.

Disclosure: Nothing to disclose.

PP0201

SPRAY COAGULATION REDUCES THE USE OF HEMOSTATIC FORCEPS FOR INTRAOPERATIVE BLEEDING IN GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

Y. Ishikawa[1], O. Goto[1], S. Nakagome[1], T. Habu[1], K. Kirita[1], E. Koizumi[1], K. Higuchi[1], H. Noda[1], T. Onda[1], J. Omori[1], T. Akimoto[1], N. Akimoto[1], K. Iwakiri[1]

[1]Nippon Medical School, Department of Gastroenterology, Tokyo, Japan

Contact E-Mail Address: i-yumiko0@nms.ac.jp

Introduction: In intraoperative bleeding during endoscopic submucosal dissection (ESD) by using a needle-tip type electrocautery knife, spray coagulation is considered helpful compared to swift coagulation. In this study, we compared the hemostatic effect of two coagulation modes (swift coagulation and spray coagulation) on intraoperative bleeding during gastric ESD in a propensity score analysis.

Aims & Methods: In an intraoperative bleeding strategy, we changed "swift-dependent" hemostasis to "spray-switching" one in 2021. Therefore, 202 bleeding events before April 2020 (33 lesions, Swift group) and 203 bleeding events after April 2022(36 lesions, Spray group) were consecutively collected. In the Swift group, hemostasis was attempted firstly by swift coagulation by using a retracted tip of the needle-type knife, and if hemostasis was not achieved, hemostatic forceps were used.

In the Spray group, when hemostasis was attempted several times by swift coagulation but hemostasis was not achieved or when hemostasis was not expected by swift coagulation, spray coagulation was used. If hemostasis was not achieved by spray coagulation, hemostatic forceps were finally used. The two coagulation modes were determined by one endoscopist who retrospective observed the difference of sparks that occurred in hemostasis on video. We performed a post-hoc propensity score-matched analysis to compare the two groups.

Results: In comparison of patient background (age, gender, whether or not intraoperative antithrombotic medication was taken) and lesion background (site of lesion occupation, resection diameter, depth, presence or absence of ulcer, histological type, etc.) between the two groups, the larger number of patients in the Swift group had antithrombotic agents on ESD (p=0.016), while no significant differences were observed in other parameters. A propensity score matching was performed in defining intraoperative administration of antithrombotic agents, location, resection size, pathology, and presence or absence of ulcer as covariates.

A total of 106 events were matched per event in the two group, respectively. There was no significant difference in the hemostatic duration per event in the two group (Swift vs. Spray: 48.2 sec. vs. 55.3 sec., p=0.22). The number of coagulations per event in the Swift group was less than that of Spray group (4.3 times vs. 5.8 times, p=0.008). The hemostatic forceps was significantly less frequently used in the Spray group than in the Swift group (31.1% vs. 17.0%, p=0.016).

The cumulative success rate of hemostasis with electrocautery knives was likely to be higher in the Spray group (p=0.104), although there was no significant difference between the two groups. In the Swift group, two patients had postoperative hemorrhage and one patient had delayed perforation, whereas no adverse events were observed in the Spray group.

Conclusion: The data suggested that spray coagulation by the tip of the needle-type knife could reduce the use of hemostatic forceps. In gastric ESD, spray coagulation may facilitate the hemostasis of intraoperative bleeding.
Disclosure: Nothing to disclose.

Introduction: There is a paucity of information on the efficacy and safety of endoscopic resection (ER) of gastric submucosal tumors (SMT) in Japan where ER for early gastric cancer is extremely popular.
Aims & Methods: A multicenter retrospective study was conducted to elucidate the current situation of ER for gastric SMT in Japanese endoscopic practice. Clinicopathological data of consecutive patients with gastric SMT who underwent ER in 12 Japanese hospitals were collected from the first case until August 2020.
Results: A total of 117 patients with 118 lesions were enrolled. The number of patients with gastric SMT who underwent ER increased over the years. The mean (SD) endoscopic tumor size was 20 (7.2) mm. The growth type was primarily intraluminal (90%). 87 (74%) of the procedures were performed in an operating room under general anesthesia.
The tunneling method was used in 5 (4%) cases. The mean (SD) resection and wound closure times were 58 (38) min and 31 (41) min, respectively. Complete ER was achieved for 117 (99%) lesions. Full-thickness resection rate was 44%; however, only 12 (10%) patients required abdominal paracentesis for pneumoperitoneum.
Endoscopic treatments were completed in 115 (97%) lesions, while three lesions required conversions to laparoscopic surgery due to luminal collapse, uncontrolled bleeding, and difficulty in defect closure. Two cases of delayed bleeding were managed by endoscopic hemostasis, one of which required a blood transfusion. Gastrointestinal stromal tumors were the most common pathology (74%). The R0 resection rate was 76%.
Survival and recurrence on August 31, 2021, were confirmed in 112 patients (96%) with a mean (SD) follow-up period of 4.3 (2.9) years. 109 (94%) were confirmed alive, the vital status of five patients was unknown, and three patients had died of other diseases. No recurrence was observed. The 5-year overall survival rate was 98.9% (95% confidence interval, 97.8–100%).
Conclusion: The performance of ER for gastric SMT is increasing in Japan. The technique seems feasible in Japanese endoscopic practice, warranting further validation in a prospective study.
Disclosure: Nothing to disclose.

Introduction: Sporadic duodenal adenomas are rare. Resection is justified because of the risk of malignant transformation and endoscopic mucosectomy is recommended. However, this technique, although less morbid than surgery, is known to be associated with a higher risk of complications and one-year recurrence rates than those observed in the resection of colonic adenomas. In the absence of published prospective data, the purpose of this French multicenter study, performed in expert centers, was to investigate the 2-year recurrence and complication rates after standardized duodenal mucosectomy.
Aims & Methods: This prospective multicenter study was conducted in 21 French expert centers (N°IDRCB : 2016-A00931-51). The modalities of mucosectomy had been validated by the GRAPHE (Groupe de Recherche et d'Action des Praticiens Hépato-gastroentérologues en Endoscopie digestive) in order to standardize the procedures. Sporadic adenomas larger than 5 mm were included. Patients were monitored endoscopically at M3, M12, and M24, and further endoscopic treatment was performed if necessary.

Results: From 2017 to 2018, 124 patients were included (mean adenoma size 21.11mm (5-65mm)). Resection was performed as a monobloc in 47.2% of cases and 79.3% of monobloc resections had free lateral and deep margins. At 3 months, 25.4% (95% CI 14.9 -37.3%) of patients had an adenomatous residue that was treated endoscopically. At 12 months, 13.4% (95% CI 6 - 22.4) had a recurrence, which was also treated by endoscopy. The recurrence rate at 24 months was 11.9% (95% CI 4.5-20.9) in the 80 patients evaluated. Initial R1 resection was the only risk factor for recurrence at 24 months (p=0.03). The overall complication rate was 7.2% and was associated with lesion size (p=0.02).
Conclusion: This prospective study demonstrates for the first time that under standardized conditions, in an expert center, duodenal mucosectomy is a reliable and effective technique for the treatment of sporadic duodenal adenoma with, however, a recurrence rate at 2 years of 12% requiring a continuation of endoscopic follow-up.

Introduction: Endoscopic submucosal dissection (ESD) is a challenging procedure for treating superficial pharyngeal cancer (SPC). While previous studies have utilized conventional endoscopes (CE), recent advancements in endoscopic equipment have made it possible to use ultra-thin endoscopes (UTE) for ESD. The purpose of this study was to evaluate the impact of using UTE on ESD for SPC.
Aims & Methods: A total of 97 lesions in 81 patients who underwent ESD for SPC between January 2021 and March 2023 were retrospectively analyzed. Patients who underwent ESD using UTE (1200N: Olympus, Tokyo Japan) were classified into the UESD group, while those who underwent ESD using CE (Q260J: Olympus, Tokyo Japan) were classified into the CESD group.
Results: Of the 81 patients, 24 underwent UESD for 30 lesions, while 57 underwent CESD for 67 lesions. In the UESD group, the mean age was 70 years, with 20 males and 4 females. The mean maximum lesion size and resection specimen size were 17.7 mm and 28.5 mm, respectively. The histologic depth was CIS/SEP 17/13. The average dissection time was 41.6 minutes, and the volume of local injection (glyceol) used was 4.2 ml. Traction was used in 28 cases. In the CESD group, the mean age was 70 years, with 52 males and 5 females. The mean maximum lesion size and resected specimen size were 18.4 mm and 29.2mm, respectively. The histologic CIS/SEP was 24/43. The mean dissection time was 32.3 minutes (p=0.099), and the volume of local injection used was 7.1 ml (p=0.002). Traction was used in all cases. Both groups had a 100% en bloc resection rate and zero treatment-related complications.
Conclusion: The use of UTE in ESD for SPC is a safe alternative to CE. The use of UTE resulted in a reduction in the amount of local injection required, and in some cases, traction was not necessary. However, the dissection time tended to be longer. From the surgeon's perspective, UTE made it easier to access the subepithelial layer and secure the dissected layer, with less interference from other devices, resulting in reduced stress during the procedure.
Disclosure: Nothing to disclose.

Introduction: Endoscopic resection margin R1 is the presence of neoplasia on the lateral and/or deep margin. The highest rate of R1 resection occurs in duodenal NENs where advanced resection techniques, such as endoscopic submucosal dissection (ESD) or full thickness resection (EFTR), are more difficult to apply. In the stomach and rectum, due to the most favorable anatomy, advanced endoscopic techniques can be used in order to obtain lower R1 resection probability (10-20%).
Furthermore, there is no direct correlation between risk of R1 resection and recurrence or progression of disease during follow-up.
Aims & Methods: The aim of this study is to assess endoscopically risk of recurrence or progression of disease in the same site of resection in patients with gastric, duodenal and rectal NENs undergoing endoscopic resection R1.
This is a retrospective and multicentric study, including a prospective series of patients with gastric NEN (type I, single or multiple, < 2 cm), duodenal NEN (not ampullary, not functioning, < 2 cm), rectal NEN (< 2 cm).
Results: A total of 110 patients were included (mean age at diagnosis, 58 years [CI 31-85]), all undergoing diagnostic endoscopic examination: 45 NEN of the stomach (41%), 21 NEN of the duodenum (19%) and 44 NEN of the rectum (40%).
The median size of primary tumor was 7 mm (CI 2-15). 86 patients (78.1%) had a NEN G1 (according to WHO) and 8 patients (7.2%) NEN G2. The median of Ki-67 was 2.5% (CI 0-10).
According to TNM staging, after endoscopic resection, 6 cases (5.4%) showed nodal metastases (N1), evaluated through CT or PET-DOTATOC. Deep endoscopic resection margin was affected in 78 cases (71%), lateral margin in 32 (29%) and both resection margins were affected in 11 patients (10%).
An enlargement resection was planned in 30 patients (27.2%); 9 patients (8.1%) were initiated to radical R0 surgery (4 duodenals, 4 rectum, 1 stomach) while the other 21 patients were addressed to advanced endoscopic treatment.
During the period of active surveillance, among patients who didn't undergo to enlargement (endoscopic or surgical), a local recurrence was found in 10 cases (9%). They were treated with endoscopic resection (6 stomach, 1 duodenal, 3 rectum). During the observation period, there were no deaths due to the disease and there was no progression disease extra organ. The free survival progression (PFS) was 65 months (CI 6-178) and the Overall Survival (OS) was 69 months (6-187).
Conclusion: From this preliminary analysis, the endoscopic R1 resection margin does not appear to affect the clinical outcome of patients. This observation is in line with the evidence in the literature and requires a prospective assessment.

COMPARATIVE STUDY BETWEEN CF-H290I AND PCF-Q260JI COLONOSCOPE IN NON-SEDATED PATIENTS WITH A HISTORY OF ABDOMINAL OR PELVIC SURGERY: A RANDOMIZED CONTROLLED STUDY

X. Chen[1], Y. Cheng[2], X. Zhu[1], B. Wei[1], L. Ji[3], Q. Zhan[1]
[1]The Affiliated Wuxi People's Hospital of Nanjing Medical University, Wuxi, China, [2]Wuxi People's Hospital, Digestive Medicine, Wuxi, China, [3]The Affiliated Wuxi People's Hospital of Nanjing Medical University, Gastroenterology, Wuxi, China

Contact E-Mail Address: 3489654307@qq.com
Introduction: Colonoscopy is the standard modality for colorectal cancer (CRC) screening and surveillance by means of an examination that achieves cecal intubation without patient pain or complications[1].
According to related literatures, patients with a history of abdominal or pelvic surgery, usually associate with lumen adhesion or normal intestinal structure changes, which lead to a more difficult colonoscopy. In addition, abdominal pain during the colonoscopy may result in incomplete operation or refusal of a second colonoscopy, causing serious impact on the diagnosis of colonoscopy and adenoma detection rate (ADR), thus reducing the quality of colonoscopy[2-3].
At present, the type of colonoscope have been demonstrated to influence the colonoscopy performance. For example, ultrathin colonoscopes are of greater utility for passing strictures and severe angulations. While variable stiffness colonoscopes may be useful for negotiating tortuous rectosigmoid junctions[4].
Until now, the value of colonoscope for reducing pain of patients, especially on patients with a history of abdominal or pelvic surgery and without sedation, have not been investigated completely. Thus, we conduct a randomized controlled trial to investigate the efficacy of different types of colonoscope for reducing pain during non-sedated colonoscopy.
Aims & Methods: The purpose of this randomized controlled study was to compare application characteristcs of CF-H290I and PCF-Q260JI colonoscope in non-sedated patients with a history of abdominal or pelvic surgery, thus helping endoscopists to use different types of colonoscopy more effectively and scientifically. From August 2022 to October 2022, a total of 397 patients in the Affiliated Wuxi People's Hospital of Nanjing Medical University were randomly allocated to the CF-H290I (n = 198) or PCF-Q260JI (n = 199) colonoscope groups by using a computer-generated system.
We compared cecal intubation time, patient satisfaction of examination, adenoma detection rate (ADR), discomfort associated with colonoscopy including abdominal distension or pain and patient acceptance of next colonoscopy between the CF-H290I group (high-definition system) and the PCF-Q260JI group (high-resolution system).
Results: Among 397 subjects, 198 were performed with the CF-H290I and 199 with the PCF-Q260JI. The patients satisfaction of colonoscopy was higher with the PCF-Q260JI group than CF-H290I group[8.91(1.09) vs 8.51(1.44), P <0.01], and there was less chance for discomfort associated with colonoscopy[23(11.6%)vs 41(20.7%), P= 0.013], patients' acceptance of next colonoscopy in PCF-Q260JI group was more than CF-H290I group[168(84.4%) vs 149(75.3%), P = 0.023]. Compared with PCF-Q260JI colonoscope group, CF-H290I colonoscope group had shorter cecal intubation time (unit: s)[256.09(155.70)vs 315.64(171.64), P =0.004]. No statistically difference was found in the adenoma detection rate (ADR) between the two groups [63(31.7%)vs 81(40.9%), P= 0.055]. There were no complications such as perforation or bleeding in both groups.
Conclusion: For patients with a history of abdominal or pelvic surgery, PCF-Q260JI colonoscope was superior with respect to reducing patients' pain and improving patient acceptance of non-sedated colonoscopy. This study was approved by the Clinical Research Ethics Committee of Wuxi People's Hospital and was registered in the Chinese Clinical Trial Registry(ChiCTR2200063092).

Introduction: Adenomatous polyposis syndromes comprise familial adenomatous polyposis (FAP), linked to a mutation in the APC gene, and MUTYH-associated polyposis (MAP), when there is a biallelic mutation in the MUTYH gene. These conditions result in a high risk of colorectal and duodenal cancers, with well-established recommendations for screening and preventive treatment for these locations. Recent studies also suggest an increased incidence of gastric cancer in these patients, associated with different types of dysplastic lesions in contact or at distance from the classic fundic gland polyps (FGP).
Aims & Methods: The aim of this study was to determine the prevalence, treatment, and follow-up of gastric dysplastic lesions in patients with an adenomatous polyposis syndrome.
We retrospectively analysed clinical and endoscopic data from all patients with adenomatous polyposis syndrome (FAP or MAP) who underwent follow-up esophagogastroduodenoscopy (EGD) in our center, between January 2015 and May 2022. Data was collected from a national prospective database of patients with digestive polyposis diseases created in 2011. We distinguished two types of dysplastic lesions: on the one hand, well-defined umbilicated sessile nodules of the antrum, and on the other hand, whitish flat lesions showing a "blue crest" sign in NBI, often fundic and within FGPs.

Results: A total of 227 patients were included. Thirteen (5.7%) presented a MUTYH mutation. Twenty-seven patients (11.9%) had gastric dysplasia (with 17 (63%) women and a mean age of 52 [23-68] years), located proximally in 70.4% of cases and mostly corresponding to low-grade dysplasia (18 cases, 66.7%), followed by high-grade dysplasia (8 cases, 29.6%) and 1 case of cancer (3.7%).

One patient died of metastatic gastric cancer not detected by endoscopy, within a very dense fundic polyposis. None of these patients had an Helicobacter pylori (HP) infection (vs 13 (6.5%) in the control group). Whitish flat areas of the proximal stomach were observed in 27 (11.9%) patients, with confirmed (low-grade) dysplasia in 17 cases (63%). Sessile antral lesions were reported in 21 cases (9.2%), with confirmed dysplasia in 6 (29%). One of the flat fundic lesions was already invasive adenocarcinoma (pT2).

Three other cases of dysplasia were revealed by systematic biopsies. The presence of fundic whitish flat lesions was strongly correlated with the presence of dysplasia (relative risk of 31 (95% CI [12.7-74.9], p <0.001)).

The mean age and smoking were significantly higher in the dysplasia group (p <0.001). In multivariate analysis, smokers or patients with high-density FGPs (>50) had a significantly higher risk of gastric dysplasia (absolute risk of 13.08, 95% CI [2.67-64.10] and 22.06, 95% CI [4.28-113.58], respectively). Among the cases of dysplasia, 21 (77.8%) were treated by endoscopic resection, mostly ESD (10 cases (47.6%), for lesions with a median diameter of 62.5 [35-160] mm). One of these patients had a deeply invasive pT2 adenocarcinoma and therefore received systemic treatment. A patient with multiple and extensive adenomatous lesions was referred for gastrectomy, which he refused. The remaining patients are still under endoscopic surveillance. The median follow-up duration after treatment was 21 [0-72] months, with 2 proximal recurrences (7%, low grade dysplasia) treated endoscopically.

Conclusion: We present one of the largest gastric follow-up cohorts of patients with familial polyposis, with a non-negligible frequency of gastric dysplasia and risk of cancer. The latter is possibly preventable by endoscopic resection if the dysplasia is recognized early. This accentuates the importance of educating gastroenterologists on recognizing these sometimes very difficult to see lesions (dyschromic flat lesions).

Disclosure: Nothing to disclose.

PP0208

A COMPARATIVE STUDY OF THE DIAGNOSTIC CAPABILITIES OF THE ENDOSCOPES OF TWO COMPANIES FOR ARTIFICIAL INTELLIGENCE (AI) DIAGNOSIS IN EARLY GASTRIC CANCER

Y. Terai[1], M. Oka[1], H. Takabayashi[1], S. Nagoshi[1]
[1]Saitama Medical Center, Gastroenterology and Hepatology, Kawagoe, Japan

Contact E-Mail Address: yuji.guri.33eto@gmail.com

Introduction: AI diagnosis is used in several medical fields; however, machine learning using deep learning methods is particularly effective in diagnostic imaging and shows high diagnostic capability even in the field of endoscopy. In Japan, endoscopes manufactured by Companies A and B are generally used, and there is a possibility that differences in the image quality will affect AI diagnosis. However, there is no report of studies comparing the AI diagnostic capabilities on images taken by endoscopes of two companies.

Aims & Methods: In endoscopic AI diagnosis of early gastric cancer, the AI diagnostic capabilities were compared using images obtained by endoscopes of Companies A and B for the purpose of clarifying whether there is a need to consider the differences between the endoscopes used. For 30 lesions of 27 patients who underwent endoscopic submucosal dissection for early gastric cancer from April 2019 to March 2022 at our hospital, 356 and 338 endoscopic images of Companies A and B were the target of analysis, respectively.The images were white light (WLI), chromoendoscopy (indigo carmine) and image-enhanced endoscopy, Company A used narrow band imaging (NBI), and Company B used blue laser imaging (BLI). The images were analyzed by AI Medical Systems Inc. using an AI diagnostic system constructed by having UNET learn images taken by either Company A or B's endoscopes as training images. The diagnostic capability was assessed by comparing the specialist-marked correct range of early gastric cancer with an AI-diagnosed range of early gastric cancer, and using a DiceScore of 1.0 for a complete match and 0.0 for no match based on the area of the match.

Results: There was no significant difference in the DiceScore between the endoscopes of both companies in WLI; however, in indigo, Company B scored significantly higher than Company A. There was no significant difference between NBI and BLI. A stratification analysis by macroscopic examination of the lesions showed that in 0-IIc, Company A scored significantly higher in WLI than Company B, while in indigo, Company B scored significantly higher than Company A. In 0-IIa+IIc, Company B scored significantly higher than Company A in WLI; however, there was no difference between the two companies in indigo. In comparison by macroscopic examination of the lesions, 0-IIa+IIc lesions scored significantly higher than 0-IIc lesions in indigo for Company A, and in WLI for Company B. When the lesions were divided into a maximum diameter of <2 cm, 2–3 cm, and ≥3 cm, lesions ≥3 cm scored lower than lesions in the other groups.

Conclusion: Endoscopic images of Company B tended to have higher sharpness and stronger bluish color compared to endoscopic images of Company A. This might be the reason why the diagnostic capability improved after indigo-carmine scattering. Therefore, proactive scattering of indigo carmine was considered preferable when observing with the Company B endoscope. Presumably, the reason 0-IIa+IIc lesions had higher diagnostic performance than 0-IIc lesions was due to differences in the elevation of the lesions. The Company A endoscope was considered significantly superior for 0-IIc lesions, which are easily overlooked in clinical practice. The complexity of the morphology of the lesion increases in large lesions, which widens the gap between the AI diagnostic range and correct range. There are lesions wherein the AI diagnostic performance increased with both endoscopes of Company A and that of Company B. Therefore, it is preferable to use the endoscopes in AI diagnosis taking these facts into consideration.

Contact E-Mail Address: goda@dokkyomed.ac.jp
Introduction: Since patients with pharyngeal squamous cell carcinoma (SCC) often have multiple pharyngeal lesions, evaluation of pharyngeal lesions before endoscopic resection (ER) is important. However, detailed endoscopic observation of the entire pharyngeal mucosa under conscious sedation is difficult.
Aims & Methods: We examined the usefulness of endoscopic surveillance with narrow band imaging (NBI) and lugol staining for detection of pharyngeal sublesions during ER for superficial pharyngeal SCC under general anesthesia (endoscopic surveillance during treatment; ESDT). From January 2021 through June 2022, we examined 78 patients who were diagnosed with superficial pharyngeal SCC and underwent ER. They underwent the ESDT and for patients who were diagnosed with new lesions of pharyngeal SCC or high-grade dysplasia (HGD) that were not detected in the endoscopic examination before treatment, ER were performed simultaneously for new lesions and the main lesions.
The primary endpoint of this study was the detection rate of new lesions of pharyngeal SCC or HGD in the ESDT.
Results: Fifteen of the 78 patients were diagnosed as having undetected new pharyngeal lesions in the ESDT and 10 (12.8%) (95% CI: 6.9 – 22.2%) were histopathologically confirmed to have new lesions of pharyngeal SCC or HGD. Among the 13 lesions of SCC or HGD, 8 were found by NBI observation; however, 5 were undetectable using NBI but detectable by lugol staining. All of the 13 lesions had endoscopic findings of pink color sign on lugol staining.
Conclusion: Endoscopic surveillance for pharyngeal sublesions with lugol staining during ER for superficial pharyngeal SCC is feasible and useful.

HIGH DIAGNOSTIC YIELD OF UPPER ENDOSCOPY IN CHILDREN WITH SEVERE IRON DEFICIENCY ANEMIA OF UNEXPLAINED CAUSE.

M. Kori[1,2], N. Yuran[3], T. Ben-Ami[4,2]
[1]Kaplan Medical Center, Pediatric Gastroenterology, Rehovot, Israel, [2]Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel, [3]Kaplan Medical Center, Pediatrics, Rehovot, Israel, [4]Kaplan Medical Center, Pediatric Hematology, Rehovot, Israel

Contact E-Mail Address: nufaryuran@gmail.com
Introduction: There are currently no established guidelines for the diagnostic workup and management of severe iron deficiency anemia (IDA) in children.
Aims & Methods: To analyze the diagnostic yield of upper endoscopy in children with severe, unexplained IDA, without overt GI bleeding, with respect to their management and outcome. A retrospective study in children <18 years, hospitalized with hemoglobin <7gr/dl, who underwent upper endoscopy between 2016 and 2022. Base line data: demographics, symptoms, laboratory results, endoscopic/ histopathological findings and treatment. Follow-up data; Hemoglobin at 6 months, the need for repeat iron treatment.
Results: We evaluated 25 children with severe IDA, mean age 10.7 ±3.9 years, 19 (76%) female, 8 (32%) of Ethiopian origin. Symptoms of anemia were present in 19/25 (76%), gastrointestinal symptoms in 10/25 (40%). Mean hemoglobin (Hb) level 6.2 gr/dl (range 3.2-6.9). Initial treatment; blood transfusion 3 (12%), intravenous iron infusions 21 (84%) and oral iron in one.
Endoscopic findings: gastric nodularity, erosions or polyps in 17/25 (68%), duodenitis / ulcers in 3/25 (12%). Histopathology demonstrated gastritis in 18/25 (72%); 9/18 (50%) *Helicobacter pylori*, 5 collagenous gastritis, 1 lymphocytic and 3 non-specific gastritis. Nonspecific duodenitis in 3, celiac disease in one. An etiology of IDA was found in 18/25 (72%) children, 15 without GI symptoms. During follow-up, Hb levels remained stable in 23/25 (92%), only two required repeat iron therapy.
Conclusion: Upper endoscopy should be included in the diagnostic investigation of severe unexplained IDA in children. It enabled to identify the cause of IDA in over 70% of children.
Disclosure: Nothing to disclose.

A PROPOSED MANAGEMENT STRATEGY OF OESOPHAGEAL FOOD BOLUS IMPACTION BASED ON A RETROSPECTIVE REVIEW OF THE SAFETY AND EFFICACY OF CAP-ASSISTED VS CONVENTIONAL ENDOSCOPIC TECHNIQUES

H. Dhillon[1], I. Lu[2], P. Te[2], D. Dowling[2], N. Heerasing[2]
[1]Monash Health, Gastroenterology, Victoria, Australia, [2]Barwon Health, Gastroenterology, Geelong, Australia

Contact E-Mail Address: hardeshdhillon92@gmail.com
Introduction: Oesophageal food bolus impaction (OFBI) is a common medical emergency, but current management strategies vary due to the availability of different endoscopic accessories and techniques. There are no clear guidelines on the safest and most effective approach, as there is a lack of safety and efficacy data for individual methods.
Aims & Methods: The aim of this study was to compare various techniques for treating OFBIs and to propose a safe, effective, and sustainable algorithm-based strategy. We conducted a retrospective review of all soft OFBI's among patients aged 18 years and above from 2010-2022 at Barwon Health, Victoria. We evaluated the efficacy and safety of medical management and endoscopic strategies with an 18mm wide rimmed Olympus oblique cap and conventional methods (polypectomy snare, biopsy forceps, three-pronged grasper, and Roth-net).
Results: Of 629 patients screened with OFBIs, 370 met the inclusion criteria of the study. Medical management was successful in 24 (6.5%) patients, and the remaining 346 (93.5%) proceeded to endoscopic evaluation. Spontaneous passage during endoscopic evaluation occurred in 66 (17.8%) patients, and the remaining 280 (75.6%) required endoscopic intervention with a "push" or "pull" strategy.
Over the last decade, there has been a shift towards a pull strategy using a distal attachment cap. In 2010, conventional instruments were used in 85% of OFBIs, but by 2022, their usage had decreased significantly, with only 16% of cases employing them. While the "push" strategy was associated with a significantly shorter procedure duration compared to all "pull" strategies (23.6+/- 12.2 vs 36.1+/-23.9 minutes) (p<0.0001), we noted the statistical difference was not seen in a subgroup analysis between a cap based "pull" strategy vs "push" [(26.81+/-11.3 vs 23.6+/-12.2 minutes) (p=0.372)].

When comparing conventional vs cap-based interventions, there was a statistically significant difference in en-bloc removal rates [(87.5% versus 15.4%) (OR=38, 95%CI=15.6-94.8) (p< 0.001)], mean procedure time [(28mins versus 45mins) (95%CI =11-25) (P< 0.001)], and mean number of instruments used (1.07 versus 1.67, p<0.001) favouring a cap-based intervention.

Except for major complications including aspiration (n=6) and major bleeding (n=1) all occurring in patients above 60 years old, we found no significant association with any other variables including airway management technique, non-endoscopic and endoscopic methods, and techniques.

Conclusion: For patients without a proximal stricture who are intubated, a cap-based endoscopic "pull" technique should be employed as a first-line strategy, while a gentle "push" strategy should be considered for patients without a secured airway. Conventional methods should only be used as a second-line strategy for patients who fail both push and cap-based interventions.

Disclosure: Nothing to disclose.

ARTIFICIAL INTELLIGENCE WITH LINKED COLOR IMAGING FOR THE DIAGNOSIS OF EARLY GASTRIC CANCERS

C. Iwashita[1], H. Osawa[1], Y. Nomoto[1], Y. Miura[1], Y. Ino[1], H. Takahashi[1], T. Ueno[1], A. Lefor[2], T. Tada[3], H. Yamamoto[1]

Contact E-Mail Address: ciwashita51@gmail.com

Introduction: There are several reports about the diagnosis of early gastric cancers (EGCs) using artificial intelligence (AI) systems, but satisfactory data for sensitivity and specificity are not yet available. Linked color imaging (LCI) produces high color contrast between malignant lesions and surrounding mucosa compared to white light imaging (WLI).

Therefore, LCI combined with AI (LCI-AI) has the potential to further improve the diagnosis of gastric cancer compared with WLI combined with AI (WLI-AI). We developed three new LCI-AI models to determine their sensitivity and specificity for the diagnosis of EGCs.

Aims & Methods: Three models including a convolutional neural network (CNN) model (high resolution net (HRNet)), a transformer model (Segformer) and a hybrid (combined CNN and transformer) model (Uniformer), were based on MMSegmentation. When each model recognized a gastric cancer lesion from test image data, it was shown with the existing position as a blue area on WLI images and green area on LCI images.

Non-neoplastic mucosa was shown as a black area on both images. Endoscopic images using WLI and LCI (LASEREO 7000 system series and scopes of EG-L600ZW and EG-L600ZW7, Fujifilm Corporation, Tokyo, Japan) were collected from patients with EGCs from January 2015 to December 2018 at Jichi Medical University Hospital.

A total of 1970 images including 1179 WLI and 791 LCI images of 236 EGCs were used for training the three LCI-AI models. Another set of 414 EGC images was selected for validation from 43 cases. Primary and secondary endpoints were the sensitivity and specificity of each AI model, respectively.

The image-based performance metric was based on Dice loss, calculated by subtracting the mean Dice similarity score. A Dice score >20% was defined as the correct diagnosis of cancer because EGCs sometimes have unclear demarcation lines. The correct diagnosis of a non-malignant lesion was defined as no reactive black areas in surrounding mucosae.

Each case had from four to 21 images. Therefore, the median Dice score was used as a representative value in each case to evaluate performance. All three models' programming and data analysis were supported by AI Medical Service Inc. (Tokyo, Japan).

Results: Analysis of lesions in all EGC images showed both sensitivity (82.8%) and specificity (83.4%) with LCI-AI to be high and similar to those with WLI-AI (83.1% and 84.3%, respectively). Sensitivities of LCI-AI/ WLI-AI among HRNet, SegFormer and UniFormer were 80.9%/81.6% (p=0.625), 83.8%/83.8% (p=0.224) and 83.8%/83.8% (p=0.450), respectively and specificities were 80.0%/86.0% (p=0.120), 86.4%/84.8% (p=0.672) and 86.8%82.0%/ (p=0.214), respectively.

Representative Dice values among cases with EGCs showed sensitivities for LCI-AI using HRNet, SegFormer and UniFormer to be extremely high, at 92.7% 90.9% and 93.0%, respectively, although not significantly different when compared to those using WLI-AI, 84.6% (p=0.67), 85.4% (p=0.15) and 80.5% (p=0.19), respectively. Higher sensitivities were found regardless of lesion size, morphology, and *Helicobacter pylori* status. All sensitivities using LCI-AI were higher than 80% whereas those using WLI-AI varied from 64% to 89%.

Conclusion: LCI-AI showed high sensitivity and specificity for the diagnosis of EGCs using all three models tested, suggesting potential for practical clinical use in the near future.

PP0213

EFFICACY OF INTENSIVE TRIAMCINOLONE INJECTION TO AVOID BALLOON DILATION IN PREVENTING STENOSIS AFTER EXTENSIVE ESOPHAGEAL ESD

K. Okimoto[1], T. Matsumura[1], N. Akizue[1], Y. Mamiya[1], A. Kurosugi[1], M. Sonoda[1], T. Kaneko[1], Y. Ohta[1], T. Taida[1], J. Kato[1], N. Kato[1]
[1]Chiba University Hospital, Department of Gastroenterology, Graduate School of Medicine, Chiba, Japan

Contact E-Mail Address: kenrunaway@yahoo.co.jp

Introduction: Balloon dilation is sometimes required to prevent stricture after esophageal endoscopic submucosal dissection (ESD), but the procedure is performed frequently and there is a risk of perforation.

Aims & Methods: In this study, we investigated whether intensive triamcinolone (TA) injection after extensive esophageal ESD can prevent stricture while avoiding balloon dilation. Thirty-one lesions in 31 patients with post ESD ulcers more than 3/4 circumference and confirmed scarring from December 2017 to February 2023 were included in this study. The total circumferential resection was defined as group A, the other group as group B, and stricture was defined as the inability to pass an endoscope of normal diameter (8.9-10.2 mm).

All patients underwent TA immediately after ESD. Basically, after ESD, weekly TA injection was performed in group A, and no additional injection/ weekly or bi-weekly TA injection was performed in group B, depending on the endoscopists' judgement.

The primary endpoint was the percentage of patients who required balloon dilation, and the secondary endpoints were the stricture rate and the number of TA injections.

Results: Group A (8 patients, 8 lesions) and Group B (23 patients, 23 lesions). Morphology (IIa/IIb/IIc) 0/1/7, 1/4/18. Histological type (squamous cell carcinoma / Barrett's esophageal adenocarcinoma) 7/1, 22/1, and en

bloc resection rate was 100% in both groups. No perforation was observed in either group. Three consecutive patients (37.5%) in the early stage of group A and three consecutive patients (13.0%) in early stage of group B were treated with oral steroids. The length of resection (mm) (median (range)) were 55 (40-80) and 50 (40-120), respectively, and the circumferential length (mm) was 30 (20-50) in group A. The longest observation period until the presence of stricture was 15 (1-38)/11 (1-37) months, respectively.

The percentage of balloon dilation required and the stricture rate (n (%)) were both 0 (0) in group A and 1 (4.3) in group B. The number of TA injections was 8 (3-12) and 1 (1-3), significantly higher in group A ($p < 0.01$. Mann-Whitney U test). One case in group B required balloon dilation because of difficulty in coming to the hospital due to poor ADL after a subcircumferential resection, and the additional injection was performed 3 weeks after ESD, later than scheduled.

Conclusion: Intensive TA injection based on weekly or bi-weekly was effective in preventing stricture after extensive esophageal ESD, and could avoid balloon dilation even in cases with circumferential resection.

Disclosure: Nothing to disclose.

PP0214

DIAGNOSTIC ABILITY OF MAGNIFIED TEXTURE AND COLOR ENHANCED IMAGING WITH INDIGOCARMINE FOR SUPERFICIAL NONAMPULLARY DUODENAL TUMOR

K. Okimoto[1], T. Matsumura[1], N. Akizue[1], K. Matsusaka[2], Y. Mamiya[1], A. Kurosugi[1], M. Sonoda[1], T. Kaneko[1], Y. Ohta[1], T. Taida[1], J. Kato[1], N. Kato[1]

[1]Chiba University Hospital, Department of Gastroenterology, Graduate School of Medicine, Chiba, Japan, [2]Chiba University Hospital, Department of Pathology, Chiba, Japan

Contact E-Mail Address: kenrunaway@yahoo.co.jp

Introduction: There is no consensus on preoperative endoscopic diagnostic methods for superficial nonampullary duodenal tumor (SNADET). We previously reported that texture and color enhanced imaging (TXI) with indigocarmine (ICME-TXI) significantly improved the visibility of SNADET surface structures compared to narrow band imaging (Sci Rep 2022).

Aims & Methods: In this study, we aimed to investigate the diagnostic ability of ICME-TXI. Forty-six consecutive lesions that were endoscopically resected and pathologically neoplastic after prospective ICME-TXI observation for SNADET from March 2021 to November 2022 were included. The components of the surface structure were classified as circular, oval, or others.

The presence of both heterogeneity (mixture of components or difficulty in visualization) and size difference (difference of 3 times or more in size with areas of components) were defined as significant findings. Immunohistochemical staining was performed to clarify whether tumor was gastric, intestinal or mixed type. ICME-TXI image and pathological findings were compared. In addition, the diagnostic ability of the lesions was retrospectively evaluated against the Vienna Classification (VCL) C4/5.

Results: Major morphology (Is/ Ip/ IIa/ IIc) = 8/ 2/ 32/ 4, median tumor diameter (mm) = 10 (3-40), location (bulb 9 lesions/ descending 37 lesions), CSP 15 lesions, UEMR 31 lesions, VCL C3 39 lesions, C4/5 7 lesions, gastric/ intestinal/ mixed type=2/ 36/ 8, respectively. 100% of gastric, 0% of intestinal and 37.5% of intestinal type had a circular component. 4 lesions (8.7%) had histopathological findings similar to traditional serrated adenoma (TSA) of the colon and were characterized by an oval component (all were intestinal type, VCL C3).

The sensitivity/ specificity/ positive predictive value/ negative predictive value/ accuracy (%) for VCL C4/5 were 57.1/ 94.5/ 66.7/ 92.5/ 89.1.

Conclusion: ICME-TXI revealed fine surface structures, and showed specific findings for a particular histological type similar to TSA. The high specificity and negative predictive value of ICME-TXI for preoperative diagnosis suggest that ICME-TXI may be a new diagnostic modality.

Introduction: Device-assisted enteroscopy (DAE) has become a well-established diagnostic and therapeutic tool for various small bowel disorders. However, unlike upper and lower gastrointestinal endoscopy, performance measures for DAE have rarely been studied.

Aims & Methods: We aimed to evaluate the performance measures for DAE across 11 hospitals in the United Kingdom (UK) and compare them with the quality benchmarks proposed by the European Society of Gastrointestinal Endoscopy (ESGE).

We retrospectively collected data on patient demographics and DAE performance measures from electronic endoscopy records of consecutive adult patients (≥18 years old) who underwent DAE for diagnostic and therapeutic purposes between January 2017 and December 2022.

Results: A total of 1,529 DAE procedures were performed in 1,261 patients (median age 62 years, 53.5% male), of whom 13.6% had surgically altered anatomy. Almost all procedures (97.5%) were performed for appropriate indications, including small bowel bleeding (42.5%), small bowel tumours or polyps (19.1%), and suspected Crohn's disease (12.5%). Double-balloon enteroscopy was used for most procedures (78.4%), followed by single-

balloon enteroscopy (20.6%) and spiral enteroscopy (1%). The antegrade and retrograde approaches were used in 76.8% and 23% of cases, respectively. The estimated depth of insertion was documented in 65.7% of procedures, with a median depth of insertion of 200 cm (IQR 150 – 245) using the antegrade approach and 100 cm (IQR 50 – 163) using the retrograde approach. The point of maximal insertion depth was tattooed in 37.2% of procedures. The overall diagnostic yield was 69.4%, with vascular (27.8%) and inflammatory lesions (25.2%) as the most common diagnoses.

Therapeutic interventions were performed in 44.4% of procedures, including argon plasma coagulation (25.3%), endoscopic haemoclipping (15%), polypectomy (8.2%) and stricture dilatation (3.2%). The interventions success rate was 97.7%, and 75.5% of detected or treated lesions were tattooed.

General anaesthesia was used in 34.3% of the procedures, while conscious and deep sedation were used in 38.3% and 25.5%, respectively. Patient comfort was significantly better with deep sedation compared with conscious sedation (98.9% vs. 34.3%, p<0.0001). Complications occurred in 0.7% of the procedures, including 5 perforations, 3 cases of pneumonia, 2 cases of post-polypectomy bleeding, 1 episode of pancreatitis and 1 case of unstable cardiac arrhythmia.

Conclusion: Performance measures for DAE in the UK meet the ESGE quality benchmarks, with high diagnostic and therapeutic yields and a low incidence of complications.

However, there is room for improvement in optimising sedation practices, increasing standardisation of depth of insertion documentation, and improving marking techniques to aid in the follow-up of detected or treated lesions.

Introduction: In recent years, there have been reports about the risk of infection with multidrug-resistant bacteria via duodenoscopes[1], as well as the outbreak of COVID-19, which has brought attention to endoscope-mediated infections. In response, disposable endoscopes have been developed and marketed worldwide.

While there have been several reports on the feasibility of disposable endoscopes for screening or emergency examinations[2,3], there are no reports on the feasibility of Endoscopic Submucosal Dissection (ESD), which requires a variety of operations with different devices.

Aims & Methods: The aim of this study was to compare the performance of disposable and reusable endoscopes in using the ESD training model (G-master, KOTOBUKI Medical), which can simulate various parts of the stomach.

ESD was performed on pseudo lesions (size: 25 mm) at the 6 simulated locations on the ESD training model using the disposable endoscope (Ambu aScope Gastro, Ambu) and the reusable endoscope (GIF-Q260J, Olympus). A total of 24 lesions were treated by 3 ESD beginners (less than 30 ESD experience) and 3 ESD experts (over 300 ESD experience), each performing on 2 locations (4 lesions).

We evaluated procedure time, dissection speed, en bloc resection rate, perforation rate, scope malfunction rate, and number of scope removals during procedure. Additionally, we administered questionnaires to assess the endoscopists' opinions on each scope, including image visibility, manipulate handle operability, tip lens washing function, the ability of device insertion and removal, and scope operability at each site, rated on a scale of 0-5. The evaluations were classified as low (<2), moderate (2<= and <4), and high (4<=).

Results: All procedures were completed using the assigned scopes. The median procedure time was 24.2 min (range, 14.2-36.5) for the disposable endoscopes (Dispo), slightly longer than 19.6 min (range, 13.5-29.5) for the reusable endoscopes (Reuse). The median dissection speed was 20.3 mm^2/min (range, 13.5-34.6) for Dispo and 25.2 mm^2/min (range, 16.7-36.3) for Reuse, and the differences were not significant in both (procedure time: p-value=0.284, dissection speed: p=0.379). In the subgroup analysis, Dispo tended to have slightly longer procedure time than Reuse in beginner group (Dispo: 29.5 min [range, 20.0-36.5], Reuse: 25.2 min[range, 16.3-29.5], p=0.206). On the other hands, in expert group there was almost no difference in treatment time (Dispo: 16.4 min [range, 14.2-25.2], Reuse: 16.6 min [range, 13.5-21.1], p=0.453). The en bloc resection rate was 100%, not only for Reuse but also for Dispo. No cases of perforation or scope malfunction were observed in any of the scopes. For either scope, there were no lesions that required removal of the scope due to wiping the adhesion at the tip lens or any other reasons.

The results of the questionnaires were as follows image visibility: Dispo 2.3±0.9, Reuse 4.0±0.6; manipulate handle operability: Dispo 3.5±0.8, Reuse 4.5±0.5; tip lens washing function: Dispo 3.2±1.1, Reuse 3.8±0.9; the ability of device insertion and removal: Dispo 3.3±0.5, Reuse 3.7±0.5; scope operability (evaluated at each site): Dispo 3.3±0.8, Reuse 3.9±0.5. The scores of all items for Dispo were slightly lower than those for Reuse, particularly in terms of screen visibility and usability, but scored moderately well in all categories.

Conclusion: In the training model, the performance of the disposable endoscope in the ESD procedure was acceptable compared to the reusable endoscope. As a next step, we are planning to conduct clinical research.

A NEW HEMOSTATIC DEVICE COAJET® FOR GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION: RANDOMIZED SINGLE CENTER STUDY

S.U. Kim[1], S.W. Jeon[1]
[1]School of Medicine, Kyungpook National University, Internal Medicine, Daegu, South Korea

Contact E-Mail Address: sw-jeon@daum.net

Introduction: Gastric endoscopic submucosal dissection (ESD) is often accompanied by bleeding. Coajet® is a new useful device for hemostasis through monopolar contact and has an injection needle inside. Therefore, this study was conducted to evaluate the effectiveness and safety of a new hemostatic device comparing to hemostatic forceps.

Aims & Methods: This prospective, randomized, single center study has enrolled consecutive patients who were candidates for gastric ESD from Feb. 2022 to Jan. 2023. The Hemograsper® group (HG) had underwent hemostasis by conventional method and the Coajet® (CG) was used for a marking of lesion, submucosal injection in initial stage of ESD and then for hemostasis.

Results: A total 56 patients were enrolled (HG, n = 28, CG, n =28). Baseline characteristics between the two groups showed no significant difference in terms of age, sex, diagnosis, locations, endoscopic sizes, and morphology. The total operation time(minutes, HG 15.97 ± 6.92 vs. CG 12.36 ± 6.73, p = 0.05) and hemostasis time(seconds, HG 186.6 ± 134.5 vs. CG 130.4 ± 81.49, p = 0.06) were shorter when Coajet® was used compared to Hemograsper®. The procedure related other variables such as complete en bloc resection rate, admission days, grade of immediate bleeding, and delayed bleeding within 30days (HG n=1 vs. CG n=1) showed no difference.

Conclusion: A new hemostatic device Coajet® showed comparable efficacy to conventional hemostatic forceps for bleeding control and prevention of delayed bleeding in gastric ESD. Lesser procedure time with Coajet® would be beneficial to both endoscopists and patients.

Disclosure: Nothing to disclose.

Introduction: Various endoscopic closure procedures including over-the-scope systems and endoscopic hand suturing have been tested in preventing delayed bleeding after endoscopic resection[1]. Conventional procedures are technically difficult with long procedure time[1], which partially explains its limited application in clinical practice.

The novel through-the-scope (TTS) helix and tack suture system has been reported with high success rates and acceptable procedure time using in vivo porcine models along with clinical experience[2,3]. However, past reports have not identified the proficiency rate of the TTS suture system.

Aims & Methods: The objective of this study is to determine the number of cases needed in achieving closure time of literature-based mean closure time. One beginner with less than 400 experiences of upper gastrointestinal endoscopy and one expert with clinical experience of over 500 endoscopic submucosal dissections participated in this study. Both endoscopists were familiarized with the functionality and troubleshooting of the novel TTS suture system via educational videos. Four in vivo porcine models were used to create 24 mucosal defects with diameter of 2-4 cm in the stomach. Each endoscopist were randomly allocated 12 mucosal defects to close with one set of TTS suture system per procedure. The TTS suture system engages four 5 mm helical tacks tethered to a suture thread into the defect margin and approximates the mucosal defect by applying suture tension with a cinch.

The primary outcome was the number of procedures required to achieve closure procedure time below the literature-based mean closure time (7.7 minutes) by inverse curve fitting with nonlinear regression. The secondary outcomes were the success rate of complete closure and the incidence of adverse events. Complete closure was defined as over 90% closure of defect in endoscopy image assessed by two certified endoscopy technicians.

Results: Mean (±SD) size of the mucosal defects was 2.9 (±0.2) cm. Both endoscopists required six cases to achieve a closure time of less than 7.7 minutes. The median closure time was 8.2 (IQR: 5.6-10.1) minutes for the expert and 8.0 (IQR: 6.3-9.4) minutes for the beginner (P = 0.8624). The success rates of complete closure were 75.0% (9/12) for the expert and 83.3% (10/12) for the beginner. Neither endoscopist experienced any adverse events.

	Beginner	Expert
Cases required to achieve closure time below 7.7 min.	6	6
Median closure time	8.2 (IQR:5.6-10.1) min.	8.0 (IQR:6.3-9.4) min.
Complete closure success rate	75.0% (9/12)	83.3% (10/12)
Adverse event rate	0.0% (0/12)	0.0% (0/12)

Conclusion: The novel TTS suture system requires a small number of cases for both expert and beginner to achieve proficiency in endoscopic closure.

Introduction: Fundic gland polyp associated with proton pump inhibitor (PPI-FGP) caused by long-term administration of proton pump inhibitors is known to be larger than normal FGP and have an edematous appearance, however, the endoscopic differentiation from normal FGP is sometimes difficult. Recently, Texture and Color Enhancement Imaging (TXI) has emerged as a novel imaged enhancement technology from Olympus Corporation and is expected to improve the visibility of the lesions by enhancing color tone and structure. The enhancement of color contrast of the mode1 is superior to that of mode2 in accordance with the color enhancement of the mode1 algorithm; however, the naturalness in mode2 is better than that of the mode1[1].

Recently, we previously detected the gray color sign as a novel endoscopic finding that was clearly visible by TXI in the edematous appearance of PPI-FGP, and defined that it was gland duct dilatation below the surface containing mucus and other substances in histopathology.

Aims & Methods: The aim of this study was to evaluate the usefulness of TXI compared with white light imaging (WLI) in the visibility of the gray color sign in PPI-FGP. We enrolled 23 PPI-FGP lesions, endoscopically imaged with WLI, TXI-1, TXI-2, and Narrow Band Imaging (NBI) between April 2021 and October 2022. All PPI-FGP lesions were diagnosed by biopsy specimen histopathologically.

Ten endoscopists (5 trainees, 5 experts) evaluated the images and scored the visibility of the gray color sign in TXI-1, TXI-2, and NBI compared to WLI. Visibility changes were scored by endoscopists as follows: 5, improved; 4,

somewhat improved; 3, equivalent; 2, somewhat decreased; and 1, decreased. For total scores, 40 points or more was considered improved visibility, 21–39 points was comparable to WLI, and a score of less than 20 was considered decreased visibility. Inter-rater reliability was also evaluated using intraclass correlation (ICC). In addition, the color difference (ΔE*) of the gray color sign was calculated using CIELAB (color space system: L* a* b*) defined by Commission internationale de l'éclairage (CIE), and compared between WLI, TXI-1 and TXI-2.

Results: The visibility and ICC scores of TXI-1 and TXI-2 in trainees, experts, and all endoscopists are shown in Table 1. TXI-1 and TXI-2 showed improved visibility of the gray color sign in PPI-FGP for all endoscopists. There was no significant difference in the visibility scores between trainees and experts for both TXI-1 and TXI-2.

Compared with WLI, TXI showed improved visibility; TXI-1 82.6% (19/23), TXI-2 86.9% (20/23). In contrast, NBI showed decreased visibility; 78.2% (18/23). The intra-rater reliability for TXI-1 and TXI-2 were "almost perfect" for trainees and experts. TheΔE* values were 12.0 for WLI, 22.3 for TXI-1, and 25.9 for TXI-2 (WLI vs. TXI-1: p< 0.01, WLI vs. TXI-2: p< 0.01).

In summary, improved visibility of the gray color sign in PPI-FGP was achieved for TXI-1 and TXI-2 compared to WLI for both trainees and experts and inter-rater reliability between trainees and experts was good. The ΔE* values were significantly larger in TXI-1 and TXI-2 compared to WLI.

Gray color sign		All endoscopists (N:10)	Trainees (N:5)	Experts (N:5)	Trainees vs.Experts (P value)
TXI	Mode 1	44.9 ± 4.3	22.7 ± 2.1	22.2 ± 2.3	0.50
	Mode 2	42.9 ± 4.6	21.8 ± 2.4	21.1 ± 2.3	0.32
ICC (2.1)	Mode 1	0.931	0.858	0.864	
	Mode 2	0.927	0.889	0.817	

Table 1.

Conclusion: The usefulness of TXI compared with WLI led to the improved visibility of the gray color sign in PPI-FGP for both trainees and experts when evaluated subjectively and objectively.

INITIAL EXPERIENCES WITH A VACUUM-STENT AS NOVEL TREATMENT OPTION FOR TRANSMURAL DEFECTS IN THE UPPER GASTRO-INTESTINAL TRACT: A SINGLE-CENTER CASE SERIES

L. Pattynama[1,2], W.J. Eshuis[2], M.I. van Berge Henegouwen[2], J.J. Bergman[1], R.E. Pouw[1]

[1]Amsterdam University Medical Centers, Dept. of Gastroenterology and Hepatology, Amsterdam, Netherlands, [2]Amsterdam University Medical Centers, Dept. of Surgery, Amsterdam, Netherlands

Contact E-Mail Address: l.m.pattynama@amsterdamumc.nl

Introduction: Transmural defects in the upper gastro-intestinal (GI) tract, e.g. anastomotic leak, Boerhaave syndrome or iatrogenic defects, are associated with severe morbidity. Treatment options include conservative, surgical and endoscopic modalities. Endoscopic vacuum therapy (EVT) has gained a greater role in endoscopic treatment of these defects and is most often applied using endoscopically placed vacuum-sponges. Recently, a vacuum-stent was introduced as a new device to apply EVT, combining the benefits of negative pressure wound therapy and an intraluminal stent, while allowing for oral intake of a soft diet.

Aims & Methods: The aim of this prospective case series was to describe the first experiences with the vacuum-stent for transmural defects in the upper GI tract, between March 2022 and March 2023, in an academic hospital that had experience with EVT using vacuum-sponges since 2018. All patients treated with a vacuum-stent were included. Patients who were already treated with vacuum-sponge and received a vacuum-stent when it became available were also included.

All patients signed informed consent for prospective registration of relevant data on treatment and outcomes in a specifically designed database. Outcome measures included successful closure of the defect, adverse events, number of EVT-related endoscopies and treatment duration.

Results: 23 patients were included (18 male, median age 65 years). Fourteen patients had anastomotic leakage after esophagectomy, five patients had an iatrogenic perforation and four had Boerhaave syndrome. Twelve patients were treated with vacuum-stent alone and eleven with a combination of vacuum-stent and vacuum-sponge (Table 1), which was mostly due to the later availability of or too little experience with the vacuum-stent.

Three Boerhaave patients also underwent surgery for nettoyage of a large mediastinal cavity with decortication of the lung and placement of an intracavitary muscle flap. Successful defect closure was obtained in 91%, requiring a median of 4 (IQR 3-8) EVT-related endoscopies, and median treatment course of 14 (IQR 12-31) days in successful cases. During median 120 (IQR 15-221) days follow-up, four patients developed an anastomotic stricture treated with endoscopic dilation. No other adverse events were observed.

	Vacuum-stent and vacuum-sponge (n = 11)	Vacuum-stent only (n = 12)
Etiology of defect		
Anastomotic leakage, *n (%)*	10 (91)	4 (33)
Iatrogenic defect, *n (%)*	0 (0)	5 (42)
Boerhaave syndrome, *n (%)*	1 (9)	3 (25)
Defect size*		
Small, *n (%)*	7 (64)	4 (33)
Intermediate, *n (%)*	2 (18)	3 (25)
Large, *n (%)*	2 (18)	5 (42)
Success rate, n *(%)*	9 (82)	12 (100)
EVT-related endoscopies, *median (IQR)*	6 (4-12)	3 (2-4)
Treatment duration in days, *median (IQR)*	21 (14-54)	13 (7-15)

*Defect size was classified in dehiscence of the circumference as small (<10%), intermediate (10-40%) and large (>40%) for anastomotic leak and in defect length as small (<10mm), intermediate (10-19mm) and large (≥ 20mm) for Boerhaave and pneumodilation. Abbreviations: EVT, endoscopic vacuum therapy; IQR, interquartile range.

Table 1. Clinical and outcome characteristics per type of treatment.

Conclusion: The vacuum-stent combines the benefits of EVT and an intraluminal stent and shows great feasibility and efficacy in treatment of transmural defects in the upper GI tract. More research is necessary, as this device could possibly prevent major (re-)surgery in these patients.

LONG-TERM OUTCOMES OF PER-ORAL ENDOSCOPIC MYOTOMY

I. Simao[1], P. Lima[1], A. Mascarenhas[1], R. Mendo[1], P. Barreiro[1,2], C. Chagas[1]
[1]Centro Hospitalar de Lisboa Ocidental, Lisbon, Portugal, [2]Hospital dos Lusíadas de Lisboa, Centro de Endoscopia Avançada de Lisboa, Lisbon, Portugal

Contact E-Mail Address: inesrsimao@gmail.com

Introduction: Per-oral endoscopic myotomy (POEM) is highly effective in the short-term management of achalasia, with recent studies showing durable success.[1,2] The aim of this study was to evaluate long term clinical outcomes of POEM for oesophageal motility disorders, in a tertiary portuguese center.

Aims & Methods: This was a retrospective single center cohort study, from prospective collecting data, of consecutive patients who underwent POEM between January 2017 and February 2021, with a minimum of 24 months follow-up.

Clinical response was defined by an Eckardt score ≤ 3. Gastroesophageal reflux was assessed through clinical interview and endoscopy.

Results: A total of 72 patients underwent POEM with technical success, during the specified study period.

Nine (12.5%) were lost to follow-up before at least 24 months. Of the remaining 63 patients, 57% were female, median age was 54 years (range 17-79) and 41.3% had prior treatments. Indication for intervention was achalasia in 62 patients (type 1, n=18; type 2, n=36; type 3, n=7; one non-specified) and esophagogastric junction outflow obstruction in one, with preoperative median Eckardt score of 6 (range 2-11).

Median follow-up duration was 42 months (range 24-63). Clinical response at one month was achieved in 61 patients (96.8%). Of the patients with initial response, clinical response at last follow-up was 90.2%. In the long term, six patients required additional treatment, with median symptom relapse at 35.5 months (range 12-48).

Two patients underwent re-poem with clinical response. Gastroesophageal reflux symptoms were reported in 27.9%, with 68.9% maintaining daily proton pump inhibitor therapy at last follow-up. Endoscopic evaluation was performed in 46 patients, showing reflux esophagitis in 22.

Conclusion: POEM is an effective therapy for achalasia, with durable success rate and possible reintervention in case of relapse. Gastroesophageal reflux is a common late adverse event. Studies with longer follow-up are needed to determine long term effectiveness and reflux exposure risk.

RESECTION OF SUPERFICIAL GASTRIC NEOPLASMS BY ENDOSCOPIC SUBMUCOSAL DISSECTION: 8-YEAR EXPERIENCE AT A TERTIARY CENTER

M.M. Estevinho[1], R. Pinho[1], J. Rodrigues[1], J.C. Silva[1], J.P. Laranjeira Correia[1], P.F. da Silva Mesquita[1], T. Freitas[1]
[1]Centro Hospitalar Vila Nova de Gaia Espinho, Vila Nova de Gaia, Gastrenterology, Porto, Portugal

Contact E-Mail Address: mmestevinho@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is increasingly being used as a minimally invasive treatment option for early gastric cancer (EGC), with a very low risk of lymph node metastasis.

Aims & Methods: This study aimed to evaluate the short-, medium-, and long-term clinical outcomes of patients undergoing gastric ESD at a tertiary hospital center. Patients undergoing ESD for superficial gastric lesions (SGLs) between September 2015 and January 2023 were prospectively evaluated. Demographic, clinical (comorbidities, medication, and relevant family history), endoscopic (location, size, and morphology of the lesion, resection scar evaluation), and pathological data (from the resected specimen, mapping biopsies, and scar biopsies) were collected.

Results: Since 2015, 195 patients with SGLs (mean age 70.7±9.8 years, 58.6% male) underwent ESD, with a median follow-up time of 28 months (interquartile range 13-54). Most patients presented with intestinal metaplasia only in the antrum (n=72) or in the antrum and corpus (n=60), and the most frequent location of SGLs was the antrum (64.6%). Resection was R0 in 95.4% of cases and curative in 87.7% (only one non-curative case had no free horizontal margins).

During the follow-up period, 15 metachronous lesions and 8 recurrences were identified, on average 24.1±3.4 months after the index procedure. It should be noted that most recurrences (n=5) were identified at the 36- and 48-month reevaluation endoscopies. The complication rate was 3.6%, corresponding to 3 intra-procedural perforations (2 treated endoscopically) and 4 cases of significant bleeding after the procedure were registered.

Conclusion: Endoscopic submucosal dissection is safe and effective, with a high cure rate and low complication and recurrence rates. The identification of mostly late recurrences suggests the need to develop risk assessment tools that allow for defining personalized follow-up intervals.

Disclosure: Nothing to disclose.

PP0224

SALVAGE SURGERY AFTER NON-CURATIVE GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION - CASE REVIEW AND EVALUATION OF PREDICTORS OF DISEASE PERSISTENCE

M.M. Estevinho[1], R. Pinho[1], J. Rodrigues[1], J.C. Silva[1], J.P. Laranjeira Correia[1], P.F. da Silva Mesquita[1], T. Freitas[1]
[1]Centro Hospitalar Vila Nova de Gaia Espinho, Vila Nova de Gaia, Gastrenterology, Porto, Portugal

Contact E-Mail Address: mmestevinho@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is the preferred method for the treatment of superficial gastric neoplasms. In cases of curative resection, the outcome is excellent with recurrence rates of less than 5% and disease-free survival rates greater than 95%. However, surgical resection is indicated in cases of non-curative resection, although recent studies suggest that this strategy may have an unfavorable risk/benefit ratio.

Aims & Methods: The aim of this study is to analyze the evolution of patients with non-curative resection in our center. Patients who did not meet the criteria for cure after ESD of superficial gastric neoplasms were pro-

spectively evaluated. Clinical (before and after ESD), endoscopic (location, size, and morphology of the lesion), pathological (tumor size, degree of dysplasia, vertical and horizontal margins, vascular, lymphatic, and perineural invasion), and surgical (type of intervention, pathological characteristics of the specimen) data were collected and analyzed.

Results: Of the 203 patients who underwent ESD of upper digestive tract lesions, 20 patients with non-curative resection of gastric neoplasms were identified (median age 70 years, 65% of whom female). The mean size of the lesions was 20 ± 9 mm, and 40% were depressed (Paris Classification 0-IIa+c [n = 6] and 0-IIb+c [n = 2]). Resection was R1 in five cases, nine had submucosal invasion greater than 500µm, nine had lymphatic invasion, and four had vascular invasion.

Of these, 15 patients underwent surgical resection (75%), mostly partial gastrectomy (n = 12). In the remaining cases, surveillance (n = 3) or pending multidisciplinary discussion (n = 2) was opted for. Pathological evaluation revealed a "white" specimen in 10 cases (2/3). The clinical characteristics and histological data of the ESD specimen (including the eCura score [Hatta et al., 2017]) were not statistically different in patients with and without residual neoplasia in the operative specimen (p>0.05).

Conclusion: Despite the small sample size, this series suggests the need to identify better predictors of "clinically significant non-curative resection," in which disease persistence after ESD is more likely.

Introduction: Recently, red dichromatic imaging (RDI), a novel image-enhanced endoscopy, which comprises wavelengths of amber (600 nm), red (630 nm) and green (540 nm), was launched. Previous studies have indicated that RDI improved the visibility of gastrointestinal bleeding. However, visibility assessments have been based on the subjective decision of evaluators. Herein, we investigated the recognition of bleeding points during endoscopic submucosal dissection (ESD) under RDI compared with that under white light imaging (WLI).

Aims & Methods: Consecutive patients scheduled to undergo esophageal or gastric ESD at a single center were enrolled. Paired videos of active bleeding during ESD under both WLI and RDI were created. Six endoscopists identified the virtual hemostasis point on still images after random video viewing. The distance between the virtual hemostasis and actual bleeding points was scored in four levels (0–3 points), and the association with the color value was analyzed in both WLI and RDI.

Results: We retrospectively evaluated 116 videos for 58 bleeding points. The median visibility score and recognition rate for RDI were significantly higher than those for WLI (2.17 vs. 1.42, p<0.001 and 62.1% vs 27.6%, p<0.001). The median visibility scores were significantly higher for RDI than for WLI under blood pooling (2.00 vs. 1.00, p<0.0016) and no blood pooling (2.50 vs. 1.67, p<0.001). The median visibility scores for RDI were significantly higher than those for WLI in oozing hemorrhage (2.17 vs. 1.33, p<0.001) and pulsating hemorrhage (2.17 vs. 1.50, p=0.030). The median visibility scores in RDI were significantly higher than those in WLI between trainees (2.00 vs. 1.33, p<0.001) and experts (2.67 vs. 1.67, p<0.001). The median color difference of RDI was significantly higher than that of WLI (8.97 vs. 3.69, p<0.001). The correlation coefficient between the visibility score and color difference was 0.712 (strong correlation).

Conclusion: RDI can provide better recognition of bleeding points than WLI during ESD, regardless of the bleeding pattern and experience of the endoscopist. Further studies are warranted to investigate whether RDI improves ESD outcomes.

Disclosure: Nothing to disclose.

A SYSTEMATIC REVIEW OF RADIOGRAPHIC AND ENDOSCOPIC SCREENING FOR GASTRIC CANCER

C. Hamashima[1], M. Hibino[2], T. Terasawa[2]

[1]Teikyo University, Tokyo, Japan, [2]Fujita Health University, Toyoake, Japan

Contact E-Mail Address: chamashi@med.teikyo-u.ac.jp

Introduction: Gastric Cancer has been a heavy burden in far East Asian countries. Although there are national programs in South Korea and Japan, their evidence has been suggested as insufficient. We aimed to synthesize currently available comparative data on gastric cancer mortality in healthy, asymptomatic adults by explicitly classifying the screening effects through study designs and types of intervention effects.

Aims & Methods: We searched multiple databases through October 31, 2022, for this systematic review and meta-analysis.

Studies of any design that compared gastric cancer mortality among radiographic or endoscopic screening and no screening in a community-dwelling adult population was included. The method included a duplicate assessment of eligibility, double extraction of summary data, and validity assessment using the Risk Of Bias In Non-randomized Studies of Interventions tool. Bayesian three-level hierarchical random-effects meta-analysis synthesized data corrected for self-selection bias on the relative risk (RR) for per-protocol (PP) and intention-to-screening (ITS) effects. The study registration number at PROSPERO is CRD42021277126.

Results: We included seven studies in which a screening program was newly introduced (median attendance rate, 31%; at a moderate-to-critical risk of bias) and seven cohort and eight case-control studies with ongoing screening programs (median attendance rate, 21%; all at critical risk of bias); thus, data of 1,667,117 subjects were included. For the PP effect, the average risk reduction was significant for endoscopy (RR 0.58; 95% credible interval: 0.39–0.90) but non-significant for radiography (RR 0.80; 95%CI 0.60–1.06). The ITS effect was not significant for both radiography (0.98; 95%CI 0.86–1.21) and endoscopy (RR 0.94; 95%CI 0.74–1.44). The effects' magnitude depended on the self-selection bias correction assumptions. Restricting the scope of East Asian studies only did not change the results.

Conclusion: In limited-quality observational evidence from high-prevalence regions, screening reduced gastric cancer mortality; however, the effects diminished at a program level.

Disclosure: Nothing to disclose.

Introduction: The prevalence of *Helicobacter pylori* (*H.pylori*) positive patients has gradually decreased in Japan due to eradication therapy, and *H.pylori*-uninfected gastric cancer (HPUGC) is expected to increase relatively. Recently, HPUGC, such as gastric adenocarcinoma of fundic-gland type (GAFG), gastric adenocarcinoma of foveolar-type (GAFV), adenocarcinoma of differentiated type (DGA) and signet ring cell carcinoma (SRCC) has been increasingly reported. Since the detection and endoscopic diagnosis of HPUGC is considered to be difficult [1]. The effective observation methods in screening endoscopy to detect HPUGC. In this context, a new image enhancement technology called Texture and Color Enhancement Imaging (TXI; Olympus Medical Systems Corporation) which optimizes the three elements: structure (texture) enhancement, color tone, and brightness correction was developed in 2020. There have been several reports on the usefulness of TXI for the detection and endoscopic diagnosis of mucosal atrophy or gastric neoplasm [2-6]. However, the usefulness of TXI for the detection of HPUGC has been investigated.

Aims & Methods: The aim of the study is to investigate whether the visibility of HPUGC improved using TXI and NBI compared with WLI as a single-center retrospective clinical study. We enrolled 40 HPUGC lesions endoscopically imaged with WLI, TXI-1, TXI-2, and NBI in our facility between October 2020 and March 2023. In addition, the visibility of HPUGCs was analyzed for each factor, such as histological type, coloration, and macroscopic type. Ten endoscopists (5 experts and 5 non-experts) evaluated the images, and visibility changes were scored by endoscopists as follows: 5, improved; 4, somewhat improved; 3, equivalent; 2, somewhat decreased; and 1, decreased. The total visibility score of ≥40 in all endoscopists and /≥20 in each of the 5 endoscopists was defined as improved visibility, 21-39/11-19 as unchanged visibility, and 20≤/10≤ as decreased visibility. The intraclass correlation coefficients (ICC) were calculated and evaluated for inter-rater agreement.

Results: The histological types were classified as GAFG (n=24), GAFV (n=9), DGA (n=4), and SRCC (n=3). There were 17 reddish lesions and 23 whitish lesions. In the macroscopic type, there were type 0-I (n=11), type 0-IIa (n=13), type 0-IIb (n=11), and type 0-IIc (n=5) lesions. The visibility improvement rate for all endoscopists in all HPUGCs was TXI-1: 55%, TXI-2: 29.7%, and NBI: 7.5%. The overall ICCs were TXI-1: 0.86, TXI-2: 0.84, and NBI: 0.90, which were almost perfect. GAFG (all/experts/trainees: 79/54/79%) and SRCC (all/experts/trainees: 67/67/67%) showed improved visibility with TXI-1. In contrast, GAFV and DGA did not improve the visibility. The whitish lesions (all/experts/trainees: 74/52/74%) showed improved the visibility with TXI-1, but the reddish lesions did not improve visibility. Among the macroscopic type , type 0-Ia (overall/experts/trainees: 85/54/85%) and type 0-Ib (overall/experts/trainees: 73/64/73%) showed improved visibility with TXI-1. The all ICCs of each factor were above 0.7, which indicated generally good correlations.

Conclusion: The usefulness of TXI-1 compared with WLI led to the improved visibility of the whitish lesions such as GAFG and SRCC for both experts and trainees when evaluated subjectively and objectively.

Introduction: Buried bumper syndrome (BBS) is a rare complication of percutaneous endoscopic gastrostomy (PEG) tubes. This study compared a newly developed Flamiongo set with conventional endoscopic techniques [A1] for BBS treatment.

Aims & Methods: This prospective, randomized controlled trial compared the Flamingo set (study group) with other endoscopic techniques (control group) for BBS treatment in nine German hospitals.

The primary endpoint was procedure time. Further outcome parameters were technical success, complication rate, and number and cost of devices used in each group.

Results: Thirty-six patients (18 in each group; mean age, 73 years; 12 females) were included in this study between xx and December, 2022. Median time since the placement of the feeding tube was 30 months.

The bumper was located in the gastric corpus in 27 patients, and the internal bumper was completely overgrown in 31 patients. The removal procedure duration was 17 min (range: 3–72 min) in the study group compared to 38 min (range: 12–111 min) in the control group (P = .046).

Primary technical success rate was 77.8% in the study group and 55.6% in the control group (P = .157), while the overall technical success rate was 100% compared to 83.3% (P = .070). Adverse events occurred in four patients (11.1 %).

Conclusion: Endoscopic removal of the buried bumper using the Flamingo device was significantly faster than that with other endoscopic techniques and showed a higher technical success. This device may become the endoscopic treatment of choice for BBS.

Disclosure: The Department of Internal Medicine and Gastroenterology, Hospital Ludwigsburg, received a research grant from FUJIFILM Medwork GmbH (Höchstadt, Germany). The company also provided the Flamingo sets used in this study free of charge.

THE IMPACTS OF SEDATION ON CARDIO-CEREBROVASCULAR ADVERSE EVENTS AFTER SURVEILLANCE ESOPHAGOGASTRODUODENOSCOPY IN PATIENTS WITH GASTRIC CANCER: A NATIONWIDE POPULATION-BASED COHORT STUDY

J.K. Lee[1]

[1]*Dongguk University Ilsan Hospital, Internal Medicine, Goyang, South Korea*

Contact E-Mail Address: jeromee1971@daum.net

Introduction: There is limited data on the impact of sedation on cardio-cerebrovascular disease (CCD) adverse events after esophagogastroduodenoscopy (EGD) in patients with gastric cancer. We investigated the incidence rate, risk factors and the impact of sedation on CCD adverse events after surveillance EGD in patients with gastric cancer.

Aims & Methods: We performed a nationwide population-based cohort study using Health Insurance Review and Assessment Service databases from January 1, 2018 to December 31, 2020. Using a propensity score-matched analysis, the patients with gastric cancer were divided into two groups: sedative agent users and non-users for surveillance EGD. We compared the occurrence of 14-day CCD adverse events between the two groups.

Results: Of 103,463 patients with gastric cancer, newly diagnosed CCD adverse events occurred in 2.57% within 14 days after surveillance EGD. Sedative agent was used in 41.3% during the EGD. The incidence rate of CCD adverse events with non-sedation and sedation are 315.4/10,000 and 173.6/10,000, respectively. Propensity score matching based on confounding variables yielded 56,016 matched patients (28,008 pairs). Between sedative agent users and non-users, there were not significantly difference in the occurrence of 14-day CCD adverse events, cardiac adverse events, cerebral adverse events, and other vascular adverse events, respectively. (2.28% vs. 2.22%, $P = 0.69$; 0.86% vs. 0.93%, $P = 0.42$; 1.44% vs. 1.31%, $P = 0.23$; 0.74% vs. 0.84%, $P = 0.20$).

Conclusion: In a population-based, matched cohort study, sedation during surveillance EGD was not associated with CCD adverse events in patients with gastric cancer. These findings suggest that use of sedative agent may be considered in patients with gastric cancer during surveillance EGD without excessive concerns for CCD adverse events.

NATURAL HISTORY, MANAGEMENT, EFFICACY AND OUTCOMES IN ESOPHAGEAL FOOD BOLUS OBSTRUCTION

S. Carlson[1], D. Abeywickrama[2], A. Nguyen[2], A. Bloom[2], A. Morgan[1], I. Cavalieri[2], A. Doran[2], B. Sarraf[2], J. Abdelmalak[2], M. Suen[2], T. Greeve[1], M. Robertson[1]

[1]*Monash Medical Centre, Gastroenterology, Clayton, Australia,* [2]*Monash Medical Centre, Clayton, Australia*

Contact E-Mail Address: andrew.nguyen2@monashhealth.org

Introduction: Esophageal food bolus obstruction (FBO) is a common presentation to Emergency Departments worldwide[1]. There remains a paucity of data relating to efficacy of pre-endoscopic and endoscopic management resulting in a wide variety of clinical practice. Consensus guidelines do not advocate strongly for pre-endoscopic medications however they remain commonly used[2,3].

This study evaluated the safety and efficacy of pre-endoscopic and endoscopic treatment in successful clearance of FBO and assessed the prevalence of underlying esophageal pathology.

Aims & Methods: ICD-10 codes retrospectively identified adult patients ≥18 years admitted to the Monash Health network (Melbourne, Australia) with esophageal FBO from 2010 to 2021. Medical records were reviewed to determine baseline characteristics, medical and endoscopic treatments and outcomes. Pre-endoscopic therapies included glucagon, glyceryl trinitrate (GTN), buscopan and Coca Cola. Multivariable analysis was performed to determine factors associated with pre-endoscopic clearance of FBO.

Results: 608 patients were included. The median age was 56 years (IQR 39 – 71) and 405 (66.6%) were male. A prior history of FBO was noted in 228 (37.5%) patients, 110 (18.1%) had gastro-oesophageal reflux disease, 71 (11.7%) had dysphagia and 51 (8.4%) had a history of esophageal strictures. Inability to swallow saliva was noted in 296 (49.7%) patients at presentation.

Pre-endoscopic therapy was administered to 389 (64.0%) patients with a mean of 2 medications prescribed. Glucagon (47.4%), GTN (37.2%) and Coca Cola (36.3%) were most commonly administered. Successful FBO clearance was documented in 36.8% patients receiving medical therapy (glucagon 35.1%, GTN 36.2%, Coca Cola 38.0%); no individual medication significantly reduced the need for endoscopic intervention. Multi-variable analysis demonstrated that tolerating saliva (OR 1.95, p=0.025) and liquids (OR 2.28, p=0.001) significantly predicted spontaneous resolution of the EFBO without endoscopy.

474 (78.0%) patients proceeded to endoscopy. Median time to endoscopy was 14 hours (IQR 6 – 16) with 36.1% patients intubated for the procedure. The FBO was most commonly located in the lower esophagus (32.7%). The most common endoscopic findings were esophagitis (30.2%) and peptic ulcer disease (18.8%), with 3 (0.6%) malignancies identified. Endoscopic complications occurred in 35 (7.4%) patients (partial esophageal tear (n=24), aspiration pneumonia (n=5)). At endoscopy, a cause for the FBO was found in 130 (27.4%) patients, most commonly due to esophageal strictures (13.9%), eosinophilic esophagitis (11.2%) and Schatzki rings (9.1%). Esophageal biopsies were taken in 155 (32.7%) patients, of which 34.2% reached the diagnostic criteria for eosinophilic esophagitis.

Conclusion: Despite limited evidence, pre-endoscopic medical treatment of FBO is safe, commonly utilised, and results in spontaneous clearance in 36.8% patients. Patients' clinical symptoms, in particular the ability to tolerate saliva or liquids, is the best predictor for spontaneous FBO clearance. Endoscopy remains highly effective and has a low complication rate.

Contact E-Mail Address: tmitsui@east.ncc.go.jp
Introduction: Gastric endoscopic submucosal dissection (ESD) has become increasingly popular worldwide as a less invasive curative treatment for early gastric cancer. However, ESD requires highly endoscopic technical skills, and it is important for trainees to develop effective training methods for ESD. ESD training is generally conducted using extracted porcine digestive tracts, but there are several issues regarding ethics, costs, infection, and logistics. In collaboration with KOTOBUKI Medical, we have developed the G-Master, a training model that can simulate ESD in several locations in the stomach. Since G-Master uses plant-derived mucous membrane sheet, there is no contamination and training can be easily performed using endoscope units and devices that are commonly used in clinical practice.

Although the G-Master has enabled pre-training before actual ESD at facilities that have adopted it, it is unclear whether it contributes to the improvement of endoscopic technical skills of trainees. In this study, we clarified the usefulness of the G-Master training for inexperienced ESD trainees.

Aims & Methods: The ESD data were collected for the first through fifth gastric ESD cases performed from March 2018 through February 2022 by 15 ESD-inexperienced endoscopists at five participating centers. The ESD data were divided into two groups, one with G-Master training and one without G-Master training and the endpoints were compared retrospectively. The endpoints were procedure speed, perforation rate, operator changing rate, and en bloc resection rate, endoscopists experiences, and clinicopathological features. The resection speed was calculated as the resected area of the specimen divided by the procedure time (mm2/min). The group with G-Master training was defined as the group of trainees who always had at least one ESD training session with G-Master before each ESD. The group without G-Master training was defined as the group of trainees who had never done G-Master ESD training.

Results: A total of 75 gastric ESD cases were enrolled, with 25 cases in the group with G-Master training performed by 5 ESD-inexperienced endoscopists and 50 cases in the group without G-Master training performed by 10 ESD-inexperienced endoscopists. There was no difference between the two groups in endoscopists experiences including the years after graduation from medical school, the number of esophagogastroduodenoscopies and colonoscopies performed, and clinical features of gastric ESD cases including the location or size. In the group with G-Master training, the median procedure speed for all cases was significantly faster (with vs without G-Master: 13.1 mm2/min vs. 8.1 mm2/min, p>0.001). And the procedure speed of the training group was linearly improved from the initial to the last cases (with vs without G-Master: initial case; 11.8 mm2/min vs 8.5 mm2/min, last case; 23.1 mm2/min vs 12.0 mm2/min).

Additionally, the rates of perforation (0 case (0%) vs 1 case (2%)) and operator change to expert (5 cases (20%) vs 15 cases (30%)) were lower. There was no difference in en bloc resection rate between the two groups.

Conclusion: It was suggested that performing G-Master training before actual ESD could improve the endoscopic technical skills of trainees who are inexperienced in ESD.

Disclosure: Nothing to disclose.

PP0232

COMPARISON OF LONG-TERM EFFICACY AFTER ENDOSCOPIC NON-CURATIVE RESECTION OF T1 ESOPHAGEAL SQUAMOUS CELL CARCINOMA

K. He[1], W. Liu[1], Y. Gu[1], Z. Fan[1], L. Liu[1]
[1]The First Affiliated Hospital of Nanjing Medical University, Digestive Endoscopy, Nanjing, China

Contact E-Mail Address: 1364282728@qq.com
Introduction: Endoscopic resection has been widely applied in T1 esophageal squamous cell carcinoma. However, for cases of postoperative pathology with noncurative resection, additional surgery or chemoradiotherapy is often required due to the high risk of lymph node metastasis and recurrence. However, quite a few patients refuse additional treatment for various reasons.

At present, it is unclear whether additional surgery or chemoradiotherapy, or close observation without additional treatment, should be applied to T1 esophageal squamous cell carcinoma with noncurative endoscopic resection.

Aims & Methods: This study aimed to compare the long-term efficacy of the different strategies. We retrospectively analyzed 121 patients with endoscopic noncurative resection of T1 esophageal squamous cell carcinoma from Jan 2012 to Dec 2018. Noncurative resection was defined as positive horizontal or vertical incisional margin, lymphovascular invasion, poorly differentiated or undifferentiated pathology, and invasion depth of submucosa and above. The rate of lymph node metastasis, recurrence rate and long-term survival rate were compared in the three groups of additional surgery, chemoradiotherapy and close observation without additional treatment.

Results: Among the 121 patients, 40 patients received radical resection of esophageal cancer, 35 patients received chemoradiotherapy, 46 patients chose close observation without any additional treatments. There was no significance among the three groups in age, sex, underlying disease score, tumor size, lymphatic vascular invasion, horizontal and vertical incisal margins, and low differentiation degree. After follow-up, it was found that the rate of lymph node metastasis in the group with no additional treatment was significantly higher than that in the group with additional treatment (26.1% vs. 10% in the observation group and the surgery group, P=0.05, 26.1% vs. 8.57% in the observation group and the chemoradiotherapy group, P=0.04).

Besides, the recurrence rate of the lesion in the group without additional treatment was significantly higher than that in the group with additional treatment (30.4% and 12.5% in the observation group and surgery group, P=0.03, 30.4% and 11.4% in the observation group and chemoradiotherapy group, P=0.03).

In addition, the 5-year overall survival rate exerted significantly higher in the groups with additional treatment than that of the close observation group (73.9%, 90% and 91.4% in the observation, surgery and chemoradiotherapy groups, respectively, P=0.04). The 5-year disease-specific survival rate was inferior in the group without additional treatment than the surgery and chemoradiotherapy groups (P=0.047). However, there were no significances in recurrence rate, lymph node metastasis, 5-year overall survival rate and disease-specific survival rate between the surgery and chemoradiotherapy groups.

Conclusion: Additional surgery and chemoradiotherapy can improve the long-term survival rate of patients with T1 esophageal squamous cell carcinoma with noncurative endoscopic resection. Taking postoperative adverse events and organ integrity into consideration, additional chemoradiotherapy might be a safe and effective alternative.

Disclosure: Nothing to disclose.

PP0233

IS THE ECURA SYSTEM (RISK SCORING SYSTEM TO STRATIFY CURABILITY AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION) USEFUL TO ESTIMATE CANCER-SPECIFIC SURVIVAL AFTER NON-CURATIVE ENDOSCOPIC SUBMUCOSAL DISSECTION OF EARLY GASTRIC CANCER?

N. Botke[1], M. Ławniczak[1], K. Karpińska-Łukaszewicz[2], A. Białek[1]
[1]Pomeranian Medical University in Szczecin, Department of Gastroenterology, Szczecin, Poland, [2]Pomeranian Medical University in Szczecin, Department of Pathomorphology, Szczecin, Poland

Contact E-Mail Address: nataliabotke@poczta.onet.eu

Introduction: According to the current guidelines the endoscopic submucosal dissection (ESD) is considered as effective treatment of choice of early gastric cancer (EGC). The most current criteria for the curative treatment include one piece (en bloc) resection of mucosal or submucosal membrane ≤500 µm with free lateral and vertical margins and lack of the limfoangioinvasion. The gold standard of treatment for patients who do not meet the curative criteria (non-R0) after ESD is additional gastrectomy. Recently, in the medical literature, there have been reports on the good prognosis of patients after non-curative endoscopic resection of early gastric cancer. In the non-R0 ESD group, eCura system developed by Japanese scientists, which allows to estimate the probable risk of lymph node metastases and the probable cancer-specific survival, may support the decision on the choice of treatment method. The effectiveness of eCura system and the follow-up for patients after non-curative ESD who did not receive radical surgery was not extensively investigated.

Aims & Methods: To investigate follow-up of patients with EGC after non-curative endoscopic submucosal dissection according to the eCura system.

The retrospective analysis of prospective assessed database of ESD procedure for EGC, from 2008 to 2020 in Department of Gastroenterology of Pomeranian Medical University Hospital in Szczecin was performed. The follow-up examinations (gastroscopy, abdominal ultrasound or CT) were performed after 3,12 and 36 months from the date of ESD. Based on the dates of the last follow-up and the incidence of deaths due to general causes and cancer-specific deaths, survival in the study group was assessed.

Results: In 102 patients with EGC (M=63, 61.8%, mean age 67.0 +/- 12 years), 106 ESD procedures were performed (in 4 patients endoscopic resection of two synchronous gastric lesions was performed). In the study group 67 patients (65.7%), 70 lesions (66.0%) were removed with the curative criteria (R0 group), 35 patients (34.5%) 36 lesions (34.0%) remained beyond the criteria for curative resection (non-R0 group). In the non-R0 group (n=35; 34.3%; mean age 70.2 +/- 11.1) initially 6 patients underwent additional surgical treatment, 26 patients were followed-up without surgery because of lack of consent or poor general condition, 3 patients were lost from follow-up. In the study group, patients were qualified only into groups with a low and medium risk of metastasis to lymph nodes according to the eCura system.

There was no significant difference (p>0.05) in the rates of deaths due to general causes and cancer-specific deaths in the group of patients after non-R0 ESD who underwent additional gastrectomy and were subject only to close oncological follow-up, as well as in the rates of cancer-specific deaths between patients after non-curative ESD who were classified into groups with a low and medium risk of metastasis to lymph nodes according to the eCura system (p>0.05). There was a significant difference (p=0.02) between general and cancer-specific deaths in the non-R0 group (25.9% vs 3.7%). No patient in the study group had metastases to lymph nodes or distant metastases.

Conclusion: In the group of patients with early gastric cancer after non-curative endoscopic submucosal dissection (non-R0 ESD), who remain at low risk of lymph node metastases group according to the eCura system, only close observation may be an acceptable option without radical surgical treatment.

Disclosure: Nothing to disclose.

DOES THE WEEKEND HAVE AN IMPACT ON THE COURSE OF NON-VARICEAL BLEEDING?

S. Riahi[1], M. Ayari[1], S. Zaouga[1], I. Abdelaali[1], T. Jomni[1], M.H. Douggui[1]
[1]Internal Security Forces Hospital La Marsa, Gastroenterology, Tunis, Tunisia

Contact E-Mail Address: ayari.myriam@hotmail.fr

Introduction: Gastrointestinal bleeding is a life-threatening emergency associated with high morbidity and mortality requiring close monitoring and early endoscopic intervention to diagnose and treat the bleeding. The “weekend effect“ often leads to concerns of delay or inappropriate management due to the usual lack of medical and paramedical staff and suggesting an additional risk and increased mortality.

Aims & Methods: The aim of our study was to investigate outcomes of non-variceal bleeding (NVB) occurring during the week-end. We conducted a retrospective, single-center analysis of clinical and endoscopic data of all patient hospitalized for NVB between 2015 and 2023 from our hospital’s computerised medical record database. Data over timing of endoscopy, therapeutic management, hospital stay and mortality were collected depending on whether the digestive bleeding occurred at the weekend (G1) or during the week (G2).

Results: A total of 91 patients were enrolled: 58 men and 33 women with a sex ratio of 1.75 and an average age of 63.9 (20-91). The two groups were comparable in terms of the mean time taken to perform upper GI endoscopy (G1:11.9 hours vs G2:15.9 hours, p=0.06) or a colonoscopy (G1:39.94 hours vs G2:49.15 hours, p=0.11).

However, there was a slight increase in the need for an endoscopic haemostasis procedures in the weekend group p=0.05. Nevertheless, there was no significant difference between the two groups in terms of total length of hospital stay (G1:7.19 days vs. G2:7.54 days, p=0.65), transfusion requirements for red blood cells (RBCs) (G1: 3,33 vs. G2:2.3, p=0.07) and the use of catecholamines to maintain an optimal hemodynamic state (p=0.51). In addition, there was no significant difference regrading overall mortality between the weekend and the weekday groups (G1: 5% vs G2:12.9% respectively, p=0.25).

Conclusion: There is no evidence of the "weekend effect" in our study, as the clinical management and outcomes were independent of the day of admission with no subsequent increase of mortality during NVB. This reflects a continuous development and a better access to interventional endoscopy, and a multidisciplinary collaboration overcoming the logistical and technical difficulties often encountered during the weekend.
Disclosure: Nothing to disclose.

PP0235

TIMING OF UPPER GASTROINTESTINAL ENDOSCOPY AND ITS RELATIONSHIP WITH ENDOSCOPIC FINDINGS IN PATIENTS WITH ACUTE UPPER GASTROINTESTINAL BLEEDING: A PROSPECTIVE COHORT STUDY

Z. Aljarad[1], B.B. Mobaed[1]
[1]*Aleppo University Hospital, Gastroenterology, Aleppo, Syria*

Contact E-Mail Address: dr.ziad-aljarad@hotmail.com
Introduction: The timing of performing upper gastrointestinal endoscopy (EGD) in patients with acute upper GI bleeding remains controversial. Different recommendations exist regarding the ideal time interval between the first clinical presentation of acute upper GI bleeding and EGD, assuming no postponement before patient arrival at the hospital.
While it is generally agreed that upper gastrointestinal endoscopy should be performed within 24 hours of the first clinical presentation of acute upper GI bleeding, this recommendation poses a significant challenge for medical staff during weekends and healthcare centres with fewer resources than major hospitals.
Aims & Methods: This study was conducted at the Department of Internal Medicine, Gastroenterology Division, at Aleppo University Hospital between July 2018 and June 2020. The study included patients who were admitted due to acute upper gastrointestinal bleeding. The clinical manifestation of upper gastrointestinal bleeding, its duration, and the interval between the first upper gastrointestinal bleeding and the GI endoscopy were determined.
Patients were divided into three groups: Group I underwent urgent endoscopy within less than 24 hours of the first bleeding; Group II underwent endoscopy between 24 and 72 hours from the first bleeding; and Group III underwent endoscopy after 72 hours or more of bleeding.
Results: 234 patients were included in the study who were admitted to the hospital and underwent upper gastrointestinal endoscopy. Among them, 58.55% were male and 41.45% were female. The average age of the patients was 57.15.
The most common manifestation of acute upper gastrointestinal bleeding was melena, which was observed in 67.59% of cases, followed by hematemesis (52.99%) and epigastric pain (30.34%). The rate of normal esophageal endoscopy findings was 40% in the first group, 54.84% in the second group, and 64.4% in the third group. Hiatal hernia was observed in 30.77% of patients in the first group, 29.03% in the second group, and 28.89% in the third group. Reflux esophagitis was diagnosed in 10.77% of patients in the first group, 10.48% in the second group, and 20% in the third group. Esophageal varices were diagnosed in 10.77% of patients in the first group, 9.68% in the second group, and 13.33% in the third group. There was no statistically significant difference in the rates of esophageal endoscopy findings among the study groups, except for the presence of blood-filled esophagus, which was significantly more common in the first group ($P < 0.05$). The highest rate of normal findings in upper gastrointestinal endoscopy was observed in the third group, which was statistically significant ($P < 0.05$). Blood in the stomach and erosive gastritis were most frequently observed in the first group, with a statistically significant difference in their favor.
The rates of observing gastric ulcers, gastric erosions, hypertensive gastropathy, gastric varices, gastric tumors, portal hypertensive gastropathy, and diffuse mucosal bleeding were similar among the three study groups without a significant statistical difference . The upper gastrointestinal endoscopy was normal in the duodenum in the highest percentage among patients in group three, with a statistically significant difference ($P < 0.05$). Blood in the duodenum and duodenal edema were observed with the highest rate in patients of the first group with a statistically significant difference compared to the other two groups ($P < 0.05$). The evaluation of the duodenum among patients of the first group could not be achieved with a higher rate compared to the other two groups, and the statistical difference was significant.
The percentage of observing esophageal ulcers, esophageal biopsies, adherent thrombus, and vascular distortion were similar among the three groups without a significant statistical difference ($P > 0.05$). The cause of bleeding was identified with certainty by visualizing the bleeding lesion in 32.31% of patients in the first group, 9.68% of patients in the second group, and 4.44% of patients in the third group. There was a statistically significant difference between the groups in favor of the first group.
Conclusion: Our research revealed no significant variance in endoscopic results in patients who underwent endoscopy at distinct time intervals. However, performing early endoscopy, within 24 hours of the first clinical presentation of acute upper GI bleeding, had a higher incidence of detecting the bleeding lesion and identifying the cause of bleeding in comparison to delayed endoscopy.
Our study emphasizes the significance of early endoscopy in patients with acute upper GI bleeding to enhance the possibility of identifying the cause of bleeding and administering timely interventions to minimize complications and mortality.

FEASIBILITY OF ENDOSCOPIC RESECTION FOR LOCAL FAILURE AND METACHRONOUS LESIONS AFTER CHEMORADIOTHERAPY OR RADIOTHERAPY FOR LARYNGOPHARYNGEAL CANCER

H. Ashizawa[1], Y. Yamamoto[1], T. Mukaigawa[2], N. Kawata[1], Y. Maeda[1], M. Yoshida[1], T. Minamide[1], K. Hotta[1], S. Ito[1], K. Imai[1], Y. Kishida[1], K. Takada[1], J. Sato[1], H. Ishiwatari[1], H. Matsubayashi[1], H. Ono[1]

Introduction: After chemoradiotherapy (CRT) or radiotherapy (RT) for laryngopharyngeal cancer, local failure (residual and local recurrence) occurs in 10-30%[1] [2].

Therefore, salvage treatment for local failure is important. However, salvage surgery is associated with high rate of adverse events and mortality[3].

In esophageal cancer, endoscopic resection (ER) has been shown technically feasible for local failure and metachronous lesions after CRT/RT[4]. Conversely, there are few reports in laryngopharyngeal cancer[5].

Aims & Methods: The aim of this study was to clarify the technical outcomes and local controllability of ER for local failure and metachronous lesions after CRT/RT for laryngopharyngeal cancer.

This study was a single-center, retrospective, observational study. We included patients with superficial laryngopharyngeal cancer (SLPC) who underwent ER (EMR: endoscopic mucosal resection, ESD: endoscopic submucosal dissection, ELPS: endoscopic laryngopharyngeal surgery) from March 2005 to September 2022.

The patients were classified into 3 groups. Local failure (LF): residual or local recurrent lesions after CRT/RT, Metachronous: second primary lesions within the irradiation field, and non-RT: lesions with no history of CRT/RT. Patients with prior laryngopharyngeal surgery and CRT/RT for cervical esophageal cancer were excluded.

Outcome measurements were short-term outcomes and local recurrence rate after ER, which were compared among 3 groups. Surveillance endoscopy was conducted every 6 months after ER. This study was approved by the Institutional Review Board of Shizuoka Cancer Center (J-2022-203).

Results: LF, metachronous and non-RT groups were analyzed in 16 patients (16 lesions), 18 patients (27 lesions), and 217 patients (306 lesions), respectively.

Patient and lesion characteristics were as follows (LF/ metachronous/ non-RT): male, 15 (94%)/ 16 (89%)/ 198 (91%); median age, 68/ 69/ 69 years; pharynx, 13 (81%)/ 26 (96%)/ 298 (97%); median size, 12/ 16/ 16 mm; ER method (ELPS), 13 (81%)/ 23 (85%)/ 259 (85%), median follow-up, 30/ 54/ 49 months. There were no differences in en bloc resection rate (88/ 93/ 88%, *P*= .851), R0 resection rate (50/ 52/ 56%, *P*=.879), and procedure time (25/ 27/ 25min, *P*=.497) among the 3 groups.

Adverse events (grade 3 or 4 in Common Terminology Criteria for Adverse Events v5.0) were as follows: delayed bleeding 0/ 1 / 1 cases; stricture 0/ 2/ 3 cases; laryngeal edema 1/ 0/ 9 cases; aspiration pneumonia 2/ 0/ 10 cases; retropharyngeal abscess 0/ 1/ 0 cases.

Adverse event rates tended to be higher in the LF and metachronous than in the non-RT group (18/ 15/ 8%, *P*=.096); however, there were no treatment-related deaths. Local recurrence occurred in 3/ 3/ 16 cases, and the cumulative local recurrence rates at the 2 years were 21%/ 13%/ 6%, respectively. It was significantly higher in the LF than in the non-RT group (*P*=.018).

On the other hand, local recurrence was more occurred in metachronous than non-RT group, but not significantly different (*P*=.259). In the treatments for local recurrence, second ER was performed in 2/ 1/ 8 cases and salvage surgery was performed in 1/ 2/ 4 cases. Locally controllable rates by ER only including second ER for local recurrence were 94%/ 93%/ 97%, with no significant difference (*P*=.177).

Conclusion: ER for LF and metachronous lesions after CRT/RT is technically feasible. Local recurrence rate in LF and metachronous lesions was higher than in the lesions with no history of CRT/RT, but local controllability by ER only without salvage surgery was comparable among 3 groups.

Introduction: Gastric cystica profunda (GCP) is a rare disease characterized by cystic dilation of gastric glands within the mucosa and/or submucosal layer.

The aim of this study was to summarize the endoscopic features of GCP and evaluate the effectiveness of endoscopic treatment to provide guidance for diagnosis and treatment.

Aims & Methods: This study summarized the endoscopic features and the effectiveness of endoscopic treatment for GCP to provide guidance for diagnosis and treatment. This retrospective study included 104 patients with GCP. In addition to demographic and clinical information, we regularly followed up the patients to evaluate local recurrence.

Results: Of the 104 patients, five experienced recurrence (4.8%). 59.6% GCP associated with early gastric cancer (EGC) was confirmed by the final pathology. The univariate analysis demonstrated that GCP patients with EGC were more likely to be elderly males. The lesions from the GCP with EGC group tended to locate in the cardia as mucosal lesion type with irregular shape and rough surface.

The multivariate analysis suggested that lesion morphology and endoscopic features were significant risk factors for GCP with EGC. Survival analysis suggested that there was no statistical difference in recurrence between GCP with EGC and GCP without EGC groups (P = 0.72).

Conclusion: GCP associated EGC (early gastric cancer) was found to be relatively common. Irregular morphology and mucosal lesion type might be the risk factors for development of EGC in GCP.

Endoscopic submucosal resection can be recommended as an effective and minimally invasive treatment for GCP with or without EGC.

Introduction: Gastric polyps represent an abnormal proliferation of the gastric mucosa. Chronic atrophic autoimmune gastritis (CAAG) targets parietal cells and results in hypo-achlorhydria and hypergastrinemia, which exerts a proliferative effect on the gastric mucosa.
Aims & Methods: We investigate the incidence of gastric polyps in CAAG patients in a single-center retrospective study examining patients with confirmed CAAG from January 1990 until June 2022. Demographic, clinical, biochemical, and serological data were collected for each included patient. The histopathological characteristics of the detected polyps were recorded.
Results: A total of 176 CAAG patients were included. Eighty-nine (50.5%) had 163 incidental polyps. Seventy-six patients (85%) had 130 non-endocrine lesions, among which 118 (90.7%) were inflammatory, 6 (4.6%) adenomatous, and 4 (3%) fundic; 33 patients (37%) had gastric neuroendocrine neoplasms (gNENs), and 21 (23.6%) both; one had MALToma and one gastric adenocarcinoma.
Higher circulating lev- els of gastrin and chromogranin A were observed among patients with polyps (median 668 vs 893 pg/ml p = 0.0237, 146 vs 207 ng/ml p = 0.0027, respectively).
Conclusion: CAAG implies a high incidence of gNENs and exocrine lesions. Gastrin plays a possible trophic role on the mucosa. Further evidence is needed to validate its predictive role for increased polyp risk in CAAG.

Introduction: Esophageal variceal (EV) bleeding is a severe complication of portal hypertension with significant morbidity and mortality. Guidelines for the American Association for the Study of Liver Diseases (AASLD) currently recommend endogastroduodenoscopy (EGD) at the time of diagnosis of cirrhosis.
Traditionally, screening and grading of EV is performed by EGD. However, EGD is an invasive procedure and not risk-free; it is mostly performed using intravenous conscious sedation increasing its risks by adding the effects of sedative drugs in the cirrhotic population. Wired magnetic-assisted capsule endoscopy (MACE) uses a wire-connected capsule steerable by an external magnet and allows examination of the upper GI tract. However, its potential usefulness in diagnosing esophageal varices in patients with liver cirrhosis has not been assessed.
Aims & Methods: Method: We prospectively enrolled patients with cirrhosis and indications to receive EGD for screening or surveillance for esophageal varices. A wired MACE study was performed followed by an EGD which was performed by one experienced endoscopist within 6 hours. Capsule videos were assessed by two investigator who were blinded to the patients' medical history and EGD findings. The diagnostic yield of wired MACE and EGD were compared. Patients' tolerance and acceptance of wired MACE and EGD were also assessed.
Results: Thirty-two patients were included for analysis (mean age: 64 years, range: 41-83 years; 59.4% male); the clinical characteristics of enrolled patients were listed in Table 1 and only 6 patients (18.8%) received sedated EGD. The mean examination time of wired MACE and EGD (including time of endoscopic variceal ligation) was 7.9 mins and 10.9 mins respectively.
The combined sensitivity, specificity and accuracy of diagnosing EV by wire-MACE was 92.1% [95% confidence interval(CI): 78.6-98.3%], 88.5% (95% CI: 69.9-97.6%) and 90.6% (95% CI: 80.7-96.5%) respectively with good interobserver agreement (kappa=0.87).
The combined sensitivity, specificity and accuracy of predicting the need for endoscopic variceal ligation (EVL) by wire-MACE was 70.0% (95% CI: 34.8-93.3%), 94.4% (95% CI: 84.6-98.8%) and 90.6% (95% CI: 80.7-96.5%) respectively with moderate interobserver agreement (kappa=0.54). Wired MACE has lower scores of discomfort (2.1 vs 4.4, p < 0.0001) and better scores of acceptance (4.2 vs 3.2, p <0.01) than that of EGD.

Cause of liver cirrhosis, n (%)	
Hepatitis B	16(50%)
Hepatitis C	12(38%)
HBV + HCV	1(3%)
HBV+ HDV	1(3%)
Autoimmune hepatitis+ Primary biliary cirrhosis	2(6%)
Child-Pugh classification A	23(72%)
Child-Pugh classification B	7(22%)
Child-Pugh classification C	2(6%)
History of esophageal variceal ligation	13(41%)

Table 1.

Conclusion: Wired MACE has good accuracy in diagnosing EV and predicting the need of prophylactic EVL; moreover, it has less discomfort and better acceptance than EGD.

POST-GASTROSCOPY UGI CANCER – A 10-YEAR SINGLE CENTRE CASE SERIES

J. Cooney[1], P. Appiahene[1], A. Wolak[1], H. Chong[1], J. Hayat[1]
[1]St George's University Hospitals NHS Foundation Trust, Gastroenterology, London, United Kingdom

Contact E-Mail Address: josephcooney@doctors.org.uk

Introduction: UGI cancer detected within 5 years of a gastroscopy (termed post-OGD UGI cancer – POUGIC) may reflect delayed diagnosis and contribute to poorer prognosis. It has been estimated to be as high as 14% and BSG quality standards (2017) recommend rates do not exceed 10%. UGI cancer often presents late and with limited curative treatment options efforts are increasingly focused on improved screening methods and earlier diagnosis. We undertook a retrospective review of all histological diagnoses of oesophageal and gastric carcinoma at our hospital over a 10-year period to describe this cohort in our own practice.

Aims & Methods: Medical records for 588 histological diagnoses of gastric and oesophageal adenocarcinoma (AC) and squamous cell carcinoma (SCC) between 13/01/10 and 24/08/20 were reviewed, including previous OGDs, histology reports, radiological staging and past medical history.

The aim was to profile patients to identify risk factors for the development of POUGIC.

Results: 42/588 pts (7%) underwent OGD up to 5y (med 22m) prior to cancer diagnosis.

POUGIC pts: aged 53-96y (med 74.5y), 21% female, 60% White, 10% Asian, 10% Black, and 20% mixed/other.

Non-POUGIC (546pts): aged 24-94y (med 71.5y), 34% female, 57% White, 10% Asian, 11% Black, and 22% mixed/other.

OGD findings within 5 years prior to UGI cancer, 42 pts (%)	
"Benign" oesophageal stricture / lesion	14
Oesophagitis	12
Oesophageal candidiasis	2
Barretts oesophagus (BO)	24
Hiatus hernia	14
Gastric ulcer	2
Gastritis	12
Normal	24
Unknown	7

7% OGDs <5y prior to cancer diagnosis were by a Consultant.

POUGIC: 57% oesophageal (33% AC, 24% SCC), 7% GOJ AC, 36% gastric AC.

Non-POUGIC: 30% oesophageal (18% AC, 12% SCC), 8% GOJ (7% AC, 1% SCC), and 19% gastric AC.

POUGIC staging at presentation: 12% T1-2, 45% T3-4, 14% metastatic and 43% unknown. Pts died 0-35m (med 5m) after diagnosis.

Non-POUGIC staging at presentation: 13% T1-2, 50% T3-4, 19% metastatic and 35% unknown. Pts died 0-120m (med 7m) after diagnosis.

All patients with POUGIC and BO were known to have had BO prior to their cancer diagnosis and had undergone endoscopic screening as per BSG guidelines.

Conclusion: POUGIC were <10% of UGI cancer diagnoses, in accordance with BSG quality standards.

Age, gender and ethnicity were similar in both POUGIC and non-POUGIC, and so were not predictive factors.

Staging and median survival were also similar between POUGIC and non-POUGIC, suggesting that these outcomes were not affected by an OGD within the previous 5y.

Oesophageal cancer was more common in those that had OGD in the preceding 5y compared to those that had not, and BO was the most common abnormality in these procedures. 78% POUGIC had risk factors for UGI cancer on their initial OGD (inflammation, ulcer, BO, hiatus hernia, stricture), raising the possibility that treatment could have been optimised, e.g. acid suppression (45% of POUGIC were on PPI before their cancer diagnosis), anti-reflux surgery, lifestyle modifications or improved surveillance.

Importantly, 24% of POUGIC also had a "normal" preceding OGD, and with only 7% of these OGD performed by a Consultant, it is possible that pathology may have been missed on initial OGD. Additional novel screening techniques, such AI-assisted endoscopy, volatile organic compounds and Cytosponge may help obtain earlier diagnoses in future.

Introduction: Routine mucosal sampling from pre-defined anatomical sites is recommended during pediatric upper gastrointestinal endoscopy regardless of macroscopic appearance, but evidence for this recommendation remains limited. We investigated this issue in a large and well-defined patient cohort.

Aims & Methods: Concordances between endoscopic and histologic findings and their association to the diagnosis after the first endoscopy was studied in 1181 consecutive children undergoing endoscopy with systematic biopsy sampling during years 2007-2014.

Furthermore, the associations between endoscopic and histologic findings and a gastrointestinal diagnosis received during follow-up up to 11 years were studied.

Results: Systematic sampling was conducted in 98.4% of the children in esophagus, 99.3% in stomach, and 98.8% in duodenum. Any endoscopic findings were reported in 51.7% and histologic abnormalities in 59.3% of the children. The Cohen's k coefficient between endoscopic and histologic findings was 0.272 overall, 0.190 in esophagus, 0.148 in stomach, and 0.520 in duodenum. The most common diagnoses were celiac disease (26.0%), inflammatory bowel disease (11.2%) and gastroesophageal reflux disease (5.2%).

Significant association between endoscopic abnormalities and presence of a diagnosis was seen in any endoscopic site and in duodenum, but not in esophagus or stomach, while histologic abnormalities associated with a diagnosis in each biopsy location (Table 1.).

Histologic abnormalities were seen in 146 (25.4%) children without diagnosis at the first endoscopy, the most common being chronic inactive gastritis (7.5%) and mild chronic esophagitis (5.8%).
Furthermore, in patients without initial diagnosis histologic abnormalities were associated with a follow-up diagnosis (odds ratio 2.59, 95% confidence interval 1.40-4.79), whereas endoscopic abnormalities did not (OR 0.61, 95% CI 0.31-1.18).

	N	%	**Gastrointestinal diagnosis** Odds ratio	95% confidence interval
Endoscopic findings Any site	610	64.3	2.98	2.35-3.77
Esophagus	125	47.2	0.83	0.57-1.20
Stomach	190	52.6	1.06	0.78-1.45
Duodenum	384	73.4	4.02	3.08-5.24
Histologic findings Any site	700	79.1	30.6	21.8-43.0
Esophagus	238	78.2	4.47	3.20-6.24
Stomach	363	76.3	4.78	3.62-6.33
Duodenum	367	90.1	19.4	13.3-28.4

Table 1. Relationships between endoscopic and histologic findings and diagnosis received in 1181 children at the time of their first upper gastrointestinal endoscopy.

Conclusion: The low concordance between endoscopic and histologic findings supports systematic biopsy sampling in pediatric upper gastrointestinal endoscopy. Histologic findings are strongly associated with initial gastrointestinal diagnosis and to a lesser extent with a follow-up diagnosis.
Disclosure: Nothing to disclose.

CHARACTERISTICS AND FEATURES OF UPPER GASTRO INTESTINAL BLEEDING IN PATIENTS ON ANTITHROMBOTIC DRUGS: A PROSPECTIVE STUDY

T. Addajou[1], A. Benhamdane[1], S. Mrabti[1], J. Benass[1], C. Jioua[1], D. Yannick[1], R. Berraida[1], E. Ilham[1], F. Rouibaa[1], A. Benkirane[1], H. Seddik[1]
[1]*Military Hospital Mohammed V, Rabat, Morocco*

Contact E-Mail Address: addajoutarik@gmail.com
Introduction: Anti-thrombotic (AT) drugs commonly prescribed in cardiovascular disease are considered a recognised risk factor for upper gastro intestinal bleeding (UGIB). However, few studies have evaluated their effect on endoscopic outcomes in patients admitted for UGIB, and have concluded that the results remain controversial.
Aims & Methods: Aims: Evaluate the effect of AT use on endoscopic outcomes in patients admitted for UGIB.
Methods: This is a prospective monocentric cross-sectional study of 332 patients conducted between June 2020 and August 2021. We considered as users of AT drugs all patients on antiplatelet agents (low-dose aspirin, thienopyrimidines) and/or anticoagulants (vitamin K antagonists, direct-acting anticoagulants, heparin).
Results: The average age was 59+/−16.7 years. Our series was characterised by a clear male predominance of 77.1%.63 patients (19%) were taking AT drugs (41 antiplatelet, 39 anticoagulant).The two groups differed in age (68 vs 57; p<0.001), comorbidities (75.8% vs 16.7%; p<0.001), however there was no statistically significant difference in active bleeding at endoscopy (12.7%vs 16.8%; p=0.425), and the need for endoscopic haemostasis (7.9%vs 16%; p=0.1). In multivariate analysis and adjusting for age, sex, comorbidities, presence of active bleeding and use of antithrombotics, only the presence of active bleeding could predict the need for endoscopic haemostasis. Indeed, the presence of active bleeding at the time of endoscopy multiplies by 26 the risk of recourse to endoscopic haemostasis (OR: 26, CI: 12.9–62.15, p<0.001), whereas the use of AT drugs does not influence the need for endoscopic haemostasis (OR: 0.386, CI: 0.105- 1.42, p=0.154).
Conclusion: Older patients using AT admitted for UGIB do not appear to have an increased risk of active bleeding at endoscopy or needing endoscopic haemostasis.
Disclosure: Nothing to disclose.

PRELIMINARY RESULTS OF A RETROSPECTIVE STUDY OF OVER 20 YEARS OF ROUTINELY TRANSNASAL PERCUTANEOUS ENDOSCOPY GASTROSTOMY PLACEMENT: SAFETY AND FEASIBILITY

G. Vincoli[1], A. Zannella[1], A. Gigliozzi[1], M. Fioravante[1], S. Boschetto[1], D. Serva[1], F. Barberani[1], M. Tosoni[1], M. Giovannone[1]
[1]*San Camillo de Lellis Hospital, Internal Medicine, Gastroenterology Unit, Rieti, Italy*

Contact E-Mail Address: vincoligiusy@libero.it
Introduction: Since the report of Shaker in 1994, transnasal esophagogastroduodenoscopy (T-EGDS) has been reported worldwide as one technique to facilitate comfortable procedures avoiding sedation. From 1996 in our Centre, we routinely use this technique in all the patients for diagnostic and selected operative EGDS. This approach is also suitable for the placement of percutaneous endoscopy gastrostomy (PEG) but in the published papers it has been performed only when conventional upper gastrointestinal endoscopy was unusable (dysphagic patients with neurological disease or with stenosis and/or occlusion of the mouth or pharynx). On the contrary, since 2000 we have routinely used the transnasal approach for all patients requiring PEG, reserving the oral technique when the transnasal access route is impossible.
Aims & Methods: We performed a retrospective analysis of all patients who underwent PEG placement between January 2000 and March 2023 in the Unit of Gastroenterology of San Camillo De Lellis Hospital, Rieti, Italy, in order to demonstrate the feasibility and safety of T-PEG placement in routine practice. We used ultrathin gastroscope through a nostril after assessment and lubrification, and the pull technique was used for tube placement.
Results: PEG placement was required for 256 consecutive patients (male 49.4%; female 51.6%), the average age was 79 years, within a range from 26 to 104 years. Transnasal approach was used in 162 patients (nasal group: 63.3%) while oral approach was used in 94 (oral group: 36.7%). The failure of transnasal approach was related to impossibility of nasal intubation due to narrow nasal passages or to inability to transilluminate the stomach. In these cases we needed transoral route. 14 patients underwent transoral PEG placement due to unavailability of transnasal gastroscope. The duration of the procedures was similar in both approaches (12 ±3 minutes oral vs 13±4 minutes nasal).
The most common indications for PEG insertion were neurologic disorders (n=132, 51.6 %), cerebrovascular accident (n=73, 28.5 %), esophageal cancer or head and neck cancer (n=18, 7 %), other pathologies (n=33, 12.9 %). 167 procedures were performed without sedation: 77.8 % (n= 130) in the nasal group and only 22.1% (n=37) in the oral group. Outpatient regimen PEG placement was also significantly higher in trans nasal group (79 % vs 58 % oral group). We registered 3 major complications, 1 in oral group and 2 in nasal group (one necessitated surgery). No procedure-related death was registered. There were no unplanned re-admissions of outpatients discharged from the gastroenterology unit for procedure-related complications.

Conclusion: The more than twenty years' experience of our center demonstrates that the transnasal approach is safety, feasible and could be routinely used in daily endoscopic practice for PEG placement. The minimally invasive technique therefore reserves sedation to a few selected cases to reduce costs, improve logistic organization and avoid anesthesia related complications.

Introduction: Post surgical fistulas of the upper digestive tract(UDT) are associated with significant morbidity and mortality.

Aims & Methods: We aimed to evaluate the efficacy and safety of a primarily endoscopic management of post surgical fistulas of the UDT.

We performed a multicentre retrospective analysis in which 126 consecutive patients underwent primarily endoscopic management of post surgical fistula between March 2009 and January 2022. Factors associated with successful fistula closure and adverse events were evaluated. Qualitative variables were expressed as percentages and evaluated with Chi-square test. Quantitative variables were evaluated for normal and non-normal distribution. Non-normal quantitative variables were expressed as median (min-max) and evaluated with Mann-Whitney's test. Logistic regression analysis was performed to determine factors associated with fistula closure and adverse events. P value <0,05 was considered statistically significant (IBM SPSS 28).

Results: The median age was 57(17-89) years and 73(60%) patients were female. Main Indications for surgery were obesity in 73(58%) and cancer in 46(36%) (of which 32(70%) were gastric cancer). The median time between surgery and fistula diagnosis was 7(1-387) days. Average size of fistula orifice was 7(1-30)mm.

Fistulas were located in the esophagus in 8 patients (6.3%), gastric cardia in 46 (36.5%), stomach non-cardia in 21 (16.7%), esophago-gastric or esophago-jejunal anastomosis in 9 (7.1%), gastro-jejunal anastomosis in 39 (31.0%), small intestine in 2 (1.6%) and unknown in 1 (0.8%).

Endoscopic interventions included placement of a covered metallic stent in 98(78%) patients (fully-covered n=46, partially covered n=37, both fully and partially covered n=15), clips in 58 (47%) patients (OTSC n=37, TTSC n=17, both OTSC and TTSC n=4) and argon plasma in 16(13%) patients.

Early adverse events (<1week) occurred in 22(17%) and included stent migration (n=10), sepsis (n=6), gastrointestinal bleeding (n=5) and death (n=1). Late adverse events occurred in 31(20%) patients, namely stricture (n=11), mucosal overgrowth (n=6), migration (n=4), vomiting (n=3), stent fracture (n=2), perforation and right hemicolectomy (n=1) and death (n=4).

After a median follow up of 25 (1-147) months, 32(25%) died, but only 15(12%) due to fistula (3 due to aorto-esophageal fistula and the others due to sepsis), 12(10%) due to neoplasia and 5 due to other causes.

Need for surgical reinterventions (p=0.002) was associated with early adverse events. Late adverse events were less frequent in patients with clip placement (p=0.011).

Clinical success defined as definitive fistula closure was documented in 106(84%) patients after a median of 8(1-192) weeks and required a median of 3(1-13) endoscopies. Factors predictive of fistula closure were female gender (p=0.01), indication for surgery (p=0.02), lower C reactive protein(p=0.003), lower urea (p=0.006), lower AST(p=0.003) and lower ALT(p=0.002).

Conclusion: The primarily endoscopic approach to management of UDT post surgical fistulas was clinically successful in >80% of the patients with a good safety profile.

Disclosure: Nothing to disclose.

DEFINING THE STANDARD LENGTH OF PERORAL ENDOSCOPIC MYOTOMY (POEM) FOR ACHALASIA: A SYSTEMATIC REVIEW AND METANALYSIS

E. Vespa[1], A. Barchi[1], F. Azzolini[1], E. Fasulo[1], M.C. Fratto[1], F.V. Mandarino[1], L. Fanti[1], D. Esposito[1], E. Viale[1], S. Passaretti[1], E.V. Savarino[2], S. Danese[1]

Contact E-Mail Address: edo.vespa93@gmail.com

Introduction: Per-oral endoscopic myotomy (POEM) has revolutionised achalasia treatment, nevertheless there is still a lack of technical standardization. No clear definition of "long", "standard" or "short" POEM exists to date. With the exception of type III achalasia, there is evidence that myotomy limited to the lower esophageal sphincter (<6 cm) may be highly effective, time-saving and associated with less post-postoperative gastroesophageal reflux, yet it is common practice to use long myotomy in these patients.

Aims & Methods: We conducted a systematic review with meta-analysis to define current myotomy length standards during POEM. A literature search was performed on MEDLINE-Pubmed, Embase, Scopus, and Cochrane Library (from inception to December 2022). We included prospec-

tive, retrospective clinical studies and randomized controlled trials reporting technical details of POEM, in which no definite or comparative myotomy length was intentionally adopted thus representing a "standard" myotomy for the operator.

The primary outcome was the pooled mean total myotomy length.

Secondary outcomes included clinical success and reflux symptoms. Main exclusion criteria were: patient age < 18 years; studies providing achalasia diagnosis without high-resolution manometry, studies including patients with non-achalasia esophageal motility disorders, studies comparing different myotomy lengths or adopting pre-specified myotomy lengths, studies including type III achalasia patients only. Sub-group analyses were performed to explore heterogeneity across studies and to assess the impact of different subtypes, geography and time trends on the primary outcome.

Results: From initial 7,172 records, after exclusion criteria were applied, a total of 25 articles were included. Of those, 6 provided results on the primary outcome in separate subgroups and were therefore included as separate studies.

Overall, 31 studies with a total 3023 patients were evaluated. The pooled mean of total myotomy length was 10.39 cm (95% CI 10.06-10.71; I^2 99.3%). The pooled mean of esophageal and gastric myotomy length, provided by 17 studies, was 7.11 cm (95% CI 6.51-7.71; I^2 99.8%) and 2.81 cm (95% CI 2.41-3-22; I^2 99.8%) respectively.

At the subgroup analysis for achalasia subtypes, pooled mean length in non-spastic achalasia (type I and II) was 10.17 cm (95% CI 9.91-10.43; I^2 94.2%), while in type III attested at 14.02 cm (95% CI 10.59-17.44; I^2 98.9%). Pooled mean myotomy length for studies conducted between 2014-2018 was 10.56 cm (95% CI 9.51-11.61; I^2 99.0%) while studies between 2019-2022 showed a mean length of 10.3 cm (95% CI 9.99-10.61; I^2 99.6%).

No geographical difference was observed: in eastern countries mean length was 10.2 cm (95% CI 9.12-10.92; I^2 98.9%), while in western countries was 10.95 cm (95% CI 9.83-12.07; I^2 99.5%). At a median follow-up of 29 months, the pooled clinical success rate was 91% (95% CI 88.9%-93.2%; I^2 67.2%), while the pooled rate of post-POEM clinical reflux was 26% (95% CI 21.0%-31.3%; I^2 89.5%).

Conclusion: Our meta-analysis found that the pooled mean myotomy length during a "standard" POEM is 10.4 cm, remaining over 10 cm in non-spastic (type I and II) achalasia. The high heterogeneity across studies confirms that POEM technique needs further standardization.

We found no time trend towards adopting short POEM, despite recent evidence supporting efficacy and safety of this approach.

Disclosure: Nothing to disclose.

Introduction: Post surgical fistulas of the upper digestive tract (UDT) are associated with significant morbidity and mortality. The indication for surgery may influence outcomes.

Aims & Methods: We aimed to evaluate the clinical presentation,efficacy and safety of a primarily endoscopic approach to management of post surgical fistula of the UDT comparing oncologic versus non-oncologic indications for surgery.

Multicentre retrospective analysis involving 126 consecutive patients who underwent primarily endoscopic management of post surgical fistulas of the UDT between March2009-January2022. Clinical efficacy (fistula closure) and adverse events in patients with fistulas after oncologic and non-oncologic surgery were compared.Qualitative variables were evaluated with Chi-square test. Quantitative variables with non-normal distribution were expressed as median(min-max) and evaluated with Mann-Whitney's test. We performed logistic regression analysis to determine factors associated with fistula closure and adverse events. A p value <0.05 was considered statistically significant (IBM SPSS28).

Results: Median age was 57(17-89) years and 73(60%) patients were female. Indications for surgery were non-oncologic in 80 patients(63.5%) ((mostly bariatric, n=73)) and cancer in 46(36.5%) patients.

Patients undergoing oncologic surgery were older and with male predominance. There were no differences regarding median time to detect fistula or fistula size between the groups. Fever, abdominal pain and abdominal collections were more frequent in non-oncologic surgery group. On laboratory analysis, only haemoglobin was significantly lower in patients undergoing oncologic surgery(Table1). We found no significant difference on leukocyte count, neutrophil percentage, C-reactive protein, AST, ALT, total bilirubin, INR or creatinine.

		Oncologic	Non-oncologic	p-value
Characterization	Median age	71(52-89),	45(17-79)	<0.001
	Female gender	21(26%)	35 (76%)	<0.001
	Median time to fistula detection(days)	8(1-83)	6(1-387)	0.08
	Fistula size(mm)	5.0(2.0-25.0)	5.0(1.0-30.0)	0.671
Clinical presentation	Fever	18(39%)	49(61%)	0.049
	Abdominal pain	13(28%)	46(58%)	0.006
	Abdominal collections	11(n=24%)	48(60%)	<0.001
	Sepsis	13(n=28)	21(26%)	0.309

Endoscopic interventions were similar in both groups and included placement of a covered metallic stent in 64(80.0%) non-oncologic patients and 34(73.9%) oncologic patients (p=0.506) and clips in 99(48.8%) oncologic patients and 19(41.3%) (p=0.461) non-oncologic patients. The frequency of early adverse events (<1 week) (8(17%) vs 14(18%), p=1.0),as well as late adverse events (10(22%)vs 21(26%), p=0.670) were similar in both groups. We documented clinical success (fistula closure) in 72(90%) of non-oncologic patients and 34(74%, p=0.023) of oncologic patients, but after a similar median duration of management (13 (1-423) weeks vs 6(1-55) weeks, p=0.11) and number of endoscopies (3(1-8) vs 2(1-13), p=0.706).
After a median follow up of 36(1-147) and 12.5(1-113) months, 6(7.5%) and 28(60.9%) patients died, respectively from the group of non-oncologic and oncologic surgery. In the oncologic surgery group, 12 patients (48%) died from progression of oncologic disease.
Conclusion: A primarily endoscopic approach is effective in >70% of patients with fistulas after UDT surgery but it´s efficacy was significantly lower in patients with fistulas after oncologic surgery compared to non-oncologic surgery and this may have been due to the higher age and male predominance.
Disclosure: Nothing to disclose.

Contact E-Mail Address: nminakat@east.ncc.go.jp
Introduction: The magnifying endoscopy (ME) with narrow-band imaging (NBI), which can visualize the microvascular (MV) architecture and the microsurface (MS) structure showed the acceptable diagnostic ability for early gastric cancer (EGC) even using second-generation NBI.
The latest endoscopic system EVIS X1 (Olympus, Tokyo, Japan) includes third-generation (3G) NBI with more brightness and clearness, however, the diagnostic performance of ME with 3G-NBI for EGC was unknown.
Aims & Methods: The aim of this post hoc analysis was to investigate the diagnostic performance of ME with 3G-NBI for EGC using the data from the 3G detection trial, which was the randomized three-arm phase II trial comparing white light imaging (WLI), 3G-NBI, and texture and color enhancement imaging (TXI) for detecting gastric neoplasms (GN).
The major inclusion criteria of 3G detection trial were as follows:
1. Scheduled surveillance endoscopy after endoscopic resection for GN or endoscopic resection, chemotherapy, or radiotherapy for esophageal cancer (EC), or;
2. Scheduled preoperative endoscopy for known GN or EC. The EVIS X1 system and a high-definition gastroscope with an optical zoom (GIF-XZ1200) were used.
Patients were randomly assigned to the following arms: WLI followed by WLI, 3G-NBI followed by WLI, and TXI followed by WLI. All suspected GN lesions were diagnosed as EGC or non-EGC using ME with 3G-NBI according to ME simple diagnostic algorithm of EGC (MESDA-G), which use the presence of irregular MV and/or MS patterns within the demarcation line, and its confidence level was recorded. Pathological diagnoses were made based on biopsied tissue or final results of resected specimens by expert pathologists at each institution.
This post hoc analysis compared the diagnosis of ME with 3G-NBI for EGC with the pathological diagnosis. The primary endpoint was the diagnostic performance of ME with 3G-NBI for EGC, and it also evaluated according to confidence level (high/low), macroscopic type (elevated/flat or depressed), and lesion size (<10 mm/≥10 mm).
Results: Of 901 patients enrolled in the 3G detection trial, a total of 228 suspected GN lesions in 187 patients were analyzed. The median size of the lesions was 5.0 mm (range: 1.0-40.0). In the macroscopic type, 43 (18.9%) lesions were elevated and 185 (81.1%) were flat or depressed. Using ME with 3G-NBI, 62 lesions (27.2%) were diagnosed as EGC, of which 27 were diagnosed with high confidence. And, 166 (72.8%) were diagnosed as non-EGC, of which 91 were diagnosed with high confidence. Finally, 61 were pathologically diagnosed as EGC and other 167 were pathologically diagnosed as non-EGC.
The overall diagnostic performance of ME with 3G-NBI for EGC was, sensitivity of 70.5% (43/61), specificity of 88.6% (148/167), accuracy of 83.8% (191/228), positive predictive value (PPV) of 69.6% (43/62) and negative predictive value (NPV) of 89.2% (148/166), respectively. For the lesions diagnosed with high and low confidence, sensitivity was 78.1% (25/32) and 62.1% (18/29), specificity was 97.7% (84/86) and 79.0% (64/81) (p<0.001), accuracy was 92.4% (109/118) and 74.6% (82/110) (p<0.001), respectively.
For the elevated and flat or depressed lesions, sensitivity was 84.6% (11/13) and 66.7% (32/48) and specificity was 96.7% (29/30) and 86.9% (119/137), respectively. For the lesions with <10 mm and ≥10 mm in size, sensitivity was 65.7% (23/35) and 76.9% (20/26) and specificity was 88.6% (116/131) and 88.9% (32/36), respectively.
Conclusion: The diagnostic performance of ME with 3G-NBI for EGC was acceptable, especially in the lesions diagnosed with high confidence.
Disclosure: Nothing to disclose.

LEARNING CURVE FOR GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION: EXPERIENCE IN A WESTERN CENTER

S. Archer[1], A.T. Ferreira[1], S. Ponte[1], C. Verde[2], G. Moreira[2], R. Marcos-Pinto[1], I. Pedroto[1], R. Küttner Magalhães[1]
[1]Centro Hospitalar Universitário de Santo António, Gastroenterology, Porto, Portugal, [2]Instituto de Ciências Biomédicas Abel Salazar, Porto, Portugal

Contact E-Mail Address: sararcher_@hotmail.com
Introduction: Endoscopic submucosal dissection (ESD) is widely implemented in Asia. Experience from the western world is still limited, so the evidence on the description of a learning curve (LC) is sparse.
Aims & Methods: The aim of this study is to evaluate the LC for ESD of gastric lesions using accepted proficiency benchmarks (PB).
Retrospective analysis with a prospectively maintained database of all patients undergoing ESD at a Western tertiary center from June 2016 to December 2022.

Inclusion criteria: ESD of gastric lesions performed by a single operator.
Primary endpoint: a LC to estimate the number of ESDs required to achieve PB (>90% for en bloc resection, >80% for histologic margin-negative (R0) resection and resection speeds (RS) >9cm2/hr), using the CUSUM method.
Results: Of 477 ESD performed, a total of 235 ESD met the inclusion criteria.
The en bloc resection rate was 100%. The R0 resection rate was 97% so no statistically significant differences were found, since it was always within PB.
Using the CUSUM method, the LC was divided into learning periods [Phase I - learning phase (cases 1-48); Phase II - adaptation phase (49-72), Phase III - consolidation (from case 73 on).
Globally, after reaching the level of 9cm2/h and after resection 73, the cumulative moving average remains above this speed for all following resections.
Several locations reach moving average proficiency levels at different number of interventions (antrum: from the beginning, body: 134th).
Conclusion: The PB regarding the en bloc and R0 resection were achieved from the beginning.
The PB regarding de RS was achieved from the beginning for the antrum.
The PB regarding de RS, globally, has a clinically significant first learning inflection at ESD number 49 and at ESD number 73 achieved sustained PB for RS.
Disclosure: Nothing to disclose

ELDERLY SUBJECT VS YOUNG SUBJECT: CLINICAL, ENDOSCOPIC AND THERAPEUTIC PARTICULARITIES IN THE EVENT OF UPPER GASTROINTESTINAL BLEEDING: PROSPECTIVE STUDY

B. Yannick[1], A. Benhamdane[1], B. Aourarh[1], J. Benass[1], C. Jioua[1], T. Addajou[1], S. Mrabti[2], R. Berraida[2], I. El Koti[2], F. Rouibaa[2], A. Benkirane[1], H. Seddik[3]
[1]Mohammed V University - Rabat / Faculty of Medicine and Pharmacy, Rabat, Morocco, [2]Military Instruction Hospital Mohammed V, Gastroenterology II, Rabat, Morocco, [3]Mohammed V Military Teaching Hospital, Mohammed V – Souissi University, Hepato-Gastro-Enterology Ii, Rabat, Morocco

Contact E-Mail Address: yannekanga@gmail.com
Introduction: Upper gastrointestinal bleeding (HDH) is the most common diagnostic and therapeutic emergency in hepato-gastroenterology that can be life-threatening, requiring multidisciplinary management.
The aim of our study is to compare the epidemiological, clinical, endoscopic, and therapeutic characteristics of upper gastrointestinal bleeding between young and elderly subjects.
Aims & Methods: This is a single-center prospective cross-sectional study of 332 patients, conducted over a period of one year between January 2022 and December 2022.
We included in our study all patients admitted to our training for HDH. We divided our patients into 2 groups, group A corresponding to subjects aged ≥ 65 years and group B corresponding to patients < 65 years.
Results: Among the 332 patients collected, 38.9% were over 65 years old. The M/F sex ratio was 2.79. Thirty-one percent of patients were on antithrombotic treatment, and 38.8% had comorbidities.
There was no statistically significant difference between the two groups A and B regarding the origin of HDH, however, it was found that there was a difference between the two groups A and B regarding the use of antithrombotic (31.8% vs 10.8%, p<0.001) the presence of comorbidities (39.1% vs 20.7% p<0.001) the presence of active bleeding (9.3% vs 18.7 %, p=0.019) and the use of endoscopic hemostasis (8.5% vs 17.7%, p= 0.019).
In multivariate analysis and adjusting for the parameters studied, namely age, sex, comorbidities, the presence of active bleeding and the use of antithrombotic; only the presence of active bleeding could predict the need for endoscopic hemostasis.
In fact, the presence of active bleeding multiplies by 29.63 the probability of recourse to endoscopic hemostasis (OR: 29.62, IC: 13.52-64.90, p< 0.001), whereas the use antithrombotics (OR: 0.24, CI: 0.067-1.452, p=0.37) and age ≥ 65 years (OR: 0.425, CI: 0.205-1.342, p=0.21) have no influence on this risk.
Conclusion: Although older subjects had more comorbidities with more frequent use of antithrombotics, HDH in this age group does not seem to be more severe with a lower rate of active bleeding on endoscopy implying a less frequent need for antithrombotics endoscopic hemostasis.
Disclosure: No conflict of interest.

PP0251

THE LEARNING CURVE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION IN EARLY GASTRIC NEOPLASM: SINGLE OPERATOR OVER 800 CASES EXPERIENCE IN EIGHT YEARS

C.-K. Noh[1], G.H. Lee[1], K.M. Lee[1]
[1]Ajou University School of Medicine, Gastroenterology, Suwon, South Korea

Contact E-Mail Address: cknoh23@gmail.com
Introduction: Endoscopic submucosal dissection (ESD) is recommended as a treatment modality for early gastric cancer because it allows organ-sparing, curative en-bloc resection, and complete histopathological evaluation. Although many endoscopists are interested in learning how to perform ESD, the procedure requires a high level of expertise and is technically challenging, especially for less experienced endoscopists.
Aims & Methods: This study aimed to investigate the single-operator learning curve and clinical outcomes of consecutive gastric ESDs. Eight hundred-eleven gastric ESDs were performed between March 2016 and December 2022. The learning curve for ESD was evaluated using the cumulative sum (CUSUM) method to analyze the number of ESDs required for achieving proficiency.
Results: Of the enrolled patients, 310 (40.9%) cases were diagnosed with early gastric cancer. Overall en-bloc resection rates, R0 resection, and curability is 98.6%, 96.3%, and 93.7%, respectively. The median ESD speed was 18.1 cm2/h (IQR 12.2 – 25.3). ESD speed was slower than average in the upper third (9.9 cm2/h), presence of submucosal fibrosis (11.0 cm2/h) and the presence of subcutaneous fat (11.1 cm2/h), and faster than 20 cm2/h in the lower third (20.2 cm2/h) and lesion sized > 3 cm (23.6 cm2/h). According to the existing literature, the proficiency benchmark is defined as en-bloc resection >90%, R0 resection and >80%, and resection speed >9 cm2/h. However, since the first case satisfies all the existing benchmarks, we should establish a new definition of speed among benchmarks. In the changes of resection speed, we defined 16.5 cm2/h as a benchmark for ESD speed, which is the median value of the rapidly changing slope, and the CUSUM curve revealed that 156 cases were needed to achieve proficiency.
Conclusion: Due to the development of endoscopic equipment, a higher level of ESD proficiency benchmark is required. One hundred sixty-five cases were required to attain a higher technical level of successful performance in gastric ESD.

ADDITIONAL ENDOSCOPIC TREATMENTS WITH ONLY POSITIVE LATERAL MARGIN AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER

H.-K. Kim[1], B. Cha[1], J. Shin[1], K. Kwon[1]
[1]*Inha University, Internal Medicine, Incheon, South Korea*

Contact E-Mail Address: chaboram@hanmail.net

Introduction: Endoscopic treatment as additional therapy for noncurative resection in the only positive lateral margin (pLM) after endoscopic submucosal dissection (ESD) for early gastric cancer (EGC) has been recommended in patients with no risk of lymph node metastasis because it is less invasive than surgical gastrectomy with favorable long-term outcome.

Aims & Methods: However, there is no guideline on how to perform follow-up observation until additional ESD is performed. We retrospectively analyzed 161 patients with only pLM after ESD for EGC who had undergone at least 2 years of follow up.

Results: Of the 161 patients, 148 patients were undergone endoscopic follow-up biopsy group and 13 patients were directly undergone additional treatment without further biopsy confirmation. In directly undergone additional treatment group (n=13), 9 cases of no residual tumor were determined (9/13, 69.2%); 3 out of 3 in additional ESD (3/3, 100%), 3 out of 4 in biopsy and argon plasma coagulation (APC) (75%), and 3 out of 6 in surgical resection (50%).

However, in endoscopic follow-up biopsy group, 121 patients showed no recurrence at least 2 years follow up. Twenty two patients (22/148, 14.9%) were confirmed positive on resection ulcer margin. Twenty patients underwent 2 nd ESD, two in APC, and one in surgical resection. Only one case of no residual tumor was determined among 20 cases of 2 nd ESD.

Conclusion: Additional treatment after endoscopic follow up biopsy confirmation could be a proper treatment strategy in patients with only positive lateral margin after ESD for EGC who has no risk factors for lymph node metastasis.

Disclosure: Nothing to disclose.

Contact E-Mail Address: mijinoh1109@gmail.com

Introduction: Borrmann type 4 gastric cancer is defined as a diffuse gastric cancer that infiltrates the gastric wall, often without an overt mass or ulceration. Clinically, it is associated with a poor prognosis and lower curative resection rate, but is easily missed in routine upper endoscopic exams.

This study aimed to develop an artificial intelligence (AI) system that can detect Borrmann type 4 gastric cancer lesions in upper endoscopic images.

Aims & Methods: Endoscopic images of patients diagnosed with Borrmann type 4 gastric cancer, along with normal controls were collected from Seoul National University Hospital. A total of 227 gastric cancer patients (1,973 images) and 227 normal controls (1,554 images) were assigned to the train dataset, while 50 gastric cancer patients (417 images) and 50 normal controls (344 images) were assigned to the test dataset. A deep residual learning network model, ResNet-152 was used for training.

Results: The sensitivity, specificity and accuracy for identification of Borrmann type 4 gastric cancer images were 87.29% (95% confidence interval [CI] 84.09-90.49%), 97.97% (95% CI 96.47-99.46%) and 92.12% (95% CI 90.20-94.03%), respectively. When the diagnosis was made in patients with more than 50% of the endoscopic images identified as Borrmann type 4 gastric cancer, the sensitivity, specificity and accuracy was improved to 94% (95% CI 87.42-100%), 100% (95% CI 100-100%) and 97% (95% CI 96.66-100%), respectively.

Conclusion: A novel AI-based model that can identify Borrmann type 4 gastric cancer from endoscopic images was developed. Although further internal and external validation is needed, it is expected to assist clinicians in the early diagnosis of Borrmann type 4 gastric cancer with high accuracy.

Disclosure: Nothing to disclose.

Introduction: There are many studies on submucosal injections, but no consensus has been reached yet. In this study, laponite/sodium glycerophosphate (La/GP) hydrogel was synthesized, and the feasibility, effectiveness and safety of its application in submucosal injections were explored.

Aims & Methods: 0.3% sodium glycerophosphate powder and laponite powder of different volumes were pre-mixed and added with pure water to synthesize hydrogels of different concentrations. The microscopic morphology was observed and the degradation rate and rheological properties were measured. Inject 2ml of normal saline, 0.4% sodium hyaluronate and hydrogel of different concentrations into the fresh isolated porcine gastric mucosa, observe the change of the height of the swelling over time; inject the same area and then simulate endoscopic submucosal dissection (ESD) Electrosurgical peeling, record the time of complete peeling. The effect of 5% hydrogel extract on the survival rate of GES-1 cells was examined with CCK8 assay.

Results: Various characterization experiments showed that the synthesized shear-thinning hydrogel showed porous structure, stable properties, and the gel formation rate was faster with the increase of laponite concentration. In the in vitro submucosal elevation test, the maintenance rate of normal saline was less than 50% at 90 minutes, 55% for 0.4% sodium hyaluronate, and 65% – 88% for 2% – 5% La/GP hydrogel, and the difference was statistically significant ($P < 0.05$).

Simulated ESD peel time was also statistically shorter than the control group. In the cytotoxicity test, GES-1 cell viability was not significantly different from the control group within 1 – 3 days after the addition of 5% hydrogel extract.

Conclusion: Laponite/sodium glycerophosphate (La/GP) shear-thinning hydrogel is easy to prepare, can maintain the ideal swelling height under the mucosa for a long time, and has good biocompatibility. It is expected to become a new type of submucosal injection.
Disclosure: Nothing to disclose.

COMPARISON OF RESECTION DEPTH BETWEEN ESD AND EMR OF GASTRIC NEOPLASMS IN A TERTIARY CARE PROGRAM IN THE WESTERN WORLD

M. Zhang[1], I. Waxman[2,3], S.-y. Xiao[1]
[1]The University of Chicago Medicine, Department of Pathology, Chicago, United States, [2]Rush Medical University, Department of Internal Medicine, Chicago, United States, [3]Digestive Disease Service Line for Rush University System for Health, Department of Surgery, Chicago, United States

Contact E-Mail Address: mengxue8855@gmail.com
Introduction: Both endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are treatment options for gastric neoplastic lesions and intervention of choice in Asia for superficial gastric cancer, yet comparative studies between the two approaches in the Western world remain sparse. Prior Western studies, mainly meta-analyses, primarily focused on the differences in en bloc resection rate, curative resection rate, and other clinical outcomes. However, little is known regarding the depth of resection by EMR versus ESD, which may critically determine the efficacy of resection.
Aims & Methods: This retrospective study aims to systemically evaluate the depth of resection following EMR and ESD procedures by histological measurement. The standardized and reproducible assessment provides important insights that may be valuable for future research and clinical practice.
Ultimately, the findings from this study will contribute to a better understanding of the most effective yet less traumatic treatment modalities for gastric lesions. Gastric EMR and ESD specimens from 20 patients in the past 5 years were analyzed microscopically for pathology. Tissue sections with intact inked deep resection margins were selected for measurement. The maximum and average depth of resection were recorded and calculated for each patient, defined as depth from muscular mucosa to inked resection margin. The normality of the data for each group was assessed using the Shapiro-Wilk test. An unpaired t-test was then performed to compare the resection depths between the two groups. Other clinical and pathological features were compared between the two groups.
Results: The mean maximum resection depth is 4.53 mm for ESD and 2.33 mm for EMR (p=0.0049). The difference in average resection depth between the 2 groups is not statistically significant (p=0.132). However, ESD resulted in a higher en bloc resection rate (85.7%) as compared to EMR (69.2%).
As could be expected, a larger proportion of ESD specimens (42.8%) were for malignant lesions as compared to EMR cases (15.3%). In addition, the lesion size is significantly larger in the ESD group than in the EMR group (p=0.0031), with a mean lesion size of 41.86 mm for ESD cases and 16.89 mm for EMR cases. There were no significant differences in age or gender between the 2 groups.
Conclusion: Our study provides a detailed and objective evaluation of the depth of resection achieved by ESD and EMR techniques for gastric neoplasms in a Western population. We have shown a significantly higher *en bloc* resection rate and greater maximum resection depth achieved with ESD. Thus, ESD may be the preferred technique for lesions requiring a greater resection depth and those with a larger size.
Furthermore, ESD allows for accurate assessment of the T stage of the gastric neoplasm and evaluation of the resection margins, which is crucial in ensuring the curative resection of the lesion. However, the decision to choose between ESD and EMR should be made on a case-by-case basis, considering the individual patient and lesion characteristics and the expertise of the endoscopist.
In conclusion, our findings suggest that ESD provides a deeper and more complete resection of gastric lesions as compared to EMR, similar to the results obtained in Asia.
Disclosure: Nothing to disclose.

Contact E-Mail Address: fra.mangiola@gmail.com
Introduction: Zenker's diverticulum (ZD) is an acquired herniation of the posterior hypopharyngeal wall through the Killian's triangle. ZD may be cause of dysphagia, regurgitation, cough and potentially life-threatening conditions, such as aspiration pneumonia. Peroral Endoscopic Myotomy (Z-POEM) has been recently used for the management of ZD as an alternative to flexible endoscope septotomy and to the open or transoral surgery. We report on the results of Z-POEM in a consecutive series of patients treated in a single referral centre.
Aims & Methods: All the patients who underwent Z-POEM between October 2020 and March 2023 were retrospectively identified. Demographics, clinical and technical aspects were retrieved from a prospectively collected database. After treatment, patients underwent a close clinical and endoscopic follow-up: technical success, incidence of adverse events and symptoms recurrence were calculated 1, 6 and 12 months after treatment.
All procedures were performed under general anaesthesia with endotracheal intubation. An high-definition endoscope with a transparent distal hood was used. Low-flow carbon dioxide insufflation was used instead of room air. A triangle-tip knife (TT-knife; Olympus Co.) and swift coagulation mode were used for both submucosal dissection and myotomy.
The procedure included:
1. Identification of cricopharyngeal muscle and the septum of the ZD;
2. Submucosal lifting directly on the septum of the ZD and mucosal incision on the septum of the diverticulum;
3. Dissection of the submucosa , on the diverticular and esophageal side;
4. Myotomy of cricopharyngeal muscle and of the proximal part of the esophageal muscularis propria until the bottom of the diverticulum;
5. Closure of the mucosal entry with clips.
Results: Fifty Z-POEM were performed on 49 patients. Thirty patients were males (73.2%), with a mean age of 71.3±9.8 years. The mean length of ZD was 15.3±8.6 mm. The mean length of myotomy was 18.2±7.4 mm, the mucosal entry site was closed with 3.3±0.6 clips. Mean procedure time was 16.6±6.3 minutes. Technical success rate was 96% (48/50). Intraprocedural, mild, complications occurred in two patients (one bleeding and one mucosal perforation) and were treated intraoperatively. A severe complication (oesophageal perforation) occurred in one patient (2%) and required surgery.

A substantial decrease in Kothari-Haber score was observed 1 month (6.3±2.2 vs 1±1.3 P < 0.0001), 6 months (6.3±2.2 vs 1.6±1.6 P < 0.0001) and 12 months (6.3±2.2 vs 2±1.6 P = 0.0004) after treatment. Clinical success was achieved in 89.6% of patients. Three patients underwent a successful endoscopic retreatment (2 flexible endoscope septotomies and 1 Z-POEM) after 1, 6 and 7 months, respectively.

Conclusion: Z-POEM is a promising technique for the treatment of ZD. Larger studies with a long follow-up and comparative trials are necessary to assess its role in the management of ZD.

Disclosure: Nothing to disclose.

Contact E-Mail Address: aurevoireurope@yahoo.co.jp

Introduction: The ulcers after duodenal endoscopic resection (ER) are exposed to bile and pancreatic juice, therefore delayed perforation and bleeding are common. As a preventive measure, the suture of the ulcer after ER has been reported to be effective. Our data are shown as follows. From January 2007 to January 2018, ER was performed for 219 duodenal tumors.

We compared 211 lesions in the suture group with 8 lesions in the non-suture group. Delayed perforation was 0% in the suture group and 13% (1/8) in the non-suture group, showing a significant difference (p=0.0365). Delayed bleeding was 1% (3/211) in the suture group and 25% (2/8) in the non-suture group, showing a significant difference (p=0.01).

Therefore, the suture of the ulcer after ER is essential. If the ulcer is small after ER, it can be sutured endoscopically, but if it exceeds 3 cm, it is difficult to suture with the endoscope alone.

Aims & Methods: The aim of this study is to investigate the outcome of duodenal laparoscopic and endoscopic co-operative surgery (D-LECS) for superficial non-ampullary duodenal epithelial tumors (SNADETs).

First, tissue around duodenum is dissected laparoscopically.

Second, endoscopic submucosal dissection (ESD) is performed using saline injection, Hook knife, and VIO 300D or VIO3. Sites with poor maneuverability endoscopically were resected with laparoscopic assistance.

Third, ulcer after ER is sutured laparoscopically. If inadequate, endo clip is added.

Thirty-five patients with SNADETs who underwent D-LECS from January 2014 to March 2023 were investigated outcome of procedure. The patient's characteristics were as follows. male/female: 23/12, median age 65 (37-83) years old, location of the tumor (bulbs/2nd/3rd portion): 3/27/5, major macroscopic type (0-I/0-IIa/0-IIc): 1/29/5. pancreatic side/ non-pancreatic side of duodenum: 26/9.

SM1 was defined as submucosal invasion of less than 500 μm, and SM2 was defined as deeper. R0 was defined as lateral and vertical margin negative, and lymph-vascular involvement negative. Median follow-up period was 13 (0-42) months.

Results: 1. Median procedure time was 351 (195-673) minutes. In it, median endoscopic procedure time and laparoscopic procedure time were 205(132-429) and 131(67-420) minutes, respectively. Median diameter of resected specimen and tumor were 40 (26-70) and 27 (14-53) mm, respectively. Intramucosal tumor (Vienna classification category 3 to 5.1) / T1bSM2 (category 5.2): 31/4. The median length of hospital stay was 9 (8-15) days.

2. The en bloc resection and R0 resection rate were 94% (33/35), 83% (29/35), respectively.

3. Complications: intraoperative perforation was 8% (3/35). The intraoperative perforation site was sutured laparoscopically after ESD was completed. Intraoperative bleeding requiring blood transfusion, delayed perforation, and delayed bleeding were 0%.

4. The rate of complete closure by laparoscopy was 0% (0/26) for pancreatic side, and all of them were sutured with endo-clips and polyglycolic acid sheets. And that for non-pancreatic side was 100% (9/9).

5. Prognosis:

Two cases of T1bSM2 were underwent pancreaticoduodenectomy, and there were no residual tumor and no lymph node metastasis. There has been no recurrence during twenty-eight and forty-two months after DLECS,

T1aM and T1bSM1 were followed up, and no local or metastatic recurrence was observed.

Conclusion: DLECS enabled complete closure of ulcers after ER regardless of size or location. Therefore, it is a safe and effective treatment for large SNADETs.

Disclosure: Nothing to disclose.

ARE AGE AND GENDER PREDICTIVE RISK FACTORS FOR BARIATRIC THERAPY WITH BIOENTERICS INTRAGASTRIC BALLOON EFFECTIVENESS?

R. Cerqueira[1], M. Correia[1], M. Sousa[1], I. Pita[1], I. Ribeiro[1], R. Veloso[1], M. Manso[2]

[1]Centro Hospitalar entre Douro e Vouga, Gastroenterology, Santa Maria Feira, Portugal, [2]University Fernando Pessoa, Porto, & REQUIMTE-UP, Portugal, Biostastistics, Porto, Portugal

Contact E-Mail Address: rute.cerqueira@chedv.min-saude.pt

Introduction: In obese patients, a large amount of data shows that bariatric therapy with Bioenterics intragastric balloon (BIB) results in weight loss in some patients. However there is paucity of data about predictive risk factors for BIB success.

Aims & Methods: The aim of this study was to determine the impact of age and gender in the effectiveness of this endoscopic device for weight loss.

Single center prospective study with 187 patients, 143 (76.5%) females, mean age 40±11.9 years submitted to BIB therapy. Data were collected for age, gender, baseline weight and baseline BMI. At BIB removal, after 41.3±12.1 weeks, the following parameters were documented: % excess weight loss (%EWL), total body weight loss (TBWL) and % total body weight loss (%TBWL). Patients were categorized according to gender, age groups (<40 years, between 40 – 49 years and age ≥ 50 years), and according to baseline BMI (<35 kg/m^2, 35-40 kg/m^2 and >40 kg/m^2).

Multiple linear regression analysis was used to assess the effect of baseline BMI, gender and age in the BIB outcomes (p<0.05).

Results: Median TBWL was 14 kg (16.0±12.2kg) in female and 14.5 kg (15.8±11.7kg) in male (p=0.994). Female with ≥50 years lost significantly more TBWL than female with <40 years and female between 40-49 years, respectively 22.5 kg vs 11.5kg median values (p=0.028) and 22.5 kg vs 13.3 kg (p=0.037). Regarding %TBWL there were significant differences between the age groups: female with ≥50 years vs <40 years (21.2% vs 13.2%, p=0.018), but no significant differences were observed between the female with 40-49 years and the younger and older ones (<40 vs 40-49 years, p=0.853; 40-49 vs ≥50 years, p=0.058). The %EWL was not significant differ-

ent in the female groups (p=0.355). In the male group the 3 endpoints were not significantly different: TBWL, p= 0.621, % TBWL p=0.835 and % EWL p=0.888. Patients with higher baseline BMI (> 40) had significantly more TBWL in both genders, female (p=0.001) and male (p=0.002), significantly more %TBWL in male (p=0.033) and significantly more% EWL in female (p=0.049).

Conclusion: Older female patients (≥ 50 years) lost greater amount of weight than younger ones with BIB therapy. On the other hand, age did not alter the outcome in male patients. Higher baseline BMI was significantly correlated with greater weight loss in both genders. Age and baseline BMI can be used as predictors of weight loss in patients submitted to BIB therapy.

Disclosure: Nothing to disclose.

Contact E-Mail Address: benjamin.norton@nhs.net

Introduction: A Zenker diverticulum is an acquired sac-like outpouching of the mucosa and submucosa that occurs at the pharyngo-oesophageal junction. When symptomatic, it is characterised by oropharyngeal dysphagia and regurgitation. Multiple treatment options are available with various success. Commonly a flexible endoscopic diverticulotomy is performed but is associated with a high risk of recurrence. Zenker peroral endoscopic myotomy (Z-POEM) represents are exciting endoscopic strategy that involves third space endoscopy by tunnelling through the submucosa to enable a more complete myotomy.

Early studies have shown a high success rate and favourable safety profile, but it is mainly limited to small retrospective cohorts outside the UK. Here, we report our experience on Z-POEM at two UK tertiary referral centres.

Aims & Methods: We conducted a retrospective cases series among patients undergoing Z-POEM between April 2021 to March 2023 at University College London Hospital and Cleveland Clinic London. Patient demographics, technical success, clinical success, and adverse events were all recorded. Technical success was defined as successful completion of all steps of the Z-POEM procedure. Clinical success was defined as a reduction in Dakkak and Bennett (DB) dysphagia score to ≤ 1 (or 0 if the pre-treatment score was 1) at three- and six-months post-procedure without need for repeat intervention.

Results: In total, 33 patients underwent Z-POEM. The median age was 76 years old (IQR 70-79), 13 patients (39.4%) were female, and the median Charlson comorbidity Index was 3 (IQR 3-4.5). Pre-procedure, the median DB score was 2 (IQR 2-3) and the mean pouch size was 3.98 cm (95% CI: +/- 0.6). Seven patients had previously undergone attempted endoscopic stapling and one open surgery.

All procedures were performed under a general anaesthetic. The mean procedural time was 48.9 minutes (95% CI: +/- 7.9), median length of stay one day, and the technical success rate was 100%.

The overall clinical success (minimum one month follow-up) was 83.3% with a median follow-up of 8 months (IQR 4-13). At 3-months, 6-months, and 12-months post-procedure, the clinical success was 87.0% (n=23), 77.8% (n=18), and 66.7% (n=12), respectively. Three patients had improved DB scores but opted for repeat intervention for persistent symptoms. Two underwent successful repeat Z-POEM to extend the myotomy and one underwent a diverticulotomy of remaining muscle fibres. One patient is awaiting work-up for a planned repeat Z-POEM. During follow-up, there were two adverse events (7.4%) due to post-operative chest infections. Two patients died, which were both unrelated to the Z-POEM procedure.

Conclusion: Z-POEM is a novel minimally invasive procedure that is associated with low adverse events and high success rates. Our early outcomes are promising and consistent with other observational cohorts. Those with persistent symptoms can be treated successfully with reintervention, which improves the clinical efficacy to >90% at one year. The marker of success appears to be completeness of the initial myotomy, and patients should be aware of the possibility and efficacy of reintervention.

Disclosure: Nothing to disclose.

INTEROBSERVER AGREEMENT RATE OF CONFOCAL LASER ENDOMICROSCOPY IMAGES IN IRRITABLE BOWEL SYNDROME

L. Balsiger[1], K. Raymenants[1,2], J. Schol[1,2], K. Routhiaux[1], J. Toth[1], T. Vanuytsel[1,2], J. Tack[1,2]

[1]University of Leuven, Translational Research Center for Gastrointestinal Disorders TARGID, Leuven, Belgium, [2]University of Leuven, University Hospital Gasthuisberg, Gastroenterology, Leuven, Belgium

Contact E-Mail Address: balsiger.lukas@yahoo.com

Introduction: Irritable bowel syndrome (IBS) is a common disorder of gut brain interaction (DGBI) characterized by abdominal pain associated with altered bowel habits – symptoms are often related to food intake. Confocal laser endomicroscopy (CLE) has shown acute food-triggered disruption of the epithelial barrier in the duodenum of IBS patients. While this technique promises new insights into the pathophysiology of IBS, image interpretation is subjective and interobserver agreement rates have not been assessed.

Aims & Methods: Aim: To assess the agreement rate between assessors regarding acute food induced mucosal changes visualized by CLE.

Methods: In Rome IV IBS (non-constipated) patients, allergic sensitization to nutrients was excluded by specific serum Immunoglobulin E tests. CLE was performed during upper GI endoscopy: duodenal mucosa was visualized before and after sequential application of 10mL dissolved aliquots of lyophilized fish, nuts, egg white, soy, milk and wheat. Two investigators (experience of ≥20 exams each) assessed separately recorded sequences for the presence or absence of acute mucosal alterations defined as fluorescence leakage and cell shedding visualized on ≥3 different mucosal spots. Assessors were blinded for patient characteristics, and for the time-point of recordings (i.e. baseline or after food administration). Agreement rates are reported in percent and using Cohen's Kappa computed with Rstudio.

Results: A total of 75 video sequences from 22 procedures in 13 patients were interpreted. Regarding presence or absence of mucosal alterations, assessors agreed in 81% (*61/75*) of assessed sequences resulting in a Cohen's Kappa of 0.63.

Overall, 52% (*32/61*) of sequences with agreement were judged by both assessors to present leakiness and cell shedding whereas 48% (*29/61*) were considered normal.

Conclusion: When assessed in a blinded manner, mucosal leakiness is visualized on CLE recordings with a high agreement rate between assessors and substantial agreement when accounting for random chance agreement. Further increasing agreement rates by possibly modifying criteria might increase the validity of this technique.

Disclosure: Nothing to disclose.

Contact E-Mail Address: fra.mangiola@gmail.com

Introduction: Per-Oral Endoscopic Myotomy (POEM) was introduced in clinical practice few years ago, and quickly become one of the first line treatments of esophageal motility disorders. We report on the outcomes of the first 1000 patients treated with POEM in a single tertiary referral center during 11 years.

Aims & Methods: The first 1000 patients treated with POEM between May 2011 and September 2022 were identified from a prospective database and included in this study.

Demographics, clinical and technical aspects and follow-up data were collected and analysed. After treatment, patients underwent a regular follow-up, after 6 month, 2 years, 5 years and 10 years. Additional follow-up visits were performed, if clinically indicated. Timed Barium Esophagram, EGD, and esophageal manometry were performed before endoscopic treatment and during post-operative follow-up; a 24-hour esophageal pH monitoring study was performed 6 months after POEM.

Clinical failure was defined by and Eckardt score > 3 and by the need for additional treatments.

Results: Mean age of patients was 51.5 years; 36 patients were younger than 18 years and 157 older than 70 years. Four-hundred ninety-eight patients were male. One hundred seventy-seven patients had received previous treatments for achalasia (110 pneumodilation, 46 surgical myotomy; 21 botulinum toxin injection).

A total of 141 patients had a type I achalasia, 626 a type II, 111% a type III, 30 non-achalasia spastic esophageal motility disorders; in 92 patients achalasia type were not adequately classified. A sigmoid-type esophagus was present in 45 patients.

Mean symptoms duration before POEM was 24±64.6 months.

POEM was technically successful in 979 patients.

The median length of myotomy was 8.0 cm (range 4-22 cm) in the esophagus and 3.1 cm (range 0-7 cm) in the stomach. An anterior myotomy was performed in the 83% of patients. Mean operative time was 50.4 minutes (11–180 minutes).

Length of hospital stay was a mean of 2.5 days (range 1 to 48 days) after POEM.

Mild or moderate complications occurred in 28 patients (2.8%) and were managed conservatively. Severe complications occurred in 2 patients and required prolongation of hospital stay and other interventional treatment. There were no perioperative deaths in our series.

A mean follow-up of 30.4 months (3–130 months) was available for 93.8% of patients. Overall clinical success rate (Eckardt score ≤ 3) was 95.1%. Clinical success was 97.3%, 95.2%, 90.8% and 82% after 6 months, 2 years, 5 years and 10 years, respectively.

Thirty-three patients (70.2 %) with clinical failure underwent pneumodilation (78.8% with persisting clinical benefits); 5 patients (10.6% underwent surgery), one (2.1%) underwent re-POEM.

Clinical success was 93.4% in achalasia-patients and 83.3% in those with spastic motility disorders (p=0.1742).

An altered esophageal pH-study was documented in 32.6% patients; esophagitis rate was 34% (88% grade A/B; 12% grade C/D). At the date of the last follow-up, 38% of patients was receiving daily proton-pump inhibitors for gastroesophageal reflux. Two patients underwent antireflux surgery. Non cases of post-operative Barrett esophagus were identified.

Conclusion: Our results confirm the efficacy of POEM in a large cohort of patients. Benefits of POEM seem durable; adverse events are rare and no specific mortality was reported. Prevalence of GERD is relatively high, but well controlled by medications in the vast majority of patients.

Disclosure: Nothing to disclose.

EPPOEM: A RETROSPECTIVE MULTICENTER COMPARATIVE ANALYSIS OF SELECTIVE INNER MUSCLE LAYER MYOTOMY VERSUS FULL-THICKNESS MYOTOMY IN THE ENDOSCOPIC TREATMENT OF ACHALASIA USING POEM PROCEDURE

M. Sanavio[1], R. Altwegg[1], A. Berger[2], B. Vauquelin[2], F. Zerbib[2], A. Debourdeau[1]
[1]CHU de Montpellier, Gastroentérologie et Transplantation hépatique, Montpellier, France, [2]CHU de Bordeaux - Hôpital Haut Leveque, Hépato-Gastroentérologie, Pessac, France

Contact E-Mail Address: mathilde.snv@gmail.com

Introduction: Since 2010, per oral endoscopic myotomy (POEM) has become an important part of the treatment for achalasia. This technique involves myotomy of the lower esophageal sphincter and can be performed using various technical modalities, some of which have already been studied (such as different myotomy lengths and anterior versus posterior approach).

The aim of this study is to compare the impact of the depth of myotomy (selective inner layer myotomy (SIM) vs full-thickness myotomy (FTM)) on the outcomes of patients treated with POEM for achalasia.

Aims & Methods: This was a retrospective, observational, bi-centric study conducted in two tertiary center between October 2018 and September 2022. Patients were divided into two groups: SIM and FTM.

The primary endpoint was clinical efficacy at 6 months, while secondary endpoints were postoperative parameters (such as pain, length of hospital stay, complications) and gastroesophageal reflux disease (GERD) parameters (esophagitis at 6 months, heartburn, and pH-metry).

Results: Out of the 166 patients who underwent POEM, 158 were included in the study (33 in the FTM group and 125 in the SIM group). The clinical efficacy rates at 6 and 12 months were similar in both groups, with 84% and 70% in the SIM group versus 90% and 80% in the FTM group, respectively (p=0.57 and p=0.74). However, more opioid analgesics were consumed in the FTM group compared to the SIM group (45% vs 21%, p<0.01). The length of hospitalization was longer in the FTM group than in the SIM group (2.94 ± 2.33 vs 2.17 ±2.62, p<0.001). The rate of esophagitis at 6 months was comparable (16% in the SIM group vs 12% in the FTM group, p=0.73). There was no significant difference in terms of pyrosis at 6 or 12 months between the SIM and FTM groups (18.5% vs 3.8%, p=0.07 and 27% vs 12.5%, p=0.35, respectively).

Conclusion: There was no significant difference in terms of clinical efficacy and GERD occurrence between FTM and SIM. However, full-thickness myotomy was associated with more postoperative pain and a longer length of hospital stay. Therefore, selective internal myotomy should be preferred over full-thickness myotomy.

Disclosure: Nothing to disclose.

ENDOSCOPIC RESECTION OF GIANT ESOPHAGEAL SUBEPITHELIAL LESIONS: EXPERIENCE OF A LARGE SINGLE CENTER

A. Xiang[1], H. Hu[1], K. Wang[1], W. Su[1], Q. Li[1], P. Zhou[1]
[1]*Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, China*

Contact E-Mail Address: ayxiang17@fudan.edu.cn

Introduction: Thoracic surgeries have been the traditional therapeutic approach for esophageal giant subepithelial lesions (g-SELs). Due to the rapid development of endoscopic techniques, increased reports on endoscopic resection (ER) of g-SELs have emerged in recent years.

Aims & Methods: We aimed to summarize the experience of our center on ER of esophageal g-SELs, and also develop a nomogram model to predict the procedural difficulty. 75 patients with g-SELs treated with ER at Zhongshan Hospital were included in the training set. Clinicopathological features, procedure-related characteristics, postprocedural outcomes and follow-up data were gathered and analyzed. A predictive nomogram model for procedural difficulty was proposed based on the risk factors identified by multivariable logistic regression analysis. Internal and external validation were conducted to verify the model performance.

Results: Of the 75 cases, the en bloc resection rate was 93.3%. Intraoperative and postoperative adverse events occurred in 7(9.3%) and 13(17.3%) patients, respectively. No recurrence or metastasis was observed.

32 (42.7%) patients underwent a difficult procedure. A younger age, maximal tumor diameter ≥ 8 cm, irregular shape and extraluminal growth pattern were independent risk factors of a difficult procedure, while adopting submucosal tunneling endoscopic resection (STER) as the ER method was inversely correlated with procedural difficulty.

The nomogram model showed good discrimination, with the area under the receiver-operating characteristics curve (AUC) of 0.858 and 0.827 of the training and validation set. Calibration curves and Hosmer-Lemeshow tests (P =0.524 of the training set and 0.413 of the validation set) also achieved favorable results.

Conclusion: ER serves as a promising therapeutic option for esophageal g-SELs. A younger age, large tumor size, irregular shape and extraluminal growth may indicate increased ER difficulty, while a STER procedure tends to be of lower difficulty. Our nomogram model performs well to predict ER difficulty for esophageal g-SELs.

Disclosure: Nothing to disclose.

Introduction: To date, most of the endoscopic trainers are not constructed according to the actual gastric morphology. Therefore, we have developed a new simulator for endoscopic therapy technology, evaluated its efficacy and authenticity in endoscopic operation, and explored the learning curve of novice endoscopic physicians and the training effect.

Aims & Methods: According to the medical image data of actual gastric transverse plane, a relatively standard gastric morphological structure was made by using computer modeling and 3D printing technology. Different endoscopic procedures were simulated by adding different training modules in the structure. First of all, 30 endoscopists with different levels of experience were recruited for the test to evaluate the effectiveness of the trainer, later 20 novice endoscopists were selected for the learning curve test.

Finally, 38 novice endoscopists were divided into group A (new simulator) and group B (traditional non-simulated stomach model) for simulated training to observe the technical progress of clinical gastroscopy.

Results: Endoscopists with different levels of experience in each group believe that the training device has high authenticity, substantial convenience, low physical and mental load, and high interest. The higher the level of endoscopists needs the less testing time. The effect of training for novice endoscopists reached the platform stage after 13 times (about 10 hours of training).

The control experiment found that group A scored higher than group B in terms of familiarity with endoscopic instruments, understanding of gastric structure, and self-confidence in clinical examination, while there was no significant difference between the two groups in terms of understanding of working principles and proficiency in the operating process.

Conclusion: The novel simulator can truly simulate some endoscopic treatment techniques and distinguish the differences of endoscopists' techniques. Meanwhile, training in the simulator can significantly shorten the cycle of skill improvement of novice endoscopists.

Disclosure: None.

PP0265

SAFETY AND TOLERABILITY OF PEG-J IN PARKINSON DISEASE

I. Botto[1], S. Carvalhana[1], L. Correia[1]
[1]*Centro Hospitalar Universitário Lisboa Norte, Serviço de Gastroenterologia e Hepatologia, Lisbon, Portugal*

Contact E-Mail Address: ines.botto@gmail.com

Introduction: Levodopa, the gold-standard drug in Parkinson Disease (PD), has an inconsistent gastric absorption, that leads to unstable dopamine levels, and consequently motor fluctuations. PEG-J (percutaneous endoscopic gastrostomy with jejunal extension) is an endoscopic technique which allows food and medication to be administred directly in the proximal jejunum, via a tube that extends from a gastrostomy.

Aims & Methods: We intend to describe our center's experience with PEG-J in PD. Unicentric retrospective study with PD patients submitted to PEG-J between september 2020 and february 2023. Safety and tolerability were evaluated.

Results: 23 patients were included, with mean age of 74.8 years, 13 patients (57%) female. Indication for PEG-J was advanced PD with motor flutuations or refractory to standard oral medication. No adverse events were reported during the procedure. Regarding device-related complications, 13 patients (57%) reported intestinal tube exteriorization, and 2 patients reported tube obstruction. Regarding stoma-related complications, 15 patients (65%) reported granuloma or mucosal extrusion, 4 patiens reported peri-stomal infection, and 2 patients reported gastric leak. During follow-up, only 3 patients discontinued levodopa. There were no deaths or need for hospitalization related to PEG-J procedure or complications.

Conclusion: PEG-J is a safe procedure, and must be considered in advanced PD. The rate of device-related and stoma-related complications was inferior to 50%.

THE USE OF ENDOSCOPIC VACUUM THERAPY (EVT) AS COMPARED TO ENDOSCOPIC STENTING (ES) FOR LEAKAGES AFTER FOREGUT SURGERY – A MULTICENTRE COHORT STUDY

S. Chan[1], I. Wong[1], C.T. Lam[2], D.H.S. Foog[3], P.H. Chu[1], C.K. So[2], H.C. Yip[1], S. Law[1], P.W.Y. Chiu[1]

Introduction: Anastomotic leakage after foregut surgeries are often difficult to manage. The conventional way of endoscopic treatment is endoscopic stenting (ES). However, it carries a risk of stent migration and erosion. Endoscopic vacuum therapy (EVT) has recently been proposed as an alternative way of treating these leaks. EVT has the benefit of providing negative suction and promotion of granulation tissue[1]. However, an exchange every 3-7 days has been suggested.

Aims & Methods: The aim of this study was to compare the treatment outcomes between ES, EVT and the combination of both. This was a retrospective multi-centre cohort study from 3 major centres in Hong Kong that performs esophagectomy and gastrectomy. All patients with anastomotic leak after total gastrectomy and esophagectomy and who were treated with ES or EVT between Jul 2008 and Apr 2023 from the Prince of Wales Hospital, Queen Mary Hospital and United Chistian Hospital were included. Patients' demographics, type of surgery, size of anastomotic defect, treatment success rate, complications, number of procedures, duration to healing were recorded and compared. Continuous data are compared with Mann-Whitney test and categorical data are compared with Chi-square/ Fisher's exact test.

Results: A total of 63 patients were recruited (ES: 49; EVT 14. The outcomes of the study are listed in Table 1.

	Endoscopic stenting (ES) n =49	Endoscopic vacuum therapy (EVT) n = 14	p-value
Age	66.67 (10.44)	61.21 (12.94)	0.22
Sex (M:F)	37:12	12:2	0.42
Pathology			0.54
Benign	2	1	
Malignant	47	13	
Surgery			<0.001***
Total gastrectomy	18	3	
Ivor Lewis esophagectomy	15	2	
McKweon	16	9	
Defect size (mm)	15.38 (15.92)	17.79 (14.06)	0.39
Single arm endoscopic treatment success rate	29/49 (59.2%)	6/14 (42.9%)	0.28
Complications	23/49 (46.9%)	2/14 (14.3%)	**0.03**
No. of procedures	3 (1-13)	6 (2-16)	**0.02**
Days required for the anastomosis to heal	61.7 (38.4)	45.3 (25.8)	0.37

Table 1.

The mean (S.D.) of defect was 15.4 (16.0)mm in the ES group and 17.8 (14.1) mm in the EVT group (p=0.39). in the EVT group, there are 3/14 patients who had failed EVT therapy and converted to ES. The success rate of each arm as a single arm therapy were similar (29/49(59.2%) in the ES group vs 6/14(42.9%) in the EVT group; p=0.28).

However, there were less complications in the EVT group (2/14 (14.3%) in ES group vs. 23/49(46.9%) in EVT group; p=0.03). On the other hand, the EVT group required more endoscopic procedures (median (range) 3 1-137) procedures in the ES group vs 6(2-16) in the EVT group; p 0.002).

The days required for the anastomosis to heal were also similar (ES (61.7 (38.4) vs EVT 45.3 (25.8); p=0.37). When comparing patients treated as a single-arm therapy (ES or ET) to combination therapy (ES + EVT), the success rates has a trend towards favouring combination treatment (p=0.07).

Conclusion: Both EVT and ES are feasible and safe in treating anastomotic leaks after foregut surgeries. Although more procedures are required, EVT achieved similar success rate while having less complications when compared to ES a single arm. The use of combination therapy as compared to single-arm endoscopic therapy may achieve a higher treatment success rate.

Contact E-Mail Address: 1054372126@qq.com

Introduction: The purpose of this study is to compare the efficacy and clinical outcomes of simplified endoscopic retrograde appendicitis treatment and Conventional endoscopic retrograde appendicitis treatment for uncomplicated acute appendicitis patients.

Aims & Methods: The simplified endoscopic retrograde appendicitis therapy (SERAT) refers to the simplification of the operation process on the basis of conventional endoscopic retrograde appendicitis treatment (ERAT), without the need for appendicography and general anesthesia.

We used propensity score matching (1:1) to compare the application of SERAT and ERAT in uncomplicated acute appendicitis patients among three hospitals from May 2017 to Jan 2022. Among 614 hospitalized uncomplicated acute appendicitis patients, 286 underwent SERAT (Group A), and 254 patients underwent ERAT (Group B). In order to adjust for baseline differences and select bias, treatment results and complications were compared after propensity score matching.

Results: After 1:1 PSM, 198 well matched patients in each group were evaluated. The median operation time for the SERAT group was 26.4 ± 7.5 minutes, while for the ERAT group, it was 41.3 ± 15.5 minutes. The difference between the two groups was statistically significant.

There was no significant difference in the success rate of intubation, time to abdominal pain relief, duration of normalization of inflammatory markers (including WBC count and CRP level), and length of hospitalization between the SERAT and ERAT groups (P=0.456, P=0.265, P=0.357,

P=0.156, respectively). The median hospitalization cost in the SERAT group was 6836.9 RMB, significantly lower than the ERAT treatment group's hospitalization cost of 113371.5RMB. The follow-up recurrence rate in the SERAT group was 9.13%, higher than that in the ERAT group, which was 6.91%.

Conclusion: Compared with conventional ERAT, the simplified ERAT is technically feasible for the treatment of uncomplicated acute appendicitis patients. SERAT can reduce hospitalization costs but to some extent increase readmission rates within an acceptable range.

Introduction: Iatrogenic defects of the gastrointestinal (GI) tract represent a challenging indication even for experienced endoscopists, with the optimal approach being often a dilemma. The increase of interventional endoscopic procedures and complex surgical operations have generated the requirement for clear options in the occurrence of a perforation or a leak. Current guidelines recommend self-expandable metal stents (SEMS), over the scope clips (OTSC) and through the scope clips (TTSC) depending on the site and the size of the defect, albeit based on low quality, indirect comparisons between different cohorts.[1,2]

This systematic review and meta-analysis aimed to evaluate the available modalities based on comparative quality studies, to elucidate reliably this field.

Aims & Methods: The systematic research was performed in MEDLINE, Cochrane, and Scopus databases until March 2023 for comparative studies evaluating the successful defect closure using SEMS, OTSC, TTSC or endoscopic vacuum therapy (EVT). Any study including at least one comparison was assessed for eligibility. Clinical success was considered as the primary outcome, representing the successful closure of the defect (perforation, leak).

Secondary outcomes included overall adverse events were compared among modalities, whereas cumulative rates of the specific complications were also estimated. Meta-analyses were based on random effects model and the results were reported as odds ratios (OR), with 95% Confidence Intervals (95%CI).

Results: Eight studies with an overall number of 744 patients were included in our analysis. In five of them (497 patients) SEMS were compared with alternatives (OTSC and EVT), whereas OTSC and TTSC were assessed in 3 studies (247 patients). SEMS were found to be significantly inferior to alternatives in achieving the primary outcome [OR: 0.38 (95%CI: 0.14-1.01, p=0.05)], however with high heterogeneity (I^2=75%). Interestingly, in subgroup analysis, OTSC achieved significantly higher clinical success than SEMS with OR: 2.07 (95%CI: 1.12-3.85, p=0.02) and reduced heterogeneity (I^2=19%), whereas the comparison between SEMS and EVT failed to reach statistical significance [OR: 0.42 (95%CI: 0.005-3.19, p=0.4; I^2=85%)]. OTSC and TTSC yielded similar rates of successful defect closure [OR: 0.07 (95%CI: 0.03-0.16), p=0.59; I^2=0%].

Considering the secondary outcome, SEMS resulted to more adverse events than alternatives [OR: 13.5 (95%CI: 4.57-37.28, p<0.001; I^2=63%)], with stent migration been the most common one (81 cases, 26.1%). In the subgroup analysis, both OTSC and ETV provided significantly less complications [OR: 0.07 (95%CI: 0.03-0.16, p<0.001; I^2=0%) and OR: 0.09 (95%CI: 0.02-0.44, p=0.003; I^2=59%) respectively]. Finally, only one complication was described in the OTSC vs TTSC group.

Conclusion: The success of endoscopic closure of luminal GI defects using SEMS is inferior to alternatives, especially when compared to OTSC, whereas it results to higher rates of adverse events. On the other hand, TTSC and OTSC seemed to be equivalent regarding efficacy and safety.

Introduction: Digestive hemorrhage is a frequent complication in advanced chronic kidney disease. Patients with end-stage renal disease (ESRD) are more likely to have gastrointestinal (GI) problems, including digestive bleeding of high or low origin.

Aims & Methods: The aim of our work is to study the particularities of HD in CKD patients.

This is a monocentric prospective analytical study over a period of 28 months: April 2020 to August 2022, including patients with HD with CKD at the dialysis stage or not, including renal transplant patients.

In order to be able to compare patients with ESRD with patients without ESRD, a control group of patients admitted for HD who had a GI endoscopy during the study period and with normal renal function were identified and grouped. In this group of patients, we took into account age, sex, indications, GI endoscopy results and ICU stay.

We also assessed all-cause mortality between the groups of CKD patients with HD versus the control group.

Results: A total of 378 patients underwent digestive exploration for HD. In this population, 46 (12.16%) patients with CKD were compared with 332 patients without RI.

70% (n=32) of the patients with RI were on chronic hemodialysis, 26% (n=12) had a GFR<60ml/min/1.73m2 but were managed without the aid of dialysis or transplantation, and 4% (n=2) patients were renal transplant recipients.
The most common etiologies in CKD patients were ulcer disease 65.2% (n=30); vascular ectasia 28.2% (n=13), gastritis 26% (n=12), esophagitis 10.8% (n=5); and tumors in 8.6% (n=4).
After statistical analysis patients with CKD had:
A higher risk of hemodynamic instability 69.5% (n=32) compared to the control group 11.14% (n=37) with p=0.002,
A higher rate of recurrence 26% (n=12) CKD patients compared to 9.6% (n=32) of the control group with a p=0.00.
A higher mortality rate 4.34% (n=2) in CKD patients compared to the control group 1.2% (n=4) with p=0.00.
Conclusion: GI bleeding in advanced chronic kidney disease is more severe it is accompanied by a higher risk of recurrence of ICU stay and mortality, hence the interest of prompt management and close monitoring. The main causes are peptic ulcer and vascular ectasia.
Disclosure: Nothing to disclose.

PP0270

WEEKENDS VERSUS WEEKDAYS ADMISSION WITH UPPER GASTROINTESTINAL BLEED: WOULD IT MAKE ANY DIFFERENCE?

S. Ayesha[1], A. Subhan[1,2]
[1]The Aga Khan University Hospital, Gastroenterology, Karachi, Pakistan, [2]The Aga Khan University Hospital, Karachi, Pakistan

Contact E-Mail Address: syedda.ayesha@aku.edu
Introduction: Upper gastrointestinal bleed (UGIB) is a significant and common medical condition that not only require prompt management but also associated with notable morbidity and mortality if not treated timely. The association of weekend effect and mortality due to UGIB has been studied with some variability in results. Lack of availability of gastroenterologist and endoscopy unit to facilitate the interventional procedure especially where the resources are limited could affect the patient's outcome. Hence, here we aim to evaluate the difference in mortality of patients presenting with UGIB on weekends as compared to those admitted on weekdays.
Aims & Methods: To evaluate the difference in mortality and length of stay in hospital of patients presenting with UGIB on weekends as compared to those admitted on week days.
This was a cross sectional study conducted at the Aga khan university hospital, Karachi during Januray-December 2021. Adult patients with age ≥18 years presented with UGIB were included. Information was collected on demographic/clinical charecteristics, timing and findings of endoscopy, length of hospital stay and mortality. Mortality and hospital stay were compared for patients admitted on weekdays vs on weekend by using chi square test.
Results: A total of 300 patients admitted with UGI bleed, of which 131 (43.7%) were admitted during the weekends. The mean age was 57.7 ± 15.5 years and 65% were male. Endoscopic intervention was performed over weekend in 23.7% cases. The most common endoscopic finding on both weekday and weekend was of esophageal varices of 174 (58%).
Multivariate analysis shows the factors affecting the mortality were TLC, Co-morbidity of IHD, Endoscopic findings of esophageal varices and female gender.
The overall mortality was 1.7%. No statistically significant difference was found in mortality among patients admitted over weekends vs weekdays (p 0.07). Hospital length of stay on average was of 3.5 ± 1.5 days, with no statistically significant difference (p 0.89).
Conclusion: No difference in mortality was observed in patients admitted with UGI bleed on weekends vs weekdays. Which depicts that in this tertiary care hospital, endoscopic interventions are practiced all seven days of the week.Multicentric studies with larger sample size would be needed to evaluate the consistency of current findings.
Disclosure: I have no conflict of interest.

UNDERWATER EMR VERSUS CONVENTIONAL EMR FOR NONAMPULLARY DUODENAL ADENOMAS

R. Medas[1], R. Morais[1], J. Amorim[2], J. Santos-Antunes[1], M. Marques[1], F. Vilas-Boas[1], G. Macedo[1]
[1]Centro Hospitalar e Universitário de São João, Gastroenterology, Porto, Portugal, [2]Faculty of Medicine of University of Porto, Porto, Portugal

Contact E-Mail Address: renatogmedas@gmail.com
Introduction: Underwater endoscopic mucosal resection (U-EMR) is an emerging technique in the management of superficial nonampullary duodenal epithelial tumours (SNADETs). Nevertheless, particularly in Western centers, its application has not been comprehensively assessed.
Aims & Methods: Our aim was to compare the efficacy and safety of U-EMR versus conventional EMR (C-EMR) for the endoscopic treatment of SNADETs.
Retrospective case-control study that analyzed all patients who underwent duodenal EMR in a tertiary reference center, between 2015 and 2022. SNADETs ≥10 mm removed by U-EMR or C-EMR were included.
Primary endpoint was residual/recurrent adenoma rate (RAR).
Secondary outcomes were rates of technical success, en bloc resection, and adverse events (AE).
Results: A total of 40 duodenal adenomas (31 patients) were included (U-EMR n=18; C-EMR n=22). Median lesion size was 16.5 ± 13.3 mm. Lesions were predominantly IIa (47.5%) and IIa+c (20%) - Paris classification. Most lesions were in the second portion of duodenum (n=35).
Groups were similar regarding age, gender and lesion size. There were no significantly statistically differences between groups regarding technical success (100% U-EMR vs. 90.9% C-EMR, p=0.19) and en bloc resection rate (44.4% U-EMR vs. 54.2% C-EMR, p=0.53). RAR was higher in the C-EMR group (n=6/20, 30% vs. n=1/10, 10%, p=0.22), although without statistically significance. Post-EMR defects were more commonly closed in U-EMR group (83.3% vs. 45.5%, p <0.05). Peri-procedural AE rate (bleeding n=2 [11.1%] U-EMR vs. bleeding n=3 [13.6%] C-EMR, p=0.81) was similar between groups. There were no delayed complications in the U-EMR group while in the C-EMR group there were 2 cases of bleeding (0% vs. 9.1%, p= 0.19).
Conclusion: In our study, compared to C-EMR, U-EMR showed similar RAR and safety, highlighting its role as a feasible therapeutic option for the management of SNADETs.

DOES NON-TARGETED DIAGNOSTIC BIOPSY HAVE A ROLE IN IRON DEFICIENCY ANAEMIA?

P. Oka[1], M. Shiha[1], R. Sidhu[1], M. McAlindon[1]
[1]*Sheffield Teaching Hospitals, Gastroenterology, Sheffield, United Kingdom*

Contact E-Mail Address: oka.priya@gmail.com

Introduction: Current quality standards in oesohagogastroduodenoscopy (OGD) recommend separate biopsies from the gastric antrum and body, as well as duodenal specimens if coeliac serology is positive or has not been previously measured in patients with iron deficiency anaemia (IDA). The aim of this study was to evaluate the role of routine biopsies in management of patients undergoing a diagnostic gastroscopy for investigation of iron deficiency anaemia (IDA).

Aims & Methods: Patients with IDA referred for endoscopy were recruited. Biopsy samples were taken during OGD according to the BSG quality standards. The diagnostic value of these biopsies was assessed based on endoscopy reports and histology. The cost of a diagnostic gastroscopy and diagnostic gastroscopy with biopsy was calculated using the NHS tariff workbook.

Results: 94.0% (63/67) of the patients had biopsies done during OGD. In total 298 samples were obtained for histology which included 8 biopsies from oesophagus in 6 patients, 64 biopsies from stomach in 31 patients and 195 biopsies from the duodenum in 70 patients.14 samples were taken for a rapid urease test out of which six were positive for H. pylori. The histological diagnosis included Barrett's- 3, H. pylori- 3, coeliac- 2, chronic gastritis- 14, cystic polyps-4, GAVE-1 and oesophageal ulcer with no evidence of malignancy-1.

Histological diagnosis lead to a change in the management of 7.4% (5) patients: those with finding of incidental Barrett's oesophagus (n=3) were invited for further surveillance procedures; a new diagnosis of coeliac disease (n=1) was made on the basis of histology of raised intraepithelial lymphocytes alone and subsequent positive tissue transglutaminase antibody (TTG) of more than 10 times upper limit of normal and subtotal villous atrophy in another patient known to have coeliac disease.

Both were referred for a coeliac clinic follow up. Total cost of per unit diagnostic gastroscopy is £370 and the unit cost of diagnostic gastroscopy with biopsy is £436. The total cost of biopsies in our group of patients with IDA was approximately £4150.

Conclusion: Non-targeted biopsies are costly and add little value to the management of patients with iron deficiency anaemia. Although H. pylori was diagnosed in a few patients based on histology and rapid urease test there are non-invasive tests which can be used and are more cost effective for making this diagnosis.

THE SAFETY AND EFFICACY OF EUS-GUIDED SCLEROTHERAPY ON CYST IN THE SUPERIOR RENAL POLE: A COMPARATIVE STUDY WITH LAPAROSCOPIC SURGERY

D. Hu[1], G. Cheng[1], W. Wu[1], Z. Gong[1]
[1]*The Second Affiliated Hospital of Soochow University, Department of Gastroenterology, Soochow, China*

Contact E-Mail Address: duanminhu@163.com

Introduction: Simple renal cyst is one of the most common diseases in the urinary system. Intervention is only considered under circumstances of large cysts (>5cm), bleeding, recurrent infection or pain[1]. Ethanol percutaneous sclerotherapy and laparoscopy are two main treatment modalities for simple renal cysts[2].

However, in cases of cysts in superior renal pole, percutaneous sclerotherapy is often excluded due to the unsafety of percutaneous puncture. In recent years, endoscopic ultrasound (EUS) guided fine-needle aspiration has been proven as a safe and efficient treatment for biopsy of renal and renicapsule lesions[3], inspired by which, we successfully performed an EUS-guided sclerotherapy on cyst in the superior renal pole[4].

Since then, we performed nine more cases of EUS-guided sclerotherapy on cyst in the superior renal pole. This research is an retrospective analysis of the nine cases and is aimed to compare the efficacy, safety and cost-benefit analysis of endoscopic ultrasound guided sclerotherapy and laparoscopic surgery treating cyst in the superior renal pole.

Aims & Methods: To compare the efficacy, safety and cost-benefit analysis of endoscopic ultrasound guided sclerotherapy and laparoscopic surgery treating cyst in the superior renal pole.

A retrospective analysis was performed in 25 patients with cyst in the superior renal pole hospitalized in the Second Affiliated Hospital of Soochow University from January 2021 to August 2022.The efficacy, operation time, intraoperative blood loss volume, hospital stay, complications and treatment cost of EUS-guided sclerotherapy (9 cases) and laparoscopic surgery (16 cases) were compared.

Results: The EUS and laparoscopic groups had comparable efficacy (100% vs 87.5%, *P*=0.520). The EUS group exhibited shorter operation time (29.8±4.8 vs 70.1±11.1 min, *P*=0.000), less intraoperative blood loss (0 vs 26.1±5.9 ml, *P*=0.000), shorter length of postoperative hospital stay (3.5±0.7 vs 5.4±2.0 days, *P*=0.014) and lower total cost (10547.85±2388.19 vs15316.09±5352.45 yuan, *P*=0.019). There were no difference on total length of hospital stay(8.1±2.0 vs 9.3±3.1 days) and operation cost (3946.79±490.82 vs 3860.18.17±857.42 yuan) (both *P*>0.05).

Conclusion: Compared with laparoscopic surgery, EUS-guided sclerotherapy was an effective but safer technique in treating cyst in the superior renal pole.

TISSUE SAMPLING OF SPLENIC LESIONS – COMPARISON BETWEEN EUS-FNA AND PERCUTANEOUS ULTRASOUND-GUIDED BIOPSY

H.H.-W. Liu[1], E.M. Godfrey[1], N.R. Carroll[1]
[1]*Endoscopy Unit, Cambridge University Hospital, Cambridge, United Kingdom*

Contact E-Mail Address: lhw738@ha.org.hk

Introduction: Splenic lesions are not uncommon, but diagnosis without tissue can be difficult. Historically, ultrasound (US)-guided percutaneous splenic biopsies were associated with a 13% risk of haemorrhage [1].
Later studies have reported a much lower complication rate [2].
EUS-FNA is an alternative route for tissue acquisition. A systemic review of several small case series have shown the accuracy and safety of EUS-FNA of the spleen [3].
However, there is no direct comparison between the two methods. We present our experience, describing diagnostic efficacy and safety of both techniques.

Aims & Methods: We aim to compare the efficacy and safety of EUS-FNA of the spleen versus US-guided percutaneous biopsy. Patients who underwent EUS-FNA of the spleen from 2011-2019 and US-guided percutaneous biopsy from 2014-2019 at Addenbrooke's Hospital, Cambridge, were retrospectively reviewed. A biopsy was considered adequate when there was sufficient material obtained for histopathological diagnosis. Biopsy negative for malignancy was considered a true negative if there was stability on clinical and imaging follow-up.
For non-diagnostic samples, a repeat biopsy was performed. The need for blood transfusion or therapeutic intervention was considered a major complication.

Results: Eight EUS-FNA of the spleen were done in seven patients, as one case had repeat FNA due to a non-diagnostic sample. Four of the seven subjects had focal splenic masses, one had a cystic lesion, and two had unexplained splenomegaly on CT. 22 or 25G FNA/B needles were used for focal lesions, while 19G needle was used for cystic lesion. Median (range) number of needle passes was 1.5 (1-3), with median (range) aggregate core length of 4mm (1-16). Diagnosis was established in 6 out of 7 patients (85.7%), which included three cases of diffuse large B cell lymphoma, one inclusion cyst, one extramedullary haematopoiesis, and the remaining case was negative for malignancy. Median (range) follow-up duration was 49.7 weeks (18.1-431). One patient had two non-diagnostic samples taken, and his splenic lesions were stable during the study period. There were no major complications.
Four patients had US-guided percutaneous biopsies. On CT, three patients had focal splenic lesions, and the remaining case had unexplained splenomegaly. 16-19G needles were used for biopsies. Median (range) number of punctures was 2.5 (1-3), with median (range) core length of 8mm (6-18). Three out of four patients had biopsy-proven diagnoses (75%), which include splenic Leishmaniasis, benign vascular proliferation, and the remaining was negative for malignancy. Median (range) follow-up duration was 58.1 weeks (3-242).
One patient developed post-biopsy hemorrhage and required splenic artery embolization. This was complicated with myocardial infarction and acute kidney injury requiring ICU care, and he passed away 24 days later. There was one false-negative result. Biopsy from her splenic lesion did not reveal any malignancy, but PET-CT showed avid uptake (SUVmax 14.7) representing a metastasis. This was confirmed by a response to chemotherapy.

Conclusion: EUS-FNA of the spleen has comparable efficacy and is potentially safer than US-guided percutaneous approach. The choice between the two depends on the location of splenic lesions and the available expertise. Further studies are required for a more robust comparison.

MACROSCOPIC ON-SITE MAGNIFIER-BASED EVALUATION TO ESTIMATE VISIBLE TISSUE CORE CUTOFF LENGTHS USING EUS-FNA WITH 22-GAUGE NEEDLES

J. Huang[1], G. Cheng[1], W. Wu[1], L. Xu[1], D. Hu[1]
[1]*The Second Affiliated Hospital of Soochow University, Department of Gastroenterology, Soochow, China*

Contact E-Mail Address: duanminhu@163.com

Introduction: Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) has been widely used as a safe and effective method for obtaining samples from Solid masses around the gastrointestinal tract. It is difficult for endosonographers to determine the timing of termination of EUS-FNA. However, several reports have validated macroscopic on-site evaluation (MOSE) as safe and effective.

Aims & Methods: We performed a prospective pilot study to explore the value of MOSE in evaluating the specimen quality during magnifier-based EUS-FNA and confirm the cut-off length of visible tissue core (VTC). 79 consecutive patients who underwent EUS-FNA of solid masses around the gastrointestinal tract using 22-G needles were included in the study. After EUS-FNA, endosonographers used a special observation table to on-site evaluate all puncture specimens. Then, the specimens containing VTC were prepared into cell block and stained with haematoxylin-eosin (HE). Pathologists explored the relationship between VTC length and specimen quality. Finally, the receiver-operating characteristic (ROC) curve of the VTC length, with respect to the final diagnoses were plotted, and the accuracy of the area under the curve (AUC) for diagnostic yield was evaluated and to determine the optimal cut-off VTC length with the Youden index. The utility of optimal cut-off VTC length in diagnosis was investigated.

Results: 1. In this study, EUS-FNA was performed on 93 masses in 79 patients, with a total number of needle passes of 249, including 221 needle passes (88.8%) containing VTC. The completion rate of EUS-FNA was 100% and the complication rate was 1.1%. Assisted by MOSE, the sensitivity, specificity, positive predictive value, negative predictive value and histological diagnostic rate of EUS-FNA in this study were 85.9% (73/85), 100.0% (8/8), 100.0% (73/73), 40.0% (8/20) and 87.1% (81/93), respectively. The kappa statistic indicated quite high agreement between EUS-FNA histologic diagnoses and final diagnoses (Kappa=0.511, P<0.05).
2. The pathologist scored the specimen and correlation analysis was performed by Spearman's rank-order correlation. It is concluded that a positive correlation between specimen quality (integrity of tissue structure) and VTC length (rs=0.427, P<0.05). The ROC curve of the VTC length showed the cut-off VTC length of 7.45 mm with area under the curve of 0.838. With this cut-off level, the sensitivity and specificity of EUS-FNA were 80.8% and 66.7%, respectively.
3. Multivariate analyses of factors affecting the tissue diagnostic

rate of EUS-FNA were performed. Inclusion factors were the maximum diameter of lesion, location of lesion, puncture method and the VTC length. The statistical results indicated that the VTC length ≥7.45mm and the maximum diameter of lesion were associated with the higher diagnostic rate of histopathology. However, the tissue diagnostic rate was not related to the location of lesion and puncture method.

Conclusion: 1. MOSE could help endosonographers better assess specimen quality, so as to predict the specimen adequacy independently. We determined that the histological diagnostic yields were significantly improved when the VTC lengths obtained by EUS-FNA ≥7.45mm.

2. MOSE based on magnifying glass is practical for improving the specimen quality and reducing the number of needle passes when ROSE is unavailable. It is a safe, effective and economical diagnostic method for the solid masses around the gastrointestinal tract.

ABERRANT RIGHT SUBCLAVIAN ARTERY: AN INFREQUENT FINDING IN ENDOSCOPY ULTRASOUND

M. Bandres[1], R. Delgado[2], D. Bandres[3]

[1]Policlinica Metropolitana, Emergency, Caracas, Venezuela, [2]Centro Medico Docente la Trinidad, Medicine Gastroenterology, Caracas, Venezuela, [3]Centro Medico Docente La Trinidad, Medicine-Gastroenterology, Caracas, Venezuela

Contact E-Mail Address: mvbandres@gmail.com

Introduction: The aberrant right subclavian artery (ARSA) is the most frequent vascular aortic anomaly with an incidence of 0.4% - 2% in the general population. In 80% of the cases it has a retroesophageal location, also 30% of ARSA is found in patients with trisomy 21. Endoscopic ultrasound (EUS) enables the diagnosis of multiple pathologies and the assessment of vascular structures, in which anomalies such as ARSA can be detected.

The main objective of our research is to evaluate the presence of the ARSA as an infrequent finding in upper EUS.

Aims & Methods: The main objective of our research is to evaluate the presence of the ARSA as an infrequent finding in upper EUS. The population of the study consists in all of the patients referred for upper EUS, for different reasons, excluding those with esophageal stenosis, those referred for linear endosonography and patients under 18y.o, at the Gastroenterology Division of both the Centro Medico Docente La Trinidad and the Clinica Atias, health centers located in Caracas, Venezuela. This is a retrospective, observational descriptive, cross-sectional study

Results: A total of 9,966 patients with upper EUS using a radial transducer were studied, six of them were diagnosed with ARSA, two males and four females, between the ages 39 to 72 (mean of age: 55 for males, 60 for females), all cases were confirmed with computed tomography angiography and none of them were previously diagnosed during their upper endoscopy or any other techniques before EUS. Furthermore, one of the patients with ARSA also had Kommerell's diverticulum.

However, of the six patients only one reported intermittent dysphagia to solids.

Conclusion: Despite being the most common aortic vascular anomaly, ARSA is still a rare finding; it may go unnoticed during upper endoscopy and EUS. With the radial echoendoscope transducer an anechoic tubular structure can be seen emerging from the distal arch of the aorta crossing to the right between the vertebral column and the posterior wall of the esophagus. When comparing the incidence of ARSA with other reports, we had 0.06% versus 0.33% found in another study.

Introduction: Endoscopic ultrasound-guided tissue acquisition (EUS-TA) has been widely used to obtain tissue for the diagnosis of gastrointestinal (GI) lesions with good accuracy and safety, but the diagnostic yield remains highly variable.

Aims & Methods: We performed this study intending to study the diagnostic yield in our center. This is a retrospective study of patients who underwent EUS-TA for upper GI lesions from September 2018 to March 2020 in our center. EUS-TA had been performed by two experienced endo sonographers, using the fanning technique with a 22-G needle without an on-site cytopathologist. Specimens were analyzed through cell blocks and thread biopsies by an experienced pathologist and were categorized into adequate and diagnostic or non-diagnostic.

Results: A total of 176 patients were enrolled with a mean age of 53.6 ± 15.5, with most being male 108 (61.4%). Most lesions were seen in the pancreas among 110 (62.5%) patients. The lesions' mean (SD) size was 2.8 ± 1.5 cm. The average number of passes was 2.35 ± 0.9. There were no complications observed during or post-procedure. The overall adequacy rate of the tissue specimen was 92% for both smears and biopsy specimens. Among pancreatic lesions, the yield rate was seen with FNA smears at 92.5%, which increased to 95.5% when both smears and biopsy specimens were taken. It was lowest for submucosal epithelial lesions at 77.7%.
Conclusion: Using a 22G needle for EUS-guided tissue acquisition by an experienced endo sonographer using MOSE is safe and yields an acceptable yield rate without an on-site pathologist.

Introduction: The development of the double balloon enteroscopy (DBE) system in 2001 and later, the single balloon enteroscopy (SBE) in 2007 allowed direct visualisation, biopsies and therapeutic interventions of lesions in the small bowel. Previous studies comparing these two techniques show mixed results.
The aim of this study is to compare the efficacy of single balloon and double balloon enteroscopy with regards to technical success, diagnostic yield, therapeutic success and complication rates.
Aims & Methods: The development of the double balloon enteroscopy (DBE) system in 2001 and later, the single balloon enteroscopy (SBE) in 2007 allowed direct visualisation, biopsies and therapeutic interventions of lesions in the small bowel. Previous studies comparing these two techniques show mixed results.
The aim of this study is to compare the efficacy of single balloon and double balloon enteroscopy with regards to technical success, diagnostic yield, therapeutic success and complication rates.
Results: There were 82 patients in the DBE group and 45 patients in the SBE group. The main indications were suspected GI bleeding (DBE 41.5% vs. SBE 48.9%), iron deficiency anemia (DBE 9.8% vs. SBE 4.4%) and small bowel lesions (DBE 28.0% vs. SBE 44.4%) with positive imaging modality, either from prior capsule endoscopy or radiological imaging. Majority of the cases via antegrade approach (DBE 67.1% vs. SBE 77.8%).
We found no significant difference in the technical success (DBE 95.1% vs. SBE 97.8%, p=0.46), diagnostic success (DBE 65.9% vs. SBE 77.8%, p=0.36) and the therapeutic success rate (DBE 61.1% vs. SBE 51.4%, p=0.09) between the groups. Complications occurred in one case from each group (mucosal tear).
Conclusion: The efficacy of DBE and SBE are similar with regards to technical success, diagnostic yield, therapeutic success and complication rate.
Disclosure: Nothing to disclose.

RELATIONSHIP BETWEEN ADENOMA DETECTION RATE AND RESPECTIVE WITHDRAWAL TIME IN DIFFERENT COLON SEGMENTS

X. Chen[1], Y. Cheng[2], B. Wei[1], X. Zhu[1], L. Ji[3], Q. Zhan[1]
[1]The Affiliated Wuxi People's Hospital of Nanjing Medical University, Wuxi, China, [2]The Affiliated Wuxi People's Hospital of Nanjing Medical University, Digestive Medicine, Wuxi, China, [3]The Affiliated Wuxi People's Hospital of Nanjing Medical University, Gastroenterology, Wuxi, China

Contact E-Mail Address: 3489654307@qq.com
Introduction: The 6-minute withdrawal time for colonoscopy is widely considered the standard of care. However, there may not be appropriate if the 6-minute is equally divided into various colon segments. Since the adenoma detection in each colon segment is not the same, there may be differences with the withdrawal time in different colon segments.
Aims & Methods: Our objective was to evaluate the relationships between adenoma detection rate (ADR) and respective withdrawal time in different colon segments. Outpatients, age range 18-75 years, undertaking complete colonoscopy were enrolled in this study from November 2019 to November 2020 in the digestive endoscopy center.
The entire colon was divided into four different segments: ascending colon, transverse colon, descending colon and rectosigmoid colon. The respective withdrawal time and ADR in each colon segment were recorded respectively.
Results: A total of 586 outpatients (279 males, 307 females) enrolled in this study and the general ADR was 38.2%. The positive withdrawal time (adenomas detected) was longer than negative withdrawal time (non-adenomas detected) (334.04±24.21 secs vs 303.65±5.20 secs, t=1.26, P<0.001). ADR in ascending colon, transverse colon, descending colon and rectosigmoid colon were respectively 30.5%, 2.9%, 3.1% and 7.5%.
While all of their positive withdrawal time were longer than negative withdrawal time (94.34±33.76 secs vs 70.40±41.84 secs, t=3.31, P=0.001; 85.40±49.76 secs vs 71.66±36.87 secs, t=1.95, P=0.025; 80.29±39.85 secs vs 69.73±35.96 secs, t=1.40, P=0.016;100.95±55.92 secs vs 80.96±42.87 secs, t=3.61; P<0.001, respectively).
The withdrawal time threshold in the ascending colon, transverse colon, descending colon, rectosigmoid colon determined by receiver operating characteristic (ROC) curve were 77s, 61s, 56s and 109s, respectively. In the ascending colon, ADR was significantly higher (47.0% vs 33.1%, P <0 .001) when the colonoscopy withdrawal time was ≥77s. When the withdrawal time was ≥61s in the transverse colon (42.7% vs 32.7%, P = 0.013), ≥59s in the descending colon (42.3% vs 29.9%, P=0.004) and ≥109s in rectosigmoid colon (52.2% vs 33.9%, P < 0 .001), ADR was also significantly higher.
After adjusting for age, sex and BMI, Logistic regression analysis showed that withdrawal time ≥ 77s in the ascending colon (OR, 1.796; 95% CI, 1.273-2.532; P < 0 .001), ≥ 61s in the transverse colon (OR, 1.535; 95% CI, 1.094-2.155; P = 0.013), ≥56s in the descending colon (OR, 1.722; 95%CI, 1.193-2.486; P =0.004) and ≥109s in the rectosigmoid colon (OR, 2.134; 95% CI, 1.446-2.350; P < 0.001) were independent risk factors for the increase of ADR.
Conclusion: ADR and withdrawal time are all various in individual colon segments. During the operation of colonoscopy, withdrawal time in the ascending colon may be shortened appropriately. The adenomas in the rectosigmoid colon are more likely to be detected and do not take longer withdrawal times. We need to choose the appropriate time according to different colon segments.

THE FEASIBILITY AND SAFETY OF THE MOTORIZED SPIRAL ENTEROSCOPE FOR ENDOSCOPIC BALLOON DILATATION OF STRICTURES IN CROHN'S DISEASE: CASE SERIES

W. Kappelle[1], P. van Boeckel[1], J. Tenthof van Noorden[1], A. Sijbring[1], H.H. Fidder[2], N. Mahmmod[1], A. Al-Toma[1]
[1]St Antonius Hospital, Dept. of Gastroenterology & Hepatology, Nieuwegein, Netherlands, [2]UMC Utrecht Dept. of Gastroenterology, Gastroenterology & Hepatology, Utrecht, Netherlands

Contact E-Mail Address: a.altoma@antoniusziekenhuis.nl
Introduction: Motorized spiral enteroscopy (MSE) has shown to be safe and effective for deep small bowel enteroscopy in patients with and without prior abdominal surgery, including patients with Crohn's disease.
This case series reports our first results regarding the feasibility and safety of the MSE with endoscopic balloon dilatation in patients with small bowel strictures due to Crohn's disease.
Aims & Methods: Data were collected retrospectively on patients who underwent MSE for endoscopic balloon dilatation of small bowel strictures due to Crohn's disease. Strictures were either postoperative (P.O.) or post-inflammatory (P.I.).
Results: A total of ten consecutive patients with Crohn's disease underwent 13 procedures. Propofol sedation without endotracheal intubation was used in all procedures. Demographic and procedure related data are shown in the table. One patient underwent three procedures with 3–4 month intervals. During the third procedure triamcinolone acetonide was injected at four quadrants of the stricture.
Fluorescence imaging was used during six procedures. The procedure was technically successful in 12/13 of procedures. In one case, dilatation was not performed because of a longer than anticipated and a sharply angulated stricture.
The number of treated strictures ranged from one to five per procedure. Dilatation of multiple strictures in two patients (4 and 5) was achieved within a relatively short procedure duration of 55 and 70 minutes. Two retained video capsules were retrieved.
Besides the anticipated mild abdominal discomfort and/or sore throat in three patients, no adverse events occurred.
Conclusion: These retrospective data show that MSE with CRE dilatation is feasible and safe in a cohort of patients with strictures due to Crohn's disease, postoperatively as well as post-inflammatory. The fact that the distal 16 cm of the endoscope are not covered by the spiral overtube makes cautious introduction of the endoscope beyond a recently dilated stricture feasible and safe.
Therefore, dilatation of multiple strictures in one session is possible, provided that they are at a short distance from each other. Fluorescence imaging guidance may be helpful in severe stenosis, multiple strictures, or sharp angulations.
Disclosure: Nothing to disclose.

	Patients (age/F/M)	Type stenosis	Procedure route	No. of strictures/ Location (cm)	Maximal dilatation (mm)	Procedure duration (min)	Fluorescence imaging (+/-)
1	44/M	P.O	Antegrade	1/ 200 cm from Treitz	15/18/18 *	50/45/40*	+/+/-
2	54/F	P.I. and VCE retention	Ante-/retrograde	4/ 300 cm from Treitz/ 1 50 cm from ICV	15	70	+
3	56/F	Mixed	Antegrade	5/ 150-180 cm from Treitz	18	55	-
4	25/M	P.I. and VCE retention	Antegrade	1/ 100 cm from Treitz	18	35	+
5	26/M	P.O.	Ante-/retrograde	1/ 120 cm from Treitz/280 cm from ICV	18 mm via retrograde route	45	-
6	23/F	P.O.	Ante-/retrograde	1/ 450 cm from Treitz/ 50 cm from ICV	15 mm of ileo-ileal anastomosis (pinpoint)	80	+
7	33/M	P.O.	Ante-/retrograde	1/ 350 cm from Treitz /100 cm from ICV	18 mm via retrograde	60	-
8	52/M	P.O.	Antegrade	1/ 200	18	30	-
9	50/F	P.I.	Retrograde	1/ 100	18	30	+

PP0280 Table.

*= 3 Procedures; P.O= Postoperative; P.I= Post-inflammatory; VCE= Video capsule endoscope; ICV= Ileocecal valve
NB: data on patient number 10 is not shown in the table because of the limited number of rows (10) allowed. No dilatation was done.

PP0281

SAFETY AND EFFICACY OF NOVEL MOTORIZED SPIRAL ENTEROSCOPY IN THE EVALUATION OF SMALL BOWEL DISEASES: A SYSTEMATIC REVIEW AND META-ANALYSIS

Z. Nabi[1], J. Samanta[2], J. Dhar[2], R. Chavan[1], D.N. Reddy[1]

Introduction: Motorized spiral enteroscopy (MSE) has recently been introduced for small bowel evaluation.
Aims & Methods: In this systematic review and meta-analysis, we aim to evaluate the safety and efficacy of MSE for evaluation of small bowel diseases.
A literature search was performed in Embase, PubMed, Medline databases for studies evaluating MSE between Jan-2010 to October-2022.
The primary outcome of the study was diagnostic yield with MSE.
Secondary outcomes included technical success, procedure duration, depth of maximum insertion (DMI), rate of pan-enteroscopy and adverse events.
Results: 10 studies with 961 patients [581(60.5%) males] were included in the analysis. 1,068 MSE procedures were performed by antegrade route in 698, retrograde route in 215 and bidirectional in 155 patients. Technical success was achieved in 94.9% (95% CI 92.9%-96.4%) procedures. The pooled diagnostic yield of MSE was 73.7% (95% CI 70.7% to 76.4%). Pooled rate of pan- enteroscopy by antegrade route was 21.9% (95% CI 18.1%-26.1%), retrograde route was 6.9% (95% CI 2.4%-18.3%) and combined route was 61.2% (95%CI 52.4%-69.3%). Pooled rate of major adverse events was 1.9%(95% CI 1.2%-3.2%).
Conclusion: MSE is a safe and effective tool for evaluating small bowel disorders. High diagnostic yield and low rate of adverse events make it a potential alternative to balloon enteroscopy. However, comparative trials are required in the future.
Disclosure: Nothing to disclose.

Contact E-Mail Address: miguel.pedro96@gmail.com
Introduction: Device-assisted enteroscopy (DAE) plays an important role in management of enteric lesions. Endoscopic observation of erosions or ulcers is frequent and can be associated in many nosologic entities, including Crohn's disease and non-steroid anti-inflammatory drug-induced enteropathy. Despite the rapid expansion of artificial intelligence (AI) application in different image-base procedures of gastroenterology, there is still lack of evidence of AI relevance during DAE. This study aimed to develop and test a Convolutional Neural Network (CNN)-based model for automatic detection of ulcers and erosions during DAE.
Aims & Methods: A unicentric retrospective study was conducted for the development of a CNN, based on a total of 258 DAE exams. DAE was performed by two experienced endoscopists using the double-balloon enteroscopy system Fujifilm EN-580T (n = 152), the single-balloon enteroscopy system Olympus EVIS EXERA II SIF-Q180 (n = 98) and the Olympus PowerSpiral Motorized Enteroscope PSF-1 (n = 8). After double validation, a total of 29513 images were used, of which 633 were considered ulcers or erosions. Data was separated into two sets: training and validation, with the latter being used for the evaluate the model's performance.
Our primary outcome measures were sensitivity, specificity, accuracy, positive predictive value (PPV), negative predictive value (NPV), and area under the curve precision-recall curve (AUC-PR).
Results: Sensitivity and specificity were 86.2% and 99.8%, respectively. PPV and NPV were 91.8% and 99.7%, respectively. Overall accuracy of the CNN was 99.5%. The AUC-PR was 1.00.
Conclusion: To the best of our knowledge, this is the first CNN constructed and validated for automatic detection of ulcers and erosions during DAE, including spiral enteroscopy. The high diagnostic performance of this CNN in multidevice solves a significant issue of technological interoperability, allowing it to be replicated in many technological contexts.

Introduction: The size or timing of endoscopic dilatation for anastomotic stricture after near-total esophagectomy is not clear.
Aims & Methods: The purpose of this study is to find out the target size and the timing of endoscopic dilatation for stenosis after near-total esophagectomy.
Medical records of patients with endoscopic dilatation for anastomotic stricture after near-total esophagectomy between January 2015 and April 2021 were reviewed. We analyzed the stricture recurrence rate and dilation-free period according to each diameter of dilation.
Results: In the study period, 78 endoscopic dilations in 24 patients were enrolled. The stricture recurrence rate was 91.4% in 13.5mm or less group, 57.9% in 15mm group, and 0% in 16.5mm group. The dilation-free period had a mean of 48.2 (range 14-679) days in 13.5mm or less group and 109.3 (range 14-347) days in 15mm group (p = 0.045). No perforation occurred in this study.
Conclusion: In patients with anastomotic stricture after near-total esophagectomy, safely consider 15mm as the target diameter of dilation, and if this is achieved, follow-up endoscopy and dilation can be considered after 3 months.
Disclosure: Nothing to disclose.

PP0284

YIELD OF CAPSULE ENDOSCOPY AND SUBSEQUENT DEVICE-ASSISTED ENTEROSCOPY OVER A 13-YEAR PERIOD: EXPERIENCE AT A SINGLE QUATERNARY CENTRE

S. Selvanderan[1], M. Noguchi[1], X. Banh[1], S. Ket[1], G. Brown[1]
[1]The Alfred Hospital, Gastroenterology, Melbourne, Australia

Contact E-Mail Address: shane.selvanderan@gmail.com

Introduction: Small bowel capsule endoscopy (SBCE) and device-assisted enteroscopy (DAE) have revolutionized the investigation and management of small bowel pathology in the past two decades.

Previous studies have reported on the yield of SBCE (60%) and DAE (57%) respectively[1], but these have reported on a seven-year period at most, and none have reported concurrently on the yield of SBCE, and any DAE performed as a direct consequence of SBCE.

Aims & Methods: To evaluate the indications, diagnostic yield, procedural factors, and interventions performed in consecutive patients undergoing SBCE and associated DAE, specifically double-balloon enteroscopy (DBE) at our institution, which is a quaternary referral centre for small bowel assessment with these investigations.

This was a single centre retrospective study of consecutive patients who underwent SBCE at the Alfred Hospital between 1st January 2009 to 31st December 2021. After obtaining institutional ethics approval, data were collected with respect to demographics, SBCE procedural factors and findings, as well as findings and interventions of any DBE procedures performed after the SBCE.

Results: A total of 1214 SBCEs were performed, with a median age of 66 years old (IQR 52 – 76; 60.8% men). The most common indications were anaemia (n=853, 70.2%), overt gastrointestinal bleeding (n=320, 26.4%), abnormal imaging (n=17, 1.4%), polyposis syndrome (n=11, 0.9%) and Crohn's disease (n=9, 0.7%). The preparation was adequate in 1139 studies (93.8%) and a complete small bowel study was obtained in 1132 (93.2%). Of the complete studies, abnormal findings were detected in in 588 cases (51.9%), and most commonly these were angioectasias (266/588, 45.2%), erosions (106/588, 18.0%), ulcers (97/588, 8.6%), subepithelial lesions (48/588, 8.2%) and diverticulae (27/588, 4.6%). 165 patients proceeded to a DBE: 117 with an antegrade approach, and 48 with a retrograde approach. Antegrade DBE had a higher yield than retrograde DBE (77.8% vs 54.2%; p=0.002) and there was a higher proportion of procedures where intervention was performed (69.2% vs 37.5%; p<0.001).

	Antegrade DBE (n = 117)	Retrograde DBE (n = 48)	p value
Abnormality detected (yield)	91 (77.8%)	26 (54.2%)	0.002
Specific abnormalities	Angioectasia - 61 Bleeding - 18 Polyp - 14 Diverticulum - 6 Stricture - 4 Erosion - 3 Ulcer - 2 Subepithelial lesion - 2 Other - 6	Ulcer - 5 Diverticulum - 5 Bleeding - 4 Polyp - 4 Angioectasia - 2 Erosion - 1 Other - 6	-
Intervention performed (excluding tattoo)	81 (69.2%)	18 (37.5%)	< 0.001
Specific interventions	Argon plasma coagulation - 60 Clip - 29 Biopsy - 9 Polypectomy - 8 Other - 3	Argon plasma coagulation - 4 Clip - 2 Biopsy - 11 Polypectomy - 4 Dilatation - 1	-

Table 1: Outcomes of double-balloon enteroscopy (DBE) performed as a consequence to small bowel capsule endoscopy.

Conclusion: The indications for SBCE at our institution are consistent with guidelines, and there is a similar yield of abnormal findings as compared to existing literature. DBE, especially antegrade DBE, had high diagnostic and therapeutic yield when pursued after a positive SBCE study.

Our findings from this large dataset of consecutively studied patients over a decade in a real-world setting may aid decision-making for clinicians when utilizing SBCE and determining whether to perform DBE (and if so by which approach) to evaluate for small bowel pathology.

A "SUGAR-COATED" PROBLEM: ELEVATED HEMOGLOBIN A1C LEVELS ARE ASSOCIATED WITH PROLONGED GASTRIC TRANSIT TIME IN DIABETIC PATIENTS UNDERGOING CAPSULE ENDOSCOPY

V. Macedo Silva[1,2,3], A.I. Ferreira[1,2,3], T. Lima Capela[1,2,3], C. Arieira[1,2,3], S. Xavier[1,2,3], P.B. Carvalho[1,2,3], M.J. Moreira Basto[1,2,3], B.J.F. Rosa[1,2,3], J. Berkeley Cotter[1,2,3]
[1]Hospital da Senhora da Oliveira, Gastroenterology Department, Guimarães, Portugal, [2]School of Medicine, University of Minho, Life and Health Sciences Research Institute (ICVS), Braga / Guimarães, Portugal, [3]ICVS/3B's, PT Government Associate Laboratory, Braga / Guimarães, Portugal

Contact E-Mail Address: vitorbmacedo@gmail.com

Introduction: Gastroparesis is common in patients with Diabetes *mellitus*, especially in those with poor glycemic control. Due to this association, diabetic patients are at risk of prolonged gastric transit time (PGTT) when undergoing small-bowel capsule endoscopy (SBCE).

Aims & Methods: In this investigation we aimed to assess if there was an association between hemoglobin A1c levels and PGTT in diabetic patients undergoing SBCE.

We have conducted a single-center retrospective study including all consecutive diabetic patients undergoing SBCE for two years. Patients without a valid hemoglobin A1c measurement within 3 months from SBCE were excluded. The assessed outcome was PGTT (defined as SBCE remaining in the stomach for >1h, requiring prokinetic administration and/or endoscopically assisted capsule delivery into the duodenum).

Possible confounders – age, gender, inpatient status, smoking habits, diagnosis of IBD, thyroid disease, prokinetics or antidepressants regular usage - were also assessed.

Results: Final sample included 77 patients, 40 (51.9%) of them males, with a mean age of 70±10 years. PGTT occurred in 33 (42.9%) individuals. Mean hemoglobin A1c levels were significantly higher in diabetic patients with PGTT (7.4±0.8% vs 6.5±0.8%; p<0.001). In a multivariate analysis including significant confounders, hemoglobin A1c levels were still an independent predictor of PGTT (B=1.35; p<0.001). Single-handedly, hemoglobin A1c levels demonstrated very good acuity in predicting PGTT (AUC=0.80; p<0.001), with an optimal cut-off of HbA1c ≥6.8% (sensitivity 81% and specificity 73%).

Conclusion: Hemoglobin A1c levels significantly influenced the occurrence of PGTT in diabetic patients undergoing SBCE. This may eventually allow the performance of preemptive measurements to avoid PGTT in diabetic patients with poor glycemic control.

Disclosure: Nothing to disclose.

PP0286

DELAYED GASTRIC TRANSIT TIME OF CAPSULE ENDOSCOPY FOR PATIENTS WITH ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

H. Takamaru[1], Y. Kakugawa[1,2], M. Saito[1], T. Tanaka[3], T. Fukuda[3], Y. Saito[1]
[1]National Cancer Center Hospital, Endoscopy Division, Tokyo, Japan, [2]National Cancer Center Hospital, Cancer Screening Center, Tokyo, Japan, [3]National Cancer Center Hospital, Department of Hematopoietic Stem Cell Transplantation, Tokyo, Japan

Contact E-Mail Address: htakamar@ncc.go.jp

Introduction: Allogenic hematopoietic stem cell transplantation is one of the effective treatment options for hematological diseases such as acute myeloid leukemia or malignant lymphoma. Graft versus host disease (GHVD) in the gastrointestinal tract and/or cytomegalovirus (CMV) colitis is often seen after stem cell transplantation.

We as endoscopists perform small intestine capsule endoscopy (CE) examinations for patients who are suspected of GVHD in the gastrointestinal tract and CMV colitis.

Gastric retention of CE makes it difficult to observe complete small bowel in several frequencies. It is well known that GVHD in the gastrointestinal tract decreases the motility of the stomach, and is one of the causes of gastric retention. We are now aware of the increasing ratio of gastric retention of the CE examination after late 2018 in our institution. This is also the period that Letermovir was introduced into our hospital.

Therefore, we hypothesize that Letermovir may affect the gastric retention of CE examination and investigated the relationship between Letermovir administration and gastric retention of CE examination.

Aims & Methods: A total of three hundred and thirty-five CE examination among 439 CE performed for patients with allogeneic stem cell transplantation between July 2005 and July 2022 in our hospital was analyzed. One hundred and four CE examinations without CE video data or transported using endoscopic assistance were excluded. Data was acquired from reporting system of CE. Gastric retention was defined that gastric transit time (GTT) being longer than 390 minutes because the average battery duration was 13 hours. CE examination during Letermovir administration was defined as Letermovir being administrated irrespective of administration oral or intravenously. the day CE examination was performed The ratio of gastric retention was compared between the Letermovir administrated and Control groups.

Results: Among 335 CE examination, 183 was male and 152 was female. The median age of the patients was 55 years old (range 15 – 86). Median GGT was 96 minutes (range 31 – 807 minutes). Gastric retention with GTT longer than 390 minutes was observed in 30 CE examinations (9.0%). CE examination during the administration of Letermovir was 142 (42.4%). Gastric retention of CE examination in the Letermovir administrated group was significantly higher than the Control group (19 (13.4%) vs 11 (5.7%), p = 0.0150).

Conclusion: Letermovir might potentially cause gastric retention of CE examination for patients with allogeneic stem cell transplantation. Endoscopic assistance, the transport of the retained CE into the duodenum using snare or net devices based on the real-time monitoring function of CE, may be one of the options to improve efficient CE examination for patients with Letermovir administration.

Disclosure: Nothing to disclose.

COMPARISON OF AN ARTIFICIAL INTELLIGENCE CAPSULE ENDOSCOPY SYSTEM (NAVICAM®) WITH CONVENTIONAL CAPSULE ENDOSCOPY (PILLCAM® SB3) IN THE STUDY OF THE SMALL BOWEL: THE NAVIPILL PILOT STUDY

A. Giordano[1], G. Casanova[1], M. Urpí[1], M. Escapa[1], A. Gines[1], M.G. Fernández-Esparrach[1], J. Llach[1], B. González-Suárez[1]
[1]Hospital Clínic de Barcelona, Endoscopy Unit, Gastroenterology Department, Barcelona, Spain

Contact E-Mail Address: dr.antoniogiordano@gmail.com

Introduction: Artificial intelligence may improve reading time and detection rate in small bowel capsule endoscopy (SBCE).

Aims & Methods: The study aimed to compare the effectiveness of artificial intelligence reading (AIR) with Navicam versus conventional reading (CR) with Pillcam SB3.

A prospective pilot trial was conducted in a single center to assess the diagnostic performance of AIR compared to CR (non-inferiority study). Both endoscopic capsules were administered to the same patient in a randomized order at a 60-minute interval. AIR and CR were performed by two experienced independent endoscopists. Diagnostic yield (percentage of significant findings according to the clinical indication), diagnostic accuracy, and reading times of both explorations were assessed. All adverse events related to the study protocol were also registered.

Results: Twenty patients (median age 60 ± 10 years) were enrolled. Navicam and Pillcam showed similar completion rates (100% vs 95%, p=1) and diagnostic yield (80% vs 90%, p=0.5). Overall agreement was 90% (Cohen's kappa 0.62). Compared to CR, in the per-patient analysis, AIR showed sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and diagnostic accuracy of 88%, 100%, 100%, 60%, and 90%, respectively. In the per-lesion analysis, AIR showed sensitivity, specificity, PPV, NPV, and diagnostic accuracy of 97%, 50%, 95%, 60%, and 93%, respectively. AIR showed significantly lower reading time than CR (3.2 vs 27.5 minutes, p<0.001). No adverse events or electromechanical interferences were observed during the study.

Conclusion: AIR with Navicam shows high agreement with CR with Pillcam. AIR demonstrates high diagnostic yield and accuracy, significantly reducing reading times.

CONFIRMATION OF FUNCTIONAL PATENCY USING THE PATENCY CAPSULE. A PROSPECTIVE STUDY USING AN EXTENDED TIME PROTOCOL TO IMPROVE RATES OF CONFIRMED PATENCY

F. O'Hara[1], C. Costigan[1,2], D. McNamara[1,2]
[1]Tallaght University Hospital, Gastroenterology, Dublin, Ireland, [2]Trinity College Dublin, Department of Medicine, Dublin, Ireland

Contact E-Mail Address: fintan.ohara@gmail.com

Introduction: Capsule retention (CR) is one of the major complications of capsule endoscopy. Rates of which range from 2.1% to 8.2% depending on the indication.[1]

Although several radiographic imaging techniques have been investigated to avoid CR, their efficacies for screening patients has not been shown to be adequate.[2]

Reported rates of retention have fallen due to recognition of risk factors for CR as well as the introduction of the patency capsule (PC). The PC is a dummy capsule of the same dimensions as the functional capsule. It begins to break down in the gastrointestinal tract after approximately

30hours reducing the risk of a symptomatic retention. Failure to confirm functional patency using the patency capsule can result in exclusion from capsule endoscopy in patients referred for this test.

Our previously published retrospective analysis of the patency capsules performed in our unit showed an overall functional patency fail rate of 43.1%.[3]

This is due to a number of limitations of the test including difficulty in assessing the position of the capsule on abdominal x-rays in settings where access to cross sectional imaging is limited. While the patency test does reduce CR rates a number of patients may be excluded from capsule endoscopy who may have benefited from the test .

Aims & Methods: The aim of this study was to improve rates of confirmation of functional patency without increasing the risk of CR in a cohort of patients referred for capsule endoscopy with risk factors for CR.

This was a single centre prospective study. All patients presenting for functional patency assessment during the period from July 2022 to February 2023 were invited to participate.

PillCam™ patency capsule (Medtronic) was administered to all patients enrolled. Functional patency was confirmed at 28 hours post ingestion by either the patient reporting the passage of an intact capsule or an abdominal x-ray showing absence of the patency capsule.

Those patients with a patency capsule seen on abdominal x-ray at 28 hours were enrolled in an extended patency arm. At 72 hours post ingestion if the patient had reported interval passage of an intact capsule this was also deemed confirmation of functional patency.

All patients with confirmed functional patency then went forward to capsule endoscopy.

Results: 90 patients were enrolled in the study. 50 (56%) female, with a mean age of 51 years.

Functional patency was confirmed in 47 cases (52%) at 28hours.

Of the 43 (48%) patients where functional patency was not confirmed at 28 hours, 8/43 (19%) patients confirmed passage of an intact capsule by 72 hours post ingestion. Of these 8/9 have had a capsule endoscopy to date. All 8 had a complete small bowel study, of which 4 were within normal limits with minor findings on the other 4. No strictures were identified.

The mean small bowel transit time was similar between the 28 hour and 72 hour groups (240 min vs 239 min, p = 0.99) 50/51 patients with confirmed functional patency went on to have a capsule endoscopy with no CR recorded.

Extended patency assessment improves the overall confirmation of functional patency from 47.8% to 56.7%, with no CR noted.

Conclusion: While effective in minimizing capsule retention rates, functional patency assessment by the patency capsule has limitations due to the nature of the test. This is especially a concern where cross sectional imaging is not available. This Extended functional protocol improves rates of confirmation of functional patency from 47.8% to 56.7% without increasing the risk of capsule retention.

COMPARISON OF THE RESULTS OF MAGNETICALLY CONTROLLED CAPSULE ENDOSCOPY AND HIGH-DEFINITION GASTROSCOPY WITH PROPOFOL SEDATION: A PROSPECTIVE STUDY IN PATIENTS WITH UNINVESTIGATED FUNCTIONAL DYSPEPSIA

A. Finta[1], B.D. Lovasz[2], R. Liebe[1], M. Szalai[1], L. Madácsy[1]

[1]Endo-Kapszula Ltd., Endoscopy Unit, Szekesfehervar, Hungary, [2]Semmelweis University, Institute of Applied Health Sciences, Budapest, Hungary

Contact E-Mail Address: traveler.uni@gmail.com

Introduction: Gastric cancer have a high prevalence worldwide, and early diagnosis and management are essential for better oncological outcomes. Conventional gastroscopies have limitations due to possible complications, patient discomfort, poor tolerance and the need for sedation. Magnetic-controlled capsule endoscopy (MCCE) is a painless and non-invasive diagnostic tool that can explore the gastric mucosal abnormalities.

Aims & Methods: The aim of the present prospective single centre study is to compare the diagnostic accuracy and patient satisfaction of MCCE and gastroscopy.

We examined a total of 89 consecutive young patients referred for uninvestigated functional dyspepsia between 2018 August and 2023 April to our endoscopy unit who preferred MCCE as an initial diagnostic test. 80 (90%) patients underwent same-day MCCE and gastroscopy examinations, while the remaining 10% underwent the procedures within a 2-week interval. All patients underwent MCCE as the first diagnostic procedure. Gastroscopy was performed using an HD Fujifilm 700 series gastroscope. The urea breath test (UBT) was administered to detect Helicobacter pylori infection in patients who were not receiving proton pump inhibitor (PPI).

After the procedures, we evaluated and compared the capsule endoscopy and gastroscopy reports and videos. After both diagnostic procedures, our patients were asked to accomplish a patient satisfaction questionnaire to evaluate the tolerability of each examination, regarding patient discomfort, pain, and anxiety levels during the procedures.

Results: A total of 89 patients were examined (53 males, 36 females, mean age 45). Urea breath test was performed in 43 cases: and detected 18 (41.9%) Helicobacter positive results, and the histology was consistent in 35 cases (81.4%). MCCE and gastroscopy were highly sensitive to detect any focal lesions 1 vs 0 hyperplastic polyp, 3 vs. 3 ulcers, 1 vs. 1 submucosal tumour, 2 vs. 2 early gastric cancer, 1 vs. 1 early gastric B cell lymphoma, and 9 vs. 2 foveolar hyperplasia, respectively. For gastritis, we found 4 vs. 1 proximal gastritis, 53 vs 56 distal gastritis, and 16 vs 16 pangastritis. MCCE had higher diagnostic yield and accuracy than gastroscopy for detecting minimal foveolar hyperplasia (MCCE 9, gastroscopy 2, p=0.01) and upper gastritis (MCCE 4, gastroscopy 1, p=0.02), meanwhile gastroscopy was more accurate in the detection of antral gastritis (MCCE 53, gastroscopy 66, p=0.03). There were no significant differences between the two tests for detecting polyps, ulcers, submucosal tumours, early gastric cancer, lymphoma and pangastritis. All the patients reported that MCCE was a more tolerable diagnostic test than gastroscopy with Propofol sedation based on the questionnaire.

Conclusion: In conclusion, both MCCE and gastroscopy are comparably sensitive diagnostic methods for detecting focal and diffuse lesions, with MCCE offering the advantage of higher patient tolerability and acceptance. The study results suggest that MCCE can be a useful alternative to gastroscopy in young patients (under age 50) referred for uninvestigated functional dyspepsia, to select those patients who really needs gastroscopy and biopsy and therefore it can shorten the waiting lists for routine upper GI endoscopy.

TIMING OF CAPSULE ENDOSCOPY IN OVERT OBSCURE GASTROINTESTINAL BLEEDING

S.H. Kim[1], E.-H. Choi[1], K.W. Kim[1], H.W. Kang[1], J.W. Kim[1], K.L. Lee[1]
[1]Seoul National University Boramae Medical Center, Seoul National University College of Medicine, Department of Internal Medicine, Seoul, South Korea

Contact E-Mail Address: schwann@naver.com

Introduction: Obscure gastrointestinal bleeding (OGIB) is defined as gastrointestinal bleeding of unknown origin that persists or recurs despite a negative finding from an initial bidirectional endoscopy. According to recent guidelines, capsule endoscopy was recommended first in overt OGIB, but it is unclear when it is appropriate to perform capsule endoscopy in overt OGIB patients.

Aims & Methods: We aimed to analyze clinical outcomes with regard to the timing of capsule endoscopy in overt OGIB patients. We conducted a single-center retrospective study enrolling patients who had undergone capsule endoscopy for overt OGIB between February 2010 to December 2021. We included hospitalized patients who underwent capsule endoscopy for overt OGIB after negative bidirectional endoscopy.

We investigated the diagnostic yield of capsule endoscopy, rebleeding rate, length of hospital stay, initial hemoglobin, and the amount of blood transfusion with regard to the timing of capsule endoscopy.

Results: A total of 118 patients underwent capsule endoscopy to assess overt OGIB. The diagnostic yields in the groups that underwent capsule endoscopy < 48h and > 48h from the last overt OGIB were 50.0% and 22.0%, respectively (P=0.017).

Rebleeding rate and the length of hospital stay were not significantly different between the two groups. Initial hemoglobin level in the group who underwent capsule endoscopy > 48h group was lower than in the < 48h group (8.8±3.0 vs. 10.7±3.7, P=0.015).

Conclusion: Performing capsule endoscopy within 48 hours from the last overt OGIB resulted in a higher diagnostic yield. Performing capsule endoscopy within 48 hours may improve the clinical outcomes of patients with overt OGIB.

Disclosure: Nothing to disclose.

EXPANSION INTO PEDIATRICS WITH SMALL BOWEL CAPSULE ENDOSCOPY

H. Kozawa[1], Shizuki Yanagihara
[1]Sapporo Kosei Hospital, Gastroenterology, Sapporo, Hokkaido, Japan

Contact E-Mail Address: kozawahiroshi@ac.auone-net.jp

Introduction: Small bowel capsule endoscopy (SBCE) is widely used in adults. However, it is difficult for gastroenterologists and pediatricians alone to ensure safety during examinations due to difficulty in swallowing and understanding of examinations in children.

At present, the onset of Crohn's disease and the like is known even in young children, and early diagnosis and treatment of small intestinal lesions are becoming necessary. So far, we have performed SBCE safely by cooperating with pediatrics, and we report on the method and status.

Aims & Methods: We investigated the safety and diagnostic usefulness of SBCE in children.

111 children aged 3 to 15 years who underwent SBCE from February 2015 to February 2022 at our hospital (75 males, 36 females, average age 11.1 ± 2.8 years)

After consultation with a pediatrician, sedation, if necessary, use of an Advance® (Capsule Endoscope Insertion Aid), and insertion of a patency capsule into the duodenum. After confirming patency, SBCE was conducted later, and the following items were examined. Number of cases with and without advanced use, frequency of use, comparison by age and weight, adverse events at the time of examination, cecal reach rate, presence or absence of lesions, and breakdown of diseases.

Results: Advance® was used in 41 cases (36.9%), used 81 times, of which 3 adverse events (ejection failure) occurred. No complications were observed. In addition, when comparing the age and weight of the advanced use group and the non-use group, a significant difference was observed between the use group (9.7±3.2 years old, 28.0±8.3 kg) and the non-use group (12.2±1.6 years old, 41.2±10.5 kg).

Diagnosis by SBCE was 71 cases (64.0%) with Crohn's disease, 21 cases (18.9%) with other diseases, and 19 cases (17.1%) without findings, for a positive rate of 92/111 (82.9%).

Discussion: SBCE in the field of pediatrics is safe by paying attention to several points, such as Advance® use when necessary, insertion in the prone position, and introduction of sedation with the cooperation of a pediatrician, considering age and weight. The prevalence of lesions was high, and it was considered useful for diagnosing Crohn's disease, especially in the early stages.

Conclusion: SBCE in children can be performed safely and is of great diagnostic value.

Disclosure: Nothing to disclose.

Contact E-Mail Address: ezahra018@gmail.com

Introduction: Though small bowel capsule endoscopy (SBCE) has revolutionised the investigation of the small bowel, small lesions may still go undetected.

Aims & Methods: This was a multicentre study whose primary aim was to assess rates of detection of ampulla of Vater during SBCEs and identify any statistically significant variation between different levels of expertise and different reading speeds.

De-identified SBCE videos, selected randomly, each of 15 minutes duration from the 1st duodenal image, were uploaded on secure virtual cloud following ethical approval, data protection clearance and patient consent. Patient age, indication for endoscopy and findings were recorded. The videos were reviewed by 7 gastroenterology experts and 6 trainees from 6 European centres. Data regarding detection of ampulla of Vater (AoV) was

collected. Each video was analysed initially using the mouse-wheel and then at a speed of 10 frames per second (fps). Data was inputted into SPSS and statistical significance assessed via Kappa coefficient.

Results: Data was collected from 30 patients of whom 63.3% were males and whose median age was 63.5 years +/- 7.164. Commonest indications were iron deficiency anaemia (56.7%), small bowel Crohn's disease (16.7%) and overt GI bleeding (13.3%). All patients were given a macrogol based osmotic laxative for bowel preparation.

The following mean detection rates of Ampulla of Vater were observed:

- Trainees using mouse-wheel; 35% (10.5)
- Trainees using 10fps; 21.6% (6.5)
- Experts using mouse-wheel; 33.8% (10.1)
- Experts using 10fps; 20.4% (6.1)

On only taking into consideration the ampullas detected by the standard, mean detection rates using mouse-wheel for trainees is 68.7% and 82.1% for experts, as compared to 50% for trainees and 55% for experts using 10fps, showing a decline in detection rate with higher reading speed.

Table 1. denotes Kappa and p values obtained by comparison of standard/trainee/expert rates in detection of ampulla of Vater.

	Mouse-wheel		10fps	
	Kappa	P value	Kappa	P value
Standard vs Trainees	0.347	0.2	0.400	0.2
Standard vs Experts	0.621	0.2	0.513	0.2
Trainee group	0.135	0.75	0.109	0.2
Expert group	0.493	0.98	0.482	0.2
Trainees vs Experts	0.260	0.2	0.284	0.2

Table 1. Comparison of AoV detection

Mathematical comparison of ampulla detection in mouse-wheel vs 10fps amongst trainees resulted in Kappa 0.323 (p=0.018); and amongst experts resulted in Kappa 0.414 (p=0.01).

Conclusion: The results demonstrate that the rate of concordance in the detection of the ampulla amongst experts declines with a higher speed of reviewing a SBCE.

This suggests that pathology may be potentially missed at higher reading speeds especially in the first part of the small bowel where sometimes a SBCE rushes through. A slower reading speed is advisable especially in those with limited experience in reviewing a SBCE.

Disclosure: Nothing to disclose.

IS ENDOSCOPIC PLACEMENT OF CAPSULE ENDOSCOPY MANDATORY IN PATIENTS WITH PREVIOUS GASTROINTESTINAL SURGERIES?

A.I. Ferreira[1,2,3], J.C. Gonçalves[1,2,3], S. Xavier[1,2,3], C. Arieira[1,2,3], P.B. Carvalho[1,2,3], B.J.F. Rosa[1,2,3], J. Berkeley Cotter[1,2,3]

[1]Hospital Senhora da Oliveira, Gastroenterology, Guimarães, Portugal, [2]School of Medicine, University of Minho, Life and Health Sciences Research Institute (ICVS), Braga, Portugal, [3]PT Government Associate Laboratory, ICVS/3B's, Braga/Guimarãesport, Portugal

Contact E-Mail Address: ai.voferreira@gmail.com

Introduction: Capsule endoscopy (CE) is an important non-invasive diagnostic modality for the evaluation of small bowel and colon. However, in patients with gastrointestinal tract anatomy altered by surgical interventions, there can be a higher risk of incomplete examination of small bowel and colon.

Aims & Methods: The aim of our study was to evaluate the rate of complete examination and diagnostic yield of CE, in patients with previous gastrointestinal surgery, as well as the impact of endoscopic placement of CE using the AdvanCE device.

Retrospective, cohort study, including patients submitted to CE of the small bowel or colon, detailing patients with previous gastrointestinal surgeries and with endoscopic placement of CE.

Results: A total of 642 patients was included, 17 with previous gastrointestinal surgery (2.6%), from which 9 with gastric bypass and Y-de-Roux (with 3 having esophagojejunostomy and 6 gastrojejunostomy), 3 patients with Bilroth II, 2 with Bilroth I e 3 patients with sleeve gastrectomy.

Endoscopic placement of CE was performed at the discretion of the responsible gastroenterologist and occurred in 8 patients (1.2%). It was 13.3 times more likely to be performed in patients with previous gastrointestinal surgery (11.8% vs 1.0%, p=0.017).

In patients without endoscopic placement of CE, the rate of complete examination of the gastrointestinal tract, adequate bowel preparation and diagnostic yield was comparable between those with and without previous gastrointestinal surgery: 86.7% vs 85.3% (p=1.000), 73.3% vs 78.1% (p=0.751) e 40% vs 38% (p=0.875), respectively.

In patients with gastrointestinal surgery, the rate of complete examination of the gastrointestinal tract was comparable between patients with and without endoscopic placement of CE: 50.0% vs 86.7% (p=0.331). The rate of complete examination of the gastrointestinal tract, adequate bowel preparation and diagnostic yield was not influenced by the different types of surgery, considering patients with gastric bypass vs Y-de-Roux vs Bilroth II: 75.0% vs 80.0% vs 66.7% (p=0.915), 50.0% vs 60.0% vs 66.7% (p=0.902) e 25.0% vs 20.0% vs 66.7% (p=0.363), respectively.

Conclusion: CE is effective, even in patients with previous gastrointestinal surgery, with diagnostic yield and rate of complete examination of the gastrointestinal tract similar to other patients, regardless of the type of surgery. Endoscopic placement of CE with AdvanCE device does not seem to improve outcomes in patients with previous gastrointestinal surgery.

Disclosure: Nothing to disclose.

PP0294

OUTCOMES, HEALTH-CARE UTILIZATION RESOURCES AND PREDICTORS OF EARLY READMISSION AFTER ESOPHAGEAL STENT PLACEMENT

P. Palacios Argueta[1], D. Han[2], F. Lukens[1], D. Ko[2], P.T. Kröner[3], B. Brahmbhatt[1]

[1]Mayo Clinic Florida, Gastroenterology, Jacksonville, United States, [2]Universidad Francisco Marroquin, School of Medicine, Guatemala, Guatemala, [3]Riverside Regional Medical Center, Gastroenterology, Newport News, United States

Contact E-Mail Address: palaciosargueta.pedro@mayo.edu

Introduction: Esophageal stents (ES) are usually placed to relieve malignant obstructions however other non-malignant indications exists. Complications and readmissions after ES continue to pose a significant issue for gastroenterologists and have a significant burden on our health-care system.

Aims & Methods: Retrospective review of the National Readmission Database (NRD) of the year 2019 of adult patients that underwent ES placement during an index admission (IA) from the month of January to November and were readmitted within 30-days of discharge. ICD-10CM/PCS codes were utilized to identified the procedures and comorbidities.

The primary outcome was readmission of any cause. Secondary outcomes were mortality, resource utilization (length of stay (LOS), total hospitalization costs and charges) associated with readmission. Independent risk factors for readmission were identified using Cox regression analysis.

Results: A total of 6,079 patients underwent ES placement in 2019. The most common indication was malignant obstruction (19.1%). A total of 1,642 patients (27.1%) were readmitted within 30-days of discharge and the most common cause of readmission was sepsis (9.3%). Patients that underwent ES placement during IA had a mean age of 65.1 years, 39.8% patients were females, 54.1% of patients had a Charlson Comorbidity Index (CCI) score of ≥3 and 45.9% of patients had associated malnutrition. Readmitted patients were younger (62.5 vs. 66.1 years, P<0.01), more likely to have associated malnutrition (49.1 vs. 44.6%, P=0.04) and there was no difference in the proportion of readmitted females.

The mortality rate during IA was 6.6% and the readmission mortality rate was 8.6% (P<0.01). The mean LOS, hospitalization charges and costs were 7.6 days, $91,543 and $21,310 respectively. Readmission was associated with a total cumulative LOS of 12,514 days and a total $150 million in charges and $34.9 in costs.

After performing a Cox regression analysis younger age [adjusted Hazard Ratio [aHR] 0.98; 95% Confidence Interval [CI] (0.97-0.99)] and undergoing ES placement for non-malignant obstruction [aHR 0.84; (0.72-0.99)] were associated with less risk of readmission. A CCI score ≥3 [aHR 1.38; (1.08-1.77)] had higher risk for readmission.

Conclusion: Early readmissions after ES placement are high (27.1%) and readmission is associated with increased mortality. The most common indication for ES placement is malignant obstruction however undergoing ES placement for benign obstruction is associated with 26% less risk of readmission. Efforts should be put in place to decrease readmission rates and future studies should focus on evaluating risk factors for development and prevention of sepsis post ES placement.

Disclosure: Nothing to disclose.

ENDOSCOPIC ULTRASOUND-GUIDED GASTROENTEROSTOMY WITH LUMEN-APPOSING METAL STENTS COMPARED TO DUODENAL STENTING FOR MALIGNANT GASTRIC OUTLET OBSTRUCTION: RESULTS FROM A PROPENSITY SCORE MATCHING ANALYSIS

A. Wannhoff[1], N. Seitz[1], B. Meier[1], K. Caca[1]
[1]Hospital Ludwigsburg, Department of Internal Medicine and Gastroenterology, Ludwigsburg, Germany

Contact E-Mail Address: andreas.wannhoff@rkh-gesundheit.de

Introduction: Malignant gastric outlet obstruction (GOO) and its symptoms significantly reduce quality of life in affected patients. Endoscopic treatment of malignant GOO consists of enteral stent placement or the use endoscopic ultrasound to perform gastroenterostomy (EUS-GE) by means of lumen-apposing metal stents (LAMS).

Aims & Methods: We conducted a retrospective analysis comparing enteral stent placement to EUS-GE for treatment of malignant GOO. Patients treated at our institution were retrospectively identified and a propensity score matching analysis was performed. Primary outcome parameter was treatment failure. Secondary endpoints were time until treatment failure, technical and clinical success rates, and adverse event rates.

Results: 88 patients were included in the final analysis, 44 in each of the two treatment groups, after propensity score matching. Stent failure occurred significantly less in the EUS-GE group (n = 4, 9.1%) compared to enteral stenting group (n =13, 29.5%; *P* = .015). Kaplan-Meier analysis revealed a median time until stent failure of 22.0 weeks (95%-CI: 4.6 – 39.4) in the enteral stenting group compared to 76.0 weeks (95%-CI: 55.9 – 96.1) in the EUS-GE group (*P* = .002 according to log-rank test, Figure 2).

There was no difference in primary technical success (*P* = .306) and clinical success (*P* = .453) between the two groups. Technical success was achieved in 97.7% in the enteral stenting group compared to 93.2% in the EUS-GE group, while rates for clinical success were 72.7% and 79.5%, respectively. There were 9 adverse events in the total study cohort (10.2%), of which three occurred in patients that received enteral stenting and six in the EUS-GE group (*P* = .291).

Conclusion: For treatment of malignant GOO, EUS-GE is superior to enteral stent placement regarding rate of treatment failure and time until treatment failure. In experienced centers, it should be considered as endoscopic first-line treatment of malignant GOO.

Disclosure: Nothing to disclose.

SIGNIFICANT ADVANTAGES OF FIXATION OF ESOPHAGEAL SELF EXPANDING METAL STENTS:A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE PUBLISHED LITERATURE

H. Patel[1], D. Radadiya[1], S. Srinivasan[1], P. Nathani[1], A. Repici[2], C. Hassan[3], V. Thoguluva Chandrasekar[4], P. Sharma[5]
[1]University of Kansas Medical Center, Dept. of Gastroenterology, Kansas City, United States, [2]Ist. Clinico Humanitas Rozzano, Dept. of Gastroenterology, Milano, Italy, [3]Humanitas University, Dept. of Gastroenterology, Rome, Italy, [4]Augusta University Health, Augusta, United States, [5]University of Kansas School of Medicine, Dept. of Gastroenterology, Leawood, United States

Contact E-Mail Address: patelhk.md@gmail.com

Introduction: Fully covered self-expandable metal stents (FCSEMS) used for benign and malignant esophageal conditionsare prone to migration, which can impact efficacy but also lead to adverse events. Fixation of proximal end of FCSEMS have shown to reduce stent migration in individual studies.

In this systematic review and meta-analysis, we aim to compare rates of stent migration of FCSEMS undergoing fixation (any technique) versus not.

Aims & Methods: PubMed, Embase and Cochrane databases were queried to identify prospective/retrospective studies that compared outcomes of FCSEMS undergoing fixation (FCSEMS-F) versus no fixation (FCSEMS-NF). FCSEMS-F group included use of methods such as sutures, hemoclips and the specific over the scope clip (OTSC).

The primary outcome was pooled estimates of the rate of stent migration. Secondary outcomes included clinical success, mean time to stent migration and overall adverse events (chest or abdominal pain, nausea+/-vomiting, tear or perforation, bleeding). Subgroup Analysis was performed to compare stent migration when FCSEMS fixation was performed with endoscopic suturing vs no fixation.

Clinical success was defined as resolution of a stricture or closure of a fistula/leak/perforation as documented by clinical and endoscopic/radiological follow-up after stent removal. Odds ratios (RR) with 95% confidence intervals (CI) were calculated for dichotomous variables using the random effects model.

Study heterogeneity was assessed using i^2 statistics.

Results: We identified 9 studies of FCSEMS placement comparing fixation versus no-fixation methods including a total 727 patients with 899 stent procedures: FCSEMS-F group (269 patient, 291 stents, mean age 60.4 years) and FCSEMS-NF group (458 patients, 608 stents, mean age 61.7 years).

The stent migration rate for all procedures was 16.1% in FCSEMS-F group compared to 32.8% in FCSEMS-NF group (9 studies, OR 0.36, 95% CI 0.20 -0.64,i^2= 53%).

Clinical success was achieved in 68.9% procedures in FCSEMS-F group compared to 56.1% in FCSEMS-NF group (3 studies, OR 1.94, 95% CI 1.10 – 3.41, i^2=0%).

Mean time to stent migration was longer for FCSEMS-F (29.4 +/- 11.2 days) compared to FCSEMS-NF (21.6 +/- 11days) with a mean difference of 7.8 days (95% CI 5.4 – 10.2; SE 1.2, p< 0.0001). There was no difference in overall adverse events between the 2 groups.

In a sub-group analysis for FCSEMS patients undergoing fixation with endoscopic suturing versus no fixation, the rate of stent migration was significantly lower in the sutured group (16.3% vs 32.8%, OR 0.37,95% CI 0.19 – 0.72, i^2= 55%).

Conclusion: Fixation of FCSEMS (sutured in particular) offer significant advantages in terms of lower stent migration rates, longer duration to stent migration and higher clinical success without any difference in adverse events when compared to esophageal stents not undergoing fixation. Randomized studies comparing various fixation methods is needed to further guide the exact method for stent fixation.

Disclosure: No Relevant Financial Disclosures.

TRANSITIONS OF TREATMENT OUTCOMES AND ADVERSE EVENTS IN GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

Y. Tahata[1], N. Mimori[1], Y. Kato[1], S. Fushimi[1], R. Abe[1], Y. Horikawa[1]
[1]Hiraka General Hospital, Gastroenterology, Yokote, Japan

Contact E-Mail Address: m05059ytakt@gmail.com

Introduction: In superficial gastric tumors, endoscopic submucosal dissection (ESD) has become the standard of care, and the treatmenttechnique and strategy have been matured.

On the other hand, the number of cases performed by trainees as anintroduction to ESD is increasing, and the types and handling of antithrombotic drugs are also changing.

Aims & Methods: On these backgrounds, we examined the transitions to clarify how the treatment outcomes and adverse events of gastric ESD have changed.

From 2014 to 2022, 565 patients of superficial gastric neoplasms who underwent ESD were divided into two groups: the first half (n=435) from 2014 to 2020 and the second half (n=130) from 2021 to 2022, where the number of trainees significantly increased. Treatment outcomes (*En bloc* resection rate, curability, procedure time, inflammatory response)and adverse events (perforation, postoperative bleeding, postoperative pneumonia, and pyrexia for unknown reasons) were retrospectively compared between two groups, using the propensity score matching analysis.

Regarding oral antithrombotic agents, antithrombotic drugs were continued, DOAC stopped only 24 hours before treatment, and warfarin was continued after INR value was controlled at <3.0.

Results: Propensity score matching yielded 130 pairs. Trainee's involvement was 29.7% in the first half and 61.4% in the second half. The comparison demonstrated a significant difference for the following outcomes: curability was 86% in the first half and 90.1% in the second half (*P*=0.028), the CRP mean [SD] was 1.32 [2.14] in the first half and 0.82 [0.97] in the second half (*P*=0.032), and postoperative bleeding rate was 5.9% in the first half and 0.0% in the second half (*P*=0.013). Others were similar values for outcomes.

Conclusion: Even with the increased involvement of trainees, treatment outcomes have not chronologically exacerbated. Additionally, inflammatory response and postoperative bleeding have improved. These results suggest that safe and secure gastric ESD can be performed by appropriate technique and strategy under supervise of experts.

Disclosure: Nothing to disclose.

ENDOSCOPIC VACUUM THERAPY (EVT) VERSUS SELF-EXPANDING METAL STENT (SEMS) IN THE TREATMENT OF NON-LARGE ANASTOMOTIC DEHISCENCES AFTER ONCOLOGIC IVOR-LEWIS ESOPHAGECTOMY: A MATCHED CASE-CONTROL STUDY

F.V. Mandarino[1], A. Barchi[1], L. Leone[1], L. Fanti[1], F. Azzolini[1], R. Rosati[2], U. Elmore[2], S. Danese[1]
[1]IRCCS San Raffaele Scientific Institute, Division of Gastroenterology and Gastrointestinal Endoscopy, Milan, Italy, [2]IRCCS San Raffaele Scientific Institute, Department of Gastrointestinal Surgery, Milan, Italy

Contact E-Mail Address: barchi.alberto@hsr.it

Introduction: Anastomotic leak remains one of the most critical complication after Ivor-Lewis esophagectomy [1][2]. While intra-cavitary approach for Endoscopic Vacuum Therapy (EVT) has been proved effective for the treatment of large dehiscences [3], no data exist comparing intraluminal EVT and Self-expanding Metal Stent (SEMS) in the management of non-large (<3 cm) anastomotic dehiscences.

Aims & Methods: In this matched-at-enrollment case-control study (1:1), we included patients who received EVT and SEMS for non-large (<3 cm) anastomotic dehiscences after oncologic Ivor-Lewis esophagectomy between May 2014 and July 2022.

The primary outcome was successful closure of the leak. Exclusion criteria were: anastomotic dehiscences > 3 cm, early (≤ 2 days) and late (4 weeks) diagnosis after surgery, severe gastric conduit necrosis, sepsis / septic shock at diagnosis.

Results: Overall, 22 patients treated with EVT and 22 treated with SEMS, were matched by age (p=0.070), sex (p=0.262), BMI (0,247), American Society of Anesthesiologists (ASA) score (p=0.386), neoadiuvant radio/chemotherapy (p=0.15), dehiscence diagnosis modality (0.761), defect type (leak or fistula) (p=1.00), PCR values (p=0.103) surgical re-intervention before endoscopic treatment (p=0.472) and leak size (p=0.931).

EVT and SEMS revealed no difference in leak resolution (90.9% vs 72.7%, respectively; p=0.21), whereas EVT group was associated with higher number of procedures (4.41 vs 2.18, p= 0.05, respectively). Concerning adverse events (AE's), both EVT and SEMS showed no statistical difference in AE's rates (p=0.61).

Overall outcomes of endoscopic procedures are shown in Table 1.

	EVT (n=22)	SEMS (n=22)	p-value
Total number of procedures	125	78	
Adjuvant endoscopic treatment	1 (4.5%)	5 (22.7%)	0.07
Mean number of procedures per patient	4.4 ± 3.2	2.2 ± 1.6	0.05
Hospitalization (days)	45.3 ± 18.0	52.6 ± 29.2	**0.01**
Efficacy outcomes			
Resolution	20 (91%)	16 (72.7%)	0.11
Failure	2 (9%)	6 (27.3%)	
Re-do surgery	1(4.5%)	4 (18.2%)	
In-hospital mortality	1 (4.5%)	1 (9.1%)	
Technical success*	125 (100%)	78 (100%)	1.00
Intraprocedural AE*	2 (1.6%)	2 (2.5%)	0.64
Bleeding	1 (0.8%)	0	
Perforation	0 (0%)	0	
Sedation-related	1 (0.8%)	0	
Ulcers	0	2 (0.9%)	
Migration*	2 (1.6%)	12 (15.3%)	**0.0001**
Follow-up (days)	396.9 ± 89.3	556.7 ± 178.4	

Table 1.

Conclusion: EVT and SEMS has shown similar efficacy outcomes in the treatment of non-large (< 3 cm) anastomotic defects after Ivor-Lewis esophagectomy. Prospective comparison data are needed to validated these findings.

Introduction: LECS was reported by Hiki in 2008 as one of the treatments for gastric GIST (1). In 2012, our hospital introduced LECS for the treatment of superficial non-ampullary duodenal adenoma (SNADA) and non-ampullary neuroendocrine tumor (NADNET) using the same method (2). From 2021, D-LECS was divided into D-LECS with FTR, which is a full-thickness resection, and D-LECS with ESD, which is intended for post-ESD reinforcement (3).

Aims & Methods: The aim of this study was to extract cases in which D-LECS with ESD was performed at our hospital and to report the important points that should be noted in treatment. FAP cases were excluded in 99 eligible cases from January 2001 to October 2022.

In addition, there were many cases in the follow-up group at SNADA. Of the 50 cases treated, there were 23 in the endoscopic treatment group, 16 in the LECS treatment group, and 11 in the surgical treatment group. There were 16 D-LECS cases, of which 4 cases for which D-LECS with ESD was performed were extracted. Before the D-LECS insurance coverage, the treatment was approved by the hospital ethics committee and the treatment was introduced.

Results: There were three points of view which were endoscopic aspects, laparoscopic aspects, and aspects to note throughout the treatment. Four examples revealed some important points.

Case 1: Preoperative discussion was insufficient and D-LECS with ESD was decided at the time of surgery. It took nearly 2 hours to resect the lesion with an endoscope and then the laparoscopic side was sutured. After the treatment, it was possible to pass the endoscope through the treated area, but a few days later, a stenosis was formed, and endoscopic dilation was needed to improve.

Case 2: Preoperative discussion was also insufficient. This case had many blood vessels, and the ST hood was needed because it is difficult to perform ESD. When the endoscope was extended, perforation occurred. Once the perforation was made, it was difficult to move the patient, so the muscle layer was sutured with OTSC, and a PGA sheet.

Case 3: The endoscopic strategy and device were improved, and the lesion could be dissected within 1 hour. ESD was performed with Dual Knife J 1.5. Pulling the lesion with an S-O clip without using an ST hood so as not to apply strong pressure to muscle layer. The RDI function was used during hemostasis to avoid the burn effect on the muscle layer. On the other hand, there was a problem that the treatment site was unclear when suturing with a laparoscope.

Case 4: Endoscope operation might be difficult, so a PCF scope was used for ESD. Blood vessels were densely existed on the upper the lesion, and the resection margin became unclear due to hemostasis. Lembert suture was added after a full-thickness suture due to a small perforation.

10 days after the operation, the peristalsis decreased, and the contents did not pass even though the endoscope passed. Most of these caveats have visions for improvement. Technical aspects and device selection can be overcome by referring to published literature.

In addition, we believe that stenosis and passage obstruction can be improved with additional treatment because restenosis has not been observed in endoscopic dilatation. It was important to find an effective treatment for hypoperistalsis.

Conclusion: At present, there are a number of caveats that must be overcome on both the endoscopic side and the laparoscopic side. Therefore, even though D-LECS has been covered by health insurance, it is necessary to consider some strategy before treatment.

ENDOSCOPIC TREATMENT FOR EARLY DUODENAL PAPILLARY CARCINOMA: LONG-TERM OUTCOMES

J. Yang[1], H. Khizar[2]
[1]*Hangzhou First People Hospital, Gastroentrology, Hangzhou, China,* [2]*Hangzhou First People Hospital, Hangzhou, China*

Contact E-Mail Address: yjf3303@zju.edu.cn

Introduction: This study aims to determine whether endoscopic papillectomy (EP) is a safe and effective treatment for early duodenal papillary carcinoma with long-term follow-up.

Aims & Methods: From June 2012 to September 2021, 48 patients with early duodenal papilloma carcinoma who received endoscopic treatment at Hangzhou First People's Hospital were included. The histological types, percentage of complete resections, postoperative residuals, adverse events, and recurrences were evaluated.

Results: Endoscopic papillectomy (EP) was successful in all patients, 46 were lumped, and two were fragmented, with a 95.8% intact removal rate (46/48). Postoperative pathology indicated 24 cases of high-grade intraepithelial neoplasia, 9 cases of moderately differentiated adenocarcinoma, and 15 cases of highly differentiated adenocarcinoma. The preoperative biopsy pathological positive rate was 70.8% (34/48).

Early postoperative adverse events (within one month after EP) were 16.7% (8/48), including 4 cases of acute pancreatitis, 3 cases of delayed bleeding, and 1 case of acute cholangitis. In addition, 4.2% (2/48) of late adverse events were bile duct stenosis.

The postoperative residual rate was 0%. The median time to recurrence was 17.5 months, and the postoperative recurrence rate was 16.7% (8/48) treated with radiofrequency ablation. Median progression-free survival was 18.6 months (95%CI, 12.1 to 25.1), and median overall survival was 121.5 months (95%CI, 105.6 to 120.9).

Conclusion: Endoscopic papillectomy is a safe and efficient alternative therapy for early duodenal papillary carcinoma. Endoscopic follow-up and treatment are essential because of recurrence.

Disclosure: Nothing to disclose.

FULLY VS. PARTIALLY COVERED SELF-EXPANDABLE METAL STENTS FOR ESOPHAGOGASTRIC ANASTOMOTIC LEAK

R. Ortigão[1], J. Chaves[2], C. Pinto[1], I. Marques de Sá[1], R.P. Bastos[1], M. Dinis-Ribeiro[1], D. Libânio[1]
[1]*Institute Portuguese of Oncology, Gastrenterology, Porto, Portugal,* [2]*Ipo Porto, Porto, Portugal*

Contact E-Mail Address: raquel.ortigao@hotmail.com

Introduction: Self-expandable metal stents (SEMS) are a minimally invasive treatment for anastomotic leaks (AL). Our aim was to compare clinical and safety outcomes of fully covered (FC) and partially covered (PC) SEMS.

Aims & Methods: Retrospective single-centre study including consecutive patients with esophagogastric (oncological) AL treated with FC-SEMS or PC-SEMS (01/2013-12/2022).

Results: A total of 49 patients received esophageal stents (14 FCSEMS and 35 PCSEMS) for AL (82% primary therapy, 18% rescue treatment; 40% submitted to esophagectomy, 60% to total gastrectomy). Technical success was similar between PC-SEMS and FC-SEMS (80 vs 71%, p=0.397). Clinical success without reintervention was 74% with PC-SEMS and 64% with FC-SEMS (p=0.388). Stent migration was higher with FC-SEMS (36% vs 12% with PC-SEMS, p=0.05). Fixation of stent with TTS clips did not reduce the risk of stent migration (p=0.036). Stenosis rate was also similar in the two groups (46% PC-SEMS vs 53% FC-SEMS, p=0.665), and there was no difference in the mean number of dilatations needed to treat stenosis (4.2 in PC-SEMS vs 95.1 in FC-SEMS; p=0.114). Severe adverse advents occurred in two patients, without mortality. Stent-in-stent technique for removal was needed in 83% patients with PC-SEMS (vs 0% with FC-SEMS). AL-related mortality was similar in the two groups (9% PC-SEMS vs 14% FC-SEMS; p=0.662).

Conclusion: PC-SEMS and FC-SEMS are similarly effective and safe for AL-treatment, although FC-SEMS are associated with slightly higher risk of stent migration. The choice of stent should be individualized based on anticipated risks of migration and tissue overgrowth.

Introduction: Gastrectomy for gastric cancer causes long term complications. However, cancer treatment-induced bone loss remains unclear[1].

We have previously evaluated osteoporosis in several disease by using Dual-energy X-ray Absorptiometry(DXA) and high-resolution peripheral quantitative computed tomography (HR-pQCT)[2-4].

Aims & Methods: The aim of this study was to evaluate osteoporosis by using DXA and HR-pQCT more than 5 years after gastrectomy.

This observational study included 42 male patients (21 distal gastrectomy (DG), 21 total gastrectomy (TG)) more than 5 years after gastrectomy due to gastric cancer (GC group) and age-matched 63 male healthy volunteer donors (control group). We excluded women to avoid the effects of menopause.

In osteoporosis markers, such as 25-OH Vitamin D (25OHVD), tartrate-resistant acid phosphatase-5b (TRACP-5b), and procollagen type-I N-terminal propeptide (Total P1NP), were measured in both groups

Areal bone mineral density (aBMD) of the lumbar spine and proximal femur were analyzed by DXA.

Total, cortical, and trabecular volumetric bone mineral density (Tt.vBMD, Ct.vBMD, and Tb.vBMD) of the radius and distal tibia were analyzed by HR-pQCT. Cortical and trabecular thickness (Ct.Th and Tb.Th) of the radius and distal tibia were analyzed by HR-pQCT.

The primary endpoint was the difference of bone mineral density, bone microstructure and bone metabolism markers between the control and the GC groups.

The secondary endpoint was the difference of bone mineral density, bone microstructure and bone metabolism markers between the DG and TG groups.

Results: 1. Gastrectomy on bone mineral density and microstructure.

In DXA, lumbar and femoral aBMD were significantly lower in the GC group (control vs GC; 1.24 ± 0.23 vs 1.08 ± 0.30, $P < 0.01$, control vs GC; 0.88 ± 0.13 vs 0.78 ± 0.15, $P < 0.01$, respectively).

In HR-pQCT, Tt.vBMD of the radius and tibia was also significantly lower in the GC group. Radial and tibial Ct.vBMD were significantly lower in the GC group .Radial and tibial Ct.Th were significantly lower in the GC group.

Radius	Control	GC	P value	Tibia	Control	GC	P value
Tot.vBMD	271.5 ± 58.5	240.8 ± 70.7	P = 0.02	Tot.vBMD	276.9 ± 46.4	243.4± 70.7	P = 0.02
Tb.vBMD	145.1 ± 34.4	130.1 ± 41.8	P < 0.05	Tb.vBMD	159.4 ± 31.2	146.4 ± 39.5	n.s.
Ct. vBMD	847.3 ± 57.5	811.0 ± 83.9	P < 0.01	Ct. vBMD	852.5 ± 52.4	798.3 ± 72.4	P < 0.01
Tb.Th	0.24 ± 0.02	0.23 ± 0.02	n.s.	Tb.Th	0.26 ± 0.02	0.25 ± 0.02	n.s.
Ct.Th	1.01 ± 0.21	0.90 ± 0.24	P = 0.02	Ct.Th	1.49 ± 0.26	1.30 ± 0.33	P < 0.01

The serum intact PTH, TRACP-5b, and Total P1NP levels in the GC group were significantly higher than in control group (control vs GC; med 44.6 vs 55.3, P < 0.01, control vs GC; med 325 vs 474.5, P < 0.01, and control vs GC; med 40.6 vs 46.9, P < 0.01, respectively). The serum 25OHVD and albumin level in the GC group were significantly lower than in control group (control vs GC; med 20.2 vs 16.3, P = 0.05, control vs GC; 4.3 vs 4.1, P < 0.01, respectively).

2. Total and distal gastrectomy on bone mineral density and microstructure

In DXA, lumbar and femoral aBMD was significantly lower in the TG group (DG vs TG; 1.17 ± 0.28 vs 1.00 ± 0.30, P < 0.01, DG vs TG; 0.83 ± 0.13 vs 0.73 ± 0.15, P < 0.01, respectively). In HR-pQCT, radial and tibial Ct.vBMD were significantly lower in the GC group (DG vs TG; 834.1 ± 71.6mg/cm3 vs 787.8 ± 90.5mg/cm3, P = 0.03, DG vs TG; 811.4 ± 72.1mg/cm3 vs 785.3 ± 72.0 mg/cm3, P < 0.01, respectively). There were no differences in osteoporosis markers between the DG and TG groups.

Conclusion: Osteoporosis after gastrectomy was more progressive than healthy volunteers over a long period. Bone deterioration after total gastrectomy was more progressive in the cortical bone than distal gastrectomy.

Introduction: Endoscopic submucosal dissection (ESD) is a common treatment for low-risk gastric cancers, but postoperative bleeding, affecting 0%-15.6% of patients, remains a concern. With aging populations and increased antithrombotic agent use, post-ESD bleeding may soon become even more frequent. Fibrin glue with polyglycolic acid (PGA) sheets has shown promise in preventing post-ESD bleeding, but challenges exist, especially when applying sheets against gravity in gastrointestinal ulcers. Moreover, the PGA sheets themselves can be difficult to manipulate and place onto the ulcer bed. The envelope method, developed in 2017, involves storing PGA sheets in a protective envelope that is carried alongside the endoscope, preventing exposure to saliva or mucus which commonly occurs when PGA sheets are individually passed down the endoscope channel. The envelope then adheres to the gastric wall, and clean PGA sheets can be drawn easily using forceps. This method has demonstrated efficient PGA sheet delivery and fixation but was only found to be effective for gravitational ulcers.

Aims & Methods: The study aims to evaluate the envelope method's efficacy in treating both gravitational and anti-gravitational post-ESD ulcers in living porcine stomachs.Gravitational and anti-gravitational artificial ulcers were created via ESD in living porcine stomachs, using a standardized template as a sizing guide. PGA sheets were then applied to each ulcer, employing the conventional and envelope methods six times each. To standardize the ulcer location and characteristics, the sheets were removed after application, and reapplied over the same ulcer bed. To account for minute changes in ulcer environment over time, the method of re-application was alternated between the conventional and envelope methods. The delivery time of PGA sheets and the endoscopic and histological observations of the treated ulcer surfaces were comparatively analyzed. The ulcers were measured with an endoscopic scale, and the delivery time was presented in min/cm^2 to allow for subtle differences in ulcer size.

Results: The envelope method showed significantly shorter application times compared to the conventional method for both gravitational (1.0 min/cm^2 vs 0.32 min/cm^2, p=0.002) and anti-gravitational ulcers (1.2 min/cm^2 vs 0.50 min/ cm^2 p=0.002). In endoscopic examinations, the envelope group demonstrated appropriately applied PGA sheets in anti-gravitational ulcers, with flat sheets and minimal overlapping, while the conventional group showed uneven sheets and clumping. Histologically, the envelope method provided uniform coverage of the ulcer floor with a mixture of PGA sheets and fibrin glue, while the conventional method left gaps between sheets.

Conclusion: The envelope method enables swift transportation and accurate fixation of PGA sheets within living porcine stomachs. This approach is applicable for addressing both gravitational and anti-gravitational ulcers, and may have utility in the prevention of post gastric ESD bleeding.

PREVALENCE OF DUMPING SYMPTOMS AFTER ESOPHAGEAL CANCER SURGERY: A SYSTEMIC REVIEW

Y. Lin[1], H.-J. Wang[1], Y.-X. Qu[1], Z.-Q. Liu[1], S.-H. Xie[1,2,3,4]
[1]Fujian Medical University, School of Public Health, Fuzhou, China, [2]Fujian Medical University, Institute of Population Medicine, Fuzhou, China, [3]Fujian Medical University, Ministry of Education Key Laboratory for Gastrointestinal Cancer, Fuzhou, China, [4]Karolinska Institute , Karolinska University Hospital, Molecular Medicine and Surgery, Stockholm, Sweden

Contact E-Mail Address: linyuzuru@outlook.com

Introduction: Esophageal cancer is the seventh most common type of cancer and sixth leading cause of cancer-related deaths worldwide. Dumping syndrome is a common type of postoperative complications in esophageal cancer patients.

Aims & Methods: This systematic review aimed to assess the prevalence of dumping syndrome after surgery in esophageal cancer patients. A comprehensive literature search was conducted in PubMed, MEDLINE, Web of Science, Embase and the Cochrane Library databases, supplemented by hand-search of reference lists, through March 2023. Random-effects meta-analysis estimated the average prevalence of dumping syndrome after esophageal cancer surgery by study design. Heterogeneity across studies was examined by the I^2 statistic and Cochran's Q test.

Results: A total of 2949 articles were retrieved from the database, among which 17 articles (7 cohort studies, 9 case-series and 1 randomized controlled trial) met the inclusion criteria. The prevalence of dumping syndrome ranged 6%-74% in cohort studies, and meta-analysis estimated the pooled prevalence of 37% (95 confidence interval [CI] 14%-65%; I^2=98%, P for heterogeneity <0.01).

The prevalence of dumping syndrome reported in case-series ranged and meta-analysis estimated the pooled prevalence of 18% (95% CI 7%-34%; I^2=98%, P for heterogeneity <0.01). The randomized controlled study involving 300 patients reported no occurrence of dumping syndrome.

Conclusion: The prevalence of dumping syndrome after esophageal cancer surgery differed greatly as reported in previous studies, which might be explained by differences in definition and assessment of dumping syndrome, length of follow-up and patients' characteristics. Standardized methods in measuring dumping syndrome are needed in future investigations.

Disclosure: None.

Introduction: The Luso-Cor esophageal stent was developed to manage fistulas and dehiscences after bariatric and gastric oncologic surgery.

Aims & Methods: The study aims to evaluate the effectiveness and safety of Luso-Cor in treating sleeve gastrectomy fistulas. Retrospective and multi-centric analysis of 28 consecutive patients with fistulas after sleeve gastrectomy who were managed with the Luso-Cor stent, between July 2016 and February 2023. Qualitative variables were analyzed as percentages. Quantitative variables were analyzed as median (min-max) and Mann-Whitney test (non-normal distribution). Predictive factors of fistula closure and adverse events were analyzed with logistic regression. A p-value <0.05 was considered statistically significative. (IBM SPSS 28).

Results: Median age was 45.5 (20-66) years, 78% (n=22) were women. Median fistula orifice size was 5(2 – 20)mm and the location of leaks was: Cardia–71.4%(n= 20); gastric tube–17.9%(n=5); other–10.7%(n=3). The median duration of stent implantation was 6(1–18) weeks. In 28.57%(n=8) patients, a re-intervention was necessary due to: inadequate coaptation of proximal flare of the stent(n=6), migration(n=1) and esophageal stricture(n=1). In 3 cases a new stent was required.

Adverse events were observed in 17.9%(n=5) patients: GI bleeding (n=3), esophageal stricture (n=1) stricture requiring balloon dilation, and recurrent vomiting (n=1). Two patients died, one due to aorto-esophageal fistula and the other one due to pulmonary embolism.

The overall success rate of Luso-Cor stent was 89.3% (25/28). One patient died before stent removal. In 2 of the remaining cases the persisting fistula orifice was closed with an over-the-scope clip (OTSC). The stent was used as first line in 50% (n=14) patients and as rescue therapy in the remaining 50% (n=14)second line, with a significant reduction in the number of endoscopies (3 vs 4) (p=0.031), without difference in efficacy (p=1.225) and adverse events (p=1.195) between groups.

Conclusion: The Luso-Cor esophageal stent was effective in managing sleeve gastrectomy fistulas, with low stent migration rates. The use of the stent as first line therapy significantly o reduced the number of endoscopies until fistula closure.

Disclosure: Nothing to disclose.

Introduction: The Luso-Cor esophageal stent was developed for management of fistulas and dehiscences after bariatric and gastric oncologic surgery.

Aims & Methods: The study aims to evaluate the efficacy and safety of Luso-Cor in managing fistulas and strictures after gastric surgery. This is a retrospective and multicentric study involving 35 consecutive patients with adverse events after gastric surgery who were managed with the Luso-Cor® esophageal stent, between July 2016 and February 2023. The adverse events were: fistulas after sleeve gastrectomy (n=28), anastomotic dehiscence (n=4) and gastric tube stricture after bariatric surgery (n=3). The technical success was defined as the effective exclusion of the fistula and the clinical success as fistula closure or effective stricture dilation after stent removal. Endoscopic reinterventions and adverse events were analyzed with descriptive statistics.

Results: Median age was 50(20-84) years, 69%(n=24) were women. Median fistula orifice size was 5.5(2–20)mm. The median duration of stent implantation was 6(1-18) weeks. An endoscopic reintervention was required in 31.43% (n=11) patients due to the following reasons:

Inadequate coaptation of the proximal flare to esophageal wall (n=6), migration (n=3), stricture (n=1), stent fracture (n=1).

Adverse events were observed in 14.23% (n=5) patients: GI bleeding (n=3), esophageal stricture requiring balloon dilation (n=1), recurrent vomiting (n=1).

The technical success in exclusion of fistulas / anastomotic dehiscences was 100%(32). There were 5 deaths: sepsis (n=3); aortoesophageal fistula 3 cm above the proximal edge of the stent (n=1) e probable pulmonary thromboembolism (n=1).

After a median stent implantation of 6 (1-18) weeks, a clinical success rate in fistula closure of 93%(26/28) was observed. In two patients with persistent fistulas after stent removal were successfully managed with 10 mm over-the-scope-clips. The clinical success of the stent in managing strictures with concomitant fistulas was 100%(13/13) and isolated stricture was 33%(1/3). One patient required endoscopic dilatation and the other underwent total gastrectomy.

Conclusion: The innovative design of the Luso-Cor. stent is very effective in managing fistulas and concomitant strictures after gastric bariatric and oncologic surgery. The esophageal anchoring reduces the migration risk and facilitates the stent removal.

Disclosure: Nothing to disclose.

PP0307

COMPARISON OF GEL IMMERSION ENDOSCOPIC MUCOSAL RESECTION (EMR) AND UNDERWATER EMR FOR SUPERFICIAL NON-AMPULLARY DUODENAL EPITHELIAL TUMORS (SNADETS)

T. Yamashina[1], M. Shimatani[1], N. Saito[1], M. Kano[1], H. Matsumoto[1], M. Orino[1], S. Horitani[1], M. Takeo[1], T. Mitsuyama[1], T. Yuba[1], M. Naganuma[2]
[1]Kansai Medical University Medical Center, Division of Gastroenterology and Hepatology, Moriguchi, Japan, [2]Kansai Medical University, Third Department of Internal Medicine, Hirakata, Japan

Contact E-Mail Address: take8047@hotmail.com

Introduction: The most popular endoscopic therapy for SNADETs is endoscopic mucosal resection (EMR), however it is difficult due to major serious adverse events and poor curative outcomes that result in a high recurrence rate. Underwater endoscopic mucosal resection (UEMR) has recently attracted attention as a safe and effective method for superficial non-ampullary duodenal epithelial tumors (SNADETs).

However, water is a fluid and it does not remain in all areas, and because it mixes easily with other substances, it sometimes becomes cloudy and reduces visibility. A new endoscopic gel product that does not mix with fluids and tends to remain in the injected area has recently been applied to EMR and is known as gel immersion EMR (GIEMR) or under-gel EMR. Unlike water, this gel product does not mix with intestinal fluids or blood, thus ensuring a good view of the gastrointestinal tract.

Furthermore, it tends to stay in the injected area due to its viscoelasticity, which may shorten the treatment time.

Aims & Methods: In the present study, we compared the efficacy and safety of UEMR and GIEMR for treatment of SNADETs.

From February 2019 to January 2023, patients who underwent UEMR or GIEMR for SNADETs at the municipal hospitals were included in the study, and treatment outcomes were compared retrospectively in both groups. We identified 31 lesions of SNADETs with 3–18 mm in diameter who underwent UEMR or GIEMR. One lesion was excluded from the analysis because it was found to be in the stomach after surgery.

The primary endpoint in this study was the difference in procedure time between the GIEMR and UEMR groups. The procedure time was defined as the time from the start of normal saline or gel injection into the lumen until the polyp was completely removed. En bloc resection rate, R0 resection rate and adverse events were evaluated as secondary endpoints.

Results: The 30 lesions in 29 patients were divided into the UEMR (n=12) and GIEMR (n=18) groups. There were no differences in age, gender, location, morphology and histological type between the UEMR and GIEMR groups, although the GIEMR group had a significantly larger median tumor diameter size (7 mm vs 11 mm, P=0.0006). GIEMR significantly reduced the procedure time compared with UEMR (5.5 min vs 10 min, P=0.016).

There was no significant difference between the UEMR and GIEMR groups for *en bloc* resection rate (91% vs 94%, P=1.0) and R0 resection rate (58% vs 78%, P=0.42). No serious complications were observed in either group.

Conclusion: GIEMR was safe and had good therapeutic results for SNADETs and showed the potential to accelerate the procedure time compared with UEMR. This method may be particularly useful in areas where immersion in water is difficult. A multicenter study is needed to confirm the validity of our results.

Disclosure: Nothing to disclose.

PP0308

EFFICACY OF ENDOSCOPIC BAND LIGATION FOR DUODENAL NEUROENDOCRINE NEOPLASMS: A SINGLE-CENTER OBSERVATIONAL STUDY

H. Rughwani[1], S. Batchu[2], A. Sekaran[3], N. Jagtap[1], P. Inavolu[1], M. Ramchandani[1], S. Fathima[4], D.N. Reddy[1]
[1]AIG Hospitals, Department of Medical Gastroenterology, Hyderabad, India, [2]AIG Hospitals, Department of Nuclear Medicine, Hyderabad, India, [3]AIG Hospitals, Department of Pathology, Hyderabad, India, [4]AIG Hospitals, Department of Clinical Research, Hyderabad, India

Contact E-Mail Address: hardik.hr@gmail.com

Introduction: Duodenal Neuroendocrine Neoplasms (dNENs) are rare neoplasms (2.7% of all NENs) (1), but their incidence is on the rise. Most of them are smaller, low-grade neoplasms with an indolent course. The role of endoscopic resection and active surveillance of dNENs needs to be reviewed (2).

The term neuroendocrine tumor (NET) generally refers to well-differentiated disease, neuroendocrine carcinoma (NEC) refers to poorly differentiated disease, and NEN is an umbrella term inclusive of both.

Aims & Methods: This is a single-center observational retrospective study of duodenal Endoscopic Band Ligation (dEBL) done between June 2020 and February 2023 at the Asian Institute of Gastroenterology (AIG Hospitals), Hyderabad, India.

The primary aim was to study the therapeutic efficacy of dEBL for dNENs. All patients having histological or molecular radiology (Gallium 68 DOTATEC) confirmation of a neuroendocrine neoplasm either at our center or outside were included. The size, number, and location of lesions were recorded. On histopathology examination, the grade and Ki 67 index were noted (3).

The presence of lymph node, hepatic, and skeletal metastasis was assessed at the time of diagnosis through cross-sectional imaging and Gallium 68 DOTATEC scans (4). All patients underwent follow-up endoscopies 3–12 months after dEBL, and those who were indicated underwent repeat imaging.

Results: During the study period, n = 138 (M: F: 107:31, age: 53.92±11.95 years) patients underwent dEBL. Most lesions (90%) were non-functional and were incidentally diagnosed on endoscopy. The most common site was the first part of the duodenum and duodenal bulb (n = 123, 89%), with the majority of patients having single lesions (n = 118, 85%). The size of lesions (endoscopic or radiologic) was <1cm in n=110 (80%) patients.

Diagnostic endoscopic ultrasound was done in n=82 (59%) patients and showed lesions arising from the 2nd layer of the duodenum. Biopsy showed Well differentiated NENs (with or without duodenitis) in n = 108 (78%) patients, with a Ki67 index less than 3% in 61/92 (67%) patients.

A DOTATEC scan done in n = 77 (56%) patients showed uptake in n = 37/77 (48%) patients. The mean SUV max was 23.61. Follow-up endoscopies were done in n = 104 (76%) patients at 3–12 months post-procedure, which showed complete clearance of the lesion in n = 92 (95%) patients (therapeutic efficacy).

Twelve patients had residual lesions on endoscopic evaluation and underwent repeat DOTATEC scans, of which four showed residual lesions for which a repeat dEBL was done. Eleven patients (8%) had post-procedure upper abdominal pain, which subsided with conservative management.

Conclusion: Endoscopic duodenal banding should be considered a safe and effective treatment modality for all well-differentiated, low-grade dNENs after excluding metastases.

Further prospective studies should be done to establish this modality as the gold standard of treatment and include it in the algorithm for the management of dNENs.

WHAT DO PATIENTS THINK OF CYTOSPONGE?: SURVEY OF 829 PATIENTS IN AN ESTABLISHED EARLY DIAGNOSIS UPPER GI SERVICE

K. Shaw[1], F. Cole[1], S. Machej[1], J. Evans[1], D. Morris[1]
[1]East and North Herts NHS Trust, Gastroenterology, Stevenage, United Kingdom

Contact E-Mail Address: kim.shaw@nhs.net

Introduction: Due to pandemic restrictions we established a new early diagnosis service for patients with reflux symptoms and those on our existing Barrett's surveillance programme using Cytosponge as initial investigation in 2020. As this was the first time Cytosponge had been used in routine clinical practice in this setting it was important to involve patients in the evaluation of the service.

Aims & Methods: The service was established in a district general hospital with catchment area 600,000**.** All patients who had a Cytosponge procedure between 01/05/2021 and 04/04/2023 were asked to complete a one-page survey about their experience on the same day as the procedure, prior to leaving the hospital. The survey contained demographic data and questions regarding their degree of discomfort using a visual analogue scale as well as whether they had had a previous endoscopy, and which one they preferred, if they thought the test was acceptable and whether they would be willing to have a Cytosponge again. There was also space for free text comments.

Results: 829 patients completed the survey at least partially. No patients declined to participate. 393 (49.5%) were female, 401 Male(50.5%) 93% described themselves as white ethnicity 3.4% as Asian/Asian British, 1.2% as Black or Black British,2.2% as Mixed/other.

99.5% found the information leaflet helpful. Only 20/816 (2.5%) respondents felt that Cytosponge was an unacceptable test. 15% described no discomfort, 77% mild or minimal discomfort, 3% moderate discomfort, 5% severe/significant discomfort. 778 patients (94%) would be willing to have a Cytosponge again.

445/819 (54%) reported having a previous gastroscopy.329/383 (86%)reporting a preference preferred Cytosponge to gastroscopy.

Conclusion: These results support previous data from the BEST studies, and are the largest single site dataset showing the excellent acceptability of Cytosponge in the real-world setting. The evidence from patients for their preference for Cytosponge over gastroscopy will also give support for its use as in Barrett's surveillance programmes going forward where multiple gastroscopies were previously required.

Disclosure: Nothing to disclose.

OUTCOME AFTER ENDOSCOPIC SLEEVE GASTROPLASTY FOR OBESITY AND IMPACT OF GLP1 AGONIST ON WEIGHT LOSS

N. Thomas[1], T. Cherukara[1], S.M. Mattoo[1], A.I. Khan[2], A.K. Dutta[1], Y. Al Serkal[1]
[1]Sharjah Kuwait Hospital, Gastroenterology, Sharjah, United Arab Emirates, [2]Al Qassimi Hospital, Medicine, Sharjah, United Arab Emirates

Contact E-Mail Address: noble.thomas@ehs.gov.ae

Introduction: Endoscopic sleeve gastroplasty (ESG) is a less invasive alternative to surgery for patients with obesity. The post procedure recovery is quicker and patients can be discharged one day after procedure.

Aims & Methods: We aimed to determine the outcome after ESG in patients with obesity and benefit of adding GLP1 agonist after ESG. All patients undergoing ESG at our center from 2017 up to 2020 were retrospectively recruited. Patients with BMI ranging from 30 to 40 kg/m^2 were eligible for ESG. The baseline demographic and clinical profile and reports of investigations were recorded. The date of procedure and follow up details including weight at various time points were noted. The procedure was done by Apollo^{TM} overstitch device.

The primary outcome was loss of at least 10% weight from baseline after ESG. The secondary outcome was loss of >20% weight after surgery. Multivariate analysis was performed using logistic regression to asses the predictors of weight loss after ESG including use of GLP1 agonist.

Results: Forty-six patients underwent ESG during the study period. Their mean age was 39.9+8.8 years and 91.3% were females. The mean BMI before ESG was 35.1±2.9 kg/m^2 and mean weight was 90.2±11.5 kg. Follow-up data was available for 41 patients: the mean duration of follow-up was 29.4±14.8months.

The primary outcome (weight loss >10%) was achieved in 68.3% patients. Weight loss >20% was noted in 19.5% subjects. The mean weight 6-12 months after ESG was 80.8±11.2 Kg and after 2 years was 87.6±12.6 Kg.

Multivariate analysis was done using age, gender, baseline weight and use of GLP1 agonist as variables for predicting weight loss after ESG (Table 1). We did not find any significant predictors including use of GLP1 agonist (p=0.2).

	Weight loss >10% (n=28)	Weight loss <10% (n=13)	p
Age (Years)	39.9±9	37.4±9.2	0.3
Gender (Female)	25 (89.3%)	12 (92.3%)	0.98
Weight before ESG (Kg)	90.4±12.8	88.9±8.6	0.76
Use of GLP1 agonist after ESG	11 (39.3%)	8 (61.5%)	0.2

Table 1.

Conclusion: ESG leads to weight loss in about two-third of patients although the effect is not sustained after 2 years. Use of GLP1 agonist does not have additional impact on weight loss.

Disclosure: Nothing to disclose.

Contact E-Mail Address: ivo.boskoski@policlinicogemelli.it

Introduction: The duodenum plays a key role in regulating metabolism and is known to be dysfunctional early in the development of metabolic diseases such as type 2 diabetes (T2D). Duodenal mucosal resurfacing (DMR) is a non-pharmacologic, investigational, endoscopic treatment designed to hydrothermally ablate the duodenal mucosa to restore the metabolic functionality of the duodenum in people with T2D. DMR has a CE mark, reimbursement in select medical centres in Germany, and has been evaluated in over 300 patients to date with favorable safety and metabolic benefits observed.

As part of the currently enrolling, global, pivotal Revitalize 1 trial for DMR, competency-based training and implementation have evolved to support scalable education of advanced-endoscopist investigators.

Aims & Methods: Here, we describe the current endoscopist training program for DMR, demonstrate its alignment with the European Society of Gastrointestinal Endoscopy[1] and the American Society for Gastrointestinal Endoscopy[2] training and effectiveness principles, and provide evidence that training methodology for DMR has led to acceptable and consistent safety outcomes in Revitalize 1.

The training program consists of three core elements designed to enhance advanced-endoscopist proficiency toward safe and efficacious execution of the DMR procedure:

1. Structured didactic overview of the DMR system, procedure, and core competencies;
2. Initial hands-on tracking of the DMR catheter through the validated DMR training simulator; and
3. Hands-on live-patient cases focused on the successful execution of the DMR procedure and demonstration of core competencies.

The DMR simulator was developed and validated to complement the didactic component of the training program and recapitulate endoscopy skills necessary to perform the procedure as intended. Successful training was defined as completion of the full program with demonstration of competency in core DMR skills and troubleshooting techniques using the simulator.

Procedural success was defined as performing ablations along the anatomical length of the duodenum from immediately beyond the ampulla of Vater to the Ligament of Treitz, while minimizing longitudinal gaps between areas of ablated mucosa.

Results: The DMR training program has been used to train therapeutic endoscopists in 6 centres in the EU and US as investigators in Revitalize 1. All centres successfully completed training in ~3 hours within 2 weeks of the first case. Nine open-label patients have been treated, to date, with 100% procedural success rate.

Baseline characteristics were consistent with uncontrolled T2D despite multiple glucose-lowering medications and insulin: 66.7% male, median (min, max), age 60 (45, 68) years, HbA1c 8.5% (7.6%, 9.1%), weight 96 (85,

128) kg, and diabetes duration 13 (7, 24) years. Adverse events (AEs) definitely or probably related to the device and/or procedure included sore throat (n=2), abdominal bloating (n=1), and abdominal pain (n=1). AEs were mild and resolved without sequalae. No observed long-term device- or procedure-related AEs, no device- or procedure-related SAEs, and no unanticipated AEs have been observed to date.

Conclusion: The three core elements of the DMR training program, inclusive of the DMR simulator, are scalable and have been reproducibly employed to train advanced therapeutic endoscopists to safely perform the DMR procedure. Results thus far suggest that DMR appears to be a safe, broadly accessible, and disease-modifying approach to treat metabolic disease, such as T2D, via therapeutic endoscopy.

Introduction: Peroral endoscopic myotomy (POEM) may result in a distended distal esophagus, referred to as a blown-out myotomy (BOM). It has been suggested that BOM may have functional and symptomatic consequences. The aim of this study was to investigate the prevalence, risk factors and associated symptoms of BOM after achalasia treatment using a clinical trial dataset (POEMA trial).

Aims & Methods: We analyzed data of newly diagnosed symptomatic achalasia patients (based on an Eckardt greater than 3) in our center who participated in a previous randomized controlled trial in which they were randomly allocated to undergo treatment with POEM or pneumatic dilation (PD). Follow-up was planned at 3 months, 1, 2 and 5 years after treatment and included an esophagram, endoscopy, HRM and symptom questionnaires. We defined a BOM as a >50% increase in esophageal diameter at its widest point in the distal esophagus between the lower esophageal sphincter and 5 cm above.

Results: In total 74 patients were treated in our center, of which 5-year follow-up data was available in 55 patients (32 (58%) patients randomized to POEM, 23 (42%) PD). During the 5-year follow-up a part of the patients received retreatment which resulted in 15 (27%) patients that were treated with PD only and 40 (73%) patients treated with POEM or PD + POEM. In the group initially treated with POEM the incidence of BOM increased from 11.5% (4/38) at three months, 21.1% (8/38) at 1-year, 27.8% (10/36) at 2-years and 31.3% (10/32). A BOM was seen in none of the patients treated with PD alone and 32.5% of the patients ever treated with POEM at 5-year follow-up (p=0.011).

There were no differences in baseline LES-resting pressure (25.8 (21.8-34.0) mmHg vs 36.0 (26.4-46.3) mmHg, p=0.168) and baseline IRP-4 (24.7 (17.8-36.5) mmHg vs 31.0 (21.7-38.7) mmHg, p=0.240) between patients ever treated with POEM with or without a BOM. Achalasia subtype type did seem to be a risk factor for the occurrence of a BOM in our cohort, as BOM occurred in 25% (2/8) of type 1, 27% (7/26) of type II and 67% (4/6) of type III achalasia (p=0.152).

Patients that developed a BOM had higher total Eckardt score and Eckardt regurgitation component compared to patients that underwent POEM without BOM development (3 (2.75-3.25) vs 2 (1.75-3) p=0.032) and (1 (0.75-1 vs 0 (0-1) p=0.041). The barium column surface (barium height * width) was not significantly different at 1 minute (12.2 (8.4-19.1) cm^2 vs 10.5 (3.0-17.6) cm^2, p=0.345) or at 5 minutes (10.8 (2.7-18.9) cm^2 vs 7.2 (0-12.8) cm^2, p=0.197) in patients with or without a BOM.

In addition, at 5-year follow-up no significant difference was seen in IRP-4 (13.4 (9.1-18.8) mmHg vs 12.1 (8.5-16.7) mmHg, p=0.377) and LES-resting rate (18.1 (14.3-26.0) mmHg vs 22.3 (13.7-29.8) mmHg, p=0.642) in patients with or without a BOM. POEM patients more often report reflux symptoms (based on GERDQ > 8) when a BOM is present compared to when no BOM is present (85% (11/13) vs 46% (2/16), p=0.023)).

BOM did not have an effect on presence of reflux esophagitis (54% (7/13) vs 41% (11/27), p=0.329) or PPI use (54% (7/13) vs 44% (12/27), p=0.413). Acid exposure time (measured at 1-year follow-up) was significantly higher in patients with a BOM compared to no BOM ((24.5% (8-47)) vs 6% (1.2-18.7), p=0.027).

Conclusion: a BOM was seen in one third of patients treated with POEM regardless of achalasia subtype, resulting in a higher acid exposure, more reflux symptoms and symptoms of regurgitation.

COMPARISON STUDY OF TREATMENT OUTCOMES OF COLD SNARE POLYPECTOMY AND UNDERWATER ENDOSCOPIC MUCOSAL RESECTION FOR NON-AMPULLARY DUODENAL ADENOMAS 10 MM OR LESS

M. Yoshida[1], T. Minamide[1], Y. Yamamoto[1], Y. Maeda[1], N. Kawata[1], K. Takada[1], Y. Kishida[1], K. Imai[1], S. Ito[1], K. Hotta[1], J. Sato[1], H. Ishiwatari[1], H. Matsubayashi[1], H. Ono[1]
[1]*Shizuoka Cancer Center, Endoscopy, Nagaizumi, Japan*

Contact E-Mail Address: ma.yoshida@scchr.jp

Introduction: Cold snare polypectomy (CSP) and underwater endoscopic mucosal resection (UEMR) represent relatively novel techniques for the management of superficial non-ampullary duodenal epithelial tumors. While CSP has been demonstrated to be safe and efficacious in a large-scale clinical trial for non-ampullary duodenal adenomas (NADAs) with a diameter of less than 10 mm [1], UEMR has been shown to be safe and effective in a prospective clinical trial for NADAs with a diameter of less than 20 mm [2]. However, there is no consensus on which technique should be used for NADAs 10 mm or less.

Aims & Methods: This study aimed to evaluate the treatment outcomes of CSP and UEMR for NADAs 10 mm or less. Patients who underwent CSP or UEMR for NADAs 10 mm or less at our institution between January 2015 and December 2022 were included, excluding FAP and local recurrence cases. Adenomas were defined as either Vienna classification category 3 on preoperative biopsy or endoscopically diagnosed as adenomas. The decision to perform either CSP or UEMR, as well as mucosal closure at the ulcer base after resection, was left to the discretion of the endoscopist. Procedure time was measured from snare visibility on the monitor until the end of resection for CSP, and from the beginning of water immersion until the end of resection for UEMR. The resected specimens were pinned to the corkboard and submitted to the pathology department. Follow-up endoscopy was conducted 2–3 months after endoscopic treatment to confirm the presence or absence of residual lesions, followed by an annual endoscopic examination.

Results: A total of 51 lesions were treated using CSP, while 29 lesions were treated with UEMR. The location of the lesions was distributed as follows: 9.8%, 84.3%, and 5.9% for the first, second, and third regions in the CSP group; and 13.8%, 82.5%, and 6.3% in the UEMR group (p=0.84). The difference in lesion diameter between the CSP and UEMR groups was not statistically significant (6.3±2.5 mm and 7.3±2.2 mm, respectively; p=0.06). Preoperative biopsy was performed in 43.1% of the CSP group and 58.6% of the UEMR group (p=0.18). The mean procedure time for CSP and UEMR was 4.6±4.2 min and 6.1±6.9 min, respectively (p=0.29). Mucosal closure at the ulcer base was performed in 56.9% of the CSP group and 100% of the UEMR group (p<0.01).

Neither group experienced intraoperative perforation, postoperative bleeding, or delayed perforation (95% CI: 0–7.0% for the CSP group, 0–11.9% for the UEMR group). The en-bloc resection rates were 96.8% for CSP and 100% for UEMR (p=0.17), and the electric current application rate for CSP was 7.8%.

The final pathological diagnosis in the CSP group was 82.4% adenoma, 3.9% intramucosal adenocarcinoma, and 13.7% non-neoplasm, while in the UEMR group, it was 89.7% adenoma, 10.3% intramucosal adenocarcinoma, and 0% non-neoplasm (p=0.02). The lateral and vertical margin-negative rates were 62.8% and 94.1% in the CSP group, and 62.1% and 100% in the UEMR group, respectively (p=0.95 for lateral margin, p=0.19 for vertical margin). Local recurrence was detected in 3.9% of the CSP group and 0% of the UEMR group.

Conclusion: The rates of negative margins for both lateral and vertical margins were comparable between CSP and UEMR. Despite this, two recurrence cases were observed in the CSP group. UEMR was as safe as CSP, with no intraoperative or postoperative adverse events reported. Furthermore, given that the preoperative diagnosis of adenoma may include a certain number of adenocarcinomas, UEMR may be considered the preferred method for endoscopic resection of NADAs ≤10 mm in size.

HYBRID ZPOEM PROCEDURE FOR ZENKER'S DIVERTICULUM TREATMENT – WHERE SPEED MEETS EFFICACY

A.R. Franco[1], I. Simao[1], R.R. Mendes[1], A. Mascarenhas[1], C. O'Neill[1], P. Barreiro[1], C. Chagas[1]

Introduction: The mainstay of treatment of Zenker's diverticulum is cricopharyngeal myotomy. Although flexible endoscopic septotomy is widely implemented, complete myotomy is difficult to assess resulting in recurrence rates of 11%. On the other hand, ZD peroral endoscopic myotomy allows complete myotomy visual confirmation, at the expense of procedure length and complexity. To overcome these limitations, a hybrid technique that allies FES simplicity and fastness to zPOEM efficacy is proposed: 1-septum isolation with overtube; 2-standard FES until middle of the diverticulum; 3-muscular septum isolation by zPOEM until the base of the diverticulum; 4-complete myotomy; 5-residual mucosal flaps section; 6-mucosotomy closure with TTS clips.

We aim to demonstrate the feasibility, effectiveness and safety of the hybrid zPOEM technique for the treatment of ZD.

Aims & Methods: A retrospective analysis including patients with ZD treated by hybrid zPOEM procedure from April 2021 to February 2023 was made. Technical success, early clinical success (dysphagia score ≤ 1), adverse events and recurrence rates were evaluated.

Results: 11 patients (male 54.5%, mean age 72.9 years) underwent hybrid zPOEM procedure for treatment of ZD (mean size 23.18mm, range 15-30mm). The procedure was technically successful in all patients, with a mean procedure time of 21.6 minutes. Early clinical success was achieved in all patients, although 1 patient maintained occasional regurgitation due to incomplete mucosal flaps section. Mean symptoms scores improved from baseline for dysphagia (1.5 vs 0), regurgitation (1.5 vs 0.1), halitosis (0.5 vs 0), cough (0.5 vs 0) and hoarseness (0.3 vs 0). During a mean follow-up time of 10 months, no recurrence was recorded. No intra- or post-procedure AE were recorded.

Conclusion: Hybrid zPOEM technique is a fast, safe and effective procedure, where, by combining classic FES and zPOEM, one can have the best of both techniques. This procedure should be considered as a first-line therapeutic option in third-space-endoscopy experienced centers.

Introduction: To evaluate the utility of the unroofing technique in the diagnosis of gastrointestinal subepithelial tumors (SETs), we performed a multicenter retrospective study.
Aims & Methods: This study was conducted in 10 hospitals and involved all eligible patients who underwent unroofing techniques to gain biopsy for gastrointestinal SETs between April 2015 and March 2021. The primary endpoint was the rate of correct diagnosis with the unroofing technique, and the secondary endpoints were the incidence of adverse events and the factors contributing to the correct diagnosis.
Results: The study included 61 patients with 61 gastrointestinal SETs, a median tumor size of 20 mm, and a median procedure time of 38 minutes with 82% successful tumor exposure. The rate of tissue acquisition was 98.4%, and the rate of pathological diagnosis was 72.1%. In 44 cases with a pathological diagnosis, two showed discrepancies with the postresection pathological diagnosis. No factors, including facility experience, organ, tumor size, or tumor exposure, significantly affected the correct diagnosis. No significant differences in the correct diagnosis rate were observed between less than ten experiences and more than ten experiences (74.1 vs. 70.6%). The correct diagnosis rates for tumors <20 mm and ≥20 mm were 76.9% and 65.7%, respectively. There was one case of delayed bleeding and two cases of perforations.
Conclusion: The diagnostic yield of the unroofing technique was acceptable. The unroofing technique was beneficial regardless of institutional experience, organ, tumor size, or actual tumor exposure.
Disclosure: Nothing to disclose.

Introduction: Esophageal strictures are major secondary complications of ingesting caustic agents. Standard management techniques are often unsuccessful.
Aims & Methods: The aim of our study is to show that endoscopic radial incision (ERI) is more effective than Savary-Gilliard's bougie dilatation (SGBD) in properly selected cases. Twenty-eight patients (10 males, 18 females, and a mean age 41.36±16.5) with post-caustic esophageal strictures were included in the study and randomly assigned to two equal groups, where 14 were treated with SGBD and the other 14 with ERI. We have defined and compared total procedure time, complications during and after procedures, as well as the necessity to repeat the technique.
Results: In short segment strictures (≤1cm in length), the requirement for repeating the procedure was 10 in SGBD vs. 3 in ERI ($p > 0.006$). Regarding the duration of the procedure, no statistically significant difference was observed ($p = 0.167$). In terms of complication rates, in SGBD, one complication occurred, while there was none in the ERI group ($p > 0.5$). In long segment strictures (≥1 cm in length), the duration, complication rate, and necessity to repeat the procedure were the same in both the SGBD and ERI groups ($p > 0.1$).
Conclusion: Overall, in short segment strictures, ERI was more effective in terms of the demand to repeat the procedure. However, there was no difference in duration or complication rate. In long segment strictures, the results were the same.

EFFICACY FOR DIAGNOSES OF SCIRRHOUS GASTRIC CANCER AND SAFETY OF ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

R. Jinushi[1], M. Mizuide[1], Y. Tanisaka[1], A. Fujita[1], T. Shin[1], K. Sugimoto[1], S. Ryozawa[1]
[1]Saitama Medical University International Medical Center, Department of Gastroenterology, Hidaka, Japan

Contact E-Mail Address: gk3273@icloud.com
Introduction: The diagnosis of advanced gastric cancer (AGC) is occasionally challenging for endoscopists. In particular, scirrhous gastric cancer (SGC) is often missed by esophagogastroduodenoscopy (EGD) alone because it may not form obvious ulcers or tumors.
Early detection of SGC is difficult, and the prognosis is often poor. Considering the rapid progression of SGC, an accurate endoscopic diagnosis of the disease is desirable. SGC is diagnosed using computed tomography, EGD, and EGD-biopsy. In AGC, except for SGC, a definitive diagnosis can be made in >90% of cases when EGD findings are combined with EGD-biopsy.

However, SGC is often difficult to diagnose even with EGD-biopsy. One report has indicated that the false-negative proportion of EGD-biopsy in SGC is >50%, because compared to other AGCs, SGC presents a variety of endoscopic findings, as well as special growth forms and morphological features.

Therefore, the usefulness of endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) instead of EGD-biopsy in the diagnosis of SGC has recently been reported, and the positive diagnosis proportion is as high as 71.4%–82.6%. Against this background, we believe that EUS-FNA is an alternative for diagnosing EGD-biopsy-negative SGC.

Therefore, we conducted a systematic review and meta-analysis to analyze the EUS-FNA diagnosis rate from previous reports in the diagnosis of SGC, verify the advantages and disadvantages of EUS-FNA, and evaluate the utility of EUS-FNA for the current SGC diagnostic landscape.

Aims & Methods: A systematic review was conducted using the PubMed (MEDLINE) and Ichushi-Web (NPO Japan Medical Abstracts Society) data and included all entries since their inception to October 10, 2022, in which SGC was evaluated using EUS-FNA.

The following electronic search terms were used to retrieve the literature in PubMed: ("endosonography" [MeSH] OR "endosonography" [tiab] OR "EUS"[tiab] OR "biopsy, fine needle" [MeSH] OR "fine needle aspiration" [tiab] OR "fine needle biopsy" [tiab]) AND ("linitis plastica" [MeSH] OR "linitis plastica"[tiab] OR "stomach neoplasms" [MeSH] OR "gastric cancer"[tiab]).

Additionally, Ichushi-Web created an electronic search strategy based on the above words. The primary outcome was the proportion of SGC diagnosed using EUS-FNA. In addition, we analyzed the proportion of adverse events associated with EUS-FNA. The study protocol was registered in the UMIN Clinical Trials Registry on October 10, 2022 (No: UMIN000049169).

Results: The electronic search identified 1890 studies; overall, 4 studies met the selection criteria and reported data on EUS-FNA performed on 114 patients with suspected SGC.

In our systematic review, the overall diagnostic yield of EUS-FNA for SGC was 82.6% (95% confidence interval, 74.6–90.6%) and the statistical heterogeneity was 0% (I^2 = 0%), indicating a low heterogeneity.

Furthermore, the EUS-FNA diagnostic proportion for SGC lymph node metastasis was 75–100%, indicating a high diagnostic performance. No apparent adverse events were observed in these 4 studies.

Conclusion: We believe that EUS-FNA is a useful examination because of its minimally invasive nature and high tissue diagnostic proportion. In particular, we consider it to be a useful alternative examination for patients with suspected SGC who cannot be definitively diagnosed by CT or EGD-biopsy.

Disclosure: Nothing to disclose.

PER ORAL ENDOSCOPIC MYOTOMY USING A NOVEL SUPER PULSED THULIUM FIBER LASER

K.D.-C. Pham[1], E. Tjora[2], R.F. Havre[1,3]

[1]Haukeland University Hospital, Department of Medicine and University of Bergen, Department of Clinical Medicine, Bergen, Norway, [2]Haukeland University Hospital, Department of Medicine and University of Bergen, Dept. of Pediatrics and Adolescence Medicine, Bergen, Norway, [3]University of Bergen, Department of Clinical Medicine, Bergen, Norway

Contact E-Mail Address: phamkdc@gmail.com

Introduction: Per Oral Endoscopic Myotomy (POEM) is typically performed with diathermy and an ESD knife. Laser is an energy source used in urology for stone management and has also been reported for POEM[1].

In this case series, we compared POEM using a novel 1920 nm super pulsed thulium fiber laser (POEM-L) to historical data of POEM performed with diathermy (POEM-D) at our center[2].

Aims & Methods: We aimed to evaluate the feasibility of a novel 1920nm super pulsed thulium fiber laser for POEM. Collected data from the first 10 patients with achalasia who underwent POEM-L at Haukeland University Hospital from February 2022 until March 2023 were analyzed. The patients were followed up with respect to acute and delayed complications and the efficiency of the treatment with Eckhart score (ES). The historical data on POEM-D were 84 patients treated from January 2014-2019. All POEM-L was performed under general anesthesia using a 365 or 550 micron 1920 nm super pulsed thulium fiber laser in combination with a 4,5-7 Fr triple-lumen cannula for fiber stability. Physiological saline was used for irrigation, and the energy used was 10-30W for all the phases of POEM-L.

Results: Ten patients, 4 males and 6 females with symptomatic achalasia and Eckardt score ≥6 were included. The mean age was 38.5 years old. Based on HRM, 2 patients had achalasia type I, 6 type II, and two with type III. Four patients (40 %) were treatment naïve, 3 (30%) had undergone pneumatic balloon dilatation, 1 (10%) had previous Heller´s myotomy combined with Dor fundoplication, and 3 (30%) had undergone previous POEM. The patients who had redo-POEM had POEM-D as the first treatment. The median resting pressure over the lower esophageal sphincter (LES) was 24.4 mmHg (Range (14.1-45.0 mmHg) prior to POEM. All 10 patients (100 %) patients had posterior myotomy. The median myotomy length was 7 cm (range 5-14 cm). The procedure time was mean 107 min for POEM-L, compared to 130 min for POEM-D, p=0.01. Dysphagia improved in all patients on follow-up, but clinical success (ES≤3) in nine patients. The ES was significantly reduced from median 7 (range 5-10) before POEM to 0.5 (range 0-8) at 1-12 months (p <0.001). None of the patients reported post-operative symptoms of daily reflux, while one had used PPI regularly before POEM. Patients who underwent POEM-L were hospitalized for mean 2.0 days compared to a mean of 3.2 days after POEM-D (p<0.001)

In 9 cases, we were able to use the same instrument to complete all steps of the POEM procedure including mucosal injection and incision, submucosal tunneling, vessel dissection and coagulation, and myotomy.

Conclusion: POEM with a novel 1920 nm super pulsed thulium fiber laser is feasible. Treatment results seem non-inferior to POEM-D. Compared to POEM-D, patients who underwent POEM-L have significantly shorter hospital stay. The mean procedure time was shorter. POEM-L is promising, but a learning curve and dedicated accessories are needed. Further studies are needed to confirm the findings.

Contact E-Mail Address: h.ayubi@nhs.net

Introduction: Approximately 1/3 patients submitted to Per Oral Esophageal Myotomy (POEM) will develop Gastro-esophageal Reflux (GERD) Symptoms. Several technical characteristics of the procedure and recently Endoluminal functional luminal imaging probe (EndoFLIP) data have been correlated to it.

Aims & Methods: We aimed to evaluate the rate of short-term GERD development among patients submitted to EndoFLIP tailored or not POEM. We included consecutive patients submitted to POEM from 11/2015 to 2/2023. GERD development was assessed by the GERD health-related quality of life (GERD-HRQL) questionnaire and considered positive if ≥13. Patients were evaluated at 3-months post-POEM.

Results: We included 96 patients (M/F: 57/39 mean age: 48 min: 17 - max: 78). Achalasia type distribution was 1/2/3/unclassified: 24/68/1/3. Treatment naïve/experienced were 55/41 .In tailored procedure were submitted 38 while in non-tailored 58 patients. Mean pre-procedural Eckardt score was 7±2 while mean pre-procedural distensibility index (DI) was 2.2±1.6. Anterior approach was selected in 77 while posterior in 19 patients and did not differ between tailored (33/38, 86.8%) vs non-tailored POEM (44/58, 75.9%, p=0.295) while the mean length of myotomy was 10.6±3.4 cm but differed (9.3±2.9 11.4±3.4, p=0.02). GERD was diagnosed in 18/96 (18.7%) and did not differ when comparing tailored vs non-tailored procedure (8/38, 21.1% vs 10/58, 17.2%, p=0.790). The rate of GERD was numerically increased in previously treated vs naïve patients (11/41, 26.8% vs 7/55, 12.7%, p=0.113). When isolating patients with non-tailored POEM, GERD rates did not differ among treated vs untreated (5/31, 16.1% in naïve vs 5/27, 18.5%, p=1.000). While in patients with tailored procedure the rate was significantly increased among previously treated vs naïve patients (6/14, 42.9% vs 2/24 8.3 %, p=0.034). Tailored procedure vs non-tailored procedure led to decreased numerically rates of GERD development in naïve patients (8.3% vs 16.1%, p=0.443) and increased numerically rates among previously treated (non-tailored 18.5% vs tailored 42.9%, p=0.140). In the total cohort GERD development was not correlated to the approach (anterior: 14/77, 18.2% vs posterior: 4/19, 21.1%, p=0.750) or the length of myotomy (10.4 ±3.7 vs 10.7 ± 3.4 cm, p=0.768). In patients with tailored procedure only Baseline DI was correlated to GERD development post POEM even if numerical differences were noted as far as post procedural DI and ΔDI were considered (Table 1).

	GERD development by GERD-HRQL at 3 months	GERD absence by GERD-HRQL at 3 months	p
IRP baseline (mmHg)	25.4±15.8	23.3±8.3	0.509
DI pre-procedural	2.9±1.7	2.0±1.5	0.038
Eckardt baseline	6±2	7±2	0.245
Length of myotomy (cm)	8.3±2.2	9.5±3.1	0.133
DI post-procedural	5.3±2.7	4.5±2.0	0.241
ΔDI	2.8±1.8	2.4±1.4	0.390

All values expressed as mean ± SD.

Table 1.

In the multivariate analysis only previous treatment was correlated to short term GERD development (p=0.004, OR: 7.412 95% CI: 1.890-29.064).

Conclusion: Short term GERD symptom development after POEM by selective circular myotomy occurs in 1 out of 5 patients. These rates did not differ among tailored vs non tailored procedure though they were significantly reduced among treatment naïve patients who underwent tailored POEM. Even if DI especially in the pre-procedural setting may predict short term post POEM GERD development in patients submitted to tailored POEM, only experience to previous treatments was independently correlated to development of GERD at 3 months post-POEM as diagnosed by the use of GERD-HRQL.

Disclosure: Nothing to disclose.

LONG TERM SINGLE CENTER COMPREHENSIVE ANALYSIS OF POST-POEM GASTROESOPHAGEAL REFLUX AND ITS SEQUELAE IN MORE THAN 500 PATIENTS

D. Simkova[1], Z. Vackova[1], J. Mareš[2], K. Hugova[1], T. Hucl[1], P. Stirand[1], R. Hustak[1], J. Spicak[1], J. Martinek[1]
[1]Institute for Clinical and Experimental Medicine (IKEM), Department of Hepatogastroenterology, Prague, Czech Republic, [2]Institute for Clinical and Experimental Medicine (IKEM), Department of Statistical Analyse, Prague, Czech Republic

Contact E-Mail Address: drazilovad@gmail.com

Introduction: Peroral endoscopic myotomy (POEM) is considered a standard method for achalasia treatment with excellent long term treatment success. However, the benefits of POEM are tempered by the risk of post-POEM reflux complications.

Aims & Methods: The aim of this retrospective analysis of prospectively collected data was to assess the long-term post-POEM reflux. Data from all consecutive patients who underwent POEM between December 2012 and April 2023 were analyzed. The patients assessed symptoms at 3 and 12 months after the procedure and every year thereafter.

The patients underwent upper GI endoscopy, high-resolution manometry (HRM) and 24-hour pH monitoring 3 months after the procedure; endoscopy was then repeated at 2-3 years and at 6 year follow-up. Reflux esophagitis, reflux parameters measured by 24h pH monitoring (off PPIs), reflux symptoms and the use of proton pump inhibitors (PPIs) were the principal outcomes.

Results: A total of 539 POEM procedures (20x re-POEM) were performed in 519 patients. Three months after the procedure, 390 patients underwent 24h pH monitoring with abnormal acid exposure in 178 of them (45.6% [95% CI: 40.7, 50.6]). Reflux esophagitis was present in 181/463 patients (39.1% [95% CI: 34.7, 43.6]; LA C/D in 20 patients, 4.3%) at 3 months, in 94/263 patients (35.7% [95% CI: 30.2, 41.7]; LA C/D in 5 patients, 1.9%) at 24-36 months and in 18/88 patients (20.5% [95% CI: 13.3, 30]; LA C/D in 0 patients) 6 years after procedure.

Follow- up questionnaires were completed in 185, 161 and 106 patients 48, 60, 72 months after the procedure and 34.6%, 35.7% and 34.4% of patients claimed occasional heartburn and 18.1%, 20.4% and 19.6% experienced occasional regurgitation of gastric content.

However, only the minority (under 2% of the patients at 48, 60, 72 months) experienced the symptoms on daily basis. PPIs were administered to 53.3%, 48.4% and 54.3% of patients at 48, 60 and 72 months after POEM with majority of them (80%) taking PPIs on daily basis.

We also investigated whether there were any differences in patients with and without PPIs. In patients with PPIs, there were less cases of reflux esophagitis 3 months after POEM (32.4% vs. 43.5%). More patients with

PPIs experienced post-POEM heartburn (42.3% vs. 25.9%) at 48 months and at 60 months (48.7% vs. 25.4%). There were no significant differences in terms of pathological reflux on 24-hour pH monitoring and in the occurrence of severe esophagitis between patients with vs. without PPIs.
Regarding severe reflux complications, there were no new cases of Barrett's esophagus and esophageal adenocarcinoma. One patient developed peptic stricture, which was successfully treated with balloon dilation. The outcomes were not different among patients who underwent anterior (60%) vs. posterior myotomy (40%).
Conclusion: The rate of post-POEM reflux esophagitis decreases over time, however approximately 50% of patients require long-term antisecretory treatment. Even if the risk of reflux complications is low, patients after POEM should remain under long-term surveillance.

G-POEM REDUCES HOSPITALIZATION RATES, NASOJEJUNAL FEEDING TUBE USE AND MEDICATION USE IN PATIENTS WITH GASTROPARESIS

I. Ahmed[1], H. Ayubi[1], T. Voulgaris[1], N. Gunasingham[1], S. Thrumurthy[1], S. Gulati[1], B. Hayee[1]
[1]King's College Hospital, King's Institute of Therapeutic Endoscopy, London, United Kingdom

Contact E-Mail Address: imran.ahmed40@nhs.net
Introduction: Gastric Per-oral Endoscopic Myotomy (G-POEM) has been proposed as a new treatment modality for patients with gastroparesis and is considered to be effective in two out three patients. Most studies focus on post procedural data of gastric retention during gastric emptying study and patient oriented self-reported scoring system as Gastroparesis Cardinal Symptom Index (GCSI) in order to measure G-POEM effectiveness.
Aims & Methods: We aimed to evaluate the effectiveness of G-POEM focusing on clinical post procedural evidence: hospitalisation rate, nasojejunal feeding tube and medication use. We analysed retrospectively data from consecutive patients undergoing G- POEM from 09/2018 to 2/2023 in our department. Epidemiological, laboratory and clinical pre-procedural and post-procedural data as also data about adverse events during and after the procedure were collected.
Results: In total 45 patients (M/F: 14/31, mean age: 36±12 years) were included, with mean follow up of 23±17 months. Gastroparesis etiology was: diabetic/idiopathic/Ehlers-Danlos syndrome/other: 23/16/5/1 with mean disease duration 6.7±5.6 years. Pre-procedural mean gastric retention (%) at 1 hour was 71.8±28.6. Two patients had gastric electrical stimulation devices in situ, while 14/45 (31.1%) reported previous Botox injection.
Baseline prokinetic (metoclopramide/domperidone/erythromycin) use was reported among 35/39 (89.7%), anti-emetics (ondasendron, cyclizine) in 21/39 (53.8%) and 9/39 (23.1%) patients were using prucalopride.
Nasojejunal feeding tube was placed in 10/45 (22.2%) patients. At least one hospitalization was documented in 24/38 (63.2%) patients. The mean number of hospital admissions was 4.3±9.1.
After G-POEM rate of prokinetics (13/38, 34.2%, p=<0.001), anti-emetic (0/38, 0%, p<0.001) and prucalopride use (10.5%, p=0.224) was reduced. Moreover NJ tube was placed in only 1 patient, rate also significantly reduced (1/45, 2.2%, p=0.007).
Additionally the rate of patient admitted at least for one time in the hospital post G-POEM was also significantly reduced (23/33, 36.4% vs 24/38, 63.2%, p=0.033). Post procedural admission rates (at least one hospital admission after G-POEM) did not differ among patients with diabetic or idiopathic gastroparesis (diabetic: 7/17 (41.2%) vs 5/12 (41.7%), p=1.000). No differences were noted also as far as prokinetics (6/16, 37.5% vs 4/17, 37.4%, p=1.000) and prucalopride (2/16, 12.5% vs 2/11, 18.2%, p=0.897).
The mean hospital stay after the procedure was 1.05±1.11 days. Perforation during G-POEM was observed in 5/45 (11.1%) patients while significant bleeding was reported in 3/45 (6.6%). All adverse event with the exception of one perforation were managed endoscopically. One patient died during hospitalization though not directly due to procedural adverse event.
Conclusion: Our study points out that G-POEM benefits significantly patients with gastroparesis as it reduces both post-procedural hospitalization rates, need for nasojejunal feeding tube use as also medication use, independently of disease etiology. Procedural complications may develop though the vast majority are managed endoscopically.
Disclosure: Nothing to disclose.

ENDOSCOPIC BAND LIGATION FOR WEIGHT LOSS: CLINICAL TRIAL

M. Abeid[1], N. Zaitoun[2]
[1]Faculty of Medicine, Cairo University, Gastrointestinal Endoscopy, Cairo, Egypt, [2]Faculty of Medicine, Zagazig University, Family Medicine, Zagazig, Egypt

Contact E-Mail Address: mohamedabeid@gmail.com
Introduction: In a previous case study, we reported the use of endoscopic band ligation for weight loss (1). Based on this, we performed the same procedure on 13 female cases.
Aims & Methods: This trial aimed to assess the efficacy and safety of endoscopic band ligation for weight loss among 13 female cases with initial body weight (kg) mean ± SD of 104.769 ± 17.316 (80–145), BMI mean ± SD of 40.4315 ± 4.9145 and a mean excess weight (kg) of 40.0769 ± 14.3669.
For the endoscopy, the patients were sedated with propofol, and oxygen was used for endoscopic air insufflation. The ligatures were applied in the gastric body, starting distally; five parallel rows were created with 20–30 bands, with the last one placed in the proximal body. The entire procedure lasted 20–30 min.
Results: No immediate complications occurred during the endoscopy. After the procedure, the patients remained well and were discharged within 2–3 h. For the first three days, most complained of nausea, vomiting, and epigastric pain, and one patient experienced mild hematemesis. All complications were controlled with medications (pantoprazole 40 mg twice daily for the 1st month, plus antiemetics and antispasmodics as required). The patients consumed a pureed diet for 2 weeks, followed by a soft diet for another 2 weeks. A follow -up endoscopy after 1 month revealed nicely healed ulcer scars in the gastric body, causing marginal narrowing of the lumen.
The patients' weight loss (kg) was mean ± SD 96.6154 ± 16.8004, corresponding to 22.336% excess weight loss and 7.8752% total weight loss after 1 month, Table 2.
Conclusion: Endoscopic band ligation for weight loss is a new procedure that may help in the management of obesity. The procedure was safe and cost-effective; however, more studies are needed to assess the effectiveness and safety of band ligations in the management of obesity.

SAFETY AND EFFICACY OF ENDOSCOPIC RETROGRADE APPENDICITIS THERAPY FOR PERIAPPENDICEAL ABSCESS: A MULTICENTER ANALYSIS

S. Ullah[1], J.-Y. Zhang[1], F.S. Ali[2], D. Liu[1], D.-L. Li[1], J. Li[3], J. Fan[4], B.-R. Liu[1]

[1]The First Affiliated Hospital of Zhengzhou University, Gastroenterology and Hepatology, Zhengzhou, China, [2]University of Texas Health Science Center at Houston, Gastroenterology, Hepatology, and Nutrition, Houston, United States, [3]Linfen Central Hospital, Gastroenterology, Linfen, China, [4]JingXing County Hospital, Gastroenterology, Hebei, China

Contact E-Mail Address: saifullah@gs.zzu.edu.cn

Introduction: Currently, endoscopic retrograde appendicitis therapy (ERAT) is indicated only for acute uncomplicated appendicitis, though its utility can be extended to patients who are poor surgical candidates in more complex appendiceal disease such as those with periappendiceal abscess. Current treatments of periappendiceal abscess include emergency surgery, nonsurgical management with or without percutaneous drainage, and interval appendectomy after nonsurgical management.

Herein, we highlight the utility of ERAT, which allows for interventional, noninvasive management of periappendiceal abscess without surgery.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of ERAT for treating periappendiceal abscess.

Twenty-four consecutive periappendiceal abscess patients were evaluated between May 2017 and May 2022 at three tertiary care Hospitals in China. The diagnosis of periappendiceal abscess was confirmed by direct colonoscopy imaging and computed tomography (CT) and/or ultrasonography (US). The baseline characteristics of all the patients, procedure success rate, procedure time, postoperative length of hospital stay, complications, and recurrence rate were recorded.

Results: The success rate of ERAT was 95.8% (intubation failed in one patient due to the closure/blockage of the appendix opening). All the patients (100%) patients had abdominal tenderness, 56. 5% had abdominal rebound pain, 21.7% had fever, and 86.9% patients had elevated white blood cells before the ERAT. The mean procedure time was 33.79 minutes with standard deviation (SD) of 17.1 min. The mean length of postoperative hospital stay was 5.4 (SD 2.6) days. Time to relief of abdominal pain after the ERAT was 28.2±19.4 hours. After the ERAT procedure WBC get back to normal range in 2.2±1.3 days. No complication observed in any of the patient. Antibiotics were routinely administered for 3 days after the ERAT. We followed up the patients at 3, 6, 12, 24 and 36 months respectively. Recurrence occurred in 8.7% of the patents at mean 26.9 (SD 10) months of follow-up.

Conclusion: Preliminary evidence suggests that ERAT is safe and effective alternative option for treating periappendiceal abscess, making it a valuable addition to the armamentarium of interventional endoscopy. The practice of ERAT currently remains predominantly limited to the Eastern world. As the treatment paradigm of appendicitis evolves, it is crucial that novel techniques such as ERAT be evaluated at a global scale alongside the evolving standard of care therapies.

Disclosure: None to declare.

Introduction: Endoscopic suturing offers a novel minimally invasive technique for deploying full thickness sutures in the gastrointestinal (GI) tract. Indications range from defect closure, post operative leaks, fistula repair, stent fixation and tissue plication for endoscopic sleeve gastroplasty.

Here we report our updated experience of endoscopic suturing for non-bariatric applications in the upper GI tract using the Apollo OverStitch™ device (Apollo Endosurgery, Austin, Texas). This represents the largest and most diverse case series in a UK cohort of patients.

Aims & Methods: We retrospectively evaluated cases where the Apollo OverStitch™ device was used at our tertiary upper GI centre. The primary outcomes were immediate technical and clinical success. Technical success was defined as the successful application of sutures. Immediate clinical success was defined according to indication. For defect closure this was evaluated using on the table fluoroscopy/endoscopic visualisation. For stent fixation it was determined by the absence of stent migration at follow up endoscopy.

Secondary outcomes included defect recurrence at follow up investigation. We also evaluated long term clinical success by assessing for resolution of the index clinical issue at the time of latest follow up.

Results: The Apollo OverStitch ™ device was used 56 times across 35 patients (57% female) between August 2018 and March 2023. The mean age of patients at the time of the index procedure was 58 (+/-17.3 years). Outcomes according to indication are highlighted below (Table 1).

Indications	Number of applications	Number of patients	Technical success rate	Clinical success rate	Recurrence	Adverse events reported
Iatrogenic duodenal perforation	5/56 (9%)	4/35 (11%)	2/5 (40%)	2/2 (100%)	1/2 (50%)	Nil
Anastomotic Oesophageal fistula	12/56 (21%)	7/35 (20%)	11/12 (92%)	11/11 (100%)	8/11 (73%)	Nil
Iatrogenic Gastric perforation	1/56 (18%)	1/35 (3%)	1/1 (100%)	1/1 (100%)	0/1 (0%)	Bleeding
Post PEG gastrocutaneous fistula	6/56 (11%)	4/35 (11%)	6/6 (100%)	6/6 (100%)	3/6 (50%)	Nil
Congenital tracheoesophageal fistula	3/56 (5%)	1/35 (3%)	3/3 (100%)	3/3 (100%)	3/3 (100%)	Nil
Spontaneous oesophageal perforation	1/56 (18%)	1/35 (3%)	1/1 (100%)	1/1 (100%)	0/1 (0%)	Nil
Iatrogenic oesophageal perforation	5/56 (9%)	3/35 (9%)	4/5 (80%)	2/4 (50%)	1/2 (50%)	Nil
Leak Post sleeve gastrectomy	9/56 (16%)	4/35 (11%)	9/9 (100%)	8/9 (89%)	5/8 (66%)	Bleeding
Stent fixation	14/56 (25%)	10/35 (29%)	14/14 (100%)	9/14 (36% Stent migration rate)	N/A	Nil

Table 1: Overview of case series for patients undergoing endoscopic suturing in the upper GI tract.

There were five cases (5/56, 8.9%) of technical failure. Three (3/5, 60%) involved iatrogenic perforations at the junction between D1/D2. Three cases (3/37, 8.1%) of immediate clinical failure were reported for the defect closure cohort. In the defect closure cohort there was a recurrence rate of 61.8% (21/34), with a long term clinical success rate of 68.2% (15/22). 14 cases of stent fixation were conducted with a stent migration rate of 35.7% (5/14).

There were two (2/56, 3.6%) cases of bleeding following endoscopic suturing. In both cases bleeding was stemmed endoscopically on the table and prior to the end of the procedure.

Conclusion: Our case series suggests that the Apollo OverStitch™ device can be used for a diverse range of indications with high rates of immediate technical and clinical success.

We note a high recurrence rate reflecting that many defects require repeat suturing attempts to achieve durable long term closure. We postulate that this may be related tissue epithelisation and/or friability impacting opposition.

Furthermore, technical failure occurred most with perforations at the D1/D2 junction. This is likely related to acute angulation which impedes the ability to deploy sutures.

The heterogenous follow up data from this case series impacts the ability to draw firm conclusions regarding long term outcomes. There is an ongoing prospective multicentre registry which will assist in evaluating long term outcomes.

HELICOBACTER PYLORI INFECTION DIAGNOSIS AND MANAGEMENT: CURRENT PRACTICES OF GREEK GASTROENTEROLOGISTS

A. Protopapas[1], A. Protopapas[1], I. Papagiouvanni[2], I. Goulis[2]
[1]Aristotle University of Thessaloniki, AHEPA Hospital, First Propedeutic Department of Internal Medicine, Thessaloniki, Greece, [2]Aristotle University of Thessaloniki, Hippokratio Hospital, Fourth Department of Internal Medicine, Thessaloniki, Greece

Contact E-Mail Address: adoprot@hotmail.com

Introduction: Helicobacter pylori infection plays a significant role in the development of diseases with high morbidity and mortality, such as peptic ulcer disease and gastric cancer. However, diagnosis and management of H. pylori infection vary significantly depending on country, area and specialty.

Aims & Methods: Aim of this study was to record the current practices of Greek gastroenterologists for screening and treatment of Helicobacter pylori infection while also comparing them to practices in other countries and recommendations of international guidelines. An anonymous questionnaire consisting of 19 questions regarding the management of Helicobacter pylori infection was sent with the aid of the Hellenic Society of Gastroenterology to all members of the society. Statistical analysis was performed with SPSS software.

Results: The questionnaire was completed by 180 gastroenterologists, with a response rate of 31.4%. Diagnostic tests to confirm Helicobacter pylori infection are ordered by 98.3% of the physicians for patients with current peptic ulcer disease, by 95.6% for patients with gastric lymphoma, by 90.1% for patients with a family history of gastric cancer and by 92.8% for patients with an endoscopic appearance suggestive of gastritis.

The majority of gastroenterologists (55.8%) tested for H. pylori in patients with gastroesophageal reflux disease (GERD). Histopathology was the most preferred (60.6%) method by the physicians for patients for which testing is decided during endoscopy, while urea breath test was the most preferred method (67.8%) for patients where the decision to test was taken regardless of endoscopy.

The sensitivity of the test had the most crucial role in the decision of the screening method for most physicians (60.2%). Most gastroenterologists use quadruple eradication regimens that are supported by international guidelines (90%) and 65.6% of the physicians answered that they systematically recommend the addition of probiotics to standard therapy. 51.7% selected ten days of treatment, while 44.4% 14 days. Lastly, most physicians answered that they always (82.8%) or usually (13.9%) confirm the eradication of the pathogen.

The majority of physicians (79.4%) used the urea breath test for confirmation of eradication. Sensitivity was again the most crucial factor influencing the decision of most physicians (59.7%). When asked about their perceived percentage of Clarithromycin-resistant species in Greece, 45.4% of the physicians believed it to be 21-30%, 19.3% believed it to be 11-20% and 14.9% believed it to be 31-40%.

Conclusion: The majority of Greek gastroenterologists conform to the recommendations of international guidelines regarding the diagnosis and management of Helicobacter pylori infection, except for the screening of patients with GERD. Greek gastroenterologists show a preference for the urea breath test for screening and confirmation of treatment success, while probiotics are used by a considerable number of doctors in addition to standard therapy.

Introduction: *Helicobacter pylori* (*Hp*), a definite carcinogen, is associated with nasal polyps. This finding encourages screening of patients with nasal polyps, with subsequent eradication of the positive subjects. *Hp* has been isolated from multiple sites throughout the body including nose and is associated with a plethora of extragastric manifestations. Current evidence reported discrepant data regarding association between *Hp* infection (*Hp*-I) and nasal polyps.

Aims & Methods: Aim of this meta-analysis was to assess for first time the strength of this association. We performed an electronic bibliographical search in established medical databases (PubMed, Cochrane, and EMBASE). The enrolled studies were evaluated for risk of bias using the Newcastle-Ottawa scale. The primary outcome was the prevalence of active *Hp*-I in nasal polyps compared to patients with normal nasal mucosa. Subgroup analysis based on the different study areas and diagnostic methods used to detect *Hp-I* (PCR, immunohistochemistry, CLO test) was performed to assess for source of heterogeneity. The study outcomes were compared between the two groups through a random-effects model, expressed as odds ratio (OR) and 95% confidence interval. Heterogeneity was calculated through I^2 tests. Publication bias was verified through visual assessment of funnel plots.

Results: Twelve studies were eligible. Male-to-female ratio was 2:1, and age ranged 17-78 years. All studies had good quality (6/8 Newcastle Ottawa scale). The cumulative pooled rate of *Hp*-I in the nasal polyp group

was 32.3%, and in controls 17.8% (OR:4.12, though with high heterogeneity I^2=66%). Subgroup analysis demonstrated that in European studies, the prevalence of *Hp*-I for nasal polyp group was significantly higher than in controls, yielding null heterogeneity. Subgroup analysis based on the diagnostic technique resulted in null heterogeneity for immunohistochemistry with preserving statistically significant difference in *Hp*-I prevalence between nasal polyp and control groups.

Conclusion: This first positive systematic review and meta-analysis strengthens further the plethora of extragastric manifestation of *Hp*. Screening for the bacterium in patients with nasal polyps with subsequent eradication might be a reasonable strategy.

ASSOCIATION BETWEEN *HELICOBACTER PYLORI* INFECTION AND GASTROESOPHAGEAL REFLUX DISEASE: MENDELIAN RANDOMIZATION STUDY

H. Wang[1], Z.-Q. Liu[1], S.-H. Xie[2,3,4]
[1]Fujian Medical University, School of Public Health, Fuzhou, China, [2]Fujian Medical University, Institute of Population Medicine, Fuzhou, China, [3]Fujian Medical University, Ministry of Education Key Laboratory for Gastrointestinal Cancer, Fuzhou, China, [4]Karolinska Institute, Karolinska University Hospital, Department of Molecular Medicine and Surgery, Stockholm, Sweden

Contact E-Mail Address: 2721366573@qq.com

Introduction: Previous epidemiological studies have examined the association between *Helicobacter pylori* and gastroesophageal reflux disease (GERD) but the findings were inconsistent.

This study aimed to explore the causal relation between *Helicobacter pylori* IgG and six specific antibody levels and risk of GERD using mendelian randomization analysis.

Aims & Methods: We used summary-level data from two large genome-wide association studies (GWAS), i.e. the FinnGen research project and the UK biobank cohort.

Eighteen single nucleotide polymorphisms (SNPs) associated with levels of IgG and six *Helicobacter pylori* specific antibodies (UreA, CagA, VacA, Catalase, OMP, and GroEL) were used as instrument variables to predict levels of these markers for *Helicobacter pylori* infection.

Associations between these SNPs and GERD risk were examined primarily using the inverse variance weighted method, and secondly using MR-Egger, weighted median, simple mode, and weighted mode methods. We further conducted multivariable mendelian randomization analysis on the association between levels of the six specific antibodies and risk of GERD.

Results: Genetically predicted Helicobacter pylori IgG antibody levels were not associated with risk of GERD in either FinnGen (odds ratio [OR]=0.992, 95% confidence interval [CI] 0.961-1.025) or UK Biobank (OR=0.999, 95%CI 0.998-1.001). Genetically predicted levels of the six Helicobacter pylori specific antibodies were not associated with risk of GERD, except for UreA antibody levels in MR-Egger method only (OR=1.138; 95%CI 1.005-1.289) for which pleiotropy was indicated (MR-Egger intercept -0.029, P=0.048). Multivariate MR also found no associations between levels of Helicobacter pylori specific antibodies and risk of GERD.

Conclusion: This Mendelian randomization study found no evidence for a causal relation between Helicobacter pylori infection and the risk of GERD.

Disclosure: Nothing to disclose.

PP0328

HELICOBACTER PYLORI AND SARS- COV-2: A DANGEROUS PATHOGENETIC CORRELATION?

F. Termite[1], G. Gasbarrini[2], S. Simeoni[3], F. Bonvicini[4]
[1]Università Cattolica del Sacro Cuore, Istitituto di Medicina Interna e Gastroenterologia, Rome, Italy, [2]Università Cattolica del Sacro Cuore, Istituto di Medicina Interna e Geriatria, Rome, Italy, [3]Univeristà di Verona, Istituto di Medicina Interna, Verona, Italy, [4]Univerisà di Bologna, Istituto di Medicina Interna e Gastroenterologia, Bologna, Italy

Contact E-Mail Address: fabrizio.termite@libero.it

Introduction: The correlation between Covid-19 and non-respiratory bacteria, such as Helicobacter pylori (Hp) is mostly unexplored. The following consideration led us to further investigate this topic: SARS-CoV-2 binds ACE-2 receptors (ACE-2r) to enter cells, which are widely expressed in the GI tract; in addition, Hp is known to induce changes in the structure of the microvilli of the GI epithelium, e.g. by increasing the expression of ACE-2r[1].

Furthermore, Hp tends to increase gastric pH due to both its urease activity and its ability to induce intestinal metaplasia and gastric atrophy[2]; an alkaline pH is a favorable condition for SARS-CoV-2 to best perform its functions to bind with ACE-2r[3].

Aims & Methods: This is a retrospective preliminary observational cohort study including 1532 outpatients with digestive symptoms referred to private gastroenterological ambulatories: 825 referring to pre-pandemic period (pPP) (Jan 2020-Apr 2022), 707 to pandemic period (PP) (Sep 2017-Dec 2019).

The study aimed to compare the C13 urea breath test (C13UBT) positivity rate and the the delta over the baseline (DOB) (an indirect indicator of Hp bacterial load) between the pPP and the PP.

Results: Patients who underwent C13UBT for the detection of Hp were 316. 36 out of 179, and 74 out of 137, respectively in pPP and PP, tested positive for Hp: the percentage of patients tested positive for Hp during the PP (54.01%) was significantly higher than the one of pPP (20.11%) (p=0.000016). The DOB in the PP was 40.4 ± 17.5, significantly higher when compared to the mean value found in the pPP: 17.4 ± 16.5 (the cut-off for positivity is > 3.5) (p =0.0001).

Conclusion: The results of this study suggest that there is a pathogenetic correlation between HP and Sars-Cov2 infection. We can assume that SARS-Cov-2 infection, whether current or previous, may somehow favour the rooting and replication of Hp.

Several hypotheses could explain this data: Sars-CoV-2 infection weakens the immune system of patients; the limited availability of BT, due to organisational restrictions in public structures (applied to contain the spread of the virus during the PP), delayed the diagnosis of Hp infection, allowing bacteria to proliferate undisturbed; Sars-CoV-2 binds to ACE-2 receptors and causes damage to GI cells leading to morphological changes that make the environment more propitius for Hp.

In this regard, it is recalled that there are no data in the literature about the morphological ultrastructural changes of GI cells in Covid 19, while the HP adhesion mechanism is deeply known[4].

In conclusion, neglecting the search for Hp represents a risk condition for GI diseases (e.g. dyspepsia, peptic ulcer, gastric cancer), especially considering the remarkable increased incidence of Hp infections and DOB during the PP.

In this respect, a recent study showed that the higher the DOB, the higher the bacterial load, but more significantly, the greater the ability of the bacterial strains to produce urease: the strains with the greatest urease activity are CagA+ strains (i.e. those with the greatest oncogenic potential)[5].

Therefore, it can be assumed that the higher the DOB, the greater the risk of developing serious gastric problems in the absence of treatment. Thus, we recommend not to neglect the symptoms that may point to an Hp infection, despite the considerable difficulties encountered in this period to access BT. All the more so considering that Hp can lead to symptoms such as heartburn, which patients often self-medicate with chronic PPI intake, an additional risk factor that increases Covid-19-related morbidity and mortality[6].

Contact E-Mail Address: Lilinjka95@gmail.com

Introduction: Nowadays the question of whether Helicobacter pylori-associated chronic gastritis is the cause of dyspepsia is controversial. There is no data about the association between dyspepsia symptoms and the presence of Helicobacter pylori (*H. pylori*) virulent factors (CagA+, VacA+).

Aims & Methods: The aim of this study was to evaluate the frequency of dyspepsia symptoms, anxiety and depression, indicators of quality of life in patients with *H. pylori*-associated gastritis with *H. pylori* virulent factors (CagA+, VacA+) and without them. The diagnosis of chronic gastritis (CG) was established based on esophagogastroduodenoscopy with proximal jejunoscopy, chromoscopy with magnification up to ×115 and narrow-band imaging (NBI) followed by morphological examination of the stomach.

The *H. pylori* virulence factors (CagA+, VacA+) were determined by the PCR method and total immunoglobulins (IgA, IgG) level to the *H. pylori* CagA, VacA protein antigen by the ELISA method. The hospital Anxiety and Depression (HADS) questionnaire was used to assess the level of anxiety and depression. The questionnaire "MOS36 - Item Short - Form Health Status Survey" (SF-36) was used to assess the quality of life.

Results: The cross-sectional study included 50 patients with *H. pylori*-associated gastritis and virulent factors (CagA+, VacA+) (Group 1) and 34 patients with CG without virulent factors (Group 2).

Dyspepsia symptoms of varying intensity were found in 64 patients (76.2%). Dyspeptic symptoms were found in 37 (74%) patients of Group 1 and in 27 (79.4%) patients of Group 2.

Epigastric pain was recorded in 30 patients (60%) of Group 1 and 12 patients of Group 2 (35.3%) (p=0.026).

There was no statistical difference between the groups in the frequency of burning in the epigastrium, feeling of early satiety and postprandial fullness (p>0.05).

Subclinical anxiety was present in 9 (18%) patients of Group 1 and 5 patients (14.7%) of Group 2, clinical anxiety in 17 (34%) patients of Group 1 and 4 (11.8%) of Group 2 (p=0.041).

Subclinical depression was detected in 13 (26%) patients of Group 1 and 2 (5.9%) patients of Group 2, clinical depression in 7 (14%) patients of Group 1 and 3 (8.8%) patients of Group 2 (p=0.032).

Role physical (RP) (50 vs. 75; p = 0.0001), bodily pain (BP) (57.5 vs 77.5; p=0.0001), general health status (GH) (45 vs. 75; p=0.0001), vital activity (VT) (55 vs. 80; p=0.0011) and mental health (MH) (56 vs. 84; p=0.0001) were significantly lower in patients with *H. pylori*-associated gastritis with virulent factors (CagA+, VacA+); physical functioning (PF) (95 vs. 95), social functioning (SF) (62.5 vs. 75) and role emotional (RE) (66.7 vs. 66.7) were not statistically different between the two groups (p>0.05).

Conclusion: Our study reveals that epigastric pain, a higher level of anxiety and depression and a decrease in the quality of life according to indicators RP, BP, GH, VT and MH were observed statistically significantly more often in patients with *H. pylori*-associated gastritis and virulent factors (CagA+, VacA+).

Disclosure: The Authors declare no conflict of interest.

ASSOCIATION OF HELICOBACTER PYLORI AND ANAEMIA

A.S.M.A Raihan[1], K. Jahan[2,3,2], S. Sarker[4]
[1]Bangabandhu Sheikh Mujib Medical Univesity, Dhaka, Bangladesh, [2]University of Dhaka, Institute of Nutrition and Food Science, Dhaka, Bangladesh, [3]Institute of Nutrition and Food Science, Dhaka, Bangladesh, [4]ICDDRB, Nutrition and Clinical Services Division, Dhaka, Bangladesh

Contact E-Mail Address: prof.raihanbd@gmail.com

Introduction: There has been a growing body of evidence to suggest a relationship between Helicobacter pylori (H.pylori) gastritis and iron deficiency anemia (IDA) in the absence of peptic ulcer disease.

This study aims to find out whether there is any association of H.pylori infection with iron deficiency and iron deficiency anaemia in Bangladesh.

Aims & Methods: This was a cross sectional study. Association of H.pylori infection and anaemia was studied in a group dyspeptic patients who was found to have no mucosal lesion at upper GI endoscopy and in whom Rapid urease test (RUT) was done to detect H.pylori infection. H.pylori positive patients were considered as group A and H.pylori negative were considered as group B. A total of 194 patients of both sex aged 18 to 60 years were included(group A-134, group B- 60) for the study.

Five ml of blood was collected from each patients for estimation of haemoglobin level, serum iron level, serum ferritin , mean corpuscular haemoglobin (MCH) and mean corpuscular volume.

Results: In the multiple regression model H.pylori infection was associated with a 28.8% decreased serum ferritin (95% CI = -4.85 to – 9.1); r2=0.271).

Mean MCV of the study patients was estimated and compared between groups. The mean MCV was found 85.45±6.93 (on fL) in group A and 88.73±4.58 (on fL) in group B. The difference was found to be statistically significant between the two groups (p=0.001).

Mean MCH of the study patients was estimated .The mean MCH was found 27.6±2.4 pg in group A and 28.8±1.4 pg in group B. The difference was found to be statistically significnat (p<0.05).

S. ferritin >39 ug/L was found in 91 % group A, 67.9% of group B and <15ug/L was found in 18% of group A and 13..4% in group B subjects. This difference is statistically significant.

In male patients frequency of depleted/low iron stores anemia was 2 in low hemoglobin level in Group A but none was in Group B. Adequate iron store was found in 8 and 5 patients in group A and group B respectively. The differences was not statistically significant (p>0.05).

In male patients frequency of depleted/low iron stores was 12 in normal hemoglobin level in Group A. In Group B depleted/low iron stores was found in 2 patients with normal hemoglobin level. Adequate iron store was found in 40 and 36 patients in group A and group B respectively. The difference was statistically significant (p<0.05)

In female patients frequency of depleted/low iron stores anemia was 8 in low hemoglobin level in Group A but none was found in Group B. Adequate iron store was found in 7 and 1 patients in group A and group B respectively. The difference was not statistically significant (p>0.05).

Frequency of depleted/low iron stores anemia was 27 in patients with normal hemoglobin level in Group A and 2 in Group. Adequate iron store was found in total 63 and 45 patients in group A and group B respectively. The difference was statistically significant (p<0.05).

Conclusion: This study revealed an association of iron deficiency anaemia, low serum ferritin , low MCH and MCV with H.pylori infection. So there is a possibility of causal relation between H. Pylori infection and iron deficiency anaemia.

RELATIONSHIP BETWEEN *HELICOBACTER PYLORI* INFECTION AND GASTRIC MUCOSAL INJURIES IN PATIENTS TAKING ASPIRIN

Y. Shimada[1], Y. Terai[1], R. Om[1], Y. Kita[1], Y. Ikeda[1], S. Sato[1], A. Murata[1], S. Sato[1], A. Nagahara[2], T. Genda[1]

Introduction: The mechanism of aspirin-induced gastric mucosal injury is thought to be mediated by multiple processes involving either topical or systemic effects. Recently, it has been reported that topical effects play a pivotal role in causing gastric mucosal injury [1,2].

It is known that almost all aspirin-induced gastric mucosal injuries were observed in low intragastic pH condition (pH<4) [3].

Though it depends on the severity and distribution of gastritis caused by *Helicobacter pylori* (*H. pylori*), gastric acid secretion is recovered after the eradication of *H. pylori* [4].

Therefore, because intragastric pH may decrease dramatically, the prevalence and severity of gastric mucosal injuries in patients taking aspirin may also change after the eradication.

Aims & Methods: The aim of this study is to reveal the relationship between *H. pylori* infection and gastric mucosal injuries in patients taking aspirin. This study was a retrospective cross-sectional study. Data were extracted from the records of subjects who underwent upper gastrointestinal endoscopy at our department between April 2015 and March 2020. We focused on the subjects taking only aspirin as an anti-thrombotic agent, and selected the subjects whose *H. pylori* infection status was known.

After that we divided into three groups (non-infection, current infection, and past infection of *H. pylori*) and compared the severity of gastric mucosal injury, individually. Severity of gastric mucosal injury was evaluated endoscopically based on the modified LANZA score (m-LANZA score). Statistical analyses were performed by using Fisher's exact test.

We evaluated separately for subjects with concomitant use of potassium-competitive acid blocker (P-CAB) or PPI (user) and subjects without concomitant use of P-CAB, PPI nor histamine H2 receptor antagonist (H2RA) (nonuser).

Results: 311 subjects out of 6,031 were taking only aspirin as an anti-thrombotic agent. In group of non-infection (43 men, 32 women; mean age 69.0±15.6 years), average MLS was 0.51±1.16 (user: n=45, score0=33, score1=8, score2=1, score3=1, score4=0, score5=2) and 1.21±1.70 (nonuser: n=29, score0=18, score1=0, score2=3, score3=5, score4=1, score5=2). In group of current infection (12 men, 5 women; mean age 67.7±11.4 years), average MLS was 0.86±1.86 (user: n=7, score0=5, score1=1, score2=0, score3=0, score4=0, score5=1) and 1.29±1.89 (nonuser: n=7, score0=4, score1=0, score2=2, score3=0, score4=0, score5=1). In group of past infection (107 men, 51 women; mean age 74.7±7.5 years), average MLS was 0.39±1.07 (user: n=104, score0=86, score1=8, score2=4, score3=2, score4=1, score5=3) and 0.90±1.62 (nonuser: n=49, score0=34, score1=4, score2=3, score3=4, score4=2, score5=4).

There was a statistically significantly difference between user and nonuser in group of non-infection (p=0.040) and in group of past infection (p=0.023). Mean MLS in group of current infection was high more than expected because intragastric pH might be high in *H. pylori*-positive patients. We considered because many subjects which were *H. pylori*-positive but whose gastric acid secretion was not so impaired might be included in this study.

Conclusion: There was no significant difference between *H. pylori* infection and gastric mucosal injuries in patients taking low dose aspirin. However, concomitant use of P-CAB or PPI can prevent gastric mucosal injuries in *pylori*-negative patients taking low dose aspirin.

INFLUENCE OF CYTOKINE GENETIC POLYMORPHISMS IN *HELICOBACTER PYLORI*–ASSOCIATED GASTRIC INFLAMMATION ACCORDING TO SEX IN SOUTH KOREA

H.J. Kim[1], N. Kim[2], J.Y. Jang[2]
[1]Gyeongsang National University Changwon Hospital, Changwon, South Korea, [2]Seoul National University Bundang Hospital, Internal Medicine, Seongnam, South Korea

Contact E-Mail Address: kheejin19@gmail.com

Introduction: Backgrounds: Genetic polymorphisms in inflammation related-cytokines are known to be associated with an increased risk of gastric cancer. However, the relationship between their polymorphisms and the severity of gastric inflammation remains unclear.

We investigated the effects of cytokine genetic polymorphisms on the severity of gastric inflammation in *Helicobacter pylori* (*H. pylori*)-infected subjects according to sex.

Aims & Methods: This study incorporated 892 subjects with current *H. pylori* infection (445 males and 447 females) including 525 healthy controls, 182 patients with gastric ulcer, 185 patients with duodenal ulcer. Genotyping of *IL-1B*-511, *IL-8*-251, *IL-8*-781, *IL-10*-1082, *IL-10*-592, *IL-6*-572, *TNF-A*-308, *TGF-B*-509, *IL1RN* variable number of tandem repeat, *ALDH2*, *GSTP1* and p53 codon 72 were determined by polymerase chain reaction-restriction fragment length polymorphism.

Degrees of monocyte infiltration, neutrophil infiltration, atrophic gastritis (AG) and intestinal metaplasia (IM) in the antrum and corpus were evaluated accordingly to the updated Sydney System. The severity of gastric inflammation was divided into two groups, no/mild and moderate/severe, and were compared between genotypes adjusted age, disease status and *H. pylori* virulent factors.

Results: In males, moderate/severe AG of the corpus was significantly higher in *IL-1B*-511 C/C than *IL1B*-511 T carriers (17.9 vs 7.7%; adjusted hazard ratio (HR) = 3.140, 95% confidence interval (CI) = 1.320-7.471; p = 0.018), while no associations between *IL-1B*-511 polymorphism and gastric inflammation were found in females. *IL-8*-251 A/A was significantly associated with moderate/severe AG of the corpus than *IL-8*-251 T carriers only in females (21.2 vs 6.6%; adjusted HR = 3.520, 95% CI = 1.539-8.051; p = 0.003). *IL-8*-781 T/T showed significantly more frequent in females with moderate/severe AG of antrum than *IL-8*-781 C carriers (12.9 vs 4.6%; adjusted HR = 2.835, 95% CI = 1.166-6.892; p = 0.022), and conversely, *IL-8*-781 C carriers were significantly associated with moderate/severe AG of the antrum than *IL-8*-781 T/T in males (23.3 vs 8.3%; adjusted HR = 3.573, 95% CI = 1.033-12.362; p = 0.044). No significant associations were observed in the frequencies of the genotypes of other genetic polymorphisms with severity of gastric inflammation.

		Male				Female			
		Atrophic gastritis of the corpus							
		No / mild	Mod / severe	P value*	HR (95% CI)	No / mild	Mod / severe	P value*	HR (95% CI)
IL-1B-511	C/T+T/T	251 (92.3)	21 (7.7)	0.018	1	238 (90.2)	26 (9.8)	0.309	
	C/C	45 (82.1)	10 (17.9)		3.140 (1.320-7.471)	64 (94.1)	4 (5.9)		
IL-8-251	T/T+A/T	258 (90.8)	26 (9.2)	0.764		256 (93.4)	18 (6.6)	0.003	1
	A/A	36 (92.3)	3 (7.7)			41 (78.38)	11 (21.2)		3.520 (1.539-8.051)
		Atrophic gastritis of the antrum							
IL-8-781	C/T+C/C	198 (76.7)	60 (23.3)	0.044	3.573 (1.033-12.362)	146 (95.4)	7 (4.6)	0.022	1
	T/T	33 (91.7)	3 (8.3)		1	148 (87.1)	22 (12.9)		2.835 (1.166-6.892)

*adjusted by age, disease status and *H. pylori* virulence factor; Mod, moderate; HR, hazard ratio; CI, confidence interval

Table. Summary of the results of this study

Conclusion: These results suggest that cytokine genetic polymorphisms such *IL-1B*-511 C/T, *IL-8*-251 T/A and *IL-8*-781 C/T are one of several factors that determine severity of AG with sex difference.

Disclosure: Nothing to disclose.

HELICOBACTER PYLORI WITH *TRX1* HIGH EXPRESSION PROMOTES GASTRIC DISEASES BY UPREGULATING THE IL23A/NF-KB /IL8 PATHWAY

X. Guan[1], J. Ning[1], W. Fu[1], Y. Wang[1], J. Zhang[1], S. Ding[1]
[1]Peking University Third Hospital, Gastroenterology, Beijing Key Laboratory for Helicobacter Pylori Infection and Upper Gastrointestinal Diseases (BZ0371), Beijing, China

Contact E-Mail Address: guanxin_330@163.com

Introduction: Gastric cancer is a malignant tumor that seriously endangers human physical and mental health worldwide. *H. pylori* infection is considered to be the major cause of gastric cancer.

Differences in clinical outcomes after *H. pylori* infection may be related to bacterial virulence. Thioredoxin-1 (Trx1) and Arginase (RocF) expressed by *H. pylori* were found to be closely related to its pathogenicity and promoted gastric cancer pathogenesis in our previous study.

Aims & Methods: To explore whether Helicobacter pylori Trx1 and RocF can be used as a marker of highly pathogenic Helicobacter pylori and its pathogenesis.

We investigated the expression level of *H. pylori trx1* and *H. pylori rocF* in human gastric antrum tissues using reverse transcription and quantitative real-time PCR (RT-qPCR) and clarified the clinical application value of *trx1* and *rocF* for screening highly pathogenic *H. pylori*. The pathogenic mechanism of Trx1 were further explored by RNA-seq of GES-1 cells co-cultured with *trx1* high or low expressing *H. pylori*.

Differentially expressed genes and signaling pathways were validated by RT-qPCR, Enzyme-linked immunosorbent assay (ELISA), western blot, immunohistochemistry and immunofluorescence. We also assessed the adherence of *trx1* high and low expressing *H. pylori* to GES-1 cells.

Results: We found that *H. pylori trx1* and *H. pylori rocF* were more significantly expressed in the gastric cancer and peptic ulcer group than that in the gastritis group and the parallel diagnosis of *H. pylori trx1* and *H. pylori rocF* had high sensitivity.

Trx1 high expressing *H. pylori* had stronger adhesion ability to GES-1 cells and upregulated the interleukin (IL) 23A/Nuclear factor κappaB (NF-κB)/IL17A, IL6,IL8 pathway.

Conclusion: In conclusion, *H. pylori trx1* and *H. pylori rocF* can be used in clinical screening of highly pathogenic *H. pylori* and predicting the outcome of *H. pylori* infection. *trx1* high expressing *H. pylori* enhances the adhesion capacity and promotes the development of gastric diseases by upregulating the NF-κB signaling pathway and related inflammatory cytokines.

Introduction: Recently, the number of ESD cases of early gastric cancer detected after Helicobacter pylori eradication (GCAE) has been increasing. As the number of years since eradication increases, the management of metachronous carcinomas after ESD for GCAE has also become an issue. Serum gastrin level has been reported to be useful in identifying groups at high-risk of developing gastric cancer.

In this study, we investigated the clinicopathological characteristics of patients with early-stage GCAE who underwent ESD at our department. Furthermore, we determined the risk of metachronous GCAE after ESD and the correlation between serum gastrin level and metachronous GCAE.

Aims & Methods: We retrospectively analyzed a total of 300 lesions in 245 patients who underwent ESD for GCAE with known period after eradication at Hiroshima University Hospital between April 2010 and December 2019 and examined their clinicopathology.

We divided 220 lesions in 194 patients with initial GCAE who had no history of gastric endoscopic resection before successful eradication into the "metachronous gastric cancer (MGC) groups" and "no metachronous gastric cancer (NGC) groups".

Then, we examined the clinicopathological characteristics of metachronous gastric cancer cases. We classified 74 lesions in 63 patients of male and differentiated type cancers who have not been using PPIs into two groups: 37 lesions in 32 patients with gastrin level of less than 80 pg/ml and 37 lesions in 31 patients with gastrin level higher than 80 pg/ml.

Results: At a median follow-up of 4.0 years, 16 patients (8.2%) developed metachronous gastric cancers. Males were more predominant in the MGC group than in the NGC group (male / female; 16/0 vs. 223/74, p=0.02), which included increased cases of severe atrophy of the background gastric mucosa (mild to moderate / severe; 3/13 vs. 94/84, p=0.01), more lesions in the U and M regions of stomach (U-M / L; 19/4 vs 121/76, p=0.05), and a higher proportion of synchronous multiple lesions (synchronous tumor/ no synchronous tumor; 11/12 vs. 160/37, p=0.01). The relationship between gastrin levels and metachronous gastric cancer was examined, revealing that gastrin levels were higher in the MGC group. The group with a gastrin level of 80 pg/ml or higher had a significantly higher incidence of metachronous lesions than the group with that of less than 80 pg/ml (OR 6.88; 95% CI, 1.61–29.3; p=0.01).

Conclusion: These results that male patient with severe atrophy, the rates of localization to the U and M regions of stomach and the incidence of synchronous multiple lesions before ESD indicate should be noted and surveyed more strictly for metachronous gastric cancers developing after ESD of GCAE. Patients with gastrin 80 pg/ml or higher had increased risk of MGC, indicating that gastrin level may be a serological marker for MGC.

ENDOFASTER® FOR MINIMALLY-INVASIVE REAL-TIME DIAGNOSIS OF HELICOBACTER PYLORI INFECTION DURING ENDOSCOPY: PRELIMINARY RESULTS FROM A TERTIARY CENTER

T. Ribeiro[1], R. Ramalho[1], J. Santos-Antunes[1], A. Peixoto[1], G. Macedo[1]

[1]University Hospital Center of São João, Gastroenterology, Porto, Portugal

Contact E-Mail Address: tiagofcribeiro@outlook.com

Introduction: *Helicobacter pylori* (Hp) is a major factor involved in both neoplastic and non-neoplastic gastroduodenal disease [1,2].

Biopsies are frequently performed to identify this agent during esophagogastroduodenoscopy (EGD). Nevertheless, the prevalence of the infection is decreasing in developed countries, thus biopsies are frequently negative and have no clinical impact [3].

Endofaster® (NISO Biomed SRL, Turin, Italy) provides real-time analysis of gastric juice ammonium, allowing the diagnosis of Hp infection [4].

Aims & Methods: This preliminary study aimed to assess the performance of this device in a real-life clinical setting. We prospectively enrolled patients undergoing EGD and biopsies following the Sydney protocol at a single tertiary center. All patients were off proton-pump inhibitors for ≥1 week. Gastric juice was aspirated (4 mL) before any water was instilled for cleaning the mucosa. The pH and NH3 values were assess.

A value of NH_3>62 ppm/mL were compatible with Hp infection. Histology was considered the *gold-standard*. The performance of the device was determined regarding its sensitivity, specificity, accuracy and area under the curve (AUC).

Results: A total of 39 patients were included in the analysis, with a similar distribution between gender (male patients, n=20, 51%). The cohort had a median age of 56 years (IQR 48-66). A total of 19 patients (50%) had severe hypochloridria (pH>4.5). A NH_3 >62 ppm/mL suggested Hp infection in 21 patients (54%). Histology confirmed Hp infection in 18 patients (46%). The *Endofaster®* had a sensitivity, specificity and overall accuracy of 77.8%, 66.7% and 71.8%. The AUC was 0.784.

Conclusion: The *Endofaster®* demonstrated an adequate performance for the detection of Hp infection when compared to gastric biopsies. Further development of these non-invasive techniques, combined with the advent of artificial intelligence, may help to optimize the diagnosis of Hp infection and reduce the high costs associated with histopathological analysis.

Contact E-Mail Address: thbutler@tcd.ie

Introduction: Antibiotic resistance is one of the main reasons for *H. pylori* treatment failure. International guidelines recommend that the choice of antibiotics used to treat *H. pylori* in a given population should be based on the pattern of antibiotic resistance in that region. However, *H. pylori* antibiotic resistance testing is not routinely carried out in the majority of Irish Hospitals. Recent evidence from the European Helicobacter and Microbiota Study Group has indicated that resistance to certain commonly used antibiotics to eradicate *H. pylori* varies between European countries, and in certain areas resistance has reached a sufficient level to avoid prescribing these antibiotics as empirical therapy (1).

In addition, previous antibiotic use positively correlates with resistance for two major classes of antibiotics commonly used to treat H. pylori infection (1).

Because antibiotic resistance is a constantly evolving process, the European Helicobacter and Microbiota Study Group and the Maastricht VI/Florence consensus report (2) have highlighted the importance for local resistance surveys to be carried out on a regular basis in order to guide clinicians in their choice of therapy for successful eradication of H. pylori.

Aims & Methods: In this multisite study we aimed to assess the rate of primary and secondary antibiotic resistance for *H. pylori* in Ireland, with a view to guiding national treatment strategies. The study comprised of four sites with samples analyzed from two large urban teaching hospitals and two rural teaching hospitals. Patients attending for gastroscopy were invited to participate in the study.

Following informed consent, 1 antrum and 1 corpus gastric biopsy were collected from each patient and transported to the laboratory in selective medium. Antibiotic susceptibility testing was carried out by E-test (bioMerieux) and resistance classified according to the EUCAST clinical breakpoints MIC values.

Results: In total, 126 isolates were successfully cultured and antimicrobial susceptibility assessed. 103 of these were isolates of treatment naïve patients (50±16 years old, 59% male) and 23 were of previously treated patients (48±12 years old, 61% female).

As can be seen in table 1, primary antibiotic resistance rates have reached alarmingly high levels for both clarithromycin and metronidazole, and reach nearly double the rate of resistance with the previously treated group.

Antibiotic	clarithromycin	metronidazole	levofloxacin	tetracycline	amoxicillin	rifampicin
Primary Resistance (%)	37.9	44.7	21.4	10.7	33.3	16.7
Secondary Resistance (%)	65.2	73.9	30.4	17.4	30.4	17.4

Table 1: Antibiotic susceptibility rates for H. pylori isolated from Irish Hospitals.

Conclusion: Antibiotic resistance rates have reached significant levels for all major classes of antibiotics for the treatment of *H. pylori*. Of note, first-line clarithromycin triple therapy can no longer be recommended in Ireland.

EVALUATION OF MOLECULAR-BASED CLARITHROMYCIN RESISTANCE TESTING IN HELICOBACTER PYLORI COMPARED TO CULTURE-BASED TESTING IN THE IRISH HEALTHCARE SETTING

S. Molloy[1], T. Butler[1], I. Merrigan[2], V. Parihar[3], K. Van Der Merwe[3], D. McNamara[1,4], S. Smith[1,4]

Introduction: Antibiotic resistance in H. pylori (Hp) is becoming a more significant challenge in the management of Hp infection. Resistance surveillance is recommended to guide clinicians in the most appropriate therapy in a given population. Molecular methods offer a more rapid alternative for the detection of Hp resistance to antibiotics than traditional culture-based methods.

Aims & Methods: To evaluate the diagnostic accuracy of molecular-based clarithromycin susceptibility testing in Hp compared to culture and E-test in the Irish healthcare setting.

Following ethical approval and informed consent, adults were recruited prospectively from 2 centres (Tallaght University Hospital and Letterkenny University Hospital, Ireland), regardless of previous Hp treatment history. During routine gastroscopy, subjects had two supplementary biopsies (1 antrum and 1 corpus) taken for Hp culturing and DNA extraction. After successful Hp growth, clarithromycin susceptibility testing was performed by the Etest (Biomerieux) method and resistance was determined according to EUCAST 2023 guidelines.

DNA was then extracted from biopsies and underwent PCR using the RIDA®GENE Helicobacter pylori assay (R-Biopharm AG, Germany) for detection of Hp and clarithromycin resistance-associated point mutations (A2146C, A2146G and A2147G).

Results: In all, samples from 191 culture-positive patients (mean age 48.4 ± 15.3 years; 45.0% (N=86) female) were analysed. The rates of clarithromycin resistance detected by culture-based and molecular methods were 49.2% (N=94/191) and 38.7% (N=74/191), respectively (P=0.05; Fisher's exact test).

Results were in agreement between both methods in 84.3% (N=161/191) of cases. The sensitivity and specificity of the Ridagene assay compared to culture for the detection of clarithromycin resistance were 74.2% (95% CI: 64.4-82.6%) and 94.7% (95% CI: 88.0-98.3%), respectively. The positive predictive value was 93.5% (95% CI: 85.5-97.9%) and the negative predictive value was 78.1% (95% CI: 69.4-85.3%).

Conclusion: While the Ridagene assay was easy to use and more rapid than Hp culture, the low sensitivity compared to culture in our cohort may limit its use to cases where culture-based methods are unsuccessful. Further studies are required to characterise the full spectrum of clarithromycin resistance mechanisms present in our population.

Disclosure: Nothing to disclose.

PP0340

SAFETY AND EFFECTIVENESS OF VONOPRAZAN AND AMOXICILLIN DUAL REGIMEN WITH *SACCHAROMYCES BOULARDII* SUPPLEMENTATION AS A RESCUE THERAPY FOR *HELICOBACTER PYLORI* INFECTION: A PILOT STUDY

X. Wang[1], J. Yu[1]

[1]The Affiliated Changzhou No. 2 People's Hospital of Nanjing Medical University, Gastroenterology, Changzhou, China

Introduction: Vonoprazan (VPZ)-based regimens are an effective first-line therapy for *Helicobacter pylori* infection. However, their value as a rescue therapy needs to be explored.

Aims & Methods: We assessed a VPZ-based regimen as a *H. pylori* rescue therapy.

Patients with a history of *H. pylori* treatment failure were administered 20 mg VPZ twice daily, 750 mg amoxicillin 3 times daily, and 250 mg *Saccharomyces boulardii* twice daily for 14 days. ^{13}C-urea breath tests were used to assess *H. pylori* status; adverse events were recorded using a questionnaire.

Results: We enrolled 68 patients with 1–3 previous eradication failures. The overall eradication rates calculated using intention-to-treat and per-protocol analyses were 92.6% (63/68) and 92.3% (60/65), respectively. The eradication rate did not differ with the number of treatment failures. The rates of clarithromycin, metronidazole, and levofloxacin resistance were 91.3% (21/23), 100% (23/23), and 60.9% (14/23), respectively. In 60.9% (14/23) patients, the *H. pylori* isolate was resistant to all 3 antibiotics. The eradication rate was higher among patients without anxiety (96.8%) than among patients with anxiety (60.0%, $P = 0.025$).

No severe adverse events occurred; 95.6% (65/68) patients showed good compliance. Serological examination showed no significant changes in liver and kidney function.

Conclusion: Vonoprazan and amoxicillin dual regimen with *S. boulardii* supplementation is a safe and effective *H. pylori* rescue therapy, with an acceptable eradication rate (>90%), regardless of the number of prior treatment failures. Anxiety was associated with eradication failure, and the regimen may need to be adjusted for patients with anxiety.

Disclosure: Nothing to disclose.

Introduction: The impact of consensus, prescription choices, and efficacy trends on clinical practice over time has not been studied in depth.

Aims & Methods: International, multicenter, prospective, non-interventional registry aimed to evaluate the decisions and outcomes of *H. pylori* management by European gastroenterologists. All infected adult patients were systematically registered at AEG-REDCap e-CRF from 2013 to December 2022. *Variables included*: previous eradication attempts, prescribed treatment, adverse events, effectiveness outcomes, by geographical region (east, south-east, centre, south-west and north). Modified intention-to-treat (mITT) and time trend analyses were performed. Data were subject to quality review.

Results: So far, 59,689 patients from 32 European countries have been included, and 46,797 (78%) were first-line empirical prescriptions. Overall, the most common prescribed treatments in the 2013-22 period were triple therapies; however, a shift in antibiotic regimens was identified. Triple therapies decreased from over 50% of prescription in 2013/15 to less than 20% in 2020/22; likewise, non-bismuth concomitant therapy use decreased from 21% in 2013/14 to 13% in 2020/22, while three-in-one single-capsule increased from 0-1% in 2014/2015 to 21% in 2020/22. An increase in the average duration of treatments from 9.7 days in 2013 to 13 days in 2022 was identified, as well as in the use of high-dose of PPIs increasing from 17% in 2013 to 35% in 2022. Detailed description of most common treatments is shown in Table 1. Regarding the effectiveness of each specific treatment, no trend was identified (data now shown); however, there was a ≈10% overall improvement in first-line mITT overall effectiveness from 85% to 93% in 10 years of evolution, both globally and in each geographic region, especially after the year 2018 (Table).

Conclusion: European gastroenterological practice is constantly adapting to the newest published evidence and recommendations (reducing the use of triple therapies and increasing both the duration of treatment and the dose of PPIs), with a subsequent progressive improvement in overall effectiveness.

Introduction: The clinical scenarios in which probiotics (PB) are useful as adjuvants to *Helicobacter pylori* eradication therapy have not been well established.

Aims & Methods: Aims: To determine the use and factors associated with the prescription of PB adjuvants to *H pylori* eradication regimens, by European gastroenterologists in clinical practice.

Methods: Prospective, multicentre, non-interventional registry (Hp-EuReg) of the clinical practice of European gastroenterologists. Data were collected in an AEG-REDCap e-CRD from 2013 to 2022. All data from countries with at least 30 cases undergoing eradication therapy and at least 1 case with associated PB were included, using patients without PB as controls. Analysis was performed by geographic area.

Results: A total of 36,699 patients were included, 8,233 (22%) with PB. Multiple PB formulations were used, including 9 genera and 32 species, the most frequent being *Saccharomyces boulardii* (2,315), *Lactobacillus rhamnosus* (1,897), *Bifidobacterium breve* (1,765), *Lactobacillus reuteri* (1,732) and *Lactobacillus acidophilus* (1,447). Forty-one percent of the formulations were multi-genus, 34% were symbiotic and 11% were combined with other products.

As factors associated with prescribing, there was a higher rate of females in the PB group (64% vs 60%; p<0.0001), with similar age (49 vs 51). Patients in the PB group had a higher rate of resistance to clarithromycin (11.4 vs 1.4), metronidazole (10.7 vs 1.4) and dual (10.7 vs 1.4). In terms of line of eradication therapy, PB use was more frequent (p<0.0001) in patients in 5th (28%) and 6th line (46%) compared to 1st (22%), 2nd (23%), 3rd (24%) and 4th (24%).

The rate of PB use varied between the different eradication regimens, being most frequent in sequential (74%), followed by hybrid (38%) and dual (33%). In contrast, the rate was lower in classic bismuth quadruple (24%), or the same in single capsule (21%), triple (17%) and non-bismuth quadruple (15%).

The percentage of PB use per country ranged from 95% in Serbia to 0.2% in Slovenia. The central geographical area had by far the highest prescription rate (83%). The rates in the rest were 38% in the east, 9% in the southeast, 7% in the southwest and 1% in the north. We observed that the rate of adverse effects in the non-PB group was higher in the central area than in the other areas (38% vs. 28%; p<0.0001), suggesting that in areas with less PB use there may be a prescription of PBs driven by the expectation of adverse effects.

Conclusion: The prescription of PB adjuvant to eradication therapy is very heterogeneous. There is greater use of PB associated with sequential, dual and hybrid therapies, patients with antibiotic resistance, advanced lines of treatment and women. In areas with lower PB use, there seems to be a prescription bias towards patients with a higher expected risk of adverse effects.

Disclosure: Nothing to disclose.

PP0343

CLINICAL PHENOTYPES THROUGH *MACHINE LEARNING* OF FIRST-LINE TREATED PATIENTS DURING THE PERIOD 2013-2022: DATA FROM THE EUROPEAN REGISTRY ON *HELICOBACTER PYLORI* MANAGEMENT (HP-EUREG)

Introduction: The segmentation of patients in homogeneous groups, according to their clinical variables and treatments, could help to improve the effectiveness of current eradication therapies.

Aims & Methods: 1. To determine the most important characteristics of the treatments used in the European Registry on *H. pylori* management (Hp-EuReg), using machine learning techniques.

2. To evaluate the effectiveness of the treatments according to the year of the visit and the country using a cluster decomposition.

Sub-study of the Hp-EuReg, a systematic, prospective, registry of the routine clinical practice of European gastroenterologists on the management of *H. pylori* infection. All cases with a first-line empirical eradication treat-

ment registered from June 2013 to December 2022, were included in the current analysis. *Boruta,* a random-forest-like method was used to determine the following 'most important' variables: compliance, duration of treatment, PPI dosage, patient's country, and treatment scheme.

Results: In total, 35,852 European patients were analysed. Table 1 shows the increasing trend in the effectiveness of treatments, from an average 87% in 2013 to 93% in 2022 (more than 100 patients/clusters). The cluster 3 in 2016 (lowest effectiveness) was composed of 97.5% triple therapy with clarithromycin-amoxicillin/metronidazole, mainly in Slovenia (54%), with a majority (85%) of 7-day prescriptions, and 99% compliance. The highest effectiveness was obtained in cluster #1 in 2022, with 81% of Spanish cases, 32% of concomitant therapy with clarithromycin-amoxicillin-metronidazole/tinidazole and 63% of bismuth quadruple therapy with tetracycline-metronidazole (prescribed as single capsule), 69% of 10 days prescriptions, and 32% of 14 days treatment length.

year	# of *clusters* (# of patients)	*Effectiveness % (number of patients)* per cluster		
		1	2	3
2013	3 (3,239)	85.2 (1,491)	90.2 (440)	85.2 (1,308)
2014	3 (4,292)	88.5 (433)	86.1 (2,706)	85 (1,153)
2015	3 (3,693)	88.9 (351)	86.5 (2,913)	85.8 (429)
2016	3 (4,350)	91.4 (1,655)	88.1 (2,084)	80.2 (611)
2017	3 (3,665)	84 (1,629)	91.4 (1,741)	85.1 (295)
2018	3 (3,668)	89.5 (2,181)	91.8 (1,171)	92.1 (316)
2019	3 (3,695)	89.1 (2,133)	88.6 (1,324)	92.3 (238)
2020	3 (3,092)	92.9 (198)	85.4 (1,573)	89.9 (1,321)
2021	3 (4,018)	85.8 (246)	91 (1,886)	80.6 (1,886)
2022	3 (2,140)	95.4 (936)	93 (128)	91.6 (1,076)

Simple underlining highlights the lowest effectiveness in clusters/year with more than 100 patients, and double underlining the highest effectiveness.

Table 1. Trends in the overall effectiveness (by modified intention-to-treat, per cluster) between 2013 and 2022 in Europe.

Conclusion: Cluster analysis allowed both to identify patients with homogeneous treatment groups, as well as to assess the effectiveness of the different first-line treatments, its compliance, the region where it was administered, and the prescription year.

Introduction: *Helicobacter pylori* treatment´s effectiveness decreases as treatment eradication attempts fail.

Aims & Methods: To evaluate the use and effectiveness of empirical rescue therapies on third and subsequent lines in Europe.

Sub-study of the the European Registry on *H. pylori* Management (Hp-EuReg), an international, multicenter, prospective, non-interventionist registry starting in 2013 aimed to evaluate the decisions and outcomes of *H. pylori* management by European gastroenterologists (32 countries, 300 researchers).

All infected adult patients were systematically registered at AEG-REDCap e-CRF until January 2023, all cases with three or more eradication attempts were extracted. Only the empirically prescribed therapies were analyzed. Data were subject to quality review.

Results: In total, 2,254 rescue treatments were included: 1,624, 424, 150 and 56 in third-, fourth-, fifth- and sixth-line treatments, respectively. Mean age was 52 years, 67% of patients were women and 5% were allergic to penicillin. Sixty-three different therapy regimens were used, being three-in-one single-capsule bismuth quadruple therapy the most commonly prescribed, as shown in the table.

Overall effectiveness was 73% by modified intention-to-treat (mITT), and 74% by per-protocol (PP) analyses. Bismuth quadruple therapy as single-capsule provided the highest mITT cure rate (86%).One regimen achieved an optimal eradication rate (≥90%, by mITT): quadruple PPI-bismuth-tetracycline-metronidazole, only when high-dose PPIs and 14 days' prescriptions were used. The use of doxycycline instead of tetracycline was associated with lower eradication rates in classical bismuth quadruple therapies (p<0.05).

		Modified intention-to-treat		Per-protocol	
Rescue therapy	**Use, N (%)**	**n**	**Effectiveness (95% CI)**	**n**	**Effectiveness (95% CI)**
PPI-Single capsule B-Tc-M	633 (28%)	588	86 (83-89)	566	88 (85-90)
Triple PPI-A-L	253 (11%)	194	77 (71-83)	193	77 (70-83)
Quadruple PPI-A-L-B	202 (9.0%)	182	72 (66-79)	176	74 (67-81)
Quadruple PPI-B-Tc-M	182 (8.1%)	176	74 (68-81)	171	74 (67-81)
Triple PPI-A-R	128 (5.7%)	108	59 (50-69)	104	61.5 (52-71)
Quadruple PPI-C-A-M	117 (5.2%)	109	62 (53-72)	106	63 (54-73)
Quadruple PPI-B-D-M	115 (5.1%)	112	62 (52-71)	108	62 (52-72)
Triple PPI-C-A	51 (2.3%)	43	56 (40-72)	41	56 (40-73)
Triple PPI-A-M	47 (2.1%)	44	59 (43-75)	42	59.5 (43-76)

A, amoxicillin; B, bismuth; C, clarithromycin; D, doxycycline; L, levofloxacin; M, metronidazole; Tc, tetracycline; R, rifabutin; CI, confidence interval.

Table 1. Overall eradication rates of the most prescribed empirical therapies on third and subsequent lines.

Conclusion: Empirical rescue treatments in third and subsequent lines obtain, in general, suboptimal eradication rates in Europe; however, bismuth quadruple therapy as single-capsule obtained encouraging results. Only the optimised bismuth quadruple therapy with tetracycline-metronidazole achieved ≥90% effectiveness.

Introduction: *H. pylori* infection can remain after several eradication attempts. The objective of this study was to evaluate the effectiveness of the sixth-line rescue treatment in Europe.

Aims & Methods: Systematic and prospective registry on the clinical management of *H. pylori* infection. All cases with six eradication attempts registered in AEG-REDCap up to December 2022 were evaluated. The modified intention-to-treat (mITT) and per-protocol (PP) effectiveness was analysed.

Results: Overall, 81 patients were included, mainly from Spain (44% of cases), Italy (26%) and the United Kingdom (17%). The mean age was 52 years, with 52% women and 1.2% of patients allergic to penicillin. Culture was performed in 26 cases (32%), of which: 13 (50%) had bacterial antibiotic resistance to clarithromycin, 12 (46%) to nitroimidazole, and 8 (31%) to quinolones. In addition, 8 (35%) patients had dual resistance (both to clarithromycin and metronidazole) and 7 (27%) triple resistance (also to levofloxacin). Twenty-two different therapeutic combinations were used, most of them prescribed for 14 days (57%) and with low doses (39%) of PPIs.

The most frequent treatments were: quadruple bismuth-tetracycline-metronidazole prescribed as three-in-one single-capsule (17%), triple amoxicillin-rifabutin (15%), quadruple bismuth-furazolidone-amoxicillin (11%), triple amoxicillin-levofloxacin (7.4%), and classical quadruple bismuth-tetracycline-metronidazole (6.2%). The highest eradication rates (mITT) were achieved with the single-capsule (77%) and with the quadruple therapy with bismuth-furazolidone-amoxicillin (67%).

Overall effectiveness was 53%, both by mITT and PP analyses. Additional information on effectiveness, tolerability, compliance, and prior therapies is shown in the table.

Use of antibiotics (or bismuth) in any of the previous treatments (1st to 5th line)	n (%)	Misuse of same antibiotic in 6th line, n (%)
Duration of previous eradication lines (1st to 5th line)	**Median**	**Interquartile range**
1st line	8.5	7-10

Triple-PPI+A+L	6 (7.4)	40 (5.2-85)
Quadruple-PPI+M+Tc+B	5 (6.2)	40 (5.3-85)
Dual-PPI+A	5 (6.2)	20 (0.5-72)
Triple-PPI+A+B	5 (6.2)	20 (0.5-72)
Quadruple-PPI+C+A+M	5 (6.2)	20 (0.5-72)
Other-PPI+C+A+M+B	4 (4.9)	50 (6.7-93)
Duration of 6th line prescriptions	**Median**	**Interquartile range**
7 days	14	10-14
10 days	**n (%)**	
14 days	2 (2.6)	
	25 (37)	
	40 (57)	
[2]PPI doses in 6th line prescriptions	**n (%)**	
Low	42 (57)	
Standard	3 (4.1)	
High	29 (39)	
Use of probiotics, n (%)	23 (28)	
Overall effectiveness	**n (%)**	
mITT	76 (53)	
PP	74 (53)	
Incidence of at least one adverse event, n (%)	19 (24)	
Compliance, n (%)	74 (94)	

TABLE: Prescriptions, effectiveness, tolerance and compliance in sixth-line treatments against Helicobacter pylori infection.

**The most frequent treatments represent 80% of the total 6th line prescriptions; mITT, modified intention-to-treat; PP, per-protocol; n, number of patients treated; CI: confidence interval; A, amoxicillin; B, bismuth; C, clarithromycin; L, levofloxacin; M, metronidazole; Tc, tetracycline hydrochloride; R, rifabutin; [1]Quadruple therapy-M+Tc+B as a single-capsule; NA, not applicable; PPI, proton pump inhibitor; [2]low doses: 4.5–27 mg; standard doses: 32–40 mg; high doses: 54–128 mg, all omeprazole equivalent 2 times a day.*

Conclusion: Sixth-line eradication treatments in Europe obtain suboptimal eradication rates. The only therapies that reach acceptable outcomes are the bismuth quadruple therapies with either tetracycline-metronidazole (single-capsule) or with furazolidone-amoxicillin.

Introduction: Antibiotic resistance is a growing challenge in the eradication of Helicobacter pylori (Hp). However, the benefits of sensitivity-guided approach compared to empirical regimens is to be established. In this study, we evaluated the effectiveness of the recommended therapeutic protocols, as well as the factors linked to therapeutic failure.

Aims & Methods: A single centre, prospective cohort study, including all consecutive patients undergoing Hp eradication therapy between 2013 and 2022. The evaluated therapeutic protocols were the triple therapy

(TRI), concomitant quadruple therapy (QUADC), sequential quadruple therapy (QUADS), and bismuth-based quadruple therapy (QUADB). We analysed the demographic and clinical characteristics of the population, and compared the regimens' effectiveness, adherence and adverse events.

Results: Included 523 patients, 57% female, with a median age of 56 years (IQR 46-65). The main indication for eradication was dyspepsia (59.8%). The prescribed therapeutic protocols were QUADC in 34.4% of patients, QUADB in 28.7%, TRI in 25.6%, and QUADS in 11.3%. The compliance rate was 97.1%, with no significant differences between the regimens (p=0.49).

According to intention-to-treat analysis, the eradication rates in naive patients were TRI 76.1%, QUADS 82%, QUADB 91.1% and QUADC 92.5%. There were statistically significant differences between QUADB/QUADC vs. QUADS/TRI eradication rates (91.9% vs. 78.3%, p<0.001) and adverse event rates (16.2% vs. 4.4%, p<0.001).

Multivariate analysis demonstrated an association between therapeutic failure and the following: previous eradication therapy (OR-2.6; 95%CI: 1.5-4.6), noncompliance (OR-80.1; 95%CI: 9.8-664.6) and lack of statin use (OR-2.7; 95%CI: 1.2-6.1).

Conclusion: Bismuth-based quadruple therapy and concomitant quadruple therapy are the most effective therapeutic regimens. To achieve the best eradication rates, attention should be direct to significantly modifiable factors such as non-compliance or absence of concomitant statin use.

Disclosure: Nothing to disclose.

Introduction: A few studies have suggested the association between *Helicobacter pylori* (HP) infection and atherosclerosis including coronary heart disease and ischemic stroke. However, the effect of HP eradication on ischemic stroke has not been well evaluated, so far.

Aims & Methods: The objective of this study was twofold: (1) to compare the risks of ischemic stroke and cerebral atherosclerosis as a pre-clinical stage of ischemic stroke according to HP eradication status among HP-infected patients (HP-eradicated vs. HP-non-eradicated), and (2) to compare these risks in HP-eradicated patients to those in HP-naive subjects.

We conducted a prospective observational cohort study. HP tests with gastroscopy were performed in Seoul National University Bundang Hospital from May 2003 to February 2023. HP infection was diagnosed through ≥1 findings of histopathology, rapid urease test or culture.

Propensity score matching for each group was calculated with relevant covariates, including age, sex, alcohol, smoking, hypertension, diabetes mellitus, dyslipidemia, atrial fibrillation, and aspirin intake. Patients in HP-eradicated group were matched in a 2:1 and 1:1 ratio with patients in HP-non-eradicated and HP-naive groups, respectively. Ischemic stroke and cerebral atherosclerosis were confirmed by brain MRI. The risk of ischemic stroke and cerebral atherosclerosis was analyzed using Cox-proportional hazard regression analysis.

Results: A total of 8,025 patients were included. After 2:1 matching, HP-eradicated group comprised 2,030 patients and HP-non-eradicated group comprised 1,015 patients(Figure). In a Cox-proportional hazard analysis, HP-eradicated group was associated with a significantly lower risk of ischemic stroke and cerebral atherosclerosis (hazard ratio [HR] 0.651, 95% confidence interval [CI] 0.451-0.941, p=0.026) (Table). In a second analysis, we included 2,064 patients with HP-eradicated and 2,064 HP-naive subjects, after PSM at a 1:1 ratio. In a Cox-proportional hazard analysis, the risk of ischemic stroke and cerebral atherosclerosis was not significantly different between the two groups (HR 1.109, 95% CI 0.777-1.584, p=0.569).

Variables	Univariate analysis			Multivariate		
	HR	95% CI	*p*-value	HR	95% CI	*p*-value
HP-eradicated	0.649	0.451 - 0.936	0.021	0.651	0.451 - 0.941	**0.026**
Age	1.043	1.028 - 1.059	<.001	1.027	1.010 - 1.043	**0.001**
Sex	1.769	1.235 - 2.532	0.002	1.500	1.042 - 2.159	**0.029**
Diabetes	2.626	1.713 - 4.025	<.001	1.263	0.778 - 2.049	0.345
Hypertension	3.175	2.226 - 4.529	<.001	1.800	1.178 - 2.049	**0.007**
Dyslipidemia	2.486	1.744 - 3.543	<.001	1.568	1.042 - 2.360	**0.031**
Atrial fibrillation	3.049	1.776 - 5.237	<.001	1.771	1.007 - 3.112	**0.047**
Aspirin	2.510	1.690 - 3.727	<.001	0.971	0.608 - 1.551	0.903

Table. Univariate and multivariate analysis of potential risk factors for ischemic stroke and cerebrovascular atherosclerosis in patients after propensity-score matching between HP-eradicated and HP-non-eradicated group

Conclusion: This large prospective observational cohort study suggested that HP eradication has preventive effect on the ischemic stroke and cerebral atherosclerosis.

Disclosure: Nothing to disclose.

PP0348

THE EFFICACY AND SAFETY OF VONOPRAZAN IN DUAL/TRIPLE/QUADRUPLE REGIMENS BOTH IN FIRST-LINE AND RESCUE THERAPY FOR *HELICOBACTER PYLORI* ERADICATION: A SYSTEMATIC REVIEW WITH META-ANALYSIS

B. Martínez[1], O. P. Nyssen[1], J. P. Gisbert[1]

Introduction: The efficacy of *Helicobacter pylori* (*H. pylori*) eradication regimens containing a proton pump inhibitor (PPI) plus antibiotics has gradually declined in recent years due to higher rates of antimicrobial resistance and insufficient acid inhibition. Vonoprazan (VPZ) is a novel potassium-competitive acid blocker which provides a stronger and longer-lasting effect on gastric acid suppression than PPIs. Our objective was to perform a systematic review and meta-analysis evaluating the efficacy and safety of VPZ for *H. pylori* eradication.

Aims & Methods: We conducted bibliographical searches in PubMed, Embase and the Cochrane Library up to April 2023. *Selection*: studies evaluating the use of VPZ in the eradication treatment. *Outcomes*: Efficacy was assessed by intention-to-treat analysis. Safety was also evaluated. Results were combined by meta-analysing risk differences (RD) and were stratified by dual, triple and quadruple therapy, first-line and rescue therapy, and by the presence of clarithromycin resistance.

Results: Overall, 75 studies were included, evaluating 44,992 patients, where 22,264 had received VPZ and 22,658 a PPI-based eradication therapy. The overall eradication rate with VPZ was 88% (95%CI=87-90%, 75 studies, I^2=88%). When only RCTs were considered, similar results were obtained (87%, 95%CI=85-90%, 35 studies I^2=84%).

When comparing dual, triple and quadruple VPZ-containing therapies, a tendency towards better efficacy with those regimens using a greater number of antibiotics was observed: 85%, 88% and 95%, respectively. However, when we compared the eradication rates between VPZ-based dual vs. triple regimens, no significant differences were reported, either in the overall analysis (P=0.17) or in the meta-analysis of studies directly comparing these regimens (P=0.21).

The eradication rate with VPZ-based therapy in first-line was 87% (95%CI=86-89%, 55 studies, I^2=89%), and 90% (95%CI=87-93%, 37 studies, I^2=84%) when used as rescue therapy. Among treatment-naïve patients, a significant superiority in the VPZ vs. PPI-based regimens was reported (87% vs. 70% respectively; RD=0.12, 95%CI=0.10-0.14, P<0.00001, I^2=83%). However, no significant differences were shown between VPZ and PPIs when used in rescue therapy. When focusing on RCTs only, similar results were obtained.

Among those patients with clarithromycin-resistant strains, an overall efficacy of VPZ-based therapies was 81% (95%CI=75-85%, 18 studies, I^2=60%), while in those with clarithromycin-susceptible strains it was 92% (95%CI=89-95%, 18 studies, I^2=87%). We found a significant superiority of VPZ vs. PPIs (75% vs. 39%; RD=0.35, 95%CI=0.27-0.42, P<0.00001, 7 studies, 797 patients) in clarithromycin-resistant patients; whereas no significant differences were found in the clarithromycin-susceptible group. RCTs subgroup analysis showed similar results.

The overall incidence of adverse events with VPZ was 18% (95%CI=15-20%, 69 studies, I^2=97%). No significant differences were found between VPZ and PPIs regimens tolerability.

Conclusion: The efficacy of VPZ-based regimens was over 85% in all treatments evaluated. The advantage of triple over dual VPZ could not be demonstrated in direct comparisons. In treatment-naïve patients as well as in those cases with clarithromycin-resistant strains, VPZ-based regimens performed better than PPIs-based ones; however, in rescue therapy and in clarithromycin-susceptible patients, this advantage was not confirmed. Tolerability was similar in both VPZ and PPIs regimens.

Introduction: Corpus atrophic gastritis(CAG) is a disease characterized by impaired gastric acid secretion and hypochlorhydria with increased risk of gastric cancer, especially in patients with *Helicobacter pylori*(Hp) infection. Efficacy of eradication therapy regimens(ETR) are commonly reported in association with pump pomp inhibitors(PPIs). In CAG patients, PPIs are not indicated. The efficacy of ETR without PPIs may be different from that with PPIs. Data on the efficacy and safety of ETR without use of PPIs in the CAG patients are lacking.

Aims & Methods: This study aimed to assess the eradication rate(ER) and safety of modified ETR with single-pill bismuth-based therapy without PPIs(SPBTnoPPIs) compared to (i) other ETR, amoxicillin-based therapy, without PPIs(ABTnoPPIs) in CAG patients, and (ii) ETR with SPBT therapy with PPIs(SPBTandPPIs) in no-CAG patients, in the first-line treatment of Hp infection.

In this retrospective study, a total of 113 consecutive patients histologically Hp positive were included between 2001 and 2020: CAG was diagnosed in 76 patients [77.6% females, median age 58.5 years(26-88)], and 37 patients were not affected by CAG [51.4% females, median age 58(22-81)].

CAG patients received SPBTnoPPIs: a modified ETR with SPBT(containing bismuth, tetracycline, metronidazole) without PPIs for 13 days, 3 pills t.i.d. since 2015(when placed on the market), or ABTnoPPIs: a sequential or concomitant amoxicillin-based therapy with or without bismuth, without PPIs before 2015. No-CAG patients received SPBTandPPIs: SPBT for 13 days, 3 pills t.i.d., with single dose of PPI in the morning, 30 min before breakfast.

The efficacy of Hp treatment was assessed by histopathology in all patients at 6 ± 3 months after treatment. Biopsy protocol and histopathological evaluation were performed according to the updated Sydney system. ER was expressed according to intention-to-treat(ITT) and per-protocol(PP) approach.

Results: 46 and 30 CAG patients underwent SPBTnoPPIs and ABTnoPPIs, respectively. 3(6.5%) patients on SPBTnoPPIs and 2(6.7%) patients on ABTnoPPIs did not complete therapy(by patient's decision)(p=1.00).

The 37 no-CAG patients were treated with SPBTandPPIs. No patients in this group interrupted the therapy.

In CAG patients, the overall ER at ITT and PP-analysis was 88.2% and 90.1%, respectively. In no-CAG patients, the overall ER was 80.4%(both at ITT and PP-analysis).

CAG-patients treated with SPBTnoPPIs compared to ABTnoPPIs showed a significantly higher ER at ITT-analysis(p=0.02) and at PP-analysis(p=0.01).

CAG-patients treated with SPBTnoPPIs compared to no-CAG patients received SPBTandPPIs showed a higher ER at ITT-analysis(p=0.07), and a significantly higher ER at PP-analysis(p=0.02)(Table1).

4 CAG-patients(8.7%) patients on SPBTnoPPIs reported mild adverse events(1 abdominal discomfort, 1 nausea, 1 vomit, 1 diarrhea) compared to 2(6.7%) CAG-patients on ABTnoPPIs(1 abdominal discomfort, 1 vomit) (p=1.00). No-CAG patients did not report any adverse events(p=0.125).

n(%) * SPBTnoPPIs vs ABTnoPPIs ** SPBTnoPPIs vs SPBTandPPIs	SPBTnoPPIs n=46	ABTnoPPIs n=30	SPBTandPPIs n=37	*p**	*p***
ER at ITT analysis	44 (95.7)	23 (76.7)	30 (81.1)	0.024	0.071
ER at PP analysis	42 (97.7)	22 (78.6)	30 (81.1)	0.013	0.022

Table.

Conclusion: A modified SPBT regimen without PPIs(3 days more but less pills/day) showed a high ER of about 95% in CAG patients with good compliance and tolerability.

This theraputical regimen may be considered beneficial in patients with CAG and it may be considered as first-line therapy in this specific setting.

Disclosure: Nothing to disclose.

Introduction: *H. pylori* represents one of the most widespread bacterial infections worldwide and increases the risk of gastric adenocarcinoma and lymphoma. It has been designated a Class I carcinogen by the WHO which leads to the recommendation that all infected patients should be treated [1,2].

Clarithromycin is a key antibiotic in the treatment of *H.pylori* infection and according to the recent Maastricht VI Consensus Report, empirical treatments for *H. pylori* eradication should be based on clarithromycin resistance rates. When individual susceptibility testing is not available, the recommended first-line empirical treatment differs according to the local rate of resistance to this antibiotic [3,4,5].

As gastric biopsy culture is invasive and expensive, this technique is mainly performed following treatment failure. However, clarithromycin resistance rates should be studied in different regions of the world according to the fore mentioned recommendations.

Aims & Methods: The aim of this study was to describe the antibiotic resistance profile of *H.pylori* isolates from gastric biopsies in our geographical area.

A prospective study was performed from October 2021 to December 2022 in our Hospital, a referral tertiary hospital covering an area of 340,000 inhabitants. Gastric biopsies from patients that underwent gastric endoscopy routinely were collected and immediately transported to the laboratory of Microbiology for *H. pylori* culture and antibiotic susceptibility testing (AST). Pathological Anatomy (PA) results and empirical treatment data were collected from medical records.

Results: 641 gastric biopsies were cultured and *H. pylori* was isolated in 148 by microbiological culture (positivity rate of culture: 22.2%). The median age of patients was 58 years; 52% of them were women and 84.7% were outpatients.

141 out of 148 isolates were available for AST. Most *H. pylori* isolates (60.3%) were susceptible to all tested antibiotics. Metronidazole and levofloxacin resistance rates were 17%.

Rates of resistance to clarithromycin, rifampicin and amoxicillin were 12%, 4.3% and 3.5% respectively. None of the isolates was resistant to tetracycline.

Co-resistance to two antibiotics was detected in 8.5 % of the isolates. The resistance phenotype levofloxacin and clarithromycin was the most frequent co-resistance detected (n=5). Four isolates (2.8%) were resistant to three antibiotics concomitantly. Two of them presented the triple amoxicillin, levofloxacin and metronidazole resistance.

Dual clarithromycin and metronidazole resistance was found in one isolate and another isolate presented the triple clarithromycin, metronidazole and levofloxacin resistance.

The multiplex real-time PCR assay that detects the most frequent mutations associated with clarithromycin resistance in *H. pylori* was performed on 84 biopsies. The most frequent detected mutation was A2143G (78.9%), followed by A2142G (21.1%).

PA results were available in 623 of 641 cultured biopsies. Results were coincident in 93.4 % of the specimens processed by PA and Microbiology.

Conclusion: The lack of resistance to tetracycline in our isolates suggests that the use of this antibiotic in bismuth containing quadruple therapies could be a good option. Clarithromycin resistance rate below 15% and the high rates of metronidazole resistance may support the use of triple therapy with clarithromycin, amoxicillin and PPI in our area.

As antibiotic susceptibility patterns depend on each geographical area and may vary over time, empirical antibiotic treatments for *H. pylori* infection should be based on local information.PA results were available in 623 of 641 cultured biopsies. Results were coincident in 93.4 % of the specimens processed by PA and Microbiology.

Introduction: *Helicobacter Pylori* (*H. pylori*) infection is a major cause of cause peptic ulcer, cancer, MALT lymphoma, etc. Bismuth-containing quadruple therapy for 14 days is the main eradication program recommended by the current guidelines[1-3]. However, the optimal duration for *H. pylori* eradication therapy remains controversial.

Aims & Methods: The aim of this study was to compare the clinical effect of the 10-day bismuth-containing quadruple treatment regimen with the 14-day regime in eradicating *H. pylori*. Eight hundred and forty-two *H. pylori* treatment-naïve patients were enrolled in the study and received bismuth-containing quadruple therapy: vonoprazan 20mg, bismuth potassium citrate 220mg, amoxicillin 1000mg twice daily, and clarithromycin 500mg twice daily (VBAC) or tetracycline 500mg (VBAT) four times daily.

And equally distributed to 10-day group or 14-day group. 624 subjects were included in the VBAC group, and 218 subjects were included in the VBAT group. Adverse effects and compliance of the subjects were recorded and ^{13}C-urea breath tests were performed six weeks after treatment.

Results: The intention-to-treat (ITT) eradication rates were 87.4% (373/427) and 86.7% (360/415) for the 10-day and 14-day group, respectively (p = 0.011). Per-protocol (PP) eradication rates were 92.8% (362/390) and 93.1% (350/376), respectively (p = 0.005). The VBAC regimen and the VBAT regimen were analyzed separately, and there was no significant difference in the eradication rates of 10-day and 14-day group. (VBAC: 10-day 91.4% vs 14-day 91.4%, VBAT: 10-day 97.0% vs 14-day 97.9% in PP analysis, and VBAC: 10-day 86.3% vs 14-day 85.4%, VBAT: 10-day 90.2% vs 14-day 90.6% in ITT analysis.)

Meanwhile, the incidence of adverse effects was lower in patients who received 10 days of treatment than in those who received 14 days of treatment (21.8% vs 32.7%). And there were no significant intergroup differences in compliance to treatment or discontinuation of therapy due to severe adverse effects.

Conclusion: The non-inferiority of 10-day to 14-day duration was demonstrated on vonoprazan-based bismuth-containing quadruple treatment. Compared to the 14-day bismuth-containing quadruple regimens, 10-day regimens had similar compliance and lower incidence of adverse effects. Therefore, 10-day vonoprazan-based bismuth-containing quadruple therapy may represent a new treatment option for *H. pylori*-positive patients and it has the potential to become a the preferred option for low-cost treatment.

PROTEIN-LIGAND DOCKING AND IN VITRO SCREENING AS A TOOL TO IDENTIFY LEAD HIT DRUGS TARGETING THE KEY SURVIVAL PURINE NUCLEOSIDE PHOSPHORYLASE (PNP) ENZYME OF *HELICOBACTER PYLORI*

T. Butler[1,2], S. Smith[1,2]

[2]*Tallaght University Hospital, Gastroenterology, Dublin, Ireland*

Contact E-Mail Address: thbutler@tcd.ie

Introduction: Resistance to many of the antibiotics used to treat Helicobacter pylori (HP) infection is on the rise. Indeed, the WHO has included *H. pylori* on their priority list of antibiotic-resistant bacteria to guide research and development into novel antimicrobials. To this end, computer aided drug design was deployed against the purine nucleoside phosphorylase enzyme (PNP), a key survival enzyme of HP. Protein-ligand docking of 550k+ compounds was carried out against the enzyme and the lead candidate antimicrobials testing against clinical isolates of the bacterium.

Aims & Methods: Our study aims were:

i. To perform *in silico* protein-ligand docking to identify compounds with potential inhibitory activity against HP via potential PNP enzyme inhibition,

ii. And to test the in vitro antimicrobial and cytotoxicity activity of the compounds on clinical isolates of HP and the gastric epithelial cell line AGS.

Methods: The binding site of the PNP enzyme was analysed using computational tools and a library of compounds was virtually screened via protein ligand docking, carried out on the Irish Centre for High End Computing's supercomputer "Kay", to identify several lead-hits to carry forward to *in vitro* screening. Lead-hits were tested for antimicrobial efficacy against reference strains (J99 and ATCC60190) and clinical isolates of HP using a broth microdilution approach. Clarithromycin was used as a positive control. Selectivity was established using a viability assay with a stomach epithelial cell line AGS.

Results: 7 lead-hits were selected from protein-ligand docking and tested *in vitro*. All compounds showed antimicrobial activity against the reference strains and both clarithromycin-sensitive and clarithromycin-resistant clinical isolates of HP (MIC_{50} 4.34– 73 µg/mL). 2 compounds showed significant selectivity against human cells, having no activity on the viability of human gastric cells.

Conclusion: Protein-ligand docking provided a cost-efficient method to identify, selective antimicrobial agents for *H. pylori* resulting in the identification of several lead targets that may be further developed to increase selectivity and potency.

Disclosure: Nothing to disclose.

Introduction: Hp infection produces chronic gastric inflammation which could eventually lead to atrophic changes. However, endoscopic recognition of atrophy could be challenging in inflamed gastric mucosa.

Aims & Methods: To evaluate the influence of Helicobacter pylori (Hp) infection on the diagnostic accuracy of endoscopic gastric atrophy (GA) in clinical practice.

Routine gastroscopies were performed prospectively by eight endoscopists in three hospitals in Spain. We used high-definition endoscopes and SFI virtual chromoendoscopy (Sonoscape®). Endoscopic diagnosis of GA was made using the Kimura-Takemoto (KT) classification. Biopsies and histological diagnosis were performed according to the updated Sydney consensus.

Results: We included 318 gastroscopies. The mean age was 57 (SD±15) years old and 193 (60%) were women. Histological atrophy was reported in 94 (30%) patients and 17 (5.5%) had high-risk GA (OLGA III-IV). Fifty-four (17%) patients were Hp(+) on the histology (±urease test). Hp status by non-invasive methods before the gastroscopy was unknown in 207 (65%) cases and this group included 46/54 (85%) of all positive cases. Sensitivity in the antrum was 49% [Hp(+) 23% vs Hp(-) 58%, p=0.03] and in the body 73% [Hp(+) 27% vs Hp(-) 88%, p<0.01].

Specificity in the antrum was 76% [Hp(+) 75% vs Hp(-) 76%, p=0.9] and in the body 84% [Hp(+) 81% vs Hp(-) 84%, p=0.7]. Diagnostic accuracy in the antrum was 71% [Hp(+) 60% vs Hp(-) 73%, p=0.08] and in the body 82% [Hp(+) 67% vs Hp(-) 85%, p<0.01].

Conclusion: Endoscopic diagnosis of GA had a high diagnostic yield mainly in the body and Hp-negative patients. Hp eradication before a routine gastroscopy should be advised to improve the optical diagnosis of gastric atrophy.

Introduction: Gastric cancer is a relevant cause of cancer-related death, often diagnosed at late stages. Intestinal-type gastric cancer develops through a preneoplastic cascade via atrophic gastritis and intestinal metaplasia.

Patients with advanced gastric atrophy and intestinal metaplasia are at increased risk of developing gastric cancer and need endoscopic surveillance.

However, screening endoscopy is not cost-effective in low-to-medium prevalence regions. A non-invasive screening test for detecting advanced gastric atrophy is desired. GastroPanel®, a serologic panel of markers related to gastric physiology (Pepsinogen I, Pepsinogen II, Gastrin17, Helicobacter pylori antibodies), has limited sensitivity for detection of advanced atrophic gastritis.

The digestive hormones Ghrelin and Leptin are produced in a significant fraction by gastric epithelial cells, but their role for detecting advanced gastric atrophy and intestinal metaplasia is unclear.

Aims & Methods: This study investigates the additional benefit of determining serum levels of Ghrelin and Leptin together with GastroPanel® for non-invasive detection of advanced gastric lesions.

Serum levels of Pepsinogen I, Pepsinogen II, Gastrin17, H. pylori antibodies, Ghrelin and Leptin were measured in a cohort of n=351 individuals with endoscopic and histologic characterization of the stomach and standardized grading of gastritis (operative link for gastritis assessment / operative link on intestinal metaplasia assessment, OLGA/OLGIM).

Receiver operating characteristic (ROC) curves were built to calculate the area under the curve (AUC) and threshold optimization was applied to calculated the diagnostic performance of each individual blood parameter for OLGA/OLGIM stages 3/4.

The dataset was randomly split into a training and testing set and a logistic regression model with 10-fold cross-validation was developed for OLGA/OLGIM stages 3/4 and serum levels of Pepsinogen I, Pepsinogen II, Gastrin17, H. pylori antibodies, Ghrelin and Leptin. The model was applied to the testing set, ROC curves were built to compute the AUC and diagnostic performance was calculated.

Results: The prevalence of OLGA/OLGIM stages 3/4 in the cohort was 13.8% (95% CI 0.11 – 0.17 %, n=72.

For individual serum markers, the diagnostic power for OLGA/OLGIM 3/4 was AUC = 0.625 (PGI), AUC = 0.523 (PGII), AUC = 0.611 (Gastrin17), AUC = 0.524 (H. pylori antibodies), AUC = 0.645 (Ghrelin), AUC 0.528 (Leptin).

Combining serum levels of Pepsinogen I, Pepsinogen II, Gastrin17 and H. pylori titers (GastroPanel®) in a logistic regression model reaches an AUC = 0.676, accuracy = 0.833 (95% CI 0.747 – 0.890), sensitivity = 0.882, specificity = 0.333, PPV = 0.932, NPV = 0.214.

Adding serum levels of Ghrelin and Leptin to the model did not increase diagnostic power (AUC = 0.620, accuracy 0.827 (95% CI 0.744 – 0.893), sensitivity = 0.890, specificity = 0.200, PPV = 0.918, NPV = 0.154).

Conclusion: The diagnostic value for detecting advanced gastric atrophy and intestinal metaplasia via serum Pepsinogen I, Pepsinogen II, Gastrin17 and H. pylori antibodies is limited. This is not improved by the addition of serum Ghrelin and Leptin.

INCIDENCE OF HELICOBACTER PYLORI INFECTION IN GASTRIC CANCER PATIENTS IN ALBANIA: ASSOCIATION WITH HISTOPATHOLOGICAL FORMS AND CLINICAL CHARACTERISTICS - A SINGLE-CENTER STUDY

I. Agolli[1], X. Pemaj[1], I. Bibolli[1]
[1]University Clinic of Gastroenterology, University Hospital Center Mother Teresa, Tirana, Albania

Contact E-Mail Address: rcitozi@gmail.com
Introduction: Helicobacter Pylori (H. Pylori) is present in about half of the world's population and it is the leading cause of infection-related cancers, including gastric adenocarcinoma and mucosa-associated lymphoid tissue lymphoma. Various studies have shown that H. Pylori is highly prevalent in Albania.
Aims & Methods: The aim of this study is to evaluate presence of H. Pylori infection in patients with gastric cancer with the purpose of providing insights for clinical management and treatment decisions. This was a single-center prospective study, conducted at University Clinic of Gastrohepatology at the University Hospital Center Mother Teresa in Tirana, Albania from 2021 to 2022. The study included patients presented at our endoscopy unit that were diagnosed with gastric neoplasm, without any history of familial or hereditary cancer. Demographic, clinical, radiological and laboratory data were collected for each patient. Based on tumor histology they were divided in two groups: gastric adenocarcinoma and lymphoma. We studied the presence of Helicobacter Pylori infection in patients with gastric cancer and its association with the histological, clinical and laboratory characteristics of these patients. The data were analyzed using SPSS statistical package version 23.0.
Results: A total of 50 patients 32 (64%) male and 18 (36%) female with a mean age of 64.5 ± 11.8 years [38-85] were included in this study. 92% had gastric adenocarcinoma while only 8 % had gastric lymphoma. Helicobacter pylori was found present in 82% of the studied patients. Among the histopathological forms, the presence of H. pylori was predominantly observed in 100% (4 patients) of lymphomas and 80 % (37 patients) of adenocarcinomas (93.8% of patients with moderately differentiated adenocarcinoma). No significant association was observed between the presence of H. pylori infection and histopathological diagnosis ($p = 0.33$) or staging ($p = 0.358$). However, the presence of H. pylori infection was significantly associated with a higher incidence of distal cancer compared to proximal cancer (60% vs 12%; $p = 0.002$. Furthermore, the average levels of CEA were significantly higher in patients with adenocarcinoma compared to lymphoma ($p = 0.035$).
Conclusion: Our study demonstrated that Helicobacter pylori infection is highly prevalent among patients with gastric cancer, with a higher incidence observed in patients with distal cancer compared to proximal cancer. However, no significant association was observed between the presence of H. pylori infection and histopathological diagnosis or staging. CEA levels were found to be significantly higher in patients with adenocarcinoma compared to lymphoma, which may indicate its potential utility as a diagnostic marker. These findings may have implications for the management and diagnosis of patients with gastric cancer.
Disclosure: Nothing to disclose.

Introduction: Patients with an ileostomy often have impaired quality of life, sodium depletion, secondary hyperaldosteronism, and other organ-specific pathologies. The osmolality of oral supplements influences ileostomy output and sodium loss.

Aims & Methods: We hypothesized the existence of an osmolality range where fluid absorption and secondary natriuresis are optimal. This was a single-center, quasi-randomized crossover intervention study, including patients with an ileostomy and no home parenteral support.

After an 8-hour fasting period, each patient ingested 500 mL of between 3 and 18 different oral supplements and a standardized meal during separate intervention periods, followed by a 6-hour collection of ileostomy and urine outputs. The primary outcome was 6-hour ileostomy output.

Results: A total of 14 adult patients with an ileostomy (median age 64.5 years (range 22 - 77)) were included. The association between osmolalities in the entire range of 5-1352 mOsm/kg and ileostomy output forecasted an S-curve. In a mixed-effect model with the patients as a random effect, we observed a linear association between the osmolality of oral supplements in the range of 290-600 mOsm/kg and ileostomy output, which increased with 57g/6 hours (95% CI 21 – 94) when the oral supplement osmolality increased 100 mOsm/kg ($p<0.005$).

Conclusion: Osmolality in oral supplements correlated with ileostomy output in patients with an ileostomy. Our results indicate that patients with an ileostomy may benefit from increasing their ingestion of oral supplements with osmolalities between 100 and 290 mOsm /kg. We suggest this range is called the Goldilocks zone, indicating optimal fluid absorption.

Introduction: Loop ileostomy has been reported to reduce the risk of leakage and reoperation in patients undergoing sphincter-preserving surgery. The structural and functional changes in the loop ileostomy may contribute to the development of ileus, such as decreased motility of smooth muscle and villous atrophy.

Aims & Methods: This study is to investigate the morphological, functional, and molecular changes of the distal limb after ileostomy and subsequent takedown.

Human ileum samples were obtained from patients who underwent diversion ileostomy after rectal cancer surgery and subsequently had ileostomy takedown. Samples were collected from the tips of the proximal and distal limbs. The whole layer of ileum was prepared for HE staining and the muscle layer which the mucosal layer was removed was prepared for motility measurement. The muscle strips (5x2 mm) were mounted to an isometric force transducer (Biopac Systems, Inc., Goleta, CA, USA) and suspended in 10 ml organ bath containing aerated (97% O_2 and 3% CO_2) and pre-warmed (36.5 ± 0.5°C) KRB solution.

Amplitude (mN) and area under the curve (AUC) of contractions were measured and analyzed. To compare myogenic contraction and relaxation between the proximal and distal limbs of ileostomy, we administrated acetylcholine (ACh), potassium chloride (KCl) and sodium nitroprusside (SNP) in human ileal strips. Quantitative real-time polymerase chain reaction (qPCR) was performed for quantitative analysis of the expression of VAChT and NOS, cholinergic and nitrergic neuronal markers, and UCHL1 and MYH11, neuronal and smooth muscle cell marker, respectively.

Results: The height of the villi and the thickness of the mucosa, submucosa and muscle layer of the distal limb decreased significantly compared to those of the proximal limb. In the contractile responses to ACh and KCl, the amplitude and AUC of contractions in the distal limb were smaller than in the proximal limb in a dose-dependent manner. The relaxation response to the SNP in the distal limb was reduced compared to the proximal limb. Expressions of VAChT which is related with cholinergic neurotransmission, UCHL1 and MYH11 were not different in both proximal and distal limbs. However, expression of NOS1 which is related with nitrergic neurotransmission was increased significantly in the distal limb compared to the proximal limb. In addition, number of interstitial cells (ICC and PDGFRa$^+$ cell) in muscle layer was not different in both proximal and distal limbs.

Conclusion: These results demonstrate that the distal limb which was not in use for a certain period of time after fecal diversion was morphologically atrophied and its motility was also impaired. Both myogenic contractile and relaxation responses were reduced in the distal limb of ileostomy although nitrergic neurons increased in the distal limb to compensate for the reduced relaxation response. These findings suggest that stimulating the distal limb can induce relaxation and may be a way to prevent ileus, which can occur after ileostomy takedown.

Introduction: Potential therapeutic effects of natural compounds, such as grape polyphenols, have been suggested in the prevention and treatment of mucositis induced by radiotherapy or bacterial infections. Lipopolysaccharide (LPS) significantly increases the paracellular permeability of gut epithelium downregulating the expression of tight junctions. In this study, the protective effect of proanthocyanidin-rich grape seed extract (GSE) was investigated on epithelial barrier damage and ROS production induced by LPS and ionizing radiations in an in vitro model.

Aims & Methods: GSE chemical analysis was performed by high-performance liquid chromatography (HPLC-DAD) and nuclear magnetic resonance (NMR).

Human intestinal epithelial cell line Caco-2, previously treated with LPS [10 µg/m] (pathogenic strain of Escherichia Coli 0111:B4) [1], GSE [6,25 mg/ml] and LPS + GSE, were irradiated with 10 Gy subdivided in 5 daily fractions using TrueBeam™ radiotherapy system by Varian Medical System. Epithelial barrier integrity was investigated measuring the paracellular flux of fluorescein isothiocyanate-dextran (FD-4) [1] and ROS production was assessed by adding 2′,7′-dichlorodihydrofluorescein diacetate (H2-DCF-DA) [3] using a multiplate reader (Tecan). Each experiment was performed twice in triplicates with independent controls among the three conditions.

Results: HPLC-DAD and NMR revealed a 70% content of total procyanidins in both the extract obtained from the virgin hydroalcoholic mixture and quantify 24 metabolites classified as amino acids, organic acids, classified as amino acids, organic acids, carbohydrates and miscellaneous molecules. Among them, it is interesting the presence of ascorbate, procyanidin B1 and polymeric procyanidins.

Our *in vitro* experiments showed a significant increased permeability was observed in LPS-treated cells over time compared to control (5.215 vs 0.3418; p<0.05), which is prevented by co-treatment with GSE (5.215 vs 0.3407; p<0.05).

Irradiation significantly increased intestinal permeability over time and in a dose dependent manner compared to control both in Caco2 cells without LPS treatment (at day 5 with maximal dose of 10 Gy: 3.64 vs 0.441; p<0.05) and in LPS-treated cells (25.5 vs 2.42; p<0.05). GSE treatment significantly reduced this damage in both conditions (25.5 vs 2.04; p<0.05 and 38.87 vs 2.675; p<0.05 respectively).

Moreover, LPS significantly increased ROS production in Caco2 cells (12,9 vs 104; p<0.0001) and GSE treatment significantly prevented this damage (104 vs 11.3; p<0.0001).

Irradiation increased ROS production in LPS-treated cells (3056 vs 362; p<0.0001) and also in this case GSE treatment was able to reduce ROS production due to irradiation (502 vs 357; p<0.0001). this beneficial effect was observed also in LPS treated cells and then exposed to irradiation (3056 vs 681; p<0.0001).

Conclusion: In an *in vitro* model, GSE is able to prevent the intestinal epithelium permeability damage and ROS production induced by LPS and by ionizing radiations suggesting a potential therapeutic effect.

Further studies are needed to better understand the mechanism underlying radiation-induced mucositis and the antioxidant effect of GSE in its prevention and management.

Introduction: Pediatric patients with recurrent functional abdominal pain (RAP) may associate small intestinal bacterial overgrowth (SIBO). Also, children with known atopy may present RAP more frequently.

Aims & Methods: The objective of this research was to establish a potential conection between intestinal dysbiosis and alimentary or respiratory allergic diseases in children diagnosed with functional RAP. The authors conducted a randomized placebo controled prospective study. All consecutive pediatric patients diagnosed with RAP between January 2022 and January 2023 were enrroled in this study. All children undergone complet work up protocol to rule out organic causes for RAP. Glucose hydrogen breath test (GHBT) was performed to asses the presence of SIBO in every case. Also, all subjects were tested for allergies by assessing specific serum IgE level or by performing skin prick tests. The control lot included sex and aged matched healthy children that undergone GHBT. The study lots were statistically compared according to the distribution of SIBO and the presence of atopy.

Results: 258 patients with RAP were enrolled (148 females and 110 males). GHBT was positive in 136 patients (52,71%). From 230 control subjects, only 15 (6,52%) tested positive for SIBO (p=0.001 compared to RAP group). All controls were negative for atopy assessment. 78% of children with SIBO and RAP tested positive to allergy assessment compared to only 23% of patients without SIBO and presence of RAP (p=0.001). The odds ratio for developing an allergy in children with SIBO was 4.42 (95% CI, 1.85-14.24; p = 0.001).

Conclusion: There is a statistic correlation between alergic disorders (cow's milk protein allergy, atopic dermatitis, allergic rhinitis) and SIBO in children with RAP. Therefore, in pediatric patients with RAP and atopy, SIBO should be investigated and treated accordingly to alleviate symptoms.

Disclosure: There is no conflict of interest.

ANTI-INFLAMMATORY EFFECTS OF *SACCHAROMYCES BOULARDII* CNCM I-745 IN A MOUSE MODEL OF PROXIMAL SMALL INTESTINE GLUTEN-RELATED DISEASE

E. Miculan[1], C. Stefanelli[1], M.L. Iribarren[1], G. Ducca[1], A. Lezcano[1], G. Perez Tolosa[1], C. Ruera[1], F. Chirdo[1]
[1]Instituto de Estudios Inmunologicos y Fisiopatologicos (IIFP) (UNLP-CONICET), Facultad de Ciencias Exactas. Universidad Nacional de La Plata, La Plata, Argentina

Contact E-Mail Address: fchirdo@gmail.com

Introduction: *Saccharomyces boulardii* CNCM I-745 probiotic properties have been demonstrated for decades. The exact mechanisms behind these beneficial effects are widely documented, notably anti-inflammatory properties and preservation of the intestinal barrier integrity. However most of the current knowledge was obtained from studies focusing on infectious or inflammatory colonic diseases and very little is known regarding the effects of this yeast on small intestine pathologies.

In previous work, we showed that after oral gavage of p31-43 gliadin peptide, a fragment of gluten-derived peptides that neither binds to HLA class II molecules nor induces T cell activation, is responsible for toxic effects and strong inflammatory responses in the proximal small intestine (Gomes Castro et al., 2019, Ruera C et al, 2020). In this mouse model, intragastric administration of p31-43 elicits mucosal damage in small intestinal together with the production of inflammatory mediators, inflammasome activation, and cell death.

Aims & Methods: Aim: To study the effects of *S. boulardii* pre-treatment on the inflammatory response in the proximal small intestine in a mouse model of sterile inflammation induced by p31-43.

Materials and methods: Seven week-old C57BL/6 mice were housed under specific pathogen-free conditions and allowed access to autoclaved food and water *ad libitum*. A three-weeks pretreating phase by gavage with *S. boulardii* CNCM I-745 (3g/kg/day) or vehicle (Phosphate-buffered saline, PBS), was performed. Then, a single dose of 20µg of p31-43 gliadin peptide (LGQQQPFPPQQPY, at > 95% purity) per mouse or PBS, was delivered by intragastric administration. Mice were euthanized 4 or 16 hours after challenge and proximal small intestine was sampled to perform different histological analysis: villus high/crypt depth (V/C) ratio, intraepithelial lymphocytes (IELs) counting, cell death by TUNEL staining. Assessment of the activation of caspase-1, a central mediator of inflammasome pathway, was performed by Western Blot on small intestinal samples. Statistics were performed using Anova Test.

Results: The evaluation of the histological changes at the proximal small intestine showed that administration of *S. boulardii* was able to prevent the damage induced by p31-43 for both 4h ($p< 0.01$) and 16h (<0.0003) after p31-43 treatment. This treatment also prevented mucosal IELs recruitment.

The assessment of cell death by TUNEL staining on sections of the small intestine showed that *S. boulardii* was effective to block the induction of cell death caused by p31-43 ($p< 0.005$).

Pretreatment with *S boulardii* before the p31-43 challenge reduced inflammasome activation by maintaining caspase-1 to basal levels ($p<0.01$).

Conclusion: Three-week phase of preconditioning with *S. boulardii* before the p31-43 treatment prevented intestinal macroscopic damage, the increase in IELs numbers, cell death and inflammasome activation. These findings show the beneficial effects of *S. boulardii* CNCM I-745 in proximal small intestine inflammatory conditions and may be of interest in celiac disease patients.

Introduction: Crohn's Disease (CD) is a chronic disease in which inflammation is sustained by continuous influx of inflammatory leukocytes into gut mucosa and may affect all segments of the gastrointestinal tract. Immune cell trafficking is regulated via chemokine gradients and adhesion molecules such as integrins. Here we explored the expression profile of gut-specific integrin and chemokine axes in different regions of the gut to identify possible targets for treating CD patients with different disease location or phenotype.

Aims & Methods: This study used transcriptomic data from gut tissue biopsies of the large and small intestine of 611 CD and 315 UC patients enrolled in a multicentred longitudinal Study of a Prospective Adult Research Cohort with IBD (SPARC IBD) obtained from the IBD Plexus program of the Crohn's and Colitis Foundation. We mapped the expression of selected chemokine receptors and their ligands as well as gut-specific integrins onto the different segments of the intestine. Expression data were then linked to available clinical disease phenotypes, as well as genotype information.

Results: In both CD and UC patients, ITGA4 and ITGB7, the targets for Vedolizumab, and their endothelial ligand MADCAM1 were ubiquitously present in all regions of the gut. GPR15 and its ligand C10orf99 were predominantly expressed in colonic biopsies.

On the contrary, expression of CCR9 and its ligand CCL25 were specific to the terminal ileum with only minimal transcriptional activity in the colon. Expression of CCL25 was significantly increased in patients with penetrating and/or stricturing CD, a disease feature associated with ileal CD that has high impact for patients and is currently an unmet for IBD patients. Further, we identified an expression quantitative trait loci (eQTL) upstream of the CCL25 promoter linked to small bowel expression of CCL25.

Conclusion: Our data highlight the potential for targeting the CCR9/CCL25 axis as a treatment for small bowel Crohn's Disease which may have been incompletely targeted to date by small molecule inhibitors.

Disclosure: All authors were employees of AstraZeneca during the conduct of the study and hold AstraZeneca stocks or stock options.

Introduction: Pathogens can translocate from the gut lumen to the systemic circulation while gut microbiota play an important role in maintaining an immunologically balanced inflammatory response and protecting against colonisation by invasive pathogens. Studies showed that among people with liver cirrhosis, proton-pump inhibitor (PPI) users had a higher risk of spontaneous bacterial peritonitis (SBP).

It has been hypothesised that PPI use can facilitate small intestinal bacterial overgrowth and related intestinal dysbiosis that lead to dysregulated bacterial translocation and subsequent SBP. However, the link between PPI use and systemic infectious complications secondary to bacterial translocation in non-cirrhotic patients is unclear.

Aims & Methods: This study aimed to investigate whether patients receiving PPI therapy have a higher risk for bloodstream infections (BSI) without an identifiable infectious focus, as an alternative indicator of BSI secondary to bacterial translocations. We conducted a hospital-based case–control study which enrolled all patients aged 20 years and older who developed BSI confirmed by two sets of positive blood culture and had inpatient care in Ichinomiya-Nishi Hospital in 2019. Patients' data were collected from medical records, and bacterial translocation type (BT-type) BSI group were defined as those who had BSI without an identifiable focus of infection, whereas the others were classified control group. PPI use at BSI onset was considered the primary exposure of interest.

To control for factors that were potentially associated with both PPI use and BSI, we retrieved data on the several factors and examined the potential confounders by using the Mantel–Haenszel stratified analyses. Logistic regression yielded adjusted odds ratios (OR) and 95% confidence intervals (CI) for BT-type BSI among PPI users and non-users. To address the possibility of outcome misclassification, we also conducted sensitivity analyses.

Results: We analysed data from 309 patients, including 66 cases (BT-type BSI group) and 243 controls. 152 patients (49%) were receiving continuous PPI therapy at BSI onset. The mean age was 78 years in both cases and controls. Patients on PPI therapy had a 2.4-fold higher risk of developing BT-type BSI compared to non-PPI-users after controlling for age, sex, the Charlson Comorbidity Index, liver cirrhosis, active gut disease, and onset location (OR: 2.41, 95% CI: 1.29–4.51). After adjustment, an association of PPI use with BT-type BSI (p=0.006) was observed. The results of the sensitivity analyses were consistent with the primary analysis.

Conclusion: PPI use is associated with higher risk of BSI without an identifiable infectious focus and therefore, PPI use may increase the risk of septic morbidity secondary to bacterial translocation.

Introduction: Cases of autochthonous *Strongyloides stercoralis* infection have been reported rarely in Northern Italy. There are no reports from Southern Italy. Since *S. stercoralis* may harbor in dogs and other farm animals, we aimed to investigate the prevalence of such infestation in farm workers in Southern Italy.

Aims & Methods: Capillary blood samples were drawn from farm and doghouse workers in the county area of Bari (South Italy). Screening test was a commercial ELISA test (Strongyloides ratti by Bordier Affinity Products SA). Serology-positive patients were offered Ivermectin therapy, single dose of 200 ug/Kg.

Patients underwent, at baseline and 4 months after therapy, clinical examination; severity of abdominal pain, diarrhea, skin rash, urticaria, asthma symptoms were estimates by a 10-point VAS scale. Stool consistency was classified according to the Bristol scale. Full blood count was also performed both at baseline and follow up. Data were expressed as median with interquartile range (IQR). Wilcoxon signed rank test was used for statistical analysis.

Results: Among 120 workers, 6 patients were serology- positive, with a prevalence of 5%. Two of them worked in doghouses. Abdominal pain was the most frequent symptom (3 patients, 50% cases), which resolved after therapy in all patients with VAS from 1 (IQR 0-5.8) to 0 (IQR 0-0), p=0.25. No variation in stool consistency was recorded (p=1).

Two patients complained of urticaria, which totally resolved in one subject and improved in the other one. Asthma was referred bytwo patients, with full clearancein one of them. We observed a non statistically significant trend of eosinophil count reduction, from 190/mm^3 (IQR 140-240) to 180/mm^3 (IQR 150-220), p=0.14.

Conclusion: In our area, the prevalence of the parasitosis is low. Therapy may be helpful to reduce the severity of some symptoms such as abdominal pain, asthma and urticaria. A marginal effect on eosinophils has been observed.

Disclosure: Nothing to disclose.

SYMPTOMS AND MEDICAL HISTORY DO NOT PREDICT HYDROGEN AND METHANE BREATH TEST OUTCOMES

J. Haworth[1], M. Otterstad[1], S. Treadway[1], N. Boyle[2], A.R. Hobson[1]
[1]Functional Gut Clinic, Manchester, United Kingdom, [2]RefluxUK, London, United Kingdom

Introduction: Recent societal guidelines suggest there is no role for hydrogen and methane breath testing (HMBT) to exclude small intestinal bacterial overgrowth (SIBO) in patients with diarrhoea predominant irritable bowel syndrome (IBS) and to treat symptoms with rifaximin empirically[1,2]. However, a positive result for SIBO with lactulose HMBT has been shown to predict more favourable outcomes to rifaximin in patients with diarrhoea predominant IBS[3].

We wanted to investigate if symptoms and medical history can predict lactulose HMBT outcome hence justifying treatment of SIBO without a formal diagnosis.

Aims & Methods: A large questionnaire-based study was conducted in over 1000 patients of which 731 completed lactulose HMBT. The 26-item questionnaire included questions about medical history, symptoms, and pattern of symptoms, and we used this to identify any positive predictors for SIBO on HMBT. A positive lactulose HMBT was determined by a rise of ≥20 ppm in breath hydrogen from baseline within 90 minutes[3].

Breath samples were analysed using gas chromatography. Associations and predictors were calculated using chi square tests and logistic regression, respectively.

Results: Bloating (93.6%), abdominal pain (87.3%), and diarrhoea (80.3%) were the most common symptoms reported by those with a positive result for SIBO, but their duration, frequency and onset were no different to patients with a negative result (P > 0.05). There were no positive predictors for SIBO on lactulose HMBT based on symptoms, medications or medical history except for chronic low ferritin (P = 0.025).

Conclusion: This large questionnaire study has demonstrated that symptoms and medical history cannot predict HMBT outcomes for SIBO. Therefore, treatment of SIBO without a diagnosis confirmed on HMBT may lead to unnecessary antibiotic use and costs.

Introduction: The serology, in terms of both positive anti-endomysial antibodies (EMA) and anti-tissue transglutaminases (a-tTG), plays a crucial role for coeliac disease (CD) diagnosis. More recently, deamidated anti-gliadin peptides (DGP) were added to the diagnostic work-up of CD in view of their accuracy. Strictly, EMA is an immunofluorescence-based tool, more expensive and operator-dependent than a-tTG and DGP (both based by ELISA).

Aims & Methods: To test the diagnostic accuracy of the a-tTG/DGP compared to the classical EMA/a-tTG combination for CD diagnosis.

From November 2020 to October 2022, we performed an observational prospective study including all consecutive adult patients with suspected CD. All subjects were tested for EMA (positive/negative), a-tTG (positive>7 U/mL) and DGP-IgA (positive>5.5 U/mL).

CD diagnosis was made in presence of Marsh ≥2 at histilogy, and positive EMA. A ROC curve was constructed to establish the best specificity cut-off of a-tTG and DGP levels, which would predict the presence of Marsh ≥2 and Marsh 3 at histology.

Furthermore, the diagnostic accuracy of the a-tTG/DG in comparison with EMA/a-tTG combination was performed. Also, a basic cost-analysis for the application of the two types of serological combination was effectuated.

Results: The study included 275 CD patients. Histology showed Marsh 1 in 9.9%, Marsh 2 in 4.5%, Marsh 3 in 85.6.%. The best cut-off value of a-tTG for predicting Marsh ≥2 was 42 U/mL (sensitivity 70%; specificity 100%; PPV 100%; NPV 24.1%) while it was 68.4 U/mL for atrophy (sensitivity 69%, specificity 100%; PPV 100%; NPV 31%). The best cut-off value of DGP for predicting Marsh ≥2 was 56 U/mL (sensitivity 59%, specificity 100%; PPV 100%; NPV 23%), being 78 U/mL for atrophy (sensitivity 68%; specificity 100%; PPV 100%; NPV 32.1%).

When considering the diagnostic accuracy of the serological combination, a-tTG/EMA showed: sensitivity 97%; specificity 100%, PPV 100%; NPV 97%; the a-tTG/DGP combination presented: sensitivity 94%, specificity of 100%, PPV 100% and NPV 93% (p=N.S.). About cost-analysis, when including our entire population, the use of the a-tTG/DGP combination determined a saving of about 3790E respect to a-tTG/EMA association.

Conclusion: The serological ELISA diagnostic combination of a-aTG/DGP is accurate for the diagnosis of CD and could reduce the costs and the operator-dependency of the EMA procedure. DGP could substitute EMA in combination with a-tTG for diagnosis of CD.

Disclosure: Nothing to disclose.

ANXIETY AND DEPRESSION IN INDIVIDUALS WITH UNTREATED CELIAC DISEASE

V. Sandaunet Fredriksen[1], E. Ness-Jensen[2]
[1]NTNU: Norwegian University of Science and Technology, HUNT Research Centre, Department of Public Health and Nursing, Trondheim, Norway, [2]NTNU, Norwegian University of Science and Technology, HUNT Research Centre, Department of Public Health and Nursing, Levanger, Norway

Contact E-Mail Address: vid.san.fre@gmail.com

Introduction: Celiac disease is an autoimmune disorder where the intake of gluten (a protein found in wheat, barley, and rye) causes damage to the small intestine and impairs nutrient absorption. Studies have shown that individuals with celiac disease have reduced quality of life and higher levels of anxiety and depression. However, this has not been studied in the general population, among individuals with newly discovered, untreated celiac disease.

Aims & Methods: The aim of this study was to investigate anxiety, depression, mental health, and subjective well-being in individuals with newly diagnosed and untreated celiac disease, compared with the general population.

This study used data from the fourth Trøndelag health study (HUNT4), conducted between 2017 and 2019 with over 56,000 adult participants from 20 years of age. Previously undiagnosed celiac disease was identified among the participants by analyses of blood samples from all participants and confirmed with endoscopy and duodenal biopsies.

The participants in HUNT4 also answered questionnaires measuring levels of anxiety and depression using the Hospital Anxiety and Depression Scale (HADS), mental distress using the Cohort of Norway Medical Health Index (Conor-MHI), and subjective well-being using a three-part questionnaire. Differences in mental health among individuals with newly diagnosed celiac disease and the remaining HUNT4 participants were compared.

Results: Celiac disease was diagnosed in 454 HUNT4 participants by March 2022. The celiac group had a lower median age (53 vs. 56 years) compared to the remaining HUNT4 population. The celiac group had significantly lower mean scores on the HADS anxiety subscale (4.0 vs. 4.4), depression subscale (2.8 vs. 3.3), and total scale (6.8 vs. 7.7) compared to the reference population.

On the CONOR-MHI scale, the celiac disease group had a lower total mean score (1.4 vs. 1.5) with lower scores in the categories of "secure and calm", "irritable", "happy and optimistic", "sad/depressed", and "lonely" compared to the reference population.

Finally, the celiac disease group had a lower mean score on the question "Do you feel mostly strong and clear, or tired and fatigued?" (3.3 vs. 3.4) and a higher mean score on the question "How is your health now?" (3.0 vs. 2.9) compared to the reference population. No significant difference was observed in the HADS or CONOR-MHI scores by Marsh grades at diagnosis among the celiac disease group.

Conclusion: The study suggests that individuals with undiagnosed celiac disease have lower levels of anxiety, depression, and mental distress compared to the general population, while also reporting slightly better subjective well-being. These findings contradict other studies on psychological health in celiac disease.

Contact E-Mail Address: Daniel.leffler@takeda.com

Introduction: Celiac disease (CeD) is a chronic, immune-mediated, systemic disorder characterized by inflammation of the small intestine and antibody formation in response to gluten ingestion. A gluten-free diet (GFD) has major limitations but is the only current treatment for CeD.

Aims & Methods: This US prospective observational study (Virtual Celiac Symptoms Study, NCT05309330) was conducted from July 25, 2022 to March 04, 2023 and aimed to assess experience with a GFD and celiac-related symptoms in patients with CeD.

Eligible participants were aged ≥12 years, had a CeD diagnosis for ≥1 year confirmed via self-reported biopsy and serology (or serology only for participants diagnosed at age <18 years), were on a GFD for ≥6 months and reported CeD-related symptoms in the past 3 months. Participants were recruited with the assistance of the Celiac Disease Foundation via digital advertisements and data were collected using an electronic patient-reported outcomes platform.

Study participants were followed up for 12 weeks and CeD-related symptoms and gluten exposure were assessed daily. Quality of life and healthcare resource utilization were also assessed. This analysis focuses on the adult participants' perception of their disease experience at study initiation.

Results: The baseline questionnaires were completed by 338 adult participants. The median age was 37 years (range 18–71), 88% were female and 99% were White. CeD-related symptoms were reported by 58% of participants in the past week. When questioned about occurrence of CeD symptoms, 23% reported "Chronic/ongoing CeD symptoms even when I don't think I've been exposed to gluten", 37% reported "CeD symptoms only while I am exposed to gluten or within a few days after exposure to gluten" and 36% reported "Chronic/ongoing CeD symptoms, but they are worse when I get exposed to gluten".

The most commonly reported symptoms were bloating (83%), tiredness (81%), abdominal pain (77%) and diarrhea (71%). All participants were following a GFD; 21% reported "never eating gluten accidentally or on purpose" and 71% reported "rarely eating gluten accidentally".

In total, 84% of participants reported that they were likely/extremely likely to experience CeD symptoms after gluten exposure. Symptom intensity was described as moderate or severe by 71% of participants, and 11% reported hospitalization or emergency department care due to CeD in the past year.

Conclusion: Despite high levels of reported adherence to a GFD, many patients still report CeD-related symptoms, especially in response to perceived gluten exposure. Symptoms were often reported as severe and over 10% reported a CeD-related hospitalization or emergency department visit in the past year. This ongoing study highlights the requirement for further understanding of persistent/recurrent symptoms and an unmet need for additional treatments for patients with CeD on a GFD.

Introduction: Gluten-related disorders include Celiac Disease (CD), Wheat Allergy (WA) and Non-Celiac Gluten Sensitivity (NCGS). NCGS is a syndrome characterized by the onset of intestinal and/or extra-intestinal symptoms after the ingestion of gluten-containing foods. Diagnosis is, firstly, based on the exclusion of CD and WA and on clinical response to a gluten-free diet (GFD). Furthermore, a single- or double-blind placebo-controlled gluten challenge is needed in order to limit placebo/nocebo effects.

However, food challenges are time consuming and require dedicated health-professionals, but, according to Salerno Criteria, they are necessary to make a correct diagnosis of NCGS.

Aims & Methods: Our aim was to evaluate the efficacy of *Test33*, a new test, in NCGS diagnosis and to simplify the diagnostic procedure through its use in daily clinical practice. It is a self-administered commercially-available kit containing undistinguishable gluten and placebo capsules, identifiable through a unique code. The patients downloaded a mobile app, which guided them through the administration of the capsules during the blind challenge.

Furthermore, the app allowed the self-assessment of symptoms by means of 33 10cm visual analogue scales (VAS), 10 for gastrointestinal symptoms and 23 for extraintestinal symptoms. After an initial three-week-long phase on a GFD, responsive patients were randomly assigned to the blind challenge. The challenge consisted of three different phases: gluten (5.6 g/day) or placebo capsules for seven days, followed by a one-week-long washout period (on GFD) and, finally, seven days of crossover period. We made an "Initial NCGS Diagnosis" after the GFD phase and a "Confirmed NCGS Diagnosis" after the challenge, following two different criteria, the second one less stringent. The primary endpoint was the worsening of symptoms (VAS increase ≥ 3 cm) during blind gluten ingestion compared to placebo.

Results: 107 persons (88 females, 38.5 ± 15.6 years of age) agreed to participate. 97 (91%) completed the GFD period, while 88 (82%) completed the entire challenge. After 3 weeks on a GFD, 96.9% of participants reported significantly improved gastrointestinal ($p<0.006$) and extra-intestinal symptoms and higher general well-being ($p<0.00001$), resulting as responsive to GFD. During the blind challenge, general well-being score was significantly lower in the gluten group ($p<0.027$).

Among gastrointestinal symptoms, abdominal pain (3.17 ± 0.32 vs 2.37 ± 0.30), constipation (3.27 ± 0.35 vs 2.38 ± 0.30), meteorism (5.40 ± 0.35 vs 3.68 ± 0.33), bloating (4.43 ± 0.31 vs 2.90 ± 0.30) and fullness (4.14 ± 0.36 vs 3.12 ± 0.33) were all worsened by blinded gluten ingestion (all $p<0.039$), while, regarding extra-intestinal symptoms, 13 out of 22 were significantly worsened after blind gluten ingestion (all $p<0.04$). None of the symptoms (both gastrointestinal and extra-intestinal) worsened during placebo assumption.

The "Initial NCGS diagnosis" was made in 54.6% of the 97 participants who completed the GFD period, while the "Confirmed NCGS Diagnosis" was made only in 8 out of 88 patients (9.1%) who completed gluten challenge, following the more stringent criterion 1.

Conclusion: This self-administered blind gluten challenge supported by a dedicated app diagnosed NCGS among patients reporting symptoms after gluten intake. Therefore, *Test33* may be a useful strategy for the assessment of symptoms (intestinal and extra-intestinal) strictly related to the blind gluten ingestion with less time and staff-consuming.

Its use may simplify NCGS diagnostic procedure in daily clinical practice.

Disclosure: Nothing to disclose.

Of Medical Gastroenterology, Oslo, Norway, [7]K. G. Jebsen Coeliac Disease Research Centre, Oslo, Norway

Contact E-Mail Address: jostein.ibsen@gmail.com

Introduction: Celiac disease (CeD) is a common chronic disease with an estimated prevalence of 1% (1). The diagnosis is based on clinical suspicion, serology and duodenal biopsy (2).

The only cure presently for CeD is lifelong dietary restriction; strictly excluding gluten from the diet. The outcome of this intervention has traditionally been expected to be good, but slow and incomplete mucosal healing is today often considered more frequent than previously thought. This lack of mucosal healing is in most cases considered to be caused by poor compliance with the diet.

Aims & Methods: The aim of this study is to investigate the pattern of serology and biopsy at time of diagnosis as well as the effect of follow-up and the outcome for treated CeD one year after diagnosis in a contemporary setting.

We prospectively enrolled patients with suspected CeD. Thus, these patients represent "regular" CeD patients and not referrals to tertiary care. The clinical work-up consisted of clinical chemistry, repeated serology and endoscopy at the first visit. All patients that received the diagnosis

of CeD were referred to one individual consultation with a clinical dietician, and they were invited to a follow-up examination after 12 months. Descriptive analyses were conducted on the collected data and the Marsh grade was used as measurement of mucosal healing.

Results: In total 126 of the 193 included participants were diagnosed with CeD. Among the participants were CeD was excluded; 2 only had IgA-Tissue transglutaminase 2 (TG2) above normal range (<4), 3 only had IgG-Deamidated gliadin peptide above normal range (<20) and 2 had both. Among the 51 participants with Marsh 3C and Serological samples, 1 had a negative TG2 at diagnosis and 5 a negative DGP. For Marsh 3B (n=36) and 3A (n=14) respectively 2 and 3 participants had a TG2 within the upper level of normal while 9 and 2 had DGP within the level of normal. Thus, 6 of 126 patients would be classified as "seronegative CeD" using TG2 as serological test.

Ninety-five (75%) of the participants participated in the one-year control and had comparable data. Seventy-two (76%) of these achieved mucosal healing (Marsh 0 or 1) whereas 89 (94%) had complete healing or improvement of the initial Marsh grade. Serologically 55 (58%) converted to within normal ranges of TG2 and 69 (73%) for DGP.

Only 9 (39%) of the patients who did not achieve complete mucosal healing were followed up for an additional year where 6 achieved complete recovery.

Conclusion: One year after the diagnosis of CeD, the prognosis for mucosal healing is good and better than what has been reported by others. Overall, almost all patients have some degree of healing.

Introduction: Coeliac disease (CD) is a chronic, multi-organ, immune-mediated disease associated with gluten intake in genetically susceptible individuals. There is an emerging trend in raising prevalence, which is generally accepted to be about 1% in the world population. To date, there is not generally used and universal noninvasive indicator of activity and functional integrity of the small intestine in patients with CD.

Citrulline, a non-essential amino acid produced almost exclusively in enterocytes, is already known to be a reliable marker of small intestinal function in individuals with severe impaired small intestinal function (e.g. complicated forms of CD with malabsorption syndrome and/or short bowel syndrome). The data about the ornithine (citrulline's intermediate) serum concentrations in CD patients are limited so far.

Aims & Methods: The aim of our study was to investigate if serum concentrations of citrulline and/or ornithine differed among patients with CD compared with healthy controls and could be used as a disease activity indicators in uncomplicated disease. We examined serum citrulline and ornithine levels in a subgroup of patients with proven coeliac disease and healthy controls. A total of 94 patients with CD (29 men, mean age 53 ± 18 years; 65 women, mean age 44 ± 14 years) and 35 healthy controls with serologically excluded CD (10 men, mean age 51 ± 14 years; 25 women, mean age 46 ± 12 years) were included in the study.

The basic clinical and laboratory data (age, weight, disease duration, BMI, body surface area, haemoglobin, leukocytes, MCV) including the serological profile of the CD (anti-tissue transglutaminase IgA in the subgroup of patients together with anti-tissue transglutaminase IgG, anti-endomysial IgA and IgG, anti-deamidated gliadin peptide IgA and IgG and anti-reticulin IgA and IgG in the subgroup of healthy controls) were collected.

Results: Significantly lower concentrations of serum ornithine were found in patients with CD (mean 65 ± 3 µmol/L; median 63 µmol/L, IQR 34 µmol/L, $p < 0.001$). No statistically nor clinically significant differences were found in the citrulline concentrations between the study and control group.

We proved statistically significant stronger correlation between plasma citrulline and ornithine levels in the group of patients with CD versus the group of healthy controls where the correlation was weak (Spearman's coefficient 0.723 vs. 0.313). For other quantitative features no significant correlation was found in the group of patients with coeliac disease and healthy controls.

Conclusion: Serum ornithine (but not citrulline) may be useful for assessing the functional status of the small intestine in uncomplicated coeliac disease. Further studies involving more detailed analysis of dietary and metabolic changes in coeliac patients will be needed to reach definitive conclusions.

Disclosure: Nothing to disclose.

THE INTESTINAL MICROBIOME CHARACTERISTICS OF INDIVIDUALS WITH GLUTEN-SENSITIVE CONDITIONS WHO ADHERE TO A GLUTEN-FREE DIET

O. Gubska[1], A. Kuzminets[1], O. Denesyuk[1], A. Koliada[2,3], V. Moseyko[3], O. Dolko[4,1]

[1]Bogomolets National Medical University, Therapy, Infectious Diseases and Dermatology Postgraduate Education, Kyiv, Ukraine, [2]Institute of Food Biotechnology and Genomics, NAS of Ukraine, Kyiv, Ukraine, [3]DIAGEN Genetic Laboratory, Kyiv, Ukraine, [4]International Institute of Clinical Research LLC, Department of Clinical Research, Kyiv, Ukraine

Contact E-Mail Address: gubskao@gmail.com

Introduction: Intestinal dysbiosis is associated with violating both the quantitative and qualitative intestinal microbiome composition (IM). It accompanies different gastrointestinal disorders, including *non-celiac gluten sensitivity* (NCGS) and celiac disease (CD). A gluten-free diet is the only existing treatment for CD and NGCC. One of the questions of interest is the characteristics of the IM of patients with gluten-related diseases (GRDs) and its relationship with diet therapy.

Aims & Methods: To determine the IM composition of patients with CD and NCGS who adhere to the agliadin diet and compare it to the IM composition of people without GRDs. The study included 25 adults: 14 (56%) with CD and 11 (44%) with NCGS; all were on agliadin diet. The control group (CG) included 24 people without gluten-sensitive pathology or gastrointestinal diseases. We determined the faecal content of the *Bacteroidetes*, *Firmicutes*, and *Actinobacteria* phylae and the rest bacterial desoxyribose nucleic acid DNA ("other" indicator) using the real-time polymerase chain reaction (real-time PCR).

Results: The *Firmicutes* content was 53.47 (IQR 49.98-57.21) % in CD patients ($p<0,05$ with CG), 53.0 (IQR 47.13-71.95) % in NCGS patients ($p>0.1$ with other groups) and 69.89 (IQR 58.58- 74.1) % of CG. *Bacteroidetes* content was 28.4 (IQR 6.58-39.28) % in CD patients, 24.98 (IQR 8.83-31.04) in NCGS patients ($p>0.1$ with CD), and 6.83 (IQR 3.69-9.22) in the CG ($p<0.05$ with GRDs). The *Actinobacteria* content was 4.8 (IQR 3.73 - 7.2) % in CD patients, 5.37 (IQR 3.89-8.56) % in NCGS patients ($p>0.1$ with CD), and 11.36 (IQR 7.07- 15.34) in the CG ($p<0.01$ with GRDs). The *Firmicutes/Bacteroidetes (F/B)* ratio was 1,996 (IQR 1.27-8.15) in CD patients, 2.0 (IQR 1.63-8.25) in NCGS patients ($p>0.1$ with CD), and 9.986 (IQR 6.37-18.80) in CG ($p<0.05$ with GRDs). The content of "other" types of IM was 15.39 (IQR 7.25-23.06) in CD patients, 13.78 (IQR 9.48-16.05) in NCGS patients, and 13.66 (IQR 8.43-17.78) in CG. This indicator had no significant difference ($p> 0.99$) between all three groups.

Conclusion: We found significant IM changes among patients with CD and NCGS, expressed in an increase in the *Bacteroidetes* content with a parallel decrease in the content of *Firmicutes* and *Actinobacteria*. The most significant changes were in *Actinobacteria* content, a less significant - the *Firmicutes*/*Bacteroidetes* ratio. Meanwhile, we did not find a difference in IM composition between CD and NCGS groups. Thus, detected intestinal microbiome changes are most likely to be a consequence of dietary features of such patients, namely the side effect of keeping an agliadin diet.

PP0372

CELIAC DISEASE IN ASSOCIATION WITH IMMUNE CHECKPOINT RECEPTOR INHIBITORS: AWARENESS IS NEEDED

A. Al-Toma[1], M. Stolk[1]

[1]St Antonius hospital, Dept. of Gastroenterology & Hepatology, Nieuwegein, Netherlands

Contact E-Mail Address: a.altoma@antoniusziekenhuis.nl

Introduction: The immune regulatory proteins, such as cytotoxic T lymphocyte antigen (CTLA)-4 as well as programmed death (PD)−1 and its ligand PD-L1 are important immune regulatory proteins collectively referred to as immune checkpoint receptors. These pathways can be used by malignant tumors as a mechanism to avert antitumoral immune responses.

Immune checkpoint inhibitors (ICIs) target these immune checkpoint receptors. ICIs have demonstrated impressive clinical activity and are now approved for the treatment of diverse malignant neoplasms.

However, inhibition of these regulatory receptors leads to loss of tolerance and a wide spectrum of inflammatory toxicities known as immune-related adverse events (ir-AEs). Colitis or enterocolitis are the most frequent GI irAEs, affecting 15%–20% of patients who undergo endoscopic evaluation.

When severe, irAEs can necessitate ICI therapy interruption, discontinuation, and treatment escalation with powerful immunosuppressive agents. Isolated ICI-associated duodenitis has been reported after treatment with different immunotherapies.

Interestingly, de novo celiac disease (CeD) specific antibodies (serum tTG antibodies) with

histological features consistent with CeD in the setting of treatment with ICIs have been reported.

Aims & Methods: A literature search in Pubmed and Scopus to identify original reports in which CeD was documented histologically in patients treated with ICIs. Clinical, endoscopic and histopathological and immunological background were reviewed.

Results: Eleven papers were identified, all case reports or case series. A total of 26 pts were described. Twelve patients had a serologic and histological diagnosis of CeD.

CeD has been rarely observed during treatment with ICIs and is morphologically similar to ICI-CeD

enteropathy. Endoscopically, duodenal congestion, nodularity, or erythema were seen in 67% of patients with ICI-duodenitis, compared with 33% of patients with ICI-CeD. Few patients had concomitant upper and lower GI tract mucosal inflammatory changes.

Correlation with medication history, the finding of typical histologic changes, and re-evaluation of pathologic changes after checkpoint receptor inhibitor therapy will help confirm if an injury is likely to be an irAE.

Patients with ICI-CeD were reported to improve on a gluten free diet (GFD) as the single therapy, while some patients required the addition of immunosuppression with variable improvement in symptoms.

Conclusion: Whether ICI-associated celiac disease (ICI-CeD) reflects new onset gluten sensitivity or unmasking of previously asymptomatic CeD remains to be answered.

There is some evidence that ICI-CeD is biologically similar to ICI-duodenitis, but treatment strategies differ. ICI-CeD often improves with GFD alone, whereas ICI-duodenitis may require systemic immunosuppression.

In patients with atypical digestive symptoms in the context of ICI treatment, there is a necessity of complementary/additional investigation. Celiac disease specific antibodies (tTG-IgA assay) and duodenal biopsy are required. In the case of morphological lesions resembling CeD, serological and genetic testing should be performed for differentiating true CeD from ICI-drug-induced villous atrophy.

It might be useful to check for CeD before scheduled ICI therapy in patients with known high susceptibility to CeD, such as a family history of CeD, dermatitis herpetiformis, or chronic unexplained bowel symptoms.
Disclosure: Nothing to disclose.

PP0373

A ONE-CENTER RETROSPECTIVE STUDY OF CELIAC DISEASE SUSCEPTIBLE POPULATION IN JIANGSU PROVINCE

X. Jiang[1], M. Wang[1], Z. Fan[1], L. Zhao[1]
[1]The First Affiliated Hospital with Nanjing Medical Universtiy, Digestive Endoscopy, Nanjing, China

Contact E-Mail Address: njmujxh@163.com
Introduction: Celiac disease is a multi-organ autoimmune enteropathy caused by exposure of genetically sensitive individuals to a gluten diet. Despite the high carrying rate of susceptibility genes, celiac disease diagnostic rates in China are merely the "tip of the iceberg."
Serological tests are frequently used to screen for celiac disease and can serve as a reference for precise clinical prevention and treatment.
Aims & Methods: In the population undergoing serological screenings for celiac disease (including anti-tissue transglutaminase and anti-gliadinantibodies) at Jiangsu Province Hospital from January 2017 to November 2022, a total of 1407 patients were retrospectively enrolled.
To identify the contributing causes, the seropositive rates of celiac disease in different population and demographic characteristics were examined.
Results: In the susceptible population, the seroprevalence of anti-tTG was 1.14% (16/1407, 95%*CI* 0.70% -1.84%) indicating that the seroprevalence of celiac disease, with positive TTGA and TTGG rates of 1.12% and 0.09%, respectively.
In 7 individuals with positive serological results, endoscopic examination revealed duodenal inflammation or ulceration, suggesting that the morbidity of celiac disease in this vulnerable population can approach 0.50% (7/1407, 95%*CI* 0.22%-1.07%). The seroprevalence of AGA in susceptible population was 22.67% (319/1407, 95%*CI* 20.52%-24.97%). Multiple celiac disease serological antibodies may be present at once.
The anti-tTG and AGA IgG antibody group showed a substantially different average age between the positive and negative participants, with the positive group being 32.9±15.6 years old and the negative group being 43.8±16.9 years old ($P < 0.001$).
Conclusion: The serological positive rate of celiac disease in susceptible population in Jiangsu is 1.14% and the morbidity of celiac disease is 0.50% according to endoscopic results, which is comparable to internationally reported data.
Therefore, for a definitive diagnosis of celiac disease in a susceptible population, serological testing and endoscopic screening are advised. These tests can serve as a crucial foundation for the early diagnosis, prevention, and treatment of celiac disease.

CORRESPONDENCE AMONG CAPSULE ENDOSCOPY FINDINGS AND MOLECULAR SIGNATURES IN ATROPHIC ENTEROPATHIES

N. Nandi[1], I. Lodola[1], L. Scaramella[2], F. Cavallaro[2], M. Topa[1], G.E. Tontini[3,1], L. Elli[2], M. Vecchi[1,2]
[1]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milano, Italy, [2]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Department of Gastroenterology and Endoscopy, Milano, Italy, [3]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Gastroenterology and Endoscopy Unit, Milan, Italy

Contact E-Mail Address: nico.nandi@hotmail.it
Introduction: Atrophic enteropathies are characterized by villous atrophy, including transglutaminase-positive and seronegative enteropathies. Diagnosis and stratification of patients with atrophic enteropathies are often challenging[1].
Indeed, especially in seronegative enteropathies, there are no defined markers (molecular, serological, or endoscopic) for accurate differential diagnosis[2,3].
Aims & Methods: The aim of our study is to describe the concordance between small bowel endoscopic markers of atrophic enteropathies and molecular signatures. We retrospectively enrolled patients that underwent capsule endoscopy (CE) for suspected atrophic enteropathy at our Center from June 2015 to July 2022.
Endoscopic findings at CE were evaluated in association with demographic and clinical data, including malnutrition universal screening score (MUST), HLA DQ haplotype, clinical disease severity, atrophy sec. Marsh, duodenal flowcytometry (cyt), TCRγ receptor rearrangement.
Results: Eighty-two patients who underwent CE were analyzed (55 females, mean age 52 years old ± 15.08). Thirteen CE resulted with normal findings; 71 CE presented at least one pathologic finding, specifically atrophy, ulcers and/or erosions and stenosis in 62, 27 and 4 patients respectively; 22 patients showed two or more findings. Patients with >33% of SB atrophy at CE had more severe disease and a higher MUST score (p 0.0006 and p 0.0005, respectively).
When only non-CD enteropathies were taken into account, atrophy extension at CE was associated only with a higher MUST score (p 0.049). Seventeen out of 29 patients that showed no atrophy at duodenal histology, showed instead signs of distal atrophy at CE. The diagnostic accuracy for atrophy at histology of both aberrant IELs and γδ IELs was poor (respectively AUC 0.56 95% CI 0.45-0.66, p 0.26 and AUC 0.56 95% CI 0.44-0.65, p 0.37).
Conclusion: Our study shows that in atrophic enteropathies, disease extension at CE is correlated to the severity of disease and nutritional status, indicating a potential role of CE in disease characterization, staging and management.
Moreover, CE could be helpful in detecting distal atrophy in a small portion of patients which could be missed with conventional upper gastrointestinal endoscopy. γδ-IELs seem to be a good tool to discriminate CD and non-CD enteropathies.
Considering the retrospective nature of the study and the sample size, further studies are required to confirm these data.

Introduction: The use of a gluten-free diet (GFD) in healthy people has been steadily increasing worldwide based upon the unproven belief that avoiding gluten enhances overall wellness. In contrast, evidence indicates that voluntary GFD has an impact on living costs, psychosocial profile and may cause malnutrition in the long-term[1,2].

Since dietary changes may significantly affect gut microbiota composition[3], we tested whether a 30-day unnecessary GFD in healthy subjects has an impact on diversity and richness of gut microbiota.

Aims & Methods: 116 fecal samples were collected from 30 thoroughly examined healthy subjects (21 females, 9 males; 34±14 years) recruited at St. Anna University Hospital in Ferrara, Italy. All subjects had no demonstrable metabolic, cardiovascular, respiratory, rheumatic and neurological illnesses and were asymptomatic for gastrointestinal symptom (established by Gastrointestinal Symptom Rating Scale, GSRS). Stool samples, collected at day 0, and 3, 7, 30 days from GFD were sequenced via shotgun metagenomic and computationally profiled (bioBAkery 3).

Data were analyzed on MetaPhlAn 4.0 and HUMAnN 3.0 for taxonomic and functional profiling, respectively and relative abundance transformed via arcsin-sqrt.

Only species present at any time point in at least 5 subjects were considered (600 species). Statistical analysis was performed using a linear mixed model and Friedman's ANOVA. P values were combined and corrected for multiple hypothesis testing (q value).

Results: Species alpha-diversity did not significantly change during 30 days of GFD ($p > 0.05$). However, during the GFD, 14 species significantly decreased ($q < 0.05$) in relative abundance. Most of the decreased bacteria belonged to Bifidobacterium genus (e.g. Bifidobacterium longum $p=0.000000003$; $q=0.000001$) or those involved in complex carbohydrate metabolism.

Conclusion: In healthy subjects, a 30-day GFD did not significantly affect gut eubiosis. However, consistent changes in the relative abundance of gut microbiota species showed a reduction of Bifidobacterium genus thus potentially affecting intestinal and immunological homeostasis and health status[4].

Contact E-Mail Address: choung.rokson@mayo.edu

Introduction: Celiac disease (CeD) is an immune-mediated disease with excess morbidity and mortality. CeD is associated with inflamed intestinal mucosa, which may be mediated IL-15. There are currently no established non-invasive biomarkers to monitor disease activity following treatment of CeD.

Aims & Methods: Thus, we aimed to characterize disease biomarkers of CeD, primarily IL-15 levels, in the gut and in the serum of non-responsive CeD (NRCD), Treated responsive CeD (TrCD), and non-CeD controls to evaluate the relationship between cytokine levels and CeD disease status. Based on the existing archives of our Olmsted County Celiac Registry, we identified 29 NRCD, 30 TrCD, and 24 non CeD controls. NRCD was defined as patients with a diagnosis of CeD presenting with continued celiac symptoms and partial or total villous atrophy after 1 or more years of following a strict gluten-free diet (GFD). In contrast, TrCD was defined as patients with a diagnosis of CeD who were presenting with no celiac symptoms and normal duodenal histology after 1 year or more of a strict GFD. Control samples were matched by age, gender, and confirmed as negative celiac serology. We assessed duodenal biopsy and serum IL-15 protein expression levels in patients with NRCD, TrCD, and controls using a quantitative ligand binding assay with electrochemiluminescent detection. Furthermore, we conducted the proteomic profiling by utilizing targeted proteomics panels to assess the changes in serum and duodenal biopsy tissues samples of patients with NRCD, TrCD, or non-CeD controls.

Results: The measured levels of IL-15 in serum and duodenal biopsy samples are summarized according to disease status in Table 1. No apparent separation in median IL-15 levels (serum and gut tissue) was observed across the three groups (non-CeD controls, TrCD and NRCD). It was also difficult to draw a correlation between serum and gut tissue IL-15 levels. In

contrast to the TrCD and control groups, high variability in IL-15 levels was seen with the NRCD group, potentially due to differences in histology and/or other clinical manifestations by the subjects within the group. Interestingly, the highest IL-15 level (serum or tissue) was noted in NRCD patients with total villous atrophy. However, small n (2 out of 29) precludes definitive association.

	Non-responsive Celiac disease	Responsive Celiac disease	Seronegative controls
Age[mean +/- SD]	50.5 ± 15.5	40.9 ± 16.6	45.4 ± 15.7
Gender (female) [percent of total]	86%	73%	71%
Duration of gluten-free diet, years [mean +/- se]	5.5 ± 6.3	6.1 ± 7.2	N/A
IL-15 levels in serum samples (pg/mL)[median (interquantile range)]	7.4 (6.3-8.9)	6.9 (5.7-7.9)	6.7 (5.5-8.0)
IL-15 levels in duodenal biopsy tissue samples (pg/mg) [median (interquantile range)]	0.71 (0.58-0.96)	0.60 (0.48-0.86)	0.77 (0.60-0.9)

NRCD: nonresponsive celiac disease; RCD: responsive celiac disease; CeD, celiac disease; Samples number analyzed in NRCD (n=29/29 and n=28/29), RCD (n=30/30 and n=30/30) and non-CeD (n=24/24 and 20/24) respectively for duodenal biopsies and serum samples.

Table 1. Demographics and IL-15 protein levels in samples from patients with NRCD, RCD, and non-CeD controls.

Conclusion: Data generated from this retrospective study did not show clear difference in the mean IL-15 (serum or tissue) levels between the responsive and non-responsive CeD groups. However, for the limited number of NRCD samples with total villous atrophy, the IL-15 levels were substantially higher (either in serum or tissue) compared to partial or near normal. Testing of more samples representing the different villous atrophy status is warranted to confirm these results.

Disclosure: Study was conducted as part of a Teva funded research collaboration between the Mayo Clinic, which provided the gut biopsies and serum samples, and Teva, Pharmaceuticals Industries, Ltd., which developed and performed the assays and analyses.

GLIADIN-RAPAMYCIN NANOPARTICLES INDUCE IMMUNE TOLERANCE TO MOUSE MODELS OF CELIAC DISEASE

W. Fan[1], Z. Fan[2], L. Zhao[2]

[1]The Forth Affiliated Hospital with Nanjing Medical University, Gastroenterology Department, Nanjing, China, [2]The First Affiliated Hospital with Nanjing Medical University, Digestive Endoscopy, Nanjing, China

Contact E-Mail Address: 596347909@qq.com

Introduction: Celiac disease is one common but refractory autoimmune intestine disease. The etiology is well-known for the gluten-sensitive enteropathy. Except dietary restriction, there is limited therapeutic methods in clinics. Nanoparticles have been demonstrated to achieve antigen-specific immune tolerance in autoimmune diseases. We improved the antigen presentation mode by nano-encapsulation of antigen.

At the same time, we give nanoparticles the ability of targeted to the liver, and investigated the safety and efficacy of nanoparticles in a mouse model of celiac disease.

Aims & Methods: C57BL/6 mice were used as the model of celiac disease and Polymeric lipid hybrid nanoparticles (PLNs) were prepared by precipitation self-assembly method using PLGA, DSPE-PEG, gliadin and rapamycin as materials. We used transmission electron microscopy, laser particle size analyzer to observe the apparent characteristics of PLNs. The antigen and drug encapsulation rate were detected, and drug release characteristics were investigated in vitro. The tissue distribution of the prepared nanoparticles was detected by loading the composite nanoparticles with IR780 fluorescent substance.

At the same time, we investigated the immune tolerance effect of PLNs in a mouse model of celiac disease through delayed hypersensitivity reaction, weight loss, intestinal injury and other apparent characteristics, inflammatory cytokines in duodenal tissue, and splenic cell proliferation activity.

Results: Animal models of celiac disease using C57BL/6 mice showed the corresponding characteristics of the disease. The three PLNs nano-drugs were stable and sustained release characteristics were obvious. Biodistribution experiments showed that the three PLNs nano-drugs targeted the liver intensively.

Results of in vivo pharmacodynamics test showed that the three PLNs nano-drugs could reduce plantar swelling hypersensitivity, weight loss, intestinal injury and inflammatory cytokines caused by Gliadin specific stimulation, and $PLN^{Gliadin+Rapa}$ had the most significant effect.

Conclusion: The nanoparticles-based drug delibery system loaded with Gliadin-Rapa has the stable structure and outstanding sustained-release effect, which can effectively inhibit the Gluten-specific allergic reactions in the C57BL/6 model, and is a potential candidate for the treatment of celiac disease.

Disclosure: Nothing to disclose.

Contact E-Mail Address: filippo.pelizzaro@gmail.com

Introduction: Many studies, mostly conducted on pediatric patients, suggested that oxidative stress as well as several micro-RNAs (miRNAs) may play an important role in coeliac disease (CeD) pathogenesis. However, the interplay between oxidative stress and miRNAs regulatory functions in CeD remains to be clarified.

Aims & Methods: This pilot study was conducted to evaluate the role of miRNAs and oxidative stress in adult CeD patients and to analyze their potential interactions.

A total of 51 subjects were retrospectively included in the study: n=12 CeD patients at the time of diagnostic upper GI endoscopy (CeD-dia); n=18 CeD patients after at least one year on a gluten-free diet (CeD-fu); n=5 patients with complicated CeD (CeD-compl); n=10 control patients undergoing upper GI endoscopy for other diseases (CP); n=6 healthy controls (HC). In these subjects, a blood sample and duodenal biopsies were collected.

Based on a literature search, several miRNAs involved in the pathogenesis of CeD and with a known relationship with oxidative stress (miR-155, miR-200, miR-125, miR-192, miR-21, miR-451, miR-146 and miR-1226) were quantified with qRT-PCR in plasma.

Oxidative stress was evaluated through the measurement of the levels of 8-OHdG adduct in the DNA extracted from the duodenal tissue and from peripheral blood using High Performance Liquid Chromatography with Electrochemical Detection (HPLC-EC).

Results: Among the evaluated miRNAs, miR-451, miR-146 and miR-155 were differentially expressed between groups. In particular, compared to HC, CeD-dia and CeD-fu groups have significantly lower levels of miR-451 (p=0.01 and p=0.006, respectively). The expression of miR-146 in CeD-dia was significantly higher compared to CeD-fu patients (p=0.03), while HC demonstrated lower levels compared to both CeD-dia and CeD-fu (p=0.03 and p=0.01, respectively).

A trend toward lower levels of miR-155 was shown in HC compared to CeD-dia (p=0.05) and CeD-fu (p=0.06). The blood level of 8-OHdG were significantly higher in CeD-dia and CeD-fu patients compared to CP (p=0.05 and p=0.001, respectively). No correlations were demonstrated between tissue 8-OHdG levels and miRNAs.

By contrast, blood 8-OHdG levels were positively correlated with miR-155 in CeD-compl (r=0.9, p=0.04) and with miR-200 in CeD-fu (r=0.68, p=0.02), while negatively correlated with miR-1226 in CeD-fu (r=-0.62, p=0.04).

Conclusion: miRNAs and the oxidative stress have a role in the pathogenesis of CeD. In this pilot study, we showed that a crosstalk between these two may exist, in particular during follow-up and in complicated CeD.

Whether oxidative stress is able to up- or downregulate some miRNAs or, conversely, whether miRNAs expression is capable to modulate the response to oxidative stress in CeD patients should be evaluated in future larger studies.

Introduction: Risk prediction model for the first-degree relatives (FDRs) of having a potential to develop celiac disease (CeD) is desirable considering that this population is high risk segment. We used a statistical method to develop risk prediction and evaluated the method performance under a wide range of predictor characteristics.

Aims & Methods: Data from 537 CeD cases classified as per ESPGHAN 2012 criteria, and their 1507 FDRs were assessed over a period for 24 months. A total of 222 FDRs were observed positive on baseline screening with serum tTG-IgA. Serology negative FDRs were kept on follow up over a period of 24 months to seek the newly developed FDRs into CeD cases (NDCeD). HLA DQ2/DQ8 genotyping, Interleukin-18 (IL-18) gene polymorphisms and plasma citrulline analysis was also performed in all subjects. Prediction models were made using all predictors and risk prediction scores were calculated using binary logistic regression analysis and ROC analysis was performed to calculate the diagnostic performance of the best fit models and evaluation of model performance criteria was performed.

Results: Diagnostic performance of serum tTG-IgA was significantly better than plasma citrulline in biopsy proven NDCD (DeLong's Test p=0.038). However, multivariate analysis of diagnostic performance of best fit model from 63 combinations showed citrulline was best predictor (OR=0.92, p=0.04). In the second part of the study, analysis was performed in between symptomatic FDRs (n=690) and oligosymptomatic/silent FDRs (n=64). For the identification of potential CeD over a period of 24 months, risk prediction model based on the combination of tTG-IgA (OR=1.01, p=0.017) and IL-18 polymorphisms (OR=18.37, p=0.005) depicts best prediction.

Conclusion: HLA DQ2/DQ8 showed poor predictor characteristics. Model based on citrulline in immediate diagnosis of the silent and potential CeD was a good model but poor predictor of developing CeD. However, the risk prediction model utilising IL-18 polymorphisms and tTG-IgA had a better performance for the identification of the development of potential CeD.

Disclosure: Nothing to disclose.

Contact E-Mail Address: salinana@hotmail.it

Introduction: Coeliac disease (CeD) has been linked to decreased quality of life (QOL) and psychological morbidity, either due to the disease course itself, or to the effort required to maintain strict adherence to a gluten-free diet (GFD) over the long-term. High levels of resilience, the ability to recover from adversity, have been associated with better QOL in patients affected by chronic diseases. However, data on resilience in coeliac patients are lacking.

Aims & Methods: We aimed to assess the resilience in patients with CeD on a GFD, and how this is associated with sociodemographic factors, clinical factors, quality of life, and psychological disorders such as anxiety and depression. Methods: Adult CeD patients on a GFD and under regular follow-up at four Italian centres were prospectively proposed participation to a survey between February-2022 to April-2023. Clinical and demographic data were collected. The Connor-Davidson Resilience Scale (CD-RISC), the Celiac Disease-specific Quality of Life Scale (CD-QOL), the State-Trait Anxiety Inventory scale (STAI-Y) and the Beck Depression Inventory scale (BDI) were used to evaluate degree of resilience, QOL anxiety and depression, respectively. A multivariate analysis, including all variables related to resilience to univariate analysis, was conducted using the backward elimination model to identify factors independently associated with the degree of resilience.

Results: We included in this study 305 patients (221 F, mean age at CeD diagnosis 36.6±16.3 years; mean age at enrolment 47.9±15.4 years) on a GFD for a mean of 11.3± 10.4 years. 298/305 (97.7%) patients had a high level of resilience (CD-RISC ≥35). QOL scores were good overall (median 84, IQR 73-91). Anxiety scores were suboptimal (STAI-Y1 median 39, IQR 32-49; TAI-Y2 median 40, IQR 33-49). Depression scores were low overall (BDI median 7, IQR 2-14). At the univariate analysis, resilience was statistically associated to gender (p=0.02), age at enrolment (p=0.01), civil

status (p=0.1), quality of life (p<0.001), anxiety (p<0.001) and depression (p<0.001). Backward elimination multivariate regression analysis showed that trait- anxiety (STAI-Y2, p<0.01) and depression (BDI, p=0.02) were the only independent predictors of lower levels of resilience (CD-RISC).

Conclusion: Patients with CD have high levels of resilience overall. Higher treat-anxiety and depression scores predicted lower levels of resilience. Targeted interventions in this subgroup of patients may be helpful for their management and follow-up.

Disclosure: Nothing to disclose.

Contact E-Mail Address: laura.kivela@fimnet.fi

Introduction: The revised Finnish guidelines for coeliac disease in 2018 enabled for the first time to establish a no-biopsy diagnosis in adults with serum transglutaminase antibodies >10x upper limit of normal and positive endomysial antibodies. We investigated the implementation of the new guidelines and significance of the diagnostic process on the treatment success and patients´ experiences.

Aims & Methods: Altogether 194 adult members of the Finnish Coeliac Society diagnosed after 2018 answered to a comprehensive study questionnaire concerning socio-demographic and health-related characteristics and quality of life and various coeliac disease-related issues. The results were compared between patients diagnosed with and without duodenal biopsy.

Results: Sixty-nine (36%) patients were diagnosed without a biopsy. They were younger (median age 44 vs. 52 years, p=0.029), diagnosed less often in hospital settings (11% vs. 35%, p=0.001), suffered less often from oesophageal symptoms (17% vs. 30%, p=0.047) and osteoporosis (1% vs. 10%, p=0.035) and experienced the diagnostic process more often easier (49% vs. 30%, p=0.032) than those diagnosed by biopsy (n=125). The no-biopsy group had also been informed on their diagnosis more often by other healthcare professional than a physician (14% vs. 4%, p=0.046) and reported more persistent symptoms (36% vs. 21%, p=0.026) and stress due to the gluten-free diet (68% vs. 47%, p=0.042). The groups did not differ in gender, socio-economic characteristics, general health, quality of life, other than oesophageal symptoms, diagnostic delay, presence of follow-up or experiences of a gluten-free diet or dietary adherence. After adjusting the groups with age, the difference in osteoporosis was no longer significant.

Conclusion: Up to one-third of adult coeliac disease patients were diagnosed without gastrointestinal endoscopy, which may provide less burdensome diagnostic process and significant healthcare savings. However, increased risk for persistent symptoms and dietary stress in these patients remind that adequate guidance at diagnosis regardless of the diagnostic process and healthcare unit should be provided.

Disclosure: Nothing to disclose.

Contact E-Mail Address: stiliano.maimaris01@universitadipavia.it

Introduction: Patients with coeliac disease (CD) and unsatisfactory clinical response to a gluten-free diet (GFD) are identified as having non-responsive coeliac disease (NRCD), and may require investigations to exclude possible complications of CD. Refractory coeliac disease (RCD) is the most common complication of CD and can be divided into RCD type 1 and type 2 based on intraepithelial lymphocyte (IEL) immunophenotyping. Methods for the assessment of IEL phenotype in RCD include traditional immunohistochemistry (IHC), PCR-based clonality analysis of TCR-ɣ gene rearrangement and flow cytometry (FC). However, the role of monitoring IEL immunophenotype with FC in patients with NRCD and known RCD is poorly defined. Moreover, very little is known about the utility of FC for evaluating IEL phenotype in patients with non-coeliac enteropathies (NCEs), for which differential diagnosis with RCD is challenging.

Aims & Methods: We aimed to investigate the reproducibility and significance of monitoring IEL immunophenotype with FC in patients with RCD, NRCD, and NCEs under regular follow-up at a referral centre. Patients who underwent FC for IEL immunophenotyping between January-2012 and February-2023 were divided into two groups: group 1) patients with known RCD or patients with NRCD in whom complications of CD were suspected; group 2) patients with NCEs lacking clinical and histological response. Data was retrospectively collected on clinical features, IEL immunophenotyping with FC, IHC, analysis of ɣ-TCR clonality, and on mortality and progression to lymphoma. An aberrant IEL phenotype was defined as >20% CD103+,CD3-,CD8-,CD3ε+ at FC. Reproducibility of FC results and concordance of FC with IHC and ɣ-TCR clonality analysis were evaluated. Overall survival and lymphoma-free survival were compared among coeliac patients based on IEL phenotype at FC.

Results: 52 patients (18 RCD, 21 NRCD, 13 NCEs; 38 F, mean age at FC testing 55±13 years) underwent 100 total FC IEL phenotype determinations and an aberrant IEL phenotype was found at FC in 9/52 (7RCD, 2NRCD). 22 patients had at least two FC determinations during follow-up. Interestingly, immunophenotype (both aberrant and normal) remained unchanged in all these 22 patients (Cohen's κ=1.00). Concordance of FC with IHC was fair (Cohen's κ=0.40) but only minimal with ɣ-TCR clonality (Cohen's κ=0.22). Over a median follow-up of 33 months (IQR 3-59) after FC, 6/52 (11%) progressed to lymphoma and 13/52 (25%) died. Mortality was markedly increased in coeliac patients with aberrant IELs compared to those with a normal immunophenotype (89% vs 7% mortality, HR 5.5, 95% CI 1.8-17.3, p<0.01). None of the 13 patients with NCEs showed an aberrant IEL phenotype at FC, although 3/13 developed lymphoma and 4/13 died (three lymphoma, one pulmonary adenocarcinoma).

Conclusion: FC is an accurate and reproducible tool for evaluating IEL phenotype in patients with RCD and NRCD and provides valuable prognostic information. Further study is needed on the diagnostic and prognostic role of FC in NCEs.

Disclosure: Nothing to disclose.

THE PREVALENCE OF COELIAC DISEASE IN RANDOM ASYMPTOMATIC INDIVIDUALS USING A POINT-OF-CARE TEST

M. Sciberras[1,2], A. Cutajar[2], K. Conti[1], P. Ellul[2,1]
[1]Mater Dei Hospital, Department of Gastroenterology, Msida, Malta, [2]University of Malta, Medicine and Surgery, Msida, Malta

Contact E-Mail Address: muscatmartina@gmail.com

Introduction: Coeliac disease is an autoimmune disease that affects the small bowel in genetically predisposed people precipitated by the ingestion of gluten. Worldwide prevalence has been estimated at around 1%.

Aims & Methods: To screen for coeliac disease using a point of care (POC) testing kit in a random cohort of asymptomatic people in the Maltese Islands, where no prevalence study data is available.

A random sample of people aged 18-75 years were invited to participate and were tested using the professional Biocard™ Celiac Test. This is a rapid immune chromatographic lateral flow test for the qualitative detection of anti-tissue transglutaminase IgA antibodies (TTG IgA) from a fingertip blood sample.

All the results were read by the same gastroenterologist within 10minutes. This test also measures total IgA measuring the presence of IgA antibodies in the sample which reduces the risk of false negatives due to IgA deficiency. Patients with a positive test were offered serological blood tests to check the level of TTG IgA and antiendomysial antibodies (EMA) and an oesophagogastroduodenoscopy (OGD) with duodenal bulb and 2nd part of the duodenum biopsies.

Results: 1251 people were tested using the point of care test (52.6% Female, Mean Age 41.2; SD +/-11.4).

9 patients (0.7%) had a low IgA level, 4 patients underwent serological testing for IgA and a TTG IgG and confirmed the low IgA and a negative TTG IgG result. The rest refused the tests.

9 patients (0.7% of the screened cohort) (77.8% female, p=0.13) had a positive POC test. From these, 1 patient refused further serological tests or an OGD. 87.5% (7/8 patients) were confirmed to have coeliac disease and these all had a TTG IgA level >100Iu/mL or more than 10 times the upper limit of normal (Normal range0.1-9.0 IU/mL) and also a strongly positive EMA of 3+. 1 patient had an OGD with normal biopsies as well as a TTG IgA level ≤30iu/mL or less than three times the upper limit of normal. The EMA level was weakly positive (1+). Marsh classification for the confirmed cases showed 55.6% Marsh 3b, 44.4% with Marsh 3c.

Conclusion: The prevalence of coeliac disease in adults in the Maltese Islands using a point of care test is 0.7%. On further testing with confirmatory duodenal biopsies, 0.56% (7/1250 patients) of patients were confirmed to have CD on duodenal biopsies. This confirms that duodenal biopsies are still required in patients whose TTG IgA levels are <10 the upper limit of normal.

Furthermore, the clinical question arises of how patients with positive coeliac serology which is <10 the upper limit of normal, positive genetic studies and normal duodenal biopsies be followed up.

Disclosure: Dr Sciberras received funding from Dr. Schär.

PP0385

OTHER SPECIAL DIETS IN ADDITION TO GLUTEN-FREE DIET ARE COMMON IN ADOLESCENTS AND YOUNG ADULTS WITH CELIAC DISEASE, BUT DO NOT ASSOCIATE WITH OVERALL WELLBEING OR TREATMENT SUCCESS

H. Pihlajamäki[1], L. Aitokari[1], L. Kivelä[1,2], K. Kurppa[1,3], K. Nissinen[4]
[1]Tampere University, Tampere, Finland, [2]University of Helsinki and Helsinki University Hospital, Helsinki, Finland, [3]The University Consortium of Seinäjoki, Seinäjoki, Finland, [4]Seinäjoki University of Applied Sciences, Seinäjoki, Finland

Contact E-Mail Address: heli_pih@hotmail.com

Introduction: Various special diets have become increasingly common. These may have particular effect on the well-being and coping of patients with celiac disease (CeD) who already have a major dietary restriction in a form of gluten-free diet (GFD).

At present, however, the prevalence and significance of other special diets in patients with CeD remain obscure. We studied these issues in a large cohort of adolescents and young adults.

Aims & Methods: Altogether 211 16-30-year-old members of Finnish Celiac Society with CeD replied to a web survey comprising questions about demographic data, education and employment, health-related issues, daily diet and treatment of CeD. All variables were compared between CeD patients with and without other special diet in addition to GFD.

Results: Median age of the responders was 25 (quartiles 19, 29) years, 83% were females, 52% students, 41% working and 6% unemployed or on parental leave.

Altogether 33% reported other special diets besides GFD, the most common of these being vegetarian or vegan diet (9%), major/multiple food allergies (4%) and low-FODMAP (3%) or other (4%) diet for irritable bowel syndrome. CeD patients with other diet reported more often non-binary gender (4% vs 0%, p=0.042) than those with GFD only, whereas there was no significant difference in age, body mass index, student or employment status, physical activity, use of alcohol and tobacco products, or age at CeD diagnosis.

Altogether 11% reported difficulties to combine GFD and other special diet, but there was no significant differences between patients with and without the other diet in GFD adherence (100% vs. 97%, p=0.481), prevalence of persisting symptoms (20% vs 27%, p=0.377), health concerns (17% vs. 11%, p=0.481) or overall well-being.

Conclusion: One-third of adolescents and young adults with CeD reported other special diets in addition to GFD, but these did not associate with overall well-being or treatment success.

Disclosure: Nothing to disclose.

PP0386

FACTORS ASSOCIATED WITH REDUCED QUALITY OF LIFE IN COELIAC DISEASE PATIENTS AT DIAGNOSIS AND IMPROVEMENT ON A GLUTEN-FREE DIET

P. Laurikka[1,2], S. Vuolle[1,3], S. Sorvisto[1], L. Kivelä[1,3,4], H. Huhtala[5], K. Kurppa[3,6], K. Kaukinen[1,2], C. Pasternack[1,7]

Contact E-Mail Address: pilvi.laurikka@tuni.fi

Introduction: Coeliac disease-associated symptoms recover usually on a gluten-free diet (GFD) while its effect on the quality of life is not as straightforward. Some patients experience the diet burdensome and socially resctritive, which predispose them to negative experiences. Deciphering factors associated with reduced quality of life at coeliac disease diagnosis and significant improvement on GFD would be important for optimal treatment outcomes. We studied these issues in a prospective patient cohort.

Aims & Methods: Medical data on 178 adult coeliac disease patients were gathered at diagnosis and after one year on a strict GFD via structured interviews including Psychological General Well-Being (PGWB) and Gastrointestial Symptom Rating Scale questionnaires. Data were supplemented with available medical records.

Decreased quality of life was defined as PGWB total score below the 25th percentile and significant improvement as a change in PGWB total score above the 75th percentile of the whole cohort. Logistic regression model was used to discover the factors associated with reduced quality of life and significant improvement on GFD.

Results: Decreased quality of life at diagnosis was associated with female sex (odds ratio 2.83, 95% confidence interval 1.15-6.97), severe gastrointestinal symptoms (4.02 [1.84-8.77]), presence of psychiatric comorbidities (17.7 [1.99-156]) and clinically vs. screen-detected presentation (2.54 [1.17-5.50]). Same factors increased risk for decreased quality of life on a GFD. Significant improvement in the quality of life was associated with reduced quality of life (5.98, [2.67-13.4]) and severe gastrointestinal symptoms (4.92 [2.24-10.8]) at diagnosis, autoimmune comorbidities (2.65 [1.12-6.31]), and clinically vs. screen-detected presentation (4.54 [1.98-10.5]).

Conclusion: Female sex, psychiatric comorbidities and severe gastrointestinal symptoms were associated with reduced quality of life both at coeliac disease diagnosis and on GFD. These patients may need additional support in health care, and good response to GFD should be documented. On the other hand, especially patients with severe symptoms and decreased quality of life at diagnosis as well as those with autoimmune comorbidities seemed to benefit from GFD.

Disclosure: Nothing to disclose.

Contact E-Mail Address: daniel.leffler@takeda.com

Introduction: Celiac disease (CeD) is a chronic, immune-mediated, systemic disorder characterized by inflammation of the small intestine, antibody formation and villous damage in response to gluten ingestion. The only current management/treatment option for CeD is a gluten-free diet (GFD), which has major limitations, not least that patients following a GFD may still experience symptoms.

The US Food and Drug Administration guidance 'Celiac disease: developing drugs for adjunctive treatment to a GFD' indicates that symptom monitoring should be a co-primary endpoint with histology for the assessment of disease improvement in clinical trials.

Aims & Methods: This US prospective observational study (Virtual Celiac Symptoms Study, NCT05309330) aimed to assess experience with a GFD and celiac-related symptoms in patients with CeD. Eligible participants were aged ≥12 years, had a CeD diagnosis for ≥1 year confirmed via self-reported biopsy (biopsy or serology for participants aged <18 years), were on a GFD for ≥6 months and reported CeD-related symptoms in the past 3 months. Participants were recruited with the assistance of the Celiac Disease Foundation via digital advertisements and data were collected using an electronic patient-reported outcomes platform. Study participants were followed up for 12 weeks and CeD-related symptoms and gluten exposure were assessed daily. Quality of life and healthcare resource utilization were also assessed. This analysis focuses on the gastrointestinal (GI) symptoms of diarrhea, abdominal pain, bloating, nausea and vomiting experienced by adults during the study.

Symptom	Participants with GI symptom(s) over the 12-week follow-up period, n (%)	Proportion of days with symptom occurrence over the 12-week follow-up period, %[a]
Bloating	333 (98.5)	60.5
Abdominal pain	335 (99.1)	52.9
Diarrhea	321 (95.0)	32.0
Nausea	319 (94.4)	30.2
Vomiting	142 (42.0)	6.0

[a]Among participants who experienced each symptom.
GI, gastrointestinal.

Table 1. GI symptom occurrence among adult participants (N = 338)

Results: The study was conducted from July 25, 2022 to March 4, 2023. Adults comprised 338 of the 480 participants (88% female; 99% White) with a median age of 37 years (range 18–71).

At baseline, 58% of adult participants reported CeD-related symptoms in the past week. All adult participants reported following a GFD; 21% reported "*never eating gluten accidentally or on purpose*" and 71% reported "*rarely eating gluten accidentally*".

The remaining 8% reported "*rarely eating gluten on purpose*". During the 12-week study, all of the adults reported at least one GI symptom, with each GI symptom (with the exception of vomiting), occurring at least once in over 90% of adults (abdominal pain 99%, bloating 99%, diarrhea 95%,

nausea 94% and vomiting 42%). Frequency of GI symptoms was high. For adults who experienced abdominal pain or bloating, these symptoms occurred on >50% of the follow-up days. For adults who experienced diarrhea and nausea, these symptoms occurred on >30% of days (Table 1).

Conclusion: Despite participants adhering to a GFD, symptom frequency in this adult population with CeD was high. GI symptoms such as diarrhea, nausea, bloating and abdominal pain may be appropriate endpoints for inclusion in clinical trials of potential CeD therapies. This study further highlights the unmet need for additional treatments for patients with CeD on a GFD.

Contact E-Mail Address: maxim_roxxana@yahoo.com

Introduction: Celiac disease (CD) is a complex multi-systemic autoimmune disease. The present study aims to determine the rate of mucosal recovery and predictors of persistent mucosal damage after GFD. There is still little evidence on the best method for assessing gluten-free diet (GFD) adherence and mucosal recovery during treatment.

Aims & Methods: The retrospective study included only adult patients (age≥18 years old), with biopsy-proven CD evaluated at a tertiary referral centre between 2016-2021.We performed a logistic regression analysis to identify factors associated with partial mucosal recovery (MR) after GFD. We included in the multivariate analysis parameters available at the time of CD diagnosis.

Results: A total of 102 patients were enrolled, two thirds were females, median age of 39 yrs. The initial biopsy analysis showed different stages of villous atrophy (VA) in 79 (77.4%) cases, while 23(22.5%) cases showed mild enteropathy (Marsh 1,2). After at least 12 months of GFD, 26 (25.5%) patients had persistent VA despite good or excellent adherence to GFD. Younger patients (< 35yrs), who showed severe mucosal damage (Marsh 3c lesions) and who had increased anti-gliadin antibody (AGA) levels were at risk for failure to obtain mucosal recovery (MR). The multivariate Cox regression analysis demonstrated that complete mucosal atrophy (p = 0.007) and high AGA antibody levels (p = 0.001) were independent risk factors for a lack of mucosal improvement after at least 12 months of GFD. Interestingly, genotype, tTG-IgA antibody levels, or duration of GFD levels did not influence the occurrence of MR.

Conclusion: Although AGA seropositivity has lost much of their diagnostic significance in recent years due to the introduction of the more sensitive and specific antibody tests, our study reported that patients aged < 35yrs, who showed severe mucosal damage (Marsh 3c lesions) and who had increased AGA antibody levels at diagnosis were at risk for failure to obtain MR. The elevated AGA levels at diagnosis could be used as a prognostic tool for assessing MR.

UTILITY OF FLOW CYTOMETRY IN THE PREDICTION OF OUTCOME OF REFRACTORY COELIAC DISEASE TYPE II (RCD II)

S. Bennett[1], D. Skrobo[2], F. Murray[3], C. Brodie[2], V. Byrnes[1]

[1]University Hospital Galway, Department of Gastroenterology, Galway, Ireland, [2]University Hospital Galway, Department of Histopathology, Galway, Ireland, [3]University Hospital Galway, Department of Haematology, Galway, Ireland

Contact E-Mail Address: siofrabennett@gmail.com

Introduction: RCD is defined by persistent or recurrent malabsorptive symptoms and villous atrophy despite adherence to a gluten free diet (GFD) for at least 6-12 months. RCD can be classified as type I (normal intraepithelial lymphocyte phenotype) or type II (abnormal or aberrant IEL phenotype, i.e. IELs that have lost surface expression of CD3 and CD8 but retained cytoplasmic CD3 expression.

RCD II can be diagnosed by immunohistochemistry (reduced CD8 staining), molecular analysis (TCR gene rearrangement studies) or flow cytometry.

Flow cytometry provides a rapid, quantitative assessment of the degree of aberrancy (% of abnormal IELs/total number IELs) in patients with non-healing CD and may help predict the risk of future development of EATL.

Aims & Methods: The aim of this study was to evaluate the utility of flow-cytometry for the prediction of EATL and mortality in patients with RCDII in a tertiary referral centre.

The results of all flow cytometry assays performed on duodenal biopsies since commencement of the service were reviewed in addition to patient outcomes. RCD II was defined as a % aberrancy of IELs of >20%.

Results: 55 assays were performed on 38 patients. RCD II was identified in 10 patients (6 females), all of whom had evidence of clonality on TCR gene rearrangement studies. 3/10 had normal staining for CD^3/CD^8 and would have been misdiagnosed on immunohistochemistry alone.

Median age of RCD II diagnosis was 63 years, and median time to RCD II development from CD diagnosis was 9 years. Mean and median follow up was 6 years.

The mean and median % aberrancy of IELs were 73% and 79%.

The mean and median % aberrancy of those who died (n=5, 4EATL, 1 neuro-coeliac) were 75% and 80% respectively, and of those who survived were 68% and 66%, respectively.

All patients were treated with budesonide which improved clinical and histological findings but serial flow studies where available failed to demonstrate a reduction in the degree of aberrancy. 5 patients received ASCT for RCD II alone.

On follow up, 1 patient had complete loss of clonality in spite of persistent aberrancy (43%) 11 yrs post ASCT. A further patient demonstrated a drop in aberrancy from 52% to 21% within 4 months of ASCT but experienced a steady rise again to 47%, 55%, and 72% at 1, 2 and 8 years post ASCT with the eventual development of EATL at 9 years post ASCT.

Conclusion: Flow cytometry is an efficient and reliable method to asses for RCDII. Mortality risk appears to correlate with the degree of aberrancy. Serial measurements demonstrating a steady rise in the percentage of aberrant IELs may signal impending EATL.
Disclosure: Nothing to disclose.

PP0391

POOR CORRELATION BETWEEN ANTI-TTG IGG AND MUCOSAL RECOVERY IN THE IGA-DEFICIENT COELIAC

J.R. Campion[1], M. Alkadhim[1], L. Thomas[1], V. Byrnes[1]
[1]*University Hospital Galway, Gastroenterology, Galway, Ireland*

Contact E-Mail Address: johnrcampion@gmail.com
Introduction: Selective IgA deficiency occurs in 0.3% of the population but is observed in 3% of people with coeliac disease (CD). Measurement of anti-TTG IgG provides an alternative screening test to anti-TTG IgA in such a cohort. However there is a paucity of data regarding the correlation between the decline in the anti-TTG IgG levels and mucosal healing following initiation of a gluten-free diet in IgA-deficient coeliac disease.
Aims & Methods: We set out to:
1. Assess the rate of decline of anti-TTG IgG following gluten elimination in patients with IgA deficient coeliac disease and
2. Assess the correlation between anti-TTG IgG and mucosal healing following gluten elimination. IgA-deficient patients were identified retrospectively from the coeliac database. Clinical, laboratory and histologic data were retrieved from the electronic patient record (EPR) and patient symptoms were recorded from the contemporaneous clinical notes.
Results: 19 patients with IgA-deficient CD were identified. Eight patients (42%) were male and 11 (58%) female. Median (IQR) age at diagnosis was 25 years (15, 39). Symptoms reported included bloating (34%), abdominal pain (21%), diarrhoea (21%) and fatigue (21%). Five patients (26%) had at least one other autoimmune condition. Three patients (15.7%) had normal tTG igG on first testing, having been diagnosed on the basis of duodenal biopsy at another centre. Of those who reported adherence to gluten free diet after diagnosis, 40%, 25% and 25% of IgA deficient coeliacs normalized their IgG anti-TTG levels at 1, 3 and 5 years respectively. Of those patients whose duodenal histology normalised after elimination of dietary gluten, only 21.4% had concurrent normalisation of anti-TTG IgG.
Conclusion: The decline in IgG anti-TTG following gluten elimination does not correlate with mucosal healing. IgA-deficient coeliacs can be reassured that a persistently positive IgG anti- TTG does not signify ongoing gluten ingestion and physicians can be reassured by histologic recovery in such patients irrespective of the anti-TTG titre.
Disclosure: Nothing to disclose.

Introduction: Celiac disease (CD) has been associated with reduced quality of life and psychological disorders, among which the most common are anxiety and depression [1, 2]. Several reports have focused on the difficulties of living with CD, particularly regarding its impact on physical, social and emotional factors in adults.
Aims & Methods: The cross-sectional study evaluated the changes in the anxiety and depression of 48 patients with CD. The control group was consisted of 20 people without gastrointestinal diseases. Several validated questionnaires were administered to measure psychological symptoms (the Medical Outcomes Study Questionnaire Short Form 36 Health Survey (MOS SF-36), Hospital Anxiety and Depression Scale (HADS) and State-Trait Anxiety Inventory (STAI)) and adherence to a gluten-free diet (GFD). Based on the results GFD the patients divided into two groups. The first group patients have not been adhered to a GFD and the second group patients have been strictly following a GFD.
Results: To decrease of the level physical and mental components of the quality of life was determined in patients with CD in comparison with the control group (36.1 and 40.0, respectively; $p < 0.01$). The most of the patients with CD (72.8%) had anxiety reactions.
According to HADS anxiety has reached clinically significant level in 43.7% patients with CD. STAI score state anxiety and trait anxiety have been elevated in patients with CD ($p < 0.01$). Its haven't been significant differences in the frequency and severity of anxiety in patients with CD without and with GFD. Symptoms of depression have been more frequently in patients with CD with GFD, however it's have not been reached a clinically significant level.
Conclusion: The features of emotional disturbances in patients with CD include the prevalence of the frequency of anxiety over the depression. The results showed no correlation between anxiety and adherence to GFD. The severity of depression increased in patients with GFD. This finding is consistent with Barratt et al.'s finding that difficulty with GPA compliance is a major factor in reduced quality of life [3].

PP0393

INCIDENCE OF VITAMIN A DEFICIENCY IN PATIENTS WITH GASTROINTESTINAL CONSEQUENCES OF CANCER TREATMENT

G. Neokosmidis[1], C. Fleuret[1], A. Wilson[1,2], C. Funnell[3], D. Cunningham[1], D. Kohoutova[1]
[1]Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom, [2]St Marks Hospital, London, United Kingdom, [3]Epsom and St Helier University Hospitals, Surrey, United Kingdom

Contact E-Mail Address: darina.kohoutova@seznam.cz

Introduction: Limited knowledge regarding vitamin A deficiency in cancer patients is available. Vitamin A is a fat-soluble vitamin crucial for cell development, immune competency, metabolism and vision.

Absorption of vitamin A in the proximal parts of the small intestine follows its hydrolyzation by pancreatic and intestinal enzymes and emulsification by bile acids. Xerophthalmia and incipient night blindness can serve as clinical reminder of vitamin A deficiency and can be a reversable phenomenon.

The aim of our study was to establish the incidence of vitamin A deficiency in patients suffering from bile acid malabsorption (BAM) and/or syndrome of intestinal bacterial overgrowth (SIBO) and/or exocrine pancreatic insufficiency (EPI) as a consequence of cancer treatment.

Aims & Methods: This was a retrospective evaluation of data in individuals reviewed within twelve months period (January 2022 - December 2022) in a specialized gastroenterology clinic in a tertiary centre. Patients who had undergone any anti-cancer treatment (chemotherapy and/or radiotherapy/and or surgery) and have been suffering from gastrointestinal (GI) symptoms are referred to this clinic.

The electronic patient records system was searched. Demographic data, incidence of BAM (assessed with SeHCAT scan: retention on day 7 <20%) and/or SIBO (evaluated by glucose breath test – positivity in production of hydrogen and/or methane) and/or EPI (based on investigation of faecal elastase: <200ug/g) and serum vitamin A levels (normal ranges: 1.07-3.55 µmol/L) were assessed.

In one patient who could not have the above investigations due to severity of symptoms, therapeutic trial resulting in clear response to medication (Rifaximin / pancreatic enzymes) was used for the diagnosis of SIBO or EPI. The study was approved by CCR committee (reference number: SE 1267

Results: A total of 453 consecutive patients were seen. Out of 453 patients, 23% (101/453) were diagnosed with BAM, 4% (17/453) with BAM and SIBO, 3% (14/453) with BAM and EPI, 3% (15/453) were diagnosed with SIBO, 3% (12/453) with EPI and 2% (10/453) with SIBO and EPI. Out of 169 patients (169/453; 37%) who suffered from BAM and/or SIBO and/or EPI, five patients (3%; 5/169) were diagnosed with serum vitamin A deficiency.

Three of them (2%; 3/169) received oral supplementation (those were diagnosed with BAM+EPI, SIBO+EPI and isolated EPI) and two (1%; 2/169) required intramuscular supplementation due to a significantly impaired vision, mainly night blindness and a very low serum vitamin A level (0.11 µmol/L; 0.25 µmol/L).

The first patient (diagnosed with SIBO in combination with EPI) received three doses of vitamin A 100.000 IU and another ten doses of 50.000 IU intramuscularly.

The second patient (diagnosed with BAM) received a single dose of vitamin A 100.000 IU and four doses of 50.000 IU intramuscularly.

In the first patient who had a more prolonged history of nutritional deficiency as well as possible additional as yet undiagnosed cause for the retinal dysfunction, vision improved but the patient continued to have reduced visual function. In the other patient the vision returned to normal. The most recent serum vitamin A levels have been 1.73 µmol/L and 1.76 µmol/L.

Conclusion: Incidence of vitamin A deficiency in a cohort of patients who underwent treatment for cancer and developed GI consequences was 3%, however it can be severe, with significant clinical consequences. Timely recognized severe vitamin A deficiency can be reversible if an appropriate parenteral supplementation is administered.

Disclosure: No conflict of interest

INCIDENTAL SMALL BOWEL LYMPHANGIECTASIA ARE ASSOCIATED WITH LOWER SERUM PROTEIN, ALBUMIN AND TRIGLYCERIDES

A.R. Robertson[1]
[1]University Hospitals of Leicester NHS Trust, Gastroenterology, Leicester, United Kingdom

Contact E-Mail Address: alexanderrrobertson@hotmail.co.uk

Introduction: Lymphangiectasia and lymphangiectic cysts result from dilated intestinal lacteals due to disordered drainage. This can result in leakage of lymph into the lumen with resultant hypoproteinaemia, hypogammaglobulinaemia, hypoalbuminaemia and a lymphopenia (1,2). This is most clinically apparent in those with widespread severe change, such as congenitally anomalous drainage or secondary causes including, infections, lymphoma/malignancy, inflammation or radiotherapy (1,3,4). This can result in malabsorption or widespread failure of lymphatic drainage.

It is unclear whether subtle incidental lymphangiectasia without clinical malabsorption are significant. Subtle, incidentally noted changes including scattered pinpoint white spots, prominent villi with white tips and small focal macules or nodules (5) are an increasingly common finding. With increased use of high-definition capsule technology, more subtle changes are increasingly recognised. Older studies show these are common, with follow up and fat absorption studies concluding that incidentally noted dilated lacteals, without clinical malabsorption likely did not require follow up (5–7).

Aims & Methods: We aim to assess whether the incidental, and "clinically insignificant", lymphangiectasia seen on capsule endoscopy are associated with changes in protein, albumin, cholesterol, triglyceride, calcium or lymphocyte levels. The hypothesis being that more subtle lymphatic anomaly will result in a more subtle biochemical picture.

Values are stated as means (+/- SD) with P values calculated using two tailed t-test or Chi square, <0.05 taken as significant.

Results: 21 patients with lymphangiectasia noted to be the only, or main, finding on capsule endoscopy were retrospectively reviewed. 21 age and gender matched controls (61.9% male, aged 52 (+/-15) years) with normal capsule and colonoscopies were extracted for comparison. Comorbidities and blood results were recorded for each.

Two patients with clinically significant widespread lymphatic changes secondary to systemic disease (disseminated mycobacterial infection and end stage cirrhosis both with lymphatic obstruction) were excluded. The remaining patients had either incidental scattered white tipped villi, discrete nodules/polyps of dilated white villi, or discrete chylous cysts (or a combination of these).

	Lymphangiectasia (n=19)	Control (n=21)	p value
Age (years +/- SD)	52 (+/-16)	52 (+/-15.1)	0.984
Male (%)	57.1	61.9	0.935
Past medical history	4 none (or IBS), 3 inactive IBD, 3 malignancy, 3 asthma, 3 hypertension, 2 diabetes, 2 IHD, 1 structural cardiac disease, 1 CKD, 1 HIV, 1 thyroid dysfunction.	7 none (or IBS), 2 inactive IBD, 1 malignancy, 3 hypertension, 2 diabetes, 1 IHD, 1 CKD, 2 COPD, 1 sarcoidosis, 1 Meniere's, 1 hypogammaglobulinaemia, 1 TIA, immunodeficiency, 1 thyroid dysfunction.	
Total protein (g/L)	66.9	72.2	**0.00967**
Albumin (g/L)	44.3	46.5	**0.032**
Adj. Calcium (mmol/L)	2.23	2.28	0.0627
Cholesterol (mmol/L)	4.5	4.87	0.401
Triglycerides (mmol/L)	1.38	1.99	**0.038**
Lymphocytes (x10-9)	2.23	2.01	0.365

Table 1: Lymphangiectasia and controls.

Conclusion: This study would suggest that those with lymphangiectasia have lower protein, albumin, calcium, cholesterol, and triglyceride levels (protein, albumin and triglycerides reaching statistical significance). There is a paucity of recent research in this field and the historical assumption that incidentally noted lymphangiectasia are meaningless may not be entirely accurate. Correlation does not equal causation as these markers are dependent on a huge number of factors. This is a small patient group, and a larger study would be required to further explore this. Selectively blocking small bowel lymphatics may represent a potential therapeutic target and further research in this field could have a range of clinical implications.

PP0395

LOW DOSE LIRAGLUTIDE WITH PRAGMATIC DOSE ESCALATION ACHIEVES REMISSION IN MORE THAN HALF OF 27 PATIENTS WITH SEQUESTRANT-REFRACTORY BILE ACID DIARRHOEA: A CASE SERIES

N. Nyboe Andersen[1], C. Borup[1], L.K. Munck[1]

[1]Zealand University Hospital, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Køge, Denmark

Contact E-Mail Address: nynne@nyboeandersen.com

Introduction: Bile acid diarrhoea is a common cause of chronic watery diarrhoea. Recent randomised studies have demonstrated the effect of the sequestrant colesevelam and the glucagon-like peptide-1 analogue, liraglutide (1, 2).

The colesevelam dose was titrated to effect, while liraglutide was increased to the maximum dose of 1.8 mg daily. No therapeutic guidelines have incorporated these findings, and the optimal dosing is not settled.

Aims & Methods: We aimed to describe the effect of second-line treatment with liraglutide with pragmatic dose-escalation on remission of bile acid diarrhoea refractory to sequestrant therapy.

From the 1st of April 2022 to the 3rd of March 2023, patients with bile acid diarrhoea either diagnosed by SeHCAT retention of less than 15% or by a history of small bowel resection were included from our outpatient clinic. The patients were either intolerant to or had treatment failure of sequestrants (colestyramine and/or colesevelam) and fulfilled the Hjortswang diarrhoea criteria (3 or more stools or 1 or more watery stool per day).

Diary-recorded bowel habits were evaluated by the mean daily total number and the daily mean number of watery stools (Bristol stool chart type 6 and 7). A dose of 0.6 mg/day liraglutide was initiated at baseline.

Patients were evaluated every two to three weeks; patients without remission and no significant adverse events had the dose increased in increments of 0.6 mg/day liraglutide, possibly to a maximum dose of 1.8 mg/day liraglutide. Remission was defined as a daily mean of < 1 watery bowel movement and < 3 total bowel movements.

The total number of bowel movements and the number of watery bowel movements were log-normally distributed. Geometric means of the baseline were compared with values at the final treatment dose using paired t-test. Clopper-pearson's confidence interval was used for the binary remission data.

Results: A total of 27 patients were included, of whom 19 (70%) were female and the mean weight at baseline was 93 kilograms (range 58-183).

Twenty-one (78%) were diagnosed by SeHCAT testing (median retention value 4%, range 0-11%), while six (22%) were diagnosed by a history of bowel resection, four of whom were due to Crohn's disease. Three patients had a history with cholecystectomy and six patients had a concurrent diagnosis of microscopic colitis.

In total 15 (56%) of the 27 patients achieved remission. Five patients had 0.6 mg/day liraglutide as the final dose, with four achieving remission; seven of nine achieved remission at 1.2 mg, and 4 of 13 patients on the maximum dose of 1.8 mg. Two patients not in remission on 1.8 mg liraglutide/day obtained remission with the addition of colestyramin 4 g once daily.

The geometric mean total bowel movements at baseline of 6.5 (95% CI, 5.1-8.3) was reduced to 2.8 (95% CI, 2.2-3.5) at the end of follow up ($p < 0.0001$). The geometric mean number of watery bowel movements at baseline of 5.1 (95% CI, 3.7-7.0) was reduced at end of follow up to 0.8 (95% CI, 0.6-1.1, $p < 0.0001$).

Conclusion: Second-line liraglutide with pragmatic dose-escalation achieved remission in 15 of 27 patients with bile acid diarrhoea intolerant or with insufficient treatment response to conventional sequestrants. Of the 15 in remission, 11 did not need maximum liraglutide dosing. Proper

diagnosis of bile acid diarrhoea is needed to enable second-line therapy.

Introduction: Lactose intolerance is defined as an impaired lactose absorption associated with symptoms including diarrhea, abdominal pain and bloating. It is caused by a genetically determined reduced expression of the enzyme lactase in the small intestine; although, several studies underline that symptoms do not depend exclusively on genetics. Among different possible causes, few information exists on microbiota signatures.

Aims & Methods: In this study, we aimed to investigate specific gut microbiota features associated with lactose intolerance and respective gastrointestinal (GI) symptoms.

Adult patients presenting GI symptoms compatible with lactose intolerance were enrolled and underwent a) a validated questionnaire for self-assessment of gastrointestinal symptoms; b) lactose breath test to confirm lactose malabsorption; c) lactulose/mannitol breath test to assess intestinal permeability and intestinal transit; d) 16S rRNA gut microbiota profiling.

Healthy controls without GI symptoms or diseases were enrolled.

Patients with inflammatory bowel disease, recent infectious enteritis, active neoplasia, pregnant women, with recent history of medications were excluded.

Results: According to the results of the tests, patients were divided into three groups: 28 patients with lactose intolerance (group 1), 7 patients with GI symptoms and negative lactose breath test (group 2), 29 healthy controls (group 3).

GI symptoms assessed by questionnaire were prevalent in patients with lactose malabsorption in comparison to patients without lactose malabsorption and in comparison to healthy controls (average GSRS group 1 14.6, group 2 9.8, group 3 2.6). Increased intestinal permeability (group 1 88.8% vs group 2 100% vs group 3 6.6%) and altered intestinal transit (group 1 50%, group 2 50%, group 3 27%) were observed in patients with GI symptoms, independently from lactose malabsorption.

Gut microbiota profiling showed an increased biodiversity between patients with lactose intolerance (group 1) and healthy controls (group 3), both in terms of alpha-diversity ($p<0.05$ according to Shannon and Simpson index) and beta-diversity ($p=0.001$). According to taxonomic analysis, Proteobacteria and Bacteroidetes phyla were significantly higher in patients with lactose intolerance in comparison to healthy controls ($p<0.05$). At the species level, significant markers of dysbiosis in lactose intolerant individuals appear to be represented by Dialister, Staphylococcus, Streptococcus, Enterobacteriacae, Bacteroides ($p<0.05$).

Conclusion: Specific gut microbiota signatures are associated with lactose intolerance, suggesting a role as a prebiotic for lactose, targeting differential microbial elements. Increased intestinal permeability and altered intestinal transit are common features of patients presenting GI symptoms, independently from lactose malabsorption. For this reason, further microbiota characterization is required to elucidate mechanisms leading to symptoms development and treatment.

SMALL-BOWEL CANCER SURVEILLANCE WITH CAPSULE ENDOSCOPY IN LYNCH SYNDROME – A SYSTEMATIC REVIEW WITH META-ANALYSIS

P. Cortegoso Valdivia[1], U. Deding[2,3], T. Bjørsum-Meyer[2,3], M. Pennazio[4], F. Gaiani[1,5], A. Koulaouzidis[6,2,7,8], L. Laghi[1,5,9]

Contact E-Mail Address: akoulaouzidis@hotmail.com

Introduction: The role of capsule endoscopy (CE) for the surveillance of small-bowel (SB) cancer in asymptomatic Lynch syndrome (LS) patients has been questioned in recent years, with contradicting results. The overall lifetime risk of SB cancer in this population is around 4-5%, with an age-dependent pattern [1]. Besides, recent data highlight that, depending on the affected *path_MMR* gene, the frequencies of tumors other than colorectal cancer vary and that affected patients develop subsequent cancers later in life. The aim of this meta-analysis is to evaluate the diagnostic yield (DY) of CE as a screening tool in asymptomatic LS patients.

Aims & Methods: A systematic literature search was conducted in Pubmed, Embase and Web of Science to identify all studies evaluating SB cancer surveillance with CE in asymptomatic LS patients.

The primary outcome was the evaluation of the DY of CE in consecutive screening rounds, for both CE-identified pathology and histologically-confirmed pathology (*i.e.*, adenoma or adenocarcinoma). Pooled estimates of DY were calculated from random effects models.

Results: Five studies including 583 patients were identified for data extraction and statistical analysis [2-6] [Table].

The estimated pooled DY for CE-identified pathology was 8% in the first screening round (95% confidence interval [CI] 4-12%) and 6% in the second (95% CI 2-10%). Limiting the analysis to histologically-confirmed pathology, the pooled DY of the second-round screening dropped to 0% (95% CI 0-6%). The time interval between screening rounds was approximately 2 years.

Adenomas were detected in 8 patients (4 males) with a median age of 47.5 years (interquartile range [IQR] 19), while adenocarcinomas were diagnosed in 8 patients (5 males) with a median age of 62.5 years (IQR 17.25). *MLH1* was the most involved *path_MMR* pathogenic variant (9 out of 16 patients), followed by *MSH2* and *MSH6* (5 and 2 patients, respectively). No adenocarcinomas were detected in *MSH6* carriers, as only adenomas were found in 2 patients, with a considerably higher median age than *MSH2* and *MLH1* adenoma carriers (70.5 years versus 43.5 and 45). No predominance was observed according to the anatomical location (duodenum, n=6; jejunum, n=6; ileum, n=4).

Conclusion: The detection of adenocarcinoma appeared to have a 15-year delay compared to adenomas, supporting a rather slow adenoma to carcinoma transition.

A surveillance strategy starting from the age of 50, with a time interval between procedures lengthened to at least 5 years (instead of 2) could likely be more effective in reducing the burden of advanced disease, both in terms of cost-effectiveness and efficacy. Prospective data may reveal whether a potential SB surveillance might benefit from gene-associated differences in cancer risk, similar to the recent de-escalation of CRC screening recommendations in *MSH6* and *PMS2* carriers [7].

In conclusion, although the DY of CE is high in detecting SB lesions in LS, the low number of positive examinations eventually resulted in an even lower number of true-positive patients, with a pooled yield proximate to 0%.

The results of this study confirm that SB cancer surveillance with CE with a 2-year interval in asymptomatic LS individuals is not an effective screening strategy.

Introduction: Follicular lymphoma primarily or secondarily occurs in the gastrointestinal tract[1]. The disease entity of intestinal follicular lymphoma was established in the last two decades and is now formally considered a distinct subcategory of follicular lymphomas in the classification of tumors of hematopoietic and lymphoid tissues published by the World Health Organization (WHO)[2].

Multiple white, polypoid lesions in the duodenum, which are incidentally found during esophagogastroduodenoscopy, are the typical endoscopic features of intestinal follicular lymphoma. Among the patients with follicular lymphoma with intestinal involvement, 66.7–100% have multiple follicular lymphoma lesions in the jejunum and/or ileum.

Because of the widespread involvement of the small intestine, radiotherapy is not feasible even in cases of localized stage intestinal follicular lymphoma. Although treatment strategies have not yet been standardized, the watch-and-wait approach is often preferred in clinical settings. However, because of the rarity of this disease, the long-term outcomes of patients who are managed with this approach have not been sufficiently investigated.

Therefore, in the current study, we analyzed the outcomes of 73 patients with primary intestinal follicular lymphoma who were diagnosed before 2016 and managed using the watch-and-wait approach.

Aims & Methods: Patients with primary intestinal follicular lymphoma who were diagnosed before 2016 and managed with the watch-and-wait approach in 20 institutions were enrolled. We retrospectively investigated the overall, disease-specific, and event-free survival rates as well as the rate of spontaneous regression.

Results: Among the 248 patients with follicular lymphoma with gastrointestinal involvement, 124 had localized disease (stage I or II_1). We analyzed the data of 73 patients who were managed using the watch-and-wait approach. During the mean follow-up period of 8.3 years, the follicular lymphoma had spontaneously resolved in 16.4% of the patients. The 5-year and 10-year overall survival rates were 92.9% and 87.1%, respectively. With disease progression (n = 7), initiation of therapy (n = 7), and histologic transformation to aggressive lymphoma (n = 0) defined as events, the 5-year and 10-year event-free survival rates were 91.1% and 86.9%, respectively. No patient died of progressive lymphoma. Thus, both 5-year and 10-year disease-specific survival rates were 100%.

Conclusion: An indolent long-term clinical course was confirmed in the patients with primary intestinal follicular lymphoma. The watch-and-wait strategy is a reasonable approach for the initial management of these patients.

Introduction: Primary small-bowel follicular lymphoma (FL) often presents as multiple white granular elevations involving from the duodenum to the deep small-bowel. Capsule endoscopy (CE) is useful in evaluating the disease surveillance for primary small-bowel FL, but objective evaluation is difficult in some cases.

Aims & Methods: We aimed to evaluate the usefulness of the deep convolutional neural network (CNN) system using CE images for assessing the disease surveillance of primary small-bowel FL. We enrolled 26 consecutive patients with primary small-bowel FL (all with multiple white granular elevations in the small-bowel at the initial CE) diagnosed between January 2011 and January 2021 who underwent CE before and after watch-and-wait or chemotherapy management. The disease surveillance was evaluated by two physicians and the developed CNN system. To construct the CNN system, it was trained with CE still images using deep learning. Evaluation of the disease surveillance by the CNN system was assessed using the percentage of FL-detected images among all CE images, from the duodenum to the terminal ileum.

Results: Eighteen cases (69%) were managed with a watch-and-wait policy, and 8 cases (31%) were treated by chemotherapy. Among the 18 cases managed with a watch-and-wait policy, the physicians evaluated the lesions as almost the same in 14 cases (78%) and as aggravation in 4 cases (22%). The evaluation of lesions by the CNN system showed almost the same in 13 cases (72%), aggravation in 4 cases (22%), and improvement in 1 case (6%). Among the 8 cases treated by chemotherapy, the physicians evaluated the lesions as improvement in 7 cases (88%) and as almost the same in 1 case (12%). The evaluation of lesions by the CNN system showed improvement in 5 cases (63%), almost the same in 2 cases (25%), and aggravation in 1 case (12%). In 23 of 26 cases (88%), both the physicians and the CNN system had similar results in evaluating the disease surveillance. In 3 of 26 cases (12%), there was a discrepancy between the evaluating by the physicians and the CNN system. This discrepancy of evaluation was attributed to poor small-bowel cleansing level.

Conclusion: Evaluation for the disease surveillance of primary small-bowel FL managed with a watch-and-wait policy or chemotherapy using CE images by the developed CNN system was considered useful under the condition of excellent small-bowel cleansing level.

Introduction: Background and objectives: Small intestinal neuroendocrine tumours (SI-NETs) are slow growing but have often metastasized at the time of diagnosis. Most patients are operated either with the intention of curation or to prolonged survival. Improved surgical resection, more comprehensive oncological treatment as well as earlier diagnoses may improve survival, but only few studies have examined survival trends. In this study we aimed to examine the trend in overall survival in patients diagnosed with SI-NETs.

Aims & Methods: Patients with a histological and / or imaging-based diagnosis of SI-NET in Central Norway from 2005 to 2021 were identified. Patient, disease and treatment characteristics including histological grade (G), European Neuroendocrine Tumour Society (ENETS) stage, surgical and oncological treatment types and survival were retrospectively recorded.

The cohort was divided in those diagnosed in period one (June 2005-November 2012) and period two (November 2012-December 2021), with 121 patients in each sub-cohort.

Overall survival was analyzed using the Kaplan Meier method and a Cox multivariate analysis was performed to identify factors independently associated with survival.

Results: The 242 patients had a median age 70 (17-91) years at diagnosis or surgery and 55.8% were males. The majority of patients underwent surgery (n=205, 84.7%) which was considered curative in 137 (66.8%) patients. Median estimated overall survival was 10.1 years (95% CI 8.5-11.7) and the median overall survival for localized, regional and distant disease stage was 10.6 years (95% CI 7.9-13.2), 11.0 years (95% CI 8.8-13.2) and 7.1 years (3.4-10.8), p=0.005, respectively.

Patients diagnosed in period one had a median survival of 9.0 years (95% CI 6.4-11.7), while median survival for period two was significantly longer and was not reached, p = 0.014. Five year survival for period one was vs. period two was 63.5% and 83.5%. The Kaplan-Meier curves for period one and two separated the first year after diagnosis and the difference persisted.

For resected patients the median survival was 9.6 years (95% CI 8.4-10.9) in period one, whereas median survival was not reached for period two, p = 0.008. The ENETs disease stage did not differ between period one and two, but a higher proportion had carcinoid heart disease in period one (7.4% vs. 1.7%, p=0.031).

A higher proportion of patients who underwent SI-NET resection were considered tumour free after surgery in period two than in period one (74.3% vs 59.6%, p=0.027). There was also a higher proportion of patients with resection of multiple primary SI-NETs in period two (37.6% vs. 24.0%, p=0.049), which was explained by a higher proportion of multifocal tumours being resected during elective surgery (42.9% vs. 21.1%, p 0.005). There was also a higher number of retrieved lymph nodes in period two (p=0.014).

Similar proportions of patients received somatostatin analogues, PRRT or transarterial embolization of liver metastases in period one vs. period two. In a Cox proportional hazard regression model age at diagnosis, ENETS stage, tumour resection and diagnosis before November 2012 were independently associated with overall survival, whereas sex and tumour grade were not.

Conclusion: Survival of patients with SI-NET improved over the study period and this seemed related to lower mortality the first year after diagnosis. Disease stage or oncological treatment did not change, but several factors associated with surgical quality improved during the study period.

Disclosure: Nothing to disclose.

Introduction: Primary small-bowel cancer (PSBC), including duodenum, jejunum and ileum, is a relatively uncommon disease. However, the number of cases has been increasing in recent years. Furthermore, since more than half of all PSBCs occurred in the duodenum, cancers of the jejunum and ileum were particularly rare tumors. Few reports have focused on the jejunum and ileum.

Aims & Methods: We analyzed the clinicopathological features and prognosis of PSBC from a large multicenter study conducted in Japan. A total of 2,388 primary small-bowel lesions were collected between January 2008 and December 2017 from 44 institutions affiliated with the Japanese Society for Cancer of the Colon and Rectum (JSCCR) in Japan. We excluded 2,032 lesions for the following reasons: site of duodenum, unavailability of patient's or tumor essential information, histology not consistent with PSBC (such as malignant lymphoma, gastrointestinal stromal tumor, metastasis of PSBC, hamartoma, adenoma, or others), and patients with background diseases such as (Crohn disease, familial adenomatous polyposis, and Peutz-Jeghers syndrome). Because it was more difficult to clearly diagnose Lynch syndrome than other diseases, we did not exclud it in this study. We analyzed the clinicopathological features and the prognosis of PSBC. Clinicopathological features and TNM classification were evaluated according to the Japanese Classification of Colorectal, Appendiceal, and Anal Carcinoma eighth edition (JCCAC).

Results: 354 patients with 358 PSBC were enrolled. The average age of enrolled patients was 64.4 years, with 218 males (61.6%). The average tumor size was 49.9 mm, and the rate of PSBC's site in the jejunum was 66.2%, while in the ileum was 30.4%. Of the 354 enrolled, 19 patients (5.4%) were diagnosed with Lynch syndrome, and 272 (76.8%) had symptoms at the initial diagnosis. Single-balloon endoscopy, double-balloon endoscopy and capsule endoscopy were used for diagnosis in 43 patients (12%), 166 (47%) and 43 (12%), respectively. Surgical resection was the most performed to the 291 patients (82.2%) for treatment and in those 115 patients (32.5%) underwent chemotherapy after surgical resection. In this study, the rate of each stage (0, I, II, III, IV) was 5.3%, 2.5%, 27.0%, 25.8% and 36.2%, respectively. The average follow-up period was 31.0 ± 30.8 months. Among the 217 patients with PSBC in stages 0 to III, there were 51 recurrences. The recurrence rate of each stage was stage 0: 5.3% (1/19), stage I: 11.1% (1/9), stage II: 18.6% (18/97) and stage III: 33.7% (31/92), respectively. The most common site of metastasis at first diagnosis (stage IV) was the peritoneum (55.8%). The 5-year overall survival rate in each stage was 92.3%, 60.0%, 75.9%, 61.4% and 25.5%, while the 5-year disease-specific survival (DSS) rate in each stage was 100%, 75.0%, 84.1%, 59.3% and 25.6%, respectively. The site of PSBC in the jejunum had a sig-

nificantly lower 5-year DSS rate than that in the ileum (50.8% vs 66.7%, p=0.0418). The patients with symptoms at initial diagnosis had a significantly lower 5-year DSS rate than patients without symptoms (51.2% vs 70.5%, p=0.0416).

Conclusion: We have identified the characteristics and prognosis of PSBC in a large number of patients. 76.8% of patients with PSBC already had symptoms at the initial diagnosis and were often detected at the advanced stage. To improve the prognosis of PSBC, identifying with high-risk patients such as Lynch syndrome and screening should be examined, and the PSBC should be detected and treated in the early stages before symptoms appear.

Disclosure: Nothing to disclose.

INCIDENCE AND SURVIVAL IN PATIENTS WITH ENTEROPATHY ASSOCIATED T-CELL LYMPHOMA: NATIONWIDE REGISTRY STUDIES FROM ENGLAND AND DENMARK

J. West[1], P. Jepsen[2], T.R. Card[3], C. Crooks[4], M. Bishton[5]
[1]University of Nottingham, Lifespan and Population Health, Nottingham, United Kingdom, [2]Aarhus University Hospital, Department of Gastroenterology and Hepatology, Aarhus, Denmark, [3]Univesity of Nottingham, Lifespan and Population Health, Nottingham, United Kingdom, [4]University of Nottingham, Translational Medical Sciences / NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom, [5]University of Nottingham, Translational Medical Sciences, Nottingham, United Kingdom

Contact E-Mail Address: joe.west@nottingham.ac.uk

Introduction: Enteropathy Associated T Cell Lymphoma (EATL) is a rare and highly aggressive T-cell non-Hodgkin's lymphoma (NHL)[1] that is strongly associated with refractory coeliac disease (RCD), particularly type 2 RCD [2], and possibly inflammatory bowel disease (IBD). The incidence and prevalence of both coeliac disease[3] and IBD[4] have been rising around the world for several decades, including in both England and Denmark. Some of the potential drivers of EATL are the antigen-driven proliferation of intra-villous T-cells from coeliac disease and chronic inflammation in IBD, so it is important to understand if changes in these diseases are altering clinical presentations of EATL and its survival.

Aims & Methods: Our aim was to describe the contemporary incidence and survival of EATL from two European countries on a national scale, given the rising incidence and prevalence of coeliac disease and use of immunosuppression in inflammatory bowel disease, to give further insights into epidemiology of this rare and often fatal malignancy.

People with EATL were identified from national cancer registries from 2013-2019 in England and 2004-2020 in Denmark. Within each country we used direct standardisation to estimate incidence, Poisson regression to compare incidence between groups and Cox regression to assess overall survival.

Results: 172 and 39 patients were identified in England (E) and Denmark (DK) respectively with a mean age at diagnosis of 66 and 68 years. Approximately half of all cases had coeliac disease (E 52%, DK 41%), and ~7% (E 6%, DK 8%) had inflammatory bowel disease (Table). The overall age-standardised incidence rate was (E) 0.48 (95% CI 0.41-0.56) and (DK) 0.44 (95% CI 0.30-0.58) per million population per year. In both countries incidence was higher in older age groups. The 5-year overall survival was 10% (95% CI: 6%-18%) in England and 20% (95% CI: 9%-33%) in Denmark. Those with coeliac disease fared better than those without: (adjusted Hazard Ratio E 0.65 (95% CI 0.45-0.93), DK 0.57 (95% CI 0.26-1.27)).

Category	England (n=172)	Denmark (n=39)
Mean Age (95% CI)	66 (44, 89)	68 (65, 72)
Male (%)	108 (63%)	18 (46%)
Ethnicity, white (%)	160 (93%)	Not available
Stem cell transplant (%)	30 (17%)	Not available
Chemotherapy (%)	89 (52%)	Not available
Coeliac disease (%)	89 (52%)	16 (41%)
Inflammatory bowel disease (%)	11 (6%)	3 (8%)
Small bowel resection (%)	112 (65%)	7 (18%)
Died (%)	144 (84%)	33 (85%)

Table: Characteristics of people with EATL in England (2013-2019) and Denmark (2004-2020).

Conclusion: This analysis of two nationwide cancer registries is the largest population-based study to date to provide contemporary and comprehensive epidemiologic estimates of all ICD-O-3 coded EATL. It shows that a higher incidence is associated with older age, male sex (in England) and that half of cases also have coeliac disease. Our finding of the high proportion of people with inflammatory bowel disease compared to the background prevalence in both countries requires further investigation, as reasons for this are unclear, but it could be related to chronic inflammation or immunosuppression. Overall survival is poor and gets worse in older age groups but is better in those with coeliac disease, following surgical resection and those able to tolerate intensive therapies.

Introduction: Small bowel cancers are rare, accounting for less than 5% of gastrointestinal cancers, but their incidence is increasing. Small bowel adenocarcinoma (SBA) accounts for one-third of small bowel cancers. Due to a lack of optimal screening program for the diagnosis of SBA and the non-specificity of symptoms, SBA tends to be diagnosed at a later stage compared with colorectal cancer. Roughly one-third ofSBA patients are initially diagnosed with distant metastases.In clinical practice, regimens used for SBA parallel those commonly administered in the adjuvant setting for colorectal cancer, owing to its anatomic proximity.

However, the genomic profiling of SBA has been shown to be distinct from colorectal cancer through comprehensive analysis of genomic alterations. Therefore, we need to establish a chemotherapy specific for SBA based on its molecular pathological characteristics.

Aims & Methods: Our first aim was to explore the localization of EGFR family members in human SBA tissue and draw comparisons and determine the relationship between their expression and clinicopathological factors. Our second aim was to explore the possibility of anti-EGFR antibody therapy by examining the correlation between the expression of EGFR family members and KRAS and BRAF mutations in SBA.
Results: EGFR family members were widely expressed in SBA, including EGFR (34%), ErbB2(28%), ErbB3 (52%), ErbB4 (14%), and phosphorylated EGFR (22%). Both EGFR and phosphorylated EGFR immunoreactivities correlated with lymph node metastasis, distal metastasis, and advancing stage. In particular, there was significant EGFR expression in stageIV whereas pEGFR expression was observed exclusively in stage IV. ErbB2 expression was not associated with any single clinicopathological factor. ErbB3 and ERbB4 immunoreactivities correlated with lymph node metastasis. Both EGFR and phosphorylated EGFR immunoreactivities correlated significantly with worse cancer specific survival in SBA according to univariate analysis. EGFR immunoreactivities correlated significantly with worse cancer specific survival in SBA according to multivariate analysis. The most common genomic alterations found in SBA tumors were TP53 (56.7%), followed by KRAS (33.3%), APC(16.7%), PIK3CA (16.7%), BRAF (6.7%), EGFR (3.3%), ERBB2 (3.3%), and ERBB4 (3.3%).Deficient MMR tumors were observed in 12% of patients. No association was found between any member of the EGFR family expression and MMR status. There was also no significant association between expression of any member of the EGFR family and any single gene mutation. KRAS wild type was observed in 5 out of 7 stage IV SBA cases examined, and EGFR expression was positive in all 5 cases.
Conclusion: All members of the EGFR family were expressed in SBA. Among them, EGFR expression associated with worse prognosis. Our findings suggest the potential use of EGFR inhibitors in the treatment of SBA patients in the clinical setting, particularly patients with SBA expressing the KRAS wild type which are not amenable to surgical resection.

Introduction: Small bowel adenocarcinoma (SBA) are rare, but their incidence is increasing. Early diagnosis of SBA remains elusive, so that about one-third of patients are initially diagnosed with distant metastases. In clinical practice, regimens used for SBA parallel those commonly administered in the adjuvant setting for colorectal cancer, owing to its anatomic proximity. However, genomic profiling of SBA has been shown to be distinct from colorectal cancer through comprehensive analysis of genomic alterations. Therefore, it is vital to establish a distinct chemotherapy regimen for SBA based on its molecular pathological characteristics. Claudin-18 plays a key role in constructing tight junctions and altered claudin-18 expression has been documented in various human malignancies. On the basis of this, both monoclonal antibodies and claudin-18.2-specific chimeric antigen receptor engineered T-cells have been recently developed and employed in several clinical trials, showing promising results in the treatment of advanced gastroesophageal and pancreatobiliary tract cancers. However, little is known about the clinicopathological significance of claudin-18 expression in SBA.
Aims & Methods: To explore the localization of claudin-18 in human SBA tissue and draw comparisons and determine the relationship between their expression and clinicopathological factors, and genomic alterations. We examined 50 surgical resections from patients with primary SBA for immunohistochemical analyses of claudin-18, CK7, CK20, CD10, CDX2, MUC2, MUC5AC, and MUC6 expression. DNA mismatch repair (MMR) status was defined by immunostaining for all MMR proteins; MLH1, MSH2, MLH6, and PMS2. Both MUC 2 and CD10 are markers of intestinal type tumors, whereas MUC5AC and MUC6 are markers of gastric type tumors. Tissue samples showing both gastric and intestinal phenotypes were classified as gastrointestinal type tumors, whereas those showing neither gastric nor intestinal phenotype expression were classified as null type tumors. In addition, genomic profiling was performed on 31 patients using targeted next-generation sequencing.
Results: Claudin-18 expression was observed in 46% of SBA patients. Claudin-18 expression was positively associated with cytokeratin 7 (P=0.003) and MUC5AC (P=0.020) expression, whereas it was negatively associated with MUC2 (P=0.010), CD10 (P=0.014), and CDX2 (P=0.003) expression. Tumor mucin phenotypes included gastric type (n=9), intestinal type (n=20), gastrointestinal type (n=17) and null type (n=4). Claudin-18 was more frequently expressed in gastric type (100%) than in intestinal type (30%) phenotypes (P=0.001). *GNAS* mutations (N=4) were found in only claudin-18 positive SBA patients, although the difference was not significant. Claudin-18 expression did not correlate with patient age at diagnosis, patient gender, site, histological type, depth of invasion, lymph node metastasis, distal metastasis, TNM stage, and MMR status. However, claudin-18 expression correlated with worse progression free survival.
Conclusion: Claudin-18 expression is associated with gastric immunophenotype and with worse progression free survival. These findings suggest that claudin-18 may be a potential therapeutic target in certain SBA cases.
Disclosure: Nothing to disclose.

EXPRESSION OF WNT/B-CATENIN PATHWAY MOLECULES IN SMALL BOWEL ADENOCARCINOMA

R. Inoue[1], A. Tatsuguchi[1], A. Hoshimoto[1], T. Nishimoto[1], J. Omori[1], N. Akimoto[1], K. Iwakiri[1]
[1]Nippon Medical School Hospital, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: s13-015ir@nms.ac.jp
Introduction: The low incidence of APC gene mutations (less than 30%) in small bowel adenocarcinoma (SBA) suggests that the adenoma-carcinoma-sequence is not the main carcinogenic mechanism. However, the presence or absence of activation of the Wnt/β-catenin signaling pathway, which is important in the adenoma-carcinoma-sequence, has not been sufficiently investigated in SBA. Therefore, we examined gene mutations involved in the Wnt/β-catenin pathway and their downstream target gene products in SBA.
Aims & Methods: We examined 30 surgical resections from patients with primary SBA. SBA genomic alterations were analyzed by targeted next-generation sequencing (NGS). DNA mismatch repair (MMR) status was determined by immunostaining for all MMR proteins; MLH1, MSH2, MLH6, and PMS2. In addition, immunostaining for cyclin D1, c-myc, and β-catenin was performed to compare the results of NGS. Nuclear/cytoplasmic or loss of membranous β-catenin staining in cancer cells was defined as aberrant β-catenin immunostaining.
Results: The main genomic alterations found in SBA tumors were TP53 (56.7%), followed by KRAS (33.3%), APC (16.7%), PIK3CA (16.7%), CTNNB1 (10%), BRAF (6.7%), and CDKN2A (6.7%). Deficient MMR tumors were observed in 20% of patients. APC mutations were significantly higher in

deficient MMR tumors than in proficient MMR tumors (P=0.041). On the other hands, CTNNB1 mutations were not found in deficient MMR tumors. No cases exhibited both the APC and the CTNNB1 mutations. Aberrant β-catenin immunostaining in cancer cells was observed in 12 out of 30 cases (40%). All three CTNNB1 mutation cases were associated with aberrant β-catenin staining, whereas only 1 of 5 APC mutation cases had aberrant β-catenin staining. The remaining 8 cases with aberrant β-catenin staining had neither APC nor CTNNB1 mutations. Cyclin D1, a representative target protein of the Wnt/β-catenin pathway, was positive in cancer cells in 18 (60%) of the cases. C-myc was positive in cancer cells in 6 (20%) cases. Of the 5 cases with APC mutations, cyclin D1 was positive in two cases and c-myc was positive in one case. Three cases were negative for both cyclinD1 and c-myc, but were associated with MMR deficiency and TP53 mutations. Of the three cases with CTNNB1 mutations, cylclin D1 was positive in two cases and c-myc was positive in one case. All three cases had proficient MMR. Two of the three cases did not have TP53 nor KRAS mutations.

Conclusion: The Wnt pathway-associated gene mutations in SBA were APC and CTNNB1, with one or the other found in 26.7% of cases examined. This frequency is much lower than in colorectal cancer, consistent with previous reports.

In addition, 3 out of 5 cases with APC mutations showed normal membranous staining for β-catenin, cyclin D1-negative, and c-myc-negative, suggesting that the Wnt pathway is less activated in these three cases. In addition, these three cases had TP53 mutations and were MMR deficient. This suggests the possibility that APC mutations do not necessarily contribute directly to the carcinogenesis of SBA.

On the other hand, the staining abnormality of β-catenin, a key component of the Wnt/β-catenin signaling pathway, suggests that this pathway is activated in half of SBA cases. These results indicate that the Wnt/β-catenin pathway may be activated or deregulated by mechanisms other than APC and CTNNB1 mutations in SBA.

Disclosure: Nothing to disclose.

MALIGNANT SMALL BOWEL NEOPLASMS – THE TWENTY-YEAR EVOLUTIVE EXPERIENCE IN A TERTIARY CENTER

A.T. Ferreira[1], J. Mesquita[2], M.L. Rocha[1], S. Archer[1], S. Ponte[1], I. Pedroto[1], M. Salgado[1]

Contact E-Mail Address: anatmendesferreira@gmail.com

Introduction: Malignant small bowel neoplasms (MSBN) are rare entities, whose knowledge is even more limited due to their histological diversity and difficulty in their investigation. Studies show that the incidence of MSBN has been growing in recent decades; thus, interest in these neoplasms has increased in parallel with their rising incidence.

Aims & Methods: The aim of this study was to describe the demographic and clinical characteristics of patients with malignant neoplasms of duodenum, jejunum, and ileum, but also the evolution in the diagnosis of these neoplasms over 20 years.

Retrospective study of patients with MSBN diagnosed between 2001 and 2020 in a tertiary hospital was performed. Demographic and clinical data were collected. Statistical analysis was performed with SPSS vs 29.0 (significance level of 5%).

Results: A total of 135 patients were evaluated. Fifty-seven percent of patients (n=77) were male; the mean age at diagnosis was 64.2 years [diagnosis between 27-91 years]. The mean age at diagnosis showed no statistically significant relationship with the histological subtype (p=0.644).

Most neoplasms were found in the jejunum/ileum (65.9%, n=89). The most frequently diagnosed neoplasms were adenocarcinomas (31.1%, n=42), followed by neuroendocrine tumors (28.10%, n=38), gastrointestinal stromal tumors (GIST) (17.8%, n=24) and metastases from other carcinomas (12.6%, n=17); lymphomas accounted for 5.9% of cases (n=8) and other primary malignancies accounted for 4.4% of cases (n=6).

The majority of patients (80,7%, n= 109) were symptomatic at time of diagnosis - 29.6% (n=40) had abdominal occlusion at diagnosis; 19.3% (n=26) of patients had hemorrhage as the initial clinical presentation, and 7.4% (n=10) of patients had intestinal perforation. It's also worth mentioning that almost half of the patients (43.7%, n=59) had anemia at diagnosis.

A regular CT was the exam that documented the neoplasm in 40.7% of cases (n=55); an upper digestive endoscopy identified the neoplasm in 22.2% of patients (n=30) and a video capsule endoscopy was necessary for diagnosis in 8.1% of cases (n=11); however, 22.2% of patients (n=30) still required surgery for making the diagnosis; the remaining patients (6.7%, n=9) were diagnosed using other complementary diagnostic methods (CDM).

It should be noted that most diagnoses were made between 2011 and 2020 (65.9%, n=89). Between 2011 and 2020, the most frequently diagnosed MSBN were neuroendocrine tumors (37.1%, n=33), whereas between 2001 and 2010, the most common diagnosed tumors were adenocarcinomas (37.0%, n=17). The diagnosis of each histological neoplasm type differed significantly statistically over the years (p=0.016).

More than half of the patients with adenocarcinoma of the small intestine died from this cause (54.8%, n=23), but only 7.9% (n=3) of the neuroendocrine tumors of the small intestine were the cause of death.

Conclusion: Although these are rare tumors, the sample of MSBN from this tertiary center over these 20 years has still been substantial. Most patients were symptomatic at diagnosis - with severe complications (occlusion, hemorrhage, perforation) in 55.4% of the cases, despite advances in CDM over the years.

In this study, 65.9% of MNDJI were diagnosed in the last 10 years of the follow-up, which validates the growing incidence of small bowel neoplasms described in the literature. Noteworthy, the diagnosis of each histological neoplasm type differed significantly statistically over the years (p=0.016), with neuroendocrine tumors being the most diagnosed in recent years.

Disclosure: Nothing to disclose.

Introduction: Small bowel adenocarcinoma (SBA) has been shown to have different genomic profiles from gastric or colorectal cancer using comprehensive genomic analysis. Therefore, it is essential to establish chemotherapy based on the characteristics of SBA. Programmed cell death-ligand 1 (PD-L1) expression in SBA is not yet fully understood. In addition, programmed cell death-ligand 2 (PD-L2) has not received as much attention and its role in modulating tumor immunity is unclear. Anti-PD-L1/PD-1 therapy uses tumor-infiltrating lymphocytes (TILs); therefore, the status of TILs in the tumor microenvironment (TME) may influence its efficacy. The ratio of FoxP3+ T cells to CD8+ T cells has been reported to be useful in predicting the prognosis of digestive system cancers.

Aims & Methods: We investigated the clinicopathological significance of PD-L1 and PD-L2 expression in association with the infiltration of FoxP3+ T cells and CD8+ T cells into the TME to identify PD-L/PD-1 immunotherapy candidates in patients with SBA.

We performed immunohistochemistry for PD-L1, PD-L2, CD8, FoxP3 using formalin-fixed, paraffin-embedded tissue from 50 patients diagnosed with primary SBA. The immunoreactivities of PD-L1 and PD-L2 were determined separately through tumor cells and tumor-infiltrating immune cells (such as lymphocytes and macrophages) throughout the tumor center and invasive margins, and finally evaluated using the combined positive score (CPS). We assessed CD8+ T cells and FoxP3+ T cells in 10 randomly selected microscopic areas of the intratumoral stroma and tumors surrounding the stroma. Subsequently, we calculated and summed the ratio of FoxP3 to CD8+ T cell counts in 10 HPF. Immune-related cell densities were graded as low (≤ median cell counts/mm2 tumor area) or high (> median cell counts/mm2 tumor area).

Results: PD-L1 expression in tumor cells (T-PD-L1) was 34% and in tumor-infiltrating immune cells (I-PD-L1) was 54%. T-PD-L2 was 34% and I-PD-L2 was 42% of cases. PD-L1 CPS ≥ 10 and PD-L2 CPS ≥ 10 were observed in 50% and 56% of cases, respectively. T-PD-L1, I-PD-L1, and PD-L1 CPS ≥ 10 were all associated with deeper depth of invasion (P=0.001, P=0.024, P=0.002). I-PD-L2 expression and PD-L2 CPS ≥ 10 were significantly more common in differentiated types (P=0.015, P=0.030). I-PD-L1 and I-PD-L2 were significantly associated with better CSS (P=0.037, P=0.015). CD8-low was significantly associated with lymph node metastases (P=0.047), distant metastases (P=0.024), peritoneal dissemination (P=0.034), and TNM stage (P=0.047). The CD8-high group had a better prognosis than the CD8-low group (P=0.018). FoxP3-high was not associated with any clinicopathological factor or prognosis. We found that patients with PD-L2 CPS ≥ 10 had worse prognosis in the FoxP3/CD8-low group, although the difference was not significant (P=0.088).

Conclusion: It was suggested that the clinicopathological significance of PD-L1 and PD-L2 expression differs depending on the TME status. The PD-L/PD-1 pathway may contribute to poor prognosis in patients with a low tumor FoxP3/CD8 ratio. PD-L2 may be a better prognostic marker than PD-L1, and immune checkpoint inhibitors may improve prognosis in these cases.

Disclosure: Nothing to disclose.

Contact E-Mail Address: clementdominique@yahoo.com

Introduction: Patients with neuroendocrine tumours (NETs) located in the gastroenteropancreatic tract (GEP) are at risk of malnutrition. NETs are rare cancers arising from enterochromaffin cells. They differ from other cancers based on morphology, clinical behaviour, treatment and relatively good prognosis even in the metastatic case. Somatostatin analogues (SSA's) are the cornerstone of treatment to control symptoms and tumour growth. Previous studies reported the presence of malnutrition, only based on weight loss or low body mass index (BMI).

The Global Leadership into Malnutrition (GLIM) criteria diagnose malnutrition if there is:

1. Weight loss or,
2. Low BMI or;
3). Presence of sarcopenia, in the presence of a disease.

Malnutrition based on these GLIM criteria has not been assessed in patients with GEP-NETs. The effect of malnutrition on overall survival has not been explored before.

Aims & Methods: The aim of this study is to describe the presence of malnutrition in patients with GEP-NET based on the GLIM criteria and correlate this with overall survival.

A Cross-sectional study was performed, between August 2018 and February 2019 in a single NET expert centre in the United Kingdom. All patients with GEP-NETs, using an SSA were screened for malnutrition using the GLIM criteria. Anthropometric data (weight, height and BMI), and body composition analysis were performed to assess the presence of sarcopenia. Patients were scored to be malnourished meeting 1 GLIM criterium, meeting 2 GLIM criteria or meeting all 3 GLIM criteria. Additional demographic and histopathologic data were collected from patient records. Stable disease was classified if there was documentation of stable disease or no change in treatment within 3 months of malnutrition screening. Overall survival was calculated from the moment of malnutrition screening and the date of death or data cut-off in June 2022. Uni- and multivariate Cox regression analyses were performed to identify malnutrition as a risk factor for overall survival.

Results: A total of 118 patients 47% male with median age 67 year (IQR 56.8 – 75.0) were included. The primary tumour was located in the small bowel in 91 patients (71%) or pancreas in 25 patients (21%). Metastases were present in 91 patients (77%). In 84 patients (71%) there was stable disease.

Malnutrition was present in 88 patients (75%), based on low BMI in 26 (22%) patients, based on weight loss in 35 (30%) patients and based on sarcopenia in 83 (70%) patients. One GLIM criterium was met in 50 patients

(42%), 2 GLIM criteria in 20 patients (17%) and all 3 GLIM criteria in 18 patients (15%). The presence of malnutrition demonstrated a significantly worse overall survival (p-value 0.01). In a multivariate analysis including age (HR 1 95% CI 0.98 – 1.01, p-value 0.43), sex (HR 0.65 95% CI0.27 – 1.59, p-value 0.35), and stable disease versus progressive disease (HR 4.5 95% CI 1.7 – 11.76, p-value 0.002), meeting 2 or 3 GLIM criteria was significantly associated with worse overall survival (HR 2.16 95% CI 1.34 – 3.48, p-value 0.002). Weight loss was the most important risk factor out of the 3 GLIM criteria (HR 3.5 95% CI 1.14 – 10.85, p-value 0.03) for worse overall survival.
Conclusion: A high percentage (75%) of patients with GEP-NETs using an SSA meet the GLIM criteria for malnutrition which influences overall survival. Meeting two or more GLIM criteria, especially if there is weight loss is associated with worse overall survival. Future research should focus on exploring the effect of nutrition support especially in patients with weight loss and its effect on overall survival.

LONG-TERM OUTCOMES OF PATIENTS WITH OBSCURE GASTROINTESTINAL BLEEDING AFTER NEGATIVE CAPSULE ENDOSCOPY

I. Hirata[1], A. Tsuboi[1], Y. Matsubara[1], A. Sumioka[1], T. Takasago[1], H. Tanaka[2], K. Yamashita[2], H. Takigawa[1], T. Kotachi[2], R. Yuge[1], Y. Urabe[3], S. Oka[1]
[1]Hiroshima University Hospital, Gastroenterology, Hiroshima, Japan, [2]Hiroshima University Hospital, Endoscopy, Hiroshima, Japan, [3]Hiroshima University Hospital, Gastrointestinal Endoscopy and Medicine, Hiroshima, Japan

Contact E-Mail Address: d213504@hiroshima-u.ac.jp
Introduction: In the European Society of Gastrointestinal Endoscopy guidelines (updated 2022), obscure gastrointestinal bleeding (OGIB) should be reserved for patients not found to have a source of bleeding by small-bowel evaluation. Herein, OGIB was defined as P0 (no bleeding potential) or P1 (less likely to bleed), based on the P classification using small-bowel capsule endoscopy (CE). We aimed to clarify the long-term outcomes of patients with OGIB.
Aims & Methods: We retrospectively examined 796 consecutive patients with OGIB who underwent CE at the Hiroshima University Hospital between March 2014 and October 2021. Of the eligible patients, 302 were excluded because of small-bowel bleeding (148 patients), incomplete observation of the small-bowel (85 patients), a bleeding source located outside the small-bowel (67 patients), or equipment failure (2 patients). Therefore, a total of 494 patients with OGIB and negative CE findings were included in this study. Of these, 33 could not be followed up for more than 1 year. Thus, a final total of 461 patients were enrolled in this study (257 males, median age: 70 years, median observation period: 654 days, and median hemoglobin value: 8.4 g/dL). These were classified into P0 and P1 groups according to CE findings, and we examined rebleeding rates and predictive factors.
Results: Of the 461 patients, 224 (49%) had P0 and 237 (51%) had P1 findings. There were no significant differences between the two groups in terms of sex, age, observation period, hemoglobin value, and bleeding pattern. Nor were there any significant differences in the use of antiplatelet agents, anticoagulants. In terms of comorbidities, the incidences of liver cirrhosis (15% vs. 33%, $P < 0.001$) and diabetes mellitus (16% vs. 28%, $P = 0.002$) were significantly higher among patients in the P1 group than those among patients in the P0 group. Rebleeding was observed after CE in 57 of the 461 patients (12.4%), specifically, 20 of the 224 patients (8.9%) in the P0 group and 37 of the 237 patients (15.6%) in the P1 group. Two patients in the P0 group and 15 patients in the P1 group were rebleeding from small-bowel. The rate of rebleeding from the small-bowel was significantly lower in the P0 group than that in the P1 group (0.9% vs. 6.6%, $P = 0.002$), as was the cumulative rebleeding rate ($P = 0.005$). According to the multivariate analysis, post-endoscopic treatment of small-bowel lesions (hazard ratio (HR) = 13.028, 95% confidence interval (CI):4.448–38.160, $P < 0.001$) and P1 CE findings (HR = 10.000, 95% CI:2.154-46.438, $P = 0.003$) were independent predictive factors for rebleeding from the small-bowel.
Conclusion: Rebleeding may occur in patients with OGIB. Patients with P1 CE findings or post-endoscopic treatment of small-bowel lesions may experience rebleeding from the small-bowel, suggesting the need for careful follow-up.

Contact E-Mail Address: lrejoicelit@gmail.com
Introduction: Video capsule endoscopy(VCE) is an useful and safe examination in diagnosis of small bowel disease. VCE is composed of one wide-view front lens, flashlight and 8 hour battery to take small bowel images.. In early models, the relative short battery time lead to a modest completion rate about 83.5% in meta-analysis. The battery time of new generation VCE increased to at least 12 hour and even up to 18 hours in real-world practice which made extended examination possible. The effect of prolonged VCE examination time on VCE performance was less explored.
Aims & Methods: This study is aimed to evaluate the completeness and diagnostic yield in patients receiving prolonged VCE examinations. From year 2016 we started to perform an overnight protocol for VCE examination in our hospital using Olympus endocapsule 10, EC-10; Olympus Corp., Japan). After 10 ml simethicone ingestion, the patient swallowed the capsule endoscope. The doctors checked the capsule endoscopy 2-3 hours after capsule endoscope for confirmation of small bowel entering. The patient kept capsule endoscope recording overnight until the coming morning when patients came back to clinic. For some inpatients with active bleeding, VCE was checked at least after 12 hours at midnight. The VCE recording was stopped earlier if colon arrival is confirmed. All the CE procedures were read by experienced endoscopist. We reviewed consecutive VCE examination records from Jan 2016 to Dec 2020. VCE Completeness was defined as the capsule endoscopy reached the cecum within recording time. We subcategorized the VCE records into within 8 hours, within 12 hours and whole procedure and compared VCE complete rate and diagnostic yield between groups. The Cochran's Q test was used for statistical analysis. P values less than .05 were considered significant.
Results: Total 88 patients aged 20-90 years old received VCE in the study period. Their median age was 69 years old and 46 patients(52.3%) were male. 69 patients(78.4%) were inpatient and 84 patients(95%) were suspected with small bowel bleeding. The small bowel transit time was 342 minutes(91-1134minutes) with total exam time measuring 1031 minutes (452 to 1273 minutes). 58% of patients completed small bowel evaluation

within 8 hours since capsule endoscope ingestion, significantly lower than 79.5% within 12 hours(p<0.001), and 93.2 %(p<0.001) in whole course overnight study. The diagnostic yield was 71.6% within 8 hours, also significantly lower than 81.8% within 12 hours(p<0.001) and 83% in whole course overnight study(<0.001%)(Table). No capsule retention was encountered in this study.

	8 hours	12 hours	Whole course overnight study	Main effect	($P_{8\text{-}12}$, $P_{8\text{-}all}$, $P_{12\text{-}all}$)
Completion rate	58.0%	79.5%	93.2%	<0.001	(<0.001, <0.001, 0.025)
Diagnostic yield	71.6%	81.8%	83.0%	<0.001	(<0.001, <0.001, 1)

Table. Video Capsule Endoscopy Completion Rate and Diagnostic Yield Among Different Study Duration.

Conclusion: 1. Prolonged overnight VCE examination can improve complete rate and diagnostic yield using capsule endoscope whose battery life over 12 hours. 2. Prolonged overnight VCE examination should be considered to be routine practice, especially for inpatients.
Disclosure: Nothing to disclose.

PROSPECTIVE AND COMPARATIVE OBSERVATIONAL STUDY BETWEEN SINGLE-BALLOON ENTEROSCOPY AND MOTORIZED SPIRAL ENTEROSCOPY

M. Urpí[1], A. Giordano[1], G. Casanova[1], L. Escudé[1], J. Llach[1], M. Escapa[1], M.G. Fernández-Esparrach[1], A. Gines[1], F. Balaguer[1], J. Llach[1], B. González-Suárez[1]
[1]Clínic Hospital of Barcelona, Endoscopy Unit, Gastroenterology Department, Barcelona, Spain

Contact E-Mail Address: miguelurpi93@gmail.com
Introduction: Single-Balloon Enteroscopy (SBE) and Double-Ballon Enteroscopy (DBE) have been the gold standard in device-assisted enteroscopy for the last years. However, since the Motorized Spiral Enteroscopy (MSE) appearance there are scarce comparative studies.
Aims & Methods: Aims: To compare the efficacy and safety performance between SBE and MSE.
Methods: Prospective and comparative observational study conducted on patients undergoing either SBE or MSE in a tertiary hospital from December 2019 to July 2022. Demographic characteristics, procedure indication, small bowel exploration time (SBET), technical success, depth of maximum insertion (DMI), diagnostic yield, interventional yield and adverse events (AE) were collected. Data analysis was performed using IBM SPSS Statistics 28.0. A propensity score matching was performed to remove confounding bias from our observational cohort.
Results: A total of 366 enteroscopies (237 anterograde and 129 retrograde) were performed in 295 patients. Capsule endoscopy findings were the most frequent indication of the procedure (72%). After a propensity score matching performed on the anterograde cohort, a total of 295 procedures were analyzed, 166 anterograde (70 SBE/ 96 MSE) and 129 retrograde (36 SBE/ 93 MSE). For the anterograde route, technical success was 98% for SBE and 94% for EMS (pNS). SBE showed significantly lower DMI than MSE (245 ± 89cm vs 431 ± 207cm; p<0.001).
However, no differences were found in the SBET (37min vs 42min, respectively; pNS). Diagnostic yield (84% vs 75%; pNS) and interventional yield (84% vs 71%; pNS) were similar for both techniques. For the retrograde route, DMI was significantly higher for the MSE group (112.2 ± 61.4cm vs 150 ± 132.8; p=0.04). No differences were observed regarding other parameters. Overall AE rate was similar in both techniques (3.9% vs 8.9%; pNS), as well as SAE rate (1.1% vs 2.1%; pNS).
Conclusion: Both techniques, SBE and MSE are effective and safe for the small bowel evaluation. MSE allows a higher DMI for both anterograde and retrograde route.
Disclosure: Nothing to disclose.

IMPACT OF NEW TIMING RECOMMENDATIONS FOR CAPSULE ENTEROSCOPY IN THE SETTING OF OVERT DIGESTIVE BLEEDING

M.M. Estevinho[1], R. Pinho[1], A. Rodrigues[1], A. Ponte[1], J.P. Laranjeira Correia[1], P. Silva Mesquita[1], T. Freitas[1]
[1]Centro Hospitalar Vila Nova de Gaia Espinho, Vila Nova de Gaia, Gastrenterology, Porto, Portugal

Contact E-Mail Address: mmestevinho@gmail.com
Introduction: Capsule endoscopy is the first-line examination for digestive bleeding with likely origin in the small bowel, in hemodynamically stable patients. In the 2022 update, ESGE guidelines recommend that, in the context of overt bleeding, capsule enteroscopy should be performed as soon as possible, ideally within the first 48 hours. In the previous guidelines, published in 2015, the recommended window was 14 days.
Aims & Methods: This study aimed to evaluate the improvement in yield offered by the new recommendations regarding the timing of urgent capsule enteroscopy. Patients with suspected overt middle gastrointestinal bleeding between January 2005 and November 2022 were retrospectively analyzed. Diagnostic and therapeutic yield, rebleeding rate, and mortality were compared when capsule enteroscopy was performed within the first 48 hours, within the first 14 days, or between the 3rd and 14th day after admission.
Results: A total of 138 patients were included (58.7% men, median age 66 years), 87 of whom (63.0%) underwent capsule enteroscopy within the first 48 hours after hospital admission. The median follow-up was 55 months (5-180). The diagnostic yield (presence of blood or lesions with bleeding potential) was slightly higher when capsule enteroscopy was performed within the first 48 hours (81.6% versus 76.5%, p=0.349). On the other hand, capsule enteroscopy within the first 48 hours was significantly associated with higher therapeutic yield (endoscopic, radiologic, or surgical treatment) - 54.0% versus 39.2%, p=0.02. The rebleeding rate was significantly lower in patients undergoing enteroscopy within 48 hours after admission (19.5% versus 29.4%, p=0.04). On the other hand, overall mortality at 36 months did not differ between strategies (21.8% and 25.5%, p=0.401).
Conclusion: Performing capsule endoscopy within the first 48 hours, as recommended by recently published guidelines, is associated with favourable short- and long-term clinical outcomes.
Disclosure: Nothing to disclose.

PP0414

ANTITHROMBOTIC THERAPY DEPICTS A DISTINCT SMALL BOWEL BLEEDING CLINICAL PATTERN: A RETROSPECTIVE COHORT STUDY

C. Marmo[1], D. Feliciani[2], E. Gaetani[2], R. Pola[3], G. Costamagna[1], M.E. Riccioni[1]

Contact E-Mail Address: clelia.marmo@outlook.it

Introduction: In patients treated with anticoagulant medication, the number of hospital admissions for gastrointestinal bleeding is up to 1.15 for 100 patients per year, with an increased risk for patients treated with DOACs (1).

Aims & Methods: The study aims to evaluate the diagnostic yield of small bowel capsule endoscopy in patients while on antithrombotic therapy for suspected small bowel bleeding. This is a single center, retrospective, observational study conducted from January 2015 to March 2019. We enrolled consecutive patients with suspected small bowel bleeding or iron deficiency anemia undergoing SBCE after bidirectional negative endoscopy. Positive findings were defined according to the P0-P2 classification reported by Saurin et al (3). Bleeding severity was defined according to the "International Society of Thrombosis and Haemostasis" (ISTH) criteria. We considered in anticoagulant therapy: direct oral anticoagulant (DOAC), vitamin K antagonist (VKA), injective anticoagulant (Low-molecular-weight heparin, unfractionated heparin, fondaparinux). We considered in antiplatelet therapy: aspirin, clopidogrel, ticagrelor. A descriptive analysis of the data was performed, with a calculation of the mean, median, proportions, standard deviation and 95% confidence limits depending on data type.

Results: We analyzed and collected data from 369 patients, 95 while on antithrombotic therapy: 40 with DOACs, 35 with VKAs, and 20 with injective anticoagulants. The mean age was, overall, 66.4 years (SD±14.9), 60.1 years (SD±16.2) in the control group, 72.4 (SD±8.8) in the antiplatelet group, 73.3 years (SD±11.49) in the anticoagulant group and 71.3 years (SD±12.2) in the anticoagulant+antiplatelet group.

Characteristics	Total	Control group	Antiplatelet Group	Anticoagulant group	Antiplatelet + Anticoagulant group	p value
	N=369	N=183	N=91	N=68	N=27	
Age	66.4 [±14.9]	60.1 [±16.2]	72.4 [±8.8]	73.3 [±11.4]	71.3 [±12.2]	<0.001
Gender; Male n (%)	211 (57.2)	96 (52.5)	58 (63.7)	35 (51.5)	22 (81.5)	
Hemoglobin g/dl	8.8 [±2.6]	9.2 [±2.8]	8.8 [±2.4]	7.9 [±2.0]	8.0 [±2.1]	0.003
Trasfusion	209 (56.6)	95 (51.9)	49 (53.8)	49 (72.1)	16 (59.3)	0.038
Diabetes	95 (25.7)	30 (16.4)	40 (44.0)	17 (25.0)	8 (29.6)	<0.001
Hypertension	170 (46.1)	60 (32.8)	61 (67.0)	33 (48.5)	16 (59.3)	<0.001
Overt bleeding	191 (51.8)	104 (56.8)	38 (41.8)	34 (50.0)	15 (55.6)	0.12

In table 1, there are reported patients' demographic and clinical characteristics. In the DOAC group we found a statistically significant higher number of patients presenting with active bleeding and without lesion identification (8 patients 20.0% Vs 11 patients 6.0% in the control group, 3 patients 8.6% in AVK group and 3 patients 15.0% in the injective anticoagulant group). The angioectasia is the most frequent lesion detected in patients with antiplatelet + anticoagulant therapy (7 patients 46.7% VS 21 patients 20.2% in the control group, 8 patients 21.1% in the antiplatelet group and 3 patients 8.8% in the anticoagulant alone group; p=0.027).

Conclusion: Our results show that patients with antithrombotic therapy are, usually, elderly and with more comorbidities than the control group. Furthermore, in this specific group, the hemoglobin level was lower and the need for transfusion was higher. Angioectasia is the most frequent positive findings in patients with both antiplatelet and anticoagulant therapy.

Contact E-Mail Address: oka.priya@gmail.com

Introduction: Current guidelines suggest upper and lower GI endoscopy to investigate iron deficiency anaemia (IDA) because of a perceived low risk of small bowel pathology. We aimed to identify the Bleeding Location In The Gastrointestinal Tract (BLITGIT) in patients with IDA.

Aims & Methods: Patients referred to three centres (Sheffield, Hong Kong and Szekesfehervar, Hungary) for the investigation of IDA underwent small bowel (SB) capsule endoscopy (Navicam, AnX Robotica, Plano, US) in the week prior to upper and lower gastrointestinal endoscopy.

All lesions were described using terms selected from a predetermined diagnostic list and according to the perceived likelihood of bleeding (P0: unlikely; P1: suspected; P2: likely. Saurin et al., Endoscopy 2003).

Results:

Gastroscopy pathology (P1/P2)	Small bowel pathology (P1/P2)	Colon pathology (P1/P2)
Oesophagitis- 2 Oesophageal ulcer- 1 Oesophageal varices- 2 Gastric erosions- 9 Gastric ulcer- 5 Gastric polyp with blood - 1 Gastric antral vascular ectasia -2 Portal hypertensive gastropathy - 1 Duodenal ulcer- 3	Angioectasia- 23 Erosion - 18 Ulcers- 16 Polyp with eroded surface- 1 Fresh blood- 3 Portal hypertensive enteropathy- 1	Haemorrhoids- 15 Colorectal cancer- 3 Ulcerative colitis- 2 Diverticulitis-2 NSAID induced Ulcers- 1 Angioectasia- 2 Radiation proctitis- 2

Table-1: Number of patients with P1/P2 pathology identified at gastroscopy, SB capsule and colonoscopy.

92 patients (median age 61 years (IQR 45-72); 54.3% male) had a median haemoglobin of 107.5 g/L (IQR 93.2-121.7), ferritin 8(IQR 8- 18) and iron 3.8(IQR 3.8- 6.4). Completion rates for gastroscopy, colonoscopy and capsule endoscopy were 98.9%, 95.6% and 84.7% respectively. Diagnostic yield of P1/P2 lesions by SB capsule (48.9%) was higher than gastroscopy (27.1%) and colonoscopy (29.3%; p=0.003). On multivariant analysis there was no correlation between age, haemoglobin level, symptoms or medi-

cation on pathology. A few patients had more than one P1/P2 lesions. Three patients had colorectal cancer and two patients had a new diagnosis of ulcerative colitis.

Conclusion: The diagnostic yield in the small bowel is higher as compared to the upper and lower GI tract and examination should be considered routinely.

Disclosure: Nothing to disclose.

Contact E-Mail Address: myriam.heilani@kgu.de

Introduction: Enteroscopy is an established method for endoscopic diagnosis and interventions in the small intestine. Currently, there are three procedures available: single-balloon enteroscopy, double-balloon enteroscopy, and motorized spiral enteroscopy. Recent studies have shown that motorized spiral enteroscopy is very effective but also associated with more complications. There are no comparative studies between double-balloon and motorized spiral enteroscopy.

Aims & Methods: This randomized, prospective trial was conducted at two tertiary centers. All consecutive patients with an indication for enteroscopy were asked to participate in the study. Patients were randomly assigned to the motorized spiral or double-balloon arm after being informed. The examination was then performed with the respective procedure.

This study aims to compare the effectiveness of the new motorized spiral enteroscopy with double-balloon enteroscopy. The time to diagnosis or complete enteroscopy and possible complications of both procedures were investigated.

Results: 39 enteroscopies (19 motorized spiral, 20 double-balloon) were performed in 36 patients. In the spiral group, access was achieved orally in 58% of cases. A complete enteroscopy was possible in 26% of cases with a median time of 36 minutes. In 16%, a complete enteroscopy was possible via the oral route. In the double-balloon group, access was achieved orally in 85% of cases. A complete enteroscopy was possible in 10% of cases with a median time of 45 minutes. In 5%, a complete enteroscopy was possible via the oral route. Diagnostic yield was higher in double balloon enteroscopy compared to spiral enteroscopy with positive findings in 75% and 32% respectively. There was one perforation in the motorized spiral group. There were no severe complications in the balloon group.

Conclusion: Motorized spiral enteroscopy seems to be more effective in terms of speed and depth. However, it is also associated with more complications

Disclosure: Nothing to disclose.

PP0417

ROLE OF FIT IN IRON DEFICIENCY ANAEMIA- CAN IT PREDICT SMALL BOWEL PATHOLOGY?

P. Oka[1], M. McAlindon[1], R. Sidhu[1]
[1]Sheffield Teaching Hospitals, Gastroenterology, Sheffield, United Kingdom

Contact E-Mail Address: oka.priya@gmail.com

Introduction: The role of faecal immunochemical testing (FIT) as a biomarker to stratify patients with lower gastrointestinal (GI) symptoms is well established. However, its use in patients with iron deficiency anaemia (IDA) is controversial. The aim of this study was to investigate the role of FIT in predicting small bowel (SB) pathology in patients with IDA.

Aims & Methods: Patients with IDA and a FIT test who had negative bidirectional endoscopy and underwent a Small Bowel Capsule Endoscopy (SBCE) were included. Patients were split into two groups:

Group-1: Positive FIT (> 4 ug Hb/g) and IDA;

Group-2: Negative FIT and IDA.

Patients demographics, past medical history, medication history, haemoglobin and ferritin results, FIT levels and capsule endoscopy findings were recorded.

Results: 58 Group-1 patients (median age 71.5years (IRQ 58.7-76); 46.5% male) had a median haemoglobin of 104 g/L (IQR 97.7- 120.3) ferritin12 (IQR 8- 18) and median FIT 31(IQR 16.7- 158). 28 Group-2 patients (median age 61.5 years (IQR 49-69); males- 60.7%) had a median haemoglobin of 107 g/L (IQR 94- 123) and ferritin 11.5 (IQR 7- 20).

There was a significant difference in median age between the two groups (p=0.008). In 26 (44.8%) patients from Group-1 there was significant pathology identified on SBCE (angioectasia- 18, visible blood- 3, polyp-1, NSAID enteropathy-3, Duodenal ulcer-1 and SB Crohns-1). In 11 (39.2%) patients from Group 2 there was significant pathology identified on SBCE (angioectasia- 6, visible blood- 2, NSAID enteropathy-2, SB Crohns-1 and coeliac-1).

Some patients had more than one lesion on SBCE. The sensitivity and specificity of a positive FIT predicting SB pathology was 70.27% and 34.6 9% respectively. 10 patient in Group-1 and 2 patients in Group-2 admitted to using NSAIDs post-procedure although they had not revealed this during their pre-procedure medication documentation.

Conclusion: In patients with IDA and no clear cause seen at conventional upper and lower endoscopy, small bowel pathology was present in over a third of cases although this was not predicted by the FIT result. Capsule endoscopy should be considered in these cases. Regular NSAID use can cause significant SB pathology. It is important to screen for NSAID use prior to SBCE. Studies with larger numbers are needed to assess correlation between FIT and SB pathology in patients with IDA.

Disclosure: Nothing to disclose.

USEFULNESS AND SAFETY OF OCTREOTIDE IN GASTROINTESTINAL BLEEDING FROM ANGIODYSPLASIAS IN THE ELDERLY: A SINGLE-CENTER 12-YEAR EXPERIENCE

S. Ponte[1], S. Archer[1], A.T. Ferreira[1], L. Maia[1], P. Salgueiro[1], I. Pedroto[1]
[1]Centro Hospitalar Universitário de Santo António, Department of Gastroenterology, Porto, Portugal

Contact E-Mail Address: sofiaponte1995@gmail.com

Introduction: Angiodysplasias (AD) are the most common source of gastrointestinal (GI) bleeding of obscure origin in the elderly. In this population, GI AD often leads to red blood cell (RBC) transfusion-dependent anemia, resulting in high rate of hospitalizations and overuse of healthcare resources. Argon plasma coagulation (APC) is the standard treatment option, but it is an invasive procedure, with possible serious complications in the presence of significant comorbidities, and frequently ineffective in preventing recurrence of GI bleeding. Octreotide has been studied in this context, but currently it is not a widely recommended drug.

Aims & Methods: Aim: To evaluate the usefulness and safety of long-acting release-octreotide (LAR-OCT) in the control of bleeding from GI AD in elderly.

Methods: Retrospective study of patients diagnosed with chronic GI bleeding due to AD and treated with intramuscular LAR-OCT between January 2010 and December 2022 in a tertiary hospital was performed. Demographic and clinical data were collected. Exclusion criteria: LAR-OCT suspension before completing 6 months of treatment.

Primary outcome: the presence of a normal Hb value (≥ 12g/dl) in the absence of any blood transfusions at 6 months(m) of therapy.

Secondary outcomes: increase in Hb value, reduction of transfusional requirements and adverse events. Statistical analysis was performed with SPSS vs 25.0 (significance level of 0.05).

Results: Nineteen out of 23 patients completed at least 6m of LAR-OCT therapy. The mean age at diagnosis of AD was 74.2 years (62 to 89 years); 63.2% were female. The mean value of Charlson Comorbidity Index was 6.37 (estimated 10-year survival around 2%). Before starting LAR-OCT, 13 patients (68.4%) were under endovenous iron supplementation and 7 patients (36.8%) had undergone APC; 31.6% required at least 4 RBC units in the last month.

Primary outcome was achieved in 5 (21.7%) patients. There was a statistically significant increase in the Hb values in the first 6m of therapy (p=0.000). Three patients (15.8%) required RBC transfusions in this period, but only one presented with overt GI bleeding.

Only 8 patients achieved 24m of therapy, showing a statistically significant increase from initial to 24-m Hb values (p=0.012).

Twelve (52.2%) patients were under antithrombotic agents; there was a statistically significant difference between initial Hb and 6-m Hb value in this subgroup (p=0.002); between initial and 24-m values, there was an increase in the Hb value but not statistically significant (p=0.068).

Concomitant iron supplementation was performed in 13 and APC in 3 patients.

Adverse events were registered in 2 patients, leading to drug suspension in only 1 (dysrhythmia).

Conclusion: In the setting of "difficult-to-treat" patients with GI bleeding due to AD, octreotide has been proposed as an alternative therapeutic strategy. In this cohort of older patients, with a relatively low estimated 10-year survival due to its comorbidities, LAR-OCT appears to be effective in increasing Hb values while reducing the need of RBC transfusions and, therefore, the number of hospital admissions. This is particularly important in elderly patients, having a potential impact on their quality of life and on the healthcare costs associated with recurrent GI bleeding. Limitations of this study are the retrospective design, the small number of enrolled patients and the inability of analyzing the individual effect of LAR-OCT. Further studies are needed.

Disclosure: Nothing to disclose.

PP0419

MITOCHONDRIA ARE BETTER PROTECTED FROM HYPOXIA-REOXYGENATION INJURY IN CRYPT-LIKE HUMAN INTESTINAL ORGANOIDS COMPARED WITH VILLUS-LIKE ORGANOIDS: A ROLE FOR MITOPHAGY?

A.M. Kip[1], A. Duivenvoorden[1], A. Alićehajić[1], M. Hadfoune[1], T. Lubbers[2], S. Olde Damink[1,2], K. Lenaerts[1]
[1]Maastricht University, Department of Surgery, Maastricht, Netherlands, [2]Maastricht University Medical Center+ (MUMC+), Surgery, Maastricht, Netherlands

Contact E-Mail Address: annet_duivenvoorden@hotmail.com

Introduction: Intestinal ischemia-reperfusion injury (IRI) is a life-threatening condition caused by an abrupt obstruction of mesenteric blood flow. Reestablishing blood flow (reperfusion) is necessary to save intestinal tissue but unintentionally exacerbates damage induced by ischemia. Mitochondria are sensitive to IRI; if damaged, they release cytotoxic molecules that can aggravate injury.

Therefore, removal of damaged mitochondria is essential for cellular survival. The selective clearance of mitochondria via autophagy, mitophagy, has been reported to protect against IRI in other organs, but its role in the intestine remains unknown.

Aims & Methods: The main objective of this study was to assess mitochondrial damage and evaluate signs of mitophagy in response to hypoxia-reoxygenation in a human small intestinal organoid (SIO) model and the differences therein between crypt-like (CL) and villus-like (VL) organoids. Both SIOs phenotypes were exposed to hypoxia-reoxygenation, and mitochondrial damage was assessed by live-cell imaging of mitochondrial membrane potential using fluorescent dye tetramethylrhodamine methyl ester (TMRM).

In addition, ultrastructural changes in mitochondria were evaluated by transmission electron microscopy (TEM). Finally, mitochondrial content, autophagy, and mitophagy markers were assessed using quantitative PCR (qPCR) and Western blot.

Results: A drastic decrease in TMRM fluorescence, indicating impaired mitochondrial activity, was mainly observed in VL organoids and not in CL organoids. Mitochondrial ultrastructural changes were observed in both phenotypes, including mitochondrial swelling and disrupted cristae following hypoxia, whereas after 480 minutes reoxygenation, mitochondria exhibited a tubular or small round shape. Mitochondrial content markers were decreased in both organoid phenotypes following hypoxia-reoxygenation. Most importantly, only CL organoids showed a significant increase in autophagy and mitophagy markers.

Conclusion: Mitochondria of VL organoids are more severely damaged by hypoxia-reoxygenation, whereas CL organoids might be protected by inducing mitophagy. The occurrence of mitophagy is currently further validated with live-cell imaging.

Disclosure: Nothing to disclose.

FIRST FRENCH INTESTINAL STROKE CENTER FOR THE CARE OF ACUTE MESENTERIC ISCHEMIA: A 7-YEAR PROSPECTIVE COHORT STUDY

A. Nuzzo[1], I. Ben Abdallah[2], L. Garzelli[3], L. Ribeiro-Parenti[4], M. Ronot[5], M. Giacca[6], E. Weiss[7], V. Vilgrain[8], B. Lortat-Jacob[9], Y. Castier[2], O. Corcos[1]
[1]Beaujon Hospital, Intestinal Stroke Center Unit, Department of Gastroenterology, IBD, Intestinal Failure, Paris, France, [2]Bichat Hospital, Vascular Surgery, Paris, France, [3]Beaujon Hospital, Radiology, Paris, France, [4]Bichat Hospital, Digestive Surgery, Paris, France, [5]Université Paris, Unit for Training and Research in Medicine, Paris, France, [6]Beaujon Hospital, Colorectal Surgery, Paris, France, [7]Beaujon Hospital, Intensive Care Unit, Paris, France, [8]Hopital Beaujon, Radiology, Clichy, France, [9]Bichat Hospital, Intensive Care Unit, Paris, France

Contact E-Mail Address: al.nuzzo@gmail.com

Introduction: The need for multidisciplinary and expert 24/7 emergency care for acute mesenteric ischemia (AMI) has led to the implementation of the first Intestinal Stroke Center (ISC) in France in 2016. This study aimed to report our results at 7 years.

Aims & Methods: A prospective cohort study was conducted in our ISC unit and included all patients admitted for acute and chronic mesenteric ischemia (CMI) or dissections of coeliomesenteric arteries without ischemia. All patients were treated according to our multimodal and multidisciplinary protocol previously published (Corcos et al. Clin Gastroenterol Hepatol 2013). Patients are treated 24/7 by an on-call gastroenterologist coordinating management and care pathways between interventional radiologists, vascular and digestive surgeons, and intensivists. Patients were then followed with a clinical visit and CT angiography at 1, 3, 6, 12, and 24 months.

Results: Between January 1, 2016 and October 1, 2022, we received 3,910 calls concerning 2,525 patients, 84% from the Paris region and 14.5% from other regions of France. This represents an average of 361 patients/year, with an annual increase in calls of 35%, going from 155 calls the first year to 684 calls for the last year. We hospitalized 719 patients (103 patients/year on average), with a median age of 65 years (IQR 54-74), of which 42% were women, and including 493 AMI (69%), 106 CMI (15%) and 116 dissections of coeliomesenteric arteries (16%). Among patients hospitalized for AMI (n=493), 395 (80%) were secondary to arterial occlusion and 87 (20%) to porto-mesenteric venous thrombosis. In the AMI group, the revascularization rate was 72% for arterial AMI (0% for venous forms), and the resection rate was 57%. The 1-year survival was 75% for arterial AMI and 97% for venous forms. In the subgroup of AMI referred to our center within the first seven days (n=373), the bowel resection rate was 39%, and the 1-year survival rate was 79%. In the CMI group (n=106), the revascularization rate was 78%, the bowel resection rate was 1%, and the 1-year survival rate was 92%. In the dissections of coeliomesenteric arteries without ischemia (n=116), the treatment was mainly medical, with a revascularization rate of 3%, with no intestinal resection or death occurring at 1 year.

Conclusion: This large prospective study is the first to report on the activity and results of a specialized ISC for mesenteric ischemia and intestinal vascular diseases. Our results show that creating an ISC with standardized management focused on intestinal viability opened a recruitment channel for these severe patients with survival > 70% and resection rates < 50%, particularly in patients admitted at an early stage. These results encourage the creation of other regional ISCs in France and other countries as a new standard of care in AMI.

TREATMENT IN A SPECIALIZED INTESTINAL STROKE CENTER IMPROVES SURVIVAL AFTER ACUTE MESENTERIC ISCHEMIA: A STUDY FROM THE FRENCH NATIONAL HEALTH DATA SYSTEM

A. Nuzzo[1], K. Zarca[2], P. Eloy[3], E. Ea[2], Y. Castier[4], I. Ben Abdallah[4], M. Ronot[5], M. Giacca[6], O. Corcos[7], I. Durand-Zaleski[2]
[1]Beaujon Hospital, Intestinal Stroke Center unit, Department of Gastroenterology, IBD, Intestinal Failure, Paris, France, [2]Hotel Dieu Hospital, Epidemiology, Paris, France, [3]Bichat Hospital, Epidemiology, Paris, France, [4]Bichat Hospital, Vascular Surgery, Paris, France, [5]Université Paris, Unit for Training and Research in Medicine, Paris, France, [6]Beaujon Hospital, Colorectal Surgery, Paris, France, [7]Beaujon Hospital, Gastroenterology, Clichy, France

Contact E-Mail Address: al.nuzzo@gmail.com

Introduction: The need for a multidisciplinary and expert 24/7 emergency care has led to the implementation of the first Intestinal Stroke Center (ISC) in France. The objective of this study was to assess the impact of treatment in this expert center on the survival of patients with AMI.

Aims & Methods: We used the French National Health Data System (SNDS), covering 99% of the French population. All patients with a diagnosis of AMI and treated in the ISC or in 11 selected university hospitals with vascular and digestive surgical teams (unexposed control hospitals: Strasbourg, Lille, Lyon, Clermont, Nantes, Nice, Toulouse, Bordeaux, Marseille) were included over a period of 9 years between January 1, 2009 and December 31, 2018. The follow-up duration was 12 months, or until death.
Survival in the ISC was compared with that of other hospitals using a Cox model with adjustment for age and sex. Survival probabilities in the ISC are presented at 1, 3, and 12 months (M1, 3 and 12) and expressed as Hazard Ratios and their 95% confidence intervals.

Results: A total of 10,126 patients with AMI were identified, including 1,206 patients managed in the ISC, and 8,920 patients managed in control hospitals. Patients managed in the ISC had a lower risk of mortality at M1 (HR = 0.70 [0.70-0.89], p<0.001), at M3 (HR = 0.77 [0.69-0.86], p<0.001) and at M12 (HR = 0.81 [0.73-0.90], p<0.001) compared to non-ISC patients. The probability of survival in the ISC was 76% at M1 [73-78] (vs. 65% [64-66], p<0.001), 71% at M3 [69-74] (vs. 59% [58-60], p<0.001), and 66% at M12 [63-68] (vs. 54% [53-56], p<0.001).

Conclusion: This study is the first to provide comparative results evaluating the benefits of a specialized care for AMI. The results show a significant benefit in terms of survival compared to patients treated in control hospitals (+10% after 12 months). With a median admission of 120 patients / year / center, these epidemiological and prognostic results suggests that regional university hospitals should implement a specialized ISC to improve the prognosis of AMI and reduce disparities in patient care. Based on these findings, treatment of AMI in a specialized ISC was associated with an absolute increase in survival of 10% at 12 months. These results provide essential data to support the implementation of regional ISCs dedicated to the care of AMI in France and in other countries.

Introduction: Mortality of acute mesenteric ischemia (AMI) is closely correlated with the development and extent of irreversible transmural intestinal necrosis (ITIN). In this context, the surgical assessment of small bowel viability is difficult, subjective (visual) and invasive. In order to better identify high-risk patients justifying an immediate surgical evaluation, the non-invasive Clichy score was developped in 2017 (Nuzzo et al. Am J Gastroenterol 2017). The aim of this study was to evaluate the diagnostic performance of this score.

Aims & Methods: The development cohort included 67 patients with AMI admitted to our center between 2009 and 2015, with a Clichy score including 3 independent factors (organ failure, elevation of plasma lactate > 2 mmol/L, and intestinal dilation on CT scan > 25mm; area under the ROC curve [AUROC] = 0.94 [95% confidence interval: 0.87–1.00]). The present validation study prospectively included patients admitted to our center for AMI between 2016 and 2018. The presence of ITIN was defined histologically as previously published. The diagnostic performance of the score was assessed by AUROC in the total cohort, and in the AMI subgroups of arterial and venous origin.

Results: 52 patients (mean age 65, 37% women) were included. Arterial and venous occlusion induced AMI occurred in 65% and 35% of cases, respectively. ITIN was confirmed in 14 patients (27%). Organ failure, elevation of plasma lactate > 2 mmol/L, and intestinal dilatation > 25 mm was observed in 17 (33%), 15 (29%) and 12 (23%) of patients, respectively. The AUROC for the diagnosis of ITIN by the Clichy socre was 0.90 (95% CI = 0.81 – 0.98). In the presence of 0, 1, 2 and 3 factors, the risk of ITIN was 0%, 14%, 55% and 75%, respectively (Figure).

In subgroup analyses, the AUROC for the diagnosis of ITIN was 0.96 (0.89 – 1.00) in arterial AMI, and 0.77 (0.53 – 0.85) in venous AMI. In arterial AMI, the risk of ITIN was respectively 0%, 13%, 67% and 100% in the presence of 0, 1, 2 and 3 factors. In venous AMI, the risk of ITIN was respectively 0%, 17%, 50% and 50% in the presence of 0, 1, 2 and 3 factors. The negative predictive value (NPV) of a score of 0 was 100% in both types of AMI. The positive predictive value (PPV) of a score of 3 was 100% in arterial AMI, and 50% in venous AMI.

Conclusion: This prospective study is the first which validates a non invasive diagnostic score of ITIN in the setting of AMI. The diagnostic performance of the score was satisfactory, especially in AMI of arterial origin. These results suggest that these factors should prompt laparotomy consideration if present. In the subgroup of venous AMI, further studies seem necessary to identify other risk factors.

Introduction: Since 2006 at our hospital, lifestyle modification, such as diet and exercise, for obese patients has been provided through a team approach with a physician, dietician, nurse, physical therapist and psychologist. From 2016, a surgeon and anesthesiologist were added to the team for metabolic/bariatric surgery (laparoscopic sleeve gastrectomy: LSG).

Aims & Methods: The aim of this study is to clarify the characteristics of obese patients with diabetes mellitus (DM) for whom LSG was effective according to body mass index (BMI). Of 24 diabetic patients who were received LSG between January 2017 and December 2021 with follow-up period of more than 1 year, 4 were with a BMI of < 35, 7 were with a BMI of 35 - 40, and 13 were with a BMI of 40 or more. The mean age was 51, 49 and 45 years. respectively. Complete remission of postoperative DM was defined as HbA1c < 6% without drug therapy, and incomplete remission was defined as a decrease in the amount of drug therapy among the other patients.

Results: Preoperative HbA1c (%) was 8.6, 7.0 and 8.0, and preoperative serum c-peptide (CPR) (ng/ml) was 1.9, 3.1 and 3.1, and preoperative ABCD score was 2.0, 4.4 and 6.0, respectively. There were no differences of preoperative complications, preoperative weight loss rate, postoperative weight loss rate, and postoperative body composition change rate. The postoperative complete DM remission rate (%) was 25, 71 and 69, respectively, and the drug dose was reduced in all patients, even in those with incomplete remission.

Conclusion: Regardless of BMI, complete remission of DM was achieved by performing LSG when CPR was maintained, even in patients with poorly controlled DM. On the other hand, even in patients with decreased CPR, benefits such as postoperative weight loss and drug reduction were observed. LSG should be actively considered in obese patients with DM.

Introduction: Due to the daily rhythm of insulin level, an increase of the morning fasting blood sugar value was known in prediabetes statements. ECG heart rate variability (HRV) parameters like low-frequency (LF) and high-frequency (HF) also have a circadian pattern. The ratio of LF/HF can show the activity of the autonomic nervous system.

The evaluation of the epidemiological and metabolic aspects of lifestyle (effects of missing meals, high carbohydrate intake, night shift etc.) could help find a more accurate pathophysiological knowledge to improve overweight in therapy-resistant patients and clearing the risk of it.

Aims & Methods: Our aim was to compare the results of the mother-child group described in our reference abstract and the group performing physical work during night shift. Searching long-term effects of regular night shift physical work and staying awake, such as anaerobic exercise. Could more objective effects on weight loss or on cardiovascular risk be identified than mentioned in other night shift studies?

17 mothers (M) and 24 children (Ch) consecutively, and 24 night shift employees (NS) were examined in the morning after their night shift. The epidemiological parameters were evaluated, then the oral loading test with orally intake of 75 g of glucose was performed. We checked the venous blood gas parameters to follow mitochondrial function indirectly. The function of the autonomic nervous system was determined by a 2-minute resting HRV and LF/HF values.

Results: Our groups (mean+SD): age were M=48.8 +/- 5.1 vs. Ch=23.5+/-5.4, vs. NS=45.7+/-10.0. The averages of BMI were M=28.59 vs. Ch=31.65 vs. NS=31.56.

The 0-minute insulin: M=5.4 +/- 3.43 vs. Ch=9.0+/-4.13, vs. NS=10.17+/-5.06 which is significant according to Student's t-test, p(M-Ch)=0.003. p(M-NS)= 0.001. The lifestyle differences were irregularity and skipping of the breakfast in the NS group.

The venous lactate was after 120 minutes of the glucose intake (mean +/- SD) M=1.37 +/-0.52 vs. Ch=1.56 +/-0.43, vs. NS=1.51 +/-0.19. Lactate reference value (Siemens Epoc Reader) <0.75 mmol/l, p (M-Ch)=0.005, vs. p(M-NS)=0.003. The 0-minute lactate values were M=1.03+/-0.44 vs. Ch = 1.02 +/- 0.31, vs. NS = 1.17 +/- 0.48. p>0.05. HRV LF/HF values (mean+/- SD) were M= 1.2+/-0.54, vs. Ch=1.05 +/-0.59 vs. NS=0.74+/-0.23, p(M-NS) =0.025, p(M-Ch)>0.05. The venosus partial pressure of oxygen (average +/- SD) were M=28.2 +/- 7.22 vs. Ch=29.8+/-7.26, vs. NS=26.8+/-6.55. p(M-NS)>0,05.

Conclusion: The higher basal insulin and lactate level and lower venosus partial pressure of oxygen in the NS group could be explained by a relative tissue hypoxia which a factor of anaerobic metabolism and could increase the consumption of glucose in the muscles by GLUT4 transporters and elevating the level of circulating glucose.

The vagus tone helped in the dynamic autonomic regulation and it was responsible for cardiovascular health. Its decreasing correlates with the lower LF/HF ratio, which could be a marker for physical overload of the NS group.

Unsuccessful weight loss could be explained with the proportionally higher insulin level in NS group, which causes a feeling of hunger and helps the fat storage. On the other hand, the lower effectiveness of calorie-restricted diets should be improved with regular meals during night shift.
We presented a possible clinically measurable sign of the pathophysiological features of the adipose tissue hypoxygenisation as in hypoxia inducible factor 1-alpha studies presented.
We were planning a long-term health risk study to demonstrate the effectiveness of these parameters.

Introduction: Endoscopic sleeve gastroplasty (ESG) is a safe and effective procedure for class 1 and 2 obese subjects[1]. The effects of smoking habits on weight are well known regarding bariatric surgery[2-6]. However, given that this patient population is inherently weight-concerned, understanding the effects of tobacco use on post-operative weight loss in bariatric endoscopy is essential to guiding clinicians in counselling patients in this field.
Aims & Methods: A prospective dataset collecting data on all ESG procedures performed in an Italian tertiary referral centre was assessed retrospectively. Data on smoking habits (smoker, non-smoker, and previous smoker) were collected. Efficacy and safety between the three smoking categories was evaluated using an ANOVA test.

	Smoker	Non-Smoker	Ex-Smoker
6-months TBWL (%)	18,1 (5,6)	16,9 (6,4)	18,1 (6,4)
6-months EWL (%)	53,8 (20,4)	53,3 (23,6)	54,7 (21,8)
6-months WL (kg)	20,4 (7,2)	17,9 (8,0)	19,7 (7,7)
12-months TBWL (%)	17,0 (9,1)	15,7 (9,1)	16,0 (10,1)
12-months EWL (%)	51,0 (29,8)	49,4 (30,9)	48,3 (30,4)
12-months WL (kg)	19,0 (10,6)	15,5 (10,3)	17,3 (12,1)
24-months TBWL (%)	12,2 (12,5)	13,3 (10,0)	14,9 (8,7)
24-months EWL (%)	32,5 (37,0)	39,6 (29,8)	43,6 (24,4)
24-months WL (kg)	14,4 (14,0)	14,7 (11,9)	16,2 (10,6)

Results: Between May 2017 and October 2021, 290 subjects underwent ESG. Out of the total, smoking habits were available for 275 subjects: 144 non-smokers (NS; 52,4%), 51 smokers (S; 18,5%) and previous smokers (EX-S; 29,1%). No statistically significant differences in BMI was observed between the three groups.
In each group, no major complication were reported in the perioperative period. Adherence to follow-up was 93,1%, 92,4% and 73,5% for non-smokers, 90,2%, 84,3% and 82,4% for smokers, 91,3%, 90,0% and 71,9% for EX-smokers, at 6,12 and 24 months.
Average TBWL, EWL and WL were similar between the three groups at 6,12 and 24 months (see Table). In the non-smoker group, five subjects underwent revision procedures (4 Re-ESG, 1 Surgery) after 24 months, whereas one previous smoker underwent Re-ESG after six months. No revision was reported in the smoker group.
Conclusion: Our analysis, with the strengths of a large cohort and a long-term follow-up, showed that smoking habits do not influence the efficacy and safety of ESG for up to 24 months.
Finally, proper counseling of patients should advise the cessation of the smoking habit.

Contact E-Mail Address: mariavaleria31191@gmail.com
Introduction: Endoscopic sleeve gastroplasty (ESG) is a safe and effective procedure in class 1 and 2 obese subjects.The effects of menopause on weight are well known. However, given that this patient population is inherently weight-concerned, understanding the effects of ESG on women in menopause is essential to guiding clinicians in counselling this patient population.
Aims & Methods: A prospective dataset collecting data on all ESG procedures performed in a tertiary referral centre was assessed retrospectively. Data on fertility status (menopause and non-menopause women) were collected. A comparison was performed using the Mann-Whitney U test.
Results: Between May 2017 and October 2021, 209 women underwent ESG. Out of the total, fertility status was available for 204 women: 79 menopause (M; 38,7%) and 125 non-menopause women (NM; 61,3%).At baseline, non-menopause women were younger, whereas there were no differences in BMI and weight.
Adherence to follow-up was 92,4%, 87,3% and 80,0% for menopause, 88,8%, 90,4% and 72,9% for non-menopause, at 6,12 and 24 months, respectively.
Six months after the procedure, non-menopause women showed significantly higher TBWL, WL and BAROS score compared to the menopausal group. In contrast, EWL showed no significant difference between the groups.Average TBWL, WL and EWL were not significantly different between the groups at 12 and 24 months (as shown in Table below).
Seven menopausal women needed revision procedures (5 Re-ESG, 1 Surgery), whereas ten non-menopausal women underwent revision (8 Re-ESG, two surgery).

		WL (kg)	EWL (%)	TBWL (%)	BAROS
6-months follow-up	Menopause (n=73)	15,0 (10)	50,8 (24,7)	15,2 (8,6)	3,5 (1,5)
	Non-menopausa (n=111)	17,0 (9,0)	54,9 (34,6)	17,2 (8,6)	4,0 (2,0)
	p	***0,017***	*0,068*	***0,0190***	***0,039***
12-months follow-up	Menopause (n=69)	13,0 (11,0)	47,8 (31,4)	14,1 (13,0)	3,5 (2,3)
	Non-menopausa (n=113)	16,0 (13,5)	52,5 (41,5)	16,3 (13,5)	3,5 (2,8)
	p	*0,162*	*0,318*	*0,223*	*0,506*
24-months follow-up	Menopause (n=40)	13,0 (15,6)	40,5 (39,3)	13,6 (14,8)	2,6 (2,9)
	Non-menopause (n=62)	10,0 (11,8)	35,4 (45,0)	10,4 (13,4)	2,5 (3,4)
	p	*0,4*	*0,716*	*0,519*	*0,776*

Table. Weight loss trajectories of subjects who underwent Endoscopic Sleeve Gastroplasty, based on menopausal status. Data are reported as median (Interquartile range).

Conclusion: Non-menopausal women who undergo ESG show better outcomes in the short term. However, this advantage does not persist in the medium and long term.
Disclosure: Nothing to disclose.

Contact E-Mail Address: mariavaleria31191@gmail.com
Introduction: Obesity, one of the most common co-morbidities in women of reproductive age, contributes to infertility and obesity-related pregnancy complications. On the other hand, pregnancy is a condition in which, physiologically, the pregnant woman undergoes weight gain. Endoscopic Sleeve Gastroplasty (ESG), an organ-sparing bariatric procedure aimed to reduce gastric volume and modify gastric motility with full-thickness endoscopic sutures, may be used for the treatment of obesity in women of childbearing age.
Aims & Methods: A retrospective analysis of a prospective database was conducted to evaluate weight trajectories, the evolution of obesity-related comorbidities, and lifestyle modification in women who became pregnant after ESG.
A comparison was made between childbearing-age women who became pregnant after ESG and non-pregnant women who reached at least the 6-month follow-up after ESG.
Results: Between January 2018 and December 2021, a total of 150 childbearing-age women underwent ESG at a large Italian tertiary medical center. Out of the total, 18 patients (12,0 %) reported a desire for pregnancy associated with unsuccessful attempts in the 12 months preceding ESG.
Eleven patients (mean age 33,4±6,2 years) became pregnant after the procedure, following a mean time interval of 5,5±3,9 months. The mean preconception BMI was 31,9±4,0 kg/m^2 (with a mean reduction of 7,24±4,0 kg/m^2 after ESG). Three patients were affected by hyperinsulinemia (H-INS), while an additional patient had both H-INS and high blood pressure (HBP). Three women reported difficulty in becoming pregnant before the ESG: two were affected by PCOS.
Total body weight loss (TBWL) of at least 5% was achieved before pregnancy in all patients (73% reached a TBWL ≥ 10%).
Six out of eleven (55%) patients had weight gain in the ranges recommended by the Institute of Medicine (IOM) during pregnancy. Among the 18 women with a reported desire for maternity associated with difficult attempts in the previous 12 months, 16,6 % (3/18) managed to start and carry out a pregnancy.
TBWL (%) was 18,08±8,00, 10,35±11,53, and 12,08±8,49, at the beginning of pregnancy, at the delivery, and at the first follow-up (mean interval, 5,18±3,57 months).
No significant differences in WL, TBWL, EWL, BMI, BAROS, and QoL were found between the pregnancy and non-pregnancy groups (99 childbearing-age women) up to 24 months after ESG.
Conclusion: ESG produces adequate weight loss before pregnancy in patients with obesity and is potentially a useful treatment option for women who have difficulty becoming pregnant, such as those with PCOS. Pregnancy after ESG does not adversely affect weight loss outcomes after delivery as lifestyle changes induced by ESG are maintained after pregnancy and allow for a gradual loss of weight gained during pregnancy.
Disclosure: Nothing to disclose.

Introduction: The obesity paradox, in patients with cancer, is a hypothesis showing patients with obesity have a prolonged overall survival compared to the ones with a normal weight. This paradox is present in different types of cancer, lung cancer, renal cell cancer, and melanoma. For gastrointestinal cancers, there are conflicting results regarding the obesity paradox. Neuroendocrine neoplasms (NENs) are rare cancers arising anywhere in the body but mainly within the gastroenteropancreatic (GEP) tract. NENs differ from other gastrointestinal cancers as they have a relatively good prognosis even in metastatic disease. NENs are classified into three different grades (G1, G2, G3) based on mitotic count and Ki-67 staining. The grades are correlated with overall survival patients with G1 GEP-NENs have significantly better overall survival compared to patients with G2 or G3 GEP-NENs.
The presence of the obesity paradox in patients with GEP-NENs is only described in one population-based study from the USA. However real-world data exploring the obesity paradox are lacking.
Aims & Methods: Aim: To explore the presence of the obesity paradox in patients with GEP-NENs in a single centre in the United Kingdom.

A cross-sectional study was performed regarding all patients with GEP-NENs and treatment with monthly somatostatin analogues (SSA's) between August 2018 and February 2019. During this period all patients weight, height and BMI were collected. Additional demographic and histopathologic data were extracted from the local hospital database. Stable disease was classed as having no change in oncological treatment within 3 months of weight/height screening. Overall survival (OS) was calculated from the moment of weight/height screening until death or the last follow-up appointment (data cut-off June 2022). Kaplan Meier, log-rank tests and Cox regression analysis were performed.

Results: In total 118 patients, n=55 (47%) males with a median age of 67 years (IQR 56.8 – 75) were included. The primary tumour was in the small intestine in n=91 (77%) and pancreas in n=25 (21%) of patients, and grade 1 in n=74 (71%) or grade 2 in n=30 (29%) of patients. In 91 patients (77%) there was stage IV disease. The median period since diagnosis was 40 months (IQR 14 – 84 months) and median period on SSA 23 months (IQR 5.5 – 59 months). The median BMI is 24.8 (IQR 21.7 – 28.7), 7 patients (6%) are underweight (BMI <18.5), 52 patients (44%) had a normal weight (BMI 18.5 – 24.9), 33 patients (28%) were overweight (BMI 25 – 29.9), 26 patients (22%) were obese (BMI >30). There are significant OS differences between BMI categories p-value 0.002. When correcting for age HR 1 (0.97 – 1.05), sex HR 1.3 (0.49 – 3.66), grading 2.06 (0.74 – 5.72), stable disease versus progressive disease HR 5.4 (1.9 – 14.9), the BMI is still significantly associated with OS with HR 0.31 (0.16 – 0.62), p-value 0.002.

Conclusion: This study shows some evidence for the presence of the obesity paradox in a real-world population of patients with GEP-NENs using an SSA. Patients with a low or normal BMI might benefit from extra attention to their nutritional status and nutritional support. Future research should focus on the pathophysiologic mechanism explaining the obesity paradox.

Introduction: Around 23% of adults in Europe are obese, with levels reaching one third in certain countries [1]. Due to its minimal invasiveness, intragastric botulinum toxin (BTX-A) injection, has become an alternative option for patients who don't want to undergo bariatric surgery. Nevertheless, there is ongoing debate regarding its clinical effectiveness [2-4]. In 2015, the European Medicines Agency granted permission for the use of daily subcutaneous (sc) liraglutide 3mg as an aid for weight loss in overweight and obese adults. Based on literature, there have been no studies combining gastric BTX-A and liraglutide administration for weight management. Therefore, we decided to conduct a retrospective study using data from our clinic record files to present the results of our experience with this approach so far.

Aims & Methods: Aim of this retrospective, cohort study is to investigate the safety and efficacy of combining intragastric BTX-A with sc liraglutide 3mg for weight management in obese and overweight individuals. A total of 300 units (U) of BTX-A were diluted in 20ml of normal saline 0.9%. Injections containing 0.5ml of the prepared solution were administered into the submucosa of the gastric antrum, body and fundus in a circular direction with 1-3cm intervals, using a standard 6mm sclerotherapy needle of 23 gauge. We incorporated liraglutide and gastric BTX-A with a reduced calorie diet and increased physical activity. The primary outcome of the study was to evaluate the effect of the combined treatment on weight loss (in kilograms, kg) in obese and overweight patients, based on measurements taken during patient follow-up at 3 and 6 months after treatment. The efficacy of the treatment was further assessed based on measurements of body mass index-BMI (kg/m^2) and visceral fat (%) taken at the aforementioned time points.

Results: Between September 2022 and April 2023, a total of 60 patients(81.7% female) received combined treatment and completed the 3 and 6-month follow-up. The baseline mean(± standard deviation) weight and BMI were 94.5±16.9kg and 33.7±4.7kg/m^2, respectively. Following intragastric BTX-A and liraglutide treatment, body weight and BMI decreased significantly: by 8.3±4.3kg and 3±1.6kg/m^2 at 3 months, and by 12±6.2kg and 4.2±2.2kg/m^2 at 6 months(all $P < 0.001$). At 3 months, BMI was reduced by 8.9±4.5% and body weight by 8.8±4%. At the same time-point, 65% of subjects had already lost more than 7% of their baseline body weight. Regarding BMI, 55% and 36.7% of patients experienced a reduction of more than 8% and 10% of their baseline BMI, respectively. The reduction in weight, BMI, and visceral fat did not differ significantly between genders or between overweight and obese patients. However, patients with moderate obesity appeared to benefit more in terms of weight loss(12±5.4 kg) and BMI reduction(4.3±1.9 kg/m^2) compared to overweight patients (6.7±2.9kg, p=0.002) and those with mild obesity(6.9±2.7 kg, p=0.001). After 6 months, visceral fat decreased significantly by 2.3±3.8%(P=0.002). Among all patients, 19% experienced mild side effects, including constipation (9%), headache (4%), diarrhea(3%), and nausea(3%).

Conclusion: This is the first study that combined gastric BTX-A with liraglutide for weight management. Results revealed noteworthy reductions in weight, BMI, and visceral fat, without any severe side-effects. To confirm these findings and establish the efficacy of this approach, randomized clinical trials are required.

Introduction: Weight regain and dumping syndrome (DS) are two relevant long term adverse events after Roux-en-Y Gastric Bypass (RYGB). Both these conditions are related to the dilation of the gastro-jejunal anastomosis. Transoral outlet reduction (TORe) is minimally invasive endoscopic procedure that was introduced to treat these conditions when medical treatment fails. As every endoscopic procedure, TORe is repeatable per definition. In this case series, we evaluate the technical feasibility and short and medium-term outcomes of the redo TORe in patients with weight regain and/or DS recurrence after primary TORe.

Aims & Methods: A retrospective analysis was done on a prospective database including patients that underwent TORe between January 2015 and October 2021; patients who received a re-TORe because of progressive loss of satiety and weight regain (≥50% of weight loss after primary TORe), or recurrence of DS were included in the analysis. DS recurrence was defined as Sigstad's dumping score ≥7. Sigstad's score, early and late Arts Dumping Score (ADS) questionnaires, and percentage of total body weight loss (%TBWL) were assessed at baseline, at 6 and 12 months after re-TORe.

Results: Of 92 patients that underwent TORe, 10 required a re-TORe. Indication to re-TORe was weight regain alone in 3 patients, while the remaining 7 repeated the procedure due to both DS recurrence and weight regain. The median time between the primary TORe and the re-TORe was 28 months (range 14-64 years). The median weight regain was 217% (IQR 400) compared to weight at primary TORe and 31.3 % (IQR 16) compared to weight at RYGB. The median Sigstad's score for patients with recurrent DS was 14 (IQR 4.5), while median early ADS was 5 (IQR 9.5) and late ADS was 8 (IQR 3.5). The redo TORe was technically feasible in all patients. No periprocedural adverse events occurred. Mean percentage of total body weight loss (%TBWL) was 7.7% (IQR 2) at 1 month, 10.1% (IQR 14.2) at 6 months and 10.1% (IQR 18) at 12 months. 6/7 patients undergoing re-TORe because of recurrent DS reached 6- and 12-months follow-up. 3/6 patients had a complete remission of DS maintained at 1 year. Trends of symptoms-based questionnaire for DS are reported in table 1.

Dumping syndrome outcomes after re-TORe

	Baseline	6 months	12 months	P#
Sigstad's Score	14 (4.5)	7 (1-14)	4.5 (1-14)	0.04
EADS	5 (1-10.5)	4 (0-4)	4.5 (0-8)	0.01
LADS	8 (5.5-9)	3 (0-4)	2.5 (0-4)	0.06

Friedman test,
Values are median (Q1-Q3)
EADS= Early Arts Dumping Score questionnaire; LADQ= Late Arts Dumping Score questionnaire.

Conclusion: According to our experience, redo TORe is technically feasible and has good short and medium-term outcomes in terms of weight loss and DS control. As such, repeating the procedure should be considered before referring patients for revision surgery.

Contact E-Mail Address: bulajic.milutin@gmail.com

Introduction: Endoscopic Gastroplasty (EG) is an endoscopic therapy focusing on gastric body emodeling to treat obese patients. Nowadays three different techniques are mainly described in literature: endoscopic sleeve gastroplasty (ESG) with an overstitch endoscopic suturing device, endoluminal vertical gastroplasty (EVG) with a triangulation platform and endoluminal suturing device, and distal primary obesity surgery endoluminal (POSE-2) with an endoscopic plication system.

Aims & Methods: Our study aimed to assess changes in anthropometric measurements (AM), body composition (BC) and quality of life (QoL) of these three EG techniques at 6 months follow-up. This was a single center, randomized study (ClinicalTrials.gov NCT04854317) of patients who underwent EG (through ESG performed by Apollo Overstitch Sx, or EVG performed by Endomina, or gastric plication performed by POSE-2) for the treatment of obesity. Outcomes included the efficacy of the three EG procedures at inducing weight loss, improving body circumferences (arm, waist, hip and calf), BC (fat mass (FM), free fat mass (FFM), body cell mass (BCM)), and QoL.

Results: Between July 2020 and October 2021, 90 obese (body mass index 36.6 ± 3.1 kg/m2) patients (mean age, 46 ± 10 years; females 87.5%; obesity class II as the main obesity class in 58.3% cases; hepatic steatosis as the main comorbidity with a 70% frequency) underwent EG through ESG or EVG or POSE-2. At 6 months, 63/90 (70%) patients attended their follow-up visit. They experienced 16% ± 6% total body weight loss (TBWL) and 39.7% ± 14.9% excess weight loss (EWL). Sixty out of sixty-three (95.2%) patients achieved at least 5% TBWL, and 54/63 (85.7%) achieved at least 25% EWL. All the body circumferences homogeneously decreased ($p<0.001$). Concerning BC, the FM and FM% significantly decreased ($p<0.001$), while the FFM% and BCM% increased ($p<0.01$). The QoL measured by BAROS test improved at 6-month follow-up ($p<0.01$).

Conclusion: EG through ESG, EVG and POSE-2, focusing on gastric body reduction and sparing the fundus and antrum, appears to be effective for the treatment of obese patients inducing weight loss and improving the other AM, BC and QoL.

THE ROLE OF THE PHASE ANGLE AS PREDICTING FACTOR OF WEIGHT LOSS IN ENDOSCOPIC GASTROPLASTY: RESULTS FROM A SINGLE CENTER, RANDOMIZED STUDY

S.F. Vadalà di Prampero[1,2], S. Masia[2], V. Cosseddu[2], P. Bazzu[2], F. Di Maio[2], J. Formichetti[2], G. Manzoni[2], C. Rocchi[2], M. Massidda[2], V. Milano[2], P. Giustacchini[2], M. Bulajic[1,2], Mater Olbia obesity

Introduction: Endoscopic Gastroplasty (EG) is an endoscopic therapy focusing on gastric body remodeling to treat obese patients. Nowadays three different techniques are mainly described in literature: endoscopic sleeve gastroplasty (ESG) with an overstitch endoscopic suturing device, endoluminal vertical gastroplasty (EVG) with a triangulation platform and endoluminal suturing device, and distal primary obesity surgery endoluminal (POSE-2) with an endoscopic plication system.

Aims & Methods: Our study aimed to assess changes in weight loss of these three EG techniques at 6 months follow-up, looking at some useful parameters which could predict these changes. This was a single center, randomized study (ClinicalTrials.gov NCT04854317) of patients who underwent EG (through ESG performed by Apollo Overstitch Sx, or EVG performed by Endomina, or gastric plication performed by POSE-2) for the treatment of obesity. Outcomes included the efficacy of the three EG procedures at inducing weight loss, measured by the percentage of Total Body Weight Loss (%TBWL) and Excess Weight Loss (%EWL).

Results: Between July 2020 and October 2021, 90 obese (body mass index 36.6 ± 3.1 kg/m2) patients (mean age, 46 ± 10 years; females 87.5%; obesity class II as the main obesity class in 58.3% cases; hepatic steatosis as the main comorbidity with a 70% frequency) underwent EG through ESG or EVG or POSE2. At 6 months, 63/90 (70%) patients attended their follow-up visit. They experienced 16% ± 6% TBWL and 39.7% ± 14.9% EWL, with no significant difference among the three techniques in both of parameters ($p>0.62$ in TBWL and $p>0.94$ in EWL ANOVA tests). Sixty out of sixty-three (95.2%) patients achieved at least 5% TBWL, and 54/63 (85.7%) achieved at least 25% EWL.

All the body circumferences homogeneously decreased ($p<0.001$). By a linear regression analysis, at 6 months follow-up a significant correlation between the Phase Angle and the %TBWL ($p<0.05$) and %EWL ($p<0.05$) was detected.

Conclusion: Our study confirms that ESG, EVG and POSE-2 are valuable EG procedures to reduce weight in obese patients. The Phase Angle could be considered a useful predictor of weight loss after the EG, at least in the short-term. Detecting valuable predictors of weight loss could be helpful not only in the post-operative, but also and mainly in the pre-operative to tailor a specific intervention for each patient according to the emerging concept of personalized therapy for obesity.

Further studies with more patients and a longer follow-up are needed to confirm our data.

Introduction: Endoscopic sleeve gastroplasty (ESG) is a minimally invasive restrictive bariatric procedure associated with significant weight loss, obesity-related comorbidities improvement, and a favorable safety profile. The suturing devices, available today, are often tricky and operator-dependent. A novel automated endoluminal-sutured gastroplasty system (EndoZip™, Nitinotes Ltd. based in Israel), has been developed to simplify and standardize ESG. The device is positioned in the gastric body under endoscopic vision and is connected to an external vacuum pump that captures the gastric wall segments into the distal end of the device. The activation of a motor system makes a custom-designed needle pass through the tissue and allows stitching, tightening, clipping, and cutting of suture wire. The suturing actions are done automatically in approximately 2 minutes, by just pressing on the operation button.

Aims & Methods: This multicenter, prospective, single-arm study aimed to assess the safety and efficacy of the ESG using EndoZip™ for the treatment of obesity. Patients with a BMI of 30 to 40 kg/m^2 unable to lose weight with non-invasive approaches and deemed suitable for bariatric endoscopic according to the multidisciplinary team were enrolled in 3 centers (Spain, Italy and Israel). The efficacy of the EndoZip™ system was assessed. %TBWL, and % of patients with %TBWL ≥5% were evaluated via ANCOVA model. Safety data and physician's satisfaction with device use, were evaluated via descriptive statistics.

Results: Forty-five patients underwent robotic endoscopy-assisted gastric volume reduction. The mean ±SD age was 44 ±8 years, and BMI was 34.6 ±2.9 kg/m^2, respectively. The majority of the patients were female (89%). the average procedure time was 30 minutes. We used an average of 3.9 sutures; At 12 months, the mean ±SD %TBWL was 13.5 ± 10.4%. We observed >5% TBWL in 79.4% of the patients (Table 1). All endoscopists found the device easy to use. Serious adverse events occurred in 2 patients (bleeding and gastric perforation). The bleeding was stopped with endoscopic clipping, and the gastric perforation required surgical closure. No mortality occurred.

	1 month	2 months	4 months	6 months	12 months
Adj. Mean %TBWL (Lower 95% CL)	**7.4%** (6.6%)	**10.3%** (8.9%)	**13.3%** (11.5%)	**14.5%** (11.7%)	**13.5%** (10.4%)
%TBWL ≥5% (Lower 95% CL)	**78.6%** (63.2%)	**92.7%** (80.1%)	**92.3%** (79.1%)	**85.0%** (70.2%)	**79.4%** (62.1%)

Per Protocol Analysis

Table 1.

Conclusion: EndoZip™ system is an operator-friendly and reproducible procedure with promising efficacy and safety results.

OVERGROWTH OF AKKERMANSIA MUCINIPHILIA BY SPRING WATER INGESTION PREVENTS OBESITY AND HYPERGLYCEMIA IN A HIGH-FAT DIET-INDUCED MOUSE MODEL

H.S. Chae[1], S.W. Kim[1], H.K. Kim[1], H.H. Choi[1], S.H. Sin[1]
[1]Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Internal Medicine, Uijeongbu, South Korea

Contact E-Mail Address: chs@catholic.ac.kr

Introduction: It has been known that type 2 diabetes may be alleviated by mineral water (MW) ingestion. We investigated whether spring water (SW) ingestion, a kind of a mixed MW, influences metabolic parameters via alteration of the gut microbiota in high-fat diet (HFD)-fed mice.

Aims & Methods: We divided total thirty two C57/BL mice into four groups: normal diet with tap water (Control, 8), high fat diet with tap water (HFD, 8), high fat diet with SW (HFD plus SW, 8), and normal diet with SW (SW, 8). During this experiment, we weekly checked body weight (BW) with fasting blood sugar (FBS) and all mice were sacrificed at 17th wk in order to observe the serologic markers, the internal organs and composition of gut microbiota.

Results: The body weight of HFD-fed mice was significantly higher than that of mice fed an HFD plus SW in the early period of the experiment. Fasting blood glucose in the HFD group showed a fluctuating pattern compared to the HFD plus SW group, and the area under the curve value of the oral glucose tolerance test was significantly greater in the HFD group than in the HFD plus SW group. Serologic markers were not significantly different between the HFD and HFD plus SW groups. Histologically, the most severe fatty changes in the liver were observed in the HFD group. The gut levels of Akkermansia muciniphilia were 100-fold higher in HFD plus SW than in HFD mice.

Conclusion: These findings indicate that SW ingestion, and the associated Akkermansia muciniphilia overgrowth in the gut, may improve early stage of obesity and ameliorate HFD-induced hyperglycemia.

PP0435

NON-LINEAR ASSOCIATIONS BETWEEN SLEEP DURATION AND VISCERAL ADIPOSITY INDEX: A POPULATION-BASED STUDY

X. He[1]
[1]Sir Run Run Shaw Hospital, Zhejiang University, Department of Gastroenterology, Hangzhou, China

Contact E-Mail Address: hexingkang1990@163.com

Introduction: Obesity is a significant global health concern, and recent research has suggested that sleep duration may play a role in its development[1]. However, previous studies have yielded inconsistent results[2,3]. Traditional methods of measuring obesity, such as BMI, do not distinguish between different types of fat. Visceral fat, which is linked to negative outcomes associated with obesity, can be assessed using the visceral adiposity index (VAI), which is based on simple measurements and lipid parameters[4]. Despite being a reliable indicator of visceral fat distribution and function, the relationship between sleep duration and VAI remains unclear.

This study aims to address this gap by examining the association between sleep duration and VAI in a population-based cohort, providing further insight into the potential connection between sleep and obesity.

Aims & Methods: The purpose of this study was to determine the association between sleep duration and VAI in a population-based cohort. In the present study, eligible participants were identified from the National Health and Nutrition Examination Survey (NHANES) between 2007 and 2018. VAI was calculated by anthropometric data (height, weight, and waist circumference) and lipid parameters (triglycerides and high-density lipoprotein cholesterol). The duration of sleep was assessed using a questionnaire and classified into three groups according to The American Academy of Sleep Medicine and the Sleep Research Society: short sleep duration (less than 7 hours per day), normal sleep duration (between 7 and 9 hours per day), and long sleep duration (more than 9 hours per day) [5]. Multiple linear regressions and subgroup analyses were used to evaluate the associations between sleep duration and VAI.

Results: A total 11,274 eligible participants with a mean age of 49.3 years were included in the current study. The mean sleep duration and VAI were 7.05 h/day and 2.03 respectively.

After adjusting for the sociodemographic, lifestyle and other covariates, short sleep was significantly associated with increased VAI (β = 0.15, 95% confidence interval (CI): 0.01– 0.29, p = 0.04) in relation to middle sleep duration, whereas no significant association was found between high sleep duration and VAI. An L-shaped relationship was observed between sleep duration and VAI. When sleep duration was less than 7.5 h/day, a negative correlation between sleep duration and VAI was obvious. However, when sleep duration was > 7.5 h/day, VAI was increased with a longer sleep duration, although it was not significant. In addition, a negative relationship between sleep duration and VAI only existed in the normal weight group, rather than in the overweight and obese groups.

Conclusion: An L-shaped relationship was observed between sleep duration and VAI. Short sleep duration, rather than long sleep, was linked independently with an augmented VAI, suggested that sleep deprivation might influence visceral adipose distribution and disfunction.

OUTCOMES OF ENDOSCOPIC SLEEVE GASTROPLASTY AFTER FAILURE OF GLUCAGON-LIKE PEPTIDE-1 ANALOG MEDICATIONS FOR WEIGHT LOSS

S. Maan[1], Y. Hadi[1], A. Krishnan[1], M. Chowdhry[2], S. Thakkar[1], S. Singh[1]
[1]West Virginia University, Department of Medicine, Section of Gastroenterology and Hepatology, Morgantown, United States, [2]West Virginia University, Morgantown, United States

Contact E-Mail Address: sobanmaan@live.co.uk

Introduction: Glucagon-like peptide-1 (GLP-1) analog medications including semaglutide, liraglutide, and tirzepatide are now available as effective weight loss therapies and are increasingly used for medical management of obesity. However, failure to achieve a high degree of weight loss is common, and many patients do not tolerate the medication due to adverse events. Over the last decade, endoscopic sleeve gastroplasty (ESG) has been established as an effective minimally invasive intervention for obesity. GLP-1 agents and ESG share some common mechanisms including favorable changes in satiety, hormones, delay in gastric emptying and feeling of restriction, thus it needs to be studied if use of ESG in patients with prior use of failure of GLP-1 agonist is effective or futile. However, it is currently unknown if ESG can be effective for weight loss in patients with prior use or failure of GLP-1 agonists.

Aims & Methods: We conducted a retrospective analysis of our prospectively maintained ESG patient registry at West Virginia University. Patients who underwent endoscopic sleeve gastroplasty were identified. We identified prior use of GLP-1 agent and other medications. GLP-1 failure was defined as </= 5% total body weight loss (TBWL) and </= 10% excess body weight loss (EBWL) with the medication. Patients with GLP-1 use less than 6 months at time of ESG were excluded. Clinical success of ESG was defined as >/= 25% excess body weight loss, per ASGE criteria. Adverse events were noted and characterised.

Results: A total of 13 patients with GLP-1 agonist failure who underwent ESG were identified and included. Most patients were female (84.6%), and all patients had at least one metabolic co-morbid condition. Mean pre procedure body mass index (BMI) was 40.94 kg/m^2 [SD (standard deviation): 5.64 kg/m^2]. Seven patients had received semaglutide and 6 patients had received liraglutide treatment. All 13 patients underwent ESG procedure uneventfully and a median of 6 sutures were placed (range 4-8). No immediate complications were noted.

At a mean follow up of 20 weeks, a mean total weight loss of 38.6 lb (SD: 17.90) was noted. Mean percentage TBWL in the cohort was 14.9% (SD: 6.67%). Mean percentage EBWL in the cohort was 39.08% (SD 19.95%). Twelve patients achieved >25% EBWL within study period and were considered treatment success, and failure rate of 1/13 was noted (7.7%).

One patient suffered mild dehydration and received IV fluids in the outpatient clinic with no further consequences. No ESG-related serious adverse events occurred in any participant; and no mortality or need for intensive care or surgery was noted in the cohort.

Conclusion: In our experience, ESG has been safe and effective in inducing weight loss after GLP-1 agent use. These data point towards possible synergistic or salvage role of ESG after GLP-1 treatment; further large studies and prospective data are needed.

Disclosure: Nothing to disclose.

Contact E-Mail Address: mariavaleria31191@gmail.com

Introduction: Endoscopic sleeve gastroplasty (ESG) is established as effective and mini-invasive procedure for obesity. Patients undergoing bariatric procedures in 80% of the cases are females. It is known that gender plays a role in several metabolic networks related to obesity; however no studies have investigated the gender impact on obesity after ESG.

Aims & Methods: To evaluate the gender impact on long-term weight loss outcomes after ESG in patients treated in our bariatric unit. We analyzed 160 patients that underwent ESG at Fondazione Policlinico Gemelli IRCCS from mese 2017 to mese 2021. A matched-pair analysis between the two groups for baseline BMI, age, and timing of the procedure was done. Weight loss outcomes were described in terms of total body weight (TBWL%) and excess weight loss (EWL%) at 12, 24 and 30 months.

Results: We found that men presenting for ESG had a higher body mass index (BMI) than women (40,7 kg/m^2 vs 39,8 kg/m^2). After ESG the TBWL% in female at 12, 24, and 30 months was 17,2%, 14,0% and 15,2% compared to 14,9%, 14,3% and 9,6% in men, respectively. The EWL% was 48,4%, 39,6% and 41,7%, compared to 41,9%, 39,5% and 24,3% in men, respectively.

Conclusion: Women have more durable weight loss compared to men. More in depth studies are needed to understand the cause of this difference.

Disclosure: Nothing to disclose.

STRONGER HUNGER CONTRACTIONS IN OBESE THAN NORMAL VOLUNTEERS CORRELATE TO PLASMA PEAK GHRELIN BUT NOT TO GLUCOSE, INSULIN OR GUT HORMONE RELEASE

P.M. Hellström[1], M. Ud-Din[1], H.O. Diaz-Tartera[1], D.-L. Webb[2]
[1]Uppsala University, Medical Sciences, Uppsala, Sweden, [2]Uppsala University, Gastroenterology & Hepatology, Medical Sciences, Uppsala, Sweden

Contact E-Mail Address: per.hellstrom@medsci.uu.se

Introduction: Obese subjects often report strong, and even painful, hunger contractions during fasting. This incites eating. However, previous studies report less frequent gastric contractions of the migrating motor complex (MMC), substantiated by lower motilin plasma levels in the obese.

Hence, the motilin-regulated MMC was considered defective in the obese. In order to study the meal-related response which is closely related to ghrelin we used the SmartPill wireless motility capsule (WMC) obese to record for a prolonged period over 5 days.

Aims & Methods: The aim of our study was to evaluate the frequency and amplitude of hunger contractions that appear in anticipation of a meal.

For both research and clinical investigations, the SmartPill wireless motility capsule (WMC) is increasingly used to quantify gastric emptying time (GET). Although the two methods are intended to measure essentially the same parameter, physiological variables affecting results can differ.

Correlation data between GET and acetaminophen was therefore pursued. In a separate group, correlations between GET, hunger contractions and the metabolic response to a meal in terms of plasma glucose and peptide hormones were studied.

WMC recordings and metabolic response were obtained from 41 healthy volunteers and 32 obese subjects. Fasted subjects ingested a 260-kcal mixed meal, 1.5g acetaminophen and the WMC. Plasma was obtained -10, 0 (meal), 10, 20, 30, 40, 50, 60, 90, 120, 180 min and stored at -80 °C for later analyses of glucose, insulin, ghrelin, glucose-dependent insulinotropic peptide (GIP), glucagon-like peptide-1 (GLP-1) motilin and peptide YY (PYY). WMC recordings were analyzed with MotiliGI 3.0 software to obtain last hunger contractions (LHC) before gastric emptying, the GET based on pH drop in stomach followed by neutralization upon reaching duodenum. GET was confirmed by a rise of pH to neutral levels representing the passage of the WMC to the duodenum. LHC defined as sudden pressure rises of >100 mmHg within 10 min of GET. Correlations of GET to the number and amplitude of LHC, plasma glucose, insulin, ghrelin, GIP, GLP-1, motilin and PYY as evaluated by plasma concentrations as time to peak (Tmax), maximum concentration (Cmax) and exposure (AUC) were quantified by Pearson correlation coefficients.

Results: LHC occurred in 20/41 healthy volunteers and 15/32 obese. The mean amplitude of LHC was 129.2 ±8.1 mmHg in healthy and 200.2 ±13.0 mmHg in the obese (p <0.002). LHC closely reflected GET (R ~0.99). Hence, GET obtained by WMC likely reflected the actual time of WMC migration into the duodenum. Peptide hormone analyses showed ghrelin strongly correlated with LHC (R 0.74; p<0.0001) and also related to GET (R 0.41, p <0.02). The timing of GLP-1 Tmax as a meal response approached significance (R 0.24, p<0.07), but Cmax and AUC did not. Neither did Cmax, Tmax or AUC of glucose, insulin, GIP, motilin or PYY reveal any correlations to GET. However, a correlation between motilin and ghrelin was seen (R 0.50, p <0.01).

Conclusion: LHC indicate presence of higher hunger contraction amplitudes in the obese as compared to healthy volunteers. GET measured by SmartPill WMC displays a high correlation to hunger contractions occurring at high ghrelin levels, but does not correlate to gastric emptying as measured by acetaminophen absorption, nor to metabolic parameters glucose absorption or insulin and gut hormone release. Hence, hunger contractions is a strong physiological indication of the terminal phase of gastric emptying, which also serve as a basic signal for eating. This function seems enhanced in the obese.

Disclosure: Nothing to disclose.

PREVALENCE OF NON-ALCOHOLIC FATTY LIVER DISEASE IN OBESE TUNISIAN PATIENTS: PRELIMINARY RESULTS OF A PROSPECTIVE STUDY

S. Hamza[1], R. Tlili[1], O. Berriche[2], K. Lassoued[1], M. Dalhoumi[2], L. Bel Haj Ammar[1], S. Nsibi[1], H. Jamoussi[2], L. Kallel[1]
[1]Mahmoud El Matri Hospital, Hepato-Gastroenterology, Ariana, Tunisia, [2]Institute of Nutrition of Tunis, Nutrition Department and Obesity Research Unit, Tunis, Tunisia

Contact E-Mail Address: sahar.hamza137@gmail.com

Introduction: Nonalcoholic Fatty Liver Disease (NAFLD) is currently the most common chronic liver disease in the developed world where it has become a leading cause of cirrhosis, Hepatocellular carcinoma, and recourse to liver transplantation. It is highly associated with overweight and obesity.

However, in Tunisia where obesity is recognized as a real public health problem, the prevalence of NAFLD, in this population, remains undetermined.

Aims & Methods: The aim of our study was to estimate the prevalence of NAFLD and the risk of advanced liver fibrosis in an obese population using Transient Elastography (Fibroscan), as well as to identify its main risk factors.

We conducted a prospective study, enrolling all patients followed for obesity in the department of Nutrition and Diabetology and referred to the department of Hepato-gastroenterology between January 2022 and July 2022, for non-invasive screening of hepatic steatosis. Controlled attenuated parameter (CAP) and liver stiffness measurement (LSM) were assessed by Fibroscan. The presence of hepatic steatosis was defined by CAP ≥ 248 dB/min. A high risk of advanced fibrosis was defined, based on EASL guidelines 2021, by LSM ≥ 12 kPa. The conditions for performing the examination, its reliability criteria, and its contraindications, as set by its manufacturer, were respected. Patients known to have pre-existing chronic liver disease, whatever its etiology, as well as chronic alcohol consumers or those with chronic medication other than that of a metabolic syndrome, were not included in this study.

For all patients diagnosed with hepatic steatosis, a specific check-up was systematically performed, in particular metabolic and virological, a measurement of ferritinemia and serum TSH levels. Statistical analysis of all data was performed using SPSS software (version 22) and P values < 0.05 were considered statistically significant.

Results: We enrolled 219 patients, 88.1% were women, with a mean age of 49 years [18-77 years], a mean body mass index (BMI) of 40.64 ± 10.08 kg/m2, and a mean waist circumference (WC) of 115.29 ± 17.51 cm.

The mean values of CAP and LSM were 291.41 ± 53.48 dB/m and 5.39 ±3.22 kPa, respectively. NAFLD was present in 76.9% of patients. Among them, 4.7% had a high risk of advanced fibrosis.

In univariate analysis, the presence of NAFLD was significantly associated with type 2 diabetes (T2D) (p=0.023), WC (p=0.033), total cholesterol level (p=0.016), triglyceride level (p=0.014), fasting blood glucose (p=0.004), while advanced fibrosis was significantly associated with T2D (p=0.031) and platelet count (p=0.014).

In multivariate analysis, only WC was independently associated with the presence of NAFLD (p=0.007). ROC curve analysis showed that WC had good specificity and sensitivity in predicting NAFLD (AUC=0.776 [0.634-0.918]) with a cut-off of 107.5. In contrast, no factor was independently associated with a high risk of advanced fibrosis.

Conclusion: More than 2/3 of obese people turned out to be affected by NAFLD in our Tunisian population, with more than 4% already having a completely unrecognized high risk of advanced fibrosis. This is an alarming result that should encourage us to implement a systematic screening for NAFLD in this population and in which case an evaluation of hepatic fibrosis in order to activate the management of obesity in its various aspects, which may go as far as to indicate metabolic surgery before it becomes contraindicated, particularly by advanced liver disease.

Disclosure: Nothing to disclose.

PP0440

EFFECTS OF FODMAPS AND GLUTEN ON IRRITABLE BOWEL SYNDROME - FROM SELF-REPORTED SYMPTOMS TO MOLECULAR PROFILING

E. Nordin[1], C. Brunius[1], R. Landberg[1], P. Hellström[2]
[1]Chalmers Univerisity of Technology, Department of Life Sciences, Gothenburg, Sweden, [2]Uppsala University, Gastroenterology/Hepatology, Uppsala, Sweden

Contact E-Mail Address: elise.nordin@chalmers.se

Introduction: Dietary regimens for symptom management in irritable bowel syndrome (IBS) include a low fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs) diet and a gluten-free diet. However, scientific evidence supporting these dietary recommendations for managing IBS symptoms is weak: trials have been non-blinded and underpowered, while mechanistic understanding and objective markers of response remain scarce.

Aims & Methods: We therefore conducted a large double-blind study to investigate the effect of FODMAPs and gluten on symptomatic and molecular data including gut microbiota and the metabolome, both at a group and subgroup (differential response) level. Moreover, the accuracy of the Bristol Stool Form Scale (BSFS) used in IBS subtype diagnosis was assessed, and thus overcome the lack of objective evaluation of IBS symptoms. The results were recently collected in a doctoral thesis.

Results: Trial data revealed that gluten caused no symptoms and that FODMAPs triggered only modest symptoms of IBS. Subjective reporting according to the BSFS conformed only modestly with stool water content. FODMAPs increased saccharolytic microbial genera, phenolic-derived metabolites and 3-indolepropionate, but decreased bile acids. Saccharolytic genera correlated with increased plasma concentrations of phenolic-derived metabolites and 3-indolepropionate, metabolites related to decreased risk of incident type 2 diabetes and inflammation. Indeed, among FODMAP-related metabolites, only weak correlations to IBS symptoms were detected, as with 3-indolepropionate to abdominal pain and interference with quality of life, warranting further investigation. Gluten displayed a modest effect on metabolites involved in lipid metabolism, but with no interpretable link to health. No molecular biomarkers of a differential response to the challenges were found, despite comprehensive exploration with multiple analytical approaches. This could be explained by the absence of baseline variables, such as other omics layers or psychological factors, that could have determined the difference.

Conclusion: Diet only had a modest effect on IBS symptoms. Caution should be taken when subtyping IBS with BSFS.

Disclosure: Nothing to disclose.

Introduction: Wheat is the most consumed cereal and widely used in the food industry around the world. Uzbekistan is one of the top countries where wheat is a major component of the diet. However, digestive disorders can occur when certain specific components of wheat are consumed. These disorders are known as gluten-related diseases (GRD) which have gradually become an epidemiologically significant phenomenon, attracting the attention of the scientific community.

Aims & Methods: To investigate whether there are significant differences in the clinical and laboratory findings in pediatric patients with GRD in the Republic of Uzbekistan.

100 pediatric patients with newly diagnosed GRD were examined: 50 with celiac disease (CD), 16 with wheat allergy (WA), 34 with non-celiac gluten sensitivity (NCGS). The diagnosis of CD was based on the clinical, serological (antibodies to tissue transglutaminase IgA, G), histopathological and HLA class 2 genetical data. The diagnosis of WA was based on the clinical findings, examination of specific IgE to wheat, molecular diagnosis of allergy and the effect of GFD. The diagnosis of NCGS was based on the Salerno Experts' Criteria (2015).

Results: The median age of children with CD was 66.5±7.7 months; with WA was 49.6±5.2 months and with NCGS was 59.3±14.1 months. Diarrhea was observed in 38 (76.0%) children with CD, in 19 (55.9%) children with WA, and in 2 (12.5%) patients with NCGS. Abdominal pain (55.9%), bloating (85.3%) and atopic dermatitis (23.5%) were frequently observed in WA. Vomiting and anemia were observed more frequently in CD (44.0% and 30.0%). Among all examined patients the lowest physical development indexes were observed in CD with median values of SD of height: -2.16; SD of weight: -2.69 and SD of BMI -1.29. In children with WA SD of height was -1.15, SD of weight: -2.04 and SD of BMI: -0.8, indicating a moderate deficit of BMI in this type of GRD. In NCGS, even smaller changes were found on the physical development which showed SD of height: -0.97, SD of weight: -0.6 and SD of BMI: -0.06. Increased enzymes (ALT, AST) were observed in children: 9 (18.0%) with CD, 2 (5.9%) with WA and 1 (6.3%) with NCGS. Bilirubin was elevated in 9 (18.0%) of patients with CD and 3 (8.8%) of patients with WA. Low total protein levels were showed in 60.0% of patients with CD, whereas in children with WA and NCGS were only 8.8% and 2.5% respectively. The lowest serum calcium levels were fixed in CD patients (median 1.7±0.03). In NCGS and WA this index was higher (median 1,9±0,06).

Conclusion: Although celiac disease is the leading cause of the lowest rates of physical development and deficits among patients GRD, many other gastrointestinal symptoms are as common in pediatric patients with NCGS and WA as they are in celiac disease.

EFFECTIVENESS OF COLOSTRUM SUPPLEMENTATION IN THE TREATMENT OF CYSTIC FIBROSIS IN CHILDREN

N. Azimova[1], A. Kamilova[1], Z. Umarnazarova[1], D. Abdullaeva[1], S. Geller[1]

[1]Republican Specialized Scientific Practical Medical Center of Pediatrics, Gastroenterology and Nutrition, Tashkent, Uzbekistan

Contact E-Mail Address: noiba.shakhova@gmail.com

Introduction: The direct link between nutritional status and lung function, and survival in cystic fibrosis (CF) is unambiguous, so diet therapy for this disease is an important part of the treatment.

Aims & Methods: To study the influence of colostrum supplements in CF based on the evaluation of symptoms and values of antimicrobial peptides and proinflammatory cytokines.

A total of 56 children aged from 2 months to 3 years with cystic fibrosis were included. To make a diagnosis of CF we used determination of immunoreactive trypsin, sweat chlorides and genetic studies. Fecal calprotectin, fecal β-defensin 2 levels, as well as Il-1β values and antibody concentrations to cell permeability-increasing protein in serum were determined in patients. Colostrum was included in addition to basic therapy. The exclusion criteria were children with allergies to cow's milk protein, which made up 16 children.

Colostrum was administered to 22 children according to the age dosages: up to 1 year -0.25 ml * 3 times a day, from 1 to 3 years - 0.5 ml * 3 times, 3-12 years - 1 ml * 3 times. The duration of use was 3 months. The control group consisted of 18 children on basic therapy.

Results: The cough with a discharge of viscous sputum which was observed in 36 children (90.0%) on admission to the hospital, remained in every fourth child after the basic therapy - 5 (27,7%, $p<0.002$). We registered a sixfold reduction of the number of patients with cough and viscous sputum - 3(13,6%, $p<0.001$) with modified therapy.

On the basic therapy protein-energy deficiency of a severe degree (-3SD) persisted in every fifth child - 4 (22,2%), moderate degree of protein-energy deficiency - in half of all patients - 9 (50%). On the modified therapy, the number of patients with protein-energy deficiency increased due to -2CO (27.7%) and -1CO (59.1%), while none of the patients had severe protein-energy deficiency.

After basic therapy, fatty stool was detected in 5 (27,8%, p<0.001), then in children of the second group this index reliably decreased by 7.3 times compared to the condition before admission (13.6%, p<0.001). In the first group children with polyfecalia recorded in 3 (16.7%, p<0.02 vs. admission), while in the second group the figure was 3.7 times less frequent (p<0.002).

The proinflammatory cytokine Il-1β had a fivefold excess at admission compared with control values. In the dynamics on the modified therapy the value of this index came to normal - 2,9+0,8 pg/ml, twofold excess was kept in the first group.

The level of antimicrobial peptides (fecal calprotectin and β-defensin) was significantly increased in comparison with reference values at admission. Fecal calprotectin decreased after 3 months on the basic therapy and was more pronounced in the group with modified therapy - 52,2±2,8 mcg/g, p<0,002, but they did not reach reference values, remaining three times higher than normal (p<0,001). A similar picture was observed in the estimation of β-defensin level. The most pronounced decrease (1,5 times) was observed in patients on the modified therapy - 72,1 ±3,6 ng/ml, p<0,001. Values in this group practically approached to the norm, which could not be said about the group with basic therapy (93,4±5,4 ng/ml, p<0,001).

Conclusion: The use of colostrum supplementation in the complex treatment of cystic fibrosis with basic therapy has a positive effect on the clinical course and reduces the activity of antimicrobial peptides and proinflammatory cytokines in children with cystic fibrosis.

Disclosure: Nothing to disclose.

NUTRITION THERAPY IN ULCERATIVE COLITIS, A SYSTEMATIC REVIEW

S. Sartie[1], A. Sheth[2], S. Maleki[3], N. Nasef[4,5], K. Rostami[2]
[1]University Of Otago, Wellington, New Zealand, Department of Medicine, Wellington, New Zealand, [2]MidCentral DHB Palmerston North Hospital, Department of Gastroenterology, Palmerston North, New Zealand, [3]University of Tabriz, Department of Computer Science, Tabriz, Iran, [4]Massey University, Riddet Institute, Palmerston North, New Zealand, [5]Massey University, School of Food and Advanced Technology, Palmerston North, New Zealand

Contact E-Mail Address: samsartie@hotmail.co.uk

Introduction: Every year, there are increasing bodies of evidence highlighting the positive therapeutic effect of the introduction and elimination of various dietary elements in inflammatory bowel disease. Despite this, nutrition therapy in ulcerative colitis (UC) is not systematically well studied. Resultingly, no recommendations for its implementation into clinical practice currently exist.

Aims & Methods: We aimed to systematically review and summarise the most up to date evidence on anti-inflammatory diet (AID) interventions in ulcerative colitis. We hoped to help clinicians make more informed decisions regarding AID implementation for their UC patients. We performed a systematic electronic search in MEDLINE, EMBASE and Scopus from inception to December 2022, to retrieve human studies investigating the effects of AID intervention on UC patients.

Results: 998 papers were screened, 101 were assessed for eligibility and 13 were selected for inclusion in this systematic review. There were 627 participants in total and six studies were randomised controlled trials (RCTs). In our analysis, we discovered that most the papers assessed showed AID had a statistically and clinically significant, positive therapeutic effect on UC (10/13). We also found AID intervention could induce and maintain remission, reduce colectomy rates, and improve patient quality of life. Efficacy was shown in mild, moderate, and severe forms of UC, and when initiated as either a monotherapy or adjunct with conventional therapy.

Conclusion: Our study is the first systematic review to both investigate and indicate that AID interventions may be efficacious in reducing UC disease severity for both patient-reported symptoms, and endoscopically or biochemically observed signs. We believe however that due to the lack of high quality studies, more RCTs are needed to strengthen the evidence behind this promising hypothesis.

LYMPHATIC ABSORPTION OF PLASMALOGENS WITH ODD-CHAIN FATTY ACIDS FROM MICROORGANISMS IN THE SMALL INTESTINE OF RATS

M. Nishimukai[1], N. Sato[1], A. Kashiwagi[2], M. Yamada[1]
[1]Iwate University / Faculty of Agriculture, Morioka, Japan, [2]Hirosaki University / Faculty of Agriculture and Life Science, Hirosaki, Japan

Contact E-Mail Address: nmegumi@iwate-u.ac.jp

Introduction: Plasmalogens (Pls) are ether-type phospholipids with vinyl-ether linkages and are widely distributed in the animal body. Pls have antioxidant properties, and the reduction of plasmalogen in plasma has been observed in diseases associated with oxidative stress, such as Alzheimer's disease (Goodenowe et al., J. Lipid. Res. 2007) and atherosclerosis (M. Nishimukai et al., Clin Chim Acta. 2014), suggesting that the ingestion of Pls may induce ameliorative effects. However, there is little structure-function information, such as whether different fatty acids bound to Pls affect the physiological functions of Pls.

Aims & Methods: Therefore, we investigated the effects of enteral administration of bacterial Pls to rats (N. Sato et al., Front. Cell Dev. Biol., 2022), focusing on the fact that bacterial Pls from *Selenomonas ruminantium* contains shorter even-chain fatty acids than Pls from animal sources (T. Watanabe et al., J. Gen. Appl. Microbiol., 1982).

In this study, the absorption kinetics of microbial Pls bound to shorter odd-chain fatty acids (carbons 13, 15, and 17) than animal Pls were investigated in the rat small intestine.

Our ultimate goal in this study is to elucidate the physiological structure-function relationship of Pls in humans by approaching the absorption mechanism of Pls in the small intestine. Male Wistar/ST rats, 9 weeks of age, were fed a standard diet (AIN 93G formula) for a 3-day acclimation period. A vinyl catheter and a silicone catheter were then implanted in the thoracic lymphatic duct for lymphatic fluid collection and in the duodenum for enteral administration, respectively. After lymph collection for 30 min (initial lymph) on the day after indwelling catheter implantation, the rats were administered 1 mL of emulsified lipid solution of lipids containing PlsEtn extracted from bacteria. Lymph was collected from the thoracic duct lymph over the next 7 hours after the administration of the test solution. Each lymph fluid before and after lipid administration was analyzed for molecular species of Pls in the lymph fluid using LC-MS/MS after lipid extraction was performed.

Results: Bacterial Pls derived from *S. ruminantium*, cultured in a medium including lactic acid as a carbon source, consisted of ethanolamine Pls (PlsEtn) with odd hydrocarbon chains, as 15:1 or 17:1, at *sn*-1 and *sn*-2 positions. At the *sn*-1 position of PlsEtn released into the lymph fluid, odd hydrocarbon chains specific to microbial Pls were bound, whereas at the *sn*-2 position of PlsEtn, 20:4 fatty acids were mainly bound, just as when Pls from microorganisms with short, even-chain fatty acids were administered. In PlsEtn with a 15-carbon hydrocarbon chain bound at the *sn*-1 position, 22:6 fatty acids were mainly bound at the *sn*-2 position.

Conclusion: These results suggest that bacterial Pls to which odd-chain fatty acids are bound are absorbed into the body while maintaining the characteristic structure of odd hydrocarbon chains at the *sn*-1 position. However, it has been suggested that the fatty acids derived from bacterial

PlsEtn are barely bound at the *sn*-2 position and undergo a conformational change similar to that of animal PlsEtn, i.e., 20:4 and 22:6 re-esterification. This finding leads not only to the elucidation of the selectivity and specificity of lipid biosynthesis in the gastrointestinal tract, but also to the effective utilization of bacterial resources as food.

Disclosure: Nothing to disclose.

RELIABILITY AND RELATIVE CONSTRUCT VALIDITY OF A FOOD FREQUENCY QUESTIONNAIRE: THE GRONINGEN INFLAMMATORY BOWEL DISEASE NUTRITIONAL QUESTIONNAIRES (GINQ-FFQ)

C.L. Stevens[1,2], I. Barth[1,2], G. Dijkstra[2,1], M. Campmans-Kuijpers[2,1]
[1]University Medical Center Groningen, Gastroenterology, Groningen, Netherlands, [2]University of Groningen, Graduate School of Medical Sciences, Groningen, Netherlands

Contact E-Mail Address: c.l.stevens@umcg.nl

Introduction: Inflammatory bowel disease (IBD) is an auto-immune disease comprising Crohn's disease (CD), ulcerative colitis (UC) and colitis-type unclassified (IBD-U). Studies have shown that diet plays an important role in the development and course of IBD.

To improve assessment of dietary intake in the IBD population, our research group recently developed the Groningen IBD Nutritional Questionnaires (GINQ-FFQ), a food frequency questionnaire designed to assess dietary intake of 218 food items using 121 questions in patients with IBD over the previous month. This questionnaire needs to be validated.

Aims & Methods: This study aims to test the reliability and relative construct validity of the GINQ-FFQ.

In total 143 patients (CD N=79, UC N=57, IBD-U N=7); median age 50 [IQR: 38,6]) of the 1000IBD cohort completed both the GINQ-FFQ and a 3-Day Food Diary (3FD).

Intake from the GINQ-FFQ was calculated using the FFQ-Tool™, which was linked to the Dutch food composition database (NEVO). Intake from the 3FD was calculated using a Dutch nutritional calculation tool (Evry, version 2.3.7.0), that converts food consumption into nutrient intake using the same NEVO database.

Nutritional data with implausible energy intake (over- and underreporting) were excluded.

Spearman's rho was performed to assess the correlation between nutrients of the GINQ-FFQ and 3FD (using 0.20-0.49 acceptable and ≥0.50 good outcome). A Bland-Altman (B&A) plot was performed to visualise level of agreement for energy intake (kcal).

Results: For macronutrients Spearman's rho varied between 0.39 and 0.63; For micronutrients between 0.20 and 0.51 (Table 1).

B&A plot for kcal showed good agreement (mean difference of -84.87, limits of agreement [-1358, 1188]).

	3FD		GINQ-FFQ		Spearman (rho)
Nutrient	**Median**	**[IQR]**	**Median**	**[IQR]**	
Energy (kcal)	2120	[1798, 2482]	1990	[1567, 2481]	0.49

Introduction: *Aloe barbadensis* Mill. (Aloe) with its complex polysaccharide composition has been suggested to have prebiotic properties, however no human intervention trials have previously been undertaken to study this effect.

Aims & Methods: With the aim of designing prebiotic strategies for human gut health promotion, this randomized, placebo-controlled study evaluated the effects of increasing doses of chemically characterized Aloe extract on gastrointestinal function and overall gastrointestinal microenvironment, including fecal microbiota and metabolite composition in healthy adults.

Fecal samples were collected from healthy subjects (56 females and 21 males, age 19 - 69) at baseline, and week 3 and week 6 after intervention with placebo or 0.5 g, 1.0 g or 3.0g of Aloe extract/day. Gastrointestinal symptoms were assessed using validated questionnaires and stool consistency was evaluated using the Bristol Stool Form Scale. A food questionnaire was used to evaluate dietary quality, adapted using an index created by the Swedish National Food Agency. Fecal microbiota was evaluated by GA-map™ Dysbiosis Test, while H-1 nuclear magnetic resonance (NMR) spectroscopy was used for metabolomic profiling. Multivariate Orthogonal Projections to Latent Structures Discriminatory Analysis (OPLS-DA) was applied to fecal microbiota and metabolite data sets. Statistical analyses were carried out using non-parametric tests.

Results: All participants completed the study and demographic parameters such as age, sex, diet quality and BMI did not differ between the study groups at baseline. Intervention with increasing doses of Aloe was safe and well tolerated and did not cause gastrointestinal symptoms, as assessed using the gastrointestinal symptoms rating scale. Stool consistency changed after supplementation with Aloe, (n= 57; 3.9 (3.2 – 4.4) vs 3.6 (2.8 – 4.2), P = 0.005), but not for placebo (n= 20; 3.9 (3.2 – 4.5) vs. 3.7 (3.2 – 4.3), P = 0.82), comparing baseline vs. end of intervention, without difference between the groups (P = 0.33).

No alterations were seen in the fecal microbiota profiles before vs. after intervention, in either of the groups, indicative of a stable overall gut microbiota. Furthermore, the fecal metabolite profiles remained unaltered after intervention with Aloe. However, Aloe modulated the fecal metabolite profile in healthy subjects with BMI ≥25 (n = 24; R2 = 0.87, Q2 = 0.51), but not healthy subjects with BMI ≤24 (n = 32; R2 = 0.44, Q2 = 0.12), when comparing baseline vs. end of intervention by OPLS-DA. Moreover, Aloe intervention showed potential to reduce the difference seen in the fecal metabolite profiles between subjects with BMI ≤24 and those with BMI ≥25 from R2 = 0.57 and Q2 = 0.30 at baseline to R2 = 0.38 and Q2 = -0.11 at end of intervention. No such tendencies were seen in the smaller placebo group (BMI ≤24, n = 12 vs. BMI ≥25, n =6).

Conclusion: Supplementation with increasing doses of Aloe extract is safe and well tolerated in healthy adults. Overall, our findings support safety of Aloe extract, and show that supplementing diet with Aloe extract has the potential to modulate intestinal microbiota function, especially in healthy adults with a BMI ≥25, with an altered intestinal microenvironment.

USE OF CHATGPT AS A GUIDE FOR LOW FODMAP DIET ADHERENCE: A PROOF-OF-CONCEPT STUDY

I. Ghersin[1], R. Brun[1], M. Damari[1], C. Pinhas[1], Y. Gorelik[1]

[1]Rambam Health Care Campus, Gastroenterology, Haifa, Israel

Contact E-Mail Address: yurigorelik@gmail.com

Introduction: Low fermentable oligo-, di-, and monosaccharides and polyol (FODMAP) diet is currently recommended for the treatment of irritable bowel syndrome (IBS). However, long-term adherence is not high due to its complex nature.

Recently, ChatGPT (OpenAI, San Francisco, California, USA), a large scale unsupervised language model, was introduced as an easily accessible internet based chat, and demonstrated unprecedented capabilities of processing natural conversations and the ability to provide insightful and comprehensive replies.

Aims & Methods: In this brief proof of concept study, we aimed to evaluate the feasibility of using ChatGPT as a readily available guide for adherence to a low FODMAP diet.

We presented ChatGPT with 3 sets of questions concerned with low FODMAP:

(1) 10 questions in the form of "is B^i low FODMAP" were prompted to ChatGPT in which B^i is the *i* element of a list of 10 base products, 5 of which are considered low FODMAP, and 5 high FODMAP; We chose base products upon which there was unanimous agreement among different available lists of FODMAP-containing foods.

(2) 10 questions in the form of "is D^i low FODMAP" were prompted to ChatGPT in which D^i is the *i* element of a list of 10 popular dishes, 5 of which are considered low FODMAP, and 5 high FODMAP

(3) 7 questions in the form of "suggest a low FODMAP C^i recipe" were prompted to ChatGPT in which C^i is the I course of a traditional 7 course meal.

Questions and answers were then presented to two dietitians from our gastroenterology institute (M.D and C.P), both experienced in the care of IBS patients and low FODMAP guidance.

Dietitians were independently asked to grade each answer as correct or incorrect, and check whether they would use this answer as future recommendation for patients.

Results: A complete agreement between the two dietitians was observed (100% same review of chatGPT answers).

Out of the 27 submitted questions, 22 answers were reviewed as correct (81%).

From the 5 answers that were deemed as wrong, 4 (80%) were from the base products list, and 3 of these 4 were of high FODMAP base products. The additional wrong answer was from the popular dishes list, in which, a dish that contained high FODMAP ingredients was suggested as low FODMAP by the ChatGPT answer.

In the dishes and recipes section ChatGPT provided suggestions for alternative ingredients and food preparation techniques that would make the dishes low FODMAP. All the suggestions were deemed as correct by both dietitians.

Conclusion: ChatGPT perfomed well in answering questions regarding low FODMAP diet. It could possibly be used as an auxiliary tool for daily decisions on low FODMAP diet.
Disclosure: Nothing to disclose.

THE INFLUENCE OF DIETARY INTAKE ON GASTROINTESTINAL SYMPTOMS AND INFLAMMATION MARKERS IN PERITONEAL DIALYSIS PATIENTS

M. Majerr[1], B.J. Knap[2], N. Rotovnik Kozjek[1,3,4]
[1]Oncology Institute, Clinical Nutrition, Ljubljana, Slovenia, [2]University Medical Center, Ljubljana, Slovenia, Department of Nephrology, Ljubljana, Slovenia, [3]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [4]Faculty of Health Sciences Izola, University of Primorska, Izola, Slovenia

Contact E-Mail Address: mia.majerr@gmail.com
Introduction: Patients with end-stage renal disease frequently experience gastrointestinal issues. Gastrointestinal symptoms (GI) in these patients are related to gastric hypomotility, increased medication intake, uremia, and changes in diet. In addition GI symptoms and problems associated with bowel dysfunction are a common cause of technique failure and poor dialysis efficacy. The chronic inflammatory state is another factor contributing to the prevalence of various GI problems. Increased protein skeletal muscle breakdown, decreased appetite, and hypercatabolism are just a few of the detrimental impacts of inflammation.
Aims & Methods: 17 peritoneal dialysis (PD) patients were included in single Department of Nephrology in the University Medical Center in Ljubljana. All patients were interviewed by a dietitian and nutritional assessments were conducted. Gastrointestinal symptom Rating Scale (GSRS) with 7-grade Likert scale was used to evaluate the intensity of GI symptoms and Bristol Stool Form Scale (BSFS) to classify patient's stool. The dietary intake of PD patients was assessed using 7-day food diaries and analyzed with Prodi program (PRODI® 6.4 Expert program, Stuttgart, Deutschland). Body composition was measured with bio impedance spectroscopy. Routine blood analysis was performed.
Results: Among 17 patients undergoing PD, most of them were male (71.4 %) with average age of 53.07 ± 12.32 years. Average protein intake was 0.87 ± 0.39 g/ kg body weight per day and average fiber intake was 13.75 ± 7.25 g per day. They were inadequate according to the dietary guidelines for PD patients. Average dietary protein-fiber index was 6.86 ± 3.81 per day. Average PRAL value was 15.84 ± 13.44 for women and 6.52 ± 17.99 for men. Average dietary potassium intake was 1917.80 ± 790.08 mg per day which corresponds to the guidelines for peritoneal dialysis patients and average potassium serum value was 4.45 ± 0.42 mmol/L. GSRS questionnaire showed PD patients had minor to mild discomfort in abdominal pain, constipation and indigestion GI symptom cluster. Patients' self-analysis of stool showed BSFS Types 3.23 ± 1.64 if BSFS Types 3-5 are defined as normal stools. Dietary potassium intake moderately to strongly correlated with dietary fiber intake (r=0.62, p=0.025). Serum value of IL-6 strongly correlated with dietary potassium intake (r=0.72, p=0.006) and moderately to strongly correlated with dietary fiber intake (r=0.6, p=0.034). The correlation between dietary potassium intake and serum hsCRP was significant (p=0.042).
The correlation between Bristol stool consistency value and serum hsCRP was significant (p=0.0255). The correlation between total GSRS score and serum value of albumin was significant (p=0.0010), between total GSRS score and dietary potassium intake was significant (p=0.0015) and between total GSRS score and dietary protein-fiber index was significant (p=0.0403).
Conclusion: GI diseases in PD patients are comparatively understudied in the literature, despite having a significant impact on dialysis efficacy and the quality of life. Analysis of GSRS questionnaire showed that abdominal pain, constipation and indigestion caused minor to mild discomfort in PD patients.
The analysis also showed that fiber intake, potassium intake and GI symptoms are significantly associated with inflammation markers and are important contributing factors to chronic inflammatory state in these patients.
The evidence base of the impact of GI symptoms on PD patients is limited and further investigation of potential interventions such as medication use and changes in diet are required in future research.
Disclosure: Nothing to disclose.

CLINICAL VALIDATION OF THE VIPUN GMS AS A GASTRIC MOTILITY MONITORING SYSTEM

K. Raymenants[1], I-H. Huang[2], N. Goelen[3], P. Janssen[4], N. Van Tichelen[4], J. Tack[5]
[1]University of Leuven, Translational Research Center for Gastrointestinal Disorders, Leuven, Belgium, [2]Translational Research Center for Gastrointestinal Disorders, University of Leuven, Leuven, Belgium, [3]Vipun Medical, Mechelen, Belgium, [4]VIPUN Medical, Mechelen, Belgium, [5]University of Leuven, University Hospital Gasthuisberg, Gastroenterology, TARGID, Leuven, Belgium

Contact E-Mail Address: karlienraymenants@gmail.com
Introduction: A novel device intended to evaluate motility in patients at risk for dysmotility and enteral feeding intolerance was developed. This VIPUN Gastric Monitoring System (GMS) consists of a feeding tube with a balloon attached to its distal end and a control unit. Once the balloon is positioned in the stomach the control unit can inflate the balloon, record intra-balloon pressure and analyze gastric motility.
Aims & Methods: Our aim was to validate the GMS as a gastric motility monitoring system by comparing its performance to the gold standard, high-resolution manometry.
The primary hypothesis was that the contraction durations recorded by the GMS and manometry are strongly correlated ($\rho > 0.70$).
Secondary objectives: To correlate the contraction frequency observed by expert gastroenterologists and by GMS analysis software on GMS and manometry, and to observe gastric accommodation upon nutrient intake.
In this monocentric, single-arm, interventional study, a GMS prototype (VIPUN Medical, Belgium) was tested in healthy adults. A solid state manometry catheter (UniTip, Unisensor AG, Switzerland) was used as comparator. The balloon catheter was inserted through the nose. The manometry catheter was inserted through the other nare and positioned with the tip in the duodenum, as verified using fluoroscopy. Afterwards, the GMS catheter balloon was inflated with 120 mL air. The participant was placed in semi-recumbent position for the 2.5 h pressure measurement. After 2 h, a liquid meal (400 kcal, 1.5 kcal/mL) was infused via the GMS catheter.
For manometry, only the channels that were consistently in the stomach were analyzed. Duration of contractility (primary outcome) was calculated as the time baseline-corrected pressure waves exceeded a subject- and technology-specific pressure threshold (1).
The identification of individual gastric contractions (secondary outcome) was done by two independent readers, a third reader served as adjudicator.
Additionally, GMS software was used for the detection of individual gastric contractions. Results are shown as mean (standard deviation).

Results: 13 healthy volunteers (6 women, 27.5 (8.1) years) were included. GMS catheter placement was feasible and safe. Intragastric balloon inflation was well-tolerated. No serious or unanticipated adverse events occurred.

For the primary outcome, the Spearman correlation between the contraction duration recorded by GMS and manometry was 0.96 ($p < 0.01$). The sum of contractile activity per subject was similar: 2588.7 (1872.2) and 2722.3 (1768.7) seconds on manometry and GMS, respectively ($p = 0.44$, paired t-test, see Table 1).

For the number of contractions identified visually by readers, the correlation between GMS and manometry was 0.71 ($p < 0.01$) . Using GMS software for detection of individual contractions on GMS, the correlation with reader-identified contractions on manometry was 0.87 ($p < 0.01$).

Nutrient infusion resulted in a significant decrease in tonic (-1.7 (0.96) mmHg) and phasic (-3.4 (3.1) contractions/10 min) contractility.

	Statistic	Manometry	Gastric Monitoring System
Duration contractile activity, summed per subject (seconds)	n	13	13
	Mean (St.Dev.)	2588.7 (1872.2)	2722.3 (1768.7)
	95% confidence interval	1457.3 – 3720.1	1653.5 – 3791.1
	Sum	33653	35390

Table 1.

Conclusion: The observed strong correlations with the gold standard, manometry, validate the performance of the VIPUN GMS as a gastric monitoring system.

ASSOCIATION BETWEEN BIOACTIVE FOOD CHEMICALS AND SYMPTOMS IN IRRITABLE BOWEL SYNDROME: A CROSS-SECTIONAL STUDY

K. Lynam[1], C. Tuck[2,1], J. Biesiekierski[3,1], J. Barrett[4], G. Trakman[1]
[1]La Trobe University, Department of Dietetics, Nutrition and Sport, Melbourne, Australia, [2]Swinburne University, Department of Nursing and Allied Health, Melbourne, Australia, [3]Monash University, Department of Nutrition, Dietetics & Food, Victoria, Australia, [4]Diet Solutions, Melbourne, Australia

Contact E-Mail Address: ctuck@swin.edu.au

Introduction: Dietary therapies have revolutionised treatment for irritable bowel syndrome (IBS). However, response rates to the diet with the highest evidence of efficacy (the low FODMAP diet) remain at 50-75%, suggesting other potential drivers of symptom onset. A low food chemical elimination-rechallenge diet targeting bioactive food chemicals (including salicylates, amines, glutamate and other additives), is commonly applied in Australia in patients exhibiting both gastrointestinal and extra-intestinal symptoms. However, data supporting the low chemical diet is scant, and safety concerns exist due to its restrictive nature potentially causing nutritional deficiencies and disordered eating.

Aims & Methods: This cross-sectional survey in patients with IBS and healthy controls aimed to evaluate the frequency of co-existing extra-intestinal symptoms, as well as explore patient perceptions and use of the low chemical diet. Participants with IBS (IBS-Severity Scoring System[1] (IBS-SSS) >75), and healthy controls (not meeting Rome IV and ≤75 on IBS-SSS) were recruited via online advertisement. Validated questionnaires were used to assess gastrointestinal symptoms (IBS-SSS[1]), extraintestinal symptoms (extended PHQ-12[2]), and food additive intake (IBD-Food additive questionnaire[3]). Additional questionnaires assessed use of dietary therapies with specific focus on food chemicals. Data was analysed using independent samples t-test and chi-square test.

Results: 204 IBS and 22 healthy controls completed the study. Total IBS-SSS for the IBS participants was 277±79, compared to 36±28 in the healthy control group ($p<0.01$). IBS participants were more likely to report extra-intestinal symptoms including headaches ($p<0.01$), migraines ($p=0.03$), fatigue ($p<0.01$), difficulty sleeping ($p=0.03$), rhinitis ($p=0.02$), urticaria ($p=0.04$) and mood disturbance ($p<0.01$). Twenty-one (10%) of IBS participants were following a low chemical diet compared to none in the control group. Of these 21 participants, dietary advice was provided by a dietitian (n=13), general practitioner (n=6), gastroenterologist (n=6), naturopath (n=3), family/friend (n=4) and/or the diet was self-initiated (n=7). IBS participants were more likely to report at least one food chemical as a trigger for gastrointestinal (38% vs 13%, $p=0.03$) and/or extra-intestinal (30% vs 9%, $p=0.04$) symptoms (Table 1). There was no significant difference in consumption (g/day or g/kg/day) of ultra-processed, additive containing foods.

	Salicylates	MSG	Artificial colours	Sulphites	Amines
Suspected a trigger for gastrointestinal symptoms					
IBS	38 (19%)	35 (17%)	28 (14%)	25 (12%)	26 (13%)
Healthy	2 (9%)	1 (5%)	1 (5%)	0 (0%)	0 (0%)
Suspected a trigger for extra-intestinal symptoms					
IBS	19 (9%)	30 (15%)	23 (11%)	24 (12%)	29 (14%)
Healthy	1 (5%)	0 (0%)	1 (5%)	0 (0%)	1 (5%)

Table 1. Suspected dietary triggers (food chemical specific) for gastrointestinal and extra-intestinal symptoms.

Conclusion: Patients with IBS are more likely to report experiencing extra-intestinal symptoms compared to healthy controls. Despite limited evidence, a low food chemical diet is utilised by patients with IBS to manage both gastrointestinal and extra-intestinal symptoms. Further data is needed to understand the efficacy and safety of the low chemical diet in IBS.

ASSESSMENT OF THE FATTY ACID PROFILE OF THE ERYTHROCYTE MEMBRANE IN PATIENTS FOLLOWING THE CROHN'S DISEASE THERAPEUTIC DIETARY INTERVENTION (CD-TDI): A PRELIMINARY STUDY

N. Haskey[1], M. Yousuf[2], L. Taylor[2], C. Letef[1], C. Ma[2], S. Ghosh[3], M. Raman[2]
[1]University of British Columbia - Okanagan / Irving K Barber Faculty of Sciences, Biology, Kelowna, Canada, [2]University of Calgary / Cumming School of Medicine, Division of Gastroenterology, Calgary, Canada, [3]University College Cork, Institute of Translational Medicine, Birmingham, Ireland

Contact E-Mail Address: natasha.haskey@ubc.ca

Introduction: Dietary fatty acids impact the fatty acid profile of cell membranes and act as a source of fatty acids for many key physiological pathways. Overconsumption of n-6 polyunsaturated fatty acids (PUFAs) with low intake of n-3 PUFAs is associated with the pathogenesis of inflammatory-driven diet-related chronic diseases, including CD. Derivatives of n-6 PUFAs, such as arachidonic acid (AA) are involved in the proinflammatory

cascade, whereas the n-3 PUFAs (eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)) maintain anti-inflammatory homeostasis. Considering that fatty acids in the cell membrane may be relevant to inflammation, we examined how changing the fatty acid composition of the diet would alter the erythrocyte cell membrane's (EM) fatty acid profile in adult patients with mild-moderate luminal CD following the CD Therapeutic Dietary Intervention (CD-TDI).

Aims & Methods: This is a sub-study (n=24, 46% female, median age 43(31-54)) of an ongoing RCT designed to determine the effectiveness of the CD-TDI to induce clinical and biomarker remission in patients with CD. We examined how the fatty acid profile of the EM changes in adults with mild-moderate luminal CD (n=13) that follow the CD-TDI or their habitual diet (HD) (n=11) for 13 weeks. The CD-TDI is a whole-food diet which incorporates principles of the Mediterranean diet, with one strategy being to shift the fatty acid profile by limiting dietary sources of n-6 PUFA, increasing dietary sources of n-3 PUFA and monounsaturated fatty acids (MUFA). The HD did not change their dietary intake. Blood samples were collected at Week 0 (W0) and Week 13 (W13) and analyzed for EM fatty acid composition. Fatty acids were extracted using a combined extraction and methylation protocol with direct-injection gas chromatography to quantify long-chain fatty acids from the EM. Dietary intake was evaluated using the ASA 24-hour Dietary Assessment Tool®.

Results: Diet analysis comparing intakes from W0 to W13 revealed a significant reduction in AA intake (p=0.05) with a trend for increased intake of n-3 PUFA from DHA (p=0.07). The HD group had a significantly higher intake of AA (p=0.03), with no other dietary changes in fatty acid intakes observed within or between groups. In the EM of the CD-TDI group, within-group differences at W13 showed a lower percentage of arachidonic acid (n-6 PUFA) (0.3±0.3% vs. 0.1±0.1%, p=0.03), a significant increase in oleic acid (MUFA) (12±2.3% vs 13±2.2% p=0.02) and a trend for higher DHA (n-3 PUFA) (2.9±0.9% vs. 3.4±0.9%; p=0.08). No significant differences within groups were observed in the HD at W0 and W13. Between-group differences at W13 demonstrated that the CD-TDI group had a significantly higher mean percentage of total EM n-3 PUFAs than the HD (4.4% vs. 3.2%; p=0.005). At week 13 a higher EM PUFA balance (EPA+DHA/n-6 PUFA) was observed between groups (CDI:15±3.1% vs HD:11±2.1%; p=0.002). PUFA balance was inversely correlated to the change in the intestinal biomarker fecal calprotectin at W13 in the CDI-group (r2=0.634; p=0.03).

Conclusion: The CD-TDI altered the fatty acid profile of the EM in patients with mild-moderately active CD. Within the EM, the CD-TDI group demonstrated significant reductions in the proinflammatory mediatory AA while increasing oleic acid, total n-3 PUFA, leading to a higher PUFA balance which correlated with intestinal biomarkers of mucosal inflammation. More research is needed to fully understand the relationship between EM and gut inflammation to determine the underlying mechanisms involved.

Disclosure: Nothing to disclose.

BARRIERS AND ENABLERS TO SUCCESSFULLY IMPLEMENTING THE LOW FERMENTABLE OLIGOSACCHARIDE, DISACCHARIDE, MONOSACCHARIDE AND POLYOL DIET IN ADULTS WITH IRRITABLE BOWEL SYNDROME

L. Manning[1], J. Biesiekierski[2], C. Tuck[3], J. Wilcox[1]

[1]La Trobe University, Department of Sport, Exercise and Nutrition Sciences, Melbourne, Australia, [2]Monash University, Department of Nutrition, Dietetics & Food, Notting Hill, Australia, [3]Swinburne University, Department of Nursing and Allied Health, Hawthorne, Australia

Introduction: The low fermentable oligosaccharide, disaccharide, monosaccharide and polyol diet (LFD) has been purported as a first line therapeutic treatment for the management of irritable bowel syndrome (IBS)[1,2]. Despite the extensive research supporting the efficacy of the LFD[3,4], there are few studies exploring the lived experience of people with IBS undertaking a dietitian-led three-phase LFD.

Aims & Methods: This study aimed to explore people's expectations of and experience with each phase of the LFD, and identify barriers and enablers to successfully completing each phase. A descriptive, qualitative design employed semi-structured interviews with adults with IBS who undertook all or part of a dietitian-led research study on predictors of response to a LFD. Participants underwent LFD restriction, reintroduction and personalisation between October 2020 and April 2022. Interviews examined expectations and experiences of the LFD process, and barriers and enablers to undertaking and completing each phase. Sociodemographic and IBS characteristics were also collected. Thematic analysis summarised key themes.

Results: Seventeen people (32%, 17/53 response rate) aged 37.5 ± 14 years (88% female) completed interviews, of whom 76% (13/17) completed all three phases of the LFD. Duration of experiencing IBS symptoms ranged from one to 40 years with 76% experiencing diarrhoea as the most predominant symptom. Four themes emerged from the data. Firstly, people presented with different IBS and healthcare experiences, and expectations of what the LFD would provide. Previous unsuccessful treatments (pre- and probiotics, gluten elimination, herbal medicine) motivated people to undertake the LFD. Secondly, people's expectations of outcomes within each phase varied and was related to their symptom response. People expected symptom resolution during the restriction phase and were disappointed that symptoms were not entirely alleviated. Symptoms during the reintroduction phase were a barrier to continuing challenges for some but others felt that symptoms assisted in identifying trigger foods. Despite overall reductions in symptoms during each phase, a residual frustration was felt as symptoms were not eliminated on completion of personalisation. Thirdly, the three-phase process required significant planning, effort and self-efficacy. Ability to adhere to personal tolerance levels of fermentable carbohydrates was an enabler to successful completion of the reintroduction and personalisation phase. Environmental barriers included eating out, multi-person households and altering meals to suit family mealtimes. Personal barriers included perceptions of food triggers, apprehension to try foods that had long been avoided and experiencing symptoms during the reintroduction phase. Lastly, most people incorporated learning and experiences from the LFD into daily life after reintroduction. Those with symptom improvement identified strategies to circumvent FODMAP intake in daily life and were understanding of the interplay between food, the environment and psychological factors on symptoms. Some used the LFD restriction to manage symptom exacerbations.

Conclusion: The LFD process is complex, and personal beliefs, experiences and expectations impact on adherence and completion of each phase. Further personalisation of the LFD to individual circumstances is

fundamental to improving the experience and outcome of this therapeutic management strategy in people with IBS. These findings will be used to inform improved implementation to optimise peoples experience and success with the LFD.

INDOLE-3-CARBOXYALDEHYDE DOES NOT REVERSE THE INTESTINAL EFFECTS OF FIBER-FREE DIET IN MICE

M. Smits[1,2], S.I.L. Dreyer[1], J. Hunt[1], I.M. Modvig[1], S.A.J. Trammell[1], J.J. Holst[1], H. Kissow[1]

Introduction: Fiber-free diet reduces intestinal and colonic health in mice, in parallel with a reduction in GLP-1 levels. Moreover, as shown here, levels of indole-3-carboxyaldehyde (I3A) in the colonic content are reduced in mice fed a fiber-free diet. Indoles are thought to bacterial metabolites of tryptophan that increase GLP-1 levels *in vitro* and *in vivo*. We therefore set out to assess whether I3A similarly increases GLP-1 levels, and whether I3A could restore the adverse effects of fiber-free diet in mice.

Aims & Methods: We started with untargeted metabolomics using LC-MS of colonic content samples from our previous study in fiber-free diet mice. Next, we exposed *in vitro* GLUTag cells to different levels of I3A (1 nM to 5 mM), and cumulative GLP-1 secretion was measured after 5 min and 240 min. We then performed isolated colon perfusions in male C57BL6/JRJ mice and male Wistar rats, where I3A (500 µM - 10 mM) was administered via the luminal or arterial side. GLP-1 levels were measured in effluent collected from the portal vein. Finally, we performed an *in vivo* study in chow or fiber-free diet fed female C57BL6/JRJ mice given oral I3A (0.6 mg/day) or vehicle once daily. After 10 days, intestinal permeability was assessed using FITC-dextran, and animals were sacrificed and organs were removed for histology. Colonic contents were analyzed for unspecific indoles with Kovac's method to ensure that I3A had reached the colon after oral administration.

Results: Mice fed a fiber-free diet had significantly lower I3A in their colonic content than in mice fed a control diet (7883±3375 AU, p=0.04). GLP-1 secretion was unchanged in GLUTag cells after five minutes of exposure to I3A. However, GLP-1 levels increased after 120 minutes of exposure to 1 mM (60% increase, p=0.016) and 5 mM (89% increase, p=0.0025) I3A. In isolated perfused mouse and rat colons, I3A applied into the luminal or vascular side did not affect GLP-1 secretion, regardless of concentration. Mice fed a fiber-free diet tended to weigh less compared to chow fed (mean±SEM at study end: 1.14±0.52 g, p=0.14). The small intestine and colon were smaller in fiber-free diet fed mice (reduction 0.65±0.09 %/body weight and 0.26±0.05 %/body weight, respectively; both p<0.0001); however, crypt depth, villus length, mucosal area and intestinal permeability were unaffected compared to chow fed. Supplementation of I3A to mice fed the fiber-free diet did not affect body or organ weight. Importantly, a substantial increase of indoles in colon content (1.9±0.2 mg/mL vs. 5.4±1.2, p=0.001) confirmed that I3A did reach the colonic lumen.

Conclusion: Fiber-free diet lowered colonic content of I3A in mice. I3A increases GLP-1 secretion in vitro, but not in isolated perfusion models. In prolonged *in vivo* intervention, the fiber-free diet decreased the weight of the small intestine and colon regardless of I3A administration. Fiber free diet did not affect body weight, crypt depth or villus length, in contrast to our previous study, perhaps due to the relatively short intervention period here. In conclusion, similar to indoles, I3A stimulates GLP-1 secretion *in vitro*, yet has no evident beneficial effects on intestinal health when administered *in vivo*. Further studies could look into possible metabolic beneficial effects.

Introduction: Patients with an ileostomy may experience postoperative electrolyte derangement and dehydration but are presumed to stabilise thereafter.

Aims & Methods: We aimed to investigate the prevalence of sodium depletion in stable outpatients with an ileostomy and applied established methods to estimate their fluid status.

We invited 178 patients with an ileostomy through a region-wide Quality-of-Life-survey to undergo outpatient evaluation of their sodium and fluid status. The patients delivered urine and blood samples, had bioelectrical impedance analysis performed, and answered a questionnaire regarding dietary habits.

Results: Out of 178 invitees, 49 patients with an ileostomy were included; 22 patients (45%, 95% CI, 31-59%) had unmeasurably low urinary sodium excretion (<20 mmol/L), indicative of chronic sodium depletion, and 26% (95% CI, 16-41%) had plasma aldosterone levels above the reference value. Patients with unmeasurably low urinary sodium excretion had low estimated glomerular filtration rates (median 76, IQR 63-89, mL/min/1.73m^2) and low venous blood plasma CO_2 (median 24, IQR 21-26, mmol/L), indicative of chronic renal impairment and metabolic acidosis. Bioelectrical impedance analysis, plasma osmolality, creatinine and sodium values were not informative in determining sodium status in this population.

Conclusion: A high proportion of patients with an ileostomy may be chronically sodium depleted, indicated by absent urinary sodium excretion, secondary hyperaldosteronism, and chronic renal impairment, despite nor-

mal standard biochemical tests. Sodium depletion may adversely affect longstanding renal function. Future studies should investigate methods to estimate and monitor fluid status and aim to develop treatments to improve sodium depletion and dehydration in patients with an ileostomy.

Introduction: Functional dyspepsia (FD) and irritable bowel syndrome (IBS) are disorders that affect approximately 20% of the population. One of the proposed pathophysiological mechanisms in these conditions is a loss of mucosal integrity, associated with low-grade inflammation and food-induced mast cell activation. To date, confocal laser endomicroscopy to monitor allergy-like reactions to luminal food protein application, or a wheal-and-flare-like reaction to submucosal injection of food proteins have experimentally been used to demonstrate allergy-like food responses in these patients.
Compared to these complex methods, urinary histamine measurement may provide an elegant and non-invasive tool to detect such food reactions in FD and IBS. In this pilot project we assessed the ability to detect an increase of urinary histamine and n-methylhistamine after ingestion of food with different histamine content.
Aims & Methods: Healthy volunteers were recruited to ingest a histamine rich meal (HRM) or low histamine meal (LHM) on two different days with one week in between, in a cross over fashion. All volunteers filled out the upper gastrointestinal ROME-IV diagnostic questionnaire to confirm the absence of disorders of gut-brain interaction. Volunteers came to the hospital fasted and received a standardized breakfast (pancake, brown sugar, water). After two hours participants were asked to empty the bladder before they consumed the study meal. After finishing the meal participants collected all urine and filled out symptom questionnaires of 10 gastrointestinal symptoms (VAS 0-4) for 4 hours. ELISA analysis of urinary histamine and n-methylhistamine were performed in accordance with the manufacturer's instructions. Data are shown as mean ± standard deviation. Statistical tests were done using a paired T-test or two-way ANOVA with correction for multiple testing as appropriate.
Results: We recruited 10 healthy volunteers (70% female) with an average age of 23,8 ± 5,05 years and an average body mass index (BMI) of 21,3±1,55. All participants finished the whole meal. Urinary output was similar after the HRM and LHM (respectively 577±167 mL and 540±128 mL, p=0,605). There was no difference in urinary n-methylhistamine excretion between the HRM and LHM (respectively 34,5±8,8 µg/g creatinine vs 36,3±10,3 µg/g creatinine, p=0,779). Urinary excretion measures of histamine were below the detection limit in the majority of samples, excluding this aspect from statistical analysis.
Overall symptom scores did not differ significantly after the HRM and the LHM. Only at 15 minutes postprandially, higher scores were found for postprandial fullness after the HRM (mean difference of 0,4 [95% CI 0,01 – 0,79], p=0,038).
Conclusion: In healthy volunteers administration of food with high histamine content compared to food with low histamine content does not increase urinary n-methylhistamine excretion. Ingestion of a histamine rich meal was associated with a transient postprandial increase of excessive postprandial fullness and did not induce a significant rise in postprandial symptoms.

Introduction: The consumption of sugar-sweetened beverages is correlated with the development of obesity and type 2 diabetes mellitus which have become major health problems in our century. Consequently, the World Health Organization has proposed sugar reduction as a preventive and therapeutic strategy [1]. The use of artificial low-caloric sweeteners (e.g., sucralose) as sugar alternatives remains controversial due to the mismatch between their sweet taste (rewarding oral effect) and energy content (lack of post-oral satiating effects).
Erythritol, a non-caloric bulk sweetener, might be a promising alternative due to its similar sweetness to sucrose and its ability to release gastrointestinal (GI) satiation hormones without affecting glucose or insulin concentrations.
Acquired preference for sweet-flavored beverages could be based on oral (flavor-flavor learning FFL, e.g., sweet taste) and post-oral associations (flavor-nutrient learning FNL, e.g., calories, hormones) [2]. In human studies, evidence is weak whether liking of a novel flavor increases most when it's paired with sucrose (FFL + $FNL_{calories+hormones}$) than with an artificial sweetener (only FFL). Furthermore, the rewarding properties of erythritol remain to be determined.
Aims & Methods: The aim of this study was to assess the effect of the non-caloric sweetener erythritol (FFL + $FNL_{hormones}$) on the reward responses (liking and wanting), GI hormone release and glycemic control compared to sucrose and sucralose.
In this randomized, double-blind crossover study, 20 participants (10 women, 10 men; mean ± SD; age: 25.8 ± 7.5 years, BMI: 22.3 ± 1.8 kg/m^2) rated explicit liking and wanting of three novel and neutral flavored beverages before and after three conditioning visits where the beverages were paired with either erythritol, sucrose or sucralose. Doses of erythritol and sucralose were individually matched to the perceived sweetness of a 10% sucrose solution.

After conditioning, participants had to perform a computerized forced choice task to measure implicit wanting. Blood samples were collected to analyze GI hormones (glucagon-like peptide 1 GLP-1, cholecystokinin CCK) and glycemic control (glucose, insulin).

Results: All 20 participants completed the test visits. The results show that:

i. explicit liking increased significantly after the conditioning (all $p < 0.01$) with no differences between the sweeteners (all $p_{Tukey} > 0.4$);

ii. explicit wanting increased significantly after the conditioning ($p = 0.07$ for erythritol, $p < 0.01$ for sucrose and sucralose) with no differences between the sweeteners (all $p_{Tukey} > 0.8$);

iii. implicit wanting did not differ between the sweeteners (all $p_{Tukey} > 0.5$);

iv. conditioning with the sweeteners had no effect on GI satiation hormone release and glycemic control.

Conclusion: Erythritol led to similar ratings in explicit liking and wanting compared with sucrose and sucralose. Conditioning with all three sweeteners increased the reward responses. Since erythritol appears to be as rewarding as sucrose and sucralose, this sweetener can be seen as potential sugar alternative. These effects may not to be associated with FNL.

DIETARY IMPACT FACTORS, FOOD RESTRICTION AND DIETARY INADEQUACIES DURING ADULT CROHN'S DISEASE REMISSION: THE INTICO2 COHORT STUDY

C. Westoby[1], M. McDonnell[2,3], V. Katarachia[1], S. Sartain[3], F. Cummings[3], C. Davis[4], A. Heinson[4], A. Shahzad[5], S. Wootton[6]

Introduction: Adults with Crohn's Disease (CD) may have dietary restrictions, micronutrient inadequacies and impaired health-related quality of life. With limited dietetic resources typically directed towards those with intestinal failure, overt malnutrition or active disease, there is a need to screen all patients to identify those at risk of nutritional issues for further assessment and support. Traditional methods of identifying nutritional risk focus on weight and BMI, and do not take account of factors related to IBD such as gastrointestinal symptoms that may limit food intake.

Aims & Methods: The INTICO2 study aimed to characterise the nutritional risk factors and nutritional status of adults with CD during disease remission. 196 adult CD outpatients in clinical and biomarker remission were recruited from a single centre UK IBD centre outpatients (Harvey Bradshaw Index<5 and calprotectin<250µg/g) as part of the INTICO2 observational study. Subjects needed to be in intestinal continuity and not under current dietetic care or treatment. Assessments comprised of a 7-day electronic food diary and a single time-point assessment of body composition (Bioelectrical Impedance), functional measurement (hand grip). Dietary impact factors (DIF) were captured using a novel patient-completed questionnaire.

The questionnaire aimed to capture:

1. Weight loss,
2. Appetite using Simplified Nutritional Appetite Questionnaire[1](SNAQ),
3. Restricted foods,
4. Disease specific factors 5) symptoms of micronutrient deficiencies.

Results: Subjects reported a mean of 4 (SD 3) DIFs, with 92% (180/196) of the cohort reporting at least 1 DIF. Food restriction was reported by 34% (67/196) of patients, with the most restricted foods being dairy, wheat, red meat, pulses, garlic and onion. In total, 47 separate food items were reported as being avoided, with a mean of 2 foods avoided per participant. Food diary analysis revealed dietary micronutrient inadequacy to be common with a mean of 6 (SD 4) nutrients below LRNI per subject. Impaired appetite (SNAQ ≤14) was reported in 30% (57/192) of participants; mean SNAQ 15.45±2.29. IBD risk factors and physical manifestations of nutritional issues DIFs are described in Table 1.

	%(n)
Nausea	25(49)
Diarrhoea	37(70)
Abdominal Pain	44(84)
Distension	42(80)
Sensation of food getting stuck in bowel	9(18)
Hair Falling out	13(25)
Mouth Ulcers	18(35)
Glossitis	4(7)
Angular stomatitis	6(11)

Table 1. IBD risk factors and physical manifestations of nutritional issues.

Correlation analysis indicated that a higher count of DIFs was associated with a lower fat free mass index (R:-0.214, *P*:0.003), lower maximum grip strength (R:-0.255, *P*<0.001), lower phase angle (R:-0.189, *P:* 0.009) and a higher number of nutrients consumed below LRNI (R:0.201, *P*:0.005) [Pearson's correlation].

Conclusion: Potentially undiagnosed nutritional issues were reported by patients completing the questionnaire. DIFs such as food restriction and impaired appetite appear to be evident in these adults with CD during clinical remission which may be associated with inadequate micronutrient intake when assessed by dietary analysis and lower fat free mass and muscle function. Developing a structured approach to exploring DIFs by a self-reported questionnaire may help identify individuals who may require a dietetic assessment.

Contact E-Mail Address: zaid.ardalan@gmail.com

Introduction: Ileoanal pouch patients frequently attribute pouch-related symptoms and pouchitis with dietary factors.

Aims & Methods: Aims: We aimed to assess perceived food intolerance rates and habitual dietary intake, specifically FODMAPs and diet quality, and their relationship with pouch indication, symptoms and current or history of pouchitis. To assess the correlation between intolerance and dietary intake, and between dietary intake and risk of pouchitis.

Methods: In this cross-sectional study, patients with an ileoanal pouch completed a dietary intolerance and a food frequency questionnaire, that specifically quantifies habitual intake of FODMAPs. Perceived dietary intolerance rates, dietary intake and diet quality, and their differences based on pouch indication, symptom, and current or history of pouchitis were assessed. Associations between intolerances and intake, and between dietary intake with pouchitis risk were analysed using univariable and multivariable regression analysis.

Results: Of the 80 patients invited to participate, complete data were available from 58 (10 FAP and 48 UC). 81% of UC and 80% of FAP patients reported dietary intolerances. Overall diet quality was good across different pouch patient groups. Differences in dietary intake were limited to a few food groups. Patients with a history of pouchitis had a lower intake of fruits (p=0.03) and nuts (p=0.004). Patients with current pouchitis had a lower intake of lean meat and alternatives (p=0.006), specifically nuts (p=0.02). On multivariable logistic regression, intake of dietary fibre was associated negatively [OR 0.68 (95% CI 0.51-0.92)] and of non-digestible oligosaccharides positively with pouchitis history [OR 5.5 (95% CI 1.04-29.1)].

Conclusion: In patients with an ileoanal pouch, perceived dietary intolerances are common but had minimal impact on nutritional adequacy and diet quality. Negative associations of the intakes of fruits, nuts and dietary fibre and positive association with non-digestible oligosaccharides with a history of pouchitis require further study to inform dietary recommendations.

Contact E-Mail Address: ayushi.chauhan@nh.org.au

Introduction: Currently available intravenous iron formulations have an excellent safety profile, but preliminary data suggests that ferric derisomaltose (FDI) may be associated with an increased risk of mild-moderate infusion reactions compared to ferric carboxymaltose (FCM). FDI may be administered following dilution of doses of up to 1.5g in between 100 to 500ml normal saline, but whether dilution affects risk of infusion related adverse reactions via altering stability of the iron compound is uncertain. This study aimed to evaluate infusion related adverse events in patients who received FCM and two dilutions of FDI in a single tertiary centre.

Aims & Methods: A retrospective study of all patients who received intravenous FDI and FCM from January 2022 to April 2023 in a tertiary healthcare service outpatient infusion centre. Patients who received FDI were age and sex matched with patients who received FCM. Infusion reactions were classified independently by a gastroenterologist and a haematologist as either a Fishbane reaction or a hypersensitivity reaction. Fishbane reactions were defined by arthralgias, flushing and chest tightness without angioedema or hypotension. Hypersensitivity reactions were then further categorised using the Ring and Messmer classification. If discrepancies occurred, the cases were discussed individually. When consensus could not be reached, the reactions were categorised as unclassified. Rates of reactions were compared using a Fishers' Exact test.

Results: 234 patients (185 [79%] female, median age 45 [IQR 37-60] years) who received FDI were age and sex matched with 234 (185 [79%] female, median age 45 [IQR 37-60] years) patients who received FCM. There were no differences in baseline haemoglobin (mean 113 [SD 21] vs 115 [SD 19] g/L) or ferritin (mean 24 [SD 103] vs 24 [SD 19] µg/L) between patients receiving FDI and FCM, respectively. The most common cause of iron deficiency in the FDI group was blood loss [112/234]. Infusion reactions occurred in 23/234 [10%] patients receiving FDI, compared with 5/234 [2%] receiving FCM (p=0.006).

Of the patients who received FDI, 69 [29%] were diluted in 100mL normal saline and 165 [71%] were diluted in 250mL normal saline. There was no difference in the rate of infusion reactions among patients who received FDI diluted in 100mL (7/69 [10%]: 5 Fishbane and 2 hypersensitivity) or those who received FDI diluted in 250 ml (16/165 [10%]: 12 Fishbane, 2 hypersensitivity and 2 unclassified) (p=1.0). Two patients with reactions to FDI were administered adrenaline (both reactions classified as Fishbane) with one requiring hospitalisation. No other patients required hospitalisation.

In the FDI cohort, 31 [13%] received a dose of 1000mg, 202 [86%] received 1500mg and 1 [<1%] received 500mg. There was no significant difference in the rate of infusion reactions between patients who received 1000mg compared with 1500mg (5/31 [16%] vs 18/202 [9%], p=0.204). There was no infusion reaction in the patient who received 500mg.

Conclusion: In this retrospective medical record review, infusion-related reactions were more common in patients who received FDI compared with FCM. Fishbane reactions were the most common reaction type overall, and all but 1 patient were able to be discharged on the same day. Neither the dilution volume of FDI nor the dose of FDI was associated with risk of

infusion reactions. Future large prospective studies are needed to confirm these findings and elucidate underlying factors that may be contributing to differing rates of infusion reactions between FDI and FCM.

Introduction: Allergic rhinitis (AR) is an atopic disease that affects the upper airways causing symptoms such as runny nose, watery eyes, sneezing, itchy nose, congestion of the nasal mucosa, breathing difficulty, thus leading to a reduced quality of life (QoL). The exposure of environmental allergens (e.g., pollens, dust, molds, and animal hair) to predisposed subjects triggers an excessive immune response mediated by IgE with the release of pro-inflammatory substances by mast cells and eosinophils. Since more than 70% of the cells of the immune system are located in the gut, and the intestinal microbiota plays a key role in the modulation of the inflammatory process and the immune response, probiotics have been recently considered as a new treatment option for extra-intestinal disorders, e.g. allergic rhinitis.

Aims & Methods: Aim: To assess the effects of a mixture of probiotic strains (*L. acidophilus PBS066, L. rhamnosus LRH020, B. breve BB077, and B. longum subsp. longum BLG240*) on symptoms and immune response in patients with chronic allergic rhinitis. These bacterial strains reduce inflammatory stress and oxidation potential *in vitro.*[1,2]

Methods: This is a randomized, double-blind, placebo-controlled study on two parallel groups of subjects (aged 18-60 years) with seasonal or chronic allergic rhinitis. Group A (n=22) was treated with a placebo; Group B (n=19) was treated with probiotics for eight weeks. The effects were evaluated at the beginning (T0) and four (T1), and eight weeks (T2) of treatment, and after four weeks of follow-up from the end of the treatment (T3, total period: twelve weeks). The allergic immune response was assessed by the analysis of inflammatory blood markers, i.e., eosinophil count, eosinophil cationic protein, and total immunoglobulin E at T0, T2, and T3. Allergic rhinitis symptoms were evaluated by the Total Nasal Symptom Score (TNSS) and the Rhinitis questionnaire score Control Assessment Test (RCAT). The Quality of Life (QoL) was assessed by the Mini Rhinoconjunctivitis Quality of Life questionnaire (MiniRQLQ) at each time point. Fecal microbiome profiling variations were determined by 16S rRNA gene sequencing analysis (SA) at T0, T2, and T3.

Results: The probiotic-treated subset (Group B) showed a statistically significant improvement in TNSS symptoms and MiniRQLQ at T3 *vs.* placebo (Group A) and statistically significant intra-group differences between T0 and T3. SA showed constant gut taxa richness and phylogenetic diversity in both groups at each time point. *Dorea*, which is inversely associated with atopy, and *Fusicatenibacter*, with known anti-inflammatory properties, increased in Group B at T2. Conversely, pro-inflammatory species (*Bilophila* and *Bacteroides*) and *Ruminococcus* unassigned and *Bacteroides*, likely associated with allergies, increased in the placebo subset (Group A) at T3.

Conclusion: The probiotic mix used in this study ameliorates symptoms and QoL in subjects suffering from chronic and seasonal allergic rhinitis. Furthermore, this specific mixture of strains appears to positively affect gut microbiota by promoting the increase of bacterial species with anti-inflammatory and anti-allergic properties.

Introduction: The interplay between diet, host and intestinal microbiota plays a key role in colorectal cancer (CRC), with processed western diets

(WD) of high fat and low fiber content as main contributors. The endoplasmic reticulum unfolded protein response effector activating transcription factor 6 (ATF6) is associated with early changes in CRC and colitis-associated cancer (CAC). We showed that murine intestinal epithelial cell specific expression of active ATF6 (nATF6) triggers spontaneous CRC (nATF6^{IEC}) and CAC (nATF6^{IEC} x IL10$^{-/-}$) in a microbiota-dependent manner.

Aims & Methods: To substantiate clinical relevance of ATF6 and validate nATF6-driven CRC and CAC mouse models, we performed ATF6 immunohistochemical staining in CRC patients (N = 972), and human-derived fecal microbiota transfer (FMT) into germfree (GF) nATF6^{IEC} and nATF6^{IEC} x IL10$^{-/-}$ mice. Microbiota profiling together with RNA sequencing, metabolomics and lipidomics were used to elucidate ATF6 functional changes in the epithelium. To clarify the role of fat and fiber in tumorigenesis, mono- and biallelic nATF6^{IEC}, and monoallelic nATF6^{IEC} x IL10$^{-/-}$ mice were fed unprocessed chow or processed polymeric diets for 6 weeks after weaning.

Results: ATF6 represents a clinically relevant putative oncogene, with 16 % of CRC patients showing high ATF6 expression in the epithelium. CRC patient FMT established tumorigenesis in GF biallelic nATF6^{IEC} and monoallelic nATF6^{IEC} x IL10$^{-/-}$ mice that are otherwise tumor-free. Multi-omics analyses in specific pathogen-free and GF nATF6^{IEC} mice point towards ATF6-induced alterations in lipid metabolism. Compared to an unprocessed chow diet, the polymeric WD enriched in fat and depleted in fermentable fiber, increased tumor load in biallelic nATF6^{IEC} mice and tumor incidence in monoallelic nATF6^{IEC} x IL10$^{-/-}$ mice.

Unexpectedly, the highly processed WD induced *de novo* tumorigenesis in otherwise tumor-free monoallelic nATF6^{IEC} mice. To understand the impact of high fat in this context, we modified the WD by lowering fat content or by supplementing with fermentable fiber. The absence of fermentable fiber in the polymeric diet already accelerated tumor load as well as *de novo* tumorigenesis.

Surprisingly, fiber supplementation failed to protect the WD-induced tumorigenic phenotype despite microbial and metabolic changes. High fermentable fiber content in the low-fat diet even exacerbated nATF6-driven tumorigenesis, suggesting a tumor promoting rather than tumor protective function of fermentable fiber in processed diets.

Conclusion: These findings highlight the ability of all processed diets to exacerbate nATF6-related tumorigenesis, with dietary fermentable fiber unexpectedly acting as a tumor driver. This implies that plant-derived metabolites of unprocessed chow diet may fulfill protective functions in our mouse models.

Introduction: Among patients with functional gastrointestinal disorders (FGID), food intake is often identified as a symptom trigger. Common foods known to cause gastrointestinal (GI) symptoms include fatty foods (1) and fermentable carbohydrates (FODMAPs) (2), but the evidence is limited and may vary among different FGID.

Aims & Methods: The aim of this study was to explore if certain foods are considered more tolerable, and which specific foods are identified as triggers of GI symptoms among participants with irritable bowel syndrome (IBS) and functional dyspepsia (FD). An online survey was conducted including n=537 participants from the Swedish general population with symptoms compatible with a functional bowel disorder. The survey included questions on demographics and an adapted food frequency questionnaire that assessed intakes of 38 different food items or aggregated food groups. For each food, participants had to answer whether or not they considered the specific food to be a trigger for GI symptoms.

Results: Among the respondents, a total of 220 participants with IBS and/or FD (mean age 34.7 years, body mass index 26.8 kg/m^2, women: 78.2%) were included in the analyses, of whom n=128 fulfilled criteria for FD and n=136 for IBS. Foods that were least commonly reported to cause GI symptoms included hard bread, fish and shellfish, berries, nuts, and seeds (Figure). The most frequently reported food triggers included pizza, crisps, confectionery, candy, ice cream, white bread, dairy, french fries, pie, and sausages. White bread, more often than whole grain bread, was reported to cause GI symptoms. Most vegetables and fruits were well tolerated in FD. A few FODMAP-rich vegetables, such as onion, garlic, beans, lentils, cauliflower and cabbage were more often reported as food triggers in IBS compared with FD. Having overlapping IBS and FD increased the prevalence of foods that were considered to cause symptoms.

	FD n=128	IBS n=136	FD+IBS n=44		FD n=128	IBS n=136	FD+IBS n=44
Dairy, milk, yoghurt	47 (36.7%)	58 (42.6%)	17 (38.6%)	Apples, pears	29 (22.7%)	34 (25%)	15 (34.1%)
Ice gream	51 (39.8%)	50 (36.8%)	21 (47.7%)	Bananas	17 (13.3%)	19 (14%)	11 (25%)
Cheese	31 (24.2%)	31 (22.8%)	13 (29.5%)	Grapes	18 (14.1%)	31 (22.8%)	12 (27.3%)
White bread	51 (39.8%)	54 (39.7%)	19 (45.5%)	Peach, plums, cherries	23 (18.0%)	32 (23.5%)	15 (34.1%)
Whole grain bread	27 (21.1%)	34 (25%)	14 (31.8%)	Watermelon	14 (10.9%)	17 (12.5%)	8 (18.2%)
Hard bread	17 (13.3%)	23 (16.9%)	8 (18.2%)	Cauliflower, aspargus	25 (19.5%)	37 (27.2%)	12 (27.3%)
French fries	39 (30.5%)	55 (40.4%)	20 (45.5%)	Berries	15 (11.7%)	19 (14.0%)	7 (15.9%)
Pasta, couscous	35 (27.3%)	39 (28.7%)	11 (25%)	Tomatoes, cucumber	15 (11.7%)	20 (14.7%)	11 (25%)
Pizza	55 (43.0%)	76 (55.9%)	26 (59.1%)	Cabbage, kale, fennel	27 (21.1%)	44 (32.4%)	15 (34.1%)

Conclusion: In individuals with IBS and/or FD, foods traditionally associated with a healthy dietary pattern were less commonly reported to cause GI symptoms, whereas foods associated with western food/junk food were more commonly reported to cause GI symptoms. Promoting healthy food choices seem compatible with dietary treatment of patients with IBS and FD.

THE EFFECTS OF SODIUM BUTYRATE SUPPLEMENTATION ON THE SEVERITY OF ABDOMINAL SYMPTOMS AND CARBOHYDRATE METABOLISM IN PATIENTS WITH TYPE 2 DIABETES - PRELIMINARY DATA

P. Panufnik[1], M. Więcek[1], P. Szwarc[1], M.A. Kaniewska[1], K. Lewandowski[1], E. Franek[2,3], G. Rydzewska[1,4]

Introduction: Patients with type 2 diabetes are prone to the development of dysbiosis, which can manifest as intestinal bacterial overgrowth (SIBO). This may explain the pathomechanism of abdominal symptoms that sometimes affect this group of patients. Disturbances in the composition and quantity of intestinal microbiota translate to impaired production of short-chain fatty acids (SCFA) in the intestinal mucosa.

To increase the concentration of butyrate in the lumen of the intestine, oral microencapsulated sodium butyrate supplementation can be proposed.

Given the limited research conducted on the topic of the effects of sodium butyrate supplementation in alleviating abdominal symptoms in patients with type 2 diabetes, it became the topic of our interest.

Aims & Methods: The aim of the study was to evaluate the effectiveness of oral sodium butyrate supplementation in the population of patients with type 2 diabetes in alleviating abdominal symptoms and to estimate the incidence of small intestinal bacterial overgrowth in this group.

In addition, the impact of the intervention on the carbohydrate metabolism was assessed. A prospective, single-centre, randomized, placebo-controlled study was conducted between October 2022 and April 2023.

52 patients with type 2 diabetes and gastrointestinal symptoms were randomly assigned to one of 2 groups - a group receiving microencapsulated sodium butyrate (Intesta Max) at a dose of 1.5 g/day and a group receiving placebo. As 8 patients (15.3%) were lost to follow-up, for the preliminary analysis 44 patients were included.

The study lasted for 6 weeks. Before and after the intervention the presence of abdominal pain, diarrhoea, constipation and flatulence was assessed, laboratory tests and hydrogen breath tests were performed, the HOMA index and body mass index were calculated.

Results: At baseline SIBO was diagnosed in 73.1% of patients in the experimental group and 58.8% of patients in the control group. After 6 weeks of the intervention there was a significant drop in SIBO occurrence in sodium butyrate group – 22.2% (p=0.001). The incidence of SIBO in the control group did not change – 64.7% (p=0.21).All patients included in the study declared abdominal pain before the intervention.

After 6 weeks the pain was reported by 42.3% of the patients receiving the sodium butyrate vs. 88.4% of the patients receiving placebo (p=0.002).

After the intervention there was a significant difference between the groups regarding diarrhea – 18.5% and 58.8% (p=0.006) in sodium butyrate and placebo groups respectively. A decrease in the incidence of bloating in the sodium butyrate group was observed - 100% before vs. 29,6% after the intervention (p<0.00001).

The study also showed a decrease in BMI level, the HOMA index and glycated hemoglobin level after consumption of the sodium butyrate vs. placebo for 6 weeks. These results need confirmation in a larger group.

Conclusion: To our knowledge this is the first study reporting the effectiveness of oral butyric sodium supplementation in relieving abdominal symptoms (abdominal pain, diarrhea, flatulence) in patients with type 2 diabetes. Furthermore, an improvement in carbohydrate metabolism parameters was noted and body weight decrease was observed after the intervention.

Disclosure: Sodium butyrate (Intesta Max) we received from the company that produces it.

PP0464

CLINICAL PRESENTATION AND DIAGNOSIS OF COELIAC DISEASE IN BULGARIAN CHILDREN: INSIGHTS FROM A WEB-BASED SURVEY

I. Rizhova[1], P. Slavov[1], A. Hachmeriyan[1], M. Georgieva[1], N. Rasheva[1], K. Koleva[2], L. Dimitrov[1], I. Yankov[3], M. Panayotova[4], J. Dolinsek[5], R. Pancheva[6]

Introduction: The diagnosis of coeliac disease (CD) in Bulgaria is an important public health issue due to the rising prevalence of the disease.

The aim of this study is to analyze the clinical presentation, diagnostic process, and diagnostic delays among newly diagnosed CD patients in Bulgaria.

Aims & Methods: A web-based survey was conducted in 2021 among pediatric gastroenterologists in Bulgaria who uploaded medical data of newly diagnosed CD children. The survey consisted of specific data fields designed to assess changes in clinical picture, diagnostic process, and diagnostic delays.

Results: A total of 78 children with CD were included in the analysis. Majority of CD patients were female (67.9%), and the mean age at diagnosis was 5 years old. Serological tests were made prior to diagnosis, and the majority of patients were diagnosed using a no-biopsy approach (85.9%). The initial test performed in children diagnosed using a no-biopsy approach was determination of TGA antibodies in 100% of cases. In most patients, confirmatory tests were performed after positive initial TGA, with EMA being used as a confirmatory test.

The diagnostic work-up for CD was initiated based on symptoms and signs in most patients, with diarrhea being the most prevalent leading symptom (65.4%). The median delay from first symptoms to the confirmation of diagnosis was 2 months.

Conclusion: Conclusion 1: The majority of newly diagnosed CD patients in Bulgaria were female, and the mean age at diagnosis was 5 years old. Serological tests were made prior to diagnosis, and the majority of patients were diagnosed using a no-biopsy approach. The diagnostic work-up for CD was initiated based on symptoms and signs, with diarrhea being the most prevalent leading symptom.

The median delay from first symptoms to the confirmation of diagnosis was relatively short (2 months) compared to other countries in the Danube region.

Conclusion 2: In conclusion, the study reveals that the median diagnostic delay in Bulgaria is 2 months, which is significantly shorter than the median delay in other participating countries in the Danube region.

However, there is still room for improvement in terms of the diagnostic process, as a considerable number of patients in Bulgaria are diagnosed using the no-biopsy approach without secondary confirmatory tests.

Therefore, there is a need for better education and awareness among healthcare professionals and patients to ensure timely and accurate diagnosis of coeliac disease, which can ultimately improve the quality of life for patients.

Disclosure: Nothing to disclose.

LACTOSE INTOLERANCE IN ADULT PEOPLE: CORRELATION BETWEEN CLINICAL FEATURES REPORTED BEFORE BREATH TEST, SYMPTOMS DEVELOPED AFTER ORAL INGESTION OF 25 G LACTOSE AND RESULTS OF LACTOSE BREATH TESTING

D.G. Cassella[1], A. Dell'Era[1], M.C. Monico[2], B. Rossi[2], G. Maconi[1]
[1]Università Degli Studi di Milano/Luigi Sacco's Hospital, Gastroenterology Unit, Milan, Italy, [2]Luigi Sacco's Hospital, Gastroenterology Unit, Milan, Italy

Contact E-Mail Address: alessandra.dellera@unimi.it

Introduction: Lactose malabsorption (LM) is a common digestive disorder. The hydrogen breath test (HBT) is currently the non-invasive gold standard in diagnosing LM and lactose intolerance (LI), which is defined only in case of developing symptoms directly related to lactose ingestion in subjects with LM. (Misselwitz et al. 2019)

The analysis of methane values in air samples may increase the accuracy of the test by including subjects "non hydrogen producers". (De Geyter et al. 2021)

Aims & Methods: The aim of this study is to describe the relationship between pre-test clinical features, symptoms reported during lactose challenge and the result of the HBT in adults.

In this prospective study we included a consecutive series of adult patients who underwent a HBT during a 5-month period. Air samples were taken every 30 minutes for 4 hours after the ingestion of a charge of 25 g of lactose. Symptoms reported in the previous 15 days (abdominal pain, bloating, diarrhoea, flatulence) and those experienced after lactose ingestion were assessed using a standard questionnaire establishing their presence or absence, and relative severity using 0-10 scale. The results were considered positive when a H_2 peak exceeded 20 parts per million (ppm) above the baseline or in case CH_4 excretion reached 10 ppm above the baseline, for experimental purpose. LI was defined by at least one symptom experienced during the test in subjects with LM.

Symptoms during the test	*Total number of patients. N=68*	*positive H_2/CH_4 BT , N=45*	*negative H_2/CH_4 BT-, N=23*	*p value*
Abdominal pain	38 (56%)	28 (62%)	10 (43%)	non statistically significant
Abdominal bloating	43 (63%)	33 (73%)	10 (43%)	**0,02**
Flatulence	40 (59%)	30 (67%)	10 (43%)	**0,08**
Diarrhoea	12 (18%)	10 (22%)	2 (9%)	non statistically significant

Table.

Results: 68 patients were included in the study and 40 of them (59%) were positive at the HBT. 52 (76%) developed at least one symptom while LI was diagnosed in 34 patients of them (65%). Only 40% of patients who referred pre-test symptoms had LM and none of the four symptoms was associated with LM or LI. A positive trend was found between abdominal bloating after lactose ingestion and a positive HBT (p 0.08).

This association was statistically significant (73% vs 43%, p 0.02), with a positive trend also for flatulence (p 0.08) (Table), implementing diagnostic test with values of exhaled methane, finding 10 more intolerant patients.

Considering the variation of symptoms (new or worsening of symptoms after lactose ingestion), the worsening of bloating was significantly more frequent in subjects with positive HBT compared to those with a negative test (40% vs 14%, p 0.03) and predictive of LI (PPV= 80%). Diarrhoea was the most predictive symptom of LI (PPV up to 88%).

An association between the number of symptoms experienced during the test and LM was confirmed, while we didn't find the same relationship with pre-test symptoms. (Beyerlein et al. 2008)

Conclusion: Symptoms reported before HBT seems to be non-related to LI. This may lead to arbitrary dietary exclusion of dairy products with consequences on bone health (Infante and Tormo 2000) and suggest that the causal role of lactose should be confirmed by HBT. In adult, the development ex-novo or the exacerbation of abdominal bloating and diarrhoea during the test, in subjects with LM, seems to be the most predictive of LI. Furthermore, the increase of the number of symptoms complained makes the diagnosis of LI more likely. On these basis, a domestic screening with 25 g of lactose (500 ml of milk) to establish whether the patient really needs the execution of breath test should be explored.

Contact E-Mail Address: meleshkotv@ukr.net

Introduction: Biologically active compounds (BACs) and plants extracts (PEs) are promising alternatives for biological preparations in personalized medicine, especially for personalized microbiota correction. However, due to fact that microbiota is a large complex system, the composition of which varies from person to person, there are various issues that needs to be solved in order to use biologically active compounds and plants extracts for microbiota correction.

Aims & Methods: The aim of this study, was to describe all these issues as well as possible solutions to them and propose the solution to the most fundamental issue for personalized microbiota correction i.e. data source (database).

Methods: Development of the database as well as user interface for its usage included such steps: 1) Search, selection, extraction and analysis of literature data on the impact of BACs and PEs on microorganisms; 2) Development of a tabular structure of the database and the filling of its relational tables with selected and appropriately grouped information; 3) Construction of tools that enable convenient use of the information.

PubMed was used to search for literature sources. Statistical analysis of extracted data was carried out by well-known methods of descriptive statistics and statistical inference, using the libraries of the Anaconda – Python environment created for scientific research and the OriginPro software package. The search for statistically significant pairwise Pearson and

Spearman correlations between types of microorganisms, and between types of BACs or PEs was carried out by using the Stats library of the SciPy library module of the Anaconda - Python environment.

Results: The developed database consists of 7,717 records on plants effects on microorganisms and 3,034 records on biologically active compounds effects on microorganisms. The database contain not only data of inhibitory effect but also stimulatory effect data as well as the unification of all data, which is a key features of this database. We also performed various types of analysis on extracted data, i.e. correlation analysis, the results of which could be used for development different prognostics and machine-learning models.

Conclusion: The described idea of using linear methods for personalized adjustment of microbiota using BACs or plants can be used for the development of appropriate biotechnology for personalized microbiota correction, as well as the development of biological preparations. The approach can also be used to select other components, such as microorganisms, and a necessary condition for this is the availability of relevant data on the effect of these components on specific representatives of the microbiota.

An important result is the developed database on the effects of plants and BACs on microorganisms, which solves the actual problem of initial data for selection and allows a wide range of users to use the relevant data also for solving other problems, in particular, preliminary evaluation of components during scientific research. The results obtained by us from the correlation analysis of the created database are unique and allow us to reveal certain regularities in the influence of certain BACs, plants or the sensitivity of microorganisms to them. These data can be used in the future to create a new, more accurate, personalized approach for microbiota correction, as well as to build various models, including machine learning.

Disclosure: Nothing to disclose.

THE EFFECT OF DIETETIC RESTRICTIONS AND GASTROINTESTINAL SYMPTOMS ON BODY COMPOSITION IN HYPERMOBILE EHLERS-DANLOS SYNDROME

C. Mocci[1], A. Cesarini[1], E. Ribichini[1], G. Scalese[1], N. Pallotta[1], C. Severi[1], D. Badiali[1], D. Curreri

[1]*Sapienza, Policlinico Umberto I, Gastroenterology, Roma, Italy*

Contact E-Mail Address: chiaramocci94@gmail.com

Introduction: Hypermobile Ehlers-Danlos Syndrome (hEDS) is a hereditary connective tissue disease characterized by joint hyperlaxity, skin hyperextensibility. Many patients report gastrointestinal (GI) involvement, including gastroesophageal reflux symptoms, abdominal pain, bloating, abdominal pain and bowel habits alteration.

In order to manage GI symptoms, patients may observe dietary restrictions which contribute to weight loss and nutritional deficiency (Zeitoun JD et al, 2013); (Di Francisco-Donoghue J. et al, 2022); (Phoebe A Thwaites et al, 2022).

Aims & Methods: The aim of the study was to assess the effect of GI symptoms and dietetic restrictions on body composition in hEDS. 25 hEDS patients (pts) (92% females, mean age 41.6±14 years) referred to the "Rare Diseases Desk" at the Polyclinico Umberto I, University of Rome "Sapienza" were enrolled in the study in the years 2017-2019.

All pts filled in the standardized "Rome III" questionnaire (in use in the referred period)investigating proximal and distal GI symptoms, The Irritable Bowel Severity Scoring System (IBS-SSS) to evaluate severity of symptoms, a 2 weeks food diary for self-monitoring dietary intake, and bioimpedance analysis (BIA) to study body composition (Akern BIA 101 instrument). Daily intake of carbohydrates (CHO), lipids and proteins was compared with "Reference Intake Levels of Nutrients and Energy for the Italian Population" (LARN) and the estimated total daily energy expenditure (BRM) was compared with the Harris–Benedict equation. Data are expressed as mean or percentage and statistical analysis using Pearson test.

Results: All patients reported almost a GI symptom with a IBS-SSS mean of 293,6 ±112. The most notable symptoms were epigastric pain (96%), bloating and abdominal pain (64%), dysphagia (4%), heartburn (64%), non cardiogenic chest pain (68%) and nausea (68%). The analysis of food diaries showed a daily calorie deficiency in 40% of pts (1330±346 kcal/day vs BMR of 235.8±219.1 kcal/day in females and 1575±176.8 kcal/day vs BMR of 174±14 kcal/day in males). Regarding macronutrients, the analysis showed an inadequate intake of protein in 66% of pts (daily percentage of protein was 15,9±2,9/day) of CHO in 41% and lipid in 50% of pts (daily percentage CHO consumed was 51%±0,6/day and 24,6±2,6/day for lipids). Analysis of BIA showed a fat free mass (FFM) level of 71.4% ±7,9 (n.v 75-82%), fat mass (FM) level of 28,4% ±7,8 (n.v. 18-25%), hydration level of 73% ±12 (n.v. 72,7-74,3%).

Conclusion: Our study confirms that gastrointestinal disorders are common in patients in hEDS and probably multiple symptoms may influence the quality of diet.The high value of IBS-SSS suggests these symptoms may have relevant role in the management of diet. According to LARN, hEDS had a sbalanced, predominantly caloric and protein- deficient diet which may negatively affect the body composition, regarding FFM and FM. It is reasonable to hypothesize that the dietetic restrictions we observed are in relation to severity of GI symptoms but studies involving more patients are needed to draw definitive conclusions.

Introduction: Patients with Hypermobile Ehlers Danlos Syndrome (hEDS) have a high prevalence of Disorders of Gut-Brain Interaction (DGBI) and pose complex nutritional challenges in gastroenterology clinic. Despite this, little is known regarding nutrient intake and adequacy in hEDS.

Aims & Methods: Our aim was to assess nutrient intake and adequacy of patients with hEDS, as well as to determine which factors, including co-existent DGBI, are associated with poor intake. We conducted a cross sectional survey of patients with hEDS from two tertiary neurogastroenterology clinics as well as the Ehlers-Danlos Support UK. Inclusion criteria were adults with hEDS, exclusion criteria were those currently or previously using artificial nutrition. Patients completed the validated semi-quantitative Scottish Collaboration Group Food Frequency Questionnaire (FFQ) alongside questionnaires characterising: demographics, DGBIs (Rome IV), gastrointestinal, mood, somatic and autonomic symptoms, past history of eating disorders and screen for Avoidant Restrictive Food Intake Disorder (ARFID) using the Nine Item Avoidant-Restrictive Scale (NIAS). Nutrient intake was calculated from the FFQ and nutrient adequacy was calculated by comparison with UK daily reference values (DRVs) for age and sex. Unpaired t-tests were performed to compare nutrient intakes among patients with and without comorbidities, including the most common DGBIs.

Results: 425 participants were included in the final analysis (mean: 41 years, 96% female). Only 48.5% reported BMI in the normal range, whereas 5.2% were underweight (BMI <18.5 kg/m^2) and 46.4% were overweight/obese (BMI >25 kg/m^2). Only one third met their estimated average requirements (EAR) for energy (kcal/d). The majority met their reference nutrient intake (RNI) for protein (87.3%) and fat (72.5%), in contrast to only 21.2% for carbohydrate. Fibre intakes were very low (AOAC mean 23.7g/day (SD: 12.7) with only 24.7% meeting the RNI of 30 g/d. More than 58% of participants met/exceeded their DRV for micronutrients (zinc, magnesium, copper, manganese and selenium) and >95% for vitamins. Patients with functional nausea (n=157) were less likely to meet their protein requirements compared to those without (82.2% vs. 90.3%, p=0.015) and also had lower intakes for sodium (p=0.02), magnesium (p=0.02), calcium (p=0.01), zinc (p=0.002), selenium (p=0.03), folic acid (p=0.02) and vitamin C (p=0.05). Patients with previous eating disorders were less likely to meet nutrient requirements for thiamine (p=0.01) and vitamin B12 (p=0.04). Patients with ARFID (n=110) were less likely to meet requirements for all nutrients (except fat, calcium, vitamin D, vitamin B12) compared to patients without.

Conclusion: Patients with hEDS are rarely underweight and tend to consume high protein, high fat diets that are low in fibre. Functional nausea is the single most important DGBI impacting nutrient intake, as well as previous eating disorders and disordered eating (ARFID). These factors should be considered by clinicians and dietitians when assessing nutrient intake in this complex patient group.

Disclosure: RT, AF and QA have received a grant from EDS-UK to conduct this study. AF undergoes consulting work for Abbvie.

TUMOUR SEEDING FROM HEAD AND NECK CANCER AT THE SITE OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY

O. Taylor[1], M. Thorpe[1], J. Phillips[1], W. Chiu[1], J. Tyrrell-Price[1]
[1]University Hospitals Bristol and Weston NHS Foundation Trust, Department of Gastroenterology, Bristol, United Kingdom

Contact E-Mail Address: jennifer.g.brazier@gmail.com

Introduction: There are around 12,400 new cases of head and neck cancer diagnosed in the UK each year. It is the 8th most common cancer in the UK and incidence rates are projected to rise by 3% over the next two decades. Between 33 and 69% of patients with Head and Neck cancer will require enteral feeding via a gastrostomy tube to support their nutrition and hydration during treatment. Percutaneous endoscopic gastrostomy (PEG) is often the preferred method of placement of the gastrostomy tube and is generally considered safe but malignant seeding of the tumour to the PEG site is a rare complication. It has been reported that rate of metastasis at the PEG site is between 0.5-3%.

Aims & Methods: We carried out a retrospective chart review of all patients undergoing PEG insertion at the Bristol Royal Infirmary between January 2015 and December 2021. The primary aim was to determine the rate of PEG site metastases at our centre. Demographic data were collected, as well as cancer type and stage, details of disease progression.

Results: A total of 284 patients underwent PEG insertion during the period of data collection. Of these, 204 patients had their gastrostomy inserted for a head and neck cancer indication. All PEG tubes were put in using the 'pull' method. 2 patients were identified as having abdominal metastatic disease and these cases were reviewed in greater detail. On further review these 2 patients were not found to have malignant spread to the PEG site specifically, but more general peritoneal disease, unrelated to the method of gastrostomy insertion. For both patients, the abdominal disease was in the context of widespread metastatic disease. There were therefore no cases of PEG site metastases at our centre between January 2015 and December 2021 (0/204, 0%).

Conclusion: Our data suggests that PEG is a safe method of gastrostomy insertion for head and neck cancer patients, without significant risk of tumour seeding to the PEG site.

MICROBIOME CHANGES UNDER NUTRIENT DEPRIVATION ARE DYNAMIC AND DEPENDENT ON INTESTINAL LOCATION

H. Bar-Yoseph[1], A. Metcalfe-Roach[2], BB. Finlay[2]

Introduction: The microbiome has a pivotal role in intestinal health, while nutrition has a major role in shaping its structure. Enteral deprivation, in which no oral/enteral nutrition is administered, is common in hospitalized/GI patients. The dynamics that enteral deprivation exerts on the microbial community, specifically in the small intestine, the site of nutrition absorption, is not well understood.

Aims & Methods: We have modelled enteral deprivation with a total parenteral nutrition (TPN) mouse model. Singly housed mice were euthanized at baseline or allocated to receive either saline and chaw (control) or TPN and euthanized after 2, 4 and 6 days. DNA was extracted from jejunum, ileum and colon luminal content. 16S sequencing was performed and changes in microbial communities were compared between the groups. Functional pathways were predicted using PICRUSt2.

Results: Across the GI tract, microbial community changes have occurred in TPN mice compared with baseline/control. Beta diversity in feces showed a clear separation between baseline/control and TPN groups (Bray-Curtis, $p<0.001$). Time-dependent dynamics were seen in ileal samples transitioning from baseline/control to TPN groups, while no change was seen in jejunal samples. While alpha diversity was lower in feces of TPN compared with control/baseline (Chao1, $p<0.01$), no change (rather a trending increase) was seen in ileal/jejunal samples (p=ns). Destabilization of the community was on day 2 and progressed through day 6, measured by the progressive loss of single taxa domination, mostly in the small intestine. This was accompanied by increase/decrease in specific taxa, as found in differential abundance analyses. A clear separation was seen in the functional capacity of the community between fed and enteral-deprived mice.

Conclusion: Enteral deprivation disturbs the microbial community in a location-specific manner. While a mild change was seen in the proximal small intestine, dramatic changes occurred in the distal small intestine and colon, differing in pattern.

NUTRITION THERAPY COMPARED TO STANDARD THERAPY IN CROHN'S DISEASE

A. Sheth[1], S. Sartie[2], N.A.I. Hj Zulkiflee[2], D. Luo[3], K. Rostami[1]
[1]Palmerston North Hospital, Gastroenterology, Palmerston North, New Zealand, [2]University of Otago, Wellington, New Zealand, [3]AgResearch NZ Ltd, Hamilton, New Zealand

Contact E-Mail Address: aditya_sheth@hotmail.com

Introduction: Dietary intervention is well recognised as an effective treatment for Crohn's disease in children, and there is a growing evidence base for its use in adults in inducing and maintaining remission[1]. It has a number of advantages over standard therapy including a low side effect profile and being cost effective, but despite this nutrition therapy is underused in practice[2].

Aims & Methods: To investigate the efficacy of the addition of dietary intervention including elemental formula and a Low Fat/ Fibre Limited Exclusion (LOFFLEX) diet in addition to standard therapy on outcomes in Crohn's disease, compared to standard therapy alone.

A cohort of patients at MDHB in Palmerston North, New Zealand, with Crohn's disease who were started on dietary intervention as monotherapy or in addition to standard therapy in non-responsive patients between the beginning of 2019 and the end of 2021 were analysed retrospectively. A cohort of patients treated with standard therapy alone, which includes treatment with 5ASA, immunomodulator and biologic therapy were also retrospectively recruited from a database of IBD patients at MDHB. Baseline data for both groups were collected and standardised using regression model analysis for baseline characteristics including duration of disease, gender, smoking status, location and behaviour of disease, baseline Harvey-Bradshaw Index (HBI) and C-reactive protein (CRP).

Outcomes for both groups were measured using number of flares (defined by course of steroids and/or hospital presentations), biochemical markers including CRP and faecal calprotectin, and a composite marker of symptoms using the Harvey Bradshaw Index.

We fitted a mixed effects model to the response (i.e. HBI, CRP, faecal calprotectin and number of flares) separately with a fixed effects of time (12 and 24 months) for the nutrition and standard groups.

Results: At the 12 month mark, patients on nutrition therapy had a significantly lower HBI (1.9126) compared to those on standard therapy alone (4.3454 with a p-value of 0.0026. There was no significant difference between groups at 24 months. There was no statistically significant difference between the groups for other outcome measures including CRP, faecal calprotectin, and number of flares.

Outcomes													
	Month 12							Month 24					
	Nutrition			Standard				Nutrition			Standard		
Response	n	Mean	SE	n	Mean	SE	Response	n	Mean	SE	n	Mean	SE
HBI	41	2.72[a]	0.44	41	4.69[b]	0.49	HBI	22	4.68	1.13	39	4.29	0.68
CRP	36	6.36	2.37	42	20.42	6.9	CRP	18	13.96	10.64	44	20.3	8.69
WBC	41	8.01	0.37	43	6.7	0.4	WBC	25	8.12	0.62	44	7.44	0.44
Faecal Calprotectin	35	168.94	26.8	18	252.44	62.7	Faecal Calprotectin	17	172.65	51.4	11	285.82	101.87
No. of flares	41	1.56	0.4	46	1.04	0.22	No. of flares	29	3.55	1.13	43	1.93	0.33

Conclusion: Our study suggests nutrition therapy in Crohn's disease is effective as monotherapy or when combined with other treatment modalities in non-responsive patients already on pharmacotherapy. At the 12-month duration nutrition therapy was more effective in this group

compared to patients on standard therapy based on the Harvey-Bradshaw Index, suggesting a potential alternative treatment approach for adults with mild to moderate Crohn's disease, and highlighting the need for further research in this area.

Introduction: Malnutrition and sarcopenia are highly prevalent in chronic gastrointestinal diseases, including short bowel syndrome (SBS, <2m of small bowel). While restoration of colonic continuity (RC) improves intestinal adaptation, the link with malnutrition and sarcopenia is unknown.

Aims & Methods: SBS patients were included at a single tertiary care expert centre. Malnutrition (GLIM-criteria) and sarcopenia (EWGSOP2-criteria) were assessed before and 6 months after RC. The primary outcome was the evolution of sarcopenia, defined as a reduced fat free mass index (FFMI, using bioimpedance analysis) and handgrip strength (HGS). Changes in C-reactive protein (CRP) and albumin were also studied with parametric analyses after testing for normality. Comparisons were done based on weaning off home-parenteral nutrition (HPN) and presence of a jejuno-colonic (JC) or jejuno-ileo-colonic (JIC) anastomosis.

Results: In total, 46 patients (23 female, mean age 59 ±15 years) were included. Complete weaning was seen in 21 (46%) patients after 6 months, with a mean caloric reduction (kcal/day) of 33% in the remaining 25 patients. Malnutrition was present in 16 (35%) patients before and 21 (46%) after RC (p= 0.29), with no significant change in BMI (table). Although proportions of reduced FFMI (42% vs. 34%, p= 0.51) and sarcopenia (16% vs. 11%, p= 0.48) were similar before and after RC, a trend for increased FFMI was found in all patients (table). Proportions of malnutrition (52% vs. 40%, p= 0.4) and sarcopenia (10% vs. 13%, p= 0.75) were also similar in those with or without complete weaning after 6 months. In contrast, a significant increase in HGS was found (table), but only in those with complete weaning (p= 0.04). While CRP decreased and albumin increased in both groups, levels were higher in case of complete weaning after 6 months (p= 0.02) with similar CRP. Results were similar between SBS-JC (n= 26) and SBS-JIC (n= 20) patients.

Variable	Baseline	6 months	p-value
BMI (kg/m^2)	25.7 (5)	25.8 (5.4)	0.78
FFMI (kg/m^2)	14.5 (5.1)	15.1 (5.2)	<0.1
HGS (kg)	23.2 (10.2)	27.5 (12.9)	<0.01
Albumin (g/L)	31.6 (5.3)	38.2 (5)	<0.0001

Conclusion: Restoration of colonic continuity allows a reduction of HPN in SBS, with stable rates of malnutrition and sarcopenia. Besides a potential effect on body composition (FFMI), muscle strength and albumin levels increased, especially in those with complete weaning. Further study of the role of the colon and use of these functional markers during adaptation is required.

Disclosure: Nothing to disclose

THE IMPACT OF NUTRITION SUPPORT TEAMS ON EMERGENCY ADMISSIONS FOR PERCUTANEOUS ENDOSCOPIC GASTROSTOMY COMPLICATIONS IN ENGLAND 2007-2021:A POPULATION BASED STUDY

N. Umar[1,2], U. Kamran[1,2], B. Coupland[3], N. Trudgill[2]

[1]University of Birmingham, Birmingham, United Kingdom, [2]Sandwell & West Birmingham Hospitals NHS Trust, West Bromwich, United Kingdom, [3]University Hospitals Birmingham, Informatics, Birmingham, United Kingdom

Contact E-Mail Address: nosheen.umar@nhs.net

Introduction: Percutaneous endoscopic gastrostomy (PEG) provides long-term enteral nutrition access in patients with a functional gastrointestinal tract and impaired swallowing. Population-based data on hospital admissions with long term PEG complications are lacking. This study examines the impact of nutrition support teams on admissions with PEG related complications and associated factors.

Aims & Methods: Adults undergoing first PEG insertion in England from 2007 to 2021 were identified in Hospital Episode Statistics. Long term complications (>30 days after PEG) were identified using ICD-10 codes and categorised into two groups: mechanical (PEG obstruction, displacement and leakage) and PEG site infection. Data on NHS trust nutrition support teams were available from GIRFT. The proportion of patients with hospital admissions associated with PEG related complications within 5 years of insertion was calculated. Cox proportional hazards models examined factors associated with both emergency and elective admissions with PEG complications.

Results: Of 108,515 patients (57.7% male; age 69(IQR 57-69)),10.8% had an emergency admission (with 84% for >48 hours) and 1.6% an elective admission due to PEG complication. Hospitals without a nutrition support team had 60.7(36.8-84.2)% emergency admissions due to PEG related mechanical complications compared with 49.5(22.5-90.6)% in hospitals with a nutrition support team.

Factors associated with any emergency admissions for PEG complications included: female (adjusted hazard ratio (aHR) 1.04(95% CI 1.01-1.08)); Asian ethnicity (aHR 1.10(1.02-1.19)); PEG insertion during an emergency admission (aHR 1.38(1.32-1.44)); dementia as PEG indication (aHR 1.27(1.08-1.49)); oesophageal cancer as PEG indication (aHR 2.28(1.99-2.62)); no trust nutrition support team (aHR 1.20(1.13-1.28)) and more recent years of PEG insertion (2021 aHR 1.75(1.52-2.00)). Factors associated with any PEG related complication admission included: PEG insertion during emergency admission (aHR 1.27(1.22-1.32)); oesophageal cancer

as PEG indication (aHR 2.24(1.97-2.54)); dementia as PEG indication (aHR 1.24(1.06-1.44); other neurological conditions than stroke as PEG indication (1.16(1.10-1.23)); no trust nutritional support team (aHR 1.16(1.09-1.23)); increasing age (>82 years aHR 0.60(0.57-0.64)); the least deprived quintile (aHR 0.83(0.78-0.87)) and increasing comorbidity Charlson score >5 (aHR 0.86(0.82-0.91)).

Conclusion: 10.8% of patients had an emergency admission with a complication within 5 years of PEG insertion, with 84% staying in hospital for >48hrs.The lack of a trust nutritional support team increased the risk of emergency admissions with complications.

THE ASSOCIATION BETWEEN VARIATION IN ENDOSCOPY PRE-MEDICATION PRACTICE AND PNEUMONIA RISK FOLLOWING PERCUTANEOUS ENDOSCOPIC GASTROSTOMY

N. Umar[1,2], D. McNulty[3], U. Kamran[1,2], H. Steed[4], F. Varyani[1], N. Trudgill[1]

[1]Sandwell & West Birmingham Hospitals NHS Trust, West Bromwich, United Kingdom, [2]University of Birmingham, Birmingham, United Kingdom, [3]University Hospitals Birmingham, Informatics, Birmingham, United Kingdom, [4]New Cross Hospital, Wolverhampton, United Kingdom

Contact E-Mail Address: nosheen.umar@nhs.net

Introduction: Percutaneous endoscopic gastrostomy (PEG) provides long term nutrition in patients with impaired swallowing and a functional GI tract. Such patients are often at increased risk of aspiration.

Aims & Methods: This study examines the association between the use of sedation and local anaesthetic throat spray during PEG insertion and aspiration pneumonia risk. Adult patients with PEG insertion were identified from Hospital Episode Statistics between January 2016 and July 2022. Data on sedation and throat spray use during PEG insertion at NHS trust level were available from the National Endoscopy Database. The proportion of patients with aspiration pneumonia and pneumonia within 7 days of PEG insertion at NHS trust level were examined.

Multivariable logistic regression analysis was used to examine the association of sedation and throat spray with pneumonia following PEG against a baseline of general anaesthetic/propofol adjusting for demographics, comorbidities, PEG trust volume and PEG indications.

Results: 33,357 patients undergoing PEG insertion were analysed (59.8% male). 71.4% of NHS trusts predominantly used sedation only compared with 28.6% who predominantly used both throat spray and sedation for PEG insertion.

Patients who had sedation only (Odds Ratio 0.45(95% CI 0.29-0.70)) had a significantly lower risk of pneumonia, compared with sedation plus throat spray (OR 0.61(0.39-0.97)) (p=0.01) and general anaesthetic/propofol. Other factors associated with pneumonia included: increasing age >82 years (1.27(1.06-1.51)) and head and neck cancer as PEG indication (0.23(0.18-0.30)).

Patients who had sedation only (1.51 (0.95-2.40)) had less aspiration pneumonia after PEG insertion, compared to sedation and throat spray (2.29 (1.41-3.71)) (p=0.001) . With general anaesthetic/propofol as baseline other factors associated with aspiration pneumonia included: less PEG procedures per trust < 27 (1.17(1.03-1.34)); PEG insertion during emergency admission (4.25(3.71-4.86)); and increasing age > 82 years (1.83(1.55-2.16)).

Conclusion: The use of sedation in combination with local anaesthetic throat spray for PEG insertion is associated with a higher risk of pneumonia and aspiration pneumonia, compared to using sedation only. Endoscopy providers and endoscopists should consider whether using throat spray with sedation in patients undergoing PEG insertion is appropriate when they are already at increased risk of aspiration.

Disclosure: No conflict of interest to declare.

A SIMPLIFIED APPROACH TO PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) TUBE PLACEMENT IN AMYOTROPHIC LATERAL SCLEROSIS (ALS) PATIENTS – SAFETY AND COMPLICATIONS

D. Shirin[1,2], Y. Shapira[1,2], O. Shibolet[1,2], L. Deutsch (Mlynarsky)[1,2]

[1]Tel-Aviv Sourasky Medical center, Department of Gasteroenterology and Liver Diseases, Tel-aviv, Israel, [2]Tel-Aviv University, Sackler faculty of Medicine, Tel-Aviv, Israel

Contact E-Mail Address: dorshirin@yahoo.com

Introduction: Amyotrophic Lateral Sclerosis (ALS) is a progressive neurodegenerative disease in which muscle weakness develops insidiously. In advanced stages of the disease dysphagia, weight loss and malnutrition occur in the majority of patients. Thus, the consideration of Percutaneous Endoscopic Gastrostomy (PEG) tube placement is common.

However, the optimal timing and setting for the procedure as well desired spirometry results are either are not stated in most guidelines or debated. Previous studies have suggested greater procedural risk for patients whose forced vital capacity (FVC) was less than 50% than predicted

Aims & Methods: The aim of this study was to assess the safety of our tertiary center simplified approach to PEG tube placement in patients with ALS.

The electronical records of patients who underwent percutaneous endoscopic gastrostomy (PEG) placement between 1.1.2020 to 1.1.2023 were retrospectively reviewed. All adult patients diagnosed with ALS who underwent ambulatory PEG tube placement were included. Patients who underwent PEG tube placement during hospitalization due to acute illness were excluded.

The common practice of our center regarding PEG placement in patients with ALS is as follows: initial evaluation at the Gastroenterology clinic of patients referred by the neurology clinic, followed by ambulatory PEG placement under sedation by an anesthesiologist.

We collected baseline information from the neurology and gastroenterology clinic visits regarding comorbidities and baseline FVC and the functional rating score [ALS-FRS, 0-48 points, lower score indicating a more severe disease). The data concerning the procedure and possible complications were collected from endoscopy reports, emergency department visits and clinic visits after the procedure.

Results: Six hundred and sixty patients had underwent PEG tube placement in our center during study period. Of them, 67 patients had an established diagnosis of ALS (10.2%). One patient was excluded due to PEG placement in the setting of an acute illness during admission, thus 66 patients were included (mean age at PEG placement 63.5±12.7 years and 37.8% were females). Mean ALS-FRS score was 23.6±8.81 and mean FVC was 49.8±19.45% of predicted. More than half (54.7%) of the patients were using non-invasive ventilation support device at home prior to the procedure and 12.1% of patients had underwent endotracheal tube placement prior to PEG tube placement.

The averaged duration of PEG tube placement was 11.96±5.3 minutes. All PEG procedures were completed successfully. Complications were documented during two PEG placements (3%): one patient suffered from aspiration and was hospitalized and later diagnosed with aspiration pneumonia and the second patient suffered from gastric perforation and peritonitis which was diagnosed a few hours after the procedure. During the 30 days following PEG placement, 3 (4.5%) complications were docu-

mented: Two patients (3%) suffered from PEG site infections and were treated with antibiotics and one (1.5%) was diagnosed with aspiration pneumonia. No deaths occurred during the procedure or during the 30 days that followed.

Conclusion: The simple straight forward approach to PEG placement in our institution was successful and safe in the vast majority of cases. The complications rate in our cohort is comparable to other studies, even though the patients in our cohort had significantly reduced lung function and functional scores then accepted in the common practice.

IMPACT OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY ON SURVIVAL AND PROGNOSTIC FACTORS IN ENT CANCER PATIENTS: A LONGITUDINAL STUDY FROM 2006-2022

S. Assawasuwannakit[1,2], C. Kaittisaksophon[3], P. Sripongpun[1], N. Chamroonkul[1], T. Pattarapuntakul[1], A. Kaewdech[1]

[1]Prince of Songkla University, Faculty of Medicine, Gastroenterology and Hepatology Unit, Division of Internal Medicine, Hat Yai, Thailand, [2]Srinakharinwirot University, Panyananthaphikkhu Chonprathan Medical Center, Department of Medicine, Nonthaburi, Thailand, [3]Prince of Songkla University, Faculty of Medicine, Division of Internal Medicine, Hat Yai, Thailand

Introduction: Percutaneous endoscopic gastrostomy (PEG) is a widely recognized procedure for delivering enteral nutrition to head and neck cancer patients who often suffer from dysphagia and malnutrition. Nevertheless, the influence of PEG on survival among ENT cancer patients is yet to be fully understood.

Aims & Methods: This research seeks to determine the overall survival rate of ENT cancer patients with PEG and identify the critical factors affecting survival during the period of 2006-2022. We conducted a retrospective cohort study on ENT cancer patients diagnosed between 2006 and 2022. The Kaplan-Meier method was employed to estimate overall survival, while Cox proportional hazards regression was used to compute hazard ratios (HRs). Forest plots were generated to illustrate the HRs and corresponding 95% confidence intervals (CIs) for factors significantly linked to survival.

Results: Our analysis included 6646 patients, with 1851 undergoing PEG (27.9%) and 4795 without PEG (72.1%). According to the Kaplan-Meier analysis, patients who received PEG had a median survival time of 2.34 years (95% CI: 2.17 to 2.65) compared to 1.09 years (95% CI: 1.03 to 1.16) for non-PEG patients. The Forest plot identified several key factors significantly related to improved survival, such as PEG (aHR: 0.66, 95% CI: 0.61 to 0.70), younger age (aHR: 1.02, 95% CI: 1.02 to 1.02), and lower cancer stage (stage 2: aHR: 1.24, 95% CI: 1.08 to 1.43; stage 3: aHR: 1.45, 95% CI: 1.26 to 1.67; stage 4: aHR: 1.87, 95% CI: 1.66 to 2.12). The relationship between PEG and survival suggests a 34% decrease in mortality risk for PEG patients.

Conclusion: This study shows that PEG plays a significant role in enhancing the overall survival of ENT cancer patients. Factors such as age and cancer stage also strongly impact patient outcomes. These results underline the potential advantages of PEG in ENT cancer patient management and stress the necessity for a multidisciplinary strategy to optimize patient care. Further prospective research is needed to establish the causal link between PEG and increased survival and to pinpoint the best timing and selection criteria for PEG in ENT cancer patients.

Introduction: Inflammatory bowel diseases (IBD) including Crohn's Disease (CD) and Ulcerative colitis (UC), are chronic and relapsing inflammatory conditions of the gut. In severe IBD and in corticosteroid-dependent or -resistant cases, the use of biological drugs, targeted towards TNF is indicated.

However, 20-40% of patients do not respond to biological agents, leading to increased direct and indirect costs. To date, there are no reliable clinical or molecular predictors of response to anti-TNF.

Aims & Methods: The aim of this study is to promote personalized medicine in IBD, using serum proteomic profiling to identify potential molecular markers, which may predict the response vs. failure of Infliximab therapy. Immunodepleted serum from 54 IBD patients, collected up to the third infusion (29 CD, 20 responders and 9 non-responders; 25 UC, 14 responders and 11 non-responders) were characterized by MALDI profiling analysis.

The acquired spectra of the responders and anti-TNF non-responders, both UC and CD patients, were compared in order to highlight the "best separating" peaks. Blood levels of anti-TNF were measured using a commercial ELISA kit for therapeutic drug monitoring (TDM).

Results: We analyzed proteomic profiles in order to identify differences between patients responding to therapy (R) and non-responder patients (NoR) in both UC or CD groups. Comparing immunodepleted serum, collected up to the third infusion, of UC R vs NoR patients, 2, 8 and 11 "best separating" peaks were differentially expressed before the first, second and third infusions, respectively ($p<0.05$, CV<25%, ROC curve≥0.75) in the m/z range 1-35 KDa. Among these "best separating" peaks we identified up-regulated proteins in NoR that participate in immune response, lipid metabolism, cell proliferation and differentiation.

Whereas, in CD pts spectra analysis between R vs NoR before the first and the second infusion showed significant variation in two and six "best separating" peaks, respectively, all up-regulated in NoR. Quantifications of circulating drug levels were performed in all pts who reached the 6th week of treatment (W6). The circulating drug level before infusion demonstrate that R pts have significantly lower circulating drug levels than NoR (7.29µg/ml ± 0.90µg/ml vs 16.42µg/ml ± 5.14µg/ ml; $p<0.001$), with no differences between disease.

Conclusion: Proteomic analysis has highlighted a number of "best separating" peaks and circulating proteins between UC and CD responders and non-responders patients to anti-TNF therapy that have the potential to be tested as predictors of non-response to IFX therapy. Prospective clinical studies should be performed to evaluate real role of these serum markers in predicting outcomes with anti-TNF treatment.

Introduction: Despite the increasing incidence of Crohn's disease (CD), its early immune disturbances have not been described yet. The preclinical period provides an opportunity to gain insight into the initial processes involved in the pathogenesis of the disease.

Aims & Methods: The main aim of our study was to describe how the subclinical inflammatory process is modifying the individual's immunologic environment while the patient is still on preclinical period. We analysed scRNASeq data from peripheral blood mononuclear cells (PBMC) of patients with incidentally-diagnosed CD according to ECCO criteria during the colorectal cancer screening programme, after histologic confirmation. Their gene expression profile was compared to healthy individuals acquired from publicly available datasets. The analytical pipeline included merging of the datasets followed by batch correction concerning integration from different studies, quality control and filtering, and finally cell-type annotation and differential gene expression analysis.

Results: Two patients with CD (mean age 53,5 years) and 2 healthy controls were included. We observed distinct transcriptomic profile in preclinical patients compared to controls, with small intragroup differences. The cell-type annotation identified B cells (B), CD4+ and CD8+ T-cells (CD4T, CD8T), dendritic cells (DC), monocytes (Mono) and natural killer cells (NK). The analytical pipeline included 17,021 cells (B:3,274, CD4T:5,798, CD8T:3,476, DC:315, 2, Mono:928, NK:3,230) and 3000 quantified genes. Considering each cell type individually, we identified 49 differentially expressed genes (DEG) between CD patients and controls (B:39, CD4T:37, CD8T:41, DC:42, Mono:37, NK:37), from which 30 were DEGs in all cell types.

Building on the list of 49 detected DEGs, we report three insights into the preclinical period of the disease.

First, pathway analysis revealed significant enrichment of the pathway that is related to immunoregulatory interactions between lymphoid and non-lymphoid cells, and functional annotation analysis identified gene

products that are related to immunological defense. Second, we identified significant transcriptomic alterations in genes that have previously been related to the symptomatic phase of IBD, or reported as potential biomarkers. Third, after performing principal component analysis we observed greater separation between the patients groups in the CD8T cells compared to the other cell-types.

Conclusion: This study reveals the initial transcriptomic profiles and the main pathways that precede the onset of symptomatic inflammatory bowel disease. Our findings may help in identifying potential targets for early disease intervention.

VISUALIZATION OF DNA DAMAGE RESPONSE AND ITS ASSOCIATION WITH CLINICOPATHOLOGICAL FEATURES IN ULCERATIVE COLITIS

E. Yoshioka[1], Y. Akazawa[2], K. Nakao[3], M. Nakashima[4]
[1]Nagasaki University, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Department of Histology and Cell Biology, Nagasaki, Japan, [3]Nagasaki University Graduate School of Biomedical Sciences, Gastroenterology and Hepatology, Nagasaki, Japan, [4]Nagasaki University, Atomic Bomb Disease Institute, Nagasaki, Japan

Contact E-Mail Address: bb20118117@ms.nagasaki-u.ac.jp

Introduction: Ulcerative colitis (UC) are characterized by chronic inflammation and ulcers in the large intestine with risk of developing colorectal cancer in the long term.

DNA damage response is implicated in inflammation in UC as well as carcinogenesis. However, *in situ* DNA damage response in epithelium in ulcerative colitis, as well as its association with inflammation status and dysplasia, is poorly explored. p53-binding protein 1 (53BP1) accumulates at double strand break legions and form a nuclear focus, thus serving as a molecular marker of DNA damage response.

Aims & Methods: The aim of this study was to visualize the patterns of 53BP1 nuclear foci expression pattern in UC specimen, and to evaluate correlations between 53BP1 expression patterns and investigate their association with clinico-pathological features.We performed immunofluorescence staining with 53BP1 on colorectal tissue of control and UC (control n=18, UC=51, total n=69). Expression pattern with 3 or more nuclear foci and/or nuclear foci larger than 1μm in diameter was defined as abnormal pattern as previously reported (Akazawa et al, Modern pathology, 2019). We then assessed the rate of each expression pattern of 53BP1 with clinical characteristics and degree of histological activity. In addition, colocalization of 53BP1 and Ki67, which indicate abnormal timing of DNA damage response in proliferative state, was examined by triple immunofluorescence study with 53BP1, Ki67, and AE1/AE3 in UC(n=4), dysplasia(n=4), three colitic cancer (n=3) specimen.

Results: The occurrence ratio of 53BP1abnormal, pattern was significantly increased in UC (without dysplasia) compared to control group (10.80% vs 43.99%, p=0.026). Rate of abnormal 53BP1 expression was positively correlated with c-reacting protein (p=0.0296), Mayo endoscopic score (p=0.0122), Mayo score(p=0.0050) and histological severity (p=0.0054) among UC. However, 53BP1 expression *per se* did not increase between UC and dysplasia. In contrast, co-localization ratio of 53BP1 and Ki67 showed step wise increase during progression of UC, dysplasia, and colitic cancer. A significant difference was observed between non-dysplastic epithelium vs dysplasia/cancer (p=0.0327).

Conclusion: The study indicates that DNA damage response associates with to the disease activity in UC, and co-localization of 53BP1 and Ki67 may be beneficial in distinguishing dysplasia.

INVESTIGATING THE ROLE OF GUT EUKARYOTIC VIROME IN CONTRIBUTING TO COLORECTAL CANCER CARCINOGENESIS

A. Facoetti[1], L. Massimino[1,2], S. Cagliani[1], S. Spanò[2], C. Errico[1], T.L. Parigi[1,2], S. Danese[2,1], F. Ungaro[1,2]

Contact E-Mail Address: facoetti.amanda@hsr.it

Introduction: Eukaryotic-targeting viruses have recently attracted considerable interest in gastrointestinal diseases such as ulcerative colitis (UC), a chronic inflammatory condition of the colonic tract, and colorectal cancer (CRC)[1–3], the third most commonly diagnosed malignancy and the fourth leading cause of cancer death in the world[4]. Both UC and CRC share several factors influencing their etiogenesis, including intestinal dysbiosis[2,5–7].

Our group has recently published a work pinpointing a gut virome-associated Orthohepadnaviridae protein, namely Hepatitis B protein X (HBx) to correlate with UC pathogenesis and promote intestinal inflammation in mice by disrupting the epithelial barrier and shaping the gut mucosal immune environment, independently of the microbiota[3].

Moreover, we showed that HBx is able to induce DNA damage-related biological processes and active biological processes related to the Wnt pathway[3] known to be involved in colorectal carcinogenesis[8].

Aims & Methods: Based on this evidence we hypothesize that HBx may fill the gap existing between intestinal inflammation and CRC onset by stimulating pro-inflammatory and/or pro-carcinogenic effects.

To verify this hypothesis, we address the following Aims:

1. To evaluate the presence of HBx-transcript in CRC-derived mucosal samples.
2. To evaluate the pro-carcinogenic properties of HBx *in vitro.*
3. To investigate the role of HBx in CRC onset and development *in vivo.*

HBx positivity of CRC patient-derived gut mucosa was assessed by RT-PCR and Sanger.

Multidimensional flow cytometry analysis was performed on HBx-overexpressing Caco-2 cells, an *in vitro* model of the gut barrier.

C57BL/6 mice underwent intramucosal injections of liposome-conjugated HBx-encoding plasmids or the control. Multidimensional flow cytometry analysis and transcriptomic analysis were performed on colonic samples from HBx-treated and control animals.

Results: Metatranscriptomic analysis revealed that HBx is significantly abundantly present in CRC-derived mucosal samples compared with healthy individuals, strengthening the link between a virome protein-induced inflammation and tumor development in patients.

Moreover, HBx overexpression in Caco-2 cells directly provokes DNA damage, as assessed by the significant increase in the number of γH2AX+ cells, a marker of double-strand DNA breaks which identifies genomic instability that can potentially contribute to cancer initiation and progression[9].

Furthermore, we already showed that HBx was able to induce colitis-like symptoms in mice after 15-20 days-long administration[3].

Interestingly, experiments conducted in C57BL/6 mice at longer time points (from 40 to 60 days-long observation) revealed that animals developed polypoid structures in the colonic mucosa, characterized by decreased abundance of T cells, including effector T cells and NK T cells[10].

Of note, in vivo HBx modulated the expression of genes involved in the regulation of transcription and activation of the proto-oncogene PIM3[11], further supporting the role of a viral protein on CRC onset.

Conclusion: This study introduces unconventional and innovative insights for giving CRC studies a new direction for the scientific and clinical investigations, looking at the gut virome as an active component and not as a mere bystander entity of the microbiota, ultimately promoting a new standpoint in the CRC studies and management in the short-term future.

PLATELET ACTIVATION AND PLATELET-MONOCYTE INTERACTIONS CORRELATE WITH MUCOSAL INFLAMMATION AND DISEASE SEVERITY IN ULCERATIVE COLITIS

Y. Sano[1], T. Tomiyama[1], M. Naganuma[1]
[1]Kansai Medical University, Third Department of Internal Medicine, Hirakata, Japan

Contact E-Mail Address: ysano.631221@gmail.com

Introduction: Ulcerative colitis (UC) is a refractory inflammatory bowel disease of the colon with repeated relapses and remissions that requires lifelong treatment. Previous studies indicated that proinflammatory cytokines involved the onsets and developments of UC. New treatments for targeting these cytokines, such as TNF-α, IL-12 and IL-23 have been developed in a recent decade, underlying that immune abnormalities are the core for the etiology of UC.

Platelets play a role not only in hemostatic coagulation but in inflammatory mediator by interacting with various cells in the innate and adaptive immunity. Chronic inflammatory response confers platelets activation leading to elevated platelet count and hypercoagulability. Moreover, platelets aggregates with leukocyte in active inflammatory milieu. In fact, thrombocytosis, thromboembolism and upregulation of platelet-monocyte complex (PMC) in UC patients have been reported, implying that platelets could be novel biomarker, therapeutic target and clues for elucidating the pathology of UC. However, the clinical significance of platelet activation and PMC formation in UC is not fully elucidated and few studies were conducted to assess how platelet activation contributes to disease aggravations of UC.

Therefore, we comprehensively analyzed platelet activation and platelet-monocyte complex by focusing on a correlation with clinical severity of UC.

Aims & Methods: Patients with UC (n=70) including MES0-2 group (n=34) and MES3 group (n=27), diagnosed according to a combination of symptoms, endoscopic findings, histologic findings, and the absence of alternative diagnoses, and age and sex-matched healthy controls (HCs) (n =19) were enrolled for this study. We analyzed the surface markers such as CD62P, CD40L, CD63, PAC-1 and Annexin V on CD61+ platelets by flow-cytometry (FCM) in patients with UC in comparison with those in healthy adults. We also analyzed the proportion of CD61+CD14+ platelet-monocyte complexes and quantified the activation of PMCs by FCM. Moreover, we also investigated the correlation among surface markers, proportion of platelet-monocyte aggregates and Mayo endoscopic score (MES) in UC patients.

Results: The expression of CD62P but not other surface markers on platelets was significantly upregulated in UC when compared to HCs ($p<0.01$), and was significantly upregulated in in MES3 group when compared to the MES0-2 group ($P<0.001$). The proportion of PMC was also higher in MES3 groups when compared to MES0-2 group ($P<0.05$), and was markedly reduced by treatment ($P<0.05$). In addition, CD16+ monocytes, phenotypically mature and pro-inflammatory cell population, were increased in patients with UC when compared to HCs ($P<0.01$). The expression of CD16 on monocytes aggregated with platelets was significantly higher when compered to that without platelet ($P<0.001$).

Conclusion: Our study suggests that platelet activation accelerates mucosal inflammation via adhesion with monocytes in UC and contributes to the aggravation of disease.

Introduction: Permeability alterations, associated with excessive and inappropriate inflammatory responses, underlie the pathogenesis of many diseases such as inflammatory bowel diseases (IBD). Identification of novel molecular players involved in the control of the intestinal barrier is therefore of great interest for the management of IBD.

A recent study has revealed that dysfunction of a cadherin-based intermicrovillar adhesion complex (IMAC), critical for brush border (BB) assembly and maturation, is associated with disease severity and treatment response in IBD [1,2,3].

Aims & Methods: The aim of this study was to determine the effects of the probiotic yeast *Saccharomyces boulardii* CNCM I-745 (*Sb*, Biocodex, France) on the protection and/or restauration of the intestinal epithelium barrier function upon inflammation.

Experimental models for the human colon were based on 2D monolayers (Transwell insert) formed by either the Caco-2/TC7 cell line or organoids. Inflammatory set-ups included treatment with TNF-a/IL1-b cytokines and IBD organoids. Paracellular and transcellular permeability were assessed by real-time transepithelial electrical resistance (TEER) and dextran-FITC measurements. Localization and expression levels of junction and BB proteins (E-cadherin, sucrase isomaltase, DPP-IV, Villin; IMAC: CDHR5, CDHR2, MYO7-b) were analyzed by Western blot and immunofluorescence. BB assembly through microvilli clustering was observed using super-resolution

spinning-disk confocal microscopy. *Sb* treatment was initiated either prior (preventive model) or after (curative model) cytokines stimulation.

Results: We showed that *Sb* supernatant strengthens intestinal barrier function both in Caco-2/TC7 cells and colonoïd organoid-derived monolayers. In Caco-2/TC7 cells exposed to pro-inflammatory cytokines, *Sb* is able to preserve the structural and functional parameters of the cell monolayer and to accelerate their recovery. We found that *Sb* treatment has a positive effect on the adherens junction localization (E-cadherin complex) in both preventive and curative situations.

In addition, we discovered that *Sb* also acts on the IMAC, favoring microvillar clustering and maintaining the presence of IMAC at the top of microvilli, thereby restoring a mature and functional BB.

Conclusion: Taken together our results demonstrate that *Sb* CNCM I-745 globally protects and reestablishes functional integrity of the intestinal epithelium in inflammatory conditions. *Sb* may thus offer a significant benefit in diseases with persistent lesions of the intestine, such as IBD. In addition, they suggest that a better understanding of BB assembly through the IMAC will foster new therapeutic opportunities.

CELL WALL DEFICIENT (CWD) MYCOBACTERIA IN WBCS AND ILEAL CROHN'S TISSUES

W. Chamberlin[1], T.J. Borody[2], G. Agrawal[3], J. Aitken[4]

[1]Protibea Therapeutics, Chief Science Officer, Georgetown, Texas, United States, [2]Centre for Digestive Diseases, Sydney, Australia, [3]Centre for Digestive Diseases, Five Dock, Australia, [4]Otakaro Pathways, ChristChurch, New Zealand

Contact E-Mail Address: wchambrlin@gmail.com

Introduction: *Mycobacterium genus* contains over 190 species. *M tuberculosis complex* (MTBC) and *M leprae* receive all the attention. *Mycobacterium avium complex* (MAC) and 'Non tuberculous Mycobacteria' (NTM) cover other members of the genus.

Mycobacteria exist in two forms:

1. Fully intact cell wall bacilli, and;

2. Cell wall deficient mycobacteria that are pleomorphic and are found in a variety of forms and often intracellularly. Current clinical laboratory procedures are optimized to stain and culture bacillary MTBC, however conventional laboratory methods are suboptimal for visualization and culture of CWDM.

Aims & Methods: A revised method of the Ziehl-Neelsen stain enables visualization of CWD-Mycobacteria (CWDM). The industry standard Mycobacteria Growth Indicator Tube (BD MGIT™) is not optimized to grow CWDM. New culture techniques are required.

Results: Combining the two methods reveals NON-TB Mycobacteria L-Forms in blood myelocytes and in diseased ileal tissue in Crohns Disease.

Conclusion: A role for mycobacteria in Crohn's Disease has been theorized for over a century. The inability to visualize or culture the microbe has been the main impediment for acceptance of this theory. It is now possible to visualize and culture mycobacteria in blood and diseased CD tissue.

The pictures we provide prove the presence of L-Forms of the Genus Mycobacterium in Crohn's Disease. CWDM-Mycobacteria are visualized in diseased ileum in 18/18 CD patients vs. 0/15 Controls. CWD-Mycobacteria in cultures of blood buffy coats is greater in clinical flares compared to times of remission. Sub-clinical infection is common.

Genetic and acquired immune deficiencies predispose to mycobacteria disease. Future treatments should strive to strengthen innate immunity.

Introduction: Granulocyte–monocyte apheresis (GMA) is a non-pharmacological therapy approved for the treatment of ulcerative colitis (UC), mainly in steroid-dependent cases. Its mechanism of action is based on the removal of activated leukocytes, but its exact immunological changes have not been fully described yet.

Aims & Methods: Our aim was to characterize the response in the transcriptome at the single-cell resolution level and cell population effects of GMA device. We analysed scRNASeq data from peripheral blood mononuclear cells (PBMC) of two UC patients undergoing their first GMA session. Their gene expression profile was compared before (PRE) and one month after (POST) the GMA treatment, from the inflow and outflow lines, respectively. The analytical pipeline included quality control and filtering, cell-type annotation, differential gene expression and pathway enrichment analysis.

Results: Two patients with UC (mean age 59 years; both E2) were included. Overall, the cell populations that appear to have been affected by the GMA treatment were natural killer cells and monocytes with both populations being reduced after the treatment. The distribution of the annotated cell-types was 2,369 B cells (PRE:50%, POST:49%), 11,462 CD4+ (PRE:49%, POST:50%) and 8,845 CD8+ T-cells (PRE:51%, POST:48%), 47 dendritic cells (PRE:40%, POST:59%), 3,773 natural killer cells (PRE:54%, POST:45%) and 2,352 monocytes (PRE:59%, POST:40%). Annotation at higher resolution identified 27 cell-types with monocytes being subannotated as 1,972 CD14 (PRE:62%, POST:37%) and 380 CD16 (PRE:48%, POST:51%) monocytes. Differential gene expression analysis identified in total 86 significant genes across six cell-types (CD4+ naive and central memory T-cells, natural killer cells, B intermediate cells, double-negative T-cells and CD14 monocytes) with 63% of these genes being downregulated after the GMA treatment. Pathway enrichment analysis identified higher contribution of the double-negative T-cells to the enriching genes.

More specifically, after the treatment the double-negative T-cells exhibited upregulation of the *NEFL* that is associated with the MAPK cascade and downregulation of genes related to immune response and signalling pathways. Regarding the CD14 monocytes, after the GMA treatment we observed significant downregulation of the genes *LINC02315*, *IGHEP1* and *IGHE*, with the latter being linked to innate immune response pathways.
Conclusion: GMA induces a range of modifications in the gene expression profile across different cell types that change the immunological environment of UC patients.

Contact E-Mail Address: ke-nomura@juntendo.ac.jp
Introduction: We previously demonstrated that fecal microbiota transplantation (FMT) following bowel cleaning with amoxicillin, fosfomycin, and metronidazole (AFM therapy) improved short-term efficacy and recovery of the Bacteroidetes composition, which is associated with ulcerative colitis (UC) severity in patients [1].
Besides, the proportion of certain Bacteroidetes species is decreased in UC and is associated with the efficacy of FMT combined with AFM (A-FMT) [2].
We speculate that Bacteroidetes species may be an important breakthrough driving the progress of UC treatment.
Aims & Methods: We have carried out *in vitro* and *in vivo* study on whether Bacteroidetes species are the key species for UC treatment by reverse-translational approach. We focused on cases of UC that had a significant response to FMT, then isolated Bacteroidetes species from effective donor stools. The immune function of Bacteroidetes was then evaluated by *in vitro*and *in vivo* studies.
Results: Twenty-four Bacteroidetes species were isolated and identified. From *in vitro* IL-10 induction assays, we found 4 Bacteroidetes species that showed remarkable IL-10 induction activity. The full genome sequences of the isolated strains differed in some structures from those in conventional databases. We found that stronger IL-10 inducing activity was observed when accidentally mixed Veillonella.sp (VE) was stimulated together with acquired Bacteroidetes spp. In the transplantation of isolated Alistipes putredinis (AP), including VE, into a gnotobiotic mice model of enteritis induced by 2.5% DSS and 1% Oxazolone, which has been verified to have strong IL-10 inducing activity, can significantly improve the symptoms of colitis and suppress body weight loss compared to vehicle ($p = 0.01$).
Conclusion: As a representative of Bacteroidetes species, AP has been confirmed to exhibit anti-inflammatory characteristics in *in vivo*and *in vitro* studies, and other Bacteroidetes species have yet to be further explored. And although our evaluation methods and conditional settings also need to be further improved. But the A-FMT-based reverse-translational approach of promising bacterial species has proven to be a breakthrough for microbiome drug development.

Introduction: Inflammatory bowel diseases (IBD) are a distinct class of gastrointestinal disorders mainly represented by Crohn's Disease (CD) and Ulcerative Colitis (UC). The dysregulation of microRNAs (miRNAs), a class of conserved endogenous, small non-coding RNA molecules, both tissue-derived and circulating, have shown to be promising biomarkers in IBD. These biomarkers can be useful for differential diagnosis, drug response prediction and can have prognostic value for the evolution of the disease. Moreover, miRNAs are interesting tools for potential future therapeutic approaches by miRNA antagonists or mimics [1].
Aims & Methods: In this study we aimed to perform a preliminary screening of a large panel of 179 miRNAs in the plasma of 6 patients with IBD and 12 non-IBD patients (CTRL) in order to identify a set of highly dysregulated miRNAs to be investigated in a larger cohort. Isolation of miRNAs has been conducted using miRNeasy Serum/Plasma Kit and the miRNAs expression has been evaluated using the Human serum/plasma focus, MIRCURY LNA miRNA Focus PCR panel (Qiagen) by qRT-PCR. After excluding 29 miRNAs that were not expressed in the investigated samples, we identified miR-19a-3p and miR-17-5p as the most stable miRNAs by the RefFinder analysis. Thus, the Ct values of the other 148 miRNAs have been normalized against the geometric mean of these two miRNAs as endogenous controls using the 2^{-DCt} method. All the clinical, sociodemographic and miRNAs expression data have been analyzed using SPSS. Categorical variables were tested by means of the chi-square test, and continuous variables with t-test or the non-parametric Man Whitney test, according to the normality of the data distribution.
Results: The two groups were age matched (mean age IBD= 45.83±21.27, mean age CTRL = 50.08±8.16, $p=0.543$) and did not differ for sex distribution (IBD= 33.3% female, CTRL=58.3% female, $\chi 2= 1.00$ and $p=0.317$). The statistical analysis revealed 45 miRNAs differentially expressed ($p<0.05$). In particular, we identified 29 overexpressed miRNAs (miR-223-3p, miR-143-3p, let-7f-5p, miR-30b-5p, miR-26a-5p, let-7a-5p, miR-142-3p, miR-374a-5p, miR-339-5p, miR-150-5p, miR-454-3p, let-7d-5p, miR-29a-3p, miR-146a-5p, miR-199a-3p, miR-221-3p, miR-142-5p, miR-191-5p, miR-338-3p, let-7g-5p, miR-103a-3p, miR-23a-3p, miR-145-5p, miR-374b-5p, miR-24-3p, miR-107, miR-27b-3p, let-7c-5p, miR-26b-5p) in the IBD group compared with the CTRL showing a fold regulation (FR)>1.5 and 7 miRNAs underexpressed reporting a FR<-1.5 (miR-421, miR-320d, miR-106b-3p, miR-320c, miR-20b-5p, miR-320b, miR-486-5p).
Notably, the expression of let-7a-5p that was upregulated in the IBD group (FR=2.45; $p=0.001$) positively correlated with the years of disease duration ($p=0.01$, Pearson $r=0.919$). The same positive correlation was observed for miR-30b-5p ($p=0.049$, Pearson $r=0.812$).
Conclusion: The reported data, showing 45 miRNAs differentially expressed in the plasma of IBD patients compared to controls, represent preliminary results that must be validated. The most statistically signifi-

cant dysregulated miRNAs, as well as those that correlated with the years of disease duration and other clinical parameters will be investigated in a large IBD cohort in order to examine the potential value of these miRNAs as diagnostic and prognostic biomarkers.

Introduction: The endocannabinoid system (ECS) can have a role in gut homeostasis, pain, intestinal inflammation and immune function. This system comprises two cannabinoid G-protein coupled receptors, CNR1 and CNR2 that are predominantly expressed in the brain and nervous system, but also in other peripheral tissues, including in the gut [1]. Both receptors have been shown to play a role in Inflammatory Bowel Disease (IBD). In particular CNR1 has been found more expressed at protein level in inflamed mucosa from ulcerative colitis (UC) and Crohn Disease (CD) patients compared with non-inflamed mucosa, whereas no changes in CNR2 have been detected so far [2]. Other ECS members have been found altered in the inflamed mucosa of UC and CD patients compared with healthy or non-inflamed mucosa. However, the results are conflicting and dependent on the technique used [2].

Aims & Methods: In this study we aimed to evaluate the gene expression profile of a panel of genes involved in ECS in the IBD colonic mucosa. Thirty patients with IBD were included in the study: 17 were diagnosed with UC and 13 with CD. For each patient inflamed mucosa (IM) and non-inflamed mucosa (NIM) was collected. Normal mucosa (NM) was collected from 17 non-IBD individuals (CTRL). The two groups of IBD patients and controls were age matched ($p>0.05$), but were different on sex distribution ($p<0.05$). The following disease parameters were considered: clinical disease status at the moment of sample collection (active/remission), age at onset, disease duration and therapeutic regimen. The expression of ten transcripts belonging to the ECS (CNR1, CNR2, DAGLA, DAGLB, FAAH, GPR18, GPR55, MGLL, PPARG, TRPV1) was analyzed by qRT-PCR in IM, NIM and CTRL specimens. The Ct values were normalized against the geometric mean of two selected housekeeping genes (HPRT1 and RPLP0). Differences among the groups were evaluated using Kruskal-Wallis Test followed by pairwise comparison, whereas Related samples Wilcoxon Signed Rank test was used to assess differences between paired tissues (IM vs NIM).

Results: The comparison between IM vs NIM in the entire IBD cohort identified the upregulation of CNR2 ($p=0.005$), whereas a downregulation of TRPV1 and GPR18 was observed ($p=0.032$, $p=0.037$, respectively). The analysis of the UC group confirmed the upregulation of CNR2 ($p=0.009$), and the downregulation of TRPV1 ($p=0.028$) in the IM compared to NIM and to CTRL ($p=0.003$). When analyzing the gene expression level in the mucosa of the 13 patients with CD only TRPV1 was identified as downregulated in IM vs CTRL ($p=0.040$). No changes in the expression of any genes were observed according to the therapeutic regimen and no difference was observed comparing patients in remission vs active disease. Moreover, no significant correlation between gene expression levels and disease duration in years was observed ($p>0.05$).

Conclusion: In this study we identified a general impairment of the expression of genes belonging to ECS in the mucosa of IBD patients. The gene expression dysregulation was more evident in patients with UC than those diagnosed with CD. Further studies on larger IBD cohorts are needed to validate the obtained preliminary results.

EARLY LIFE EMULSIFIER EXPOSURE INDUCES DYSBIOSIS AND DEFECTIVE INTESTINAL BARRIER IN THE OFFSPRING

J. Ma[1], G. Jin[1], H. Cao[1]

[1]Tianjin Medical University General Hospital, Tianjin, China., China

Introduction: During the first 3 years of life, gut microbiota undergoes critical development and maturation, making it a vital stage for health.[1, 2] Proper colonization relies on delivery mode, feeding mode, and environmental exposure.[3] Maternal-infant transmission of microbiota occurs during delivery and breastfeeding.[4] Interference with maternal gut microbiota during gestation/lactation can affect offspring's microbiota, persisting through 3 generations.

Polysorbate 80 (P80), a nonionic surfactant, disrupts intestinal barrier, causes dysbiosis/metabolic disorders. Maternal P80 intake during gestation/lactation may impact offspring. Study aims to investigate its influence on ontogeny and intestinal microbiota of 2nd and 3rd-generation offspring.

Aims & Methods: The study used six-week-old C57bl/6 mice, which were randomly assigned to two groups. One group was given sterile water throughout the study, while the other group was continuously provided with drinking water containing 1% P80. After co-housing with male mice from the same group for one week, successfully pregnant female mice were raised, and their offspring were delivered. The second generation of offspring were co-housed with their mothers and fed by maternal breast milk until weaning. Some of the second generation mice in both groups were sacrificed, and their body weight and liver weight were recorded. The remaining second generation mice were raised alone for five weeks using sterile water.

Afterward, each female mouse was co-housed with male mice from the same group for one week, respectively. Successfully pregnant female mice were raised, and their offspring were delivered. The third generation of offspring were co-housed with their mothers for three weeks before being sacrificed. The body weight and liver weight were recorded. Fecal samples and intestinal specimens were collected and stored for later assays. Ontogeny was estimated by comparing the body weight and liver mass and measuring the length of villi using HE stained specimens. The amount of goblet cells was counted using Periodic Acid-Schiff (PAS) dye. The ex-

pression of secretory IgA (sIgA) was evaluated using immunofluorescent staining. Real-time PCR (RT-PCR) was used to quantify the expression of components of tight junction and MUC2, as well as the expression of inflammatory cytokines. The fecal microbiota was analyzed using 16srDNA sequencing techniques.

Results: 1. The second and third generations of mice exposed to P80 showed shorter intestinal villus, and the third generation had shorter jejunal villus. Additionally, the P80 group had shorter colonic glands in both generations.

2. The P80 group exhibited a different composition of gut microbiota compared to the control group in both the second and third generations. Notably, Mucispirillum was less abundant in both generations.

3. Both the second and third generations of mice in the P80 group had higher expression of IL-6 and IL-1β.

4. The P80 group had lower amounts of colonic goblet cells in both the second and third generations. Additionally, the P80 group had lower expression of ZO-1 and claudin-3, lower expression of MUC2, and a lower positive rate of sIgA dye in both generations.

Conclusion: This statement suggests that exposure to P80 during gestation and lactation could potentially cause negative effects on the offspring's gut health, including disruptions to intestinal barrier function, dysbiosis, and low-grade inflammation. These effects could, in turn, impact the ontogeny or developmental trajectory of the gut.

INTESTINE-SPECIFIC DELETION OF TNK1 KINASE AMELIORATES COLITIS BY MODULATING MICROBIOTA COMPOSITION

V. Hentschel[1], H. Li[1], T. Seufferlein[1], M. Armacki[1]
[1]University Hospital Ulm, Internal Medicine I, Ulm, Germany

Introduction: Intestinal mucosa harbours a unique microbial community of central importance for the mutualistic relationship between the host and its microbiota. Additional research is warranted to characterise this "hidden" ecosystem and uncover mechanisms by which it can promote health in intestinal and systemic pathological states. We decipher how TNK1 kinase impacts the composition of mucosa-associated microbiota and its interplay with host mucosa via microbial extracellular vesicles (mEVs) and metabolites.

TNK1 is an essential player in development and functioning of the gastrointestinal tract. Whereas TNK1 expression is tightly regulated in the adult gut, and only cellular stress can reverse the otherwise strong repression of the TNK1 promoter. Indeed, TNK is highly expressed in the gut in gastrointestinal and systemic pathological conditions, e.g. IBD, sepsis, hemorrhagic shock and critical conditions. We showed that TNK1 is an essential mediator of intestinal barrier breach and subsequent organ failure. Intestinal overexpression of TNK1 elicits a sepsis-like condition by inducing stem cell apoptosis, followed by epithelial disruption and microbial translocation. Conversely, intestine-specific knockout of Tnk1 (Tnk1-KO) alleviates local and systemic signs of inflammation in a murine model of colitis.

Aims & Methods: We aim to establish the link between TNK1, microbial EVs and metabolites, and host intestinal regeneration. Mucosal microbial samples from Tnk1-KO and wild-type littermates were subjected to microbiome profiling by 16S rRNA sequencing. The therapeutic potential of Tnk1-KO microbiota was probed by microbiota transfer to germ-free wild-type recipient mice, subsequently challenged with dextran sodium sulfate colitis. Murine stool samples were obtained to characterise faecal microbial EVs and metabolites. Murine colon organoids were exploited as an ex-vivo platform to analyse TNK1 downstream signalling and cross-talk between microbial extracellular vesicles and colon epithelium.

Results: The current study shows that the TNK1 expression pattern impacts the composition of mucosa-associated microbiota in response to colitis. Namely, we show that targeting TNK1 in the intestine preserves microbial diversity and facilitates an increase in the abundance of beneficial butyrate-producing bacterial phyla. Moreover, we demonstrated in the colitis model that microbiota transplantation from Tnk1-KO mice has beneficial therapeutic potential. Further data suggest TNK1 directs changes in microbiota composition via regulation of the expression of antimicrobial peptides in the intestinal epithelium. However, how TNK1 and changed microbiota impact intestinal integrity needs to be clarified. Microbial extracellular vesicles (mEVs) and metabolites are critical components of bacterial communication with the host. Thus, we also characterised the number and size of mEVS and showed an increase in their number in stool from Tnk1-KO mice. We hypothesise that TNK1's protective effect on intestinal mucosa in colitis is mediated via microbial products-metabolites and EVs.

Conclusion: Transplantation of microbiota modified by targeting TNK1 results in the preservation of the intestinal barrier, which may be related to the modulation of bsEV secretion. Additional cargo analysis of mEV is necessary to identify potential host targets.

Introduction: Insulin-like growth factor binding protein 3 (IGFBP3) signals through the death receptor TMEM219 to modulate survival of target cells; inhibition of this signaling has been associated with a rescue of intestinal stem cell death.

Aims & Methods: Here we report the screening, generation, and characterization of fully human IgG monoclonal antibodies (mAbs) through phage display or by hybridoma technology, that block IGFBP3 or TMEM219. We used in vitro large crypts organoids (mini-guts) generated by crypts obtained from healthy subjects and from patients with inflammatory bowel

disease to test the effect of the mAbs on the regenerative potentials. Expression of intestinal stem cell markers and apoptotic markers by RT-PCR was also analyzed.

Results: Both anti-IGFBP3 and anti-TMEM219 mAbs showed high affinity binding with the target antigens and potent effects in protecting self-renewal ability of intestinal stem cells in *in vitro* relevant assays. Among all the mAbs tested, anti-TMEM219 mAbs generated by phage display, particularly Ent001, showed the highest score in displacing the IGFBP3/TMEM219 binding and in rescuing ISC expression and function in IGFBP3-cultured human mini-guts obtained from healthy donors. In human *in vitro* proof-of-concept studies, in which we generated mini-guts from patients with immune-mediated intestinal disease such as Crohn's disease, Ent001 successfully restored mini-guts growth and ISC markers' expression, while expression of the proapoptotic IGFBP3-related factor Caspase 8 was downregulated.

Conclusion: Ent001 may represent a novel IGFBP3/TMEM219 inhibitor to be further tested and developed in *in vivo* models and in clinical studies as a novel therapeutic in human diseases.

Disclosure: P.F. and F.D. hold a patent on IGFBP3/TMEM219 axis. V.M., M.N., F.C. are employees of Enthera S.r.l.

A HIGHER TH2/TREG RATIO MAY BE A MARKER OF REFRACTORY ULCERATIVE COLITIS WITH LONGER DISEASE DURATION AND FREQUENT USE OF STEROIDS AND/OR IMMUNOSUPPRESSANTS, WHEREAS HLA GENOTYPE IS NOT

M. Kaneko[1], J. Imai[2], H. Suzuki[1], K. Hozumi[3]

Introduction: Personalized therapy offers great potential to improve disease outcomes. To this end, identifying different subsets of patients according to their disease prevalence may be helpful in building therapeutic strategies. Unlike Crohn's disease (CD), ulcerative colitis (UC) is highly variable in response to treatments, including biologic agents (1). UC patients may be stratified according to distinctive cytokine profiles, excluding classical pro-inflammatory cytokines such as TNF-α and IL-6. We hypothesized that clarifying this difference in cytokine profile would help optimize therapeutic strategies.

Aims & Methods: To prove this hypothesis, both helper T-cell (Th) cytokine profiles of UC patients and HLA genotyping, which may have caused differences in immune responses, were analyzed. In this study, in a cohort of clinically and endoscopically diagnosed UC patients and/or healthy control subjects (HC) and CD patients, blood samples were examined for Th cell profiles (Th1, Th2, Th17, Treg (regulatory T cell)) and HLA typing by surface chemokines.

Results: Sixty-two patients with UC [male/female 40:22, mean age 51.1 years (22-80), mean disease duration 14.74 years (2 months-54 years), disease distribution; 11 proctitis, 18 left-sided colitis 31 cases with pancolitis and 2 other cases (right-sided colitis and local type)] were analyzed with full informed consent. Most of the UC patients were in clinical remission (8/62 active), and 31 patients had current or previous steroid use, including 1 resistant case and 23 dependent cases. Sixteen UC patients were treated with biologics (4 patients with infliximab, 1 patient with golimumab, 1 patient with adalimumab, 2 patients with ustekinumab, 1 patient with vedolizumab, and 4 patients with tofacitinib). Compared to CD and HD, UC was characterized by significantly higher Th2 and Treg low ($p<0.05$). UC was divided into high and low groups with a Th2/Treg ratio of 1.0. Those with a higher Th2/Treg ratio had significantly longer disease duration (18.91±12.45 vs 12.58±9.84, p=0.04) and tended to use steroids/immunosuppressants more frequently (66.7% vs 48.5%, p=0.26).

Moreover, such aberrant immune responses were derived from HLA typing, but interestingly, a characteristic HLA bias oriented toward lower Th2/Treg ratios (DRB1*15:02:01, DQB1*06:01:01, DPB1*09:01) (40.0% vs 78.5% , p=0.05; 92.8% vs 40.0%, p=0.02; 40.0% vs 78.5%, p=0.05).

Conclusion: Cytokine assessment may help identify patient subgroups that may benefit from therapeutic approaches that modulate Th2 cytokines. However, disease pathophysiology is not necessarily correlated with genetic factors, and various causes such as intestinal microbiota must also be considered.

Introduction: Inflammatory bowel disease (IBD), a chronic inflammatory disease of the gastrointestinal tract, is caused by various factors, including genetic factors and environmental factors, as well as dysregulated immune responses. LMT503, a novel organic small-molecule compound, has the potential to suppress pro-inflammatory cells and induce anti-inflammatory cells by modulating their cell metabolisms.

We evaluated the anti-inflammatory effects of LMT503 in a murine adoptive T cell transfer-induced colitis model.

Aims & Methods: This study was conducted to evaluate the anti-inflammatory effect of LMT503 in the murine chronic colitis model. Naïve $CD4^+CD25^-CD45RB^{high}$ $CD62L^{high}$ T cells that were isolated from wild-type mice by flow cytometry based-method and transferred to *Rag1* knock-out mice by intraperitoneal injection to induce murine adoptive T cell transfer-induced colitis. LMT503 was orally administrated (50mg/kg, 100mg/kg) for 2 weeks starting at 5 weeks after naïve T cell transfer. The disease activity index (DAI) was checked daily, and histopathological score, macroscopic injury score, and colon length were evaluated upon sacrifice. Macrophages and T cells from the spleen were analyzed by flow cytometry. Gene expression in colon tissue was measured by qRT-PCR and cytokine profiles in plasma was measured by cytometric bead array. Myeloperoxidase (MPO) activity was measured using the MPO activity kit.

Results: Oral administration of LMT503 ameliorated adoptive T cell transfer-induced colitis in mice. The DAI, histopathological score, and macroscopic injury score were significantly decreased after the administration of LMT503 in a dose-dependent manner. The LMT503-treated group showed significantly increased mucin production in the colon. Th1, Th17 cells, and M1 macrophages in the spleen were suppressed, and M2 macrophages were induced by the administration of LMT503. MPO activity and gene ex-

pressions of pro-inflammatory cytokines, such as IL-6, IL-1β, and TNF-α, in colon tissue were suppressed by the administration of LMT503. And the level of inflammatory cytokines, such as IL-2, TNF-α, and IFN-ɣ, in plasma were significantly suppressed by the administration of LMT503.
Especially, LMT503 treatment significantly increased the gene expression of peroxisome proliferator-activated receptor gamma coactivator 1-alpha (*Ppargc1a*), a master regulator of mitochondrial biogenesis, suggesting that LMT503 modulates cellular metabolism towards an anti-inflammatory metabolism.
Conclusion: Our data suggest that the anti-inflammatory effect of LMT503 ameliorates murine adoptive T cell transfer-induced colitis by modulating cellular metabolism and immune cell modulation. Therefore, LMT503 may be a novel therapeutic drug that opens new avenues for the treatment of IBD.

Introduction: Crohn's disease (CD) is a chronic disabling condition in which a consistent proportion of patients may develop stricturing complications. Despite the increasing availability of therapeutic options, to date no treatment exists for prevention or treatment of intestinal fibrosis in CD patients. Autophagy is a vital metabolic process by which the cell degrades, eliminates and recycles misfolded proteins and damaged organelles, and autophagy-related genes have been linked to CD occurrence, particularly in disease with fibrostricturing phenotype. In the intestinal mucosa, autophagy regulates oxidative stress and plays a role in controlling the inflammatory process by eliminating and degrading pathogenic bacteria and inhibiting the inflammasome complex. Increased levels of oxidized circulating biomarkers have been implicated in the pathogenesis of CD, particularly in the occurrence of tissue damage and fibrosis.
Aims & Methods: Aim of the study was to evaluate the potential role of defective autophagy in CD, and, in particular, we tested the novel hypothesis that autophagy/oxidative stress imbalance can be a relevant feature in CD patients with stenosing phenotype. We collected blood and bioptic samples from patients with CD (n=25) and in healthy controls (n=11). CD patients were divided into three groups based on their clinical history and colonoscopy findings: A) Inflammatory phenotype in remission (B1 according to Montreal Classification, with normal appearing mucosa); B) Inflammatory phenotype with active disease (B1, with endoscopic findings of inflamed mucosa); and C) stenosing (B2). We evaluated autophagy using the autophagosomal marker Lc3b-II, after extraction of total protein from bioptic samples and Western Blot analysis. Serum oxidative stress markers sNOX2-dp, H2O2, and serum hydrogen peroxide (H2O2) breakdown activity (HBA) were measured by means of ELISA method and HBA assay kit. Comparison between groups for continuous variables was carried out by ANOVA with Bonferroni correction.
Results: Lc3b-II levels are significantly reduced in samples with active inflammation (P<0.01) and stenotic phenotype (P<0.001). Remission samples have lower levels of autophagosomes (P<0.05) than healthy patients but higher than the stenotic phenotype. sNOX2-dp levels are significantly increased in groups with active inflammation (P<0.001), in remission (P<0.001), and in the stenotic group (P<0.0001).
Moreover, H_2O_2 levels are significantly increased in groups with active inflammation (P<0.01) and stenosis (P<0.01) compared to the control group. Lastly, antioxidant power is significantly reduced in groups with active inflammation (P<0.001), in remission (P<0.01), and in the stenotic group (P<0.01).
Conclusion: Autophagic and redox homeostasis are impaired in CD patients, in particular in those with stenosing phenotype. Autophagy stimulation may represent an innovative pathway for the development of future anti-fibrotic therapies in CD patients and deserves further research.
Disclosure: Nothing to disclose.

Introduction: Several changes in microbes of the gut and decreased diversity especially in inflammatory bowel disease (IBD) are well-known. The exact pathophysiological connection is lacking, but the systemic inflammation due to the microbial alterations are assumed.
Aims & Methods: This study aimed to perform analysis of faecal microbiota composition simultaneously with body composition and lipid characteristics in Crohn's disease (CD) patients to find specific microbiota profiles connected to altered metabolism and obesity. In our prospective cohort study, CD patients were enrolled. At the inclusion, demographic and clinical data, blood, and faecal samples were obtained. Disease activity was assessed by CDAI, and SES-CD. Laboratory tests were made including C-reactive protein (CRP), albumin and lipids (triglyceride, cholesterol). Faecal bacterial composition was assessed using shotgun method. Each

patient underwent a body composition analysis via bioelectrical impedance analysis. A nutritional questionnaire was filled by each subject.

Results: We analysed 27 CD patients in this study (median age was 35 IQR 13.5 years). A 44,4% and 27,3% of patients were obese based on BMI and VFA. Beta diversities were higher in non-obese patients (VTA, p<0,001), however relative abundances did not differ. Firmicutes has a lower, while C.innocuum has a higher abundance at high cholesterol level (p=0,001, p=0,0034). Adlercreutzia, *B.longum* and Blautia alterations were correlated with triglyceride level. Higher Clostridia (p=0,009) and *B.schinkii* (p=0,032) and lower Lactobacillus (p=0,035) were connected to high VFA. *B.bifidum* had richness amongst low-weight patients (p=0,01). Beside Clostridia, Eubacteriales and *R.hominis* also correlated with waist-hip ratio (p=0,04, p=0,04 and p=0.048). Higher body fat mass was paired with increased *B.schinkii* (p=0,021) and decreased *L.paragasseri* (p=0,015) and *R.intestinalis* (p=0,035). Disease activity was coupled with dysbiotic elements. Microbiota alterations were found during different treatments.

	n = 27
Gender (male, N, %)	9 (33.3)
Age (years, median (IQR)	35 (13.5)
Disease duration (years, median (IQR)	7 (11.0)
CDAI at inclusion, mean (± SD)	141 (97.2)
SES-CD at inclusion, mean (± SD)	7.4 (8.0)
Fecal calprotectin (ug/g, median, (IQR))	728.6 (626.3)
CRP at inclusion, mean (± SD)	17.0 (35.3)
Serum cholesterol (mmol/l, mean, ± SD)	4.3 (0.9)
Serum triglyceride (mmol/l, mean, ± SD)	1.6 (1.0)

Table 1. Baseline demographic and clinical characteristics of the study population [n = 27].

Conclusion: Changes in Blautia, Lactobacillus, Clostridia and Bifidobacterium abundances in obesity highlight the importance of gut microbiota in diseases with similar inflammatory background. It suggests to treat obesity to achive better disease contol in IBD and it helps to develop new therapeutic approaches, such as pre- or probiotics or personalized faecal microbiota transplantation.

Introduction: The usage of intestinal stem cell-derived organoids for intestinal diseases studies is emerging. The main reason for this is that they can be generated from the intestinal tissue and cultured *in vitro* for prolonged period. It has been shown that long-term cultured intestinal organoids maintain stable genetic and transcriptome profiles, spatial and compositional cellular arrangement and reflect the *in vivo* state of the tissue of origin [1-3].

However, the data on DNA methylation levels and its stability in colon organoids derived and sub-cultured from adult intestinal stem cells remain very scarce, especially in the context of ulcerative colitis (UC) [4-5].

Aims & Methods: The aim of the study was to evaluate the epigenetic stability of human intestinal organoids obtained and cultured from colonic biopsies of UC patients and healthy controls during long-term culture by assessing quantitative methylation level of LINE-1.

Study included control subjects (CON, n=6), patients with active UC (aUC, n=6) and quiescent UC (qUC, n=7) recruited at the Department of Gastroenterology, Hospital of Lithuanian University of Health Sciences. Bisulfite conversion of DNA samples of colon biopsies, crypts primary and sub-cultured organoids was performed (in total, n=95 DNA samples), followed by PCR amplification using biotin-labeled LINE-1 primers. Quantitative determination of methylation of LINE-1 CpG islands was performed by pyrosequencing on *PyroMark Q24* machine.

Pyrograms were analyzed using the *PyroMark Q24* software (v. 2.0.8, Qiagen), statistical analysis of quantitative methylation data (Wilcox-test) and data visualization were performed using R studio (R version 4.0.3).

Results: LINE-1 region was highly methylated in all studied biological sample groups of all conditions. The average LINE-1 methylation level when assessing all collected biological samples of corresponding group was identical in CON (66.4% ± 5.1) and qUC (66.6% ± 4.0) groups while it was slightly lower in the group of aUC (64.5% ± 4.7). Further, the tendency indicating that regardless the condition, methylation level of the initial colon biopsy samples differ significantly when comparing them to the respective epithelial colon organoid cultures was observed. In CON group, LINE-1 methylation level of late-passage organoids decreased significantly when compared to colon biopsy (by 8.1%), crypts (by 8.0%), and passage 0 (by 6.3%) and passage 1 (by 5.9%) organoids. Similarly, methylation levels of passage 1 and passage 5 organoids also differed from primary biological material in the groups of qUC (by 4.0 and 5.0%, respectively) and aUC (by 4.9 and 4.6%, respectively).

Finally, LINE-1 methylation level comparisons of organoids-derived data revealed significant differences between health conditions. Methylation level of LINE-1 region was lower in the passage 1 organoids of aUC patients when compared to either CON or qUC group (by 4.7 and 3.7%, respectively).

Interestingly, sizable decrease in LINE-1 methylation level was observed in the late-passage organoids of CON group, which, in turn, resulted in significant difference of 3.8% when compared to passage 5 organoids of qUC.

Conclusion: LINE-1 region of both healthy control and UC patients colon tissues and corresponding intestinal organoids is highly methylated, and long-term culturing of these organoids results in decrease of LINE-1 methylation level which proceeds at different pace depending on the inflammation status of primary tissue.

Introduction: Ulcerative colitis (UC) is a chronic inflammatory bowel disease with a high social and health care system burden. Despite recent advances in UC treatment with available drugs acting in different signalling pathways related to the disease, there is still a significant proportion of non-responders who end up being overtreated and exposed to treatment's secondary effects. Therefore, it would be helpful to know the activity of each inflammatory pathway involved in UC pathogenesis in order to tailor the best treatment for each patient.

Aims & Methods: The aim of our study was to measure the activation of JAK/STAT pathway and IL-6 levels in colonic biopsies from patients with UC.

Methods: A prospective, observational single-centre study was designed and it is currently on going. Adult UC patients with any endoscopic activity (Mayo Endoscopic Score (MES) > 0) in a routine colonoscopy were included. Biopsies from inflamed (endoscopically active) and non-inflamed (endoscopically inactive) colon of each patient were homogenised and processed by using RIPA buffer and ultrasounds to obtain cell lysates. Determination of the activation of JAK/STAT pathway was performed by detecting phosphorylated forms of JAK1, JAK2, JAK3, TYK2, STAT1, STAT3 and STAT4 by Western blot. Human Luminex discovery assay was used for IL-6 quantification. Data are shown as percentage, median, interquartile range (IQR) and mean ± standard deviation as appropriate.

Results: So far, 19 patients were consecutively included (median age 60.9 years (IQR 40.8-66.6), 58% female). About 47% had left-sided UC, 32% extensive UC and 21% had proctitis. Regarding endoscopic activity, 52.6% of patients showed MES-3, 42.1% MES-2 and 5.2% MES-1. IL-6 was increased in biopsies from inflamed colon, while no IL-6 was found in biopsies from non-inflamed colon (p=0.00). Median IL-6 in inflamed colonic biopsies from patients with MES-2 was 41.5pg/ml (IQR 7.4-106.7) and 51.9pg/ml (IQR 17.5-220.5) in patients with MES-3 (p=0.4). Every patient showed, at least, one phosphorylated JAK protein and one phosphorylated STAT protein from JAK/STAT pathway in inflamed colonic biopsies. Nevertheless, the pattern of activation of JAK/STAT pathway was different in all patients as shown in table 1.

Introduction: Vedolizumab is one of the current treatments for patients with inflammatory bowel disease (IBD). The efficacy and safety, along with its gut specificity, make this drug an appealing therapeutic option for IBD patients with moderate to severe disease. However, as observed for other biologic treatments, a significant proportion of patients do not have an initial response to vedolizumab treatment. Currently, there is a lack of reliable predictive tools for vedolizumab treatment response, although this would help to alleviate the socioeconomic costs derived from this disease.

Aims & Methods: The primary aim of this study is to show putative transcriptional signatures associated with vedolizumab treatment response.

Methods: For the realization of this study, we used RNA-seq datasets from the Gene Expression Omnibus (GEO) database: GSE191328. This dataset includes samples from peripheral blood cells from responder and non-responder ulcerative colitis (UC) patients treated with vedolizumab and infliximab at baseline. Gene Set Enrichment Analysis (GSEA) was performed to compare the differential expression and the enrichment analysis was calculated using ssGSEA of the different groups under study.

Results: The analysis of the transcriptome of peripheral blood cells from responder (R) and non-responder (NR) vedolizumab-treated patients at baseline revealed interesting enrichment results. We found 20 gene sets positively enriched in NR versus R and only 9 gene sets negatively enriched in the same phenotypes. In order to find vedolizumab specific transcriptional signatures, we performed a similar analysis in samples from infliximab-treated patients. After that second round of analysis, we observed that around 50% of the enriched gene sets were similar for both biological treatments. Nevertheless, several interesting biological functions such as peroxisome function, reactive oxygen function or beta-catenin signalling are specifically enriched in NR patients to vedolizumab treatment.
Conclusion: Our data suggest that vedolizumab NR patients specifically show a transcriptional enrichment profile, which differs from vedolizumab R patients. Also, the comparative analysis with infliximab-treated patients reveals that those specific transcripts are modulated in response to this α4β7 integrin antibodies in peripheral blood cells. Therefore, we found a solid system to search for vedolizumab therapy predictive response markers using low invasive techniques.

Introduction: MicroRNAs (miRs) can modulate the development and/or progression of chronic inflammation in patients with Crohn's disease (CD), influencing the efficacy of treatments.
Aims & Methods: The objective was to assess the miRs content of circulating exosomes in the peripheral blood of patients with CD to identify new biomarkers useful in disease management. Patients with CD diagnosed and followed up at the Hospital General Universitario de Alicante and healthy controls were included. Extracellular vesicles were isolated from serum and exosomes were quantified by "Nanoparticle Tracking Analysis" (NTA), confirmed by Transmission Electron Microscopy (TEM) and by specific markers (Tsg101, CD63, CD81) by Western blot, performing an expression analysis of a non-targeted panel of human miRs from exosomal RNA. Patient and control samples were also subjected to enzyme-linked immunosorbent assay (ELISA) measurement of different target-predicted protein substrates.
Results: Thirty patients and ten controls were included in the study. Patients were 42±9 years old, disease duration 62±9 months, 40% women and 80% showed ileal or ileocolonic involvement. Six patients (20%) had perianal disease. Ninety-three per cent were undergoing biological treatment with infliximab (IFX, n=13), adalimumab (ADA, n=8) or ustekinumab (USTE, n=7). A significant increase in exosome concentration was observed in the serum of patients vs controls. NTA and TEM confirmed the size and purity of the obtained exosomes. The distribution in the expression of miRs and its differential analysis showed a significant increase in miR-376a-3p as well as a reduction in miR-20a-5p in patients vs. healthy controls. Functional analysis of miR-376a-3p determined its interaction with gene targets involved in autophagy (ATG4C), TGF-b signaling (ACVR1C) and cell survival (PIK3R1, IGF1R). Protein levels of these substrates indicated the potential control of TGF-beta signaling pathway by the downregulation of ACVR1C, and the increase in survival pathway measured by IGFR1 presence in patient's serum.
Conclusion: CD patients show a higher number of circulating exosomes, with an overexpression of miR-376a-3p. The involvement of this microRNA in different intracellular signaling pathways suggests its participation in the unbalance of the immune activity present in CD.
Disclosure: The authors declare that they have no conflict of interest.

Introduction: The pathogenesis of inflammatory bowel disease (IBD) involves a complex interplay among a genetically susceptible host, environmental factors, dysregulated immune response, and intestinal microbiota. Multiple studies have documented differences in the composition of gut microbiota between patients with IBD and healthy individuals, particularly regarding microbial diversity and relative abundance of specific bacteria. However, studies generally include patients treated with immunosuppressive therapy, which may modify the microbiota and can make a result harder to interpret.

Aims & Methods: Our aim was to elucidate the microbiota in newly diagnosed IBD patients compared to healthy controls (HC), and the differences between patients with Crohn's disease (CD) and ulcerative colitis (UC). Stool samples were collected from IBD patients before having started any treatment for the disease and HC from a biobank. Shotgun metagenomic sequencing was performed in each sample, and subsequent bioinformatic analyses were done with Cutadapt, Kraken2 and Bracken programs. IBD activity was classified by the Simple Endoscopic Score in the case of CD (SES-CD) and by the endoscopic subscore of the Mayo index in the case of UC.

Results: We included 104 patients with CD, 145 with UC and 49 HC. Patients with CD had a statistically significant decrease in the α-diversity, calculated with Shannon Index on species-level taxa, compared with UC and HC groups; in addition, an inverse relationship was observed between the severity of activity and microbial α-diversity. However, in patients with UC the microbial α-diversity was similar to HC cohort. We also calculated the β-diversity between pair-wise combinations using Bray-Curtis dissimilarity, showing that this index was lower in UC vs. HC compared to CD vs. HC. Regarding to the severity of disease in CD patients, β-diversity index increased directly with severity. On the other hand, we found no differences between severity activity groups in UC patients. Considering the taxonomic abundance at the microbial species taxonomic level, the greatest differences in patients with CD globally and those with severe activity, were found in *Lactobacillus paragasseri* and *Gemella haemolysans*, compared to HC. However, patients with mild CD had the greatest differences in several species of *Shigella* genus, and those with moderate CD in *Granulicatella elegans*. Patients with UC globally, and particularly with mild, moderate and severe activity, showed the greatest differences in *Toxoplasma gondii* and *Aspergillus oryzae*, compared with HC.

Conclusion: Our data suggest that patients with CD, from the moment of diagnosis, showed relevant differences in the composition of the microbiota compared with UC patients and HC individuals; however, UC microbiome is relatively closer to HC. Moreover, the severity of IBD is associated with the distribution of species in fecal microbiota.

Introduction: Intestinal fibrosis affects most inflammatory bowel disease (IBD) patients, resulting in severe clinical complications and reduced treatment response. With no treatments approved for intestinal fibrosis, there is a need for preclinical models to investigate the pathobiology and novel treatments. Myofibroblasts are the main drivers of intestinal fibrosis and the excessive accumulation of extracellular matrix in IBD patients. We investigated a prolonged scar-in-a-jar model of colonic fibrogenesis to validate protein fingerprint (PF) biomarkers of collagen formation for clinical use and the *in vitro* model as a screening tool.

Aims & Methods: Human colonic fibroblasts (CCD-18co, ATCC) were grown in EMEM supplemented with 10% FBS and 1% P/S in culture flasks with 200 µg/cm^3 gelatin to reduce cell activation. At 80% confluency, the cells were seeded at 30,000 cells/well in a 48-well plate noted as day -2. The cells were either stimulated from day 0 and every fourth day, except day 15, with either 50 pM TGF-β or 0.1 % DMSO. Starting at day 4 certain wells were co-stimulated with TGF-β1 and an ALK5 inhibitor (ALK5i) (0.01, 0.1, 1.0, or 10.0 µM). The experiment was terminated on day 15 upon which wells were decellularized and the collagen matrix stained with Sirius Red for visual confirmation of collagen formation. Imaging was done using light microscopy at X20 magnification using similar settings for all images. Fibrogenesis was quantitatively determined by measuring the biomarkers PRO-C1, PRO-C3, and PRO-C6 in the supernatants. The biomarkers reflect type I, type III, and type VI collagen formation, respectively. We applied Šídák's multiple comparisons test for differences in the collagen formation biomarker levels calculated as ng/mL or percentage change from day 4 following ALK5i stimulation.

Results: Stimulation with TGF-β signifcantly increased type I, III, and VI collagen formation at days 4, 8, 12, and 15 compared to DMSO stimulated cells quantified with the PRO-C1, PRO-C3, and PRO-C6 biomarkers as ng/mL (p value <0.0001) (Table 1). On day 4 certain cells were co-stimulated with TGF-β1 and an ALK5i, resulting in a significant reduction of type I, III, and VI collagen formation at days 8, 12, and 15 (p value <0.0001) (Table 1). The reduction of the collagen formation biomarkers were largest when stimulating with 1.0 or 10.0 µM of ALK5i, reducing PRO-C1 up to 125.7% on day 12, PRO-C3 up to 560.1% on day 12, and PRO-C3 up to 68.2% on day 8. Collagen deposition was confirmed by Sirius Red (data not shown). To determine stimulation effects on the metabolic activity, Alamar blue was measured on days 0 and 15 demonstrating no significant difference between TGF-β1 and the highest concentration of ALK5i (10.0 µM) (Table 1).

Stimulation comparison	PRO-C1, Type I collagen formation (Day)	PRO-C3, Type III collagen formation (Day)	PRO-C6, Type VI collagen formation (Day)	p-value for comparison(s) (Days 0, 4, 8, 12, and 15)
TGF-β1 vs. DMSO	191.7 vs. 75.9 (Day 4); 282.5 vs. 94.9 (Day 8); 273.1 vs. 100.4 (Day 12); 209.2 vs. 99.3 (ng/mL)	1.5 vs. 1.4 (Day 4); 3.8 vs. 1.4 (Day 8); 9.0 vs. 2.0 (Day 12); 10.5 vs. 1.7 (ng/mL)	0.8 vs. 0.4 (Day 4); 0.7 vs. 0.4 (Day 8); 0.5 vs. 04 (Day 12); 0.4 vs 0.4 (ng/mL)	PRO-C1 (all: <0.0001); PRO-C3 (ns, <0.01, <0.0001, <0.0001); PRO-C6 (<0.01, <0.01, ns, ns)
TGF-β1 vs. 0.01 µM ALK5 inhibitor	50.2% vs. 21.5% (Day 8); 43.3% vs. 14.4% (Day 12); 10.0% vs. 4.6% (Day 15)	155.1% vs. 128.8% (Day 8); 511.7% vs. 419.8% (Day 12); 606.6% vs. 400.1% (Day 15)	14.3% vs. -30.1% (Day 8); -29.4% vs. -51.4% (Day 12); -35.2% vs. -52.3% (Day 15)	PRO-C1 (all: ns); PRO-C3 (ns, ns, ns, <0.01); PRO-C6 (all: ns)
TGF-β1 vs. 0.1 µM ALK5 inhibitor	50.2% vs. 19.0% (Day 8); 43.3% vs. 1.7% (Day 12); 10.0% vs. 2.3% (Day 15)	155.1% vs. 66.5% (Day 8); 511.7% vs. 473.2% (Day 12); 606.6% vs. 437.4% (Day 15)	14.3% vs. -9.6% (Day 8); -29.4% vs. -42.4% (Day 12); -35.2% vs. -40.3% (Day 15)	PRO-C1 (ns, ns, <0.05, ns); PRO-C3 (ns, ns, ns, <0.05); PRO-C6 (
TGF-β1 vs. 1.0 µM ALK5 inhibitor	50.2% vs. -31.9% (Day 8); 43.3% vs. -63.4% (Day 12); 10.0% vs. -62.3% (Day 15)	155.1% vs. 22.5% (Day 8); 511.7% vs. 84.5% (Day 12); 606.6% vs. 51.1% (Day 15)	14.3% vs. -53.9% (Day 8); -29.4% vs. -54.0% (Day 12); -35.2% vs. -54.0% (Day 15)	PRO-C1 (ns, <0.0001, <0.0001, <0.0001); PRO-C3 (ns, ns, <0.0001, <0.0001); PRO-C6 (
TGF-β1 vs. 10.0 µM ALK5 inhibitor	50.2% vs. -56.1% (Day 8); 43.3% vs. -82.4% (Day 12); 10.0% vs. -82.1% (Day 15)	155.1% vs. 6.1% (Day 8); 511.7% vs. 100.7% (Day 12); 606.6% vs. 46.5% (Day 15)	14.3% vs. -49.1% (Day 8); -29.4% vs. -54.3% (Day 12); -35.2% vs. -54.3% (Day 15)	PRO-C1 (ns, <0.0001, <0.0001, <0.0001); PRO-C3 (ns, <0.05, <0.0001, <0.0001); PRO-C6 (ns, <0.05, ns, ns)
	Metabolic Activity at Day 0	Metabolic Activity at Day 15		
TGF-β1 vs. 10 µM ALK5i	11928 vs. 11352	12058 vs. 10368		Day 0 (ns) and Day 15 (ns)

Conclusion: PF biomarkers can be applied *in vitro* to quantify fibrogenesis objectively, demonstrating a significant increase following TGF-β stimulation of colonic fibroblasts. The model may be combined with the biomarkers to evaluate drug targets of intestinal fibrosis.

Introduction: Lymphocyte trafficking to the inflamed gut is one of the hallmarks of Inflammatory Bowel Disease (IBD) pathology. Integrin a4b7 and its ligand MADCAM1 play an important role in targeting immune cells in the bloodstream to mucosal tissues and blocking this pathway using the anti-a4b7 monoclonal antibody Vedolizumab (VDZ) proved to be an effective treatment in IBD.

However, VDZ is most efficient in treatment of Ulcerative Colitis (UC) and of colonic rather than ileal Crohn's Disease (CD), for which the reasons have not been completely understood.

Aims & Methods: Aim: To compare the expression of ITGA4, ITGB7 and MADCAM1 in gut tissue biopsies from small and large bowel with respect to the underlying severity of tissue inflammation.

Methods: Differential gene expression analysis was conducted using bulk RNA Sequencing data generated from gut tissue biopsies of the large and small intestine of 611 CD and 315 UC patients enrolled in a multicentred longitudinal Study of a Prospective Adult Research Cohort with IBD (SPARC IBD) obtained from the IBD Plexus program of the Crohn's and Colitis Foundation. Gene expression levels of ITGA4, ITGB7 and MADCAM1 were compared across ileal, colonic and rectal segments of the intestine and data were then linked to available measures of local inflammation.

Results: ITGA4, ITGB7 and MADCAM1 were expressed at comparable levels in large vs small bowel biopsies. Expression of MADCAM1 was significantly increased in both ileal and colonic biopsies from patients with moderate to severe CD based on segmental or composite endoscopy score (SES-CD) across all bowel segments. Expression of both ITGA4 and ITGB7 was similarly increased in colonic biopsies of moderate/severe CD patients, whereas only minor changes were observed for both genes in ileal biopsies. Similar findings were obtained from UC patients, where expression of MADCAM1 was significantly increased in inflamed or ulcerated biopsies from both sigmoid colon and cecum as compared to normal appearing biopsies. Expression of ITGA4 and ITGB7 was only increased in inflamed/ulcerated biopsies of the sigmoid colon but not the cecum and correlated with the modified Mayo endoscopic score (MMES).

Conclusion: Our analysis suggests that influx of leukocytes to inflamed tissue via ITGA4/ITGB7 and MADCAM1 interactions is more common in the distal colon compared to proximal colon or ileum. This provides a possible mechanistic explanation as to why VDZ is most effective in patients with colonic IBD. Further work is needed to understand the differential regulation of cell trafficking to different regions of the gut.

AIR POLLUTION PARTICULATE MATTER FROM COTTONWOOD AS A DEVELOPMENT FACTOR OF INFLAMMATORY BOWEL DISEASES

M. Korbush[1], T. Dovbynchuk[2], T. Borisova[3], G. Tolstanova[1]
[1]Taras Shevchenko National University of Kyiv, Institute of High Technologies, Kyiv, Ukraine, [2]Taras Shevchenko National University of Kyiv, ESC Institute of Biology and Medicine, Kyiv, Ukraine, [3]O. Introduction: Worldwide, air pollutants shorten the average human lifespan by approximately 1.8 years (1). Recent studies are drawing attention to the fact that particulate matter (PM) – one of the major air pollutants (2) and can contribute to the development of gastrointestinal tract (GI) diseases (3). At the same time, the role of PM in the development of inflammatory bowel diseases (IBD) remains poorly understood. An important aspect is the dependence on the type of pollutant and the strength of its negative impact. Previously, we have shown that carbon-containing nanoparticles from the combustion of cottonwood are the most toxic compared to wood and leaves of birch and pine (4).

Aims & Methods: Our work aimed to study the chronic effect of air pollution particulate matter obtained from the combustion of cottonwood (PM_C) on the state of the intestinal barrier and to evaluate their ability to promote the development of inflammation under conditions of experimental colitis in rats.

PM_C was administered orally to Wistar rats (180-200 g, n = 40) at a dose of 180 µg/100 g once a day for 7 days. Experimental colitis was induced by a single rectal injection of 0.1 ml of a 6% solution of iodoacetamide (IA) dissolved in a 1% solution of methylcellulose (7 cm from the anus using a rubber catheter). Colitis modelling was performed on the 8th day of the experiment. Rats were euthanized 2 hours after iodoacetamide administration. We examined endothelium permeability by Evans blue (EB) extravasation (µg/g wet colon), level of myeloperoxidase (MPO) activity, total glycoprotein level at the mucosal surface by PAS-staining, colon weight, bodyweight percentage changes and water content in feces.

Results: After a seven-day oral administration of PM_C or vehicle, the body weight gain in the PM_C-pretreated group was 10% less compared to the control ($p < 0.01$), and the water content in feces was elevated by 7% ($p < 0.05$), which may denote an impairment of water absorption processes in the large intestine. Induction of IA-colitis on the 8th day of the experiment revealed a decrease from 185.00±19.28 units up to 85.67±23.37 units ($p < 0.01$) in the colonic surface mucus glycoproteins and increased colonic mucosa MPO level from 6.75±2.06 to 8.73±1.29 ($p < 0.05$) in PM_C-pretreated vs vehicle-pretreated group of rats. Moreover, PM_C-pretreated rats had increased colonic vascular permeability vs the vehicle-pretreated group. For the control group, the level of EB dye extravasation was 18.80±1.79 µg/g wet colon, while in the group with chronic exposure to PM_C, it was 24.00±0.66 µg/g wet colon ($p < 0.05$). The colon weight was also higher ($p < 0.05$) in PM_C-pretreated rats (1.07±0.04 g/100 g of body weight) vs vehicle-pretreated group (0.92±0.01 g/100 g of body weight) after the IA-colitis induction.

Conclusion: Long-term exposure to PM_C contributes to the violation of intestinal barrier integrity in the colon of rats. In particular, it reduces the level of the glycan part of mucus glycoproteins and increases colonic

endothelial permeability. In aggregate, this results in the development of proinflammatory changes in the colon, confirmed by the increase in MPO activity and diarrhoea development, and can be the reason for the development of iodoacetamide-modelled colitis.

HUMAN DENTAL-PULP MESENCHYMAL STEM CELLS AMELIORATE TNBS-INDUCED INTESTINAL FIBROSIS VIA BALANCING PRO-AND ANTI-FIBROTIC SIGNALING PATHWAYS

F. Zhou[1], X. Qian[2], J. Zheng[2], C. Peng[1], Y. Xie[1], X. Zou[1], X. Zhang[1], L. Wang[1]

Introduction: Intestinal fibrosis is a late Crohn's disease (CD) complication characterized by poor treatment efficacy and prognosis[1]. Mesenchymal stem cells (MSCs) have the characteristics of multidirectional differentiation and immune regulation and are expected to become a new means of CD treatment[2]. Human dental-pulp MSC (hDP-MSC), originating from the neural crest, is easy to obtain and exhibits a strong immune-modulating ability[3].

Aims & Methods: We aimed in this study to demonstrate the roles of hDP-MSC in intestinal fibrosis. We established a TNBS-induced mouse chronic intestinal fibrosis model and observed the effect of hDP-MSC on the mouse model, with human umbilical cord MSC (hUC-MSC) as a positive control. To track the location of MSC in vivo, MSCs tagged with indocyanine green were injected into the tail vein of the mouse, and fluorescence was analyzed with in vivo imaging system. Besides, we performed Hematoxylin-Eosin staining, Masson staining, western blotting, and ELISA to determine the expression level of pro-fibrotic markers and inflammatory cytokines. Furthermore, to determine the possible mechanism of MSC in intestinal fibrosis, transcriptome sequencing of intestinal tissues of all four groups was applied to analyze pathway changes in the MSC treatment group.

Results: Both intravenous injections of hDP-MSC and hUC-MSC attenuated body weight loss, reduced colon length shortening, lowered disease activity index (DAI), and macroscopic fibrosis score of TNBS modeling mice, with hDP-MSC more statistically significant. Western blotting showed that the expression level of Fibronectin, Collagen I, and α-SMA was increased in the TNBS modeling group, but was decreased in the MSC treatment group. ELISA showed that hDP-MSC significantly decreased the levels of proinflammatory cytokine IL-1β, IL-6, and TNF-α. For transcriptome sequencing, the top ten differentially expressed gene (DEG) of the hDP-MSC versus TNBS modeling group was *MMP3, Pla2g5, Rfx2, Sh3rf3, H4c4, Slc34a2, Cldn4, Hbegf, Ibhba, Myo18b*. KEGG pathway enrichment of all DEGs showed that the TGF-β signaling pathway was inhibited in the hDP-MSC group, while the IFN-γ signaling pathway was activated.

Conclusion: Collectively, our findings identify that hDP-MSC ameliorates intestinal fibrosis through balancing pro-and anti-fibrotic signaling pathways, which might act as a novel therapeutic approach for the treatment of intestinal fibrosis in Crohn's disease.

Introduction: Inflammatory bowel disease (IBD) is a chronic inflammatory disease of the gastrointestinal tract that results from various factors, including genetic factors, inappropriate immune response, changes in gut microbiota balance, and oxidative stress.[1, 2] *Bifidobacterium longum* is a representative bifidobacterium that exists in the human gastrointestinal tract and plays a significant role in protecting against colitis.[3] Oxidative stress elicits an unfavorable environment for the survival and colonization of beneficial probiotics as well as causing tissue damage in colitis.[4, 5]

Aims & Methods: In this study, we aimed to identify the genome characteristics, ROS-resistant properties, colonization abilities, and anti-colitic effects of the newly isolated *B. longum* strain (*B. longum* S2) from the feces of a healthy adult in South Korea. Viability of *B. longum* S2 against hydrogen peroxide was assessed using H_2O_2-containing media. The antioxidant activity of *B. longum* S2 was measured using the ABTS and DPPH assays. Colonization in the colon was observed using a scanning electron microscope. Whole genome sequencing, data assembly, and gene analysis were performed. The anti-colitic effects were evaluated in mice using 2.5% DSS-induced colitis and adoptive T cell transfer models. Bifidobacterium was

administrated by oral gavage 1 × 10^9 CFU and the disease activity index (DAI) was scored. Colon length was measured and the histopathologic score was assessed with PAS-stained colon tissue. T cells in lamina propria mononuclear cells from the small intestine, lymphocytes from the spleen, and peritoneal cavity cells were analyzed using flow cytometry. Epithelial barrier function was evaluated using a FITC-dextran permeability assay on Caco-2 cells. Gene expression and cytokine profiles were analyzed using qRT-PCR.

Results: *B. longum* S2 colonies in H_2O_2-containing media were observed more frequently than those of other bifidobacterium strains. The antioxidant activity of *B. longum* S2 on ABTS and DPPH radicals was higher than that exhibited by other bifidobacterium strains. We identified that *B. longum* S2 possesses oxidative response genes, such as LexA and HrcA, through pan-genome and comparative genome analysis. However, the average nucleotide identity highlights a 94.92% value with respect to *B. longum* ATCC, 98.65% with respect to *B. longum* JCM1217 and 98.64% with respect to *B. longum* NCTC 11818, supporting the characteristics of *B. longum* S2 as a novel strain of bifidobacteria. *B. longum* S2-treated group showed alleviation of the colitis index, including a higher survival rate, restoration of body weight loss and colon shortening, and improvement of the DAI compared to the control group. *B. longum* S2 treatment significantly decreased the loss of goblet cell and the histopathological score in colon tissues. *B. longum* S2 induced the expression of markers of Treg cells and M2 macrophages in the isolated mouse tissues. Moreover, the *B. longum* S2-treated group showed decreased gene expression of pro-inflammatory cytokines, including mucin gene, compared to the control group. Pre-treatment with *B. longum* S2 significantly reduced the TNF-α-induced permeability of intestinal epithelial cells, suggesting that B. longum S2 improves epithelial barrier function.

Conclusion: Our study revealed that the newly isolated *B. longum* strain, *B. longum* S2, possesses unique anti-colitic effects and colonization abilities, as demonstrated in both in vitro experiments and in two different mouse colitis models. These findings strongly suggest that *B. longum* S2 holds great promise as a potential treatment for IBD.

Introduction: Lymphocytic colitis (LC) is a debilitating, non-destructive inflammatory bowel disease (IBD) that causes intense watery, non-bloody diarrhoea. LC is diagnosed by an increased lymphocyte infiltration in the mucosa that has been correlated with increased Th1/Th17 cytokine secretion and subsequent sodium malabsorption. Still, LC pathomechanisms have not been fully characterized and its relation to other forms of IBD is unclear.

Aims & Methods: Our aim was to define a LC-specific transcriptome to gain insight into LC pathology, identify genetic signatures uniquely linked to LC, and uncover potentially druggable disease pathways. For that, we performed whole mucosa bulk RNA-sequencing of LC and collagenous colitis (CC) samples from patients with active disease, and healthy controls (n=4-10 per cohort). Differential gene expression was analyzed by gene-set enrichment and deconvolution analyses to identify pathologically relevant pathways and cells, respectively, altered in LC. Key findings were validated using reverse transcription quantitative PCR and/or immunohistochemistry. Finally, we compared our sequencing data to a previous cohort of ulcerative colitis and Crohn's disease patients (n=4 per group) to distinguish non-destructive from classic IBD.

Results: The LC-specific transcriptome was defined by a limited mucosal immune response against microbiota compared to CC and classic IBD samples. In contrast, we noted a distinct induction of regulatory non-coding RNA species in LC samples. Moreover, compared to CC, we observed decreased water channel and cell adhesion molecule gene expression, which was associated with reduced intestinal epithelial cell proliferation.

Conclusion: We conclude that LC is a pathomechanistically distinct disease that is characterized by a dampened immune response despite massive mucosal immune cell infiltration. Our results point to regulatory micro-RNAs as a potential disease-specific feature that may be amenable to therapeutic intervention.

Introduction: Xanthine oxidase (XO) catalyzes the oxidation of hypoxanthine to xanthine and xanthine to uric acid (UA) with the production of superoxide anion. The accumulation of UA has been shown to initiate the inflammatory process through NLRP3 inflammasome and the production of reactive oxygen species (ROS), which contributes to inflammation-related tissue damage observed in inflammatory bowel disease (IBD). In murine models of colitis, XO inhibitors, allopurinol or febuxostat, reduced the expression of proinflammatory cytokines supporting the involvement of XO in the intestinal inflammatory process.

Aims & Methods: The aim of this study was to evaluate the expression level and enzymatic activity of XO in the intestinal mucosa of IBD patients (pts), both ulcerative colitis (UC) and Crohn's disease (CD), compared to healthy controls (HC).

Sigmoid-colon biopsies from consecutive UC and CD pts, with a confirmed diagnosis (by ECCO guidelines) in regular follow-up at University Hospital of Cagliari with an indication to endoscopy according to standard clinical practice, were collected. Site-matched biopsies from individuals undergoing screening colonoscopy for colorectal cancer were used as controls.

Demographic data and endoscopic grade for disease activity scored by endoscopic Mayo and SES-CD score were collected. Real-Time PCR was used to evaluate XO relative expression levels (RQ) and data was confirmed by analyzing GEO database (study code GSE11223). XO activity was measured in whole protein extracts from biopsies by spectrophotometric quantification of UA production and expressed as nmol of UA/min/mg of total protein. The relative abundance of XO was further investigated by Western Blot. Finally, XO expression was assessed in sections of paraffin-embedded intestinal biopsies by immunohistochemistry.

Results: Biopsies of 15 HC, 20 UC, and 15 CD pts were collected. Mean age was 50 for UC, 49 for CD and 54 for HC. Mayo endoscopic subscore was 0 in 25% of UC pts, 1 in 18,75%, 2 in 21,2% and 3 in 25%. SES-CD was between 0-2 in 28,6% of CD pts, 3-6 in 21,4%, 7-14 in 42,8% and >14 in 7,1%. Real-time PCR showed that XO expression values were increased in the sigmoid mucosa of pts with UC compared with HC individuals (RQ 1,93 vs 0,99. p=0,004). This data was confirmed by analysis of XO expression in the GEO database study code GSE11223. The difference in XO expression between HC and CD was not statistically significant (p=0,13). Western blot analysis of XO protein expression in CD and UC pts compared with HC showed a significant increase in IBD pts (p<0,001).

XO activity was significantly higher in UC and CD pts as compared to HC. XO activity mean was 3,75 in UC pts and 5,10 in CD pts vs 1,11 nmol of UA/min/mg of protein in HC individuals (p<0.001). Moreover, in UC pts XO activity was correlated with Mayo endoscopic sub-score (r= 0.346; p=0.05). Immunohistochemistry confirmed higher expression of XO in IBD pts than HC with a prevalent expression observed in epithelial cells.

Conclusion: XO expression was higher in UC pts than in HC individuals. XO activity was higher in both CD and UC pts than HC and in UC pts XO activity correlated with endoscopic disease suggesting its potential role as therapeutic target.

Introduction: Collagenous colitis (CC) and lymphocytic colitis (LC), the two main subtypes of microscopic colitis (MC), are chronic inflammatory diseases of the colon of unknown etiology. Colonic barrier dysfunction has been identified in patients with MC. However, whether molecular and structural alterations underlie an aberrant barrier in MC remains to be defined.

Aims & Methods: To identify the molecular pathways involved in the colonic epithelial brush border structure and its ultrastructural alterations in MC. Total RNA and protein were obtained from sigmoid mucosal biopsies of healthy controls (Hc) (N=11), patients with active diarrhoea predominant irritable bowel syndrome (IBS-D) patients (N=13), and active newly diagnosed naive of treatment MC patients (N=12 CC and N=12 LC). Transcriptomic and proteomic analyses were performed by RNAseq analysis and liquid chromatography mass spectrometry, respectively. Additionally, in a subset of patients (N=8 CC, N=8 LC, N=8 IBS-D and N=8 Hc) sigmoid biospies were collected and processed for scanning and transmission electron microscopy (SEM and TEM, respectively), to perform a qualitative and quantitative assessment of the colonic epithelium. Integrated data assessment was performed to explore biological and molecular functions.

Results: By RNA-Seq enrichment study, three microvilli-related pathways (organization, regulation of microvilli organization and length) were significantly enriched in the colonic mucosa of CC patients compared to LC, IBS-D and Hc. The integrated multi-omic analysis identified 28 genes with a significant positive correlation between RNA expression and its corresponding protein expression, (4 genes with a strong correlation (r>0.7, p<0.05) and 21 genes with a moderate correlation (0.3<r<0.7, p<0.05)), which were related to each other at the network level by string database

analysis. Reduced expression of the microvilli proteins, was observed in CC compared to Hc, IBS-D and LC patients. Reduced expression of the actin-binding proteins, was also observed in CC. Moreover, decreased protein expression and an increased expression of proteins in the actin-membrane junction, were observed in CC and LC. Ultrastructural observation revealed that microvilli on the colonic surface of MC patients were more scattered, irregular and shorter in MC than IBS-D and Hc.

Furthermore, the number of microvilli per colonocyte length (microvilli/um) was lower in CC (3.7[2.8-5.3], p<0.0001) and LC patients (5.2[4.0-6.6], p=0.01) compared to Hc (7.5[6.6-8.7]). Similarly, microvilli length was also reduced in CC (0.5[0.4-0.8], p=0.0003) and LC (0.6[0.4-1.1], p=0.04) patients compared to Hc (1.1[1.0-1.4]). No differences in the number and length of microvilli were observed between IBS-D and Hc groups.

Conclusion: Dysregulated brush border molecular pathways underlie epithelial colonic dysfunction in MC compared to Hc and IBS-D patients at both molecular and ultrastructural levels. These previously undescribed data open new perspectives in defining the pathophysiological mechanisms of MC, especially in CC. Given the fundamental role of the brush border in maintaining intestinal homeostasis and even water absorption, further understanding of these mechanisms may have significant diagnostic and therapeutic implications for MC.

Introduction: Crohn's disease (CD) is a chronic inflammatory disease that can affect all segments of the gastrointestinal tract, resulting in deficiencies, particularly of vitamins. They result from a decrease in ingesta, malabsorption or exudative enteropathy and metabolic alterations induced by the inflammation. These deficiencies may alter the course of the disease.

Aims & Methods: The aim of our work is to describe the most frequent deficiencies in patients with CD: they concern in particular iron, vitamin D, vitamin B12, folate and vitamin B1.

This was a single-centre retrospective descriptive study including all patients followed for Crohn's disease in the hepato-gatsroenterology department. Biological assays of iron, vitamins B12, B9, B1 (if called) and vitamin D were performed in all patients at the time of diagnosis.

Results: Among 1045 patients followed for Crohn's disease in our department, 199 or 19.04% of patients had vitamin deficiencies, of which 64.3% (n=128) were women with an average age of 36.4 years.

Vitamin D deficiency was found in 76.7% (n=153) of cases, of which ileocolic deficiency was found in 63.4% (n=97), colonic deficiency in 24.8% (n=38), ileal deficiency in 8.5% (n=13), and greensecolic deficiency in 3.3% (n=5). Iron deficiency in 74.4% (n=148) of which ileo-colic in 58.8% (n=87), colonic in 25.7% (n=38), ileal in 10.8% (n=10) and greacolic in 4.7% (n=7). Vitamin B9 deficiency in 14.6% (n=28) of cases, of which ileocolic deficiency was found in 60.7% (n=17), colonic deficiency in 17.8% (n=5), ileal deficiency in 10.7% (n=3), and greacolic deficiency in 10.7% (n=3) respectively And vitamin B12 deficiency in 6% (n=12); of which the involvement was colonic in 66.8% (n=8), ileo-colic ileal in 16.6% (n=2) respectively. Concerning vitamin B1, 1% (n=2) of the patients had a deficiency; of which one patient presented a neurological complication such as "Wernicke-Korsakoff syndrome" which recovered well after vitamin correction.

Conclusion: Vitamin deficiencies are common in CD and can impact on patient outcomes by increasing morbidity and complications. These deficiencies require systematic screening during follow-up, as well as appropriate management with dietary advice.

Disclosure: Nothing to disclose.

Introduction: Type 2 glycoprotein (GP2) is a quantitatively predominant membrane protein of excretory granules of pancreatic acinar cells. In a number of studies, it has been demonstrated that this protein is the main antigen for pancreatic antibodies associated with Crohn's disease (CD). Zonulin – a protein that can reversibly increase the permeability of the intestinal wall by changing the structure of tight junctions of the lateral surfaces of intestinal epithelial cells. The determination of fecal zonulin is used for noninvasive assessment of increased intestinal permeability. Normal values of fecal zonulin (≤ 110 ng/ml) indicate the absence of damage to the villous surface of the intestinal mucosa and normal density of intercellular contacts.

Aims & Methods: The aim of the study was to establish the dependence of the level of type 2 glycoprotein on the level of fecal zonulin (FZ) in the feces of CD patients with exacerbation of the disease.

Material and methods. 122 patients with CD in the form of ilekolitis with exacerbation of the disease (Me age — 32 years) were examined. FZ was evaluated by ELISA (IDK ® Zonulin ELISA Kit, Immunodiagnostik AG, Germany) in ng/ml. Reference values: < 83.15 ng/ml is a variant of the norm, 83.15-110 ng/ml is an elevated level, 110 ng/ml is a high level.

The level of IgG and IgA to GP2 (antibodies to glycoprotein) antigen of pancreatic centroacinar cells (Anti-GP2, IgG, IgA) was determined by ELISA. Reference values: IgG GP-2 less than 10 units/ml, Ig and GP-2 less than 5 units/ml – positive values.

Results: In the stool samples of CD patients during the period of exacerbation in 92 (75,4%) patients, an increase in FZ was detected, the average value was 333.4 ±16.9 ng/ml. In the blood samples of 81 (66,4%) patients with CD during the period of exacerbation, an increase in Ig A GP-2 was detected, the average value was 43.4±6.9 units/ml. In the blood samples of 107 CD patients during the period of exacerbation, an increase in Ig G GP-2 was detected, the average value was 17.1 ± 1.3 units/ml. There is a high correlation force between the concentration of FZ and the concentration of Ig A GP-2 (r-0.760) (p=0.010). There is a moderate correlation force (r-0.490) (p=0.023) between the concentration of FZ and the concentration of Ig G GP-2.

Conclusion: An increase in the concentration of FZ in the feces of CD patients during exacerbation significantly correlates with an increase in the concentration of Ig A GP-2 and Ig G GP-2.

Contact E-Mail Address: marta.seco@uv.es

Introduction: Fibrosis is a complication commonly present in Crohn's disease (CD) patients with a structuring (B2) or penetrating (B3) behaviour, with no available treatment. This process is characterized by an excessive extracellular matrix deposition, mainly associated with a dysregulated function of myofibroblasts.

Aims & Methods: We analyse here, the expression of markers of senescence in human small intestinal fibroblasts (HSIF). HSIF (P10760, Innoprot, Spain) were treated during 48h with 20ng/ml of TNFα, 2ng/ml of IL-1β, 5ng/ml of TGFβ1, and 100ng/ml of PDGF. In some cases, fibroblasts were treated with 20nM of siRNA to ETS1 gene (siETS1) or negative control (NC). Gene expression profiles were analysed by RT-qPCR.

Results: Treatment of fibroblasts with IL-1β, PDGF, and TNF-α significantly increased the mRNA expression of different senescence-associated secretory phenotype (SASP) factors (IL-1α, IL-1β, IL-8, and Serpine1). In addition IL-1β also increase the expression of metalloprotease ADAM12 and the chitinase CHI3L1 and the transcription factor related to senescence ETS proto-oncogene 1 (ETS1) and the antiapoptotic factor MCL1, all compared with vehicle treatment. Furthermore, treatment with PDGF significantly increased the mRNA expression of MCL1, ETS1, P21 and P16. Treatment with TGFβ1 increase extracellular matrix components COL1A1 and COMP and the senescence related factor ETS1 and decrease the expression of IL1B. Treatment with TNFα increase the expression of ETS1 but decrease the expression of ADAM12. Finally, a cellular model of depletion of ETS1 treated with IL1β showed that deficiency of this protein can reduce levels of IL1B, IL1A, and CHI3L1 gene expression that were upregulated with IL-1β treatment. Also, this depletion increases the induction of SERPINE1 and ADAM12 observed after treatment with IL-1β.

Conclusion: In human primary intestinal fibroblasts, treatment with IL1-β, PDGF, and TNF-α increased the expression of senescence associated secretory phenotype while treatment with PDGF increased the expression of markers involved in cell cycle arrest. The induction of ETS1 by both treatments and the involvement of this transcription factor regulating gene expression could suggest that ETS1 functions as a double-edged sword inducing inflammation but also repressing the expression of ECM remodelers in intestinal fibroblasts.

Disclosure: Nothing to disclose.

THE NLRP3 INFLAMMASOME IS UPREGULATED ON MRNA EXPRESSION LEVEL AND ACTIVATED ON PROTEIN LEVEL IN INFLAMMATORY BOWEL DISEASE PATIENTS IN A SYSTEMATIC META-ANALYSIS AND IN A NEW OBSERVATIONAL STUDY COHORT

P. Metselaar[1], R. Menke[1], N. Seretis[1], R. Schilder[1], W.J. de Jonge[1], M. Lowenberg[2], A. te Velde[1]

Contact E-Mail Address: p.i.metselaar@amsterdamumc.nl

Introduction: Inflammatory bowel diseases (IBD), including ulcerative colitis (UC) and Crohn's disease (CD), are non-infectious chronic inflammatory disorders of the gastro-intestinal tract. The continuous presence of inflammatory stimuli, such as increased circulation of cytokines and danger-associated molecular patterns (DAMPs), leads to an enhanced immune response in these patients that could explain some types of disease relapse. An important receptor for DAMPS and pathogen-associated molecular patterns (PAMPs) is NLRP3, a cytosolic pattern recognition receptor. The NLRP3 inflammasome is exclusively activated by inflammatory stimuli, like DAMPs and PAMPs, and therefore not expressed without inflammation. It is thought that NLRP3 associates with ASC to recruit pro-Caspase 1 to the NLRP3 inflammasome and cleave it to its active form. In turn, Caspase 1 cleaves pro-interleukin 1 beta (IL-1β) and pro-interleukin 18 (IL-18) to their mature forms. IL-1β is a known elevated pro-inflammatory cytokine in IBD, promoting intestinal inflammation and immune cell recruitment. We hypothesized that the NLRP3 inflammasome pathway is therefore upregulated in IBD patients.

Aims & Methods: We first set out to systematically analyze gene expression of *NLRP3* and *IL1B* in IBD patients by performing a systematic literature review and subsequent meta-analysis according to the PRISMA guidelines and Cochrane Collaboration methods. Subsequently, an observational cohort of 70 active and quiescent patients with CD or UC was sampled for whole blood, to study NLRP3 inflammasome gene regulation, protein production, assembly and secretion. We performed *ex vivo* LPS and ATP challenges of whole blood, with and without NLRP3 inflammasome formation inhibitor MCC950.

Results: Across thirty studies with publicly available mRNA expression data, we found *NLRP3* and *IL1B* expression to be significantly higher in IBD patients than in non-IBD controls. In fresh IBD patient-derived whole blood, LPS and ATP stimulation activated the NLRP3-related genes, protein production and subsequent cytokine secretion. No IL-1β and IL-18 were secreted upon incubation with MCC950, suggesting a crucial role for NLRP3 inflammasome assembly in IL-1β and IL-18 production in immune cells. In patients with active IBD, the inflammasome was transcribed at a higher level than in patients in remission. However, this effect was lost on the protein level. We found a large spread in IL-1β and IL-18 production, suggesting a variation in activation of the NLRP3 inflammasome between individuals which was not related to disease activity.

Conclusion: *NLRP3* and *IL1B* mRNA transcription is significantly increased in IBD patients compared to non-IBD controls, and significantly higher in patients with active disease than in patients in remission. While this fits the inflammatory state of active IBD, we found that the level of IL-1β and IL-18 production by the NLRP3 inflammasome is not significantly different between disease states. This suggests a variance in individual immune response to challenges, that could help identify a subset of IBD patients that would benefit from additional therapies directed at NLRP3 and IL-1β.

Disclosure: Nothing to disclose.

Contact E-Mail Address: Giusiarboretto@gmail.com

Introduction: *Hericium erinaceus* (*H. erinaceus*), berberine and quercetin showed anti-inflammatory potential in mouse models of experimental colitis. *H. erinaceus* (class *Agaricomycetes*, phylum *Basidiomycota*) is a mushroom belonging to traditional Chinese medicine that has been demonstrated in experimental colitis to be able to control pathways induced by Nuclear Factor kappa-light-chain-enhancer of activated B cells in an anti-inflammatory direction by suppressing the production of Tumor Necrosis Factor (TNF) and increasing the expression of Interleukin-10 (IL-10).

Aims & Methods: This *ex vivo* study aimed to evaluate the anti-inflammatory potential of a nutraceutical compound of *H. erinaceus*, berberine, quercetin, biotin and niacin (HBQ-Complex®) in Inflammatory bowel diseases (IBD) tissues obtained from both Normal-Appearing Mucosa (NAM) and Inflamed Mucosa (IM) tracts of patients with Crohn's Disease (CD) and patients with Ulcerative Colitis (CD). NAM tracts were identified from colic segments with Simple Endoscopic Score for CD = 0 or Mayo Endoscopic subscore = 0 (for CD and UC, respectively). NAM and one IM samples were frozen at -70° and then evaluated at T0. Two other IM samples were grown in DMEM medium in a temperature-controlled incubator and exposed to HBQ-Complex® for 120 minutes (T1) and 180 minutes (T2). RT-PCR and Western blot evaluations were performed for TNF, IL-10 and cyclooxygenase 2 (COX-2) at T0, T1, and T2. The HBQ-Complex® consisted of 525 mg of *H. erinaceus* powder (5 % polysaccharides from sporophorum) and 225 mg of *H. erinaceus* as an extract (30 % polysaccharides from sporophorum), 75 mg of quercetin titled to 98 %, 225 µg of biotin, 27 mg of niacin and, finally, 75 mg of Berberis vulgaris titled to 97 %.

Results: 20 IBD treatment-*naïve* patients (50% CD, 50% UC) were enrolled. None of them had other comorbidities or was taking drug therapies within six months of the start of the study. According to the Harvey-Bradshaw index and partial Mayo score, four patients had mild CD and six moderate CD. The same was for UC patients. At T0, both CD and UC samples showed TNF and COX-2 genic expressions higher in IM than NAM ($p < 0.0001$). In IM samples, Incubation with HBQ-Complex® resulted in a progressive decrease in gene and protein COX-2 and TNF expression at T1/T2 in CD ($p=0.002$) and UC ($p=0.003$) samples.

However, IL-10 showed an opposite trend, with a progressive genic expression increase from T0 to T1 ($p=0.054$) and T1 to T2 ($p=0.002$). The same was for UC samples ($p < 0.01$). These variations in PCR expressions of mRNAs were also recalculated from the same protein variations at Western blot analysis.

Conclusion: HBQ-Complex® might possess nutraceutical therapeutic potential in IBD. This could be explored in translational studies evaluating whether HBQ-Complex® can impact IBD's already validated clinical, endoscopic, and histological parameters.

THE DEPENDENCE OF THE CONCENTRATION OF TYPE 2 GLYCOPROTEIN ON THE CONCENTRATION OF ZONULIN IN CROHN'S DISEASE DURING REMISSION OF THE DISEASE

A. Kagramanova[1], O. Knyazev[1,2], A. Novikov[1], E. Alexandrova[1], B. Nanaeva[2], R. Gudkova[1], D. Kulakov[1], A. Parfenov[1]

[1]Moscow Clinical Scientific Center named after A.S. Loginov, Moscow, Russia, [2]State Scientific Centre of Coloproctology named after A.N. Ryzhyh, Moscow, Russia

Contact E-Mail Address: kagramanova@me.com

Introduction: Type 2 Glycoprotein (GP2) is a quantitatively predominant membrane protein of excretory granules of pancreatic acinar cells. In a number of studies, it has been demonstrated that this protein is the main antigen for pancreatic antibodies associated with Crohn's disease Zonulin – a protein that can reversibly increase the permeability of the intestinal wall by changing the structure of tight junctions of the lateral surfaces of intestinal epithelial cells. The determination of fecal zonulin is used for noninvasive assessment of increased intestinal permeability. Normal values of fecal zonulin (≤ 110 ng/ml) indicate the absence of damage to the villous surface of the intestinal mucosa and normal density of intercellular contacts

Aims & Methods: The aim of the study was to establish the dependence of the level of type 2 glycoprotein on the level of fecal zonulin (FZ) in the feces of CD patients with exacerbation of the disease.

Material and methods. 217 patients with CD in remission of the disease (Me age — 38 years) were examined. FZ was evaluated by ELISA (IDK ® Zonulin ELISA Kit, Immunodiagnostik AG, Germany) in ng/ml. Reference values: < 83.15 ng/ml - a variant of the norm, 83.15-110 ng/ml - an elevated level, 110 ng/ml - a high level.

The level of IgG and IgA to GP2 (antibodies to glycoprotein) antigen of pancreatic centroacinar cells (Anti-GP2, IgG, IgA) was determined by ELISA. Reference values: IgG GP-2 less than 10 units/ml, Ig And GP-2 less than 5 units/ml – positive values.

Results: In the stool samples of CD patients during remission in 76 (35%) patients, an increase in the FZ was detected, the average value was 235.4±11.6 ng/ml. In the blood samples of 59 (27.2%) CD patients during remission, an increase in Ig A GP-2 was detected, the average value was 24.4±1.9 units/ml. In the blood samples of 137 CD patients during remission, an increase in Ig G GP-2 was detected, the average value was 19.7±1.1 units/ml. There is no correlation between the concentration of FZ and the concentration of Ig A GP-2 (r-0.260) ($p>0.05$). There is a moderate correlation force (r-0.310) ($p=0.033$) between the concentration of FZ and the concentration of Ig G GP-2.

Conclusion: There is no correlation between the concentration of FZ in the feces of CD patients during remission with the concentration of Ig A GP-2 and Ig G GP-2 in the blood serum of patients.

Disclosure: Nothing to disclose.

THE ROLE AND MECHANISM OF A20 IN INTESTINAL INFLAMMATION BY REGULATING MITOCHONDRIAL DAMAGE/MITOPHAGY

J. Xu[1], M. Yu[1], Y. Chen[1], J. Li[2], L. Wang[1], L. Chen[1], H. Liu[1], Y. Shen[1], D. Tian[1], U. Seidler[3], F. Xiao[1]
[1]Tongji Medical College, Huazhong University of Science and Technology, Department of Gastroenterology, Wuhan, China, [2]Tongji Medical College, Huazhong University of Science and Technology, Department of Nephrology, Wuhan, China, [3]Hannover Medical School, Hannover, Germany

Contact E-Mail Address: 958827277@qq.com

Introduction: A20 is a protein encoded by tumor necrosis factor alpha-inducible protein 3 (TNFAIP3) that acts as an important negative regulator of inflammation through its cooperative activity as a de-ubiquitinating enzyme and a ubiquitin ligase. Intestinal inflammation is associated with the dysregulation of mitophagy, in which ubiquitination and deubiquitination systems play a key role. However, whether A20 participates in intestinal inflammation by regulating mitophagy remains unclear. This study aimed to investigate whether the A20 protein is involved in mitophagy in intestinal inflammation with its function as a ubiquitin-editing enzyme.

Aims & Methods: WT and *Tnfaip3*$^{+/-}$ mice were fed with 3% Dextran Sulphate Sodium (DSS) for 7 days continuously to induce colitis models. Colon length, DAI, colon histological score, and expression levels of pro-inflammatory cytokines were evaluated among groups. Oxidative stress indicators, the structure of mitochondria, the number of mitochondria and autophagosomes, and mitophagy-associated proteins in the colon were detected by transmission electron microscope and western blot, etc. Co-immunoprecipitation and immunofluorescence were performed to detect the regulatory relationship between A20 and PINK1 and TOM20 in HT-29 cells.

Results: A20 knockdown led to severe colonic inflammation and greater oxidative stress in colon tissue, and this difference was more pronounced in DSS-induced colitis. Mitochondrial damage in the *Tnfaip3*$^{+/-}$ group was more severe with or without DSS treatment, which was specifically manifested as disordered mitochondrial structure, decreased mitochondrial number, increased mitochondrial membrane potential, and decreased mitochondrial ATP content. In addition, more mitophagy was observed in the *Tnfaip3*$^{+/-}$ group, and even more so after DSS treatment. A higher number of lysosomes and autophagosomes, and higher expression levels of PINK1, P62, and LC3BII/I ratio were shown in both mitochondria and cytoplasm. Furthermore, the interaction between PINK1 and A20 is enhanced during mitophagy. Knocking down the expression of PINK1 or A20 both affected the normal mitophagy process. The expression of A20 and phosphorylated A20 protein in mitochondrial components increased and the binding of A20 with mitochondrial outer membrane protein TOM20 was enhanced during mitophagy, these phenomena were attenuated after PINK1 siRNA transfection.

Conclusion: A20 was involved in the regulation of mitophagy by PINK1 phosphorylation and binding to mitochondrial outer membrane protein TOM20 to reduce intestinal inflammation.

Disclosure: Nothing to disclose.

Introduction: The etiology and pathogenesis of inflammatory bowel disease (IBD), which includes Crohn's disease (CD) and ulcerative colitis (UC) are complex and the mechanisms that lead to the development of these diseases remain unclear.

Extracellular vesicles (EVs) are small particles covered with a cell membrane, originating from the emitting cell, excreted into the extracellular medium, and subsequently captured by receptor cells. EVs have a role in multiple diseases and they could also have a function in IBD pathogenesis. Therefore, the analysis of EVs isolated from the serum of newly diagnosed IBD patients (before starting any treatment) may represent an appropriate experimental approach to elucidate their role in IBD pathogenesis.

Aims & Methods: We aimed to evaluate EVs' composition and potential effects in the pathogenesis of IBD. To assay this, EVs were isolated by size exclusion chromatography from the 500 µl of serum from 100 patients with IBD (50 patients with CD and 50 patients with UC) recently diagnosed and 50 healthy controls (HC). Then, the protein loaded in the EVs was characterized by proteomics and their size and concentration in serum by

Nanoparticle tracking analysis (NTA). The biological function of EVs and alterations in signaling pathways related to IBD were determined using Ingenuity Pathways Analysis (IPA) to analyze the OMICs results.

Results: A total of 1,100 proteins have been identified, of which 105 proteins were differentially expressed by patients with CD versus HC, 111 proteins by patients with UC versus HC, and 32 proteins by patients with UC versus CD. IPA analysis revealed that proteins carried in EVs are involved in the dysregulation of immune pathways such as the acute phase response, LXR/RXR activation pathway, and the complement pathway. These pathways were regulated differentially in IBD patients compared with HC, but also when the CU group was compared with the CD group being upregulated nuclear receptors signaling and cytotoxicity pathways.

Conclusion: EVs carry proteins that can be involved in the dysregulation of the immune system in IBD; this effect would be different in UC and CD since their EVs show a differential profile. Consequently, EVs may play role in IBD pathogenesis and source of strong biomarkers candidates for diagnosis in UC and CD. Further studies on their specific function during IBD are warranted.

REMOVAL OF DIETARY FIBER INCREASES THE SEVERITY AND DELAYS THE RECOVERY OF DSS-INDUCED COLITIS IN MICE, INDEPENDENT OF SHORT-CHAIN FATTY ACID RECEPTOR SIGNALING

J. Hunt[1], M. Yassin[2], B. Hartmann[1], S. Offermann[3], L.O. Dragsted[4], J.J. Holst[1], H. Kissow[1]

Contact E-Mail Address: jenna.hunt@sund.ku.dk

Introduction: Dietary fiber influences the intestinal mucosa and improves intestinal function. The beneficial role of fiber is thought to be mediated by short chain fatty acids (SCFAs) - the main fermentation products of dietary fiber. Glucagon-like peptide-1 (GLP-1) is known to protect against intestinal injury and mice fed a fiber-free (FF) diet have shown loss of intestinal mass and decreased tissue levels of GLP-1. Here, we aimed to 1) investigate how a FF diet might affect the colonic luminal content of SCFAs 2) investigate ability of SCFAs to drive colonic GLP-1 secretion and 3) assess the impact of a low fiber diet on the colonic vulnerability to intestinal injury. We also aimed to investigate the involvement of the free fatty acid receptors 2 (FFAR2) and 3 (FFAR3) and the GLP-1 receptor (GLP-1R) in a model of intestinal injury.

Aims & Methods: Female C57BL/6JRj mice were fed a FF diet (Altromin 1013), or standard chow diet (Altromin C1310) for 21 days and the SCFA concentrations in colonic contents were analyzed by liquid chromatography–mass spectrometry. A SCFA mix (100 mM) was applied luminally in our isolated perfused colon model and GLP-1 levels were measured in the venous effluent. Female C57BL/6JRj mice fed a FF diet or chow were exposed to 3% dextran sulfate sodium (DSS) in drinking water for up to 7 days to induce colitis. Mice were killed at day 13. This was repeated in FFAR2/3 knock out (KO) mice and in GLP-1R KO mice. Wild type (WT) littermates were used as controls. End points were body weight (BW) loss, disease activity index (DAI), colon weight, colon length and histological severity score.

Results: 21 days of FF feeding decreased the concentrations of SCFA in colon content significantly. Overall, the total measured SCFAs were decreased by more than 50% in the FF fed group ($p<0.05$) with specific decreases in acetate ($p<0.05$), propionate ($p<0.05$), and butyrate ($p<0.001$). SCFAs delivered to the isolated perfused colon increased GLP-1 secretion by 40% ($p<0.01$). In the DSS model, the removal of dietary fiber increased the severity of colitis and delayed the recovery. At day 4 FF fed mice had bloody diarrhea and DSS treatment was discontinued. From day 4 to the end of the experiment, FF fed mice had a significantly larger BW loss than chow fed mice (day 7: 25% vs 10%, $p<0.001$). At day 13 all chow fed mice had recovered their BW, but FF fed still showed a significant BW loss of 15% of baseline BW. DAI was significantly increased in the FF fed mice. Only 50% of the FF fed mice survived to day 13 whereas all mice fed chow survived. At day 13 colonic weight was increased ($p<0.001$), colonic length decreased ($p<0.05$) and histological severity score increased ($p<0.001$) in the FF fed mice. GLP-1 KO mice exposed to DSS had a significant larger BW loss from day 10 to day 13 day compared to WT ($p<0.05$). WT mice recovered their BW to normal at the end of experiment, whereas GLP-1R KO mice had a weight loss of 8% of baseline BW. No other parameters in the GLP-1R KO mice differed from WT mice. Colitis severity was independent of FFAR2 and FFAR3 signaling, FFAR2/3 KO mice were comparable to WT littermates in all parameters.

Conclusion: A low intake of dietary fiber reduced the colonic SCFA and reduced the resilience to colitis. Luminal SCFA were able to increase GLP-1 secretion in the isolated perfused colon and GLP-1 receptor signaling showed importance in the maintenance of BW in the diseased mouse. However, the pathway from a low fiber diet to severe colitis seemed to be independent of FFAR2/3 signaling.

References:

A low intake of dietary fiber reduced the colonic SCFA and reduced the resilience to colitis. Luminal SCFA were able to increase GLP-1 secretion in the isolated perfused colon and GLP-1 receptor signaling showed importance in the maintenance of BW in the diseased mouse. However, the pathway from a low fiber diet to severe colitis seemed to be independent of FFAR2/3 signaling.

Introduction: Micronutrient deficiency of amino acids display a hitherto underappreciated role in the pathophysiology of IBD. Serine is a nonessential amino acid and directly involved in the cellular redox balance. In the absence of sufficient external supply, serine can be synthesized via glycolysis through the rate-limiting enzyme phosphoglycerate dehydroge-

nase (PHGDH). Serine metabolism is upregulated in cancer and immune cells, maintaining survival and growth. However, its role in coordinating cellular function in the context of IBD is not known.

Aims & Methods: We hypothesized that serine metabolism provides a novel and underappreciated metabolic switch to maintain immunological homeostasis in the intestinal epithelium of IBD patients.We assessed the gene expression of the rate-limiting enzymes of de novo serine synthesis *PHGDH* in two cross-sectional IBD cohorts (1. N=67, 2. N=212 patients) and linked *PHGDH* expression with endoscopic or clinical disease activity. We used murine small intestinal epithelial cells (Mode-K cells) and murine small intestinal and colon organoids to understand the molecular regulator of de novo serine synthesis via PHGDH.

To assess the potential role of PHGDH in coordinating innate immune response, Mode-K cells were treated with LPS or tunicamycin in the presence or absence of the Phgdh inhibitor BI-4916. The impact of proinflammatory cytokines *Cxcl1* and *Il6* was assessed through qPCR and ELISA. Upstream activation of the NFκB signaling pathway was assessed by WB. Seahorse assay was conducted to evaluate the impact of Phgdh on mitochondrial function.

Results: Compared with healthy control, serine metabolic enzyme *PHGDH* was significantly increased in both UC and CD patients. *PHGDH* expression correlated with the degree of inflammation in tissue biopsies of IBD patients correlated with ER stress marker (*HSP90B1*). Chemical induction of ER stress strongly increased the expression of *Phgdh, Psat1,* and *Psph* in Mode-K cells and intestinal organoids. To assess the regulatory role of serine metabolism on innate immune function, Mode-K cells were treated in serine/glycine-deprived medium. PHGDH function was inhibited using the specific inhibitor BI-4916. Treatment with tunicamycin or LPS resulted in strong induction of the proinflammatory cytokines *Cxcl1* and *Il6.* Parallel Seahorse assay displayed significantly disrupted mitochondrial function (basal-, ATP linked- and maximum respiration). As serine feeds into the 1C-metabolism to provide mitochondrial-derived formate, we co-treated cells with glycine and formate to overcome the functional consequences of deprived de novo serine synthesis. We show that co-treatment of glycine and formate rescued mitochondrial dysfunction and inhibited *Cxcl1* overactivation in intestinal epithelial cells.

Conclusion: Our data provide a novel link on how disrupted serine metabolism directly fuels epithelial-derived proinflammatory mechanisms via disruption of mitochondrial function. Our data suggest a so far underappreciated role of cellular serine metabolism on IBD pathophysiology.

Contact E-Mail Address: v.lopez-agudelo@ikmb.uni-kiel.de

Introduction: Women with IBD have an increased risk of preterm and cesarian delivery and low birth weight infants. Although IBD pathogenesis has been associated with different factors including genetics and dysbiosis in gut microbiome, very little is known about the relationship between IBD, microbiota, and pregnancy. Mutations in the *ATG16L1* gene have been associated with Crohn's disease susceptibility, impaired autophagy, and Paneth cell defect. Here, we explored the gut microbiome composition and functional potential of *Atg16l1* knockout (KO, *Atg16l1*$^{\Delta IEC}$) restricted to intestinal epithelial cells (IEC) and their floxed littermates (WT, *Atg16l1*$^{fl/fl}$) mice during pregnancy.

Aims & Methods: Fecal samples of pregnant mice were collected during trimester three (just before delivery) and after weaning and the isolated DNAs were subjected to 16S rRNA amplicon sequencing and shotgun metagenomics sequencing. 16S data were pre-processed, quality filtered, trimmed, and denoised on established pipelines inside QIIME2. Shotgun reads were processed using an in-house established workflow from our institute that relies on BBtools and bowtie2 for mapping and host decontamination, and bioBakery tools for taxonomic and functional assignments. Taxonomic profiles were assigned by classifying all ASVs on the SILVA 138 rRNA reference database and clade-specific marker genes from MetaPhlAn4. Functional potential profiling (stratified pathways, gene families, and enzyme categories) in the metagenomics samples were captured using HUMAnN 3.6. Longitudinal and pair-wise differences were evaluated using the R package MaAslin2.

Results: Pregnancy resulted in a temporal shift in microbial composition between WT and KO pregnant mice at trimester 3 with partial recovery of microbial composition after the weaning period (b-diversity). Likewise, we observed longitudinal alterations in relative abundances of some IBD-specific microbiota biomarkers genera such as *Lachnospiraceae*, *Roseburia*, *Ruminococcus*, *Colidextribacter* and *Turicibacter*. In addition, we found that the gut microbiota of *Atg16l1*$^{\Delta IEC}$ mice has increased potential to synthesize fatty acids, glutamine, and branched-chain amino acids.

Conclusion: Late stages of pregnancy induce changes in gut microbiota composition and metabolic potential in mice lacking *Atg16l1* specifically in the intestinal epithelium (*Atg16l1*$^{\Delta IEC}$) compared to WT (*Atg16l1*$^{fl/fl}$) mice. Understanding these pregnancy-dependent microbiome changes may constitute the first steps in the identification of bacteria-specific biomarkers that could help maintaining a healthy and successful pregnancy in IBD patients.

EFFECTS OF ANTI-TNF AND ANTI-INTERLEUKINS 12 AND 23 DRUGS ON CIRCULATING DENDRITIC CELLS MIGRATORY CAPACITY IN INFLAMMATORY BOWEL DISEASE

I. Soleto[1], C. Ramirez[1], C. Gómez[1], M. Baldan Martin[1], S. García[1], M. Orejudo del Río[1], J. Mercado[1], M. Chaparro[1], J. Gisbert[1]

[1]Hospital Universitario de La Princesa, Instituto de Investigación Sanitaria Princesa (IIS-Princesa), Universidad Autónoma de Madrid (UAM), and Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain

Contact E-Mail Address: mbaldanm@gmail.com

Introduction: Inflammatory bowel disease (IBD) is an idiopathic and chronic disorder that includes ulcerative colitis (UC) and Crohn's disease (CD). Both diseases are different but show an uncontrolled intestinal immune response that generates tissue inflammation. Dendritic cells (DC) are phagocytic professional antigen presenting cells that link the innate and adaptive immune systems. Indeed, they are the only cell type able to stimulate naïve T cells generating an antigen-specific immune response. In humans, DC can be divided into plasmacytoid (pDC) and c conventional type 1 and 2 (cDC1, cDC2). Although cDC migration towards the GI mucosa is enhanced in IBD, the mechanisms underlying these migrations and whether biological drugs can modulate them are currently unknown.

Aims & Methods: This study aimed to analyze DC migratory capacity towards the GI mucosa, and whether biological drugs with different mechanisms of action can modulate this process in health and IBD.This is a

cross-sectional observational postmarketing study where the modulatory effect of different biological treatments on samples from patients with an endoscopic diagnosis of IBD and healthy controls was studied *ex vivo*. Peripheral blood mononuclear cells (PBMC) were obtained from 15 patients per group and were cultured in presence of golimumab or ustekinumab. Following culture, surface markers expression was determined, assessing the differential effect of biological drugs (if any) over the DC subsets in the different groups. After that, the migratory capacity of circulating DC towards CCL2, CCL25, and MadCam1 from the different study groups was determined. Finally, we evaluated the DC migratory capacities in presence of biological drugs or with culture media alone.

Results: The cDC2 subset showed higher expression levels of β7 and CCR5 compared to cDC1. Golimumab and ustekinumab did not modify the expression of the homing markers in any studied subset in pDC and cDC2.On the contrary, in cDC1 both golimumab and ustekinumab increased CCR6 expression in qCD patients and CCR9 in aUC patients. Regarding to the migratory capacities of the different DC subsets toward intestinal chemoattractants ustekinumab decreased the migratory capacity of cDC2 from CD patients towards a medium supplemented with MadCam1 and increases toward CCL2 in case of cDC1 from CU. In the case of migratory capacities of cDC2 from HC were increased by ustekinumab and golimumab toward CCL2 and CCL25 just in case of golimumab.

Conclusion: cDC2 showed more migratory profile markers than other DC populations. Golimumab and ustekinumab modify the expression of the homing markers just in cDC1 subset. Nevertheless, ustekinumab and golimumab modify the migratory capacities of cDC in IBD patients and HC, but do not exert any effect on pDC. These effects occur in a different manner in CD and UC indicates that the behavior of cDC is different in CD and UC, and that the migration capacity of this subset is not dependent exclusively on homing markers.

Contact E-Mail Address: mbaldanm@gmail.com

Introduction: The response rate to hepatitis B virus (HBV) vaccination in the general population is about 90%. However, the response rate to the vaccine in patients with inflammatory bowel disease (IBD) is significantly lower. IBD is a multifactorial disease so, it is important to study which cell subsets are involved in the failure of the HBV vaccine.

Aims & Methods: Our main objective was to study the differences between the peripheral immune system of responders and not responders to the vaccine. It is an observational clinical practice study on the factors associated with the immunogenicity of the HBV vaccine in patients with IBD. Per clinical practice, 19 IBD patients vaccinated for the first time against HBV were included. Patients were divided according to their vaccination response after three doses of the vaccine at 0, 1, and 6 months as responders (≥ 100 anti-HBV) and non-responders (< 100 anti-HBV). Blood was collected before and after vaccination to characterize the different immune subsets by flow cytometry. Data were analyzed manually and by high dimensional data analysis (UMAP and FlowSOM).

Results: Non-responders displayed a lower percentage of naïve T cells compared with those who responded while responders had a lower percentage of Th2 and CD4 central memory subsets before vaccination. According to the high dimensional data analysis, 22 different T-cell metaclusters were identified. Indeed, the percentage of type 2 conventional dendritic cells was increased following vaccination in both responders and non-responders, allowing us to identify 11 submetacluster.

Finally, The percentage of IgG class switch and IgG plasmablasts were increased following vaccination in the responders group, while the percentage of IgM plasmablast was increased in non-responders. Using the high dimensional data analysis 26 different subpopulations, were identified.

Conclusion: The proportion of circulating T cell subsets can be used as predictor markers of the response to the HBV vaccine in IBD patients: while non-responders showed a lower percentage of naïve T cells, responders presented a lower percentage of Th2 T cells compared with their counterparts. The analysis of the data reveals that high-resolution and high-dimensional data, show several clusters containing events that evade the canonical definition.

EXAMINING MENTAL HEALTH DISEASE BURDEN AMONG CROHN'S DISEASE (CD) PATIENTS IN EUROPE

M. Thoo[1], P. Robinson[2], D. Baldock[2]

[1]Ipsos, Healthcare Syndicated, Kuala Lumpur, Malaysia, [2]Ipsos, Healthcare Syndicated, London, United Kingdom

Contact E-Mail Address: denise.baldock@ipsos.com

Introduction: Mental health is an overlooked aspect of inflammatory bowel disease (IBD) patient care and the most common psychological conditions in patients with IBD are anxiety and depression[1]. The objective of this study was to examine the possible factors that will impact mental health burden of CD patients in Europe.

Aims & Methods: A multi-centre online medical chart review study of patients with CD was conducted between Jul – Sep 2022 among UK, FR, DE, IT & ES gastroenterologists practicing across hospital and private practices. Physicians were screened for practice duration and patient volume. Charts of patients prescribed with advanced therapy were included in the analysis.

Results: 206 sampled physicians collectively reported 1178 CD patients. From the reported CD patients, 190 suffered mental health burden (depression or anxiety) and 988 CD patients did not suffered any mental health burden. Among CD patients suffered mental health burden, a higher proportion of CD patients are female vs those who did not suffered any (55% vs 46%). 'Family history of IBD' was the co-morbidity more likely to experience in reported CD patients suffered mental health burden vs those who did not (11% vs 7%).

When looking at employment status between these two patient groups, reported CD patients suffer mental health burden was less likely to be in full-time employment vs those not suffered mental health burden. A higher proportion of reported CD patients suffered mental health burden were in part-time employment or housewife/househusband.

CD patients	Suffered mental health burden	NOT suffered mental health burden
% full-time employment	47%	62%
% part-time employment	22%	14%
% housewife/ husband	8%	4%

Table 1: Employment status in reported CD patients (% patients)

CD patients with mental health burden had greater CRP level than patients without mental health burden (CRP mean: 16 vs 12). This aligns with reported CD patients with mental health burden had frequent surgery times vs without mental health burden (Mean surgery times: 2 vs 1) and had greater steroid usage (% reported patients currently on steroids – 18% vs 13%).

Conclusion: Comparisons in this study cohort highlight there are other factors could impact CD patients' mental health burden other than IBD itself. This coincided with low full-time employment rate that attributed to financial stress may increase CD patients' mental health burden. Also, higher rate of surgery and steroid usage in CD patients experienced mental health burden might suggest they had more severe or complications with their disease that will impact overall mental health. Further investigation using comparator cohort is warranted.

Introduction: In recent years, evidence shows that long non-coding RNAs (lncRNAs) are key regulators of gene transcription and play important roles in the pathogenesis of inflammatory bowel diseases. LncRNAs are involved in the regulation of intestinal epithelial cell apoptosis, cell-cell interactions, and enhancing inflammation, among others. Biological therapies, which are considered the most potent for disease control, only benefit one-third of patients. For this reason, a deeper understanding of the mechanisms by which biological drugs elicit their effect on intestinal mucosal is needed. Hence, we aimed to unravel the *ex vivo* modulator effect of infliximab on the lncRNAs expression in intestinal biopsies from patients with Crohn's Disease (CD).

Aims & Methods: We performed an unbiased transcriptomic analysis of intestinal biopsies from the ileum and colon from 30 patients [active CD = 10, quiescent CD = 10, healthy controls (HC) = 10] to identify lncRNA differentially expressed in the setting of infliximab modulation. Endoscopic biopsies were cultured with or without infliximab and the transcriptome was determined by Illumina gene expression array. We used different databases (Ensembl Biomart, RNAcentral and ToppGene) to search for non-annotated lncRNA information and data on the location (cellular component), biological process and molecular function of differentially expressed lncRNAs.

Results: Transcriptomic results revealed a widespread dysregulation of lncRNAs in ileum biopsies from patients with active CD, quiescent CD and HC compared to the colon at baseline and after infliximab culture. These differentially expressed lncRNAs were enriched in such pathways as proliferation, apoptosis, migration, inflammatory response of fibroblasts, response to wounding, posttranscriptional regulation of inflammatory genes and activation of the mitogen-activated protein kinase signaling pathways. Regarding the effect of infliximab according to intestinal location, presence of disease and activity, no significant lncRNAs were identified in the different study comparatives.

Conclusion: We have characterized the basal transcriptomic landscape of lncRNAs in patients with CD (active and quiescent) and HC both in ileum and left colon. However, we have not found differential lncRNA expression due to the effect of infliximab, suggesting that the location (ileum or colon) is more relevant when analyzing differences in lncRNA expression in the intestinal tissue.

Disclosure: Nothing to disclose.

Contact E-Mail Address: marta.insmk@gmail.com

Introduction: Interleukin 33 (IL-33) is a pro-inflammatory cytokine that has been implicated in the pathophysiology of inflammatory bowel disease (IBD), ulcerative colitis (UC) in particular. IL-33 as a cytokine and an alarmin might evoke systemic inflammation, which could have ramifications for the functioning of the central nervous system, contributing to mood and sleep disorders. Disruptions in IL-33 concentration are well known to occur in the course of numerous psychiatric disorders as well as obstructive sleep apnea, a condition characterized by chronic low-grade inflammation and sleep fragmentation. To date, however, this protein has not been studied in relation to insomnia or poor sleep quality, frequently comorbid to chronic inflammatory and psychiatric diseases.

Aims & Methods: The study aimed to compare serum IL-33 concentrations of IBD patients and healthy controls as well as evaluate the association between the expression level of this interleukin, depression, sleep quality, and insomnia. IBD patients (n=81) and healthy controls (HC=44) were recruited. Harvey-Bradshaw index or partial Mayo were applied in the as-

sessment of clinical disease activity for Crohn's disease (CD) or UC respectively. Venous blood samples as well as questionnaires: Beck Depression Inventory (BDI), Epworth sleepiness scale (ESS), Athens Insomnia Scale (AIS), and Pittsburgh Sleep Quality Index (PSQI) were collected. Human IL-33 High Sensitivity Magnetic Luminex Performance Assay was used for the analysis of serum IL-33 protein concentration according to the manufacturer's protocol. Fluorescence measurements were taken with MAGPIX, Luminex. The study has been funded by National Science Centre, Poland (2018/31/N/NZ5/03715).

Results: No differences were noted regarding IL-33 concentrations, sleep, or psychological variables between IBD patients and HC, except for sleep efficiency, which was higher in HC (p=0.004). Only in the IBD group, a positive correlation between IL-33 concentration and BDI, PSQI, and AIS (R=0.521, p=0.003; R=0.458, p=0.01; R=0.40, p=0.03), as well as negative one with sleep efficiency (R=-0.475, p=0.008) was noted. IBD individuals with high scores on ESS or PSQI (ESS>10, PSQI>5) had elevated IL-33 serum level compared to IBD patients without sleep problems (IL-33 concentration [pg/ml]: 53.385 (30.070-313.020) vs 18.795 (11.790-26.175), P=0.01 for PSQI; 270.900 (156.225-438.680) vs 21.840 (11.870-47.720), P=0.006 for ESS). IL-33 concentrations and questionnaire scores were comparable in patients with different disease activity. As for IBD types, in the CD, but not the UC group, IL-33 was positively correlated with the severity of depression symptoms and poor sleep quality (R=0.581, p=0.02; R=0.531, p=0.03) and negatively with sleep efficiency (R=-0.667, p=0.005).

Conclusion: IL-33 might be associated with mood and sleep disorders in IBD. It could exert its effect by promoting systemic and neuroinflammation, thus negatively affecting the well-being of IBD patients. Further research on the subject of changes in mental health of IBD patients in the context of anti-inflammatory or immunosuppressive treatment would be valuable.

Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel disease (IBD) is a complex multi-factorial disease characterized by chronic inflammation of the gastrointestinal tract. Despite significant efforts to understand the pathogenetic *mechanisms* of *IBD,* the elucidation of its etiopathology and progression is far from fully understood. The direct analysis of the intestinal tissue from the endoscopy which lead to IBD diagnosis (before starting any treatment) would the ideal samples to elucidate IBD pathogenesis.

Aims & Methods: High-throughput mass-spectrometry-based quantitative proteomic analysis was performed using formalin-fixed paraffin-embedded human intestinal samples from newly diagnosed patients to elucidate the potential mechanisms responsible for gut inflammation in Crohn's disease (CD) and ulcerative colitis (UC). For this purpose, 193 formalin-fixed paraffin-embedded samples from 40 active UC patients, 67 active CD patients and 46 normal biopsies from healthy controls (HC) were analyzed. Proteins with p-value < 0.05 were considered as significantly dysregulated. Moreover, we used Ingenuity Pathway Analysis (IPA) to analyze the pathways and functions in different locations of the gut (ileum or left colon) that could be related to IBD pathogenesis.

Results: A total of 2,903 proteins were identified, of which 1,010 were differentially expressed between left colon from CD patients and HC. 1,242 proteins were differentially expressed between left colon from UC patients and HC, and 952 differential proteins discriminated between left colon from CD and UC patients. In the comparative study of ileum biopsies from Crohn's disease patients and healthy controls, 956 proteins were differentially expressed. IPA revealed multiple canonical pathways, including

EIF2 signaling, regulation of eIF4 and P7056K signaling, mitochondrial dysfunction, and oxidative phosphorylation altered in ileum biopsies from CD patients compared to HC. Regarding the proteomic study in left colon samples, the main canonical pathways enrichment in the comparison of UC and CD with HC were the following: neutrophil extracellular trap signaling pathways, fatty acid oxidation, sitruin signaling pathway, tRNA charging, and mitochondrial dysfunction.

Conclusion: The proteomic results revealed dysregulated proteins and pathways in ileum and left colon biopsies from patients with active CD and UC compared to HC that may unravel key mechanisms contributing to the pathogenesis of these diseases. The results of the study serve as a starting point for hypotheses to understand the pathogenesis and search for therapeutic targets.

Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel diseases (IBD) are chronic, heterogeneous, and inflammatory conditions mainly affecting the gastrointestinal tract. Currently, endoscopy is the gold standard test for assessing mucosal activity and healing in clinical practice; however, it is a costly, time-consuming, invasive, and uncomfortable procedure for patients. There is, therefore, a need for sensitive, specific, fast and non-invasive biomarkers for the diagnosis of IBD.

Aims & Methods: Label-free quantification by nanoscale liquid chromatography coupled to tandem mass spectrometry (nLC MS/MS) was performed to profile the urinary and serum proteomes of 100 patients with newly diagnosed IBD, before starting any treatment [50 patients with Crohn´s disease (CD) and 50 patients with ulcerative colitis (UC)] and 50 healthy controls (HC). Data Mining and Pattern Recognition techniques were used to identify hidden relationships that are not detectable by using the classical and most commonly used lineal classifiers; thus, identifying potential markers able to discriminate the studied cohorts. Finally, we applied Ingenuity Pathway Analysis (IPA) to analyze the pathways and functions of differentially expressed proteins.

Results: Serum proteomics results revealed 45 differentially expressed proteins in the comparison between UC and HC groups, 32 proteins significantly expressed in CD versus HC, and 12 proteins in CD compared with UC. In urine samples, 110 proteins were significantly changed in UC versus HC, 50 proteins were differentially expressed between CD and HC, and a total of 31 proteins were significantly changed in CD compared with UC patients. Receiver operating characteristic curve (ROC) analysis found multiple proteins with a high area under the curve values, up to 0.94, indicating that these serum and urine proteins are of value as new non-invasive diagnostic classifiers of IBD patients. For each study comparative, the 5 most significant classifiers were selected. IPA revealed multiple signaling pathways, including prothrombin activation, acute phase response signaling, complement and coagulation system and liver X receptor/retinoid X receptor (LXR/RXR) activation, altered in IBD patients compared to HC (p-value < 0.05).

Conclusion: Our findings indicate that analysis of the urine and serum proteome using nLC MS/MS is a feasible approach for biomarker discovery. We identified several serum and urine proteins that could serve as new non-invasive markers for the diagnosis of IBD patients after further validation. After bioinformatic analyses, we found multiple proteins that may play important roles in the pathogenesis of IBD.

Disclosure: Nothing to disclose.

Contact E-Mail Address: cristina.bauset@uv.es

Introduction: Fibrosis constitute an important complication of CD. MicroRNAs (miRNAs), which are small RNA molecules that regulate gene expression, have been shown to participate in the molecular interactions of both inflammation and fibrosis. Lower levels of miR-378a-3p have been reported associated to murine liver fibrosis [1] and we analyze here the relevance of miR-378a-3p on intestinal fibrosis.

Aims & Methods: B57BL/6 mice were intravenously injected with 2,5mg/kg of negative control (NC) or mm-miR-378a-3p mimic, twice a week and received vehicle or Dextran Sulfate Sodium (DSS) for 2 cycles (7 days drinking DSS 2% in water solution followed by 10 days drinking water). Body weight and DAI score was obtained every day and the colon was collected after sacrifice. Sirius and hematoxylin-eosin dyes were employed to determine the fibrosis and structural state in 5µm slides of intestinal tissue. Gene expression and miRNA profiles were analyzed by RT-qPCR. Human small intestinal fibroblasts (HSIF; P10760, Innoprot, Spain) were transfected with 20nM of NC or hsa-miR-378a-3p mimic during 24h.

Results: No significant changes in body weight, DAI score, and colon length were detected between mice receiving NC and those receiving mimic, all along the two DSS cycles. Colon of mice treated with DSS, exhib-

ited a significant diminution in the mRNA expression of mm-miR-378a-3p compared with naïve samples. In DSS-treated mice, the iv administration of the mimic compared with the NC:
a. significantly increased levels of miR-378a-3p in the colon;
b. increased the number of neutrophils, and heightened changes in the glandular epithelia and architectural distortion
c. decreased the number of lymphoid follicles;
d. slightly increased collagen deposition, as analyzed by sirius red and;
e. significantly increased the mRNA expression of Tgfb1, Il1b, and Mmp2.
Treatment of human intestinal fibroblasts with hsa-miR-378a-3p mimic did not significant modify the mRNA expression of markers of fibrosis but it significantly increased the mRNA expression of two antiapoptotic molecules *BCL2* and *MCL1*.
Conclusion: Levels of mm-miR-378a-3p are diminished in a murine model of intestinal fibrosis; The exogenous administration of miR-378a-3p, increased the acute inflammatory response and the expression of fibrosis markers in murine fibrotic colon and the expression of antiapoptotic molecules in human intestinal fibroblasts.

Contact E-Mail Address: ikrama2020@gmail.com
Introduction: Crohn's disease (CD) is associated with a high risk of complications, stenosis and fistula frequently requiring surgery.
The aim of our work is to study the epidemiological profile of patients operated on for CD, to compare operated and non-operated patient and to determine the predictive factors for recourse to surgery.
Aims & Methods: This is a retrospective descriptive, comparative and analytical monocentric study over 40 years from January 1983 to april 2023 in a gastroenterology department including all patients followed for CD and operated on. Data was collected from patient registers.
We compared the operated and non-operated group, then we studied the factors associated with surgery in univariate and then multivariate analysis.
Results: Of 1103 patients followed for CD, 31.82%(351) were operated, including 86%(302) operated once, 12%(43) operated twice and 1.4%(5) operated 3 times. The median age of diagnosis was 31[22.5-40]years and the sex-ratio F/M=1.1.
A history of appendectomy was found in 17.2%(60) of patients. Smoking is found in 26.9%(94) of patients.
Patients operated on have an ileocolic location in 68.5%(237), colonic in 14.7%(52), ileal in 12.7%(44) of cases, and upper location in 3.8%(13).
The stenosing phenotype is observed in 38.4%(131) of patients, fistulizing in 35.2%(120) and inflammatory in 26.4%(90). Anoperineal manifestations were associated in 38.8%(122).
Recourse to corticosteroid is observed in 44.2%(155) of operated patients, 40.5%(142) who received immunosuppressive treatment and 26.6%(93) who had benefited from biotherapy.
19.9% (70%) were operated on following a complication of their disease, including 11.4%(8) of those operated on for severe acute colitis, 51.4%(36) for an occlusion, 22.8%(16) for an intestinal perforation, 17.1% (12) for a deep abscess and 4.2% (3) following degeneration.
By comparing the group of operated and non-operated patients, the diagnosis age <40 years was found at a higher rate in the operated p <0.001. In these patients, there is a higher frequency of ileocolic localization, fistulizing and stenosing forms and associated MAP (p<0.001/0.009). We noted a higher rate of patients who were under immunosuppressant p<0.001 and under biotherapy p=0.03 in operated patients.
In multivariate analysis, a history of appendectomy is associated with a high risk of surgery (OR=1.8, 95%CI:0.06-1.2, p=0.02) as well as the fistulizing phenotype (OR=6.5, 95%CI:1.4-2.3 , P<0.001) and the stenosing phenotype (OR=5.3, 95% CI:1.2-2, P<0.001). The occurrence of a complication (OR=9, IC95%=1.5-2.8, p<0.001) as well as the use of immunosuppressants (OR=1.6, IC95%: 0.1-0.8, p=0.001) are associated with a risk surgery high.
The use of corticosteroid therapy is associated with a lower risk of surgery (OR=0.6, 95%CI: -0.8;-0.1, p=0.006).
Other factors such as sex, smoking, location, anoperineal manifestations and biotherapy are not factors associated with surgery.
Conclusion: Despite the revolution in medical treatment, surgery remains a fundamental treatment in the management of CD. In our series, the history of appendectomy, the fistulizing and stenosing character of the disease, the treatment with immunosuppressant and the occurrence of complications are associated with an increased risk of recourse to surgery.
Corticosteroid therapy is associated with a low risk of surgery.
Sex, smoking, location and anoperineal manifestations are not associated with the risk of surgery.
Disclosure: Nothing to disclose.

ENTERIC GLIAL CELLS IN COORDINATED REGULATION OF DUAL INTESTINAL BARRIER FUNCTION DURING ULCERATIVE COLITIS DEVELOPMENT

P. Qiu[1,2], Y. Chen[1,2], X. Chen[1,2], C. Xiao[1,2], Q. Zhao[1,2], L. Liu[1,2]

Contact E-Mail Address: qiupeishan7299@163.com
Introduction: Rarely is it mentioned how the synergistic disruption of the gut vascular barrier (GVB) and intestinal epithelial barrier (IEB) contributes to the pathophysiology of ulcerative colitis (UC). Enteric glial cells (EGCs) play a vital role in intestinal homeostasis maintenance, but their possible interactions with dual intestinal barrier function are unknown.
Aims & Methods: We aimed to investigate the role of EGCs in regulating dual intestinal barrier function in the pathogenesis of UC and the underlying mechanisms. This study was performed on the mouse models of DSS-induced colitis and biopsies from UC patients. Impaired dual intestinal barrier function was examined by permeability assays and electron microscopy. The phenotype and function of EGCs were assessed by Western Blot, Immunofluorescence, and Flow Cytometry. Dihydroartemisinin (DHA) was used to reduce inflammation in vivo and in vitro.
Results: Mice with chronic colitis had impaired IEB and GVB such as increased double intestinal barrier permeability, reduced intestinal tight junction protein expression, and increased blood circulating endotoxin

levels have been observed in the chronic colitis mice model. EGCs, mainly the subgroup of GFAP$^+$/S100$^+$-EGCs, have been activated and proliferated when the dual intestinal barrier function is compromised. And the content of GFAP$^+$/S100$^+$-EGCs corresponds to the damage severity of the barrier. Both proliferation and activation of GFAP$^+$/S100$^+$-EGCs were markedly reduced by the DHA treatment. In addition to alleviating weight loss and colonic shortening in the model mice, DHA treatment considerably ameliorates intestinal epithelial and vascular endothelial barrier function, thus significantly reducing intestinal permeability.

Moreover, DHA treatment reduced the proliferative activity of GFAP$^+$/S100$^+$-EGCs in vitro, and restricted the recruitment of monocytes to EGCs by inhibiting the production of CCL2, thereby alleviating intestinal inflammatory response.

Conclusion: EGCs are essential for coordinated regulation of the double intestinal barrier efficient operation, and the proliferation and activation of GFAP$^+$/S100$^+$-EGCs speed up UC development. Those findings will contribute to identifying novel UC treatment targets and practical neurological markers.

Disclosure: Nothing to disclose.

Contact E-Mail Address: ikrama2020@gmail.com

Introduction: The occurrence of AA amyloidosis can intersperse the evolution of various chronic inflammatory diseases, in particular inflammatory bowel disease (IBD). Renal amyloidosis during IBD is a rare extra digestive manifestation occurring in 0.6 to 6% of cases that can be life-threatening in these patients.

Aims & Methods: This is a retrospective descriptive monocentric study of cases of renal amyloidosis developed in patients followed for IBD, conducted in a hepato-gastroenterology department over a period of 40 years from January 1983 to April 2023. Data was collected from the department's Crohn's and RCH registers.

Results: Out of 1664 patients followed for IBD (1103 Crohn's disease and 561 ulcerative colitis), only 5 patients followed for Crohn's disease (CD) developed renal amyloidosis.

They were 4 men and 1 woman, all followed for CD with a sex ratio M/F=4. The average age of diagnosis of CD was 45.2 years (28-67). Chronic smoking was noted in 80%(4) of our patients. A family history of IBD was noted in 40%(2) cases.

Topographically, 3 (60%) patients had an ileocecal location, compared to 20%(1) with an ileal location (20%) and 20%(1) patient with a colonic location. The disease was inflammatory in 40%(2) patients and stenotic in 60%(3) cases. An anoperineal manifestation such as an anal fistula was associated in 40%(2) of the patients.

Extra-digestive manifestations such as polyarthralgia were noted in 40%(2) of the patients and one case of skin involvement. Ankylosing spondylitis was diagnosed in 20%(1) cases and viral hepatitis b in 20%(1).

Therapeutically, 60%(3) were operated on: ileocecal resection with anastomosis. The treatment was based on an immunosuppressant of the azathioprine type in 80%(4) patients, then 60%(3) patients benefited from biotherapy, including 2 based on adalimumab and 1 case on infliximab.

Renal amyloidosis was diagnosed on average 6 years (1-9) after the diagnosis of Crohn's disease. The average age at diagnosis was 46 years (29-76). Renal failure was the discovery circumstance in 3 cases (60%) against 2 cases of nephrotic syndrome (40%). 60%(3) of patients received colchicine treatment (60%) and 20%(1) received a kidney transplant and 20%(1) was on hemodialysis. The evolution was marked by deterioration of renal function in 60%(3) of cases. 60%(3) had died, including 1 patient in an array of myocarditis and 1 case for septic shock. 1 patient is currently on hemodialysis.

Conclusion: Renal amyloidosis is a systemic manifestation of IBD that is rare but potentially serious despite the use of biotherapy. Its diagnosis in time would remain the only guarantor for a better prognosis.

Disclosure: Nothing to disclose.

Introduction: Inflammatory bowel diseases (IBD) are mainly represented by Crohn's Disease (CD) and Ulcerative Colitis (UC). Among several factors related to these diseases, dysbiosis is considered an immediate environmental factor for the development of IBD. Dysbiosis is related to the imbalance of the intestinal microbiota, which affects the existing symbiotic relationship between the intestinal microbiota and its host that provides a nutrient-rich environment for intestinal bacteria, while the microbiota plays a fundamental role in maintaining the intestinal function of its host. Among these functions, the microbiota has its participation in the digestion of complex polysaccharides present in the host diet, important for the formation of monosaccharides and short-chain fatty acids (SCFA), such as acetate, propionate, and butyrate.

These SCFA are important in maintaining the intestinal barrier and intestinal homeostasis, in proliferation, differentiation and modulation of gene expression of intestinal cells, in the production of essential vitamins in the intestinal lumen, in addition to acting in regulation of the mechanisms that provide balance between the intestinal mucosa and its immune system, resulting in the tolerance of harmless bacteria and immune responses against pathogenic bacteria.

There are several studies on the intestinal microbiota in patients with IBD, however, there are still few studies on the SCFA profile in these patients. Therefore, the present study aimed to evaluate and compare the SFCA profile in patients with IBD and healthy individuals.

Aims & Methods: 94 patients from a public outpatient healthcare service in Brazil and 63 healthy individuals were included in the study. Exclusion criteria: diagnosis of other chronic diseases, use of antibiotics, prebiotics, probiotics or symbiotics in the last 4 weeks. Participants were divided into two groups, IBD group and control group (healthy), fecal samples from all participants were collected for qualitative and quantitative analysis of SCFA, which was performed by gas chromatography technique coupled

with mass spectrometry (GC/MS). Statistical analysis: descriptive statistics and association tests. Values of $p \leq 0.05$ were considered significant. Data presented in mean (SD).

Results: The SCFA profiles were different in IBD patients compared to healthy individuals, with higher SCFA values in the IBD group when compared to the control group: acetic acid (0.32 ± 0.18 vs 0.12 ± 0.11, with $p< 0.0001$), propionic acid (0.24 ± 0.10 vs 0.15 ± 0.09, with $p< 0.0001$), butyric acid (0.19 ± 0.11 vs 0.39 ± 0.25, with $p< 0.0001$) and sum of SCFA (0.75 ± 0.32 vs 0.39 ± 0.25, with $p< 0.0001$) concentration.

Conclusion: The SFCA profile in patients with IBD showed a difference when compared to healthy individuals, where the values of SFCA fecal were higher in patients with IBD compared to healthy individuals. Such a difference may occur because the IBD group, due to the inflammatory process characteristic of the disease, may have greater difficulty in absorbing the SCFA produced in the intestine, releasing more SCFA in the feces, since most of the SCFAs produced in the colonic lumen (90-95%) are absorbed by the intestinal mucosa and only 5 to 10% are excreted in the feces. However, to confirm this hypothesis, further studies would be needed to evaluate and compare the SFCA systemic between these groups, through blood test, and thus determine the SFCA profile of these individuals, being able to propose therapies that help in the modulation of the microbiota of these patients and in the development of new treatment targets in the future.

SKELETAL MUSCLE DUPD1 LINKS COLITIS WITH OBESITY-ASSOCIATED METABOLIC DISEASES

S. Roy Choudhury[1], A. Martin[1]
[1]University of Toronto, Immunology, Toronto, Canada

Contact E-Mail Address: saurav.choudhury@utoronto.ca

Introduction: Inflammatory bowel disease (IBD), comprising of Crohn's disease and Ulcerative Colitis (UC), is a debilitating inflammatory disease of the gastrointestinal tract with no known cause. Although extensive work has linked numerous genetic loci to IBD, most of these associations remain poorly understood. In addition, some studies have associated IBD to metabolic diseases such as diabetes and non-alcoholic fatty liver disease (NAFLD), although the precise molecular and pathophysiological mechanisms underlying these associations are unknown.

Aims & Methods: The central objective of this study was to understand the molecular mechanisms underlying the associations between IBD and obesity related metabolic diseases. To address this research question, we used multiple mouse models of colitis (dextran sodium sulfate or DSS), DSS and Azoxymethane induced colitis associated colon cancer and *Helicobacter hepaticus* infection induced colitis in *Il-10-/-* mice) and high fat diet (HFD) and genetic models of obesity and obesity associated metabolic diseases. In addition, for mechanistic studies, we used chimeric mice generated through bone marrow transplantation as well as conditional knockout mouse models. Lastly, we employed CRISPR/Cas9 edited cells *in vitro* to understand the molecular mechanism.

Results: Employing multiple murine models of colitis, colitis-associated colon cancer (CAC) and obesity associated metabolic diseases, we have identified DUPD1, a phosphatase of unknown function, that links IBD with metabolic diseases.

Specifically, *Dupd1*$^{-/-}$ mice are protected from dextran sodium sulfate (DSS) and *Helicobacter hepaticus* induced colitis, and DSS/azoxymethane (AOM) induced CAC. *Dupd1*$^{-/-}$ mice also exhibited protection against high fat diet (HFD) induced obesity and fatty liver disease and glucose intolerance. DUPD1 is highly expressed in the skeletal muscle.

Indeed, using skeletal muscle specific conditional DUPD1 knockout mice (*Dupd1*$^{fl/fl}$*Myf6*^{Cre}), we show that DUPD1 exerts its colitogenic effects from the skeletal muscle through modulation of autophagy, a pathway whose dysfunction is known to play a role in IBD.

Importantly, a dual specificity phosphatase inhibitor (NSC-663284) inhibited DUPD1 enzyme activity and reduced DSS-induced colitis in wild type mice but not in *Dupd1*$^{-/-}$ mice.

Conclusion: Our study identifies *Dupd1* as a central gene that links IBD and obesity-associated metabolic diseases and suggests that it is a new therapeutic target in IBD, and obesity associated metabolic diseases.

Introduction: Chronic fatigue is a debilitating symptom and has major impacts on the quality of life of patients with chronic inflammatory conditions. In IBD, an estimated 50% of patients suffer from persistent fatigue despite successful treatment of intestinal inflammation. During active disease flares, this number jumps to 80% (Borren et al. 2018). Tryptophan metabolites are not only associated with disease activity in UC and CD, but also with chronic fatigue (Kavyani et al. 2022). Thus, our aims are (1) to characterize the relationship between fatigue and tryptophan derivatives and (2) to understand the metabolic dynamics arising when fatigue symptoms improve following therapeutic intervention.

Aims & Methods: In a prospective open label cohort of patients with moderate-to-severe Crohn's disease (CD, $n = 71$) and ulcerative colitis (UC, $n = 94$) assigned to biologics therapy or JAK inhibitors, fatigue was assessed by the fatigue subscale of the Functional Assessment of the Chronic Illness Therapy – Fatigue (FACIT-F) questionnaire at therapy induction and 2 and 14 weeks thereafter. A FACIT-F score of <30.1 was considered severe fatigue while a score of >40 was considered no relevant fatigue. Clinical response at week 14 was defined as Crohn's Disease Activity Index (CDAI) <150 and reduction of Partial Mayo Clinical Score (PMCS) >50% vs. baseline, respectively. We used targeted mass spectrometry to quantify the levels of 13 tryptophan derivatives and neopterin in a subset of patient serum in the weeks following therapy induction (at 0, 2, and 14 weeks, $n = 120$ individuals).

Results: Half of the recruited patients had severe fatigue at baseline (50.3%). Of the 120 patients who reached week 14 and had FACIT-F scores available, severe fatigue was experienced by 45.9% of the patients who

did not respond to therapy and the rate was reduced to 13.2% in therapy responders. We found 8 metabolites positively associated with FACIT-F: tryptophan, kynurenic acid, kynurenine, picolinic acid, xanthurenic acid, serotonin, indole-3-proprionic acid, and quinaldic acid, while neopterin was negatively associated (FDR < 0.05).

Four of these metabolites changed dynamically as a function of the extent of fatigue improvement: tryptophan, kynurenine, xanthurenic acid, and serotonin (FDR < 0.05). In all cases, the rate of change of these metabolites increased as a function of fatigue improvement.

Conclusion: Fatigue is linked to a diverse array of tryptophan metabolites. Notably, all of the significantly associated tryptophan derivatives were positively associated with FACIT-F, meaning that as fatigue symptoms improve, tryptophan metabolite levels increase.

Many of these metabolites have previously been linked to symptom severity in IBD: for example, tryptophan, kynurenic acid and xanthurenic acid all tend to increase with symptom alleviation (Nikolaus et al. 2017, Michaudel et al. 2022). While the kynurenine-to-tryptophan ratio is elevated in active IBD (Nikolaus et al. 2017), this ratio did not convey a specific, fatigue-related signature.

Considering that some patients continue to suffer from persistent fatigue even during disease quiescence, further work is needed to disentangle the impact of tryptophan metabolism on therapy response from its role on fatigue improvement.

Contact E-Mail Address: eleuljoumayma@gmail.com

Introduction: Cytomegalovirus (CMV) belongs to herpesvirus family. While common and mostly asymptomatic in general population, CMV infection can lead to serious condition in immunocompromised patients. Many definitions of CMV infection or intestinal disease are found in literature, which explains the different prevalence rates reported. (1)

Aims & Methods: To describe prevalence, and the clinical and prognosis outcomes of CMV infection in our IBD patients.

Methods : A retrospective study conducted from 01/2015 to 09/2022 including 505 patients with IBD diagnosis including ulcerative colitis and Crohn's disease. Clinical, biological, endoscopic and histological data were collected from patient's hospitalisations and follow-up reports. Parameters were analyzed using Microsoft Excel.

Results: 505 patients were included. We considered CMV positive infection or intestinal disease in patients with the presence of inclusions on biopsies or a positive CMV PCR. 5 patients had an intestinal CMV infection (0,9%), with a sex ratio M/F at 0,8. Mean age was 44,8 Y.O (26-69 YO). 4 patients were already followed-up for ulcerative colitis for an average of 3,3 years and were all under immunomodulators (thiopurines or methotrexate), while it was inaugural for the diagnosis in the other one. CMV intestinal disease was discovered during a severe acute colitis episode in 3 patients and moderate colitis in the remaining ones. Severe endoscopic lesions were found in 2 patients, while Mayo score was at 3 for all of them. Anatomopathology showed the presence of CMV inclusions in 40% (2 patients). Average CRP before treatment was 94 mg/l (22-169mg/l). Labtests showed positive CMV IgM antibodies in 4 patients. All patients were treated during 21 days using gemciclovir in consultation with infectious diseases physicians. For patients in acute severe colitis episode, mean Lichtiger at the end of the treatment was at 3, the other patients also had a good clinical outcome, such as the decrease of the number of stools and an improvement in the general state. Average CRP at the end of the treatment was at 20 mg/l(14-32).

Conclusion: Our study shows a low prevalence of CMV intestinal disease or infection, including the different definitions found in literature (1). Prevalence seems underestimated, and could be higher if diagnosis tools were more accessible. Even in our immunocompromised patients, CMV infection or intestinal disease had a good clinical and biological outcome in all of them after treatment.

ARYL HYDROCARBON RECEPTOR AMELIORATES EXPERIMENTAL COLITIS BY MODULATING TOLEROGENIC DENDRITIC CELLS AND TH17/TREG BALANCE

S. Wang[1], X. Zhao[1], H. Zhang[1]

[1]The First Affiliated Hospital of Nanjing Medical University, Gastroenterology, Nanjing, China

Contact E-Mail Address: 15380117361@163.com

Introduction: Intestinal immune dysfunction plays a vital role in inflammatory bowel disease (IBD). Dendritic cells (DCs) function as key regulators in the maintenance of intestinal immune homeostasis, which are able to induce both regulatory and effector T cell responses. Aryl hydrocarbon receptor (AhR), a ligand-activated transcription factor, is widely expressed in immune cells, including DCs. Although AhR plays an important role in differentiation of tolerogenic DC (TolDC), its role in the TolDC remains vague.

Aims & Methods: This study aimed to evaluate the effect and mechanism of AhR in TolDC and experimental colitis.Wild-type (WT) and $AhR^{-/-}$ mice were induced colitis by drinking dextran sulphate sodium (DSS) with or without intraperitoneal injection of 6-formylindolo[3,2-b] carbazole (FICZ). Bone marrow-derived cells (BMDCs) derived from WT or $AhR^{-/-}$ mice were cultured under TolDCs polarization condition and adoptively transferred to DSS-induced WT mice. WT and $AhR^{-/-}$ BMDCs were cultured under

TolDCs polarization condition in vitro. Ratios of DCs surface markers such as CD80, CD86 were evaluated by flow cytometry. Cutokines, like IL-1β, TGF-β and IL-10 were detected by ELISA.

Results: AhR$^{-/-}$ mice developed more severe colitis compared with WT mice. TolDCs and Tregs were both decresed in the colon of AhR$^{-/-}$ mice. WT mice, which transferred with AhR$^{-/-}$ TolDCs, developed more severe colitis than those receiving WT TolDCs, as evidenced by decreased Treg cells and incresed Th17 cells. In vitro, AhR deficiency in the DCs resulted in less TolDC formation confirmed by a higher expression of surface markers such as CD80 and CD86, increased secretion of pro-inflammatory cytokines (IL-1β) and lower anti-inflammatory production (TGF-β, IL-10) compared to the WT DCs.

Conclusion: AhR activation ameliorates experimental colitis by modulating TolDCs and Th17/Treg balance. Thus, our data suggest that AhR-TolDCs may be a potential therapeutic target for IBD.

THE POTENTIAL OVERLAP BETWEEN CANNABINOID AND NOCICEPTIN SIGNALING AND ITS ROLE IN INTESTINAL INFLAMMATION IN A MOUSE MODEL AND HUMAN SAMPLES

M. Wolyniak[1,2], M. Talar[2], A. Mokrowiecka[1], E. Malecka-Wojciesko[1], A. Fabisiak[1]

[1]Medical University of Lodz, Department of Digestive Tract Diseases, Lodz, Poland, [2]Medical University of Lodz, Department of Biochemistry, Lodz, Poland

Contact E-Mail Address: maria.wolyniak@stud.umed.lodz.pl

Introduction: The pathogenesis of inflammatory bowel diseases has been linked to both the endognous cannabinoid system and its receptors (CB1, CB2) and nociceptin receptor (NOP). Considering the functional similarities between the CB and NOP systems along with the anti-inflammatory effects exerted by their ligands, we hypothesize that there is an interaction between CB1 and CB2 and NOP receptors during colitis.

Aims & Methods: Colitis was induced in mice by dextran sodium sulfate (DSS). NOP agonist (SCH 221510. 3 mg/kg), CB1 antagonist (AM 6545, 3mg/kg) or CB2 antagonist (AM 630, 5mg/kg) were given intraperitoneally, twice daily, alone or in combination. On day 8th the mice were sacrificed, macroscopic scoring was performed and colonic samples were taken. The levels of IL-6, pERK and STAT3 was quantified using Western blot.

The expression of genes encoding CB1 and CB2 receptors was determined in the mouse and human colonic samples collected from patients suffering from Crohn's disease (CD) and ulcerative colitis (UC) and from healthy controls (HC) using real time RT-PCR. One-way ANOVA followed by the Tukey's post-hoc test was used for analyses of multiple treatment means. Pearson correlation coefficient was used to evaluate the correlation between the CB1, CB2 and NOP receptors expression in healthy and inflamed colon.

Results: We observed increase in total colon damage score in DSS-treated mice as compared to control group (6.40±1.52 vs. 1.20±0.46), which decreased after treatment with SCH 221510 (4.10±0.50). Interestingly, addition of AM 6545, AM 630 or combination of both drugs significantly increased the total damage score as compared to mice treated with SCH 221510 alone (11.83±0.44 vs. 4.10±0.50, (P<0.01) for AM 6545, 9.12±1.54 vs. 4.10±0.50 (P<0.05) for AM 630 and 8.57±0.86 vs. 4.10±0.50 (P<0.05) for combination of both).

Similar trend was found in comparison of myeloperoxidase activity in colon tissues (14.69±5.84 vs. 13.96±3.67, 18.97±2.40 vs. 13.96±3.67, and 17.60±3.31 vs. 13.96±3.67, respectively). We found a significant reduction in relative protein expression of IL-6 in the colon collected from SCH221510-treated mice, CB1 or CB2 antagonists-treated mice and SCH 221510- and both antagonists-treated mice as compared to DSS-treated group 7160471±3267620 (P<0.0001), 3675987±772660 (P<0.0001), 3379473±642716 (P<0.0001), and 25433153±11477866 (P<0.005) vs. 78758951±21976725 respectively. The relative protein levels of pERK and STAT3 tended to be elevated in groups treated with any ligand as compared to DSS-treated group and no difference between treated groups was noted. Real time RT-PCR analyses showed that combination of SCH 221510 and CB1 and CB2- antagonists increased the relative expression of CB1 and CB2 receptors as compared to mice treated with each drug solely. For CB1: 10819±4625, 20769±6775, 22558±8771 vs. 15044±6033, 3349±753.7 and 2660±546.4. For CB2: 15536±6860, 17696±7221, 16929±5452 vs. 9960±4043, 4406±2090, 3085±981.3.

The relative expression of CB1 receptor in human samples was significantly lower in patients with CD and UC, as compared to HC 2284±1074 (P<0.01) and 1348±446.8 (P <0.05) vs. 6621±2935 respectively. Noteworthy, we discovered a strong, statistically significant positive correlation between the relative expression of CB1 and NOP receptors in CD (r= 0.71, P <0.05). These trends were not observed in UC patients, nor HC.

Conclusion: We obtained promising results suggesting the existence of cross-talk between the CB and NOP receptors. Fully elucidating this phenomenon could aid in developing novel treatment options for IBD patients.

Disclosure: Nothing to disclose.

Introduction: The specific and sensitive biomarkers of inflammatory bowel disease (IBD) had not been found.

Aims & Methods: The aim of this study was to observe the metabolic characteristics of IBD patients and its damp heat syndrome (IBD-DH).

From May 2020 to July 2021 at Affiliated Hospital of Nanjing University of Chinese Medicine, patients with active inflammatory bowel disease (IBD), including damp heat syndrome (IBD-DH) and spleen-deficiency syndrome (IBD-SD), functional diarrhea patients (FD), and healthy volunteers (Con) were recruited. Fasting venous plasma and 2nd urine were collected from all patients and healthy volunteers; Using pseudotargeted metabolomics based on ultra-high performance liquid chromatography-high-resolution mass spectrometry (UHPLC-HRMS) and triple-quadrupole mass spectrometry (TQMS).

Results: A total of 60 patients with IBD (30 each in damp heat and spleen deficiency syndrome group), 23 patients with functional diarrhea, and 30 healthy volunteers were recruited in this study. A total of 60 plasma samples (30 IBD-DH and 30 IBD-SD) and 30 urine samples (15 each in IBD-DH and IBD-SD) were collected for IBD patients; 23 plasma samples and 20 urine samples from FD patients; 30 plasma samples and 15 urine samples from healthy volunteers.

In the IBD group compared with the Con group, 73 and 98 differential metabolites were screened in plasma and urine, respectively. The differential metabolites mainly included acylcarnitine, aromatic amino acid metabolites, glycerophospholipids, amino acids, and glucose metabolism intermediates. Abundance of ACar 16:1, ACar 18:1, ACar 20:4, LPC P-18:0 and malate increased significantly; abundance of PC 33:3, glycocholic acid, hippuric acid, p-cresol and p-cresol sulfate decreased significantly. Differential metabolite ROC analysis suggested L-glutamic acid, ACar 18:1, and Lactic acid as potential diagnostic biomarkers for IBD.

Forty-eight plasma differential metabolites and 69 urinary differential metabolites were obtained in the IBD group compared with the FD group. The differential metabolites mainly included fatty acids, acylcarnitine, aromatic amino acid metabolites, bile acids, and glycerophospholipids. The abundance of ACar 6:0, PC 24:0, 5b-cholestane-3a,7a,12a,24,25-pentanol, and 3-methoxybenzenediol in plasma was significantly decreased; the abundance of glycocholicacid and glycochenodeoxycholic was increased. The abundance of corticosterone, 5-hydroxy-N-formyl-kynurenine and other substances in the urine was significantly decreased. By ROC analysis, ACar 6:0, 5b-cholestane-3a,7a,12a,24,25-pentanol were found to be potential diagnostic markers to differentiate IBD from FD.

28 differential metabolites in plasma and 15 differential metabolites in urine were found .The abundance of 25 substances, including PC 16:1_20:4, PC 18:0_20:4, LPC 16:0-2, LPC 3:1, L-tryptophan, tyramine, and 3-hydroxybutyrate, increased in plasma; the abundance of indolelactic acid was decreased. By ROC analysis, indolelactate, tyramine, L-tryptophan, LPC 16:0-2, PC 38:7-sn1, and itaconic acid were found to distinguish IBD-SD and IBD-DH and were expected to be potential diagnostic biomarkers for IBD-DH.

Conclusion: As an organic lesion closely related to inflammation and immunity, IBD had prominent changes in the abundance of plasma ACar 6:0, 5b-cholestane-3a,7a,12a,24,25-pentanol in comparing with FD, a functional disease of the intestine. In terms of different syndromes, The differential metabolites mainly include aromatic amino acids and glycerophospholipids could be used to distinguish damp heat syndrome from spleen deficiency syndrome.

Disclosure: No Conflict of Interest to be declared

Introduction: Inflammatory bowel diseases are chronic disabling conditions with a complex and multifactorial aetiology, which is still not completely understood. OCTN1, an organic cation transporter could have a role in modulating the inflammatory response, whose genetic polymorphisms were associated to increased risk of inflammatory bowel diseases. Up to now, limited information exists on its role in predicting/modulating response to therapies.

Aims & Methods: The aim of this study was to evaluate the role of OCTN1 in modifying gut microbiota and immune composition to Infliximab therapy in murine colitis. Dextran sodium sulphate model of colitis on C57BL/6 mice and *ocnt1* gene knockout mice was used to assess clinical efficacy of infliximab administered intravenously. Stool, colon and mesenteric lymph node samples were collected to assess differences in gut microbiota composition, histology for Rachmilewitz score and T cell populations respectively.

Results: *Octn1*$^{-/-}$ influences microbiota profile and is associated with a worse dysbiosis in colitis mice. Infliximab treatment attenuates colitis-associated dysbiosis with increase of bacterial richness and evenness in both strains. In comparison with wild type, *octn1*$^{-/-}$ mice have a higher baseline percentage of Treg, Tmemory, Th2 and Th17.

Conclusion: Our data support murine model to study OCTN1 genetic asset in inflammatory bowel diseases. This could be the first step to consider this membrane transporter as a biomarker in inflammatory conditions and as a predictor of response to therapies.

Disclosure: Nothing to disclose.

Introduction: Sarcopenia is a syndrome characterized by the progressive and generalized loss of skeletal muscle mass. Primary sarcopenia is associated with the aging process, while the secondary one is caused by several factors including inflammatory conditions, such as inflammatory bowel disease (IBD). Since there is a complex interaction between inflammation, intestinal dysbiosis and malnutrition which lead to muscle degeneration in IBD patients, it is referred to as the gut-muscle axis. In particular, the high level of cytokines and the gut dysbiosis which characterizes IBD is responsible for the activation of pathways that cause an imbalance in muscle protein synthesis. However, the involvement of molecular and microbial mechanisms of sarcopenia, at present, has not been extensively studied in IBD.

Aims & Methods: In order to identify the mechanisms that are potentially involved in the onset of sarcopenia, a DSS-induced colitis mouse model has been created. To ensure that the model developed sarcopenia, we performed physical performance assessment at rotarod. On this well-characterized model, we studied the muscle by immunohistochemistry, by fiber count per field and by Cross Sectional Area. Next, we evaluated the gut microbiota and serum LPS detection. *In vitro*, with the aim to create a situation of intestinal inflammation and to assess the activation of pathways of muscle atrophy, we used the immortalized murine myoblast cell line C2C12 at different time points, 30'-2h-6h. Treatments performed included pro-inflammatory cytokines (TNF-α, IFN-γ, IL-6), LPS and drugs (Infliximab, Upadacitinib, Tofacitinib) in order to assess cellular response to the most promising drugs used in the treatment of IBD.

Results: The mouse model showed a reduction in body weight and muscle performance, probably associated with quantitative and qualitative alterations in muscle fibers. In addition, increased expression of markers of muscle atrophy (myostatin and Murf-1) was found in colitic mouse muscle. Also we observed increasing expression of the pathway STAT3-pSTAT3 involved in muscle wasting and decreasing pAKT, which is associated with muscle growth. Most relevant, a condition of dysbiosis was found in the colitic model, as well as increased LPS in the serum of mice.

In vitro, Upadacitinib and Tofacitinib in the presence of inflammatory cytokines decrease the expression of muscle atrophy-associated pathways (STAT3, its active form pSTAT3, and the transcriptional factor NFkB) and increase the expression of pAKT, a protein associated with muscle synthesis. When cells were treated with LPS, NFkB expression did not decrease with drug addition, suggesting that LPS is able to activate NFkB independently of the JAK/STAT pathway.

Conclusion: These data open new scenario for the gut-muscle axis as a promising area of research for the management of sarcopenia in IBD. Therefore, we might also consider the role of microbiota and LPS in addition to inflammatory cytokines in the pathogenesis of sarcopenia in IBD, since LPS-induced signaling is only partially controlled by drugs.

Disclosure: Nothing to disclose.

THE *CAUDOVIRALES* CLASS OF VIRUSES IS ASSOCIATED WITH DENDRITIC CELL IMPAIRMENT IN CD PATIENTS

C. Errico[1], L. Massimino[1], A. Facoetti[1], S. Cagliani[1,2], S. Spanò[1], T.L. Parigi[1,2], O. Almolla[1], S. Danese[3], F. Ungaro[1]

Introduction: The gut virome has been established to hold a key role in the pathogenesis of Crohn's disease (CD), belonging to the Inflammatory Bowel Disease (IBD) class. Indeed, some years ago Norman and colleagues described the expansion of *Caudovirales* as associated with CD pathogenesis and coupled with decreased bacterial diversity[1].

Aims & Methods: Therefore, to further explore this aspect we exploited the IBD TaMMA framework[2], to find which viral family was highly abundant in the CD colon by comparison with the healthy control. Moreover, to investigate the role of this family in the different mucosal cell compartments, CD- and healthy-derived intestinal biopsies were digested to obtain a cell suspension undergoing flow cytometry cell sorting (FACS) to isolate immune and non-immune cells according to cell population-specific markers. Specifically, CD8 and CD4 T cells, B cells, macrophages, dendritic cells, epithelium, endothelium, and fibroblasts were obtained and underwent transcriptomics and metatranscriptomics.

Results: We found that the *Autographiviridae*, belonging to the class of *Caudovirales* was highly abundant in the CD colon by comparison with the healthy control, confirming Norman study. Interestingly, the gene ontology (GO) revealed that the sole CD cell populations showing impaired biological response to viral insults by comparison with the healthy were the dendritic cells, fibroblasts, and epithelial cells suggesting that in CD mucosa only specific cell compartments were impacted by viral entities. Furthermore, by metatranscriptomics analysis we identified the CD dendritic cells and endothelial cells to retain a higher abundance of the *Autographiviridae* family by comparison with the healthy, indicating that the virome dysbiosis in these cells may underlie CD pathogenesis by altering their biological functions. Consistently, the heatmap of differentially regulated genes in CD versus healthy dendritic cells displayed downregulation of the transcripts key for dendritic cell-directed immune response.

Conclusion: Similar results have been recently proposed by our group to explain ulcerative colitis (UC) pathogenesis, where we identified a virome-derived protein, belonging to the *Hepadnaviridae* family, to directly disrupt the epithelial barrier and guide the development of intestinal inflammation[3]. Therefore, given the growing evidence of the viral entities as triggers for IBD, these data are promising and may pave the way to the discovery of viruses directly involved in CD pathogenesis that can represent a target for the development of novel strategies of intervention, ultimately ameliorating the CD management.

Introduction:

Inflammatory bowel disease (IBD) is a chronic inflammatory process closely linked to diet and nutrition. Diet and nutrition have been proposed to be significantly involved in the pathogenesis of IBD, although their specific propagation and attenuation of gut inflammation remains unclear.

Aims & Methods: Using paired dietary history and serum immunoproteins, we sought to investigate the association of various nutritional components in multi-ethnic Asian IBD patients from a single-center academic hospital in Singapore. Participants completed a self-administered validated 163-item semi-quantitative food frequency questionnaire to determine dietary intake. Adequate micronutrient intake was determined by the recommended dietary allowance (RDA) as stipulated by the Singapore Health Promotion Board. Participants also had 88 paired serum immunoproteins profiled using the Olink Target 96 Inflammation assay. Spearman correlation analysis, with false discovery rate, was used to identify significant diet-immune associations.

Results: Our study cohort included 40 (55.6%) patients with Crohn's disease and 32 (44.4%) patients with ulcerative colitis, with a median age of 40 years (range 30.5 - 57.0). More than two-thirds (n=51, 70.8%) were male. The median body mass index was 23.4kg/m2 (range 20.0 - 26.3). In our study, IBD patients self-reported to be taking insufficient dietary fiber and vitamin A, whereby 86.1% and 58.3% of IBD patients, were taking lower than the RDA for dietary fibre (n=62, median 15.9g/day) and vitamin A (n=42, median 706mcg/day), respectively.

Using spearman correlation, we identified 192 significant ($p<0.05$) diet-immune associations from only 39 (44%) of the 88 immunoproteins screened. Of note, 8 immunoproteins (4E-BP1, CASP-8, CDCP1, FGF-23, IL-17A, IL-20RA, IL-22 RA1, STAMBP) accounted for almost half (n=92/192) of all the significant diet-inmune associations. Only beta carotene and vitamin A were negatively associated with pro-inflammatory immunoproteins, such as Interleukin-18, Interleukin 10-receptor subunit beta, C-C motif chemokine 19, Vascular endothelial growth factor A, and and Urokinase-type plasminogen activator.

Table 1. List of immunoproteins and their key molecular functions and micronutrient-immunoprotein associations. Eight immunoproteins (4E-BP1, CASP-8, CDCP1, FGF-23, IL-17A, IL-20RA, IL-22 RA1, STAMBP) were identified to have the most diet-immune associations, accounting for almost half (n=92/192) of all significant associations identified.

Protein Name	Function	Count of diet-immune associations	Specific dietary associations
Eukaryotic translation initiation factor 4E-binding protein 1 (4E-BP1)	Enables protein binding (GO:0005515) Enables eukaryotic initiation factor 4E binding (GO:0008190) Enables translation repressor activity (GO:0030371)	11	Iron Calcium Riboflavin MUFA Protein Zinc CHO Starch Energy SFA Total fat
Caspase-8 (CASP-8)	Enables cysteine-type endopeptidase activity (GO:0004197) Enables death receptor binding (GO:0005123) Enables tumor necrosis factor receptor binding (GO:0005164) Enables protein binding (GO:0005515) Enables peptidase activity (GO:0008233)	13	Vitamin AIron Thiamine Potassium Calcium Riboflavin MUFA Protein Zinc CHO Energy PUFA SFA Total fat
CUB domain containing protein 1 (CDCP-1)	Enables protein binding (GO:0005515)	10	BCarotene Vitamin A Vitamin C Potassium Riboflavin MUFA Protein Zinc SFA Total fat
Fibroblast growth factor 23 (FGF-23)	Positive regulation of protein kinase B signalling (GO:0051897) MAPK cascade (GO:0000165) Fibroblast growth factor receptor binding (GO:0005104) Enables type 1 fibroblast growth factor receptor binding (GO:0005105) Enables protein binding (GO:0005515) Enables growth factor activity (GO:0008083)	11	Iron Thiamine Potassium Calcium Riboflavin Zinc Energy PUFA SFA Total fat Dietary fiber
Interleukin-17A (IL-17A)	Positive regulation of antimicrobial peptide production (GO:0002225) Adaptive immune response (GO:0002250) immune system process (GO:0002376) Apoptotic process (GO:0006915) Inflammatory response (GO:0006954)	11	Iron Potassium MUFA Protein Zinc CHO Starch Energy PUFA SFA Total fat
Interleukin-20 receptor subunit alpha (IL-20RA)	Cytokine receptor activity (GO:0004896) Enables protein binding (GO:0005515) Enables interleukin-20 binding (GO:0042015)	11	Thiamine Potassium Calcium Riboflavin MUFA Protein Zinc Energy PUFA SFA Total fat
Interleukin-22 receptor subunit alpha-1 (IL-22RA1)	Cytokine receptor activity (GO:0004896) Enables interferon receptor activity (GO:0004904) Enables protein binding (GO:0005515) Enables interleukin-20 binding (GO:0042015)	13	BCarotene Vitamin C Iron Potassium Calcium Riboflavin MUFA Energy PUFA SFA Total fat Dietary fiber Sugar
STAM-binding protein (STAMBP)	Enables protein binding (GO:0005515) Peptidase activity (GO:0008233) Metallopeptidase activity (GO:0008237) Hydrolase activity (GO:0016787) Enables protein domain specific binding (GO:0019904)	16	Vitamin A Iron Thiamine Potassium Calcium Riboflavin Protein Zinc CHO Starch Energy PUFA SFA Total fat Dietary fiber Sugar

Conclusion: Our study found specific components of the diet, such as carbohydrates, starch, fiber to be positively associated with inflammatory immunoproteins. Only vitamin A and beta-carotene were negatively associated with circulating immunoproteins.

We hope our findings assist in the development of specific dietary therapies to provide IBD patients with specific nutrient requirements and yet limit specific dietary substrates that may propagate gastrointestinal inflammation.

Further studies are required to investigate the mechanisms of these nutritional factors involved in inflammation and to evaluate the application of specific diets during the course of IBD.

THE DISAPPEARANCE OF CELL DEATH BRAKES: A NEW MOLECULAR DEFECT IN INFLAMMATORY BOWEL DISEASE (IBD)

A. Al-Ani[1,2,3], J. Rickard[2], A.L. Samson[2,4], J.M. Murphy[2,4], B. Christensen[1,2,3]

Contact E-Mail Address: aysha05@gmail.com

Introduction: The precise aetiology of inflammatory bowel disease (IBD) remains unclear with excess intestinal cell death implicated yet vastly understudied. Necroptosis, a recently described lytic cell death pathway, is emerging as a key player in intestinal inflammation in mouse models of colitis (1, 2), however clinical data are sparse. This non-apoptotic regulated cell death can be initiated by tumour necrosis factor (TNF) receptor activation and is executed by a core axis of proteins, including receptor-interacting protein kinase (RIPK) -1 and -3, and mixed lineage domain-like pseudokinase (MLKL) independent of caspases (3). The pathway is usually repressed by cellular inhibitor of apoptosis protein (cIAP) -1 and -2, and cellular FLICE-like inhibitory ($cFLIP_L$).

This project proposes the first study to comprehensively assess programmed cell death in intestinal tissue of adult patients with IBD using a novel toolbox of affinity reagents (4). By comparing this with non-inflamed control tissue, we have uncovered a new molecular defect in IBD: loss of essential cellular death brakes, even in tissue with apparent mucosal and histologic healing. This novel finding may underpin the vicious cycle of remission and disease relapse and poses a step towards molecular healing through restoration of these brakes.

Aims & Methods: Aims:

1. Assess cell death prevalence in IBD
2. Determine why cell death brakes disappear in intestinal IBD tissue, regardless of inflammatory status
3. Determine whether IBD phenotypes can be uniquely profiled according to cell death signals

Methods: Matched intestinal biopsies are retrieved endoscopically from patients without IBD (healthy controls) and those with IBD. Patients requiring endoscopy as part of standard of care are screened for eligibility: exclusion criteria comprise active malignancy, non-IBD inflammation, infection, use of non-steroidal anti-inflammatory drugs, and polyposis syndromes. Biopsies from participants with IBD are taken from macroscopically non-inflamed, margin and inflamed areas. Control specimen are taken from healthy-appearing bowel. Specimen are collected fresh for investigation of pertinent targets (*Table 1*). Clinical/endoscopy activity indices, biochemical markers (C-reactive protein, faecal calprotectin) and blinded histologic (Robarts Histopathology Index) scoring are correlated with laboratory data in a multi-parametric manner.

MEDIUM	TECHNIQUE	PURPOSE
Phosphate buffer system + protease + phosphatase inhibitors	Immunoblotting	Protein quantification of 26 cell death-related proteins
10% formalin	Immunohistochemistry	Visualisation of 12 cell death-related markers
Methanol + 5% acetic acid	Immunofluorescence	Optic microscopy of necroptosis hot-spots
RNA later	RNA sequencing	Shotgun transcriptomics of host microbiome, immune and inflammatory infiltrates
Dulbecco's Modified Eagle Medium: Nutrient Mixture F12 (DMEM F12) + Primocin	Organoid development	Gut organoid challenges to identify factors impacting cell death

Results: Intestinal biopsies from 28 healthy controls and 52 patients with IBD: 25 UC; 25 CD; and 2 pouchitis have been collected. Interim analysis demonstrates suppression of cell death inhibitory proteins- cIAP-1, -2 and $cFLIP_L$ even in non-inflamed tissue in patients with IBD, unleashing apoptosis (hallmarked by a statistically significant increase in cleaved caspase-3) and/or necroptosis (hallmarked by statistically significant increases in phosphorylated RIPK-3) in nearby tissue.

Conclusion: For the first time, we demonstrate that cellular death brakes are removed in intestinal tissue in IBD, despite histologic remission. Our findings challenge current dogma that necroptosis occurs in the absence of apoptosis and that necroptosis is universally increased in all forms of IBD. Disinhibition of programmed cell death is likely intrinsic to the inflammatory sequence underlying disease recurrence and progression.

IL-33 ACTIVATES CD73-EXPRESSING CELLS PROMOTING TUMORIGENESIS DURING COLITIS-ASSOCIATED COLORECTAL CANCER

L.R. Lopetuso[1], G. Privitera[2], L. Di Martino[3], D. Corridoni[3], A. Gasbarrini[4], F. Cominelli[3], C. De Salvo[3], T.T. Pizarro[5]

Introduction: Colorectal cancer associated to chronic colitis (CAC) has a different pathogenesis compared to sporadic or familial colorectal cancer (CRC) and represents the major complication of inflammatory bowel disease (IBD). It is now well-established that IL-33 and its receptor, ST2, are important factors in the pathogenesis of IBD. Emerging evidence also suggests its critical role in epithelial proliferation and the potential contribution to inflammation-driven tumorigenesis that can lead to CRC.

Aims & Methods: The aim of our study was to characterize the precise contribution of IL-33/ST2 axis in the azoxymethane (AOM)/dextran sodium sulfate (DSS) model of colitis-associated CRC. C57/BL6 wild-type (WT), *Il33*

$^{-/-}$, T1/*St2*$^{-/-}$ and *Nt5e*$^{-/-}$ mice were given a single dose of AOM (10 mg/kg) followed by two cycles of 3% DSS for 7d in drinking water. Vehicle-treated WT mice served as controls and were sacrificed at the same time points. Another group of WT followed the same protocol and received CD73 inhibitor i.p. treatment or vehicle. Disease Activity Index (DAI), as well as endoscopic, stereomicroscopic and histological evaluations of colons were performed. IHC, immunofluorescence (IF), qPCR, and ELISA were done on full-thickness colons of WT for IL-33 and ST2 localization and identification, as well as mRNA and protein expression, respectively. RNA-Seq was performed on whole tissues from AOM/DSS treated WT, *Il33*$^{-/-}$ and T1/*St2*$^{-/-}$. qPCR analysis was done on isolated polyps from WT, *Il33*$^{-/-}$ and *T1/St2*$^{-/-}$ for *Nt5e* (CD73) and adenosine pathway targets.

Results: *Il33*, *Ilrl1*(ST2L), and *Ilrl1*(sST2) mRNA transcripts, as well as IL-33 and total ST2 proteins were dramatically elevated in AOM/DSS-treated WT mice vs. controls. IHC and IF of treated WT mice revealed localization of IL-33 to the colonic epithelium and to cells within the polyp LP morphologically consistent with stromal and mast cells. Little to no staining for IL-33 was present in controls. Using IF, IL-33 co-localized with sub-epithelial myofibroblast markers Actin and Vimentin, or with mast cell markers Tryptase and MCPT1. AOM/DSS treatment in *Il33*$^{-/-}$ and T1/*St2*$^{-/-}$ mice resulted in a significant decreased polyp number and size *vs.* WT, with colonoscopy revealing the development of protruding lesions with abnormal vascular patterns, suggesting tumorous lesions in WT mice, while all deficient mice showed their absence with a more impressive mucosal inflammation, likely due to reduced epithelial proliferation and repair caused by the deficiency of IL-33 signaling. RNA-Seq identified a significant reduction of *Nt5e* and adenosine pathway targets in *Il33*$^{-/-}$ and T1/*St2*$^{-/-}$ *vs.* WT. qPCR on isolated polyps confirmed this observation. AOM/DSS-treated *Nt5e*$^{-/-}$ showed a significant decreased polyp number and size *vs.* controls. Therapeutic inhibition of CD73 produced similar results.

Conclusion: Our results suggest that the IL-33/ST2 axis promotes tumorigenesis in colitis-associated CRC through the activation of CD73. Further studies are underway to determine mechanisms of action that support these findings.

Introduction: Inflammatory bowel diseases (IBDs), primarily ulcerative colitis (UC) and Crohn's disease, are complex chronic immune-mediated disorders. Although etiopathogenesis of UC is still unknown, several studies suggest a clear association to altered gut microbiota, impaired mucous layer and epithelial barrier disfunction. Fecal microbial transplantation (FMT) emerged as a promising therapeutic approach aimed at repopulating gut microbiota with beneficial taxa from a healthy donor, and indirectly influencing the recipient's immune system. At present, FMT represents a well-established effective therapy for patients suffering from recurrent C. difficile infections. Promising data suggest FMT efficacy in patients with mild to moderate UC, but mechanism of actions are still yet to be fully understood.

Aims & Methods: Our study aims to evaluate the impact that FMT, using feces from UC patients with active and inactive disease, on microbiota composition and mucosal integrity in a murine model of colitis. We used mice (n=40) that were pre-conditioned for a week with a cocktail of broad spectrum antibiotics to deplete most of the intestinal microbiota, then a 7-day DSS 3% treatment was carried out to induce the colitis and, during those days, two FMT infusion were performed. The mice were sacrificed at the end of seven days of recovery, and feces, colon and whole blood were collected.

Results: The use of antibiotics allowed the engraftment of FMT colitis in mice. Disease activity index of murine colitis was ameliorated by the infusion of feces from inactive UC patients, associated with the decrease of LPS in serum, lower levels of pro inflammatory cytokines (such as IF-Ngamma, TNFalpha, IL17), an increase of FOXP3 and MUC2 as a marker of intestinal integrity. A modulation of gut microbiota was assessed after each phase of treatment.

Our study suggests the infusion of fecal suspension from inactive UC patients is able to induce an anti-inflammatory response at mucosal level and to induce proliferation of those bacterial families associated with remission.

Conclusion: These data open new scenario about the use of autologous FMT in UC. Autologous FMT reduces the potential for donor-recipient microbial-interactions/incompatibilities which have been shown to influence strain engraftment outcomes.

Disclosure: Nothing to disclose.

Introduction: The Notch signaling pathway and senescence are both complex processes that play important roles in a wide range of biological processes, including tissue repair and regeneration, as well as the development of age-related diseases. Studies have suggested that the Notch pathway may be involved in the regulation of senescence and in the development of fibrosis. Senescence is a normal physiological process that plays a role in tissue repair and regeneration, however the accumulation of senescent cells has been implicated in the development of fibrosis. Fibrosis represent the main complications related to Crohn´s disease (CD). Previous studies carried out by our group have shown a high expression of NOTCH pathway in CD samples (Rodriguez-Antequera, et al., 2019).

Aims & Methods: The general aim of the present study is to determine the possible potential of Notch pathway as a therapeutic target in intestinal fibrosis associated with Crohn's disease. Specifically, we pretend: to analyze the localization of the receptors of NOTCH3/4 and the expression of NOTCH markers in the intestinal tissue of patients with complicated CD, and to study the relevance of the Notch pathway in the senescence of intestinal fibroblasts. We have analyzed in intestinal samples from CD patients with complicated lesions: the localization of NOTCH3/4 receptors by

IH, the protein expression of senescence/apoptotic markers (BCL2, P16, MCL1 and P53) and NOTCH markers (NOTCH3/4, DLL3/4 and HES1) by WB. We correlated the expression of NOTCH pathway markers with senescence markers of each patient. We carry out in vitro studies and analyze: the protein expression of HES1 (effector Notch pathway) and the protein expression of senescence/apoptotic proteins in HSIF fibroblasts treated with DLL4 or DLL3. Results are expressed as fold induction (mean±SEM). Statistical analysis was performed with one-way ANOVA followed by Newman-Keuls test or by unpaired Student's t test.

Results: NOTCH4 is found more specifically in the crypts of the mucosa, as well as in cells of the lamina *propria*. NOTCH3 was located preferentially in muscular areas -muscularis mucosa, endothelium and muscularis externa. The expression of DLL4/3, NOTCH4 and HES1 were significantly higher in the affected tissue compared to the ileal samples of control patients. BCL2, MCL1, P16 and P53 showed significantly elevated levels in the affected CD tissue, compared to the ileal sample of control patients. P16, the main marker of senescence, correlates positively and significantly with DLL3/4, NOTCH3 and HES1 in intestinal tissue (Table). DLL3, and not DLL4, produced in intestinal fibroblasts a significant increase in the protein expression levels of BCL2 and P53, compared to the vehicle.

	DLL3	DLL4	NOTCH3	NOTCH4	HES1
MCL1	r=0,885***	r=-0,242	r=0,763***	r=0,388	r=-0,138
BCL2	r=-0,0183	r=0,559**	r=-0,101	r=0,4383	r=0,445*
P53	r=-0,099	r=0,828***	r=-0,236	r=0,397	r=0,668***
P16	r=0,473*	r=0,428*	r=0,428*	r=0,311	r=0,487*

Table. Protein correlation of NOTCH markers with senescence/apoptotic markers in intestinal mucosa. The table show the Pearson r. The results of applying the Spearman's correlation analysis were considered significant at P < 0.05, P < 0.01** and P < 0.001***.*

Conclusion: NOTCH pathway is involved in the regulation of key cellular functions and processes essential for the pathogenesis of intestinal fibrosis in CD patients. DLL3 seems to have a relevant role in activation of senescence in fibroblasts.

Introduction: Recent evidence suggests that appendectomy is associated with a reduced risk of developing ulcerative colitis (UC) or even the risk of flare after UC is diagnosed, thus suggesting a potential involvement of the appendix in UC pathogenesis. Interestingly, several studies support the role of the appendix in the maintenance of the intestinal microbiome and gut immunity1. We hypothesize that the appendix in UC may function as a reservoir for dysbiotic microbiota capable of promoting and re-establishing dysbiosis that could fuel inflammation in the colon in patients with UC.

Aims & Methods: The current study aimed to define the tissue-associated microbiota of the UC appendix, and investigate the changes compared to non-UC appendix. Thirty-seven patients operated on for UC or acute appendicitis were recruited. Appendicular wall tissue samples were obtained, inflammatory cells were isolated and analyzed by flow cytometry, and total DNA was extracted from the whole tissue. The V3-V4 region of the 16S rRNA gene was sequenced utilizing a MiSeq Platform (Illumina, USA). Sequences were processed using the QIIME22 pipeline, the taxonomy was assigned using the Greengenes3 database, and statistical analysis was performed in R.

Results: Twenty-seven samples were analyzed from 37 patients, 19 from UC, and 8 from acute appendicitis patients. Analyses revealed Firmicutes was the most proportionally abundant bacterial phylum in the UC appendix (mean=72.6%), followed by Proteobacteria (16%). Analysis of alpha diversity revealed no significant difference in terms of species richness, Shannon, and Pielou indices between UC and non-UC appendix (p=0.9;p=0.087;p=0.26). The PERMANOVA test revealed that UC appendix communities were significantly different from non-UC appendix communities (p=0.015). We identified 5 differentially abundant species in the study's samples, all of these significantly decreased in UC appendix vs. non-UC appendix: *Fusobacterium* unknown species (p=4.36x10-4), *Pseudoramibacter* unknown species (p=4.46x10-3), *Streptococcus anginosus* (p=2.67x10-2), *Mogibacterium* unknown species (p=2.67x10-2) and *Actinomyces hyovaginalis* (p=3.64x10-2). Fusobacterium, Pseudoramibacter, and Mogibacterium were also differentially abundant at the genus level (p=3.10x10-4; p=3.17x10-3; p=2.53x10-2).

The expression of CD86 on activated dendritic cells (CD1a+HLAdr+CD86+) was significantly higher in UC patients than in appendicitis patients (p=0.049) and in UC patients CD1a+HLAdr+CD86+ cells rate directly correlated with disease activity as expressed by Harvey Bradshaw Index (rho=-0.513, p=0.025). The abundance of *Fusobacterium* unknown species inversely correlated with CD1a+HLAdr+CD86+ mean fluorescence intensity (rho=-0.466, p=0.047).

Conclusion: These preliminary data showed that specific taxa are significantly less present in the UC appendix compared to the non-UC appendix, suggesting that a distinctive UC appendix microbiota exists. Taxa with altered abundance may contribute to UC pathogenesis. These data may provide microbial signatures useful for guiding both the treatment and diagnosis of UC.

DOUBLE-EDGED SWORD EFFECT OF GLUCOCORTICOIDS IN EXPERIMENTAL COLITIS – IS THERE A ROLE OF RAPAMYCIN?

D. Ceacero-Heras[1], M. Tena-Garitaonaindia[1], A. Seguí-Pérez[1], G. Ruiz-Henares[2], Á. Jiménez-Ortas[1], O. Martínez-Augustin[1], F. Sánchez de Medina[2]

Introduction: Glucocorticoids (GC) are important antiinflammatory and immunosuppresive agents in the management of inflammatory bowel disease and many other conditions. However, GC also display deleterious effects on the intestinal barrier which may limit their clinical benefit. These effects may be ascribed partly to actions on the epithelium [1]. In this regard, mice carrying a deletion of the GC receptor in intestinal epithelial cells are protected against experimental colitis [2]. It may be therefore beneficial to limit GC epithelial actions in the inflamed intestine. On the other hand, recent evidence shows that dexamethasone-treated mice aggravate acute experimental colitis due to the activation of mTOR pathway in intestinal epithelial cells [3].

Aims & Methods: Our aim is to limit harmful GC effects in intestinal epithelium in experimental colitis, with the ultimate goal of improving the management of inflammatory bowel disease with GC.

This study features two experiments. First, experimental colitis was induced by administration of 2.5% dextran sulfate sodium (DSS) for 7 days to C57BL/6J mice and treated with prednisolone 200 µg/day by either the oral or parenteral route (as prednisolone phosphate). Secondly, effects of glucocorticoid-dependent mTOR pathway activation were assessed by administering prednisolone at the same dose in combination with rapamycin 60 µg/day, a specific mTOR signal inhibitor, both by the oral route, to DSS-induced colitic C57BL/6J mice, in the same conditions as the first experiment.

Results: Prednisolone ameliorated colitis, based on downregulated expression of inflammatory markers (*S100a8, S100a9, Cxcl1*, *Il6*) and lower colon thickening. However, oral (but not intraperitoneal) prednisolone augmented 4 kDa FITC-dextran permeability. This correlated with plasma lipopolysaccharide (LPS) levels, which were higher with oral prednisolone. In addition, colonic hemorrhage was enhanced by prednisolone treatment, particularly when given orally, as it both accelerated and enhanced blood loss. Besides, mice treated with oral prednisolone showed an increased disease activity index (DAI, based on body weight loss, feces consistency and rectal bleeding). On the other hand, GC administration suppressed *Cyp11a1* expression in the colonic mucosa and also in jejunal organoids, suggesting inhibition of colonic steroidogenesis by exogenous treatment. These findings were largely reproduced using 6 µg/day of budesonide but, in this case, body weight loss was also augmented by glucocorticoid treatment. In the second experiment, rapamycin reduced DAI compared to prednisolone-only treatment, and additionally decreased bacterial adherence to colonic mucosa. This is consistent with previous findings with dexamethasone [3].

Conclusion: Our data are consistent with GC weakening of the mucosal barrier coexisting with an antiinflammatory response, which may be enhanced by oral administration. Addition of rapamycin appears to limit this detrimental effect of prednisolone, thus improving its benefit:risk ratio in this model.

MIG (CXCL9) CHEMOKINE IS A KEY BIOMARKER THAT DISCRIMINATES BETWEEN PEDIATRIC IBD PATIENTS AND NON-IBD PATIENTS IN A NOVEL BIOMARKER MODEL

A. Eindor[1], K. Tsai[2], K. Jacobson[2]

[1]Shamir Medical Center, Zeriffin, Israel, [2]BC Children's Hospital, Pediatric Gastroenterology, Hepatology and Nutrition, Vancouver, Canada

Contact E-Mail Address: adiabarbanel@gmail.com

Introduction: The current gold standard for diagnosis of Inflammatory bowel disease (IBD) is based on clinical and endoscopic evaluation as well as histologic and radiologic evaluation. However, endoscopic evaluation can be uncomfortable and carry some risks, especially in the pediatric population that requires general anesthesia in order to perform the procedure.

Aims & Methods: Our aim was to investigate whether serum biomarkers can differentiate between pediatric patients with and without IBD. Secondary aims were to determine whether there are biomarkers that can differentiate between Crohn's disease (CD) and Ulcerative colitis (UC), and whether we can predict progression to biologic treatment within one year from diagnosis using these biomarkers.

Pediatric patients undergoing a first diagnostic colonoscopy at British Columbia Children's Hospital (BCCH) between December 2019 and June 2022 were invited to participate in the study. A 2 ml blood sample was taken from each participant at the time of colonoscopy. Demographic and clinical data were collected from each patient. Blood samples were analyzed using the Legendplex™ flow cytometry kits investigating which included 50 different inflammatory cytokines and chemokines associated with IBD. A prediction model was built via a supervised learning method to determine how well we can predict the different groups.

Results: One hundred pediatric patients participated in the initial study. Five were excluded from the analysis due to uncertain diagnosis. Median age was 13.36 years, 39 were females (41%) and 54 (56.84%) were diagnosed with IBD, with 35 (64.81%) diagnosed with Crohn's disease. On a univariate analysis and Volcano plot 6 biomarkers were found to be

strongly associated with the diagnosis of IBD: IL22, IL8, TARC, GROA, MIG, and IL18. The cross-validated AUROC was 0.70. Using SPLS-DA the classification accuracy was improved to 0.84, and MIG was found to be the key biomarker to discriminate between pediatric IBD patients and non-IBD patients.

On a univariate analysis only TSLP was found statistically significant as a predictor of CD, and RANTES and TARC were found as negative predictors for initiating biologic treatment within one year of diagnosis. However, the prediction model did not predict well the subclasses nor progression to biologic treatment.

Conclusion: Using serum biomarkers can predict the diagnosis of Pediatric IBD. MIG was found to be the key biomarker in the prediction model.

Introduction: IL-33/ST2 axis and gut microbiota are important factors in the pathogenesis of IBD with a potential reciprocal influence. IL-33/ST2 axis controls the mucosal healing process during intestinal inflammation. Restorative proctocolectomy with ileal pouch-anal anastomosis is a surgical procedure in patients with ulcerative colitis (UC) refractory to medical therapies. Pouchitis, the most common complication, is the inflammation of the pouch with a controversial etiology.

Aims & Methods: We aimed to explore the potential role of IL-33/ST2 and gut microbiota axis in the inflammatory process of pouchitis.

30 UC patients with ileal pouch-anal anastomosis were enrolled. After clinical, endoscopic and histological assessment 18 showed pouchitis and 12 a normal pouch. Mucosal samples were collected from the afferent ileal loop and from the pouch and processed for cytokines assessment, histological evaluation and gut microbiota analyses. Multiplex analysis for inflammatory and regulatory cytokines was performed. ELISA and western blot were run to assess IL-33/ST2 protein levels and to evaluate protein isoforms, respectively. IHC was done to evaluate mucosal IL-33/ST2 expression and localization. Microbiota was analyzed by 16S ribosomal RNA gene amplicon pyrosequencing. Pouchitis Disease Activity Index and Pouchitis Histological Score were calculated, and CRP and fecal calprotectin were obtained for each patient. Multivariate analyses were run to generate transcriptional interaction networks and identify biomarkers for patients with inflamed pouches.

Results: IL-1Ra, IL-6, IL-8, IL-17, IP-10, MCP-1, MIP-1a, MIP-1b resulted increased in inflamed pouch vs. normal pouch. No differences were registered between samples obtained from the afferent ileal loop. In pouchitis, IL-7 resulted reduced in the inflamed pouch vs. the afferent ileal loop. In pouchitis, IL-33 and ST2 protein levels were reduced in the pouch vs. the afferent ileal loop and resulted overall decreased vs. patients with normal pouch indicating a potential IL-33/ST2-mediated defective healing process. Full-length, bioactive IL33, ST2L and sST2 were expressed in all experimental groups; the cleaved, less active form of IL33 was increased in only patients with pouchitis. IHC confirmed these observations. IL-33 and ST2 staining was less intense within the inflamed and ulcerated mucosa of pouchitis patients compared to normal pouch, and in close proximity to areas of re-epithelialization. An overall decreased biodiversity in patients with pouchitis vs. patients with normal pouch (both at pouch and afferent ileal loop level) was shown. Lower levels of Verrucomicrobia and increased abundance of Actinobacteria were recorded in inflamed pouch vs normal pouch. In pouchitis, the afferent ileal loop and the pouch showed significantly decreased levels of Akkermansia muciniphila and augmented abundance of Collinsella vs. samples obtained from patients with normal pouch. In pouchitis, multivariate analyses evidenced a significant inverse correlation between Collinsella e Collinsella aereofaciens abundance and ST2 levels.

Conclusion: In patients with pouchitis vs patients with normal pouch divergent inflammatory molecular pathways and microbial populations distinctly characterize the pouch and the afferent ileal loop. Overall, our results suggest a potential role for IL-33/ST2 and gut microbiota axis in driving the gut mucosal wound healing in patients with ileal pouch-anal anastomosis. Further studies are underway to determine mechanisms of action that support these findings.

Introduction: The advent of biologics and small molecule inhibitors targeting immunologic mechanisms has revolutionized the landscape of inflammatory bowel diseases (IBD) treatment. However, a significant proportion of patients remain primary non-responders and initial responders can relapse over time. Combining treatments with different mechanisms of action holds potential to increase the clinical response rates in IBD patients. The aim of this study was to examine the potential utility of combining distinct anti-inflammatory mechanism(s) with α4β7 integrin inhibition in IBD. We utilized the clinically relevant $CD4^{+}CD45RB^{hi}$ T cell transfer (TCT) colitis mouse model, which has been used to validate the preclinical monotherapy efficacy of these agents for IBD.

Aims & Methods: At initiation of TCT colitis, *Rag2*$^{-/-}$ mice received anti-α4β7 monoclonal antibody (mAb) alone, or in combination with subtherapeutic doses of an anti-IL12p40 mAb, an anti-IL23p19 mAb, or a small molecule inhibitor (SMi) of TYK2 (deucravacitinib, BMS-986165) for 7 weeks. Colitis development was evaluated via readouts including body weights, gross colon weight by length ratios, transcriptomic analysis of the colonic tissue, and histopathological scores.

Results: In monotherapy settings, treatment with anti-α4β7 significantly inhibited the development of moderate to severe colitis in mice. This was reflected by improved body weights, gross colon weight/length ratios, and histopathology scores (sum of inflammation, erosion, hyperplasia, and gland loss scores) compared to vehicle controls. The combination treatment of anti-α4β7/IL12p40 was the most robust, indicated in part by a highly consistent therapeutic response across study animals, surpassing the therapeutic efficacy of both anti-α4β7 monotherapy and other combination treatments with anti-IL23p19 or TYK2 SMi. On the other hand, anti-α4β7/IL23p19 and anti-α4β7/Tyk2 SMi showed only moderately improved efficacy, compared to anti-α4β7 monotherapy. Finally, tissue transcriptomic analysis revealed involvement of mechanistic pathways related to efficacy, including T cell activation/differentiation for all groups with inhibitors but to different degrees. Additionally, combination treatments showed differences focused within cytokine signaling, innate immune receptor signaling, and antigen presentation pathways.

Conclusion: Inhibition of cytokines IL12/IL23, which drive effector Th1 and Th17 responses, and regulate innate and Jak-STAT signaling, in combination with blockade of the cell trafficking integrin α4β7, resulted in significantly increased protection from colitis compared to monotherapy groups. Combining these agents with different mechanisms of action offers a rational approach to test these combinations for potential increased therapeutic activity in patients with IBD.

CRYPT-VILLUS DYNAMICS POST-DSS EXPOSURE IN MURINE COLITIS MODEL OF INFLAMMATORY BOWEL DISEASE

M. Antolic[1], V. Milutinović[1], A. Markota[1], A. Volaj-Bijelić[1], A. Ognjenović[1], H. Brzica[1], I. Glojnarić[1], S. Čužić[1]
[1]Selvita Ltd., In vivo Pharmacology and Toxicology, Zagreb, Croatia

Contact E-Mail Address: maja.antolic@selvita.com

Introduction: Ulcerative colitis (UC) is a chronic inflammatory disease characterized by mucosa barrier damage, accumulation of neutrophils, formation of crypt abscesses, crypt distortion, loss of goblet cells and in severe cases presence of broad-based ulcers. During the clinical remission phase of the disease mucosa regeneration may occur. Physiological and abortive mucosa healing processes are the focus of pharmaceutical research in attempt to support mucosal regeneration, prevent excessive proliferation accompanied with aberrant differentiation of crypt epithelial cells that can cause development of colorectal carcinoma in latter stages of the disease. In different phases of ulcerative colitis, there is epithelial cell differentiation disorder in the stem cell zone of the crypt base, so the ratio of absorptive and secretory epithelial cells shifts. The aim of this study was to investigate crypt-villus axis dynamics in colon epithelium of regenerative mucosa during recovery phase of DSS-induced colitis mouse model.

Aims & Methods: C57BL/6 mice were exposed to 2% DSS in water for 6 days followed by 6 days recovery phase without DSS consumption. Colon tissue was formalin fixed, paraffin embedded and double stained on: IHC transcription repressor hairy and enhancer of split (HES1) as a marker for absorptive progenitor cells and Alcian-blue Periodic-acid Schiff (AB-PAS) as a marker for secretory goblet cells. Colon mucosa samples from both groups were analysed using digital pathology software (Visiopharm, Denmark). Regions of interest were: regenerative zone next to ulcer and not-inflamed colon mucosa.

Results: In comparison to animals exposed to water only, DSS exposed animals post 6 days recovery period, HES1 expressing absorptive type of epithelial cells within crypts of regenerative mucosa significantly increased. At the same time, goblet cell population in those crypts decreased. Statistically significant difference in presence of goblet cells between regenerative and non-inflamed mucosa in DSS group was observed. Proportion of goblet cells within non-inflamed mucosa of DSS-treated animals remained unchanged compared to negative control, while proportion of HES1 positive cells increased.

Conclusion: In this study we showed changes in stem cell zone niche and crypt-villus axis, in terms of changing cell differentiation from secretory to absorptive lineage within crypts in regenerative colon mucosal layer. This may alter protective role of colon epithelium due to lack of goblet cells that produce mucus thus contributing to the severity of the disease. Results of this study evoke pathological changes within colon crypts observed in human disease and indicate translational value of data obtained by exploration of recovery phase in animal colitis model.

Introduction: Collagenous colitis (CC) is a debilitating, non-destructive inflammatory bowel disease (IBD) that causes intense watery, non-bloody diarrhoea. The abnormal immune response is thought to be initiated by deficient tolerance to commensal gut microbiota, and fecal sample analyses indicate similarities with classic IBD forms as ulcerative colitis and Crohn's disease. Yet, the exact members of the microbiome that might trigger and maintain the disease remain unknown.

Aims & Methods: To identify primary microbial triggers of CC pathogenesis that could directly interact with intestinal epithelial and submucosal cells, we isolated subepithelial mucosa from CC and healthy control (Hc) formalin-fixed paraffin-embedded samples (n=7-10) by using a laser microdissection microscope (PALM MicroBeam LCM, Zeiss, Germany). Isolated nucleic acids were sequenced using shotgun metagenomics in a NovaSeq 6000 platform (Illumina, USA). Microbial communities were identified using MetaPhlan3/4, and microbial metabolic and molecular function pathways using Humann3.2 algorithms.

Results: Bray-Curtis and Jaccard similarity coefficients showed that CC subepithelial microbiome was similar to that from Hc samples. Still, further analyses indicated that microbial metabolic pathways and molecular functions could differ. Microbiota that was associated with CC included Anoxybacillus and Barnesiella, whereas microbiota associated with Hc comprised Bacteroides, Leuconostoc and Lactobacillus.

Conclusion: Mucosa-associated microbiota in CC did not significantly differ from healthy microbiota. However, our results point to a relation of CC with bacteria that form biofilms (Anoxybacillus) and affect the variability of colitis development (Barnesiella). Thus, validation and further follow-up of these results could help us identify CC triggers in the future.

Introduction: Ulcerative colitis (UC) involves inappropriate apoptosis of intestinal epithelial cells and an imbalance between pro-apoptotic and pro-survival molecules, leading to intestinal damage (1). Vagus nerve stimulation (VNS) is of interest for UC treatment due to its anti-inflammatory and protective effects (2). Noninvasive transcutaneous auricular VNS (NitaVNS) can exert protective effects without invasive VNS-associated side effects (3), making it a promising option for UC treatment. Recently, we showed a beneficial correlation between NitaVNS and inflammatory markers in a preclinical model of UC (4).

Aims & Methods: We assessed the effectiveness of NitaVNS in regulating apoptosis in acute UC colitis in mice. Colitis was induced in C57BL/6 male mice (11–12 weeks old) by administering 5% dextran sodium sulfate (DSS) for five days, while the control mice received regular water. NitaVNS (10 V voltage, 10 min stimulation, 500 µS pulse width, and 20 Hz frequency) or sham stimulation started one day before colitis induction and lasted six days. The disease activity index (DAI) was evaluated daily, and macro- and histological scores were evaluated at sacrifice. Colonic and splenic tumor necrosis factor (TNF)-α, interleukin (IL)-1β, IL-6, tumor growth factor (TGF)-β, IL-10, pro-apoptotic markers Bcl-2-associated X protein (BAX), Bcl-2 homologous antagonist killer (BAK1), caspase-8, and pro-survival BCL2 associated agonist of cell death (BAD) were assessed using qRT-PCR and ELISA.
