Aims & Methods: From April 2001 to December 2022, a total of 45,419 colorectal neoplasms, excluding advanced cancer that were resected endoscopically or surgically at Showa University Northern Yokohama Hospital. Among them, 37,098 were low-grade dysplasia, 6,802 were advanced dysplasia, and 1,519 cases were submucosal invasive carcinoma. In this study, we investigated the characteristics of depressed carcinomas with respect to Pit patterns and EC classification.

Results: Of all the T1 colorectal cancers, depressed lesions accounted for 61.4% (324/528). In contrast, flat and protruding lesions accounted for only 2.9% (575/19,578) and 2.7% (673/25,313) of T1 cancers, respectively. Flat (95.1% (18,619/19,578)) and raised (94.2% (23,844/25,313)) lesions showed mostly type IIIL and type IV pit patterns corresponding to adenomas. Among depressed lesions, 92.2% (486/528) were types IIIS, VI, and VN, corresponding to adenocarcinoma in pit pattern classification. On endoscopy, most of the flat or protruding lesions corresponded to adenomas and were classified as type EC2 in the EC classification, whereas the depressed lesions were mostly classified as EC3a and EC3b (91.2%), indicating invasive carcinoma according to the EC classification.

Conclusion: This study demonstrates that depressed colorectal cancer is prone to invade the submucosa, highlighting the need for magnifying endoscopy and endoscopy, regardless of the size of the lesion. Nonetheless, detecting this type of colorectal cancer can present a significant challenge. Thus, greater attention must be devoted to the morphological characteristics of depressed colorectal cancer during routine colonoscopy.

A SYSTEMATIC REVIEW AND META-ANALYSIS OF CONVOLUTIONAL NEURAL NETWORK IN THE DIAGNOSIS OF COLORECTAL POLYPS AND CANCER

A.R. Safarpour[1], K. Keshtkar[2], A. Keshtkar[3], S. Shojaei-Zarghani[4], R. Heshmat[5], R. Sotoudehmanesh[6]
[1]Gastroenterohepatology Research Center, Gastroenterohepatology Research center, Shiraz, Iran, [2]School of Electrical and Computer Engineering, University of Tehran, Tehran, Iran, [3]Department of Health Sciences Education Development, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, [4]Colorectal Research Center, Shiraz, Iran, [5]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran, Iran, [6]Department of Gastroenterology, Digestive Disease Research Center, Digestive Disease Research Institute, Tehran, Iran

Contact E-Mail Address: k.keshtkar@ut.ac.ir

Introduction: Colorectal cancer (CRC) is the third most common cancer and the second cause of cancer-related deaths worldwide [1]. Although the biological pathways that transform the normal colon tissue into malignant tissue are different, polyps are presumed to be the precursor lesions for malignant tumors in all cases [2]. Colorectal polyps (CRP) can be seen in various forms or shapes on colonoscopy. Convolutional neural networks (CNNs) are a class of deep neural networks used for different clinical purposes, including improving the detection rate of colorectal lesions.

Aims & Methods: This systematic review and meta-analysis aimed to assess the performance of CNN-based models in the detection or classification of colorectal polyps (CRP) and colorectal cancer (CRC). A systematic search was performed in MEDLINE, SCOPUS, Web of Science, and other related databases. The performance measures of the CNN models in the detection of CRP and CRC were calculated in the two scenarios of the best and worst accuracy. Stata and R software were used for conducting the meta-analysis.

Results: From 3368 searched records, 24 primary studies were included. The sensitivity and specificity of CNN models in predicting CRP in worst and best scenarios ranged fr3om 84.7-91.6% and 86.0-93.8%, respectively. These values in predicting CRC varied between 93.2-94.1% and 94.6-97.7%. The positive and negative likelihood ratios varied between 6.2-14.5 and 0.09-0.17 in these scenarios, respectively, in predicting CRP, and 17.1-41.2 and 0.07-0.06 in predicting CRP. The diagnostic OR and accuracy measures of CNN models in predicting CRP in worst and best scenarios ranged between 36-162 and 80.5-88.6%, respectively. These values in predicting CRC in the worst and the best scenarios varied between 239.63-677.47 and 88.2-96.4%. The area under the ROC varied between 0.92 to 0.97 in the worst and the best scenarios in CRP, respectively, and 0.98 to 0.99 in CRP prediction.

Conclusion: CNN-based models showed an acceptable accuracy in detecting CRP and CRC.

COMPARISON BETWEEN YOUNG-ONSET VERSUS CLASSICAL COLORECTAL CANCER: CLINICAL, BIOCHEMICAL AND TUMOUR PROFILING

S. Poo[1], K. Andrews[1], G. Chander[1], A. Shrestha[1], J. Fahim[1], F. Amjad[1], A. Rajendran[2], R. Rameshshanker[1]
[1]Hillingdon Hospital, Gastroenterology, London, United Kingdom, [2]Hillingdon Hospital NHS Foundation Trust, London, United Kingdom

Contact E-Mail Address: stephanie.pooxw@gmail.com

Introduction: There is an increasing incidence of young-onset colorectal cancer (YOCRC), which is defined as patients with colorectal cancer at age 50 years and younger. They present with a distinct clinical phenotype compared to classical-onset CRC (COCRC), with a more aggressive disease at presentation, as well as different tumour location and mutational signatures. There is an unmet clinical need to elucidate the unexplained epidemiologic rise in incidence as well as disease pathogenesis of YOCRC.

Aims & Methods: To compare the clinical presentation, tumour characteristics and survival of young-onset versus classical-onset CRC.

A retrospective evaluation of patients diagnosed with colorectal cancer from 2019 to 2022 at a district general hospital was performed. We extracted data from electronic patient records for clinical, biochemical, radiological as well as histopathological reports. Comparisons were made between patients diagnosed at </=50 years (YOCRC) and >50 years of age (COCRC) respectively, and statistical analyses were performed. A p-value of <0.05 was considered statistically significant.

Results: 34 (11.1%) and 273 (88.9%) patients were diagnosed as YOCRC and COCRC respectively. There was a difference in clinical presentation between the two groups, with haematochezia (n=12, 35.3%) (p=0.03) and change in bowel habit (n=7, 20.6%) predominating in the YOCRC group, versus positive faecal immunochemical test (FIT) (n=102, 37.4%) and anaemia (n=78, 28.6%) in the COCRC group respectively. There were no differences in the tumour location between groups, with >50% of cases arising from the left colon (22 YOCRC versus 149 COCRC). Thrombocytosis (platelet count>450x10^9/L) (24% vs 11%, p=0.038) and tumour budding (12% vs 3%, p=0.006) were significantly increased in the YOCRC group. There were no significant differences in the histological subtype, TNM staging, mutational profiling and survival between groups. 6 (17.6%) YOCRC patients had died compared to 116 (37.8%) in the COCRC cohort over a median follow-up of 16 months.

Clinical presentation n (%)	YOCRC (n=34)	COCRC (n=273)	p
Positive FIT	8 (23.5)	102 (37.4)	0.113
Anaemia	6 (17.6)	78 (28.6)	0.178
Change in bowel habit	7 (20.6)	70 (25.6)	0.522
Haematochezia	12 (35.3)	53 (19.4)	0.033*
Abdominal pain	6 (17.6)	34 (12.5)	0.396
Weight loss	5 (14.7)	30 (11.0)	0.520

*p<0.05

Table 1: Clinical presentation of YOCRC and COCRC

Conclusion: Young-onset colorectal cancer represents a challenging subset of CRC, which has a different clinical and tumour phenotype to classical-onset CRC. Our study reflects the reported incidence rates of YOCRC of 11%, although the true epidemiology and frequency of YOCRC remains to be clarified. Haematochezia was the commonest presentation, while thrombocytosis and tumour budding were higher in the YOCRC group, suggesting a more advanced disease at diagnosis. Although the overall

survival rates were similar between groups, further research would benefit from larger prospective studies with subdivision of YOCRC cases by age as poorer survival have been suggested in patients aged <30 years. There is a need to elucidate the respective aetiologies, environmental risk factors and pathogenesis of YOCRC, to allow early targeted treatment of such cases.

Introduction: The incidence of early-onset colorectal cancer has been increasing worldwide, and action is urgently needed to address this problem. Although we have previously reported age-related changes with respect to molecular pathology, the vast majority remains unknown regarding the clinicopathologic characteristics of early-onset colorectal cancers and adenomas, especially those resected by endoscopic approaches. In this study, we defined early-onset colorectal tumors as adenoma and carcinoma diagnosed age at 40 or under. The aim of this study was to examine the clinicopathologic characteristics of endoscopically resected early-onset colorectal tumors compared with later-onset colorectal tumors diagnosed at age 40 or older.

Aims & Methods: We examined the clinicopathological characteristics of endoscopically resected colorectal adenomas and carcinomas in 1,005 patients with 2,367 lesions including early-onset colorectal carcinoma/adenoma (159 lesions in 96 consecutive cases from January 2010 to December 2020), late-onset colorectal carcinoma (183 lesions in 90 cases from January 2010 to December 2020), and late-onset adenoma (2,025 lesions in 819 consecutive cases from January 2020 to July 2020) endoscopically resected at the Nippon Medical School Hospital. The chi-square test was used to compare categorical variables, and the Mann-Whitney U test was used to compare continuous variables.

Results: Median age (quartiles) and sex (female/male) of cases were 37 (34-38), 34 (35%) / 62 (65%) in the early-onset tumor group; and 55 (46-72), 277 (30%) / 632 (70%) in the late-onset tumor group, respectively. The distribution rate of tumor location was 49 cases (31%) for proximal colon, 97 (61%) for distal colon, 13 (8.2%) for rectum in the early-onset group; and 1085 (49%), 899 (41%), 83 (10%) in the later-onset group, respectively. Macroscopic types were classified into Ip for 46 cases (29%), Is and Isp for 100 (63%), II for 13 (8.2%) in the early-onset group; and 278 (13%), 1574 (71%), 356 (16%) in the late-onset group, respectively. Histological types were classified into tubular adenocarcinoma or papillary carcinoma for 14 cases (8.8%), high-grade tubular adenoma (TA) for 36 (23%), low-grade TA for 97 (61%), sessile serrated lesion or traditional serrated adenoma for 12 (7.5%) in the early-onset tumor group; and 183 (8.3%), 281 (13%), 1655 (75%), 89(4%), respectively. Compared with the later-onset colorectal tumors, a higher rate of left-sided tumor location and macroscopic type Ip was observed in the early-onset colorectal tumor (p <0.001, respectively). When limited to adenoma lesions, the rate of high-grade was significantly higher in the early-onset colorectal adenomas than those in the later-onset colorectal adenomas.

Conclusion: Regarding tumor location and macroscopic type, unique clinicopathological features were observed in early-onset colorectal tumors compared with later-onset colorectal tumors. Further studies are needed to investigate the association between early-onset colorectal cancer and adenomas stratified by the method by tumor resection.

ASSESSING EMPIRICAL THRESHOLDS FOR INVESTIGATION IN PEOPLE REFERRED ON A SYMPTOMATIC COLORECTAL CANCER PATHWAY: A COHORT STUDY UTILISING FAECAL IMMUNOCHEMICAL AND BLOOD TESTS IN ENGLAND

C. Crooks[1], A. Banerjea[2], J. Jones[2], J. West[3], C. Chapman[4], S. Oliver[5], D.J. Humes[1]
[1]University of Nottingham, Nottingham Digestive Diseases Centre / NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom, [2]Nottingham University NHS Trust, Colorectal Surgery, Nottingham, United Kingdom, [3]Univesity of Nottingham, Division of Epidemiology and Public Health, Nottingham, United Kingdom, [4]Nottingham University NHS Trust, Bowel Cancer Screening Hub, Nottingham, United Kingdom, [5]Nottingham City Clinical Commissioning Group, Nottingham, United Kingdom

Contact E-Mail Address: colin.crooks@nottingham.ac.uk

Introduction: In colorectal cancer (CRC) the pathway to diagnosis has rapidly evolved over the past 5 years incorporating Faecal Immunochemical Testing (FIT) as the chosen biomarker in the field. A FIT cut off of ≥10 µg Hb/g faeces is recommended by NICE for investigation of colorectal cancer (CRC) on an urgent pathway based on an expected CRC risk threshold of 3% in England. It is crucial to balance the risk of CRC against the ability of the health service to investigate and diagnose cancer in an appropriate and timely manner.

Aims & Methods: Our aim was to determine the empirical thresholds of CRC risk in a representative population at different FIT cut offs to assess optimal use of FIT in patients with symptoms of CRC. Cohort study of a symptomatic CRC pathway from primary care with a FIT test in Nottingham, UK (November 2017-2021) with 1-year follow-up. Heat maps showed the cumulative 1-year CRC risk using Kaplan-Meier estimates stratified by FIT (fHb <4 µg Hb/g faeces, 4-9.9 µg Hb/g faeces, 10-19.9 µg Hb/g faeces, 20 – 39.9 µg Hb/g faeces, 40- 99.9 µg Hb/g faeces and ≥100 µg Hb/g faeces), age, anaemia (≤130g/l in men; ≤120g/l in women), and thrombocytosis (≥400 x10^9/l). We estimated the number of investigations that could potentially be re-purposed if a threshold of ≥3% 1-year risk of CRC was instigated.

Results: In total 514 (1.5%) CRC's were diagnosed following 33694 index FIT tests. Individuals with a FIT ≥10 µg Hb/g faeces had a greater than 3% risk of CRC, except patients under the age of 40 years (CRC risk 1.45% (95% CI 0.03-2.86%)). Non-anaemic patients with a FIT <100 µg Hb/g faeces had a CRC risk of less than 3%, except those between the age of 70-85 years (CRC risk 5.26% 95% CI 2.72-7.73%). Non-anaemic patients do not meet the 3% threshold set by NICE for investigation until they have a FIT ≥40 µg Hb/g faeces. In contrast, those patients with anaemia meet the 3% threshold at a FIT of ≥20 µg Hb/g faeces. Using a ≥3% CRC threshold in patients < 55 years calculated using FIT, age and anaemia would allow 160-220 colonoscopies per 10000 FIT tests to be re-purposed, at a cost of missing 1-2 CRCs.

Conclusion: CRC risk varies by FIT, age and anaemia when fHb levels are below 100 µg Hb/g faeces. Tailored FIT cut offs for investigation on a CRC pathway could reduce the number of investigations needed at a 3% CRC risk threshold rather than a single cut off of ≥10 µg Hb/g faeces.

EVALUATION THE EXPRESSION OF MAP1LC3A AUTOPHAGY GENE AND ITS RELATED LNCRNAS AND MIRNA IN 5-FU CHEMORESISTANT COLORECTAL CANCER CELL LINES

E. Shams[1], E. Nazemalhosseini-Mojarad[2]
[1]RIGLD, Cancer, Tehran, Iran, [2]RIGLD, Tehran, Iran

Contact E-Mail Address: elaheshams.bio@gmail.com

Introduction: One of major obstacles of treatment in colorectal cancer (CRC) is drug resistance, specially 5-Fu chemoresistance which is a fundamental drug in CRC chemotherapy. Also, there is no reliable biomarkers in order to identify chemoresistance patients and improve their treatment. There are several factors that cause 5-FU chemoresistance include autophagy. This cell death phenomenon is played key role in 5-FU chemoresistance in CRC patients by providing nutritarians for CRC cells in hard circumstances; also, autophagy has regulated by different factors like genes and non-coding RNAs(ncRNA).

Aims & Methods: Verifying key gene in autophagy pathway at KEGG database. Moreover, evaluation the expression of key gene in CRC patients at TCGA database. Investigation on the key gene related LncRNAs and miRNAs in CRC at LNCpedia and mirTARBase database respectively, in order to find most relevant ncRNAs of this gene and obtain proper biomarkers. Developing 5-FU chemoresistance Caco2 and SW480 cell lines by increasing dosage of drug and MTT assay was performed to confirm the chemoresistance cell lines and western blot was performed to confirm autophagy in cell lines. Finally, evaluating the expression of MAP1LC3A and its related ncRNAs in 5-FU chemoresistant CRC cell lines by qRT-PCR.

Results: MAP1LC3A was confirmed as key gene based on KEGG analysis; also, FAM225A, NCK1-DT, LINC01825, LINC02188 and miR-335-5p have nominated as most relevant ncRNAs based on bioinformatic analysis. Furthermore, qRT-PCR analysis of MAP1LC3A and its related ncRNAs have shown differential expression between chemoresistant and chemoresistant CRC cell lines.

Conclusion: These findings indicate that FAM225A, NCK1-DT, LINC01825, LINC02188 and miR-335-5p participate in autophagy by effecting the expression of MAP1LC3A gene and they can function as proper biomarkers for 5-FU chemoresistance CRC patients. Not only they can function as biomarkers but also, they can attend in target therapy by designing siRNAs to knockdown this ncRNAs and enhance chemotherapy in CRC patients.

THE OPTIMIZATION AND EVALUATION OF CELL LINE-DERIVED XENOGRAFT MOUSE MODELS FOR COLORECTAL CANCR WITH LIVER METASTASIS

Y. Liu[1], J. Wang[1], Q. Lu[1], B. Xia[1], J. Yang[1]
[1]West China Hospital of Sichuan University, Chengdu, China

Contact E-Mail Address: liuyuzhi121@foxmail.com

Introduction: Liver metastasis is one of the main reasons for colorectal cancer (CRC)-related deaths due to the lack of effective therapeutic. CRC cell line-derived xenograft (CDX) mouse models developed by orthotopic injection in the cecum, ectopic injection in the spleen or the portal vein are essential invivo tools for exploring the mechanism of liver metastasis and testing potential chemotherapeutic agents. We did this study to evaluate and optimize the establishment of these models, and emphasize characteristics of liver metastatic foci derived from different CRC cell lines.

Aims & Methods: Luciferin-expressing HCT116 cells, SW480 cells and SW620 cells were used to induce mouse models of CRC with liver metastases by the cecum injection, intrasplenic injection and intraportal injection. The metastatic characteristics of tumors were confirmed and evaluated by bioluminescence imaging, macroscopic and microscopic appearance. Furthermore, we improved and evaluated the procedures of these CRC CDX mouse models, and comprehensively summarized their performances in the aspect of liver metastasis with three popular cell lines.

Results: Models established by cecal injection and intrasplenic injection displayed similarly in the operation difficulty, cell number to need and frequency of metastasis. The bioluminescence imaging usually had a strong and concentrated signal in cecum, but a weak or moderate signal in the spleen respectively, and accompanied with a diffuse signal or no signal in the liver. The model for HCT116-induced liver metastasis could be well established by intrasplenic injection, showing granular lesions with tumor pleomorphic variation, invasion, erosion and necrosis. SW480 and SW620-derived models by cecal or intrasplenic injection characterized macroscopically with nodular, white grey metastatic foci throughout the liver tissue, and identified with scattered, sub-rotund, uniform-sized and infiltrative pathological changes. However, the metastatic lesions were more and larger in the interior of liver tissues in the cecum injection model within 6 weeks, suggesting its superiority. Intraportal injection had technique difficulty in the discovery and puncture of the portal vein, probably leading to post-operated hemostasis and mouse deaths. The metastatic foci developed from intraportal injection were hardly displayed obvious findings in macroscopic appearance, and few or small-sized sporadic lesions under microscopy could be detected.

	Orthotopic injection in the cecum	Intrasplenic injection	Intraportal injection
Cell number for injection	~3,000,000	~3,000,000	~700,000
Bioluminescence imaging performance	Strong and concentrated signal in the cecum, no signal or diffuse signal in the liver	Weak or moderate signal in the spleen, no signal or diffuse signal in the liver	Almost no signal anywhere
Macroscopic appearance of liver metastatic foci	HCT116: Shapeless lesions with erosion or necrosis	HCT116: Granular, dark-red changes with diffuse erosion or necrosis throughout the liver tissue	HCT116: Hard to identify
	SW480: Scatterd nodular, white or grey medium-sized foci	SW480: Nodular, white or grey medium-sized foci throughout the liver tissue	SW480: Rare nodular foci
	SW620: Scatterd nodular, white or grey small-sized foci	SW620: Nodular,white or grey, small-sized foci throughout the liver tissue	SW620: Rare nodular foci
Microscopic characteristic of liver metastatic foci	HCT116: Scattered, irregular, infiltrative and even necrotic foci	HCT116: Large-area, irregular, invasive and necrotic foci	HCT116: Concentrated, irregular, infiltrative and even necrotic foci
	SW480: Scattered or diffuse, subrotund,uniform in medium size	SW480: Scattered, subrotund, uniform in medium size	SW480: Sporadic, isolated, subrotund
	SW620: Scattered, subrotund,uniform in smaller size	SW620: Scattered, subrotund, uniform in smaller size	SW620: Scattered, tiny and slightly infiltrative foci
The comprehensive evaluation of the models for liver metastasis	HCT116: Suboptimal SW480: Suboptimal SW620: Excellent	HCT116: Excellent SW480: Suboptimal SW620: Suboptimal	HCT116: Mediocre SW480: Mediocre SW620: Mediocre

Table 1: The opitimization and evaluation of the establishment of three CDX models.

Conclusion: The study provides not only useful information for the establishment of CRC CDX models for liver metastasis, but also novel insights for identifying characteristics of metastatic foci induced by different cell lines.

Disclosure: No conflict of interest.

PP1025

ORGAN PRESERVATION USING CONTACT RADIOTHERAPY FOR EARLY RECTAL CANCER: AN ATLAS OF CLINICAL RESPONSE

M. Metry[1], I. Hunter[2], A. Dhadda[2]
[1]Castle Hill Hospital, Hull University Teaching Hospitals NHS Trust, Colorectal Surgery, Doncaster, South Yorkshire, United Kingdom, [2]Hull University Teaching Hospitals, NHS Trust, Colorectal Surgery, Hull, United Kingdom

Contact E-Mail Address: mario_elia123@yahoo.com

Introduction: Contact radiotherapy enables organ preservation in a subset of early cancer patients. An 80% response rate followed by an 80% sustained response is indicated by published results. Early detection of relapse is crucial to successful salvage. Even without recurrence, luminal change between 90 and 110 g/m2 can be significant and long-lasting. One of the most challenging parts of care is still follow-up.

As a result, endoscopy, histology, and imaging are used in combination for follow-up. Endoscopy results are highly variable and challenging to interpret clinically without training.

Our main goal is to identify a typical luminal appearance pattern and assign a classification scheme for straightforward documentation.

Aims & Methods: In order to make documentation easier, our main goal is to identify a typical pattern of luminal appearance.

Hull Teaching Hospital's medical cancer clinic between September 2015 and August 2019. Patients underwent an endo-rectal ultrasound, a chest CT, an MRI of the liver, and an MRI of the pelvis. Patients who were either deemed unfit for radical surgery or who declined it because they required a permanent stoma Three flexible sigmoidoscopies per month, a liver MRI, and a 12-monthly chest CT scan made up the patient's follow-up.

During follow-up for patients who were enrolled, we implemented our grading system in the stratification of endoscopic findings. All endoscopic findings were staged using our grading system by a colorectal consultant surgeon, an oncologist, and two foundation-year doctors in order to account for inter- and intraobserver variability.

The endoscopy findings were graded as G0: non-visible luminal change, G1: complete clinical response (flat white scar), G2: superficial ulceration (flat edge, partial reepithelization, slough, or granulation tissue base), G3: raise or nodule (adenomatous tissue like a polyp), and G4: rolling edges (visible tumor) or satellite lesions.

Results: A total of 64 patients have been treated with contact radiotherapy plus or minus external beam radiotherapy without primary surgical excision. The median age is 78 years (50–94 years). We found out that the overall survival rate was 88%. Disease-free survival was 86%, and overall survival was 88% with a median follow-up of 24 months. Mortality from the primary contact procedure was 0%.

Statistical analysis: We calculated the intraclass correlation coefficient (ICC) to access inter-observer agreement, and the results presented include the 95% confidence interval. We also reported the inter-observer correlation matrix and adopted the classification system for ICC as described in Landis (1977) http://pubmed.ncbi.nlm.nih.gov/843571/ with values higher than 0.8 to be deemed "almost perfect" agreement. Analysis was run using SPSS version 25.

Results: The interobserver correlation matrix shows that agreement between the colorectal consultant score and the juniors is slightly better than their agreement with the oncology consultant scores. The ICC was 0.966(95% CI: 0.958 to 0.972) showing almost perfect agreement.

Conclusion: The grading system is an easy-to-reproduce tool for monitoring the response of radiotherapy in patients undergoing organ preservation using contact radiotherapy for early rectal cancer. It will establish a typical pattern of luminal appearance and assign a classification system for ease of documentation and case-to-case follow-up.

EFFECTS OF IRON TREATMENT PATHWAY ON MACROPHAGE POLARISATION IN COLORECTAL CANCER PATIENTS WITH IRON DEFICIENCY ANAEMIA

A. Marley[1], H. Cooke[1], E. Dickson[2], K. Povey[1], A. Mushtaq[1], B. Keeler[3], N. Yassin[4], A. Acheson[2], H. Omar[1], M.J. Brookes[1]

Contact E-Mail Address: alexandramarley@nhs.net

Introduction: Colorectal cancer (CRC) is strongly associated with iron due to the role of gut epithelium in iron uptake and the exposure of luminal epithelial cells to iron, iron trafficking within the tumour microenvironment (TM), and the role of iron in cell function including that of immune cells and tumour cells (1,2).

Tumours do not grow in isolation; they are reliant on the function of other cells within the TM (3). These cells interact with the tumour, providing tumour cells with nutrients including iron (4,5).

Within the TM, monocytes are polarised into proinflammatory (M1) macrophages and alternatively activated (M2) macrophages. M1 macrophages are characterised by production of pro-inflammatory cytokines such as IL-12, production of reactive oxygen species, and activation of Th1 responses. These cells are involved in immune surveillance and anti-cancer functions. In contrast, M2 macrophages have an anti-inflammatory phenotype and tumour promotion (6).

Tumour associated macrophages that resemble M2 macrophages have been shown to promote angiogenesis, matrix remodelling, and immune suppression (7,8) and have been associated with worse patient outcomes (9).

Iron may affect the tumour cells within the TM by influencing macrophage polarisation. Mice fed an iron-enriched diet increased M2 polarization of macrophages with increase in M2 markers (10). However, the situation is more complex as extravasation of red blood cells during neoangiogenesis resulting in a haemorrhagic environment repolarised the macrophages to an M1 phenotype with the ability to kill cancer cells (8). These results suggest that haemolytic RBCs and iron influence macrophage polarisation and are important players within the TM and an important focus for research in CRC.

Aims & Methods: The study aims were to determine the effects of iron treatments on the differentiation of macrophages within the TM in anaemic patients with CRC.

Normal and tumour tissues were obtained from patients in the IVICA trial (REC reference 11/EM/0237). Patients with CRC and iron deficiency anaemia were randomised to receive oral ferrous sulphate (n=20) or IV ferric carboxymaltose (n=20). Using immunofluorescence microscopy, we identified macrophages as being CD68 positive and demonstrated the expression of TLR2, suggesting that these are M1 macrophages. The pattern of M1 macrophages were confirmed with further experiments as cells that were CD68 and MHC-II (HLA-DR) positive. M2 macrophages were identified as CD68 and CD163 positive cells.

Results: Macrophages expression was significantly higher on tumour tissues from patients who received IV ferric carboxymaltose compared with oral ferrous sulphate ($p<0.02$). In CRC tissues, macrophages were localised as clusters mainly in the stromal tissue.

The number of M1 polarised macrophages was significantly higher in the TM of patients treated with IV ferric carboxymaltose than in those colorectal cancer patients treated with oral ferrous sulphate ($p=0.01$).

There was a trend towards an increase in M2 polarised macrophages in the tumour samples of those patients treated with oral iron, however, this was not significant.

Conclusion: This is the first study in humans to investigate the effect of iron treatment on the phenotype of macrophages within the TM. Data demonstrates that IV ferric carboxymaltose may increase the recruitment and / or polarisation of macrophages to an M1 phenotype within the TM in anaemic CRC patients. These results have the potential to influence patients' management as our work suggests that IV ferric carboxymaltose may be preferable to oral ferrous sulphate.

Introduction: Reovirus, a naturally occurring oncolytic virus, triggers the lysis of tumor cells while also releasing tumor antigens or proapoptotic cytokines into the tumor microenvironment to enhance anticancer immunity. However, reovirus has developed a strategy to evade antiviral immunity by inhibiting interferon production, which negatively affects the induction of antitumor immune responses. The mammalian adaptor protein Stimulator of Interferon Genes (STING) has been identified as a crucial regulator that orchestrates immune responses by sensing cytosolic DNA derived from pathogens or tumors, resulting in the production of type I interferon.

Thus, we hypothesize that activation of the STING axis can counteract the suppression of type I IFN responses by reovirus, and combination treatment with reovirus and a STING agonist can promote anticancer immunity by improving the tumor microenvironment. In this study, we investigated the effects of combining reovirus with a STING agonist on antitumor immunity.

Aims & Methods: To investigate the role of immune responses in primary tumor growth inhibition, we performed a dual flank study using an immunocompetent syngeneic model. In the dual flank syngeneic mouse tumor model, CT26 cells were implanted on both sides of a mouse, and then one tumor was injected with reovirus, ADU-S100, or reovirus and ADU-S100, while the other tumor remained untreated. To further verify the immunotherapeutic effect of the T cell infiltration in tumor tissues of mice receiving the combination treatment, we also performed the tumor-infiltrating lymphocytes profiling in the tumor tissues of mice with the treatment using fluorescence-activated cell sorting (FACS).

Results: The combination treatment of reovirus and ADU-S100 induced significant regression in the treated tumor and the untreated distant tumor, indicating that the combination treatment activated a systemic immune response in the dual-flank tumor model. However, intratumoral (IT) injection of reovirus or ADU-S100 alone did not significantly delay tumor growth in the untreated distant tumor. The combination treatment also significantly prolonged the survival of mice bearing dual tumors. The tumor-infiltrating lymphocyte profiling showed a significantly lower CD4:CD8 T cell ratio in the treated and untreated tumors from CT26 tumor-bearing mice treated with the combination IT injection of reovirus and ADU-S100, compared to the untreated controls. However, there were no significant differences in the CD4:CD8 ratio between the control and other treatment groups. We also detected a significant reduction in the ratio of regulatory T cells in tumors treated with reovirus alone or the combination of reovirus and ADU-S100 compared to the control.

Conclusion: We demonstrated the ability of oncolytic reovirus to induce tumor regression in a CT26 syngeneic tumor model and showed that the combination treatment of reovirus and a STING agonist enhanced antitumor immunity. This enhanced antitumor response was partially mediated by IFN-induced T cell activation. Although further investigation is required to clarify the mechanism underlying the synergy between STING agonist

and reovirus in promoting immune responses and anti-tumor activity, our combination treatment strategy may have potential as an immunotherapy against colorectal cancer.

Introduction: Recently, the increase of young-onset colorectal cancer (yCRC) has been reported, and the age at which colorectal cancer screening is started has been lowered in some countries. Although the characteristics of advanced-stage yCRC or high-grade dysplasias(HGDs) have been reported, there have been few reports of early-stage yCRC or HGDs so far.

Aims & Methods: The aim of this study is to investigate the clinical and pathological characteristics of early-stage yCRC and colorectal HGDs. We retrospectively reviewed the electrical health record data of pathologically diagnosed pT1 colorectal cancers and colorectal HGDs that were resected endoscopically or surgically in our institution from January 2019 to December 2021. The pathological diagnosis was done according to the Japanese Classification of Colorectal Carcinoma. The cases were categorized into two groups: the young group (Y group) or the elderly group (E group). The definition of Group Y and Group E were patients aged 50 years or younger, and those aged 51 years or older respectively. The following factors were evaluated by univariate analysis; age, sex, and the number of experienced endoscopies of the patients; location, size, macroscopic type, histology of the lesion; and depth of invasion. Regarding the morphology or the lesions, 0-Ip, and 0-Is were categorized as protruded lesions, whereas 0-IIa and 0-IIc were categorized as superficial lesions. Statistical analysis was done by the Mann-Whitney U test for continuous variables and Fisher's exact test for categorical variables. All tests were two-sided, and P<0.05 was considered to be statistically significant.

Results: There were 34 cases in group Y and 314 cases in group E, with a median age (range) of 45 years old (32-50) and 72 years old (51-93), respectively. Sex was male:female=20:14 and male:female=204:110. First-time examination cases were significantly higher in the Y group than in the E group (91.2%:50.6% ;P<0.0001). Regarding the location, the sigmoid colon was the most common in both Y and E groups (55.9%:30.3%). The number of CRC in the left side colon is significantly larger in the Y group than in the E group (79.4%: 62.7%; p=0.0375). In terms of macroscopic type, 0-Ip was most common in group Y(16(41.7%)), whereas 0-lla was most common in group E(137(43.6%)). The number of protruded type early-stage CRC is larger in the Y group than in the E group (82.3%: 58.9%; p=0.005). The median tumor diameter (range) was 16 mm (8-60) and 12 mm (5-155) in Y and E groups respectively. Regarding the histology, well-differentiated tubular adenocarcinoma (Tub1) was the most common histological type in both groups, they were 32(94.1%) in group Y and 282(89.8%) in group E respectively(p=0.4756). pTis (HGDs) were also the most common depth of invasion in both group, they were 25(73.5%) in group Y and 241(77.0%) in group E respectively(p=0.7903).

	Group Y (n=34)	Group E (n=314)	p value
Age, year, mean, (range)	45(32-50)	72(51-93)	
Sex, n, (%) male / female	20(58.8) / 14(41.2)	204(65.0) / 110(35.0)	0.5721

Introduction: Treatment of rectal cancer requires an understanding of presenting stage and therapeutic modalities to provide appropriate and effective multimodality approaches that are oncological sound and respectful in terms of organ preservation and survivors' quality of life. Imaging (endoscopic ultrasound (EUS) and/or magnetic resonance imaging (MRI)) determines the locoregional staging and optimal treatment for rectal cancer patients. However, for pT1 rectal cancer usually arising into a locally resectable polyp, the yield and role of this diagnostic techniques are no well-established.

Aims & Methods: Aim: To describe the use of locoregional staging and analyze its yield in a pT1CRC state-wide population-based cohort of pT1 rectal cancers.

Patients and methods: Nation-wide population-based cohort, multicenter study (EpiT1Consortium), including 33 centers from 12 different Spanish states. All pT1 CRC cases diagnosed between 2007-2018 were included regardless of the treatment received. Exclusion criteria were: histology other than adenocarcinoma, cancer hereditary syndromes, inflammatory bowel disease, synchronous and metachronous colorectal cancer in the previous 5 years, metastatic neoplastic disease at the time of diagnosis. Information on the demographic of the patient, diagnosis, staging, treatment, complications and histology of pT1 as well as a minimum of 2 years follow-up were collected. Multivariate analysis was performed using binary logistic.

Results: From 3161 patients of the EpiT1 cohort, 681 pT1 rectal cancer with complete information on staging were included for the analysis. 424/681(62.3%) underwent staging: 234(55.2%) with MRI only, 131(30.9%) MRI and EUS, 59(13.9%) only EUS. The characteristics independently associated with the staging (MRI and/or EUS) were: location in lower/middle vs upper rectum (69.1% vs 30.9%; OR 2.8[1.7-4 .5]), suspicion of invasive carcinoma at baseline colonoscopy (64.8% vs 35.2%; OR 2.6[1.6-4.2]), high risk vs low risk histology (69.5% vs 30.5%; OR 2.4[1,3-4,2]), patient management by other specialist (surgeon, oncologist, MDT) vs gastroenterologist (82.7% vs 17.3%; OR 2.2[1.3-3.7]). T staging was correct with MRI in 54/191(28,3%) and with EUS in 69/117(59%) and considering staging by MRI or EUS, 67.1% of patients were over-staged for the T. For N staging considering MRI or EUS the sensitivity and specificity were 15.4% and 82.6%, respectively (Table 1).

	MRI and EUS		Only MRI		Only EUS	
	N+ or recurrence (all therapies) N=82	N+ (oncological surgery) N=39	N+ or recurrence (all therapies) N=243	N+ (oncological surgery) N=122	N+ or recurrence (all therapies) N=121	N+ (oncological surgery) N=49
Sensitivity %	0% (0/2)	0% (0/1)	15,8% (3/19)	16,7% (2/12)	0% (0/6)	0% (0/2)
Specificity %	87,5% (70/80)	78,9% (30/38)	91,1% (204/224)	85,4% (94/110)	96,5% (111/115)	93,6% (44/47)
PPV %	0% (0/10)	0% (0/8)	13% (3/23)	11,1% (2/18)	0% (0/4)	0% (0/3)
NPV %	97,2% (70/72)	96,8% (30/31)	92,7% (204/220)	90,4% (94/104)	94,9% (111/117)	95,6% (44/46)

Table 1. Diagnostic accuracy for N: in MRI+EUS, only MRI and only EUS

Conclusion: The limited yield of locoregional staging imaging techniques should be taken into account when choosing the therapeutic strategy of suspected/known T1 rectal cancers. For T staging, considering the high rate of over-staging with imaging modalities, a stepwise approach using histopathology from a local en-bloc resection as a first step seems reasonable. For N staging, a major effort has to be performed to increase the yield of staging modalities in clinical practice.

EFFECTS OF THE NEWLY DEVELOPED LARGE NEUTRAL AMINO ACID TRANSPORTER1 INHIBITOR, JPH203 ON TUMOR MICROENVIRONMENT IN COLORECTAL CANCER

R. Otani[1], H. Takigawa[1], M. Ariyoshi[1], D. Shimizu[1], R. Miyamoto[1], Y. Hiyama[2], R. Yuge[1], Y. Urabe[3], A. Ishikawa[4], Y. Kitadai[5], S. Oka[1]

Introduction: The large neutral amino acid transporter family (LAT1-4) is responsible for the cellular uptake of essential amino acids. LAT1, in particular, is dominantly expressed in cancer cells and attracts attention as a target for therapy. Previously, the tumor growth inhibitory effect of pan-LAT inhibitor, 2-aminobicyclo-(2,2,1)-heptane-2-carboxylic acid (BCH), has been reported in *in vitro* and *in vivo* therapeutic experiments. However, because BCH inhibits whole LAT family proteins including LAT1 and LAT2, it is expected that agents with high LAT1 specificity will be superior to BCH regarding fewer side effects. JPH203, a novel LAT1 inhibitor with high LAT1 specificity, was recently developed. We aimed to evaluate the efficacy and anti-tumor action mechanism of JPH203 in colorectal cancer (CRC).

Aims & Methods: LAT family gene expressions in public databases were analyzed using UCSC Xena, and LAT1 expression was evaluated using immunohistochemistry in surgically resected CRC. Moreover, we evaluated the growth inhibitory effect of JPH203 in several CRC cell lines. Furthermore, JPH203 treatment experiments were conducted using the allogeneic immune-responsive mouse model with abundant stroma, which was created by orthotopic transplantation of the mouse-derived CRC cell line CT26 and mesenchymal stem cells (MSCs). The anti-tumor effect was evaluated by comprehensive gene expression analysis using mouse tumor tissue-derived RNA and validated in mouse tumors, clinical specimens, and *in vitro*.

Results: Database analysis and immunohistochemistry for clinical specimens showed that LAT1 expression was cancer-dominant and correlated with prognosis. JPH203 showed high efficacy in *in vitro* and significantly reduced tumor size and metastasis in *in vivo*. RNA sequencing-based pathway analysis showed that not only tumor growth and amino acid metabolism pathways but also stromal activation-related pathways were suppressed. The inhibitory effect on tumor stroma was validated by vimentin immunostaining in clinical specimens, co-culture assay with CT26 and MSCs *in vitro*, and E-cadherin and vimentin fluorescent double staining in *in vivo*.

Conclusion: LAT1 expression in CRC plays a significant role in tumor progression, and JPH203 may inhibit CRC progression and tumor stroma. The stromal inhibitory effect of JPH203 may be beneficial in considering its application to other stroma-abundant carcinomas and its use combined with other drugs.

Disclosure: Nothing to disclose.

CHEMORADIOTHERAPY AS A THERAPEUTIC APPROACH FOR RECTAL ADENOCARCINOMA AFTER LOCAL EXCISION WITHOUT CURABILITY CRITERIA

I. Pestana[1], A. Mascarenhas[2], P. Barreiro[2,3], G.M. de CCR do IPOLFG[4], I. Rosa[5], C. Chagas[2], I. Claro[5]

Introduction: Rectal adenocarcinomas (ADC) are associated with a higher rate of recurrence but also with greater surgical morbidity when compared to those of the colon. Local excision (LE) of early colorectal ADC that meet curability criteria (CC) is associated with excellent outcomes, and only surveillance is recommended. However, in the presence of non-curative LE criteria, salvage treatment should be performed. Although in most cases this includes surgery with lymphadenectomy, another possible approach is radio +/- chemotherapy (RT/CRT) followed by surveillance, in a "watch and wait" (WW)-like strategy, with surgery only in case of persistence or recurrence of injury.

Aims & Methods: This work aims to evaluate oncological outcomes in a cohort of patients after LE of early rectal ADC without CC, submitted to different clinical options (surveillance, RT/CRT followed by WW and surgery). It is a retrospective study including patients evaluated at two tertiary hospital centers for pT1/pT2 rectal ADC who underwent LE (endoscopic or transanal resection - TAR) between 12/2011-12/2022.

ADC pT1, low grade, sm1, without lymphovascular or perineural invasions, without high grade budding and with free margins were considered CC.

Clinical options in patients without CC, their complications and outcomes were analyzed.

Results: 64 patients were included in which the CC for LE were not met (5 for pT2; 3 for high grade; 8 for lymphovascular invasion; 54 for positive resection margins; 36 for sm>1, 28 (44%) patients failed >1CC). Of these, 49 were male patients, mean age 65.4 years (44-88), 14 with a family history of colorectal cancer and 12 with current or past smoking habits. ADCs: 12 excised by polypectomy, 20 by mucosectomy, 26 by submucosal or intramuscular dissection, 1 endoscopic transmural resection; 2 TAR and 3 endoscopic+TAR resections; 47 lesions excised in a single fragment; 29 in flat lesions, 31 in sessile polyps, 4 in pedunculated polyps.

In 24 patients, surgery was performed with lymphadenectomy (4 with definitive colostomy); in 16 patients, only surveillance was performed (8 due to comorbidities; 2 due to risk of Abdominoperineal Resection; 4 due to LE > 12 weeks/unidentified site; 2 due to refusal of surgery); 19 patients received CRT and 5 only RT, followed by surveillance. There were CRT complications in 4 patients (grade 2/3) and surgery complications (grade II/III) in 6.

Average follow-up: 35 months; 3 relapses were identified in the surveillance only group (19%) – 2 local and 1 distant; 1 distant recurrence in the surgery group (4%); 1 local and 1 local+distant recurrence in the RT/CRT group (8%). All recurrences occurred in pT1. Two of the patients with recurrence died of the disease (1 of them had undergone surveillance, the other had surgery with lymphadenectomy).

Conclusion: Despite the short series, this work confirms the worse outcome of patients with malignant polyps and pT2 of the rectum excised without CC and only monitored, and supports promising results from RT/CRT; this may be an organ-preserving option with less morbidity than surgery in patients with malignant rectal polyps excised without CC.

HIGH-THROUGHPUT AND HIGH-CONTENT DRUG SCREENING ON A LARGE-SCALE PATIENT-DERIVED HIGH-RISK COLORECTAL ADENOMA ORGANOID PLATFORM

B. Wang[1]
[1]*Nanjing Medical University, Nanjing, China*

Contact E-Mail Address: 18111220022@fudan.edu.cn
Introduction: Colorectal adenoma (CA), especially high-risk CA (HRCA) is a precancerous lesion with high prevalence and recurrence rate, and accounts for about 90% incidence of sporadic colorectal cancer cases worldwide. Currently, recurrent CA can only be treated with repeated invasive polypectomies, while safe and promising pharmaceutical invention strategies are still missing due to the lack of reliable *in vitro* model for CA-related drug screening.
Aims & Methods: In order to discover chemopreventive alternatives, we established a large-scale patient-derived high-risk colorectal adenoma organoid (HRCA-PDO) biobank containing 37 PDO lines derived from 33 patients, and then conducted a series of high-throughput and high-content HRCA drug screening.
Results: We established the primary culture system with the non-WNT3a medium which highly improved the purity while maintained the viability of HRCA-PDOs. We also proved that the HRCA-PDOs replicated the histological features, cellular diversity, genetic mutations and molecular characteristics of the primary adenomas. Especially, we identified the dysregulated stem genes including *LGR5*, *c-Myc* and *OLFM4* as the markers of adenoma, which are well preserved in HRCA-PDOs. Based on the HRCA-PDO biobank, a customized 139 compound library was applied for drug screening. Four drugs including metformin, BMS754807, Panobinostat, and AT9283 were screened out as potential hits with generally consistent inhibitory efficacy on HRCA-PDOs. As a representative, metformin was discovered to hinder HRCA-PDO growth *in vitro* and *in vivo* by restricting the stemness maintenance.
Conclusion: This study established a promising HRCA-PDO biobank and conducted the first high-throughput and high-content HRCA drug screening in order to shed light on prevention of colorectal cancer.

Introduction: Recent advances in endoscopic technology have allowed many T1 colorectal carcinomas (CRCs) to be resected endoscopically. After endoscopic resection (ER), we often wonder if we should perform an additional surgical resection (SR) with nodal dissection. At present, the indication of additional SR is based only on the risk of simultaneous lymph node metastasis, with no consideration of prognosis in mind. Although in particular elderly people generally have some complications and are more likely to die from other diseases, it is not clear whether the criteria for additional SR after ER should be the same as for non-elderly patients.
Aims & Methods: The aim of this study is to investigate the overall survival (OS) in patients with T1 CRCs treated by ER alone or SR with nodal dissection. After excluding complications of advanced cancer or hereditary colorectal cancer and so on, we retrospectively analyzed 1461 patients with T1 CRCs resected ER or SR at our center from April 2001 to June 2020, and followed them up over a mean period of 77.1 months. We divided the patents into two groups: ER alone group and SR with lymph node dissection group, and compared the OS using the Kaplan–Meier method and the log-rank test. In addition, the same analysis was conducted by dividing the above subjects into those ≤ 75 years of the age and those > 75 years.
Results: In the overall T1 CRC patients, the OS was significantly shorter in the ER alone group than in the SR group ($p < 0.01$). Among those ≤ 75 years old, that was also shorter in the ER alone group ($p < 0.01$), while in those > 75 years, no significant difference was found in the OS ($p = 0.08$).
Conclusion: Among T1 CRC patients > 80 years of age, there was no difference in the remaining life expectancy, with or without SR with nodal dissection, even if additional SR was indicated after ER based on the current criteria. For elderly patients, T1 CRCs could be initially resected endoscopically, and the indication for additional SR with nodal dissection might be carefully considered.

USEFULNESS OF ENDOSCOPE INSERTION USING THE GEL IMMERSION METHOD FOR ENDOSCOPIC COLONIC STENTING

T. Mizumoto[1], T. Kuwai[1], S. Semba[1], N. Kato[1], S. Sugata[1], Y. Okuda[1], Y. Teraoka[1], Y. Tamaru[1], R. Kusunoki[1], A. Yamaguchi[1], H. Kouno[1]

Contact E-Mail Address: mizumoto.takeshi.ea@mail.hosp.go.jp

Introduction: Endoscopic colonic stenting is a treatment method in which a colonoscope is used to insert a self-expandable metal stent (SEMS) into a stenotic site and allow its expansion to alleviate colonic obstruction and permit urgent colonic decompression. It is an effective and extensively practiced minimally invasive procedure compared with emergency surgery. However, perforation, stent migration, and reocclusion may occur. Perforation is particularly a serious adverse event with a mortality rate of 50%. There are three possible causes of perforation:

(1) Local perforation due to stimulation of the stent itself directly into the intestinal tract;

(2) Perforation due to guidewire or catheter manipulation during stent insertion; and

(3) Perforation due to increased pressure in the intestinal tract at the oral side of the obstruction (especially in the cecum) caused by air supply during colonoscopy insertion.

For the first possible cause, an improved colonic stent was developed to reduce irritation to the intestinal tract, and for the second possible cause, a strategy for safe stent insertion was established.

However, perforation due to the third possible cause remains a concern, and appropriate countermeasures should be urgently developed.

In endoscopic colonic stenting, we hypothesized that colonoscope insertion using the gel immersion method, which uses a recently developed endoscopic view-securing gel, would allow safe and rapid access to the lesion without increasing intestinal pressure, thereby decreasing the incidence of perforation.

Aims & Methods: This study aimed to clarify the usefulness of the gel immersion method during colonoscope insertion with endoscopic view-securing gel for colonic stenting. Eight patients in whom colorectal stenting was performed using the gel immersion method between May 2022 and January 2023 were included.

The primary endpoint was the endoscopic lesion reach rate, and the secondary endpoints were the technical and clinical success rates of SEMS deployment, colonoscope insertion time, total procedure time, and adverse event rate.

Results: Of the included patients, four were males (50%), and the mean age of patients was 67.6 ± 15.6 years. Seven patients (87.5%) had colorectal cancer and one patient (12.5%) had gastric cancer. The cancer was localized at the following sites: sigmoid colon in three patients, descending colon in three patients, transverse colon in one patient, and ascending colon in one patient. The purpose of SEMS deployment was bridge to surgery in four (50%) and palliation in four (50%) patients. In all cases, the endoscope was inserted without the preparation and insertion of the endoscope into the lesion at the origin of the obstruction without insufflation, and the endoscopic lesion reach rate was 100% (8/8). No worsening of intestinal dilatation was observed. The technical and clinical success rates each were 100% (8/8). The scope insertion time was 9.8 ± 5.2 min, total procedure time was 27.3 ± 6.5 min, and the adverse event rate was 0% (0/8).

Conclusion: For endoscopic colonic stenting, endoscope insertion using the gel immersion method could be performed safely and effectively and has the potential to become the standard method.

Disclosure: Nothing to disclose.

PEUTZ-JEGHERS SYNDROME: OUTCOMES OF SURVEILLANCE AND LONG-TERM COMPLICATIONS

S.Y. Mak[1], A. Wong[1], P. Collins[1,2,3]
[1]Royal Liverpool University Hospital, Department of Gastroenterology, Liverpool, United Kingdom, [2]Liverpool John Moores University, Liverpool, United Kingdom, [3]University of Liverpool, Liverpool, United Kingdom

Contact E-Mail Address: maksiewyew@yahoo.com

Introduction: Peutz-Jeghers Syndrome (PJS) is a rare hereditary gastrointestinal (GI) polyposis syndrome, characterised by the development of hamartomatous GI polyps and mucocutaneous pigmentation. The risk of GI and non-GI cancers in PJS is elevated, although the magnitude of the risk that has been reported has varied. A meta-analysis reported a rate of GI tract cancers of 57% by the age of 70 years (Hearle 2006). The malignant potential of Peutz-Jeghers polyps is poorly understood and controversial. Patients with PJS undergo surveillance to detect / prevent cancers and to prevent polyp-related complications of which intussusception is the most common.

Aims & Methods: The outcomes and long-term complications in patients with PJS attending a tertiary referral centre were assessed.

This is a retrospective review of electronic health care records. All patients with PJS were identified from the surveillance database at the Royal Liverpool University Hospital.

Results: 27 patients were identified from the surveillance database. Patient were followed up for 219 patient years. The median follow up was 7 years (range 2-18). The median age was 36 (range 17-67).

258 endoscopic procedures were performed in the cohort. Of those, there were 82 gastroscopies, 80 colonoscopies, 8 sigmoidoscopies, 41 Small bowel Capsule endoscopies (SBCE), 27 antegrade single balloon enteroscopies (SBE), 4 antegrade double balloon enteroscopies (DBE), 2 retrograde SBEs, 1 retrograde DBEs and 13 surgically-assisted panenteroscopies. 44 MRI small bowels, and 14 CT enterographies were undertaken to assess the GI tract.

407 polyps were resected during the follow up period. Of these 60% (n=243/407) were removed by colonoscopy, 13% (n=52/407) by gastroscopy, 10% (n=41/407) by antegrade enteroscopy, 17% (n=71/407) by surgically assisted panenteroscopy. The median number of polyps removed per patient was 7 (range 0-102). There were two perforations following polypectomy. One occurred following a polypectomy of a caecal polyp undertaken at another centre requiring an emergency right hemicolectomy. A second occurred following removal of a 30mm polyp in the duodenum. This was managed successfully with endoscopic through-the scope clips.

The most common polyp-associated complication was small bowel intussusception. 74% (20) had at least one event, 30% (6) subsequently went on to have another intussusception event. The median age of first intussusception was 16 (range 8-38), the median size of polyps leading to intussusception was 25mm (range 15mm-32mm). Of the 20 patients with an intussusception, 70% (n=14/20) required emergency surgery. None of the hamartomatous polyps contained dysplasia. Gastric foveolar-type low grade dysplasia was seen in a duodenal biopsy containing gastric metaplasia. .

No patients developed a GI malignancy. 5 extra-GI malignancies occurred (2 ovarian, 1 lung, 1 thyroid, 1 osteochondroma). All patients were referred for pancreatic cancer screening within an ethically approved study (EUROPAC). All females were referred to a local high risk breast screening unit.

Conclusion: The absence of any GI tract cancers in this cohort of PJS patients could reflect an overestimation of risk in previous studies, a potential protective effect of GI surveillance or the small cohort size. The absence of dysplasia in any of the GI hamartomas supports the position that the malignant potential of hamartomas themselves is low. All intus-

susceptions were caused by polyps > 15mm in size, supporting a strategy of small bowel surveillance and removal of polyps of this size.

OUTCOMES FROM A VIRTUAL CLINIC DEVELOPED TO MANAGE GI CONSEQUENCES OF COLORECTAL CANCER

D. Fernandes[1], J. Andreyev[1,2]
[1]United Lincolnshire Hospitals NHS Trust, Gastroenterology, Lincoln, United Kingdom, [2]University of Nottingham, The Biomedical Research Centre, Nottingham Digestive Diseases Centre, School of Medicine, Nottingham, United Kingdom

Contact E-Mail Address: dcrfernandes@gmail.com
Introduction: Reductions in cancer mortality rates are the result of better screening and the use of improved treatments[1]. Whilst there has been a longstanding awareness of the psychological and social impact of cancer therapy, there has been little emphasis on dealing with the physical symptoms that are a frequent complication of treatment[2]. This can include living with chronic and debilitating bowel symptoms as well as problems with sexual and urinary function[3]. In our hospital, over 400 patients are diagnosed and treated for colorectal cancer annually. Data suggest that up to half, depending on the treatment(s) received, will develop chronic symptoms.
Aims & Methods: A virtual telephone clinic was set up in October 2020. Patients requiring gastroenterology review were identified at follow-up by colorectal cancer nurse specialists, colorectal surgeons or oncology specialists. Patients were reviewed by a Gastroenterology Research Fellow via a telephone consultation and investigations requested following a predefined, structured checklist according to their symptoms.
Results: 66 patients (30 male, 36 female), median age 71 (range 40-89) were reviewed between October 2020 to September 2022. The mean duration of symptoms was 33 months (range 4 to 108). All had been diagnosed with colorectal cancer (20 right colon, 10 left colon and 36 rectum). Previous treatment included surgery (n=31), surgery + chemotherapy (n=13), surgery + radiotherapy (n=4), surgery + radiotherapy + chemotherapy (n=13) and radiotherapy + chemotherapy (n=5).
Patients' symptoms pre-referral and after treatment were assessed objectively using the gastrointestinal symptoms rating scale (GSRS), with a mean GSRS on referral of 25, improving to 16 following investigation and treatment. 10 different symptoms were identified in patients (loose stool (n=45), bloating/wind (n=31), frequency (n=31), urge (n=28), incontinence (n=19), constipation (n=14), abdominal/rectal pain (n=13), mucous discharge (n=6), nocturnal symptoms (n=6) and rectal bleeding (n=1)). Outcomes of investigations are shown in Table 1. The mean overall package of care cost £803.53 (range £86.83 - £1778.49) / patient.

Outcome	Number	Outcome	Number
Constipation	13	Low Anterior Resection Syndrome (LARS)	2
Bile Acid Malabsorption (BAM)	12	Mucous Discharge	2
Dual Pathology	11	Radiation Proctopathy	1
Pancreatic Insufficiency	8	Recurrence	1
Declined Investigation	4	Colitis	1
Small Intestinal Bacterial Overgrowth (SIBO)	3	Anal Fissure	1
Excess Fibre	3	Awaiting Result	1
Fistula	2	Resolved	1

Table 1. showing the outcomes of investigations in patients.

Conclusion: In most patients referred to our specialist clinic, one or more causes for their symptoms were identified. Treatment frequently lead to a dramatic improvement in symptoms. Future recommendations include earlier recognition of patients in need of specialist referral through the use of objective questionnaires. Results from a virtual clinic are consistent with previously reported data from face-to-face consultations.

THREE-YEAR OUTCOME DATA FOR PATIENTS DISCUSSED AT NORTHERN REGIONAL COMPLEX RECTAL LESION (CRL) MDT

A. Vozza[1], N. Gao[2], M. Eltringham[2], M. Katory[2], P. O'loughlin[2], K. Osman[1], K. Khan[1], S. Rahman-Casans[1], S. Harrison[1], D. Westwood[1], A. Mishreki[1], C. Dennison[2], R. Briggs[1], C. Hobday[2], S. McConnell[1], J. Silcock[1], J. Barbour[2]
[1]County Darlington and Durham NHS Foundation Trust, General Surgery, Darlington, United Kingdom, [2]Gateshead Health NHS Foundation Trust, Gateshead, United Kingdom

Contact E-Mail Address: a.vozza@nhs.net
Introduction: Queen Elizabeth Hospital (QEH) Gateshead and County Durham and Darlington NHS Foundation Trust (CDDFT) have collaborated since 2018 on a Complex Rectal Lesion (CRL) Multidisciplinary Team Meeting (MDT). The aim is to offer optimal individualised treatment for each patient: conservative management for those who choose or who are more likely to do badly with interventional treatment; organ sparing local resection for all benign and T1 Cancers; and full bowel resection for T2 or greater cancers. Discussing uncertainty and risk with patients is challenging and the CRL MDT values the input of the specialist nurse assigned to each patient to assess fitness and to support patients through the decision-making process. Given the known cancer risk of complex polyps, patients opting for local resection are recommended en bloc resection either with trans-anal surgery or Endoscopic Submucosal Dissection (ESD). We reviewed the outcomes for all patients discussed over a 3-year period.
Aims & Methods: Retrospective case note review of 318 new consecutive CRL MDT patients identified between January 2020 and December 2022 with complex rectal polyps or presumed early rectal cancer. We included patients with either adenoma or adenocarcinoma at final histology and excluded rectal cancer that appeared advanced or deeply invasive endoscopically or on imaging, as these were discussed at the colorectal cancer MDT and local resection was not an option. 305 patients (110 QEH patients and 195 CDDFT) met the inclusion criteria.
Results: Median patient age was 69 years (18 – 91 years). 292 patients were diagnosed at endoscopy, 7 at CT scan, 5 at CT colonography, and 1 at MRI (prostate). Median time between diagnosis and treatment was 75.5 days (interquartile range 70 days). Optimal endoscopic and radiological assessment of rectal lesions is essential to risk stratify these lesions. Prior to first treatment modality the MDT recommended and arranged repeat radiological imaging in 31 patients (10%) and repeat endoscopy in 65 patients (21%). 33 patients (11%) preferred or were recommended conservative treatment. 85 patients (28%) had rectal cancers at final outcome.

15 patients were referred to oncology due to deeply invasive disease on imaging and positive cancer biopsy. The remaining cancer stage post intervention was 50 T1, 15 T2, and 5 T3. 231 patients (76%) who were offered interventional treatment had organ sparing local resection. Major resection was offered to only 19 patients (6%). 3/19 of these were benign adenomas, 8 T1 cancers and 8 T2 or greater cancer at final histology. Table 1 shows breakdown of treatment modality, rate of cancer and T stage at first procedure.

Modality	No	Cancer (% of pt in that modality)	T stage for cancers			
			T1	T2	T3	T4
EMR	75	10 (14%)	9 (90%)	1 (10%)	0	0
ESD	86	11 (13%)	11 (100%)	0	0	0
Trans-anal Surgery	70	33 (47%)	22 (66%)	8 (24%)	3 (9%)	0
Major surgery	19	16 (84%)	8 (50%)	6 (38%)	2 (13%)	0
Chemoradiotherapy	15	15 (100%)	-	-	-	-
Conservative	33	-	-	-	-	-

Table 1. Breakdown of treatment modality, rate of cancer and T stage at first procedure

Conclusion: Getting it right first time is challenging in patients with complex rectal lesions. Optimal staging and careful discussion of all the options with the patient is essential. Approximately 1/3 of patients coming through our CRL MDT ultimately had rectal cancer. 71% of the rectal cancers that had intervention were early stage (T1) with good prognosis which supports en bloc organ-sparing local resection.
Disclosure: Nothing to disclose.

COMPARISION OF USE OF SUBMUCOSAL INJECTION SUBMUCOSAL INJECTION USING EPINEPHRINE-ADDED SALINE IN COLD SNARE POLYPECTOMY AND ONLY COLD SNARE POLYPECTOMY FOR COLORECTAL POLYPS: A RANDOMIZED, PROSPECTIVE STUDY FROM PAKISTAN

F. Kayani[1]
[1]Bolan University of Medical and Health Sciences, Gastroenterology, Quetta, Pakistan

Contact E-Mail Address: farhana_kayani@hotmail.com
Introduction: Complications like Immediate and delayed bleeding , perforation and hemostasis issue after cold snare polypectomy for colorectal polyps might hinder the procedure causing economical burden ,prolong the time required for resection and prolong hospital stay. We investigated whether submucosal epinephrine-added saline injection reduces the complication rate,time required for the cold snare polypectomy (CSP) procedureand hospital stay.
Aims & Methods: We conducted a single-center, prospective, randomized controlled trial. Patients with colorectal polyps were randomly allocated to either CSP with epinephrine-added submucosal injection (CSP-ES group) or conventional CSP (CSP group). The primary outcome was the complication rate including perforation , immediate bleeding (within 5-10 seconds of polypectomy) , delayed bleeding (after 10 seconds of polypectomy) time required for resection (TR), and the secondary outcome was the time to spontaneous cessation of CSP-immediate bleeding(TB).
Results: A total of 75 patients were randomly assigned.105 lesions in these patients (CSP-ES) group, n Z 59; CSP group, n Z 46) were analyzed. The perforation rate was lower in the CSP-ES group(1 % , 95 % CI 0-1.5%) as compared to CSP group(10% , 95 % CI 7 to 13 %) [P<0.001] , similarly immediate bleeding rate was high in CSP group when compared(20%, 95% CI 16 to 25%) [P<0.001] however there was no statistically significant difference in these two groups regarding delayed bleeding as only one patient suffered delayed bleeding in CSP.The TR calculated using the least-square mean was significantly shorter in the CSP-ES group (150.3 s, 95% CI 105.5 to 175.4 s) than in the CSP group (207.9 s, 95% CI 167.2 to 240.7 s (P < 0.001). The TB was also significantly shorter in the CSP-ES group (25.4 s, 95% CI 17.3 to 29.5 s) than in the CSP group (89.2 s, 95% CI 67.6 to 110.7 s) (P < 0.001).
The subgroup analysis by characteristics of the lesion (size , type and location) associated with TR was also performed. According to the size of the lesion, the difference in TR between the two groups was larger when the size of the lesion was > 5 mm (-37.2 s, 95% CI -56.8 to -17.6 s) than when the size of the lesion was < 5 mm (-19.2 s, 95% CI -34.2 to -4.2 s) (p 0.1346). Comparable result was noted in comparison with the type of the lesion (flat type; -26.6 s, 95% CI -41.9 to -11.2 s and polypoidal; -21.9 s, 95% CI -45.1 to 1.1 s)[p 0.73].On comparison by the location of the lesions, the difference in TR between the two groups was larger in the lesions located in the right colon (-29.2 s, 95% CI -44.5 to -13.9 s) than in these located in the left colon (-13.1 s, 95% CI -34.2 to 8.0 s) (p for interaction Z 0.1941).
Conclusion: CSP-ES reduced the complication rate like perforation and immediate bleeding and saved the time for resection and shortened the time to cessation of CSP-IB compared with conventional CSP in colorectal polyps.
Disclosure: Nothing to disclose.

PREVALENCE AND CHARACTERISTICS OF COVERT CARCINOMA IN LARGE NON-PEDUNCULATED COLORECTAL POLYPS AFTER PIECEMEAL ENDOSCOPIC MUCOSAL RESECTION

D. Shlon[1], T. Arraf[2], M. Abu Arisha[2], F. Mazzawi[1], R. Muaalem[3], A. Klein[2]
[1]Rambam Heath Care Campus, Technion Institute of Technology, Department of Internal Medicine D, Haifa, Israel, [2]Rambam Heath Care Campus, Technion Institute of Technology, Gastroenterology, Haifa, Israel, [3]Holy Family Hospital, Gastroenterology, Nazareth, Israel

Contact E-Mail Address: deema.shlon@gmail.com
Introduction: Large non-pedunculated colorectal polyps (LNPCP's) are significant precursors of colorectal cancer, commonly treated by piecemeal endoscopic mucosal resection (pEMR). When histology reveals a focus of adenocarcinoma invading the sub-mucosa, the resection is often considered non curative and salvage surgery is performed. Recent evidence shows that the risk of residual cancer in the bowel wall or lymph nodes of the surgical specimen are uncommon and that in some cases surgery may be avoided even when a focus of invasive cancer is found in the EMR specimen.
Aims & Methods: This is a retrospective observational study aimed to evaluate the prevalence, characteristics, and outcomes of covert carcinoma in LNPCPs resected by EMR in a two academic centers.
Data was collected from a prospective cohort of LNPCPs at two academic centers in Israel. We collected patient, lesion and procedural characteristics prospectively.
EMR was performed by 3 experienced endoscopist with dedicated EMR training. Piecemeal EMR was performed after endoscopic assessment for polyps that were deemed not to have sub-mucosal invasion according to accepted classification systems. Lesions suspected to containing invasive cancer were referred to surgery without endoscopic resection were excluded from the analysis.

For lesions containing invasive carcinoma, data was collected on Kikuchi classification, presence of tumor budding and lymphovascular invasion, grade of tumor differentiation, and status of the deep margin. Surgical data included presence of residual carcinoma in the surgical specimen, grading, margin involvement, and lymph node involvement.

Results: We analyzed 546 LNPCPs referred for resection at the two centers. We identified 27 cases of covert carcinoma, accounting for 4.9% of all LNPCPS resected by piecemeal EMR. A multidisciplinary tumor board deemed resection curative in 7 cases, and 18 patients were refferd for surgical resection. One patient refused surgery, and One patient was lost to follow up.

None of the surgical specimens had lymph node metastasis. In one case residual carcinoma was found in the bowel wall of the surgical specimen. No recurrence of colorectal cancer, presence of metastasis on imaging or elevation of CEA was documented for any of the patients during follow up of two year.

Conclusion: In conclusion, our study shows that covert carcinoma is relatively rare when EMR is performed in a high-volume center by expert endoscopists. In addition, the data suggests that even in these cases, the risk of metastatic disease is probably very low.

OSMI-1'S FOLATE-TARGETED DISELENIDE-RESPONSIVE LIPOSOME INHIBIT COLON CANCER DEVELOPMENT BY SUPPRESSING OGT-MEDIATED YAP O-GLCNACYLATION

H. Zhuang[1], H. Wang[1], Y. Wang[1], L. Liu[1], L. Yu[1], Z. Fan[1]

[1]The First Affiliated Hospital with Nanjing Medical University, Digestive Endoscopy Department, Nanjing, China

Contact E-Mail Address: 996024344@qq.com

Introduction: Colorectal cancer ranks second in cancer-related deaths worldwide. O-GlcNAc glycosylation, as a crucial post-translational modification, is overexpressed in various cancer. Hippo pathway effector YAP can be O-GlcNAc glycosylated to promote development of some types of cancer. However, the effects of YAP's O-GlcNAc glycosylation on colorectal cancer growth are poorly understood, and the development of targeted drugs is still blank.

Aims & Methods: We aim to develop a novel anti-colorectal cancer drug targeting OGT and investigate its anti-tumor mechanism. The expression level of OGT, YAP and YAP's phosphorylation were examined through WB, IHC and bioinformatics analysis. YAP's O-GlcNAc glycosylation and OGT/YAP interaction were assessed by molecular dynamics simulations and Co-IP. OSMI-1, an OGT inhibitor, was used to construct an OSMI-1's folate-targeted diselenide-responsive liposome. Basic characteristics of liposome were identified. Next, the effect of OSMI-1's liposome on colon cancer development and invasiveness was examined, and the change of Hippo-YAP pathway as well as downstream gene expression were assessed. Finally, the metabolism, drug distribution, toxicity, and therapeutic effect of OSMI-1's liposome were investigated in subcutaneous tumor mice model.

Results: Based on TCGA and GTEx database, gene of YAP ($p<0.05$) and OGT ($p<0.01$) were remarkably overexpressed in colon cancer. High level OGT gene expression was linked with poor OS ($p=0.016$) and DFS ($p=0.02$). OGT ($p=0.05$) and YAP ($P<0.01$) expression raised with stage. WB and IHC revealed an over-expression of YAP and OGT in both colon cancer tissue and cell lines. Co-IP verified the YAP/OGT interaction and molecular dynamics simulations predicted glycosylation sites of serine 103, 366, and 216, and threonine 213 and 41, which might affect the neighboring amino acids phosphorylation. OSMI-1's folate-targeted diselenide-responsive liposome appeared as stable particles of average 205.5 nm in size. Drug loading amount was 280ug/ml. Mass spectrum indicated a standard $(Cholesterol\text{-}Se)_2$ in liposome and it stably released over 90% of OMSI-1 within 16 hours in GSH/H2O2 environment. IC50 of the drug for colon cancer was 1240ug/ml, while it presented low toxicity to normal colon cell. OSMI-1's liposome effectively inhibited the proliferation and invasion ability of colon cancer cell CACO2 and HCT116. It suppressed glycosylation of YAP but increased its phosphorylation level relatively and YAP presented more cytoplasmic translocation. The downstream target genes CTGF, Bcl-2, E-cadherin, and Vitemin were all significantly downregulated. In nude mice, the drug was significant accumulated at the subcutaneous tumor site within 12 hours and its half-life time was 20 hours. After treated with OSMI-1's liposome for 15 days, the average subcutaneous tumor volume of mice was significantly smaller than OSMI-1 group and the control group ($16.9mm^3$ vs $27.6mm^3$ vs $46.6mm^3$, $p<0.05$, $n=15$), and there was no significant change in the body weight of the mice.

Conclusion: In summary, we successfully constructed an OSMI-1's folate-targeted diselenide-responsive liposome, which exhibited well targetability and efficacy against colon cancer tissue with low toxicity to normal tissue. Furthermore, we demonstrating that OGT inhibition can reduce the YAP's O-GlcNAcylation and enhance its phosphorylation thus suppress YAP nuclear translocation, to suppress the development of colon cancer. Our research provides a brand new targeted therapy for colon cancer, with significant application value and broad development prospects.

COMPARISON OF POLYP RECURRENCE BETWEEN DIFFERENT POLYPECTOMY TECHNIQUES (CSP VS HSP/EMR)

R. Cama[1], C. Parr[1], S. Popat[1], R. Rameshshanker[1]
[1]*The Hillingdon Hospital, Gastroenterology, London, United Kingdom*

Contact E-Mail Address: r.cama@nhs.net

Introduction: Endoscopic removal of colorectal polyps has been shown to reduce the incidence and mortality from colorectal cancer. High quality colonoscopy includes careful polypectomy using appropriate technique to ensure complete and safe excision. We compared the outcomes of cold snare polypectomy (CSP) vs hot snare polypectomy (HSP)/endoscopic mucosal resection (EMR) on polyp recurrence.

Aims & Methods: Retrospective data (Jan 2019 to Dec 2020) was obtained from Endoscopy software (HICCS) at a London district general hospital. Number of procedure, polyp characteristics, polyp surveillance and recurrence data were analysed.

Results: 520 polypectomies in 340 patients were analysed, median age 69 (IQR 60-78), male 227 (66.8%). 112 polypectomies were HSP/EMR (median size 11mm). 408 polypectomies were CSP (median size 5mm). Sigmoid and ascending colon polypectomy were most common. 286 (70.0%) of polyps resected by CSP were adenomas (13 high grade dysplasia). 77 (68.8%) of polyps resected by HSP/EMR were adenomas (7 high grade dysplasia) Two adenocarcinomas identified in this group and were subsequently managed with surgical resection.

Surveillance colonoscopy (3–36 months) was carried out in 127 patients (37.4%) and the remainder of the patients either awaiting a planned surveillance or were discharged as per BSG surveillance guidance. Metachronous recurrence rate following CSP was 7.4% (30/408) and HSP/EMR was 8.9% (10/112). 90.0% (9/10) of HSP/EMR recurrence group were polyps ≥10mm and 20.0% (2/10) had high grade dysplasia (HGD). 10.0% (3/30) of CSP recurrence group were polyps ≥10mm and 16.7% (5/30) had HGD.

	CSP	HSP/EMR
Male patient % , median age (IQR)	68.9%, 69 (60-78)	64.3%, 69 (61-80)
Median polyp size (mm), range	5 (1-15)	11 (4-100)
Polyp histology, n (%) Adenoma High grade dysplasia	286 (70.1%) 13 (3.2%)	77 (68.7%) 7 (6.3%)
Polyp location n, (%) Left sided Right sided	187 (45.8%) 221 (54.2.3%)	60 (53.6%) 52 (46.4%)
Recurrence in 3-36 months n (%)	30 (7.4%)	10 (8.9%)

Table 1. Results Summarised.

Conclusion: The recurrence rate in our cohort was similar in both CSP and HSP/EMR however the study is limited by a small sample size. The larger polyps and/or with high grade dysplasia as expected had higher recurrence rates irrespective of polypectomy technique.

Disclosure: Nothing to disclose.

GENOME-WIDE CRISPR/CAS9 SCREENING FOR SENOLYTIC TARGETS IN PALBOCICLIB-INDUCED SENESCENT COLORECTAL CANCER CELLS

H. Wang[1], H. Zhuang[1], Y. Wang[1], L. Liu[1], L. Yu[1], Z. Fan[1]
[1]*The First Affiliated Hospital with Nanjing Medical University and Jiangsu Province Hospital, Digestive Endoscopy Department and General Surgery Department, Nanjing, China*

Contact E-Mail Address: nanjingwhy@126.com

Introduction: Colorectal cancer (CRC) is the third fatal cancer in the world and medicine resistance is a clinical difficulty to be solved urgently. Cells subjected to treatment with anti-cancer therapies can evade apoptosis through cellular senescence. Persistent senescent tumor cells remain metabolically active, possess a secretory phenotype, known as the senescence-associated secretory phenotype (SASP) and can promote tumor proliferation and metastasis. While the cell senescence may represent an initial desirable outcome of treatment, prolonged presence of senescent cells can be deleterious. Therefore, removal of senescent tumor cells (senolytic therapy) combined with pro-senescence therapies has emerged as a promising therapeutic strategy.

Aims & Methods: The aim of this study is to screen the senolytic targets of palbociclib induced senescence CRC cells using genome-wide CRISPR/Cas9 technology.

The senescence of CRC cells induced by palbociclib, a cyclin-dependent kinase (CDK4/6) inhibitor, was confirmed by senescence associated β-galactosidase (SA-β-gal) assay and western blot. The expression of SASP gene was detected by RT-PCR. Next CCK8, Annexin V-PI assay kits and transwell co-culture system were used to detect the effect of SASP on the medicine resistance, apoptosis, invasion and migration of CRC cells.

A genome-wide CRISPR/Cas9 knockout library was applied to screen the senolytic target-MCL1 in palbociclib induced senescent CRCcells. Subsequently, the proliferation and apoptosis of doxycycline induced MCL1 knockdown CRC cells treated with palbociclib were investigated by CCK8 assay and flow cytometry. We further analyzed the effect of MCL1 inhibitor S63845 on the elimination of palbocicib-induced senescent CRC cells in vitro and in vivo.In vitro, the cell senescence and apoptosis were analyzed through SA-β-gal assay and flow cytometry respectively. In vivo, PDX mouse model of CRC was established to evaluate the senolytic effect of S63845.The expression of senescence markers P21 and Ki67 in tumor tissues was evaluated by immunohistochemistry.

Results: SA-β-gal assay verified that palbociclib could induce cell senescence. The expression of senescence-related marker proteins P53, P21 and P16 increased in a dose-dependent manner, and the expression of SASP factor gene increased in a dose - and time-dependent manner. SASP could enhance the resistance and anti-apoptosis ability of CRC cells to palbociclib as well as the invasion and migration ability.Subsequently, we screened and identified MCL1 as a senolytic target for palbociclib induced senescent CRC cells through genome-wide CRISPR/Cas9. Doxycycline conditional knockdown of MCL1 not only enhanced the sensitivity of CRC cells to palbociclib treatment, but also promoted apoptosis in palbociclib induced senescent CRC cells. S63845 also increased apoptosis and reduced the positive rate of β-galactosidase staining in palbociclib induced senescent CRC cells. In vivo,mice treated with the combination of palbociclib and S63845 showed a stronger reduction in tumor volume without the side effect of weight loss. We observed combination treatment massively eliminated senescence in the tumors as judged by P21and Ki67 staining.

Conclusion: The “one-two punch“ therapy in which palbociclib induces senescence and MCL1 inhibitor eliminates senescent cells can achieve great long-term cancer inhibition effect, which opens up a new strategy for CRC treatment.

PERITONEAL TUBERCULOSIS : PREDICTIVE FACTORS OF DELAYED RESPONSE TO ANTI-TUBERCULOSIS TREATMENT

M. Mohamed[1], F. Saidani[1], M. Ben Abdelwahed[1], O. Alaya[1], I. Jemni[1], L. Safer Ep Saad[1]
[1]*Fattouma Bourguiba Hospital of Monastir, Department of Gastro-Enterology, Monastir, Tunisia*

Contact E-Mail Address: Mohamed2020mabrouk@gmail.com

Introduction: Tuberculosis is a major public health problem in Tunisia. The pulmonary form, which is the most common, is decreasing while there is an increase in extra-pulmonary forms. Peritoneal tuberculosis is one of the most frequent of these localizations and is characterized by a diversity of clinical, radiological, and evolutionary aspects.

Aims & Methods: The aim of this work is to study the epidemiological, clinical, laboratory, radiological, and evolutionary characteristics of peritoneal tuberculosis in a Tunisian center in order to determine predictive factors for delayed response to anti-tuberculosis treatment.

This was a retrospective, descriptive study conducted at the Hepatogastroenterology Department of Fattouma Bourguiba University Hospital in Monastir, covering a period of 17 years (from 2005 to 2022), collecting all patients presenting with peritoneal tuberculosis. Epidemiological, clinical, radiological, therapeutic and evolutionary data were collected. The diagnosis confirmation relied on anatomopathological evidence.

Results: In total, 6 men and 30 women with a mean age of 42.6 years (ranging from 14 to 69 years) were included. Two patients (5.6%) had a personal history of tuberculosis, and a history of tuberculosis contact was found in 6 patients (16.7%).

The circumstances of discovery were variable, dominated by ascites in 56% of cases (20) and abdominal pain in 19% of cases (7). The average delay between the onset of symptoms and consultation was 2.2 months.

Diagnostic paracentesis revealed exudative ascites with an average protein level of 53g/L (32-70), with a mean cell count of 1560 white blood cells/mm3 (100-8000), and a lymphocytic predominance ranging from 65 to 100% (100-7600).

The complete blood count showed lymphopenia in 19.4% of patients (7) and leukocytosis in 8.3% of cases (3).

Abdominal CT scan showed peritoneal nodules in 38.9% of cases (14) and ascites in 72.2% of cases (26) compared to 63.9% (23) and 88.9% (32), respectively, on diagnostic laparoscopy.

The diagnosis was confirmed by histopathological examination, which showed a giant cell granuloma in all cases. In 75% of cases (27), it was associated with caseous necrosis.

An extra-peritoneal localization was found in 41.6% of cases (15), with lymph node and liver involvement being the most common, accounting for 19.4% (7) and 11.1% (4) of cases, respectively.

All patients were treated with the same therapeutic protocol, which consisted of HRZE for 2 months, followed by HR for 4 months.

The patients were clinically and biologically monitored at M1 and M2, and underwent an abdominal CT scan between M6 and M8. The course of the disease was marked by drug toxicity in 19.4% of cases (7), mostly hepatic in 5 cases, including 1 case of severe acute hepatitis.

The cure was achieved at 6 months in 25 patients (69.4%). For the other patients, the cure was delayed: at 12 months for 7 patients and at 18 months for 3 patients, with one death case.

We conducted an analytical study to identify predictors of unfavorable outcome. The factors studied were the presence of other extra-peritoneal localizations, drug toxicity requiring treatment adaptation, initial CRP and albumin levels, and vaccination against BCG.

Non-vaccination and the presence of secondary locations were associated with a negative outcome (p=0.03 and 0.028).

Conclusion: Peritoneal tuberculosis remains a public health problem in Tunisia, affecting mainly young female subjects. Clinical signs are varied, with isolated ascites being the most common. Treatment effectiveness is reduced in non-vaccinated patients with extra-peritoneal involvement.

Disclosure: Nothing to disclose.

PP1045

IMPLEMENTING A COMMUNITY BASED FAECAL IMMUNOCHEMICAL TEST (FIT) STRATEGY INCREASES THE YIELD OF COLORECTAL CANCER DIAGNOSIS AT COLONOSCOPY

N. Hawkes[1], J. Berrill[1], A. Dodd[1], J. Geen[1]
[1]*Royal Glamorgan Hospital, Gastroenterology, Cardiff, United Kingdom*

Contact E-Mail Address: neilhawkes@aol.com

Introduction: In the UK guidance National Institute of Clinical Excellent (NICE) guidance [1] advised early referral for colonoscopy based on symptoms suggesting lower GI malignancy. In June 2022 updated national guidance [2] was published recommending the use of FIT for all community based referral for colonoscopy. A regional FIT testing strategy (cut off 10gHb/g faeces) was implemented from July 2022.

Aims & Methods: To evaluate the outcome of implementing a community based FIT strategy on a regional Health Board colonoscopy service, focussing on diagnostic rates for colorectal cancer (CRC). Data sources included laboratory based FIT registry, EMS endoscopy reporting system and Welsh Clinical Portal (pathology, laboratory, and imaging) for all patients with a community based FIT test between July-December 2022. CRC rates for this cohort were compared with 1) Index Bowel Screening Wales programme patients (aged between 58 and 74 years of age) (referred if FIT result >120 ugHb/g faeces) undergoing colonoscopy in the same time period [n=180], and 2) a historical cohort of symptomatic patients [n=191, 78M:113F, mean age 47.7years, range 18-92] referred for lower GI endoscopy (July-December 2021) when symptom-based referral criteria applied. Differences between the CRC detection rates between each cohort were tested using the Chi-squared test.

Results: A total of 3291 FIT tests were performed (Jul-Dec 2022), 162 were positive (FIT+ rate 4.9%) [89M,73F; mean age 65.7years (range 23-91)]. 48/162 (29.6%) were anaemic. Of the FIT+ cohort 107 underwent colonoscopy and 36 had CT colonography (21 did not complete definitive diagnostic testing). 17/162 (10.4%) had colorectal cancer, with a further 20 (12.3%) have advanced neoplasia. CRC rates increased with increased FIT values: 10-80, 4.8%; 80-120, 11.1%; 120-400, 18%; >400, 25.9%. 107 colonoscopies performed to screen the FIT test cohort detected 16 CRC (14.9% detection rate and were significantly higher than comparator groups attending for colonoscopy; 12/180 (6.7%) in the BSW group [Chi-squared=6.18, d.o.f.1, p<0.025], and 3/191 (1.6%) in the historical symptomatic cohort [Chi-squared=20.65, d.o.f. 1, p<0.001]. Clinically important incidental pathology was detected in a further 11 patients during the course of their investigative pathway.

Conclusion: A regional community FIT testing strategy has been successfully implemented and supported. This has increased significantly diagnostic yield of CRC at colonoscopy vs previous symptom-based referral and national screening programmes. These benefits must be offset against the additional costs of FIT testing, providing clinical oversight and pathway safety netting and managing incidental pathology detected.

Introduction: There is controversy about the management of low-risk pT1 CRCs resected in piecemeal, due to impossibility in assessing margins and potential suboptimal histological risk stratification in a fragmented and cauterized specimen.

Aims & Methods: Aims:To compare en bloc and piecemeal resected low-risk pT1CRC in terms of overall survival (OS) and metastasis free survival (MFS).

Materials and Methods: Low risk pT1 CRCs (no poor differentiation and no lymphovascular invasion) either piecemeal or en bloc resected were selected from two combined European multicenter cohorts (EpiT1 Consortium and Dutch pT1CRC study group). The exclusion criteria were primary surgical treatment, incomplete local resection, lack of information on type of resection , lack of follow-up of at least 2 years. The outcomes studied were metastasis free survival(MFS) and overal survival(OS). Cox regression analysis was performed adjusting for rectal location, size, and peduncu-lated morphology.

Variable	Piecemeal (N = 822)	En bloc (N = 3096)	P
Age, median±SD	66.88 ± 9.7	66.59 ± 9.4	0.46
Female Sex, n (%)	317 (38.6)	1168 (37.7)	0.66
ASA Classification ,n (%) I-II III-IV	N=795 636 (80.0) 159 (20.0)	N=2971 2399 (80.7) 572 (19.3)	0.63
Polyp size, mm, DE	28.04+13.23	18.93+10.32	<0.001
Location, n (%) Rectum No rectum	N=818 284(34.7) 534 (65.3)	N=3079 816 (26.5) 2263(73.5)	<0.001
Morphology Not Pedunculated Pedunculated	N=789 516 (65.4%) 273 (34.6%)	N=3002 1263 (42.1%) 1739 (57.9)	<0.001
Treatment Surveillance Oncological surgery	N=822 441(53.6%) 381 (46.4%)	N=3096 2366 (76.4%) 730 (26.6%)	<0.001

Table 1. Baseline characteristics of the patients (Multivariate analysis)

Results: Results: 3918/7043 patients with a pT1 CRC met the inclusion criteria: 822 (21%) resected in piecemeal and 3096 (79%) resected en bloc (Table 1). After local treatment, 46.6% in the piecemeal group received completion oncological surgery and 26.6% in the en bloc group. Adjusted 5-yrs MFS was lower for the piecemeal resected pT1 CRCs (94.6% (95%CI) vs. en bloc 97.4% (95%CI);p=0.001). Within the piecemeal resected pT-1CRC group, the adjusted 5-yrs MFS did not differ between the group which underwent completion surgery versus the group who received only surveillance. (93.7%(95%CI) vs 96.3% (95%CI), p=0.08). Patients with a pT1 CRC resected in piecemeal followed by secondary surgery showed more endoluminal recurrence than en bloc resected pT1 CRCs followed by surveillance (10.8% VS 1.6%, p<0.00), higher proportion of distant metastasis (13/381 (3.4%) vs 14/730 (1.9%), p = 0.04) despite a similar 5-yrs MFS (96.3% vs 97.8%, p=0.08).

Conclusion: Conclusions: Even after secondary surgery Piecemeal resected pT1 CRC have a worse outcome than en bloc resected pT1 CRCs with surveillance . This is probably due to suboptimal histological risk stratification in a fragmented and cauterized specimen.

FOUR DECADES OF ENDOSCOPIC SURVEILLANCE IN LYNCH SYNDROME REVEALS A HIGHER COMPLICATION RATE - A RETROSPECTIVE COHORT STUDY ON SAFETY AND ADVERSE EVENTS

A. Frank[1], S. Walton Bernstedt[1], N. Jamizadeh[1], A. Haxhijaj[1], A. Andreasson[2], J. Blom[3], A. Forsberg[4], C.R.H. Hedin[5], A.-S. Backman[1]

Contact E-Mail Address: alexander.frank@ki.se

Introduction: Lynch syndrome (LS) is a hereditary cancer syndrome, with an increased lifetime risk of developing colorectal cancer (CRC). Current guidelines recommend colonoscopy intervals of 2 years which requires high procedural quality for the patient's safety. Although colonoscopy is a relatively safe procedure, there are risks of adverse events (AEs) such as perforation, bleeding, splenic injury and death. Thulin et al 2019, showed that the relative frequency of bleeding and perforation varies in Sweden (bleeding: 0.02%–0.27%; perforation: 0.02%–0.27%). There are insufficient data regarding safety and quality of coloscopy surveillance for LS patients.

The aim of this study was to investigate the risk of AEs amongst LS patients during colonoscopy.

Aims & Methods: There are insufficient data regarding safety and quality of coloscopy surveillance for LS patients. The aim of this study was to investigate the risk of AEs amongst LS patients during colonoscopy.

Retrospective cohort study including 366 LS patients in endoscopic surveillance at the Karolinska University Hospital, August 1989-April 2021. Data from endoscopic surveillance colonoscopies were extracted from standardized protocols and medical records.

Results: Out of 1,887 endoscopies, 11 complications were documented within 30 days (0,58%). In this study 5/1887 (0,26%; 5/366 pts, 1,3%) endoscopies led to a documented complication of bleeding or perforation. Total number of colonoscopies per patient leading to occurrence of one complication were 6 (mean, 0-12).

Conclusion: Complications were higher compared to previously described data regarding AEs in Sweden. Due to high number of performed colonoscopies of LS patients, the lifetime risk for participation in a surveillance program needs to be considered in health economic risk-benefit analyses. Experienced high-volume endoscopists at selected centers and adherence to appropriate surveillance intervals may decrease the risk of complications.

Introduction: Only retrospective single-centre studies have compared the efficacy of transanal endoscopic microsurgery (TEM) and endoscopic submucosal dissection (ESD) for the local excision of early rectal tumours (ERT).
Aims & Methods: This was a multi-centre prospective comparative study of parallel cohorts, according to a "here-elsewhere" design. The main objective of the study was the cost-effectiveness analysis, the effectiveness being defined by the rate of complete resection. We present here the clinical, oncological and quality of life results according to the SF-36 and GIQLI scores. The medico-economic results, not yet available, will be presented during the congress. The inclusion criteria were any ERT (adenomas or usT1N0 adenocarcinomas) that could be treated either by TEM or ESD. Preoperative radio-chemotherapy was a non-inclusion criterion.
Results: We included 215 ESDs and 119 TEMs. The patients were comparable for age (p=0.62) and BMI (p=0.08). Tumours were comparable for the distance of the lower limit (ESD 4.8 ± 4 cm vs. TEM 5.8 ± 5 cm; p=0.21) and the upper limit (ESD 8.5 ± 4 cm vs. TEM 7 .7 ± 4 cm; p=0.317) of the tumour from upper limit of the internal sphincter, and its semi-circumferential (p=0.64) and circumferential aspect (ESD 3.5% vs. TEM 7.7%; p =0.29). Tumour size was greater in the ESD group (39.2 ± 18 mm vs. 30.8 ± 16 mm; p=0.004). The adenocarcinoma rate (ESD 21.8% vs. TEM 32.6%; p=0.08) and the degree of deep invasion were also comparable (ESD 381.6 ± 663 microm vs. TEM 389, 1 ± 1318 microm; p=0.97). The complete excision rate was comparable (ESD 84.5% vs. TEM 76.9%; p=0.12), but the en-bloc excision rate was in favor of ESD (99% vs. 91, 2%; p=0.001). Overall (ESD 9.4% vs. TEM 11.9%; p=0.50) and major morbidities(ESD 2.3% vs. TEM 4.2%; p=0.70) were comparable. Length of stay was reduced for ESD (ESD 2.2 ± 1 days vs. TEM 3.5 ± 3 days; p<0.001). At 3 years, overall survival was comparable (ESD 95.3% vs. TEM 97.4%; p=0.71) whereas recurrence-free survival was better after ESD (ESD 89.7% vs. TEM 78, 9%; p=0.005). Digestive quality of life was better after ESD at M1, M12, M24 and M36 although comparable preoperatively between the 2 groups.
Conclusion: The results of this study are in favor of ESD compared to TEM for ERT in terms of quality of excision, recurrence and quality of life.

Introduction: There are two approaches for neoadjuvant treatment in locally advanced rectal cancer: conventional radiotherapy (RT) with concomitant chemotherapy and hypofractionated RT. In the RAPIDO study, preoperative hypofractionated RT versus conventional chemo-radiotherapy was proven to be equally effective. In our country and in our center (approximately 90%) previously, the standard treatment was conventional RT, however due to the COVID 19 pandemic in 2020, an increase in the use of hypofractionated RT was observed, this because it was a more accessible therapy for patients due to visits. In our country, the results of hypofractionation therapy compared to a conventional one have not been explored, therefore we decided to compare the outcomes between these modalities.
Aims & Methods: To compare early radiotoxicity of conventional vs. hypofractionated RT.
Methods: Retrospective study conducted in a national reference cancer center at National Institute of Cancer (INCAN) at Mexico City, during the period of April 2020 to December 2020.
Results: We analyzed 61 patients with rectal adenocarcinoma. Locally advanced were 91.8% and metastatic 8.2%. By tumor location upper third 11.4%, middle third 16.4%, middle third 72.1%. Regarding treatment, 72.1% received hypofractionation (25Gy in 5 fractions) and 27.9% conventional (45-50.4 Gy in 25-28 fractions). Techniques used 93.4% 3DCRT, 4.9%

IMRT and 1.6% VMAT. Regarding general toxicity, it was observed in 30 patients (68%) in the hypofractionated group and 11 patients (64%) in the conventional treatment group p=0.794. Type of radiotoxicity is described in table 1. We observed a greater radiation mucositis grade 3 in the hypofractionated group compared with standard therapy. The other types were similar with no statistical significance. Table 1.

	25Gy/5Fx	45Gy/25Fx	*p*
Proctitis	Grade 1: 17(38%)	6 (35%)	
	Grade 2: 3 (6.8%)	1 (17.6%)	0.383
Cystitis	7 (15%)	0 (0%)	0.80
Radiation mucositis	Grade 1: 3 (6.8%)	1 (17.6%)	
	Grade 3: 1 (9.1%)	3 (5.9%)	0.017

Table 1.

Conclusion: We observed a considerable increase in the use of hypofractionation in which we did not observe proctitis and cystitis in relation to conventional treatment, however caution and special attention must be exercised in radiation mucositis. We can increase the use of hypofractionated treatment with almost similar radiotoxicities. Further prospective studies are required to confirm these findings.

Introduction: The interdisciplinary Bergen BrainGut study was designed to stratify the complex interaction between the brain, gut and microbiota in patients with irritable bowel syndrome (IBS) (1). IBS has been associated with increased gut permeability and impaired gut barrier integrity and function.

Aims & Methods: In this in-depth substudy, we aimed to assess relevant biomarkers by analysing plasma levels of gut integrity and permeability markers in patients with IBS with moderate to severe symptoms (n = 36, IBS-SSS > 175), compared to healthy controls (HCs, n = 20), and investigate changes after a dietitian-led strict 12-week low FODMAP diet (LFD) and changes in IBS symptom severity score (IBS-SSS; only patients). Responders were classified as having ≥ 50 p reduction in IBS-SSS from baseline to week 12. Blood samples were collected at baseline and after 12 weeks. ELISA was used to analyse the gut integrity markers intestinal fatty acid-binding protein (i-FABP), lipopolysaccharide-binding protein (LBP) and zonulin, and tight junction proteins Zonula Occludens 1 (ZO1) and Claudin-1 in plasma.

Results: Fifteen patients were classified as IBS-D (diarrhea), 21 as IBS-M (mix of diarrhea and constipation), mean age 38 years, 46 (77%) females and 20 HCs with a mean age 30 years, 13 (65%) females. At baseline, trends indicated higher levels of ZO1, LBP and Claudin-1, lower levels of i-FABP, and similar levels of zonulin in IBS compared to HCs. However, there was no statistically significant difference observed. Overall, there was a significant reduction in IBS-SSS after the 12-week strict LFD ($p < 0.005$), and 80% (n = 28) were classified as responders. Analysis of blood samples collected at 12 weeks revealed a trend of reduced levels of ZO1, i-FABP, LBP and Claudin-1.

However, these were not statistically significantly different from baseline concentrations. No change was seen in zonulin following LFD. At baseline, higher IBS-SSS was associated with higher levels of i-FABP ($r = 0.394$, $p = 0.031$), but no associations between gut integrity or tight junction protein markers was observed at week 12. No difference in plasma levels was observed between responders and non-responders post LFD.

Conclusion: Higher symptom severity was associated with higher levels of i-FABP at baseline, but no associations with gut integrity markers or tight junction proteins were observed following a 12-week LFD despite the significant reduction in symptom severity. Hence, our results provide no clear evidence of differences in plasma levels of gut integrity markers and tight junction proteins in IBS patients compared to HCs, nor between LFD responders and non-responders.

Introduction: The interdisciplinary Bergen BrainGut study was designed to stratify the complex interaction between the brain, gut and microbiota in patients with irritable bowel syndrome (IBS) (1). Some bacterial species have a critical function in the gut and a functional bacterial profile is useful to identify potential dysfunction when there are observations of deviation from expected normal abundance (Table 1).

Aims & Methods: In this in-depth sub-study we aimed to assess the functional bacterial profile and dysbiosis in patients with IBS compared to healthy controls (HCs), and investigate changes in the patients after a dietitian-led strict 12-week low FODMAP diet (LFD). Sixty patients with Rome IV-confirmed IBS (mean age 38 years, 46 (77%) females) with moderate to severe symptoms (IBS-SSS > 175), and 42 HCs (mean age 35 years, 27 (64%) females) were included. Participants answered IBS Symptom Severity Scale (IBS-SSS) and delivered fecal samples at baseline (IBS and HC) and 12 weeks post LFD (IBS only). Functional bacterial profiles were assessed by GA-map™ Dysbiosis Test Lx® based on 16s rRNA sequence of bacterial species or groups (Table 1). Patients were classified as LFD responders if they had a ≥ 50-point reduction in IBS-SSS from pre to post LFD. Dysbiosis was classified as dysbiosis index (DI) > 2 (range 0-5).
Results: Twenty-one patients were classified as IBS-D (diarrhea), 31 IBS-M (mixed diarrhea and constipation) and eight IBS-C (constipation). Thirty-six patients with IBS-M and IBS-D completed the 12-week LFD. At baseline, the relative frequency of dysbiosis was higher in IBS (24.6%) compared to HCs (5.6%, p = .023), but no significant difference in functional bacterial profile was observed between the groups. In week 12, patients showed a significant reduction in symptom severity (IBS-SSS, p < .005) and a significant increase in dysbiosis (BL: 17.6% vs week 12: 58.8%, p < .001). Eighty percent (n = 28) were classified as responders, but no significant change in functional bacterial profile from pre to post LFD was observed for this group, nor between responders and non-responders post LFD.

Functional profiles	Description
Butyrate producing bacteria	Low levels or balance in butyric acid producing bacteria: *Eubacterium hallii, Eubacterium rectale* and *Faecalibacterium prausnitzii*
Gut mucosa protective bacteria	Low levels or balance in important gut mucosa protective bacteria: *Faecalibacterium prausnitzii* and *Akkermansia muciniphila*
Gut intestinal health marker	Low levels of or balance of *Faecalibacterim Prausnitzii*, a key bacterium that promotes gut intestinal health
Gut barrier protective bacteria and potentially harmful bacteria	Balance or imbalance of gut barrier protective bacteria and potentially harmful bacteria: *Faecalibacterium prausnitzii, Ruminococcus gnavus,* Proteobacteria and Shigella spp. & Escherichia spp.
Pro-inflammatory bacteria	High levels or balance in pro-inflammatory bacteria: Proteobacteria and Shigella spp. & Escherichia spp.

Table 1. Description of functional bacterial profiles. Modified table from ga-map.com.

Conclusion: Although the literature suggests a different bacterial profile in IBS compared to healthy controls, our results provide no evidence for a difference in functional bacterial profile between IBS and healthy controls, nor associations with changes in symptom severity score. However, the relative frequency of dysbiosis in patients with IBS increased after a 12-week strict low FODMAP diet as avoiding some of the high FODMAP food items in a long period might lead to missing their prebiotic effects in gut.

PATHWAYS LINKING ADVERSE CHILDHOOD EXPERIENCES TO ADULT DISORDERS OF GUT-BRAIN INTERACTION: UPREGULATION OF ADVERSE PSYCHOLOGICAL TRAITS AND DOWNREGULATION OF POSITIVE TRAITS

M.P. Jones[1], M. Goldring[1], A. Shah[2], G.J. Holtmann[2], N.J. Talley[3]

Introduction: The biopsychosocial model that underpins our understanding of disorders of gut-brain interaction (DGBI) has childhood trauma as a predisposing factor for adult symptoms[1]. The model is supported by empirical data linking childhood emotional, physical and sexual abuse to the severity of adult gastrointestinal (GI) symptoms[2].
However the mechanisms by which childhood trauma affects GI symptom burden later in life are poorly understood. Given the strong association between a number of adverse psychological traits and elevated GI symptom burden, one theory is that childhood adverse experiences (ACEs) induce a widespread negative attitude which might manifest as high levels of neuroticism and anxiety, among other possible traits[3,4], leading to increased allostatic load and amplified perception of bodily sensations[5]. However whether this is actually what happens remains unknown.
Aims & Methods: We aimed to empirically evaluate the hypotheses that:
1. Traits that are negative at high levels, neuroticism, anxiety and depression provide indirect positive paths between ACEs and adult GI symptom burden
2. A trait that may buffer the effect of ACEs, higher dispositional mindfulness, provides a risk-protective path between ACEs and adult GI symptom burden
In contrast to many previous studies, we used a validated measure of ACEs[6] as well as considering individual traumatic events. GI symptom burden was measured via the gastrointestinal symptom rating scale (GSRS)[7] and other psychological traits through validated measures. Our primary hypotheses were tested via path models.
Results: A sample of n=241 community individuals was recruited, of whom n=10 reported a physician diagnosis of an organic GI condition and were excluded. Of the remaining sample, 38% (n=88) met Rome IV criteria for irritable bowel syndrome and/or functional dyspepsia and 76% were female. The sample was generally young adults with mean age 19 years (SD=2, min=18, max=36).
GSRS scores correlated positively with overall ACEs score (r=0.16, p=0.02), neuroticism (r=0.35, p<0.001), anxiety (r=0.38, p<0.001), depression (r=0.27, p<0.001), but negatively with dispositional mindfulness (r=-0.39, p<0.001). Conversely, ACEs scores correlated positively with neuroticism (r=0.34, p<0.001), anxiety (r=0.23, p<0.001), depression (r=0.22, p=0.001), but negatively with dispositional mindfulness (r=-0.32, p<0.001).
Of the individual paths between ACEs and GSRS taken separately, the strongest was for mindfulness which explained 74%, followed by neuroticism which explained 70% of the association between ACEs and GSRS. In a model (Figure 1) where all psychological traits are considered jointly, 98% of the association between ACEs and GSRS, 98% is accounted for by indirect paths via psychological traits. Of these paths, the strongest are via mindfulness (44%) and anxiety (23%).
Conclusion: This study provides empirical support for the hypothesis that adverse childhood experiences are associated with later adult GI symptom burden via upregulation of adverse psychological traits and downregulation of positive traits (mindfulness). These findings offer opportu-

nity for early intervention with the buffering effects of positive traits and support previous findings that mindfulness can act as a buffer to negative traits, such as neuroticism[8].

CORRELATION ANALYSIS BETWEEN AUTONOMIC NERVOUS FUNCTION AND CLINICAL MANIFESTATIONS OF PATIENTS WITH FUNCTIONAL CONSTIPATION

T. Yu[1], Y. Tang[1]
[1]The First Affiliated Hospital with Nanjing Medical University, Department, Nanjing, China

Contact E-Mail Address: njmuyt@163.com

Introduction: Abnormal brain-gut interactions have a role in functional gastrointestinal disorders. The ANS is influenced by emotions, possibly affecting anorectal physiological function and the disease status of patients with constipation. However, their correlations are unclear.

Aims & Methods: To determine the association between autonomic nervous system (ANS) function and psychological status, symptoms of constipation, and life quality of functional constipation (FC) sufferers. According to Heart rate variability (HRV) tests, 139 FC sufferers were classified into low frequency (LF)/high frequency (HF) normal, LF/HF sympathetic, and LF/HF parasympathetic groups. The results of Zung's Self-Rating Anxiety and Depression Scale (SAS/SDS), Constipation Scoring System (CSS), Patient Assessment of Constipation Symptom (PAC-SYM), and the Patient Assessment of Constipation Quality of Life (PAC-QOL) were compared.

Anorectal manometry and electrointestinogram parameters were assessed. The associations between the patients' life quality and ANS function, mental or psychological status, and constipation symptoms were assessed.

Results: Anorectal physiology and intestinal electric activity were not different among the groups. Compared with the LF/HF normal group, the sympathetic group had a higher SAS/SDS score, a higher PAC-SYM score and a higher PAC-QOL score. The parasympathetic group manifested the highest CSS score, which might result from a predominance of depression. Regression analysis showed that anxiety/depression and ANS functional state significantly affected the life quality of FC sufferers.

Conclusion: FC sufferers with autonomic dysfunction apparently coexisted with anxiety/depression. The life quality of FC sufferers was negatively affected by ANS function and anxiety/depression. Autonomic adjustments, psychological interventions, and central nervous system drugs might help to treat FC.

Disclosure: Nothing to disclose.

PSYCHOLOGICAL MORBIDITY AND ATOPY DIFFERENTIATE INDIVIDUALS WHO ARE DIAGNOSED WITH DISORDERS OF GUT-BRAIN INTERACTION IN CHILDHOOD VS ADULTHOOD

M.P. Jones[1], M.M. Walker[2], G. Eslick[2], N.A. Koloski[2], N.J. Talley[2]
[1]Macquarie University, School of Psychological Sciences, North Ryde, Australia, [2]University of Newcastle, Faculty of Health & Medicine, New Lambton Heights, Australia

Contact E-Mail Address: mike.jones@mq.edu.au

Introduction: Although the peak prevalence of disorders of gut-brain interaction is in the 40-50 year range[1], the biological and psychological processes leading to a diagnosis are thought to start in childhood[2]. Some individuals are diagnosed early in life but for many the diagnosis comes much later. Risk factors for a diagnosis have been well studied and include psychosocial factors[3] and demographic factors, particularly female gender[4]. However determinants of how early an individual receives their initial diagnosis is not well studied and is an important question since it has been shown that early intervention in gastrointestinal disorders can lead to long-term resolution of symptoms[5].

Aims & Methods: This study sought to:

1. Describe the age at first diagnosis of irritable bowel syndrome (IBS) or functional dyspepsia (FD) in general practice
2. Identify clinical determinants of individuals who are diagnosed as children vs adults
3. Among children diagnosed with IBS or FD, identify clinical determinants of those who receive a further diagnosis as adults

The sample was obtained from general practice electronic medical records via The Health Improvement Network (THIN)[6] which has been shown to be representative of the health care-seeking United Kingdom population. We report on two samples, sample 1 combined patients with record of IBS and/or FD plus a large sample of individuals with no recorded gastrointestinal conditions. Sample 2 included patients on the basis of receiving a clinical diagnosis of IBS or FD at some point in their medical record. To ensure the potential for child and adult diagnoses, patients had to have been with the practice from at least the ages of 12 years to 25 years.

Results: Sample 1 comprised 1.27 million patients. A total of n=16,663 met all inclusion criteria for sample 2, were with their practice, on average, between the ages of 8 and 29 years and 36% were female.

Overall, a childhood DGBI diagnosis was identified in 1.3% (n=16206) and an adult diagnosis in 31% (n=393148) of patients. Across the sample, the mean age of first FGID diagnosis was 45 years (SD=18), being younger for IBS (mean=40, SD=16) than FD (mean=49, SD=18). Childhood diagnoses were first made, on average, at age 14 years (SD=3) and this was similar for IBS (mean=14, SD=3) and FD (mean=13, SD=4).

Among the sample 2 there were relatively few clinical diagnoses that differentiated patients whose first DGBI diagnosis came as a child rather than in adulthood. A lifetime diagnosis of eczema was more common in childhood onset (39% vs 34%) as was a lifetime diagnosis of recurrent abdominal pain (0.6% vs 0.1%) and type I diabetes (1.2% vs 0.7%).

Of patients diagnosed in childhood, 19% (n=542) received a further diagnosis as adults. Prominent factors that differentiated these patients from those who did not included these patients were less likely to be female

(27% vs 40%), twice as likely to receive a lifetime diagnosis of anxiety (24% vs 12%) or depression (38% vs 18%) and a lifetime diagnosis of sinusitis (22% vs 11%).

Conclusion: In general practice, patients are more likely to be diagnosed with a DGBI as adults rather than in childhood. The factors that differentiated these groups are known to be risk factors for DGBI, such as eczema, and point to early predispositions to disorders expressed in the GI tract as well as elsewhere. This study suggests that DGBI maybe be lifelong, and a smooth transition from paediatric to adult care should be accomplished.

Contact E-Mail Address: talengel@gmail.com

Introduction: Irritable bowel syndrome (IBS) is a common gastrointestinal condition with global prevalence ranging between 10-20%. The etiology of IBS is multifactorial and includes low grade inflammation, abnormal neuromodulation, dysbiosis, impaired integrity of the intestinal barrier, activated nociceptive sensory pathways, and dysregulation of the enteric nervous system. Treatment options include dietary modifications, which are limited due to insufficient patient adherence, and essential need for ingredient restrictions. Immune assay guided diet may provide an individualized intervention, which may increase its effectiveness compared with non-personalized dietary strategies.

Aims & Methods: A randomized, double-blind, two-arm trial, comparing the efficacy of Alcat-based personal diet versus a "Sham" balanced diet for eight-week treatment of IBS. The primary outcome was defined as a reduction of ≥50 points on the IBS-severity scoring system (IBS-SSS) [Δ IBS-SSS scores during follow-up]. Secondary outcomes included the raw scores of IBS-SSS, Irritable Bowel Syndrome Quality of Life Questionnaire (IBS-QoL) and the Visual Analogue Scale for Irritable Bowel Syndrome (VAS-IBS). IBS-Adequate Response rate and the rates of moderate / substantial improvement on the IBS Global assessment of improvement (IBS-GAI) and the IBS Global Improvement Scale (IBS-GIS) were documented. We aimed to test the effectiveness of a dietary intervention, based on Leukocyte activation to dietary components test (Alcat, Germany), to direct an individualized immune-based elimination diet.

Results: 68 patients with IBS-D (44) and IBS-M (24) were enrolled. Baseline characteristics were comparable between the study groups, except for the higher median IBS-SSS score in the Alcat-group compared with the Sham-group (390 [305-435] vs. 330 [240-390], respectively, p=0.013). At week 8 of dietary intervention, 30/35 (85.7%) patients in the Alcat-group met the primary outcome, compared with 18/33 (54.5%) of the controls (p=0.005). After 8 weeks, there were higher rates of patients in the Alcat-group who reported a significant overall improvement (i.e., positive response, 85.7% vs. 57.6%, p=0.010). Following 8 weeks of dietary intervention, patients in the Alcat group experienced a significant alleviation in abdominal pain (Δ VAS-IBS abdominal pain score of 49.7±29.8 vs. 31.6±28.8, respectively, p=0.020) and a non-significant improvement in diarrheal symptoms (Δ VAS-IBS diarrhea score of 51.0±30.4 vs. 34.4±40.8, respectively, p=0.072), compared with the controls. Performing analysis restricted to patients who were naïve to dietary-intervention, we revealed that these patients were more likely to take an advantage of the Alcat-diet compared with the Sham-diet (ΔIBS-SSS≥50 rate: 100% vs. 57%, respectively, p=0.010), while patients who had previously tried any dietary-intervention were less likely to benefit from the Alcat-diet compared to the Sham-diet (ΔIBS-SSS≥50 rate: 77% vs. 50%, respectively, p=0.148). No serious adverse events were reported during follow-up.

	ALCAT group (n=35)	Control group (n=33)	p-Value
IBS-SSS score reduction ≥50 points	85.7%	54.5%	0.005
IBS Adequate Relief	74.3%	54.5%	0.089
Significant overall improvement	85.7%	57.6%	0.010
GIS score (substantial / moderate improvement)	60.0%	42.4%	0.147
GAI score (substantial / moderate improvement)	74.3%	42.4%	0.008

Table. Study outcomes at 8-week time point.

Conclusion: Immune-based personalized diet was more efficient than Sham-diet for reducing symptoms in IBS patients, and may serve as a safe treatment option in this population.

Disclosure: This work was partially supported by a research grant from **Cell Science Systems GmbH** (Alcat Europe).

Introduction: The pathogenesis of irritable bowel syndrome with constipation (IBS-C) remains unclear. Several studies reported that gut dysbiosis had been observed in IBS patients. The treatment of IBS mostly focuses on symptomatic therapy. Acupuncture is one of the alternative therapies for IBS symptoms. However, the effects of acupuncture on symptoms and gut microbiota profiles of IBS-C patients are still unclear. The present study aimed to determine the alterations of the gut microbiota profiles between IBS-C patients and healthy subjects as well as to investigate the effect of electroacupuncture (EA) on the alterations of the profiles of gut microbiota and IBS symptoms in IBS-C patients.

Aims & Methods: We aim to determine the alterations of the gut-brain-microbiota axis between IBS-C patients and healthy subjects and to investigate the effect of electroacupuncture on the alterations of the gut-brain-microbiota axis in IBS-C patients. Thirty-two participants were enrolled in the study, including 16 healthy participants, as the control group and 16 IBS-C patients. Clinical data, blood, and fecal samples were collected from all participants. Then, 16 IBS-C patients were treated with EA nine times for 1 month. Clinical data, blood, and feces were collected in those IBS-C patients at 2-time points: after the end of EA and 1-month follow-up.

Results: Irritable bowel syndrome symptoms severity scale scores (IBS-SSS) and Irritable bowel syndrome quality of life (IBS-QoL) of IBS patients were significantly greater than the control group. There was no significant difference in cognition and depression scores in Hospital Anxiety and Depression Scale (HADs) between the control and the IBS-C groups. A significant increase in serum cortisol level in the IBS-C group was observed when compared to controls. Clinical outcomes of IBS symptoms were significantly improved after EA. These significances were also found in the 1-month follow-up. There was no significant change in serum cortisol levels following EA therapy. Regarding gut microbiota profiles, alpha diversity was not different between the four groups: control, IBS-C, after EA treatment, and 1-month follow-up. However, the beta diversity was significantly different among groups. The beta diversity used of PERMANOVA analysis showed a significant difference between the controls and IBS-C patients (PERMANOVA q-value < 0.05 in Bray-Curtis, Jaccard, and unweighted UniFrac distances). Immediately after EA therapy in IBS-C patients, the beta diversity showed no difference between pre- and post-treatment. Interestingly, the cluster of gut microbiota profiles shifted away from the IBS group and was similar to the control group after a 1-month follow-up.

Conclusion: Our findings demonstrated the differences in profiles of gut microbiota profiles between IBS-C patients and healthy, and EA treatment showed the benefit of improving clinical outcomes and profiles of gut microbiota.

NAVIGATING IRRITABLE BOWEL SYNDROME EPIDEMIOLOGY AND BURDEN IN MEDICAL AND NURSE STUDENTS IN THE "VANVITELLI-IBS STUDY": GOOD ANXIETY CONTROL AND ADHERENCE TO THE MEDITERRANEAN DIET AS POSSIBLE PROTECTIVE FACTORS

A.G. Gravina[1], R. Pellegrino[1], M. Romeo[1], G. Palladino[1], M. Cipullo[1], G. Iadanza[1], S. Olivieri[1], G. Zagaria[1], C. Mazzarella[1], T. Durante[2], A. Federico[1]

Introduction: Gastrointestinal functional disorders, including irritable bowel syndrome (IBS), are the gastroenterological disorders with the most frequent epidemiology in the general population. Among university students (medical and nursing), there is an increased prevalence of IBS, so much so that it has repeatedly been called a "global challenge."
However, despite this, data in such populations are still scarce and not fully represented in all geographic people considering the wide variability that the epidemiology of IBS encounters moving latitude and longitude. In southern Europe and, in detail, in Italy, data in this regard are lacking.

Aims & Methods: In this cross-sectional observational survey study (VANVITELLI-IBS Study), undergraduate medical and nursing students were enrolled and sent an anonymous questionnaire. The latter was sent only after a careful interview with the gastroenterologists included in the study that excluded red flags of organic gastrointestinal disease. Criteria suggestive for diagnosing IBS according to ROME IV were assessed in the questionnaire. In addition, clinic-demographic variables and variables related to university life (i.e., year of study, being on or off campus, possible receipt of scholarships or being in a delayed time-to-degree condition (i.e., outside prescribed time) were collected.
In addition, the "Beck Anxiety Questionnaire Inventory" (BAI) and the "PREDIMED questionnaire" were provided. The former assesses anxiety symptoms, the latter the degree of adherence to the Mediterranean diet.

Results: Two hundred and fifty students were considered for enrolment; however, 89 participants were excluded (39 due to flags of non-functional gastrointestinal disorders and 50 refused to take the questionnaire). In the end, 161 patients were included. Of these, 34/161 met the criteria for IBS according to ROME IV [age 22 (21 - 25.25) years, 17 (50%) males and 17 (50%) females, 22 (65.7%) medical students and 12 (35.3%) nursing students] while 127/161 did not [age 22 (21 - 24) years, 59 (46.5%) males and 68 (53.5%) females, 59 (46.5%) medical students and 68 (53.5%) nursing students]. In addition, students who declared Bristol 1-2 stool in more than 25% of cases and Bristol 6-7 stool in less than 25% were 11/34 (32.35%) compatible with IBS-C. Those who declared an inverse percentage ratio (consistent with IBS-D) were 5/34 (14.7%). The remainder of the students (18/34, 52.9%) had a mixed phenotype (IBS-M). The rate of outside prescribed time was higher in IBS-positive than in IBS-negative (29.4% vs 4.7%, p=0.000168), while on the contrary, for that of perceived scholarship (14.7% vs 33.9%, p=0.035). BAI levels were different between positive and negative IBS [17.5 (10.5 - 40) vs 13 (7 - 20), p=0.002] as were those of PREDIMED score [4 (2.75 - 6) vs 7 (3 - 10), p=0.009]. In binary logistic regression, being outside the prescribed time was associated with a higher likelihood of IBS occurrence (OR: 8.403, p=0.000155); the opposite behaviour was for adherence to the Mediterranean diet (OR: 0.258, p=0.002). No correlations between the PREDIMED score and BAI (τ= - 0.38; p=0.493) and no significant changes in BAI (p=0.205) and PREDIMED (p=0.641) as a function of students' year of enrolment were found. More than half of the sample (61.75%) had moderate-to-severe anxiety levels, and 73.52% of the students adhered poorly to the Mediterranean diet in the IBS group.

Conclusion: This study confirms how IBS, in this setting, is a significant epidemiological problem and campaigns in favour of the Mediterranean diet and proper anxiety management could be helpful.

Introduction: Irritable bowel syndrome is characterized by colonic hypersensitivity (CHS) and comorbidities such as anxiety or depression. When IBS occurs following a gastrointestinal infection, it is called post-infectious IBS. These patients present abdominal pain months or years after infection resolution. *Citrobacter rodentium* infection in mice leads to the development of IBS-like symptoms as CHS, anxiety-like behavior and cognitive impairment 8 days after pathogen clearance.

Moreover, recent data have shown that the induction of colonic IL-22 expression during the post-infectious phase allows the correction of IBS-like symptoms induced by *C. rodentium* infection.

Aims & Methods: Our first objective was to study the overtime chronicization of PI-IBS symptoms in this *C. rodentium* infection mouse model. In addition, since, the cytokine IL-22 is involved in *C. rodentium* clearance *via* regulation of Reg3γ antimicrobial peptide expression, the second objective was to evaluate the effect of Reg3γ expression on IBS-like symptoms in *C. rodentium*-infected mice.

Wild-type C57Bl6/J mice were infected with *C. rodentium* reference strain DBS100. Colonic sensitivity and anxiety- or depression-like behaviors were evaluated by colorectal distension (CRD) and several behavioral reference tests, respectively, at different days post-infection (DPI): 24, 42, 56, 84 or 112. In addition, a treatment with IL-22 or Reg3γ colonic vectorization expression were evaluated on IBS-like symptoms.

This treatment was administered daily between 16 and 24 DPI, using a *Lactococcus lactis* strain allowing Reg3γ (*L. lactis*$^{Reg3\gamma}$) or IL-22 (*L. lactis*$^{IL\text{-}22}$) expression in the colonic mucosa. The fecal microbiota was also analyzed by 16S rRNA sequencing.

Results: CHS persisted in a subgroup of *C. rodentium* infected mice until 84 DPI, despite anxiety-like behavior was observed only until 42 DPI. No cognition impairment was noticed after 24 DPI.

However, several post-infected animals developed depressive-like behavior at 42 DPI, which persisted over time. Finally, *L. lactis*$^{IL\text{-}22}$ and *L. lactis*$^{Reg3\gamma}$ treatments corrected CHS and anxiety-like behavior induced by *C. rodentium* infection at 24 DPI.

In addition, fecal microbiota sequencing data suggested that Reg3γ-colonic induced expression, like IL-22, modified the microbiota composition in the PI-IBS model. The effectiveness of Reg3γ delivery on long-term depressive-like behavior symptoms is being evaluated.

Conclusion: *C. rodentium* infection induced long-term IBS-like symptoms as chronic CHS associated with transient anxiety- and depression-like behaviors which is consistent with clinical symptoms observed in PI-IBS patients. Moreover, these initial data suggest that recovery of PI-IBS symptoms correlated with the correction of gut dysbiosis and that Reg3γ would represent an interesting therapeutic target to relieve these IBS-like symptoms.

PRIOR PROTON PUMP INHIBITOR (PPI) USAGE IS AN INDEPENDENT RISK FACTOR FOR A GUT-TO-BRAIN PATHWAY IN PATIENTS WITH DISORDERS OF BRAIN GUT INTERACTION (DBGI) IN GENERAL PRACTICE

N. Koloski[1,2], M.P. Jones[3], M.M. Walker[4], G.J. Holtmann[5], N.J. Talley[6]

Contact E-Mail Address: nicholas.talley@newcastle.edu.au

Introduction: Individuals with disorders of brain gut interaction (DBGI) such as irritable bowel syndrome (IBS) and functional dyspepsia (FD) have symptoms that generally originate either first in the GI tract (e.g. fullness, pain: gut to brain) or brain (e.g. anxiety: brain- to –gut). It is unclear however what risk factors may moderate the order of incidence of either a DBGI or psychological diagnosis.

Aims & Methods: This study aimed to determine the proportion of individuals in general practice with a diagnosis of a DBGI (IBS and/or FD, IBS only, FD only, overlap IBS/FD) prior to a mood or anxiety disorder (gut to brain), and vice versa (brain to gut) and whether specific factors moderate the order of incidence of the diagnosis. Data was collected from a retrospective study of 152,674 patients diagnosed with a DBGI (excluding inflammatory bowel disease, coeliac disease, peptic ulcer disease, colorectal and gastric cancer) and psychological disorder (mood or anxiety disorder) at general practices in the United Kingdom over an average period of 16 years (SD=7 years). Information on which diagnosis appeared first was recorded (January 1994 to end 2022, inclusive). Multiple logistic regression was performed to compare a diagnosis of a DBGI (IBS and/or FD) first versus psychological diagnosis first on a range of sociodemographic factors (age, gender), medical conditions (allergy, eczema, *Helicobacter pylori*, Type 1 and Type 2 diabetes, autoimmune disease, rheumatoid arthritis, lupus, scleroderma, alcohol related diseases and prior gastrointestinal infection) and medication usage (antibiotics, proton pump inhibitors (PPI) and non-steroidal anti-inflammatory drugs (NSAIDs)) ever and prior to a diagnosis of either a DBGI or psychological disorder. Only individual moderators that reached the criterion of p<0.01 are included in the multivariate model.

Results: Of the 152,674 eligible individuals in the UK GP data set, just over half (56.2% n=85843) were diagnosed with a mood or anxiety disorder first compared with (42.9%, n=64739, 55.43%) a DBGI first. In a multivariate model being female, prior GI infection and prior PPI, antibiotic and NSAID use significantly increased the odds of being diagnosed with a DBGI first, whereas alcohol related diseases, asthma and ever having PPI and NSAID use significantly reduced the odds of having a DBGI diagnosis first (Table 1).

Variable	OR (95%CI)	P Value
Female Gender	1.21 (1.18,1.23)	0.0000
Alcohol related diseases	0.66 (0.61,0.71)	0.0000
Asthma	0.92 (0.90,0.95)	0.0000
Prior GI infection	1.23 (1.16,1.31)	0.0000
Ever PPI use	0.66 (0.64,0.67)	0.0000
Ever NSAID use	0.89 (0.86,0.91)	0.0000
Prior PPI use	2.0 (1.94,2.06)	0.0000
Prior NSAID use	1.06 (1.04,1.09)	0.0000
Prior antibiotic use	1.19 (1.16,1.22)	0.0000

Table 1. Multivariate model of predictors of a DBGI prior to a mood or anxiety disorder.

Of clinical relevance people diagnosed with a DBGI first were twice as likely to have had prior PPI use compared with those with a psychological diagnosis first (OR=2.0, 95%CI 1.94, 2.06; P=0.000). These results were similar for IBS only, FD only and overlap DBGI.

Conclusion: In a large sample of primary care patients, prior PPI use was associated with an increased probability of a gut to brain pathway. While PPI use may indicate the presence of a upper gut DGBI, the data may equally point towards the possibility that PPI use may cause changes in the gut microbiome including reduced bacterial richness.

Contact E-Mail Address: hanna.tufvesson@med.lu.se

Introduction: Postural orthostatic tachycardia syndrome (POTS) is a disorder of cardiovascular autonomic dysfunction, characterized with heart rate (HR) acceleration and orthostatic intolerance upon standing. Gastrointestinal (GI) symptoms are common in POTS (1).

Aims & Methods: The aim of this study was to explore the prevalence and severity of GI-symptoms in a Swedish POTS-cohort, and to investigate whether previously tested HR acceleration correlates with GI-symptoms.

To this cross-sectional study, we included 43 patients with POTS (93% female, median age 30.6 years) and 74 healthy controls (78% female, median age 35.6 years), who completed a study questionnaire, including prevalence of GI symptoms (2).

GI symptom severity was assessed by the IBS severity scoring system (IBS-SSS) (3) and the visual analog scale for IBS (VAS-IBS) (4), both measured in millimetres (0-100).

Five items from the IBS-SSS were added, producing a total IBS-SSS (maximum score 500). In addition, extra-intestinal symptoms from the IBS-SSS were assessed. All patients were examined by head up tilt test during 2010-2021, which included monitoring of blood pressure and HR at supine position and after 1, 3 and 10 minutes in upright position (5).

Also, the maximum HR was measured. ΔHR was calculated from supine position to each time point of upright position. All continuous variables on the IBS-SSS and VAS-IBS-scale were correlated to ΔHR at each time point and adjustments were made for psychological well-being.

Results: In patients with POTS, all variables on the GI questionnaire were significantly higher than in controls. The most prevalent symptoms were nausea (79,1%), abdominal fullness (69.8%) and bloating (66.7%). The most severe GI symptoms measured on the VAS-IBS scale, were bloating and flatulence and constipation (see table, values presented as median (IQR), measured in millimetres). Total IBS-SSS was 213 (135-319) in POTS. The most common self-reported comorbidities in POTS were IBS (n=12) and hypermobile spectrum disorders (n=12). Seven patients reported organic GI disorder. There was an inverse correlation between ΔHR_{max} and abdominal pain (r=-0.406, p=0.007). The same tendency was seen at ΔHR_{10min} (p=0.054). No positive correlations were found between ΔHR and any GI-symptom and no correlations were found between ΔHR and ex-

traintestinal symptoms. When excluding patients with organic GI disorder, we saw significantly inverse correlations between ΔHR_{10min} and ΔHR_{max} and abdominal pain, constipation, GI symptom's influence on daily life, and total-IBS-SSS, respectively. Adjustments for psychological well-being did not affect the results.

	Healthy controls (n=74)	POTS (n=43)
Abdominal pain	0 (0-0)	30 (16-62)
Diarrhea	0 (0-2)	28 (0-64)
Constipation	0 (0-13)	61 (11-74)
Bloating and flatulence	0 (0-14)	65 (25-88)
Vomiting and nausea	0 (0-4)	44 (23-70)
Psychological well-being	8 (0-30)	50 (28-62)
Symptom's influence on daily life	0 (0-7)	58 (23-76)
Total IBS-SSS	13 (0-54)	213 (135-319)

Conclusion: This study confirms that GI-symptoms are widespread in POTS, equivalent to moderate IBS. Nausea is the most prevalent symptom, whereas bloating and flatulence, and constipation are the symptoms that are reported as most severe. Higher HR acceleration at diagnosis upon tilt testing seems to be associated with less severe chronic GI-symptoms in POTS. This finding may reflect the heterogeneity and possibly different underlying pathophysiological mechanisms in POTS, but it may also reflect treatment bias.

THE INHIBITORY EFFECT OF KEISHI-KA-SHAKUYAKU-TO (TJ-60), A TRADITIONAL JAPANESE HERBAL MEDICINE, ON VISCERAL PAIN INDUCED BY COLORECTAL DISTENSION

T. Kamiya[1], M. Shikano[1], H. Fukuta[1]
[1]Nagoya City University Graduate School of Medical Sciences, Department of Medical Innovation, Nagoya, Japan

Contact E-Mail Address: kamitake@med.nagoya-cu.ac.jp

Introduction: Introduction: KeishI-ka-shakuyaku-to (TJ-60), a traditional Japanese herbal medicine, has been reported to relieve abdominal pain in patients with irritable bowel syndrome (IBS) and has been used to IBS patients in Japan. However, its precise mechanisms of action are not well understood.

Aims & Methods: Aims: The aim of this present study was to investigate the effects of TJ-60 on visceral pain induced colorectal distension (CRD) in mice. Knockout (KO) studies were employed to determine the involvement of transient receptor potential vanilloid1 (TRPV1) in mediating the effects of TJ-60. TRPV1 is a nonselective cation channel known to play an important role in visceral hypersensitivity and inflammation.

Methods: CRD was induced to assess visceral perception thresholds in the gut. The behavioral responses to CRD were evaluated by measuring the score of abdominal withdrawal reflex (AWR) in mice. The AWR score (AWR 0 to AWR 4) was measured by two blinded observers while inflating the plastic balloon inserted intrarectally into the distal colon, with air pressures of 10, 15, 20, 25, 30, 35, 40, 45, 50, and 55 mmHg for 30 seconds in C57BL wild mice (control) and TRPV1 KO mice. In order to let the mice recover from the previous distension, 3-minute rest was allowed between each distension. After 1g/kg TJ-60 was administrated for 7 days, CRD was induced to investigate the efficacy of TJ-60 in both control and TRPV1 KO mice.

Results: Results: CRD caused an increase in AWR scores in control (n=7) and TRPV1 KO mice (n=6), that was depended on the distension pressure. The higher the pressure of distension, the higher the score of AWR. TRPV1 KO mice exhibited reduced behavioral response scores to CRD at distension pressures of 15 and 20 mmHg when compared to control mice ($p<0.01$). AWR scores significantly decreased at distension pressures of 20, 25, and 30 mmHg following the administration of TJ-60 in control mice, while a distension pressure of more than 40 mmHg produced decreases in pain response after TJ-60 administration in TRPV1 KO mice ($p<0.05$).

Table 1 Mean changes in AWR score induced by CRD.

	distension pressure (mmHg)								
	10	15	20	25	30	35	40	45	50
Control	0	0.5	1.2	1.8	1.9	2.4	2.6	3.1	3.3
TRPV1 KO	0	0.1	0.3	0.5	1.6	2.0	2.5	3.1	3.5
Control+TJ-60	0	0.1	0.3	0.4	1.0	1.4	2.1	2.8	2.9
TRPV1 KO+TJ-60	0	0.1	0.7	0.7	1.2	1.6	1.8	2.2	2.8

Conclusion: Conclusions: TJ-60 inhibited the visceral pain responses. These results suggest that TJ-60 exerts an antinociceptive effect, which in part mediated by TRPV1 signal transduction.

Disclosure: Nothing to disclose.

POOR AGREEMENT BETWEEN MANOMETRY-BASED AND BAROSTAT-BASED RECTAL SENSORY TESTING

L. Marinica Grando[1], J. Halfvarson[2], M. Van Nieuwenhoven[1]
[1]Örebro University Hospital, Gastroenterology, Örebro, Sweden, [2]Örebro University, Dept. of Gastroenterology, Faculty of Medicine and Health, Örebro, Sweden

Contact E-Mail Address: mglucian@yahoo.com

Introduction: Rectal sensory function plays a critical role in normal bowel function. For example, rectal hypersensitivity is associated with Irritable Bowel Syndrome (IBS), whereas rectal hyposensitivity is linked to constipation.

The International Anorectal Physiology Working Group (IAPWG) (1) has established a standardised investigation protocol for anorectal physiological function. According to this protocol, the rectal sensory function is evaluated by simple balloon distension using an elastic balloon during a standard high-resolution anorectal manometry investigation (HRAM).

However, the gold standard for rectal sensory assessment is the rectal barostat investigation, as described by the European COST action GENIEUR group (2).

The correlation between these two methods is largely unknown. The two methods use different balloons (elastic vs. non-elastic balloons, different size and shape). Moreover, the barostat is pressure-controlled whereas the HRAM is volume-controlled. For this reason, assessment of the level of agreement is not feasible.

Aims & Methods: We assessed the correlation between rectal sensory testing with the HRAM and rectal barostat investigations for each sensory threshold, in a group of healthy volunteers.

Twenty-six healthy volunteers (mean age 42 years, 50% females) were recruited and investigated using both HRAM according to the IAPWG protocol and rectal barostat using the GENIEUR protocol on the same day. Sensory thresholds for first sensation (FS), first urge (FU), intense urge (IU) and maximum tolerable volume (MTV) were recorded for both methods.

Spearman's rank correlation coefficient was used for analysis, since it does not assume normal distribution.

Results: Median values, along with the 1st and 3rd quartile are presented in Table 1.

There were statistically significant positive correlations between the sensory thresholds for first urge, intense urge and maximum tolerable volume. However, the correlation coefficients were generally weak, with only MTV showing a correlation coefficient above 0.5.

	First sensation		First urge		Intense urge		MTV	
Quartiles	HRAM	B	HRAM	B	HRAM	B	HRAM	B
1st	12.00	43.00	60.25	91.75	86.25	155.00	116.75	189.25
2nd	27.50	76.00	79.00	142.50	111.50	210.00	175.50	230.50

Table 1. Quartiles of the four sensory thresholds used and Spearman's correlation factor between HRAM and barostat based investigations.

Conclusion: There is a weak correlation between the two methods, suggesting that HRAM balloon distension and barostat cannot be used interchangeably with respect to rectal sensory testing. Standardisation of rectal sensory testing is warranted to improve the accuracy and reliability.

POOR SUBJECTIVE SLEEP QUALITY PREDICTS SYMPTOMS IN IRRITABLE BOWEL SYNDROME USING THE EXPERIENCE SAMPLING METHOD

R. Topan[1], L. Vork[2], H. Fitzke[3], S. Pandya[4], D. Keszthelyi[2], J. Cornelis[5], J. Ellis[6], L. Van Oudenhove[7], M. Van Den Houte[8], Q. Aziz[9]

Introduction: Sleep disturbances are more common in individuals with Irritable Bowel Syndrome (IBS) compared to healthy subjects. Sleep quality is an independent factor affecting gastrointestinal (GI) symptoms but the directionality of effects is unknown.

Aims & Methods: Our aim was to investigate relationships between subjective sleep quality, objective sleep measures and GI symptoms using actigraphy and the Experience Sampling Method (ESM). Single-centre, prospective, cross-sectional study conducted at the Wingate Institute of Neurogastroenterology in London, from March 2020 to May 2021. IBS patients were recruited from a tertiary neurogastroenterology clinic and the community. GI symptoms and mood were recorded on a smartphone application, ten times per day, over seven consecutive days (*i.e.* ESM). Subjective sleep quality was recorded every morning to reflect the night before. Objective measures of sleep quality were estimated from wrist-worn actigraphy. Cross-lagged structural equation models were built to assess the directionality of sleep-symptom relationships over time.

Results: Eighty IBS patients completed the study (mean age: 37 (range 20 – 68), 89% female, 78% community). The median IBS - Symptom Severity Score (IBS-SSS) score indicated moderate IBS severity (279 (IQR: 237-350)). Sixty-six % had a Pittsburgh Sleep Quality Index (PSQI) score ≥ 8 indicating a clinically significant sleep disturbance. Eighty-two % (95% CI: 72-90) screened positive for a sleep disorder, most commonly insomnia. Sleep efficiency, measured by actigraphy, was at the lower end of normal range (median: 86% (CI 95%: 85-87). In cross-lagged analysis, poor subjective sleep quality predicted next day abdominal pain ($0.036 < p < 0.040$) and lower GI symptoms ($0.030 < p < 0.032$), but not vice versa. Although the direction of the effect was the same for abdominal pain and lower GI symptoms, it was not significant for upper GI symptoms. No significant relationship with GI symptoms was found for any objective sleep measure.

Conclusion: Poor subjective sleep quality is associated with higher next day abdominal pain and lower GI symptom scores in IBS patients, but not vice versa. Objective sleep measures did not predict next day abdominal symptoms, potentially supporting the conclusion that it is the perception of sleep quality which is most influential.

This study supports the use of real-time patient reported outcome measures when interpreting potential influencers of IBS symptoms and may be used to guide future research into the effect of sleep interventions on GI symptoms.

CHOLINERGIC MUSCARINIC RECEPTOR SIGNALING MODULATES COLONIC INTESTINAL STEM CELL ACTIVITY AND DIFFERENTIATION

J. Wieland[1], T. Agibalova[1], A. Ermolova[1], I.E. Demir[2], B. Kohnke-Ertel[1], M. Quante[3], M. Ragab[1], R.M. Schmid[1], M. Middelhoff[1]

Introduction: Acetylcholine (*Ach*) is the main transmitter in the enteric nervous system, which is considered an essential component of the intestinal stem cell (ISC) niche. *Ach* modulates epithelial homeostasis and secretion predominantly via cholinergic, muscarinic G-protein coupled receptors such as M3R and M1R.

Aims & Methods: In our previous work, genetic ablation of M3R in the murine small intestine induced a significant reduction in Lgr5+ ISC and was sensed by Prox1+ progenitor cells, which orchestrated the selective, compensatory expansion of DCLK1+ tuft cells.

Surprisingly, this phenotype did not occur in the colon of the same mice, hence we here aimed to elucidate potential regional differences in the modulation of ISC homeostasis by cholinergic signaling in the murine intestine.

Immunohistochemical analysis and RT-PCR analysis of colonic tissues from transgenic Vil-Cre x M3R fl/fl mice and Vil-Cre x M1R fl/fl mice compared to WT mice were performed. Further experiments included in-situ hybridization for *Lgr5*, flow cytometry analysis of transgenic Lgr5-EGFP-IRES-CreERT2 and Prox1-CreERT2 mice, bulk RNA sequencing analysis and immunoblot analysis of key signaling pathways.

Results: Immunohistochemical analysis of small intestinal and colonic segments from Vil-Cre x M3R fl/fl mice showed significant differences in differentiation. In contrast to an expansion of DCLK1+ tuft cells in small intestine, these showed significantly reduced in the colon of Vil-Cre x M3R fl/fl mice, while p-EGFR+ tuft cells expanded. This pointed to potential differences in sensing cholinergic signaling interruption by ISC subtypes, which we currently investigate employing Lgr5-EGFP-IRES-CreERT2 x M3R fl/fl and Prox1-CreERT2 x M3R fl/fl mice.

Similar to small intestine, however, colonic Vil-Cre x M3R fl/fl tissues revealed a pronounced decrease in Lgr5+ ISC concomitant to increased mucosal *Ach* levels. Also, Vil-Cre x M3R fl/fl tissues showed a prominent upregulation of PI3K, which was abrogated in Vil-Cre x M3R fl/fl x M1R fl/fl mice.

In addition, RT-PCR and bulk RNA sequencing results from WT tissues or organoids showed more prominent expression of *Chrm1* (gene encoding M1R) in colonic epithelia than *Chrm3* (gene encoding M3R), and analysis of Vil-Cre x M1R fl/fl colonic tissues revealed more prominent changes to differentiation and Lgr5+ ISC compared to Vil-Cre x M3R fl/fl mice.

Conclusion: Our data point to prominent regional differences in the modulation of ISC by cholinergic muscarinic niche signaling and local ISC subtypes sensing cholinergic signaling interruption. Moreover, the receptor subtypes M3R and M1R appear to modulate distinct intracellular pathways, and M1R more prominently modulates colonic ISC. Hence, our data point to potentially distinct roles of cholinergic receptor subtype signaling in intestinal homeostasis and regeneration in small and large intestine.

ESTROGEN INCREASES THE EXPRESSION OF BK_{CA} AND IMPAIRS THE CONTRACTION OF COLON SMOOTH MUSCLE VIA UPREGULATION OF SPHINGOSINE KINASE 1

Y. Wang[1], Y. Jiang[1], T. Yu[1], Y. Tang[1]
[1]The First Affiliated Hospital with Nanjing Medical University, Gastroenterology, Nanjing, China

Contact E-Mail Address: story_tyr@163.com

Introduction: Strogen (E2) may impair the contraction of colonic smooth muscle leading to constipation. Large conductance Ca^{2+}-activated K^+ channels (BK_{Ca}) are widely expressed in the smooth muscle cells (SMCs) contributing to hyperpolarization and relaxation of SMCs. Sphingosine kinase 1 (SphK1) is known to influence the expression of BK_{Ca}.

Aims & Methods: We aimed to elucidate the potential underlying molecular mechanism of BK_{Ca} and SphK1 that may influence E2-induced colonic dysmotility. In ovariectomized rats, smooth muscle contraction and expression of BK_{Ca}, SphK1, sphingosine-1-phosphate receptor (S1PR) were analyzed after the treatment with vehicle, BSA-E2, E2, and estrogen receptor antagonist. The role of BK_{Ca}, SphK1, and S1PR in E2-induced smooth muscle dysmotility was investigated in rat colonic SMCs. The effect of SphK1 on smooth muscle contraction as well as on the expression of BK_{Ca} and S1PR was analyzed in *SphK1 knock-out* mutant mice and wild-type mice treated with or without E2.

Results: The E2-treated group exhibited a weak contraction of colonic smooth muscle and a delayed colonic transit. The treatment with E2 significantly upregulated the expression of BK_{Ca}, SphK1, S1PR1, and S1PR2, but not S1PR3, in colon smooth muscle and SMCs. Inhibition of BK_{Ca}, SphK1, S1PR1, and S1PR2 expression attenuated the effect of E2 on Ca^{2+} mobilization in rat colon SMCs. Wild-type mice treated with E2 showed impaired gastrointestinal motility and enhanced expression of BK_{Ca}, S1PR1, and S1PR2 compared with those without E2 treatment. Conversely, in *SphK1 knock-out* mice treated with E2, these effects were partially reversed. E2 increased the release of S1P which in turn could have activated S1PR1 and S1PR2. Loss of SphK1 attenuated the effect of E2 on the upregulation of S1PR1 and S1PR2 expression.

Conclusion: These findings indicated that E2 impaired the contraction of colon smooth muscle through activation of BK_{Ca} via the upregulation of SphK1 and the release of S1P. In the E2-induced BK_{Ca} upregulation, S1PR1 and S1PR2 might also be involved. These results may provide further insights into a therapeutic target and optional treatment approaches for patients with constipation.

SEROTONIN RECEPTORS INVOLVEMENT IN RELAXANT PROPERTIES OF *SACCHAROMYCES BOULARDII* CNCM I-745. AN *EX-VIVO* MODEL RELEVANT TO IBS

P. Girard[1], C. Lesueur[1], P. Cloarec[1], M. Verleye[1], V. Castagne[1]
[1]*BIOCODEX, Pharmacology, Compiegne, France*

Contact E-Mail Address: p.girard@biocodex.fr

Introduction: Irritable bowel syndrome (IBS) is often associated with gastrointestinal motility disorders, these being modulated by the endogenous serotonin system through many serotonin receptor subtypes (Guzel, 2022). *Saccharomyces boulardii* CNCM I-745 is a probiotic yeast with antidiarrheal properties (Szajewska, 2020) and efficacy in IBS clinical studies (McFarland, 2021). It has been shown to inhibit gut motility through upregulation of the intestinal serotonin transporter (Gu, 2022). The present study explored the possible involvement of serotoninergic receptor subtypes in this effect in a rat isolated ileum model.

Aims & Methods: Isolated ileum from adult Wistar rat is incubated in organ bath (20 mL) containing Krebs (oxygenated with 95% O_2 and 5% CO_2 at 37°C) according to Briejer (1997). Contractions of the ileum are measured by an isotonic force transducer (Ugo Basile). Cumulative administration of serotonin or specific agonists induce concentration-dependent contractions. Serotonin antagonists or lyophilised *S. boulardii* are added into the bath 10 minutes before the various agonists. EC_{50} values determination from concentration-response curves and comparisons between treatments are made by GraphPad Prism.

Results: Serotonin induced a concentration-dependent contraction of the ileum with an EC_{50} value of 0.074 µM. This effect was inhibited by 5-HT_{1A} WAY100635, 5-HT_{2A} ketanserin and 5-HT_4 GR113808 antagonists, but not 5-HT_{2C} SB242084, 5-HT_3 tropisetron and ondansetron or 5-HT_7 SB266970 antagonists. *S. boulardii* at 0.05-0.15-0.5-1.5 mg/mL shifted the serotonin concentration-response curve to the right, with EC_{50} values of 0.13-0.19-1.0-2.1 µM respectively, suggesting an inhibitory effect. *S. boulardii* also inhibited contraction induced by 5-HT_{1A} 5-carboxamidotryptamine or 5-$HT_{2A/2B/2C}$ α-methyl-5-HT agonists. 1.5 mg/mL of *S. boulardii* significantly increased EC_{50} values of 5-carboxamidotryptamine (0.15 µM) and α-methyl-5-HT (0.27 µM) to 2.4 and 1.3 µM, respectively.

Conclusion: These results show that in our model, the effects of *S. boulardii* CNCM I-745 on intestinal motility are mainly mediated by serotonin 5-HT_{1A} and 5-$HT_{2A/2B/2C}$ receptor subtypes. Additional studies are currently needed to better explain S. *boulardii* mechanism of action in IBS motility disorders.

Introduction: Chronic constipation (CC) is a prodromal and severe symptom in up to the 80% of Parkinson's disease (PD) patients (PD/CC) often refractory to standard laxative treatments. The molecular mechanisms underlying PD/CC are still unclear, although changes of enteric nervous system and intestinal epithelial barrier (IEB) have been thought to play a pathogenetic role.

Aims & Methods: In this study, PD/CC and chronic constipated (CCs) patients were functionally characterized, and possible abnormalities to IEB and the key neuromodulator vasoactive intestinal polypeptide (VIP) were investigated. N=12 PD/CCs (2 females; age range: 51-80 yrs), 20 CCs (15 females; 27-78; yrs) and 23 controls (Ctrls; 11 females; 32-74yrs) were enrolled. PD was diagnosed according to the United Kingdom Parkinson's Disease Society Brain Bank clinical diagnostic criteria, whereas CC was established following Rome IV criteria. Ctrls were otherwise asymptomatic subjects undergoing screening colonoscopy. Ten PD/CCs and 10 CCs were functionally characterized by anorectal manometry (AM) and transit time (TT). Colonic mucosal / submucosal biopsies were obtained in all patients / subjects and tested for gene, protein expression and localization of IEB tight junction markers claudin-4 (CLDN4), occludin-1 (OCCL-1) and zonula occludens-1 (ZO-1) and VIP, by RT-qPCR, immunoblot and immunofluorescence staining.

Results: PD/CCs were clustered in two groups: a) patients with delayed TT and altered AM (60%); b) those with altered AM only (13%). The evaluation of IEB markers on mucosal specimens showed an increase of CLDN4 mRNA in PD/CCs (1.26 ± 0.26) *vs.* Ctrls (1.00 ± 0.19) and CCs (0.95 ± 0.33), whereas a trend to CLDN4 protein reduction in PD/CCs (0.88 ± 0.33) *vs.* Ctrls (0.96 ± 0.25) and CCs (1.02 ± 0.51) was observed.

Moreover, the OCCL-1 transcript was significantly increased in PD/CCs (1.36 ± 0.36) *vs*. Ctrls (1.05 ± 0.33) and CCs (0.81 ± 0.18). ZO-1 mRNA relative levels were consistent with those of OCCL-1 showing a significant increase in PD/CCs (1.35 ± 0.38) *vs*. Ctrls (1.02± 0.27) and CCs (0.85 ± 0.24). Notably, both OCCL-1 and ZO-1 showed a tendency to be reduced in CCs *vs.* Ctrls. Immunofluorescence highlighted a decrease in OCCL-1 immunoreactivity

(IR) in PD/CCs (score= 1.5) *vs.* CCs and Ctrls (score= 4). Conversely, ZO-1-IR displayed an intense pattern (score=4) in both Ctrls and PD/CCs, but it was decreased in CCs (score= 2). VIP mRNA levels resulted significantly greater in CCs (3.98 ± 3.93, p<0.05) *vs.* Ctrls (1.52 ± 1.55) and PD/CCs (0.86 ± 1.056), whereas a decreasing trend was observed in PD/CCs *vs*. Ctrls (p>0.05). Both immunofluorescence and immunoblot confirmed this tendency showing a 15% drop of the VIP protein (PD/CCs 0.86 ± 0.43 *vs*. Ctrls 1.01 ± 0.56, p>0.05).

Conclusion: Transit and anorectal dysfunctions in PD/CCs are associated with ZO-1, OCCL-1, CLDN-4 and VIP changes, hence suggesting that a leaky IEB contributes to submucosal neurochemical abnormalities underlying PD/CC. These findings suggest that the expression of the IEB markers are subject to both transcriptional and post-translational regulatory mechanisms, presumably distinct in CC and PD/CC.

REGULATOR OF G PROTEIN SIGNALING (RGS) PROTEIN 6 BLUNTS THE EFFECT OF CANNABINOIDS ON INTESTINAL MOTILITY AND VISCERAL PAIN SENSATION

M. Swierczynski[1], A. Makaro[1], D. Strapagiel[2], A. Tarasiuk[1], M. Salaga[1]

[1]Medical University of Lodz, Department of Biochemistry, Lodz, Poland, [2]University of Lodz, Department of Molecular Biophysics, Lodz, Poland

Contact E-Mail Address: macieks100@wp.pl

Introduction: Agonists and antagonists of G protein-coupled receptors (GPCRs) are widely used medications that serve in the therapy of constipation, diarrhea, and pain. However, little is known about how the effect of those drugs is modulated by Regulator of G Protein Signaling (RGS) proteins which promote timely silencing of the GPCR responses. RGS proteins have been documented to regulate the magnitude and duration of signals initiated by several types of GPCRs occurring in the GI tract, including opioid and cannabinoid receptors. Serving as a central control point in GPCR signaling cascades, RGS proteins hold great promises as targets for the drug development however their expression profile and function in the gut constitute a major gap in the knowledge.

Aims & Methods: The major emphasis of this study is on elucidating the expression and function of RGS proteins in physiology and pathophysiology of the GI tract. We hypothesize that identification of RGS proteins and GPCR signaling pathways that they control will reveal novel molecular targets combating GI disorders. METHODS: We used total RNA sequencing to evaluate the expression profile of RGS proteins in the mouse ileum and colon. Then we confirmed the expression of the most abundant transcripts with the qPCR and measured the expression of proteins with Western blot. Then in the in vivo conditions we used an RGS6 knockout (RGS-/-) mouse model to evaluate the effect of this protein on intestinal motility, pain and inflammation in naïve mice as well in the presence of the cannabinoid agonist WIN 55,212-2.

Results: RNA sequencing showed similar profile of expression of RGS proteins in the ileum and colon. qPCR analyses showed that Rgs2, 5 and 6 are the most abundant transcripts in the colon. At the level of protein we observed that RGS6 exhibits the highest expression in the ileum colon as well as intestinal intraepithelial lymphocytes. Moreover we observed a significant increase in RGS6 expression in the mouse colon samples during intestinal inflammation. In vivo experiments showed that RGS6-/- animals exhibit increased intestinal motility in physiological conditions and resistance to stress-induced diarrhea. Moreover RGS6-/- animals exhibit anti-nociceptive phenotype and are more susceptible to the analgesic effect of WIN 55,212-2. We did not observe the impact of RGS6 on the severity of colitis in the DSS-induced model.

Conclusion: Here we present RGS6 protein as a novel candidate for drug targeting in the GI tract. Our study suggests that loss and perhaps also pharmacological blockade of RGS6 might be used as standalone or an adjunct treatment to increase the potency of cannabinoids in the gut. The project is ongoing and further experiments are pending.

INTERMITTENT COLONIC EXOPERISTALSIS (ICE) REDUCES USE OF SUPPOSITORIES AND ORAL LAXATIVES IN WOMEN WITH FUNCTIONAL CONSTIPATION

I. Herrero-Fresneda[1]

[1]USMIMA S.L., Scientific & Medical Dpt., Esplugues Llobregat, Barcelona, Spain

Contact E-Mail Address: ihf@mowoot.com

Introduction: Female sex and increasing age are risk factors for constipation. Studies have found colon transit times to be longer in women. When estrogens decrease, constipation appears or worsens among perimenopausal women. After recommendation of lifestyle changes, second-line treatment are pharmaceutical solutions such as laxatives. However, most laxative agents show limited efficacy for chronic use, especially in people with comorbid conditions or concomitant medication inducing constipation (antihypertensives, calcium supplements to prevent osteoporosis, ...) in addition to potential adverse effects.

Intermittent colonic exoperistalsis (ICE) administered with the MOWOOT medical device, is a non-invasive, non-pharmacological treatment for chronic constipation. It has been developed to facilitate natural bowel movements and reduce the side effects of laxatives, enemas, or other invasive approaches. ICE has been proven safe and effective in constipation from both neurogenic or idiopathic aetiology in a multicentric clinical trial. Here, its use among women with functional chronic constipation was evaluated.

Aims & Methods: Adult women with chronic functional constipation were recruited in 4 hospitals in Germany. The treatment consisted of using the ICE device for 15 to 30min daily, at home. Patient outcomes were self-reported through anonymous, structured feedbacks collected at baseline (F1) and after some time under ICE treatment (F2).

Results: Data resulted from n=17 women(6 aged 18-39 yr, and 11 aged 40-80 yr). Twelve of them had a previous diagnosis of slow colonic transit. The mean time of ICE treatment at F2-feedback collection was 6,60(5,21) months (min 0,5; max 16). No one reported any serious adverse event. Three patients described occasional low self-remitting adverse events which did not affect the treatment compliance.

		Baseline (F1)	Treatment (F2)	Change (F2-F1)	P
Suppositories	Yes(F1)/Same(F2)	*12*	*1*	*-11*	0,0002 [a]
	No(F1)/No or Less(F2)	5	*16*		
Oral Laxatives	Yes(F1)/Same(F2)	*15*	*6*	*-9*	0,0039 [a]
	No(F1)/No or Less(F2)	*2*	*11*		
Number Bowel Movements / week		2,65 (1,86)	5,75 (2,97)	3,10	<0,0001 [b]
Time (min) / Bowel Movement		110,4 (149,7)	52,4 (73,0)	-57,94	0,0314 [b]
Average Bristol scale (1-7)		2,65 (1,54)	3,75 (1,73)	1,25	0,0099 [c]

Results are shown as *N* or mean(SD). a: Chi² & Fisher's exact test; b: Student's t-Test for paired values; c: Wilcoxon matched-pairs test.

Of the 12 women using suppositories at F1, 11 (92%) had reduced its use at F2, including 9 (75%) that stopped completely. Of the 15 women using oral laxatives, 9 (60%) had reduced its use, including 4 (27%) that fully stopped.

Overall, 3 women (25%) had stopped both suppositories and oral laxatives, and only 1 (8%) maintained the same dose of both. In total, 80% (12/15) of women stopped or reduced some form of laxative (Table).

In addition to laxative reduction, bowel movements increased on average by more than 3 per week, fecal consistency ameliorated (Bristol scale), and time spent in each bowel movement was reduced by nearly 1h (Table).

Conclusion: The use of ICE treatment by chronically constipated adult women significantly improved their bowel function. Importantly, this amelioration was accompanied by a notable reduction in laxatives, with a high percentage of women stopping the use of suppositories.

This in-use structured feedback in the out-patient sector points to the clinical benefit of ICE treatment. Therefore, the ICE device has the potential to substitute more invasive and pharmacological approaches in bowel management strategies for women with functional constipation.

PREVALENCE AND BURDEN OF DISORDERS OF GUT-BRAIN INTERACTION AMONGST UK MEDICAL STUDENTS

L. Brown[1], I. Aziz[1]

[1]*University of Sheffield, Academic Department of Gastroenterology, Sheffield, United Kingdom*

Contact E-Mail Address: lcbrown1@sheffield.ac.uk

Introduction: Disorders of Gut-Brain Interaction (DGBI) are common, affecting 40% of the global population[1]. They are associated with psychological distress and somatisation, and detrimentally impact quality of life. The prevalence of DGBI is highest amongst young adults, with medical students reportedly having higher rates than the general population. However, data assessing the prevalence and burden of DGBI amongst medical students is mainly confined to studies from Asia and Africa.

Aims & Methods: We aimed to assess the prevalence and burden of DGBI amongst medical students within a UK based university. An internet-based, cross-sectional, anonymous health survey on physical and mental health was disseminated to medical students enrolled at the University of Sheffield (UK). Information on demographics, past medical history, and gastrointestinal symptoms were collected, the latter using the Rome IV diagnostic questionnaire to determine the presence of DGBI. Additional validated questionnaires screened for somatisation, psychological distress, eating disorders, quality of life, and burnout.

Results: The questionnaire was completed by 378 of 1621 medical students (mean age 21 years, 73% female, and 70% white). The prevalence of having at least one DGBI was 76% (n=289), of which two-of-three had multiple affected sites. The most frequently met diagnostic criteria for DGBI were gastroduodenal (57%), followed by bowel (49%), oesophageal (29%), and anorectal (26%) disorders. Approximately 50% of students with DGBI experienced painful gastrointestinal symptoms at least one day per week.

Compared to students without DGBI, those with DGBI had significantly higher anxiety and depression scores, increased somatic symptom reporting, reduced mental and physical quality of life, poorer eating habits, and more frequent medication use (p-values, all <0.05). They were also at significantly higher risk of burnout, including study exhaustion and disengagement. The greatest health impairment across these domains was seen in those with multiple, painful, DGBI. Only 23% and 5% of students with DGBI had consulted a primary care provider and gastroenterologist, respectively, for their gastrointestinal symptoms.

Conclusion: DGBI are common amongst UK medical students and are associated with psychological distress, somatisation, reduced quality of life, and burnout. However, students with DGBI infrequently seek help for gastrointestinal symptoms. Greater awareness of the high prevalence and burden of DGBI amongst medical students may lead to increased support, improvement in health status, and better study engagement.

OUTCOME PREDICTORS FOR SIGMOID VOLVULUS: A SINGLE-CENTER RETROSPECTIVE COHORT STUDY

S. Choi[1], J.H. Ji[1], J. Park[1], S.J. Park[1], J.H. Cheon[1], T.I. Kim[1], J.J. Park[1]
[1]Yonsei University College of Medicine / Institute of Gastroenterology, Department of Internal Medicine, Severance Hospital, Seoul, South Korea

Contact E-Mail Address: sychoi18@yuhs.ac

Introduction: Although sigmoid volvulus is potentially life-threatening condition in elderly patients, prognostic factors for sigmoid volvulus are not well known.

Aims & Methods: The aim of this study is to evaluate clinical outcomes and investigate prognostic factors for patients with sigmoid volvulus. We retrospectively reviewed 85 patients who were treated with sigmoid volvulus from January 2005 to January 2023 at a single tertiary referral center.

After exclusion of patients who received emergency bowel resection surgery or improved by conversative treatment alone, a total of 59 patients were included. Patient and abdominal computed tomography (CT)-related factors potentially associated with clinical outcomes were analyzed by logistic and Cox regression analyses.

Results: The mean age of the patients was 72.4 years, and 74.3% were male. 49 patients (83.1%) were improved on initial endoscopic decompression therapy. Regarding factors related with failure of initial endoscopic decompression therapy, suspected bowel ischemia on initial CT (odds ratio 8.847, 95% CI 0.666–117.462), age<65 (odds ratio 5.138, 95% CI 0.574–46.025), larger (>85 mm) cross-sectional diameter of distended colon (odds ratio 25.400, 95% CI 1.015–635.804) were related with endoscopic treatment failure. On the other hand, of the 35 patients without previous volvulus episode who improved after initial endoscopic decompression therapy, 14 patients (40.0%) had recurrence of sigmoid volvulus during a mean follow-up of 411 days. Patients showing larger cross-sectional diameter of distended colon (>85mm, hazard ratio 9.925, 95% CI 1.618–60.863), larger maximal long (>230mm, hazard ratio 4.456, 95% CI 0.931–21.327) and short (>150mm, hazard ratio 2.828, 95% CI 0.639–12.505) axis length of overall twisted sigmoid colon were related with volvulus recurrence.

Conclusion: Prognostic factors unravelled in our study may be useful in management of patients with sigmoid volvulus. Early surgical backup consultation may be needed in patients having factors related with failure of endoscopic decompression therapy. Meanwhile, elective surgical treatment after improvement on initial endoscopic therapy may be considered in patients showing high risk features for recurrence on CT scan.

Introduction: Abdominal bloating is a prevalent condition that affect up to 30% of the population. The aim of the current study was to investigate the impact of cefixime and probiotics on the bloating sensation among patients with functional abdominal bloating (FAB).

Aims & Methods: Of 763 patients with bloating 122 patients were diagnosed with FAB. Patients were, Group I treated by a combination of non-activated herbal charcoal and Silicone Dioxide with Dimethylpolysiloxane (conventional treatment group), group II treated by the same lines in group I in addition to cefixime 400 mg once daily for 6 days, and group III patients were treated by the same lines given to group I in addition to a probiotic formulation harboring the probiotic strain *Lactobacillus helveticus candisis* for 2 weeks. All patients were evaluated by history taking, clinical examination, lab assessment and relevant imaging and symptom questionnaire before and by the end of treatment.

Results: The prevalence of FAB was 15.9% (122/763). Most of the patients were females (58.1%). Patients treated with probiotics and cefixime reported significant improvement in the sense of bloating and the visible abdominal distension in comparison to conventional treatment (P 0.008 and 0.000 respectively). Abdominal pain, belching, bowel habits change, and nausea improved and were comparable among the three groups by the end of treatment. No adverse events related to the used medications.

Conclusion: Cefixime and probiotics exert significant improvement in the subjective sensation of bloating and objective abdominal distension among patient with FAB in comparison to the conventional anti-flatulence therapy.

COMPARISONS OF DIFFERENT CLINICAL PHENOTYPE AND FECAL MICROBIOME IN IRRITABLE BOWEL SYNDROME AND SMALL INTESTINAL BACTERIAL OVERGROWTH

S. Lu[1], Y. Chen[1], H. Guo[1], L. Duan[1]
[1]*Peking University Third Hospital, Department of Gastroenterology, Beijing, China*

Contact E-Mail Address: 602458052@qq.com

Introduction: Irritable bowel syndrome (IBS) is a prevalent functional gastrointestinal disorder characterized by abdominal pain and changes in bowel habits. Small intestinal bacterial overgrowth (SIBO) refers to a group of gastrointestinal syndromes caused by an excessive number of bacteria in the small intestine. Up to now, the relationship between IBS and SIBO remains contentious. So we set out to investigate the differences between these two conditions.

Aims & Methods: Participants who met the Rome III diagnostic criteria for IBS and had a negative lactulose hydrogen and methane breath test (LHMBT) were diagnosed with IBS. Those who presented with gastrointestinal symptoms and had a positive LHMBT were diagnosed with SIBO. Overlapping cases were excluded. Participants who had a negative LHMBT and no significant abdominal symptoms were classified as healthy controls (HC). All participants were instructed to provide fecal samples for 16S rRNA sequencing.

Results: Our results showed that a history of enteritis was more common in IBS patients, and the severity of gastrointestinal symptoms was significantly higher in IBS and SIBO groups compared to healthy controls. IBS patients also reported more severe symptoms than SIBO.

Additionally, IBS patients were more affected by their symptoms, while the SIBO group reported more dissatisfaction with bowel habits. We observed differences in dietary intake between the groups, with IBS patients having the highest total energy and protein intake, and the lowest dietary fiber intake. SIBO patients had higher fat intake and significantly lower carbohydrate intake compared to the other two groups. Regarding the fecal microbiome, both IBS and SIBO patients had higher structural diversity and lower functional diversity than the HC group. The abundance of *Firmicutes/Bacteroidetes* in the IBS group was significantly higher than in the other two groups.

Our analyses indicated that the fecal microbiome could significantly distinguish the three groups, and specific bacterial species were associated with different symptoms in each group. In SIBO, *Thalassospira* and *Christensenellaceae_group* were associated with intestinal motility abnormalities, while *Ruminococcaceae_group, Butyricimonas*, and *Oscillospira* were associated with gas production. In the IBS group, *Klebsiella* and *Mitsuokella* were associated with abdominal pain, and other bacteria such as *Escherichia_Shigella* and *Enterobacter* were generally associated with enteritis infection, abdominal pain, and diarrhea.

We also found that the predicted KEGG pathways were enriched in various nutrient metabolism pathways, with potential implications for elevated blood folate levels and vitamin B12 deficiency in SIBO patients. Protein bacterial motility and biofilm formation_ Escherichia coli, were mainly enhanced in IBS, and these functions were related to the mucosal barrier damage.

Conclusion: Our study shows that although IBS and SIBO share similar symptom spectra, they may be two distinct diseases. Despite the potential differences in the fecal flora of small intestinal flora in SIBO group, significant differences were found between IBS and SIBO in terms of clinical phenotype and fecal microbiome.

Further exclusion of SIBO using lactulose hydrogen and methane breath testing in patients who meet the diagnostic criteria for IBS is warranted, as the differences suggest that different treatment strategies may be needed for these two populations. Future studies are needed to explore the underlying mechanisms and potential therapies for these conditions, which may ultimately benefit patients with IBS and SIBO.

Contact E-Mail Address: jallegretti@bwh.harvard.edu

Introduction: Ulcerative colitis (UC) is characterized by inflammation of the colon, with neutrophils playing a key role in disease activity, prognosis, and response to therapies. Though several therapeutics are available for the treatment of UC, they have limited efficacy and potential for significant side effects, including infections and malignancy. Substantial unmet need remains for effective and safe therapies. ADS051 is a novel, oral, gut-restricted, small molecule derived from a cyclosporine A scaffold. It is specifically designed to inhibit both MRP2-driven neutrophil migration into the colon and FPR1-mediated neutrophil activation, without blocking T-cell activation, which limits off-target immunosuppression. Study NCT05084261 evaluated the safety, efficacy, and pharmacokinetics (PK) of ADS051 in patients with moderately to severely active UC.

Aims & Methods: Phase 1B, multiple ascending dose, randomized, placebo-controlled, double-blind, multicenter study enrolled patients with a complete Mayo score ≥6 and on stable treatment with aminosalicylates, thiopurines, and/or corticosteroids (≤20mg prednisone). Patients received oral ADS051 or placebo (3:1) once daily for 28 days (dose cohorts: 200mg, 800mg, and 3200mg) followed by 30 days off study drug.

Primary outcome was safety and tolerability of ADS051 with secondary efficacy endpoints at Day 28 of clinical remission (modified Mayo score ≤2, endoscopic subscore ≤1 point, stool frequency subscore ≤1 point, rectal bleeding subscore=0), endoscopic response (decrease in baseline UC endoscopic index of severity [UCEIS] ≥2 points), and histologic remission (Geboes score ≤2B.0 or Nancy index=0 OR Robarts histopathological index [RHI] ≤3).

Weekly assessments of PK, disease activity, and fecal calprotectin were performed during the treatment period. Safety was evaluated throughout the study. Endoscopy was performed at screening and Day 28.

Results: All 24 patients enrolled completed the study (8/cohort). 16.7% of patients on ADS051 vs 66.7% on placebo had at least 1 *treatment*-emergent adverse event (*TEAE).* No serious adverse events were reported. No TEAE resulted in dose modification or drug discontinuation. Concentrations of ADS051 achieved in stool were greater than IC_{50} for MRP2 and FPR1 targets at all dose levels. There was low systemic exposure, with <1% of daily dose of ADS051 excreted in urine. For pooled ADS051 and pooled placebo, clinical remission was achieved in 22% ADS051 vs 0% placebo at Day 28, and endoscopic response was achieved in 50% ADS051 vs 17% placebo at Day 28. Of the 4 patients on ADS051 with clinical remission, 3 achieved histologic remission.

Conclusion: Phase 1B study of ADS051, a novel, oral, gut-restricted neutrophil modulator, demonstrates favorable safety and tolerability with signals of pharmacologic activity, warranting additional investigation in larger studies.

Introduction: Chronic constipation (CC) is one of the most frequent non-motor features of Parkinson's Disease (PD). Previous studies highlighted the association of CC with PD duration and severity [1].

Furthermore, gut microbiota changes and brain-gut-axis (BGA) dysregulation are common in PD and these alterations are related with clinical manifestations [2,3]. For this reason, probiotics, balancing the gut microbiota, are emerging as a potential therapeutic approach in PD patients.

Aims & Methods: Objective*:* To evaluate the patients' satisfaction rates as well as gastroenterological and neurological effects of the administration of a synbiotic in PD patients with CC.

Methods*:* This study enrolled patients with stable PD who fulfilled Rome IV Criteria for CC or irritable bowel syndrome with constipation (IBS-C). Patients received a synbiotic treatment (Enterolactis ® duo, 4 sachets/day, containing probiotic Lactobacillus casei and prebiotic inulin) for 12 weeks. Two primary endpoints were chosen to monitor the satisfaction with therapy (SWT). SWT was defined when patients were satisfied (satisfaction score >4 on a 7-point Likert scale) or improved after therapy (increase in the global rating of change scale of at least two points on a -7 to +7 visual analogue scale). In addition, a gastrointestinal (GI) evaluation with the Patient Assessment of Constipation-symptoms questionnaire (PAC-SYM), number of complete bowel movements per week, Bristol stool Scale (BSS) were calculated before and after the treatment. The neuropsychological evaluation was performed by the Montreal Cognitive Assessment (MoCA), Movement Disorder Society-Sponsored Revision of Unified Parkinson's Disease Rating Scale (MDS-UPDRS), SCales for Outcomes in Parkinson's disease - Autonomic Dysfunction (SCOPA-AUT), Toronto Alexithymia Scale (TAS-20), Reading the Mind in the Eyes Test (RMET), Parkinson Anxiety Scale (PAS), State-Trait Anxiety Inventory (STAI-Y), Beck Depression Inventory (BDI II), Hamilton depression rating scale (HAM-D) pre- and post-intervention.

Results: 30 patients (10 F) were consecutively enrolled. Satisfaction >4 (endpoint 1) significantly changed from 17% to 60% patients after treatment, p = 0.002. The calculated satisfaction score significantly increased from 4(1) to 5(2) (median (IQR), p = 0.003. Improvement after treatment (endpoint 2) was achieved by 83% of patients. The Global Rating of Change Score changed significantly from 0(3) to 4(2)(median (IQR), p <0.001. Moreover, a beneficial effect of treatment was shown on GI symptoms. Specifically, PAC-SYM Questionnaire score changed from 1.42(0.94)

to 0.91(0.77), p < 0.001, number of complete bowel movements per week from 3(3.5) to 5.5(4.1) p < 0.001 and Bristol stool Scale (BSS) from 2(2) to 3(2) p < 0.001. After treatment PD patients performed better in motor and non-motor features. Specifically, the scores (median (IQR) of TAS-20 significantly changed from 55.0 (22) to 49.5 (21), p=0.03, SCOPA-AUT from 17.0 (7) to 13.5 (10), p = 0.002, MDS-UPDRS part 1 from 13.5 (13) to 9.0 (6), p = 0.001, HAM-D score from 12.5(10) to 9.0 (12), p = 0.045. PAS-A showed a trend towards significance from 7.0(6) to 5.0(7), p = 0.06.

Conclusion: Our results showed that a considerable number of PD patients with CC or IBS-C were satisfied with their defecation after treatment. GI symptoms as well as motor and non-motor features in PD patients improved. Our data suggest that the addition of a synbiotic Enterolactis ® duo may be a useful therapeutic approach in PD possibly acting on the gut-brain-gut axis.

RADIATION THERAPY INDUCED CHANGES OF SMOOTH MUSCLE MOTILITY IN HUMAN RECTUM

Y.-H. Kwon[1], S.-B. Ryoo[2], T.S. Sung[3], K.J. Park[3]
[1]Uijeongbu Eulji Medical Center, Surgery, Uijeongbu City, South Korea, [2]Seoul National University Hospital, Surgery, Seoul, South Korea, [3]Seoul National University College of Medicine, Department of Surgery, Seoul, South Korea

Contact E-Mail Address: kjparkmd@gmail.com

Introduction: Radiation therapy is widely used in the treatment of carcinoma in the abdomen and pelvic cavity, but as a side effect, acute and chronic damage to the gastrointestinal tract may occur. It is well known that the rectum is more prone to radiation damage since it is fixed in the pelvis. Acute symptoms of radiation enteritis are mainly associated with inflammation of the intestinal mucosa and loss of normal mucosa, but changes in gastrointestinal motility due to exposure to high-concentration radiation may also be a cause. Previous studies are demonstrating that patients who received radiation therapy had increased bowel movements, symptoms of urgency, and decreased rectal compliance. But there are only limited studies investigated the pattern of changes in the motility of human rectal smooth muscle following irradiation.

Aims & Methods: This study was conducted to investigate changes in motility and their mechanisms after irradiation in human rectum.

Human rectal tissues were obtained immediately in the operating room from patients undergoing colorectal resection. After removing the mucosal layer of rectum, muscle layer was cut in strips of 5-6 mm in length and 2-3 mm in width. The muscle strips were mounted to an isometric force transducer (Biopac Systems, Inc., Goleta, CA, USA) and suspended in 10 ml organ bath containing aerated (97% O_2 and 3% CO_2) and warmed (36.5 ± 0.5°C) KRB solution. The area under the curve (AUC) for 5 min and tone of spontaneous contractions were analyzed to compared the responses to KCl, ACh (acethylcholine), SNP (sodium nitroprusside), a nitric oxide donor, and ATP (adenosine triphosphate), a purinergic receptor agonist. The mechanical responses were recorded and digitized using Acknowledge software (Biopac Systems, Inc., Goleta, CA, USA). Data were analyzed offline using Clampfit (version 10.2. Molecular devices, San Jose, CA, USA). qPCR was performed for expression of VChAT, NOS1 and PDGFRα to quantify cells mediating cholinergic, nitrergic and purinergic neurotransmission.

Results: KCl and ACh increased the tonic contraction and area under the curve (AUC) in a concentration-dependent manner in both normal and irradiated rectum. The difference in contractile pattern between the two groups was not statistically significant. SNP and ATP decreased AUC and reduced tonic contractions in a concentration-dependent manner in both normal and irradiated rectum. The response to SNP between the two groups was not statistically significant.

However, the response to ATP reduced significantly in irradiated rectum compared to normal rectum. In addition, expression of VAChT and NOS1 which are related with cholinergic and nitrergic neurotransmission was not different in both normal and irradiated rectum, however, PDGFRα expression which is related with purinergic neurotransmission was significantly decreased in irradiated rectum compared to normal rectum.

Conclusion: In this study, we analyzed contractile changes in irradiated rectum using neurotransmitters. There were no differences in contractile responses to KCl and ACh and in relaxation response to SNP, however, the relaxation response to ATP was significantly reduced in irradiated rectum. Cholinergic and nitrergic neurotransmission were not changed, however, purinergic neurotransmission was decreased in in irradiated rectum.

These results may explain one of the causes by which increased bowel movements, symptoms of urgency, and decreased rectal compliance in irradiated patients.

Disclosure: Nothing to disclose.

LAXATIVE USE IS ASSOCIATED WITH CHRONIC DIARRHOEA IN OLDER ADULTS LIVING IN CARE: A CROSS-SECTIONAL OBSERVATIONAL STUDY

L. O'Brien[1], R. Gearry[1], T. Wilkinson[1], C. Wall[1]
[1]University of Otago, Medicine, Christchurch, New Zealand

Contact E-Mail Address: leigh@canterburydietitians.co.nz

Introduction: Chronic diarrhoea affects 5% of the general population and has negative impacts on quality of life, but the prevalence in vulnerable older adults living in care is unknown. This study aimed to ascertain the prevalence of chronic diarrhoea in New Zealand older adults living in residential care and to explore associations between diarrhoea and medication use.

Aims & Methods: In 2021 a two-part study was conducted involving healthcare-recorded data and self-reported data from residents. The first part was a cross-sectional observational study of daily nursing records of residents living in 32 Ryman Healthcare facilities over three months. Bowel motion, anthropometric, medication and quality of life data were extracted and analysed. The prevalence of chronic diarrhoea was determined using the Rome IV criteria (at least 25% of bowels motions are type 6 or 7 on the Bristol stool chart for the last 3 months). Residents in rest home and hospital level of care at six facilities were invited to participate in the second part of the study. Residents completed Hospital Anxiety and Depression scale (HADS), the EQ-5D-3L, bowel habit and gastrointestinal symptom (ROME IV) questionnaires. Data were analysed using independent two sample T-tests and chi-square tests, p<0.05 was defined as statistically significant.

Results: The nursing records of 2411 residents were available for analysis; mean age of 87 years (SD 6.8), 70% were females (n=1682). Most lived in rest home care (n= 1140, 47%), 31% lived in hospital level of care (n=

745) and 22% were residents with dementia living in special care units (n= 536). Chronic diarrhoea was experienced by 618 (26%) residents; mean age 88 years, 68% females (n= 420, 47%). The frequency of bowel motions over the three-month period was significantly greater for the diarrhoea cohort (mean 102 bowel motions, range 26-373) compared to the normal bowel cohort (mean 85 bowel motions, range 21 – 280) (p <0.001). Polypharmacy, defined as five or more medications daily, was more likely in the residents with diarrhoea compared to residents with a normal bowel state (84 vs 48%, p= <0.001). Laxatives were administered to 66% of residents with chronic diarrhoea (404/618), 37% of whom were charted two or more different types. The most common laxative was Docusate sodium. The prevalence of chronic diarrhoea not related to laxative use was 9% (n=214). Residents experiencing diarrhoea, including those taking laxatives, were more likely to experience lower mood (18% v 12%, P< 0.01), be more at risk of pressure injuries (4% v 13%, P<0.001) and less likely to enjoy time with friends and family than residents without diarrhoea (38% v 20%, P<0.001). Weight loss was more likely in the laxative-taking diarrhoea cohort than the constipation cohort (50% v 39%, P< 0.001).

Self-reported data were collected from 110 rest-home and hospital-level care residents (mean age 88 years, SD 7.4). Chronic diarrhoea was experienced by 23 (21%) residents. Laxatives were charted to more than half of those residents (n=12, 52%). The prevalence of chronic diarrhoea not associated with laxative use was 10%; mean age 89 years (SD 4.5), 60% men (n=14), 56% living in rest home level of care (n=13).

Conclusion: Chronic diarrhoea is prevalent in care facilities and in most cases is associated with laxative use which may be inappropriate. Experiencing diarrhoea is negatively associated with QOL, mood and pressure injury risk, irrespective of the cause of diarrhoea. Prevalence is similar when obtained from nursing records and directly from residents.

Introduction: Patients with organic gastrointestinal (GI) diseases and diabetes mellitus (DM) can have concomitant symptoms compatible with a disorder of gut-brain interaction (DGBI). The differentiation of symptoms related more to a DGBI than to the organic disease is important since this influences treatment strategies.

Aims & Methods: This study aimed to compare the global prevalence of symptoms compatible with DGBI in adults with and without self-reported organic GI diseases or DM. Data was collected in a population-based internet survey in 26 countries; the Rome Foundation Global Epidemiology Study (N=54,127). Adult subjects were asked if they had ever been diagnosed by a doctor with any of several organic diseases including gastroesophageal reflux disease (GERD), celiac disease (CeD), peptic ulcer, diverticulitis, inflammatory bowel disease (IBD), and DM. Individuals not reporting each respective organic diagnosis were considered as the reference group. DGBI-compatible symptoms were grouped in regional subgroups based on the diagnostic questions of the Rome IV Adult Diagnostic Questionnaire: esophageal, gastroduodenal, bowel, and anorectal with special focus on five of the most frequently reported DGBI in those groups

Symptoms compatible with *Odds ratio's: presence vs absence of the respective organic disorder.*	Global Prevalence *n = 54,127*	GERD *n = 7,148*	Peptic Ulcer *n = 1,613*	Celiac Disease *n = 323*	IBD *n = 993*	Diverticulitis *n = 902*	Diabetes *n = 3,884*

PP1080 Table 1. Prevalence rates as % (95% confidence intervals) of symptoms compatible with DGBI in self-reported organic GI diseases and DM.

(functional dyspepsia (FD), irritable bowel syndrome (IBS), functional constipation, functional diarrhea and functional abdominal bloating)[1]. Mixed logistic regression, with country as random intercept, was used to calculate the odds ratios (ORs, including [95% confidence interval]) of having DGBI-compatible symptoms, comparing every respective organic disease to their reference group.

Results: The total prevalence rates of a self-reported history of organic disease were 13.2% (n=7,148) for GERD, 3.0% (n=1,613) for peptic ulcer, 0.6% (n=323) for CeD, 1.8% (n=993) for IBD, 1.7% (n=902) for diverticulitis, and 7.1% (n=3,884) for DM. Having any organic GI disease of interest increased the odds of symptoms compatible with a DGBI (prevalence 63.4% vs 43.0% in the reference group, OR 2.76 [2.64-2.90]), which was stronger than for DM (48.5% vs 43.0%, OR 1.26 [1.18-1.35]). Among the individual DGBI, symptoms compatible with IBS and FD were most commonly seen in all organic GI diseases. Increased OR for having symptoms compatible with DGBI were seen across the organic GI diseases. Expected strong links between the organic GI disease and DGBI were seen in the corresponding regions for the disease pathology (e.g. IBD and bowel DGBI, GERD and esophageal DGBI), but also with other regions (e.g. IBD and esophageal DGBI, GERD and anorectal DGBI) (Table 1).

Conclusion: DGBI-compatible symptoms are more common in patients with self-reported organic GI diseases and, to lesser extent, DM compared to the general population. Since this difference is also seen between organic disorders and DGBI-compatible symptoms where not expected, this may influence the focus of treatment strategies.

Introduction: Disordered eating is reported to be common in disorders of gut-brain interaction. In this study, we aimed to identify symptoms compatible with disordered eating, including ARFID and other eating disorders (i.e., anorexia and bulimia nervosa) in a large population-based cohort with bowel symptoms.

Aims & Methods: An internet-based survey was completed by individuals (18-70 years) who met symptom thresholds to diagnose a functional bowel disorder. The survey included self-report measures for quality of life (QoL), bowel and gastroduodenal disorders of gut-brain interaction, gastrointestinal (GI) symptom severity, body mass index, non-GI symptoms, GI-specific anxiety, general anxiety, depression, symptoms of ARFID (NIAS), and screening for anorexia and bulimia nervosa (SCOFF). Validated cutoffs for NIAS (≥10 Picky eating; ≥ 9 Appetite; ≥10 Fear) and SCOFF (total score ≥2) were used to detect ARFID and other eating disorders, respectively. Hence, we identified three groups: 1) ARFID (≥ cutoff for any NIAS subscale and SCOFF <2); 2) eating disorder (SCOFF ≥2); 3) no disordered eating.

Results: In total, 825 adults participated (age 34.0±15.0 years (mean ± SD); 66.2% females). Of these, 65.1% fulfilled the Rome IV criteria for a FBD, and 15.5% met the criteria for functional dyspepsia. A positive screening for anorexia and bulimia was more common among participants with FD and overlapping FBD and FD compared to participants with only FBD (44.7% and 50.6% respectively vs 30.3%, p<.001), which in turn was higher compared to participants that did not fulfill diagnostic criteria for FBD or FD (14.9%, p<.001). Symptoms of ARFID were more common among participants with overlapping FBD and FD compared to participants with only FD, only FBD or participants who did not fulfill diagnostic criteria for FBD or FD (27.2% vs 14.9%, 9.9% and 14.1% respectively, p<.001). Both groups with disordered eating consisted of more females and reported more severe non-GI somatic and GI symptoms, general anxiety, depression as well as lower QoL compared to the group with no disordered eating (Table). Body weight/shape related disordered eating had also more GI-specific anxiety whilst symptoms of ARFID was associated with a lower body weight.

	No disordered eating (n=481)	ARFID (n=108)	Eating disorder (n=236)	P
Female sex, %	60.1*	75.9§	74.2#	<0.001
Age (years)	40.2 ± 15.4	36.8 ± 14.4§	31.8 ± 12.5#	<0.001
BMI (kg/m^2)	26.5 ± 6.0*	24.5 ± 6.7§	27.3 ± 6.2	<0.001
Non-GI somatic symptoms (PHQ-12)	7.5 ± 3.8*	9.4 ± 4.7	10.5 ± 4.5#	<0.001
GI-specific anxiety (VSI)	33.3 ± 17.0	36.4 ± 16.6	37.7 ± 13.1#	.001
Anxiety (PHQ-4)	1.5 ± 1.7*	2.4 ± 2.1	2.9 ± 1.9#	<0.001
Depressive symptoms (PHQ-4)	1.5 ± 1.6*	2.5 ± 2.0	3.0 ± 2.0#	<0.001

Quality of life (EQ-5D)	0.89 ± 0.11*	0.83 ± 0.16	0.82 ± 0.14#	<0.001

Data are mean ± SD or proportions (%) and groups were compared by Chi-square tests and ANOVA with pairwise comparisons (Bonferroni correction).
* P<0.05, No disordered eating vs. ARFID;
§ P<0.05, ARFID vs. eating disorder;
# P<0.05, No disordered eating vs. eating disorder.

Table. Demographics and symptoms in adults with bowel symptoms grouped by presence or absence of disordered eating.

Conclusion: Symptoms of ARFID and other eating disorders are very common in adults with bowel symptoms. Presence of disordered eating is associated with comorbid functional dyspepsia, more severe GI, non-GI, and psychological symptoms, as well as reduced quality of life. It is important to identify these individuals to optimize their medical, psychological, and dietary treatment.

Disclosure: Nothing to disclose.

PP1082

EFFICACY OF LUBIPROSTONE FOR TREATMENT OF CHILDHOOD FUNCTIONAL CONSTIPATION: AN OPEN LABEL RANDOMIZED CONTROLLED TRIAL

E.S. Elkaragy[1], M.M. Shamseya[2], R.H. Metwally[1], E.R. Mansour[3], S.A. Lashen[4]

[1]Faculty of Medicine, Alexandria University, Pediatrics, Alexandria, Egypt, [2]Medical Research Institute, Alexandria University, Clinical and Experimental Internal Medicine, Alexandria, Egypt, [3]Faculty of Medicine, Alexandria University, Physical Medicine, Rheumatology, and Rehabilitation, Alexandria, Egypt, [4]Faculty of Medicine, Alexandria University, Internal Medicine, Hepatogastroenterology Division, Alexandria, Egypt

Contact E-Mail Address: sameh.lashen@alexmed.edu.eg

Introduction: Up to 30% of the under 18 years age group suffer from functional constipation with significant impact on health-related quality of life. In addition to lifestyle and dietary modifications, the currently available medication (e.g. polyethylene glycol, lactulose, stimulant laxatives) have low response rates, frequent side-effects, and non-sustained effects. Lubiprostone is an oral chloride channel-2 activator that stimulates gastrointestinal fluid secretion, softens stools, and facilitates bowel movements. It is approved in the United States for the treatment of chronic idiopathic constipation in adults. The evidence about the effectiveness and safety of lubiprostone in pediatric age group is still limited, representing a gap in clinical practice.

Aims & Methods: Aim: To evaluation of the effectiveness and safety of lubiprostone in children and adolescents with functional constipation.

Patients and Methods: In an open label, randomized, controlled trial, we included 277 patients in the age group 8-18 years diagnosed as functional constipation (FC). The diagnosis of FC was dependent on ROME IV criteria. After physical evaluation, patients were randomly (Simple randomization) assigned to one of 2 arms.

First arm (*n* =137): patients received lubiprostone at doses of 24 mcg/day on divided doses or 24 mcg BID if weighing < 50 kg or ≥ 50 kg, respectively. Second arm (control, *n* = 140): patients received Bisacodyl, lactulose, or Sodium Picosulfate in appropriate doses. Treatment extended for 12 weeks followed by 4 weeks follow-up after treatment cessation (week 16). Evaluation during the study was done at baseline, weeks 2, 8, 12, and 16 of the study.

The primary endpoint was spontaneous bowel movements (SBM) at week 12 and 16 compared to baseline. Improvement in the constipation was defined as increased SBM ≥ 1 SBM/week in frequency compared with baseline and maintaining ≥ 3 SBMs/week for at least 8 weeks (including the last 4 study weeks and the 4 weeks of follow-up). Safety assessment was done at clinic visits and by telephone as well as recording of patient-reported AEs.

Results: The two arms were matched as regards the mean ± SD of SBM at baseline (1.23 ± 0.37 motions/week for lubiprostone vs. 1.19 ± 0.28 motions/ week for control, P = 0.24). the primary endpoint was achieved in 128 (93.4%) patients of lubiprostone group, and in 48 (34.3%) patients of the control group (p < 0.001, χ^2 = 105.42). In subgroup analysis, lubiprostone was superior to different laxatives in the control arm (p< 0.001, F = 95.6). At 12 weeks, the mean SMB in lubiprostone arm was (4.78 ± 0.99 motion/week) vs. (2.70 ± 1.04 /week) for control group (P <0.001).

This difference was sustained for 4 weeks follow-up in lubiprostone group only. The overall side-effects occurred among 46% of lubiprostone group, and 48% in control group (p = 0.99). The most common adverse event in lubiprostone group were colicky abdominal pain (26%), and headache (14%), There was no life-threatening drug-related adverse events.

	Lubiprostone, n = 137	control, n = 140	P
Spontaneous bowel motion baseline	1.23 ± 0.37	1.19 ± 0.28	0.24
Spontaneous bowel motion 2 weeks	3.05 ± 0.94	2.64 ± 1.58	0.008
Spontaneous bowel motion 8 weeks	4.24 ± 0.97	2.97 ± 1.32	< 0.001
Spontaneous bowel motion 12 weeks	4.78 ± 0.99	2.70 ± 1.04	< 0.001
Spontaneous bowel motion 16 weeks	4.73 ± 1.14	2.25 ± 1.01	< 0.001

Conclusion: Lubiprostone is superior to conventional laxatives, and well tolerated treatment for functional constipation in pediatric and adolescent age groups.

IRREGULAR BOWEL HABIT INCREASES THE RISK OF ANXIETY AND DEPRESSION

K. Shemerovskii[1], R. Kantemirova[2], P. Seliverstov[3]

[1]Medical Social Institute, Dept. Internal Medicine, St Petersburg, Russia, [2]Federal Scientific Center for Rehabilitation of the Disabled named after G.A. Albrecht, Internal Medicine, St Petersburg, Russia, [3]S.M. Kirov Military Medical Academy, Dept. Internal Medicine, St Petersburg, Russia

Contact E-Mail Address: constshem@yandex.ru

Introduction: It is known that the irregular rhythm of defecation in the form of constipation increases the risk of colorectal cancer by almost 2 times [1-3]. Constipation increases the risk of cardiovascular mortality by 39% - 56% [4 - 6]. Irregular bowel habit increases the risk of obesity, stroke and comorbidity [6 - 8]. However, the effect of irregular bowel habits on the risk of anxiety and depression remains poorly understood.

Aims & Methods: The aim was to screen irregularity of the circadian rhythm of defecation and the occurrence of anxiety and depression in cardiological patients.

We used the method of "Chronoenterography" – weekly monitoring of the regularity of the rhythm of defecation and the study of the level of Anxiety and Depression using a special questionnaire HADS and took into account the level of quality of life (SF-36). 66 patients (38 women and 28 men aged 40-79 years) who were hospitalized for metabolic syndrome in a cardiology clinic were examined.

Results: Irregular Bowel Habit (IBH) occurred in 65% of the examined patients (in 43 out of 66). Regular Bowel Habit (RBH) was detected in 35% of patients (in 23 out of 66). 3 stages of IBH have been identified. The first stage (mild, 5-6 bm/w) occurred in 61% of patients. The second stage (moderate, 3-4 bm/w) – in 30% of patients. The third stage of IBH (severe, 1-2 bm/w) – in 9% of patients. It should be noted that the first two stages of IBH were almost 10 times more common than the third (constipation stage). Anxiety and depression were not detected in patients with RBH.

Subclinical anxiety in patients with mild stage of IBH was detected in 12% of cases, in patients with moderate stage of IBH – in 33% of cases, in patients with severe stage of IBH – in 57% of cases. Subclinical depression in patients with mild stage of IBH was diagnosed in 12% of cases, in patients with moderate stage of IBH – in 17% of cases, in patients with severe stage of IBH – in 43% of cases. Consequently, a progressive dependence of the level of anxiety and depression on the stage of severity of IBH was revealed. In patients with a Regular Bowel Habit, an "excellent" quality of life was found in 55% of cases. Among patients with IBH, "Excellent" quality of life was found in 10% of cases. Consequently, the probability of an "Excellent" quality of life in patients with RBH was 5 times higher than in patients with IBH. Patients with IBH have an almost 5-fold increased risk of deterioration in the quality of life.

Conclusion: 1. Irregular Bowel Habit was detected in 63% of cardiac patients.

2. Irregular Bowel Habit increases the risk of subclinical anxiety gradually from mild to moderate and severe stages of this habit (12%, 33% and 57%, respectively).

3. Irregular Bowel Habit increases the risk of subclinical depression gradually from mild to moderate and severe stages of this habit (12%, 17% and 43%, respectively).

4. A high level of quality of life in patients with a regular (daily) Bowel Habit was 5 times more common than in patients with an Irregular Bowel Habit.

ARTIFICIAL INTELLIGENCE AND ANORECTAL MANOMETRY: AUTOMATIC DETECTION AND DIFFERENTIATION OF ANORECTAL MOTILITY PATTERNS - A PROOF OF CONCEPT STUDY

T. Ribeiro[1], M.J. Mascarenhas Saraiva[1], M. Vila Pouca[2], J. Afonso[1], P. Cardoso[1], F. Mendes[1], M. Martins[1], H. Cardoso[1], P. Sousa[3], J. Ferreira[2], I. Froehner[4], G. Macedo[1]

[1]University Hospital Center of São João, Gastroenterology, Porto, Portugal, [2]Faculdade de Engenharia da Universidade do Porto, Porto, Portugal, [3]INEGI – Institute of Science and Innovation in Mechanical and Industrial Engineering, Porto, Portugal, [4]Pelvia – Gastrointestinal Motility and Continence, Coloproctology, Curitiba, Brazil

Contact E-Mail Address: miguel.pedro96@gmail.com

Introduction: Anorectal disorders, causing fecal incontinence or evacuation dysfunction are common, affecting up to 5% of the general population (1).

Most of these disorders result from an intricate combination of disturbances, including neurologic and pelvic floor musculature dysfunction, and have a significant impact in the quality of life of patients (2,3).

Anorectal manometry (ARM) is the gold standard for the evaluation of anorectal functional disorders. Nevertheless, the accessibility to this exam is limited, and the complexity of data analysis and report is a significant drawback (4).

Aims & Methods: This pilot study aimed to develop and validate an artificial intelligence (AI) model to automatically differentiate motility patterns of fecal incontinence (FI) from obstructed defecation (OD) using ARM data.

We included ARM exams performed at a large gastrointestinal motility clinic in Brazil (Pelvia – Gastrointestinal Motility and Continence, Paraná, Brazil) between 2015 and 2021. All ARM procedures were performed using water-perfused probes with eight radial transducers with a distal latex balloon.

We developed and tested multiple machine learning algorithms for the automatic interpretation of ARM data. Four models were tested: k-nearest neighbors (KNN), support vector machines (SVM), random forests (RF) and gradient boosting (xGB). These models were trained using a stratified 5-fold strategy. Their performance was assessed after fine-tuning of each model's hyperparameters, using 90% of data for training and 10% of data for testing.

Results: A total of 827 ARM exams were used in this study, 493 of patients diagnosed with obstructed defecation (OD), while the remaining 334 presented FI. The performance marks of the different tuned models, including the precision, sensitivity and the F1-score, is summarized on table 1.

After fine-tuning, the xGB model presented an overall accuracy (84.6 ± 2.9%), similar to that of RF (82.7 ± 4.8%) and SVM (81.0 ± 8.0%), and higher that of KNN (74.4 ± 3.8%). The xGB models showed the highest discriminating performance between OD and FI, with an area under the curve of 0.939.

Model	Class	Precision (mean % ± SD)	Sensitivity (mean % ± SD)	F1-score (mean % ± SD)
KNN (K-Nearest Neighbors)	OD	79.6 ± 2.7	76.6 ± 5.4	78.0 ± 3.7
	FI	68.0 ± 5.1	72.0 ± 3.7	69.8 ± 3.6
SVM (Support Vector Machines)	OD	85.0 ± 6.1	82.2 ± 8.8	83.6 ± 7.4
	FI	75.6 ± 10.2	79.4 ± 8.0	77.6 ± 8.9
RF (Random Forests)	OD	81.8 ± 1.6	90.0 ± 7.3	85.6 ± 4.4
	FI	84.0 ± 10.5	71.6 ± 1.3	76.8 ± 4.7
xGB (Gradient Boosts)	OD	83.6 ± 4.3	92.4 ± 3.6	87.6 ± 2.2
	FI	87.4 ± 4.8	73.6 ± 8.2	79.6 ± 4.6

Table 1.

Conclusion: The tested machine learning algorithms, particularly the xGB model, accurately differentiated between FI and OD manometric patterns. Subsequent development of these tools may optimize the access to ARM studies, which may significantly impact on the management of patients with anorectal functional diseases.

Introduction: Functional diarrhea (FDr) is a disorder of gut-brain interaction (DGBI) characterized by chronic or recurrent diarrhea, not explained by structural or biochemical abnormalities. It is distinct from diarrhea predominant irritable bowel syndrome (IBS) with recurrent symptoms and notably the absence of pain. While functional conditions present with complex, likely heterogenous pathophysiology, we aimed to investigate if proxy measures of sociocultural risk factors have any association with the prevalence of FDr in populations across the world.

Aims & Methods: We performed an ecological study utilising peer-reviewed published datasets reporting country prevalence of FDr[1], Helicobacter pylori (H.p) prevalence[2] as proxy measures for orofecal infections, and the density of quick service restaurants (QSR) per population as proxy measure for processed food exposure. In addition, we used proxy measures of development including household size, median age, gross domestic product (GDP) per capita. The data were retrieved from publicly accessible datasets (United Nations, CIA, World Bank, commercial/financial reports of a global QSR chain). Spearman rank correlations were used to test univariate associations.

Results: The prevalence of FDr in 33 countries was negatively correlated with both the number of people per QSR (r= -0.44, p= 0.02), and household size (r= -0.69, p <0.0001), while positively correlated with median age (r= 0.58, p= 0.004) and GDP/capita (r= 0.56, p= 0.006). Assocaitions with H.Pylori infection did not reach significance (r= -0.27, p= 0.16).

Conclusion: Utilising publicly available data, the prevalence of FDr across diverse countries are linked to various markers of social development and a proxy marker of processed food consumption.

PP1086

EFFECT ON CLINICAL SEVERITY AND QUALITY OF LIFE OF SPECIFIC TREATMENTS FOR SOFT STOOLS IN WOMEN WITH FECAL INCONTINENCE

A. Raventós[1], S. Carrión[1], P. Clavé[1,2], L. Mundet[1,2]
[1]Consorci Sanitari del Maresme, Gastrointestinal Physiology Laboratory, Mataró, Spain, [2]Centro de Investigacíon Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain

Contact E-Mail Address: alba.ravens92@gmail.com

Introduction:
Fecal incontinence (FI) has a strong impact on quality of life (QoL). The main treatments focus on the rehabilitation of anorectal function. In a previous study we found that sphincter dysfunctions were severe and similar in patients with or without soft stools, but their presence worsened clinical severity and QoL significantly, requiring a specific diagnostic and therapeutic approach. FI and diarrhea are strongly associated, and treatment of the latter may be an effective method to ameliorate FI.
Some studies show that loperamide or fiber supplements in these patients is effective at least in the short term, although effective long-term and specific treatments aimed at the cause of diarrhea need to be identified.

Aims & Methods: To assess the impact on clinical severity and QoL of specific treatments for soft stools or diarrhea in patients with FI and diarrhea. Quasi-experimental study. We assessed anorectal function with high-resolution anorectal manometry, fecal consistency (Bristol Stool Chart), clinical severity (Wexner Score) and QoL (FIQL/EQ5D) in women with FI, and feces with Bristol≥5; patients underwent a breath-test to detect lactose, fructose/sorbitol malabsorption and SIBO, as potential causes of diarrhea, and an empirical test using cholestyramine to assess the presence of malabsorption of bile salts. Patients with SIBO were treated with Rifaximin 1200mg/day for 15 days. Those intolerant to lactose and fructose/sorbitol were given an exclusion diet. Those who did not show intolerances were administered Resincholestyramine 4g/12 hours for 15 days. Bristol, QoL and clinical severity were re-assessed in a follow-up visit one month later.

Results: Seventy-four women with FI and soft stools completed the study; mean age was 64.92±11.70 years. Of them, 59.18% had dysfunction of the external anal sphincter, 51.02% of the internal sphincter and 15.59% of both. Rectal hypersensitivity was shown in 12% of patients and 20% had hyposensitivity. Cough reflex was altered in 41.7%. Regarding the origin of the diarrhea, 43.9% showed bile salt malabsorption, 26.6% fructose/sorbitol intolerance, 17.1% SIBO and 12.2% lactose malabsorption. After one month of specific pharmacological treatment or exclusion diet we observed that 92.9% of the patients improved fecal consistency (Bristol 3-4). Clinical severity (Wexner) was reduced by 66% (11.61±3.64 pre-treatment vs 3.89±4.05 post-treatment; p<0.001). QoL improved in all dimensions of the FIQL score (pre/post-treatment): Lifestyle (2.69±0.91/3.40±0.72 p<0.01), coping (2.32±0.88/3.03±0.78 p<0.01), depression/self-perception (2.77±0.70/3.33±0.56 p<0.01) and embarrassment (2.77±0.90/3.33±0.77 p<0.01). Health perception (EQ5D) also improved after the treatment (61.96±15.91/70±7.39 p=0.017).

Conclusion: Presence of soft stools or diarrhea is a very prevalent and important risk factor in women with IF in addition to sphincteric and anorectal alterations. Our findings suggest that specific treatment aimed at the cause of diarrhea can be highly effective in improving patient outcomes

and QoL, regardless of disorders of the anorectal function. We suggest that rehabilitation strategies must start after stool assessment. This study highlights the importance of continued research in this area to help improve treatment options for this debilitating condition.

Disclosure: Nothing to disclose.

STUDY OF CORTICO-ANO-RECTAL NEUROPHYSIOLOGY IN WOMEN WITH FECAL INCONTINENCE

L. Mundet[1,2], O. Ortega[1,2], A. Raventós[1], P. Clavé[1,2]

[1]Consorci Sanitari del Maresme, Gastrointestinal motility laboratory, Mataró, Spain, [2]Centro de Investigacíon Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Instituto de Salud Carlos III, Madrid, Spain

Contact E-Mail Address: lluismundetp@gmail.com

Introduction: Fecal incontinence (FI) is a very prevalent health condition, affecting up to 15% of community-dwellers, 24% in the case of women. While the pathophysiological aspects of pelvic biomechanics associated with FI have been extensively studied, recent research has shown that neurophysiological alterations at a higher level (cortical or spinal) can also be present. The neurophysiology of the entire cortico-anal motor pathway and its possible dysfunction in FI is rather unknown.

Aims & Methods: To characterize the integrity of the cortico-spino-anorectal efferent pathways in women with FI, and compare them with age-matched healthy volunteers (AM-HV), and young nulliparous healthy volunteers (Y-HV), 18-35 years of age.

Observational study on 18 women with FI and a mean age of 63.4±11.5 years in whom sphincter function and structure were assessed with high-resolution anorectal manometry (HRAM) and endoanal ultrasound (EUS); neurophysiology was assessed by pudendal nerve terminal motor latency (PNTML) and anal and rectal motor evoked potentials (MEP) after transcraneal and translumbosacral magnetic stimulation (TMS and TLSMS) (efferent pathways). The main parameters evaluated were PNTML latency/amplitude of the action potential; and latency and amplitude of the anorectal MEPs in the cortico-ano-rectal segment, and lumbo-ano-rectal and sacro-anorectal segments, on both sides. In addition, the neurophysiology of a cohort of 15 AM-HV (60.7±9.01 years old) and 15 Y-HV (24.8±5.59 years old) was also studied.

Results: a) Structure and function. HRAM: 83.24% of patients with FI had impairment of the external anal sphincter (EAE), 40% of the internal (IAS), and 23.57% of both. EUS: 11.76% had injuries on the puborectalis, 58.82% showed tears in the EAE and 11.76% IAS disruptions.

b) Neurophysiology. Efferent motor pathways: mean left PNTML of the patients was 2.37±0.32; for HV was 2.29±0.29, and for YHV 1.9±0.33 (significant between patients and YHV; $p<0.05$). Right PNTML was 2.11 ± 0.34 and 2.14 ± 0.41 for patients and HV, respectively (ns).

Among the patients, 20% showed motor neuropathy in at least one branch of the pudendal nerve. Motor pathways (MEP): Patients showed longer MEPs latencies compared to HV in several neural segments (cortico-spinal, lumbo-anal right, Lumbo-rectal right, and Sacro-anal right; ($p<0.05$).

We also found statistically significant differences between all sacral segments between HV and YHV. Taking the reference values from HV, 50% of patients with FI had impairments in the cortico-spinal segment, also 50% in the lumbo-anal and 44.4% in the sacral segment.

Overall, we found that 82.4% of patients showed delayed latencies in at least one of the cortico-ano-rectal segments studied.

Conclusion: We found a high prevalence of motor efferent cortico-anorectal pathway impairments in women with FI, with delayed latencies in most segments, beyond the pelvic floor. These findings suggest a complex pathophysiology of FI, which involves impairment of neural pathways at a higher level. Future treatment strategies based on neural stimulation at cortical or spinal level might be key in the rehabilitation of these patients.

Disclosure: Nothing to disclose.

PP1088

EFFECTIVENESS OF *SACCHAROMYCES BOULARDII* CNCM I-745 IN ADULT PATIENTS WITH DIARRHOEA – A RETROSPECTIVE, MULTICENTER, COMPARATIVE STUDY FROM INDIA

R. Bandagi[1], K. Pebbili[2]

[1]Dr Reddys Laboratories Private Limited, Bangalore, India, [2]Dr Reddys Laboratories Private Limited, Hyderabad, India

Contact E-Mail Address: kranthikiranpebbili@drreddys.com

Introduction: Diarrhoea is a common condition caused by bacterial, viral, protozoal infection and certain medications.[1,2] Management of diarrhoea involves maintenance of hydration by oral or intravenous fluids, antidiarrheal drugs, probiotics etc.[3,4] *Saccharomyces boulardii* (*S. boulardii*) CNCM I-745 is a probiotic which has been found to be effective in controlling pathogenic as well as antibiotic associated diarrhoea.[5,6,7]

The efficacy of S boulardii CNCM I-745 was evaluated and confirmed through multiple RCTs across the globe.[8]

Though there are few real world studies from Western countries which have evaluated the effectiveness of *S. boulardii* CNCM I-745 in reducing duration as well as frequency of diarrhoea, such studies are scarce in the Indian population.

Aims & Methods: Aims: Primary objective was to evaluate the effectiveness of *Saccharomyces boulardii (S. boulardii)* CNCM I-745 in adult patients with diarrhoea. Secondary objective was to compare the effectiveness of *S. boulardii* CNCM I-745 and treatment modalities other than probiotics in adult patients with diarrhoea and also in subset of patients who were using concomitant antibiotics.

Methods: This is a retrospective, multicenter, comparative study analyzing electronic medical records (EMR) of 1727 adult patients with diarrhoea in India.

From the EMR database, the total number of adult patients diagnosed with diarrhoea at baseline and administered *S. boulardii* CNCM I-745 (test group) was 270. A control group was formed of 1457 patients who were administered any anti-diarrhoeal and /or oral rehydration therapy for managing diarrhoea excluding probiotics. Patients were enrolled at baseline with complaints of diarrhoea or loose motions with one follow up visit within 15 days. A total of 112 patients with diarrhoea at baseline in test group, and 392 patients with diarrhoea in control group, were noted to have been administered concomitant antibiotics.

Results: For the test group, the mean age was noted to be 48.54 + 16 years and for control group it was 45.84 + 16.08 years. There was female preponderance in both the control and test group (56.7% Vs 51.5%).

At follow-up, 22.2% patients in test group complained of diarrhoea Vs 84.2% in control group. Thus proportion of patients with continued diarrhoea at follow-up was significantly lower in the S Boulardii group versus the control group ($p<0.05$). The odds ratio for noting absence of diarrhea in test group versus control group was 18.7, with 95% confidence interval of 13.6 to 25.7.

Amongst the subset of patients who received concomitant antibiotics, 23.2% patients in test group complained of diarrhoea Vs 81.6% in control group, at follow up visit. The proportion of patients receiving concomitant antibiotics with continued diarrhoea at follow-up was significantly lower in the test group versus the control group ($p<0.05$). The odds ratio for noting absence of diarrhea in test group versus control group receiving concomitant antibiotics was 14.7, with 95% confidence interval of 8.8 to 24.4.

Conclusion: The effect of *S. boulardii* CNCM I-745 probiotic in controlling diarrhoea in Indian patients was better than anti-diarrhoeal and/or oral rehydration therapy in real-world setting, irrespective of concomitant antibiotic usage.

NALOXEGOL RESTORES CODEINE-INDUCED INHIBITION OF HIGH-AMPLITUDE PROPAGATING CONTRACTIONS AND INCREASE OF RETROGRADE CONTRACTIONS IN A RANDOMIZED, THREE-WAY CROSSOVER COLONIC HIGH-RESOLUTION MANOMETRY STUDY IN HEALTHY VOLUNTEERS

A. Verheyden[1], J. Pannemans[1], I. Demedts[2], T. Vanuytsel[2], J. Tack[2]
[1]KU Leuven, Translational Research Center for Gastrointestinal Disorders, Leuven, Belgium, [2]KU Leuven, University Hospital Gasthuisberg, Gastroenterology, Leuven, Belgium

Introduction: Opioid-induced constipation (OIC) is a highly prevalent condition among patients treated with opioids for chronic pain. Although constipation and other gastrointestinal side effects can present in 40-90% of opioid users, their effects on colonic motor function and their reversal by opioid antagonists are poorly understood.

Aims & Methods: Our aim was to evaluate the effects of opioids and the reversal effects of a peripheral-acting mu-opioid receptor antagonist (PAMORA) on colonic motor patterns in healthy volunteers (HV), using colonic high-resolution colonic manometry.

We invited 15 healthy volunteers for our randomized, placebo-controlled, double-blind crossover study. The combination of naloxegol/placebo, placebo/codeine, or naloxegol/codeine was administered during three study visits, each separated by at least 1 week of wash-out. Participants underwent a colonoscopy after a half dose of standard PEG preparation for colonic manometry catheter (40-sensor high-resolution manometry catheter 2.5 cm spacing, Laborie, Mississauga, Canada with attached perfusion catheter) placement. Colonic pressure waves (PWs) were evaluated during sleep (1h), in the fasted state (1h), after a standardized bread meal (645 kcal) (2h), and after intraluminal administration of 10 mg bisacodyl (1h). We analyzed the number and direction of propagation of short PWs (over 3-4 sensors), long PWs (>4 sensors), and high-amplitude propagating contractions (HAPCs; long PWs with an amplitude of ≥100 mmHg for at least 1 sensor and 2 sensors of ≥90 mmHg). Upon awakening, participants received 25 mg of naloxegol or matching placebo. In addition, placebo or 60 mg codeine was administered orally, followed by another intake of half this dose one-hour post-prandial. Statistical analyses used a Friedman test and corrected for multiple testing.

Results: Fifteen HV (6 men/9 women, 31.9±3.6 years) finalized all three study visits; one participant was omitted from the analysis because of a missing trace. Both short and long synchronous PWs did not occur statistically significantly more or less in one of the 3 conditions, for all time periods. The same result was found for the antegrade PWs in all time periods. Postprandially, long retrograde PWs occurred statistically significantly less often with naloxegol/placebo compared to placebo/codeine (p=0.04). Additionally, short retrograde PWs occurred less often with naloxegol/placebo than with placebo/codeine (p=0.03). Post bisacodyl administration, both short and long retrograde PWs occurred more often with placebo/codeine, and HAPCs occurred less compared to both naloxegol conditions (Table).

	naloxegol/placebo	placebo/codeine	naloxegol/codeine	p-value
Long synchronous	19.00 (7.75-37.25)	10.00 (2.75-36.75)	9.50 (5.75-41)	0.49
Long retrograde	10.00 (3.75-19.50)	24.50 (3.75-43.00)	9.50 (2.75-16.50)*	0.02
Long anterograde	6.00 (4.00-8.00)	3.00 (0.75-12.25)	6.00 (1.75-9.50)	0.67
Short synchronous	21.50 (15.75-37.00)	25.50 (14.50-32.25)	18.00 (13.00-28.75)	0.75
Short retrograde	16.50 (11.00-20.25)*	41.50 (21.50-74.25)	19.00 (8.75-25.50)*	0.01
Short anterograde	12.00 (8.75-20.50)	18.00 (12.00-26.25)	13.50 (9.00-18.00)	0.66
HAPCs	7.00 (5.75-13.25)*	0.00 (0.00-0.00)	7.50 (1.50-9.75)*	0.0003

Table.

Median (25-75% interquartile range) number of colonic pressure waves in the post bisacodyl period (n=14). * significantly different from placebo/codeine with the Friedman statistical test and correction for multiple testing (p<0.05).

Conclusion: Codeine administration enhances retrograde contractions and inhibits high-amplitude propagating contractions after intraluminal bisacodyl administration in healthy volunteers and these effects are reversed by the PAMORA naloxegol. These observations enhance our understanding of the mechanisms underlying OIC and its treatment with naloxegol.

THE EFFECT OF S-ADEMETIONINE ON PLASMA CITRULLINE LEVEL IN PATIENTS WITH CHRONIC LYMPHOPROLIFERATIVE DISORDERS WITH CHEMOTHERAPY-INDUCED DIARRHEA

I. Skrypnyk[1], G. Maslova[1], R. Skrypnyk[1]
[1]Poltava State Medical University, Internal Medicine, Poltava, Ukraine

Contact E-Mail Address: inskrypnyk@gmail.com

Introduction: The principal treatment option for treating chronic lymphoproliferative disorders (CLPD) is chemotherapy. The central concept in chemotherapy (CT) is adherence to the dose and drug administration regimens. It is impotent that infusion of CT agents in high doses is associated with an increased risk of chemotherapy-induced injury of the entire gastrointestinal tract (GIT).

The clinical manifestations of chemotherapy-induced mucositis are diarrhea. The presence of chemotherapy-induced injury mucositis can be assessed by the level of N-acetylneuraminic acid (NANA) and citrulline in the blood. The primary mechanism of the cytotoxic influence of CT agents is strongly associated with oxidative stress.

Aims & Methods: The aim is to investigate the effect of S-ademetionine on plasma NANA and citrulline levels in patients with CLPD during chemotherapy-induced injury The aim is to investigate the effect of S-ademetionine on plasma NANA and citrulline levels in patients with CLPD during chemotherapy-induced injury GIT.

Materials and methods: 24 patients with CLPD were examined (15 (75%) patients with B-cell chronic lymphocytic leukemia and 10 (25%) patients with Small B-cell non-Hodgkin lymphoma, 7 (28 %) females and 18 (72 %) males, ages 30-76. The inclusion criteria were the progression of B-CLL, Small B-NHL, and diarrheal syndrome on the background of CT. The examinations were conducted twice: before CT and after 3 courses of CT. Patients were analyzed the concentration of NANA in the blood, and the concentration of the citrulline in the plasma.

All patients received CT: BR (bendamustine, rituximab), FCR (fludarabine, cyclophosphamide, rituximab), R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisolone). Depending on the inclusion of S-ademetionine as an adjuvant treatment, patients were divided into groups: I (n=13) – patients with CLPD, who received only CT. II (n=14) – patients with CLPD, who received S-ademetionine at a dose of 1000 mg/day intravenously for 10 days, then 500 mg twice a day for 20 days. III (n=20) – the control group of 20 practically healthy individuals (9 (45 %) females and 11 (55 %) males, ages 22-26).

Results: Patients in both groups with CLPD had pre-existed mucosal injury characterized by 1.25 (p=0.0025) and 1.26 times (p=0.006) higher blood NANA concentration than the control group. The conduction of CT was associated with injury enterocytes, which was characterized by 1,66 times (p=0,0002) lower plasma citrulline level in patients of group I compared to the initial examination. The infusion of S-ademetionine attenuated intestinal dysfunction associated with 1,23 times (p=0,0005) higher blood citrulline level after the CT compared to group I.

Conclusion: The infusion of S-ademetionine as adjuvant treatment in patients with CLPD provided effective prophylaxis of GIT injury that was associated with higher blood citrulline levels after the conduction of CT.

Disclosure: Nothing to disclose.

UTILITY OF CT COLONOGRAPHY AS A DIAGNOSTIC PROCEDURE FOR IRRITABLE BOWEL SYNDROME

T. Wada[1], E. Kubota[2], T. Yamada[1], A. Ohara[1], T. Kamiya[3], H. Kataoka[2]
[1]Okazaki City Medical Association, Public Health Center, Okazaki, Japan, [2]Nagoya City University Graduate School of Medical Sciences, Department of Gastroenterology and Metabolism, Nagoya, Japan, [3]Nagoya City University Graduate School of Medical Sciences, Department of Medical Innovation, Nagoya, Japan

Contact E-Mail Address: wadat0123@yahoo.co.jp

Introduction: Computed tomography colonography (CTC) has been developed as a less invasive alternative method to colonoscopy for colorectal cancer screening. Some subjects who underwent CTC reported abdominal pain induced by carbon dioxide gas injection during examination. We speculated that pain perception during CTC might reflect visceral hypersensitivity related to irritable bowel syndrome (IBS).

Aims & Methods: In this study, we investigated whether pain perception induced by carbon dioxide gas injection during CTC is different between patients with IBS and healthy controls. Furthermore, we evaluated the correlation between the pain score during CTC and the severity of the IBS symptom or the quality of life of patients with IBS. A prospective study of consecutively registered patients who underwent CTC for colorectal cancer screening in a single medical center was conducted. IBS was diagnosed using the Rome IV criteria, and patients with IBS were classified into IBS subgroups according to the predominant stool pattern experienced by the patient. In addition, all subjects completed the IBS Severity Scale (IBS-SS) and IBS-QOL questionnaire. Pain perception during CTC was quantified using the visual analog scale (VAS) at six time points during the CTC as follows: (1) before CTC, (2) immediately after carbon dioxide gas injection, (3) until the injection pressure reached a plateau (18 mmHg), (4) in the prone position after carbon dioxide gas injection, (5) in the supine position after carbon dioxide gas injection, and (6) after CTC. We also evaluated the association between the VAS and IBS-SS scores.

Results: One hundred twenty-three subjects who underwent CTC were enrolled in this study. Thirteen subjects were excluded because of incomplete questionnaires (n = 10) or a diagnosis of colorectal cancer with CTC (n = 3). Fifteen patients were diagnosed as having IBS on the basis of the Rome IV criteria for IBS. Patients with IBS were classified into the following groups: IBS with diarrhea (IBS-D, n = 1), IBS with constipation (IBS-C, n = 3), mixed IBS (IBS-M, n = 3), and unspecified IBS (IBS-U, n = 8). No significant differences in background characteristics, including age, sex, alcohol consumption, and smoking habit, were found between the IBS and control groups. The volume of carbon dioxide gas injected during CTC did not show a significant difference between the two groups. The total colon length was not significantly different between the two groups. The VAS score of the IBS groups was significantly higher than that of the control group at two time points, (2) immediately after carbon dioxide gas injection ($p < 0.01$) and (3) until the injection pressure reached a plateau (18 mmHg; $p < 0.01$). The maximum VAS score during CTC was also significantly higher in the IBS groups than in the control group ($p < 0.05$). Although the IBS-SS score was significantly higher in the IBS groups than in the control group, we found no significant correlation between the VAS and IBS-SS scores in the IBS groups. The IBS-QOL score also did not show any significant correlation with the VAS score.

Conclusion: Our study indicates that pain perception evaluated using the VAS during CTC might be a potential diagnostic method for IBS. Further study is necessary to clarify the association between pain perception induced by CTC and IBS severity.

Disclosure: Nothing to disclose.

Introduction: Previous studies indicate that patients with irritable bowel syndrome (IBS) may present with altered fecal microbiota and metabolite profiles. While changes in bowel habits seem to not influence the microbiota dynamics, the stability of fecal metabolites in IBS patients has not been addressed yet.

Aims & Methods: This study aimed to assess the stability of the fecal metabolite profile over time, and its link with fluctuations of stool consistency. It used fecal samples from two cohorts (A and B) comprising healthy subjects and patients with IBS diagnosed according to either Rome III (Cohort A) or Rome IV (Cohort B) and subtyped using the Bristol Stool Form (BSF) scale. Cohort A collected fecal samples for 5 consecutive days that were analyzed by gas chromatography-tandem mass spectrometry (GC-MS/MS).

Additionally, IBS patients collected up to 3 additional samples within one of those days. Cohort B collected fecal samples at week 0 (healthy and IBS) and week 4 (only IBS), later analyzed by liquid chromatography-MS (LC-MS).

All participants reported stool consistency using BSF scale. Metabolome variation based on the metabolite intensity signals was assessed by Bray-Curtis dissimilarity in R (version 4.2.1). Additional statistical analyses were conducted in GraphPad (version 9.4.1).

Results: Cohort A (7 healthy subjects and 8 IBS patients with mixed bowel habits, IBS-M) provided 66 fecal samples. Twenty-nine samples were collected from Cohort B (7 healthy subjects, 3 IBS-M, and 8 IBS patients with predominant diarrhea). The metabolome of Cohort A (n=155 spectral features) at day 1 showed similar composition with a tendency towards a higher Bray-Curtis dissimilarity in the IBS group (0.026 (0.023-0.028) vs 0.028(0.025-0.032); p=0.10).

Over a period of 5 days, metabolome dissimilarities were higher between- than within- individuals (Table 1) and fluctuated minimally over time for both healthy subjects and IBS patients. The stool type however changed more over time in the IBS than the healthy group (p<0.001).

Consecutive samples taken within the same day showed higher compositional variance between- than within- IBS patients (Table 1). At individual level, the metabolomic profiles remained stable despite changes in the BSF score. In Cohort B, the metabolome profile comprised 6 999 spectral features.

The metabolome dissimilarity was higher in IBS patients as compared to healthy subjects at week 0 (0.045(0.040-0.048) vs 0.048(0.042-0.054); p<0.05). In the IBS group, the metabolome was stable between week 0 and week 4 regardless of stool form and differed more between- than within-patients (Table 1).

Cohort A		Within-individuals	Between-individuals	P value
Healthy	*Over 5 days*	0.020 (0.018-0.024)	0.028 (0.025-0.32)	<0.0001
IBS	*Over 5 days*	0.021 (0.016-0.029)	0.029 (0.026-0.033)	<0.0001
	Within a day	0.017 (0.015-0.033)	0.034 (0.031-0.036)	<0.01
Cohort B: *IBS*	Over 4 weeks	0.028 (0.023-0.038)	0.048 (0.042-0.054)	<0.0001

Table 1. Fecal metabolome variation in healthy subjects and IBS patients using Bray-curtis dissimilarity analysis. Dissimilarity index ranges from 0 (identical composition) to 1 (totally different composition).

Conclusion: The metabolite profile of fecal samples remains stable over time within an individual IBS patient independently of the variation in stool consistency. This study suggests the use of fecal metabolites as a potential non-invasive diagnostic tool in IBS.

Disclosure: Nothing to disclose.

A CASE-BASED SURVEY ON THE CUSTOMARY MANAGEMENT OF IBS IN PRIMARY CARE AND AMONG GASTRO-ENTEROLOGISTS

P. Casteels[1], S. Kindt[1]
[1]UZ Brussels, Gastro-enterology and Hepatology, Brussel, Belgium

Contact E-Mail Address: sebastien.kindt@telenet.be

Introduction: Irritable bowel syndrome (IBS) is a highly prevalent disorder. According to Rome IV, the diagnosis relies on the presence of abdominal pain in association with a change in stool consistency or frequency. Guidelines recommend minimal testing to exclude other diseases, while advising on therapeutic options. However, the actual application of these guidelines into practice needs confirmation.

Aims & Methods: This study aims to assess the management of IBS by general practitioners (GP) and gastro-enterologists (GE) in their daily practice. Methods: Belgian GP and GE completed an online vignette-based survey between January and July 2022. Apart from data about years of experience, participants indicated their preferred diagnostic modality or therapeutic option for eight cases of diarrhoea-predominant IBS. Cases varied in age (25, 48 and 65 years), cardinal symptom (pain, discomfort, or diarrhoea) and availability of test results (none, limited to biochemistry and ultrasound, or extensive including endoscopy), while stressing out the prolonged duration of the symptoms and the absence of red flags. Frequencies were compared by Chi-square. The main determinants to the diagnosis of IBS were assessed by logistic regression.

Results: Sixty-four gastroenterologists and 31 general practitioners completed the survey. When considering pain and discomfort as cardinal symptoms in a young patient, 87.4% and 84.1% of participants diagnosed IBS, which decreased to 58.3% with diarrhoea. The diagnosis of IBS dropped to 26.8% for a patient of 65 years. In those cases, GP less frequently diagnosed IBS (all p<0.05), except with diarrhoea as cardinal symptom (p=0.78). According to logistic regression, diagnosing IBS was related to patient age, cardinal symptom, availability of prior test results and specialty, and only borderline related to the experience of the practitioner (p<.001, R^2=.293). Even when diagnosing IBS, 89.5% ordered one or more additional tests (77.9% biochemistry, 59.3% stool culture and parasites, 60.5% faecal occult blood testing, 17.4% breath testing, 12.8% imaging, 9.3% endoscopy). Upon normal results, 57% would not order further investigations. Both GP and GE opted for spasmolytics (62.3%) and dietary interventions (28.3%) as the preferred first-line treatment for IBS. Second-line treatment consisted of referral to a specialist or colleague (19.4%), dietary intervention (22.6%), neuromodulators (19.4%) and spasmolytics (14.5%). In second-line, GP favoured referral (61.1%) and dietary intervention (22.2%), while GE preferred neuromodulators (27.3%) and spasmolytics (18.2%). No GP initiated modulators. Similar figures were obtained in third-line.

Conclusion: In Belgium, abdominal pain or discomfort are equivalent cardinal symptoms when diagnosing IBS. Diarrhoea as cardinal symptom, older age and absence of prior testing lowered the preference for IBS, especially in GPs. Even when diagnosing IBS, healthcare providers order a large variety of tests. Spasmolytics and dietary interventions are favoured in first-line. Upon failure, only GE prescribe neuromodulators, while GP opt for referral. Future education of GP and GE should focus on harmonising the diagnostic approach and medical treatment of IBS with existing guidelines.

Disclosure: Consultancy for Truvion Healthcare.

Contact E-Mail Address: tarek.mazzawi@gmail.com

Introduction: Irritable bowel syndrome (IBS) is a chronic functional gastrointestinal disorder with recurrent symptoms but without any known radiological feature or biomarker test to diagnose it. Intestinal ultrasound (IUS) has been used to measure the bowel wall thickness (BWT) of the colon with a cut-off value >3mm indicating active inflammation (1).

IUS has increased sensitivity and specificity for detection of disease activity when combining BWT with fecal calprotectin measurements (2).

Aims & Methods: The aim was to measure BWT of the colon in patients with diarrhea-predominant irritable bowel syndrome (IBS-D) using ultrasound and to correlate it with fecal calprotectin measurement during IBS exacerbation.

The study included 50 IBS-D patients (25 females and 25 males) according to Rome IV criteria. The patients were examined with a 10 MHz linear array ultrasound transducer to measure the BWT in the ascending and descending colon and to assess bowel wall vascularity using color Doppler ultrasound where Limberg score 2 or above is considered abnormal (3).

Blood test and stool analysis with culture were performed. Fecal calprotectin was measured during the same day of the ultrasonographic examination. Colonoscopy with colon biopsy samples was performed within 48 hours to rule out any pathology.

Results: The IBS severity scoring system (mean±SEM) was 285±15. The value for fecal calprotectin was 260±46. Blood test and stool analysis with culture were normal. Colonoscopy was normal macroscopically but showed edematous lamina propria microscopically. Intestinal ultrasound showed that the BWT of the descending and ascending colon in millimeters (mean±SEM) were 3.0±0.11 and 1.2±0.08, respectively, with a significant difference (P<0.0001) between them. Significant correlation was found between fecal calprotectin and BWT of descending colon (r 0.45, P 0.0012) but not between BWT of ascending colon (r 0.18, P 0.3). Further measurements of the layers of the descending colon showed a significant correlation (r 0.50, P 0.0005) between fecal calprotectin and thickness of the submucosal layer (1.4±0.09) but not the other layers (mucosa and proper muscle). Color Doppler ultrasound showed no mural flow of the thickened bowel wall, assessed as grade 1 of the Limberg score.

Conclusion: Patients with IBS-D during symptom exacerbation with elevated fecal calprotectin exhibit thickened BWT in the descending colon without increased vascularity. Fecal calprotectin correlated with wall thickening of the descending colon especially of the submucosal layer.

Introduction: Glucose (GBT) and lactulose (LBT) breath tests have been recommended by international consensus for the indirect diagnosis of small intestinal bacterial overgrowth (SIBO) and the newly introduced intestinal methanogen overgrowth (IMO), based on the variations of respectively hydrogen and methane concentrations in breath avec ingestion of the above-mentioned sugars.

UEG consensus has recommended preferring glucose, due to the difficulty to differentiate, with lactulose as substrate, between rapid intestinal transit and true SIBO (1,2).

Aims & Methods: The aims of this retrospective study were to compare the positivity of GBT and LBT in a population of well-characterized patients with IBS. Among 995 glucose (75 grs) or lactulose (10 grs) breath tests performed in our unit between January 2021 and January 2023, we extracted a cohort of 287 patients with typical IBS according to Rome IV criteria, after exclusion of patients with a past history of digestive surgery (except appendectomy and cholecystectomy), diabetes, neurological diseases, active or in remission IBD, scleroderma and other connective tissue disorders, chronic intestinal pseudo-obstruction, cirrhosis.

Breath tests were performed after a 8 hour fast, and a strict no fiber and fermentable food the day before. GBT or LBT were performed according to the physician request. During the test, patients filled in a standardized questionnaire to evaluate digestive symptoms, anxiety and depression, and food intake disorders.

Various cutoffs for the positivy of the tests were used, according to recommendations: + 12 ppm or +20 ppm for hydrogen variations over baseline (SIBO), and values greater than 10ppm for methane (IMO). For LBT, values were considered only between baseline and 90 minutes after sugar ingestion, to limit false positive results in relation with colonic fermentation of lactulose (120 minutes for GBT) (3).

Results: 155 GBT and 132 LBT were performed in IBS patients (71% women, mean age 45, mean BMI: 22.6 kg/m^2). There was no difference between both groups in terms of demographics, IBS type, severity of symptoms, anxiety and depression.

Results were clearly different for the positivity of tests: LBT was 10 times more frequently positive than GBT with the +20 ppm cut-off for hydrogen. There was no difference for the positivity of both tests for methane (table 1).

	Glucose (N=155)	Lactulose (N=132)	p value
Hydrogen +12 ppm	12 (8%)	72 (55%)	0.0001
Hydrogen +20 ppm	7 (4.5%)	62 (47%)	0.0001
Methane ≥10 ppm	52 (34%)	45 (34%)	1.000

Table 1.

There was no significant association between symptoms and the positivity and negativity of the tests, whatever the substrate or the cut-offs. Methane levels were lower in IBS-D patients, and in patients complaining of diarrhea as the predominant symptom (p<0.04).

Conclusion: GBT and LBT are not comparable for the diagnosis of SIBO, in a population of well-characterized IBS patients, without comorbidities The very high prevalence of positive LBT (around 50% of IBS patients would be considered SIBO positive) does not make this test acceptable for this diagnosis. Furthermore, the positivity of both tests for SIBO were not correlated with symptoms, which may indicate a poor clinical significance of this diagnosis in IBS. With regards to IMO, both tests give similar results, mainly because baseline values are taken into account: the prevalence of IMO according to these tests is also rather high, and inversely correlated with diarrhea. The significance of the association between IMO and IBS should be tested in prospective interventional studies.

Introduction: Intestinal ultrasound (IUS) is a non-invasive, reproducible, low-cost technique for the assessment of intestinal diseases.[1]

Crohn's disease (CD) and irritable bowel syndrome (IBS) are two of the major causes of chronic diarrhoea and abdominal pain in high-income countries.[2] IBS, especially in the diarrheal (IBS-D) or mixed (IBS-M) variants, has clinical features similar to those of CD.

The role of IUS in the diagnosis and monitoring of CD is well established,[3,4] whereas only scanty data are available on IBS. Current IBS guidelines do not recommend the use of IUS even to distinguish between IBS-D or IBS-M and CD.[5,6]

Aims & Methods: The aim of this two-gate diagnostic study was to assess the accuracy of IUS in discriminating between IBS-D or IBS-M and CD in patients presenting with similar symptoms.

In a high-volume tertiary Centre, consecutive patients symptomatic for chronic diarrhoea and abdominal pain underwent IUS performed by three experienced gastroenterologists.

In the group with clinically active CD, patients had a previous diagnosis based on clinical, biochemical, endoscopic, radiologic and histologic criteria, while in the IBS group subjects had a previous diagnosis based on Rome IV Criteria.

Bowel wall thickness (BWT) of the terminal ileum, ascending colon, transverse colon and descending colon/sigma was evaluated using two cut-offs of 3 mm and 4 mm.[7] Enlarged lymph nodes, mesenteric fat hypertrophy, bowel wall stratification and submucosal vascularity were also assessed.

The diagnostic accuracy of IUS in discriminating between the two groups was estimated in terms of sensitivity, specificity, positive and negative likelihood ratios (LR+ and LR-) and overall accuracy (OA) (Table 1).

Results: A total of 50 patients with IBS (62% female, mean age 41 years, SD ± 13 years, 54% IBS-D) and 50 subjects with CD (44% female, mean age 47 years, SD ± 17 years) were enrolled.

Forty-nine patients with IBS (98%) and 8 patients with CD (16%) and had a BWT < 3 mm. 49 patient with IBS (98%) and 12 patients with CD (24%) had a BWT < 4 mm.

Sensibility, specificity, LR+ and LR- of BWT < 3 mm were 98%, 84%, 6.13 and 0.02, respectively.

Sensibility, specificity, LR+ and LR- of BWT < 4 mm were 98%, 76%, 4.08 and 0.03, respectively.

BWT with 3 mm and 4 mm cut-offs showed an OA in discriminating between CD and IBS-D or IBS-M of 91% and 87%.

The absence of altered IUS parameters had 94% OA in discriminating between CD and IBS (Table 1).

Intestinal ultrasound parameters	IBS-D / IBS-M n.50 (%)	CD n.50 (%)	Sensibility	Specificity	Positive likelyhood ratio	Negative likelyhood ratio	Overall accuracy
BW thickness < 3 mm	49 (98)	8 (16)	98%	84%	6.13	0.02	91%
BW thickness < 4 mm	49 (98)	12 (24)	98%	76%	4.08	0.03	87%
Enlarged lymph nodes (absence)	49 (98)	36 (72)	98%	28%	1.29	0.07	63%
Mesenteric fat hypertrophy (absence)	50 (100)	39 (78)	100%	22%	1.28	0.004	61%
Maintained BW stratification	49 (98)	34 (68)	98%	32%	1.44	0.06	65%
Normal BW vascularity	50 (100)	31 (62)	100%	38%	1.61	0.002	69%
Normal ultrasound parameters	48 (96)	4 (8)	96%	92%	12.0	0.04	94%

Table 1. Intestinal ultrasound parameters used to discriminate between IBS-D or IBS-M and clinically active CD with similar clinical presentation IBS: irritable bowel syndrome; CD: Crohn's disease; BW: bowel wall.

Conclusion: IUS seems able to discriminate between IBS-D or IBS-M and CD in patients with chronic diarrhoea and abdominal pain. Particularly, a BWT < 3 mm may rule out the presence of clinically active CD and support the diagnosis of IBS. On the other hand, a BWT > 3 mm or a single altered ultrasound parameter might raise suspicion of CD and justify further testing. Cross-sectional studies are needed to confirm these preliminary results.

SYSTEMIC INFLAMMATORY PROTEIN PROFILES OF IRRITABLE BOWEL SYNDROME PATIENTS - A PRELIMINARY STUDY

S.N. Tan[1], S.M. Sim[2], L. Liu[2], J. Lee[1,2], A. Soh[1], K. Siah[1]
[1]National University Hospital, Division of Gastroenterology and Hepatology, Singapore, Singapore, [2]National University of Singapore, Department of Medicine, Singapore, Singapore

Contact E-Mail Address: shi_ni_tan@nuhs.edu.sg
Introduction: Irritable Bowel Syndrome (IBS) is a complex gastrointestinal functional disorder characterized by abdominal pain or discomfort and altered bowel habits. Despite its prevalence, and often chronic relapsing nature, the underlying pathophysiology of IBS remains incompletely understood. The etiology is likely multifactorial. Chronic low-grade subclinical inflammation has been implicated in the disease process and thought to perpetuate the symptoms of IBS.

Through previous studies on the serum proteomic profiles of IBS patients, it was seen that some inflammatory proteins are overexpressed in IBS, giving rise to a different serum proteome signature in IBS compared to healthy controls. [1,2]

Systemic inflammatory protein profiles have also been used to distinguish patients with ulcerative colitis from IBS patients. [3]

This suggests that proteomic profiling can potentially give us more insight into understanding the inflammatory mechanisms driving IBS.

Aims & Methods: This study aims to determine if systemic inflammatory protein profiles differ between patients with IBS and healthy controls.

Serum inflammatory proteins from 42 asymptomatic healthy controls undergoing screening colonoscopy with no colonic pathology, and 41 IBS patients fulfilling ROME IV criteria were analyzed using the Olink Target 96 Inflammation Panel. A partial-least square discriminant analysis was undertaken to identify additional discriminative inflammatory proteins. Univariate t-test analyses, with false discovery rate correction, were also performed to identify proteins unique to varying subtypes of IBS.

Results: Among IBS patients, the mean age was 48.6 years (SD +/- 15.5), while 31.7% were male. Among the controls, the mean age was 61.6 years (SD +/- 7) and 50% were male. There were 18 (43.9%), 14 (34.1%), 8 (19.5%) and 1 (2.4%) IBS patients with IBS-D, IBS-M, IBS-C and IBS-U respectively. 73.2% of IBS patients and 90.5% of controls were Chinese, with the rest being Indians, Malays or others.

Majority of the proteins (n=88, 96%) were prevalent in >40% of the study participants. Of which, 6 proteins (AXIN1, CCL19, CCL28, CD8A, EN-RAGE, MMP10) were differentially abundant ($p<0.05$) in IBS patients. Participants with IBS-C displayed higher levels of CD8A, while participants with IBS-D showed higher levels of AXIN1 and EN-RAGE (Table 1).

Interestingly, a recent study showed that CCL28 is elevated in IBS patients, which is consistent with our findings. [4]

EN-RAGE has also been studied to be elevated in several digestive diseases including IBS, inflammatory bowel disease, digestive tract cancers, necrotizing enterocolitis and gastroenteritis. [5]

Immunoprotein Marker	Molecular function	Biological Processes	Selectively differentially abundant IBS subtypes ($p<0.05$)
Axin-1 (AXIN1)	Developmental protein	Apoptosis WNT signaling pathway	IBS-D, IBS-M
C-C motif chemokine 19 (CCL19)	Cytokine	Chemotaxis Inflammatory response	
C-C motif chemokine 28 (CCL28)	Cytokine	Chemotaxis	
T-cell surface glycoprotein CD8 alpha chain (CD8A)	Glycoprotein	Adaptive immunity	IBS-C, IBS-M
S100A12 (EN-RAGE)	Antibiotic Antimicrobial Fungicide	Innate immunity Inflammatory response	IBS-D, IBS-M
Stromelysin-2 (MMP-10)	Hydrolase Metalloprotease Protease	Collagen degradation	

Table 1. Differentially abundant immunoproteins in IBS

Conclusion: We conclude that the serum cytokine profiles of IBS patients differ from that of healthy controls. We identified 6 immunoproteins that distinguish IBS from controls, and found that the levels of these immunoproteins also differ amongst the IBS subtypes. As this was a pilot study, the data collected was preliminary and limited by a small sample size. Future larger scale studies on proteomic profiling can potentially help with understanding the immune dysregulatory mechanisms driving IBS, and guide the diagnosis of and differentiation between subtypes.

Introduction: Irritable bowel syndrome (IBS) is a bothersome condition with long term pain and bowel symptoms and the most common cause of referral to gastroenterologists in the United Kingdom. Despite this, IBS is poorly understood as a clinical entity. Furthermore, IBS has numerous comorbidities but the full spectrum of these and how they relate to IBS has not been studied.

Aims & Methods: Using clustering analysis on the UK Biobank dataset, an adult cohort (age > 40 years), we aimed to define the top co-morbidities associated with IBS and develop a machine learning model to predict IBS. Co-morbidities in patients based on ICD-10 Summary Diagnosis codes 2 years prior to and 2 years following diagnosis with IBS were assessed and clusters defined.

These were compared with a control group of non-IBS patients. Several machine learning algorithms (K-Means, Linear Discriminant Analysis, Gaussian Mixture Models) were compared for accuracy.

Results: Amongst 18000 total adults (aged over 40), 8168 patients coded for IBS, 75% of whom were female. The top ten comorbidities (Table 1) found in IBS patients included diverticular disease, hypertension, hernia, haemorrhoids, osteoarthritis, asthma, gastro-oesophageal reflux disease without oesophagitis, history of psychoactive substance abuse, hypercholesterolaemia, and cholelithiasis. K-Means achieved the highest accuracy (83%) for predicting IBS based on the co-morbidity profile.

Comorbidities	Importance(%)
Diverticular disease	16.68
Hypertension	5.69
Hernia	4.64
Haemorrhoids	4.42
Osteoarthritis	3.29
Asthma	2.82
Gastro-oesophageal reflux disease without oesophagitis	2.74
Personal history of psychoactive substance abuse	2.51
Pure hypercholesterolaemia	2.38
Cholelithiasis	2.20

Conclusion: Most clusters identified contained obesity, hypercholesterolemia, and hypertension, indicating a possible link with metabolic syndrome. Asthma and allergies suggest a possible cohort of IBS patients with atopy.

Further research is needed to establish these links. In clinical practice, this could help both in predicting development of IBS, and also identify the cohorts of IBS on which certain therapies are more likely to work.

Introduction: Irritable bowel syndrome (IBS) is a disorder of gut-brain interaction, commonly associated with psychosocial comorbidities[1]. Probiotics targeting the gut-brain axis are a potential component of the clinical management of IBS[1]. Clinical research has suggested improved gastrointestinal (GI) and psychosocial symptoms with a probiotic supplement containing a combination of *Bifidobacterium longum* strains 35624 and 1714 in adults with IBS[2].

Aims & Methods: A prospective, observational study with 133 adults (recruited via a product sampling service in UK) with IBS (ROME IV) and ≥1 psychosocial comorbidity, evaluating symptoms before and after 12 weeks of daily supplementation with a probiotic containing a combination of *Bifidobacterium longum* 35624 and 1714 strains ($1x10^9$ colony forming units in total combined). Participants rated severity and frequency of their GI (abdominal pain, urgency to empty bowels, diarrhoea, constipation, bloating, flatulence) and psychosocial (feelings of stress, anxiousness, low mood and fatigue; difficulty sleeping) symptoms over the previous week via online surveys. Paired sample t-tests compared mean scores from baseline and week 12. Data are presented as mean±SD and percentage of participants experiencing improvement by week 12. Participants also rated their wellbeing (1=*least* to 10=*most*), time until symptom improvement (1-12 weeks) and likelihood to recommend the probiotic (5-point Likert scale, *very likely* to *very unlikely)*.

Results: 84% completed both surveys and were included in the analysis (n=111; 84% female; 96% 18-54y). At 12 weeks, all GI and psychosocial symptoms were significantly reduced in severity and/or frequency from baseline (table). Improvements in the frequency and severity ratings for difficulty sleeping and feelings of fatigue were also observed by 12 weeks (all *P*<.001 vs. baseline). Sub-analysis showed participants with severe (rated 6-10) or more frequent (5-7 days) symptoms at baseline experienced greater reductions in severity and frequency for all symptoms by week 12 (all *P*<.001 vs. baseline). Wellbeing significantly improved (6.93±2.05 vs. 4.81±1.56; *P*<.001), 77% of participants reported symptom improvement within 4 weeks, and 72% would recommend the probiotic to others.

Symptom	Baseline Severity Rating	Week 12 Severity Rating	Participants improved (%)	Baseline Frequency	Week 12 Frequency	Participants improved (%)
Abdominal pain	4.46 ± 2.13	2.85 ± 2.38†	68	3.57 ± 1.80	1.42 ± 1.78†	77
Urgency to empty bowels	4.58 ± 2.63	4.05 ± 3.32	52	3.4 ± 2.02	1.46 ± 1.71†	78
Diarrhoea	3.73 ± 2.77	3.49 ± 3.36	45	1.98 ± 1.95	0.84 ± 1.50†	54
Constipation	4.36 ± 2.75	3.45 ± 3.20‡	56	2.61 ± 2.11	1.10 ± 1.67†	63
Abdominal bloating	5.46 ± 2.20	3.98 ± 3.01†	64	4.32 ± 1.79	4.32 ± 2.42	38
Flatulence	5.70 ± 2.41	4.01 ± 3.12†	66	5.18 ± 1.65	2.56 ± 2.13†	38
Feelings of stress	6.28 ± 2.15	4.22 ± 2.98†	68	5.15 ± 1.80	2.31 ± 2.06†	86
Feelings of anxiousness	6.21 ± 2.22	4.32 ± 3.00†	64	4.90 ± 1.98	2.09 ± 2.06†	86
Feelings of low mood	5.98 ± 2.61	4.21 ± 3.11†	65	4.39 ± 2.18	2.05 ± 2.09†	76

*Severity rated 1=*least* to 10=*most*; frequency rated as number of days, 0=none to 7=all; †*P* <.001 versus baseline; ‡*P*=.009 versus baseline.

*Table. Mean±SD severity and frequency of symptoms before and after 12 week probiotic supplementation period**

Conclusion: These real-world data suggest supplementation with a dual strain probiotic containing *Bifidobacterium longum* strains 35624 and 1714 may significantly improve the GI and psychosocial symptoms of IBS, confirming the findings of previous clinical research[2].

Contact E-Mail Address: andreascostantino@gmail.com

Introduction: Irritable bowel syndrome (IBS) is a highly prevalent chronic gastrointestinal disorder.[1] Physical activity (PA) improves IBS symptoms[2] and may be recommended among first-line interventions.[3]

Digital Apps may increase PA,[4] but whether this intervention can improve symptoms in patients with IBS has not yet been investigated.

Aims & Methods: The aim of this randomized controlled trial was to evaluate the effects of PA prescription with the use of a mobile App in comparison with PA prescription alone on IBS symptoms and PA levels in patients with IBS.

From June to October 2022, we enrolled 97 consecutive patients with IBS defined according to the Roma IV criteria. 22 patients aged <18 or >60 years or with comorbidities limiting PA were excluded.

Patients were randomized to two intervention groups: 1) (Not APP) PA prescription with 10 min counselling according to the recommendations for IBS of *Exercise is Medicine*[5] or 2) (APP) the same PA prescription with the indication to use the mobile App Google Fit (Google, Mountain View, USA) after a brief explanation. This App is free and with no advertisements, available both for IOS and android, and available in different languages including Italian. It promotes PA according to the latest World Health Organization (WHO) guidelines and it has been already used and validated in other studies.[6,7] Other treatments for IBS were allowed in both groups. Patients were evaluated at the first visit (T0) and after 3 months (T3).

The severity of IBS symptoms (primary endpoint) was assessed by the Irritable Bowel Severity Scoring System (IBS-SSS). The Structured Assessment of Gastrointestinal Symptoms Scale (SAGIS), the Hospital Anxiety and Depression Scale (HADS), and the Bristol Stool Scale (BSS) were also used. The adherence to WHO guidelines for aerobic physical activity, and PA levels, were measured as Metabolic Equivalent of the Task (MET) minutes per week through the International Physical Activity Questionnaire-Short Form (IPAQ-SF).

Statistical analysis was performed with R 4.2.3.

Results: Seventy-five patients with IBS (mean age 41, SD ± 11.7 years; 70 % female) were randomized. Baseline characteristics of the two groups (age, sex, IBS subtypes, other treatments, IBS-SSS, SAGIS, HADS and BSS scores and PA levels) were not significantly different (data not reported). Three patients dropped out of the trial in the Not APP group.

The improvement in IBS-SSS and in SAGIS total score in the App group were significantly greater than in the Not APP group, whereas the difference of the improvement in HADS between groups remained at borderline significance level (Table 1). Normalization of stool form was observed in

21% of patients in the Not APP group and in 41% of patients in the APP group (P= 0.077). Although PA increased in both groups, the increase was greater in the APP than in the Not APP group (MET min global activity at IPAQ-SF=791±1026 vs 262 ± 807; P=0.025) as well as the adherence to the WHO indications (41% vs 15 %, P=0.048). The increase of PA was significantly correlated with the improvement of IBS-SSS (r=0.33, P=0.03).

	APP (n=39)	Not APP (n=33)	P value
IBS-SSS	88.2 ± 67.5	47.6 ± 72.0	0.021
SAGIS	9.2 ± 8.7	4.1 ± 8.7	0.021
HADS	4.3 ± 5.0	2.3 ± 3.7	0.065

mean ± SD

Table 1. Improvement (T3-T0 scores) of the IBS-SSS, SAGIS and HADS in the two groups after three months

Conclusion: Prescription of a digital APP promoting PA improved symptoms compared to PA counselling alone, suggesting that such Apps may be useful tools in the treatment of IBS.

Introduction: Gut-brain dysregulation and microbiome dysfunction are central to the pathogenesis of irritable bowel syndrome (IBS). Depressive and anxiety symptoms are highly prevalent and contribute to disease burden but are not commonly addressed in practice. The low FODMAP diet is efficacious for managing gastrointestinal symptoms but may not be appropriate in those with psychological comorbidity due to its complexity. A Mediterranean diet (MD), rich in vegetables, pulses, wholegrains and olive oil, has potential benefit in IBS as it leads to positive shifts in microbiome composition and function, and RCTs have demonstrated antidepressant effects.

Aims & Methods: The TANDIM trial aimed to assess the feasibility of a MD in patients with IBS and psychological comorbidity. Adults aged 18-65 years with Rome IV IBS and mild or moderate anxiety and/or depressive symptoms were recruited to a 6-week RCT. Significant medical or mental health conditions (e.g. inflammatory bowel disease, bipolar disorder) and recent change in IBS or psychotropic treatment were excluded. Patients were randomised to MD advice from a dietitian or advice to continue habitual diet. MD advice was individualised and incorporated advice regarding gradual reintroduction of high fibre or high FODMAP foods in individuals in which these components were restricted. Habitual diet controls undertook identical research activities to MD but were not provided dietary advice. Diet adherence was measured using a Mediterranean diet adherence screener (MEDAS) and 3-day diet records were collected at baseline and follow up. Gastrointestinal symptoms (IBS-SSS), psychological symptoms (HADS) and quality of life (IBS-QOL) data were collected at baseline and follow up. Stool samples were collected for metagenomic sequencing. Data were analysed on an intention-to-treat basis. For continuous variables, analysis of covariance with adjustment for baseline was used; for categorical data, Fisher's exact tests were used. Between group differences in diversity and differential abundance of taxa and potential functions of the microbiome were analysed using linear mixed effects models and FDR correction.

Results: In total, 59 individuals were randomised (29 MD, 30 control) and 48 completed the trial. Seven of 11 withdrawals were due to antibiotic commencement. The MEDAS score was higher, indicating better adherence to MD, at week 6 in MD vs controls (7.5 [95% CI: 6.9, 8.0] vs 5.7 [5.2, 6.3], p<0.001) and there was no difference in total FODMAP intake (p=0.51). There was a lower IBS-SSS at week 6 in MD vs controls (168 [95% CI: 146, 191] vs 260 [95% CI: 238, 282], p<0.001) and a greater proportion of IBS-SSS responders in MD vs controls (≥50-point reduction; 83% vs 37%, p<0.001). There was also a greater proportion of HADS-D responders (52% vs 20%, p=0.015) and IBS-QOL responders (≥14-point reduction 62% vs 23%, p=0.004). Gastrointestinal adverse events were similar between groups (p=0.588). There were no differences between groups in change in microbiome alpha diversity (richness, Shannon Index), beta diversity, relative abundance of taxa, or functional potential.

Conclusion: The MD is a feasible and potentially therapeutic dietary intervention for reducing gut and psychological symptom burden in IBS. The broader health benefits with a MD style eating pattern provide further impetus for studying its effects in IBS. Larger blinded RCTs, in which influence of expectation bias is minimised, are required.

Introduction: Intestinal microbiota are prominent in the etiology of irritable bowel syndrome (IBS). In this exploratory study, we investigated short- and long-term changes in the microbiota of IBS patients after intervening with a low-FODMAP diet (LFD) or probiotics (an 8 strains lactobacilla) using a standardized microbiota characterization test intended for routine use.

Aims & Methods: We analyzed data and fecal samples collected in a previous trial from non-comorbid IBS patients before treatment, and then again after four weeks and one year of treatment. Response to treatment was defined by a reduction in the IBS-SSS score, and the gut microbiota were characterized using the standardized and GA-map® Dysbiosis Test Lx.

Results: Of the 25 responders to either treatment, two of the 22 with fecal samples available were dysbiotic at baseline, increasing to eight out of 19 after four weeks; after one year all responders providing a sample were normobiotic (n=15).

After four weeks, the abundance of Bacilli, *Lactobacillus* spp. and *Streptococcus salivarius* ssp. *thermophilus* were temporarily increased in the probiotic responder group ($p<0.05$), while for LFD responders *Anaerobutyricum hallii* had decreased. There was a greater abundance of R. gnavus at baseline in those responding to probiotics than in those responding to LFD.

Conclusion: In addition to improving IBS symptoms, sustained LFD or repeat probiotics tended to temporarily alter the microbiota profile in responders. Microbiota characterization is a promising tool for monitoring IBS treatments; however, more extensive studies are needed.

Introduction: Irritable bowel syndrome (IBS) is a common functional disorder caused by an imbalance in the brain-gut axis. Visceral hypersensitivity (VHS) plays a leading role in the pathogenesis of IBS, leading to pain syndrome. To assess pain syndrome in IBS, researchers usually rely on subjective patient reports using a visual analogue scale (VAS), which does not reflect VHS and does not allow for an objective evaluation of clinical manifestations of the disease or the effectiveness of therapy.

Aims & Methods: Aim: To study the value of the balloon-dilation test (BDT) in determining the threshold of visceral sensitivity and its potential for evaluating therapy effectiveness in patients with IBS with diarrhea (IBS-D). Materials and methods: 46 patients with severe IBS-D (Drossman DA, 1999) were examined, including 24 women with a median age of 31 (25;39) years and 22 men with a median age of 28.5 (23;35) years. The diagnosis corresponded to Rome IV criteria. Pain syndrome in IBS-D was evaluated using a 10-point VAS. BDT was performed to determine the threshold of visceral sensitivity. Patients were consulted by a psychiatrist to identify mental status disorders and prescribe antidepressants. Therapy effectiveness was evaluated after 8 weeks. Statistical analysis was performed using Statistica 12 software (StatSoft Inc., USA). The level of significance was set at $p<0.05$.

Results: In all patients with IBS-D, the severity of pain (VAS) reached 8 (7;10) points. BDT revealed a violation of all visceral sensitivity parameters (VSP) (see Table 1). Mental status disorders were detected in all patients: 56.4% had anxiety, 26.12% had anxiety-depression, and 17.48% had depressive disorders. After 8 weeks of therapy, a significant decrease in the level of pain syndrome from 8 (7;10) to 1 (0;3) points on VAS was noted ($p<0.05$).

Indicator (ml)	Before treatment	After treatment	Wilcoxon, p-value
	Me (25%; 75%)		
First urge	32(21;43)	78 (72;86)	p <0,05
Intense urge	40(30;54)	98(86;113)	p <0,05
Maximally tolerated volume	59 (50;71)	134(116;198)	p <0,05

Table 1. Dynamics of visceral sensitivity parameters according to BDT

According to BDT, the threshold of VHS significantly improved in all patients: the maximal tolerable volume of air in the balloon increased, and the first urge to defecate occurred later (see Table 1). After antidepressant therapy, the mental status of patients improved: anxiety disorders were alleviated, anxiety-depressive disorders persisted in 8.7%, and depressive disorders in 10.9% with minimal severity.

Conclusion: BDT allows for an objective characterization of VHS and provides a quantitative assessment of pain syndrome in IBS, unlike the subjective VAS scale. In the examined group of patients with IBS-D, an increase in the threshold of VHS was noted after antidepressant therapy, leading to pain syndrome remission. Manifestations of mental disorders decreased, leading to IBS-D remission.

Disclosure: Nothing to disclose.

Introduction: Irritable bowel syndrome (IBS) is a heterogeneous disorder of gut-brain interactions characterised by pain and altered bowel habits[1]. The low fermentable oligosaccharide, disaccharide, monosaccharide and polyol (FODMAP) diet is efficacious for improving symptoms and quality of life (QoL)[2], however not all individuals will have a therapeutic response resulting in adequate symptom relief[3]. Behavioural, emotional and cognitive predictors of response have been explored in psychological therapies, but not in dietary treatments of IBS[4].

Aims & Methods: The aim of this study was to identify psychological predictors of treatment response to the low FODMAP diet. Participants underwent a three-phase dietitian-led low FODMAP diet between August 2018 and July 2021. Participants completed questionnaires to obtain scores for psychological factors and symptoms (predictor variables). Data on depression, anxiety, gastrointestinal (GI) specific anxiety, somatic symptoms, illness perceptions, behavioural avoidance, treatment beliefs and expectations, symptom severity and QoL was collected at five time points; pre dietitian (week 0), post dietitian (week 1), post FODMAP restriction (week 5), post FODMAP reintroduction (week 13) and personalisation (week 25). Linear mixed models (LMM) were used to test the effect of baseline psychological scores on IBS symptoms and QoL over time. Cross lag panel models (CLPM) were used to identify directional relationships between predictor variables on the one hand, and IBS symptoms and QoL on the other.

Results: 112 participants, (89% female, median age 30 ± 17 years) were included. LMM showed that higher treatment beliefs predicted a stronger initial symptom response (effect on linear slope p=0.036). Of the illness perceptions, lower emotional representations predicted a stronger initial and later QoL response (effect on linear (p=0.006) and quadratic (p=0.049) slopes). Increased cyclical time beliefs predicted poorer initial and later QoL response (effect on linear (p=0.015) and quadratic (p=0.029) slopes). CLPM showed that lower GI specific anxiety predicted a stronger reduction in symptoms from week 0 to 25. Of the illness perceptions, positive perceptions relating to higher personal and treatment control predicted a stronger reduction in symptoms from week 0 to week 25. Increased QoL predicted reductions in GI specific anxiety and stress from week 0 to week 25 and week 1 to week 25, respectively. Increased personal and treatment control predicted improved QoL across all time points.

Conclusion: Negative illness perceptions were associated with poorer symptom and QoL response, whereas positive illness perceptions and treatment beliefs predicted better QoL and symptom responses to the low FODMAP diet in adults with IBS. Illness perceptions and treatment beliefs can be easily assessed in clinical practice and should be considered when determining if the low FODMAP diet is a suitable treatment, and may serve as targets to enhance treatment response.

Introduction: IBS is a functional disorder of the gut-brain axis characterized by recurrent abdominal pain related to defecation and/or to a change in bowel habits [1]. According to stool type, 4 IBS-subtypes can be recognized: constipation prevalent (IBS-C), diarrhea prevalent (IBS-D), mixed (IBS-M) and unspecified (IBS-U) [2]. As a majority of IBS patients report symptom exacerbation by food, it is important to find a nutritional approach that could effectively reduce symptoms [3]. The present work is a post hoc analysis of the previously published DOMINO trial [4] conducted in Belgium in primary care. It showed that a FODMAP - lowering diet provided by a smartphone application was more effective than otilonium bromide after an 8-week treatment.

Aims & Methods: For this post hoc analysis, the diet arm population was stratified according to IBS subtype, with the aim of reporting a detailed evaluation of symptoms and psychosocial aspects with this new dietary intervention. 222 primary care IBS patients (85 IBS–M, 62 IBS–D, 44 IBS-C, and 31 IBS–U) followed a FODMAP-lowering diet for 8 weeks with the support of a smartphone application. Two follow up visits were scheduled after 16 and 24 weeks. IBS-Symptoms Severity Score (IBS-SSS), somatisation (PHQ 15), depression (PHQ 9), anxiety (GAD 7) and Quality of Life (QoL) status were evaluated. A One-way ANOVA with Dunnett's post hoc test was conducted to assess differences between each time and the baseline. Significance was assessed with a $p<0.05$.

Results: After 8 weeks, IBS-SSS improved in all IBS-subtypes ($p<0.0001$) and this result was maintained until week 24 ($p<0.0001$). At week 8 the responder rate was 72% and it remained high (70%) until the end of the study. Evaluating each single subtype at week 8, IBS-C showed a responder rate of 79%, followed by IBS-U (74%), IBS-D (70%) and IBS-M (67%). After 8 weeks, PHQ-15 improved only in the IBS-D subgroup ($p<0.05$) and this result was maintained until week 24 ($p<0.0001$). PHQ-9 and GAD-7 did not show any significant differences after 8 weeks but they both significantly

	IBS-SSS			PHQ-15			PHQ-9			GAD-7			QoL		
	V0	8 weeks	24 weeks	V0	8 weeks	24 weeks	V0	8 weeks	24 weeks	V0	8 weeks	24 weeks	V0	8 weeks	24 weeks
IBS-C	295.9 ± 94.1	184.0 ± 112.5[b]	184.0 ± 97.6[b]	13.2 ± 5.3	10.7 ± 5.7	10.8 ± 4.05	7.7 ± 5.9	6.2 ± 5.4	5.0 ± 3.9	7.3 ± 5.2	5.7 ± 4.6	4.7 ± 3.6	79.6 ± 27.4	70.4 ± 27.1	63.4 ± 19.0[a]
IBS-D	264.8 ± 89.2	161.6 ± 93.8[b]	147.9 ± 112.7[b]	13.1 ± 4.6	9.9 ± 5.0[a]	8.6 ± 4.3[b]	6.6 ± 4.5	4.9 ± 3.7	4.3 ± 3.3[a]	7.0 ± 5.1	5.2 ± 4.3	4.4 ± 3.8[a]	75.6 ± 20.6	65.2 ± 19.6[a]	58.6 ± 15.1[a]
IBS-M	269.2 ± 102.7	184.5 ± 123.4[b]	170.9 ± 116.0[b]	13.0 ± 5.7	10.9 ± 5.7	10.6 ± 5.9	6.8 ± 4.7	5.8 ± 5.1	5.8 ± 5.4	6.6 ± 4.7	5.9 ± 4.9	5.2 ± 4.7	78.9 ± 22.5	67.3 ± 24.3[a]	62.1± 19.0[b]
IBS-U	224.8 ± 79.8	128.1 ± 82.0[b]	119.2 ± 74.9[b]	11.1 ± 5.2	9.2 ± 4.1	9.4 ± 6.1	7.3 ± 5.4	5.0 ± 4.1	4.7 ± 4.9	6.6 ± 4.5	5.0 ± 4.2	5.7 ± 4.7	68.1 ± 18.0	59.0 ± 18.4	54.4 ± 19.6[a]

PP1105 Table 1. Symptoms Scores in the whole population; legend: a) p<0.05; b) p<0.0001.

improved at the end of the follow up period (p<0.05) in the IBS-D subtype. QoL improved both in the IBS-D and IBS-M (p<0.05) subtypes after 8 weeks while at the end of the follow up the improvement was observed in all subtypes (p<0.05 in IBS-C, IBS–D and IBS-U and p<0.0001 in IBS-M) (Table 1).

Conclusion: Symptom severity improves significantly in all IBS subtypes when using a smartphone app-based FODMAP lowering diet intervention, and improved QoL especially in IBS-D and IBS-M subtypes. The DOMINO app-based dietary intervention should be considered the first-line treatment choice for primary care in IBS.

EVIDENCE OF JEJUNAL LONGITUDINAL MUSCLE ATROPHY AND VASCULAR ABNORMALITIES IN PATIENTS WITH IDIOPATHIC CHRONIC INTESTINAL PSEUDO-OBSTRUCTION

I. Neri[1], E. Boschetti[1], C. Malagelada[2], L. Caporali[3], R. D'Angelo[4], R. Rinaldi[4], E. Bonora[5], V. Stanghellini[6], S. Ratti[1], V. Carelli[7,3], L. Manzoli[1], R. De Giorgio[8]

Contact E-Mail Address: irene.neri3@unibo.it

Introduction: Chronic intestinal pseudo-obstruction (CIPO) is a rare syndrome characterized by severe gastrointestinal (GI) dysmotility that mimics a GI obstruction in the absence of any detectable mechanical cause [1]. CIPO can be classified as primary (e.g. linked to a genetic disorder), secondary (to a wide array of conditions) or idiopathic.

We recently demonstrated that jejunal longitudinal muscle layer abnormalities associated to vascular changes can contribute to GI dysfunction in a genetically driven form of CIPO [2].

Aims & Methods: The aim of this study was to investigate the presence of jejunal longitudinal muscle layer atrophy and vascular alterations in idiopathic forms of CIPO. Full thickness jejunal biopsies were collected from n=27 well characterized patients and n=10 controls. Formalin fixed-paraffin embedded (FFPE) tissue sections were stained with Sirius Red/Fast Green-collagen-assay to measure longitudinal muscle layer thickness and to spectrophotometrically determine fibrosis. FFPE full thickness jejunal sections were also stained with orcein to quantify and measure blood vessel size. The blood vessels were subdivided in >300µm (large), 300-101µm (medium), 100-51µm (small) and <50µm (very small). Frozen full-thickness tissue was used to assess by western blot the expression of HIF-1α as marker of hypoxia and of thymidine phosphorylase (TP), as this enzyme is involved in the pathophysiology of angiogenesis and is found absent in previously documented CIPO secondary to a genetic disorder [3].

Finally, jejunal muscle thickness was correlated with patients' clinical data.

Results: Idiopathic CIPO patients showed 1.87 times (431.9±192.2 vs. 837.2±446.4 µm; P=0.0026) decreased thickness of the jejunal longitudinal muscle layer and a higher fibrosis index compared to controls. Idiopathic CIPO patients displayed a lower vascular area with more submucosal ves-

sels/mm² *vs.* controls; vessels <50 µm increased at the expense of medium and large vessels. Moreover, the jejunum of idiopathic CIPO patients presented an increased HIF-1α expression indicative of hypoxia and a lower TP enzyme expression suggesting alterations in local angiogenesis. Finally, from a clinical standpoint, the jejunal muscle thickness was inversely correlated to the number of sub-obstructive episodes, abdominal distension and pain.

Conclusion: In addition to genetic CIPO, also idiopathic forms of this syndrome exhibit significant changes, *i.e.* muscular atrophy and fibrosis associated with major vascular remodeling likely dependent to hypoxia and a lower local TP protein expression. These data are clinically relevant as reduced muscular thickness correlates with worse clinical phenotypes of idiopathic CIPO.

Introduction: The underwater immersion technique has so far been used for the resection of sessile polyps, with satisfactory results in terms of efficacy and complications (due to the use of water instead of medical air (CO2) and the absence of fluid substances in the submucosa.

Aims & Methods: The aim of this work is to demonstrate the effectiveness of the underwater technique for diagnostic purposes, in patients suffering from diverticular disease with insurmountable stenosis at traditional colonoscopy.A cohort of 50 patients (20 D and 30 U - mean age 72 years) with incomplete colonoscopy due to stenosing diverticular disease (DICA 4) confirmed by CT colon (virtual colonoscopy) examination was enrolled. Previously, all the patients had been evaluated at other endoscopy centers , and studied at the Gastroenterology and Digestive Endoscopy Center of the Benevento ASL, subsequently for the detection, in at least 15 patients, of lesions compatible with polyps > 6 mm on the colon CT scan. All patients underwent colonoscopy under conscious sedation with a thin colonoscope (Olympus PTH PF 190), filling the stenotic lumen with water instead.

Results: In 41 patients, the use of the UW technique allowed the stenotic section to be overcome, allowing the examination to be completed; in the remaining 9 the stenosis was insurmountable. In the 15 patients with lesions compatible with polyps > 6 mm on colon CT, only 5 pts were positive, 2 of which with the finding of polypoid formations > 1 cm in sections other than those reported on colon CT. No complications were recorded both in the diagnostic phase and in the operative phase.

Conclusion: The UNDERWATER technique can represent an alternative method in the diagnosis of certain pathological and inflammatory conditions with a high risk of perforation. The irrigation of the colonic lumen with water also allows the magnification of the mucosa, improving the identification and treatment of polypoid lesions (particularly the sessile ones).

Contact E-Mail Address: nicola.imperatore@alice.it

Introduction: Segmental colitis associated with diverticulosis (SCAD) is an increasingly recognized clinical and pathological disorder, characterized by a chronic inflammatory response involving the inter-diverticular mucosa of a colonic segment, sparing the rectum and the right colon. However, its prevalence and outcome in the setting of colorectal cancer (CRC) screening is unknown.

Aims & Methods: Aims: to assess the prevalence of SCAD in the setting of a CRC screening program and to evaluate the differences in terms of oncological outcomes between SCAD and "simple" diverticulosis. We performed a retrospective analysis from a prospectively-maintained database including all subjects undergoing first screening colonoscopy according to regional CRC program from 2019 to 2022. Patients with incomplete colonoscopy, inadequate bowel preparation or known diagnosis of SCAD or CRC were excluded. Endoscopic signs of SCAD were registered as "crescentic fold disease", "mild-to-moderate UC-like", "Crohn's disease-like" and "Severe UC-like". The number of adenomas (ADR) and cancers was also recorded. Statistical analysis included chi-square, Student's t-test and odds ratio (OR) with 95% confidence interval (CI) when indicated.

Results: a total of 1518 patients were included (males 51.8%, mean age 63.48±6.39). Adenomas were detected in 638 patients (ADR 42%), while CRC was diagnosed in 86 cases (5.7%). Diverticulosis was described in 570/1518 patients (37.5%), while SCAD was endoscopically diagnosed in 69 patients (4.5%). Among them, 48 (69.6%) presented a crescentic fold disease, 14 (20.3%) a mild-to-moderate UC-like pattern, 6 (8.7%) a CD-like pattern and 1 (1.4%) had a severe UC-like pattern. When SCAD patients were compared to subjects with simple diverticulosis (501 patients), we found no differences in terms of gender (males 55.1% vs 50.7%, p=0.46) or age (63.86±6.45 vs 64.45±6.38, p=0.47). Interestingly, the use of anticoagulant/antiplatelet (28.9% vs 30.1%, p=0.79), anti-hypertensive (46.4% vs

48.1%, p=0.89) or anti-hyperglycemic drugs (36.2% vs 41.1%, p=0.52) had no effect on SCAD onset as compared with patients with diverticulosis. However, patients with SCAD had significant lower rate of adenomas (ADR 31.9% vs 47.3%, p=0.018, OR 0.52, 95%CI 0.31-0.89), and lower –but not significant– rate of CRC (1.4% vs 6.2%, p=0.14, OR 0.22, 95%CI 0.02-1.66). Most patients were successfully treated with 5-ASA and none needed surgery for SCAD.

Conclusion: SCAD can be diagnosed in about 5% of population undergoing screening colonoscopy and in about 12% of those with diverticulosis. SCAD seems to be associated with a reduced rate of adenomas or CRC as compared with diverticulosis.

Disclosure: Nothing to disclose.

THE USE OF SELF-ASSEMBLING PEPTIDES (PURASTAT) HAS NO ADDITIONAL EFFECTS

Y. Shigehisa[1], K. Uchita[1], S. Kanazawa[1], A. Hoji[1], A. Maeda[1], A. Kubota[1], R. Daike[1], T. Iwasaki[1], M. Okazaki[1]
[1]Kochi Red Cross Hospital, Gastroenterology, Kochi-shi, Japan

Contact E-Mail Address: yurikonoguchi630@gmail.com

Introduction: A self-assembling peptide solution (PuraStat) is a new hemostatic agent for gastrointestinal bleeding just by smearing through an endoscope. Recently PuraStat has been reported to be useful for hemostasis of gastrointestinal bleeding. In colonic diverticular hemorrhage, endoscopic clipping was often used, because of its simplicity and safety. Although PuraStat is expected to useful for hemorrhage, there is no study of its usefulness of hemostasis and hemostatic effects such as rebleeding were unknown.

Aims & Methods: The objective was to investigate the usefulness of PuraStat in diverticular hemorrhage. This study was a retrospective case-control study conducted by at Kochi Red Cross Hospital in between April 2021 and January 2023 under ethical approval. The study included with 57 patients with colonic diverticular hemorrhage who were treated with only endoscopic clipping (Group A: 43 patients) or endoscopic clipping with PuraStat (Group B: 14 patients). The success rate for endoscopic hemostasis, the rate of rebleeding, the rate of transition to arterial embolization and time to rebleeding were evaluated in each group, and differences between two groups were also examined by Fisher's exact test or Student's t-test.

Results: Total procedure times both Group A and Group B were 16.3 min and 27.5 min. This study in Group A and Group B showed 90.1% and 100% for success rate (p=0.563), 32.5% and 42.9% for the rate of rebleeding (p=0.530), 7.0% and 12.5% for the rate of transition to arterial embolization (p=0.587), 26 h and 33 h for time to rebleeding (p=0.438) respectively. Treatment result is not improved by a combination of clipping and Purastat.

Conclusion: The combination treatment endoscopic clipping of PuraStat has no additional effects in colonic diverticular hemorrhage than endoscopic clipping alone.

Disclosure: Nothing to disclose.

COMPARATIVE ANALYSIS OF DIETARY AND LIFESTYLE HABITS BETWEEN PATIENTS WITH AND WITHOUT DIVERTICULAR DISEASE

A. Ferronato[1], F. Busin[2], K.I. Rodriguez-Castro[1], M. Franceschi[1], L. Brozzi[1], L. Cuoco[1], F. Sofi[2], G. Baldassarre[1]
[1]Azienda ULSS 7 Pedemontana, Endoscopy Unit - Ospedale Alto Vicentino, Santorso (VI), Italy, [2]University of Florence, Department of Experimental and Clinical Medicine, Florence, Italy

Contact E-Mail Address: antonio.ferronato@aulss7.veneto.it

Introduction: A sedentary lifestyle, poor fiber intake and other unhealthy dietary habits have been associated with diverticular disease (DD). On the contrary, the Mediterranean Diet (MD), which involves factors such as consuming locally grown food products, family meals, conviviality, involvement in the preparation of meals, as well as high intake of vegetables, legumes, fruit and cereals, medium intake of fish, low intake of meat and saturated fat, high intake of unsaturated fat (particularly olive oil), a medium-low intake of dairy products (yogurt and cheese), and a moderate intake of wine, seems to protect against DD. Moreover, populations that follow the MD pattern show a 50% lower rate of cardiovascular mortality due to cardiovascular disease and show highest longevity[1].

Aims & Methods: Aim: to compare adherence to MD as a whole and its different components in subjects with and without diverticular disease. Materials and methods: all patients undergoing colonoscopy at our Endoscopy Unit of a Tertiary Hospital in Northeastern Italy from January to June 2022 were invited to participate in the study, completing three questionnaires including personal/medical history and medications, symptoms, physical activity questionnaire, and Medi-Lite (ML) questionnaire for the assessment of adherence to MD. Subjects were then divided in two groups based on the endoscopic diagnosis of diverticular disease (DD).

Results: A total of 3757 patients underwent colonoscopy at our center during the 6-month study period, 1112 of whom completed the questionnaires and therefore constituted the study population. Overweight (BMI>25 kg/cm^2) was observed in 61% of males and 40.2% of females, and correlated inversely (OR<1) with higher education attainment, daily physical activity of at least 30 minutes, and, in females, the performance of a structured physical activity/sport for at least 60 minutes a week. Moreover, being married or widowed and consuming meals preferably at home, as opposed to consuming meals at restaurants or cafeterias, were significantly associated with overweight (OR>1), especially in female patients. In the overall population, normal weight was more frequently associated with consumption of meat, while in females, it is associated with greater consumption of raw vegetables. Overweight was more frequently associated with consumption of salami and cheese, especially in the female population, and it correlated with the presence of cardiovascular diseases (especially hypertension). DD was present in 400/1112 (35.9%) of subjects and this condition was significantly associated with (OR>1) male sex, older age (61-75 years), overweight (BMI>25 kg/cm^2), cardiovascular disease, polypharmacy, cigarette smoking, alcohol use, cheese consumption, abdominal pain as the chief complaint, and lower education attainment. No correlation was found between DD and the MD score or its components. In patients with DD, abdominal pain was inversely and significantly associated with an elevated ML score (OR=0.085) and consumption of meat (OR=0,096) and legumes (OR=0,079) (p<0.05).

Conclusion: Subjects undergoing colonoscopy share similar dietary and lifestyle habits, while in the presence of DD, ingestion of certain products seems to have an impact on symptoms.

Introduction: Lower abdominal pain in patients with diverticular disease (DD) can be very challenging in clinical practice. In fact, it is matter of debate whether symptomatic uncomplicated diverticular disease (SUDD) could be considered a disease its own or it represents the coexistence of irritable bowel syndrome (IBS) in patients with colonic diverticulosis. Moreover, after an episode of acute diverticulitis, patients may complain of chronic-recurrent lower abdominal pain, only sometimes related to a recurrent diverticulitis.

Aims & Methods: We aimed to assess clinical features of lower abdominal pain, in terms of presence, severity and characteristics of short-lasting and long-lasting, and the possible overlap with IBS in patients with SUDD and previous diverticulitis (PD). We utilized baseline data from the REMAD (Diverticular Disease Registry), a 5-yr prospective, observational, cohort study, involving 47 Italian centres. Patients who fulfilled criteria for diagnosis of SUDD (n=300) and PD (n=212) were asked to fill in questionnaires for characterization of abdominal pain in the past 6 months:
i. Questionnaire for short-lasting abdominal pain (<24 hours);
ii. Questionnaire for long-lasting abdominal pain (>24hours);
iii. Questionnaire for IBS following Rome III Criteria.

Results: One hundred and forty-eight SUDD and 118 PD patients fulfilled all questionnaires. Seventy-five patients out of 266 (28.2%) fulfilled criteria for IBS diagnosis following Rome III Criteria. IBS criteria were reported more frequently in SUDD (37.2%) compared to PD patients (17.1%) (p<0.001). The prevalent IBS subtype was the diarrhoea-one (IBS-D), that was more frequent in SUDD compared to PD (22.3% vs 10.2%, p=0.009), followed by the constipation subtype (IBS-C: 12.2% vs 5.9%, p=0.084) and mixed subtype (IBS-M: 2.7% vs 0.8%, p=0.268). Considering the abdominal pain pattern, several differences were found between SUDD and PD in terms of long-lasting abdominal pain characteristics. The number of episodes was significantly higher in SUDD (6.6±11.9) compared to PD patients (3.4± 6.9) (p <0.001). PD patients reported long-lasting pain more frequently localized in the lower left abdomen (p <0.001), while in SUDD it was more frequently diffuse (p= 0.008) or localized in the lower right quadrant (p=0.016). Features associated with long-lasting abdominal pain were more often reported in patients with PD than SUDD [fever (p<0.001), confinement to bed (p=0.021), medical consultations (p=0.026), antibiotic therapy (p<0.001), and hospitalization (p<0.001)]. Compared to PD, SUDD patients reported a significantly more frequent amelioration of pain with antispasmodics use (43.8% vs 36.1%, p=0.003) and a more frequent onset of long-lasting pain after acute gastrointestinal symptoms (i.e. fever, vomit or diarrhoea) (90.8% vs 72.4% p=0.002). Episodes of short-lasting abdominal pain were significantly more frequently reported in SUDD than in PD patients (90.5% vs 78.8% p = 0.007), although there were no significant differences in terms of severity, localization, and pain's relief with defecation between the two groups of patients.

Conclusion: This study shows that less than a third of patients with diverticular disease reported an overlap with IBS. Moreover, SUDD patients have a different pattern of lower abdominal pain compared to PD (i.e. length of pain, number of episodes, localization, amelioration with antispasmodics, associated features). Recognizing these differences could help clinician's through a correct differential diagnosis addressing the diagnostic approach and therapeutic management.

Introduction: Diverticulosis was once regarded as an uncommon anatomic variant with different types of complication, Faecal calprotectin (FC) is a cytoplasmic antimicrobial
compound prominent in granulocytes, monocytes, and macrophages (1).

Aims & Methods: we aim to assess the fecal calprotectin values in colonic diferticulosis as a non invasive marker of disease severity.

Results: We enrolled in this study 360 consecutive patients who had undergone a total colonoscopy and MSCT on Abdomen and complete laboratory investigation including fecal calportectin, Age was distributed as 46.61±11.57 with minimum 15 and maximum 80 years and regard sex distribution female were majority with 59.7% fecal calportectin significantly positive correlated with CRP, NIS and Hinchey classification. Mild diverticulosis showed Significant area under curve with cutoff >65 and with sensitivity 97.0%and specificity 82.8%. moderate diverticuosis showed Significant area under curve with cutoff >162 <175 and with sensitivity 83.3%and specificity 96.0%. Severe Significant area under curve with cutoff >175 and with sensitivity 85.0%and specificity 92.5%.

Conclusion: Faecal calprotectin (FC) is inflammatory marker considered as a stronger predictor of diverticulosis diseases in Non IBD Patients.

Introduction: Ischemic damage, caused by the compression of vascular structures in the neck of diverticular task has been proposed as one of the pathogenetic mechanisms diverticular disease (DD). However, as suggested for other gastrointestinal chronic diseases, another factor that can contribute to ischemia might be the activated platelet-dependent throm-

bosis through an oxidative imbalance mediated by arachidonic acid (AA) metabolism. The dominant oxidative imbalance described ex vivo in colonic wall human models of diverticulosis and diverticular disease supports this ischemic hypothesis.

Aims & Methods: Aim of the study was to assess the presence of relative circulating biomarkers that could be potentially useful to clarify DD pathogenesis and to highlight possible new target therapies. A cross-sectional study including 30 patients (Male=15; age:60.5±2.4years) referred to the DD outpatient clinic and sex- and age-matched healthy subjects (HS) (n=10) has been designed. Patients were subdivided in asymptomatic diverticulosis (DIV), symptomatic uncomplicated and complicated DD (SUDD and cDD) (n=10 per group). Circulating oxidative stress markers such as soluble Nox2-derived peptide (sNox2-dp), a direct marker of NADPH oxidase activation, hydrogen peroxide (H_2O_2) and isoprostanes production, together with antioxidant capacity (HBA) were evaluated by ELISA and colorimetric assay. Moreover, thromboxane B (2) (TxB2), generated as isoprostanes, upon arachidonic acid (AA) metabolism-derived platelet activation, as well as TNF-α and LPS were determined using the ELISA method. Gut permeability was assessed by evaluation of circulating levels of zonulin. Data (mean±SE) were expressed as fold variations from HS, $p<0.05$ was considered significant.

Results: The analysis of circulating biomarkers reflected the oxidative imbalance observed in DD colonic tissues. In respect to HS, a significant progressive increase from asymptomatic to symptomatic DD was observed both for H_2O_2 (DIV:1.68±0.26, SUDD:2.48±0.35, cDD:2.99±0.21) and isoprostanes (DIV: 2.53±0.35, SUDD: 3.46±0.21, cDD: 3.57±0.2), counteracted by a significant progressive decrease in HBA (DIV:0.74±0.04, SUDD:0.63±0.04, cDD:0.57±0.03). The AA-driven metabolites isoprostanes and TxB2 resulted significantly correlated to the progressive increase in sNox2-dp levels (DIV:1.69±0.13, SUDD:2.68±0.22, cDD:2.92±0.18) (r=0.61, 95%CI:0.37-0.77; r=0.73, 95%CI:0.55-0.85 respectively) supporting the involvement of platelet activation. TxB2, similarly to isoprostanes, progressively increased from asymptomatic (2.42±0.13) to symptomatic DD (SUDD: 4.44±0.13 and cDD:4.25±0.52). A significant progressive increase was also observed in the known platelet activators TNF-α (DIV: 1.39±0.08, SUDD:2.04±0.19, cDD:2.03±0.11) and LPS (DIV:1.59±0.17, SUDD:2.59±0.14, cDD:2.78±0.13). LPS increase correlated to that of zonulin (r=0.59, 95%CI:0.35-0.76, $p<0.0001$) highlighting the presence of low-grade endotoxemia related to increased permeability.

Conclusion: These preliminary results showed a progressive increase of circulating oxidative biomarkers from asymptomatic to symptomatic DD opening a new pathogenic scenario in diverticular disease. The evidence of a pathogenic role of platelet activation and increased intestinal permeability in DD oxidative imbalance deserves further studies. Circulating oxidative biomarkers might represent a useful clinical tool in the management of this disease.

ACCELERATION OF WOUND HEALING AFTER TOPICAL APPLICATION OF HYALURONIC ACID-SOAKED COTTON TO HEMORRHOIDECTOMY WOUNDS IN A RAT MODEL

M.J. Choi[1], H.-K. Oh[2], J.W. Suh[3]

[1]Seoul National University Bundang Hospital, Department of Surgery, Seongnam, South Korea, [2]Seoul National University Bundang Hospital, Department of surgery, Seongnam, South Korea, [3]Dankook University Hospital, Department of Surgery, Cheonan, South Korea

Introduction: Anal wounds resulting from hemorrhoidectomy cause severe pain, with the possibility of postoperative bleeding. Therefore, the recovery rate of anal wounds is closely associated with the degree of patient recovery and, furthermore, quality of life. By accelerating cell migration and proliferation, hyaluronic acid (HA) stimulates tissue regeneration and accelerates wound healing.

Aims & Methods: This study aimed to investigate differences in wound healing rate and completeness of recovery of perianal wounds topically treated with HA-soaked cotton in rat model animals.

Forty-eight, 8-week-old Sprague-Dawley rats with perianal wounds created using a biopsy punch were divided into 2 groups: simple dressing with gauze (control); and topical dressing with HA-soaked cotton. A single application of HA-soaked cotton was performed following surgery. The wound healing rate and completeness of recovery were evaluated by measuring the healed area and histological analyses.

Results: The time required for complete wound healing in the HA-cotton group was shorter than in the control group (13.9 vs 16.4 days; $p=0.031$). The difference in wound healing area between the two groups was the largest on postoperative day 2 (51.6% vs 28.8%; $p<0.001$). Upon complete wound healing, fewer cases of granulation tissue (2 vs 5 cases) or redness (0 vs 3 cases) were observed in the HA-cotton group. Compared with the control group, the HA-cotton group exhibited histologically accelerated re-epithelialization, rapid shift to lymphocyte-dominant inflammation, enhanced fibroblast proliferation, and greater collagen deposition.

Conclusion: In a rat model study, HA-soaked cotton topically applied to perianal wounds resulted in an accelerated wound healing rate, especially in the initial stage, and the completeness of recovery improved. These results suggest that the topical application of HA-soaked cotton to hemorrhoidectomy wounds in human patients may improve the wound recovery rate.

Introduction: The treatment of symptomatic hemorrhoidal disease (HD) in patients with bleeding disorders (BD) is challenging. This vulnerable group benefits the most from less invasive office-based procedures associated with low bleeding complications, namely polidocanol foam sclerotherapy (PFS).

Aims & Methods: The present study aimed to compare the efficacy and safety of polidocanol foam sclerotherapy (PFS) in the treatment of hemorrhoidal disease (HD) in patients with and without bleeding disorders (BD). This was a prospective, multicentric, cohort study that enrolled patients with symptomatic internal HD grades I-III with BD (group B) and without BD (group A) following a 18-months period. HD baseline severity was assessed using the Goligher classification, the hemorrhoidal disease bleeding grade (HDBG) and the Sodergren hemorrhoid symptom severity (SHSS) scoring system. Both groups were treated with PFS prepared according to the Tessari's technique. Patients with congenital BD did not perform prior bleeding prophylaxis and patients with acquired BD due to antithrombotic drugs did not discontinue therapy.

The efficacy outcomes included therapeutic success (defined by an improvement of HDBG and SHSS score over baseline) and recurrence of HD (defined by HDBG and SHSS score greater than at the end of the intervention period) during a 12-months follow-up period. The safety outcomes comprised the rate and severity of complications related to PFS.

Results: The study included 228 patients (Group A: 155; Group B: 73). At baseline, the group B presented higher HDBG ($p<0.001$) and SHSS ($p=0.019$). The overall therapeutic success rate was 93.4% with an average number of sessions of 1.51±0.74, significantly higher for group B (1.68±0.86 *vs* 1.43±0.65, $p=0.013$). A 11.4% complications rate was reported, the majority were mild (96.2%); bleeding complications occurred in 4.8% of the patients. No significant differences were reported between the two groups concerning therapeutic success, recurrence rate, and complications rate.

Conclusion: Patients with BD may present with more symptomatic HD at baseline. Nevertheless, PFS decreased hemorrhoidal bleeding and symptom severity with low incidence of complications in these patients, demonstrating similar effectiveness and safety comparing to patients without BD. Notably, performing PFS did not expose patients with BD to an increased thrombotic risk.

Disclosure: Nothing to disclose.

EFFICACY OF ADALIMUMAB IN PATIENTS WITH PERIANAL CROHN'S DISEASE: A PROSPECTIVE RANDOMIZED TRIAL

S. Vaiciunas[1], K. Nocrato Loiola Vaiciunas[1], S. Frota Loiola[1]
[1]Afya Sao Lucas Medical School, Gastroenterology, Porto Velho, Brazil

Contact E-Mail Address: spencervaiciunas@hotmail.com

Introduction: Adalimumabe (ADA) 160/80 mg is efficacious for induction of clinical remission in patients with intestinal Crohn's disease (CD), but data on its long-term efficacy for perianal CD are more limited.

Aims & Methods: To determine whether treatment with Adalimumab is effectiveness in patients with perianal CD. A prospective randomized study , from January 2019 until January 2023 was enrolled with 100 patients (38f/62m, mean age 41, 15 smokers). The patients presented (trans or suprasphinteric, horse-shoes, multiple with or without rectal involvement), perianal fistulising disease or resistant to immunosuppressive. All patients received 160/80 mg of Adalimumab as induction dose. Immunosupressive therapy was suspended at the start of treatment and steroid dose was reduced of 5 mg/week after the induction phase. The study was performed in a reference public/medical school hospital in Porto Velho, north region of Brazil

Definition of remission: complete closure of the fistula assessed with colonoscopy and magnetic resonance imaging (MRI).

Results: Medical charts of 100 patients with perianal CD receiving Adalimumab were investigated. Among them, 42 had infliximab failure, 67/100 colonic disease, 82/100 rectal involvement, 42/100 were also using steroid. At week 6, 18/100 patients (18%), were in remission; at week 30, 29/100 patients (29%) were in remission; at week 52, 66/100 (66%), were in remission and at 3 years, 77/96 patients (80%) were in remission. 4 patients loss response and moved to a temporary loop-ileostomy. No serious adverse events were registered.

Conclusion: Adalimumabe treatment was effective in the remission of perianal CD in 80% of the patients after a 4 years follow-up, showing the effectiveness of adalimumabe.

DIAGNOSTIC ACCURACY OF LONDON PROTOCOL RECORDING PERIOD CHANGES APPLIED TO HIGH-DEFINITION ANORECTAL MANOMETRY IN CHRONIC CONSTIPATION

C. Lambiase[1], F. Rettura[1], A. Bottari[1], A. Grosso[1], G.D. Sciumè[1], R. Tedeschi[1], G. Berti[1], L. Cancelli[1], M. Bellini[1]
[1]University of Pisa, Gastrointestinal Unit, Department of Translational Research and New Technologies in Medicine and Surgery, Pisa, Italy

Contact E-Mail Address: rettura.fra@gmail.com

Introduction: Anorectal manometry (ARM) is the most widely established diagnostic tool for studying defecation disorders. The London protocol and classification provide a standardized format for performing and interpreting High Resolution ARM. However, these are not based on clinical evidence, but only on expert consensus.

Aims & Methods: The aims of our study were to assess the impact of protocol modification on diagnostic agreement, focusing on resting pressure and push using the High Definition-ARM (HD-ARM) probe. A retrospective analysis was conducted of HD-ARM recordings performed in patients with chronic constipation at our digestive pathophysiology laboratory from January to October 2022. Evaluation of recordings was performed by applying both the London protocol and the proposed changes, as reported below. Resting pressure was assessed by combining modifications in both the baseline rest period (60, 50, 40, 30, 20 and 10 s) and stabilization period (3, 2 and 1 min). Each of the pushes was evaluated for 10 s, selecting the most qualitatively normal one for analysis. The diagnostic agreement between the standard protocol and the proposed modifications was compared by using Cohen's Kappa (k).

Results: Recordings of 69 patients with chronic constipation (53 F, mean age 53 [SD: ± 17]) were analyzed. At resting pressure assessment, performed according to the London protocol and classification, 30% and 27% of patients presented with anal hypotonia and hypertonia, respectively. As recording periods gradually changed, there was a concomitant change in some diagnoses; up to a stabilization period of 2 min and a baseline rest period of 30 s, a strong agreement with the standard protocol was maintained (κ = 0.823). Correlation was perfect between pushes assessed at 15 and 10 s (k = 1.000), respectively.

	Mean anal pressure, (SD) mmHg	Mean rectal pressure, (SD) mmHg	Abnormal expulsion with dyssynergia, n	Abnormal expulsion with poor propulsion, n	Abnormal expulsion with poor propulsion and dyssynergia, n	Abnormal expulsion with normal manometric pattern of rectoanal coordination, n	Normal expulsion with abnormal manometric pattern of rectoanal coordination, n	No disorder of rectoanal coordination, n	Cohen's Kappa
Push 15 s	79.7 (40.5)	43.3 (26.6)	24	8	15	5	13	4	/
Push 10 s	82.7 (43.0)	44.2 (27.4)	24	8	15	5	13	4	1.000

Conclusion: A 2-min stabilization period, 30-s baseline rest period, and 10-s push analysis allow a reduction of 105 s in study duration, thus obtaining very good diagnostic accuracy compared to the London protocol. In conclusion, we provide the first evidence-based study of a modified HD-ARM probe protocol (focusing on resting pressure and push) by analyzing recordings of patients with chronic constipation.

Disclosure: Nothing to disclose.

PP1118

EVALUATION OF THE IMPROVEMENT IN THE QUALITY OF LIFE OF PATIENTS SUBMITTED TO INSTRUMENTAL TREATMENT OF HEMORRHOID DISEASE

I. Malta Carvalho[1], T. Gago[1], S. Barros[1], L. Relvas[1], P. Caldeira[1]
[1]Centro Hospitalar Universitário do Algarve, Gastrenterology Department, Faro, Portugal

Contact E-Mail Address: isamalta_c16@hotmail.com

Introduction: Hemorrhoidal disease is one of the most common diseases of the lower gastrointestinal tract and related complications are one of the most frequent reasons for seeking medical help. Symptoms associated with hemorrhoidal disease may occur in 5% to 50% of the adult population. The aim of treatment is to reduce blood flow to the hemorrhoidal plexuses, partially obliterate the plexus, and form a connective tissue scar that prevents its prolapse.

This process can be achieved through medical therapy and behavioral measures, instrumentation or surgical intervention in severe or refractory cases.

Aims & Methods: We carried out a prospective study in order to assess the improvement in symptoms and quality of life in patients undergoing medical therapy and instrumentation with the application of elastic bands or sclerotherapy with foamy polidocanol.

Two validated questionnaires for the classification of symptoms of hemorrhoidal disease (HDSS) and the Short Health Scale of Hemorrhoidal Disease (SHS-HD) were applied to patients seen in a proctology consultation in the year of 2022. The inclusion criteria in the study were patients with at least one initial assessment and a subsequent one during the period in which it took place, with understanding of the purpose of the study and reliable completion of the scales.

Results: A total of 65 patients were selected. Of these, 15 patients were excluded due to the presence of confounding comorbidities, such as anal fissure. Of the 50 patients, 42% (n=21) underwent rubber band ligation and 58% (n=29) underwent sclerotherapy. Among the evaluated patients, 98% (n=49) reported global improvement in symptoms. Of these, 86% (n=43) reported complete resolution of hematochezia, while the remaining 14% (n=7) reported a decrease in the frequency of these symptoms. 58% (n=29) reported complete resolution of the prolapse and 34% (n=17) a decrease in the frequency of the prolapse.

Only 1 patient reported continued complaints, which we associate with non-compliance with conservative and behavioral measures. In terms of quality of life, all patients reported a significant improvement, mainly in the components of "general feeling of well-being" and "interference in activities of daily life".

Conclusion: Our study demonstrates an overall improvement in symptoms and quality of life for patients undergoing instrumental treatment associated with medical measures. We emphasize, however, the fact that these are preliminary data from a prospective study in progress, so that the data and their interpretation are limited by the sample size and poor adherence. We also emphasize that some patients have not yet been discharged from the consultation because they still have some symptoms, and will still be subject to additional instrumental treatments.

With the increase in sampling, we intend to obtain more information about the improvement in symptoms and quality of life of these patients, the differences between the application of each instrumental method, the comparison with the use of combined strategies and the validation of these scales for the Portuguese population.

PARITY SIGNIFICANTLY AFFECTS BASAL ANAL TONE, BUT NOT OTHER PARAMETERS OF ANAL SPHINCTER FUNCTION IN PATIENTS WITH FECAL INCONTINENCE: A SINGLE CENTRE EXPERIENCE

A. Ladic[1], K. Grubelic-Ravic[1], Z. Krznaric[1]
[1]University Hospital Centre Zagreb, Division of Gastroenterology and Hepatology, Zagreb, Croatia

Contact E-Mail Address: agata.ladic@gmail.com
Introduction: Fecal incontinence frequently affects multiparous women. The aim of this study was to evaluate the relationship of parity and anal sphincter function in female patients with fecal incontinence.
Aims & Methods: 36 patients underwent HRAM procedure. Manometry was performed in the left lateral decubitus position. Reusable solid state HRAM catheter (MMS, the Netherlands) with 8 circumferential and one balloon pressure was used. We analyzed resting, squeeze and residual pressure in push test, cough pressure and rectal sensations (first sensation, urgency and intense urgency). Demographic data were also obtained and evaluated. ANOVA analysis was used to determine the relationship between parameters of anal sphincter function and parity, with post-hoc Tukey HSD test when appropriate. Significance was set at a $p<0.05$. The statistical package "R" was used for the analysis.
Results: 36 females with fecal incontinence were included in the study. Median age was 63 years (25-82), parity 2 children (0-4), anal resting pressure 45.5mmHg (3-96), squeeze pressure 86mmHg (30-270), endurance pressure 88mmHg (18.6-716), push pressure 37.50mmHg (-4-100) and cough pressure 107.5mmHg (26-716). Median for the first sensation was 40ml of inflated air (20-360), urgency 80ml (40-390) and intense urgency 110ml (50-390). We found statistically significant difference for the resting pressure (F-value=3.06, p-value =0.031), with Tukey's HSD test which found significant difference between group with four children and no children (p=0.02), as well as between group with four children and one child (p=0.029). There was no statistically significant difference between groups for any other pressure variable (p=0.294, p=0.69, p=0.214, p=0.8 for squeeze, endurance, push and cough pressure, respectively) or sensation (p=0.938, p=0.453 and p=0.5 for the first sensation, urgency or intense urgency, respectively).
Conclusion: Our results show that parity significantly affects basal anal tone in women who have more than three children. We found no relationship of parity to other parameters, which could be due to a relatively small number of patients investigated. There is also a high need to incorporate other variables which potentially alter anal sphincter function such as is the age at delivery, fetal weight and other comorbidities, mainly spinal injuries throughout life and obstetric tears.
Disclosure: Nothing to disclose.

Introduction: Motility function of the entire gastrointestinal tract belongs to the most complex and most fragile systems in human body. There is no single gold standard for its investigation. Usually, it is necessary to combine several methods. Wireless motility monitoring involves a novel concept which provides a complex information on gastrointestinal function (gastrointestinal transit time, intra-luminal pH, pressure and temperature). Gastrointestinal motility functions of experimental pigs are very similar to those of humans. That is why porcine studies have already provided suitable experimental models for several preclinical projects.
Aims & Methods: The aim of our study was to adopt methods of non-invasive wireless monitoring of gastrointestinal functions (Ref. 1) to our own porcine experimental setting. Studies on gastrointestinal motility are of utmost importance, especially in the context of side effects induced by drugs, e.g. medication used for treatment of dementia and malignancies. Five experimental adult female pigs (4-month-old; mean weight 41.2±5.5 kg; median 39.5 kg) were enrolled into the study. Medetomidine 0.1 mg/kg i.m., butorphanol 0.3 mg/kg i.m. and midazolam 0.3 mg/kg i.m. were used as an induction of anaesthesia. Subsequent short-term general anaesthesia was maintained by i.v. propofol (repeated one-mL boluses per 20 mg, in total less than 5 mL; time < 10 min.). Wireless motility capsules (SmartPill, Medtronic, Dublin, Republic of Ireland) were delivered into the middle part of the gastric body endoscopically. After full recovery from a short-term general anaesthesia, animals were free to move in unlimited manner with an unrestricted access to water. Food intake was allowed from four hours onwards. Data from wireless motility capsules were recorded for five days continuously, and these were available for subsequent detailed analysis.
Results: Records of animals provided good (3 pigs) or very good quality files (2 pigs). Mean time of overall recording was 6,537±712 min. (median 6,538 min.). In total, 31,150 variables were evaluated. Mean time of the presence of capsules in the stomach was 926±295 min. (median 1,091 min.), transfer of a capsule from the stomach into the duodenum lasted 5 - 34 min. (median 8 min.). Capsules migrated back from the duodenum into the stomach spontaneously three times (for 13, 14 and 63 min.). Mean small intestinal transit time was 251±43 min. (median 233 min.). Food intake was associated with an increase of gastric luminal temperature and a decrease of intra-gastric pressure. The highest intra-luminal pH was present in the ileum. The highest temperature and the lowest intra-luminal pressure were found in the colon. All data displayed a substantial inter-individual variability.

Conclusion: This pilot study has proven that a long-term function monitoring of the gastrointestinal tract by means of wireless motility capsules in experimental pigs is feasible. This will enable future experimental studies on gastrointestinal side effects of oncology chemotherapy. It will also facilitate further research of acetylcholinesterase inhibitors, modulators and reactivators and last but not least will extend possibilities of preclinical pharmacokinetic projects.

Introduction: Romania has started in 2020 four regional EU-funded pilot programs for colorectal cancer (CRC) screening (ROCCAS projects). The program was developed with FIT as first tool of screening, followed by a colonoscopy invitation for FIT positive cases. By the end of December 2023 a cohort of 200.000 individuals is supposed to be tested with FIT (50.000 from each region).

Aims & Methods: Three out of four involved regions were screened using OC Sensor™ as FIT (South-Muntenia, Bucharest-Ilfov, South-East). Persons aged between 50-74 years were invited to participate to the screening program. Initially, they completed a risk-assessment survey in order to stratify the cohort into two subgroups: average and high risk for CRC. This survey was conducted by the family doctor which then provided FIT for persons with average risk. Individuals belonging to the high risk group were directly invited to perform a colonoscopy. A FIT cut-off of 20 µg Hb/g feces was chosen and a colonoscopy was proposed to positive patients. The following quality parameters for FIT screening were evaluated: FIT return rate and colonoscopy acceptance rate according to age category, sex, and region of provenience. Data were retrieved from the ROCCAS national electronic register, managed by the Romanian National Public Health Institute.

Results: Between January 2022 and March 2023 a number of 79860 FIT were offered. A total of 70989 FIT were returned (preliminary return rate 88.8%). The overall return rate was similar between males (87.17%) and females (89.94%) independently from the region of origin and similarly distributed in the two considered age categories (Age<65= 88.22%; Age≥65=89.9%).

At the moment of data analysis the laboratory results were available for 70008 FIT: 5.61% positive FIT and 2.13% inconclusive, the rest 92.26% being negative. No difference in FIT positivity was observed among the three regions, while inconclusive tests were 2.67% and 2.31% in Bucharest Ilfov and South Muntenia respectively, the Sud-East region reported only 1%. The initial acceptability rate for colonoscopy was 52.3 %, however patients have a 6 month delay in which they can decide to undergo the procedure. Obviously, there is a delay between FIT processing, colonoscopy scheduling and data processing that needs to be taken into consideration.

Conclusion: In these preliminary results there was a high return rate when compared to other EU country reports. We consider that the high return rate is due to the direct involvement of the family doctors and probably it will diminish with the roll-out national extension. The FIT positivity interval between 5 and 6 % during this entire period was considered acceptable and the FIT cut-off was maintained.

Our preliminary data are within EU recommended quality parameters and create beneficial premises for the expansion into the future national screening program beyond 2024. On the other hand, we need to make important efforts in order to increase the colonoscopy acceptance rate.

COST-EFFECTIVENESS OF PERSONALIZED SCREENING FOR COLORECTAL CANCER BASED ON PRIOR HEMOGLOBIN LEVELS

D.M.N. van den Berg[1], L. de Jonge[1], E. Toes-Zoutendijk[1], I. Lansdorp-Vogelaar[1]
[1]Erasmus MC, Public Health, Rotterdam, Netherlands

Contact E-Mail Address: d.m.n.vandenberg@erasmusmc.nl

Introduction: There is growing evidence that the balance of harms and benefits of colorectal cancer (CRC) screening can be improved by risk stratification. One way to stratify participants is to assign a personalized invitation interval based on prior screening test results. Previous studies have shown that prior hemoglobin (Hb) concentrations determined by fecal immunochemical test (FIT), have greater predictive power for the detection of CRC in the next screening round than age and sex (1-3).

Therefore, a randomized controlled trial, the PERFECT-FIT study (4), was initiated within the Dutch national CRC screening program in which participants with a prior negative FIT are invited using tailored invitation intervals (1,2 or 3 years) based on prior Hb concentrations.

We aimed to investigate long-term outcomes of such personalized CRC screening based on prior Hb concentrations and to compare those to uniform CRC screening.

Aims & Methods: We simulated the Dutch national CRC screening program using a microsimulation model, MISCAN-Colon, to mimic the natural history of CRC and long-term outcomes of CRC screening interventions. We added a module to MISCAN-Colon that explicitly simulates a Hb concentration for every participant based on their age, sex, CRC state and an individual risk factor. Next, to mimic the PERFECT-FIT study, all participants with a negative FIT got assigned to either the low (0 µg Hb/g), intermediate (>0-15 µg Hb/g) or high (>15-<47 µg Hb/g) risk category.

We evaluated different invitation intervals (ranging between 0.5 and 4 years) for each risk category and estimated short- and long-term effects of the different screening strategies. We compared each personalized screening strategy to uniform biennial screening. Using cost-effectiveness analysis with a willingness-to-pay threshold per QALY gained of €20,000,-,

we determined optimal invitation intervals for each risk category, assuming (i) unlimited colonoscopy capacity and (ii) current colonoscopy capacity levels.

Results: Uniform biennial screening resulted in 177 QALYs gained and €101,852 saved compared to no screening per 1,000 individuals (Table 1). The PERFECT-FIT strategy resulted in 162 QALYs gained and €111,248 saved. The optimal invitation interval was 1 year for the low-risk group and 6 months for the intermediate and high-risk groups with 209 QALYs gained and €19,828 saved. With limited colonoscopy capacity, the optimal invitation interval changed to 2.5 years for the low-risk group, 1 year for the intermediate-risk group and 6 months for the high-risk group with 180 QALYs gained and €124,640 saved.

Strategy*	FITs	Colono-scopies	CRC diagnoses	CRC death	Cost**	QALYs gained**	ICER
No screening	0	0	86	38	0	0	Dominated
Uniform 2 – 2 – 2	8,781	549	57	18	-101,852	177	Dominated
PERFECT-FIT 3 – 2 – 1	6,449	478	60	20	-111,248	162	Dominated
2.5 – 1 – 0.5	7,896	547	57	18	-124,640	180	Reference
2 – 0.5 – 0.5	9,733	609	54	17	-115,337	192	752
1.5 – 0.5 – 0.5	12,234	675	51	16	-88,729	201	2,905
1 – 0.5 – 0.5	16,829	776	48	15	-19,828	209	8,504
0.5 – 0.5 – 0.5	27,830	974	44	14	180322	216	29,775

* The strategy name indicates the invitation interval for, respectively, the low, intermediate and high risk group. ** Compared to no screening

Table 1. Model outcomes per 1,000 individuals.

Conclusion: The optimal personalized CRC screening strategy is more cost-effective than uniform biennial screening, both with unrestricted and restricted colonoscopy capacity. Consequently, personalizing CRC screening invitation intervals based on prior FIT results may be an important next step to improve the balance between the harms and benefits of screening.

UTILIZATION OF COLORECTAL CANCER SCREENING AND DIAGNOSTIC COLONOSCOPY IN GERMANY: A LONGITUDINAL ANALYSIS

M. Hornschuch[1], S. Schwarz[1], U. Haug[1,2]
[1]Leibniz Institute for Prevention Research and Epidemiology – BIPS, Clinical Epidemiology, Bremen, Germany, [2]University of Bremen, Faculty of Human and Health Sciences, Bremen, Germany

Contact E-Mail Address: haug@leibniz-bips.de

Introduction: It is often reported that participation in the German colorectal cancer (CRC) screening program is low. However, as there are two parallel screening offers (fecal occult blood test, screening colonoscopy) and as there is also a high use of diagnostic colonoscopy, the existing, typically cross-sectional analyses fall short. Based on longitudinal analyses, we aimed to assess the proportion of persons utilizing any colorectal examination over a period of 10 years.

Aims & Methods: Using the claims database GePaRD (~20% of the German population), we identified persons aged 50 (cohort 1) or 55 (cohort 2) in 2011 and assessed whether they utilized colorectal examinations (fecal occult blood test (FOBT), screening colonoscopy, diagnostic colonoscopy) until age 59 (cohort 1) or 64 (cohort 2). We stratified the analyses by sex and also assessed potential differences by socioeconomic status.

Results: Overall, we included 186,832 persons (55% female) in cohort 1 (i.e. aged 50 in 2011) and 157,479 persons (55% female) in cohort 2 (i.e. aged 55 in 2011). In the following 10 years, 81% of women and 65% of men in cohort 1 had at least one colorectal examination. In cohort 2, these proportions were 79% (women) and 70% (men). Considering men and women together, there were no relevant differences by socioeconomic status. The proportion with at least one colonoscopy in cohort 1 was 43% in women and 41% in men. In cohort 2, these proportions were 50% (women) and 49% (men).

Conclusion: Our study shows that a high proportion of the German population utilizes CRC screening offers and/or diagnostic colonoscopy. It also illustrates that longitudinal analyses of data covering not only information on screening examinations provide valuable insights into the actual coverage and uptake of colorectal examinations in the population, which is important to interpret trends in CRC incidence and mortality in Germany.

EFFECTS OF HEALTH INSURANCE COVERAGE GAINS FOR UNINSURED INDIVIDUALS ON COLORECTAL CANCER OUTCOMES IN THE US

R. van den Puttelaar[1], K.S. Shi[2], V.P. Doria-Rose[3], M. Harlass[1], A.I. Hahn[4], A.G. Zauber[4], K.R. Yabroff[2], I. Lansdorp-Vogelaar[1]

Contact E-Mail Address: r.vandenputtelaar@erasmusmc.nl

Introduction: Health insurance is a strong and potentially modifiable determinant of access to care and health outcomes in the United States. Lack of health insurance is linked to advanced stage at cancer diagnosis and worse survival. Individuals without insurance are less likely to receive recommended screening and timely, if any, follow-up of abnormal screening results. In this study, we estimate the effects of health insurance coverage gains for uninsured individuals on colorectal cancer (CRC) outcomes.

Aims & Methods: The MISCAN-Colon model was used to simulate the effects of health insurance coverage gains for uninsured individuals. Model inputs of CRC screening, stage distribution, and survival were estimated by age and health insurance status from the National Health Interview Survey and National Cancer Database. We evaluated the effects on CRC outcomes if cohorts of uninsured individuals gained health insurance coverage at different ages (45, 50, 55, 60 years) compared with a cohort remaining uninsured until age 65, and then becoming age-eligible for Medicare coverage. CRC outcomes included incidence, mortality and costs per 1,000 45-year old individuals.

Results: In an uninsured population, the model predicted 59 CRC cases and 23 CRC deaths per 1,000 individuals, with a total cost of $5.6 million. If individuals gained health insurance coverage at age 45, 5.0% and 16.0% of CRC cases and deaths could be prevented, respectively. Although cancer treatment costs would decrease (-3.9%), total costs would increase by 5.0%, as a result of increased screening costs (+36.7%). Increasing the age of insurance gain would lower these benefits and costs (Table 1). Gaining health insurance coverage at age 60 would only prevent 1 CRC death and 2 CRC cases per 1,000 individuals, compared with a cohort that remained uninsured until gaining Medicare coverage at age 65 years.

	CRC cases per 1,000	CRC deaths per 1,000	Costs per 1,000
Uninsured	59	23	$5.60 million
Age at insurance coverage gain			
45	56 (-5.0%)	19 (-15.0%)	$5.87 million (+5.0%)
50	56 (-4.8%)	20 (-14.6%)	$5.84 million (+4.3%)
55	57 (-4.0%)	20 (-11.7%)	$5.75 million (+2.8%)
60	58 (-1.9%)	22 (-6.3%)	$5.66 million (+1.0%)

Conclusion: If uninsured individuals gain health insurance at an early age, up to 5% and 16% of CRC cases and deaths could be prevented, respectively, because of more screening, earlier diagnosis, and better survival. However, increased use of screening, and recommended cancer treatment would also increase costs of care.

COLORECTAL CANCER RISK AND MORTALITY WITH COLONOSCOPY VERSUS FAECAL IMMUNOCHEMICAL TEST SCREENING: A LARGE MULTICENTER STUDY

S. Maan[1], Y. Hadi[1], A. Krishnan[1], J. Foryoung[2], W. Roy[3], S. Thakkar[1], S. Singh[1]

[1]West Virginia University, Department of Medicine, Section of Gastroenterology and Hepatology, Morgantown, United States, [2]West Virginia University, Department of Medicine, Morgantown, United States, [3]West Virginia University, Morgantown, United States

Contact E-Mail Address: sobanmaan@live.co.uk

Introduction: The U.S. Multi-Society Task Force on Colorectal Cancer recommends both colonoscopy and faecal immunochemical test (FIT) as first-tier screening options due to their effectiveness. There is a scarcity of data comparing their efficacy.

Our objective in this study was to conduct a head-to-head comparison of colonoscopy and FIT as screening modalities for colorectal cancer using a large-scale multi-institutional dataset.

Aims & Methods: This population-based retrospective cohort study was conducted using the TriNetx health research network. Patients aged ≥ 50 with history of colorectal cancer screening between January 1, 2005 and December 31, 2020 were included. Patients at high risk of colorectal cancer, history of polyps or malignancy and/or diagnostic or therapeutic colonoscopies were excluded. 2 cohorts were formed: those who underwent colonoscopy screening and those who underwent faecal immunochemical testing. 1:1 propensity score matching was performed according to demographics, comorbidities, and socioeconomic status. Follow-up of patients ended on December 31, 2022. The primary outcome of interest was the incidence of colorectal cancer and the secondary outcome was incidence of all-cause mortality. The time window used for outcomes analysis was 10 years starting from the day of the index event. Hazard ratios (HRs) and 95% confidence intervals (CIs) were computed using the Cox proportional hazards model.

Results: 130,895 patients in the colonoscopy cohort (mean [SD(standard deviation)] age at index, 60.4 [8.3] years; 75,451 [57.6%] female) were matched with 130,895 patients in the FIT cohort (mean [SD] age at index, 60.3 [9.0] years; 76,479 [58.4%] female). The colonoscopy group was found to have a significantly lower risk of colorectal cancer (HR, 0.34; 95% CI, 0.30-0.39) compared to the FIT group. All-cause mortality was also considerably lower in the colonoscopy group (HR, 0.54; 95% CI, 0.53-0.56). These results were consistent at follow-up periods of 1, 3, 5 and 10 years.

Colorectal cancer, follow-up, years	Colonoscopy cohort (number of events)	FIT cohort (number of events)	HR (95% CI)
1	95	380	0.25 (0.20-0.31)
3	165	600	0.27 (0.23-0.32)
5	212	721	0.27 (0.23-0.32)
10	309	818	0.32 (0.28-0.36)
All-cause mortality, follow-up, years			
1	812	3,353	0.24 (0.23-0.26)
3	2,448	6,286	0.37 (0.36-0.39)
5	3,928	8,018	0.44 (0.42-0.46)
10	6,344	9,630	0.52 (0.51-0.54)

Table 1: Comparison of outcomes between colonoscopy and FIT cohorts following propensity score matching.

Conclusion: Our findings suggest that colonoscopy screening is associated with a significantly lower risk of colorectal cancer and all-cause mortality compared to faecal immunochemical testing. Further studies, especially large-scale randomised controlled trials, are required to corroborate these findings.

Disclosure: Nothing to disclose.

SAFETY AND EFFICACY OF LOW POWER PURE-CUT HOT SNARE POLYPECTOMY FOR NONPEDUNCULATED COLORECTAL POLYPS 10 TO 14 MM IN SIZE: A MULTICENTER RETROSPECTIVE STUDY

H. Kimura[1], K. Takada[2], K. Imai[2], Y. Kishida[2], S. Ito[2], K. Hotta[2], T. Imai[1], Y. Morita[3], S. Bamba[1], O. Inatomi[3], H. Ono[2], A. Andoh[3]
[1]Shiga University of Medical Science, Division of Digestive Endoscopy, Shiga, Japan, [2]Shizuoka Cancer Center, Division of Endoscopy, Shizuoka, Japan, [3]Shiga University of Medical Science, Division of Gastroenterology, Shiga, Japan

Contact E-Mail Address: hidenori.kim.6416@gmail.com

Introduction: Cold snare polypectomy (CSP) for polyps 10-14 mm is unsatisfactory, with higher rates of unclear/positive histologic margins compared to small polyps,[1] which is similar for CSP with submucosal injection.[2] Therefore, hot snare polypectomy (HSP) or endoscopic mucosal resection (EMR) has been widely performed for polyps measuring ≥10 mm.[3]

However, these procedures often cause adverse events such as delayed bleeding and perforation due to deep thermal injury related to the use of electrocautery.[4]

A recent large-scale study reported a low incidence (0.9%) of invasive cancer in 10-19 mm colorectal polyps.[5]

Therefore, the development of less invasive therapeutic options for this size category is demanding.

Thus, we have developed HSP with low power pure-cut current (LPPC-HSP), a polypectomy technique with low power, low voltage, and no coagulation current (UMIN Clinical Trials Registry; UMIN000037678). This method uses pure-cut current and reduces the power of electrocautery, expecting less deep thermal damage compared with conventional HSP with blend or coagulation current, resulting in a lower risk of perforation and bleeding.

This study aimed to evaluate the efficacy and safety of LPPC-HSP for colorectal polyps 10 to 14 mm, compared with conventional EMR.

Aims & Methods: In this multicenter, retrospective, observational study, records of patients who underwent EMR or LPPC-HSP for nonpedunculated colorectal polyps 10 to 14 mm at two Japanese institutions between January 2021 and March 2022 were evaluated consecutively.

EMR was performed with blend cut current (Endocut Q; effect 3, time interval 2, time duration 2), while LPPC-HSP with a low power pure-cut current (Autocut; effect 1, 10 W in VIO300D or Autocut; effect 0.4 [Pmax 13 W] in VIO3). We analyzed the treatment outcomes of the two techniques using propensity score matching to reduce selection bias.

The following variables expected to affect treatment outcomes were selected: age, sex, polyp size, morphology, lesion location, endoscopists (experienced endoscopists or gastrointestinal fellows), and antithrombotic agents. R0 resection was defined as en bloc resection with histologically tumor-free margins.

Results: We retrospectively enrolled 203 EMR (168 patients, 203 lesions) and 208 LPPC-HSP (169 patients, 208 lesions) cases. After propensity score matching, the baseline characteristics between the groups were comparable, with 131 pairs. The en bloc and R0 resection rates were not significantly different between EMR and LPPC-HSP groups (93.9% vs. 96.9%, *P*=0.38; 90.8% vs. 91.6%, *P*=1.00).

The vertical margin was negative in all lesions except one in the EMR group. Immediate bleeding requiring hemostasis was observed in 10.7% of cases in the EMR group versus 2.3% in the LPPC-HSP group (*P*=0.010). The rates of delayed bleeding and perforation didn't differ between the groups (0% vs. 0.8%, *P*=1.00; 0% vs. 0%).

Baseline characteristics	EMR n=131	LPPC-HSP n=131	P value	standardized difference	Treatment outcomes	EMR n=131	LPPC-HSP n=131	P value
Age, years (interquartile range)	72 (67-76)	72 (68-78)	0.29	0.105	En bloc resection (%)	123 (93.9)	127 (96.9)	0.38
Male sex (%)	91 (70)	96 (73)	0.59	0.085	R0 resection (%)	119 (90.8)	120 (91.6)	1.00
Lesion size, mm (interquartile range)	10 (10-12)	10 (10-12)	0.93	0.017	Immediate bleeding (%)	14 (10.7)	3 (2.3)	0.01
Location right colon/left colon/ rectum (%)	61 (47) / 53 (41) / 17 (13)	63 (48) / 53 (41) / 15 (12)	0.95	0.049	Delayed bleeding (%)	0 (0)	1 (0.8)	1.00
Morphology 0-Is/0-IIa (%)	89 (68) / 42 (32)	87 (66) / 44 (34)	0.90	0.033	Perforation (%)	0 (0)	0 (0)	N/A
Antithrombotic agents (%)	24 (18)	35 (27)	0.14	0.202				
Gastrointestinal fellows performed (%)	42 (32)	44 (34)	0.90	0.033				

Table 1. Baseline characteristics and treatment outcomes after propensity score matching.

Conclusion: LPPC-HSP showed treatment outcomes comparable to conventional EMR, with fewer adverse events. These results suggest that this technique is a safe and effective treatment for nonpedunculated colorectal polyps 10 to 14 mm.

Introduction: Rectal retroflexion (RR) is an important manoeuvre performed during colonoscopy to increase mucosal visualisation of the distal rectum and anorectal junction. A minimum RR rate of 90% is a quality indicator for colonoscopy in many national and international societal guidelines. However, its measurement is often imprecise and cumbersome to audit as it relies on manual photo documentation and/or manual data en-

try in endoscopy reporting systems. Furthermore, it is currently not possible to quantify the time spent inspecting the distal rectum and anorectal junction in the RR position.

Aims & Methods: We aimed to develop a convolutional neural network (CNN) to detect RR and quantify the inspection time in the RR position ('rectal retroflexion time').

Lower gastrointestinal endoscopy videos were prospectively collected from a single centre in the United Kingdom (UK) (site 1) for training data to develop the CNN. Each video frame with visualisation of the endoscope in the RR position was annotated with an image level label 'rectal retroflexion', and the remaining images were labelled as 'negative' for RR.

The RR CNN was then evaluated with colonoscopy videos recorded from nine UK sites enrolled in a randomised controlled trial ("CADDIE Trial") that evaluated a polyp detection CNN. For the evaluation of the RR CNN, we randomly selected two endoscopists from each site (n=18) enrolled in the CADDIE trial and ten procedures from each endoscopist (n=180) ('overall test set'). These nine sites include site 1 (internal test-set) (n= 20) and sites 2 – 9 (external test-set) (n=160) (Table 1). The videos were annotated following the methodology described above, with the annotations referenced as the ground truth.

Results: During the training phase of the study, a weakly-supervised ResNet-101 CNN was developed with 185 video procedures collected from site 1. This training set consisted of 71,121 RR frames (no frames were excluded) and 142,242 randomly sampled negative frames.

In the per-frame analysis (51,134 RR frames, 102,268 negative frames), the overall test-set (n=180) accuracy was 97.6%, sensitivity 94.7%, specificity 99.0% and area under the curve of 0.98 (Table 1).

RR was performed in each procedure in the CADDIE Trial test set. The CNN correctly detected RR in 98.3% of procedures for the overall test set (177/180). For the internal test-set (site 1), the CNN correctly detected RR for all 20 procedures. For the external test sets (site 2 – 9), the CNN correctly identified RR in 98.1% of procedures (157/160), with each of the three procedures where it failed to detect RR from a different site.

For the overall test set (n=180), the ground truth median rectal retroflexion time was 7.6 seconds (IQR 4.5 – 12.3) and the range was 1.4 – 49.7 seconds. The AI predicted median RR time was 7.4 seconds (IQR 4.2 – 12.2) (Figure 1) and the range 0 – 50.2 seconds.

Test dataset	Endoscopists	Procedures	Ground Truth RR Time (Median seconds; IQR)	CNN Predicted RR Time (Median seconds; IQR)	Accuracy (%)	Sensitivity (%)	Specificity (%)
Internal (site 1)	2	20	6.8 (5.2, 10.3)	6.8 (4.6, 10.5)	98	96	99
External (sites 2 – 9)	16	160	7.6 (4.4, 12.4)	7.5 (4.1, 12.4)	98	95	99
Overall	18	180	7.6 (4.5, 12.3)	7.4 (4.2, 12.2)	98	95	99

Table 1: CNN performance for rectal retroflexion (RR) detection and rectal retroflexion time measurement.

Conclusion: This is the first study to evaluate the use of artificial intelligence for automated RR detection and measurement of the novel metric 'rectal retroflexion time'. We demonstrated robust performance of the CNN amongst multiple sites across the UK. Further exploration is warranted to evaluate 'rectal retroflexion time' as a replacement or adjunct to RR detection as a quality indicator for colonoscopy.

Introduction: Measurement of the size of colorectal polyps during colonoscopy is carried out mainly by visual estimation. We developed a novel polyp size measurement system (*Poseidon*) based on artificial intelligence that uses the auxiliary water jet as a measurement reference.

Aims & Methods: Visual estimation, biopsy forceps measurement, and *Poseidon* were compared using a CT colonography-based silicon colon model with 28 polyps of known size. Four experienced endoscopists estimated polyp size visually and with biopsy forceps. The endoscopists took images of each polyp with the water jet in its proximity. These images were then analyzed by *Poseidon* to measure the size of the polyp.

Additionally, the *Poseidon* measurements were compared to visual size estimates of 29 colorectal polyps examined during clinical routine.

Results: In the silicone colon model, the visual estimation had the largest median percent error (PE) of 25.2% (interquartile range (IQR: Q1, Q3): 11.8, 43.1), followed by the biopsy forceps measurements with a median PE of 20% (IQR: 9.1, 34.3). Poseidon had a significantly lower median PE of 7.4% (IQR: 3, 15.7, $p<0.001$) than the other two methods.

At routine colonoscopies, Poseidon had a significantly lower median PE (7.7%; IQR: 2.7, 12.6) than the visual estimation (22.1%; IQR: 12.4, 34.1, $p<0.001$).

Conclusion: In this work, we present a novel method to measure the size of colorectal polyps, which has a significantly higher accuracy than other common polyp sizing methods.

HEMORRHOIDS AT RISK FOR COLORECTAL ADENOMAS ON COLONOSCOPY: A CROSS-SECTIONAL STUDY

O. Toyoshima[1], T. Nishizawa[2,1], S. Yoshida[1], T. Matsuno[1], T. Yamada[3]

[1]Toyoshima Endoscopy Clinic, Gastroenterology, Tokyo, Japan, [2]International University of Health and Welfare, Narita Hospital, Department of Gastroenterology and Hepatology, Narita, Japan, [3]The University of Tokyo, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: t@ichou.com

Introduction: Colorectal premalignant polyps and hemorrhoids are important findings in colonoscopy; however, the association between them is unclear. Therefore, we investigated the association between the presence and severity of hemorrhoids and the detection of precancerous colorectal polyps on colonoscopy.

Aims & Methods: This retrospective, single-center, cross-sectional study enrolled patients who underwent colonoscopy at Toyoshima Endoscopy Clinic between May 2017 and October 2020. Anorectal mucosal elevations with dilated veins were defined as hemorrhoids. Hemorrhoids were examined in the retroflexed view during colonoscopy.

Hemorrhoids with mucosal elevation ≥10 mm were diagnosed as severe hemorrhoids. All polyps suspected to be cancers, adenomas, or clinically significant serrated polyps were excised or biopsied during colonoscopy. The association between hemorrhoids and other outcomes (patient age, sex, withdrawal time for colonoscopy, expert endoscopist, number of adenomas per colonoscopy, detection rates of adenoma, advanced neoplasia, clinically significant serrated polyp, and sessile serrated lesion) was assessed using a binomial logistic regression model. This study was approved by the Certificated Review Board, Yoyogi Mental Clinic on July 16, 2021 (approval no. RKK227).

Results: A total of 12,408 patients were enrolled in this study. Hemorrhoids were identified in 1,863 patients. The mean age was 53.9 years and female sex accounted for 50.5%. Expert endoscopists performed 68.3% of the colonoscopies. Mild and severe hemorrhoids are found in 1,735 and 128 patients, respectively. Number of adenomas per colonoscopy was 0.821. Detection rates of adenoma, advanced neoplasia, clinically significant serrated polyp, and sessile serrated lesion were 44.9%, 2.68%, 8.89%, and 3.47%, respectively. Univariable analysis showed that patients with hemorrhoids were older (61.0 vs. 52.5 years, $P < 0.001$), had a higher number of adenomas per colonoscopy (1.16 vs. 0.756, $P < 0.001$), and had a higher adenoma detection rate (56.4% vs. 42.7%, $P < 0.001$) than those without hemorrhoids. Multivariable analyses also demonstrated that hemorrhoids were associated with a higher number of adenomas per colonoscopy (odds ratio [OR]: 1.061, 95% confidence interval [CI]: 1.022-1.101, $P = 0.002$) and a high adenoma detection rate (OR: 1.152, 95% CI: 1.035-1.282, $P = 0.010$), regardless of patient age, sex, and expert endoscopist. Next, we performed a subgroup analysis that was limited to the expert endoscopists. Multivariable analysis showed that the presence of hemorrhoids was independently associated with a high number of adenomas per colonoscopy (OR: 1.066, 95% CI: 1.024-1.109) regardless of patient age and sex. Among patients with hemorrhoids, severe hemorrhoids were associated with a higher number of adenomas per colonoscopy than mild hemorrhoids (OR: 1.120, 95% CI: 1.003-1.250), regardless of patient age, sex, and expert endoscopist.

	Odds ratio	95% confidence interval	P value
Age	1.055	1.050-1.059	<0.001
Male sex	1.106	0.998-1.226	0.055
Expert endoscopist	1.542	1.360-1.747	<0.001
Number of adenomas per colonoscopy	1.061	1.022-1.101	0.002

Conclusion: Hemorrhoids, especially severe ones, are associated with a high number of adenomas. Complete colonoscopy should be performed in patients with hemorrhoids.

Disclosure: There is no conflict of interest for this study.

PP1130

ARTIFICIAL INTELLIGENCE–ASSISTED COLONOSCOPY FOR ADENOMA AND POLYP DETECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

M.G. Shiha[1,2], P. Oka[1,2], S.A. Raju[1,2], F.W.D. Tai[1], H.-L. Ching[1], M. Thoufeeq[1], R. Sidhu[1,2], M. McAlindon[1,2], D.S. Sanders[1,2]
[1]Sheffield Teaching Hospitals, Academic Unit of Gastroenterology, Sheffield, United Kingdom, [2]University of Sheffield, Department of Infection, Immunity & Cardiovascular Disease, Sheffield, United Kingdom

Contact E-Mail Address: shiha202@gmail.com

Introduction: There is a growing interest in the role of artificial intelligence in colonoscopy. In this systematic review and meta-analysis, we aimed to evaluate the efficacy of computer-aided detection (CADe) of colorectal adenomas and polyps.

Aims & Methods: We searched MEDLINE, EMBASE and CENTRAL (from inception to December 2022) for randomized controlled trials (RCTs) comparing colonoscopy with CADe versus standard colonoscopy (SC). We performed a random-effects meta-analysis and reported the results as relative risks (RR) or mean difference (MD) with 95% confidence intervals (CI).

Results: Twelve RCTs comprising 11,340 patients were included in the final analysis. The pooled adenoma detection rate (ADR) was significantly higher in the CADe group compared with the SC group (41.4% vs 33%; RR 1.26, 95% CI 1.18 – 1.35). CADe increased the detection of adenomas regardless of their size (≤5mm [RR 1.56, 95% CI 1.38 – 1.77], 6 – 9mm [RR 1.24 95% CI 1.05 – 1.47] and ≥10mm [RR 1.30, 95% CI 1.11 – 1.53]), location (proximal colon [RR 1.41, 95% CI 1.26 – 1.58] and distal colon [RR 1.44, 95% 1.29 – 1.61]) or morphology (polypoid [RR 1.35, 95% CI 1.17 – 1.56] and non-polypoid [RR 1.55, 95% 1.25 – 1.93]).

There was no difference between the CADe and SC groups in detecting advanced adenomas or sessile serrated lesions. Colonoscopy withdrawal time was longer in the CADe group compared with the SC group (MD 0.34 minutes, 95% CI 0.17 – 0.51).

Conclusion: Using CADe during colonoscopy is associated with a significant increase in ADR and adenoma per colonoscopy, which was mainly due to the increased detection of diminutive adenomas. Long-term longitudinal studies are required to evaluate the effect of CADe on the risk of interval colorectal cancer and cancer-related deaths.

Disclosure: Nothing to disclose.

EFFICACY AND SAFETY OF ENDOSCOPIC SUBMUCOSAL DISSECTION USING A SCISSOR-TYPE KNIFE AND TRACTION DEVICE FOR EARLY COLORECTAL NEOPLASMS

Y. Tamaru[1], T. Kuwai[1], S. Semba[1], N. Kato[1], S. Sugata[1], Y. Okuda[1], Y. Teraoka[1], T. Mizumoto[1], R. Kusunoki[1], A. Yamaguchi[1], H. Kouno[1]
[1]National Hospital Organization Kure Medical Center and Chugoku Cancer Center, Gastroenterology, Kure, Japan

Contact E-Mail Address: tamaru.yuzuru.vh@mail.hosp.go.jp

Introduction: Although endoscopic submucosal dissection (ESD) can be useful for treating early colorectal neoplasms, colorectal ESD is technically more difficult, with certain organ characteristics rendering the procedure even more challenging and increasing the risk of perforation. Herein, we used scissor-type knives (SB Knife Jr and Jr2, Sumitomo Bakelite, Japan) that enabled the maintenance of an adequate dissection layer and prevented unexpected muscular layer injuries. However, scissor-type knives demonstrated slower resection compared with needle-type knives. This

drawback was overcome by using a traction device on the lesion, which facilitated accurate visualization and easier dissection as well as increased the resection speed during colorectal ESD using a needle-type knife. Nevertheless, reports regarding the effectiveness of a traction device when using a scissor-type knife for colorectal ESD remain scarce.

Aims & Methods: This study aimed to evaluate the efficacy and safety of ESD performed using a scissor-type knife with and without a traction device for treating early colorectal neoplasms. Between October 2010 and January 2023, ESD was performed for 619 lesions in 582 patients (male-to-female ratio, 332:250; mean age, 70.0 years) in the Kure medical center. ESD was performed without a traction device for 531 lesions (Group A) and with a traction device for 88 lesions (Group B). We compared the en-bloc resection rate, complete resection rate, tumor size, procedure time, resection speed, and adverse events of the groups.

Results: Five and two interruptions occurred in Groups A and B, respectively. The en-bloc resection rate was 99.0% (521/526) in Group A and 97.7% (84/86) in Group B ($p = 0.26$). The complete resection rate was 97.0% (510/526) and 95.3% (82/86) in Groups A and B, respectively ($p = 0.51$). The mean tumor diameter was 33.4 ± 16.9 and 37.2 ± 20.9 mm in Groups A and B, respectively ($p = 0.11$). The mean procedure time was 86.4 ± 67.6 and 73.2 ± 66.0 min in Groups A and B, respectively ($p = 0.09$). The mean resection speed (the resected specimen area [mm^2] divided by the procedure time [min]) was 13.2 ± 10.4 and 22.9 ± 11.9 mm^2/min in Groups A and B, respectively, with the speed in Group B significantly faster than that in Group A ($p < 0.01$). There was one case each of intraoperative perforation and delayed perforation in Group A (1/526, 0.2% each), while there were none in Group B (0/86, 0%). Both cases of perforation were treated conservatively. There were 10 cases of delayed hemorrhage in Group A (10/526, 1.9%), and none in Group B (0/86, 0%; $p = 0.37$). The hemorrhage was controlled with endoscopic hemostasis in all cases.

Conclusion: ESD using a scissor-type knife either with or without a traction device is technically efficient and safe. Moreover, its drawback of slow resection speed may be overcome by the use of a traction device.

Disclosure: Nothing to disclose.

CAN TIP-IN ENDOSCOPIC MUCOSAL RESECTION BE PERFORMED EFFECTIVELY AND SAFELY BY TRAINEES FOR 15-25 MM COLORECTAL NONPEDUNCULATED NEOPLASMS?

K. Shigeta[1], Y. Kishida[1], K. Hotta[1], K. Imai[1], S. Ito[1], K. Takada[1], J. Sato[1], T. Minamide[1], Y. Yamamoto[1], M. Yoshida[1], Y. Maeda[1], N. Kawata[1], H. Ishiwatari[1], H. Matsubayashi[1], H. Ono[1]

Contact E-Mail Address: k.shigeta0607@gmail.com

Introduction: Tip-in endoscopic mucosal resection (EMR) has shown a favorable resection outcome for large colorectal polyps.[1, 2] However, reported outcomes have been limited to experts' performance. To generalize the outcomes, trainees' performance of Tip-in EMR is an interest, however, available data are absent.

Aims & Methods: To clarify whether Tip-in EMR can be achieved effectively and safely even by trainees, in this single-center retrospective study, clinical outcomes of Tip-in EMR between experts and trainees were compared. Inclusion was 15–25 mm non-pedunculated colorectal neoplasms resected by Tip-in EMR between January 2014 and December 2020. Exclusion was residual lesions after the previous resection. Data were collected from medical records and prospectively recorded endoscopy and pathology databases. Baseline characteristics, treatment results, histological outcomes, and surveillance outcomes were analyzed. In our institution, trainees perform Tip-in EMR under the supervision of experts, and switch to experts when experts decide to switch during the procedure, all of which were also analyzed as the trainee group. Independent procedure completion and independent en bloc resection were defined as achieving procedure completion and en bloc resection without switching, respectively. Failure of independent en bloc resection was defined as piecemeal resection or switching. Residual lesions were defined as endoscopically detected residuals that were pathologically confirmed as neoplasia.

All procedures performed by trainees were grouped into three periods (period 1: 1–10 cases, period 2: 11–20 cases, and period 3: ≥21 cases), and the learning curve was assessed. A logistic regression analysis was performed to examine the risk factors of failure of independent en bloc resection.

Results: A total of 597 lesions (550 patients) were analyzed. Among them, 438 lesions (402 patients) and 159 lesions (148 patients) were resected by 6 experts and 14 trainees, respectively. The independent procedure completion was 146 cases (91.8%) in the trainees and 438 cases (100%) in the experts. The en bloc resection rates did not differ between trainees and experts (83.0% vs. 88.6%, $P = .098$).

However, the independent en bloc resection rate was significantly lower in trainees (77.4% vs. 88.6%, $P = .001$). There was no significant difference in the incidence of adverse events (2.5% vs. 5.7%, $P = .165$). Among 380 lesions (63.6%) of 347 patients who received surveillance colonoscopy, 11 residual lesions were identified; 3 lesions (3.1%) in the trainees and 8 (3.5%) in the experts ($P = 1$), all of them were removed endoscopically. For the learning curve of trainees, the independent en bloc resection (OR 3.4, 95%CI 2.0–5.7, $P < .001$) was significantly lower and took longer procedure time (median 8.6 min vs. 5.8 min, $P < .001$) in period 1 than those of experts, but not in period 2 and 3.

In multivariate analysis, risk factors of failure of independent en bloc resection were non-polypoid morphology (OR 3.4, 95% CI: 1.6–7.3; $P = .001$), positive non-lifting signs (OR 3.1, 95%CI: 1.2–8.0; $P = .023$), lesions with an underlying semilunar fold (OR 3.6, 95%CI: 2.0–6.3; $P < .001$), and trainees with experience ≤10 procedures (OR 3.6, 95%CI: 2.1-6.3, $P<.001$).

Conclusion: We demonstrated favorable outcomes of Tip-in EMR for 15-25 mm lesions performed by trainees. However, Tip-in EMR should be performed under the supervision of experts, especially for trainees with experience of ≤10 cases.

Introduction: Bowel cleansing completion time is one of the important factors for optimal bowel preparation. The recommended completion time is within 3-8 hours of colonoscopy.

Aims & Methods: In this randomized study, we investigated the optimal bowel preparation completion time between short interval and long interval. Study participants were randomized into two groups: short interval, bowel preparation completion time (2-4 hours of colonoscopy); long interval (4-8 hours of colonoscopy).

The primary endpoint was successful bowel cleansing assessed by Boston bowel preparation (BBPS) scale. Secondary endpoint included Aronchick scale and patient's tolerability investigated by sleep disturbance and patients' satisfaction. Bowel preparation was performed using 4 L polyethylene glycol.

Results: A total of 504 individuals were included (short interval, 255; long interval, 249). Mean time for bowel preparation finish time was 2.99 and 5.12 hours respectively. The rate for successful preparation was comparable between the two groups (short interval, 97.6% and long interval, 95.2%, p=0.136). Total BBPS score was 8.22 in the short interval group, which was higher than that of long interval group (7.82, p<0.001). Regional score for Rt. colon (2.65 vs 2.44, p < 0.001) and Lt. colon (2.65 vs 2.56, p=0.057) of short interval group was higher than that of long interval group. Regional score for T-colon (2.92 vs 2.82, p = 0.002) and was comparable between the two groups. Sleep disturbance was higher in the long interval group. Safety did not differ between the two groups.

Conclusion: The rate for successful preparation were similar for the two groups. Total BBPS score and regional scores for Rt. colon and T-colon were higher in the short interval group. For better bowel cleansing, bowel preparation finish time is recommended 2-4 hours of colonoscopy.

Contact E-Mail Address: danielrenteln@gmail.com

Introduction: Accurate measurement of polyp size is important for colonoscopy related decision making, especially for choosing appropriate polypectomy instruments and surveillance intervals. The virtual scale endoscope (VSE) allows for laser-based polyp size measurement during colonoscopy (1).

VSE is integrated in the endoscope, superimpose a calibrated scale on a polyp in real-time and aims to overcome endoscopist and technology bias when measuring colorectal polyps' size.

Aims & Methods: This study aimed to compare polyp size measurement relative accuracy (RA) when using an endoscope with integrated laser-based adaptive scale function (VSE) and visual assessment (VA). Patients undergoing screening, surveillance or diagnostic colonoscopies were randomly assigned (1:1) into two groups. In the intervention group, all detected polyps were measured for size using VSE; in the control group, all polyps were measured using VA. Size measurements were compared to a reference standard of digital caliper measurement of fresh polyp specimens immediately after polypectomy. The primary outcome was the RA of VSE measurement when compared to VA. Secondary outcomes included the mean differences and the correlations between VSE or VA sizes and the reference standard of measurement.

Results: Overall, 230 patients were enrolled and randomized. In the intervention and control groups, 204 polyps (in 79 patients) and 166 polyps (in 80 patients) were found and measured with VSE and VA, respectively. The RA of VSE was 84%, which was significantly higher than that of VA (68.4%, p<0.001). The RA of the measurement with VSE decreased with increasing polyps size estimations during the live colonoscopies but did not reach the statistical significance (B=-0.009; p-value=0.31; 95% CI, -0.03–0.01). In contrast, the RA of the measurements with VA significantly increased with increasing polyp size estimations during the live colonoscopies (B=0.025; p<0.001; 95% CI, 0.01–0.04). VSE had significantly lower percentage for >5mm polyps incorrectly sized as 1–5mm compared to VA (13.5% vs. 57.1%; p=0.0005). No difference was observed between VSE and VA for 1–5mm polyps mis-sized as >5mm (3.7% vs. 2.4%; p=0.62), ≥10mm polyps mis-sized as <10mm (20% vs. 16.7%; p=0.87), or <10mm polyps mis-sized as ≥10mm. When estimating the percentage of size measurements that were within 25% of true size measured by caliper, 41% (43/105) of measurements with VA and 81.4% (96/118) of measurements with VSE were within 25% of true size (p<0.001). The normalized mean showed a tendency towards size underestimation for both VSE and VA measurements (p<0.001). There was a significant lower tendency of underestimation for VSE compared to VA (p<0.001; 95% CI, 0.15-0.30). The correlations between size measurements with VSE or VA and the reference standard were substantial and statistically significant (0.87 and 0.89, respectively; p<0.001 for both methods). The interclass coefficients of the agreement between each measurement method and the reference standard were statistically significant (p<0.001 for both).

Conclusion: VSE significantly improves size measurement accuracy of colorectal polyps during colonoscopies compared to visual size estimation. (NCT05236790)

Introduction: Colonic stents (CS) are usually placed for palliative purposes in patients with malignant obstructions[1]. Paucity of data exist in regards causes, rates, mortality and predictors of readmission.
Aims & Methods: Retrospective review of the National Readmission Database (NRD) of the year 2019 of adult patients that underwent CS placement during an index admission (IA) from the month of January to November and were readmitted within 30-days of discharge. ICD-10CM/PCS codes were utilized to identified the procedures and comorbidities. The primary outcome was readmission of any cause. Secondary outcomes were mortality, resource utilization (length of stay (LOS), total hospitalization costs and charges) associated with readmission. Independent risk factors for readmission were identified using Cox regression analysis.
Results: A total of 2,786 patients underwent CS placement in 2019. 46.4% of patients were female and mean age was 65.6 years, most of the patient had a Charlson Comorbidity Index (CCI) score of ≥3 (62.4%) and 44.6% of stents were placed to relieve a malignant obstruction. The 30-day readmission rate was 29.1% (N=811), the most common diagnosis associated with readmission was neoplasm of the sigmoid colon (64.3%). The mortality rate of readmission was 6.7% and 4.5% for the IA (P<0.01). A higher proportion of females were readmitted (50.8% vs. 44.5%, P=0.04), readmitted patients had lower rates of CCI score of ≥3 (55.3% vs. 65.3%), more likely to be from large metropolitan areas with at least 1 million residents (70.4% vs. 64.1%, P=0.04), to have associated obesity (17.8% vs. 11.5%). Patients that had CS placed for obstruction (45.1% vs. 39.3%; P=0.04) and colonic fistula (2.9% vs. 1.2%; P=0.02) were more likely to be readmitted. The mean LOS, hospitalization charges and costs were: 10.4 days, $93,780 and $24,758, respectively. The total cumulative hospitalization charges and costs associated with readmission were $76.2 million and $20.1 million. Independent predictors of 30-day readmission were obesity [adjusted Hazard Ratio (aHR) 1.40, 95% Confidence Interval [CI] (1.07-1.85)], stent placement for colonic fistula [aHR 2.92 (1.74-4.90)], stent placement in the descending colon [aHR 1.40(1.03-1.90)] and residence in not metropolitan or micropolitan [aHR 3.25(1.35-7.85)].
Conclusion: Readmissions after CS placement are high. The mortality rate associated with readmission is significantly higher than in the IA. Obesity increases the risk of readmission by 1.4 times. Further prospective studies are needed to evaluate the mechanisms and causes to decrease readmission rates and in-hospital mortality in this set of patients.

BOOKLETS TO IMPROVE BOWEL PREPARATION QUALITY IN COLONOSCOPY: SYSTEMATIC REVIEW WITH META-ANALYSIS

G. Losurdo[1], M.L. Martino[1], M. De Bellis[1], A. Iannone[1], A. Di Leo[1]
[1]University of Bari, Section of Gastroenterology, DIMEPREJ, University of Bari, Bari, Italy

Contact E-Mail Address: ludovicamarti@gmail.com
Introduction: A good bowel preparation for colonoscopy is fundamental to improve the quality of the examination, reduce procedural complications and achieve optimal polyp detection. Among possible strategies to enhance bowel preparation, visual booklets have been proposed with conflicting results.
Therefore we aimed to perform a systematic review with meta-analysis of randomized controlled studies (RCT) to ascertain whether booklets may be useful in this setting.
Aims & Methods: Literature search was performed in July 2022, in main databases (PUBMED, SCOPUS, ScienceDirect, the Cochrane Central Register of Controlled Trials and ClinicalTrials.gov). only RCTs were selected. The primary outcome was the quality of bowel preparation. Further outcomes were the adenoma detection rate (ADR), number of polyps detected per patient, rate of cecal intubation, time of insertion and withdrawal, adverse events, willingness to repeat preparation and colonoscopy. We estimated odd ratios (OR) for dichotomous outcomes. mean differences (MD) or standardized mean differences (SMD) were used for continuous outcomes. We estimated heterogeneity among studies with the Chi2 (Cochran Q) and the I2 statistics. In case of high heterogeneity, a random effect model was used, otherwise a fixed effects model was preferred. All analyses were performed using RevMan version 5.4.1.
Results: Six studies were selected, enrolling overall 1755 patients (857 in the booklet and 898 in the control group). Adequate bowel preparation was achieved in the 86.7% (743 out of 857) of booklet preparation versus the 77.5% (696 out of 898) in the control group, with an OR of 2.31 in favour of booklet (95% CI 1.20-4.45, p = 0.01). Booklet was more effective than control in the transverse colon (MD = 0.37, 95% CI 0.01-0.72, p = 0.03), while no differences were found in right colon and left colon.
In four studies a 4-L PEG-based preparation was used and the pooled analysis did not find any difference compared to controls, while when sodium phosphate and magnesium citrate or sodium phosphate or PEG were used, preparation with booklet was better than in controls (OR = 5.10, 95% CI 1.82-14.27, p = 0.002).
Two studies were performed in inpatient setting, without difference between booklet and controls while in outpatients patients receiving booklets were better prepared than controls (OR = 7.13, 95% CI 5.39-9.45, p < 0.001). ADR was similar between the two groups, with an OR = 0.93 (95% CI 0.75-1.16, p = 0.53). The mean number of polyps per patient did not differ between the two groups (MD = 0.22, 95% CI -0.14-0.58, p = 0.23).
Conclusion: The present meta-analysis demonstrated that booklets are useful to enhance bowel preparation. Outpatients and non PEG-based preparations seem to benefit more from booklets, while no effect on ADR has been observed.
Disclosure: Nothing to disclose.

FACTORS AFFECTING BOWEL PREPARATION FOR COLONSCOPY IN INPATIENT SETTING: A PROSPECTIVE, CASE-CONTROL STUDY

G. Losurdo[1], G. De Giosa[1], I. Loconte[1], I. Lacavalla[1], C. Lillo[1], M.L. Martino[1], A. Iannone[1], S. Rizzi[1], A. Di Leo[1]

Introduction: It is well known that inpatients more frequently undergo inadequate bowel preparation for colonoscopy, mainly due to factors such as old age, comorbidities and polypharmacy. we therefore aimed to investigate factors associated to inadequate bowel preparation in a group of hospitalized patients.

Aims & Methods: We prospectively enrolled inpatients at University Hospital Policlinico of Bari, who underwent colonoscopy in the last year. Outpatients undergoing colonoscopy represented a control group. For each patients we collected data about age, diseases and drugs consumed. all patients received a 4-L polyethilenglycole (PEG) based preparation in a split regimen, and colonoscopies were performed in the morning. Inadequate preparation was defined if Boston bowel preparation scale (BBPS) was total <6 or <2 in at least one colonic segment. Continuous and discrete variables were respectively compared by t-test and chi-square test. Binomial logistic regression was used to find factors associated to inadequate preparation and estimate of risk was defined as odds ratio (OR).

Results: We recruited 167 hospitalized patients and 167 controls. Inpatients were more commonly bedridden (p<0.001) or had chronic kidney disease (p=0.004) and were older than controls (64.7 ± 16.3 versus 50.9 ±18.6, p<0.001). Adequate preparation was attained only in the 73.6% of hospitalized patients versus the 88.0% of outpatients (p=0.001), and the BBPS was lower in inpatients (6.8 ± 1.7 versus 5.8 ± 2.5, p<0.001). Adequate preparation was more often achieved if patients was admitted in Gastroenterology units than in other units (81.6% versus 67.7%, p=0.04). Adenoma detection rate was higher when preparation was adequate (28.5% versus 13.6%, p=0.05). At multivariate analysis, inadequate preparation was associated with admission in a ward other than Gastroenterology (OR=1.88).

Conclusion: Our results confirm that hospitalization negatively impact on the quality of bowel preparation for colonoscopy. Interestingly, admission in Gastroenterology Unit allows a better preparation, maybe due to a better care of medical and nurse personnel.

JOINT MULTIVIEW LEARNING ENHANCES CHARACTERIZATION OF COLORECTAL POLYPS IN WHITE LIGHT ENDOSCOPY

Introduction: Automatic optical characterization (CADx) systems aim to support gastroenterologists in identifying the type of polyps found during a colonoscopy procedure (e.g. “adenomatous” or “non adenomatous”). It has the potential to decrease the risks, workloads, and costs of polypectomy and pathology tests. The majority of reported CADx systems provide a classification score for each polyp frame, followed by an aggregation of the scores to determine a final prediction of the polyp diagnosis. A common aggregation mechanism is a simple voting procedure. Other aggregation methods include the average or maximum score of the entire sequence. In all of the above, longer sequences should provide more information necessary to get an accurate prediction. However, the aggregation approach does not leverage complementary information (e.g. polyp geometry) that can be learned by jointly processing multiple views. In addition, views diversity and quality are not considered as part of the inference process. At the aggregation stage, only the per-frame score is taken into account, while the appearance of the polyp in each view is not considered. Joint processing of multiple frames, on the other hand, allows relative weighing of each frame with respect to the other available frames in the sequence, while considering their quality and diversity.

Aims & Methods: We propose a multiview learning model, in which multiple frames of a polyp are processed jointly as part of the training process, resulting in a single score for the entire sequence. We apply a convolutional neural network (CNN) to embed each frame into a vector representation. We then use an attention model (Transformer) to jointly process these representations and predict a single score for the entire sequence, rather than for each frame separately. The system is trained in an end-to-end manner, allowing the model to learn to predict a score based on multiple views with varying quality and diversity.

Here we test the performance of the proposed approach in predicting the endoscopic appearance-based polyp classification done by GIs. Predicting the histology results is left for future work. The polyps are annotated by expert GIs into adenomatous or non adenomatous. The test set consists of 565 polyps taken from 317 videos that were unanimously classified by 2 expert GIs, independently. We compare our suggested model to a baseline model which was trained to predict a score for each frame separately, followed by aggregation of the scores for each polyp.

Results: We compare the AUROC of the joint learning model (“Joint Learning“) and 3 baseline aggregation schemes - averaging the per-frame scores (“Mean Score“), maximum score (“Maximum Score“), and majority voting (“Voting“). We use polyp frames sequences of varying lengths and evaluate the performance repeatedly on 10 random selections of frames from each sequence. We report the mean and STD of the AUROC for each sequence length. As seen in the table, the joint learning model outperforms all baseline aggregation schemes.

Aggregation Method \ Sequence Length (# Frames)	1	10	20	30	40
Joint Learning	0.913 ± 0.007	0.959 ± 0.003	0.962 ± 0.003	0.962 ± 0.002	0.961 ± 0.001
Mean Score	0.907 ± 0.013	0.952 ± 0.003	0.955 ± 0.003	0.955 ± 0.002	0.956 ± 0.002
Maximum Score	0.907 ± 0.015	0.954 ± 0.004	0.957 ± 0.001	0.956 ± 0.003	0.956 ± 0.002
Voting	0.831 ± 0.022	0.937 ± 0.007	0.945 ± 0.044	0.946 ± 0.002	0.948 ± 0.002

Conclusion: Joint learning of polyp appearance in multiple frames results in better performance for polyp classification in colonoscopy. The joint learning process allows the model to consider diversity, quality and complementary information from multiple views of a single polyp, rather than process each frames separately.

A NOVEL STIFFENING WIRE INCREASES THE DEPTH OF INSERTION DURING DOUBLE BALLOON ENTEROSCOPY – FINDINGS FROM A SINGLE BLIND RANDOMIZED CONTROLLED TRIAL

M. Sey[1,2], M. Archer[2], E. Liu[3], C. McDonald[2], V. Jairath[2,1,4]
[1]Western University, Division of Gastroenterology, London, Canada, [2]Lawson Health Research Institute, Medicine, Gastroenterology, London, Canada, [3]McMaster University, Division of Gastroenterology, Hamilton, Canada, [4]Western University, Epidemiology and Biostatistics, London, Canada

Contact E-Mail Address: msey2@uwo.ca

Introduction: Deep intubation of the small bowel can be difficult during double balloon enteroscopy (DBE). A stiffening wire may help by reducing loop formation and improving handling characteristics of the enteroscope. We conducted a single blind randomized controlled trial to determine the effectiveness of a stiffening wire to increase insertion depth.

Aims & Methods: Consecutive patients undergoing DBE between 2016 to 2022 were eligible to participate in the study. All patients had an abnormality on small bowel imaging before the procedure. Patients underwent DBE using standard technique and were excluded if the abnormality was reached since further insertion was not necessary. If the abnormality could not be reached, patients were randomized to either the stiffening wire or control, after which the endoscopist was given three attempts to advance the enteroscope further. The primary outcome was insertion depth after randomization and secondary outcomes included total insertion depth, diagnosis, intervention, pain score, and adverse event. Insertion depth was determined using the fold counting method[1] and scored by a blinded outcome assessor who reviewed recorded videos of the withdrawal phase of each procedure.

Results: A total of 54 subjects were enrolled (median age 68, 46% female, 28 to stiffening wire and 26 to control). The most common indication was small bowel bleeding (57%) and most cases were performed after an abnormal capsule study (83%). Overall, post-randomization insertion depth was significantly greater in the stiffening wire group compared to the control (135 cm vs. 19 cm, p<0.001), as was total insertion depth (502 cm vs. 391 cm, p=0.015). There were no significant differences in the types of diagnoses or interventions performed between the two groups although there was a trend towards fewer procedures having no intervention in the stiffening wire group (42% vs. 26%, p=0.25). There were no significant differences in pain scores but there were two adverse events in the intervention group, neither of which were related to the stiffening wire.

Conclusion: A stiffening wire is a simple and useful tool to increase the depth of insertion during DBE.

APPLICATION OF A REAL-TIME ARTIFICIAL INTELLIGENCE SYSTEM FOR COLORECTAL POLYP DETECTION

M. López Ibáñez[1], R. Díaz Ruiz[1], J. De la Maza Ortiz[1], C. Carbonell Blanco[1], E. Martos Vizcaíno[1], R. Borobia Sánchez[1], C.P. De Gracia Fernández[1], A. Conthe Alonso[1], O. Ortega Lobete[1], M.E. Velilla Aparicio[1], A. Baines García[1], R. Bañares Cañizares[1], B. Merino Rodríguez[1]
[1]Hospital Universitario Gregorio Marañón, Endoscopy, Madrid, Spain

Contact E-Mail Address: beamerino80@gmail.com

Introduction: Colonoscopy is the "gold-standard" technique for early diagnosis and resection of colorectal cancer precursor lesions. However, this technique has limitations, and can result in missed adenomas and polyps. In recent years, artificial intelligence (AI) systems have been developed for the automatic detection of polyps. This study aims to investigate the impact of an AI system applied in real time on the detection rate, compared with conventional detection by the endoscopist.

Aims & Methods: A prospective observational study was carried out by seven gastroenterologists in the Digestive Endoscopy Unit of a tertiary hospital. Colonoscopies were performed on consecutive patients for polyp screening or surveillance. High-definition colonoscopes were used for the examinations and an AI system was applied in real time.

Each procedure consisted of two phases: (1) an initial assessment was performed by the endoscopist who withdrew the endoscope after reaching the cecum, identifying all visualized lesions without resecting them, and (2) the colonoscope was reintroduced up to the cecal pole with an AI device. The automatic detection of the AI device was assessed by means of a light and sound signal.

The primary objective was to compare the detection rate of adenomas and polyps. Secondary objectives were to compare the total number of polyps and serrated lesions detected, as well as detection of polyps by size, location and morphology, with and without the device.

	Examination by endoscopist	Examination IA assisted	p value
Adenoma detection rate (ADR)	0.7575	0.7878	0.678
Polyp detection rate (PDR)	0.7878	0.8333	0.505
Total number of adenomas, n (mean)	159 (2.41)	188 (2.85)	< 0.05
Total number of polyps, n (mean)	193 (2.92)	243 (3.68)	< 0.05
Total number of serrated lesions, n (mean)	34 (0.52)	55 (0.83)	< 0.05
Polyp location			
Right colon, n (%)	70 (36.3)	98 (40.3)	< 0.001
Transverse colon, n (%)	52 (26.9)	64 (26.4)	0.012
Left colon, n (%)	71 (36.8)	81 (33.3)	0.018
Polyp morphology			
Paris 0-IIa, n (%)	123 (63.7)	165 (67.9)	< 0.001
Paris 0-IIb, n (%)	8 (4.2)	13 (5.3)	0.096
Paris 0-IIc, n (%)	1 (0.5)	1 (0.4)	1.000
Paris 0-Ip, n (%)	17 (8.8)	17 (7)	1.000
Paris 0-Is, n (%)	41 (21.2)	42 (17.3)	0.564
LST, n (%)	3 (1.6)	5 (2.1)	0.157
Polyp size			
0-5 mm, n (%)	135 (70)	178 (73.2)	< 0.001
6-9 mm, n (%)	30 (15.5)	33 (13.6)	0.450
> 10 mm, n (%)	28 (14.5)	32 (13.2)	0.102

Table. Detection of adenomas and polyps and characteristics.

Results: The sixty-six patients included in the analysis were examined simultaneously by colonoscopy, and the AI device was applied. The AI system identified a greater mean number of adenomas (2.85 vs 2.41, p<0.05) and polyps (3.68 vs 2.92, p<0.05), as well as a greater number of serrated

lesions (0.83 vs 0.52, p <0.05), compared with the endoscopist. No significant differences were found in the adenoma detection rate (78.8% vs 75.7%; p > 0.05).

AI significantly increased the detection of small lesions (178 vs 135, p<0.001), and those of Paris type IIa flat morphology (165 vs 123, p<0.001). There were no differences in the detection of lesions larger than 5 mm or with other morphologies.

Conclusion: In a high-risk population, the application of an AI system allowed a significantly higher number of polyps and adenomatous lesions to be detected, at the expense of small lesions and those with flat morphology, compared with conventional evaluation by the endoscopist. There were no differences in the adenoma detection rate.

COMPARISON OF LOWER GI ENDOSCOPIC SUBMUCOSAL DISSECTION OUTCOMES: WESTERN VS. ASIAN COUNTRIES

S. Kannan[1], P. Mundre[1], R. Lord[1]
[1]Bradford Teaching Hospitals NHS Foundation Trust, Gastroenterology, Bradford, United Kingdom

Contact E-Mail Address: sakthikannan12dis@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) has been routinely used for en-bloc resection of superficial lower GI neoplasms as it provides precise information on the histology, margins and invasion (lateral and deep). The meta-analysis by Fuccio et al (2017, pp 74) compared the outcomes of the Asian countries with the non-Asian countries and concluded that there was a high disparity between the two groups. There were higher R0 resections rates and lower postoperative complications, and recurrences at 12 months in the Asian setting, suggesting that the possible factors could be the low number of ESD procedures and reduced expertise in this field in the West.

Aims & Methods: We analysed the key performance indicators of Colorectal ESDs at a teaching hospital in the UK from 2017 to 2022. The procedures were performed by a single operator, who was trained in the West and has had no prior exposure to the Eastern training framework and guidelines. All procedures done between the above years were included starting from 2017 when ESD service was newly introduced in hospitals. Data was collected on R0 resections rates(deep and lateral margins free of neoplasia), post-operative bleeding and perforation rates, and recurrences/residual lesions at 6-12 months post-resection. We then compared the data with the results of the meta-analysis previously published. We then theorised the probable reasons for the disparity, based on potential contributing factors.

Results: The data presented in the table suggests that comparable outcomes to the Standard ESD technique in Asian countries can also be achieved in Western countries. The study analyzed data from 82 patients for R0 resection, 82 patients for delayed bleeding, 84 patients for perforation, and 38 patients for recurrence at 12 months. The discrepancy in the number of patients between the primary procedure and post-resection surveillance is attributed to various factors, including patient preferences, the need for further management of malignant lesions, and patients awaiting their follow-up appointment.

Parameters/Setup	Our Outcomes in Percentages (2017-2022)	Asian - Fuccio et al (2017, pp 74)	Non-Asian- Fuccio et al (2017, pp 74)
R0 resection	83.1%	85.6%	71.3%
Delayed Bleeding	1.3%	2.4%	4.2%
Perforation	1.2%	4.5%	8.6%
Recurrence at 6-12 months	0%	1.1%	5.2%

Table.

Conclusion: Our data indicate that the Eastern standards can be met in the West with regard to key performance indicators for lower GI ESD. The reasons for underperformance can't be attributed to training and exposure. The above table and analysis indicate a need for the exploration of other probable factors and an updated review of Eastern and Western standards.

Introduction: The endoscopic appearance of colorectal cancer (CRC) with high microsatellite instability (MSI-H) is poorly understood. This study aimed to develop and validate a novel scoring system based on the endoscopic appearance of CRC to predict MSI-H.

Aims & Methods: We retrospectively reviewed the records of patients with CRC. A derivation cohort of 764 patients was used to develop and internally validate the model. The model was first developed as a nomogram, and then modified into a novel scoring system. The scoring system was then externally validated in an independent cohort of 468 patients. The performance of the model was determined by receiver operating characteristic (ROC) curve, calibration belt, and decision curve analysis (DCA).

Results: The novel scoring system is composed of mucus surface (+10.0 points), tumor size ≥ 57 mm (+7.1 points), right-sided CRC (+4.2 points), and intestinal stricture (+3.9 points). With a cut-off value of 14.0 points, the area under the ROC curve (AUC), specificity, and sensitivity for predicting MSI-H were 0.897, 0.911, and 0.690, respectively, in the derivation cohort. In the validation cohort, the AUC, specificity, and sensitivity were 0.933, 0.937, and 0.756, respectively. A score ≥ 14.0 points indicates MSI-H with a specificity > 90%. Good consistencies were confirmed in the calibration belt analysis, and DCA showed that the scoring system yielded a positive net benefit.

Conclusion: We developed and validated a novel scoring system based on the endoscopic appearance of CRC to predict MSI-H. The scoring system is convenient to use and accurate.

Disclosure: Nothing to disclose.

Introduction: Large or complex colorectal polyps have a greater than average risk of malignancy, incomplete resection/recurrence or complications associated with treatment. Appropriate management is therefore crucial for preventing cancer and improving patient outcomes. UK guidelines exist for the management of large non-pedunculated colorectal polyps (LNPCPs)[1]. This review aims to evaluate the case mix and outcomes from a multidisciplinary team (MDT) approach to managing such polyps.

Aims & Methods: This study is a retrospective analysis of cases referred to the Complex Polyp MDT at a single centre in the United Kingdom between January 2020 and December 2021 (two-year period). Data collected included patient characteristics, index investigation and polyp complexity as defined by the size, morphology, site, and access (SMSA) score.

Therapy details, including standard endoscopic techniques (EMR, polypectomy) and advanced options (ESD, eFTR, Endorotor), as well as trans-anal surgery, were documented. Complications and re-admission needs were recorded, along with recurrence rates at first surveillance. Any subsequent treatment for recurrence was also documented.

An electronic survey was conducted among MDT members to gather feedback on the MDT's impact on clinical practices, perceived benefits, and suggestions for improvement.

Results: Over a two-year period, 258 cases were reviewed at the complex polyp MDT, with annual cases rising from 91 to 167. After exclusions (diagnosed cancer prior to MDT, discussion regarding management of already treated polyps), 220 cases were reviewed. The median polyp SMSA score was 11, with 34% of polyps classified as level 3 and 38% as level 4. Conservative management was recommended in 35 cases, in patients with a median age of 81 (IQR 78-84), 73% of which suffered from severe systemic disease. 110 colonic polyps (62% overall) were treated with EMR. 67 rectal polyps (38%) were managed with a combination of therapies, including EMR (36, 54%), ESD (13, 19%), or trans-anal surgery (18, 27%). Only 4 complications were observed: post-polypectomy bleeding in 3 cases (from rectal EMR, colonic EMR, and trans-anal surgery) and a small perforation from a low rectal ESD. All complications were managed conservatively, and patients discharged the next day.

MDT discussion led to downgrading of 44% of cases initially deemed high-risk for malignancy; none were subsequently found to contain cancer. Three cases were upgraded to high-risk; none were found to contain cancer, but all contained high-grade dysplasia.

Of 26 patients who experienced recurrence after initial polypectomy, 17 (65%) underwent endoscopic therapy, while others either had surgical excision or were awaiting ongoing surveillance.

Of those who underwent endoscopic treatment, 16 cases (94%) were successfully treated using various techniques, such as eFTR and endoscopic mucosal debridement (Endorotor resection) via one or more further sessions. 3 of the 16 recurrent lesions contained HGD. The remaining case required right hemicolectomy for early-stage adenocarcinoma. Of note, the initial site check in that case had identified HGD.

Survey responses reflected an overall feeling of significantly improved management of complex polyps since the inception of the MDT. Improvements included increased understanding of therapeutic options and better polyp assessment amongst endoscopists.

Conclusion: Multidisciplinary team management of large or complex polyps is effective, and meets standards set by national guidance. The team approach fosters learning amongst members, leading to wide reaching improvements in practice.

Introduction: Videocolonoscopy (VCC) remains the gold standard in the diagnosis of colorectal carcinoma (CRC) and premalignant lesions. Around 26% of polyps are missed during conventional colonoscopy due to operator (e.g., expertise, fatigue, etc.), and technical (e.g., suboptimal bowel preparation and withdrawal time) dependent-factors.

Artificial intelligence (AI) aids in adenoma and polyp detection, thus increasing adenoma and polyp detection rates (ADR and PDR, respectively).

Aims & Methods: We aim to evaluate the real-world effectiveness of an AI-assisted colonoscopy (AI-VCC) and compare the results among experts and non-experts endoscopists. Consecutive patients ≥45 years old who underwent VCC (Nov/2020-Mar/2021) were invited to participate. Patients with BBPS≤6, history of inflammatory bowel disease, familial polyposis syndrome, colorectal carcinoma, colorectal surgery, or uncontrolled coagulopathy were not considered. The study protocol was conducted according to the declaration of Helsinki and approved by the local Institutional Review Board (IRB). All patients signed an informed written consent. First, a standard HD-VCC was performed. Then, an AI-VCC was performed by a second operator blinded to previous findings.

We determined the adenoma detection rate (ADR) as a quality indicator of the procedure. The polyp detection rate (PDR), and the adenoma and polyp miss rates (AMR and PMR, respectively) were also calculated. The results were compared between experts and non-experts endoscopists. Data was analyzed in R v4.0.

Results: A total of 115 patients were included. Median age was 57.0 (51.0 - 67.5) years, 82/115 (71.3%) were females. 58/115 (50.4%) patients had a total of 205 polyps/adenoma, with a PDR and ADR of 132/205 (64.3%) and 73/205 (35.6%) with VCC, respectively: 19/205 (9.3%) NICE II, 7/205 (3.4%) >10 mm. With AI-assistance, the ADR and PDR increased from 16.5% to 18.2% and from 50.4% to 60%, respectively.

According to the level of expertise, the ADR increased from 10.8% to 16.2% in the junior group with the AI-VCC, whereas no difference in ADR was observed in the senior cohort (Table 1). The calculated PMR was 43.13% while the AMR was 5.19%. Sensitivity among different colon segments ranged from 56.25% (rectum) to 78.26% (ascending colon). Meanwhile, capability of AI for appropriate polyp and adenoma presence discharging (negative predictive value, NPV) ranged from 61.54% (sigmoid) to 89.09% (cecum). However, lower rates for specificity (8.42-49.49%) and positive predictive value (PPV, 9.89-19.78%) were observed due to high false positives. (Table 2).

	Standard VCC	Secondary AI-assisted VCC	Standard + AI-assisted VCC	Missed Lesions Cases
		Total (n=115; 100%)		
ADR	19 (16.5)	6 (5.2)	21 (18.2)	2
PDR	58 (50.4)	33 (28.7)	69 (60.0)	11
		Senior (n=78; 67.8%)		
ADR	15/78 (19.2)	3 (3.8)	15/78 (19.2)	0
PDR	39/78 (50.0)	23 (29.5)	49/78 (62.0)	10
		Junior (n=37; 32.2%)		
ADR	4/37 (10.8)	3 (8.1)	6/37 (16.2)	2
PDR	19/37 (51.1)	10 (27.0)	20/37 (54.0)	1

ADR, Adenoma detection rate; PDR, polyp detection rate; HD-VCC, high-definition video colonoscopy; AI-VCC, Artificial intelligence-assisted video colonoscopy

Table 1. ADR and PDR during HD-VCC and AI-VCC in senior and junior endoscopists.

Conclusion: The AI-assisted polyp detector is a feasible tool to aid endoscopists during screening colonoscopy. Additionally, with AI-assistance, junior endoscopists can achieve an ADR comparable to that of senior endoscopists. NCT04915833.

PROGNOSIS AFTER COLD POLYPECTOMY IN ELDERLY PATIENTS

M. Matsumoto[1], K. Nagashima[1], N. Kawagishi[1], M. Dazai[1], M. Onodera[1], S. Kato[1]

[1]*Sapporo Medical Center NTT EC, Dept. of Gastroenterology, Sapporo, Japan*

Contact E-Mail Address: miosakra@outlook.jp

Introduction: The number of elderly people undergoing colonoscopy is increasing. Along with this trend, there has been an increase in the use of cold polypectomy as a safe procedure for elderly patients. However, it remains unclear whether cold polypectomy is effective for elderly patients.

Aims & Methods: We conducted a study to examine the prognosis of elderly patients who underwent Cold Polypectomy after 5 years.

We retrospectively studied elderly patients aged over 80 who underwent cold polypectomy at Sapporo Medical Center NTT EC between April 2014 and July 2016, and assessed their 5-year prognosis after the procedure (2019-2021).

Results: The number of Cold Polypectomy procedures performed in our hospital during the evaluation period for elderly patients aged 80 and above was 152 cases. The median age was 82 years (range: 80-89), and there were 34 cases (22.3%) of very elderly patients aged 85 years or older. No cases of postoperative bleeding or complications were observed in any of the cases.

Upon confirmation of the condition after 5 years, 50.6% (77 cases) were unable to be followed up due to completion of outpatient visits, etc., 36.8% (56 cases) were confirmed to be alive, and 12.5% (19 cases) were confirmed to have passed away. Among the cases that resulted in death, 12 cases were due to cancer, 2 cases were due to pneumonia, 4 cases were due to cardiovascular-related deaths, and 1 case was due to liver cirrhosis. There were no deaths due to colorectal cancer among the cases that resulted in cancer-related deaths. And no cases of colorectal cancer treatment were observed after Cold Polypectomy. So there is a possibility of preventing the occurrence of new colorectal cancer, although it may not necessarily prevent colorectal cancer death.

We compared the Charlson Comorbidity Index (CCI) between the survival and death cases. The CCI was 1.65 in the survival cases and 3.31 in the death cases, showing a significantly higher value in the death cases ($p<0.001$). Additionally, we drew a ROC curve and obtained a cut-off value of 2 points.

Conclusion: Cold polypectomy can be a preventive measure for colorectal cancer even in elderly patients. Before deciding whether to perform a cold polypectomy on elderly patients, their individual suitability should be evaluated. CCI could potentially be used as a criterion for determining the suitability for the procedure.

Disclosure: Nothing to disclose.

Introduction: Fewer adenomas are detected at colonoscopy in women compared to men. Failure to detect adenomas and sessile serrated polyps is associated with an increased risk of post-colonoscopy colorectal cancer (PCCRC). There are differences between men and women that may influence different diagnostic yields by colonoscopy. Different attitudes towards the procedure may account for a lower attendance rate for colonoscopy in women.

Colonoscopy can be technically more difficult in women than men, and women have an increased need of analgesia and sedation. Men and women have a different probability of complete examinations. A considerable variation in colonoscopy quality among different endoscopists has been observed in two randomized controlled clinical screening trials: the Nordic-European Initiative on Colorectal Cancer (NordICC) trial (1) and the SCREESCO (Screening of Swedish Colons) trial (2, 3).

Endoscopist performance may affect male and female patients differently given the more technically challenging procedure in women. In previous studies, the adenoma detection rate tends has been higher in men while high-grade sessile serrated polyps, in particular those found in right colon, are more frequent in women , and the risk for post-colonoscopy CRC (PCCRC) within three years was lower in men (6.9%) than in women (7.6%) in Sweden and in England (7.0% vs 8.0%).

Aims & Methods: Aims: The aim of this study was to investigate whether this was in part due to the greater difficulty of conducting colonoscopy in women, with the difference being more apparent in colonoscopies conducted by less skilled endoscopists.

Methods: Cross-sectional exploratory analysis of data on 16,551 individuals undergoing a primary colonoscopy (PCOL group) or colonoscopy after positive fecal immunochemical test (FIT group) within the randomized controlled trial SCREESCO, Screening of Swedish Colons. Endoscopist skill (low or high) was determined based on each endoscopist's adenoma detection rate in all first-time colonoscopies performed in SCREESCO. Colonoscopy yield was assessed by gender in each study group and by endoscopist adenoma skill.

Effect modification of the gender difference by endoscopist adenoma detection rate (a measure of endoscopist skill) on colonoscopy yield was assessed by use of multiplicative interaction tests.

Results: Most endoscopists performed equally many colonoscopies in men and women (median 52% men) and the adenoma detection rate was higher in male patients (median: 32.6%) compared to female patients (median: 22.9%). There were no signs of effect modification of the risk ratio of any finding (men vs women) by endoscopist skill in the PCOL group (p=0.33) and the FIT group (p=0.3).

The proportion of incomplete index colonoscopies was lower in men than in women in both groups and there was no effect modification by endoscopist skill in neither the PCOL group (p=0.41) nor the FIT group (p=0.96).

Conclusion: Endoscopist skill affected yield similarly for men and women in both the PCOL group and the FIT group, both regarding diagnostic yield and caecal intubation rate. Differences in endoscopist adenoma detection rate in male and female patients suggest that quality indicators should be assessed by patient gender.

EFFICACY AND SAFETY OF COMBINED ENDOSCOPIC MUCOSAL RESECTION AND ENDOSCOPIC FULL-THICKNESS RESECTION (HYBRID-EFTR) FOR LARGE NON-LIFTING COLORECTAL ADENOMA

B. Meier[1], I. Elsayed[1], N. Seitz[1], A. Wannhoff[1], K. Caca[1]
[1]Klinikum Ludwigsburg, Ludwigsburg, Germany

Contact E-Mail Address: benjamin.meier@rkh-gesundheit.de

Introduction: Endoscopic full-thickness resection (EFTR) with the full-thickness resection device (FTRD) has become the standard technique for selected non-lifting colorectal adenoma but tumor size is the major limitation. However, large lesions might be approached in combination with endoscopic mucosal resection (EMR).

Herein, we report the largest single-center experience to date of combined EMR/EFTR (Hybrid-EFTR) in patients with large (≥ 25 mm) non-lifting colorectal adenoma not amenable to EMR or EFTR alone.

Aims & Methods: This is a single-center retrospective analysis of consecutive patients who underwent Hybrid-EFTR of large (≥ 25 mm) non-lifting colorectal adenoma.

Outcomes of technical success (successful advancement of the FTRD with consecutive successful clip deployment and snare resection), macroscopic complete resection, adverse events and endoscopic follow-up were evaluated.

Results: 75 patients with non-lifting colorectal adenoma were included. Mean lesion size was 36.5 mm (range 25-60 mm) and 66.6 % were located in the right-sided colon. Technical success was 100 % with macroscopic complete resection in 97.3 %. Mean procedure time was 83.6 minutes. Adverse events occurred in 6.7 % leading to surgical therapy in 1.3 %. Histology revealed T1 carcinoma in 16 %.

Endoscopic follow-up was available in 93.3 % (mean follow-up time: 8.1 months, range 3-36 months) and showed no signs of residual or recurrent adenoma in 88.6 %. Recurrency (11.4 %) was treated endoscopically.

Conclusion: Hybrid-EFTR is safe and effective for advanced colorectal adenoma which cannot be approached by EMR or EFTR alone. Hybrid-EFTR expands the indication of EFTR substantially in selected patients.

Introduction: Optical diagnosis of colorectal polyps is challenging. Artificial intelligence based systems allow the detection and histological characterization of polyps.
Aims & Methods: The aim of this study is to compare the diagnostic accuracy of Polydeep, a CADe/x system with expert endoscopists for the optical diagnosis of colorectal polyps.
We designed a diagnostic test study based on the evaluation of 2364 polyps still images with confirmed histological diagnosis (69.12% adenomas, 14.8% Traditional Serrated Adenoma, TSA, or Serrated Sessile Lesion, SSL, 16.7% hyperplastic). The lesions was classificated as neoplastic (adenomatous, TSA, SSL) and no neoplastic (hyperplastic lesions). The images were shown to Polydeep and to the expert endoscopists to obtain the predicted histology. The endoscopists classified the lesions as adenoma, TSA, SSL or hyperplastic lesions, while PolyDeep classified the lesions as neoplastic and non-neoplastic. We calculated sensitivity, specificity, predictive values, likelihood ratios, diagnostic odds ratio and the Area Under the Curve (AUC). We compared sensitivity and specificity using the McNemar test and the AUC using the homogeneity areas test.

	Endoscopists	PolyDeep	P-value
Sensitivity	91.56%	90.34%	<0.001
Specificity	35.23%	35.31%	0.355
PPV	88.21%	88.72%	
NPV	44.07%	39.37%	
LR +	1.41	1.39	
LR -	0.24	0.27	
OR	5.89	5.11	
AUC	0.634	0.628	0.91

Table 1: The table show the comparison of diagnostic test between endoscopists and PolyDeep, furthermore the AUC and p-values of McNemar test and the comparison between both ROC curves. Positive Predictive Value (PPV), Negative predictive Value (NPV), positive Likelihood Ratio (LR+), negative Likelihood Ratio (LR-), Odds Ratio (OR), Area Under the Curve (AUC).

Results: PolyDeep classified 77.62% of evaluated lesions as neoplastic and the endoscopists classified 87.1% of the lesions as neoplastic (adenomas: 75.76%, TSA: 3.86%, SSL: 7.55%). The diagnostic accuracy results as well as the comparison between PolyDeep and the endoscopists for the neoplastic category is shown in the attached table.
Conclusion: Polydeep, a CADe/x system, is as accurate as expert endoscopists for the optical diagnosis of colorectal polyps.
Disclosure: Nothing to disclose.

Introduction: Although CADe/x systems increase colorectal polyp detection, their ability to predict histological diagnosis is limited.
Aims & Methods: The aim of this study is to determine which factors related to morphology, histology and the image characteristics are associated with histology prediction by PolyDeep, a CADe/x system.
For this analysis, 5546 still images of colorectal polyps collected in PIBAdb database (https://www.iisgaliciasur.es/home/biobanco/colorectal-polyp-image-cohort-pibadb/?lang=en) were used. The images were obtained from videos recorded by endoscopist. Each image was associated with the endoscopy description (morphology, size), the final histology diagnosis and the characteristics (size, area) related with the Red, Green and Blue model (RGB model) and the Hue, Saturation and Value model (HSV model). Finally, the Convolutional Neural Network (CNN) determined the probability a polyp was classified as neoplastic lession (adenomatous, Traditional Serrated Adenoma,TSA, Sessile Serrated Lession, SSL). We determined Polydeep classified lesions as neoplastic if the probability was ≥0.5. We performed three analysis: (1) linear multiple regression in order to determine which variables are associated with the probability of classification as neoplastic lesions. (2). A multivariate logistic regresion analysis to define the variables associated with the classification as a neoplastic lesions. (3) A multivariate logistic regression to establish which variables are associated with missclassification of polyps. We use the R software for statistical computing.
Results: PolyDeep classified 84,51% of the lesions as neoplastic lession and managed to correctly classify 85.02% of the evaluated polyps (92.8% adenomas, 82.5% TSA, 84.2% SSL and 51.6% hyperplastic). The R^2 in the multiple linear regression is the 0.3655. The model associated to the neoplastic diagnosis has an Akaike Information Criterion (AIC) of 3363.3 and the model associated with missclassification, has an AIC of 3547.5. The variables associated to each regression model showed in the attached table.

Predictor variables		Neoplastic lesion classification - Predictive model		Missclassification - Predictive model
		Multiple linear regression OR / (CI 95%) R^2 = 0.3655	Multivariate logistic regression OR / (CI 95%) AIC = 3363.3	Multivariate logistic regression OR / (CI 95%) AIC = 3547.5
Histology	TSA	-0.09 / (-0.11 - 0.07)	0.44 / (0.32 - 0.61)	1.88 / (1.34 - 2.60)
	SSL	-0.05 / (-0.07 - 0.02)	0.65 / (0.47 - 0.92)	2.52 / (1.77 - 3.53)
	Hyperplastic	-0.37 / (-0.39 - 0.35)	0.17 / (0.13 - 0.22)	15.67 / (11.98 - 20.63)

HIGH-RISK POLYPS AT SCREENING COLONOSCOPY ARE ASSOCIATED WITH UPPER GASTROINTESTINAL CANCER MORTALITY

J. Zessner-Spitzenberg[1,2], E. Waldmann[3,2], L. Jiricka[4], L.-M. Rockenbauer[1,2], D. Penz[5,2], J. Cook[1,2], B. Majcher[1,2], A. Hinterberger[1,2], A. Asaturi[1,2], M. Trauner[1], M. Ferlitsch[2,1]

Contact E-Mail Address: jasminzesp@gmail.com
Introduction: Currently, gastric cancer screening is only cost-effective in countries with high incidence. Colorectal cancer screening is an effective method for the reduction of CRC incidence and receives high attendance rates. Integrated screening, where gastroscopy is performed in conjunction with colonoscopy, could help reduce the gastric cancer screening procedure burden in countries with low or intermediate incidence.
However, there is a lack of population-based studies providing data on groups at high risk for mortality from gastric malignancies that might benefit from this approach.
Aims & Methods: In this retrospective analysis of a colorectal cancer screening program database, we used Cox proportional hazards model to identify an association of high-risk and low-risk finding (polyps ≥ 10mm or with high-grade dysplasia vs <10 mm and no high-grade dysplasia or advanced adenoma vs non-advanced adenoma) with time to death from upper gastrointestinal (esophageal and gastric) cancer. To quantify the burden of deaths from upper GI cancer in screening participants with high-risk or low-risk polyps in relation to the general population, we calculated standardized mortality ratios.
Results: We included 331,284 CRC high-quality screening colonoscopies in our study. The median follow-up time was 5.04 years (95% CI 5.03-5.07). 4.4% of participants had polyps ≥10 mm or with HGD and 7.7% had advanced adenomas. At the end of the study period, 296 deaths of upper GI cancer had occurred, corresponding to a rate of 10.29 deaths per 100,000 person years in women and 26.61 deaths per 100,000 person years in men. In participants with non-advanced adenomas, hazards for upper GI cancer death were similar compared to participants with advanced adenomas (HR 1.37, 95% CI 1.01-1.72 and HR 1.35, 95% CI 0.94-1.95) when taking participants with a negative colonoscopy as the reference. However, in participants with polyps ≥10 mm or HGD, hazards for upper GI cancer death were higher (HR 1.70, 95% CI 1.07-1.66). Participants with polyps <10 mm and no HGD experienced significantly fewer deaths from upper GI cancer than the general population (SMR 0.71, 95% CI 0.61-0.83, p<0.001), however, participants with high-risk polyps had an upper GI cancer mortality which was similar to that of the population (SMR 0.90, 95% CI 0.60-1.29, p = 0.6).
Conclusion: CRC screening participants with polyps <10 mm and no HGD have a lower risk for mortality from upper gastrointestinal cancers compared to participants with polyps >10 mm and HGD or the general population. In these participants, additional upper GI screening efforts might not be useful. However, future studies will demonstrate whether integrated screening with additional gastroscopy is effective in CRC screening participants with large or highly dysplastic polyps.

THE DEVELOPMENT AND CLINICAL EVALUATION OF A NATURAL LANGUAGE PROCESSING-BASED AUTOMATIC SURVEILLANCE SYSTEM FOR COLORECTAL POST-POLYPECTOMY PATIENTS

C. Shi[1], L. Wu[1], J. Li[1], H. Yu[1]
[1]*Renmin Hospital of Wuhan University, Wuhan, China*

Contact E-Mail Address: wu_leanne@whu.edu.cn

Introduction: The adherence of doctors and patients to published colorectal post-polypectomy surveillance guidelines varies greatly, and patient follow-up is critical but time-consuming.

Aims & Methods: Aims: We aimed to develop an automatic surveillance (AS) system to accurately identify post-polypectomy patients, assign surveillance intervals for different risks of patients and proactively follow up with patients on time.

Methods: The endoscopic and pathological reports from 47,544 patients from three hospitals were used to develop AS system based on natural language processing. The performance of AS system was fully evaluated in internal and external tests according to five different guidelines worldwide and compared with that of doctors. Furthermore, a multi-reader-multi-case (MRMC) trial was conducted to evaluate the effect of AS system on improving doctors' guideline adherence and efficiency, and a prospective trial was performed to evaluate the success rate for automatically informing patients and its effect on reducing the burden of nurses.

Results: In internal, external 1, and external 2 tests, the system reached an overall accuracy of 99.73%, 99.54%, and 99.77% for identifying different types of patients, respectively; and achieved an overall accuracy of ≥99.45%, ≥98.89%, and ≥98.56% for stratifying patients' risk levels and assigning surveillance intervals according to five guidelines. The system greatly increased the accuracy of doctors (98.67% *vs.* 78.10%, p=0.043) in MRMC trial. In a prospective trial, AS system successfully informed 93·18% of patients, and significantly reduced the follow-up time cost (127.4s *vs.* 14.02s per patient).

Conclusion: This system has great potential to improve doctors' adherence to guidelines while relieving the workload of doctors and nurses.

Disclosure: The authors declare no conflict of interest.

VIRTUAL REALITY AS AN ALTERNATIVE TO SEDATION DURING COLONOSCOPY: A PROSPECTIVE EQUIVALENT STUDY IN NANCY

E. Neuville[1], J. Sitte[1], C. Baumann[2], M. Francois[1], S. Daude[1], B. Caron[1], M. Vinson[1], M. Simonnot[1], M. Bensenane[1], J.-B. Chevaux[1], M. Schaefer[1]
[1]*University Hospital of Nancy, Gastroenterology, Nancy, France,* [2]*University Hospital of Nancy, Unit of Methodology, Nancy, France*

Contact E-Mail Address: elise.neuville@aol.com

Introduction: Colonoscopy is an invasive procedure that may cause patients pain and discomfort. Moderate to deep sedation is mostly used to allow the quality of the procedure and patients comfort. However, sedation is associated with some risks and side effects. Virtual reality (VR) offers immersive and three-dimensional experiences that distract attention and patients pain. This prospective study aims to define rate of complete colonoscopies with sedation and VR to determine if the two methods are equivalent.

Aims & Methods: 140 adults patients who underwent a ambulatory colonoscopy were included between April 2021 and December 2022 at University Hospital of Nancy : 70 patients under sedation and 70 others with VR. Patients and gastroenterologist completed questionnaires. The main outcome was cecal intubation. Secondary outcomes were patient pain, anxiety and comfort, patient et gastroenterologist satisfaction, total time of procedure and resection of polyps if detected.

Results: The rate of cecal intubation was 95.7% for the sedation group and 88.6% for the VR group. There was no confounding factor. The univariate analysis did not allow to conclude to an equivalence between the two methods on the success rate at the threshold of 5% (p=0.685).

There was no statistically significative difference on pain (p=0.518) and anxiety (p=0.247) before the colonoscopy.

However, statistically significant difference was observed on peri-procedural pain between sedation group (0.9/10 on the numeric scale) and VR group (3.3/10) (p=0.0006) and on the state trait anxiety inventory (STAI) rising to 40.4/80 for sedation group and 42.4/80 for VR group (p=0.003).

Patient and gastroenterologist satisfaction (respectively p=0.441 and 0.629), patient comfort (p=0.215), total time of procedure (p=0.391) and resection of polyps (p=0.888) were equivalent.

Conclusion: Our study doesn't allow to conclude in a equivalence in the cecal intubation rate between VR and sedation.

Nevertheless, VR represents an interesting alternative for performing colonoscopy, eliminating risks associated with sedation while maintaining comfort and acceptable level of pain and anxiety for the majority of patients. Total time of procedure and polyps resection rate are not affected by the use of VR

Disclosure: Nothing to disclose.

Introduction: In recent years, the prevalence of colonic diverticulosis has been increasing all over the world. Colorectal lesions are occasionally found in proximity to the diverticulum. There are generally considered pseudodiverticulum and lack a muscularis layer. Therefore, endoscopic resection (ER) for such lesions is often contraindicated because of the high risk of perforation. Recently, several studies have reported which such lesions were treated via endoscopic submucosal dissection (ESD). However, the usefulness and safety of ESD for lesions in proximity to diverticulum (D-ESD) has not been fully investigated.

Aims & Methods: Aim of this study was to evaluate the usefulness and safety of D-ESD. We defined that the D-ESD was ESD for lesion within 3mm of a diverticulum in this study. This study was performed at Kobe University Hospital and Kishiwada Tokushukai Hospital, which are tertiary referral centers in Japan, between January 2010 and April 2020. Totally, twenty-six consecutive patients who underwent D-ESD were enrolled. We used two strategic approaches for D-ESD, depending on whether submucosal dissection of the diverticulum-associated area was necessary (strategy B) or not (strategy A).

Strategy A was indicated for lesions that submucosal dissection including the diverticulum was not necessary because there was sufficient space between the lesion and the diverticulum for mucosal cutting. Strategy A was

performed using the same technique as conventional ESD. Strategy B was indicated for lesions wherein sufficient space to make an incision could not be confirmed between the edge of the lesion and the orifice of the diverticulum. Strategy B used the pocket creation method (PCM), which provides stability of endoscopic manipulation and good countertraction to diverticulum part. The treatment outcomes and adverse events of the two strategic approaches were analyzed.

Results: Strategies A and B were applied in management of 17 lesions and 9 lesions, respectively. Most of lesions (23/26; 88.4%) were located in the right side of the colon. The median tumor size (range) was 33 (15-115) mm. As histological findings, A total of three adenomas, two sessile serrated lesions and 21 cancerous lesions were found. The cancerous lesions included 15 cases of intramucosal carcinoma, five cases of T1a, and one case of T1b. The median diverticular size (range) in all cases was 4 (3-10) mm. Except for one case in which ESD was discontinued because of the high risk of perforation due to deep tumor invasion into the diverticulum, all other cases were achieved en-bloc resection (25/26; 96.2%). The R0 resection and curative resection rates were 76.4% and 70.6% for Strategy A, and 88.9% and 77.8% for Strategy B, respectively. There was one case of lymphatic invasion in each of Strategies A and B. The median operative time was 69 minutes (24-140) for strategy A and 100 minutes (42-188) for strategy B. Regarding adverse events, two cases of intraoperative perforation and one case of delayed perforation occurred in the strategy A. On the other hand, no perforation was observed in strategy B, but two cases of post-electrocoagulation syndrome (PECS) were noted. There was no recurrence during the follow-up period (median duration: 24 months).

Conclusion: D-ESD achieved high en-bloc and R0 resection for both strategies. There were no cases of perforation in strategy B, which is considered to have a high risk of perforation. D-ESD may be a useful treatment option for such lesions.

Contact E-Mail Address: aihattor@east.ncc.go.jp

Introduction: Advancements in colonoscope technology have been identified as one of the factors that can affect the quality of colonoscopy, positively affecting adenoma detection rate (ADR). In recent years, new-generation endoscopic system (video system center and colonoscope) and 4K monitors have been released. These instruments provide endoscopists with higher resolution and lower noise images than previous-generation endoscopic instruments. However, it is unclear whether these new-generation endoscopic instruments can enhance the adenoma detection ability.

Aims & Methods: We aimed to clarify the colorectal adenoma detection ability of new-generation endoscopic instruments by comparing them with previous-generation endoscopic instruments. This study was a retrospective single-center study in patients undergoing screening colonoscopy or surveillance colonoscopy after endoscopic resection or surgical resection for colorectal neoplasm. The X1 group was the group of patients who underwent colonoscopy using new-generation endoscopic instruments (video system center: EVIS X1 CV1500, colonoscope: CF-XZ1200I/CF-EZ1500DI, monitor: 4K) between April 2022 and March 2023. The ELITE group was the group of patients who underwent colonoscopy using previous-generation endoscopic instruments (video system center: EVIS LUCERA ELITE CV290, colonoscope: PCF-H290ZI/CF-HQ290Z, monitor: Full HD) between April 2019 and March 2020. We conducted an analysis for propensity score matched patients using known factors (patient age, sex, purpose of colonoscopy, observation mode, and endoscopists' expertise) that may have affected the ADR. The patients who were familial adenomatous polyposis, lynch syndrome, or inadequate bowel preparation (Aronchick scale: over 3 score) were excluded. The primary outcome was the ADR. The secondary outcomes were the mean number of adenomas detected per procedure (MAP) and flat polyp detection rate (FDR). We also performed a subgroup analysis comparing ADR, MAP, and FDR by observation mode between white light imaging (WLI) and narrow band imaging (NBI).

Results: 480 patients in the X1 group and 1560 patients in the ELITE group were enrolled in this study. After propensity score-matching, 960 patients were finally included in the analysis (480 patients in each group). The patient characteristics were well balanced after propensity score matching between each group. The ADR in the X1 group was significantly higher than that in the ELITE group (55.0% vs 49.0% [McNemar test p=0.049]). The MAP and FDR in the X1 group were also significantly higher than that in the ELITE group (MAP(±SD), 1.52±2.25 vs 1.13±1.77, [Wilcoxon signed rank sum test p=0.004]; FDR, 50.0% vs 39.4%, [p<0.001]). In the subgroup analysis by observation mode, in NBI mode, the MAP in the X1 group was significantly higher than that in the ELITE group (1.52±2.00 vs 1.20±1.83, [Wilcoxon rank sum test p=0.047]). In WLI mode, the FDR in the X1 group was significantly higher than that in the ELITE group (46.3% vs 30.2%, [Fisher's exact test p=0.0012]).

	X1 group	ELITE group	p-value
ADR, n (%)	264/480 (55.0)	235/480 (49.0)	0.049*
MAP, mean (±SD)	1.52 (±2.25)	1.13 (±1.77)	0.004*
FDR, n (%)	240/480 (50.0)	189/480 (39.4)	<0.001*

Table.

Conclusion: Our study indicated that the use of new-generation endoscopic instruments improved the colorectal adenoma detection ability.

Disclosure: Nothing to disclose.

PROCEDURALIST FATIGUE NEGATIVELY IMPACTS QUALITY OF COLONOSCOPY – 'AN 'EFFECT' THAT MAY BE TRANSFERABLE' AFFECTING PATIENT, CLINICIAN AND HOSPITAL OUTCOMES

W.L. Tan[1], T.H. Wu[1], R. Alcock[1], T. Rahman[1]

[1]The Prince Charles Hospital, Gastroenterology, Brisbane, Australia

Contact E-Mail Address: weiliantan92@gmail.com

Introduction: The quality of colonoscopy is influenced by patient and operator factors. Studies investigating operator attentional fatigue on adenoma detection rate (ADR) have yielded conflicting results.

Aims & Methods: This study aims to compare ADR, polyp detection rate (PDR) and sessile serrated lesion detection rate (SSLDR) and complication rates between elective colonoscopies performed early and late in the list, across multiple operators (n>15), over 10 years, in a tertiary Brisbane (Australia) hospital.

A retrospective study was conducted on elective colonoscopies performed between 2012 and 2022 at The Prince Charles Hospital. 'Early procedures' are defined as procedures starting in the first hour of the first procedure starting and 'late procedures' are defined as procedures starting within the last hour of the last procedure starting. This pre-defined early and late procedures were used as surrogate markers for operator fatigue, accounting for a possible non-linear relationship between time and onset of fatigue, as well as the variation in number of colonoscopies performed every hour. Timing and the order of colonoscopy were used as alternative surrogates, in a secondary analysis.

Logistic regression was performed on all categorical outcome variables, and Poisson regression was modelled on continuous outcome variables, due to their non-linear distribution. Multivariate analysis included all potential confounding variables related to outcomes of interest. Statistical significance was defined as a P-value less than 0.05. Statistical analyses were performed using the SAS® statistical software (SAS Institute Inc, USA). Exclusion included; surveillance for IBD and elective ESD.

Results: In total, 15 proceduralist (11 gastroenterologists, 4 surgeons) performed 39, 206 elective colonoscopies from 2012 to 2022. The baseline characteristics of patients, year and procedure sessions are similarly distributed between the early and late groups.

Multivariant analysis found significant associations between late procedures and lower adenoma detection rates, polyp detection rates and SSL detection rates. After adjusting for age, gender, proceduralist, year, morning or afternoon procedure, and bowel preparation quality, PDR, ADR and SDR remain 20-28% lower in late colonoscopies compared with early ones. We also found that age, gender, proceduralist, year and bowel preparation independently affected ADR in multivariant analysis. However, morning or afternoon ADRs did not significantly differ after adjusting for other variables. Proceduralist were found to be the only additional significant variable for SDR in multivariant analysis. There was no significant association between timing of procedures and major adverse events.

Conclusion: This is the largest single-centre study on operator fatigue and its effect on colonoscopy quality. Although the minimum standards for ADR was achieved, 'late procedures' have statistically significant lower ADR, PDR and SSLDR compared to 'early procedures'. There was no difference in the complication rates between 'early procedures' and 'late procedures'.

This study highlights the detrimental effect of fatigue in later procedures affecting the quality of colonoscopies and may be applicable in principal to other procedural based clinical work. Importantly, this may or perhaps will or is having an impact on patient safety, satisfaction, outcomes and clinical KPI's for the operators and hospital administrators.

Introduction: The incidence of colorectal neuroendocrine tumors (NETs) has increased over the past decades with early detection during screening colonoscopy.[1,2] The C-NET STUDY is a Japanese multicenter prospective cohort study, in which patients with colorectal NETs were consecutively enrolled.[3]

Aims & Methods: The study aimed to evaluate the short-term outcomes of various methods of endoscopic resection for colorectal NETs. Among the C-NET STUDY registrants, patients with colorectal NETs who underwent endoscopic treatment as the initial therapy were included. Patients who received treatment at a previous institution before participating in this study, biopsy diagnosed but the resected lesion was not pathologically diagnosed as NET, and who had defective data were excluded. The study protocol stated that endoscopic treatment should be performed if the tumor size is <10 mm in depth from the mucosa to the submucosa, with no ulceration or depression on the surface. For lesions with no treatment consensus in various guidelines, treatment selection was determined by each physician according to their policy in clinical practice. With respect to endoscopic resection procedures, several techniques were available in clinical practice, including endoscopic mucosal resection with a ligation device (ESMR-L), endoscopic mucosal resection using a cap (EMR-C), and endoscopic submucosal dissection (ESD). The major outcome measurements were short-term treatment outcomes, including en bloc resection rate, complete resection (defined as en bloc resection with tumor-free margin (R0)) rate, need for hospitalization, and treatment-related complications based on treatment modalities. Clinicopathological risk factors of incomplete resection (R1/RX) was also examined.

Results: A total of 472 patients with 477 colorectal NETs received endoscopic treatment. Of these, 418 patients with 421 lesions, who met the eligibility criteria, were included in the analysis. The median patient age was 55 years, and 56.9% of the patients were male. The lower rectum was the most common site (88.6%), and lesions <10 mm accounted for 87% of the cases. Among all cases, en bloc resection and R0 resection were achieved in 421 (100%) and 398 (94.5%) lesions. A total of 267 (63.4%) patients required hospitalization for treatment, with a median hospital stay of 3 days. Endoscopic mucosal resection with a ligation device (ESMR-L, 56.5%) was the most common method, followed by endoscopic submucosal dissection (ESD, 31.4%) and endoscopic mucosal resection using a cap (EMR-C, 8.5%). R0 resection rates <10 mm were 95.5%, 94.8 %, and 94.3% for ESMR-L, ESD, and EMR-C, respectively. All the treatment-related complications observed in 16 (3.8%) patients were treated conservatively. There were no independent clinicopathological risk factors for R1/X resection.

Conclusion: ESMR-L, ESD, and EMR-C were equally effective and safe techniques for colorectal NETs with diameter <10 mm (UMIN000025215).

Introduction: With a growing interest in sex-specific differences in bowel preparation outcomes, current literature shows inconsistent results. Females have been associated with poor bowel preparation [1], while males may have inadequate bowel preparation due to poor compliance with instructions [2].

Analyses of randomized clinical trials of 1L polyethylene glycol (PEG) plus ascorbic acid (ASC) indicated greater high-quality (HQ) cleansing success in females than in males despite greater adenoma detection in males [3].

Aims & Methods: The effectiveness and tolerability of 1L PEG+ASC was compared in males versus females in a large real-world population. This post-hoc analysis of an observational, multi-centre, retrospective study in Spain and Portugal included patients who received 1L PEG+ASC before undergoing a colonoscopy [4].

Cleansing quality was assessed using the Boston Bowel Preparation Scale (BBPS). Adequate success was BBPS ≥6 with all segmental scores ≥2 and HQ success was BBPS ≥8 with BBPS 3 in the right colon. Polyp detection rate (PDR), adenoma detection rate (ADR) and adverse events (AEs) were also assessed. Results are reported either as mean ± SD. Chic-square test was used to compare outcomes.

Results: A total of 13,169 patients, (M/F: 6,406/6,763 aged 57.6 ± 12.7 / 56.4 ± 13.4 years) were included. The main indication for colonoscopy was (in males vs females) colorectal cancer screening: 42.5% vs 41.2%; diagnostic: 25.9% vs 32.7%; follow up: 28.6% vs 23.9%; or other: 2.9% vs 2.2%. Bowel preparations were taken either as an overnight split dose (males vs females: 32.3% vs 33.2%) or a same-day split dose (67.7% vs 66.8%).

Males and females had similar (97.5% vs 97.1%) colonoscopy completion rates. Incomplete colonoscopies due to poor bowel preparation quality were rare and occurred at similar rates in males vs females (0.7% vs 0.9%). In the overall colon, adequate success was similar in males vs females (89.5% vs 89.1%) (p = 0.40) while HQ success was more frequent in females vs males (54.1% vs 51.8%; p = 0.007). In the right colon segment, adequate success was similar in males vs females (91.4% vs 91.6%; p = 0.61), while HQ success was more frequent in females vs males (50.7% vs 47.8%; p < 0.001). The mean BBPS was similar overall and by segment (Table). As expected from the literature, the PDR and ADR were greater in males vs females in the overall colon and in the right colon (Table).

Variable	Males (n=6,406)	Females (n = 6,763)	P-value
Overall colon adequate success, n (%)	5,734 (89.5)	6,023 (89.1)	ns
Overall colon high-quality success, n (%)	3,317 (51.8)	3,660 (54.1)	0.007
Right colon adequate success, n (%)	5,853 (91.4)	6,196 (91.6)	ns
Right colon high-quality success, n (%)	3,063 (47.8)	3,429 (50.7)	0.0009
Overall colon total BBPS, mean ± SD Right colon BBPS, mean ± SD Transverse colon BBPS, mean ± SD Left colon BBPS, mean ± SD	7.3 ± 1.8 2.4 ± 0.7 2.5 ± 0.7 2.5 ± 0.7	7.3 ± 1.9 2.4 ± 0.7 2.5 ± 0.7 2.4 ± 0.7	ns
PDR overall colon, n (%)	3,552 (55.5)	2,926 (43.3)	<.0001
PDR right colon, n (%)	1,643 (25.7)	1,381 (20.4)	<.0001
ADR overall colon, n (%) n[a]	2,200 (47.3) 4,654	1,753 (37.7) 4,656	<.0001
ADR right colon, n (%) n[a]	1,139 (27.2) 4,193	915 (21.5) 4,264	<.0001

[a]Number of patients for whom histological information was available.

Table. Sex differences in bowel preparation parameters with 1L PEG + ASC

Males had fewer adverse events than females (1.8% vs 2.7%; p = 0.0008). While 98.2% males did not report any adverse events, those who did reported nausea (0.9%) or vomiting (0.6%). Similarly, 97.3% females did not report any adverse events, but those who did reported nausea (1.5%) or vomiting (1.0%).

Conclusion: In real-world clinical practice, 1L PEG + ASC was effective and well tolerated in both males and females. Females attained greater HQ cleansing success both overall and in the right colon.

POOR TOLERANCE OF BOWEL PREPARATION FOR INDEX COLONOSCOPY DECREASES SURVEILLANCE RATE IN HIGH-RISK ADENOMA REMOVAL PATIENTS

A. Higashimori[1,2], N. Maeda[1,2], M. Nakatani[2], I. Yamamoto[2], T. Yanagida[2], D. Kin[2], Y. Matsumoto[2], K. Morimoto[2], E. Sasaki[2], T. Fukuda[2], T. Arakawa[2], Y. Fujiwara[1]

Introduction: Individuals with high-risk adenomas have increased risk of developing metachronous advanced adenomas and colorectal cancer after colonoscopy. While US and Japanese guidelines recommend triennial surveillance colonoscopy in this high-risk population, surveillance rate is suboptimal and barriers to surveillance colonoscopy should be investigated. Patient tolerance of bowel preparation (BP) affects the willingness to repeat colonoscopy. However, it is unknown whether poor tolerance of BP for index colonoscopy actually decreases the surveillance colonoscopy compliance.

Aims & Methods: This prospective study aimed to investigate the surveillance rate in patients with removal of high-risk adenomas and the predictors associated with the compliance in surveillance colonoscopy, focusing on the patient tolerance of BP for index colonoscopy. A prospective cohort study was conducted of 1157 consecutive outpatients receiving colonoscopy under moderate sedation between March and November 2019, and included patients aged 45-84 years old with removal of high-risk adenomas (≥ 1 cm, with villous features, with high-grade dysplasia, or ≥ 3 of any size). All patients with high-risk adenoma removal were educated to receive surveillance colonoscopy in 3 years, and surveillance rate was evaluated 3 years after removal of high-risk adenomas. Tolerance of BP was rated on a 5-point scale (1 = very intolerable to 5 = very tolerable) before receiving index colonoscopy and poor tolerance was defined as ≤ 2. The patients who did not receive surveillance colonoscopy were called to inquire the reasons. Patients who could not be contacted or had already died were excluded. Factors associated with surveillance colonoscopy compliance were determined by logistic regression analysis.

Results: A total 186 patients with high-risk adenomas were included, and 62 patients (33%) did not receive surveillance colonoscopy in 3 years. Poor tolerance of BP was found in 36 patients (36/186, 19%). The surveillance rate was significantly lower in patients with poor BP tolerance than those with good tolerance (48% vs 74%, *P* < 0.01), and decreased with poorer tolerance on index colonoscopy (*P* for trend < 0.05). In multivariate analysis, poor tolerance [odds ratio (OR)=2.45, 95% confidence interval (CI) 1.11-5.41] and absence of primary care physician (OR=4.63; 95% CI 1.60-13.4) were independent risk factors for non-compliance in surveillance colonoscopy. The main reason for non-compliance were unwillingness to repeat BP for surveillance colonoscopy (N =17/62, 27 %).

	Multivariate	
	OR (95%CI)	P value
Age, /1-year increase	1.04 (1.03-1.05)	0.001
Male sex	1.13 (0.85-1.52)	0.40
BMI, /1-kg/m^2 increase	1.05 (0.96-1.15)	0.28
Family history of colorectal cancer	0.93 (0.16-5.25)	0.92
Low education	0.92 (0.39-2.15)	0.90
Comorbidities	1.05 (0.51-2.13)	0.90
Low tolerance of BP for colonoscopy	2.45 (1.11-5.41)	0.006
Absence of primary care physician	4.63 (1.60-13.4)	0.001

Table.

Conclusion: Our findings highlight the need for improvement of the surveillance colonoscopy rate, especially for patients who had poor tolerance to BP on index colonoscopy and absence of primary care physician. Providing a well-tolerated BP regimen may lead to an increase in surveillance colonoscopy compliance.

Introduction: Colonoscopy is a promising diagnostic procedure for removal colorectal neoplasia, which can help prevent colorectal cancer. With an increasing trend towards colorectal cancer prevention, the number of colonoscopies and polypectomies is increasing, with approximately 11 million colonoscopy procedures performed annually in the United States alone. This has resulted in a significant burden on physicians and healthcare resources. Previous studies have demonstrated the utility of computer-aided diagnosis (CADx) systems in improving the characterization of colorectal polyps. However, the time-saving aspect of implementing AI-based CADx systems has not been thoroughly investigated. In this study, we aim to evaluate the potential of CADx systems to reduce the time required for polyp characterization.
Aims & Methods: This was a single center, retrospective study, was conducted at a university hospital between July 2021 and January 2022. We randomly extracted pathologically confirmed 100 polyps and one representative NBI image was prepared for each lesion. Three non-experts (a resident with no endoscopic experience, a gastroenterologist with one year of experience, and a gastroenterologist with two years of experience) were included. Randomly selected NBI images were shown separately to these doctors separately using laptop computer. They diagnosed each lesion diagnosed each lesion as neoplastic or non-neoplastic. For this study, we considered sessile serrated lesions (SSLs) as neoplasms. In the first examination, non-experts diagnosed without any assistance. After a four-week interval, a second examination was conducted with the assistance of a CADx system that provided a pathological prediction (neoplastic or non-neoplastic). We recorded the time required for diagnosing each polyp and compared it between the first and second examinations. The outcomes were, difference in diagnostic time and diagnostic accuracy of the endoscopists with or without CADx assistance. Wilcoxon signed rank test and McNemar test were used.
Results: Out of the 100 lesions, there were 72 adenomas/intramucosal carcinomas, 6 SSLs, 21 hyperplastic polyps, and 1 juvenile polyp. With the use of CADx, the mean (±SD) diagnostic time was significantly shorter than without CADx assistance (10.7±8.2 sec vs 5.3±3.6 sec, P value < 0.001). Regarding the diagnostic performance for differentiating neoplasms from non-neoplasms, diagnostic accuracy was significantly higher in with CADx assistance (75% [95%CI 69.7-79.8] vs 92.3% [95%CI 88.7-95.1], P value < 0.001). Assuming the mean number of polyps per patient as 1.87 (Taku Sakamoto, et al. *United European Gastroenterol J, 2019*), time saving effect was estimated as 17 min / 100 colonoscopies.
Conclusion: Our study demonstrates that the utilization of the CADx can save diagnosing time and increase accuracy for non-experts. Therefore, we suggest that the CADx has the potential to decrease examination time by expediting the diagnosis of lesions.

Introduction: Colorectal cancer (CRC) screening patients are prone to developing CRC when high-risk polyps were identified. Other malignancies, such as hepatobiliary cancers share risk factors like obesity, but there are no combined screening programs for these conditions.
The aim of this study was to assess whether patients with high-risk colonic polyps are more likely to die from liver related tumors than patients with a negative colonoscopy.
Aims & Methods: This was a retrospective cohort study. Screening participants of an Austrian colorectal cancer screening database were included. We assessed the association of time to death of hepatobiliary cancer by Cox proportional hazards model.
Results: 343,838 colonoscopies between 01/2007 and 12/2020 were included in the analysis, of which 17,678 (5.1%) were performed on patients with high-risk polyps. Hepatobiliary cancer mortality was more than twice as high in patients with high risk polyps (cumulative incidence of death 0.39%, 95% CI 0.37-0.41%) compared to patients with a negative colonoscopy (cumulative incidence of death 0.16%, 95% CI 0.16-0.16%). When adjusting for age and sex, no significant association of low-risk polyp status with liver cancer death (HR 1.18, 95% CI 0.93-1.51, p = 0.18) was observed, however having high-risk polyps at screening colonoscopy was significantly associated with liver cancer death (1.62, 95% CI 1.07-2.45, p= 0.02).
Conclusion: In a CRC screening cohort, patients with certain colonic polyp characteristics are at increased risk for mortality of hepatobiliary malignancies. Further studies are needed to determine whether an additional screening for liver diseases might be beneficial in these patients.

CARBON DIOXIDE VERSUS ROOM AIR IN COLONOSCOPY: A SINGLE CENTER RANDOMIZED CONTROLLED TRIAL

A. Altonbary[1], E. Abdel Maksood[1], E. Othman[1]
[1]Mansoura Specialized Medical Hospital, Gastroenterology and Hepatology, Mansoura, Egypt

Contact E-Mail Address: a.tonbary@gmail.com

Introduction: Pain, discomfort, and bloating can occur during and after colonoscopy, secondary to bowel distention. Insufflation is the major reason for bowel distention after a colonoscopy. Room air (RA) has slower re-absorption through the intestinal mucosa than carbon dioxide (CO2). Theoretically, with a faster resorption speed, abdominal pain, discomfort, and bloating are expected to be less with CO2 use. Nevertheless, in some clinical studies, CO2 was not found to be superior to RA in terms of post-procedure pain sensation.

Aims & Methods: The aim of this study was to compare abdominal pain sensation and bloating after colonoscopy using RA versus CO2 insufflation. A prospective randomized controlled study conducted on patients performing diagnostic colonoscopy. Enrolled patients were randomized to RA (group 1) versus CO2 insufflation (group 2). All patients were sedated with midazolam (2.5-5 mg) and all colonoscopies were performed by a single endoscopist. Abdominal pain sensation and bloating after the procedure as the primary outcome measure was assessed by a 10-point visual analogue scale (VAS), numerical rating scales from 0 (no pain) to 10 points (maximal pain). The participants were asked about abdominal pain and bloating at 15, 60, and 180 minutes and 24 hours post-procedural.

Results: From July 2021 to August 2022, a total of 64 patients were enrolled. There was 31 males and 33 females. Their mean age was 48.27±16 years. There was a statistically significant increase in abdominal bloating in group 1 (59.4%) compared to group 2 (18.7%), (P=0.018). Also, there was a statistically significant increase in abdominal pain sensation in group 1 compared to group 2 at 60 min (43.8% vs 21.9%) (P=0.011), 180 min (28.1% vs 9.4%) (P=0.017), respectively. None of the studied patients developed pain after 24 hours and there was no statistically significant difference between the studied groups regarding cecal intubation time and total examination time. No adverse events were noted in both groups.

Conclusion: CO2 insufflation is associated with significantly less bloating and less abdominal pain after diagnostic colonoscopy compared to RA insufflation.

Disclosure: Nothing to disclose.

Introduction: Adequate bowel cleansing is essential for colonoscopy quality. A novel 1L polyethylene glycol plus ascorbate (1L PEG+ASC) solution has been recently introduced. Nevertheless, the efficacy of 1L PEG+ASC as compared to that of high-volume bowel preparation in both inpatients and outpatients is still unclear.

Aims & Methods: This single-blinded, non-inferiority RCT aims to compare the efficacy, safety, and tolerability of 1L PEG+ASC versus a high-volume 4L PEG-based preparation in both inpatients and outpatients. The primary endpoint was the overall cleansing success. Secondary endpoints were excellent cleansing and high-quality cleansing of the right colon, as well as lesions detection rate, patient compliance, and safety.

	Outpatients			Inpatients		
	4L PEG (N = 123)	1L PEG-ASC (N=135)	P value	4L PEG (N = 90)	1L PEG-ASC (N = 85)	P value
BBPS total	7.4 ± 1.7	7.8 ± 1.4	0.035	6.6 ± 1.7	7.1 ± 1.8	0.062
BBPS partial						
- right colon	2.4 ± 0.6	2.6 ± 0.5	0.003	2.2 ± 0.6	2.3 ± 0.6	0.251
- transverse colon	2.6 ± 0.5	2.7 ± 0.5	0.048	2.4 ± 0.6	2.5 ± 0.6	0.497
- left colon	2.5 ± 0.6	2.6 ± 0.5	0.528	2.2 ± 0.6	2.5 ± 0.7	0.016
Cleansing success	109 (88.6)	130 (96.3)	0.018	69 (76.7)	72 (84.7)	0.179
Excellent cleansing	47 (38.2)	61 (45.2)	0.257	12 (13.3)	25 (29.4)	0.009
Right colon cleansing	57 (46.3)	84 (62.2)	0.010	25 (27.8)	31 (36.5)	0.218

Results: Overall, 478 patients (mean age 59.3 ± 14.9 years) were randomized to 1L PEG+ASC (N = 236) or 4L PEG (N = 242). The 1L PEG+ASC showed higher cleansing success rate as compared to 4L PEG preparation (91.8% vs 83.6%; OR = 2.207; 95% CI: 1.2-4.0; *P* = 0.01), as well as higher excellent cleansing (39.1% vs 27.7; OR, 1.67; 95% CI: 1.1-2.5; *P*= 0.001) and high-quality cleansing of the right colon (52.3% vs 38.5%; OR, 1.75; 95% CI: 1.194-2.564; *P* = 0.004). As compared to the high volume, 1L PEG+ASC achieved a higher cleansing success rate in out-patients (96.3%% vs 88.6%; *P* = 0.018) and a similar success among the in-patients (84.7% vs 76.7%; *P* = 0.18). No significant differences in colonoscopy performance, including caecal intubation rate (97.3% vs 96.2%, *P*= 0.5), withdrawal time (9.6 ± 3.2 vs 9.9 ± 4.1, *P*=0.3) and adenoma detection rate (25.5% vs 23.5%, *P*= 0.6) were

found between 1L PEG+ASC and 4L PEG preparation, respectively. The 1L PEG+ASC and 4L PEG preparation did not differ significantly in terms of tolerability, as documented by the similar rate of patients reporting total adverse events (AEs) (75.1% vs 77.8%, *P* = 0.5), mild AEs (68.0% vs 70.3%, *P* = 0.6) and moderate to severe AEs (32.0% vs 29.5%, *P* = 0.6) after bowel preparation.

Conclusion: Data of this randomized study showed that quality of bowel preparation for colonoscopy achieved with 1L PEG+ASC solution is not inferior as compared to that of 4L PEG. No differences in the tolerability and safety were detected. (Registration/protocol: EudraCT Number 2018-004543-24).

Introduction: Adenoma detection rate (ADR) is a robust quality indicator independently associated with the risk of interval colorectal cancer (I-CRC) and death. Nevertheless, reliable adenoma detection requires adequate bowel cleansing since it improves mucosal visualization of the surface of the colorectal mucosa.

Aims & Methods: This post-hoc analysis of a randomised phase-IV clinical trial aims to assess the predictors of polyp detection rate (PDR) and ADR in a population of in and outpatients undergoing split preparation with 1L polyethylene glycol plus ascorbate (1L PEG+ASC) and 4L PEG solution. The 'OVER' trial was a phase-IV RCT performed across 10 Italian centers (registration/protocol: EudraCT Number 2018-004543-24). Four hundred seventy-eight patients were randomized 1:1 to receive split-dose 1L PEG+ASC or a split-dose 4-L PEG-based regimen. In this post-hoc analysis, multivariable logistic regression models were designed to assess the presence of variables associated with PDR and ADR. All statistical analyses were performed using SPSS v. 28.0 for Macintosh (SPSS Inc., Chicago, USA).

Results: No differences in PDR (34.1% vs 32.9%, *P*=0.787), ADR (25.5% vs 23.5%, *P*=0.632) were found in patients undergoing 1L-PEG+ASC and 4L-PEG, respectively.

At multivariable logistic regression analysis, older age (OR=1.040, 95%CI=1.023-1.057; *P*<0.001), cleansing success (OR=2.250, 95%CI=1.009-5.020; *P*=0.048) and higher withdrawal time (OR=1.155, 95%CI=1.079-1.236; *P*<0.001) were independently associated with PDR.

Besides, older age (OR=1.042, 95%CI=1.021-1.063; *P*<0.001), shorter intubation time (OR=0.891, 95%CI=0.816-0.972; *P*=0.010), higher withdrawal time (OR=1.171, 95%CI=1.094-1.253; *P*<0.001) and 100% consumption of the first dose (OR=8.368, 95%CI=1.025-68.331; *P*=0.047) were independently associated with ADR (Table 1).

In the subgroup of patients undergoing colonoscopy for screening or surveillance (N=220/478), longer preparation time (OR=1.559, 95%CI=1.161-2.093; *P*=0.003), and colonoscopy within 5h after the end of preparation (OR=3.119, 95%CI=1.013-9.608; *P*=0.047) were independently associated with ADR.

	Univariable analysis			Multivariable analysis	
Variable	No adenoma detected (N=327)	Adenoma detected (N=106)	P value	Odds Ratios (CI-95%)	P value
Age	57.4 ± 15.3	64.8 ± 11.8	<0.001	1.042 (1.021-1.063)	<0.001
Diabetes	290 (88.7%) 37 (11.3%)	86 (81.1%) 20 (18.9%)	0.046	1.035 (0.522-2.051)	0.923
Preparation regimen - Afternoon-morning - Same-day	215 (65.7%) 112 (34.3%)	82 (77.4%) 24 (22.6%)	0.025	1.668 (0.957-2.907)	0.071
Preparation duration	2.8 ± 2.0	3.4 ± 3.0	0.018	1.094 (0.999-1.198)	0.051
Intubation time	8.7 ± 4.1	7.8 ± 2.8	0.043	0.891 (0.816-0.972)	0.010
Withdrawal time	9.2 ± 3.2	11.3 ± 4.6	<0.001	1.171 (1.094-1.253)	<0.001
Compliance with bowel preparation (I dose) - 100% intake of overall volume - <100% intake of overall volume	308 (94.2%) 19 (5.8%)	105 (99.1%) 1 (0.9%)	0.038	8.368 (1.025-68.331)	0.047

Table 1. Univariable and multivariable logistic regression analysis of variable associated with ADR in overall study population.

Conclusion: In a large RCT bowel preparation type was not associated to PDR and ADR. Cleansing success is independently associated to PDR but not with ADR. Compliance to bowel preparation, timing of colonoscopy and accurate withdrawal are key elements to ensure adequate ADR with potential implications in reducing I-CRC.

Introduction: Reported rates of delayed bleeding (DB) after endoscopic resection with each direct oral anticoagulant (DOAC) are high and heterogeneous. This large-scale multicenter study analyzed lesions resected by colorectal endoscopic submucosal dissection (ESD) under DOACs to compare the DB of each DOAC with warfarin.

Aims & Methods: We retrospectively reviewed 1,019 lesions with DOAC and 459 lesions with warfarin among 34,455 cases of ESD in 47 Japanese institutions from 2012 to 2021. The rate of DB in each DOAC was compared with warfarin. Risk factors of DB for DOAC and warfarin were also investigated.

Results: In the DOAC and warfarin groups, the mean age was 75.1±13.7 and 73.6±10.4 years, and the male rate was 70.2% and 71.4%, respectively. The mean tumor sizes (mm) were 29.5±14.0 and 30.3±16. The en bloc resection rates were 97.5% and 96.5%, respectively. Among 31,968 ESD cases from 46 institutions, the rate of DB was significantly higher in cases with anticoagulation (10.08%, 149/1478) than in cases without anticoagulation (2.21%, 677/30526) (p<0.001). Among the total 34,455 ESD cases, the rates of DOAC and warfarin were 9.32% (95/1019) and 11.76% (54/459), respectively (p=0.149).

The rate of DB with dabigatran (18.26%, 21/115) was significantly higher than with apixaban (10.08%, 25/248, p=0.029), edoxaban (7.73%, 25/323, p=0.001), and rivaroxaban (7.21%, 24/333, p=0.001). The rate of dabigatran was slightly higher than that of warfarin (11.76%, 54/459, p=0.055) and only the rate of rivaroxaban was significantly lower than that of warfarin (p=0.033).

Multivariate analysis showed that the significant risk factors of DB for DOAC were heparin exchange (odds ratio (OR), 95% confidence interval (CI), 2.185, 1.277-3.739, p=0.005), rectal site (2.013, 1.282-3.161, p=0.002), and longer procedure time ≥55 min (2.434, 1.498-3.956, p<0.001). The significant risk factors of DB for warfarin were antiplatelet combination (2.286, 1.274-4.100, p=0.006), rectal location (2.261, 1.248-4.095, p=0.007), and tumor size ≥35mm (2.019, 1.163-3.652, p=0.008).

The number of significant risk factors and the risk of DB (OR, 95%CI) for DOAC were 2.136 (1.301-3.507) and 4.53 (2.525-8.155) for one and two risk factors, respectively. Those for warfarin were 1.646 (0.742-3.650), 3.624 (1.593-8.243), and 13.037 (3.929-43.266) for one, two, and three risk factors, respectively.

Conclusion: The DB rate of dabigatran was higher than that of other DOACs, and only rivaroxaban was significantly lower than that of warfarin. The risk factors for DB with DOACs have been elucidated.

Contact E-Mail Address: m-kobayashi5@hotmail.co.jp

Introduction: The degree of fibrosis during colorectal ESD varies and sometimes makes the procedure itself difficult. Preoperative prediction of fibrosis is expected to help develop a reliable strategy.

Aims & Methods: Of 1309 colorectal ESD lesions performed at our hospital between April 2012 and September 2022, 953 lesions larger than 20 mm were included after excluding post-treatment recurrence, SMT, and other conditions. Intraoperative fibrosis was classified into F0 (none), F1 (mild), and F2 (severe).

Results: Fibrosis was observed in 192 (20.1%) patients (F1; 143, F2; 49). The tumor diameter (median, range) was 23 (20-135), 30 (20-210), and 35 (20-115) mm in F0, F1, and F2 groups, respectively. The rate of the cecum (%) was 13.3 : 29.4 : 16.3, which was higher in F1. Overall, bleeding was observed in 17 patients (1.8%) and perforation in 3 patients (0.3%), and the frequency was similar in each group. The curative resection rate (%) was 98.4:91.6:59.2, with F2 being significantly inferior. The long treatment time (≥120 minutes) (%) was 1.7 : 9.1 : 46.9, showing a significant difference between F0 vs F1 and F1 vs F2, and the dissection speed (mean±SD, mm^2/min) was 25.9±14.5 : 23.2±13.6 : 15.3±10.6, which was significantly slower in F2.

The predictive factors of F1 and F2: straddling the folds, prior biopsy, lesion diameter, site, and morphology, were included in the study, and multivariate analysis showed that the predictive factors of F1 were straddling folds (OR;2.07,95% CI;1.39-3.11), lesion diameter ≥50mm (OR;4.68,95% CI;2.45-8.94), biopsy (OR;6.44,95% CI;3.32-12.5), NGPD (OR;4.31,95% CI;2.37-7.83), and cecum (OR;3.73,95% CI;2.35-5.92). The predictive factors of F2 were straddling folds (OR;2.34,95% CI;1.21-4.51), lesion diameter ≥50 mm (OR;7.29,95% CI;3.03-17.5), biopsy (OR;5.07,95% CI;1.81-14.1), and protruded type (OR;6.44,95% CI;3.23-12.8).

Conclusion: Colorectal ESD for fibrotic lesions was safe, but the curative resection rate was low in F2. F1-specific predictors were cecum and NGPD, and F2-specific predictors were protruded type, suggesting that the choice of surgeon and strategy should depend on the expected degree of fibrosis.

CLINICOPATHOLOGICAL AND ENDOSCOPIC CHARACTERISTICS OF SESSILE SERRATED LESION WITH DYSPLASIA/CARCINOMA

T. Murakami[1], N. Tsugawa[1], E. Kamba[1], K. Nomura[1], H. Fukushima[1], T. Shibuya[1], T. Yao[2], A. Nagahara[1]

Introduction: Sessile serrated lesion (SSL), is a precursor lesion in the serrated neoplasia pathway [1]. These lesions are considered a major contributor to the failure of colonoscopy to prevent colorectal cancers (known as "interval cancer" or "post-colonoscopy colorectal cancer") [2]. Therefore, improved awareness of the clinicopathological and endoscopic characteristics of SSL and their dysplastic components is important.

Aims & Methods: This study aimed to elucidate the clinicopathological and endoscopic features of SSLs with and without dysplasia or carcinoma. We reviewed the data of all colorectal lesions that were pathologically diagnosed as SSLs at Juntendo University Hospital, Tokyo, Japan, between 2011 and 2022. During this period, all suspected SSLs were resected endoscopically or surgically. The histological diagnosis of SSLs was based on the World Health Organization Classification of Tumours of the Digestive System 2019 [3]. We analysed the clinicopathological features of all the patients, including age, sex, tumour location and size, and conventional endoscopic findings.

Results: The clinicopathological and endoscopic characteristics of the lesions are summarised in Table 1. Out of 2132 SSLs (1368 patients), 1972 (92.5%) had no dysplasia (ND), 101 (4.7%) had low-grade dysplasia (LGD), 39 (1.8%) had high-grade dysplasia (HGD), and 20 (0.9%) had submucosal invasive carcinoma (SIC). Older age is more frequently associated with SSLs and dysplasia/carcinoma. The most frequent location of tumours was the proximal colon. A stepwise increase in the size of the SSL series was identified, along with dysplastic progression from ND to dysplasia to invasive carcinoma. Similarly, larger lesions were associated with higher rates of dysplasia or cancer (≥ 5 mm, 1.2%; 6 - 10 mm, 6.5%; 11-15 mm; 9.5%, 16-20 mm, 12.9%; ≥ 21 mm, 17.3%). However, 66 of the 160 (41.3%) SSLs with dysplasia/carcinoma were ≤ 10 mm in size. Macroscopically, (semi)pedunculated morphology, reddishness, double elevation, and central depression were more frequently observed in SSLs with dysplasia/carcinoma than in those without.

	Clinicopathological and endoscopic characteristics of colorectal lesions studied.			
Variable [Lesions / Patients]	ND [1972 (92.5%) / 1276]	LGD [101 (4.7%) / 94]	HGD [39 (1.8%) / 38]	SIC [20 (0.9%) / 20]
Age (years)	62.8 ± 12.1 (23 - 91)	64.8 ± 10.0 (35 - 85)	71.6 ± 8.9 (51 - 86)	72.2 ± 9.7 (47 - 90)
Sex: Male / Female	667 (52.3%) / 609 (47.7%)	41 (43.6%) / 53 (56.4%)	14 (36.8%) / 24 (63.2%)	7 (35.0%) / 13 (65.0%)
Location: Proximal / Distal	1637 (83.0%) / 335 (17.0%)	81 (80.2%) / 20 (19.8%)	33 (84.6%) / 6 (15.4%)	18 (90.0%) / 2 (10.0%)
Size of tumour (mm)	10.8 ± 7.6 (2 - 65)	15.0 ± 9.0 (5 - 42)	14.2 ± 8.4 (6 - 43)	20.2 ± 12.7 (8 - 65)
(Semi) pedunculated morphology	51 (2.6%)	14 (13.9%)	10 (25.6%)	5 (25.0%)
Reddishness	77 (3.9%)	40 (39.6%)	21 (53.8%)	16 (80.0%)
Double elevation	70 (3.5%)	61 (60.4%)	19 (48.7%)	10 (50.0%)
Central depression	44 (2.2%)	6 (5.9%)	2 (5.1%)	6 (30.0%)

Table 1.

Conclusion: Our findings suggest that SSLs with dysplasia/carcinoma may be more frequently associated with older age, the proximal colon, and larger lesions. However, dysplasia/cancer could coexist in SSLs even if the size was ≤ 10 mm.

Additionally, in an SSL series, endoscopic characteristics, including (semi) pedunculated morphology, reddishness, double elevation, and central depression, might be useful for the accurate diagnosis of advanced histology within an SSL. These results may may contribute to improvement in the recognition and complete resection of SSLs with dysplasia or invasive carcinoma, thereby reducing the rates of colorectal cancer.

THE FEASIBILITY OF THE STRIP BIOPSY OF THE COLORECTAL LESIONS INVOLVING THE APPENDICEAL ORIFICE

M. Kobayashi[1], H. Chiba[1], A. Hayashi[1], Y. Ebisawa[1], J. Arimoto[1], H. Kuwabara[1], M. Nakaoka[1]
[1]Omori Red Cross Hospital, Gastroenterology, Ota-Ku, Japan

Contact E-Mail Address: m-kobayashi5@hotmail.co.jp

Introduction: ESD of the colorectal lesions involving the appendiceal orifice (AO) is technically challenging because of the thin wall and narrow working space. On the other hand, even if the lesions are small and benign, it is difficult to perform EMR because of the narrow snaring space.

We previously reported strip biopsy (SB) resection of the AO lesion. The SB technique is as follows (1) Insert a 2-channel scope and check the lesion. (2) Insert a snare and grasping forceps into each channel, and hold the grasping forceps in the snare. (3) Grasp the appendiceal end of the lesion with the grasping forceps, open the snare, grasp the lesion, and resect it. This method makes it possible to snare the lesion after confirming the distal border of the AO. In the present study, we evaluated the feasibility of SB for AO lesions.

Aims & Methods: This was a retrospective study in which SB for AO lesions was performed on 10 patients at our hospital. Inclusion criteria for the study cohort were (1) the lesion less than 15 mm, and (2) visible lesion margin on the appendicular side. Polyps suspected to be cancerous were excluded.

Results: Male to female ratio was 8:2, median age (range) was 76 years (44-89). The median tumor size was 10 mm (10-15). The pathological findings were 8 cases of SSL and 2 cases of low-grade tubular adenoma. All lesions were resected en bloc, with a median treatment time of 10 minutes (range (5-10)). No complications were observed. Pathology results were negative for 8 cases and unknown for 2 cases. All lesions were resected endoscopically with no residuals.

Conclusion: SB technique for AO lesions is safe and it appeared that this could be one option for endoscopic treatment of AO lesions.

Disclosure: Nothing to disclose.

Contact E-Mail Address: marcello.maida@hotmail.it

Introduction: One-fourth of colorectal neoplasia is missed at screening colonoscopy, representing the leading cause of interval colorectal cancer (I-CRC). Colonoscopy assisted by artificial intelligence (AI) with computer-aided polyp detection (CADe) showed higher adenoma detection rate (ADR) and higher adenoma per colonoscopy compared to white light (WL) colonoscopy in randomized clinical trials (RCTs). Despite ADR is a reliable quality indicator and has been associated to the risk of I-CRC and death, an adequate ADR does not eliminate the risk of lesion miss rate since the relationship between ADR and adenoma miss rate (AMR) is only indirect.

Aims & Methods: The aim of this meta-analysis is to summarise the performance of CADe systems on miss rate of colonic lesions. PubMed/Medline, Embase and Cochrane Library were systematically searched through October 2022 by two independent reviewers (M.M. and A.F.) for tandem-design RCTs comparing miss rate of colonic lesions in CAD-first colonoscopy followed by WL colonoscopy (experimental arm) vs WL-first colonoscopy followed by CAD colonoscopy (control arm).

The primary outcomes were pooled AMR and polyp miss rate (PMR). Secondary outcomes were advanced adenoma miss rate (aAMR) and sessile serrated lesion miss rate (SMR). Lesion miss rate was defined as the number of lesions detected at second colonoscopy divided by the total number of same lesions detected at first and second colonoscopy. A random-effect model was applied for pooling results. Heterogeneity was expressed as I^2.

Results: Overall, 4 RCTs (1166 patients), were included in the analysis. Pooled AMR was significantly lower in the CAD-first compared to WL-first arm (131/842, 15.5% vs 300/857, 35.0%; RR, 0.45; 95% CI, 0.35-0.58; P<0.001; I^2=49%). PMR was also lower in the CAD-first compared to WL-first arm (192/1198, 16.0% vs 474/1244, 38.1%; RR, 0.43; 95% CI, 0.30-0.61; P<0.001; I^2=82%).

No significant difference in aAMR (2/23, 8.7% vs 5/32, 15.6%; RR, 1.28; 95% CI, 0.34-4.83; P=0.71; I^2=0%) and in SMR (5/43, 11.6% vs 27/67, 40.3%; RR, 0.44; 95% CI, 0.15-1.28; P=0.13; I^2=46%) were observed.

Study	Country	Study type	Design	CADe system	Colonoscopy indication	Arm (subjects, n)	APC (mean)	AMR	aAMR	PMR
Wang P, 2020	China	RCT	Tandem	EndoScreener, Wision AI, Shanghai, China	Symptomatic: 224 Screening or surveillance: 145	CADe-first (184)	0.78	13.9%	50.0%	13.0%
						WLE-first (185)	0.65	40.0%	25.0%	45.9%
Kamba S, 2021	Japan	RCT	Tandem	YOLOv3, LPIXEL Inc. and Jikei University School of Medicine	Symptomatic: 0 Screening or surveillance: 344	CADe-first (171)	1.42	13.8%	0.0%	14.2%
						WLE-first (173)	1.25	36.7%	13.3%	40.6%
Glissen JR, 2022	US	RCT	Tandem	EndoScreener, Wision AI, Shanghai, China	Symptomatic: 0 Screening or surveillance: 223	CADe-first (113)	1.19	20.1%	11.1%	20.7%
						WLE-first (110)	0.90	31.2%	0.0%	33.7%
Wallace M, 2022	US	RCT	Tandem	GI-Genius; Medtronic, Minneapolis, US	Symptomatic: 0 Screening or surveillance: 230	CADe-first (116)	1.79	15.7%	-	16.8%
						WLE-first (114)	1.46	32.2%	-	31.1%

Table 1. Characteristics of the studies included in the meta-analysis.

Conclusion: According to available evidence, the use of colonoscopy assisted by AI with CADe results in a significant lower AMR and PMR, with a potential implication in reducing the incidence of I-CRC. No significant difference in aAMR and SMR has been observed, even if these results should be further confirmed in studies with larger sample sizes.

Disclosure: Nothing to disclose.

PP1170

POOR ADHERENCE TO DIETARY RESTRICTION IMPACTS QUALITY OF COLONOSCOPY IN CLINICAL PRACTICE

K. Nuija[1], K. Besherdas[1]
[1]Royal Free London, Endoscopy, Enfield, United Kingdom

Contact E-Mail Address: katrin.nuija1@nhs.net

Introduction: Colonoscopy is the 'gold standard' investigation for assessment of the large bowel allowing diagnosis, biopsies, and therapy to be undertaken. Colonoscopy detects and prevents colorectal cancer through detection and removal of polyps, and is important in the diagnosis and treatment of non-neoplastic conditions. Poor quality colonoscopy is associated with increased rates of interval cancers. High quality colonoscopy cannot occur without good quality bowel preparation. Evidence in the UK show that 22% of failed colonoscopies were due to poor bowel preparation. Apart from the bowel cleansing agent, dietary restriction prior to colonoscopy has been shown to enhance quality of bowel preparation at colonoscopy.

Aims & Methods: We aimed to assess the information received and followed by patients in terms of dietary modification prior to colonoscopy.

A single centre prospective analysis of 60 consecutive patients attending colonoscopy at Chase Farm Hospital in London was undertaken in May 2022. Patients were asked to complete a questionnaire with information gathered about: type of bowel prep undertaken, whether written information about how to take bowel prep was received, whether a telephone consultation explaining dietary restriction prior to procedure happened, whether they followed a low fibre diet and the amount of fluid drunk.

Results: 57 patients returned the questionnaire.

Of the 57 patients, 39% patients received written information on dietary restriction. A further 35% of patients received telephone information, 26% of patients receiving both written and verbal information. 56.9% of patients followed the 3 day dietary restriction. The quality of bowel preparation was inadequate (fair and poor by Aronchick scale) in 60% of those who did not follow the low fibre diet compared to 24% when followed.

Patients who had seen a clinician in clinic and patients undergoing surveillance procedure were more likely to follow dietary restriction compare to direct access patients.

Conclusion: In this prospective study of clinical practice, we conclude that advice regarding dietary fibre restriction prior to colonoscopy is variable. In clinical practice, there is low compliance of dietary restriction prior to colonoscopy. We find that those who followed a low fibre diet are 40 % more likely to have a favourable bowel preparation compared to those following a high fibre diet. Those that had inadequate bowel prep required a repeat colonoscopy adding to the burden of the already stretched service. We recommend improvements in the implementation of the low residue diet in addition to the guidance of cleansing agents prior to colonoscopy.

Disclosure: Nothing to disclose.

A SINGLE-CENTER, PROSPECTIVE COHORT STUDY OF NEW ELECTROCOAGULATION SYSTEM FOR PREVENTING COLORECTAL POST-ESD COAGULATION SYNDROME (NEWPEC STUDY)

T. Ozeki[1,2], T. Shimura[1], H. Iwasaki[1], T. Katano[1], Y. Okuda[1], Y. Mizuno[1], N. Sugimura[1], S. Fukusasda[1], H. Kataoka[1]

[1]Nagoya City University Graduate School of Medical Sciences, Department of Gastroenterology and Metabolism, Nagoya, Japan, [2]Toyokawa City Hospital, Department of Gastroenterology, Toyokawa, Japan

Contact E-Mail Address: takacpv@gmail.com

Introduction: Post-ESD coagulation syndrome (PECS), which reveals abdominal pain, inflammation or fever without perforation after ESD, is a recognized complication of colorectal ESD; however, prevention of PECS remains unknown. In our previous RCT, clipping closure after colorectal ESD did not reduce the incidence of PECS (Gastrointest Endosc. 2020: 859-867). The maXium unit is a new electrosurgical unit, which is expected to reduce tissue damage during ESD.

Aims & Methods: We conducted a prospective study (NewPEC study) to assess usefulness of the maXium unit for the prevention of PECS. The NewPEC study is a single-center, prospective cohort study, and patients who will undergo ESD for superficial colorectal neoplasms were prospectively enrolled. All participants routinely received computed tomography (CT) scan and blood examination on day 1 after ESD and pain severity was assessed on day 1-3 after ESD using visual analogue scale (VAS). PECS was defined as VAS ≥30mm, a raise of VAS ≥20mm from baseline, BT ≥37.5°C or WBC ≥10,000/μl after ESD. The PECS was classified into type I, conventional PECS without extra-luminal air and type II, PECS with peri-luminal air. The primary endpoint of this study was the incidence of PECS. The preplanned sample size for the analysis was 92 patients by estimating that upper limit of 90% CI for the PECS rate is less than 15% that is a threshold based on the previous RCT, with β errors of 0.20.

Results: Prior to the initiation of the present study, electrical circuit analysis was performed, and the maXium unit allowed submucosal dissection with lower power than with the VIO300D unit. From October 2019 to September 2021, 173 patients who undergo colorectal ESD were screened, 104 patients with inclusion criteria were enrolled in the primary enrollment, and finally, 92 patients were analyzed after excluding 12 patients in the present study. Median tumor size was 22mm. Final pathological diagnosis was 7 in SSL, 47, in adenoma, 24 in pTis CRC, 13 in pT1 CRC and 1 in pT2 CRC. The PECS rate was 15% [90%CI, 10-24%], including 10 % in the type 1 and 5 % in the type 2. The simple peri-luminal air without PECS was observed in 7 patients (8%). One patient revealed delayed perforation post-ESD day1, who underwent emergency surgery. As for the incidence of PECS, experienced skill was only significant factor for reducing the risk of PECS.

Conclusion: A new electrocoagulation system, maXium unit, did not reduce the incidence of colorectal PECS, compared to the historical control. However, the maXium unit showed equivalent results to the VIO300D unit that was used in the previous RCT.

LONG-TERM PROGNOSIS OF COLORECTAL CARCINOMA TREATED BY COLD SNARE POLYPECTOMY

S. Nakamura[1], T. Yoshimoto[1], T. Kawamura[1], K. Uno[1]

[1]Kyoto Second Red Cross Hospital, Department of Gastroenterology, Kyoto, Japan

Contact E-Mail Address: shihosun.1030@gmail.com

Introduction: Cold snare polypectomy (CSP) has become popular as a safe and simple treatment for small colonic lesions. According to the Japanese guidelines, CSP is indicated for adenomas <10 mm with no suspicion of carcinoma [1]. Occasionally, colorectal carcinoma is diagnosed after resection, and there is no consensus on the treatment of such lesions [2-4].

Aims & Methods: This single-center retrospective study aimed to investigate the long-term prognosis of Japanese patients with pathologically diagnosed colorectal carcinoma after resection by CSP. Patients who underwent CSP for small colonic lesions at our hospital in 2013–2022 and were histopathologically diagnosed with colorectal carcinoma were included in this study.

We examined the local residual or recurrence rate, scar detection rate, and recurrence-free survival rate in patients who underwent at least one colonoscopy after CSP.

Results: Out of 12,935 lesions (6,082 cases) that were resected using CSP during the study period, 81 lesions (0.63%; 81 cases) were histologically diagnosed as colorectal carcinoma (mean age, 69.7 years; male patients, 69% [56/81]). Histologically, all tumours were well-differentiated adenocarcinomas. Negative lateral and vertical margins of the resected specimens were 47% (38/81) and 72% (58/81), respectively. Of these 81 cases, 47 (58%) were followed up at least once by colonoscopy. The breakdown of cases that were not followed up endoscopically is as follows: concurrent advanced cancer (n=15), advanced age (n=7), dropout (n=7), and others (n=5). Endoscopic evidence of residual disease or recurrence was found in 1/47 patients (2%), and the remaining 46 patients had a median colonoscopic follow-up of 425 days (interquartile range, 192.5–1078.5 days) with no endoscopic evidence of local recurrence. In 51% (24/47) of cases, post-polypectomy scars could be identified. In one case where local residual carcinoma was confirmed, a retrospective review of the CSP revealed incomplete resection at the time of treatment. Abdominal CT performed immediately after CSP showed coincidental peritoneal dissemination, and the patient died 177 days after diagnosis. In 46 patients with no endoscopic evidence of local recurrence, the median observation period was 921 days (interquartile range, 475–1654.5 days), with six cases of death from causes other than colorectal cancer, and the others were alive without recurrence.

Conclusion: The frequency of residual disease or recurrence of colorectal carcinoma treated by CSP was low, and the long-term prognosis was favourable once the absence of residual lesions was confirmed endoscopically.

DECIPHERING FACTORS ASSOCIATED WITH METACHRONOUS ADVANCED NEOPLASTIC LESION IN SURVEILLANCE COLONOSCOPY BY MACHINE LEARNING MODELS

T.K.L. Lui[1], S.H.K. Liu[1], W.K. Leung[1]
[1]Li Ka Shing Faculty of Medicine, the University of Hong Kong, Department of Medicine, Hong Kong, Hong Kong

Contact E-Mail Address: tkllui@hku.hk
Introduction: Detection of metachronous advanced colorectal neoplasia is the main purpose of surveillance colonoscopy. Current guidelines are largely based on observational stuides or expert opinions which may not accurately predict the chance of metachronous advanced neoplasia.
Aims & Methods: This study aimed to assess the performance of machine learning (ML) models to predict the presence of advanced neoplasia during surveillance colonoscopy and also attempted to decipher the factors associated with advanced neoplasia as determined by machine learning models.
The training dataset consisted of 348 patients who had undergone surveillance colonoscopy between 2016 and 2019 in our hospital. Dataset included 20 baseline clinical parameters during the index colonoscopy, findings and performance metric of the index colonoscopy. Tweleve different advanced machine learning models were trained to predict the presence of advanced neoplasia during surveillance colonoscopy.
Advanced neoplasia was defined as the presence of adenoma with high grade dysplasia, ≥1 cm adenoma or sessile serrated polyp (SSP) , ≥ 3 adenoma or SSP, SSP with dysplasia or traditional sessile adenoma (TSA). Trained models were further validated in another cohort of 320 patients with surveillance colonoscopy between 2020 and 2021.
The performance was determined by the area under the receiver operating characteristic curve (AUC). The feature of importance was computed by Gini importance.
Results: Metachronous advanced neoplasia was present in 32.7% (n=114) and 24.4% (n=78) in the training and validation set, respectively.
Among the 12 machine learing models, the Grandient Boosting Classifier (GBC) had the highest AUC (0.85, 95%CI: 0.83-0.86). The sensitivity, specificity, positive and negative predictive value of the GBC was 0.77, 0.77, 0.29 and 0.96, respectively. Miss rate was 3.7% with number need to screen of 3.4 in the validation set. The other 11 models have AUC ranging from 0.70 to 0.84, which were all significantly higher than the performance if follow the USMSTF (0.60) and ESGE (0.51) recommendations.
Feature extraction of the GBC model showed that the time between index and surveillance colonoscopy (44.9%), patient's age (15.5%), and withdrawal time (8.1%), adenoma detection rate (ADR) (7.7%) and number of polyp of index colonoscopy (6.6%) were the top five predictive factors for advanced neoplasia on surveillance colonoscopy (Table 1).

Predictors	Feature of importance (%)
Time between surveillance colonoscopy and index colonoscopy	44.9
Patient's age	15.5
Withdrawal time of index colonoscopy	8.1
Adenoma detection rate of index endoscopist	7.7
Number of polyp in index colonoscopy	6.6
Number of advanced adenoma in index colonoscopy	4.7
History of diabetes mellitus	3.0
Number of advanced serrated lesions in index colonoscopy	2.7
History of ischemic heart disease	1.8
Patient's sex	1.5

Table 1: Feature of importance of GBC model

Conclusion: Most machine learning models could help to predict the chance of metachronous advanced neoplasia during surveillance colonoscopy and are better than current recommendations. Feature extraction shows that apart from interval between index and surveillance colonsocopy, the performance metrics and findings of index colonoscopy play pivotal role on detection of advanced neoplasia in surveillance colonoscopy.
Disclosure: Nothing to disclose.

TIME-ZERO VIOLATIONS CAUSE BIAS IN OBSERVATIONAL STUDIES ON SCREENING COLONOSCOPY

M. Braitmaier[1], S. Schwarz[2], V. Didelez[1,3], U. Haug[2,4]
[1]Leibniz Institute for Prevention Research and Epidemiology - BIPS, Biometry and Data Management, Bremen, Germany, [2]Leibniz Institute for Prevention Research and Epidemiology – BIPS, Clinical Epidemiology, Bremen, Germany, [3]University of Bremen, Faculty of Mathematics and Computer Science, Bremen, Germany, [4]University of Bremen, Faculty of Human and Health Sciences, Bremen, Germany

Contact E-Mail Address: haug@leibniz-bips.de
Introduction: Previous observational studies reported a higher effectiveness of colonoscopy in preventing distal vs. proximal colorectal cancer (CRC) which we could not reproduce in a recently published observational study using target trial emulation (TTE). The design of the previous studies suffered from "time zero violation", i.e. eligibility check, treatment assignment (screening vs. no screening) and start of follow-up were not synchronized.
Aims & Methods: We aimed to assess whether this "time zero violation" falsely induces a site-specific difference in the effect of colonoscopy. We used the same dataset underlying our recently published analysis (Braitmaier et al. 2022) based on German claims data (20% population coverage). We assessed the effect of screening colonoscopy in preventing distal and proximal CRC over 11 years of follow-up in 55–69-year-old persons at average CRC risk. Unlike in our recently published analysis, we used the design of previous observational studies with "time zero violation". We compared the findings of both analyses.
Results: While in the recently published analysis using TTE, the relative risk (RR) of distal and proximal CRC in the screening colonoscopy vs. control group was similar (RR: 0.67 for distal, 0.70 for proximal), the analysis with "time zero violation" indicated a difference in site-specific performance. In this latter analysis, the RR was 0.41 for distal CRC and 0.66 for proximal CRC.
Conclusion: Our study demonstrates that "time zero violation" can substantially bias the results of observational studies. In our example, it falsely suggested an almost double preventive effect of colonoscopy in the

distal vs. the proximal colon. The difference disappeared when the same data were analyzed using a TTE approach, which is known to avoid design-induced biases.

Introduction: Two phase III non-inferiority studies (ESTOS [Russia] and EASY [China]) compared split-dose oral sulphate solution (OSS) to 4L polyethylene glycol (PEG) for bowel preparation in adults scheduled for routine colonoscopy. A post-hoc analysis was conducted using pooled data from these studies to provide more information on efficacy and safety overall and in sub-groups of interest.

Aims & Methods: Analyses in intention-to-treat (ITT) were confirmed in the per protocol (PP) population. Sub-analyses were conducted on subgroups of interest (age; gender; body mass index [BMI]; inflammatory bowel disease [IBD] status). A boundary of -15% was used to assess non-inferiority. Primary endpoint: proportion of patients with successful overall preparation (centrally assessed global Boston bowel preparation scale [BBPS] score ≥6). Secondary endpoints: excellent overall preparation (BBPS score ≥8; centralized assessment), mean BBPS score, BBPS score ≥2 by segment, adenomas, polyps and other lesion detection rate, completion and duration of total colonoscopy, investigator satisfaction (Likert score), compliance to bowel preparation administration and safety.

Results: 588 patients received OSS (n=294) or PEG (n=294). ITT results confirmed in the PP population are reported. The pooled analysis confirmed non-inferiority of OSS to PEG (successful overall preparation: 93.7% vs 92.1%; Δ 1.6%; 95% CI: −2.6, 5.7). OSS was non-inferior in males (96.2% vs 91.9%) and females (90.9% vs 90.7%), presence (95.9% vs 93.5%) and absence of IBD (95.0% vs 94.2%), BMI ≤25 kg/m^2 (89.7% vs 94.0%) and age ≤65 years (93.6% vs 90.9%). In patients with BMI >25 kg/m^2, OSS was superior to PEG (97.0% vs 89.8%, p=0.029). Non-inferiority in patients >65 years was not confirmed (91.6% vs 98.2% p=0.2449). Pooled analyses of secondary endpoints showed higher rates of excellent overall preparation with OSS than with PEG and in segments for most subgroups (Table). Investigator satisfaction was higher with OSS compared with PEG (p=0.0003), as was compliance (92.4% vs 85.1%, p=0.0024).

Other secondary endpoints were similar for both treatments. Safety and tolerability were similar for both treatments. Overall, more adverse events (AEs) were experienced in the group with BMI ≤25 than in the group with BMI >25. There was one serious AE considered related to OSS: acute proctitis, which was treated with local mesalamine. The most frequently reported adverse events were non-serious gastrointestinal disorders.

	ALL SEGMENTS			RIGHT COLON			TRANSVERSE COLON			LEFT COLON

OSS, oral sulfate solution. PEG, polyethylene glycol

Table. Rates of excellent overall bowel preparation (overall BBPS score ≥8, individual segment score ≥3)

Conclusion: Pooled analysis confirmed that OSS is non-inferior to PEG for bowel preparation in adults before colonoscopy. This post-hoc analysis also showed that OSS is superior to 4L PEG in achieving excellent preparation overall and in all colon segments, and is linked to superior compliance and investigator satisfaction in most subgroups with similar safety and tolerability

HIGH JOULE HEAT LOAD ON THE PEELED MUCOSAL SURFACE AS AN INDEPENDENT RISK FACTOR FOR POST-ENDOSCOPIC SUBMUCOSAL DISSECTION ELECTROCOAGULATION SYNDROME: A PROSPECTIVE OBSERVATIONAL STUDY

T. Kamoshida[1], M. Ochi[2,1], S. Suematsu[3], K. Fukuda[3], A. Yamamoto[1], Y. Yamaguchi[1], D. Suenaga[1], Y. Hamano[1], H. Ohkawara[1], A. Ohkawara[1], N. Kakinoki[1], S. Hirai[1], F. Kusano[3]

Introduction: Colorectal endoscopic submucosal dissection (ESD) is more difficult than gastric/esophageal ESD from anatomical aspects. Post-ESD complications, such as post-hemorrhage and perforation, have been frequently reported. In particular, a post-ESD complication, post-ESD electrocoagulation syndrome (PECS), may lead to delayed perforation. A previous study reported that risk factors for PECS were a long duration of treatment (≥90 min), specimen diameter (≥30 mm), and right colonic lesion[1)]. However, no risk factor has been established, and risk factors remain controversial.

Aims & Methods: Our purpose was to clarify risk factors that can be unitarily explained with respect to PECS after colorectal ESD and achieve adequate postoperative management. Patients with fever (≥37.5°C) or a leukocyte count of ≥10,000/mL during admission and a visual analogue scale of ≥3 cm or 2 cm or longer increase from the baseline were regarded as having PECS. A total Joule heat load of ≥15389 J on a tumor during ESD was regarded as high Joule heat[2)]. Joule heat was measured using a special device. For multivariate analysis, logistic regression analysis was used.

Results: We conducted a prospective observational study in 84 patients who underwent colorectal ESD at two facilities between January 2021 and March 2023. The median age was 70 years, and there were 63 males (75.0%). PECS occurred in 12 patients (14.3%). The only independent factor associated with PECS was high-level Joule heat (odds ratio: 7.28, 95%CI: 1.9-27.5, p<0.01). PECS was not associated with a long duration of treatment, large specimen diameter, or right colon.

Conclusion: Previously reported risk factors for PECS were associated with difficulties in performing colorectal ESD. In patients in whom tumor peeling is difficult, the heat load on a peeled surface increases, and PECS may readily occur. An index of high-level Joule heat made it possible to unitarily explain risk factors, such as a long duration of treatment, specimen diameter, and right colon, as risk factors for PECS. The total Joule heat can be quantified, facilitating the prediction of PECS onset.

Contact E-Mail Address: anne.marie.jelsig@regionh.dk

Introduction: The risk of cancer in patients with solitary colorectal juvenile polyps is poorly investigated, but several studies have reported polyps with dysplastic and adenomatous alterations.

Aims & Methods: We aimed to investigate the long-term risk of cancer and mortality in these patients when merging data from national registers and comparing them to a matched control cohort. Patients with a solitary juvenile polyp were identified in The Danish National Pathology Register and Data Bank (DNPR). Included patients were matched on sex, age, and place of birth with 50 controls. The groups were then analyzed for risk of cancer using the Danish Cancer Registry and mortality using the Danish Cause of Death Registry.

Results: We identified 1,781 patients with solitary juvenile polyps and matched them to 83,713 controls. The mean follow-up time was 7.65 years for cases and 7.36 years for controls. The risk of cancer, including colorectal cancer, did not differ for the two groups and when adjusting for sex and year of birth the hazard ratio (HR) was: 1.15 (CI 95% 0.94-1.41, *p*=0.162). There was no increased risk of death (HZ: 1.07, CI 95% 0.88-1.30, *p*=0.486). The risk did not differ for different age groups or sex.

Conclusion: There is no increased risk of cancer or mortality for patients with solitary colorectal juvenile polyps. Thus, endoscopic follow-up may safely be omitted in these patients.

PILOT DATA EVALUATING LEARNING CURVE IN SPEEDBOAT-ASSISTED SUBMUCOSAL DISSECTION (SSD) IN A UK TERTIARY HOSPITAL – A SINGLE-OPERATOR EXPERIENCE WITHOUT ON-SITE TUTORING

B. Tan[1], R. Kader[1], O. Ahmad[1], E. Seward[1], R. Vega[1]
[1]University College London Hospital, Endoscopy, London, United Kingdom

Contact E-Mail Address: joeytanbt@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is widely performed in Asia. Its adoption in Western countries has been slow, primarily due to concerns about longer learning curves and higher complication rates. A new ESD service based on a single operator without an on-site tutor was introduced in a UK tertiary hospital using exclusively speedboat-RS2 device (advanced bipolar radiofrequency for cutting and microwave coagulation).

Aims & Methods: This study aims to evaluate the learning curve and outcomes of the first 100 SSDs. Data were collected prospectively from September 2019 to April 2023. The learning curve was analyzed based on 4 quartiles (n=25 per quartile) and the outcomes evaluated were resection speed, en-bloc and R0 resection rate. The adverse events rate in the first 30 days post-SSD was used as safety outcomes.

Results: 100 patients underwent SSDs and the median age was 67 years. The median Charlson Comorbidity Index (CCI) score was 3. 61% were male and 53% of the lesions were in the rectum. Majority (75%) of the lesions were removed en-bloc and 69% had R0 resections.

Row Labels	Count	Count of en-bloc procedures	Resection speed (cm^2/hr)	En-bloc (%)	R0 resection (%)	Mean duration of procedure (mins)	Mean size of lesions (cm)
1	25	16	4.0	64	63	233	4.9
2	25	17	6.6	68	71	194	4.8
3	25	21	6.7	84	67	152	4.7
4	25	21	7.9	84	76	142	5.2
Total	100	75	6.0	75	69	180	4.9

Table.

The en-bloc resection rate for quartiles 1, 2, 3 and 4 were 64%, 68%, 84%, and 84%. The R0 resection rate was 63%, 71%, 67% and 76%, respectively. The 4th quartile met the European Society of Gastrointestinal Endoscopy (ESGE) recommendation for the R0 resection rate ≥75% but not for the en-bloc resection rate ≥90%.[1]

The mean duration of SSDs for respective quartiles were 233, 194, 152 and 142 minutes which indicated shorter resection times (142mins) despite larger lesions in the 4th quartile (5.2cm). The resection speed was 4.0, 6.6, 6.7 and 7.9cm^2/hr, respectively. The 4th quartile resection speed of 7.9cm^2/hr after 100 SSDs demonstrated a shorter learning curve than the 7.0cm^2/hr achieved after 200 ESDs in a similar study performed in the US which evaluated a new ESD service from a single operator without on-site tutoring.[2]

The adverse event rate was 7%(n=7). 5% were due to delayed bleeding, requiring further endoscopic interventions. The risk factors were use of anticoagulants and liver cirrhosis. 2% had localized perforation with Sydney classification of mucosal injury type III which were managed with endoscopic clips. This study achieved the safety standards of ESGE which recommends an adverse event rate of <10% and perforation rate of <3%.[1]

The surgical conversion rate post-SSDs in early stages of training was 4%(n=4). These were adenocarcinomas with hybrid(n=2) and R1 en-bloc resections(n=2).

The results have an understandably longer learning curve than Japan but

we demonstrated remarkable progress in resection speed, en-bloc and R0 resection rate over the 4 quartiles as well as a shorter learning curve than previously reported in the West for a new service based on a single operator without on-site tutoring.[2,3]

Conclusion: This study demonstrated that a new ESD service based on a single-operator without an on-site tutor achieved safety outcomes and R0 resection rate recommended by ESGE. Whilst further experience is required to achieve en-bloc resection rate ≥90% and resection speed ≥9cm^2/hr, the results from the first 100 cases suggest that the learning curve for SSD without on-site tutoring may be shorter than previously reported in the West.[2,3]

POTENTIAL SIDE EFFECT OF A SUBMUCOSAL LIFTING AGENT FOR ENDOSCOPIC RESECTIONS

T. Ichiya[1], K. Elahi[1], A. Forsberg[2]

[1]Capio Sankt Göran Hospital, Endoscopy center, Stockholm, Sweden, [2]Karolinska Institutet, Institution of Medicine Solna, Stockholm, Sweden

Contact E-Mail Address: tamaki.ichiya@gmail.com

Introduction: Submucosal lifting agent is critical to perform endoscopic submucosal dissection (ESD) and even used sometimes in conventional endoscopic mucosal resection (EMR). ORISE Gel is a recently introduced and approved lifting agent in United States and Europe and one of the most used injection solutions for ESD. However, it has recently been revealed in some cases that ORISE Gel induces a foreign body reaction histologically. Most publications have been reported as case series from United States, but few from other countries. We aim to analyze the characteristic findings and clinical implications with Orise Gel injection and literature review to increase awareness.

Aims & Methods: We used a prospectively maintained ESD database at our center in Sweden between January 2020 and March 2023. Colorectal ESD or converted EMR during ESD (rescue EMR) specimens injecting ORISE Gel were included. The literature review included from PubMed between January 2019 to March 2023.

Results: A total of 99 cases (89 ESD or rescue EMR and 10 subsequent surgeries) were identified during the study period. There are 48 male and 51 female patients with a median age of 69.4 years.

Orise gel injection was used in 57 cases (57.6%). 8 cases had radiological follow-up because of T1 cancer. Of these, 5 cases underwent subsequent surgical resections, where the injection sites were in distal rectum in 3, cecum in 1 and descending colon in 1 case. The surgical resection specimens showed histopathologically T2 colorectal cancer in one, residual adenoma with low grade dysplasia in 2, and no dysplasia cell in 2 cases. All of them showed histologically extensive foreign body-type granulomatous giant cell reaction. These changes were detected in 3 cases by MRI or CT image with a sign of local wall thickness before surgical resections. This resulted in a clinical overdiagnosis of more advanced T-staging. Meanwhile, 3 cases were followed up by radiological imaging and 2 of them showed a similar change as local wall thickness, however both were diminished as time advanced.

Conclusion: This large Swedish case series raises the awareness that the submucosal lifting agent causes extensive histological reaction at the injection site in all surgical specimens. These changes are observed at the radiological follow-up. This gel deposits in the specimens may lead to a misinterpretation of a mass as tumor growth and they can change differently with time.

Disclosure: Nothing to disclose.

Introduction: Little is known on the outcomes of endoscopic submucosal dissection (ESD) in patients with recurrent lesions after surgical local excision (transanal endoscopic surgery TES, transanal endoscopic microsurgery TEM, transanal minimally invasive surgery TAMIS) of superficial rectal neoplasms (1). We aimed to evaluate the feasibility, safety and efficacy of ESD for incomplete or recurrent rectal neoplastic lesions after transanal surgery.

Aims & Methods: This multicenter retrospective study assessed 38 patients who underwent ESD between June 2016 and February 2022 for recurrent or incompletely resected after TES or TEM. Treatment outcomes were evaluated. Primary outcome was the non-recurrence tumoral lesion at first endoscopic follow-up control. Secondary outcome were En bloc resection, R0 resection, curative resection.

Results: Main results are given in Table 1**.** There were 16 male and 22 female patients. Median age (range) was 68.7 (44–88) years. Seventy-four percent of lesions were located in the lower rectum, and 55% reached the pectineal line. Sixty-one percent of lesions were laterally spreading

tumor granular type (LST-G), and 34% were polyps. Forty-four percent of lesions were 0-IIa, and 23% were 0-Is according to the Paris classification. Seventy-one of lesions were Sano II, and 45% of lesions were Kudo IV. The median size of lesions (range) was 44 mm (10-100). Sixty-six percent of ESD were performed starting with full circumferential incision. Median operation time (range) was 79 (10–270) minutes. Thirty-nine percent of lesions has low vascular supply. Severe fibrosis was present in 78%of lesions. Ninety-two percent of lesions were successfully resected en bloc. R0 resection and curative resection rates were both 68%.

Rectal fat is visualized in eleven patients, none of them requiring a surgery. Four post-operative bleeding and two stenosis occurred. Median (range) hospital length of stay after ESD was 1.8 days (0-4). Pathological examination revealed 32 adenomas (23 with low-grade dysplasia, 9 with high-grade dysplasia) and 3 adenocarcinomas (3 T2; there was no Tis or T1).

All patients were followed up with endoscopic control after ESD, with biopsy samples if residual or recurrent tumor.Median (range) of follow-up period until first endoscopy control was 6.2 (1-13) months. « Only one residual lesion (one of three non-en bloc resections) actually showed low-grade dysplasia adenoma at follow-up.

En bloc Vs Non	35 / 3
R0 resection	26/38 (68%)
Curative resection, n (%)	26/38 (68%)
Operation time (median) min.	79
Follow up interval median	6.2 months
Residual lesion at first follow-up	1/38 (3%)

Table 1 : Treatment outcomes.

Conclusion: ESD for incomplete or recurrent superficial rectal neoplastic lesions after transanal surgery (TEM,TES, TAMIS) is highly feasible and safe, and allows curative resection in a vast majority of cases.

Introduction: Sessile Serrated Lesions (SSLs) show an “ultra flat” morphology, a mucus cap and are predominantly located proximally to the splenic flexure (PSF) (1). Hypothetically, previous knowledge in detection of flat or non-protruding conventional adenoma could be a predictor factor for endoscopic detection of SSLs.

Aims & Methods: Aim: To investigate in a South American Private Hospital, the relationship between Flat Adenomas Detection Rate (FADR) and Sessile Serrate Lesion Detection Rate (SDR)

Methods: This study is a retrospective, single-center analysis carried out at Centro Medico Docente La Trinidad Caracas-Venezuela from total selected colonoscopies performed by the gastroenterologists between 2008 and 2018 in patients 51-80 years old (YO). For this study, Adenoma Detection Rate (ADR) includes the whole morphologic spectrum of colon & rectum traditional adenomas from Paris Classification of Colorectal Lesions (2). We will consider the “General ADR” as “GADR”, including Non-protruding or flat ADR: “FADR” plus Protruding ADR: “PADR”, as well as the last two separately. By using logistic regression generalized estimating equation models, the location in colon & rectum and morphology of all types of adenomas (ADs) were assessed. The relationship between the global number of colonoscopies (GNC), GADR, FADR, PADR and the SDR was investigated calculating a correlation coefficient (CC) weighted by the number of total colonoscopies. In addition, 3 linear regression equation models to estimate the relationship between the 3 different types of ADR and SDR and the probability of occurrence of SDR based on the proportion of colonoscopies with SDR presenting every type of ADR weighted by the number of colonoscopies with SDR were calculated.

Results: For this study, 8432 colonoscopies were validated for 9 gastroenterologists (G1-G9). For patients between 51 and 80 YO, GADR for all 9 Gastroenterologists was 19.76%. GADR-SDR individually for 9 gastroenterologists (G1-G9) varies from as high as G9 GADR-SDR: 33.21%-4.19% to as low as G1: 12.67%-0.50%. The most frequent location for ADs was PSF: OR 1.95, IC 95% (1.30-2.84), P<0.001. SSLs were mostly located PSF OR 2.18, IC 95% (1.44, 2.92) P<0.001. The morphology of ADs was mainly pedicle OR 1.00 IC 95% P<0.001 and for SSL it was flat by far: OR 6.84 IC 95% (2.08-9.02) P<0.001. The CC demonstrated a good association between GADR and SDR: 0.98 P<0.05; and for FADR: 0.87, P<0.05 but not for PADR: 0.56 P=0.113. The GNC was not associated with the SDR CC: -0.197, P=0.6117. The GADR and FADR show robust strength of the linear relationship with SDR and probability of occurrence, but not for PADR (table).

Category of ADR	R^2	β	P	SDR Correlation coefficient	Probability of occurrence (%)	Colonoscopies in each category of ADR validated for SDR calculation
General ADR	0.9687	0.1632	<0.001	0.9842	94.26	148
Flat ADR	0.759	1.888	0.002	0.8712	92.35	145
Protruding ADR	0.3186	0.1664	0.113	0.5644	37.58	59

R^2 : Determination coefficient. This evaluates the strength of the linear relationship between the two variables.
β: Partial regression coefficient. It indicates the average effect that the increase in one unit of the predictor variable has on the dependent variable.
ADR: Adenoma Detection Rate. SDR: Serrated Detection Rate. 157 colonoscopies were valid for the calculation of the SDR

Table. Results of the linear regression models used to estimate the relationship between the different types of ADR and SDR and the probability of occurrence based on the number of Centro Medico Docente La Trinidad colonoscopies.

Conclusion: A sine qua non factor for a good SDR for the gastroenterologist is previous knowledge about “FADR”. To the best of our knowledge, this is the first time that ADR has been divided into “General, Flat and Protruded” in order to investigate the impact of the endoscopic skills on flat colorectal lesions detection for a good SDR.

Introduction: Colorectal adenomatous polyp is a precancerous lesion. Screening for detection and removal of colorectal adenomatous polyps has been shown to reduce mortality related to colorectal cancer. Recent studies have shown that colorectal adenomatous polyp is associated with atherosclerosis. Cardio-ankle vascular index (CAVI) and ankle-brachial index (ABI) are non-invasive methods to evaluate atherosclerosis and cardiovascular disease as well as peripheral artery disease.

This study aimed to investigate the association between atherosclerosis and high-risk adenoma based on CAVI and ABI.

Aims & Methods: We retrospectively analyzed data of patients aged ≥ 50 years who had CAVI, ABI, and a colonoscopy from August 2015 to December 2021 in Kangwon National University Hospital.

After having a colonoscopy, subjects were divided into groups with and without adenoma or high-risk adenoma (size ≥ 1 cm, high-grade dysplasia or villous adenoma, 3 or more adenomas) based on pathologic findings. Data were then subjected to univariate and multivariate logistic regression analyses.

Results: A total of 1,164 subjects were included. Adenomas were found in 613 (52.6%) subjects and the high-risk adenomas were found in 118 (10.1%) subjects.

The rate of positive ABI (< 0.9) and positive CAVI (≥ 9.0) were significantly higher in the high-risk adenoma group (22.0% and 55.9%) than those in the no adenoma (12.3% and 39.6%) and the overall adenoma group (15.7% and 44.0%) (p = 0.008 and p = 0.006, respectively). In a multivariate analysis, positive CAVI and smoking were significantly associated with high-risk adenoma (p = 0.027 and p = 0.021, respectively).

Conclusion: In this study, a significant correlation between positive CAVI and high-risk adenoma was observed. The use of CAVI could be a significant predictor of the presence of a high-risk adenoma.

13-YEAR COLORECTAL CANCER RISK: COMPARING PERSONS WITH A LOW- VS. HIGH-QUALITY SCREENING COLONOSCOPY VS. NO SCREENING COLONOSCOPY

S. Schwarz[1], M. Braitmaier[2], V. Didelez[2,3], U. Haug[1,4]
[1]Leibniz Institute for Prevention Research and Epidemiology – BIPS, Department of Clinical Epidemiology, Bremen, Germany, [2]Leibniz Institute for Prevention Research and Epidemiology – BIPS, Department of Biometry and Data Management, Bremen, Germany, [3]University of Bremen, Faculty of Mathematics and Computer Science, Bremen, Germany, [4]University of Bremen, Faculty of Human and Health Sciences, Bremen, Germany

Contact E-Mail Address: sschwarz@leibniz-bips.de

Introduction: Several studies have shown that a low quality of colonoscopy reduces its effect in preventing colorectal cancer (CRC), but it is not clear to which extent a low-quality colonoscopy is still effective compared to no colonoscopy. We aimed to compare the 13-year risk of developing CRC between persons with I) a high-quality screening colonoscopy, II) a low-quality screening colonoscopy and III) without a screening colonoscopy.

Aims & Methods: Using observational data from a German claims database (GePaRD; 20% population coverage) we emulated a target trial with three arms: High-quality screening colonoscopy (highQualSC) vs. low-quality screening colonoscopy (lowQualSC) vs. no screening colonoscopy (noSC) at baseline. The quality of baseline colonoscopy was categorized based on the polyp detection rate of the examining physician. We included persons at average CRC risk aged 55–69 years and without a colonoscopy, polypectomy or fecal occult blood test before baseline. We estimated adjusted cumulative CRC incidence over 13 years of follow-up.

Results: Overall, we included 142,960 persons in the highQualSC arm, 62,338 persons in the lowQualSC arm and 124,040 persons in the noSC arm. The adjusted 13-year risk of any CRC was 1.77% in the highQualSC arm, 2.09% in the lowQualSC arm and 2.74% in the noSC arm. Compared to the noSC arm, the adjusted relative risk (aRR) was 0.76 (95% CI: 0.70-0.84) in the lowQualSC arm and 0.65 (95% CI: 0.60-0.69) in the highQualSC arm.

Conclusion: Our study demonstrated that the effect of screening colonoscopy in preventing CRC is substantially lower in persons with a low-quality as compared to a high-quality screening colonoscopy. However, it also showed that attending a low-quality screening colonoscopy still markedly reduces the risk of CRC compared to no screening colonoscopy.

Disclosure: Nothing to disclose.

DEVELOPMENT AND VALIDATION OF A NOVEL CODING ANALYTIC TO IMPROVE ASSESSMENT OF ADENOMA AND SERRATED POLYP DETECTION RATES FOR COLONOSCOPY QUALITY STANDARDS

M. Chew[1], B. Anderson[2], W. Swansson[2], M. Garg[1,2], D. Lewis[1,2]
[1]Northern Health, Department of Gastroenterology, Melbourne, Australia, [2]University of Melbourne, Department of Medicine, Northern Health Clinical School, Melbourne, Australia

Contact E-Mail Address: diana.lewis@nh.org.au

Introduction: Adenoma detection rate (ADR) and serrated polyp detection rate (SDR) are internationally recognised quality indicators of colonoscopy. However, determining ADR and SDR requires the matching of endoscopy and histology reports, which can be challenging in the presence of separate electronic medical record systems. The use of coding analytics may expedite this process, enabling rapid and efficient data collection and extraction from reports. This study aimed to validate an innovative coding analytic in measuring ADR and SDR.

Aims & Methods: A coding analytic algorithm was developed to semi-automatically extract patients' names, polyp type, caecal intubation rate, and bowel preparation quality, from colonoscopy and histology reports. These reports were then manually reviewed to verify the concordance of patient names, ADR and SDR between the two methods. This process was applied in the initial phase, repeated following coding analytic change, and again with a validation cohort.

Results: The initial phase, which included 5911 colonoscopies performed by 53 endoscopists from January 2021 to June 2022, revealed that the coding analytic program extracted all patient names with 99.9% concordance and had a 98.9% accuracy in ADR and SDR. The discrepancies were mainly limited by spelling variation, different histology report dates, missing histology reports from the hospital's pathology database, and overlapping terms such as tubular adenoma and tubulovillous adenoma, or villous changes that were not specific to polyps. Coding analytic search terms were subsequently modified to take into consideration these limitations. Following modification, using data from the same cohort, accuracy of the coding analytics improved to 100%, excluding 4 colonoscopies that had missing histology reports.

A total of 2022 colonoscopies performed by 40 endoscopists at the same hospital network, over July to December 2022, were included in a validation cohort. The updated coding analytic program accurately extracted all patient names with 100% concordance, and a 99.9% accuracy in ADR and SDR. The sensitivities of ADR and SDR were 99.9% and 99.6% respectively, with specificities of 100% for both ADR and SDR (Table 1).

	Initial phase Before search term modification (%)	Validation phase After search term modification (%)
Colonoscopies performed in:		
Patients >50 years old	72.4	74.0
Non-IBD patients	91.3	90.3
Patients without previous colonic resection	91.9	92.3
Accuracy	98.9	99.9
Adenoma Detection Rate (ADR)		
Sensitivity	99.5	99.9
Specificity	99.2	100
Positive Predictive Value	98.6	100
Negative Predictive Value	99.7	99.9
Serrated polyp Detection Rate (SDR)		
Sensitivity	99.6	99.6
Specificity	100	100
Positive Predictive Value	100	100
Negative Predictive Value	99.9	99.9

Table 1: Performance of coding analytics before and after modification of coding search terms.

The discrepancies in the validation phase arose from 2 histology mismatches, that were a result of missing histology reports from the hospital's histology database program. Excluding this software error renders the coding analytic program to be 100% accurate.

Conclusion: This study demonstrated and validated an automated extraction coding algorithm to have an accuracy of almost 100% in determining ADR and SDR for endoscopists in a large tertiary healthcare colonoscopy service. Wider adoption of these coding analytics may enable significant improvements in auditing of colonoscopy quality that is more time-efficient.

Disclosure: Nothing to disclose.

TREATMENT STRATEGY FOR THE COLORECTAL LESIONS INVOLVING THE DIVERTICULUM ; SINGLE-CENTER RETROSPECTIVE OBSERVATIONAL STUDY

Y. Ebisawa[1], H. Chiba[1], A. Hayashi[1], M. Kobayashi[1], J. Arimoto[1], H. Kuwabara[1], M. Nakaoka[1]
[1]Oomori Red Cross Hospital, Gastroenterology, Ota-ku, Japan

Contact E-Mail Address: you.ebisawa603@gmail.com

Introduction: Endoscopic treatment of the colorectal lesions involving the diverticulum is difficult, due to the lack of muscular layer. There have been no investigations of the safety and feasibility of treatment strategy for the polyp close to or extending into the diverticulum. We investigated the outcomes of our treatment strategy for involving the diverticulum and verify the safety and the feasibility of our strategy.

Aims & Methods: Between November 2014 and January 2022, 33 cases of 33 diverticular polyp (16 males/17 females, age were 74 (54-92) years old) were enrolled in this study. Our treatment strategy for the colorectal lesions involving the diverticulum is determined by the location of polyps and diverticulum, the size of polyp, and the potential of malignancy. Cold polypectomy (CP) and gel-immersion EMR (GIEMR) are selected for the benign polyp of 10 mm or less that can be snared. The polyp with large diverticular openings, we try to inverted diverticulum.When snaring is difficult, ESD is performed. The lesions close to the diverticular opening could be resected by first incising and trimming the area close to the diverticular opening. When lesions extending into the diverticulum, ESD with the ring thread traction is performed. If traction alone cannot complete the procedure, ESD with a minor incision in the muscular layer is used in combination with traction.

Results: 3 cases of CSP, 8 cases of GI EMR, and 22 cases of ESD were performed. All cases in which CSP was performed were flat type, two polyps were located in the ascending colon and one in the sigmoid colon, the median size of polyps is 3 (3-5) mm, and all polyps were adenomas. The median time of treatment was 3 (2-5) minutes, en-bloc resection was achieved in all cases, and resected margins were all negative. GI EMR: Endoscopic classification were flat type lesions in 5 cases and elevated type lesions in 3, Four polyps were located in the ascending colon and one each in the cecum, transverse colon, descending colon, sigmoid colon, the median size of lesions is 10 (8-15) mm, the pathological findings were adenomas in 5 cases and SSLs in 3 cases. The median time of treatment was 5 (2-10) minutes, en bloc resection in all cases, and margins were negative. ESD: Of the 22 cases, 17 lesions located near the diverticular opening, and 5 lesions extended completely into the diverticulum. The lesions that extended into the diverticulum, 1 case was resected by diverticulum inversion, 3 cases by ring thread traction, and 1 case by traction with a minor incision in the muscular layer. Endoscopic classification were flat type lesions in 11, elevated type lesions in 11, 5 lesions were located in the cecum, 10 lesions in the ascending colon, one lesion in transverse colon, 6 lesions in sigmoid

colon, the median size of lesions is 25 (10-108) mm, the pathological findings were adenomas in 5 cases and intramucosal carcinoma in 17 cases. The median time of treatment was 35 (14-120) minutes, the median diameter of resection was 35 (20-110) mm, no complications were observed, and the horizontal margins were negative.

Conclusion: Endoscopic treatment can be performed safely by selecting a treatment method/strategy suitable for the characteristics of the colorectal lesions involving the diverticulum.

Disclosure: Nothing to disclose.

PP1186

THE VALIDITY OF FORCED COLD SNARE POLYPECTOMY: A PROSPECTIVE OBSERVATIONAL STUDY

Y. Ebisawa[1], J. Arimoto[1], A. Hayashi[1], M. Kobayashi[1], M. Nakaoka[1], H. Kuwabara[1], H. Chiba[1]
[1]Oomori Red Cross Hospital, Gastroenterology, Ota-ku, Japan

Contact E-Mail Address: you.ebisawa603@gmail.com

Introduction: CSDP (Cold Snare Defect Polypectomy) after CSP (Cold Snare Polypectomy) for colorectal lesions has been reported to be a factor related to pathological incomplete resection because it causes incomplete mucosal resection and specimen fragmentation. When CSP is performed, it is difficult to resect only with snaring, so it may be necessary for the endoscopist to pull the snare sometimes. However, There is no previous reports about CSP with this technique, and no study has examined “Forced” CSP (FCSP). We have the impression that CSDP is often recognized empirically in FCSP, and we investigated the frequency, safety, and validity of FCSP.

Aims & Methods: A prospective observational study was conducted with the primary endpoint being the frequency of FCSP among the CSPs performed at our hospital from November 2020 to June 2021. The patients were classified into the FCSP group and the conventional CSP group (CCSP). The rate of perforation was evaluated for safety, and the incidence of CSDP and the rate of unclear pathological margins were evaluated for validity.

Results: CSP was performed in 1391 lesions, and Forced CSP was performed in 110 lesions (7.9%). There were no cases of perforation, but CSDP was significantly higher in the Forced CSP group (96.4% (106/110) vs 6% (77/1281), p<0.001), and cases with unclear pathological margins were also used. It was significantly higher in the Forced CSP group (12.7% (14/110) vs 5.7% (75/1279), p=0.0126).

In an investigation of predictors for the need for Forced CSP, cecal polyps (OR, 2.6; 95% CI=1.483-4.55; p<0.001) and polyps ≥6 mm (OR, 11.36; 95% CI=7.277 -17.727; p<0.001) was identified as an independent related factor in the multivariate analysis.

Conclusion: FCSP does not affect the complication rate, but the incidence of CSDP and the rate of unclear pathological margins are significantly high. Further investigation at multiple institutions is desired in the future.

Disclosure: Nothing to disclose.

Introduction: Treatment of patients with locally advanced rectal cancer consists of neoadjuvant chemoradiotherapy (nCRT) followed by surgery[1]. Remarkably, standard treatment does not consider the fact that 15-27% of rectal cancer patients achieve a pathological complete response (pCR) after nCRT[2-5] and may not need the surgery. Unfortunately, current imaging modalities lack sensitivity and specificity to adequately predict a pCR. Previously, we have proven the potential of bevacizumab-800CW for assessing the pCR[6]. Cetuximab-800CW targets endothelial growth factor receptor (EGFR) which is tumor-specific and may therefore be even more promising as biomarker.

Aims & Methods: This study aimed to determine the safety and feasibility of quantitative fluorescence molecular endoscopy (qFME) using cetuximab-800CW for evaluation of response to nCRT in rectal cancer. Patients received an intravenous dose of 15 mg cetuximab-800CW preceded by 75 mg unlabeled cetuximab 2-4 days prior to the endoscopy. In vivo FME was performed to analyze fluorescence in both potential residual tumor and healthy tissue and biopsies were taken from both sites. Additionally, both in vivo and ex vivo the fluorescent signal intensity was quantified using spectroscopy. Subsequently, extensive ex vivo analyses were performed on both biopsies and the resected specimen including immunohistochemistry and fluorescence microscopy for specific localization of the fluorescent drug and observation of the immune cell composition.

Results: Five out of ten included patients had a pCR after nCRT. Quantification showed a significantly higher fluorescent signal in the (former) tumor area when compared to healthy tissue in both patients with a partial (p<0.0001) and complete response (p<0.0001). Although immunohistochemical EGFR analysis in the biopsies showed a significantly higher expression in tumor epithelium when compared to healthy mucosa (p=0.0070) and fibrosis (p=0.0083), a clear difference between tissue with residual tumor and a pCR could not be distinguished (p=0.5334). Fluorescence microscopy revealed that specific binding of cetuximab-800CW to tumor epithelium was only visible in the submucosa. Remarkably, aspecific binding to macrophages was observed in the mucosa of both patients with a pCR and partial responders resulting in enhanced off target fluorescence signals.

Conclusion: Even though cetuximab-800CW was visualized in the “former” tumor area using qFME and during subsequent ex vivo analysis of the biopsies, cetuximab-800CW could not be used to identify pCR patients. However, due to our extensive further analysis we discovered that specific binding to tumor epithelium was not enough located at the luminal side to be detected during qFME and that the detected signal may be caused

by aspecific binding to off target uptake of mucosal macrophages. Novel techniques like ultrasound guided needle biopsy single fiber fluorescence spectroscopy that can measure fluorescence below the superficial layer may enable the use of cetuximab-800CW during qFME for monitoring after nCRT in rectal cancer.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is an effective treatment for large colorectal tumors, but the technique is more difficult and is associated with more complications such as bleeding and perforation compared to EMR. Therefore, accurate identification of blood vessels and muscle layers is essential for safe colorectal ESD. However, it is often difficult to perform the treatment while recognizing all of the image information on the monitor.

Therefore, in this study, we conducted a proof of concept study to determine whether deep learning can be used to identify the submucosa and muscular layer in images taken during ESD procedures.

Aims & Methods: We used 11 procedure videos randomly selected from cases of colorectal ESD performed at our center between January 2020 and July 2022. The videos were cropped every second as still images, and these still images were labeled with semantic segmentation (hereafter referred to as segmentation). This is a method of labeling each pixel in an image, and Artificial intelligence (AI) trained with this method can segment regions of the target image according to the tissues and devices depicted in the image.

In this study, 16 different labels were performed for each pixel of each image, including mucosa, submucosa, muscular layer, and blood vessels. Of the 11 labeled case images, 9 cases were used for training and 1 case with no duplicate training was used for validation. The training images were machine learned with a representative method of medical image segmentation called U-NET and evaluated for accuracy.

Results: Characteristics of patients and tumors of the 11 cases in this study were male to female ratio of 7:4, mean age of 71.9 years (36-83), mean tumor diameter 25.2 mm (3-54 mm), colon/rectum ratio of 8:2, adenoma to T1 cancer ratio 5:6. One thousand and five hundreds sixty-one images were used for training, and 90 images were used for evaluation as validation. The accuracy (corresponding to the number of pixels correctly answered out of the labeled pixels) of the trained AI to the validation images was 83.0%. The submucosa, muscular layers, and vessels, which have a large labeled area, were relatively discriminated.

Conclusion: The use of segmentation technology demonstrated the feasibility of real-time ESD navigation by AI. In the near future, we aim to further improve the system by increasing the number of training images.

Introduction: Currently, colorectal cancer is the second leading cause of death worldwide[1]. Therefore, colon cancer screening tests such as colonoscopy and fecal occult blood test (FOBT) are performed to reduce the mortality and incidence of colorectal cancer[2-5]. Although FOBT is a simple test, positive patients eventually require colonoscopy to confirm the presence of lesions. Thus, colonoscopy is gold standard to detect and diagnose colon cancer. However, performing a colonoscopy requires a high level of skill in colon insertion, making it challenging for beginner colonoscopists to achieve total colonoscopy. Furthermore, cases involving longer colons and adhesions require even more advanced techniques. Therefore, a new colonoscope that allows safe and easy colon insertion is desired.

Aims & Methods: To simplify colon insertion, a prototype of robotic colonoscope was developed using 3D printer. The device consists of an outer and an inner tube with a balloon and a bending function. Therefore, the mechanism is characterized by the tip of the inner tube being pushed out to the off-axis by tip direction of outer tube. The insertion method is expected to avoid excessive stretching of the intestinal tract. They are independently and electrically manipulated to bend and push/pull using servo motor via a controller, so it has potential to insert total colon alone.

The model was designed with a maximum outer diameter of 14 mm. Therefore, it can insertion test using colon model. In this study, insertion to colon model of case 1 (Colonoscope training model, KYOTO KAGAKU Co., LTD, Japan) was investigated using the developed device.

Results: Investigation of the operation of the developed device confirms that the controller can be used to control bending of the outer and inner tubes, inflation and deflation of balloons attached to the outer and inner tubes, and pushing and pulling of the inner tube. The maximum angles of the outer and inner tubes were approximately 90 and 180 degrees, respec-

tively. The balloons were confirmed to inflate to a diameter of approximately 7 cm, which is sufficient for intestinal fixation. In addition, the tips of the outer and inner tubes could lift up to 200 and 50 g, respectively.
In the insertion test, the device was reached from the anus to the cecum in approximately 440 s by a non-medical operator alone. In addition, the device can be inserted into the colon model without excessive stretching during the test.
Conclusion: In this study, a prototype of robotic colonoscope with double-balloon and double-bend tube was developed to simplify insertion, and it was confirmed well operated properly. In insertion test, the device could be reached to cecum of colon model (Case 1) by non-medical operator alone. In addition, the behavior was free from over-extended colon model, thus, it suggests that the mechanism of prototype can contribute to comfortable colonoscopy.

Introduction: Early-stage colorectal cancer (T1CRC) patients are confronted with complex medical information and considerations throughout the course of their treatment. This study explored patients' perspective on information provision and therapeutic decision-making.
Aims & Methods: Patients who underwent endoscopic or local surgical resection for T1CRC were eligible for participation in this cross-sectional multicenter study. Information provision was evaluated using the EORTC QLQ-INFO25 questionnaire (INFO25)(1). In patients with a high-risk T1CRC we additionally evaluated patients' perception of involvement in decision-making regarding the choice to opt for or refrain from additional treatment after local resection, and the degree of decisional conflict using the decision conflict scale (DCS)(2).
Results: In the 98 responders (response rate: 71.5%), patients with high-risk T1CRC (n=45) reported to have received more information on multiple disease aspects compared to patients with low-risk T1CRC (n=53). However, the need for more information was not significantly different between both groups (p=0.31). Overall, 29 patients expressed a need for more information, with 'prevention' and 'post-treatment care' reported as the most common areas with unmet information needs. Of the 45 patients with high-risk T1CRC, 24 (53.3%) underwent additional treatment, whereas 21 (46.7%) opted for close monitoring. Twenty-seven patients (60%) reported that they were actively involved in this decision (i.e. 'I made the decision myself'), while 18 patients (40%) reported to be passively involved (i.e. 'I let my physician make the decision' or 'I didn't feel like there was a choice'). Satisfaction scores regarding information provision were similar between patients that underwent additional treatment or opted for close monitoring (range 0-100, 70.8 vs. 73.0, p=0.77). Higher educated patients were more likely to report active involvement in therapeutic decision-making compared to lower educated patients (92.9% vs. 43.3%, p=0.002) and to eventually undergo additional treatment (78.6% vs. 40%, p=0.02). The satisfaction scores regarding how the treatment decision was made did not differ significantly between patients with higher and lower levels of education (range 0-100, 83 vs. 85.1, p=0.78).
Conclusion: From the T1CRC patient's perspective, this study found that higher educated patients were more likely to be actively involved in therapeutic decision-making than lower educated patients, although decisional satisfaction was irrespective of educational level. With respect to information needs, patients expressed a desire for more information on disease prevention and post-treatment care.

Contact E-Mail Address: Hann_A@ukw.de
Introduction: Automated identification and discrimination of individual colorectal polyps through artificial intelligence (AI) is a crucial step towards the development of colonoscopy report generation systems. The basic information of a colonoscopy report should contain the total number of identified polyps and characteristic images of the polyps, which will determine the follow-up time and treatment. However, there is no widely adopted solution to accomplish this task.
Aims & Methods: In this study, we propose an AI-based pipeline for automatic individual polyp identification and retrieval of corresponding polyp images to simplify and accelerate colonoscopy report generation. A pipeline consisting of a Siamese Twin Neural Network and a hierarchical density-based spatial clustering method was implemented for individual polyp

identification and discrimination. The AI model was trained and validated using frames containing polyps which were extracted from 549 and 61 full-length colonoscopies videos respectively, recorded in 7 different endoscopy centers. The pipeline was tested on frames containing a total of 29 different polyps extracted from 10 colonoscopies. The evaluation metrics were two measures to estimate the quality of clustering ranging from 0 (no correlation) to 1 (perfect correlation): normalized mutual information (NMI) and adjusted rand index (ARI). Additionally, we calculated the precision of corresponding individual polyp images.

Results: Testing on frames with visible polyps obtained from 10 colonoscopy examinations demonstrated that the pipeline achieved an NMI of 0.862 and an ARI of 0.835, indicating that at least 80% of the data can be accurately clustered and identified. The average precision was 0.763, representing the probability of retrieving the correct and corresponding individual polyp images.

Conclusion: We have developed a pipeline that uses artificial intelligence techniques to identify individual polyps and retrieve representative polyp images. These approaches have the potential to simplify and accelerate the process of automatically generating a colonoscopy report, while also providing characteristic images for each detected polyp for future use.

Introduction: Chromoendoscopy improves the visualization and differentiation of mucosal structures and enhances the polyp and adenoma detection rates. The dye-spray technique is a lengthy and laborious procedure. An oral formulation could serve as alternative, as demonstrated by Methylene Blue MMX. In contrast to methylene blue, patent blue V (E131) is an EFSA-approved food dye and practically free of side effects.

Aims & Methods: The aim of our case series was to encapsulate patent blue V in shellac food-grade microcapsules for oral intake and to evaluate the delayed release and mucosal staining as proof of principle.

Capsules filled with shellac microcapsules containing 100 mg patent blue V were produced by food technology for pH-dependent release in the ileum.

Between December 2016 and March 2022, 37 patients scheduled for a chromocolonoscopy volunteered to receive oral microcapsules for staining instead of the conventional dye-spraying procedure. 20 of the patients were additionally scheduled for a gastroscopy. Patients self-administered 4 capsules during the second half of the bowel preparation with Klean-Prep (Norgine), at the latest 5 hours before chromocolonoscopy. Staining was rated by a score (0 points = not stained, 4 points = optimal even staining).

Results: The best staining quality was observed between the cecum and the sigmoid (ranges between 3.3 and 3.6 points). The terminal ileum (2.9 points) and rectum (3.1 points) were also stained acceptable. Absence of staining or overstaining were not reported. The mucosa in the upper gastrointestinal tract was not stained (0 points) in patients who underwent a gastroscopy on the same day. The polyp detection rate in our cohort was approximately 64%, the adenoma detection rate was 56%. The patent blue V capsules produced a good staining intensity, contrast of lesions, polyps and adenomas. The staining quality was rated equivalent to experience with dye-spraying chromocolonoscopy, with the advantage of clean equipment and a reduction of colonoscopy time.

Conclusion: Patent blue V microcapsules produced an even staining of the mucosal surface for chromocolonoscopy. Delayed-release patent blue V may be a superior and safe alternative to dye-spray techniques and Methylene Blue MMX with potential advantages in time of the procedure, sedation, cleaning, costs and skills. After this proof of concept, a randomized study with delayed-release patent blue V appears warranted.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is not widely performed in western countries due to technical complexity, risk of adverse events, and procedure time. Hybrid ESD (H-ESD) - partial submucosal dissection followed by snare-assisted resection – may be useful

to achieved endoscopic resection in difficult situations. In our center we use H-ESD as rescue therapy during conventional ESD in case of unstable position, inability to achieving appropriate and safe knife angle, advanced submucosal fibrosis or thin submucosal layer and patient instability.

Aims & Methods: We retrospectively analyzed colorectal ESD performed in our centre between January 2014 and March 2023, colorectal lesions in inflammatory bowel diseases were excluded. Univariate and multivariate analyses were conducted to examine factors that may have influenced switch to H-ESD.

Results: A total of 281 colorectal ESDs for superficial neoplasms in 276 patients were considered. 160 patients (58%) were male with an average age of 68,9 years. In 55 (19,6%) cases ESD was switch to H-ESD.. 171 lesions were located in the colon (60.8 %) and 110 (39.1%) in the rectum; mean maximum diameter of the neoplasms was 35,9 mm (SD 18,4 mm). En bloc resection and complete resection (en bloc resection and R0) were achieved in 259 (92 %) and 245 (86 %) cases respectively.

On univariate analysis, the use of waterjet system-assisted knife (OR 0,3; 95% CI 0,17-0,57), underwater-ESD (OR 0,24; 95% CI 0,09-0,63), rectal localization (OR 0,17; 95% CI 0,07-0,40) and granular laterally spreading morphology (OR 0,40; 95% CI 0,21-0,75) were significantly associated to the achievement of complete ESD. Proximal colon localization (OR 3,9; 95% CI 2,08-7,30), severe submucosal fibrosis (OR 4,9; 95% CI 2,51-9,63), non-granular laterally spreading morphology (OR 2,31; 95% CI 1,27-4,21) and maximum diameter < 40 mm (OR 3,91; 95% CI 1,83-8,38) were related to the switch to H-ESD. On multivariate analysis only waterjet system-assisted knife use and U-ESD were significantly correlated with achievement of complete ESD; severe submucosal fibrosis and proximal colon localization resulted significantly related to the switch to H-ESD.

	Univariate Logistic Regression			Multivariate Logistic Regression		
VARIABLE	OR	CI	P	OR	CI	P
Proximal colon	3,90	2,08-7,30	<0.0001	3,0481	1,21-7,68	0.0181
Rectum	0,17	0,07-0,40	<0.0001	0,3956	0,13- 1,21	0,1048
LST NG	2,31	1,27-4,21	0.0061	0,6277	0,22-1,78	0,3812
LST G	0,40	0,21-0,75	0.0039	0,4494	0,15-1,32	0,1452
Maximum diameter < 40 mm	3,91	1,83-8,38	0.0004	1,9589	0,81-4,76	0,1378
Severe submucosal fibrosis (F2)	4,91	2,52-9,63	<0.0001	4,6588	2,10-9,88	0.0001
Waterjet system-assisted knife	0,30	0,17-0,57	0.0002	0,4297	0,21-0,88	0.0219
Underwater ESD	0,24	0,09-0,64	0.0039	0,1612	0,06-0,47	0.0008

Conclusion: The use of waterjet system-assisted knife and underwater technique reduce the need to switch to H-ESD during endoscopic submucosal dissection of superficial colorectal lesions. Severe submucosal fibrosis and proximal location are risk factors for the need for the H-ESD switch.

Contact E-Mail Address: katie.siggens@nhs.net

Introduction: The use of optical diagnosis for "resect and discard" and "diagnose and leave" strategies has been postulated for several years, but despite promising early results this has not been implemented outside of expert centres due to the challenge of accurate characterisation and sizing (1,2). Computer aided diagnosis (CADx) has shown promising potential for improving optical diagnosis. However, there is still no data on real-time sizing and characterisation together which is what will be required for the introduction of this strategy and meeting Preservation and Incorporation of Valuable endoscopic Innovations (PIVI) thresholds.

Here we aimed to assess the performance of a novel CADx algorithm and its use during real-time colonoscopy.

Aims & Methods: A dedicated colon CADx algorithm was developed to categorise polyps by histology (neoplastic or non-neoplastic) and by size (diminutive or non-diminutive). In the first phase of this study, the system was tested on a customised video based platform using prospectively collected endoscopy videos. Ground truth for characterisation was histology and for sizing was the use of an instrument e.g. biopsy forceps along with 3 expert endoscopists review.

The next phase was a pragmatic study to test real-time performance of CADx during colonoscopy. In this phase endoscopists were asked to characterise and size of polyps which were removed or biopsied for histology. Videos were recorded for external validation by 3 expert endoscopists.

Results: In video based analysis, 292 polyp videos (202 neoplastic and 90 non-neoplastic) were assessed using the CADx device. Video based AI sizing demonstrated sensitivity, specificity, accuracy and NPV for non-diminutive size of 93.40%, 79.03%, 93.40% and 95.45% respectively. Video based characterisation results are summarised in Table 1.

In real-time analysis, 116 (66 neoplastic and 50 non-neoplastic) polyps in 36 patients were assessed with CADx during real-time colonoscopy. Real-time characterisation results are summarised in Table 1. Real-time concordance for sizing between endoscopist and AI as diminutive or non-diminutive was 84.61%. Subgroup analysis was carried out for video based and real-time CADx for performance on diminutive polyps. The NPV for diminutive rectosigmoid polyps for adenomatous diagnosis was 93.3% in real-time.

There was 97.2% concordance between surveillance intervals (ASGE and BSG guidelines) based on histology versus AI diagnosis for diminutive polyps and histology for non-diminutive.

	Video based CADx (n=292)		Real-time CADx (n=116)	
	WLI	IE	WLI	IE
Sensitivity (%)	86.14	91.76	89.20	90.50
Specificity (%)	85.56	78.75	82.70	94.10
Accuracy (%)	85.96	87.79	87.10	92.10
NPV (%)	73.33	80.77	86.00	88.90

Table 1. Overall CADx performance.

Conclusion: This is the first study demonstrating the outcome of AI based sizing and characterisation of polyps in real time. The system meets PIVI 1 and PIVI 2 threshold suggesting we are close to being able to implement 'resect and discard' and 'diagnose and leave strategies'. Further validation from a multicentre prospective study will help guide this.

THE INFLUENCE OF PATIENT AND EXAMINER FACTORS ON SEDATION USAGE AND INTUBATION RATES DURING COLONOSCOPIES: PRELIMINARY RESULTS OF A RETROSPECTIVE COHORT STUDY

B. Brandstrup[1,2], T.W. Bauer[3], M.T. Madsen[3], M. Bulut[4]

[1]Holbæk Hospital, part of Copenhagen University Hospitals, Department of surgery, Holbaek, Denmark, [2]University of Copenhagen, Institute for Clinical Medicine, Copenhagen, Denmark, [3]Slagelse Hospital, Department of surgery, Slagelse, Denmark, [4]University Hospital Zealand, Department of Surgery, Koege, Denmark

Contact E-Mail Address: bbrandstrup@hotmail.com

Introduction: In the Region Zealand 17.000-18.000 colonoscopies are performed annually, predominantly in an outpatient setting with or without sedation. The usage of sedation is often given on an on-demand basis, however, multiple factors like preexisting abdominal pain, preferences of the endoscopist or the patient, and local guidelines may be at play. The most common drugs used as sedatives in our region are midazolam and fentanyl and only to a lesser extend propofol or general anesthesia.

Aims & Methods: The aim of the study is to describe the usage of sedation in relation to elective outpatient colonoscopy stratified for demographics, and to analyze the influence of sedation on the colonoscopy completion rate.

This is a cohort study of patients undergoing elective colonoscopy at any hospital unit in Region Zealand from 01-Jan-2018 to 31-December-2022. All data were entered prospectively into the Endo-Database and analyzed using descriptive statistics and Chi-square test. A multivariate analysis is planned including further data such as examiner factors, but not yet completed. The results given here are therefore preliminary.

Results: From January 1st, 2018 to December 31st, 2022 (5 years) 43,364 men and 42,122 woman with a median age of 66 years (range 3-102) underwent colonoscopy. 356 (0.4%) had general anaesthesia, 1272 (1.5%) had propofol, 53,671 (62.8%) had midazolam and fentanyl, and 29,799 (34.9%) had no sedation. A total of 249 endoscopists at all levels of experience performed the examinations.

Significantly more woman than men received sedation during the procedure: 33,421 (79.6%) woman vs. 21,878 (50.7%) men, p<0.00001. This difference were independent of the reason for colonoscopy (cancer control, screening, HNPCC, adenoma control, referral in "cancer package", or referral for other reasons).

Caecum or the terminal ileum was reached for 91.1% of woman and 91.4% of men, p=0.143. The usage of sedation significantly influenced the completion of the colonoscopy:

For men 93.3% of colonoscopies were complete with sedation versus 91.2% without sedation, p<0.00001. For woman 92.7% of colonoscopies were complete with sedation versus 88.5% without sedation, p<0.00001.

Procedures registered (No)	Endoscopists (No)	Procedures/ endoscopist (mean)	Sedated* (%)	Completion (%)
1-199	137	35	70	86
100-299	40	171	69	90
300-1000	47	564	69	87
1000-2000	18	1519	69	86
2000-3635	7	2956	51	92

*With midazolam and fentanyl

The table show the number of procedures performed by the endoscopists, percent of patients receiving sedation and percent complete procedures (cecum or ileum reached). The endoscopists with >2000 procedures reach cecum even without sedation. Otherwise no clear trend is found.

Conclusion: Woman received sedation significantly more frequently than men. Sedation increased the completion rate of colonoscopy in both genders seemingly more in females. Endoscopists with >2000 procedures in 5 years reached cecum even with a low usage of sedation. The current abstract is limited by univariate analysis at a preliminary stage.

Disclosure: Nothing to disclose.

OPTIMIZATION AND MULTI-CENTER VALIDATION OF A COMPUTER-AIDED POLYP DETECTION SYSTEM IN COLONOSCOPY

W. Wang[1], X. Tan[1], L. Yao[1], H. Yu[2]

[1]Renmin Hospital of Wuhan University, WuHan, China, [2]Renmin Hospital of Wuhan University, Gastroenterology, Wuhan City, China

Contact E-Mail Address: wwdoct@163.com

Introduction: Colorectal cancer (CRC) is the third most common type of cancer and leading cause of death from cancer worldwide. Colonoscopy for CRC screening is widely implemented by countries worldwide to reduce the incidence and mortality of CRC. However, the overall missed diagnosis rate of colorectal adenoma under colonoscopy is 22%. In recent years, computer-aided polyp detection (CADe) has developed rapidly, yet the majority of research concentrates on the analysis and testing of image sets and video with polyps. However, in practical applications, numerous video clips do not contain polyps but instead feature considerable noise. These images or video clips will cause a lot of false positive detection. High false positive rate will reduce the overall accuracy and ease of use of the system, and increase the burden of endoscopists.

Aims & Methods: The purpose of this study is to optimize the existing polyp model, improve its specificity without reducing the sensitivity of the model and make it more suitable for clinical use.In view of the speed advantage of YOLOv5 in target detection, we used YOLOv5 model to complete the detection of polyps in colonoscopy video.The training set contained 8166 positive images with polyps and 11417 negative images without polyps. The positive polyps were obtained from 2834 patients while the negative images were from 1852 patients. All the patients were enrolled from Renmin Hospital of Wuhan University between November 2016 and December 2019.ALL the images with polyps were annotated using an online image annotation tool, VGG Annotator (http://www.robots.ox.ac.uk/~vgg/software/) by Endoscopists with more than 5-year experience of colonoscopy operation from the Endoscopy Center of Wuhan

University.At the same time, the method of adding negative marker boxes to false positive images was creatively used to suppress false positive detection ,Using noise as the background and negative marker boxes as the object to be predicted. In the training process, more noise features are extracted as the background. In the prediction process, the step of filtering the negative mark box is added to filter too many false positive images to achieve the purpose of suppressing false positive. At the same time, the Mosaic data enhancement method is used to train the model and realize the optimization of the model.

Results: We retrospectively collected polyp images from nine centers from 2021 to September 2022. After excluding unqualified images (such as surgery, blur, chromoendoscopy, etc.), we finally collected 3906 adenoma images, 3406 inflammatory polyp images and 2523 sessile serrated lesions SSL images for external validation of the model. In addition, 4186 images without polyps were collected. All polyps are manually marked by the endoscopists. The sensitivity of the polyp detection model is described from three levels: image level, 0<IOU<0.5, and IOU>0.5. The total sensitivity of the model for identifying all types of polyps reached 96.25%, 96.09%, and 91.32%, respectively. The sensitivity of adenomas was 98.39%,98.28%and 94.96%. At the same time, The sensitivity of inflammatory polyps was 95.98%, 95.77%, and 91.57%. The overall sensitivity of sessile serrated lesions was 93.30%, 93.10%, and 85.33%, respectively (Table 1).The specificity of the model was 97.66%.

Conclusion: We have optimized the existing polyp detection model by adding the negative marker box and Mosaic data enhancement, which improves the specificity of the model without reducing the sensitivity of the model, reduces the false positive rate, and is more conducive to clinical use.

Introduction: Colonoscopy is the gold standard for accurate exploration of the colon. Thus, it must be performed as efficiently as possible with the respect of pre-established quality standards to ensure optimal exploration. The patient's tolerance considerably affects the quality of sedation-free examinations and exposes to a high rate of interruption. Pharmacological sedation can solve this issue, however it can expose to significant adverse events and is not always available.

Aims & Methods: The aim of this study was to evaluate the impact of intraprocedural immersive virtual reality (VR) combining visual and auditory distraction in the improvement of the tolerance and the progress during unsedated colonoscopy. We conducted a prospective controlled study from February to April 2023 including outpatients presenting to the endoscopy unit for unsedated colonoscopy after consent. Patients were randomized into two groups: Group 1: colonoscopy with virtual reality headset. Group 2: control group without intervention.The material used was a virtual reality headset provided with a fully adjustable headband. The video content displayed on the hardware is made of several clips showing nature scenes. The audio content was adapted to allow optimal communication with the patient. We have excluded patients with severe visual and/or auditory impairment, dementia, cognitive impairment and epilepsy. All participants initially completed a form covering health issues and a validated anxiety questionnaire (STAI). After colonoscopy, all patients completed a form with questionnaires assessing per-procedural patient comfort (Gloucester), anxiety (STAI) and pain (EVS). In addition, patients in the intervention group completed a satisfaction questionnaire (NPS: net promoter score) assessing their experiences with the VR headset.

Results: In total, 63 patients were included in the final analysis: intervention group G1 (n=33) and control group G2 (n=30). The mean age was of 57 years. No patient encountered a technical problem with the equipment used and no adverse events occurred during the immersive experience. The two groups were comparable in terms of age, gender, comorbidities, body mass index (BMI) and colonic preparation assessed by the Boston score. A slightly lower time to caecal intubation was noted in the intervention group without significant difference (G1: 19 min vs G2: 26 min, p=0.07). Patients with VR mask expressed lower levels of post-procedural anxiety than those in the control group (Mean STAI G1: 47 vs G2: 53, p<0.01) and a significant decrease in the STAI score compared to pre-endoscopy values (8 points vs 4 points, p<0.01). The per-procedural pain assessed by EVS was significantly lower in the patients using VR (Mean G1: 0.44 vs G2 :1,32, p<0.01). Moreover, endoscopic examination was found to be more comfortable with virtual reality based on the Gloucester scale p <0.01. No patient reported any impediment to communication with medical staff due to the VR mask. Four patients were not satisfied with the resolution of the videos and 8 patients have expressed their preference to choose the content themselves. Patients of the intervention group were greatly satisfied with the VR experience with a mean NPS at 30.

Conclusion: Immersive VR technology is a promising, non-invasive and well-accepted simple tool for improving tolerance by reducing colonoscopy induced pain and anxiety allowing an optimized examination. It can be a useful alternative to conventional sedation if undesired or contraindicated or in health care institutions with a lack of adequate anesthesia facilities.

Disclosure: Nothing to disclose.

Introduction: Endoscopic removal of large gastrointestinal polyps can be technically challenging. A novel rigidizing overtube (ROT) was developed as a platform to facilitate endoscopic removal of these polyps. The purpose of our study was to prospectively evaluate the clinical efficacy and safety of ROT in the management of GI polyps.

Aims & Methods: This was an observational, prospective, single-center study between May 2021 - March 2023 enrolling patients undergoing EMR (endoscopic mucosal resection) or ESD (endoscopic submucosal dissection) for large polyps. The primary outcome was device safety and technical success of ROT. Safety and performance data were collected intraprocedurally and at 1 month post. Secondary endpoints included clinical

success, insertion times, total procedure time, and investigator feedback post-procedure. Technical success was defined as a successful placement of the overtube resulting in safe manipulation of the lesion/polyp. Clinical success was defined as the ability for the ROT to allow endoscopic removal of polyps without changing the initial resection intent.

N= 109 subjects (114 polyps)	
Male, n (%)	54 (49.5%)
Age, mean +/- SD	65.4 +/-9.8
BMI, mean +/- SD	29.3 +/- 6.3
Concomitant medications

Mean surface area for polyps undergoing complete ESD, mm2 +/- SD	719.9mm2 +/- 618.8
Mean dissection speed for ESD, cm2/hr	9.33cm2/hr
En bloc resection, n (%)	73 (90.1%)
R0 resection, n (%)	68 (84%)
Adverse events, n (%)	6 (5.5%)
Device related, n	0
Post polypectomy syndrome, n	1
Delayed bleeding, n	3
Small bowel obstruction, n	1
Death	1

Table. Demographical data and polyp characteristics for patients undergoing endoscopic resection of GI polyps using the ROT (rigidizing overtube).

Results: A total of 109 subjects were enrolled into the study comprising 114 total polyps. The most common polyp location was the ascending colon and cecum (Table). 28.95% and 71.05% of polyps were removed via EMR and ESD/Hybrid ESD, respectively (Table).

Technical and clinical success was achieved 98.24% and 77.19% of the time, respectively. Total mean size of all polyps was 65.1mm +/- 57.7. There was a significant difference in total procedure time between EMR and ESD (69.6 minutes +/-41.5 vs 91.6 minutes +/- 38.9, p=0.0087). Dissection speed for polyps undergoing ESD was 9.3cm2/hr. Tissue traction during ESD was only needed in 45.6% of polyps most commonly via clip-band traction. En bloc and R0 resection rates for polyps removed via ESD were 90.1% (n=73) and 84% (n=68), respectively. On endoscopist feedback, the ROT was thought to assist in resection in 98.2% of polyps, although the polyp was in a somewhat/very difficult location 76.3% of the time. For polyps in difficult locations, the ROT was able to maintain scope position without falling back even once 64.9% of the time. There was no device related malfunctions that necessitated device removal. Mean time to reach the polyp was only 6.98min +/- 4.7. No device related adverse events occurred (Table 2).

Conclusion: In this prospective study, the novel rigidizing overtube was safe and maintained a high technical/clinical success rate during the resection of GI polyps. Its ease of use, ability to provide stability, and conduit function allow for efficient endoscopic resection despite difficult polyp locations. Further randomized studies are needed to determine when its use should be implemented during endoscopic resection.

Introduction: People can die from unwarranted variation in colonoscopy quality; endoscopists with low polyp detection rate have higher post-colonoscopy colorectal cancer incidence and mortality. The UK's National Endoscopy Database (NED) automatically captures real-time patient data and provides endoscopy key performance indicators (KPIs).

Aims & Methods: The primary objective of this study was to assess if a theory-informed and evidence-based behaviour change intervention, involving automated feedback of endoscopist case-mix adjusted Mean Number of Polyps (aMNP), improves detection performance.

The NED Automated Performance Reports to Improve Quality outcomes Trial (APRIQOT) is a national multicentre, prospective, cluster-randomised control trial. UK NHS endoscopy centres were randomised to intervention or control arms. Intervention-arm endoscopist were emailed personalised and tailored monthly reports automatically generated within NED. These contained their aMNP and an action plan, developed using evidence from qualitative interviews and informed by behaviour change theory, and access to a bespoke website. The primary outcome was endoscopists' aMNP during the 9-month intervention. Secondary outcomes included traditional KPI. Analysis plans and a full trial protocol were published.(1)

Results: During November 2020-July 2021, 541 endoscopists across 36 centres (19 intervention; 17 control) performed 54,770 procedures during the intervention period, and 15,960 procedures during the 3-months post-intervention. Comparing intervention-arm to control-arm endoscopists during the intervention period: aMNP was 7% higher although not statistically significance (95% confidence interval (CI) -1% to 14%; p=0·08). Unadjusted MNP (10%, 95%CI 1-20%, p=0.04) and polyp detection rate (PDR) (10%, 95%CI 4-16%, p=0.002) were significantly higher. Intervention participants were significantly more likely than controls to be above the aMNP minimum standard (OR 1.77, 95%CI 1.02-3.10, p=0.04). Differences were not maintained in a 3-month post-intervention period. The intervention effect on aMNP was modified by centre workload (aMNP in low-workload centres: intervention 108.85 vs. control 92.75; high-workload centres: intervention 100.48 vs. control 102.5; p for interaction=0.01).

Within the intervention-arm, endoscopists accessing the website had higher aMNP than those who did not (118 vs 102 aMNP, p=0.03). Intervention arm endoscopists prescribed hyoscine butylbromide in a larger proportion compared to the control group (p<0.001). There was no difference in withdrawal times between groups.

Conclusion: Our evidence-based and theory-informed automated feedback intervention impacted behaviour and significantly improved MNP and PDR during the intervention period. aMNP was non-significantly higher, but more intervention endoscopists achieved minimum standards. Differences were not maintained post-intervention, suggesting feedback should be ongoing.

We demonstrate a highly efficient, scalable and entirely automated process for endoscopy feedback; and the positive impact it can have on performance. This methodology holds great potential to improve clinical practice and patient outcomes in a wide range of settings.

Intervention effects were greater in lower workload centres, this may reflect the increased effectiveness of feedback on lower baseline performance. Endoscopists engaging in the intervention benefited most. Low-performing endoscopists have the most to gain from feedback intervention, and future research should focus on engagement in feedback.

Introduction: Bowel preparation is recognized as the most burdensome aspect of the whole colonoscopy procedure, sometimes even worse that the examination itself, and represents a major barrier to screening colonoscopy. Mannitol could significantly improve patient acceptability as it is rapid, requires a single dose, a low volume and has a pleasant taste. The SATISFACTION study compared oral mannitol 100g/750ml with standard split-dose 2L PEG-ASC (MoviPrep®).

Aims & Methods: The SATISFACTION Phase III study was an international, multicentre, randomized (1:1), parallel-group, endoscopist-blinded non inferiority trial. Primary endpoint was the proportion of patients with adequate bowel cleansing. Secondary endpoints concerned efficacy (adenoma detection rate, caecal intubation rate, time of evacuation), safety

(intestinal gases concentration, haematobiological parameters, adverse events) and patient satisfaction. The study included 703 patients (352 treated with mannitol and 351 with PEG-ASC) undergoing elective colonoscopy.

Results: Mannitol was not inferior to PEG-ASC for proportion of patients with adequate cleansing (91.1% and 95.5% respectively; p value for the non-inferiority =0.0095). There was no significant difference for secondary efficacy endpoints. The profile of acceptability was significantly better in mannitol group for easy to use, taste, willingness to use (p<0.0001 for all parameters). The concentration of intestinal gases (H_2, CH_4) was similar in the two groups and well below those potentially critical.

Conclusion: Mannitol was not inferior to PEG-ASC for proportion of patients with adequate cleansing (91.1% and 95.5% respectively; p value for the non-inferiority =0.0095). There was no significant difference for secondary efficacy endpoints. The profile of acceptability was significantly better in mannitol group for easy to use, taste, willingness to use (p<0.0001 for all parameters). The concentration of intestinal gases (H_2, CH_4) was similar in the two groups and well below those potentially critical.

RENAL REPLACEMENT THERAPY DOES NOT AFFECT BOWEL PREPARATION SUCCESS

M. Vanhooren[1], S. Kindt[1], K. Francois[2]
[1]UZ Brussels, Gastro-Enterology, Brussels, Belgium, [2]UZ Brussels, Nephrology, Brussels, Belgium

Contact E-Mail Address: mypsi@me.com

Introduction: Adequacy of bowel preparation (ABP) directly affects colonoscopy performance and adenoma detection rate. Studies attributed a role to the dosing regimen of the bowel cleansing agent, social and economic factors and comorbidities. However, data on the impact of kidney failure and renal replacement therapy (RRT) are lacking.

Aims & Methods: This study investigated how ABP compares between patients on RRT and age-matched subjects with normal kidney function. All patients on RRT undergoing an elective colonoscopy between January 2016 and December 2021 were identified from the medical records of a university hospital, and matched to 2 closest age controls undergoing colonoscopy at the same date ± 7 days. Study subjects and controls were compared for demographics, comorbidities including history of abdominal surgery, use of bowel transit-influencing drugs, residential care stay and colonoscopy-related data (bowel preparation regimen, sedation type, colonoscopy findings, ABP defined as a cumulative Bristol Bowel Preparation Score >= 6 and a score of >= 2 for each colon segment). Statistical significant contributors to ABP were assessed by logistic regression.

Results: Ninety-one patients on RRT (76 on haemodialysis and 15 on peritoneal dialysis) and 182 controls were identified. Patients on RRT were older (69±12 vs. 64±14y, p=.008) and less frequently women (34% vs. 50%, p=.013). They had more diabetes (40% vs. 24%, p=.008), more history of abdominal surgery (32% vs. 21%, p=.047) and took more bowel transit-influencing drugs (50% vs. 28%, p<.0001). Bowel preparation regimens were equally distributed between both groups.

There was no difference in the rate of ABP between groups (87% vs. 81%, p=NS). Logistic regression analysis did not reveal an association between RRT and ABP. ABP was negatively influenced by residency in residential care, overnight stay in the hospital before colonoscopy, history of central nervous system disease, and positively by split-dose regimen (Nagelkerke R square 0.329, p=<.001).

Conclusion: Despite less favourable associated conditions, ABP in RRT patients remains comparable to controls. Split-dose regimen, neurological conditions and in-hospital stay are significant predictors of adequate bowel preparation.

Introduction: The evolution of endoscopic techniques allows the treatment of multiple lesions previously reserved for surgical treatment. There are few data of the feasibility of endoscopic submucosal dissection (ESD) for the resection of lesions involving the ileocecal valve and/or invading the terminal ileum. The objective of this study was to assess the efficacy and safety of ESD in this indication.

Aims & Methods: All patients who benefit from an ESD for ileocecal valve lesion were identified from a prospective database. The precise location of the lesion (anal/caecal lip, anterior/posterior commissure, ileal invasion) was collected retrospectively from computer reports and a review of endoscopic films when available. The primary endpoint was the R0 resection rate defined as En Bloc resection with histological free lateral and deep margins.

Results: A total of 116 patients (median age 71 years, 55.2% men) in 3 expert centers were identified. The majority of lesions were granular laterally spreading tumors (LST). The median diameter of the lesions was 45 mm (IQR 36-60) by 35 mm (IQR 27-45). 44.8% (52/116) of the lesions invaded the terminal ileum over 10 mm. The lesion covered less than 50% of the valve in 63.6% of cases, more than 75% in 4% of cases, and the entire valve in 3% of cases.

The median speed of ESD was 25.2 mm2/min (IQR 16.6-46). The en bloc resection rate was 93.9% and the R0 resection rate was 78.4%. Resection was curative in 74.1% of patients (90/116). Factors associated with failed R0 resection were ileal involvement (59.2% vs 85.9% p = 0.041), anal lip involvement (67.8% vs 89.7% p = 0.012) and an involvement of more than 50% of the valve circumference (66.7% vs 84.1% p = 0.011).

Four ESD failed due to muscle ascension (retractile sign) (2/4), a perforation of the ESD resected piece, and a difficult positioning to perform the ESD. Seven patients presented postoperative complications (6.0%) including 6 delayed bleeding and one perforation requiring surgical management.

Conclusion: ESD could be proposed in expert centers as the first option to treat lesions developed on the ileocecal valve. Ileal involvement, anal lip involvement and involvement of more than 50% of the valve appear to be predictive factors for failure.

Disclosure: Nothing to disclose.

PP1203

ADENOMA MISS RATE IN BACK-TO-BACK ENDOCUFF-ASSISTED COLONOSCOPY. A SINGLE-CENTER PROSPECTIVE STUDY

M. Fragaki[1], P. Nikolaou[1], A. Psistakis[1], D. Arna[1], G.A. Paspatis[1]
[1]Venizelio General Hospital, Gastroenterology, Heraklion, Greece

Contact E-Mail Address: andrew_psistos@hotmail.com

Introduction: To conduct a back-to-back endoscopy study and to evaluate the contribution of endocuff assisted colonoscopy to the detection of missed adenomas in a mixed population of colorectal cancer (CRC) screening/surveillance and symptomatic patients. To the best of our knowledge, this is the first study on this issue.

Aims & Methods: It is a prospective study conducted from March 2021 to March 2022 in a tertiary endoscopy department. Two consecutive same day, endocuff assisted, colonoscopies were performed in 124 patients. ClinicalTrials.gov Identifier: NCT04805567.

Results: 124 patients were enrolled (58.9% male/ median age 62 years). All examinations were complete (100% cecum intubation, 54% ileal intubation). The indications were CRC screening (77 patients, 62.1%), post-polypectomy surveillance (24 patients, 19.4%) and diagnostic assessment (23 patients, 18.5%). 54.8% of the patients had diverticulosis. 368 polyps were overall found and removed. 321 in the first and 48 in the second examination. Only 4 patients with no adenoma found in the first examination had one adenoma found in the second examination. The overall miss rate for adenomas was 12.01% and 11.32% for adenomas≥10mm.

Conclusion: This back-to-back study has shown that endocuff- assisted colonoscopy has a low adenoma miss rate. These data further strengthen the existing evidence recommending the use of endocuff for decreasing the adenoma miss rate.

Disclosure: Nothing to disclose.

Introduction: Serrated lesions in the colon, that can contribute to up to 20% of colon cancers, are often difficult to detect during standard white light colonoscopy (SC). Artificial intelligence specifically Computer-aided Detection (CADe) has been shown to positively impact the adenoma detection rate (ADR) and adenomas per colonoscopy, but data on SSLs are scarce. We aimed to evaluate the effect of CADe on detecting SSLs byperforming a meta-analysis of all the randomized controlled trials.

Aims & Methods: PubMed, Embase, and Cochrane databases were searched (upto November 2022) to identify randomized controlled studies comparing CADe and SC. Our primary outcome was the comparison of pooled estimates of SSL-detection rate (SSLDR) between those undergoing CADe and SC. The secondary outcome was the mean number of SSL per colonoscopy (SSLPC). Subgroup analyses were performed for studies only including screening or surveillance colonoscopy. Risk ratios (RR) and mean differences (MD) with 95% confidence intervals (CI) were calculated for dichotomous and continuous variables, respectively, using the random effects model. Study heterogeneity was assessed using i^2 statistics and prediction intervals

Results: 12 RCTs were eligible with a total of 9237 patients: CADe group-4595 patients (mean age 58.5 years; 53.5% men) and SC group-4642 (mean age 58.4 years; 52.1% men). There was no significant difference in SSLDR between CADe (4.6%) vs. SC (4%) with a Risk Ratio of 1.15 (95% CI 0.95-1.39, i^2= 0%) (Table 1a).

Similarly, for SSLPC, there was no significant difference between CADe and SC (MD 0.01, 95% CI -0.02 –0.03, i^2= 98%). When our analysis was limited to studies including only screening or surveillance colonoscopy, again, there were no significant differences between CADe and SC in terms of SSLDR (5.7% vs 4.9%, RR 1.15, 95% CI 0.92-1.45) and SSLPC (MD -0.02, 95% CI -0.07 – 0.030).

Outcome		No of Patients		SSLDR (%)		RR	95% CI	Prediction Interval	I^2 %
		CADe	SC	CADe	SC				
SSLDR	All Studies	4595	4642	4.6	4.0	1.15	0.95 – 1.39	0.93 - 1.42	0
	Screening/ Surveillance Only	2475	2524	5.7	4.9	1.15	0.92 - 1.45	0.80 - 1.67	0

Table 1. Comparison of SSLDR between CADe and Standard Colonoscopy

Conclusion: Compared with standard colonoscopy, currently evaluated AI systems do not show improved sessile serrated lesion detection rate or mean sessile serrated lesions per colonoscopy, even when including only screening or surveillance colonoscopy. Further RCTs should be designed with SSL as one of the primary outcomes using highly trained AI systems.

Disclosure: No Relevant Financial Disclosure.

Introduction: We aimed to study the impact of a novel AI system on non-expert endoscopists detection, characterisation and sizing of colorectal polyps compared to experts in view of the recent ESGE position statement on the expected value of AI in GI endoscopy.

Aims & Methods: Prospectively collected endoscopy videos from 12 centres in Europe and Japan were uploaded on a bespoke online platform. All polyps were histologically proven and sized by 3 experts. The AI model detects polyps and classifies them as neoplastic/non-neoplastic and diminutive/non-diminutive. We asked 6 experts to detect, characterise and size polyps without AI support, and 6 non-experts to detect, characterize and size polyps assisted by AI.

Results: A total of 600 videos including 298 polyps were included. The average sensitivity, specificity, accuracy and NPV of adenoma diagnosis by non-experts+AI compared to experts on EI was 90.84% vs 86.81% (p value 0.003), 76.46% vs 85.21% (p value <0.001), 86.45% vs 86.32% (p value 0.917), and 78.59% vs 73.96% (p value 0.084) respectively. Agreement between histology-based and non-experts+AI based surveillance intervals (BSG guidelines) was 91%.

Conclusion: This study suggests AI system may potentially bridge the gap between expert and non-expert endoscopists in regards to polyp detection, sizing and optical diagnosis and support adoption of resect-and-discard strategy. However, AI did not meet PIVI threshold required for diagnose-and-leave strategy (NPV of 90%).

Disclosure: K Takoh, T Okuno and S Goda are employed by NEC Japan.

PP1207

ARE TISSUE SAMPLING GUIDELINES FROM THE ESGE IN COLITIS FOLLOWED IN CLINICAL PRACTICE?

R. Canda[1], C. Tai[1], P. Giuffrida[1], K. Besherdas[1]
[1]Royal Free London, Gastroenterology, Enfield, United Kingdom

Contact E-Mail Address: besherdasdr@hotmail.com

Introduction: Guidelines for tissue sampling have been published by The European Society of Gastrointestinal Endoscopy (ESGE) on colitis. They recommend in patients with clinical signs and endoscopic signs of colitis, performing segmental biopsies (at least two from each segment), which should be placed in different specimen containers (ileum, caecum, ascending, transverse, descending, and sigmoid colon, and rectum). The ESGE recommends pancolonic dye-based chromoendoscopy or virtual chromoendoscopy with targeted biopsies of any visible lesions during surveillance endoscopy in patients with inflammatory bowel disease. ESGE also recommends that, in patients with known ulcerative colitis and endoscopic signs of inflammation, at least two biopsies be obtained from the worst affected areas for the assessment of activity or the presence of cytomegalovirus.

Aims & Methods: We aimed to observe clinical practice and compare these to the ESGE guidance in patients attending endoscopy for colitis.
A single centre, retrospective of patients with colitis attending endoscopy at a district general hospital was performed. 50 consecutive patients with new diagnosis of colitis, 50 consecutive patients with colitis for surveillance, and 20 consecutive patients with colitis for assessment of severity of activity were studied. Findings from clinical practice observed was scrutinised and compared to ESGE guidance. Data was obtained from the endoscopy reporting tool (unisoft) and from the electronic patient records.

Results: 32 of the 50 patients (64%) with endoscopic signs of colitis followed guidance on biopsy protocol as per ESGE. In this study, the caecal intubation rate was 94%, with terminal ileal intubation rate of 80%. In this group 25/50 (50%) the colitis activity was documented by way of either the Mayo score or Ulcerative colitis endoscopy index of severity.
29 of 50 patients (58%) with colitis having a surveillance colonoscopy followed the ESGE biopsy protocol. 4 of 50 patients (8%) had chromoendoscopy as part of their colonoscopic surveillance procedure.
17 of 20 patients (85%) biopsies assessed for activity of colitis had biopsies. 7 of 17 patients (41%) having a biopsy had a comment regarding CMV inclusion bodies on histology. The histology request form specifically asked for assessment of CMV inclusion bodies in 5 of 17 patients (29%).

Conclusion: From this study of clinical practice of patients attending endoscopy for colitis, either in terms of new diagnosis, surveillance, or for colitis severity assessment with presence of CMV, the tissue sampling protocol of the ESGE is poorly implemented. We recommend improved dissemination of the guidelines within the endoscopy department to improve practice. Specifically asking for CMV inclusion bodies to histopathology on the request form may increase its assessment.

Disclosure: Nothing to disclose.

PP1208

QUANTITATIVE EVALUATION OF FALSE-POSITIVE ALERTS DURING POLYP DETECTION IN COLONOSCOPY

C. Zhang[1], L. Yao[1], H. Yu[1]
[1]*Renmin Hospital of Wuhan University, Department of Gastroenterology, Wuhan, China*

Contact E-Mail Address: 3487483127@qq.com

Introduction: Previous studies have demonstrated the superiority of the CADe system in the detection of polyps and adenomas in randomized controlled setting, even among less experienced endoscopists. While implementing CADe systems in routine clinical practice, however, several studies have found that the efficacy of CADe on adenoma diminished. What accounts for these conflicting results is worth exploring.False positives (FPs) have become an important issue in the application of artificial intelligence (AI) to detect polyps during colonoscopy. The occurrence of FPs may lead to fatigue and distraction of endoscopists and even unnecessary biopsies. Excessive FPs can reduce users' trust in the model and then affect enthusiasm for its use. We aimed to quantitatively evaluate the impact of FPs of computer-aided (CADe) system on endoscopists and explore a reasonable minimum false positive threshold.

Aims & Methods: The FPs levels of the model were divided into four gradients: 0-5, 5-10, 10-15 and 15-20 false positives per minute (FPPM). A total of 56 colonoscopy videos were retrospectively collected. By varying the model confidence based on the original CADe system, colonoscopy videos with different false-positive gradients were generated. Using a crossover design, 10 endoscopists were randomly assigned to the CADe-assisted first group and the unassisted first group. All endoscopists were asked to watch colonoscopy videos of all false-positive gradients, with the CADe-assisted group watching the model-processed colonoscopy videos and the unassisted group watching the original colonoscopy videos.

With the hypothesis that the increase in FPs for CADe leads to an increase in missed polyps, polyp missed rate (PMR) was set as the primary outcome.

Secondary outcomes included the number of false positives (NFPs), false negative rate (FNR), false positive rate (FPR) of the endoscopists and the change in fatigue of the endoscopists before and after each reading.

Results: PMR increased from 19.2% to 49.2% when the FPPM increased from 0-5 to 5-10 in the CADe-assisted group (odds ratio, 4.079; 95% CI, 2.287-7.275, P<0.001). For the analysis of different false-positive gradients, compared with the routine colonoscopy group, group 0-5 achieved a lower PMR in CADe-assisted group (37.5% vs 19.2%; odds ratio, 4.143; 95% CI, 1.815-9.458, P<0.001), while PMR of group 5-10 increased from 39.2% to 49.2% (odds ratio, 2.714; 95% CI, 1.141-6.457, P<0.05). In addition, group 15-20 showed a lower FNR in CADe-assisted group (24.3%) than routine colonoscopy group (45.7%), and a higher FPR (71.4% vs 54.3%; odds ratio, 5.000; 95% CI, 1.448-17.271, P<0.05). Endoscopists' fatigue did not change significantly when using CADe with different false-positive levels.

Conclusion: The level of FPs of the CADe has a significant negative impact on its auxiliary effect. Future design of CADe should keep FPPM under 0-5.

Disclosure: Nothing to disclose.

PP1209

COMPARATIVE ANALYSIS OF EFFICACY AND SAFETY BETWEEN ORAL SODIUM SULFATE TABLET AND 1 L POLYETHYLENE GLYCOL PLUS ASCORBATE

J.-S. Byeon[1], S.W. Hong[1], D.-H. Yang[1]
[1]*Asan Medical Center, Dept. of Gastroenterology, Seoul, South Korea*

Contact E-Mail Address: jsbyeon@amc.seoul.kr

Introduction: Low-volume bowel preparation solutions, including 1 L polyethylene glycol plus ascorbate (PEG-A), have been developed to improve tolerability because of the low tolerability of high-volume polyethylene glycol agents.

However, 1 L PEG-A still has its typical odor that is not pleasant for most patients. The oral sodium sulfate tablet (OST) is a new agent with simethicone as a preloaded component. OST may have the better tolerability because of little odor due to its tablet formula.

Aims & Methods: We aimed to investigate the efficacy, safety, and tolerability of OST compared to 1 L PEG-A. We randomized patients aged 18 years or older who underwent colonoscopy into the OST (group A) and 1 L PEG-A (group B) groups. Bowel preparation efficacy was assessed on the Boston bowel preparation scale (BBPS) and bubble scale. Bowel preparation success was defined as BBPS score ≥ 6. The bubble scores ranged from 0 to 3 per segment (total from 0 to 9), with a lower score indicating lower bubbles in the colonic lumen. Safety and tolerability were evaluated using a systematized questionnaire.

Results: A total of 171 patients (group A: 87, group B: 84) were included in the final analyses. The average BBPS score of group A was 8.0±1.3, which was similar to that of group B (7.7±1.4) (p=0.215). The proportion of patients showing bowel preparation success was 95.4% in the group A whereas that in the group B was 96.4% (p=0.736). The adenoma detection rate was also similar between groups A (59.6%) and B (41.9%) (p=0.087). The bubble scale in the group A was 0.2±0.9, which was significantly better that that of the group B (1.9±1.7) (p<0.001).

All adverse events were mild in both groups. The group A showed lower frequency of nausea compared to the group B (14.9% vs. 38.1%, p=0.001). Overall satisfaction was better in the group A (8.1 ± 2.1 vs. 6.4 ± 2.8, p<0.001).

Conclusion: Although both OST and 1 L PEG-A were efficacious, safe, and tolerable for bowel preparation of colonoscopy, the OST showed fewer bubbles and slightly better tolerability.

Disclosure: Nothing to disclose.

PP1210

DIFFERENCES IN TYPES OF PRECURSOR LESIONS BETWEEN INDIVIDUALS OVER AND UNDER 50 YEARS

D. Penz[1,2], E. Waldmann[3], L.-M. Rockenbauer[3], J. Zessner-Spitzenberg[2], E. Klenske[4], M. Trauner[2], M. Ferlitsch[2]

Contact E-Mail Address: daniela.penz1220@gmail.com

Introduction: Colorectal adenomas are commonly found in individuals over the age of 50, but their occurrence in younger individuals is increasing. However, it is still unknown if colorectal cancer in young patients follow different pathways. Therefore, this study aims to compare the types of colorectal adenomas/lesions in individuals under the age of 50 versus those over 50.

Aims & Methods: To assess the differences in adenoma subtypes amongst individuals aged 50 and older versus those under the age of 50.

Results: 488.767 screening colonoscopies between 2008 and 2023 were analyzed within the Austrian quality assurance program. 17.216 (3,5%) individuals were under and 471.551 (96,5%) were above. 14,3% (n=2.454) patients under 50 and 25,5% (n=120.018) above had adenomas. 11.8% (n=289) of precursor lesions within those under and 7,9% (9503) above, were Sessile serrated lesions (p<0,001). 3,3% (n=81) were traditional serrated adenomas (TSA) among those <50 and 1,1% (n=1.362) above (p<0,001). 12.7% (n=311) vs. 12.6%(n=15.120; p=0,92)) of adenomas were tubulovillous and 0,57% (n=14) vs. 0,76% (n=915) (p=0,28)were villous comparing <50a and >50a. 71,7% (n=1.759) of adenomas within individuals under 50 and 77,6% (n=93.118) above were tubular (p=0,12).

	Age		
Type of precursor lesion	<50	<50	p-value)
sessile serrated lesion SSA	11.8% (n=289)	7.9% (n=9503)	40.1 (p<0.001)
traditionell serrated Adenoma TSA	3.3% (n=81)	1.1% (n=1362)	92.7 (p<0.001)
tubulaer	71,7% (n=1759)	77,6% (n=93118)	6.3 (p=0.012)
tubulovilloes	12,7% (n=311)	12,6% (n=15120)	0.01 (p=0.92)
villoes	0.57% (n=14)	0.76% (n=915)	1.16 (p=0.28)
Adenomas/lesion total	14.3% (n=2,454)	25.5% (n=120.018)	
Total	17216	471551	

Conclusion: Individuals under 50 have a significant higher proportion of SSA and TSA but a significant lower proportion of tubular adenomas than those aged 50 and older.

Disclosure: Nothing to disclose.

PP1211

DEVELOPMENT AND VALIDATION OF SPEECH AND IMAGE RECOGNITION BASED SYSTEM FOR REAL-TIME REPORTING DURING COLONOSCOPY

C. Zhang[1], L. Yao[1], H. Yu[1]
[1]Renmin Hospital of Wuhan University, Department of Gastroenterology, Wuhan, China

Contact E-Mail Address: 3487483127@qq.com

Introduction: Colonoscopy is the gold standard for colorectal cancer screening. Proving the integrity of the colorectal exam has become a mandatory procedure, and the colonoscopy report is the only way to prove the integrity of the colonoscopy procedure. Unfortunately, even with a structured report generator, some key quality fields were often incomplete. A substandard report may mislead patients and have a negative impact on subsequent follow-up. Moreover, these systems do not allow endoscopists to record their findings during the endoscopic procedure. Instead, this can only be done after the procedure. The labor-intensive ways of reporting require more personnel, increasing the risks of errors and costs.

Aims & Methods: We aimed to develop and validate a novel reporting system for real-time reporting during colonoscopy based on speech recognition and image recognition, which is available during endoscopic procedures and able to generate standard photographic and textual reports. The system automatically captured images of anatomic landmarks and bowel segments according to information received by the speech recognition model from the endoscopist about the bowel segment. Moreover, for each lesion, system identified mucosal lesions and captures typical images in real time. Each individual lesion observation was captured as one typical image tagged with lesion type and bowel segment. In addition, detailed information about the lesion and colonoscopy procedure was incorporated into this system, such as the size of polyps, the morphology of polyps, withdrawal time, bowel preparation and biopsy. Finally, the semi-structured colonoscopy report with images and text was automatically generated, along with specific information about lesions and bowel mucosa. The endoscopists could recheck and edit the content of texts. After all the processes, the report with images and texts with automatic generation and manual review was generated. 15 AI algorithm modules were incorporated into the report system to achieve real-time analysis and records of abnormalities and landmarks during colonoscopy.

Results: For colonoscopy video preprocessing: the accuracy of DCNN1, 2 and 3 reached 100%, 98.9% and 98.6%, respectively. For anatomic segment capture and assessment: the accuracy of DCNN4 reached 100%. For lesion capture and diagnosis: the accuracy of DCNN5, DCNN6, DCNN7 and DCNN8 were 93.1%, 97.3%, 90.0% and 89.3%, respectively. For detailed information obtaining for endoscopic lesions: the accuracy of DCNN 9, DCNN10, DCNN11, DCNN12, DCNN13 reached 88.9%, 89.0%, 100%, 95.4% and 80.6%.

DCNN1: distinguish in-vivo images from in-vitro images	DCNN2: filter out unqualified images (blurred and flushing images)	DCNN3: identify white light (WLI) images and non-white light (non-WLI) images
DCNN4: receive voice messages about key landmarks from the endoscopists	DCNN5: detect and locate common lesions (melanosis coli, erosion and ulcer)	DCNN6: identify polyps
DCNN7: detect diverticulum	DCNN8: identify hemorrhoids	DCNN9: evaluate the morphology of polyp detected (pedunculated, sessile and flat)
DCNN10: evaluate the size of polyp	DCNN11: receive voice messages about lesions from the endoscopists, including the location and the number of polyps	DCNN12: for polyp NICE classification
DCNN13: for polyp JNET classification	DCNN14: evaluate the bowel preparation (BBPS)	DCNN15: identify biopsy forceps

For additional information process for image capture: the accuracy of DCNN14 was 95.3%, and UNet++ achieved an overall IoU of 0.92 in DCNN15. Further video validation and crossover study are in preparation. The detailed functions of the model are shown in the table.

Conclusion: A novel reporting system for real-time reporting during colonoscopy based on speech recognition and image recognition, which is available during endoscopic procedures and able to generate standard photographic and textual reports has potential to improve the quality of colonoscopy reports.

DEVELOPMENT AND VALIDATION OF ARTIFICIAL INTELLIGENCE ALGORITHM FOR AUTOMATED BOWEL PREPARATION SCORING

J.-S. Byeon[1], J.-Y. Lee[1]

[1]*Asan Medical Center, Dept. of Gastroenterology, Seoul, South Korea*

Contact E-Mail Address: jsbyeon@amc.seoul.kr

Introduction: Reliable assessment of bowel cleanliness is important for qualified colonoscopy including improved adenoma detection with lower risk of interval colorectal cancer. However, current bowel preparation scoring systems are limited by inter-observer variability because the bowel preparation status is assessed by the operating endoscopists.

Aims & Methods: This study aimed to investigate whether the artificial intelligence, deep learning algorithm could assess bowel preparation status objectively. Convolutional neural network was developed using retrospectively collected 1400 still colonoscopy images from 346 colonoscopy procedures. Three experts reviewed and annotated the training images and videos based on Boston Bowel Preparation Scoring (BBPS) system (0-3).

We validated the developed algorithm with 522 stll images from 219 colonoscopies and tested the performance of the algorithm with 369 still images from 128 colonoscopies. In addition, we validated the algorithm using 113 10-sec video clips and tested the performance of the algorithm on 30 full colonoscopy videos.

Results: In the still image test set, the algorithm achieved the accuracy of 78.7% for 4 classes of BBPS. The algorithm achieved the accuracy of 93.9% for binary classification of BBPS (0-1: inadequate vs. 2-3: adequate). In the 10-sec video validation set, the algorithm demonstrated the accuracy of 74.3% for 4 classes of BBPS. In the 10-sec video validation set, the algorithm showed the accuracy of 94.7% with 0.983 of area under the ROC for binary classification of BBPS. In the test of the algorithm with the withdrawal phase of full colonoscopies (80 segments; 25 right colon, 25 transverse colon, and 30 left colon), the overall accuracy was 91.3%. The sensitivity for inadequate bowel preparation was 86.7% in the test with full colonoscopy videos.

Conclusion: The deep learning algorithm developed for objective assessment of bowel preparation based on BBPS showed good performance in the test with still colonoscopy images and full colonoscopy videos.

Contact E-Mail Address: jjh608@yuhs.ac

Introduction: Considering the impaired platelet function in uremic patients, the risk of post-polypectomy bleeding may increase in patients with end-stage renal disease undergoing colonoscopic polypectomy. Nevertheless, little is known about the risk factors of bleeding after colonoscopic polypectomy in these patients. This study investigated the incidence and risk factors of post-polypectomy bleeding, including immediate and delayed bleeding, in patients with end-stage renal disease (ESRD).

Aims & Methods: Ninety-two patients with ESRD who underwent colonoscopic polypectomy between September 2005 and June 2020 at a single tertiary referral center were included. The patients' medical records were retrospectively reviewed. Patient- and polyp-related factors associated with immediate PPB (IPPB) were analyzed using logistic regression analysis. Additionally, the optimal cutoff polyp size related to a significant increase in the risk of IPPB was determined by performing receiver operating characteristic (ROC) analysis and calculating the area under the ROC curve (AUC).

Results: In total, 286 polyps were removed. IPPB occurred in 24 (26.1%) patients and 46 (16.1%) polyps, and delayed post-polypectomy bleeding occurred in 2 (2.2%) patients. Regarding the hemostasis method for IPPB, clipping was used in 31 (67.4%) cases and a combined method with clipping and coagulation was used in 15 (32.6%) cases. According to multivariate analysis, the polyp size (> 7 mm) (odds ratio=5.259, 95% confidence interval [CI]: 2.367–11.684), old age (>70) (odds ratio=4.186, 95% CI: 2.012–8.708), and endoscopic mucosal resection (EMR) as the polypectomy method (EMR versus non-EMR: odds ratio=3.339, 95% CI: 1.440–7.743) were found to be independent risk factors for IPPB. According to the Youden index method, the optimal cutoff polyp size to identify high-risk polyps for IPPB was 7 mm (AUC=0.755; sensitivity, 76.1%; specificity, 69.6%).

Conclusion: Colonoscopic polypectomy should be performed with caution in patients with ESRD, especially in those with the following risk factors: advanced age (>70 years), polyp size >7 mm, and EMR as the polypectomy method.

Disclosure: Nothing to disclose.

Contact E-Mail Address: tomas.grega@uvn.cz

Introduction: With the improvement of endoscopic resection techniques, there has been recent interest in real-time in vivo characterization of polyp histology. Of all the new imaging technologies for characterizing polyp histology, narrow-band imaging (NBI) has been the most extensively studied and is easy to feasible. Correct histological prediction allows determining the optimal endoscopic technique for resection of lesions with the achievement of R0 resection. The NBI International Colorectal Endoscopic Classification (NICE) and the Japanese NBI Expert Team (JNET) classification are mostly used to predict the depth of invasion.

However, the effectiveness of diagnostics using NBI in clinical practice is variable and is associated with low sensitivity for superficial invasive carcinoma.

Aims & Methods: Primary aim was to determine and compare the diagnostic accuracy of NICE and JNET classifications in predicting histology in community practice. Secondary aim was to determine the positive predictive value (PPV) for the NICE and JNET classification.

In this single-center prospective study we have included 211 patients aged 18–75 years (130 men, 62%; 81 women, 38%; mean age 60 years) who underwent colonoscopies with endoscopic resection of advanced colorectal neoplasia (defined by size lesions ≥ 10 mm). The NICE and JNET classifications were used for each lesion. The results were compared with the final histopathological finding to determine and compare NICE and JNET classification accuracy.

Results: 257 lesions were analyzed including 8 (3.1 %) hyperplastic polyps, 47 (18.3 %) sessile serrated polyps, 152 (59.1 %) adenomas with low grade dysplasia, 36 (14.0 %) high-grade adenomas, 12 (4,7 %) intramucosal carcinomas, 1 (0.4 %) T1sm1 carcinoma and 1 (0.4 %) T2 carcinoma. A total of 199 lesions (77.4 %) were correctly classified according to the JNET classification and 241 lesions (93.8 %) were correctly classified according to the NICE classification. The PPV for NICE 1 lesion was 95.9 %, NICE 2 97.0 % and NICE 3 22.0 %. The PPV for JNET 1 lesions was 95.9 %, JNET 2A 83.0 %, JNET 2B 52.2 % and JNET 3 22.5 %.

Conclusion: The NICE classification was associated with a higher proportion of correctly classified lesions (93.8 %) compared to the JNET classification (77.4 %). However, NBI virtual chromoendoscopy shows a low PPV for HGD adenomas, intramucosal carcinomas and T1sm1 carcinomas (NICE 2 22.1 %, JNET 2B 52.2 %). Therefore, additional investigations in these lesions are still required with magnifying chromoendoscopy prior a final decision of endoscopic therapy. Improvement of predictive accuracy of these lesions and determining the limiting factors will be the subject of further investigation.

Supported by program projects of the Ministry of Health of the Czech Republic with reg. no. NV18-08-00246, NU22-08-00424, MO1012 and Cooperatio.

Introduction: Polydeep is a CADe/x system that has demostrated a high diagnostic yield for in vitro detection and characterisation of colorectal polyps. We have designed a diagnostic accuracy study, Polydeep Advance 1 (NCT05514301) in order to confirm these preliminar results.

Aims & Methods: Polydeep Advance 1 is a unicentric prospective diagnostic test trial. Endoscopists performed the colonoscopy blinded to Polydeep. A second observer alerted the endoscopists when Polydeep detected a lesion not identified by the endoscopists. The main objective of this study was to compare Polydeep sensitivity for colorectal polyps (adenoma and serrated lesion with confirmed histology) detection with experienced endoscopists.

Additionally, we evaluated the diagnostic accuracy for detection of colorectal adenomas, advanced colorectal lesions (advanced adenoma or serrated lesion) and lesions ≤ 5mm.

Finally, we evaluated the characterization capacity of Polydeep for neoplasia detection (adenoma, Sessile Serrated Lesion-SSL, and Traditional Serrated Adenoma-TSA) and compared it with the optical diagnosis of endoscopists using the NICE classification.

Results: We included 205 patients (mean age 63.0 ± 6.2 years, 51.1% male) in the trial, between February and April 2023. The indications for colonoscopy were positive fecal immunochemical test (124) and surveillance after colorectal adenomas (81). We excluded 8 patients due to incomplete colonoscopy. Endoscopists detected 384 lesions (39 not detected by Polydeep). In contrast, Polydeep detected 409 additional lesions, but the endoscopists only confirmed 26 of these lesions. In total, 410 lesions were detected and resected/biopsed. Out of these lesions, 22 were not retreived, 4 were colorectal adenocarcinoma and 384 were colorectal polyps

(231 adenomas, 35 SSL, 3 TSA, 73 hyperplastic polyps) and 42 were normal mucosa. We show in the attached table the results of the diagnostic accuracy of endoscopists and Polydeep for histologically confirmed colorectal polyps. With regard to the optical diagnosis, Polydeep classified as neoplastic (>50% probability) 273 (73.6%) of the lesions detected and gave no classification in 24 (6.4%) of the lesions. The endoscopists classified 242 as NICE II and 142 as NICE I. In the lesions with histological diagnosis, Polydeep showed a 82.6% sensitivity and 31.1% specificity for neoplasia detection. On the other hand, the sensitivity and specificity of the NICE II classification were 76,5% and 61,8% respectively.

	Sensitivity (%)		Specificity (%)		Positive predictive value (%)		Negative predictive value (%)	
	Poly-deep	Endo-scopist	Poly-deep	Endo-scopist	Poly-deep	Endo-scopist	Poly-deep	Endo-scopist
Polyp	91.5%	94.1%	14.3%	9.5%	89.7%	89.4%	17.1%	16.7%
Adenoma	92.6%	94.4%	11.8%	7.2%	61.3%	60.6%	51.4%	45.8%
Advanced lesion	98.6%	98.6%						
Polyp ≤ 5mm	89.5%	92.3%	14.6%	9.8%	86.4%	86.1%	18.8%	17.4%

Conclusion: We confirm the preliminar results of Polydeep in the clinical validation. These results will be confirmed in ongoing multicentric trials.
Disclosure: Nothing to disclose.

MAGNETIC BALLOON TECHNOLOGY FOR COMPLETION OF VERY DIFFICULT COLONOSCOPIES: A CASE SERIES

O. Tarantino[1], A.L. Inghilesi[1], G. Kadiu[1], F. Calella[1], S. Messeri[1]
[1]Ospedale S. Giuseppe Nuovo, Medicine, Empoli, Italy

Contact E-Mail Address: ottaviano.tarantino@gmail.com
Introduction: Colonoscopy is not a difficult procedure for most of the colonoscopists. However, some procedures can be challenging even for highly-skilled 4th-level colonoscopists (Kudo's classification). Magnetic balloon technology was developed to facilitate loop solving and colonoscopy completion.
Aims & Methods: Patients with prior incomplete sedated colonoscopy performed by the author were selected if tortuosity, redundancy or laxity were reported in prior failed colonoscopy. For each patient a colonoscopy with magnetic balloon was rescheduled and performed in the same center (Ospedale San Giuseppe, Empoli, Firenze, Italy) by the same endoscopist (4 th level expert according to Kudo's classification with completion rate higher than 98%).
Complete colonoscope insertion was judged by the colonoscopist if ileocecal valve and the appendiceal orifice could be observed. Magnetic balloon technology includes a balloon catheter that can be inserted on demand in the 3,2 mm colonoscope tool channel, filled with a syringe of ferromagnetic fluid and anchored with an external permanent magnet. The magnetic anchorage is performed to facilitate manoeuvres to solve loops and thus straightening and shortening the colonoscope.
Results: From February to March 2022 a colonoscopy with magnetic balloon and conscious sedation with midazolam and fentanyl were performed in four Caucasian patients (50-74 yrs, 3 males, BMI: 24,6- 37,1). All patients completed the colonoscopy with magnetic balloon. Tortuosity, laxity and/or redundancy were identified in all cases. Magnetic balloon anchorage has been always achieved even in an obese male patient (BMI 37,1). No adverse events occurred.
Conclusion: Magnetic balloon technology may represent a new safe and effective on demand solution forcompleting very difficult colonoscopies and preventing rescheduling of a second procedure.

ENDOSCOPIC RESECTION OF A PEDUNCLATED TYPE ADENOMA: PROS AND CONS OF COLD SNARE POLYPECTOMY

N. Akimoto[1], O. Goto[1], Y. Ishikawa[1], E. Koizumi[1], A. Hoshimoto[1], K. Higuchi[1], T. Nishimoto[1], J. Omori[1], A. Tatsuguchi[1], R. Ohashi[2], K. Iwakiri[1]
[1]Nippon Medical School, Department of Gastroenterology, Tokyo, Japan, [2]Nippon Medical School, Department of Integrated Diagnostic Pathology, Tokyo, Japan

Contact E-Mail Address: naohiko.akimoto07@gmail.com
Introduction: While cold snare polypectomy (CSP) has been proven effective and safe in the resection of small polyps, it is not actively recommended for the pedunculated (Ip type) polyps in the European Society and Gastrointestinal Endoscopy and US Multi-Society Task Force on Colorectal Cancer guidelines. Although Japanese guidelines recommend that CSP should be limited to lesions less than 10 mm, preoperatively diagnosed as adenomas, the guideline does not address how to resect pedunculated (Ip type) adenomas. This study aims to examine the pros and cons of CSP for the resection of Ip type adenoma.
Aims & Methods: Among patients with colorectal adenomas resected endoscopically at Nippon Medical School Hospital in Japan, from January to July 2020, 85 lesions in 67 consecutive cases of type Ip, and 762 lesions in 346 cases of non-Ip type (types Is, Isp, and II) resected by CSP, were observed.
Regarding clinicopathologic features, R0 resection rate, and adverse events, we evaluated the difference in the resection method (Ip-CSP group vs Ip-hot polypectomy (HP)/EMR group) as Study 1; and the macroscopic classifications (Ip-CSP group vs Non-Ip-CSP group) as Study 2.
Results: In Study 1, 23 lesions were included in the Ip-CSP group and 62 lesions were included in the Ip-HP/EMR group. A higher percentage of proximal colon lesions (74% vs. 27%, p<0.001) and smaller mean tumor size (5.1±1.6mm vs. 11±5.0mm, p<0.001) were observed in the Ip-CSP group, compared to Ip-hot polypectomy (HP)/EMR group. The R0 resection rate was also significantly lower in Ip-CSP group (61% vs. 90%, p=0.03). While the R0 resection rate tended to be low for lesions 6 mm or greater (67%/93%), no difference was observed among lesions less than 5 mm (59%/50%). No perforation or postoperative bleeding was observed in both groups.
In Study 2 using 23 lesions for the Ip-CSP group and 762 lesions for the Non-Ip-CSP group, no significant difference was observed in tumor location or mean tumor diameter, as well as R0 resection rates (61% vs. 45%, p=0.13). No perforation was observed in either group. Postoperative bleeding was observed only in the Non-Ip group for 5 lesions (0.7%).
Conclusion: To achieve pathological complete resection for Ip adenomas, HP/EMR should be selected for adenoma with a diameter of 6 mm or greater. Conversely, CSP was considered acceptable for lesions of 5 mm or less. Further studies with a larger number of patients are warranted.
Disclosure: Nothing to disclose.

Introduction: Magnifying endoscopy enables the diagnosis of advanced neoplasiathroughout the gastrointestinal tract.The Unified Magnifying Endoscopic Classification (UMEC)framework unifies optical diagnosis criteria in the esophagus, stomach, and colon, dividing lesionsinto three categories: non-neoplastic, intramucosal neoplasia, and deep submucosal invasivecancer.This study aims to ascertainthe performance of North American endoscopists when usingthe UMEC.

Aims & Methods: In this retrospective cohort study, five North American endoscopists without priortraining in magnifying endoscopy independently diagnosed images of gastrointestinal tract lesionsusing UMEC. All endoscopists were blinded to endoscopic findings and histopathological-diagnosis. Using histopathology asthegold standard, the endoscopists' diagnostic performancesusing UMEC were evaluated.

Results: A total of299 lesions (77 esophagus, 92 stomach, and 130 colon) were assessed. Foresophageal squamous cell carcinoma, the sensitivity, specificity, and accuracy ranged from 65.2%(95%CI: 50.9–77.9) to 87.0% (95%CI: 75.3–94.6), 77.4% (95%CI: 60.9–89.6) to 96.8% (95%CI:86.8–99.8), and 75.3% to 87.0%, respectively. For gastric adenocarcinoma, the sensitivity,specificity, and accuracy ranged from 94.9% (95%CI: 85.0–99.1) to 100%, 52.9% (95%CI: 39.4–66.2) to 92.2% (95%CI: 82.7–97.5), and 73.3% to 93.3%. For colorectal adenocarcinoma, thesensitivity, specificity, and accuracy ranged from 76.2% (95%CI: 62.0–87.3) to 83.3% (95%CI:70.3–92.5), 89.7% (95%CI: 82.1–94.9) to 97.7% (95%CI: 93.1–99.6), and 86.8% to 90.7%.Intraclass correlation coefficients indicated goodto excellent reliability.

Conclusion: UMECis a simple classification thatmay be used to introduce endoscopists tomagnifying narrow-band imaging and optical diagnosis, yielding satisfactory diagnostic accuracy.

Disclosure: Nothing to disclose.

ENDOSCOPIC SUBMUCOSAL DISSECTION IN SCARRED COLO-RECTAL LESIONS: A RETROSPECTIVE MULTICENTRIC STUDY WITH LONG-TERM FOLLOW-UP

F.V. Mandarino[1], E. Fasulo[1], A. Barchi[1], F. Azzolini[1], L. Fanti[1], E. Viale[1], D. Esposito[1], P. Cecinato[2], S. Grillo[2], R. Sassatelli[2], S. Danese[1]

[1]IRCCS San Raffaele Scientific Institute, Division of Gastroenterology and Gastrointestinal Endoscopy, Milan, Italy, [2]Arcispedale Santa Maria Nuova - Reggio Emilia, Gastroenterology and Digestive Endoscopy, Reggio Emilia, Italy

Contact E-Mail Address: barchi.alberto@hsr.it

Introduction: Scarred colo-rectal lesions still represent an endoscopic challenge due to technical feasibility and histologic radicality. The optimal endoscopic technique of choice remains controversial.

Endoscopic submucosal dissection (ESD) has been proposed as an option since it allows "en-bloc" resection and low rates of recurrence [1],[2].

Nevertheless, it represents a time-consuming procedure, burdened by complications in non-experts' hands. Hybrid ESD (H-ESD), has been suggested as rescue therapy in cases where complete ESD is not feasible [3].

Aims & Methods: We retrospectively analyzed a prospectively collected cohort of 180 patients who underwent ESD for scarred colorectal lesions at San Raffaele Scientific Institute in Milan and Arcispedale Santa Maria Nuova, Reggio Emilia, Italy, between January 2009 and October 2022. Procedures were performed by expert endoscopists, who had completed more than 60 colo-rectal ESD. Primary outcome was to assess technical success, defined as the completion of an "en-bloc" ESD.

Technical failure was defined as the need of conversion to H-ESD to complete the procedure. Secondary outcomes included: curative resection (cR), defined as submucosal invasion < 1,000-micron, complete resection (CR), defined as en-bloc resection with free histologic margins and recurrence rate at follow-up. Lesions characteristics, technical data of procedures, adverse events rate were also collected. Predictive factors of technical success were assessed through univariate analysis and multivariate logistic regression.

Results: Mean age was 68.42±11.4 years (range 38-89), with a 56/44 female to male ratio. Most of the lesions were in the rectum (50.6%), followed by left colon (13.9%), transversum (9.4%) and right colon (26.1%). Grade of fibrosis was mostly severe (F3 56.7%; F2 24.4%; F1 18.9%), due to previous treatment attempts (70.6%) or biopsy sampling (29.4%). Mean diameter of lesions was 35.06±20.04 cm^2 with a mean procedural time 99.9±60.4 min and a mean dissection speed of 9.13±8.13 mm^2/min.

Technical success with completion of the ESD was 62.2% (112/180) with an overall en-bloc resection rate of 96.4%, while conversion to H-ESD was needed in 37.8% (68/112) of cases with en-bloc resection rate of 32.3%, due to severe fibrosis (38/68), difficult access (17/68), perforation (4/68), hemodynamic instability (2/68). Overall, CR rate was 60.6%, while cR was obtained in 92.3% of cases.

No difference between ESD and H-ESD were found in term of neither CR and cR (p=0.725 and p=0.787 respectively). Nine patients (4.8%) were referred for additional surgery due to non-curative histology after endoscopic treatment (adenocarcinomas 11.7% and neuroendocrine carcinomas 1.7%). In total, 24 adverse events (13.3%) occurred, the majority in completed ESD group (20/24 cases), mostly perforations (7%) which were all managed endoscopically. Recurrence occurred in 13 patients (7%) during a mean follow-up period of 374 days (range 55-1808). At the multivariate analysis fibrosis due to previous treatment (OR 3.08 [95 % CI 1.25-7.58], p=0.0243), high grade of fibrosis (OR 2.30 [95 % CI 1.35-3.93], p=0.0021) and right colon location (OR 1.96 [95 % CI 1.48-2.62], p=0.000003) resulted as predictive factors of technical failure.

Conclusion: ESD is a feasible, safe and effective treatment for colorectal-scarred lesion, when performed by expert endoscopists, showing high rates of "en-bloc" resection and assuring high histologic radicality and low rate of recurrence. H-ESD is a viable rescue treatment when the completion of ESD is not feasible.

Introduction: Previous studies showed that adhering to high-quality screening colonoscopy leads to markedly decreased incidence and mortality of colorectal cancer. However, more is needed to know about the impact of the duration of participation on quality parameters.

Aims & Methods: This study aims to evaluate the relationship between the duration of endoscopists' participation within the Austrian quality assurance program for screening colonoscopy and their quality parameters. A generalized linear mixed model, adjusted for sex and age, was utilized to evaluate the effect of the time elapsed since participation on quality parameters, such as adenoma detection rate (ADR), advanced adenoma detection rate (AADR) and carcinoma detection rate (CDR).

Results: 392 endoscopists provided data from 326,445 screening colonoscopies from 2007 to 2022. Results showed that each year of participation in the quality assurance initiative led to a 1.02% increase in ADR (95% CI [1.004-1.034], p-value = 0.013) as well as a 1.17% increase in CDR (95% CI [1.107-1.245], p-value <0.001) adjusted for patients' age and sex. The advanced adenoma detection rate increased by 1.00% each year of participation (95% CI [0.983-1.023], p-value = 0.762).

Conclusion: The participation of endoscopists in the quality assurance initiative was associated with a significant increase in ADR and CDR for each year of participation. However, the increase in AADR was not statistically significant.

RETROSPECTIVE STUDY OF TWO DIFFERENT ENDOSCOPIC RESECTION REGIMENS ON THICK-STALKED PEDUNCULATED RECTAL POLYPS AND POSTOPERATIVE BLEEDING

L. Wenjie[1]

[1]Jiangsu Province Hospital, Nanjing, China

Contact E-Mail Address: 515443874@qq.com

Introduction: To evaluate the effects of three different endoscopic resection regimens on thick-stalked pedunculated rectal polyps and postoperative bleeding

Aims & Methods: A retrospective analysis was conducted on the clinical data of 265 patients with thick-stalked pedunculated rectal polyps who were treated between January 2018 and Novenber 2022. They were divided into an endoscopic submucosal dissection group (ESD group, n=124), pre-ligation of stalks with clips or nylon ring group (pretreatment group, n=141). The clinical efficacy (complete resection rate), the bleeding rate, length of hospital stay were observed.

Results: No significant differences were observed in clinical efficacy within the two groups (P>0.05). However, the incidence rate of bleeding in the ESD group was lower than that of the pretreatment group (4.0% *vs.* 10.6%, *P*<0.05).The length of hospital stay in the ESD group was longer than the pretreatment group(4.6±1.9 days vs 3.4±1.5 days, *P*<0.05).

Conclusion: The ESD group is the preferential one because of its obviously lower bleeding rate. However, this method must be conducted by skilled endoscopist.

Disclosure: Nothing to disclose.

PP1222

A PRE-COLONOSCOPY PERSONALIZED DIGITAL PLATFORM MARKEDLY REDUCES AMBULATORY COLONOSCOPY ‚NO-SHOW' RATES

E. Ritter[1], O. Shibolet[1], L. Deutsch (Mlynarsky)[1]

[1]Tel Aviv Sourasky Medical Center, Department of Gastroenterology and Liver Diseases, Tel Aviv, Israel

Contact E-Mail Address: Liatml@tlvmc.gov.il

Introduction: Colonoscopy is a well-established screening tool for detection of colorectal lesions. Colonoscopy waiting lists can last for months, however, the rates of unperformed procedures due to patients' absence ('no-show') are 8-15% globally.

Aims & Methods: The aim of this study was to evaluate whether a personalized digital platform would reduce 'no-show' rates for ambulatory colonoscopies.

We retrospectively analyzed prospectively collected data regarding scheduled ambulatory colonoscopies. The GistMD digital platform includes a patient-tailored animated video, individualized according to age, gender, comorbidities and language. It also includes links to written instruction forms and consent forms, and a set of reminders. During 01/2022-06/2022, a link to the GistMD system was randomly sent to patients before a scheduled colonoscopy. The study group ('GM-Link') included all patients that were sent the link by SMS. The control group received standard written instructions by email.

Results: During the study period, a total of 2114 colonoscopies were included. The GistMD link was randomly sent to 1621 (76.7%) patients ('GM-Link') and standard written prepration instructions to 493 (23.3%) controls ('No link').

The 'no-show' rates were reduced by half among the 'GM-Link' group compared to controls [190 (11.7%) vs. 114 (23.1%), respectively, p<0.001]. This significant ‚no-show' rate reduction in the 'GM-Link' group compared to

the 'No Link' group was consistent among males and females subgroups analysis (11.8% vs. 27.5%, p<0.001 and 11.7% vs. 19.3%, p=0.003, respectively) and among all age groups (p<0.05, for all groups). Furthermore, the 'GM-Link' group was divided according to usability: 1. 'No video' - Video was not watched at all, 757/1621 (46.7%), 2. ,Min users' - Watched<75% of the video,77/1621 (4.8%) and 3. 'Max users' - Watched >75% of video, 787/1621 (48.6%). There was a "dose-dependent" trend between usability groups and 'no-show' rates: 'No link' - 23.1%, 'No video'-17.4%, 'Min users' -10.4%, 'Max users'- 6.4% (P<0.001).

In two multivariate logistic regression adjusted for age, sex and morning vs. afternoon colonoscopy, 'GM-Link' receivers and 'Max users' were each independently associated with 51% and 76% ,no show' rate reduction compared to 'No link' controls (OR 0.491, P<0.001 and OR 0.242, p<0.001, respectively). According to number needed to treat analysis, the number of sent links required for prevention of one ,no show' was 8 links. In terms of economical calculations, using the digital platform will reduce the monthly income loss due to 'no-show' by ~70,000 ILS (~17,550 euro) and the yearly income loss by ~840,000 ILS (~210,500 euro), considering 400 colonoscopies/month of which 35% include polypectomy.

Conclusion: Implementation of a digital platform significantly reduced 'no show' rates for ambulatory colonoscopy. This reduction can result in increased efficiency and reduced financial losses as well as shorter waiting times in gastroenterology units.

Disclosure: Nothing to disclose.

OPTICAL DIAGNOSIS IN COLONOSCOPY: MORE TO IT THAN MEETS THE AI

R. Varley[1], M. Hanly[2], E. Gibbons[1], L. Kumar[2], G. Doherty[2], O. Kelly[1], G. Horgan[2], B. Hall[1]

Contact E-Mail Address: varleyr@tcd.ie

Introduction: Computer-Aided Diagnosis (CADx) allows for real-time characterisation of polyps. In a small number of studies to date, CADx accuracy in polyp characterisation has been similar to expert endoscopists and better than novel endoscopists. CADx may allow for a resect and discard strategy with sub-centimetre polyps which would have significant economic impacts on our health service. CADx may also be a useful tool in improving the accuracy and efficiency of polyp diagnosis and management in a training setting.

Aims & Methods: To compare the performance of expert endoscopists, trainee endoscopists and CADx in characterising colonic polyps.

In this multi-centre prospective comparison study, two endoscopists performed high-definition colonoscopies with GI Genius (Medtronic, Dublin, Ireland) between August and November 2022. All detected polyps were photo-documented (white light imaging, narrow band imaging and near focus), resected and retrieved. CADx diagnosis was recorded (adenoma/non-adenoma/no prediction). Histologic diagnosis was recorded. Blinded to both CADx and histologic diagnosis, expert and trainee endoscopists independently predicted polyp type based on photo documentation. Comparison of diagnosis was made between experts, trainees & CADx and compared against final histologic diagnosis. Sensitivity and specificity was calculated for each group using histologic diagnosis as gold standard.

Results: 139 polyps across two centres were photo-documented during the study timeframe. Expert endoscopists (Sensitivity 91.67% [95% CI 77.53-98.25%]) were better at polyp characterisation than both CADx (Sensitivity 84.31% [95% CI 71.41-92.98%]) and trainee endoscopists (Sensitivity 87.23% [95% CI 74.26-95.17%]). Expert endoscopists (Sensitivity 77.27% [95% CI 54.63-92.18%] and trainee endoscopists (Sensitivity 63.16% [95% CI 38.36-83.71%]) performed better than CADx (Sensitivity 42.11% [95% CI 20.25-66.50%]) in the characterisation of non-adenomatous polyps.

Conclusion: Our data corresponds with previously published studies. Interestingly, trainee characterisation was similar to CADx predictions in our study. Both trainee endoscopists are experienced endoscopists nearing the end of their respective training schemes. CADx polyp characterisation may be useful in an earlier training phase but further studies are necessary. A resect and discard strategy utilising CADx does not at present appear feasible.

Contact E-Mail Address: muneer20@hotmail.co.uk

Introduction: The 'Speedboat-RS2/SRS2' (Creo-Medical/Wales/UK) is the first multi-modality device, incorporating bipolar-radiofrequency/BRF energy cutting, microwave energy coagulation/MWC, an integrated needle for submucosal injection and a rotatable blade with a heat insulated hull for protection.

Aims & Methods: A prospective cohort of colorectal Speedboat-assisted Submucosal Dissection (SSD) was initiated for a duration of three operational years. One experienced operator performed all cases. Short and long-term clinical outcomes were recorded. Linear regression was used to explore whether factors, such as polyp size/surface/location/morphology could implicate with the duration of the procedure in minutes.

Results: 184 patients were subject to SSD using tunnelling technique. 19 abandoned (14 for muscle retraction sign, 7 advanced cancer), 5 for medical emergencies. Out of 165, endoscopically complete en-bloc resection was achieved in 91.5% (n=151), curative rate 82% (n=18). Conversion to piecemeal resection 8.5% (n=14)due to inappropriate booking and scope difficulties.Within the en-bloc group, mean polyp 5.45cm +/- 2.81 SD, mean polyp surface 22.63cm2 +/- 25.03 SD.Overall mean procedural time in minutes was 105.98 +/- 82.78 SD. Non-rectal polyps 75/151 (49.7%), non-granular polyps 51/151 (34%), high dysplastic polyps 36/151 (25.2%), cancers 20/151 (14%). Six out of 20completely excised (R0) T1 cancers had no recurrence in endoscopy (4/6) or surgery (2/6). Fourteen out of 20T1 cancers with adverse histology features had no residual malignancy in the surgical specimen with 2/4showed LN metastases requiring chemotherapy. A case of advanced NET within a benign adenoma requiredchemotherapy. Three out of 14 opted for surveillance only with no recurrence on endoscopy in two of them.First surveillance endoscopy available for 71/151 (47%) with no recurrence identified.MWC used to pre-coagulate and control bleeding in all cases. Hemostatic monopolar forceps was required in11/151 cases. Endoscopically controlled delayed bleeding occurred in 3 patients (2%).

No perforation wasrecorded.Regression analysis revealed significant effect of cm2 size and fibrosis on the duration of the procedure (p <.001, R2 = .778), indicating an increase of 2.271t minutes per 1cm2 of increase in polyp surface and anincrease of 37.34 minutes when severe fibrosis is encountered; with a baseline time of 23 mins reflecting polypof 10cm2.

Conclusion: These first results demonstrate that Speedboat is an effective and safe device for submucosal colorectal dissections. SRS2 performed in a timely manner, and the preliminary correlation of the time of the procedure affected by polyp surface and degree of fibrosis warrants further analysis.

Disclosure: Nothing to disclose.

PP1225

CURATIVE OUTCOMES IN SMALL PT1 LESIONS RESECTED BY EITHER ESD OR EFTR: A NORTH-EASTERN ITALIAN EXPERIENCE

A. Gubbiotti[1], D. Caroli[1], E. Guido[1], L. Peraro[1], F. De Lazzari[1], E. Rosa-Rizzotto[1]

[1]Padua Hospital, Department of Gastroenterological, Surgical and Oncological Science, Padua, Italy

Contact E-Mail Address: gubbio92@hotmail.it

Introduction: ESD (endoscopic submucosal dissection) and EFTR (endoscopic full-thickness resection) are treatments of choice in the endoscopic resection of small and superficially submucosal invasive GI lesions. It is often challenging to assess the best curative option in this setting. ESD is currently thought to be the gold standard technique.

Aims & Methods: We retrospectively analyzed all gastrointestinal pT1 lesions < 30 mm resected by either ESD or EFTR in our Unit from 2016 and December 2022. As primary endpoints we assessed en bloc resection, R0 resection (clear margins) and curative resection (no further need for surgery) rate. As secondary endpoints we analyzed mean procedural time, cost and adverse events that occurred within or after both procedures. Statistical analysis was performed with Pearson chi-square test.

Results: 35 ESD and 32 EFTR were enrolled. En bloc resection was achieved in, respectively, 90 % (32/35) and 96% (30/32), with no statistical difference (RR 0.93, p= 0.9), likewise R0 resection (29/35, 83% vs 30/32, 96%, RR 0.86, p=0.7) and curative resection (23/35, 66% vs 20/32, 64%, RR 1.03, p= 0.7). Mean procedural time was lower in EFTR, although not significantly (67 ± 37 min vs 50 ± 15.6 min, p=0.7), while adverse events rate was similar (5/35, 13% vs 3/32, 10%). Eventually, mean procedural cost per hospitalization day was lower in ESD than EFTR (1503 ± 360 € vs 2260 ± 210€), considering a medium hospitalization time of 2.4 days and 2 days, respectively.

Conclusion: ESD and EFTR turned out to be equally successful in achieving R0 and curative resection in pT1 small lesions, so that ESD should remain gold standard in an experienced setting, even though EFTR could allow easier and faster en bloc resection in most challenging ESD, albeit more expensive.

Disclosure: Nothing to disclose.

PP1226

FRAILTY INDEX AND COMORBIDITIES PREDICT ADVERSE EVENTS FOLLOWING COLONOSCOPY IN THE ELDERLY: A SINGLE-CENTER EXPERIENCE

M.-J. Kim[1], J. Chun[1], Y. Kim[1], J.-H. Kim[1], Y.H. Youn[1], H. Park[1]

[1]Yonsei University College of Medicine, Internal Medicine, Seoul, South Korea

Contact E-Mail Address: kmj0630@yuhs.ac

Introduction: The number of colonoscopies performed on elderly patients is increasing because of the rapidly progressed aging population, but in the case of elderly patients, safety and advantage of colonoscopy are still insufficient when compared with procedure risk. FI-lab, which is a frailty index calculated by laboratory test and vital sign, and is expected to be a measure that can predict the clinical outcome of elderly patients. We evaluated and analyzed the safety of colonoscopy by analyzing the association between the adverse events of colonoscopy with FI-lab and Charlson's comorbidity index (CCI).

Aims & Methods: A total of 8154 patients were enrolled in this study retrospectively at a Gangnam Severance Hospital from July 2017 to August 2022. Patients were aged 60 or older, underwent colonoscopy for screening, and there were blood test results within two months before and after the procedure.

Those who underwent endoscopy for therapeutic purposes, those under the age of 59, and those who missed blood test results or vital sign records were excluded. FI-lab was calculated by the closest blood test results at the time of the procedure and the vital signs at the time of the procedure, and CCI was calculated based on the patient's history recorded in the hospital and the age at the time of the procedure. The occurrence of side effects was based on an unplanned visit to the emergency room or hospitalization within a month after the procedure.

Results: The total number of participants was 8154, with 3102 in the 60-64 age group, 2160 in the 65-69 age group, 1506 in the 70-74 age group, 904 in the 75-79 age group, and 482 in the age group of 80 years or older.

The study population comprised 4354 males (53.4%). The mean age of the participants was 67.9 years, ranging from 60 to 94 years. The CCI mean was 3.31. The mean value of the FI-lab was 0.168.

Most of the participants (86.2%) had a low frailty index, followed by 11.9% with a moderate frailty index, and 1.9% with a high frailty index. Adverse events of colonoscopy within 30 days were occurred in 115 cases, gastrointestinal events such as perforation or bleeding were 27, mortality cases were 9, major adverse events were 48, minor events were 67. CCI and FI-lab were showed strong associations with complications (p<0.001, each), and categorized FI-lab showed statistically significant differences between low group and moderate or high group (p<0.001).

	Without AE	AE	p-value
number	8039	115	
Age, mean, years(range)	67.9(60-94)	71.8(60-91)	<0.001
Male sex, number(%)	4277(53.2)	77(67.0)	0.003
CCI, mean	3.29	4.9	<0.001
FI-lab, mean	0.167	0.261	<0.001
low(<0.25), number(%)	6977(86.8)	53(46.1)	
moderate(0.25-0.4), number(%)	925(11.5)	44(38.3)	
high(>0.4), number(%)	137(1.7)	18(15.6)	

Table. Factors affected to adverse events.

Conclusion: CCI and FI-lab can be a predictive scoring system in elderly patients who received screening colonoscopy. Therefore, if CCI or FI-lab is high, physicians should decide and perform colonoscopy carefully.
Disclosure: Nothing to disclose.

PP1227

PREVALENCE OF INCIDENTAL ASYMPTOMATIC TERMINAL ILEITIS DIAGNOSED ON ILEO-COLONOSCOPY

M. Khanfour[1], S. El Helou[1], L. Amer[1], R. Slim[1], K. Honein[1], J. Amara[1], S. Khalife[1], E. Mahfouz[1], E. Mikhael[1], C. Yaghi[1]
[1]Hotel Dieu de France, Saint Joseph University, Faculty of Medicine, Gastro-Enterology and Hepatology, Beirut, Lebanon

Contact E-Mail Address: melissakhanfour@gmail.com
Introduction: Terminal ileitis is the endoscopic manifestation of a wide range of diseases: inflammatory, infectious, vasculitic, ischemic, drug-induced and malignancy. When it comes to asymptomatic terminal ileitis, it is incidentally found on screening ileo-colonoscopy. The prevalence of this entity was not well established and is found in few studies with heterogenous results.
Aims & Methods: We conducted this study to define the prevalence and histopathologic characteristics of asymptomatic terminal ileitis. This is a cross-sectional study. The study population is composed of all the patients that underwent a colonoscopy between September 2020 and March 2023. Selection bias were avoided by excluding patients with inflammatory bowel disease (IBD), sacroiliitis, chronic diarrhea, elevated calprotectin, medical history of ileitis diagnosed either on previous colonoscopy or on imaging showing wall thickening, and those with altered anatomy (colectomy with ileo-colic anastomosis).
Results: A total of 3901 colonoscopies were realized in a single center between September 2020 and March 2023; 3035 met our inclusion criteria based on medical history and the indication of the colonoscopy that excluded the above-mentioned reasons. Ileal intubation was performed in 91.4% (n=2773) of these cases, representing the final study population. Terminal ileitis was found in 5% (n=139) of patients, of whom 58.3% (n=81) were men and 41.7% (n=58) were women. The median age at diagnosis was 50 and and the mean age was 49.43 +/-15.5. The three main indications for colonoscopy were: colorectal cancer screening in 57.5% (n=80) of cases, gastrointestinal red flag symptoms including bleeding, anemia, and weight loss in 28.8% (n=40) of cases, and abdominal pain in 13.7% (n=19) of cases. Biopsies were performed in 90.6% (n=126) of ileo-colonoscopies and showed, regardless of the indication, normal histology, erosive and ulcerated ileitis, and non specific and other findings in 12.7% (n=16), 36.5% (n=46) and 44.4% (n=56) of samples respectively. Definitive Crohn's disease diagnosis was found in 5.75% (n=8) of asymptomatic ileitis patients.
Conclusion: The prevalence of asymptomatic terminal ileitis was 5% in our population. This finding was not associated with the indication of the colonoscopy, namely colorectal cancer screening, gastrointestinal red flag symptoms including bleeding, anemia, and weight loss and abdominal pain. The clinical significance of this finding requires longitudinal follow-up studies to assess the incidence of IBD or other conditions.
Disclosure: Nothing to disclose.

PP1228

CAP CUFF ENHANCED COLONOSCOPY: DOES IT IMPROVE POLYP DETECTION AND MAKE RETROFLEXION UNNECESSARY?

O. Dupuis[1], S. Mavromatis[2], A. Mavromatis[2], P. Hassard[3], C. Sabbagh[3], L. Oliveira[3], C.-N. Compas[4]
[1]University of Ottawa, Faculty of Medecine, Ottawa, Canada, [2]Université de Sherbrooke, Medecine, Sherbrooke, Canada, [3]Montfort Hospital, Gastroenterology, Ottawa, Canada, [4]Montfort Hospital, Institut du Savoir Montfort (ISM), Ottawa, Canada

Contact E-Mail Address: oliviadupuis@montfort.on.ca
Introduction: Screening for colorectal cancer (CRC) by colonoscopy has contributed to a steadily declining rate of incidence and mortality related to CRC in recent years. The caveats of the former are difficult mucosa and polyp visibility, among others. The Cap cuff is an endoscopy-enhancing device aiming to improve mucosal inspection, and thus, polyp detection. However, there is limited evidence-based knowledge surrounding its true clinical impact.
Our study investigates the degree of clinical effectiveness of the Cap cuff-enhanced colonoscopy (CCEC) when assessing for colonic polyps and distal rectal pathology.
Aims & Methods: We conducted a non-randomized trial by recruiting consenting and eligible participants aged 18 years or older, that were undergoing either a screening, surveillance, or urgent colonoscopy at the Montfort Hospital (Ottawa, CAN) from August 2022 to February 2023. All participants (N=375) underwent an CCEC. The colon was assessed once; while the rectum was initially assessed with direct visualization and subsequently reassessed by retroflexion. The polyps were removed and documented. Our study's primary outcome focused on evaluating the CCEC's impact on colonic polyp detection rate (cPDR) when compared to retrospective controls of standard colonoscopy dating from January 2017 to August 2022. It also focused on investigating the distal rectal pathology detection rate (rPaDR) with Cap cuff-enhanced direct visualisation (CCEDv) compared to Cap cuff-enhanced retroflexion (CCER). Secondary outcomes included procedure safety and patient tolerance. cPDR data was acquired by the review of prospective and retrospective operative reports for polyp presence.
The control group was established by sample-matching based on age and sex. rPaDR data was acquired by the review of participant's operative report for distal rectal pathology presence and modality of pathology visualisation.
Results: The results demonstrate a lower overall cPDR in the treatment group compared to the control group (72.2% vs. 88.7%, respectively; p< 0.01). By age group, the CCEC demonstrated a cPDR of 60.2% for participants aged 31-50 years (n=88) compared to 82.9% in the retrospective control group (n=88), 74.8% for participants aged 51-65 (n=171) compared to 89.4% in the retrospective control group (n=142) and 79.5% for participants aged 66+ (n=112) compared to 93.7% in the retrospective control group (n=112). CCEC's cPDR for participants 18-30 years was not statistically significant (n=4) but included in the overall cPDR. As for the rPaDR, specifically for rectal polyp detection (n=16), 2 polyps were only viewed by CCEDv, while 6 polyps were only viewed by CCER. The other 8 were viewed by both CCEDv and CCER.
Regarding hemorrhoid detection (n=159), CCER was a significantly better modality compared to CCEDv (89.9% vs. 1.3%, respectively; p< 0.01). A majority tolerated the procedure very well (94.7%) and there were no adverse events associated with the usage of the Cap cuff during the study.
Conclusion: In contrast to prior promising studies, the CCEC failed to meet expectations. CCEC did not distinguish itself from standard colonoscopy. With respect to distal rPaDR, sole CCEDv was significantly inferior to CCER, demonstrating the importance of the use of retroflexion during colonos-

copy despite the use of the Cap cuff. This study unveils possible criticisms in the clinical effectiveness of the Cap cuff. Further studies should evaluate these initial findings by means of a larger scaled study.
Disclosure: Nothing to disclose.

Contact E-Mail Address: stipe.pelajic@gmail.com
Introduction: Due to long waiting lists and limited resources, referring patients for colonoscopy requires assessment of both need (indication) as well as urgency of performing the procedure. Symptomatic patients are usually perceived as more urgent when compared to asymptomatic individuals sent for screening.
Aims & Methods: Our aim was to explore if indication for colonoscopy had any association with colon cancer or colon polyp incidence, size and number. We hypothesised that patients with most common symptoms (rectal bleeding, change in bowel movements, abdominal pain) were more likely to have pathological colonoscopy findings when compared to asymptomatic individuals sent for screening or due to positive faecal occult blood test (FOBT).
We performed a retrospective analysis of prospectively collected data included 7701 colonoscopies performed between January 2017 and December 2021 in Sestre Milosrdnice University hospital, Zagreb, Croatia. We included patients undergoing first-time colonoscopy due to history of either rectal bleeding, change in bowel movements or abdominal pain, as well as asymptomatic individuals without family history screened with colonoscopy (with or without positive guaiac-based FOBT). Exclusion criteria were all other indications for colonoscopy and a repeated procedure. Final dataset included 2321 patients. Statistical analysis was done in Python 3.2 with statsmodels module for creating logistic regression models to analyse relationships within data.
Results: Mean age in the cohort was 59 +\- 15 years, with 56.8% being female. When comparing symptomatic to asymptomatic individuals, adenomas were found in 30.1% vs. 40.6% and carcinomas in 4.0% vs. 4.2% respectively.
After adjusting for age and sex there was however no significant difference between these two groups regarding polyps or carcinoma findings. For polyp detection OR was 0.61 (95% CI 0.41- 1.09); for polyp size >2cm OR 0.68 (95% CI 0.38-1.2) and for carcinoma detection 1.15 (95% CI 0.56 -2.33). Age was the only factor that was consistently associated with pathological colonoscopy findings, as follows: for every year of age odds of finding an adenoma increased by 1.027 (95% CI 1.021-1.033), having >5 adenomas increased by 1.04 (95% CI 1.016-1.065), and finding a carcinoma by 1.057 (95% CI 1.039-1.075). None of the investigated factors were associated with polyp size.
Conclusion: Presence of most common symptoms/causes for sending patients to colonoscopy does not seem to increase the odds of pathological findings and therefore should not raise the urgency of performing the endoscopy. Increasing age is the only consistent risk factor for colonic neoplasia in these patients.

COLON CAPSULE ENDOSCOPY IN A UK DISTRICT GENERAL HOSPITAL: WHAT ARE THE REAL ISSUES?

T. Min[1], J. Wood[1], B. Humphrey[1], K. Kapur[2], S. Oliver[1], E. Said[1]
[1]Barnsley Hospital NHS Trust, Gastroenterology, Barnsley, United Kingdom, [2]Barnsley Hospital NHSFT, Gastroenterology, Barnsley, United Kingdom

Contact E-Mail Address: tmin@doctors.org.uk
Introduction: Colon capsule endoscopy (CCE) is deemed to be feasible, safe and accurate and has a similar diagnostic sensitivity to colonoscopy in routine clinical practice [1]. The ScotCap project study suggested that CCE could enable 70% of patients to avoid a colonoscopy if used as a primary diagnostic tool [2]. Our study looks at the data collected from a district general hospital to ascertain what the real terms issues with using CCE are and therefore whether protocols need to be altered to enable CCE to be used within a small centre as a primary diagnostic tool.
Aims & Methods: An observational restrospective study using data for all completed CCE was collected between February 2020 and February 2022 at Barnsley District General Hospital, South Yorkshire, United Kingdom by using our online request system and the reports that were generated. This data was then categorized into relevant sub-categories such as age, indication and outcome- both in terms of clinical findings and whether subsequent endoscopic evaluation was required. The data was analysed using R and Excel.
Results: A total of 142 colon capsule was done with the predominate age group ranging from 51 to 70 years old. The main 2 indications were positive faecal immunochemical test (FIT) 46.9% (67/143) and iron deficiency anaemia (IDA) 11.9% (17/143). The results from the capsules did show 23.8% had poor bowel preparation and 18.9% was a normal examination. Following this, 12% had either diverticulosis or poor bowel preparation with pathology (example polyps or inflammation seen). Based on the results, 52% of all capsules still recommended further endoscopy either colonoscopy or flexible sigmoidoscopy for better visualisation.
Conclusion: The predominant impact on the quality of the results was related to poor bowel preparation requiring almost half of capsule endoscopy to proceed with further direct endoscopic visualisation. Addressing the issue and improving the quality of bowel preparation could potentially improve the sensitivity for pathology detection and reduce of the endoscopy burden on the unit.

CORRELATION BETWEEN PRESCRIBING DOCTOR ATTRIBUTES AND INTESTINAL CLEANLINESS IN COLONOSCOPY: A COHORT STUDY OF 22522 PATIENTS

H. Khizar[1], H. Zhou[1], J. Yang[1]
[1]*Hangzhou First People Hospital, Hangzhou, China*

Contact E-Mail Address: yjf3303@zju.edu.cn

Introduction: This study aimed to analyze the correlation between different attributes of doctors who prescribe colonoscopies and the cleanliness of the intestine to guide the development of colonoscopy application protocols.

Aims & Methods: Data on colonoscopy cases conducted in the gastroenterology department of Hangzhou First People's Hospital between April 2018 and March 2021 were collected. The gender, age, professional attributes of the prescribing doctors, and Boston Bowel Preparation Scale (BBPS) score were recorded.

In addition, the correlation between the prescribing doctors' characteristics and the intestine's cleanliness was analyzed.

Results: The study included 22,522 patients with a mean BBPS score of 6.83±1.94. There were 16,459 male and 6,063 female doctors with similar BBPS scores (P = 0.212). The study found no significant difference in BBPS scores between 19,338 physicians and 3,184 non-physicians (P = 0.154). However, BBPS scores differed significantly between 18,168 gastroenterologists and 4,354 non-gastroenterologists (P = 0.016) and between 19,990 intestinal-related specialties and 2,532 non-intestinal-related specialties (P = 0.000).

In addition, BBPS scores were significantly different between 18,126 prescribing doctors with colonoscopy ability and 4,352 without (P = 0.014). However, there was no significant difference in BBPS scores among doctors of different ages (P = 0.190). The study found significant differences in BBPS scores between male and female patients and those under or over 40 years (P = 0.000).

Conclusion: To improve colonoscopy preparation quality, priority should be given to doctors in gastroenterology, intestinal-related specialties, and with colonoscopy operation ability. Their expertise may result in better education and improved bowel cleanliness.

Disclosure: Nothing to disclose.

PP1232

EFFECTIVENESS OF SCREENING COLONOSCOPY IN REDUCING COLORECTAL CANCER INCIDENCE IN GERMANY: A TARGET TRIAL EMULATION

U. Haug[1], M. Braitmaier[1], S. Schwarz[1], B. Kollhorst[1], V. Didelez[1]
[1]*Leibniz Institute for Prevention Research and Epidemiology – BIPS, Bremen, Germany*

Contact E-Mail Address: haug@leibniz-bips.de

Introduction: In Germany, screening colonoscopy has been offered to all adults aged 55 or older since 2002. In parallel to screening colonoscopy, fecal occult blood testing is offered (Guaiac test until 2017, fecal immunochemical test afterwards) and, in addition, there is a high use of diagnostic colonoscopies. In view of this context, we aimed to quantify the effectiveness of screening colonoscopy in reducing colorectal cancer (CRC) incidence in Germany in men and women aged 55–69 years.

Aims & Methods: Using a German claims database (GePaRD, 20% population coverage) we included persons at average CRC risk aged 55–69 years and without a colonoscopy, polypectomy or fecal occult blood test before baseline.

We emulated a target trial with two arms: Colonoscopy screening vs. no colonoscopy screening at baseline. We estimated adjusted cumulative CRC incidence over 11 years of follow-up stratified by sex (at the time of the conference, 14-year follow-up data will be available).

Results: Overall, we included 99,101 men (women: 99,288) in the screening arm and 583,861 men (women: 664,052) in the control arm. In men, the adjusted 11-year CRC risk was 1.89% in the screening group and 2.85% in the control group resulting in a relative risk of 0.66 (95% CI: 0.63–0.73). In women, the adjusted 11-year CRC risk was 1.31% in the screening group and 1.96% in the control group resulting in a relative risk of 0.67 (95% CI: 0.63–0.73).

Conclusion: Our study shows that screening colonoscopy in Germany is effective in preventing CRC both in men and women. In the interpretation of the strength of the effect (~33% incidence reduction), the high background prevalence of diagnostic colonoscopy should be considered.

As previously shown, screening colonoscopy accounts for less than half of the overall 10-year prevalence of colonoscopy in persons aged 55-69 years in Germany.

Disclosure: Nothing to disclose.

PP1233

EFFECT OF LOW-VOLUME AND INTERMEDIATE VOLUME BOWEL PREPARATION ON COST-EFFECTIVENESS AND QUALITY OF LIFE: OPEN-LABEL, NON-INFERIORITY, RANDOMIZED CONTROLLED TRIAL

M. van Riswijk[1], F.A. Indemans[2], K. Hawinkels[3], R.-M. Schreuder[3], L. Wildeman[4], A.C.I.T.L. Tan[5], P.D. Siersema[1,6]

Contact E-Mail Address: milou.vanriswijk@radboudumc.nl

Introduction: Bowel preparation is essential for colonoscopy. Patients often experience bowel preparation as the most deterrent factor for undergoing colonoscopy. To alleviate burden for patients, intermediate (2L) and low-volume (1L) bowel preparation solutions have been developed. Little is known on the effect of low-volume bowel preparation on patient reported outcomes.

Aims & Methods: We aimed to assess the impact of bowel preparation on quality of life and productivity loss. We performed an open-label, non-inferiority, randomized trial in 4 centers in the Netherlands. Patients scheduled for screening, surveillance, or diagnostic colonoscopy were invited to participate and 1:1 randomized between a split-dose 2L Poly Ethylene Glycol with ascorbate (2LPEG+Asc, intermediate volume) laxative or a split-dose 1L PEG+Asc laxative with added sodium sulfate (low-volume). Before and after bowel preparation, patients filled out the following validated questionnaires: *Institute for Medical Technology Assessment Productivity Costs Questionnaire* (iPCQ), *Mayo Florida bowel preparation tolerability questionnaire* (MBTQ), *Short form 36* (SF-36), and *Euroqol group 5 Dimensions 5 Levels* (EQ-5D-5L). Colonoscopy data included Boston bowel preparation score (BBPS) and surveillance interval as provided by the endoscopist. Primary outcome was non-inferiority of low-volume to intermediate volume bowel preparation, defined as the rate of adequately prepared colonoscopies with a non-inferiority margin of 5%.

Secondary outcomes included change in SF-36 and EQ-5D-5L scores after bowel preparation, tolerability, and impact on working productivity.

Results: We included 467 patients (intermediate-volume, n=229 and low-volume, n=238). Questionnaire response rates were 86.3% and 88.7%, respectively (p=0.378). Low-volume bowel preparation was non-inferior to intermediate volume bowel preparation, with adequate cleaning rates of 96.8% (95% confidence interval [CI] 93.5-98.6) and 96.1% (95%CI 92.6-98.0), respectively (p=0.801). Low-volume bowel preparation had a higher high-quality cleaning rate (i.e., BBPS 3-3-3) with 72.7% vs 63.4% in the intermediate-volume group (P=0.032). No clinically significant changes were found on the EQ-5D-5L and SF-36 questionnaire. Patients in the low-volume group were more willing to repeat the bowel preparation with 60.1% vs 47.8% in the intermediate volume group (p=0.034), but nausea/vomiting and a bad taste were more frequent in the low-volume group (p=0.007 and p=0.006, respectively).

Absenteeism and impaired working productivity were present in 15.1% and 23.0% of patients, respectively, but did not differ significantly between groups or before and after bowel preparation.

Conclusion: Low-volume bowel preparation is non-inferior to intermediate volume bowel preparation but has a higher willingness to repeat compared to intermediate volume bowel preparation, at the expense of more non-serious side-effects. This data can help patients to select their preferred bowel preparation.

Contact E-Mail Address: abdellah.hedjoudje@gmail.com

Introduction: Benign gastrointestinal strictures are often refractory to endoscopic dilations and standard covered stents have been disappointing. Our aim was to evaluate the clinical efficacy of lumen apposing metallic stent in the treatment of short and anastomotic benign strictures"

Aims & Methods: This study was conducted by the endoscopic department at a tertiary level hospital in France. Consecutive patients who underwent lumen apposing metal stent placement from February 2018 to August 2021 for lower gastrointestinal benign anastomotic strictures were prospectively followed for a minimum of 6 months. Primary outcome measure was clinical success, defined as improvement or resolution of underlying symptoms; secondary endpoints were technical success and adverse events.

		IBD versus non IBD patients		
	Overall (n = 20)	No (n = 6)	Yes (n = 14)	p
Technical success, n (%)	20 (100)	6 (100)	14 (100)	/
Clinical success, n (%)	16 (80)	4 (83.4)	11 (78.6)	0.292
Any adverse event (%)	2 (10.0)	0 (0.0)	2 (14.3)	0.871
Post-procedure pain (%)	2 (10.0)	0 (0.0)	2 (14.3)	0.871
Incarcerated stent (%)	1 (10)	0 (0.0)	1 (7.1)	1.000
Spontaneous migration	10 (50.0)	2 (33.3)	8 (57.1)	0.240
Death unrelated to the procedure	1 (5.0)	1 (16.7)	0 (0.0)	0.654
Follow up (years) (mean (SD))	1.26 (0.94)	1.66 (1.07)	1.09 (0.86)	0.222

Results: A total of 20 patients bearing as many strictures were included and underwent a total of 22 procedures for stent placement. Etiology of GI stricture included : prior carcinologic surgery (n = 5), IBD surgery (n = 14), sigmoiditis (n= 1).

Technical success was achieved in 22/22 procedures. Mean follow-up was 1.26 +/- 0.94 years . Sustained clinical success (up to the end of follow-up) was observed in 16/20 patients (80%). Three adverse events occurred in 2 patients patients (10%), including 2 cases of post procedure pain and one unextractable stent. An indwelling stent was left in situ permanently in 1 patient while all the other remaining stents were easily removed (n= 19 , 95%).

Conclusion: Lumen apposing metal stent for the treatment of benign anastomotic strictures is technically feasible and safe with a high rate of clinical success on the medium term. Also, removal of lumen apposing metal stent is generally easy and safe. lumen apposing metal stent may be an option to treat selected patients with benign anastomotic stricture.

Disclosure: Nothing to disclose.

PP1237

10 YEAR REVIEW OF ENDOSCOPY UTILISATION IN PATIENTS POST ILEAL POUCH-ANAL ANASTOMOSIS SURGERY

G. Howell[1], R. Cooney[1]
[1]University Hospitals Birmingham NHS Foundation Trust, Department of Gastroenterology, Birmingham, United Kingdom

Contact E-Mail Address: ghowell6@doctors.org.uk

Introduction: Pouchoscopy is indicated for pouch assessment and surveillance following ileal pouch-anal anastomosis (IPAA) surgery. Annual surveillance is suggested in cases who are at high risk of neoplasia (i.e. Primary Sclerosing Cholangitis (PSC)/ colonic dysplasia/ neoplasia), and 5 yearly in low risk patients[1,2].

Biopsies are recommended. With the pressures on endoscopy services continuing we reviewed endoscopy utilisation in our cohort of pouch patients.

Aims & Methods: We searched via health informatics for all patients who underwent IPAA surgery at our centre the Queen Elizabeth Hospital, Birmingham, United Kingdom, from 2012 to 2022. Via case note review, we reviewed indication, timing, presence of high-risk features and pouchoscopy report

Results: 56 patients underwent surgery for formation of new IPAA during this study period. The majority were performed were performed from 2012- 2015 (36 cases, 62%). 6 (10%) were undertaken as a single stage procedure, the remainder were 2 stage and 1 (1.8%) was a conversion from an ileo-rectal anastamosis. Indication for IPAA was medically refractory inflammatory bowel disease (IBD) in 48 (86%) cases, colonic dyslpasia in the context of IBD in 5 (9%), and 3 (5%) had an underlying genetic disorder for malignancy e.g. FAP or HNPCC. 16 patients had high risk features (PSC colitis=5, Dysplasia/neoplasia =11), although 2 were referred elsewhere for surveillance.

148 pouchoscopies were performed on this cohort of patients, with an average of 1 pouchoscopy every 3 years from IPAA date (range: 1 pouchoscopy per 0.4 – 10 years). The majority (113, 76%) of procedures were for pouch symptoms e.g. frequency, pain. Biopsies were taken in 98 (66%). Dye spray surveillance was not performed. No biopsy showed pouch or rectal neoplasia, but 73 (74%) showed pouchitis/cuffitis/inflammation.

Despite high resource utilisation, adherence to surveillance protocols remained poor.

	Appropriate number of pouchoscopies as per guidelines	Appropriate number of pouchoscopies with biopsies	Number of patients who did not undergo pouchoscopy despite pouch duration >1 years (high risk) or >5 years (low risk)
High risk (n=14)	2 (14%)	1 (7%)	3 (21%)
Low risk (n=40)	30 (75%)	29 (73%)	10 (25%)

2 patients went on to have their IPAA excised, and 5 have since died; 2 due to PSC associated liver failure, 2 due to non-pouch malignancy and 1-details unavailable.

Conclusion: This study shows poor implementation of pouch surveillance guidelines yet high use of endoscopy for pouch assessment often without biopsy. Our findings suggest that surveillance for neoplasia is an overlooked component of the care of patients who have under IPAA surgery. Furthermore, there is uncertainty within guidelines about frequency of surveillance particularly in low risk groups, although these patients do have a recognised risk of neoplasia[2,3].

We recommend that endoscopists take biopsies routinely when assessing pouch such as Type C mucosa in the pouch (mucosa exhibiting permanent persistent atrophy and severe inflammation) has a greater propensity for neoplastic changes. In addition, more data is needed to determine the risk of neoplasia in different subgroups of patients who have undergone IPAA surgery, as well as develop robust guidelines on use of endoscopy in pouch management.

PILONIDAL SINUS AND EFFECTIVENESS OF SURGICAL TREATMENT BY OPEN EXCISION: EXPERIENCE OF A MOROCCAN DEPARTMENT

R. Laroussi[1], J. Benass[2], H. Laraqui[3], M.T. Tajdine[2]
[1]Faculty of Medicine and Pharmacy of Rabat, Gastroenterology Department of the Mohamed V Military Hospital, Rabat, Morocco, [2]Faculty of Medicine and Pharmacy of Rabat, Rabat, Morocco, [3]Faculty of Medicine and Pharmacy of Rabat, Proctology Surgery Department of the Mohammed V Military Instruction Hospital, Rabat, Morocco

Contact E-Mail Address: laroussirachid89@gmail.com

Introduction: The pilonidal sinus is a dermal-epidermal recess with hair elements that leads to suppuration of the gluteal groove, with no natural tendency for spontaneous healing. Numerous surgical techniques have been developed, but to date, there is no consensual management. The aim of our study is to demonstrate the efficacy of open resection in the surgical treatment of pilonidal sinus.

Aims & Methods: A retrospective study was conducted in our proctology department, spanning a 6-year period from January 2016 to July 2022. We included 237 patients with pilonidal sinus operated by open excision. All patients were followed up with regular consultations every 15 days for 3 months and then once a month for 6 months, for a period of 2 years in order to monitor healing and look for complications or recurrences. Healing was defined as complete healing of the surgical site. Statistical analysis was performed using SPSS25 software. Quantitative variables were described as mean and standard deviation and qualitative variables were described as numbers and percentage.

Results: The mean age was 24 years (16-51 years). The sex ratio was 8.9 (24F, 213H). In all our patients, we performed a wide and meticulous shaving of the upper gluteal region and the intergluteal fold preoperatively. The surgical procedure consisted of a monobloc excision taking all the fistulous orifices and extending to the retro-coccygeal aponeurosis. The incision was parabolic upwards opposite the sacrum. After controlling hemostasis, we coagulated the edges of the wound in order to promote budding from the depth to the surface and thus allow directed healing, which would avoid the persistence of deep cavities, which would be a source of infection. Finally, we placed a wick in the surgical site and closed with a pressure dressing. The first dressing was changed 24 hours after the

procedure and every other day for 6 weeks. We then recommended that the patients continue their care (daily cleaning with an antiseptic solution, careful drying and weekly shaving of the areas surrounding the surgical site) without covering the wound. In our series, the postoperative morbidity, evaluated at 11.8%, included 21 cases of superinfection of the surgical site (12%) and 7 patients (2.9%) presented a hemorrhage requiring a hemostatic procedure. 95.8% (n=227) of the patients obtained a complete healing. The average healing time was 79 days with extremes between 6 weeks and 12 weeks. The final scar was linear, median and aesthetic. 4.2% of patients (n=10) had a recurrence. They underwent open excision again. Of these patients, 4 had a recurrence and were operated on a 3rd time successfully.

Conclusion: According to the results of our study, open excision is a safe and effective surgical technique for pilonidal sinuses, despite a long healing time.

Disclosure: Nothing to disclose.

NOVEL SURGERY FOR REFRACTORY MIXED CONSTIPATION: ANALYSIS OF THE TECHNICAL NOTES AND OUTCOME TO TONGJI PROCEDURE

H. Tian[1], Q. Chen[2], H. Qin[2]

[1]Tenth People's Hospital of Tongji University, Department of Colorectal Disease, Shanghai, China, [2]Tenth People's Hospital of Tongji University, Department of Colorectal Disease, Shanghai, China

Contact E-Mail Address: kevin_thl@163.com

Introduction: To discuss a new surgical strategy: Tongji procedure (subtotal colectomy combined with modified Duhamel procedure), of which the indications, technical notes and outcomes were analyzed.

Aims & Methods:

The 220 patients with refractory slow-transit constipation associated with outlet obstruction was strictly included between February 2019 and February 2023. The patients induded 60 males and 160 females. Their age were 18-80 years (average 46±14). The 198 patients received laparoscopic-assistant Jinling procedure, and 32 patients with open Jinling procedure. The pre- and post-operation data were collected. The follow up rate were 100%, 95.1%, 92.8% and 91.7% at 3, 6, 12 and 24 months.

Results: There was no surgery-related death. Mean hospital day was (8±1.5) days. Most complications were managed conservatively without significant events. The common complications after surgery were adhesive intestinal obstruction (3.2%), anastomosis bleeding (5.1%) and anastomosis leakage (3.9%). The gastrointestinal quality of life index score was 72±9 preoperatively and increased to 68±11, 99±6, 105±9, 106±9 at 3, 6, 12 and 24 month follow-up, respectively (t=62.1, -25.1, -126.5, -143.2, P<0.01). The Wexner constipation scale was 21.9±4.5 preoperatively and decreased to 9.6±2.4, 5.9±2.1, 4.6±1.9, 4.5±1.8 at 3, 6, 12 and 24 month follow-up, respectively (t=48.6, 61.8, 58.2, 45.9, P<0.01). The satisfactory rate was 77.5%, 92.1%, 93.0% and 94.1% at 3, 6, 12, and 24 month follow-up.

Conclusion: Tongji procedure provides a good surgical option for refractory slow-transit constipation associated with outlet obstruction.

LASER THERAPY IN PROCTOLOGY: PRELIMINARY RESULTS OF A A PROSPECTIVE BICENTRIC MOROCCAN STUDY

H. Delsa[1], Z. Saad[1], A. Nadi[1], N. Morsad[1], K. Jemal[1], N. Benjelloun[1], F. Belabbes[1], W. Khannoussi[1], I. Ben El Barhdadi[1], M.E.H. Tahiri[2]

[1]Cheikh Khalifa International University Hospital, Mohammed VI University of Sciences and Health, Gastroenterology and Hepatology Unit, Casablanca, Morocco, [2]Cheikh Khalifa International University Hospital, Mohammed VI University of Sciences and Health, Proctology Unit, Casablanca, Morocco

Contact E-Mail Address: delsa.hanane@gmail.com

Introduction: Laser therapy is a relatively recent technique that allows the treatment of anal fistulas (FIstula-tract LAser Closure: FilaC®), and anal fissure (Laser anal fissure: LSL) with the FilaC fibre, pilonidal sinuses with the SiLaC® fibre (Sinus Pilonidalis treatment), and haemorrhoids with the Laser Hemorrhoido Plasty fibre (LHP®).

Aims & Methods: Our study aims to report the preliminary results of a prospective bicentric study including all patients treated with laser therapy in two private hospitals.

This prospective descriptive study includes 141 patients treated with laser therapy for proctological pathology (anal fistulas, pilonidal sinuses, anal fissures, and hemorrhoids) performed in two proctology units. The majority of these procedures were performed under spinal anesthesia.

Data were collected directly from the patients using an evaluation form. We studied their clinical data and the immediate and medium-term postoperative follow-up

Results: 141 patients were included. The mean age was 44 years (18-76 years). 78% were male and 22% female (sex ratio = 3.5). The anal fistula was the main indication for laser therapy, with FilaC® performed in 105 patients (74.5%), followed by SiLaC® in 16 patients (11.3%), LHP® in 7 patients (5%) and 4 cases of LSL (2.8%).

9 patients benefited from combined treatment: 5 LHP®+ LSL patients (3.5%), 2 FilaC®+ LSL patients (1.4%), 1 FilaC®+ SiLaC® patient (0.7%), and 1 FilaC®+ LHP® case (0.7%). 79 patients (73.2%) benefited from initial drainage of the fistula with a loose seton for 1 to 5 months before FilaC®, while 29 patients (26.8%) with a short direct extrasphincteric fistula benefited from laser therapy. 18 patients were lost to follow-up (12,8%). 104 patients (84,5%), all pathologies combined, progressed well with 19 cases of failure (15,5%) with a follow-up time of 1 to 50 months.

Fistulas healed in 74 patients (80%). There were 18 confirmed failures. 15 of these were treated surgically with 4 FilaC. Failure was diagnosed within an average of 6 months and was manifested by persistent leakage with no healing of the external orifice.

There were no continence problems after the procedure. 16 patients were lost to follow-up. In patients with LHP, 2 patients (15,4%) experienced early post-operative bleeding requiring surgical suturing. All patients treated with SiLaC® had a favorable outcome. The 4 patients treated for anal fissures were satisfied with the procedure.

Conclusion: Laser proctology is a minimally invasive conservative procedure with significant postoperative pain reduction. In the literature, the success rate of this technique ranges from 65 to 80%. Our hospitals were the first in Morocco to introduce this procedure. Preliminary results from our pilot study showed satisfying healing in 84.5% of patients. However, long-term confirmation is required.

ENHANCED SURGICAL PERFORMANCE OF LAPAROSCOPIC COLORECTAL SURGERY USING ARTICULATED INSTRUMENTS (ARTISENTIAL®) AS COMPARED TO THAT USING CONVENTIONAL DEVICES: SINGLE INSTITUTION, OPEN, BEFORE-AND-AFTER PROSPECTIVE STUDY

H.R. Shin[1], H.-K. Oh[1], J. Lee[1,2], H.-M. Ahn[1], T.-G. Lee[1], M.-J. Choi[1], D.-W. Kim[1], S.-B. Kang[1]

Contact E-Mail Address: smallwheel91@gmail.com

Introduction: Rigid surgical instruments used for conventional laparoscopic surgery provide limited movement, and it is difficult to perform skillful surgery due to their long, jointless straight features. Articulated instruments could have the same advantages seen in robotic surgery, such as excellent control in smaller spaces, restoration of more intuitive and ergonomic movements, and the ability to overcome obstacles on a direct visual line.

The aim of this study was to evaluate the surgical performance and clinical outcomes of patients following laparoscopic colorectal surgery with multijoint laparoscopic instruments, ArtiSential® (LivsMed, Seongnam, Korea), compared with those using conventional instruments.

Aims & Methods: Patients aged 19–80 years undergoing elective laparoscopic surgery for colorectal disease between December 2021 and November 2022, were consecutively enrolled. The first 20 cases underwent conventional laparoscopic surgery, and the latter 50 cases underwent laparoscopic surgery using ArtiSential®.

Unedited operative videos were submitted to the Crowd-Sourced Assessment of Technical Skills (C-SATS) platform for evaluation using the Global Operative Assessment of Laparoscopic Skills (GOALS), which is a validated tool for technical proficiency.

Each of GOALS' four domains (bimanual dexterity, depth perception, efficiency, and tissue handling) was scored on a Likert scale between 1 and 5, scoring anchor, with a total score ranging from 4 to 20. The learning curve analysis was performed using the cumulative sum control chart (CUSUM) for GOALS grades (Registration number: KCT0006798).

Results: There was no significant difference between group with regards to type of operation, hospital stay, and 30-day postoperative complication. The GOALS' grades were similar between the two groups (15.7 ± 0.7 vs. 15.9 ± 0.5, P = 0.190), but the scores in two domains (depth perception and tissue handling) were significantly higher in the ArtiSential® group (3.9 ± 0.3 vs. 4.0 ± 0.2, P = 0.014 and 3.9 ± 0.2 vs. 4.1 ± 0.2, P = 0.048, respectively) compared with those in the conventional group.

In addition, patients in the ArtiSential® group experienced a shorter operation time (122.3 ± 58.9 vs. 88.1 ± 35.1, P = 0.022) and less intraoperative blood loss (56.5 ± 69.9 vs. 29.8 ± 1.4, P = 0.002) than those in the conventional group. According to the CUSUM learning curve analysis, the first 10 cases using ArtiSential® were in the inexperienced phase, and the remaining 40 cases were in the experienced phase.

The GOALS' score in the experienced phase of ArtiSential® was improved compared with that in the conventional group (16.0 ± 0.5 vs. 15.7 ± 0.7, P = 0.037).

Conclusion: A plateau in the learning curve of laparoscopic colorectal surgery performed with an articulated instrument was observed in approximately 10 cases, and it can be expected that surgical proficiency in the experienced phase increases without deterioration of clinical outcome as compared to that in conventional surgery.

Introduction: Colorectal malignancy ranks third in global cancer incidence, with 1.9 million cases and nearly 1 million deaths reported in 2020. Total mesorectal excision (TME) is the gold-standard treatment for rectal cancer. Our meta-analysis evaluated surgical and functional outcomes of various anastomoses types, comparing end-to-end (EEA) to either side-to-end (SEA) or colonic J pouch (CJP).

Aims & Methods: Our protocol was registered on PROSPERO (CRD42022368907) beforehand. The systematic search was conducted on the 8th of November, 2022 in three major databases (Pubmed, Embase and CENTRAL). Randomized controlled trials (RCT) assessing adult patients following TME, where EEA was compared to another type of anastomosis were included.

For data synthesis a random-effects model was used. In the case of categorical outcomes such as anastomotic leakage (AL) and mortality, the effect size was risk ratio (RR) with a 95% confidence interval (CI), whereas in the case of bowel movement mean difference (MD) with a 95% CI was used. The Risk of bias was evaluated using the Revised Cochrane risk-of-bias tool for randomized trials (ROB-2). The certainty of evidence level of the included studies was performed using GRADE-Pro.

Results: Following a careful search and selection process, 29 studies out of 4459 were included in our analysis. Comparing EEA to CJP, in terms of early (30 days) morbidity, we have found no difference in either AL (RR: 1.03; CI: 0.84;1.26) or mortality (RR: 0.77; CI: 0.30; 1.98). The functional outcome of patients was evaluated, and daily bowel movement was assessed at two-time points. At 6 months postoperatively, the EEA group had a slightly higher number of stools per day (MD: 1.89; CI: 0.39; 3.39), however at one year the MD dropped down to 1.59 (CI: -0.66; 3.84), reaching a statistically non-significant result. Because of limited data, only AL was assessed for the comparison with SEA, where no difference was found (RR: 1.19; CI= 0.60; 2.35). Twelve RCTs showed a high risk of bias due to unblinded surgeons, intervention deviations, and loss of follow-up data. According to the GRADE approach, the quality of evidence was moderate (AL, mortality) to low (bowel movement) because of the high risk of bias and imprecision.

Conclusion: In terms of early postoperative morbidity, EEA is not inferior to other types of reconstruction techniques. Regarding bowel movement, the slightly impaired intestinal function will resolve within one year following surgery. EEA should be used routinely following TME.
Disclosure: Nothing to disclose.

THE EFFECT OF DIABETES MELLITUS ON OUTCOMES FOLLOWING RESECTIONAL COLORECTAL SURGERY

S. Gysling[1,2], C. Lewis-Lloyd[3], D.N. Lobo[1,2], C. Crooks[1,2], D. Humes[1,2]
[1]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom, [2]University of Nottingham, Nottingham, United Kingdom, [3]University Hospitals of Derby and Burton Foundation Trust, Derby, United Kingdom

Contact E-Mail Address: s.gysling@nhs.net
Introduction: Diabetes mellitus affects 6-7% of the population in the United Kingdom (UK), with a consistently increasing prevalence over the last 15 years. The impact of diabetes on outcomes after resectional colorectal surgery have yet to be fully quantified. We aimed to investigate the effect of diabetes mellitus on perioperative outcomes following resectional colorectal surgery using a national cohort.
Aims & Methods: All adult patients undergoing colorectal resections in England registered in the Clinical Practice Research Database (CPRD) with linked Hospital Episode Statistics (HES) data between 2010 and 2020 were included. Data relating to diabetes status and insulin use were extracted using CPRD read codes. Gestational diabetes and type 3c diabetes subtypes were excluded. The primary outcome was all-cause 90-day mortality, whilst secondary outcomes included hospital length of stay and unplanned hospital readmission within 90 days of discharge.
Adjusted hazard ratios (HR) were calculated using Cox proportional hazard models for 90-day mortality and 90-day readmission. Length of stay was analysed using an accelerate failure time model, with results presented in the form of adjusted time ratios (TR).
The hazard and time ratios resulting from these multivariate models were adjusted for patient age, sex, deprivation, comorbidity burden (excluding diabetes), operative urgency (elective *versus* emergency), operative indication (benign *versus* malignant disease) and surgical access (open *versus* minimally-invasive). P values of <0.05 were considered statistically significant. All data were analysed using STATA v17.
Results: 106139 (50% male) patients with a median age of 66 years (Interquartile Range (IQR) 52 to 76) were included. The prevalence of diabetes in this cohort was 10% (n = 10931), including 653 (6%) patients with Type 1 and 10278 (94%) with Type 2 diabetes. 20% of all patients with diabetes had a record of insulin use.
The overall unadjusted 90-day mortality risk was 5.7%, with an increased hazard rate for patients with diabetes compared with those without diabetes (adjusted HR 1.28, 95% CI 1.18 to 1.40, p < 0.001).
This risk was higher in patients with diabetes with associated insulin use (adjusted HR 1.49, 95% CI 1.23 to 1.78, p < 0.001), and without insulin use (adjusted HR 1.24, 95% CI 1.23 to 1.36, p < 0.001), compared to patients without diabetes. The median length of stay was 8 days (IQR 5 to 15) for the overall cohort. Patients with diabetes experienced a 10% longer hospital length of stay (adjusted TR 1.10, 95% CI 1.08 to 1.11, p < 0.001) compared with those without diabetes. Emergency readmission within 90 days occurred in 23% of those operated for benign disease, *versus* 18% of patients operated for malignant disease. Patients with diabetes were more likely to experience 90-day readmission (adjusted HR 1.22, 95% CI 1.16 to 1.28, p < 0.001) compared with those without diabetes.
Conclusion: Patients with diabetes undergoing resectional colorectal surgery are at a higher risk of 90-day mortality, prolonged length of stay and 90-day readmissions.
Awareness of these increased risks should be considered during perioperative optimisation of the patient, as well as in consent discussions and the patient selection processes.

LONG-TERM EFFICACY OF TRANSANAL DOPPLER-GUIDED HEMORRHOIDAL ARTERY LIGATION WITH MUCOPEXY (HAL-RAR) IN HEMORRHOIDAL DISEASE

J. Benass[1], H. Laraqui[1], M.T. Tajdine[1]
[1]Mohammed V University, Rabat, Morocco

Contact E-Mail Address: jihane.benass@gmail.com
Introduction: Doppler-guided artery ligation with Mucopexy, or HAL-RAR, is a minimally invasive surgical technique that allows for better postoperative comfort. An anoscope linked with a light source and a doppler probe allows the proctologist to locate the submucosal branches of the superior rectal artery and to ligate them via a transfixing parietal approach.
Mucosal pexis is performed afterward : the mucosa of the prolapsed hemorrhoidal pedicles is vertically sutured, consequently leading to a plication of the prolapsed muco-hemorrhoidal tissue and its reposition inside the canal anal.
Nevertheless, long-term recurrence rate of internal hemorrhoidal disease after this procedure has been poorly studied.
Aims & Methods: The aim of our study is to evaluate the long-term recurrence rate of hemorrhoidal disease post Doppler-guided artery ligation (HAL-RAR) with Mucopexy in our center.
An ambispective observational and analytical study was conducted over a 5-year period, from January 2017 to January 2022. Surgical indications included grade II and III internal hemorrhoids that resisted to medical treatment and small localized non-circumferential grade IV hemorrhoids. Patients with external hemorrhoids, bulky grade IV hemorrhoids or pelvic floor disorders were excluded.
All data were analyzed using Jamovi version 2.0.0.0 software. Patient characteristics were described as number and percentage for qualitative items and median (interquartile range [IQR]) or mean (± standard deviation) for quantitative ones. A *p* value of ≤0.05 was deemed to be significant.
Our primary objective was to evaluate the rate of recurrence more than 24 months after surgery. The secondary objectives were to determine the clinical features of relapsing patients.
Results: 114 patients were included in this study. The mean age was 46.5 ± 9.6 years. The sex ratio was 6 (16f, 98H). Preoperatively, 69% (n=79) of the patients reported proctalgia, 53% (n=60) post-defecation rectal pain and 58% (n=66) prolapse. We staged the internal hemorrhoidal disease according to Goligher's classification, identifying 32 with grade II hemorrhoids, 61 with grade III hemorrhoids and 21 grade IV hemorrhoids.
At the end of a median follow-up of 4 years (7-2), 9 patients (7.9%) presented a recurrence, made in 6 cases of a muco-hemorrhoidal prolapse and in 3 cases of post-defecation rectal bleeding. None of our patients presented with anal stenosis or incontinence during the follow-up period. In our study, there was no statistically significant relationship between the recurrence and the preoperative clinical symptomatology (p=0.21) nor with grade of hemorrhoids (p=0.17).
Overall, 94% of the patients included were satisfied with this technique. 4 of the patients who relapsed benefited from Milligan-Morgan hemorrhoidectomy. However, they claimed that they were more satisfied following the HAL-RAR procedure.

Conclusion: Transanal doppler-guided hemorrhoidal artery ligation with mucopexy (HAL-RAR) is easy to perform and is a safe minimally-invasive technique. It can be considered an effective long-term treatment for internal hemorrhoidal disease.

PP1245

ROLE OF PREOPERATIVE CT RECONSTRUCTION IN RIGHT COLECTOMY WITH COMPLETE MESOCOLIC EXCISION FOR RIGHT COLONIC CANCERS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M.I. Hussain[1], M.A. Chaouch[2], J. Khan[1]
[1]Portsmouth Hospitals University NHS Trust, General Surgery, Portsmouth, United Kingdom, [2]University Hospital of Fattouma Bourguiba, Department of Visceral Surgery, Monastir, Tunisia

Contact E-Mail Address: mihussain@nhs.net
Introduction: Complete mesocolic excision (CME) is a well-established procedure to treat right colonic cancers. Laparoscopic surgery improved post-operative outcomes but it has its own limitations such as lack of tactile feedback, ergonomically challenging, and a 2-dimensional view of the operative field. In addition to these features the complex and variable anatomy of the superior mesenteric artery and veins and its branches make laparoscopic right hemicolectomy with CME a challenging procedure often resulting in catastrophe.
Aims & Methods: Compare perioperative outcomes such as intraoperative blood loss, operative time, anastomotic leak, hospital stay, and harvested lymph nodes between right hemicolectomy and CME with and without preoperative CT reconstruction.
A systematic search of multiple electronic databases was conducted. A systematic review and meta-analysis were conducted according to the PRISMA guidelines 2020 (1) and AMSTAR 2 guidelines (2). Population: Adults of either sex that underwent right colectomy with CME. Intervention group: Patients that underwent right-sided colectomy with CME with preoperative CT reconstruction. Control group: Patients that underwent right-sided colectomy with CME without preoperative CT reconstruction. Outcomes: The different outcomes of this study were overall morbidity, intraoperative complications, anastomotic leak, blood loss, operative time, hospital stay, and harvested lymph nodes. Morbidity was considered when they occurred within 30 days after surgery. Study Selection: Two authors independently reviewed all abstracts of the studies that met the inclusion criteria. Disagreements were resolved through discussion after consulting with a third review team member.
Results: 4 studies published between 2013 and 2023 were included in the metanalysis (3-5). There were two RCTs, one prospective non-randomized trial, and one retrospective study. They included 420 patients, 203 in the preoperative navigation group and 217 in the no navigation group. The sex ratio of the included patient was 1.2 with male predominance. The mean age ranged between 64.3 to 71.7 years in the preoperative navigation group and from 58.9 to 71.6 years in the no preoperative navigation group. The mean BMI ranged from 26.3 kg/m² to 29.8 kg/m² in the two groups. All the included patients were operated using the laparoscopic approach. There was significantly lower blood loss in the preoperative CT reconstruction group compared to the non-CT reconstruction group (SMD= -1.75; 95% CI [-2.94, -0.56], p = 0.004). Operative time was shorter in the preoperative CT reconstruction group (SMD= -0.90; 95% CI [-1.10, -0.70], p < 0.00001). There was a higher number of the harvested lymph node in the preoperative CT reconstruction group (SMD = 0.33; 95% CI [0.14, 0.53], p=0.0007). There was no significant difference between the two groups in terms of hospital stay, anastomotic leak, intraoperative complication and overall morbidity.
Conclusion: This systematic review and meta-analysis concluded that the preoperative CT reconstruction group is associated with lower intraoperative blood loss, shorter operative time, and a higher number of harvested lymph nodes in comparison to the non-CT reconstruction group. This study did not find any difference between the two groups in terms of morbidity, intraoperative complications, anastomotic leak, and hospital stay. Future high-quality studies need to be undertaken to corroborate these findings and better understand the role of preoperative CT reconstruction in right hemicolectomy with CME for right colonic cancers.

LAPAROSCOPIC VERSUS OPEN ADHESIOLYSIS IN ADHESIVE SMALL BOWEL OBSTRUCTION: A META-ANALYSIS OF MATCHED OBSERVATIONAL STUDIES AND RANDOMIZED TRIALS

A.C. Quiroga Centeno[1], D. Chaparro-Zaraza[1], P.F. Pinilla-Merchán[2], K. Hoyos-Rizo[1], S. Padilla[2], M.C. Pinilla-Chávez[1], L. Chaparro-Zaraza[1], J.P. Serrano-Pastrana[1], S.A. Gómez Ochoa[1]
[1]Universidad Industrial de Santander, Surgery, Bucaramanga, Colombia, [2]Universidad Autónoma de Bucaramanga, Bucaramanga, Colombia

Contact E-Mail Address: caroline_aqc@hotmail.com
Introduction: Adhesive small bowel obstruction (ASBO) constitutes one of the most common causes of emergency room admissions worldwide. Although open adhesiolysis (OA) has long been the most widely adopted surgical approach, laparoscopic adhesiolysis (LA) is gaining momentum. However, current evidence remains controversial, as most of the studies suffer from a high risk of bias. This study aims to elucidate the comparative clinical outcomes and safety profiles of LA and OA in ASBO.
Aims & Methods:
A systematic search of Medline, Embase, CINAHL, Cochrane Central Register of Controlled Trials, and Scielo databases was performed to identify eligible studies that compared LA and OA for ASBO published up until March 2023. Only randomized controlled trials (RCTs) and matched observational studies were included. The primary outcomes encompassed duration of surgery, postoperative complications, mortality, and postoperative hospital stay. We used random-effects models for data pooling. Heterogeneity amidst studies was evaluated via the I2 statistic.

Results: From 1955 articles screened, six studies evaluating a total of 1053 patients (mean age: 65 years; 67% females) fulfilled the selection criteria and were included. From these patients, 39% had an ASA classification ≥3 (95% CI 23%-57%. I2: 96%), 21% had two or more previous abdominal surgeries (95% CI 6%-42%. I2: 94%), 8% had evidence of irreversible bowel ischemia detected at surgery (95% CI 5%-12%. I2: 31%) and 48% (n=507) underwent laparoscopic lysis of adhesions.

No significant differences regarding surgery duration (MD -5.52; 95% CI -15.98, 4.94. I2: 50%), iatrogenic bowel injury (OR 1.20; 95% CI 0.56, 2.55. I2: 0%), mortality (OR 1.30; 95% CI 0.46, 3.68. I2:0%), and the development of any postoperative complication (OR 2.61; 95% CI 0.19, 36.34. I2: 91.7%) were observed. However, LA was associated with a reduced postoperative stay compared to the open approach (MD -2.40; 95% CI -3.26, -1.54. I2: 12%).

Figure. Forest plot of postoperative hospital stay (days)

Conclusion: Although OA remains the standard procedure for the treatment of ASBO, LA appears to be a feasible approach to treat this condition in selected populations, with comparable results in terms of postoperative complications and mortality, while being associated with a significantly reduced postoperative length of stay. Additional RCTs with robust methodology should be performed in order to confirm these findings.

Disclosure: The authors have nothing to disclose.

THE DUMPLING TECHNIQUE: A NEW METHOD FOR INJECTING FIBRIN GLUE INTO A POCKET CREATED BY ENDOSCOPIC SUTURE TO PREVENT DELAYED BLEEDING FROM POST-ESD ULCERS

Y. Takegawa[1], T. Takao[2], H. Sakaguchi[2]
[1]KM Biologics Co., Ltd., Kumamoto, Japan, [2]Kobe University, Internal Medicine, Kobe, Japan

Contact E-Mail Address: yoshitaka.takegawa@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is a common treatment for early-stage gastrointestinal cancers, but managing delayed bleeding from post-ESD ulcers can be challenging. With more patients taking antithrombotic drugs, reliable bleeding prevention methods are crucial. This study presents the Dumpling technique, a new solution for preventing delayed bleeding from these ulcers.

Aims & Methods: Dumpling technique: The technique involves using a double-lumen catheter to inject fibrin glue into the pocket created after suturing an artificial ulcer post-ESD. This technique not only covers the ulcer but also provides a tamponade effect through compression. The fibrin glue is encased by the sutured mucosa, giving it the appearance of a dumpling. An important point of this technique is the use of a double-lumen catheter for fibrin glue injection. Fibrin glue consists of a fibrinogen solution and thrombin solution. Single-lumen catheters cannot be used because the two solutions begin to form a gel in just a few seconds when mixed. One advantage of this technique is that it combines existing products, so no new product development time is required.

An artificial ulcer was created in the resected bovine rectum by ESD flow, fixed to a jig, and a defect of 2.7 mm in diameter was created using an Aorta/Vein Punch. Pig blood that had lost coagulability was then injected to create a hemorrhage model. First, pressure resistance was measured after clip sutures only. Next, the same ulcer was used as is, the blood was washed out, fibrin glue was injected, and pressure resistance was measured again and compared between the two groups (Clip suture group vs Dumpling technique group). In addition, to confirm the feasibility of the technique, the Dumpling technique was performed endoscopically on porcine explanted stomach and bovine explanted rectum, and the excised specimens were evaluated.

Results: The mean ± SD pressure resistance in the bleeding model was 40.2 ± 14.0 mmHg in the clip suture group and 134.5 ± 36.8 mmHg in the Dumpling technique group (N = 5). Feasibility checks confirmed that suture spacing could be performed endoscopically without problems by setting the suture spacing to allow catheter tip insertion. The resection specimen was confirmed to be sufficiently filled with fibrin glue in the pocket.

Conclusion: This study suggests that the Dumpling technique improves the bleeding prevention effect of ulcer closure. Although various methods of ulcer suturing are still being developed, the injection of fibrin glue itself is expected to be adoptable by many clinicians because it does not require high skill if the tip of the catheter can be inserted through the gap between the sutures. We plan to confirm the feasibility of the Dumpling method in an in vivo study using pigs, followed by a clinical trial to confirm the effectiveness of the Dumpling technique.

Disclosure: Mr. Takegawa is employees of KM Biologics Co., Ltd. and the fibrin glue (BOLHEAL®) used in this article is manufactured by KM Biologics Co., Ltd.

Introduction: Colorectal carcinoma (CRC) is one of the most important indications for colorectal surgery despite the availability of screening measures. Anastomotic leakage is among the most common potentially life-threatening complications. Increasing evidence suggests a causal role of the gut microbiota in the pathogenesis of anastomotic leakage.

Aims & Methods: The aim of the study was to evaluate the dynamics of microbiome changes in patients with colorectal carcinoma before, during and after surgical intervention in relation to anastomotic insufficiency. From a total of 18 patients recruited, the records of 16 patients were systematically analysed according to inclusion/exclusion criteria and sequencing quality. Biopsies were taken from the 3 sites (proximal to the tumour, tumour region, distal to the tumour) before, during and after surgery. All patients received preoperative Metronidazole and Paromomycin for intraluminal bowel decontamination and a single intravenous dose of Ertapenem during surgery. DNA extraction was followed by amplification of the V1-V2 region of the 16S rRNA gene and Illumina sequencing.

Results: *Phocaeicola*, *Prevotella* and *Enterococcus* were the most abundant of the 259 different genera found in the cohort. Hierarchical clustering showed that samples from the same patient at the same time point generally had high similarity (66%), and in 6 cases all samples from more than one time point formed a cluster. These results were corroborated by comparing the Bray-Curtis similarity of sample sites and time points. Periinterventional procedures were associated with a significant decrease in diversity in samples collected during or after surgery.

Samples with anastomotic leakage had a different microbial structure at all time points, with Prevotella being more abundant in the anastomotic leakage group (p<0.0001), whereas *Phocaeicola* was more abundant in the sufficient anastomosis group (p=0.04). Systematic longitudinal analysis revealed an increasing abundance of bacterial species, particularly *Enterococcus* and *Escherichia/Shigella*, at subsequent sampling times.

Conclusion: The mucosal microbiota is substantially altered by colorectal surgery, and the microbiome of patients with anastomotic leakage differs from that of patients with sufficient anastomoses.

Further studies are needed to unravel the molecular and functional interactions between the microbiota and mucosal tissue.

AN EXTREMELY SIMPLE EDUCATIONAL METHOD OF LEARNING HOW TO PROPERLY CONTRACT THE PELVIC FLOOR MUSCLES USING A BALLOON TO TREAT PELVIC FLOOR WEAKNESS

M. Kozelj[1]

[1]University Medical Centre Ljubljana, Department of Gastroenterology, Ljubljana, Slovenia

Contact E-Mail Address: matjaz.kozelj54@gmail.com

Introduction: Fecal incontinence is a symptom characterized by the involuntary excretion of liquid or formed stool, so it impairs the quality of life. It is most often the result of weakened muscles of the pelvic floor, which were exposed to heavy loads and injuries during life.

The muscles of the pelvic floor provide support to the pelvic organs and play an important role in the retention and excretion of stool and urine, and the quality of sexuality. We can strengthen them with exercises, thus preventing or mitigating disorders of stool and urine retention.

Aims & Methods: Aim: Present a simple method of learning how to properly contract the pelvic floor muscles with a balloon.

Methods: A simple device, consisting of a balloon, a plastic tube, a bow-tie, and a 100-milliliter syringe was used. The balloon was attached to the plastic tube with a thread. Patients were included in education about the anatomy and physiology of the pelvic floor and how to perform exercises.

The patients lay on their left side with their hips and knees bent. The balloon was folded and wrapped around the back of the plastic tube. This part was smeared with anesthetic ointment and introduced into the rectum up to 10 cm deep.

When introducing it, we took into account that the anal canal is directed diagonally forward towards the symphysis and the rectum back towards the sacrum. The angle between the anal canal and the rectum was approximately 90°. The balloon was filled with air up to 30 ml. The plastic tube was slowly pulled outwards in the opposite direction of the rectum. When feeling the resistance, the balloon was on the upper part of the pelvic floor, up the entrance to the anal canal. The plastic tube was carefully pulled further in the same direction, so the patient usually felt and became aware of the position of the pelvic floor. If the patient did not feel it, the procedure was repeated several times.

After successfully identifying the position of the pelvic floor muscles, the patient was instructed to raise the pelvic floor or contract the muscles. With a properly isolated contraction of the pelvic floor muscles, the balloon pulled the plastic tube behind it. This was how the force of muscle contraction was evaluated.

Results: 117 anorectal manometries were performed. 69 (59.0%) patients had an indication of incontinence. Before the investigation, 14 (20.3%) patients performed Kegel exercises correctly. The other 55 (79.7%) patients performed Kegel exercises incorrectly. An educational school on how to use the pelvic floor muscles was introduced to these patients; 37 (67.3%) patients performed exercises correctly. The rest 18 were once again referred to education. 13 patients applied to the school, 8 were taught how to perform Kegel exercises correctly, and 5 patients failed. Out of total 55 patients who initially did not perform Kegel exercises correctly, 45 patients were educated on how to contract the pelvic floor muscles correctly leading to a success rate of 81.8%.

Conclusion: The balloon learning method helped the patient identify the position of the pelvic floor and contract the pelvic floor muscles in isolation. Learning how to properly contract the muscles of the pelvic floor with a balloon is a simple and effective method that requires recognition of the physiology of the pelvic floor and a lot of patience on the part of the doctor or healthcare worker.

After successfully completing education, the success of pelvic floor reconstruction depended primarily on the patient and his commitment to regular exercise.

Disclosure: No conflict of interests.

A NOVEL PHYSIOLOGICAL ANALYSIS USING BLOOD FLOW VELOCITY MAY HAVE THE POTENTIAL TO DISTINGUISH COLONIC POLYPS: A PILOT STUDY

E. Kamba[1], T. Murakami[1], N. Tsugawa[2], Y. Akazawa[3], H. Ueyama[1], T. Shibuya[1], T. Yao[4], A. Nagahara[3]

Introduction: Magnifying endoscopy (ME) enables clear visualization of microvascular (MV) architecture and microsurface structure [1] [2] and allows real-time visualization of red blood cell flow within subepithelial microvessels. Mean MV blood flow velocity is significantly lower in early gastric cancer than in non-neoplastic lesions [3].

However, MV blood flow velocity in the colorectum has not been investigated and it is unclear whether it is useful for the qualitative diagnosis of colorectal polyps in clinical practice.

Aims & Methods: We aimed to calculate the blood flow velocity in colorectal polyps and the surrounding mucosa, and evaluate its usefulness for the differential diagnosis of colorectal polyps. We retrospectively reviewed videos of colorectal polyps that were endoscopically resected at our hospital between March 2019 and January 2023. All procedures were carried out with a high-resolution optical magnifying endoscope (EC-L600ZP7; Fujifilm Corporation, Tokyo, Japan) and endoscope video system (LASEREO; Fujifilm Corporation). The blood flow velocities of each lesion and surrounding mucosa were carefully evaluated using magnifying blue laser imaging (M-BLI) prior to endoscopic resection. All M-BLI video images were split into 30 fps, and mean blood flow velocities were calculated by the mean movement distance of one tagged red blood cell using split images of videos. We compared mean MV blood flow velocities between lesions and the surrounding mucosa.

Furthermore, we calculated the MV blood flow imaging ratio (inside lesion/surrounding mucosa) to avoid the influence of individual differences such as blood pressure.

Results: This study included 30 adenomas (ADs) from 20 patients and 20 hyperplastic polyps (HPs) from 13 patients. No significant differences in age or sex were found between lesion groups. The mean size for ADs and HPs were 4.8 ± 3.1 mm and 3.6 ± 1.8 mm, respectively. The macroscopic

type of ADs and HPs were 1 and 0 of 0-Isp, 20 and 13 of 0-Is, and 9 and 7 of 0-IIa, respectively. The mean MV blood flow velocity was significantly lower in ADs (1.65 ± 0.66 mm/sec; range 0.46–2.90) than HPs (2.83 ± 1.10 mm/sec; range 1.07–4.50) or the surrounding mucosa (4.12 ± 1.11 mm/sec; range 1.80–6.20; $p < 0.001$, respectively). The ratio of the blood flow velocity of lesions compared to the surrounding mucosa was significantly lower in ADs (0.41 ± 0.16; range 0.10–0.82) than HPs (0.89 ± 0.25; range 0.46 – 1.51; $p < 0.001$).

In summary, MV blood flow velocity was significantly lower in ADs than HPs and the surrounding non-neoplastic mucosa, suggesting blood flow in ADs may be congested. A lower subepithelial MV blood flow rate in ADs compared with non-neoplastic lesions may be due to a difference in caliber and tortuosity of microvessels.

	Adenomas				Hyperplastic polyps		
	Blood flow velocity (mm/sec)		(A) / (B)		Blood flow velocity (mm/sec)		(C) / (D)
	(A) Lesions	(B) The surrounding mucosa			(C) Lesions	(D) The surrounding mucosa	
mean ±SD	1.65±0.66	4.12±1.11	0.41±0.16	mean±SD	2.83±1.10	3.1 3±0.85	0.89±0.25
(range)	(0.46-2.90)	(1.80-6.20)	(0.1-0.82)	(range)	(1.07-4.50)	(2.30-5.07)	(0.46-1.51)

Conclusion: Our results suggest using MV blood flow velocity and ME as a novel dynamic diagnosis for the differential diagnosis of ADs and HPs. However, since this was a single-center retrospective study with a small sample size, further investigation is needed to validate our results and confirm their clinical usefulness.

Introduction: Hot snare polypectomy (HSP) has been commonly applied for 10-19 mm polyps. The incidence of delayed bleeding after HSP for 10-19 mm is reported to be 2.1-2.8% [1-2], which is not negligible and expected to be higher in cases with antithrombotic drug use. Blended or coagulation currents are commonly used for HSP, but the coagulation current causes thermal injury to the deeper submucosal layer including larger vessels, resulting in a risk for delayed bleeding [3].

Cold snare polypectomy (CSP) reduces the risk for delayed bleeding compared with HSP [4], but CSP for colorectal polyps 10-19 mm is unsatisfactory for its higher rates of incomplete resection, leading to a higher incidence of local recurrence [5].

We hypothesized that low-power pure cut current (LPPC) without coagulation current can decrease thermal injury and conducted a phase I study assessing the feasibility of LPPC HSP for 10-14 mm adenoma (UMIN Clinical Trials Registry; UMIN000037678). Although there was no delayed bleeding among 90 patients with 100 polyps, sample size was insufficient to assess the safety of LPPC HSP.

Aims & Methods: This study aimed to evaluate the safety of LPPC HSP for colorectal neoplasms. In this multicenter, retrospective, observational study, consecutive patients who underwent LPPC HSP for nonpedunculated colorectal neoplasms 10-14 mm at two Japanese institutions between December 2018 and March 2022 were evaluated. Data were collected from medical records and prospectively recorded databases of endoscopic and pathologic findings. LPPC HSP was performed using a 10-mm or 15-mm thin hexagonal snare with either of the following modes; PureCut, effect 1, 10W (ESG-300), Autocut, effect 1, 10 W (VIO300D), or Autocut, effect 0.4 (VIO3). We analyzed the treatment outcomes of LPPC HSP. We also compared the delayed bleeding rate of LPPC HSP with the historical control of HSP, which was set as 2.1% (55/2629) based on the previous meta-analysis [1], and calculated the power value using a one-sample proportion test.

Results: A total of 339 patients with 410 lesions sized 10-14 mm were identified. The en bloc and R0 resection rates were 94.9% and 86.7%, respectively. Immediate bleeding requiring hemostasis developed in 4 lesions (1.0%). No perforation developed. Delayed bleeding developed in two patients, both of them required hospital admissions but were conservatively managed without endoscopic hemostasis or blood transfusion. Delayed bleeding rate was 0.6% per patient (2/339). LPPC-HSP was associated with a 71.4% reduction in the risk of delayed bleeding compared to the historical control (2.1%), with a power of 80.4% using a 2-sided significance level of 0.1.

Age, years, median (interquartile range)	71 (67-77)
Male sex (%)	232 (68.4)
Lesion size, mm, median (interquartile range)	11 (10-12)
Location right colon/left colon/rectum (%)	235 (57.3) / 141 (34.4) / 34 (8.3)
Morphology 0-IIa/0-Is/0-Isp (%)	189 (46.1) / 133 (32.4) / 88 (21.5)
Antithrombotic agents (%)	55/339 (16.2)
En bloc resection (%)	389/410 (94.9)
R0 resection (%) *	352/406 (86.7)
Prophylactic clipping (%)	49/410 (14.5)
Delayed bleeding (%)	2/339 (0.6)

* four lesions were excluded for no information on margin status

Table. Baseline characteristics and treatment outcomes of low-power pure cut hot snare polypectomy.

Conclusion: Delayed bleeding rate of LPPC HSP for nonpedunculated colorectal neoplasms 10-14 mm was 0.6%, which may be lower than conventional HSP. A large prospective study is warranted to assess the safety of LPPC HSP.

Introduction: Endoscopic closure of mucosal defects following colorectal endoscopic submucosal dissection (ESD) helps prevent delayed complications. The Sure Clip Traction Band, a recently developed traction device for endoscopic procedures, features a silicone ring attached to the clip's base, allowing for traction between clips.

We have developed a traction-band-assisted endoscopic closure (TBEC) method using the Sure Clip Traction Band [1]. In TBEC, tension between the clips at both ends of the mucosal defect narrows the defect, facilitating the placement of additional clips.

Aims & Methods: We conducted a prospective study to evaluate the feasibility of TBEC in colorectal ESD. Patients with 20-50mm colorectal neoplasms were enrolled. Patients underwent TBEC following the completion of ESD. The primary outcome was the complete closure rate. Secondary outcomes included closure time, number of devices required, and complication rate. The sample size was calculated to be 34 cases based on previous data.

Results: Thirty-four patients were enrolled across three institutions. Data are shown as median (IQR), if applicable. The median age was 75 years (72-80), with a male-to-female ratio of 19:15. Lesion locations were the right colon, left colon, and rectum in a ratio of 22:10:2, respectively. The median lesion diameter was 30 mm (25-35). All ESDs achieved en-bloc resection. The complete closure rate was 100% (34/34). The median closure time was 15 minutes (10-22). The number of devices used was one (1-2) traction band and eight (7-10) clips. Procedure-related complications included intraoperative perforation in 5.8% (2/34), delayed bleeding in 2.9% (1/34), and post-ESD electrocoagulation syndrome in 3.1% (1/32, excluding intraoperative perforation).

Conclusion: A high complete closure rate of mucosal defects following colorectal ESD was achieved using TBEC. Further studies are required to verify the efficacy of TBEC in preventing delayed complications.

ENDOSCOPIC SUBMUCOSAL DISSECTION OF COLORECTAL NEOPLASMS WITH MUSCLE RETRACTING SIGN – OUTCOMES, SAFETY AND CLINICAL IMPLICATIONS

A.R. Franco[1], I. Simao[1], R.R. Mendes[1], A. Mascarenhas[1], C. O'Neill[1], P. Barreiro[1], C. Chagas[1]
[1]Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal

Contact E-Mail Address: ana.rita.franco@campus.ul.pt

Introduction: During endoscopic submucosal dissection (ESD) of colorectal neoplasms, an interesting feature is occasionally detected in which the muscle layer under the tumour seems to be pulled upwards into the lesion in a triangle-shape. This feature is named muscle retracting sign (MR sign) and appears to indicate a potentially difficult ESD with high risk of incomplete and non-curative resection, although data about this subject is still scarce, without current studies in western countries.

The aim of this study was to evaluate whether or not MR sign is associated with worst outcomes.

Aims & Methods: A retrospective analysis, using a prospectively collected database from 2 western centres, including all patients who underwent ESD for colorectal neoplasms with positivity for MR sign from July 2017 to January 2023 was performed. The presence of MR sign was determined by the endoscopist during the procedure. The results were evaluated in terms of complete, en bloc, R0 and curative resection rates, complications and local recurrence.

Results: In a total of 411 lesions treated by ESD, 26 presented MR sign (6.3%, mean size 62,3mm, range 20-180mm): 9 colonic and 17 rectal, corresponding to 26 patients (male 61.5%, mean age 70 years): 9 in colon and 17 in rectum. Morphologically and according to Paris classification, 13 were 0-Is (50%), 10 LST-G-M (38.5%), 1 0-Isp, 1 LST-G-N and 1 LST-NG-F. Technical success was achieved in 24 lesions (24/26, 92.3%) with 2 procedures aborted due to the perception of high perforation risk, both located in the colon (2/9, 22%). In the rectum, there was the need to perform intramuscular dissection in 3 procedures to complete the resection (3/17, 17.6%). Among resected lesions, en bloc and R0 resection rates were 100% and 66.7% (16/24).

According to ESGE 2022 criteria, resection was considered curative in 66.7% (16/24), non-curative with high risk in 8.3% (2/24) and with local-risk recurrence in 25% (6/24). Intraprocedure complications were recorded in 2 resections (8%), both in the rectum and both perforations endoscopically managed. No recurrence was recorded in a mean follow-up time of 7 months (range 1-22 months).

Conclusion: This analysis show that MR sign is mostly present in large bulky protruding lesions and seems associated with a higher incomplete resection procedure rate in colon lesions but in rectum. Also, it seems associated with higher complication rate, namely perforations, and non-curative resection rates among resected lesions.

Therefore, in the colon, an anticipated switch for surgery in clinically fit patients should be considered in the presence of this sign or even before initiating ESD when lesion morphology suggests its presence. To the authors' best knowledge, this is the first study of the impact of the present of MRS in ESD in the West.

IMPACT OF FOUR-WEEK, DAILY CONSUMPTION OF GREEN KIWIFRUIT ON COLONIC TRANSIT AND FERMENTATION PROFILE IN ADULTS WITH CHRONIC CONSTIPATION

J. Maggo[1,2], S.B. Bayer[1,2], H.M. Ng[1,2], N.C. Roy[3,2], R.B. Gearry[1,2]
[1]University of Otago, Medicine, Christchurch, New Zealand, [2]New Zealand National Science Challenge—High-Value Nutrition, Liggins Institute, University of Auckland, Auckland, New Zealand, [3]University of Otago, Human Nutrition, Dunedin, New Zealand

Contact E-Mail Address: jasjot.maggo@postgrad.otago.ac.nz

Introduction: In patients with chronic constipation, slow colonic transit is hypothesised to be associated with altered colonic fermentation profiles. Green kiwifruit is known to have laxative effects. This could be caused by the modulation of colonic microbiota, which has a role in regulating colonic transit[1].

The wireless motility capsule measures gastrointestinal anatomical landmarks through changes in pH and temperature, while a novel gas-sensing capsule measures anatomical landmarks and colonic fermentation[2,3].

In this study, both technologies were used to investigate the effects of green kiwifruit on gastrointestinal transit and colonic fermentation profiles in participants with constipation.

Aims & Methods: Participants with chronic constipation (N = 62) were randomised to consume two green kiwifruit (*Actinidia deliciosa*, ~150g per serving, ~90 kcal) or

calorie-matched maltodextrin (~90 kcal = 25g) daily for four weeks. A subset of the participants (N = 21) consumed a standardised breakfast and ingested the wireless motility capsule or both wireless motility devices (wireless motility capsule and gas-sensing capsule) at baseline and post-intervention. Participants fasted six hours post-ingestion and wore data receivers until device excretion.

Results: Preliminary blinded results show that the wireless motility capsule measured colonic transit time decreased in participants on intervention A (median decrease = 1.4 hours, interquartile range (IQR) (-32.00, 9.12)) and increased on intervention B (median increase = 15.8 hours, IQR (-46.89, 23.48)), the change in colonic transit time was not significant (p = 0.628). There was no significant difference between the median colonic H_2 and CO_2 (% concentration/hour) at baseline and post-intervention (H_2: p = 0.50; CO_2: p =0.138). The difference between interventions was not significant for median colonic H_2 and CO_2 concentrations (H_2: p = 0.200; CO_2: p =0.800).

Conclusion: The wireless motility capsule and the gas-sensing capsule technologies assessed the differences in colonic transit time after dietary intervention. The gas-sensing capsule measured the colonic gas profile accurately and safely. The gas-sensing capsule has the potential to be used as a tool for measuring colonic fermentation profile. Despite encouraging results, this study had several limitations, including a small sample size, unusable data due to data loss, and transit time beyond the battery life of the capsules.

Further analyses will explore the relationship of colonic gas concentration with colonic transit time and faecal microbiota.

Introduction: Cold snare polypectomy (CSP) has been recommended as the preferred option for removing nonpedunculated colorectal polyps smaller than 10 mm owing to its high rate of complete resection and low incidence of adverse events[1-4].As one of the main steps during endoscopic mucosal resection, submucosal injection can elevate the lesion and separate it from the muscularis propria, allowing safe and fast resection of gastrointestinal lesions.

However, current guidelines do not address the application of submucosal injection during CSP for polyps smaller than 10 mm.The role of submucosal injection during cold snare polypectomy (CSP) remains uncertain.

Aims & Methods: In this study, we investigated the impact of submucosal saline injection during CSP for colorectal polyps sized 3-9 mm.

This was a multicenter randomized controlled trial conducted in six Chinese centers between July and September 2020 (ChiCTR2000034423). Patients with nonpedunculated colorectal polyps sized 3-9 mm were randomized in a 1:1 ratio to either CSP with submucosal injection (SI-CSP) or conventional CSP (C-CSP). The primary outcome was the incomplete resection rate (IRR). Secondary outcomes included procedure time, intraprocedural bleeding, delayed bleeding, and perforation.

Results: One hundred fifty patients with 234 polyps in the SI-CSP group and 150 patients with 216 polyps in the C-CSP group were included in the analysis. The IRR was not decreased in the SI-CSP group compared with the C-CSP group (1.7% *vs.* 1.4%, *P*=1.000). The median procedure time in the SI-CSP group was significantly longer than that in the C-CSP group (108 seconds *vs.* 48 seconds, P<0.001). The incidences of intraprocedural bleeding and delayed bleeding were not significantly different between the two groups (*P*= 0.531 and *P*=0.250, respectively). There was no perforation in either group.

Conclusion: Submucosal saline injection during CSP for 3-9 mm colorectal polyps did not decrease the IRR or reduce adverse events but prolonged the procedure time.Therefore, we do not recommend the routine submucosal injection during CSP.

Introduction: Endoscopic full thickness resection (EFTR) is emerging as an effective modality for mucosal and submucosal lesions in colorectum.

Aims & Methods: In this systematic review and meta-analysis, we aimed to analyze the success and safety of device assisted EFTR in colon and rectum. A literature search was performed in Embase, PubMed, Medline databases for studies evaluating device assisted EFTR between inception to October-2022. The primary outcome of the study was clinical success (R0 resection) with EFTR. Secondary outcomes included technical success and adverse events.

Results: 29 studies with 3467 patients [2045(59%) males] with 3492 lesions were included in the analysis. The lesions were located in right colon in 1660 (47.5%), left colon in 990 (28.6%) and rectum 840 (24.3%). EFTR was performed for sub-epithelial lesions in 252 (7.2%) patients. Pooled mean size of the lesions was 16.6 mm (95% CI 14.9 – 18.2, I^2 98%). Technical success was achieved in 87.1% (95% CI 85.1%-88.9%, $I^2$39%) procedures. The pooled rate of en bloc resection was 87.9% (95% CI 85.1%-88.9%, $I^2$50%) and R0 resection was 81.6% (95% CI 78.8% to 84.2%, $I^2$57%). In sub-epithelial lesions, pooled rate of R0 resection was 94.3% (95% CI 89.7% to 96.9%, I^2 0%). Pooled rate of adverse events was 12.1%(95% CI 10.3%-14.1%, $I^2$44%) and major adverse events requiring surgery was 2.5% (95% CI 2.0%-3.1%, $I^2$0%).

Conclusion: Device assisted EFTR is a safe and effective treatment modality in cases with adenomatous and sub-epithelial colorectal lesions. Comparative studies are required with conventional resection techniques including endoscopic mucosal resection and submucosal dissection.

Disclosure: Nothing to disclose.

Introduction: Among the various forms of NOTES (Natural Orifice Translumenal Endoscopic Surgery), Endoscopic Full-Thickness Resection (EFTR) is a minimally invasive endoscopic surgical technique that allows radical resection of epithelial neoplasia with significant fibrosis or suspected deep submucosal invasion.

We describe our initial experience with non-tunnelled exposed EFTR for rectal lesions, with subsequent closure of the defect using an endoscopic suturing device.

Aims & Methods: We performed a retrospective analysis of 11 consecutive patients treated at our centre with non-tunnelled exposed EFTR for removal of 11 lesions located in the distal rectum, below the peritoneal reflection. Indications included 7 recurrences of previous mucosectomy, 1 large circumferential lesion without evidence of submucosal invasion, 2 lesions with suspected submucosal invasion (without imaging evidence of overt muscular invasion) and 1 T3 N0 adenocarcinoma of the pelvic RM treated with neoadjuvant radiotherapy in a patient unfit for surgery. The transmural defect was closed by endoscopic suturing.

Technical success, safety and R0 resection were evaluated.

Results: All lesions were successfully treated by EFTR and no intraoperative or postoperative complications were observed.

EFTR was R0 in 8/11 patients: 1 patient underwent surgery due to high risk of lymph node metastasis.

In 3/11 patients EFTR was R1: in 2 patients the vertical margins were involved by neoplastic tissue and the patients underwent surgery, in 1 patient only the horizontal margins were involved and no endoscopic or histological evidence of recurrence was seen at 12 months.

EFTR proved to be curative in 8 out of 11 patients.

Conclusion: Our initial experience shows that rectal EFTR is a feasible and safe technique, useful for resection of complicated lesions with curative or at least diagnostic intent. Larger randomised trials are needed to better define the clinical benefits and long-term outcomes of rectal EFTR in selected patients.

Disclosure: Nothing to disclose.

TRANSCECAL ENDOSCOPIC APPENDECTOMY FOR MANAGEMENT OF COMPLEX APPENDICEAL POLYP: A SINGLE-CENTER CASE SERIES

T. Keihanian[1], D.H. Zamil[1], F.Z. Aloor[1], W. Qureshi[1], M.O. Othman[1]
[1]Baylor College of Medicine, Houston, United States

Contact E-Mail Address: tara.keihanian@bcm.edu

Introduction: Endoscopic resection of the appendiceal orifice polyps extending into the appendiceal lumen is challenging given the inability to determine polyp's lateral margins. Endoscopic full thickness resection (EFTR) is an alternative technique for managing these polyps, but it is limited in polyps larger than 2 cm, or polyps extending to the base of the cecum or inside the appendiceal lumen. In addition, EFTR may lead to appendicitis. In this case series, we describe a novel technique for the removal of complex appendiceal orifice polyps via transcecal endoscopic appendectomy (TEA).

Aims & Methods: This case series includes patients who underwent TEA performed by a single endoscopist in the US for polyps larger than 2 cm that extended deeply into the appendiceal lumen or obstructed the appendiceal lumen. All cases were done under general anesthesia in endoscopy unit. The technique entailed performing a circumferential incision around the lateral margin of the polyp in the base of the cecum. Once the polyp was dissected by endoscopic submucosal dissection (ESD) technique from the base of the cecum, the incision was extended into the serosa of the cecal wall with continuous dissection of the appendix from the mesoappendix. Traction was then applied to pull the tip of the appendix intra-luminally within the cecum. The appendix was then dissected from the remining mesoappendix and cecal base. The defect was then closed using hemostatic clips. A 14-gauge catheter was routinely inserted above the umbilicus to prevent tension pneumo-peritoneum. Technical success was defined as achieving complete removal of the appendix and the polyp in an en bloc fashion.

Results: In total, five patients were included (60% female). The mean age of patients was 65.6 ± 7.5 years old. The average polyp size was 3.08 ± 0.6 cm. Technical success was achieved in 100% of the patients. The average procedure length was 98.6 ± 36.22 minutes. Completed closure of the defect was made via clips in all cases (average 5.8 ± 1.7 clips). The en bloc resection rate, R0 resection rate and curative resection rates were 100%. Patients were observed post procedurally for an average of 3 ± 1.3 days (range 1-5 days). Post-procedural mild abdominal discomfort (n=4) and leukocytosis (n=3) were managed conservatively with empiric antibiotics. One patient developed loculated fluid collection nine days post-procedure without development of any clinical symptoms. After treatment with empiric antibiotics, complete resolution of all collection was noted on follow-up outpatient imaging on day 17.

Conclusion: This is the first reported experience of transcecal endoscopic appendectomy for management of complex appendiceal orifice polyps in the West. This novel technique is safe and is associated with minimal risk profile in expert hands. Further prospective studies are needed to standardize the technique.

Contact E-Mail Address: Jensn81@gmail.com

Introduction: Surgery is the standard treatment for colorectal cancer (CRC). Following the introduction of screening programs for CRC, a substantial shift toward the diagnosis of CRC at an earlier stage is observed (1).

In T1 CRC merely 10% of carcinomas have spread to lymph nodes or distant organs (2), suggesting that a vast majority of T1 CRC can be successfully treated with a minimal invasive approach. Endoscopic treatment for early CRC (pT1), rather than surgical resection, is expected to reduce mortality, morbidity and costs (3, 4).

We evaluated oncological outcomes and patient safety of endoscopic resection of suspected pT1 CRC in a Norwegian CRC screening centre.

Aims & Methods: From January 2020 until November 2022, we prospectively registered all endoscopic procedures performed for suspected pT1 CRC. We recorded endoscopic technique, optical evaluation, pathology results, staging using CT and MRI, additional surgery as well as complications and final outcome. All patients were informed about the advantages and potential risks of endoscopic treatment vs. surgical resection, and all gave informed consent before treatment after shared decision-making. All patients were discussed at our multidisplinary team (MDT) meeting.

	Age/ Gender	Polyp size (cm)	Appearance	Paris	Path	Procedure length (minutes)	Knife used	Over-tube	Traction	# of clips	R0 resection	Curative resection	Length of stay (days)	Follow up
# 1	72/F	3.7 x 2.2	Entire AO	Is	SSA	65	Dual knife	Lumendi	Lumedi double balloon	5	R0	Yes	3	Post procedure ileus, managed conservatively
# 2	69/M	2.8 x 2.0	Entire AO, extending inside	Is	TA	90	Orise ProKnife	None	Rubber-band clip	8	R0	Yes	1	None
# 3	67/F	3.9 x 2.8	50% of the AO	IIa	SSA	169	Orise ProKnife	Lumendi	Rubber-band clip	3	R0	Yes	5	Multiple walled-off fluid collections on day 9, management conservatively with complete resolution of collections of day 17
# 4	51/M	2.6 x 2.1	Entire AO, extending inside	Is	SSA	86	Orise ProKnife	Pathfinder	Rubber-band clip	7 (2 DAT and 5 hemostatic clips)	R0	Yes	3	Mild abdominal pain
#5	69/F	2.4 x 0.9	Entire AO, extending inside	IIa	SSA	83	Orise ProKnife	Pathfinder	Rubber-band clip	6	R0	Yes	3	Mild abdominal pain

PP1258 Table 1. Patient, polyp and procedure characteristics, outcome and follow up information.

Results: A total of 42 suspected T1 CRC cases treated endoscopically were included. 95% (38/40) of the lesions were identified as possibly malignant with optical evaluation (JNET 2B/NICE III/SANO IIIa) before treatment. 62% (26/42) of patients were deemed to have completed treatment with endoscopic resection. Sixteen patients underwent surgery following endoscopic treatment after discussions in the MDT meeting. Of these, three had lymph node metastasis, one of these had both lymph node metastasis and residual disease; at the site of the primary tumor. All three patients had one or more histopathological risk factors (one T2 stage + lymphovascular invasion (LVI) + poor differentiation, one T1 with LVI, one T1 with Rx and LVI). The remaining 13 patients (81% of those operated) had no residual disease and were thus overtreated. No severe adverse events were recorded, and no patients needed hospitalization with intensive care treatment.

Conclusion: Our study suggests that endoscopic treatment of suspected early-stage CRC is efficient and safe.

Introduction: Colorectal endoscopic submucosal dissection (ESD) allows high rate of en bloc resection of colorectal neoplasm. It is still not widely used; however, the factors that limit its diffusion are its technical difficulty, its duration and the risk of complications. Due to the long duration and the high risk of intra-procedural discomfort, colorectal ESD is usually performed under deep sedation or in narcosis.

The aim of the study is to determine the factors associated with intra-procedural discomfort.

Aims & Methods: We retrospectively analyzed colorectal ESD performed in our centre between November 2018 March 2023. Procedures performed in narcosis with anaesthesiologist assistance were excluded. We collected data of sedation, in particularly the presence of pain during the procedure was measured with the Gloucester scale from nursing records. The patients were divided into two groups: the first with no/mild discomfort (Gloucester 1-2), the second group with moderate/severe discomfort (Gloucester 3-4). Univariate and multivariate analyses were performed to examine factors that may have influenced intra-procedural discomfort.

Results: A total of 154 colorectal ESD for superficial neoplasms were considered. 18 colorectal ESD were excluded because performed in narcosis. The remaining 136 colorectal ESD (male 59,6% with a median age of 68.4 ± 10.1) achived en bloc resection and complete resection in 124 (91 %) and 121 (89 %) cases respectively; mean major diameter's neoplasms was 3.8 cm (±1.81cm), in 79 cases the size was < 40 mm (42%). 65 neoplasms were located in the right colon (48%), 30 in the left colon (22%) and 41 in the rectum (30%). 53 colorectal ESD (39%) were performed using underwater technique. 92 patients (67 %) were included in the first group (Goucester 1-2), the other 45 patients (33 %) in the second group (Goucester 3-4). On univariate analysis, underwater-ESD (OR 2.2; 95% CI 1.03 – 4.92) and small size of the neoplasms (< 4 cm) (OR2.3; 95% CI 1.11 – 4.78) were significantly associated with lower intra-procedural discomfort during the procedure. The morphology (non granular, granular or sessile) and the localization were not associated with intra-procedural discomfort. The multivariate analysis confirmed the significantly correlation of underwater-ESD and small neoplasms size with lower discomfort during procedures.

	UNIVARIATE ANALYSIS			MULTIVARIATE ANALYSIS		
VARIABLE	OR	95% CI	p	OR	CI	p
Size lesion < 40 mm	2.30	1.11 - 4.77	0.0237	2.78	1.29 - 5.99	0.0092
Underwater-ESD	2.26	1.03 - 4.92	0.0357	2.76	1.21 - 6.28	0.0154
Rectum	1.81	0.79 - 4.13	0.1501			
Right colon	0.72	0.35 - 1.47	0.3632			
Left colon	0.82	0.35 - 1.90	0.6391			
Non granular	0.74	0.35 - 1.55	0.4214			
Granular	0.93	0.46 - 1.91	0.8531			
Sessile	2.55	0.69 - 9.36	0.1293			

Conclusion: Underwater-ESD and lesion size < 40 mm are associated to less discomfort during colorectal ESD. These findings should be taken into consideration approaching colorectal ESD.

Introduction: Organ preservation is increasingly preferable in the management of large and complex colorectal lesions. Innovative platforms are emerging with the advancement in technologies alongside multi-disciplinary practices.

Aims & Methods: The study aims to assess clinical outcomes and organ preservation of a novel trans-anal technique in the management of left colorectal lesions.

Consecutive patients (January 2021/November 2022) were considered for either traditional surgical resection or Speedboat-assisted endoscopic

Submucosal Dissection (SSD-Bibolar Cut and Microwave coagulation) using the innovative ATASER (Aireseal- Trans-anal Speedboat Endoscopic Resection) platform.

The operator accesses the left colorectum by introducing an endoscope via a trans-anal platform (Gelpoint™/Applied Medical/USA). Airseal™(ConMed/USA) maintains a stable intraluminal pressure and a smoke free dissection filed by a constant carbon dioxide exchange. Submucosal dissection is performed with the novel Speedboat™ Inject (Creo-Medical/Wales/UK) incorporating bipolar energy cutting and microwave energy coagulation.

Results: 79 patients (Mean age 69 years/40males) with complex lesions in the left colorectum underwent SSD. 6 abandoned (5 for muscle retraction sign, 2 advanced cancer), 1 for a medical emergency. Complete en-bloc resection was achieved in 93% (n=68) out of 73 endoscopically removed lesions with 5 cases (7%) converted to piecemeal EMR. Early cancer was found in 6 cases (3 patients opted for enhanced surveillance with no local or distant recurrence, 2 had surgery with no residual tumour or lymph node metastases and one required chemotherapy for a neuroendocrine tumour)

The A-TASER platform was used in 36/73 (49.3%) patients. The endo-surgical group had significantly larger lesions when compared with the traditional endoscopic group (Mean length 6.9cm vs. 5.1cm p 0.009, Mean surface 39.8cm^2 vs. 19.7cm^2 p 0.003). Even though the A-TASER approach took significantly longer (144 minutes vs. 100 minutes p 0.03), there was no difference in the speed of the dissection (15.7cm^2/h vs. 14cm^2/h p 0.4). Microwave used to control bleeding in all cases. Delayed bleeding did not occur in any of the groups. One post polypectomy syndrome was recorded. No perforation occurred. Hospital stay was less than 24 hours in most patients (68/73 93%). 3 patients in the A-TASER and 2 in the endoscopy only group remained for longer than 24 hours.

Conclusion: Emerging and innovative technologies allow hybrid approach in the management of gastrointestinal lesions. A-TASER appears to be technically feasible, safe and effective endo-surgical technique that enhances radical removal of large and complex lesions in the left colorectum. Its wider role in organ preservation by avoiding surgery warrants further studies. A propensity analysis of our data will follow to further explore its efficacy.

Introduction: Endoscopic full thickness resection (EFTR) of the colon has been described as an effective practicable method for resection of recurrent /advanced neoplastic lesions, but its performance and success may be difficult or different according to location of the lesion in the corresponding colonic segment.

The aim was to investigate the segment-specific efficacy and safety of EFTR in the colon using a full thickness resection device (FTRD) from real-world data.

Aims & Methods: EFTR was conducted in patients being referred to either of the 4 participating centers after previous colonoscopy leading to a diagnosis suitable for EFTR. The primary efficacy measure of EFTR was histologically complete resection (R0) of the lesion. Safety was investigated considering the frequency of adverse events (AE) to EFTR occurring during the procedure or afterwards.

Results: 105 patients (66m/39f; median 70yrs) were included in the analysis. FTRD was technically successful in 101 patients (96.2%) with a median lesion size of 20 x 19mm (15-24). Histologically R0 resection was obtained in 77.1% of the patients with a segment-specific range from 90% (rectum), 70.6% sigmoid, 78.6% descending colon to 62.5% (transverse colon), while in ascending colon and cecum resection rates of 76.9 and 83.3% could be achieved.

Overall, adverse event rate (AE, any) were documented in 33 patients (31.4%), with only 1 perforation in sigmoid (0.95%), while the others were minor, abdominal postsurgical pain (18.1%), hematochezia (9.5%), and haemoglobin decline (7.6%). Topographical analysis revealed that AE were most attributable to transverse colon (12.5%), while in the other segments AE were each lower or equal than 8.2%; the lowest rate of AE was found in rectum with 1.4%.

Conclusion: EFTR is efficacious for the endoscopic treatment of colorectal lesions with best outcome parameters in rectum (high R0 rate, low AE), followed by cecum. The other segments appeared to be more difficult for complete resection and showed a higher AE rate. Transverse colon was identified with lowest R0 resection rates and highest frequency of AE. While only one major complication occurred, minor complications in all other segments were below 8.2% and short-lived.

Disclosure: Nothing to disclose.

SURVEILLANCE OF COLORECTAL ENDOSCOPIC MUCOSAL RESECTIONS (EMR): A SINGLE CENTRE TEN-YEAR EXPERIENCE

M.I. Viegas[1], L. Elvas[1], M. Areia[1], M. João[1], S. Alves[1], D. Brito[1], S. Saraiva[1], A.T. Cadime[1]

[1]Portuguese Oncology Institute of Coimbra, Gastroenterology, Coimbra, Portugal

Contact E-Mail Address: mariainesviegas96@gmail.com

Introduction: Colorectal endoscopic mucosal resection (EMR) is associated with high recurrence rates, which requires a regular surveillance program by colonoscopy. Our aim was to study the 5-year follow-up of a population undergoing EMR and the risk factors associated with recurrence.

Aims & Methods: Prospective cohort study, single centre, including patients who underwent colorectal EMR of lesions ≥20mm with a minimum follow-up of 5 years, between 2009 and 2019. We analysed the lesions' characteristics, as well as the recurrence rate, and logistic regression conducted for risk factors associated with recurrence.

Results: Included 407 EMR and patients were 58% male, with a mean age of 68.5±9.8 years. From our analysis: 65.8% of the lesions were 20-40mm, 21.4% 40-60mm and 12.8% were ≥60mm; 49.4% were sessile and 50,6% flat; 34.1% were localized in the right colon, 21.6% in the transverse colon, 15.5% in the left colon, and 28.7% in the rectum; 85.7% were granular and 14.3% non-granular. The mean SMSA score was 12.5±1.8. The overall recurrence rate was 19,9%, with rates and respective time of follow-up as follows: 15,8%, 7,4%, 3,6% and 0% at 3, 12, 36 and 60 months.

Evaluating the risk factors for recurrence, anal location (32.6% vs. 18.4%; p=0.02) and size of lesion: ≥60mm vs. 40-60mm vs. ≤40mm (34.7% vs. 33.7% vs. 12.8%; p<0.001) were statistically significant, but not with argon

plasma therapy (23.3% vs. 18.1%; p=0.21) and non-granular morphology (19.0% vs. 20.3%; p=0.82). Logistic regression analysis revealed that only an escalation in size in multiples of 20mm had a significant risk of recurrence (OR 1.98; p<0.001). The global complication rate was 6.1%, including early complications (perforations, n=3) and late complications (bleeding, n=17 and post-polypectomy syndrome, n=3).

Conclusion: Despite the high overall recurrence rate, a 5-year surveillance has demonstrated to be an adequate time interval to evaluate the EMR's efficacy and safety.

Disclosure: Nothing to disclose.

COLONIC DEFECT CLOSURES AFTER ENDOSCOPIC RESECTION USING ENDOSCOPIC CLIPS COMPARED TO THROUGH-THE-SCOPE HELIX TACK AND SUTURE DEVICE

A. Krishnan[1], M. Zitun[1], M.S. Arif Maan[1], Y. Hadi[1], W. Roy[1], S. Singh[1], U. Rizwan[1], S. Thakkar[1], S. Singh[1]

[1]West Virginia University School of Medicine, Section of Gastroenterology and Hepatology, Morgantown, United States

Contact E-Mail Address: sobanmaan@live.co.uk

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are currently the most used technique for resection procedures for advanced gastrointestinal lesions. Endoscopic resections are associated with bleeding and perforation.

They may be managed with over-the-scope clips and endoscopic suturing, and a new through-the-scope suturing (TTSS) device has recently been introduced.

Aims & Methods: This study aimed to compare the technical success of closure and adverse events using TTSS To TTS clips (TTSC). A retrospective review was performed for consecutive patients who underwent the application of the TTSS or TTSC. Demographic and clinical variables were collected.

The primary outcomes were technical and adverse to the procedure, and the secondary outcome was the cost analysis.

Results: Fifty-six patients (mean age, 63.6 y; 60.7% females) underwent TTSS closure, and 124 patients with TTSC were included in the study. The most common site of application was the colon (n= 37, 69.8%), followed by the ascending colon (35.7% vs. 32.2%), followed by the cecum (26.7% vs. 25%) (Table 1).

Technical success was achieved in 96.4% of patients with TTSS and 100% for TTSC, with a mean defect size of 32.6± 11.9 mm and 33.1± 10.1 mm, respectively. Two patients (3.6%) had failed after initial technical success and required rescue treatment with TTSC for defect closure in the TTSS cohort.

The adverse events were more common in the TTSC, with 4.8% bleeding and one perforation (0.8%). However, the TTSS group had one adverse event as self-reported bleeding that did not require further intervention.

We used a mean number of TTSC of 3.8 clips for defect sizes of 20-30 mm, whereas 4.2 for 30-40 mm defects, 4.2 clips for 41-50, and 5.3 clips for defect sizes more than 50mm, whereas we used only 2 X-tack devises for the defect more than 40mm.

Conclusion: The use of the TTTS helix system is an effective and safe method for the closure of large colonic defects.

In addition, in our experience, the Helix Tack device ($695/device) achieves cost parity with approximately 4 TTSCs (U.S.$150- $250/clip). The helix tack device can reduce the defect size, making it amenable to closure completion by clips when the original defects may be too large or cumbersome for primary clip closure with cost-effectiveness.

Introduction: It has been suggested that gut transition time (GTT) and gut microbiome could have a possible role in non-alcoholic fatty liver disease (NAFLD) development.

Aims & Methods: Our study aims to compare the GTT between healthy volunteers and NAFLD patients, regarding their microbiome composition. Method: A total of 34 healthy volunteers and 34 NAFLD patients, without previous history of intestinal resection, inflammatory bowel disease, radiotherapy, or course of antibiotic, probiotic, and immunosuppressive therapy 2 weeks prior, were asked to provide a fresh stool sample. The gut transition time was measured by the timing of the „blue poop" appearance after ingestion of two chocolate muffins with 1.8g of blue dye gel (dr Oetker). The microbiome composition was determined using a 16s rRNA sequencing technique with a focus on V3-V4 hypervariable region.

Results: The two groups had similar age and sex distribution. The group of NAFLD patients had significantly longer GTT when compared to healthy volunteers (36h vs 41h, p=0.0137), with a lower Bristol Stool chart score (2.32 vs 2.76, p=0.037). The main difference between gut microbiome composition in the two groups was a greater abundance of bacterial genera Faecalibacterium (0.0162 vs 0.0245, p=0.043) and bacterial family Lachnospiraceae (0.279 vs 0.331, p=0.036) in the group of healthy volunteers. NAFLD patients showed a higher abundance of Intestinibacter genera (0.00582 vs 0.003421, p=0.041). The correlation substudy showed a positive correlation between gut transition time and abundance of Methanobacteriaceae (Rho=0.231, p=0.03) and Clostridiaceae (Rho=0.197, p=0.01) bacterial families.

Conclusion: Prolonged gut transition time paralleled by gut microbiome composition disturbance might play an important role in NAFLD pathogenesis.

Introduction: This study explores potential associations between the gut microbiome and fibrosis in patients with viral hepatitis, using network analysis to reveal correlations between multiple microbes and clinical data. The gut-liver axis plays a crucial role in human health, with weakened tight junctions, increased influx of substances into the liver, and IgA-related immune abnormalities observed in patients with chronic hepatitis and liver cirrhosis.

However, the causative bacteria remain elusive. Network analysis can reveal potential biomarkers and therapeutic targets, with the hope of improving patient outcomes.

Aims & Methods: We aimed to elucidate the relationship between fibrosis markers and gut microbiome by constructing networks, analyzing fecal samples and clinical indicators of 145 HCV antibody-positive (HCV group) and 84 HBs antigen-positive (HBV group) patients with chronic liver disease who visited our hospital between June 2016 and April 2021. We identified microbes at the genus level by analyzing DNA from the 16S rRNA region (V3-V4) obtained from fecal samples using the Miseq platform, QIIME2, and Silva database.

Patients were divided into HBV and HCV groups to establish reproducible relationships. We calculated Spearman rank correlation coefficients between relative microbial abundance and clinical data, including BMI, age, albumin , total cholesterol, estimated glomerular filtration rate , AST, ALT,GTP, total bilirubin, hemoglobin, platelet count, Fib4-index, prognostic nutritional index (PNI), and ALBI score.

We considered p-values below 0.05 and absolute correlation coefficients above 0.3 as significant correlations, which will help in understanding the complex relationships between fibrosis markers and gut microbiome in patients with viral hepatitis.

Results: Patient backgrounds differed between the HBV group (median age 56.5 years, Fib4-index 1.74, PNI 49.5, ALBI -2.8) and the HCV group (68 years, Fib4-index 3.21, PNI 46.5, ALBI -2.6). We identified 263 microbial genus and 34,453 combinations ($_{263}C_2$). Among these, 1,619 combinations in the HBV group and 4,730 in the HCV group showed significant correlations with over 90% showing positive correlations. There were 586 common combinations between both groups, which were highly likely to be a unique bacterial combination maintained across different patient backgrounds.

We found 85 correlations in the HBV group and 20 in the HCV group in the 3,682 combination between 14 types of clinical data and 263 bacterial genus. Specifically, only Veillonella and Streptococcus demonstrated a positive correlation with Fib4-index and a negative correlation with PNI. Lactobacillus showed a positive correlation with age in common between the HBV and HCV groups . They did not have a direct correlation with age, ALT, AST, or platelet count, suggesting a potential relationship with fibrosis. However, the age-correlated Lactobacillus showed a positive correlation with Veillonella and Streptococcus, indicating a possible secondary

relationship. Additionally, Streptococcus, occupying a key position in the network with positive correlations with multiple bacteria, may have a significant influence on these microbes.

Conclusion: We found potential associations between specific gut microbes and fibrosis in viral hepatitis patients. Streptococcus, Veillonella, and Lactobacillus were significant in their relationship with fibrosis markers, with Streptococcus playing a central role in the network. Thhs suggests Streptococcus as a potential biomarker and network analysis as a valuable tool for potential diagnostic and therapeutic applications.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is the most common chronic liver illness in Western countries. Bisphenol A (BPA) is a well-known endocrine disrupter, widely produced worldwide primarily as a monomer for polycarbonate plastics and plenty cumulated in the human body. Its exposure is epidemiologically related to type 2 diabetes mellitus and cardiovascular and liver diseases. Trained Immunity (TI) represents a novel concept of immunological memory that promotes a response of innate immune cells, triggered by a second antigenic stimulus, and determines a long-term reversible pro-inflammatory phenotype.

Although further studies are needed to clarify the role of BPA in the alteration of immune mechanisms, current evidence suggests its implication in the immunometabolic switch and in the remodeling of epigenetic marks which could result in a different immune reactivity.

Aims & Methods: We aimed to explore whether BPA affects TI reactivity in NASH patients due to a possible hyperelicitation of pro-inflammatory pathways.

Serum samples of healthy individuals (n.25) and histologically proven NASH patients (n. 10) were subjected to liquid-liquid extraction of bisphenol A with methanol (1:1, v/v), then to solid-phase extraction cartridge for clean-up and concentration. The analysis of sample extracts was carried out by the HPLC system coupled to a triple quadrupole mass spectrometer. In parallel, for each subject, a peripheral venous blood sample was collected (20 mL).

Consequently, monocytes were isolated through a density gradient centrifugation and then stimulated with BPA for 24 h (1 nM, 10 nM, 20 nM) and lipopolysaccharide (LPS) (10 ng/mL) for 24 h (at day 0 and day 6 respectively). In order to assess the pro-inflammatory (tumor necrosis factor TNF-α, interleukin IL-6) and anti-inflammatory response (IL-10) ELISA assays were performed.

Results: The mean values of BPA quantification in serum samples of healthy individuals were 0.1398 ± 0.0495 ng/mL in comparison to NASH patients 7.79 ± 2.34 ($P < 0.0001$).

The induction of TI mediated by BPA (1 nM, 10, nM, and 20 nM) emerged higher in NASH patients compared to healthy individuals ($p<0.05$). The hyperelicitation of TI mechanisms in monocytes has been expressed by the high levels of pro-inflammatory cytokines (TNF-α and IL-6) in NASH patients compared to the healthy subjects, in each concentration chosen for the stimulation. Additionally, our data also showed an increased concentration of IL-10 in NASH patients, probably due to a compensative phenomenon for the excessive inflammatory process.

Conclusion: Considering the emerging role of BPA as a strong stimulator of innate immune training in healthy subjects and NASH patients, it is conceivable to address a key role of BPA in the induction of TI as a priming antigen and in the establishment of a pro-inflammatory phenotype potentially involved in the pathogenesis of the disease.

Introduction: Liver Sinusoidal Endothelial C-type Lectin (LSECtin) is a type-C lectin expressed mainly by Liver Sinusoidal Endothelial cells (LSECs), involved in pathogen recognition but also capable of interacting with T lymphocytes inducing its inhibition.

It is known to be downregulated during chronic liver disease while the proinflammatory hepatic response increases. Its loss compromises the protolerogenic activity promoted by LSECs antigenic receptors in favour of inflammation.

Aims & Methods: Our aim is to elucidate LSECs cytokine production in an in vitro model of LSECtin downregulation. For that Immortalized mouse LSECs (imLSECs), either wild type (wt) or LSECtin-Crispr (Crispr), were cultured with LSECtin ligands (CD44Fc and LAG3Fc at 1 ug/mL) or in combination with ligands of Toll-like Receptors (TLRs) (LPS, Pam3CSK4 y CpGs at 0.1 ug/mL). After 72 hours supernatants were collected. To study cytokine production multiplexed immunoassay kits based in fluorescent beads were used.

Results were analyzed by flow cytometry. Experiments were done in triplicates. LSECtin downregulation and its downstream signaling was checked by Western Blot.

Results: LSECtin-Crispr LSECs exhibit a downregulation in LSECtin protein expression. Chemoattractant mediators (CCL5 or CXCL10) and proinflammatory cytokines (IL-6 or TNFalpha) secretion increased significantly upon cell stimulation with LSECtin and/or TLRs ligands in Crispr LSECs. On the contrary, IL-10 production was lower in LSECtin-Crispr LSECs than in wt cells upon stimulation.

		Concentration at supernatant (ng/mL	
Stimulus	Cytokine	Wt	Crispr
LPS	IL-6	501,62 ± 42,88	739,47 ± 114,95
	CCL5	527,99 ± 17,74	752,12 ± 70,42
	CXCL10	359,78 ± 24,07	852,42 ± 20,44
	IL-10	2,21 ± 0,09	1,52 ± 0,10
LPS + LAG3	IL-6	463,42 ± 21,52	794,17 ± 65,66
	CCL5	434,83 ± 21,97	785,18 ± 68,58
	CXCL10	414,84 ± 36,85	832,05 ± 58,11
	IL-10	1,80 ± 0,21	1,59 ± 0,13

Conclusion: LSECtin regulates the cytokine production of LSECs reducing the production of proinflammatory mediators and favoring Il-10 secretion. LSECtin loss may therefore contribute to the inflammatory microenvironment in cirrhosis.
Disclosure: Nothing to disclose.

Introduction: The prevalence of autoimmune hepatitis (AIH) is increasing, yet specific pharmacotherapies remain to be explored. Sophoricoside (SOP), a bioactive component of Sophora japonica L., has been previously reported anti-inflammatory properties.
Aims & Methods: This study aims to investigate the effects of sophoricoside on AIH and the underlying mechanism. Bioinformatic approaches were used to predict the potential targets and underlying regulatory mechanisms of SOP on AIH. The effects of SOP on AIH were evaluated by inflammatory cytokines expression, histological liver injury, and hepatic fibrosis in an improved chronic cytochrome P450 2D6 (CYP2D6)-AIH mouse model and the concanavalin-A (ConA)-induced acute immune-mediated liver injury model. The antioxidant activity of SOP was detected in vivo and in vitro experiments. The selected signal targeted by SOP in AIH was further confirmed using western blotting and immunofluorescence.
Results: Results of the bioinformatic analysis revealed that targets of SOP on AIH were related to oxidative stress and the NF-κB gene set. In the animal experiments, SOP could alleviate CYP2D6/ConA-induced AIH, evidenced by a significant reduction of hepatic enzymes in serum, inflammatory cytokines expression, and histological lesions in the liver. The oxidative response in AIH was also significantly inhibited by SOP, evidenced by a decrease of hepatic malondialdehyde, and elevations of total antioxidant capacity and glutathione peroxidase.
The results of in vivo and in vitro experiments showed that SOP significantly reduced the enhanced expression and nuclear translocation of phospho-p65 NF-κB in AIH mouse liver and lipopolysaccharide-stimulated AML12 cells.
Conclusion: Our study revealed the protective role of SOP on AIH, which may exert by limiting oxidative response and activation of the NF-κB signaling pathway in hepatocytes.

EVALUATION OF THE RELATIONSHIP BETWEEN LIVER BIOPSY AND FIBROSCAN MEASUREMENTS AND LIVER FIBROSIS, CAP SCORE AND SPLEEN STIFFNESS

I.V. Senkal[1], S. Genc[1], A. Rustemzade[1], K. Nuriyev[1], Z. İstemihan[1], Z. İmanov[1], B. Cavus[1], A. Ciftcibasi Ormeci[1], F. Akyüz[1], K. Demir[1], F. Besisik[1], S. Kaymakoglu[1]
[1]Istanbul Medical Faculty, Istanbul, Turkey

Contact E-Mail Address: drvolkans@hotmail.com
Introduction: As a noninvasive method for evaluating liver fibrosis with the Fibroscan used, it is possible to measure not only liver but also spleen stiffness has become possible. In this study, we aimed to evaluate the correlation of liver fibrosis and Controlled Attenuation Parameter (CAP) scores obtained by Fibroscan measurement with histopathological findings in our patients who underwent liver biopsy for different etiologies, and to evaluate spleen stiffness in this patient group.
Aims & Methods: Stiffness measurements, spleen stiffness and CAP scores are carried out with FibroScan device (Echosens, France) to the patient who have undergone biopsy due to different indications and etiologies. The measurements have done to patients while they are in the supine position, via intercostal spaces, after at least three fasting hours, with using the M/XL probe.
Results were expressed as the median value of kilopascal measurement for stiffness, and the CAP score as dB/m. Only 10 confirmed measurements and measurement results with interquartile range / median value (IQR / Med) < 30% were considered.
Results: 72 patients who underwent liver biopsy were included in our study. The mean age of the patients was 43.26±12.7 years, 52.8% (38) were female. Liver biopsy indications of the patients included elevated liver enzymes in 30.6%, hepatitis B infection in 31.9%, fatty liver in 6.9%, autoimmune hepatitis in 13.9%, and toxic hepatitis in 4.2%. The BMI of the patients was 26.28±4.5 kg/m2. Liver fibrosis mean was 9.19±10.56 kPa, mean spleen stiffness was 29.15±24.01 dB/m, and mean CAP score was 240±55.38. When fibroscan measurements were evaluated according to gender, spleen stiffness was found to be higher in males ($p<0.005$). It is detected that there is an increase in liver fibrosis (kPa) with aging ($p<0.005$). With the fibrosis score indicated in the liver biopsy of the patients. While a positive correlation was found between liver stiffness obtained from fibroscan measurement with the fibrosis score indicated in the liver biopsy of the patients ($p<0.005$), no statistically significant correlation was found with HAI score. Relationship between spleen stiffness and liver biopsy fibrosis score and HAI score not detected. Also no correlation was found between platelet levels and splenic stiffness.
Conclusion: The correlation was found to be significant between Fibroscan which is used as a noninvasive diagnosis in the evaluation of liver fibrosis and spleen stiffness with liver biopsy for detecting fibrosis. Advanced age and male gender was determined to be a risk factor for spleen stiffness. Comprehensive studies are needed to determine splenic stiffness importance in terms of portal hypertension and its relationship with liver fibrosis.
Disclosure: Nothing to disclose.

PP1272

ELIFT AND BARD SCORE COMPARED TO TRANSIENT ELASTOGRAPHY FOR THE ASSESSMENT OF HEPATIC FIBROSIS IN OBESE PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

S. Hamza[1], R. Tlili[1], O. Berriche[2], K. Lassoued[2], M. Dalhoum[2], L. Bel Haj Ammar[1], S. Nsibi[1], H. Jamoussi[2], L. Kallel[1]

Introduction: Liver fibrosis is the main prognostic driver and an independent risk factor for both hepatic and extrahepatic events and global mortality in patients with non-alcoholic fatty liver disease (NAFLD). Thus, many serum markers and scores for the assessment of fibrosis severity have been drawn up.

Recently, researchers developed the easy Liver Fibrosis Test (eLIFT) and the BMI, AST/ALT ratio and Diabetes (BARD) score.

Aims & Methods: This study aimed to compare the eLIFT and the BARD scores with Transient Elastography for the assessment of liver fibrosis in obese patients with NAFLD.

We conducted a transversal study including obese patients recruited from the Department of Nutrition referred to our center for screening for liver steatosis and a non-invasive evaluation of liver fibrosis. We excluded patients who had pre-existing chronic liver disease, chronic alcohol consumers, or those with ongoing medication other than those for metabolic syndrome.

Demographic and clinical features of the participants were recorded. All participants underwent Transient Elastography (TE) and had their AST, ALT, gamma-glutamyl transferase (GGT), platelet count, and prothrombin time measured in a random blood sample, taken the same day of the TE. We calculated for each patient the eLIFT and BARD scores using standard formulas.

Liver stiffness measurements (LSM) used to define the risk for advanced fibrosis as low, indeterminate, and high, based on EASL guidelines 2021, were respectively: <8 kPa, ≥8 and < 12 kPa, and ≥12 kPa.

An eLIFT <8 indicated a low risk of advanced fibrosis, whereas a result ≥8 identified patients at risk of advanced fibrosis. The BARD score ranges from 0 to 4, considered low from 0 to 1 with a high negative predictive value (NPV) for advanced fibrosis, and considered high from 2 to 4 with a high risk of advanced fibrosis.

Results: A total of 213 obese patients with NAFLD were included, with a mean age of 49.04 ± 11.76 years, 88% were female. The mean body mass index (BMI) was 40.67 ± 10.16 kg/m^2 and the mean waist circumference (WC) was 115.07 ± 17.49 cm.

TE results revealed that 191 patients had a low risk of advanced fibrosis (89.7%), 13 had an indeterminate risk of advanced fibrosis (6.1%), and nine patients had a high risk of advanced fibrosis (4.2%). Using eLIFT, 195 patients were classified in the low-risk of advanced fibrosis group of which 187 had also a low risk based on TE and only 8 had a high risk of advanced fibrosis, which corresponds to a rate of sensitivity at 92.6%; specificity at 27.3%; NPV at 95.9%; and positive predictive value (PPV) at 16.7%.

The BARD score was low in 21 patients (9.9%) and high in 192 (90.1%). Among the 21 patients with a low BARD score, 19 had a low risk of advanced fibrosis based on LSM and two had a high risk of advanced fibrosis. In the group of patients with a high score, only nine had advanced fibrosis. Sensitivity was 8.5%; specificity was 90%; NPV was 94.4%; and PPV was 4.7%. Both scores had high NPV for a high risk of advanced fibrosis, but the BARD score had a lower sensibility than eLIFT, with better specificity.

AUROC were 0.515 (95% CI, 0.11-0.92) and 0.743 (95% CI, 0.49-0.99) for eLIFT and BARD scores, respectively.

Conclusion: Both eLIFT and BARD scores were useful for ruling out advanced fibrosis (NPV > 90%) in an obese population with NAFLD. As such, they are adequate for use in clinical practice or as a part of referral and follow-up programs.

Disclosure: Nothing to disclose.

Contact E-Mail Address: mireiatena@ugr.es

Introduction: Tissue non-specific alkaline phosphatase (TNAP) is an enzyme that catalyses the removal of phosphate groups from different physiological substrates. The enzyme is encoded in the mouse by the Alpl gene and gives rise to the liver, bone and kidney TNAP isoforms, which differ in their glycosylation and sensitivity to different inhibitors (1).

TNAP is widely known for its role in bone mineralization, by hydrolyzing the extracellular mineralization inhibitor inorganic pyrophosphate and allowing normal skeletal/dental mineralization (2).

Additionally, TNAP has been related to purinergic signalling pathway, as it can act as an ectonucleotidase and hydrolyse extracellular ATP via ADP and AMP to adenosine (3).

Recently, TNAP has been shown to be crucial in many biologic functions, such as, hepatic metabolism (4, 5), thermogenesis (6) or immune cell homeostasis (7, 8). Phosphocholine is a TNAP substrate that could be a link between TNAP activity and liver metabolism (9).

TNAP is also expressed in the gut, specifically in the lamina propria leukocytes and in intestinal epithelial cells (IECs). However, the function that TNAP exerts in IECs remains unclear.

Aims & Methods: We aimed to characterize the role of TNAP in intestinal epithelial cells in basal conditions. We studied the role of TNAP using epithelial-specific Alpl deficient mice (Alpl$^{flox/flox}$-Villin-CreERT2, referred to as Alpl$^{IEC-/-}$). Colon, intestinal epithelial cells and liver were analysed by qRT-PCR. Colon alkaline phosphatase activity was determined spectrophotometrically, using 5.5 mM disodium nitrophenyl phosphate as substrate. Jejunum organoids were generated, and qRT-PCRs were performed.

Results: The expected decrease in Alpl expression was shown in the colon of Alpl$^{IEC-/-}$ mice; the extent of the decrease suggests that the main Alpl source in the colon in basal conditions is IECs. No differences were detected in the expression of colonic inflammatory markers (Il6, Tnf, S100a8, S100a9).

To assess the effect of TNAP silencing in IECs, colonic enterocytes were obtained from WT and Alpl$^{IEC-/-}$ mice. KO cells were found to exhibit reduced Alpl and increased (p=0.08) Akp6 expression, suggesting that the latter may compensate for the loss of function of Alpl.

Besides, the lack of Alpl in colonic IEC causes the downregulation in one of the ectonucleotidases related to purinergic signalling pathway, Nt5e, which hydrolyses AMP to adenosine. Jejunal organoids derived from Alpl$^{IEC-/-}$ mice exhibit higher expression of both intestinal AP isozymes (Akp3 and Akp6), suggesting a mechanism of compensation.

Interestingly, knocking down Alpl in jejunum organoids increased the expression of the chemokine Cxcl10 and drastically reduced the expression of Cxcl1. Finally, the effect of intestinal Alpl deletion was analysed in the liver. A large increase in Tff3, Tnf and Tgfb1 expression and modulation

of metabolic genes (Fads2 and Sult3a1) were observed in the liver of Alpl$^{IEC-/-}$ mice. Finally, consistent with recently published data (9), there was a decrease in liver choline (with a similar trend in phosphocholine, methionine, betaine and methylglycine) in mice in which Alpl was depleted in intestinal epithelial cells.

Conclusion: Our data show that the deletion of Alpl in IEC affects normal cell physiology. Furthermore, the expression of intestinal Alpl appears to have a critical role in liver metabolism.

APRI , FIB -4 AN ALTERNATIVE TO TRANSIENT ELASTOGRAPHY IN OBESE PATIENTS WITH NAFLD

A. Abdelmoula[1], L. Khouloud[1], B. Olfa[2], T. Raja[1], D. Meriam[2], B.A. Leila[1], N. Soumaya[1], J. Henda[2], K. Lamia[1]

Contact E-Mail Address: amiraabdelmoula@yahoo.fr

Introduction: Obesity is a serious healthcare burden associated with an increased risk of morbidity and mortality. It reprensents a risk and prognostic factor for non alcoholic fatty liver disease (NAFLD) and its complications, mainly hepatic fibrosis. It is therefore essential to identify within the obese population, patients at high risk of developing advanced fibrosis in order to optimize their management.

In our study, we investigated the correlation between two biological scores: Fibrosis-4 (FIB-4) and aspartate aminotransferase (ASAT)/platelet ratio index (APRI) and a physical mean which is transient elastography (FibroScan®) for the assessment of liver fibrosis in obese patients with NAFLD.

Aims & Methods: This is a transversal, descriptive and analytical study, conducted over a seven months period (August 2022- March 2023). We collected obese patients with NAFLD who had a FibroScan, a serum AST, ALT and a platelet count, performed within the same day. Fib-4 and APRI scores were calculated for each patient, accordingly to the standard formulas. We used a cutoff <0.5 for APRI score and a cutoff <= 1.45 for Fib-4 to identify patients with a low probability of advanced fibrosis. For patients with high probability of advanced fibrosis we used a cutoff >4 for Fib-4 and a cutoff >1,5 for APRI. Advanced fibrosis was considered in patients with a Liver Stiffness Measurement (LSM) > 12 kPa. We studied the correlation between transient elastography and biological scores.

Results: We collected 207 obese patients with hepatic steatosis. A female predominance was noted with a sexe ratio of 0,12. The mean age was 48.8 +/- 11.9 years.

The mean liver elasticity was 5 .38 +/- 3.22 kpa and the mean APRI and Fib-4 scores were 0.2 and 0.89, respectively.

Liver elasticity was less than 12 kpa in 95.7% of patients. Patients with a low risk of advanced fibrosis according to APRI and Fib-4 scores were 97.1% and 95.2%, respectively.

We noted a significant correlation between the transient elastography results, APRI score and Fib-4 in the identification of patients with low probability of advanced fibrosis (p=0.037 and p<0.001, respectively). Of the 9 patients with an LSM ≥12kPa , only one patient had a Fib4 score >4 (44,4 %) and no one had an APRI score >1,5.

The statistical analysis showed that the APRI score has a sensitivity of 100% but no specificity (0%).The positive predictive value(PPV) was 0% while the negative predictive value (NPV) was of 95,7% .For the Fib 4 score the sensitivity was 99,5 % and the sensitivity was 0%. The PPV was 0% and the NPV 95,6% .

Conclusion: Fib-4 as well as APRI are two non-invasive scores that can be routinely performed based on simple biological parametres with a good NPV to exclude advanced fibrosis in obese patients with NAFLD. They can be used within this population when other more performing tests are not available.

Disclosure: Nothing to disclose.

OPERATOR VARIABILITY IN TRANSIENT ELASTOGRAPHY ANALYSIS OF OVERWEIGHT/OBESE PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE: A REAL CHALLENGE

S. Hamza[1], R. Tlili[1], O. Berriche[2], K. Lassoued[1], M. Dalhoum[2], L. BelHajAmmar[1], S. Nsibi[1], H. Jamoussi[2], L. Kallel[1]

Introduction: Transient Elastography (TE) is a well-validated, non-invasive method to assess hepatic fibrosis and steatosis using liver stiffness measurement (LSM) and controlled attenuation parameter (CAP), respectively. However, due to interobserver variability, uncertainties still exist regarding the reliability and reproducibility of the technique especially in obese patients.

Aims & Methods: We aimed to evaluate the interobserver agreement of transient elastography in overweight and obese patients with Nonalcoholic Fatty Liver Disease (NAFLD).

We conducted a cross-sectional study including obese patients with NAFLD. We analyzed the results of TE performed by two different experienced operators, on two different days, within the same month. For each patient, the probe size (M or XL) used in both exams was the same; the weight remained stable and all patients had normal liver function.

LSM was recorded after obtaining at least 10 valid readings, a success rate ≥ 60% and an interquartile range to a median ratio (IQR/M) < 0.3. We classified the risk for advanced fibrosis as low, indeterminate and high, based on EASL guidelines 2021, which were respectively: <8 kPa, ≥8 and < 12 kPa, and ≥12 kPa. Hepatic steatosis was defined by CAP values ≥ 248 dB/m.

Results: Sixty-eight patients were recruited (70.6% female) with a mean age of 53.21±12.9 years. The mean body mass index (BMI) was 42.05±9.57 kg/m2 and the mean waist circumference (WC) was 119.51±22.07 cm. 10.4% of patients were overweight, 18.8% were obese and 70.8% were severely obese.

There was no statistically significant difference in both mean LSM (7.3 vs 6.9 kPa; P=0.475) and mean CAP values (313 vs 309.8 dB/m; P=0.507), assessed by the first and the second operators, respectively. The measurements made by operators of LSM and CAP were correlated [(Spearman's ρ = 0.512; P< 0.001) and (Spearman's ρ = 0.525; P< 0.001), respectively]. The interobserver intraclass correlation coefficient was 0.860 (95% CI 0.772-0.914) for LSM and 0.710 (95% CI 0.526-0.822) for CAP values. A discrepancy of at least 2 kPa between both results was noted in 30 cases (44.1%). There was no statistically significant difference in mean IQR/M values between the two exams (0.14 vs 0.12; P=0.15). The discordance between operators was 16.2% for at least one level of risk of advanced fibrosis and 14.7% for two levels.

In fact, among the patients considered with a high risk of advanced fibrosis by the first operator, 60% had low risk, 20% had indeterminate risk and 20% had high risk, assessed by the second one. For those who had an indeterminate risk of fibrosis, according to the measurements made by the first operator, 60% of them were at low risk of advanced fibrosis, based on those made by the second one.

Among those at low risk of advanced fibrosis assessed by the first operator, 8.7% had a high risk of advanced fibrosis as measured by the second one. Interobserver reliability values were κ = 0.32 for low risk of advanced fibrosis, κ = 0.12 for indeterminate risk, and κ = 0.16 for high risk for advanced fibrosis. The interobserver discrepancy in LSM was significantly associated with LSM (P=0.001), BMI (P<0.001), and WC (P=0.025).

Conclusion: Although TE is a very convenient method to assess liver fibrosis and steatosis in clinical practice, the interobserver discrepancy in results was not negligible, especially in severely obese patients and mainly for indeterminate and high risk of advanced fibrosis, which represents a significant problem with the technique. Thus, the evaluation of liver fibrosis, including TE results, should be carefully analyzed by expert hands.

Introduction: The neutrophil-to-lymphocyte (NLR) ratio is a marker of systemic inflammatory response, which has been studied as an interesting prognostic biomarker in various tumor types. This ratio incorporates two immune systems: neutrophils which exemplify the continual inflammation and lymphocytes which exemplify the regulatory pathway.

Aims & Methods: The aim of our study was to establish the correlation between NLR, the severity of cirrhosis and the occurrence of complications. This is a retrospective descriptive study including all patients followed for cirrhosis between January 2015 and January 2021.

Results: 60 patients were collected during the study period. The mean age at the time of diagnosis was 52 ± 14.88 (26-87) years. Fifty-three patients (53.3%) were female. Etiologies found for cirrhosis were: hepatitis B virus infection in 30% of cases, primary biliary cholangitis in 16.7%, non-alcoholic steatohepatitis in 11.7%, hepatitis C virus infection in 8.3 % of cases and alcohol intake in 1.7% of cases. The aetiological assessment was negative in 28.3% of cases. The average MELD score at admission was 42 points (9-80). Cirrhosis was classified as CHILD A in 19 cases, CHILD B in 31 cases and CHILD C in 10 cases. Endoscopic signs of portal hypertension were present in 95% of cases at the time of diagnosis, of which 33% were represented by grade 1 esophageal varices, 35% by grade 2 esophageal varices and 3.3% by grade 3 esophageal varices. 11.7% of the patients had gastric varices and 48% of the patients had hypertensive gastropathy. Ascites was the main complication present in 66.7%.

The other complications of cirrhosis were upper gastrointestinal bleeding by rupture of esophageal varices in 28.3% of cases, hepatic encephalopathy in 16.7% of cases and hepatocellular carcinoma in 11.7% of cases. The average NLR score was 4.4 (0.82-22.7).

The analytical study had shown that the RNL ratio was positively correlated with the MELD score with (p = 0.03); as well as with the occurrence of cirrhosis complications (p=0.05). However, there was no correlation between NLR and CHILD score (p=0.29.)

Conclusion: In our study, the neutrophil-to-lymphocyte (NLR) ratio was significantly correlated with the MELD score and the occurrence of complications and can thus be used to assess the prognosis of cirrhotic patients.

Introduction: Non-alcoholic steatohepatitis (NASH) is a chronic liver disease characterized by liver steatosis and inflammation which abnormal immune responses involved in pathogenesis, and there is no approved therapeutic drug. Rhein, one of the main bioactive components of Rheum palmatum, has exerted anti-inflammatory properties. However, the mechanism by which Rhein exerts beneficial effects against NASH is far from elucidated.

Here, our study aimed to investigate the therapeutic effects of Rhein on liver steatosis and inflammation and elucidate the related mechanisms of immunoregulation.

Aims & Methods: Male C57BL/6 mice were given high-fat diet for 10 weeks to induce NASH, followed by Rhein suspension administration at a dose of 100mg/kg and 200mg/kg for 4 weeks. The therapeutic effect of NASH was estimated by body weight, liver weight, LW/BW, food intake, the liver appearance and the histological analysis of liver section stained with hematoxylin and eosin. The proportion of lymphocyte cells in the mesenteric lymph nodes (MLNs) was detected by flow cytometry.

Results: Our findings demonstrated that high-fat diet treatment resulted in severe liver inflammation and severe steatosis, while Rhein appreciably reverse these phenomenon, as evidenced by the reduction of body weight, liver wet weight, LW/BW, and liver size in mice. Histological analysis of liver section revealed that administration of Rhein exhibited improvement of severe steatosis, elimination of inflammatory cells and resolution of balloon-like changes when compared to mice in the HFD group. Interestingly, there were no significant differences in food intake among groups of mice, suggesting that the protective effect of Rhein is not achieved by inhibiting appetite. Mechanistically, flow cytometry analysis showed that higher Th1 and Th17 polarized response were detected in the MLN compartments in HFD-induced mice, evidenced by the detection of increased numbers of

Th1 cells (CD3+CD4+IFN-ɣ+) and Th17 cells (CD3+CD4+IL-17+), and Rhein intervention showed significant decrease numbers of Th1 and Th17 in MLNs. In contrast, Rhein treatment significantly increased the numbers of Treg cells (CD3+CD4+Foxp3+) with anti-inflammatory effects in the MLN of NASH mice.

Conclusion: Our results provide novel insights into the protective role of Rhein in modulating the liver steatosis and inflammation, with therapeutic potential for immunology-targeted strategy in the treatment of NASH.

ETHANOL-PRODUCING LACTOBACILLACAE CONTRIBUTE TO LIVER DAMAGE IN METABOLIC DISEASE AND COUNTERACT THE EFFECTS OF LIFESTYLE INTERVENTION

J. Su[1], K. Krishnadath[2], Z. Ma[3], M.P. Peppelenbosch[1]

Introduction: The gut Lactobacillaceae have been shown to drive the onset of fatty liver disease[1], through a mechanism by which dietary carbohydrates are fermented into ethanol. Increased levels of Lactobacillaceae provoke high levels of portal blood ethanol and in turn promote the development of metabolic dysfunction-associated fatty liver disease (MAFLD) [1,2,3]. Although the potential importance of ethanol production by the microflora is well recognized, the implications on the clinical course of MAFLD remain obscure at best. A systematic study comparing Lactobacillaceae levels and liver condition has not been performed.

Furthermore, while lifestyle intervention is the mainstay in the clinical management of MAFLD, its effects on the levels of Lactobacillaceae remain unknown, prompting investigations in this respect. Such studies, however, are complicated by the potential consumption of alcoholic beverages by the study subjects involved[1], hampering the interpretation of results.

Aims & Methods: We examine the relationship of the Lactobacillaceae with circulating risk biomarkers for MAFLD in alcohol-free-use individuals (for religious reasons), who underwent time-restricted food intake (Ramadan). Microbiome determinations were performed by bacterial 16S rRNA sequencing.

Results: A total of 271 fecal samples were longitudinally collected from 93 individuals who subjected themselves to 30 days of intermittent fasting for religious reasons (a cohort of healthy volunteers [n = 35]; a cohort of morbidly obese individuals [n = 18]; and a cohort of patients with type 2 diabetes [n = 40]). The mean age of the cohort was 44.3 years (SD = 8.10), consisting of 51.6% males (n = 48).

Firstly, we observed in the participants that intermittent fasting is not effective in influencing the levels of Lactobacillaceae in all three cohorts (one-way ANOVA followed by multiple comparisons using Bonferroni corrections, $P_{adj} > 0.2$ for all intra-comparisons). Strikingly, however, when compared to healthy controls, a significant fraction of patients with type 2 diabetes shows high levels of alcohol-producing Lactobacillacea ($p < 0.0001$) suggesting that such bacteria contribute to the onset of disease. Furthermore, a significant correlation between GGT levels and the Lactobacillaceae component in the microbiome was observed ($R = 0.18$, $P = 0.002$).

Interestingly, significant correlations of this bacterial with both glucose ($R = 0.32$, $P < 0.0001$) and HbA1c ($R = 0.28$, $P < 0.0001$) were also observed, in line with the notion that hepatic insulin resistance induced by the gut microbiome-derived ethanol is an important contributor to liver damage in the context of MAFLD[3,5]. In a multivariable model, glucose levels were shown to have the largest effect size on the variation of the Lacbotacillaceae community ($R^2 = 1.60$ %, $p_{adj} < 0.001$), with age contributing an additional 1.06% to the Lactobacillaceae microbiome variation ($P_{adj} = 0.004$). GGT tends to exert a moderate contribution to the variation of this community ($P_{adj} = 0.099$). However, intermittent fasting as a prominent external lifestyle factor is not identified as a significant contributor in this respect ($P_{adj} = 0.254$).

Conclusion: Overall, while the Lactobacillaceae clearly emerges as a driver of liver damage in alcohol-abstaining individuals, our data suggest that lifestyle intervention is not sufficient to counteract Lactobacillaceae in MALFD calling for alternative approaches in the management of the patients involved.

MICROBIOLOGY OF PYOGENIC LIVER ABSCESSES – A NON-TROPICAL CENTRE'S EXPERIENCE

M. Teixeira[1], B. Bonito[2], R. Tavares[3], P. Rodrigues[3]

[1]Hospital de São Bernardo, Setúbal, Portugal, [2]Centro Hospitalar Barreiro Montijo, Barreiro, Portugal, [3]Hospital Beatriz Ângelo, Loures, Portugal

Contact E-Mail Address: madalenammteixeira@gmail.com

Introduction: Pyogenic liver abscesses (PLA) are the most common type of visceral abscesses. Microbiology of PLAs is diverse and microorganisms involved differ mostly due to factors related to the patient, pathogenesis and geographic differences. Treatment includes percutaneous abscess drainage and empiric broad-spectrum antibiotic that covers streptococci, gram-negative bacilli, and anaerobes.

Aims & Methods: We present a retrospective study of 115 patients with pyogenic liver abscesses (PLA) diagnosed and treated in a peripheral portuguese hospital, in Lisbon district, from January 2012 to December 2022. The aim of this study is to analyze microbiology of PLAs and antibiotic treatment in an European Centre. Amebic liver abscesses were excluded.

Results: Of the 115 patients included, the majority were men born in Portugal. The most common risk factors identified were biliary calculi (32%, N=36) and diabetes mellitus (27%, N=31). At the time of PLA diagnosis, 41% of the patients had bile duct obstruction and 32% had undergone biliary tract manipulation in the prior 30 days.

Around 10% of the PLAs were attributed to hematogenous seeding from the systemic circulation. Blood cultures were obtained in 73% of the patients (N=84), and only 33% were positive (N=38). The most frequent iso-

lated microorganisms in blood samples were Escherichia coli (34%, N=23) and Klebsiella Pneumoniae (17%, N=11). Only one extended-spectrum beta-lactamase bacteria (ESBL) was identified in the systemic circulation and no Klebsiella Pneumoniae Carbapenemase (KPC) was identified. 49% underwent CT or ultrasound-guided liver abscess drainage and culture of the collected fluid (N=57).

All abscesses larger than 5cm were drained. Drainage cultures were positive in 70% of patients (N=40). Around 60% of these patients had one microorganism isolated and the others had 2 to 4 microorganisms isolated. The most common isolated microorganisms in the drainage liquid were also Escherichia coli (22%, N=11) and Klebsiella Pneumoniae (16%, N=8). Three ESBL were detected in drained liquid cultures and no KPC was found. Piperacillin-Tazobactam (54%,N=63) was the most used empiric antibiotic followed by Meropenem (14%,N=16) and Ceftriaxone (12%, N=14). Piperacillin-Tazobactam was effective in 84% of patients, Meropenem was effective in 100% and Ceftriaxone was effective in 90%. Metronidazol was added to the previous antibiotics in 21% of cases (N=24); it was mostly added to Ceftriaxone and Piperacillin-Tazobactam, 64% and 17% of cases, respectively. The most frequent anaerobes identified were Fusobacterium Nucleatum and Bacterioides Fragilis.

All patients that had Fusobacterium Nucleatum identified had previous history of dental procedure (N=4). A total of 28 different microorganisms were isolated in blood and abscess drainage culture. The average antibiotic duration and was 24±9 days, which is similar to the average hospital length of stay: 24±15 days. 30-day mortality was 9% (N=10).

Conclusion: The diversity of pathogens associated to PLAs in a single centre reflects the different cause of each PLA. Escherichia coli and K. pneumoniae were the most commonly identified pathogens. Bacteremia was documented in 33% of cases and drainage culture was positive in 70% of cases. More than one microorganism was identified in 40% of drainage cultures. PLA are associated to significant use of broad-spectrum antibiotics, frequently unnecessarily.

Introduction: Hepatocyte sheet (HS) transplantation is expected to be an effective therapeutic strategy as an alternative to liver transplantation. We have developed a unique HS formation technique and have conducted study on the improvement of liver function (Miyamoto et al., Regen Ther. 2021). However, although HS has shown improvement in liver function for a short period of time, long-term functional improvement has not been achieved.

This may be due to the lack of multidimensional structures in existing hepatocyte sheets, although the liver maintains various functions by possessing unique structures such as sinusoids and biliary ducts. In fact, the lack of biliary structures in the HS may induce liver damage due to bile stasis. (Fujii et al., J Tissue EngRegen Med, 2018). In other words, the formation of bile drainage mechanism is considered an important issue to maintain long-term liver function. In parallel, we have established a biliary drainage system with a luminal structure in vitro using chemically induced hepatic progenitor cells (CLiPs) (Huang et al., Biotechnol Bioeng. 2021).

Aims & Methods: In this study, we attempted to develop a new novel Hepato-Biliary Sheet (HBS) based on our biliary drainage system and evaluated its structure and hepatic function.Mouse embryonic fibroblasts (MEFs) and GFP-positive rat-derived CLiPs were sequentially seeded in temperature-responsive culture dishes and cultured for 2 weeks to induce the biliary drainage system. HBS was formed by seeding and culturing primary mature rat hepatocytes. The HBS was then implanted on the liver surface of a mouse model of liver failure, which was created by administration of Retrorsine and 70% hepatectomy, and its structure and function were evaluated in vivo.

Results: First, immunofluorescence image analysis of the prepared HBS revealed a structure consisting of CLiP-derived bile ducts (GFP-positive) and mature hepatocytes (Alb-positive, Glutamine-positive). To evaluate the incorporation of bile into the HBS, a fluorescent reagent (Cell Tracker Orange) as a marker substance was added to culture medium and bile excretion via hepatocytes bile duct cells was observed 24 hours later. Compared to HS prepared from mature rat hepatocytes alone, drug metabolism (CYP3A4 activity) and albumin production were significantly improved. CYP3A4 activities in HBS and HS were 139.3±59.9 and 75.4±47.1 (LUM/hr) ($p<0.0001$) and albumin productions were 1.5±0.5×104 and 1.1±0.1 x104 (ng /day) ($p=0.005$), respectively. Next, when the HBS was transplanted to the liver surface in non-liver failure mouse, it was confirmed that a bile duct-like structure (CK7-positive) was maintained and that mature hepatocytes (ALB-positive) were adjacent to the bile duct-like structure, and that vascular components (CD34-positive) derived from mice were infiltrated, confirming long-term cell viability, at least 1 month. Finally, to evaluate the effect of transplantation in a mouse model of liver failure, rat albumin concentration in blood was measured, and the HBS transplantation group showed higher albumin concentration than the HS group at 7 days (9.5×10^5±8.2×10^5 ng/mL vs 5.8×10^5±6.1×10^4ng/mL, $P<0.05$) and 28 days (1.1×10^6±9.2×10^5 ng/mL vs 3.2×10^5±3.2×10^5 ng/mL, $P<0.05$),respectively.

Conclusion: We have observed formations of hepatocyte and bile duct structure in HBS which is confirmed to have biliary drainage and drug metabolizing activities. HBS are expected to improve liver function, and to play a valuable role in the treatment of liver diseases through regenerative medicine.

Introduction: Although Crohn's disease (CD) patients are expected to be at high risk for developing NAFLD, because of their altered nutrition state and some CD medication, little is known about prevalence of this condition in this population.

Aims & Methods: The aim of our study was to describe the prevalence of hepatic steatosis and fibrosis in patients with Crohn's disease and to assess their risk factors.

This was a cross-sectional, descriptive study including patients with CD, diagnosed since at least one year. We excluded patients known to have chronic liver disease or a condition that could lead to it (chronic alcoholism, viral infection with hepatotropic viruses, portal thrombosis, etc.). Patients included were at least in clinical remission. Elastometry and Controlled Attenuation Parameter (CAP) measurement were made in all patients, using a fibroScan® with an XL probe. Data were collected and analyzed by SPSS software version 26.

Results: We included 100 patients, 55 men and 45 women with a mean age of 42 ± 12 years. Seven patients had diabetes and 4 had hypertension. Forty-one patients were smokers. The mean duration of CD was 11.09 years. The disease was ileal, colonic or ileocolic in 39%, 24% and 29% of cases respectively. An upper gastrointestinal tract's involvement was observed in 7 patients and ano-perineal lesions was observed in 36 patients. The phenotype was inflammatory, stricturing and fistulizing in 55%, 21% and 24% of the patients respectively. Almost half of our patients (45%) had already received at least one course of corticosteroids. CAP measurement had shown S1, S2 and S3 stage steatosis in 8%, 3% and 7% of patients respectively. Factors associated with the presence of hepatic steatosis were diabetes (p=0.002, OR=15), presence of overweight or obesity (p=0.005, OR=4,71), age over 35 years at the time of study (p=0.038). ALT level greater than 10.75IU/L was also associated with the presence of hepatic steatosis (p=0.04). Several factors related to corticosteroid courses were associated with the presence of hepatic steatosis such as a duration shorter than 18 months since the last corticosteroid course (p=0.038), maximum achieved prednisolone dose of more than 55mg/d (p=0.04) and duration on full dose of corticosteroids exceeding 4.5 weeks (p=0.016). FibroScan® showed a fibrosis stage F1 in 4% and F2 in 7%. Elasticity in the remaining patients was less than 6 Kpa. The factors associated with the presence of F1 and/or F2 fibrosis were: diabetes (p=0.003, OR=16), age at the time of the study of more than 51.5 years (p=0.049) as well as an age of more than 36.5 years at diagnosis (p=0.020).

Conclusion: Apart from the known epidemiological factors associated with steatosis and hepatic fibrosis, our study showed that features related to corticosteroid therapy were associated with hepatic steatosis in patients with CD.

Introduction: An international expert panel recently proposed a new name for fatty liver disease, namely metabolic (dysfunction)-associated fatty liver disease (MAFLD), and a new definition regardless of alcohol consumption. In a large cohort study using the National Health and Nutrition Examination Survey III database, the definition of MAFLD was found to be more practical than the criteria for non-alcoholic fatty liver disease (NAFLD) for identifying subjects with fatty liver who are at high risk of advanced hepatic fibrosis.

The prevalence of NAFLD is approximately 25% of the world's adult population, and the global prevalence of MAFLD is estimated to be even higher. Therefore, MAFLD is commonly managed in the primary care setting. In view of the economics of health care, the ability to detect hepatic steatosis in a noninvasive, non-imaging manner is desirable. The fatty liver index (FLI), which is calculated using the body mass index (BMI), waist circumference (WC), and levels of ɣ-glutamyl transferase (GGT) and triglycerides, is a noninvasive and simple surrogate diagnostic marker for hepatic steatosis. The FLI has good capability for discriminating NAFLD. Furthermore, the FLI has been recommended as a biomarker to detect hepatic steatosis in subjects with MAFLD.

Although a few studies have examined the validity of the FLI in the diagnosis of MAFLD none have mentioned the amount of alcohol consumed. The predictive power of the FLI in moderate drinkers has not been determined to date; however, because moderate drinkers are so numerous, we considered that an analysis of this group is essential. In addition, alcohol consumption shows a complex association with hepatic steatosis, with substantial differences by race/ethnicity and sex. In the present study, we investigated the usefulness of the FLI as a noninvasive marker to predict hepatic steatosis according to alcohol consumption and sex in a large number of Asian subjects.

Aims & Methods: This study was performed to investigate the utility of the fatty liver index (FLI) as a noninvasive tool for predicting hepatic steatosis based on alcohol consumption and sex in a large Asian population.

We conducted a single-center observational cohort study at the HITO Medical Center in Japan and enrolled 1,976 Asian subjects. The participants were categorized into non-drinkers and light drinkers (0–19 g/day) and moderate drinkers (20–59 g/day) based on their self-reported alcohol intake.

We used physical examinations, laboratory tests, and a questionnaire to collect information on various factors related to the FLI, including body mass index, waist circumference, and levels of ɣ-glutamyl transferase and triglycerides.

Results: The diagnostic accuracy of the FLI was assessed by calculating the area under the receiver operating characteristic curve (AUROC), and optimal cutoff values were determined using Youden's index. The FLI had an acceptable performance index of >0.7 both overall and in all subgroups, with an overall AUROC of 0.844. The AUROCs were higher in women and moderate drinkers of both sexes. We also compared the cutoff values obtained in the present study with the previously reported values of 30 and

60. Optimal cutoff values for the FLI were calculated for the total population and subgroups and were found to differ from the previously established values in other countries.

Conclusion: Our study suggests that the FLI is a useful noninvasive marker for predicting hepatic steatosis in a large Asian population, irrespective of alcohol consumption and sex.

ASSESSMENT OF URINARY VOLATILE ORGANIC COMPOUNDS: A NON-INVASIVE TOOL FOR DISCRIMINATION OF TYPE 2 DIABETES MELLITUS (T2DM) AND METABOLIC DYSFUNCTION ASSOCIATED FATTY LIVER DISEASE (MAFLD)-FREE T2DM

M. Romeo[1], M. Dallio[1], M. Cipullo[1], P. Vaia[1], F. Di Nardo[1], F. Scognamiglio[1], L. Ventriglia[1], A. Coppola[1], A. Federico[1]

Contact E-Mail Address: mariomeo@virgilio.it

Introduction: Volatile organic compounds (VOCs) derived from gut dietary non-starch polysaccharides fermentation become detectability in biological fluids due to the impairment of the gut permeability ("leaky-gut syndrome") occurring in several pathological contexts such as insulin-resistance (IR)-related chronic disorders. The urinary VOCs profile, configuring a specific disease biosignature, has been proposed as a useful non-invasive diagnostic tool. In Metabolic dysfunction Associated Fatty Liver Disease (MAFLD) affected patients, IR and Diabetes Mellitus Type 2 (T2DM) crucially promote the progression, according to the disease's natural history, from simple steatosis (SS) to steatohepatitis (NASH) and advanced fibrosis.

However, despite the crucial role exerted by IR, MAFLD patients may be characterized by IR stigmata without T2DM as well as T2DM subjects may not be affected by hepatic steatosis.

Aims & Methods: In the present study, the differences in the urinary VOCs profile of T2DM, MAFLD, and MAFLD/T2DM patients were investigated and compared to define the MAFLD/T2DM group's characteristics and to find out new features occurring when these two conditions coexist, otherwise not detectable in each pathological state. We consecutively enrolled T2DM, MAFLD, and MAFLD/T2DM patients. For each participant, anthropometrical, biochemical (including insulin levels assessment), and clinical data were recorded. A sample of morning urine after overnight fasting was also collected. The samples were immediately frozen and stored until the analysis. Headspace solid-phase microextraction (HS-SPME), coupled with gas chromatography-mass spectrometry (GC-MS), was used to identify VOCs in urine samples. Subsequently, VOCs previously isolated were profiled via a mass selective detector. VOCs classification was performed by matching mass spectra within the available database libraries and comparing their retention indices (RI) with literature data.

Results: 13 T2DM, 13 MAFLD, and 13 MAFLD/T2DM patients were enrolled. All patients presenting hyperinsulinemia (insulin >24 microU/ml). VOCs profiles obtained by using acid pH extraction did not show statistical differences among the analyzed groups, while VOCs acquired in alkaline conditions revealed differences among the three groups.

The multivariate and univariate data analysis showed 21 metabolites levels statistically significantly different in the urine of MAFLD/T2DM compared to T2DM (p=0.021) and MAFLD (p=0.031) subjects. Among these metabolites, 1-pentanol (A16), Pyridine (N5), Dimethyl sulfone (S3), and 1-piperidine carboxaldehyde (N19) were higher in MAFLD/T2DM subjects compared to T2DM patients; 3-heptanone (K10) and 3-octane (K13) were lower in MAFLD/T2DM subjects than MAFLD patients; 2-hexanone (K6) presented lower levels in MAFLD/T2DM patients in comparison to T2DM subjects.

Conclusion: VOCs'profiling could non-invasively discriminate insulin-resistant T2DM, MAFLD, and MAFLD/T2DM patients. Moreover, the highlighted different VOCs' signatures suggest specific pathogenetic mechanisms in MAFLD and T2DM to explore and remark MAFLD and T2DM coexistence as not the mere sum of two diseases.

PREVALENCE OF SARCOPENIA IN PATIENTS WITH METABOLIC-ASSOCIATED FATTY LIVER DISEASE (MAFLD)

T. Mullikapipat[1], A. Pulsombat[1], D. Warodomwichit[1]
[1]Ramathibodi Hospital, Mahidol University, Division of Gastroenterology and Hepatology, Department of Medicine, Bangkok, Thailand

Contact E-Mail Address: mullikapipat@gmail.com

Introduction: Metabolic-associated fatty liver disease (MAFLD) and sarcopenia are closely associated with insulin resistance and inflammatory cytokines. However, the relationship between MAFLD and sarcopenia remains unclear. The purpose of this study was to investigate the prevalence of sarcopenia in MAFLD, as well as the relationship and association between muscle mass and hepatic steatosis.

Aims & Methods: Bioelectrical impedance analysis (BIA), transient elastography, dynamometer and 5-time chair stand test were measured in 91 patients with MAFLD (37 men and 54 women). Sarcopenia was defined according to the criteria of the AWGS: low ASMI and low hand grip or high on the 5-time chair stand test. The Spearman's correlation coefficient was calculated for muscle mass and hepatic steatosis.

Results: A total of 91 patients with MAFLD were analyzed. The prevalence of sarcopenia in MAFLD was 11% (5 men and 5 women). Sarcopenia patients had significantly lower hepatic steatosis than patients without sarcopenia (263±47.53 vs 299.42 ± 34.44, P=0.004). Body mass index and HOMA-IR were significantly associated with low risk for sarcopenia (OR 0.51; [95%CI 0.34-0.78], P=0.002, OR 0.26; [95%CI 0.08-0.84], P=0.024). There were significant positive correlations with muscle mass, percentage of body fat, and hepatic steatosis (r = 0.34; P 0.001, r = 0.21; P = 0.042, respectively).

Conclusion: In the study, prevalence of sarcopenia in MAFLD was 11%. BMI and HOMA-IR associated with low risk for sarcopenia. Low muscle mass was not correlated with severity of hepatic steatosis. However, the high percentage of body fat has a significant correlation with severity of hepatic steatosis, especially in the obese population.

NONALCOHOLIC FATTY LIVER DISEASE IN LEAN SUBJECTS: CLINICAL , EPIDEMIOLOGICAL AND METABOLIC FEATURES

S. Souissi[1], C. Makni[1], M. Ellafi[1], R. Tlili[1], L. Belhajammar[1], S. Nsibi[1], L. Kallel[1]
[1]*Mahmoud Matri Hospital, Gastroloenterology, Ariana, Tunisia*

Introduction: Non-alcoholic fatty liver disease (NAFLD) has become the most common chronic liver disease. It has been strongly connected to metabolic syndrome, and for many years, fatty liver was considered to be an exclusive feature of obese patients.

However, recent studies have highlighted the presence of NAFLD in non-obese subjects, with or without increased visceral fat or even in lean subjects without increased waist circumference.

"Lean NAFLD" is a relatively new concept and there is significant scientific interest in understanding the differences in pathophysiology, prognosis and management compared with NAFLD in overweight/obese patients.

Aims & Methods: The aim of our study was to compare the epidemio-clinical and metabolic features of lean and obese NAFLD patients. We conducted a comparative observational study of all patients referred to our departement to evaluate their liver elasticity using Fibroscan®.

A simultaneous measurement of steatosis was performed by the Controlled Attenuation Parameter (CAP) of Fibroscan®.

The threshold used to define the presence or not of steatosis was 245 dB.

A measurement of the metabolic parameters (Cholesterol, TG, Glycemia) was performed.

Our study population was then divided into 2 groups:

Group 1 (G1): a lean NAFLD group (BMI < 25 kg/m^2)

Group 2 (G2): an overweight or obese NAFLD group (BMI >= 25 kg/m^2).

A descriptive and comparative study (p significant if <= 0.05) was performed between the two groups.

Results: We included 317 patients with a mean age of 52.31 +/- 13.40 years old. The prevalence of NAFLD in the overall population was 58%. Among the 184 subjects with NAFLD, 19% had a BMI <25 Kg/m^2.

G1 consisted of 35 patients (19%) with a mean age of 50.3 +/-13.06 years old, a sex ratio M/F of 1.05 and a mean BMI of 23.08 +/- 1.2 Kg/m^2. G2 was composed of 149 patients (81%) with a mean age of 53.13 +/- 11.7 years old , a sex ratio M/F of 0.5 and a mean BMI of 32.4 +/- 1.5 Kg/m^2.

When comparing the two groups, we found that lean patients with NAFLD were significantly younger than the obese NAFLD patients (50.3+/-13.06 years old versus 53.13+/- 11.7 years old ; p=0.02). Regarding biological parameters, the mean triglycerides and fasting plasma glucose (FPG) were significantly higher in G1 patients than in G2 patients with mean values of (1.9 mmol/l versus 1.6 mmol/l; p=0.03); (8.3 mmol/l versus 6.4 mmol/l; p=0.01) respectively. Liver function disturbances were greater in G1 patients than in G2 patients with mean levels of AST, ALT, PAL and GGT (56 versus 40 ; p=0.4); (66 versus 45; p=0.3); (458 versus 179; p=0.02); (123 versus 61; p= 0.09) respectively. The prevalence of advanced fibrosis was similar in both groups at 1.8% (p=0.6).

Conclusion: Our study suggests that NAFLD is more severe in lean subjects than in obese subjects and is associated to more hepatic and extrahepatic metabolic disturbances. That is why clinicians must be particularly cautious with these patients who had a healthier metabolic profile but seems to have a worse prognosis.

Disclosure: Nothing to disclose.

Introduction: Patients with non-alcoholic fatty liver disease (NAFLD) are at a higher risk of developing cardiovascular disease (CVD).

Aims & Methods: This study aimed to determine if there is an association between increased steatosis and fibrosis with a higher risk of CVD in patients with diabetes mellitus (DM). This study enrolled 288 patients with DM who were over 40 years of age, between January and August 2023, after excluding viral hepatitis, cirrhosis, and cancers. Patients provided written informed consent and underwent clinical measurements and answered questions about their past medical history. The following measurements and data were taken: body weight (BW), body mass index (BMI), waist circumference (WC), laboratory data, presence of hypertension, dyslipidemia, alcohol consumption, and smoking.

The degree of steatosis was estimated using the fatty liver index {FLI, $(e^{(0.953\times\ln(\text{triglyceride, TG})+0.139\times\text{BMI}+0.718\times\ln(\text{gamma-glutamyltrasnsferase, GGT})+0.053\times\text{WC}-15.745)})/(1+e^{(0.953\times\ln(\text{TG})+0.139\times\text{BMI}+0.718\times\ln(\text{GGT})+0.053\times\text{WC}-15.745)})\times100$}, hepatic steatosis index {HSI, 8x(alanine aminotransferase (ALT)/aspartate aminotransferase (AST) ratio+BMI (+2, if female; +2, if diabetes mellitus)}, and controlled attenuation parameter (CAP by FibroScan®). The degree of fibrosis was estimated using the fibrosis-4 (FIB-4) index, NAFLD fibrosis score (NFS), and liver stiffness (LS by FibroScan®). CVD was defined as ischemic heart disease or hemorrhagic or ischemic stroke. The past history of CVD was asked and reported by trained nurses and chart review.

Results: The mean age was 60±9 years old, and the proportion of males was 54.9% (n=158). The mean CAP and LS values were 273±48 dB/m and 6.8±3.5 kPa, respectively. The CAP values were correlated with BW (r=0.473, p<0.001), BMI (r=0.618, p<0.001), WC (r=0.565, p<0.001), FLI (r=0.603, p<0.001), and HSI (r=0.622, p<0.001). The LS values were cor-

related with BW (r=0.230, p<0.001), BMI (r=0.446, p<0.001), WC (r=0.371, p<001), and FIB-4 (r=0.419, p<0.001). The LS values were not correlated with NFS. Ninety three (32.3%) patients had CVD and 57 patients were male. The mean age (62±9 vs. 58±9 years, p=0.001), BW (73.2±13.2 vs. 69.1±12.9 kg, p=0.013), BMI (27±4.1 vs. 25.6±3.7 kg/m^2, p=0.004), and WC (91.5±10 vs. 87.7±9.6 cm, p=0.002) were higher in patients with CVD than in those without CVD. The prevalence of HTN (81.7% vs. 41.5%, p<0.001) and dyslipidemia (75.3% vs. 61.5%, p=0.021) were also higher in patients with CVD.

However, the prevalence of alcohol consumption (18.3% vs. 26.7%) and smoking (48.4% vs. 47.7%) were not different between the two groups. The CAP value (275±48 vs. 271±49 dB/m), FLI (51±29 vs. 43±27), and HSI (39±6 vs. 38±6) were not different between the two groups. The LS value (7.4±3.8 vs. 6.5±3.3 kPa, p=0.049) and FIB-4 (1.5±0.9 vs. 1.2±0.7, p=0.006) were higher in patients with CVD than those without CVD.

However, NFS (-0.8±1.2 vs. -1.1±3.1, p=0.335) was not different between the two groups. Multivariate logistic regression analysis revealed that age [odds ratio (OR): 1.059, 95% confidence interval (CI): 1.023-1.095, p=0.001], hypertension (OR: 4.843, 95% CI: 2.611-8.985, p<0.001), and BW (OR: 1.032, 95% CI: 1.008-1.056, p=0.008) were significant risk factors for CVD. However, the LS and FIB-4 were not risk factors for CVD.

Conclusion: In contrast to the steatosis, the fibrosis estimated by LS and FIB-4 were associated with the risk of CVD in patients with DM. However, multivariate analysis did not show the LS and FIB-4 as risk factors for CVD.

Disclosure: Nothing to disclose.

PP1288

ASSOCIATION OF CONTROLLED ATTENUATION PARAMETER AND LIVER STIFFNESS WITH CHRONIC KIDNEY DISEASE IN PATIENTS WITH DIABETES MELLITUS

H. Lee[1], O.S. Kwon[1], S.K. Shin[1], K. Lee[1], Y.S. Eom[1], B.-J. Kim[1], Y.S. Kim[1], J.H. Kim[1]

[1]Gachon University Gil Medical Center, Incheon, South Korea

Introduction: Patients with nonalcoholic fatty liver disease (NAFLD) have a higher risk of chronic kidney disease (CKD).

Aims & Methods: This study aimed to investigate whether the degree of steatosis and fibrosis is associated with an increased risk of CKD in patients with diabetes mellitus (DM). Between January and August 2023, 324 patients with DM were enrolled in the study, after excluding those with viral hepatitis, cirrhosis, and any cancers. Patients provided written informed consent, underwent several clinical measurements, and provided past medical histories. Body weight (BW), body mass index (BMI), waist circumference (WC), laboratory variables including serum creatinine and estimated glomerular filtration rate {eGFR, 175 × Serum Cr$^{-1.154}$× age$^{-0.203}$ × 1.212 (if patient is black) × 0.742 (if female)}, presence of hypertension, and dyslipidemia were investigated.

The degree of steatosis was estimated using the fatty liver index {FLI, ($e^{(0.953\times\ln(\text{triglyceride, TG})+0.139\times\text{BMI}+0.718\times\ln(\text{gamma-glutamyltrasnsferase, GGT})+0.053\times\text{WC}-15.745)}$)/(1+ $e^{(0.953\times\ln(\text{TG})+0.139\times\text{BMI}+0.718\times\ln(\text{GGT})+0.053\times\text{WC}-15.745)}$)×100}, hepatic steatosis index {HSI, 8x(alanine aminotransferase (ALT)/aspartate aminotransferase (AST) ratio+BMI (+2, if female; +2, if diabetes mellitus)}, and controlled attenuation parameter (CAP by FibroScan®). The degree of fibrosis was estimated using fibrosis-4 (FIB-4) index, NAFLD fibrosis score (NFS), and liver stiffness (LS by FibroScan®). CKD was defined as eGFR less than 60 mL/min/1.73m^2.

Results: The mean age of the patients was 57±12 years, and 54.9% (n=178) were male. The mean CAP and LS values were 276±50 dB/m and 7.0±3.7 kPa, respectively. CAP values were correlated with BW (r=0.524, p<0.001), BMI (r=0.625, p<0.001), WC (r=0.592, p<0.001), FLI (r=0.637, p<0.001), and HSI (r=0.653, p<0.001). LS values were correlated with BW (r=0.364, p<0.001), BMI (r=0.531, p<0.001), WC (r=0.46, p<001), and FIB-4 (r=0.3, p<0.001), but not correlated with NFS. Twenty-nine (8.9%) patients had CKD, of whom 14 were male. Patients with CKD were older (mean age: 63±11 vs. 56±12 years, p=0.005) and had a higher prevalence of hypertension (79.3% vs. 49.8%, p=0.002) compared to those without CKD. AST (29±22 vs. 30±20 IU/L), ALT (36±39 vs. 37±27 IU/L), GGT (40±30 vs. 44±73 IU/L), and HbA_1C (7.3±1.3 vs. 7.3±1.4%) were not different between the two groups.

The prevalence of dyslipidemia (75.9% vs. 63.4%), BW (73±15 vs. 72±15 kg), BMI (28±4 vs. 27±5 kg/m^2), and WC (92±11 vs. 90±11 cm) were also not different between the two groups. CAP value (273±55 vs. 276±50 dB/m), FLI (49±29 vs. 48±29), and HSI (40±7 vs. 39±7) were not different between the two groups. LS value (7.0±2.2 vs. 7.0±3.8 kPa), NFS (-1.0±1.3 vs. -1.2±2.6), and FIB-4 (1.3±0.6 vs. 1.2±0.8) were also not different between the two groups.

Multivariate logistic analysis revealed that age [odds ratio (OR): 1.047, 95% confidence interval (CI): 1.008-1.088, p=0.019] and hypertension (OR: 3.260, 95% CI: 1.274-8.339, p<0.014) were the independent risk factors for CKD.

Conclusion: The steatosis estimated by CAP and the fibrosis estimated by LS were not associated with the risk of CKD in patients with DM.

Disclosure: Nothing to disclose.

Introduction: As the most common form of chronic liver disease, the increasing prevalence of non-alcoholic fatty liver disease (NAFLD) is a global concern. NAFLD and obesity are independently related to an increased risk for atherosclerotic cardiovascular disease (ASCVD), the primary cause of mortality in NAFLD patients. Even though many subjects with NAFLD are normal weight, it still remains uncertain whether their ASCVD risk is of major importance.

Aims & Methods: The aim of this study is to assess and compare the ASCVD risk between lean and obese patients with NAFLD. Normal weight and obese patients were evaluated between January 2020 and February 2023 and their data was analyzed. NAFLD was diagnosed by vibration-controlled transient elastography (VCTE) with controlled attenuation parameter (CAP) and the American College of Cardiology/American Heart Association guidelines was used to evaluate the ASCVD risk. Moreover, medical history and biochemical data were collected.

Results: In total, 221 patients were included in the final analysis. In the obese group, 164 (63.8%) patients were diagnosed with NAFLD, compared to 57 (12.3%) in the lean population. In comparison to those with obese NAFLD, subjects with lean NAFLD had significantly higher ASCVD scores (mean 15.3% vs 22.7%, p<0.001). Moreover, subjects with lean NAFLD and significant liver fibrosis had a higher risk of ASCVD events, compared to their obese counterparts (OR, 2.51 vs 1.95, p=0.034).

On the other hand, in terms of liver stiffness measurements, the prevalence of at least significant liver fibrosis was substantially higher in the obese group. Regarding the presence of the components of the metabol-

ic syndrome, the prevalence of type 2 diabetes mellitus was higher the obese group, while changes in the lipid profile and higher systolic blood pressure were more frequently found in lean subjects.

Conclusion: The ASCVD scores of subjects with lean NAFLD were significantly higher than those with obese NAFLD. The presence of significant liver fibrosis was a notable risk factor associated with an ASCVD event in both study groups, but the effects were more pronounced in individuals with a low body mass index.

Disclosure: Nothing to disclose.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common liver condition, and liver biopsy is considered the gold standard to diagnose and stage the disease [1].

However, the risks associated with the invasive procedure limit its widespread use, making noninvasive methods for assessing the severity and progression of fibrosis essential in pediatric NAFLD cohorts [2].

Aims & Methods: To investigate the levels of transforming growth factor-beta 1 (TGF-β1) and glycosaminoglycans (GAGs) in obese children with NAFLD and assess their diagnostic accuracy.

94 children aged 9 to 17 years (average age 12.15 ± 2.51 years) were examined. According to the transient elastography data (FibroScan®502touch, Echosence, France) and body mass index, children were divided into four groups:1 group - 27 obese NAFLD children with fibrosis ≥F1, group 2 - 35 obese NAFLD children without fibrosis, group 3 - 18 obese children without NAFLD and fibrosis. Group 4 (control) comprised 14 children with normal weight without NAFLD and liver fibrosis.

Serum transforming growth factor-beta 1 (TGF-β1) levels were evaluated by enzyme-linked immunosorbent assay (ELISA) using the IBL International (Germany) test system, and glycosaminoglycans (GAG) levels were determined spectrophotometrically. ROC analysis was performed for cut-off values calculation.

Results: The highest level of TGF-β1 was found in 1 group children –up to 153.4 (99.7; 189.1) pg/ml, which was significantly higher than in 2 group-72.4 (53.1; 111.3) pg/ml (p<0,05), 3 group - 74.0 (50.6; 99.4) pg/ml (p<0,05) and 4 group - 56.1 (46.0; 77.4) pg/ml (p<0,05).

Moreover, 1 group of children demonstrated increased GAG content up to 4.50 (3.21; 4.60) mmol/L (p<0,05). ROC analysis revealed that cut-off serum TGF-β1 96.8 pg/ml predicted liver fibrosis in NAFLD children.

The area under the curve (AUROC) was 0.787 (p<0.001), the sensitivity of the test was 80.0%, and the specificity was 65.7%. The threshold GAG value for fibrosis was 4.24 mmol/L (sensitivity 70.6%, specificity 69.6%, AUROC 0.743 (p<0.01)).

Conclusion: TGF-β1 and GAG are reliable noninvasive fibrosis markers in children with NAFLD, allowing for their use in liver fibrosis screening.

Introduction: Ataxia-telangiectasia (AT) and ataxia-oculomotor apraxia (AOA), which are both autosomal recessive cerebellar ataxia disorders, are characterized by elevated serum alpha-fetoprotein (AFP) levels. However, the source of this increase, its potential clinical consequences, and its relationship with liver diseases remain unknown.

This study explored the prevalence of liver diseases and how they contributed to increased AFP in patients with AT and AOA.

Aims & Methods: Eighteen adult patients with AT or AOA followed up between January 1992 and March 2023 were included in the study. Demographic data, clinical findings, liver enzymes, AFP levels, and liver and brain imaging were reviewed retrospectively.

Results: Data of 13 (72%) AT and 5 (28%) AOA patients were analyzed. The mean age of 11 (61%) male and 7 (39%) female patients was 27.3±4.8, and the median age at diagnosis was 7.5 (2-23). The most common clinical findings were ataxia (78%) and dysmetria (56%), and cerebellar atrophy was present in 8 patients who underwent brain imaging. During a mean follow-up period of 15.2±9.1 years, 5 (28%) patients died; 4 (22%) patients had malignancy (1 ALL, 1 pancreatic cancer, 1 gastric cancer and 1 glioblastoma mutliforme) and 1 (6%) patient had sepsis.

Liver enzyme elevation was present in half of the patients; ALT/AST in 2 patients, ALP/GGT in 7 patients. Ultrasonography revealed normal findings in the liver in 7 (58%) of 12 patients, hepatomegaly and hepatosteatosis in 4 (33%), and hemangioma in 1 (8%) patient.

One of the 2 patients who underwent liver biopsy had chronic active hepatitis and biliary tract injury, and the other patient had granulomatous hepatitis. Serum AFP level was higher than normal in all patients and the median value was 121 (12-913) ng/ml. The AFP level of AT patients [226 (41-913) ng/ml] was significantly higher than that of AOA patients [19 (12-42) ng/ml] (p=0.006). There was no significant relationship between AFP level and age (p=0.437), gender (p=0.568), elevated liver enzymes (p=0.534), hepatosteatosis (p=0.913), or cancer history (p=0.31).

Conclusion: Half of the patients with cerebellar ataxia have elevated liver enzymes and one-third have hepatosteatosis. Although AFP was high in all patients, none developed primary liver cancer during the 15.2±9.1 years follow-up period. The causes of death in these patients are non-hepatic cancers and sepsis.

Disclosure: Nothing to disclose.

PP1292

SCREENING FOR ADVANCED LIVER DISEASE IN THE DISEASE MANAGEMENT PROGRAM FOR TYPE 2 DIABETES

M. Michel[1], M. Doll[1], N. Albert[1], C. Labenz[1], P.R. Galle[1], J. Schattenberg[1]
[1]*University Medical Centre Mainz, Metabolic Research Program, I. Department of Medicine, Mainz, Germany*

Contact E-Mail Address: maurice.michel@icloud.com

Introduction: Type 2 diabetes mellitus (T2DM) is associated with end-organ injury and is a major risk factor for non-alcoholic fatty liver disease (NAFLD) and advanced liver disease. Despite the high relevance of NAFLD in T2DM, it remains unconsidered in the routine screening of T2DM-related comorbidities in the German diabetes disease management program (DMP).

Aims & Methods: The aim of this prospective cohort study was to assess the prevalence of liver disease from NAFLD and associated clinical risk factors in primary care centers participating in the diabetes DMP in Germany. A total of 175 participants with the diagnosis of T2DM were enrolled in two primary care outpatient centers within the diabetes DMP. The prevalence of steatosis, fibrosis, and cirrhosis was assessed non-invasively using vibration-controlled transient elastography (VCTE). Steatosis was defined as a controlled attenuation parameter (CAP) of ≥ 275 dB/m. Liver fibrosis and cirrhosis were defined as a liver stiffness measurement (LSM) of ≥ 8 kPa and ≥ 15 kPa, respectively. Multivariable logistic regression analysis with stepwise selection was performed to identify clinical predictors of liver fibrosis and cirrhosis.

Results: The majority of participants were male (62%, n = 109), and the median age was 66 years (IQR 59; 71). The median BMI was 31.1 kg/m^2 (IQR 27.7; 35.3), with 58.9% (n = 103) of the participants being obese. The median HbA1c was 7.0% (IQR 6.5; 7.8). The prevalence of hepatic steatosis, fibrosis, and cirrhosis was 77.1%, 42.3%, and 12%, respectively. NAFLD was identified in the majority of participants (69.9%; n = 121).

Obese individuals showed the highest median LSM values (11.3 kPa, IQR 9.4; 16.2). In multivariable logistic regression analysis, obesity was associated with increased odds of hepatic fibrosis (OR = 4.818, 95% CI 2.243-10.350) and cirrhosis (OR = 3.873, 95% CI 1.073-13.977). Although higher blood levels of HbA1c correlated with liver fibrosis, it did not remain an independent predictor.

Conclusion: The prevalence of advanced liver disease is high within the diabetes DMP in Germany. People with T2DM and obesity are at an increased risk to exhibit liver fibrosis, and eventually cirrhosis. Building on VCTE for risk stratification within the DMP would allow identifying the subgroup recommended for intensified management.

Disclosure: Nothing to disclose.

Contact E-Mail Address: Alinamircea.popescu@gmail.com

Introduction: Early detection and staging of liver steatosis is important for establishing prognosis of patients with fatty liver.

The aim of this study was to evaluate two new quantitative ultrasound (QUS) parameters, TSI (tissue scatter-distribution imaging) and TAI (tissue attenuation imaging) for steatosis assessment, as compared to controlled attenuation parameter (CAP).

Aims & Methods: A prospective study was conducted in which liver steatosis was assessed in the same session by QUS (Samsung Medison RS85, CA1-7A probe) and CAP (FibroScan Compact M 530, M/XL probes) in 275 patients [59%(162) males, mean age 55.9±12.2 years]. Reliable measurements were defined for CAP as the median value of 10 measurements with IQR/M<0.3. For QUS, five consecutive measurements of TAI and TSI were acquired by a color-coded map overlaid on B-mode ultrasound. TAI and TSI were automatically calculated and considered reliable when reliability index, R^2>0.6. The CAP cut-off value to identify the presence of at least mild steatosis was 248 dB/m.

Results: Reliable measurements were obtained in 100% of cases both by CAP and TAI/TSI. Moderate correlations were observed between TSI vs. CAP r=0.56, and TSI vs. TAI, r=0.49. The best cut-off values to identify at least mild steatosis were: for TAI>0.73 (AUROC=0.87, p<0.0001, Se=67.6%, Sp=95.1%, PPV=96.9%, NPV=56.1%), for TSI>96.5 (AUROC=0.84, p<0.0001, Se=76.9%, Sp=82.9%, PPV=91.1%, NPV=61.3%).

Conclusion: TAI and TSI are feasible methods for assessing liver steatosis, with good accuracy to diagnose at least mild steatosis

Contact E-Mail Address: htkani@yahoo.com

Introduction: This paired biopsy study aimed to investigate the predictive value of various non-invasive scores for identifying the temporal evolution of hepatic fibrosis in patients with non-alcoholic fatty liver disease (NAFLD).

Aims & Methods: A total of 69 patients with NAFLD who had undergone two paired liver biopsies (mean interval: 21.3 ± 9.7 months) were examined. Fibrosis progression and regression were defined as an increase or decrease of at least one stage in fibrosis between the initial and second biopsy. Fibrosis-4 index (FIB-4), NAFLD Fibrosis Score (NFS), Agile 3+ score, Agile 4 score, and FibroScan-AST (FAST) score were calculated at the time of the initial biopsy.

Results: Upon comparing the results of paired biopsies, 45% of the participants (n = 31) showed no change in fibrosis, 26% (n = 18) experienced fibrosis progression, and 29% (n = 20) had evidence of fibrosis regression. In multivariable logistic regression analysis, the only independent predictive factor for progressive fibrosis was the FAST score. The odds ratio for progressive fibrosis was found to increase by 19% (95% confidence interval: 8–38%, p < 0.05) with every unit increase in FAST score at the time of the initial biopsy. No independent predictors for fibrosis regression were identified.

Conclusion: Patients with higher baseline FAST scores were more likely to experience fibrosis progression independent of potential confounders. Consequently, FAST could serve not only as a diagnostic tool for screening fibrosis in NAFLD, but also as a prognostic indicator.

Disclosure: Nothing to disclose.

PP1295

PREVALENCE AND MEANING OF AN ELEVATED FIB-4 IN PATIENTS REFERRED TO A TERTIARY HOSPITAL

I. Rodrigues[1], R. Ortigão[2], D. Nunes[3], C. Lemos[3], M. Moura[1], S. Carvalhana[1], H. Cortez-Pinto[4,1]

[1]Centro Hospitalar e Universitário de Lisboa Norte, Gastrenterology and Hepatology Department, Lisboa, Portugal, [2]Institute Portuguese of Oncology, Gastrenterology, Porto, Portugal, [3]Centro Hospitalar e Universitário de Lisboa Norte, Clinical Pathology Department, Lisboa, Portugal, [4]Faculdade de Medicina de Lisboa, Clínica Universitária de Gastrenterologia, Lisbon, Portugal

Contact E-Mail Address: mines.bcrodrigues@gmail.com

Introduction: Liver biopsy remains the gold standard for fibrosis diagnosis and liver elastography is an accurate method for non-invasive evaluation, although often unavailable. FIB-4, a fibrosis index based on age, AST, ALT and platelet count, is increasingly used to predict advanced fibrosis, mostly in primary care. There are different cut-offs, however considering Non-Alcoholic Fatty Liver Disease (NAFLD) patients FIB-4 <1.30 was able to exclude advanced fibrosis, while FIB-4 >2.67 presented good positive predictive value. For populations older than 65years old, a cut off of 2.0 was advocated.

Aims & Methods: We aim to evaluate this tool on a tertiary hospital.

Using a tertiary hospital database of blood workup we selected the 3575 blood collections in ambulatory patients between 1st-31st august 2021 with laboratory data for FIB-4 calculation. We excluded patients under 18 years, those followed on Haematology, and those with AST or ALT >100 UI/L. We considered only the first blood collection for each patient in this period. On our study we compared patients according to FIB-4 value respective of their association with chronic renal disease, dyslipidaemia and altered glucidic metabolism. We investigated what percentage of those with FIB-4 >1.3 were followed on Gastroenterology.

Results: During the study period, among 3213 blood collections that fulfilled the criteria, 1290 (40.1%) had a FIB-4 >1.3. Male gender (51.4% vs 37.7%, p<0.001) and older age (70.1 vs 49.4, p>0.001) were significantly associated with FIB-4 >1.3. FIB-4 >1.3 associated with glomerular filtration rate (GFR) <90ml/min/1.73m^2 (p<0.001), chronic renal disease (GFR<60ml/min/1.73m^2) (p<0.001), serum cholesterol >200mg/dL (p=0.22) and serum glucose >130 mg/dL. (p=0.003). There was no difference in ALT values (p=0.513) but on AST (p=0.001). Only 12.9% of patients with FIB-4>1.3 had a Gastroenterology appointment in our institution.

On a subgroup analysis for patients older than 65 years old, 405 (31.4%) patients had a FIB4 >2.0 among 1286. Male gender (48.8% vs 57.1%, p=0.005) and age (73.3 vs 80.0, p=0.005) significantly associated with FIB-4 >2.0. FIB-4>2.0 associated with GFR <90ml/min/1.73m^2 (p<0.001), GFR <60ml/min/1.73 (p=0.003) and cholesterol >200mg/dL (p=0.001) but no difference on glucose >130mg/dL (p=0.192). There was no difference in ALT values (p=0.695) but on AST (p=0.001).

Conclusion: Using the lower cut-off for FIB4, it is frequently elevated in referrals to a tertiary hospital. FIB-4 is associated with declining GFR and disturbances on lipid and glucose metabolism. Awareness of FIB-4 tool, may help recognizing the risk of advanced liver disease in patients and suspect renal disease or diabetes, as part of NAFLD phenotype.

Disclosure: Nothing to disclose.

PP1296

THE IMPACT OF ALPHA-1-ANTITRIPSIN DEFICIENCY AND PI*Z ALLELE IN LIVER FIBROSIS

A.I. Ferreira[1,2,3], T. Lima Capela[1,2,3], S. Xavier[1,2,3], J.L.T.M. Magalhães[1,2,3], C. Guimarães[4], C. Marinho[1,2,3], J. Berkeley Cotter[1,2,3]

[1]Hospital Senhora da Oliveira, Gastroenterology, Guimarães, Portugal, [2]School of Medicine, University of Minho, Life and Health Sciences Research Institute (ICVS), Braga, Portugal, [3]PT Government Associate Laboratory, ICVS/3B's, Braga/Guimarãesport, Portugal, [4]Hospital Senhora da Oliveira, Pneumology, Guimarães, Portugal

Contact E-Mail Address: ai.voferreira@gmail.com

Introduction: Alpha-1-antitripsin deficiency (AATD) is a codominant autosomal hereditary condition that predisposes patients to the development of pulmonary and/or hepatic disease, with Pi*Z mutation being the most clinically relevant.

Aims & Methods: Our aim was to evaluate the impact of AATD and Pi*Z allele in hepatic fibrosis.

Prospective, cohort, single-centred study including adult patients with AATD followed in Pneumology or Hepatology consultation. A control group was created with patients without liver disease. Liver fibrosis was assessed through non-invasive methods via serum tests, NAFLD fibrosis score (NFS) and Fibrosis-4 (FIB-4) index, and transient elastography.

Results: A total of 98 patients were included, 69 with AATD (70.4%) and 29 controls (29.6%). In the AATD group, the median value of alpha-1-antitripsin (AAT) at diagnosis was 67 mg/dL and the presence of at least one Pi*Z allele occurred in 55 patients (79.7%).

Patients with AATD regardless of genotype had a significantly higher liver stiffness measurement (LSM) compared to controls, although in both groups without significant liver fibrosis (median 5.0 vs 3.8kPa, p<0.001). Additionally, patients with AATD had significantly higher aspartate-transaminase (AST) (median 25 vs 17 UI/L, p<0.001) and alanine-transaminase (ALT) (median 29 vs 18 UI/L, p<0.001), with the two groups having values within normal range. The same occurred with alkaline phosphatase (ALP) (median 71 vs 59 UI/L, p<0.001) and gamma-glutamyl transferase (GGT) (median 25 vs 20 UI/L, p=0.007).

AAT values at diagnosis showed a negative and weak correlation with NFS (s=-0.327, p=0.007), as well as with FIB-4 index (s=-0.309, p=0.011). AAT value at diagnosis equal or superior to 77 had a sensitivity of 0.944 and specificity of 0.646 in predicting a NFS value that excludes advanced liver fibrosis (AUC 0.681; p=0.025).

In patients with at least one Pi*Z allele, the presence of diabetes mellitus was associated with 8 times higher likelihood of significant liver fibrosis with LSM≥7.1kPa (p=0.035). Furthermore, patients with at least one Pi*Z associated with both metabolic syndrome and alcohol consumption (>25 grams daily) had significantly higher NFS values (-1.18±1.45 vs -2.43±1.30, p=0.006) and FIB-4 index values (median 1.41 vs 1.0, p=0.011), being 6.55 times more likely to have an intermediate to high risk of advanced fibrosis, according to NFS (p=0.008).

Conclusion: Patients with alpha-1-antitripsin deficiency had higher liver stiffness and higher levels of serum transaminases, ALP and GGT. Alpha-1-antitripsin values at diagnosis were associated with NFS and FIB-4 index during follow-up. In patients with Pi*Z mutation, the presence of diabetes mellitus, metabolic syndrome and alcohol consumption was significantly associated with significant liver fibrosis, highlighting the need for controlling these coexisting comorbidities in this subset of patients.

Introduction: There are conflicting epidemiological studies on the association between selenium and metabolic disorders. Higher selenium intake and blood levels have been associated with an elevated risk of diabetes [1], hyperlipidemia [3], hypertension [4], and NAFLD [5].

Nonetheless, some evidence suggested no or a negative association between selenium and the risk of NAFLD or diabetes [6].

Aims & Methods: Due to the limited evidence and conflicting data, we aimed to perform the present cross-sectional study to investigate the association between dietary selenium intake and NAFLD in the general population of Kavar County. A total of 3026 subjects from the PERSIAN (Prospective Epidemiological Research Studies in IrAN) Kavar cohort study were included in the analysis.

The daily selenium intake was evaluated using a semi-quantitative food frequency questionnaire, and energy-adjusted quintiles of selenium intake (μg/day) were calculated. NAFLD was defined as the fatty liver index (FLI) ≥60 or the hepatic steatosis index (HSI) >36. The association between dietary selenium intake and NAFLD was evaluated using logistic regression analysis.

Results: The prevalence rates of NAFLD were 56.4% and 51.9%, based on the FLI and HSI markers, respectively. The odds ratios (ORs) for FLI-defined NAFLD were 1.31 (95% confidence interval (CI): 1.01–1.70) and 1.50 (95% CI: 1.13–1.99) for the fourth and fifth quintiles of selenium intake, respectively, after adjustment for sociodemographic variables, smoking status, alcohol drinking, physical activity, and dietary factors (P trend=0.002). There was also a similar association between selenium intakes and HSI-defined NAFLD (OR=1.34 (95% CI: 1.03–1.75) for the fourth quintile and OR=1.50 (95% CI: 1.12–2.01) for the fifth quintile of selenium intake) (P trend=0.006).

Conclusion: In this large sample study, we observed a weak positive association between dietary selenium intake and NAFLD risk.

Introduction: Currently, non-alcoholic liver disorder (NAFLD) is the most predominant chronic liver disorder. NAFLD has been linked to hepatic and extra-hepatic morbidities.

The need for non-invasive prediction of hepatic and extra-hepatic consequences of NAFLD is a demand, due to the complexity of the disease, high burden, and the need for early intervention.

Aims & Methods: to investigate the role of serum microRNA-130b and liver stiffness [as measured by acoustic radiation force impulse (ARFI)], to non-invasively predict chronic kidney disease (CKD) in NAFLD patients.

Patients and Methods: In a case-control design, we included 40 NAFLD patients (20 NAFLD with CKD, and 20 NAFLD without CKD), and 20 healthy controls.

After clinical evaluation, laboratory assessments including liver test profile, renal function test, and quantification of microRNA-130b were done. Liver stiffness was evaluated using ARFI.

Results: The median values (interquartile range "IQR") of mRNA-130b in patients with NAFLD+CKD, patients with NAFLD without CKD, and healthy subjects were [32.10 (27.3 -37.3), 27.01 (24.8 – 31.7), and 25.36 (23.5 – 27.1), copies/μl, respectively, P <0.001].

The median (IQR) value of Liver stiffness as measured by ARFI was significantly higher among NAFLD with CKD patients compared to NAFLD without CKD [2.97 (2.87 – 3.3) vs. 2.45 (2.18 – 2.8) m/sec, P = 0.002]. The median (IQR) value of microRNA-130b was significantly higher among NAFLD with CKD patients compared to NAFLD without CKD [P = 0.032].

In the current study, ARFI readings were negatively correlated with platelet count (n = 40, rs = -0.33, P = 0.038). ARFI readings were positively correlated to serum mRNA-130b values in both groups (rs = 0.49, P = 0.02 and rs = 0.64, P = 0.002, respectively).

At a cut-off value > 28.13 copies/μl, microRNA-130b could differentiate between "NAFLD with CKD" and "NAFLD without CKD" patients with a sensitivity and specificity of 75%, and 70 %, respectively (AUC = 71.9 %, P = 0.018, 95% CI: 0.56 – 0.87).

Similarly, At a cut-off value > 2.81 m/sec, ARFI could differentiate between "NAFLD with CKD" and "NAFLD without CKD" patients with a sensitivity and specificity of 80% (AUC = 77.8 %, P = 0.003, 95% CI: 0.62 – 0.93).

Conclusion: MicroRNA-130b and liver stiffness measurements are suggested as potential markers for the prediction of CKD among NAFLD patients. Serum microRNA-130b, and ARFI are valuable non-invasive tools for the assessment of NAFLD severity.
Disclosure: Nothing to disclose.

Contact E-Mail Address: mirko.zonca@gmail.com
Introduction: Currently, about 25-30% of the world population is affected by non-alcoholic fatty liver disease (NAFLD); over time, about 20% tends to develop a certain degree of inflammation in the liver tissue, defying the non-alcoholic steatohepatitis (NASH).
Moreover, approximately 20% of NASH patients evolve into a high-grade liver fibrosis condition that leads to severe liver impairment (cirrhosis) (1, 2, 3).
The serial use of non-invasive fibrosis tests can refine prognosis in patients with non-alcoholic fatty liver disease (NAFLD) and evaluate the progression or improvement of liver fibrosis.
Aims & Methods: We evaluated predictors of improvement or worsening of liver stiffness measurements (LSM) in well characterized cohorts of patients with NAFLD from London (UK) and Milan (Italy).
We included two consecutive cohorts of 405 patients with at least two outpatient visits between 2014 and 2022. The minimum time interval between baseline and follow-up LSM was >6 months. LSM worsening was defined as an increase of >20% kPa if the baseline LSM was ≥5 kPa, or a follow-up LSM >6 kPa if the baseline LSM was <5 kPa. An LSM improvement was defined as an LSM decrease of >20% kPa (if the baseline LSM was >6 kPa).
A significant change in weight was defined as a >5% reduction or increase at follow-up, while a significant change in glycated hemoglobin (HbA1c) was defined as a >10% reduction or increase.
The variation between the true and expected FIB-4 index (based on the patient's age at the follow-up visit, but using the blood tests performed at the first visit) was calculated. A significant improvement or worsening in FIB-4 was defined as a >20% variation between the actual and "expected" FIB-4.
Results: Of the 405 patients, 282 (70%) were males; mean age was 54±11 years. The median time from the first visits was 20.3 (13.9 – 28.7) months.
128 and 54 patients had an LSM >8 kPa and LSM>12 KPa at follow-up, respectively.
77 patients (19.3%) had an LSM improvement, while 67 (16.8%) had an LSM worsening; 256 patients (63.9%) maintained a stable value.
In patients with an LSM improvement, 22 had an improvement, 12 had worsening, while 37 had stable FIB-4.
In patients with an LSM worsening, 10 had an improvement, 20 had worsening, while 33 had a stable FIB-4.
In multiple logistic regression analysis, LSM worsening was independently associated with an increase in ALT and in HbA1c levels (OR 1.02 and 1.03 respectively), but also with a reduction in total cholesterol and AST levels (OR 0.98 for both). LSM improvement was independently associated with weight and ALT reduction (OR 0.93 and 0.98 respectively), but also with an increased AST level (OR 1.02).
Conclusion: More than 35% of patients with NAFLD have significant changes in their LSM measurements over a period of 20 months, with worsening or improvement at similar rates. Improvement in weight is independently associated with significant improvement in LSM measurements. On the converse, worsening in metabolic comorbidities, particularly glycemic control, could be associated with significant worsening in LSM, further supporting a multidisciplinary model of care.

EFFECTS OF GLP1 ANALOGUES ON: WEIGHT LOSS, GLYCEMIC PARAMETERS; HEPATIC PARAMETERS, AND HEPATIC FIBROSIS IN "REAL LIFE SITUATION": RESULTS IN 132 TYPE 2 DIABETIC PATIENTS

H. Zougmore[1], J.F. Cadranel[1], G. Bellaiche[2], G. Fantognon[1], R. Smadhi[1], J.R. Ngele-Efole[1], P. Pulvermacher[1], D. Belloula[1], M. Medmoun[1], O. Nabi[3]
[1]GHPSO, Hepatology and Gastroenterology, Creil, France, [2]Centre Hospitalier Intercommunal, Hepatology and Gastroenterology, Aulnay-sous-Bois, France, [3]Washington University School of Medicine, Saint Louis, United States

Contact E-Mail Address: honoretz87@gmail.com
Introduction: Weight loss correlates with improvement in necroinflammatory lesions and fibrosis in patients (pts) with nonalcoholic steatohepatitis (NASH). The diabetic pts are often overweight or obese and the usual treatments (Metformin) have no effect on the weight loss. The analogues of Glucagon-like-peptide (GLP1), which are part of the treatments of type 2 diabetes, lead to frequent weight loss and have been shown to improve NASH lesions and/or fibrosis in several studies fibrosis in several studies [1,2]. This "real life" study aims to evaluate the effects of dulaglutide (Du) or semaglutide (Se) on weight loss, glycemic parameters, liver parameters, and liver injury in diabetic with NAFLD pts
Aims & Methods: Type 2 diabetic pts with NAFLD in two France hospital were included and monitored prospectively at a semi-annual rhythm after initiation of the Du or Se treatment proposed for the treatment of diabetes.
Weight, glycemic parameters, and liver enzymes were recorded at each visit, and liver injury was assessed prospectively at a semi-annual using Fibroscan® (FS), Fibrotest® (FT) or FIB-4.
Results: One hunded thirty two (132) type 2 diabetic with NAFLD pts (66 NASH), with mean age 60 years, and 52% of male were included.). 88.5% were treated with Du at a dose of 1.5 mg to 3 mg and 11.5% with Se at

a dose of 0.25 to 0.50 mg . The mean weight at inclusion was 93.8 kg (SD=19.6) and 44.3% of the pts were obese. Fifty percent (50%) of the pts had anti hypertensive treatment. Liver fibrosis was assessed in 39 patients using FS, 55 pts by FT and 90 pts by FIB-4.The baseline mean scores were 14.7 kPa (SD=11.3), 0.3 (SD=0.2) and 1.3 (SD=0.6) for FS, FT and FIB-4 respectively. Nineteen (19) pts had cirrhosis and 19 had F3 fibrosis stage. The average follow-up was 14 months (12-24) after the start of treatment. Weight decreased on average by 7.3 kg (SD=9.4, p<0.0001) and BMI by 2.6 kg/m2 (SD=3.7, p<0.0001).). Blood glucose and glycated hemoglobin decreased by 0.2 (p=0.35) and 0.2 (p=0.24), respectively.

ALT activity decreased by 12 U/L(SD=22, p<0.0001) and ASAT activity by 7 U/L (SD=13, p=0.0001). Sixty three percent (63%) pts had fibrosis reassessment after 1 year of follow-up. Elastometry score decreased by 2.4 kPa (SD=4.7 kPa, p=0.007); FT decreased by 0.03 (p=0.01) and FIB-4 by 0.06 (p>0.05).

There was a significant correlation between weight loss and elastometry score reduction (r=0.44; p=0.0104).

Conclusion: A significant decrease in weight, BMI, ALT, ASAT, elastometry score and FT were observed during the follow-up of patients treated with Du and Se. This real life study shows that GLP1 analogues could be one of the elements of the therapeutic management of NAFLD in type 2 diabetic pts.

Introduction: Patients with type 2 diabetes (T2D) have a high prevalence of non-alcoholic fatty liver disease (NAFLD) (1).

The most validated non-invasive method to assess liver steatosis and fibrosis is transient elastography (TE), whereas some new ultrasound-based technologies still lack substantial clinical evidence in this setting (2,3).

In this line we aimed to evaluate performance of Shear Wave Measurement (SWM) and Attenuation (ATT) Measurement by Fujifilm to diagnose liver steatosis and fibrosis in the cohort of patients with T2DM, using TE as the reference.

Aims & Methods: Consecutive outpatients with T2D (N=147) were referred for controlled attenuation parameter (CAP) and liver stiffness measurements (LSM) to assess the presence of liver steatosis and fibrosis by using TE. The presence of any grade of liver steatosis was considered in patients with CAP≥297 dB/m, and advanced fibrosis in those with LSM≥10 kPa by TE, which served as the reference method (4,5).

All consented patients also underwent SWM and ATT (by Fujifilm Arietta 65), as the investigated methods, and their results were compared to LSM and CAP as measured by TE.

All measurements were performed in fasting patients, whereas patients with conditions that might have influenced the results of LSM (ALT>5xULN, congestive liver disease, biliary obstruction, infiltrative liver neoplasms) were excluded.

Results: Of 147 included patients with T2D, 76 (51.7%) were females, average age 66, median Body Mass Index 30.5 kg/m^2, 113 (76,9%) had arterial hypertension, 111 (75,5%) dyslipidemia, 27 (18.4%) were smokers, 26 (17.7%) reported risky alcohol consumption. As for TE, M probe was used in 104 (70.7%) patients, median LSM was 5.9 kPa, median CAP 290 dB/m.

Any grade of steatosis (CAP≥297 dB/m) was detected in 62 (42,2%) patients, and advanced fibrosis (LSM≥10 kPa) in 17/145 (11.6%) patients by using TE. Median SWM was 5.5 kPa, and median ATT 0.62 dB/cm/MHz. We observed good correlation between LSM as measured by TE and SWM (Pearson's R=0.68, 95 CI: 0.58-0.76, p<0,001), whereas SWM produced lower (mean -0,7 unit, Bland-Altman) LSM values in comparison to TE.

SWM had AUROC of 0.905 at the LSM cut-off ≥ 8.3 kPa (Youden) to diagnose advanced fibrosis (sen. 76.5%, specif. 93.8%). LSM by SWM optimized for ruling-in and ruling-out advanced fibrosis were respectively ≥10.1 kPa (specif. 97%) and <6.2 kPa (sens. 94.1%). Presence of advanced fibrosis would be missed in 23.5%, 41.2% and 5.8% patients by using reported LSM cut-offs (≥ 8.3, ≥10.1 and <6,2 kPa respectively).

In multivariate analysis only platelet count (OR 0.979; CI 0.96-0.998, p=0.03) and LSM as measured by TE (OR 1.197; CI 1.031-1.391, p=0.02) were significantly associated with LSM measured by SWM.

Correlation between ATT and CAP was poor (Pearson' R=0.31, 95 CI: 0.16-0.45, p<0.001), as was the overall diagnostic performance of ATT to diagnose any grade of liver steatosis (AUROC 0.673 at the cut-off ≥0.66 dB/cm/MHz (Youden); sens. 56.5%, specif. 75.3%). ATT cut-offs optimized for ruling-in and ruling-out any steatosis were ≥0.75 dB/cm/MHz (specif. 89.4%), and <0.50 dB/cm/MHz (sens. 88.7%) respectively. Presence of any steatosis would be missed in 43.5%, 62.9% and 11.2% by using reported ATT cut-offs (≥0.66, ≥0.75 and <0.50 dB/cm/MHz respectively).

Conclusion: SWM reliably recognizes presence of advanced liver fibrosis in patients with T2D. The diagnostic performance of ATT was suboptimal, and this should be further investigated by using more reliable reference methods, such as liver biopsy or magnetic resonance.

SPLENIC STIFFNESS IN NON-ALCOHOLIC FATTY LIVER DISEASE: CORRELATION TO SERUM BIOMARKERS AND LIVER ULTRASOUND TECHNOLOGY OF FIBROSIS

H. Smaoui[1], B. Bouchabou[1], A. Medhioub[1], N. Hemdani[1], A. Nakhli[1], R. Ennaifer[1]
[1]*Mongi Slim Hospital, Gastroenterology, Tunis, Tunisia*

Contact E-Mail Address: hanou.smaoui@gmail.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) can progress to fibrosis and cirrhosis. The evaluation of fibrosis in chronic liver disease using non-invasive methods is a current topic. Standard methods are liver stiffness measurement and serum biomarkers. Splenic elasticity measurement is a recent and interesting non-invasive approach that arouses the interest of the latest studies to evaluate fibrosis severity in NAFLD.

The aim of this study is to identify patients with NAFLD and advanced liver fibrosis, by establishing correlations between splenic and liver elasticity and fibrosis serum biomarkers.

Aims & Methods: This is a prospective study conducted in the hepato-gastroenterology department including all patients followed for hepatic steatosis during the period from July 2022 to January 2023. Patients with a family or personal history of chronic liver disease, and women with acute steatohepatitis in pregnancy or cholestasis in pregnancy were excluded. Measurement of hepatic and splenic stiffness and the degree of hepatic steatosis was done using liver elastrography (Fibroscan®) and Transient elastography with controlled attenuation parameter (CAP), respectively. NAFLD fibrosis (NFS) and Fibrosis-4 scores were calculated. Data were entered and processed using SPSS software version 22.0.

Results: We included 44 patients, divided into 28 women and 16 men (Sex-ratio F/M = 1.75), with a mean age of 61.4 years [32 to 84 years]. Three patients were smokers and four were alcoholics. Hypertension was found in 56.8%, 54.5% were diabetics and 52.3% were dyslipidemics. The mean BMI was 29.6 kg/m^2±4.15 kg/m^2. Obesity was found in 45.5%, 36.4% were overweight and 18.2% of patients were normal weight. Hepatic steatosis was discovered following pain in the right hypochondrium in 79.5% of the cases and in front of a cytolysis in the remaining cases. All patients had diffuse steatosis without portal hypertension or degeneration signs on ultrasound.

Biological results showed cytolysis in seven patients. No patient had cholestasis. All patients had preserved liver function: normal prothrombin level and albumin. Hyperglycemia and lipid disturbance were observed in 43.2% and 36.4% of cases respectively.

Fibrosis was assessed by FIB4 score with a mean value of 1.11± 0.78; NFS score with a mean value of -1.16±1.18 and liver stiffness ranging from 2.4Kpa to 28.4Kpa (mean value 6.67Kpa). The degree of fibrosis judged by Fibroscan results was F0-F1 in 31 cases, F2 in 5 cases, F3 in 5 cases and F4 in 3 cases. Advanced fibrosis was correlated with NFS score (p=0.016), FIB-4 (p=0.001); but not associated with CAP value (p=0.51).

The mean splenic elasticity was 27.57 Kpa (ranging from 8.3 to 75 Kpa). It was significantly associated with liver elasticity (p=0.012) with an AUROC of 0.784. A threshold of 17.4 Kpa was predictive of advanced fibrosis with a specificity of 85.7% and a sensitivity of 73.5% (CI [0.029-0.404]). Similarly, splenic elasticity was correlated with CAP value (p=0.013). No association was identified with NFS and FIB4 scores.

Conclusion: Measurement of splenic elasticity is a simple and reliable non-invasive tool, comparable to liver elasticity, for the prediction of liver fibrosis during NAFLD.

Disclosure: no conflict of interest

RELEVANCE OF PNPLA3, TM6SF2, HSD17B13, AND GCKR GENOTYPES TO THE RISK OF NAFLD IN AN EGYPTIAN POPULATION

N. Elmansoury[1], A. Kamal[2], M. Labane[3], M. Abdel-Magiud[4], A.K. Daly[5], A. Wahid[1]
[1]*Alexandria University, Department of Pharmaceutical Biochemistry, Faculty of Pharmacy, Alexandria, Egypt,* [2]*Alexandria University, Department of Internal Medicine and Hepatology, Faculty of Medicine, Alexandria, Egypt,* [3]*Alexandria University, Faculty of Pharmacy, Alexandria, Egypt,* [4]*Alexandria University, Department of Experimental and Clinical Internal Medicine, Medical Research Institute, Alexandria, Egypt,* [5]*Newcastle University, Translational and Clinical Research Institute, Faculty of Medical Sciences, The Medical School, Newcastle, United Kingdom*

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a widespread clinical condition that affects about 1/4th adults globally. It can lead to liver fibrosis, cirrhosis, and hepatocellular carcinoma (HCC). More than one-third of Egyptians are affected by NAFLD. Unfortunately, many patients diagnosed with NAFLD after cirrhosis has already occurred.

Single Nucleotide Polymorphisms (SNPs) associated with NAFLD have been proposed to identify the causal variants of the disease and also as potential pharmacological targets. Heritability of NAFLD estimates range from 20% to 70% based on ethnicity, and environmental factors. The first gene variant found to be a consistent genetic risk factor for NAFLD was Patatin-like phospholipase domain containing 3 (PNPLA3) rs738409. In addition, other studies have shown that, Transmembrane 6 superfamily 2 (TM6SF2) rs58542926 and Hydroxysteroid 17-beta dehydrogenase 13 (HSD17B13) rs9992651 also affect risk of NAFLD developmen. Some studies also show a role for Glucokinase regulatory protein (GCKR) rs1260326.

Aims & Methods: We aimed to investigate genetic risk factors for NAFLD occurrence in Egyptian patients.

Cases of clinically diagnosed NAFLD (n= 205) and controls (n= 187) were recruited. A subgroup of individuals with NAFLD that had progressed to liver fibrosis (n= 131) was compared with the control individuals. TaqMan-based genotyping assays were employed to explore the association of selected SNPs (PNPLA3 rs738409, TM6SF2 rs58542926, HSD17B13 rs9992651 and GCKR rs1260326) with NAFLD in Egyptian patients.

Results: NAFLD cases versus controls genotype data: rs738409 -genotype showed statistical significance. Univariate analysis for TM6SF2 rs58542926, HSD17B13 rs9992651, and GCKR rs1260326 did not show statistical significance.

After adjusting for the other risk factors -age, gender, BMI, and waist circumference, the association of PNPLA3 rs738409 -genotype, and allele models- with the variant G allele more common in NAFLD remained statistically significant with an increased odds ratio. PNPLA3 rs738409 GG carriers have 5.296 times NAFLD risk than CC carriers. For GCKR rs1260326 genotype model, after correction for the other risk factors, the variant T allele acquired statistical significance.

Fibrotic-NAFLD cases versus controls genotype data: Univariate analysis for PNPLA3 rs738409 showed statistical significance. The univariate analysis for TM6SF2 rs58542926, HSD17B13 rs9992651, and GCKR rs1260326 did not show statistical significance.

After adjusting for the other risk factors -age, gender, BMI, and waist circumference, the association of PNPLA3 rs738409 -genotype, and allele models remained statistically significance with an increased odds ratio. Of note, PNPLA3 rs738409 GG carriers have 9.267 times higher risk of Fibrotic-NAFLD than CC carriers.The association of HSD17B13 rs9992651 -genotype model-with the variant A allele protective against fibrosis acquired statistical significance and decreased odds ratio. Notably, HSD17B13 rs9992651

GA carriers have a fibrosis risk 0.487 times less than GG carriers. The association of GCKR rs1260326 -genotype model, after correction for the other risk factors acquired statistical significance and an increased odds ratio.
Conclusion: We discovered that in our study population, PNPLA3 rs738409 and GCKR rs1260326 variants increase the risk of NAFLD generally as well as its progression to fibrosis. On the other hand, the HSD17B13 rs9992651 variant may protect against fibrosis development in NAFLD.

ROLE OF INULIN AS PREBIOTIC ON NONALCOHOLIC FATTY LIVER DISEASE

K. Kvit[1], N. Kharchenko[2], V. Kharchenko[2]
[1]Danylo Halytsky Lviv National Medical University, Therapy N 1, Medical Diagnostics, Hematology and Transfusiology, Lviv, Ukraine, [2]Shupyk National Helthcare University of Ukraine, Department of Gastroenterology, Dietology and Endoscopy, Kyiv, Ukraine

Contact E-Mail Address: akskris88@gmail.com
Introduction: The NAFLD prevalence is estimated to be near 25% of the world population. There is a theory that inulin intake can reduce endotoxemia. This prebiotic could increase the SCFA production by bacteria with further the pro-inflammatory markers decreasing in gut-liver axis. Thus, microbiota regulation by prebiotic treatment could be a key role player in NAFLD prevention.
Aims & Methods: The aim of the study was to compare the microbiome before and after 20 days of inulin intake in patients with NAFLD and to find the correlational relationship between prebiotics treatment and liver biochemical markers.
93 patients (44 men, 49 women), and 46.64±2.52 (average age) with NAFLD (based on liver transient elastography) were examined. All patients followed the recommendations of 5 mg Inulin per os twice a day for 20 days. The study excluded any other pre-, probiotics, and antibacterial drugs during the course of treatment. Before and after the treatment the next biochemical markers were examined: lipid profile, C-reactive protein high sensitivity, ALT, AST, GGTP, bilirubin, TNF-a, and HOMA index. Determination of microbial composition was carried out by identification of total bacterial DNA, and DNA of Bacteroidetes, Firmicutes, and Actinobacteria by quantitative real-time PCR (qRT-PCR), using gene-targeted primers.
Results: The microbiome of patients with NAFLD before Inulin intake (Figure 1): Bacteroidetes - 51%, Firmicutes - 28%, Actinobacteria 6%, F/B index - 1.62. After the treatment - Bacteroidetes 45%, Firmicutes 39%, Actinobacteria 10%, F/B index 1.29.
Biochemical tests before treatment (Figure 2): GGTP 42 U/L, Triglycerides 2.72 mmol/L, HDL 1.12 mmol/L, CRP (high sensitivity) - 9 mg/L, HOMA index 3.51.
After the treatment, GGTP decreased to 29 U/L, Triglycerides to 1.26 mmol/L, and CRP to 5 mg/L.
HOMA index to 3.12. HDL level increased to 1.36.
What was unexpected - in half of the patients (46) Candida was found in the microbiome. After the treatment - in 37 of them Candida was absent. Patients did not receive any antifungal drugs.
The growth of Actinobacteria was in a negative correlational relationship with Candida.
Conclusion: Inulin could be part of therapy, directed for steatohepatitis prevention in patients with NAFLD by influencing a few risk factors:
1. Decreasing the lipids
2. Reducing pro-inflammatory agents
3. Improvement the insulin sensitivity.

Additionally, Inulin could be a good microbiome-targeted drug for pathogenic microbiota regulation and potentially Candida eradication.
Disclosure: Nothing to disclose.

PP1305

THE ROLE AND PREVALENCE OF CANDIDA IN GUT MICROBIOME IN PATIENTS WITH NAFLD

K. Kvit[1], N. Kharchenko[2], V. Kharchenko[2], M. Aksentiychuk[1], V. Vozniuk[1], L. Mulka[3]
[1]Danylo Halytsky Lviv National Medical University, Therapy N 1, Medical Diagnostics, Hematology and Transfusiology, Lviv, Ukraine, [2]Shupyk National Helthcare University of Ukraine, Department of Gastroenterology, Dietology and Endoscopy, Kyiv, Ukraine, [3]St. Paraskeva Medical Center, Gastroenterology, Lviv, Ukraine

Contact E-Mail Address: akskris88@gmail.com
Introduction: The development of nonalcoholic fatty liver disease (NAFLD) is significantly influenced by genetic and environmental factors. Hepatobiliary diseases are associated with an imbalance of bacterial subpopulations and the associated deleterious effects on the colonized host. Otherwise, more and more evidence points to a close relationship between the composition of the microbiota and the development and progression of NAFLD.
The genus Candida and the species Candida albicans could play a central role in the pathogenesis and progression of fatty liver infiltration with further steatohepatitis progression by the impact on the gut-liver axis. For example, rodents colonized with C. albicans develop liver disease without additional stimuli.
Fungi might hence possibly exacerbate liver disease in a two-hit model, one hit being alcohol, the Western diet, or a toxin, and another hit being the presence and deleterious impact of fungi.
Aims & Methods: The aim of the study was to examine the prevalence of Candida and comporision of the gut microbiome in patients with NAFLD.
93 patients (44 men, 49 women), 46.64±2.52 (average age) with NAFLD (based on liver transient elastography) were examined.
The control group included 85 patients (45 men, 40 women), average age 49.5±2.3 without fatty liver infiltration and anothe liver disease.
Biochemical markers were: lipid profile, C-reactive protein high sensitivity, ALT, AST, GGTP, bilirubin, TNF-a, and HOMA index.
Determination of microbial composition was carried out by identification of total bacterial DNA, and DNA of Bacteroidetes, Firmicutes, Actinobacteria and Candida by quantitative real-time PCR (qRT- PCR), using gene-targeted primers.
Results: The prevalence of Candida in patients with NAFLD was 35% in comparing the control group, where the prevalence was 13%.
The Bacteroidetes level was significantly higher in controls (45,54±5,49 vs.21,10±3,39).
Actinobacteria (22,13±2,47 vs 14,53±2,75), F/B index (4,02±1,00 vs 1,82±0,45) in patients with NAFLD was above than in controls. F/B index growth was leading to the triglycerides (TG) (r=0.53), ALT (r=0.61) and VLDL (r=0.4) increasing.
Microbiota of the control group played a protective role by reducing aggressive factors - the Actinobacteria growth led to the decreasing of GGTP (r=-0.42), direct bilirubin (r=-0.34) and CRP (r=-0.36). F/B index growth caused the decreasing of GGTP (r=-0.36) and TNF-a (r=-0.29).
There was the positive correlational relationship between Candida and F/B index (r=0.63), and Candida and TG (r=0.56) and TNF-a (r=0.8) in patients with NAFLD. Surprisingly, there was no significant correlational relationship in the control group between Candida and biochemical and microbial markers.

Conclusion: The prevalence of Candida in gut microbiota of patients with NAFLD is significantly higher than in patients without fatty liver infiltration (36% vs. 13%).

The Candida growth can impact TNF-a and TG increasing in patients with NAFLD.

Candida could be associated with F/B index growth in patients with NAFLD. Such results are potentially interesting for the search of personalized approaches in treatment and prevention the NAFLD. The role of gut microbiome is one of the important parts of the fatty infiltration development pathogenesis.

SERUM FIBROSIS MARKERS IN OBESE CHILDREN WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Y. Stepanov[1], N. Zavhorodnia[2], O. Tatarchuk[3], I. Klenina[3], O. Petishko[3]

[1]Institute of Gastroenterology of NAMN of Ukraine, Cathedra of Gastroenterology, Dnipro, Ukraine, [2]SI "Institute Gastroenterology of NAMS of Ukraine", Pediatric Gastroenterology Department, Dnipro, Ukraine, [3]SI "Institute Gastroenterology of NAMS of Ukraine", Research Department, Dnipro, Ukraine

Contact E-Mail Address: nzavgorodni75@gmail.com

Introduction: The part of NAFLD children has a progressive sub-phenotype known as nonalcoholic steatohepatitis (NASH), characterized by the ability to develop advanced fibrosis, cirrhosis, and end-stage liver disease [1].

Given the high prevalence of NAFLD and invasiveness of the liver biopsy, there is an essential need to find safe non-invasive modalities to determine liver fibrosis in children [2].

Aims & Methods: To investigate serum fibrosis markers in obese children with non-alcoholic fatty liver disease (NAFLD) depending on the presence of liver fibrosis.

94 children aged 9 to 17 years (average age 12.15 ± 2.51 years) were included in the study. According to the transient elastography data (FibroScan®502touch, Echosence, France) and body mass index, children were divided into four groups: group 1 - 27 obese NAFLD children with fibrosis ≥F1, group 2 - 35 obese NAFLD children without fibrosis, group 3 - 18 obese children without NAFLD and fibrosis. Group 4 (control) consisted of 14 children with normal weight without NAFLD and liver fibrosis.

The serum levels of vascular endothelial growth factor (VEGF) (Wuhan Fine Biotech Co Ltd, China), transforming growth factor-beta 1 (TGF-β1) (IBL International, Germany), cytokeratin-18 (CK-18) (IDL Biotech AB, Sweden) were determined by enzyme-linked immunosorbent assay (ELISA). Serum content of hydroxyproline free (HPf) and hydroxyproline protein-bound (HPp/b) according to Osadchuk and glycosaminoglycans (GAG) according to Rimington were evaluated.

Results: In 1 group children, a significant increase in the median level of CK-18 (in 2.2 times, p<0.05), VEGF (in 2.4 times, p<0.05), and TGF-β1 (in 2.7 times, p<0.05) was found compared to 4 group children. Moreover, CK-18 level was significantly higher in 1 group of patients compared to 2 group (in 1.4 times, p<0.05) and 3 group (in 1.8 times, p<0.05). In all group children, an increase in the serum HPp/b content was found: in 1 group - in 1.2 times (p<0.01), in 2 group - in 1.2 times (p<0.05), in 3 group - in 1.3 times (p<0.05) compared to 4 group. The changes in the content of hydroxyproline led to an increase in the HPp/b/HPf ratio in all groups: 1.4 times (p<0.01) in 1 and 2 groups, in 1.3 times (p<0.01) in 3 group. Also, in 1 group of children median GAG level was increased by 1.3 times (p<0.001).

In children with NAFLD HPf content negatively correlated with CAP (r= -0.408; p<0.01), CK-18 (r=-0.469; p<0.01), the ratio HPp/b/HPf positively correlated with CAP (r=0.307; p<0.05). CK-18 positively correlated with fibrosis degree (according to METAVIR) (r=0.468; p=0.008) and liver steatosis degree (r=0.357; p=0.048). A positive correlation was also found between VEGF levels and the degree of liver fibrosis (r=0.372, p=0.036).

Conclusion: Serum levels of VEGF, TGF-β1, HPp/b, and GAG were significantly elevated in children with non-alcoholic fatty liver fibrosis. Assessment of these parameters may be useful for early diagnosis of liver fibrosis in children with NAFLD.

THE RELATIONSHIP BETWEEN ALCOHOL CONSUMPTION AND THE PRESENCE OF ADVANCED LIVER FIBROSIS IN THE GENERAL POPULATION

H.-O. Minea[1], C. Stanciu[1], S. Zenovia[1], R. Nastasa[1], E. Stratina[1], R. Stafie[1], A. Rotaru[1], C. Sfarti[1], S. Chiriac[1], A.M. Singeap[1], I. Girleanu[1], T. Cuciureanu[1], C.M. Muzica[1], C. Cojocariu[1], L. Huiban[1], A.-V. Trifan[1]

[1]University of Medicine and Pharmacy Gr.T.Popa/Institute of Gastroenterology and Hepathology Iasi, Gastroenterology, Iasi, Romania

Contact E-Mail Address: horia.minea@yahoo.com

Introduction: Although chronic alcohol consumption has progressively decreased in recent years, a third of people over 15 years declare at least one episode of excessive use every month, which ranks Romania on second position, with a rate of 35%, far above the average registered in the EU (20%). Therefore, Romania has one of the highest incidence rates of alcohol-related liver cirrhosis, which has become a major public health problem. This study aimed to investigate the prevalence of liver fibrosis in the asymptomatic alcohol-consuming population.

Aims & Methods: The study aimed to evaluate the relationship between advanced liver fibrosis measured by transient elastography, laboratory parameters, and the amount of alcohol consumed depending on non-modifiable risk factors such as age and gender. Between January 2022 and December 2022, we examined patients with day hospitalization in the Institute of Gastroenterology and Hepatology in Iasi, without liver history, who admitted a moderate or high consumption (women <7 versus >7 drinks/week; men <14 versus >14 drinks/week) for at least one year. The classification of the fibrosis stage by transient elastography was adjusted according to transaminase values. The results were analyzed by univariate analysis and logistic regression to establish models of prediction.

Results: The study included 689 patients with an average age of 49.32±14.31 years, a proportion of 63.7% represented by men. Advanced fibrosis (^{3} F3) was detected in 19.30% of the examined patients, predominantly in men (14.1%) and patients over 55 years old (12.5%). Excessive alcohol consumption is associated 2 times more with advanced fibrosis in women (OR=5.08; CI 95%: 3.45-9.50, p<0,001) and the group under 40 years old (OR=6.29; CI 95%: 1.67-9.43, p<0,001) compared to men (OR=2.27; CI 95%: 1.76-3.81, p=0,012) respectively patients over 55 years old (OR=3.21; CI 95% : 2.28-4.45 p<0,001). Using logistic regression, it was demonstrated that there was a strong correlation between advanced fibrosis, excessive alcohol consumption, low serum albumin level and the

reduction of triglycerides in men (R^2 Nagelkerke = 0.854; p<0.001) supplemented with the reduction of cholesterol in the age group 40-55 years (R^2 Nagelkerke = 0.785; p<0.001), respectively of ferritin in those over 55 years old (R^2 Nagelkerke = 0.804; p<0.001). The association of excessive alcohol consumption, age, low levels of albumin, LDL-cholesterol and C-reactive protein generated a significant predictive model (R^2 Nagelkerke = 0.784; p<0.001) for female patients.

Conclusion: Screening using transient elastography represents an approach that could provide early diagnosis of advanced liver fibrosis in an asymptomatic population, with the possibility to prevent the evolution of ALD and the development of complications of cirrhosis.

Introduction: Alcoholic steatohepatitis (ASH) is a severe form of alcoholic liver disease (ALD) characterized by the presence of steatosis and inflammation. Kinases p38 ɣ/δ have been found to be involved in liver steatosis and inflammation, and have a significant role in the development of non-alcoholic liver disease caused by high-fat diets.

Aims & Methods: The objective of this study was to investigate the role of p38 ɣ/δ kinases in a murine model of alcoholic steatohepatitis (ASH) and to analyze the reduction of steatosis and inflammation in p38 ɣ/δ knockout (KO) mice treated with ethanol (ETOH).

Wild-type (WT) and p38 ɣ/δ KO male mice were fed a chronic and binge ethanol diet (NIAAA model) to induce liver damage. Histopathological analysis was performed after Oil Red staining. The molecular effects of ethanol in the liver were explored through qPCR and western blot.

Results: Ethanol-treated KO (ETOH KO) mice showed a smaller liver size, decreased liver steatosis after histopathological analysis, and lower expression of inflammatory cytokines compared to ethanol-treated WT mice. The NIAAA diet caused oxidative stress and mTOR pathway activation in the liver in both ETOH WT and ETOH KO. ETOH WT mice had p62 phosphorylated at Thr269 and Ser272, which was reduced in ETOH KO mice.

Conclusion: The knockout of p38 ɣ/δ alleviates ALD in mice by reducing inflammation and steatosis. Alcoholic diet increased oxidative stress and inhibited autophagic pathways and p38 ɣ/δ KO restored, at least in part, this inhibition. EFFECT OF CELECOXIB ON SPLENOMEGALY IN CIRRHOTIC RATS BASED ON TRANSCRIPTOMIC ANALYSIS

S. Tang[1], L. He[1], A. Li[1], S. Yu[1], W. Chen[1]

[1]Chongqing University Cancer Hospital, Gastroenterology, Chongqing, China

Contact E-Mail Address: 812903560@qq.com

Introduction: Splenomegaly can exacerbate liver cirrhosis and portal hypertension. Thus, inhibiting splenomegaly may be a novel treatment for liver cirrhosis. We have previously demonstrated that cyclooxygenase-2 (COX-2) inhibitor can attenuate cirrhotic splenomegaly.

However, the transcriptome profiles and precise pathogenesis of cirrhotic splenomegaly remain unknown, and few effective therapies are available. The role and mechanism of cyclooxygenase-2 (COX-2) in cirrhotic splenomegaly remain unclear.

Aims & Methods: Aims: We attempt to identify the transcriptomic profile of cirrhotic spleen, providing comprehensive valuable information for pathogenesis of splenomegaly. And to further validate the protective role of celecoxib on cirrhotic splenomegaly.

Methods: Thirty male Sprague-Dawley rats were randomized into the control group, TAA and TAA+Celecoxib groups. The control group: received intraperitoneal injection of normal saline (1ml, twice a week); the TAA group: received intraperitoneal injection of thioacetamide (TAA, 200 mg/kg, twice a week for 16 weeks); the TAA+celecoxib group: received TAA intraperitoneally and celecoxib via gastric gavage (20 mg/kg/day). Splenic gene profiling was analyzed by high-throughput RNA sequencing.

Histological analysis of spleen tissue was evaluated by H&E, Sirius red, Prussian blue staining, and transmission electron microscopy. The splenic mRNA levels of collagen III and α-SMA and splenic contents of Ki-67 and VEGF were quantified.

Results: A total of 1461 differentially expressed genes (DEGs) were identified in the spleens of the TAA group compared to the control group. The immune response and immune cell activation might be the major signaling pathways involved in the pathogenesis of cirrhotic splenomegaly. With its immunoregulatory effect, celecoxib can ameliorate cirrhotic splenomegaly and liver cirrhosis.

Furthermore, 304 coexisting DEGs were obtained between TAA vs. control and TAA+celecoxib vs. TAA. According to GO and KEGG analyses, celecoxib may attenuate cirrhotic splenomegaly by suppressing splenic immune cell proliferation, inflammation, immune regulation, and fibrogenesis.

The impacts of celecoxib on splenic immune cell proliferation, inflammation, immune regulation, and extracellular matrix were then validated by the decreased splenic Ki-67-positive cells, macrophages, fibrotic areas, and mRNA levels of collagen III and α-SMA.

Conclusion: Celecoxib attenuates cirrhotic splenomegaly by inhibiting splenic immune cell proliferation, inflammation, and fibrogenesis. The current study further validate that COX-2 inhibitors could serve as a novel medical treatment for cirrhotic splenomegaly based on transcriptomic analysis.

Introduction: Chronic liver disease (CLD) is a disease of the liver that involves progressive destruction and regeneration of the liver parenchyma, leading to fibrosis and cirrhosis. Although liver fibrosis and cirrhosis have been considered irreversible, it has recently been suggested that even advanced fibrosis and cirrhosis may be reversible. The use of platelet-rich plasma (PRP) in tissue regeneration is a developing area of research for clinicians and specialists. Platelets contain proteins required for hemostasis as well as numerous growth factors. They have a prominent role in suppressing the progression of liver fibrosis in vitro and in vivo. Elevating growth factors induced by platelet transfusion can enhance liver function in patients with CLD and cirrhosis. However, PRP could increase the risk of rejection or immune response in allogenic transfusion; therefore, searching for effective therapeutic strategies is much needed.

Aims & Methods: This study evaluated the possible regenerative effect of purified platelet-derived growth factors on an experimentally induced model of liver cirrhosis. Purified Platelet Derived Growth Factors were prepared using a patented method (Gooris & Fahmy, 2019). Twenty-eight mice were included and categorized into four groups.

The 1st group acted as a normal control group.

The 2nd group acted as a Purified Platelet Derived Growth Factors control group and was injected subcutaneously with Purified Platelet Derived Growth Factors only twice weekly for eight weeks.

The 3rd group acted as a pathological control group and was injected intraperitoneally with thioacetamide (TAA) three times a week for eight weeks. At the same time, the 4th group was injected with both Purified Platelet Derived Growth Factors and TAA for eight weeks. After eight weeks, animals were euthanized, and liver specimens and blood samples were collected for pathological and biochemical assessment.

Results: Our results showed that Purified Platelet Derived Growth Factors administration could improve the hepatic status of the mice, as cirrhotic livers were regenerated back into normal-appearing parenchyma when compared to the pathological control group.

In addition, the levels of ALT, AST, and total bilirubin decreased significantly ($P<0.001$), and the Relative expression of hepatic Alpha-SMA was significantly down-regulated ($P<0.001$) after Purified Platelet Derived Growth Factors administration.

Conclusion: Purified Platelet Derived Growth Factors can be used as a new therapeutic modality for liver cirrhosis.

Introduction: Hepatitis C virus (HCV) infection is one of the leading causes of liver cirrhosis and hepatocellular carcinoma. Myeloid-derived suppressor cells (MDSC) are a heterogeneous population of activated immature myeloid cells that are characterized by different specific surface molecules, they express each of CD11b+CD33+ and lack expression of HLA-DR. MDSC are immunosuppressive cells that decrease immune cell activation and induce immunological tolerance in inflammation and cancer.

Under normal conditions, MDSC remain in the bone marrow until differentiation; however, under pathological conditions these cells arrest at various stages of development, migrate out of the bone marrow in an immature state and, accumulate in circulation and peripheral lymphoid organs, causing negative regulation of immune responses via various mechanisms, primarily T cell suppression. MDSC are known to increase in patients with chronic hepatitis C virus infection. But it is not clear till now if eradication of HCV using directly acting antivirals can restore normal levels of MDSC on long term or not.

Aims & Methods: This study aimed to assess the levels of MDSC in patients with previous chronic hepatitis C after achieving sustained virologic response (SVR) for at least 2 years using sofosbuvir containing regimens.

This study was a case-control one. Fifty five subjects were involved in the study. All patients had completed DAAs therapy 2-3 years before involvement. Estimation of (CD33+ HLA-DR– CD11b+) expressing cells by flow cytometry was done and levels were compared between HCV patients achieved SVR for 2-3 years and healthy control without any current or previous chronic disease.

Results: MDSC were significantly higher among patients with eradicated HCV for 2-3 years than in healthy controls (4.98% (IQR=3.3 – 7.7) vs 3.09% (1.4 – 3.9), $p = 0.001$)

Conclusion: Normal MDSC levels are not restored after eradication of HCV using directly acting antivirals even after passage of 2 years on viral eradication. Clinical implications and consequences of these findings should be further investigated.

Introduction: Liver fibrosis is primarily caused by the activation of hepatic stellate cells (HSCs), which results from chronic liver damage. Understanding the pathogenesis of HSC activation could identify new therapeutic targets to treat liver fibrosis.

Aims & Methods: In this study, we examined the protective role of the mammalian cleavage factor I 25 kD subunit (CFIm25, NUDT21) in inhibiting hepatic stellate cell activation. CFIm25 expression was measured in liver cirrhosis patients and a CCl4-induced mouse model. Adeno-associated viruses and adenoviruses were used to alter hepatic CFIm25 expression in vivo and in vitro to investigate how CFIm25 functions in liver fibrosis. The underlying mechanisms were explored using RNA-seq and co-IP assays.

Results: Here, we found that CFIm25 expression was drastically decreased in activated murine HSCs and fibrotic liver tissues. CFIm25 overexpression downregulated the expression of genes involved in liver fibrosis, inhibiting the progression of HSC activation, migration and proliferation. These effects resulted from direct activation of the KLF14/PPARɣ signaling axis. KLF14 inhibition abrogated the CFIm25 overexpression-mediated reduction in antifibrotic effects.

Conclusion: In conclusion, we reported a protective role for CFIm25 in liver fibrosis. Our findings showed that CFIm25 reversed HSC activation and inhibited CCl4-induced liver fibrosis through the KLF14/PPARɣ signaling pathway, which might provide a novel approach for liver fibrosis treatment.

Introduction: Decompensated alcohol-related cirrhosis (ArC) is a major cause of liver-related morbidity and mortality. There is a significant proportion of patients with ArC who achieve recompensation, defined as the absence of ascites or encephalopathy and no active treatment for either. Thus, recompensation is a relevant event in clinical practice. However, the factors and metabolic pathways involved in the resolution of clinical decompensation are poorly understood.

Aims & Methods: We aimed to assess the metabolomic profile associated with recompensated ArC. Patients with ArC were recruited from a prospective cohort followed between 2016 and 2020 in a referral hepatology unit (n=63). According to the evolution event at the end of follow-up, they were classified into 4 groups: group 0 patients compensated at baseline and during follow-up; group 1 patients who achieved recompensation; group 2 patients decompensated throughout the study period; group 3 patients who died in the 3 first months since inclusion. Demographic, clinical, and analytic parameters were retrieved from chart review together with evolution events. Plasma samples were analyzed at baseline to identify a metabolic signature using high-performance liquid chromatography-tandem mass spectroscopy. A principal component analysis of the implicated pathways was done using the Metaboanalyst platform.

Results: 63 patients with ArC were included: 18 in group 0, 15 in group 1, 15 in group 2 and 15 in group 3. All four groups were similar in terms of age and sex. Baseline MELD score was 8, 17, 16 and 27, respectively. In relation to abstinence during follow-up, 61% of patients in group 1, 47% in group 2 and 20% in group 3 achieved alcohol abstinence (p=0.04).

Median follow-up time was similar when comparing group 1 and 2 (3.5 years and 3.3 years), which were the groups of interest (recompensated vs. decompensated). Each group displayed a distinct metabolic signature. By comparing groups 1 and 2, differences among 32 metabolites were detected: 20 lipids were at a higher concentration in recompensated individuals, which included polyunsaturated fatty acids (docosahenoic and docosapanthenoic acid 2 times greater (p<0.05)) and acylchcoline metabolism compounds; 7 amino acids, as phenyl-lactate (three times less in the recompensated group (p=0.04)) and 5 vitamins.

	Group 0 N=18	Group 1 N=15	Group 2 N=15	Group 3 N=15	p
Age (years)	52 (43-58)	55 (38-59)	48 (39-54)	56 (50-63)	0.354
Sex, women (%)	6 (33)	3 (20)	1 (7)	5 (22)	0.309
Baseline MELD score	8 (7-11)	17 (13-23)	26 (19-33)	26 (19-33)	0.000
Final MELD score	6 (6-8)	9 (8-11)	31 (23-38)	31 (23-39)	0.000
Abstinence (%)	13 (72)	10 (71)	2 (29)	2 (29)	0.022
Follow-up (days)	1462 (549-1846)	1273 (442-2142)	45 (13-104)	45 (13-104)	0.000

Table.

Conclusion: Patients who achieved recompensation at the end of follow-up exhibited a distinct metabolomic profile, regarding the metabolism of polyunsaturated fatty acids, acylcarnitines and amino acids. It is likely that these metabolic pathways may play a role in resolution of decompensations in patients with ArC.

A NOVEL, NURSE-LED 'ONE STOP' CLINIC FOR PATIENTS WITH LIVER CIRRHOSIS RESULTS IN FEWER LIVER-RELATED UNPLANNED HOSPITAL ADMISSIONS AND IMPROVED SURVIVAL

E. Kalo[1,2], A. Baig[2,3], E. Gregg[2], J. George[4,5], S. Read[1,2,4], W.-S. Ma[2], G. Ahlenstiel[1,2,4]

Introduction: Delivering effective secondary preventive and integrated care has the potential to break the revolving-door phenomenon of frequent readmissions in patients with advanced chronic liver disease. To address this, we launched the Care Coordination of Liver Disease (CCoLD) pilot, a novel nurse-led cirrhosis clinic in Western Sydney.

Aims & Methods: Following an index presentation to Blacktown or Mount Druitt hospitals (BMDH), patients (n=89, matched by age, sex, and MELD-NA liver disease severity score) were either followed up by the CCoLD clinical nurse consultant (intervention cohort) or received standard care (control cohort). Controlled evaluation of the impact of the nurse led clinic was carried out for a 3-month period including readmission rates and survival.

Results: The inaugural nurse led clinic led to a remarkable improvement in patient-level outcomes including a reduction in unplanned liver-related readmissions (2.08% for intervention cohort vs 12.2% for control cohort, p<0.01), and mortality at 30 days (0% for intervention cohort vs 7.3% for control cohort, p=0.03).

Similar trends were observed at 90 days from index discharge. No deaths were observed in the intervention cohort as compared to the control cohort at 90 days (0% versus 7.3%, p=0.03), while unplanned liver-related readmissions were 19.5% for the control cohort vs 10.41% for the intervention cohort (p=0.115).

Moreover, a longer time was required for emergency readmissions among the intervention cohort. Our nurse-led cirrhosis clinic was cost-effective with the number needed to treat (NNT) of 10 to prevent 1 readmission within 30 days or 4 over the entire study period to prevent 1 readmission.

Conclusion: These findings highlight the significant impact of optimised care-coordination. Post-discharge follow-up and education through a nurse-led clinic delivers goal-directed, and cost-effective secondary prevention and care. A multicentre randomised trial for wider evaluation of these findings is warranted.

Introduction: Sarcopenia is an underdiagnosed complication occurring during cirrhosis. Assessing its influence on the morbi-mortality is not enough studied in cirrhotic patients especially in countries where hepatic transplantation is rarely available.

Aims & Methods: Aims: Evaluate the prevalence and prognostic impact of radiological sarcopenia in cirrhotic patients

Methods: Longitudinal retrospective study including cirrhotic patients who had an abdominal computed tomography (CT) scan over 6 years. Sarcopenia was defined ,on a sagittal CT slice at the umbilicus, by a psoas muscle thickness related to height (TPMT/h) of less than 16.8 mm/m. Two groups were defined (G1: presence of sarcopenia/G2: absence of sarcopenia) and compared regarding their survival and the occurrence of subsequent complications.

Results: 70 patients were included with a mean age of 62 year and a sex ratio of 0.8. Their average mean BMI was 27.67 kg/m^2. Viral etiology of cirrhosis was predominant (49%) with a mean MELD score of 12.81. The mean TPMT/h was 13.56 mm/m. Radiological sarcopenia was noted in 44 patients (63%). At the time of inclusion, the baseline characteristics of the 2 groups were comparable except for the predominance of women (p=0.006) and refractory ascites (p=0.032) in G1. At the end of an average 21-month follow-up, sarcopenia was associated with a higher number of complications per patient (p=0.013) and a longer average duration of hospitalization per patient (p=0.001). Overall survival was decreased in G1 with a statically significant difference (p=0.035). Survival rates at 6 months, 1 year and 2 years were respectively 42%, 30% and 24% in G1 versus 67%, 40%, 27% for G2. The survival study concluded that sarcopenia is an independent factor of mortality (OR=2,5 ;95% IC [1,02-6,16] ; p=0,045) in our patients.

Conclusion: Sarcopenia is frequent in patients with cirrhosis. It is an independent poor prognostic factor that needs to be recognized in this population. The TPMT/h offers an easy and often available method for the diagnosis of this complication.

Disclosure: Nothing to disclose.

PP1318

EFFICACY OF SIMVASTATIN PLUS NON-SELECTIVE BETA BLOCKER IN IMPROVING SURVIVAL OF CIRRHOTIC PATIENTS WITH VARICEAL BLEED: A SYSTEMATIC REVIEW AND META ANALYSIS

G.P.A. Soliman[1], J.A. Fajardo[1,1]
[1]*St. Luke's Medical Center, Internal Medicine, Quezon City, Philippines*

Contact E-Mail Address: gibeau.soliman@gmail.com

Introduction: Around 60% of patients with decompensated liver cirrhosis have esophageal varices with a high propensity to bleed which is the major cause of death in these patients. Pharmacological treatment in addition to endoscopic intervention has been documented to prevent variceal bleeding. Simvastatin, a lipid-lowering therapy, can also be used in liver generation of nitric oxide and hepatic endothelial dysfunction. We therefore assessed the efficacy of simvastatin with a non-selective beta blocker in improving survival for cirrhotic patients with variceal bleed.

Aims & Methods: A comprehensive systematic search through Pubmed, Cochrane and Google scholar was performed to include clinical studies that examined the use of statin with a beta blocker in improving survival in cirrhotic patients. Two reviewers independently screened and reviewed all abstracts and full text papers available. An inclusion and exclusion criteria was made which was a basis for selection of included studies. The Cochrane Risk of Bias tool was used to assess possible bias in each article. Data was analyzed using RevMan 5.4 and GRADEPro. The dichotomous outcomes were analyzed using relative risk with a confidence interval of 95% and the primary outcome pertained to improvement in survival, with a secondary outcome of rebleeding also noted.

Results: The study included 3 randomized control trials with 361 patients with variceal bleeding. There was significant survival benefit among patients given simvastatin therapy with a risk ratio of 0.43 (95% CI 0.26 - 0.73; p = 0.002). A secondary outcome of rebleeding was also studied and showed a trend towards benefit with a risk ratio of 0.72. However, the results were not statistically significant (95% CI; 0.47-1.09; p = 0.12).

Conclusion: Among cirrhotic patients with variceal bleeding, the addition of simvastatin, a readily available and accessible medication with an excellent safety profile, provides a significant benefit in survival, but not in rebleeding. However, there remains a need for larger studies with more participants to strengthen this evidence, and a deeper look into its safety profile in cirrhotic patients specifically.

Introduction: Adrenal dysfunction is known to occur in patients with liver cirrhosis during infection or acute decompensation and is associated with adverse outcomes, especially acute-on-chronic liver failure (ACLF) in these patients (1).

However, little is known about pituitary-adrenal signaling in stable patients with ACLD.

Aims & Methods: We aimed to evaluate (i) the pituitary-adrenal axis and (ii) the prognostic value of total serum cortisol (t-Cort) in a cohort of outpatients with advanced chronic liver disease (ACLD).

Consecutive outpatients with ACLD and hepatic venous pressure gradient (HVPG) ≥6 mmHg within the prospective VICIS (NCT03267615) study were included.

Exclusion criteria were intake of corticosteroids, a history of liver transplantation (LT), hepatocellular carcinoma, vascular liver disease, occlusive portal vein thrombosis and evidence of infection.

According to d'Amico et al. (2) patients were stratified into 6 subgroups for their clinical stage of ACLD (S0: subclinical portal hypertension [PH], S1: clinically significant PH (CSPH) without varices, S2: CSPH with varices; S3: history of variceal bleeding, S4: non-bleeding decompensation S5: ACLD with further decompensation). Competing risk regression was conducted considering LT and death - or non-liver-related death, as appropriate - as competing.

Results: In total, 137 patients (compensated: S0: n=13, S1: n=12, S2: n=26; decompensated: S3: n=7, S4: n=46, S5: n=33) with male predominance (67.9%; median age: 58.1 years) were included. Median ACTH (from S0: 44.0pg/mL to S5: 20.0pg/mL; p=0.006), cortisol binding globulin (from S0: 49.3µg/mL to S5: 38.9µg/mL; p<0.001) and serum total cortisol (t-Cort; from S0: 13.9µg/dL to S5: 9.2µg/dL; p=0.091) levels decreased throughout the substages of ACLD, while serum free cortisol (f-Cort; from S0: 6.5ng/mL to S5: 5.7ng/mL; p=0.474) stayed unchanged.

Importantly, t-Cort showed a strong correlation with f-Cort and (Spearman's ρ: 0.889). Lower levels of t-Cort were independently predictive of bacterial infections (adjusted subdistribution hazard ratio [asHR] per µg/dL: 1.11, 95% confidence interval [95%CI]: 1.04-1.19; p=0.002), (further)

decompensation (asHR: 1.08; 95%CI: 1.02-1.12; p=0.008), ACLF (asHR: 1.11; 95%CI: 1.04-1.19; p=0.002), as well as liver-related death (asHR: 1.09; 95%CI: 1.01-1.18; p=0.045).

Youden's index determined t-Cort level <12 µg/dL as ideal cutoff for the prediction of ACLF. Overall, n=87/137 (63.5%) patients exhibited t-Cort <12 µg/dL. The cumulative incidence of ACLF was more than 3 times higher in patients with t-Cort <12 µg/dL at 1 year (15.6% vs. 4.4%), 2 years (28.4% vs. 6.9%) and 3 years (34.4% vs. 11.0%) of follow-up (p=0.005).

Conclusion: Pituitary-adrenal signaling is impaired in cirrhosis. Lower levels of both t-Cort are independently linked to bacterial infections, (further) decompensation, ACLF and liver-related death, possibly due to impaired stress response. Moreover, t-Cort <12 µg/dL identifies stable patients with ACLD with a particularly high risk of ACLF.

Contact E-Mail Address: papp.maria@med.unideb.hu

Introduction: The gut-liver axis is substantially involved in the pathogenesis of chronic inflammation of the liver. Disruption of both the mucosal immunity and the structural integrity of the gut barrier results in sustained leakage of bacterial antigens from the gut lumen (i.e., bacterial translocation, BT) to the portal circulation. Enhanced BT triggers the activation of the proinflammatory signaling cascade and consequently increases tissue damage of the liver. This latter hence accelerates the progression of the liver disease. Markers of gut barrier integrity and function were hypothesized to be associated with severity an outcome of acute decompensation (AD) episodes in patients with cirrhosis.

Aims & Methods: In various chronic gastrointestinal diseases a bundle of serologic markers were identified as a hallmark of the intestinal barrier disruption and tissue damage in general. These serologic markers were tested in a prospective cirrhotic patient cohort suffering in AD to determine their prognostic potential for worse outcome. Serum samples of 131 patients with cirrhosis and AD have been assayed for gelsolin, intestinal fatty acid binding protein (I-FABP), zonulin, secretory immunoglobulin A (sIgA), free Ig kappa and lambda light chains, immunoglobulin (Ig) A and/or IgG antibodies against to EndoCab gliadin, F-actin, Saccharomyces cerevisiae (ASCA), glycoprotein 2 (GP2), as well as total IgA, IgG and IgM levels. Disease severity was assessed by different liver related scores (CLIF-C AD, MELD and Child-Pugh).

Presence of acute-on-chronic liver failure (ACLF) was defined by CLIF-OF score. Hospital readmission, ACLF development and liver-related death were assessed in a 3-month follow-up observational study.

Results: Presence of anti-microbial and other target specific IgA type antibodies was associated with diseases severity. The more types of IgA antibodies present the higher the total IgA level was. High CLIF-C AD score (≥ 50) was associated with increased gelsolin and decreased total IgG levels at baseline, while presence of ACLF at hospitalisation with increased free Ig kappa light chain (p=0.043) and decreased total IgG levels (p=0.046). Hospital readmission due to a further AD episode within 3-month was associated with increased gelsolin level at baseline episode (p=0.042), while ACLF development was associated with increased free Ig kappa light chain level (p=0.018).

Short-term mortality was associated with increased gelsolin level (AUROC: 0.814 and 0.664, p<0.001 and =0.012 for 1 and 3-month mortality, respectively). The addition of high (> 68 µg/ml) serum gelsolin level significantly increased 3-month mortality prediction in all 3 severity category (CLIF-C AD <50: 0% vs. 24.3%; CLIF-C AD ≥50: 15.9% vs. 36%; ACLF: 22.2% vs. 54.5%, respectively, cumulative LogRank p<0.001).

Conclusion: Presence of specific IgA type antibodies signifying enhanced BT contributes to the increased total IgA level in advanced liver cirrhosis. Serologic hallmark of overwhelming damage-associated molecular patterns (DAMPs) in AD episode is able to predict more presicely the accelerated progression of liver disease adding to CLIF-AD score that comprises extent of certain organ dysfunctions and systemic inflammatory response.

Disclosure: Nothing to disclose.

PIVKA-II AS A MARKER OF CHRONIC LIVER DISEASE SEVERITY

M. Majerovic[1], D. Segulja[2], I. Lapic[2], A. Bogic[2], I. Knezevic Stromar[1], D. Rogic[2], R. Ostojic[1], Z. Krznaric[1]

[1]University Hospital Centre Zagreb, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Zagreb, Croatia, [2]University Hospital Centre Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia

Contact E-Mail Address: matea.majerovic@gmail.com

Introduction: Protein Induced by Vitamin K Absence or Antagonist-II (PIVKA-II) is regarded as a diagnostic marker for hepatocellular carcinoma (HCC).

However, the optimal cut-off level for HCC diagnosis is not precisely defined, and it depends on the assay used as well as on the etiology and the stage of the underlying liver disease.[1,2]

Aims & Methods: The aim of this study was to assess PIVKA-II levels in patients with different stages of chronic liver disease without signs of malignancy. Laboratory data of 69 patients were analyzed (69.5% male, median age 58 years). The serum PIVKA-II concentrations were determined using the Elecsys PIVKA-II immunoassay (Roche Diagnostics, Mannheim, Germany). The cut-off level set by the manufacturer was <31.2 µg /L. Patients were divided into three groups: decompensated cirrhosis (N=24), compensated cirrhosis (N=20), no signs of liver fibrosis (N=25). Kruskal-Wallis test with post-hoc analysis was used to compare the groups. Correlations between PIVKA-II levels, bilirubin, INR and MELD-Na score were described by Spearman`s rank correlation coefficients (ρ). The values P ≤ 0.05 were considered statistically significant.

Results: Concentrations of PIVKA-II were significantly higher in patients with decompensated cirrhosis (median 245 µg/L, IQR 102.5-485.5) when compared to patients with compensated cirrhosis (median 35.1 µg /L, IQR 17.4-342) and patients without signs of liver fibrosis (median 25.6 µg /L, 17.2-110) (P=0.0008). A statistically significant correlation was found between the concentrations of PIVKA-II and total bilirubin (ρ = 0.576

(95% CI: 0.326-0.750), P=0.0001), INR (ρ = 0.471 (95% CI:0.191-0.680), P=0.0019) and calculated MELD-Na score (ρ = 0.483 (95% CI:0.205-0.688), P=0.0155).

Conclusion: Elevated PIVKA-II concentrations, well beyond the cut-off levels proposed by the manufacturer, may be seen in benign liver disease. Correlations with bilirubin, INR and MELD-Na suggest that higher PIVKA-II concentrations can be expected in more severe forms of chronic liver disease.

HOW DO HOSPITALIZED PATIENTS WITH CHRONIC LIVER DISEASE DIE? - END-OF-LIFE QUALITY ANALYSIS

A.C. Bravo[1], C. Nascimento[1], B. Abreu[1], J. Revés[1], B. Morão[1], C. Frias-Gomes[1], M. Canhoto[1], L. Glória[1], C.A. Fidalgo[1]

[1]Hospital Beatriz Angelo, Gastroenterology Department, Loures, Portugal

Contact E-Mail Address: catarina.bravoo@gmail.com

Introduction: Chronic liver disease (CLD) is a major cause of morbidity and mortality. However, there are poorly established metrics to assess the quality of end-of-life (EOL) care in this context. Offering better care to who is dying is an important mission of health professionals, but EOL interventions can be futile, prolong suffering and consume resources better allocated to other needs.

Aims & Methods: Our goal was to characterize and compare the EOL of patients with CLD and compare them. We did a retrospective cohort study including all patients who died with CLD between 2012-2021 in charge of Gastroenterology, in a tertiary hospital.

Results: We included 72 patients, 89% male, with a mean age of 64±11 years. 68% of patients were Child-Pugh C and 50% had HCC. In the last 6 months of life, patients had a median of 2 (IQR 1-6) hospitalizations, and they were hospitalized a median of 21.5 (IQR 13.25-38.5) days, 15 (IQR 9.25-24.5) in the last month. Only 38% were referred to palliative care (PC), with a median of 5 (IQR 2-15) days between referral and death. 86% of patients had prescribed do-not-resuscitate order, with a median of 3 (IQR 1-9) days between this and death. In 42% of patients, endoscopic procedures were performed in the last hospitalization. In 58% and 17% of patients, it was documented in the clinical process discussion of the prognosis with the family and the patient, respectively. There was a significant difference between patients with and without HCC in their referral to PC (78% vs 47%, p=0.007) and sharing the prognosis with the patient (31% vs 19%, p=0.002).

Conclusion: In this cohort, there was a low and late referral to PC in general, being lower in the group of patients without HCC. It is imperative to select and apply quality of death metrics in patients with CLD, with and without HCC, aiming to improve care, manage expectations and resources.

Disclosure: Nothing to disclose.

Introduction: Urinary tract infections (UTIs) are common and important cause of deterioration and mortality in cirrhosis. Infection caused by MDR bacteria are more likely to result in treatment failure, septic shock, and high mortality. UTI is a common bacterial infection and is the second most frequent infection and it accounts for 12-29% of infections in decompensated cirrhosis.

Previous studies have shown that Escherichia.coli was the most common organism isolated and presence of infection were double the risk of death. Limited literature is available from India regarding the clinico-microbiological profile and its impact on survival in cirrhosis patients.

Aims & Methods: The main aims of this study was to determine the spectrum of UTI in cirrhosis and to estimate its effect on 90-day outcomes in hospitalized cirrhosis patients. This is an ambi-spective observational study conducted from October- December 22 2022. All cirrhosis patients with culture proven urinary tract infections (UTI) who were admitted under the department of Gastroenterology & Hepatology were included. Socio-demographic, clinico-microbiological profile and 90 day outcomes of UTI were studied in those patients. The study was approved by the institutional ethical committee (IEC-AIMS-2022-PHARM-263).

Results: A total of 202 patients with mean age of 57 ± 11 years with male : female ratio of 5:1 with culture proven UTI were included. The most common etiology of cirrhosis were alcohol (38.6%) followed by NASH (20.3%). Of all, 122 patients (60%) had infection by MDROs. The common MDROs isolated from the patients are ESBL: Extended spectrum beta lactamase (n=40, 32.85%).

CRE: Carbepenam resistant Enterobacterales (n=18, 14.8%), MDR-enterococcus (27.8%) and MDR-pseudomonas (n=6, 6.9%). There was a significant correlation (p<0.05) with the admission CRP and presence of MDRO. The significant predictors of poor 90-day survival were higher total leucocyte count, neutrophil count, bilirubin, CRP, prothrombin time, INR, admission MELD-Na. There was a trend toward poorer 90-day survival among patients with Foley's catheterization (p=0.06). There was no difference in 90-day survival between patients with and without MDRO infection. However, re-admission were higher among MDROs (p<0.05) and there was a significant association between blood stream infection and survival rate [OR =4.23] in multi-variable analysis.

Conclusion: About 3 in 5 Urinary Tract Infections in cirrhosis are due to MDROs. Enterobacterales and Enterococci are the two major organisms causing UTI in cirrhosis. The short-term mortality is not affected by the resistance pattern.

MELD 3.0 SCORE IN CIRRHOTIC PATIENTS: PREDICTIVE VALUE OF OVERALL AND COMPLICATION-FREE SURVIVAL

S. Chtioui[1], A. Khsiba[1], M. Mahmoudi[1], A. Ben Mohamed[1], M. Medhioub[1], M. Yaakoubi[1], L. Hamzaoui[1], M.M. Azouz[1]
[1]*Taher Maamouri hospital, Nabeul, Tunisia*

Contact E-Mail Address: saharchtioui2@gmail.com
Introduction: In cirrhosis, several prognostic scores have been developed to predict overall and complication-free survival. The MELD (Model for End-Stage Liver Disease), MELD-Na and MELD3.0 scores have been proposed as a criteria for allocating organs.
Aims & Methods: The aim of our study was to assess the performance of these 3 scores for the prediction of overall and complication-free survival in decompensated Tunisian cirrhotic patients.
Methods: We conducted an observational, retrospective study involving all patients with decompensated cirrhosis managed in Gastroenterology department of Taher Maamouri hospital during the period from January 2010 to December 2021. Mortality was assessed using the Kaplan Meier model. The performance of the scores was assessed using the AUROC (Area under the Receiver Operating Characteristic curve).
Results: One hundred and fifty-two patients were included with an average age of 61 years. Viral liver cirrhosis was the most common (65.13%). The mean value of the MELD-Na and MELD3.0 scores was 17.74 and 19.4, respectively. The mean follow-up time was 17.1 months. The rate of complications and short-term mortality was 33.6% and 18.4% respectively.
The AUROC of the MELD3.0 score in predicting of the occurrence of further decompensation was the highest (0.775) compared to those of the MELD and MELD-Na score (0.743 and 0.756 respectively). The cut-off value of the MELD3.0 score in predicting further decompensation was 20 (sensitivity 60.7%, specificity 73.3%).
In the prediction of 3-month mortality, the AUROCs of the MELD, MELD-Na and MELD3.0 scores were 0.786; 0.841 and 0.850 respectively. The cut-off value of the MELD3.0 score was 24 (sensitivity 68%, specificity 88%). A statistically significant correlation was noted between the MELD3.0 score ≥24 and 3-month mortality (p=0.04).
Conclusion: The MELD3.0 score had the best predictive value for the occurrence of further decompensation and short-term mortality in decompensated cirrhotic patients. Those with a MELD 3.0 score ≥24 should be prioritized on waiting lists.
Disclosure: Nothing to disclose.

PREDICTION IN ACUTE VARICEAL BLEEDING – CLINICAL UTILITY OF PALBI AND CLIF-C AD SCORES

S. Lopes[1], I. Costa Santos[1], M. Teixeira[1], C. Sequeira[1], C. Cardoso[1], J. Mangualde[1], R. Freire[1], E. Gamito[1], A.L. Alves[1], A.P. Oliveira[1]
[1]*Centro Hospitalar de Setúbal, EPE, Gastroenterology, Setúbal, Portugal*

Contact E-Mail Address: saramarlopes@gmail.com
Introduction: Acute variceal bleeding (AVB) is a medical emergency that requires urgent evaluation. It is a complication of portal hypertension and, despite the improvements in the management of these patients, mortality is still high. According to the best available data, all patients should be risk stratified according to the validated clinical scores MELD and Child-Pugh.
Aims & Methods: To access the predictive capacity of PALBI and CLIF-C AD scores and to compare them with the currently recommended MELD and Child-Pugh scores for the following outcomes: in-hospital mortality, mortality at 6 weeks and rebleeding.
Retrospective review of all cirrhotic patients admitted for AVB between January 2016 and December 2022 in a Gastroenterology department in Portugal. The area under the receiver operating characteristics curve (AUROC) was calculated for all scores and compared with DeLong test.
Results: 100 patients included, average age 61.87±14.68years, 77% male. Alcohol was the most frequent aetiology (n=56).
All patients were hemodynamically resuscitated and more than 90% underwent endoscopic evalutation within 12hours from admission. 30% of patients had active bleeding at the time of upper GI endoscopy. 90% of patients had esophageal varices (GOV-1) bleeding treated with endoscopic band ligation. 10% of patients had acute gastric (cardiofundal) variceal (GOV2, IGV1) bleeding treated with cyanoacrylate injection. 5% of patients had persistent bleeding and thus a Sengstaken-Blakemore tube was placed. Rebleeding occurred in 11% of patients.
Median time of admission was 6 days (1-30 days). In-hospital mortality was 28% and mortality at 6 weeks was 19%.
The average scores were MELD: 15.98 ± 6.89 points; Child-Pugh 8.65 ± 2.10 points; PALBI -1.71 ± 0.47 points; CLIF-C AD 58.48 ± 11.42 points.
The AUROC of PALBI for in-hospital mortality (AUROC=0.742) and for mortality at 6 weeks (AUROC=0.616) was similar to the traditional scores MELD (AUROC=0.747 and AUROC=0.698) and Child-Pugh (AUROC=0.794 and AUROC=0.673). PALBI was also a good predictor for rebleeding (AUROC=0.795), superior to MELD (AUROC=0.726) and inferior to Child-Pugh (AUROC=0.801). Comparison of the AUROCs of the three scores showed no statistically significant differences.
Regarding CLIF-C AD, it was a good predictor for in-hospital mortality (AUROC=0.708) and mortality at 6 weeks (AUROC=0.706), with no statistically significant differences compared to MELD and Child-Pugh scores. The predictive capacity for CLIF-C AD for rebleeding was not satisfactory (AUROC=0.552).
Conclusion: In addition to liver-specific scores, the predictive performance and clinical utility of PALBI and CLIF-AD C scores for identifying patients with AVB at higher risk for in-hospital mortality, mortality at 6 weeks and rebleeding is very good.
PALBI score deserves recognition, not only because of it is very good predictive capacity for all outcomes, but also because it does not take into account variables whose evaluation has some degree of subjectivity, like hepatic encephalopathy and ascites.
Disclosure: Nothing to disclose.

IMPROVEMENT OF CLINICAL OUTCOMES IN PATIENTS WITH DECOMPENSATED CIRRHOSIS UNDERWENT TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT BY SELECTIVE COX-2 INHIBITORS: A RETROSPECTIVE STUDY

Z. Yang[1], Y. Tai[1], H. Tong[1], S. Qian[1], Q. Cai[1], L. Zeng[1], Y. Xiao[1], M. Chen[1], R. Yang[1], X. Ren[1], J. Gao[1], C. Tang[1]
[1]West China Hospital, Sichuan University, Department of Gastroenterology, Chengdu, China

Introduction: Liver cirrhosis, the end stage of chronic liver diseases, is associated with high morbidity, mortality, and medical costs worldwide(1). The progression of liver cirrhosis from compensated to decompensated cirrhosis, portal hypertension (PHT) with complications is developed(2). Transjugular intrahepatic portosystemic shunt (TIPS) is an effective procedure for treating PHT. Whereas complications of post-TIPS, especially hepatic encephalopathy and stent dysfunction, limit the application of TIPS as a first-line treatment for liver cirrhosis.

Osteoarthritis (OA) and rheumatoid arthritis (RA) are characterized by chronic polyarticular inflammation which may cause irreversible joint damage. The conventional agent of modifying antirheumatic drugs and corticosteroids are associated with hepatotoxicity and are contraindicated in chronic hepatitis (3,4). Treatment of liver cirrhosis combined OA/RA should be carefully considered.

Systemic inflammation is tightly associated with the progression of liver cirrhosis and RA/OA. Selective COX-2 inhibitor is one of the most well-investigated anti-inflammation drugs with antifibrotic effects (5,6,7). However, there are no relevant studies about the anti-inflammatory concept of cirrhotic patients with RA or OA after TIPS.

Aims & Methods: Aim：To assess the effects and safety of anti-inflammatory therapy of selective cyclooxygenase-2 (COX-2) inhibitors in patients with decompensated liver cirrhosis undergone transjugular intrahepatic portosystemic shunt (TIPS) accompanied with rheumatoid arthritis (RA) or osteoarthritis (OA).

Methods：Clinic data from patients with liver cirrhosis underwent TIPS were collected from January 2017 to October 2022 for a retrospective analysis. According to whether receiving selective COX-2 inhibitors orally for arthritis, patients were divided into the TIPS and TIPS+COX-2-I group. Occurrences of clinic adverse events were examined.

Results: Eligible patients in the TIPS (n=95) and TIPS+COX-2-I group (n=51) were analyzed. Clinic events containing variceal rebleeding, hepatic encephalopathy, ascites (>grade 2), hepatocellular carcinoma (HCC) and stent dysfunction in the TIPS+COX-2-I group was less than the TIPS group (5.88% vs. 27.37%, p=0.002). Among those patients in the TIPS+COX-2-I group, 1.96% (1/51) patient experienced esophageal and gastric variceal bleeding (EGVB) again. No patients occurred HE with only 1 patient experienced ascites relapse, and 1 patient finally progressed to HCC. However, in the TIPS group, the rates of clinic adverse events including EGVB, HE, ascites, HCC and stents dysfunction were all higher, which were 10.53%, 4.21%, 4.21%, 2.11%, 6.32% respectively. No concerned side effects related to selective COX-2 inhibitors mainly including cardiovascular events and gastrointestinal hemorrhage occurred during follow-up periods.

	TIPS (n=95)	TIPS+COX-2-I (n=51)	p
Decompensated events, n (%)	20 (21.05%)	3 (5.88%)	0.016
Variceal rebleeding, n (%)	10 (10.53%)	1 (1.96%)	0.097
Hepatic encephalopathy, n (%)	4 (4.21%)	0 (0.00)	0.298
Ascites > 2 grade, n (%)	4 (4.21%)	1 (1.96%)	0.658
Hepatocellular carcinoma, n (%)	2 (2.11%)	1 (1.96%)	1.000
Stent dysfunction, n (%)	6 (6.32%)	0 (0.00)	0.092

Table 1. Clinic advers events between two groups.

Conclusion: Anti-inflammatory therapy of selective COX-2 inhibitors for post-TIPS patients with RA or OA, not only can reduce the occurrence of adverse clinic events, but also safe in those patients, which is a completely effective and safe therapy.

ENCEPHALAPP STROOP TEST AS SCREENING TOOL FOR DETECTION OF MINIMAL HEPATIC ENCEPHALOPATHY IN PATIENTS WITH LIVER CIRRHOSIS – PILOT STUDY

M. Vojnovic[1], I. Pantic[1], M. Stojkovic Lalosevic[1], G. Jankovic[1], T. Milovanovic[2]
[1]University Clinical Center of Serbia, Belgrade, Serbia, [2]University Clinical Center of Serbia, School of Medicine University of Belgrade, Clinic for Gastroenterology and Hepatology, Belgrade, Serbia

Contact E-Mail Address: marko.vojna@gmail.com

Introduction: Minimal hepatic encephalopathy (MHE) is the mildest form of hepatic encephalopathy (HE), and is defined as presence of signs of brain dysfunction (only detectable by specific psychometric tests) in absence of disorientation and asterixis.

One of the neuropsychological test which is being frequently used in order to evaluate patients psychomotor speed and cognitive flexibility, and therefore detect MHE, is Stroop test (via EncephalApp).

Aims & Methods: The aim of this study was to evaluate the Stroop test for the screening and diagnosis of MHE. This prospective case-control study was performed at Clinic for Gatroenterology and Hepatology, University Clinical Center of Serbia (February 2020-August 2022), and included patients with cirrhosis and MHE and healthy controlos. Patients with uncontrolled overt HE (defined as mini mental status examination score <25), and those who consumed alcohol or psychoactive substances at least one month prior to testing were excluded. In all patients the presence of MHE was confirmed using animal naming test. In each participant the Stroop test was performed, and the results were compared between the two groups.

The test itself has two components, the “OFF” and “ON” state. The specific outcomes recorded after the Stroop test are:

1. OFFTIME (total time for five correct runs in the “OFF” state),

2. number of runs needed to complete the five correct "OFF" runs,
3. ONTIME (total time for five correct runs in the "ON" state), and;
4. number of runs needed to complete the five correct "ON" runs.

Results: A total of 111 participants were included (59 cases and 52 healthy controls). The majority of patients were classified as Child-Pugh class B (n=37, 62.7%), while the etiology of liver disease was most commonly alcohol-related (n=22, 37.3%). Median OFFTIME did not differ between the two groups (106.3 (84.5-126.3) and 91.4 (79.8-124.6), p>0.05). However, in patients with MHE median values of ONTIME and total time (OFF+ON) were significantly higher (122.3 (97.8-150.2) and 105.3 (84.5-136.3); 228.0 (180.7-274.9) and 195.6 (166.0-262.6); respectively, p<0.05). Participants were further divided into subgroups based on age and education level. Statistical significance between patients and controls in examined parameters was detected in younger participants, as well as in the group with higher educational level (Table 1).

	Patients (n=37)	Healthy (n=38)	p	Patients (n=22)	Healthy (n=14)	p
≤ 12 years				≥13 years		
OFFTIME	99.9 (81.5-134)	95.6 (80.9-139.1)	0.63	111.1 (92.3-121.9)	85.5 (78.8-90.5)	0.004
ONTIME	121 (96.3-147.2)	106.6 (84-149.8)	0.21	127 (108.6-150.2)	91.2 (86.8-109.6)	0.003
Total time	224.3 (175.5-274.9)	199.5 (166-297.9)	0.28	236.9 (199.3-271.1)	178.6 (166-197)	0.003
<45 years				≥45 years		
OFFTIME	84 (75.3-103.1)	78.8 (65.9-84.5)	0.01	118.8 (98.3-164)	113.5 (92.5-156.9)	0.522
ONTIME	98 (90.6-119.4)	82.8 (75.1-91)	0.001	137.7 (121-188.1)	127 (107.5-173.7)	0.266
Total time	178 (165.7-227.5)	161.2 (139.1-181)	0.002	258.5 (222-359.2)	243 (199.4-338.1)	0.335

Table 1. The difference in Stroop test parameters in respect with educational level.

Conclusion: Stroop test could be a valuable tool in detecting MHE in patients with cirrhosis, especially younger population and those with higher educational level.

Introduction: Several studies have investigated the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with chronic liver disease (CLD) and the relationship to severity and progression of disease. However, the reported rates of SIBO vary.

Aims & Methods: Against this background we conducted a systematic review and meta-analysis of case-control studies, to assess and compare the prevalence of SIBO in patients with CLD and controls and identify risk factors for SIBO in CLD. Electronic databases were searched from inception up to April 2023 for case-control studies reporting SIBO prevalence in CLD patients. Prevalence rates, odds ratios (ORs), and 95% confidence intervals (CIs) of SIBO in patients with CLD and controls were calculated utilizing a random-effects model. This study was registered with PROSPERO (CRD42022379578).

Results: We included 34 case-control studies with 2136 patients with CLD and 1240 controls. Overall, odds for SIBO prevalence in CLD patients (37.8%, 95%CI 35.7-39.8) as compared to controls (13.9%, 95%CI 12.1-16.0) was 6.1 (95%CI 4.5-8.3, p=0.0001) with moderate heterogeneity seen (I^2=46.8, p=0.002).Stratified by mode of SIBO diagnosis, SIBO prevalence in CLD patients as compared to controls was highest in studies utilizing small bowel aspirate and culture (OR=11.6, 95%CI 3.6-36.6, p=0.0001), followed by glucose breath test (OR=8.1, 95%CI 3.9-16.5, p=0.0001) and lowest in those utilizing lactulose breath test (OR=5.3, 95%CI 3.6-7.7, p=0.0001).

There was no difference in the prevalence of SIBO in patients with cirrhosis (41.2% 95%CI 31.2-46.8) as compared to those without cirrhosis (39.7%, 95%CI 29.7-50.7). The odds for SIBO in patients with decompensated cirrhosis was significantly higher as compared to those with compensated cirrhosis, (OR=2.7, 95%CI 1.7-4.4, p=0.0001). Furthermore, SIBO prevalence was increased in CLD patients with portal hypertension (PHT) (49.9%, 95%CI 34.5-65.3) and in CLD patients with complications of PHT, highest in those with spontaneous bacterial peritonitis (SBP), (57.7%, 95%CI 38.8-74.5) followed by hepatic encephalopathy (41.0%, 95% CI 15.7-72.3) and variceal bleed (39.5%, 95% CI 12.1-75.6).

According to etiology of liver disease, SIBO prevalence was highest in patients with CLD due to non-alcoholic fatty liver disease (NAFLD) 41.5% (95%CI 30.9-53.0), followed by viral hepatitis 38.4% (95%CI 28.3-49.5), alcoholic liver disease 37.3% (95%CI 25.7-50.5), cryptogenic liver disease 31.9% (95%CI 13.9-57.6) and lowest in those with autoimmune liver disease 25.5% (95%CI 12.4-45.2). SIBO prevalence in CLD patients on proton pump inhibitors (PPI) (41.3%, 95%CI 30.3-52.8) was numerically higher as compared to those not on a PPI (26.5%,95%CI 19.9-34.2), but this failed significance.

Conclusion: Overall, there is a 6-fold increase in the prevalence of SIBO in patients with CLD as compared to controls. Although SIBO prevalence was similar in CLD patients with cirrhosis as compared to those without cirrhosis, patients with decompensated cirrhosis had approximately 3-fold increased SIBO prevalence as compared to those with compensated cirrhosis.

Furthermore, SIBO was increased in CLD patients with PHT, particularly those with SBP. No significant difference was seen in SIBO prevalence in CLD patients according to aetiology of liver disease, with highest SIBO prevalence in patients with NAFLD. Moreover, as compared to breath tests, small bowel aspirate and culture for SIBO diagnosis yielded substantially higher SIBO prevalence rates in CLD patients and controls.

STUDY OF PLATELET PARAMETERS DURING PORTAL VEIN THROMBOSIS IN CIRRHOTIC PATIENTS

R. Saidani[1], D. Cherif[1], W. Neffati[2], A. Chakroun[2], H. Dabbebi[1], S. Mahjoub[2], N. Maamouri[1]
[1]La Rabta Hospital, Gastroenterology, Tunis, Tunisia, [2]La Rabta Hospital, Hematology, Tunis, Tunisia

Contact E-Mail Address: dhouha.cherif@fmt.utm.tn

Introduction: Cirrhosis is a condition of hypercoagulability that increases the risk of portal vein thrombosis (PVT) contrasting with thrombocytopenia related to hypersplenism. In this context, we propose to determine the profile of platelet parameters at the diagnosis of cirrhosis and to study their relevance in predicting PVT in this population.

Aims & Methods: This is a retrospective case-control study involving cirrhotic patients diagnosed between 2000 and 2015, at the Gastroenterology department of La Rabta Hospital. Epidemiological, clinical, and biological data were collected from medical records. Platelet parameters, including platelet count (PC), mean platelet volume (MPV), and platelet distribution width (PDW) were recorded at diagnosis. The MPV/PC, PC/lymphocytes, and PC/splenic index ratios were calculated. The occurrence of portal vein thrombosis, documented by abdominal Doppler ultrasound, was recorded. Statistical analysis was performed using SPSS 23.0 software.

Results: A total of 103 patients were included in our study. The gender ratio was 0.5, and the median age at diagnosis of cirrhosis was 59 years [14-80]. The etiological distribution of cirrhosis was as follows: post-hepatitis C cirrhosis (n=47), post-hepatitis B cirrhosis (n=35), cirrhosis due to other etiologies (n=10), and undetermined for 11 patients.

The median platelet count (PC) for the entire population was 85 G/L [16-480], with thrombocytopenia in 82% of cases. Portal vein thrombosis (PVT) was diagnosed in more than 1/5 of cases (n=23). The splenic index was significantly higher in the “cirrhosis with PVT” group (15.865 cm vs. 14.646 cm in the “cirrhosis without PVT” group; p=0.04).

However, no statistically significant differences were found between the two groups regarding platelet parameters such as PC, mean platelet volume (MPV), platelet distribution width (PDW), and MPV/PC ratio (respectively: 92 G/L vs. 83 G/L, p=0.9; 10.9 fl vs. 11.35 fl, p=0.2; 15.5% vs. 15.1%, p=0.2, and 0.12 fl/G/L vs. 0.11 fl/G/L, p=0.9). Nevertheless, the PC/lymphocytes ratio showed a modest discriminating power between the two groups, with an area under the curve (AUC) of 0.6; 95% CI: [0.475-0.748].

In addition, 19% of patients developed hepatocellular carcinoma (HCC) during the course of their disease. Analysis showed that the presence of HCC increases the risk of PVT occurrence (odds ratio 3, 95% CI: [1.052-8.679], p=0.03).

Conclusion: Platelets are key players in the inflammatory response found in several pathologies. In our study, the predictive power of platelet parameters for portal vein thrombosis could not be demonstrated due to the presence of other likely confounding factors (infection at diagnosis, used automated methods...). A larger prospective study would be desirable.

Disclosure: Nothing to disclose.

Introduction: Bacterial infections are common and difficult to diagnose in decompensated chronic liver disease (DCLD) patients (1). Early diagnosis and treatment of infection in DCLD can improve the outcome. Studies show that neutrophilic cluster of differentiation 64 (nCD64) is more accurate than procalcitonin (PCT) and C-reactive protein for identifying bacterial infections (2,3). nCD64 is rapidly upregulated to >10-fold higher in an immune response to infection. Pediatric studies on the role of nCD64 in liver disease are lacking.

Aims & Methods: We prospectively studied the role of nCD64 as a biomarker of bacterial infection in children with DCLD. We also compared the accuracy of nCD64 with PCT and total leucocyte count (TLC) for diagnosis, severity, and post-treatment persistence or resolution of infection.

Consecutive children admitted with DCLD were enrolled. Neutrophils were gated according to CD64 activity by flow-cytometry and expressed as percentage of neutrophil expressing CD64 positivity. nCD64, PCT and hemogram were measured at admission and 7-14 days after treatment in those with infection.

Appropriate tests like urine microscopy, ascitic fluid analysis, chest x-ray and cultures (blood, urine, ascitic fluid) were done. Presence of infection, site and severity were classified as per standard guidelines (4,5).

Results: 107 children [64 boys, median age 97 (18-168) months] were studied. Autoimmune hepatitis was the commonest etiology.72.9% (78/107) cases had infection, 24.2% had severe sepsis and 56% had SIRS at admission. Ascitic fluid (n-37) was the commonest site of infection, followed by pneumonia (n-24), urinary tract (n-15), bacteremia (n-10), cholangitis (n-8) and cellulitis (n-3). For nCD64 we derived a cut-off of 51% to diagnose infection and for PCT the best cut-off was > 0.58 ng/mL.

Table 1 shows the sensitivity, specificity, positive and negative likelihood ratio (LR+ and LR-) and diagnostic accuracy of the biomarkers. nCD64 performed better than PCT alone. Elevated nCD64, PCT and TLC had a specificity of 100%, suggesting that infection is always present if all tests are elevated.

nCD64 and PCT correlated well with infection severity. The levels of nCD64 and PCT were highest in severe sepsis [88 (70.73-96.5) % and 1.98 (0.83-10.36) ng/mL], than infection alone [71.8 (45.07-84.37) % and 1.09 (0.45-2.07) ng/mL], and no-infection [36 (20.2-47.7) % and 0.42 (0.19-1.08) ng/mL] respectively.

There was no difference in PCT or nCD64 with regards to site of infection, both were elevated almost equally in systemic infections except cellulitis (local infection). Subjects with resolved infection (n-64), showed a significant decline in proportion of cases with elevated nCD64 and PCT in follow-up.

However, the biomarkers continued to be positive in those with persistent infection (n-14). Only, 10% of children with clinically resolved infection had elevated nCD64, as compared to 43% with elevated PCT, suggesting that nCD64 shows a faster decline with resolving infection than PCT.

Biomarker	AUC	Sensitivity %	Specificity %	Accuracy %	LR-positive	LR-negative
nCD64 (>51%)	0.82	79.5 (0.68-0.87)	82.8 (0.63-0.93)	80.4 (71.58-87.42)	4.61 (2.06-10.31)	0.24 (0.15-0.38)
PCT (>0.58 ng/mL)	0.74	76.9 (0.65-0.85)	62.1 (0.42-0.78)	72.9 (63.45- 81.04	2.02 (1.25-3.28)	0.37 (0.23-0.58)
TLC (age-appropriate cut-off)	0.62	29.4 (19.7-40.89)	79.3 (60.28-92.01)	42.99 (33.46- 52.92)	1.42 (0.64-3.14)	0.88 (0.75-1.04)
nCD64 +PCT		62.8 (51-73.2)	93.1 (75.7-98.7)	70.1 (60.48- 78.56)	9.1 (2.36-35.07)	0.4 (0.29-0.54)
nCD64 +PCT+TLC		23.1 (14.29-34)	100 (88.06-100)	43.93 (34.34-53.85)	Infinity	0.77 (0.68-0.87)

Table 1: Comparison of biomarkers of infection in children with chronic liver disease.

Conclusion: nCD64 can identify infection better than PCT and correlates well with infection severity in children with DCLD. Combination of nCD64, PCT and TLC can identify infection with 100% specificity.

Introduction: The early detection, prediction, and risk stratification of liver cirrhosis and its sequelae eventually facilitate proper management of advanced liver cirrhosis with substantial improvement in patient outcomes.

The synthesis of active Vitamin D3 involve the hepatic 25 hydroxylase enzyme, and the final step of activation occurs in the kidney. Vitamin D3 plays an essential role in calcium homeostasis and has been involved in the mechanisms of cellular proliferation, differentiation, and immunomodulation. 60-90% of chronic liver disease patients are vitamin D deficient. Whether this is a result or a cause, remains unclear. Vitamin D deficiency in liver disease has been linked to hepatocellular carcinoma, severity of alcoholic and non-alcoholic liver disease, and hepatitis B treatment outcomes.

Aims & Methods: *Was to assess the relation between vitamin D3 level, spontaneous bacterial peritonitis (SBP), and severity of liver dysfunction in patients with liver cirrhosis.

*In a case-control design, 50 patients with cirrhotic ascites who were categorized into two age- and sex-matched groups: 25 patients having liver cirrhosis, ascites with SBP; and 25 patients having liver cirrhosis, ascites without SBP. After clinical evaluation, laboratory investigations were conducted, including, liver test profile, hemogram, ascetic fluid analysis and culture. Serum level of vitamin D3 was measured using chemiluminescence immunoassay. Abdominal ultrasound for liver evaluation, as well as upper gastrointestinal endoscopy for varices screening/grading were done. The severity of liver disease was assessed by Child-Pugh and MELD-Na scores. Patient clinical outcome of SBP (inpatient mortality) was assessed.

Results: Low vitamin D3 level (i.e. < 30ng/ml) was present in 100% of patients with SBP, compared to 40% in patients without SBP. Patients with ascites and SBP had lower Vitamin D3 level compared to patients without SBP (13.3±4.5 ng/ml vs. 30.5±5.5 ng/ml, p<0.001). Low vitamin D3 (n = 35) were associated with low platelet count, lower serum albumen, higher serum bilirubin and INR (P < 0.001).

In addition, low vitamin D3 was associated with more severe ascites (57% vs. 0.0% for normal vitamin D3 levels), high median MELD-Na (30 points vs. 11 points for normal vit D3), and higher Child-Pugh scores (p< 0.05). In addition, vitamin D level was highest in F1 varices, 24.6 (18.7- 31.9) ng/ml and lowest in F3, 12 (8-12) ng/ml. Patients without esophageal varices had sufficient serum vitamin D levels with a median of 36 (36- 39) ng/ml. Differences were statistically significant (where χ^2 of Kruskal-Wallis = 20.467, p= <0.001). Of patients with SBP, 16% died from septic shock and multiple organ failure, all of them had low vitamin D3 level < 30 ng/ml.

Vitamin D3 levels were also correlated to liver functions as well as severity scores (Table).

Parameter	Correlation coefficient (r)	P
MELD score	-0.836	<0.001
Child–Pugh score	-0.818	<0.001
Serum Albumin	0.765	<0.001
INR	- 0.732	<0.001
Serum Bilirubin	-0.550	<0.001
Platelets count	0.685	<0.001

Table.

Conclusion: Vitamin D3 level is suggested as a potential non-invasive prognostic biomarker for severity of liver disease where its associated with worse clinical outcomes. Its advised that vitamin D3 to be maintained at sufficient serum levels in cirrhotic patients because its deficiency is associated with worse liver functions and higher incidence of SBP morbidity and mortality.

Introduction: Bacterial infections are a frequent and common complication of cirrhosis and are responsible for a significant morbidity and mortality.
The presence of acute kidney injury (AKI) is often considered a poor prognostic factor.
Aims & Methods: The aim of our study is to evaluate the prevalence of AKI during bacterial infections in cirrhotic patients and to determine its prognostic value.
We conducted a retrospective and analytical study over a period of 3 years, including all patients followed for cirrhosis who were hospitalized for management of a bacterial infection. The different clinical, biological, and therapeutic data were collected.
Results: We included 80 patients (38 men and 42 women). The mean age was 62 years [26 - 93].
The main comorbidities noted were type 2 diabetes mellitus in 38% of cases and arterial hypertension in 10% of cases.
The etiologies of cirrhosis were dominated by viral (38.8%), autoimmune (18%) and metabolic (11.3%) causes.
Cirrhosis was Child-Pugh A, B and C in 25%, 68.8% and 6.3% of cases respectively.
The clinical signs were mainly represented by oedemato-ascitic decompensation in 56.3% of cases, hepatic encephalopathy in 22.5% of cases and only 30 % of patients had fever.
The identified infections were mainly urinary infection (35.3%), Spontaneous bacterial peritonitis (35.3%) and pulmonary infection (23.3%).
The prevalence of AKI was 35% (n = 28), classified as Stage I, II and III in 42%, 22% and 36% of cases respectively.
The presence of AKI was statistically associated with an initial Child-Pugh's score ≥ B7 (3% vs 21%, p = 0.001) , refractory ascites (40% vs 22% , p = 0.001) and the presence of a documented spontaneous bacterial peritonitis (58 vs 9% , p = 0.001) .
The analytical study found a statistically significant correlation between AKI and 15 days mortality (24.2% vs 4.3%, p=0.01).
When analyzing the receiver operating characteristic (ROC) curve, AUC of serum creatinine in predicting 15 days mortality was 0.781 (p=0.03).
Conclusion: In our study AKI is associated with a poor prognosis and higher mortality rates. Therefore serum creatinine is a valuable marker allowing better initial stratification.

FUROSEMIDE TREATMENT AS A RISK FACTOR FOR HIP FRACTURES IN PATIENTS WITH ALCOHOL-RELATED CIRRHOSIS – A POPULATION-BASED COHORT STUDY

T. Deleuran[1,2,3], F. Kraglund[2], H. Vilstrup[2], P. Jepsen[2]
*[1]Aalborg University Hospital, Department of Gastroenterology and Hepatology, Aalborg, Denmark, [2]Aarhus University Hospital, Department of Hepatology and Gastroenterology, *Aarhus, Denmark, [3]Aalborg University Copenhagen, Center for Molecular Prediction of Inflammatory Bowel Disease, PREDICT; Department Of Clinical Medicine, Copenhagen, Denmark*

Contact E-Mail Address: thomas.deleuran@clin.au.dk
Introduction: Patients with alcohol-related cirrhosis are at an increased risk for hip fractures (1). Furosemide may impair bone quality and affect the rate of hip fractures (2).
Aims & Methods: We aimed to estimate the hazard ratio for hip fractures during furosemide treatment compared with time-periods without.
We identified all patients with a first-time diagnosis for alcohol-related cirrhosis and no history of hip fractures in 2000–2018 in Danish nationwide healthcare register (3-5). We included furosemide use as a time-varying binary variable in a Cox regression analysis. We estimated the hazard ratio for hip fractures adjusted for age, sex, diagnosis for ascites, variceal bleeding, hepatocellular carcinoma, diabetes, alcohol disorders, comorbidity, and prescriptions for other drugs (spironolactone, non-selective beta-blockers, proton pump inhibitors, selective serotonin re-uptake inhibitors, opioids, benzodiazepines, glucocorticoids, and sedatives).
Results: We included 24,377 patients, and 5,738 patients received furosemide treatment at the diagnosis for alcoholic cirrhosis. Furosemide users and non-users had almost similar distribution of age (60.6 vs. 57.2 years), males (70.3% vs. 69.0%), diabetes (9.8% vs. 7.8%), ascites (14.1% vs. 17.3%), and HCC (1.1% vs. 1.5%), but users had more comorbidity (25.0% vs. 14.8%), and less frequent variceal bleeding (10.6% vs. 16.4%) and alcohol diagnoses (17.2% vs. 32.4%). We observed 1,318 hip fractures during 87,861 person-years. During furosemide treatment, the incidence rate of hip fractures per 1,000 person years was 19.2 (17.6–20.9) compared with 13.5 (12.6–14.4) without. The adjusted hazard ratio for hip fractures during furosemide treatment was 1.29 (95% CI: 1.15–1.44). This estimate was unchanged in sub-groups defined by age at diagnosis and sex.

Subgroup	N	N hip fractures	Hazard ratio
Overall	24,377	1,367	1.30 (95% CI: 1.16–1.45)
Sex			
Men	16,888	827	1.26 (95% CI: 1.09–1.46)
Women	7,489	540	1.37 (95% CI: 1.15–1.64)
Age group (years)			
< 50	5,382	247	1.27 (95% CI: 0.95–1.69)
50–70	16,034	947	1.31 (95% CI: 1.14–1.50)
> 70	2,961	173	1.26 (95% CI: 0.92–1.72)

Table 1: Adjusted hazard ratio for hip fracture, overall and in subgroups defined by sex and age.

Conclusion: Furosemide was associated with an increased rate of hip fractures in patients with alcohol-related cirrhosis independent of age and sex.

Contact E-Mail Address: Benedikt.S.Hofer@meduniwien.ac.at
Introduction: Portal hypertension (PH), a key driver of liver-related morbidity, arises as a consequence of static and dynamic changes in the liver parenchyma. While the static PH component is determined by the degree of fibrosis, the analysis of dynamic PH components remains challenging.
Aims & Methods: We aimed to investigate the influence of inflammation on the dynamic component of PH in the setting of liver disease regression in (i) well-standardised mouse models and (ii) abstinent patients with alcohol-related liver cirrhosis (ALD).
In male C57BL/6JRj mice, disease regression was modelled by administering carbon tetrachloride or thioacetamide for 12 weeks to induce cirrhosis before discontinuing the toxic stimulus and thus enabling regression for either one (R1; n=15) or two (R2; n=15) weeks. In our patient cohort, we included 128 ALD patients with prolonged abstinence (>1 month) undergoing same-day hepatic venous pressure gradient (HVPG) and liver stiffness measurement (LSM). The static component of PH during regression (histological collagen proportionate area [CPA; %] in mice; LSM in patients) was used to predict portal pressure (PP) based on a linear model.
Subsequently, we explored parameters affecting the dynamic PH component (i.e., difference between the predicted PP based on LSM/CPA and the true/measured PP) by analysing the linear model's residuals.
Results: When compared to mice at peak disease severity, withdrawing the toxic stimulus led to a significant decrease in PP, CPA and intrahepatic expression of inflammatory genes (see Table). Despite improvements in hepatic inflammation during regression, the linear model demonstrated a significant association between an increased expression of inflammatory genes and higher-than-expected PP levels in R1 and R2 mice, as shown by the positive correlation between Tnfα (Spearman's r:0.46; p=0.012), Il6 (r:0.48; p=0.008), Il1β (r:0.39; p=0.036), Cxcl1 (r:0.33; p=0.075) and Mcp1 (r:0.26; p=0.159) with the model's residuals. Similarly, a longer duration of abstinence in ALD patients was associated with a significantly lower HVPG (r:-0.21; p=0.017), LSM (r:-0.37; p<0.001), IL-6 (r:-0.24; p=0.006) and CRP (r:-0.28; p=0.001). Nevertheless, patients with higher levels of systemic inflammation also demonstrated a higher HVPG than predicted by LSM in the linear model. Specifically, IL-6 (r:0.18; p=0.043) and CRP (r:0.21; p=0.016) were positively correlated with the model's residuals. Furthermore, levels of complement factor C3c (r:-0.22, p=0.049) and C4 (r:-0.15, p=0.203) were markedly decreased in patients with higher-than-expected HVPG.
Interestingly, while the impact of systemic inflammation was primarily found in long-term abstinence (>6 months), the negative correlation with C3c was only present in short-term abstinence (≤6 months).

	Healthy animals n=13	Diseased animals n=14	R1 n=15	R2 n=15	p-value
PP (mmHg)	5.4 (5.2-5.7)	8.3 (7.7-9.9)	7.7 (7.2-8.2)	6.4 (6.0-8.1)	<0.001
CPA (%)	0.77 (0.73-0.97)	4.35 (3.79-16.20)	4.33 (3.58-9.74)	3.29 (2.94-5.09)	<0.001
Tnfa (log_2 fold change)	0.00±0.50	2.96±0.71	1.92±0.57	1.98±0.92	<0.001
Il6 (log_2 fold change)	0.00±0.91	1.39±1.34	-0.69±1.27	0.04±1.26	<0.001
Cxcl1 (log_2 fold change)	0.00±0.72	1.52±0.74	-0.16±0.71	-0.16±0.78	<0.001
Il1b (log_2 fold change)	0.00±0.44	0.33±0.43	0.10±0.55	0.77±1.09	0.021
Mcp1 (log_2 fold change)	0.00±0.57	3.77±1.23	1.50±0.63	0.87±1.02	<0.001

Conclusion: Despite significant improvements during disease regression, intrahepatic inflammation in mice and systemic inflammation in ALD patients remain critical determinants of the dynamic component of PH.

IMPACT OF CHOLESTASIS IN PATIENTS WITH CHRONIC LIVER DISEASE AND SARS-COV-2 INFECTION

D. Feijó[1], J. Madaleno[2,3], A. Carvalho[2,3], A. Simão[2,3]
[1]Centro Hospitalar e Universitário de Coimbra, Gastroenterology, Coimbra, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Internal Medicine, Coimbra, Portugal, [3]Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Contact E-Mail Address: diogofeijo96@gmail.com

Introduction: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection has been associated with a variety of complications, including liver damage. However, its impact on chronic liver disease (CLD) and its association with cholestasis remains unclear. This retrospective cohort study aimed to investigate the incidence of cholestasis and its impact in patients with CLD after SARS-CoV-2 infection.

Aims & Methods: We retrospectively analyzed medical records of 428 patients followed in a tertiary center Liver Unit who were diagnosed with SARS-CoV-2 infection between March 2020 and September 2022. Patients were stratified as having no CLD, non-advanced CLD (NACLD) or advanced CLD (ACLD). Liver chemistries before and several times after SARS-CoV-2 infection were registered. The incidence of cholestasis and its associated risk factors were analyzed using multivariate logistic regression.

Results: A total of 428 patients were included, 357 (66.1% males) with CLD (NACLD in 198 and ACLD in 159 patients). Alcohol-associated liver disease (ALD) was the main etiology (30.8%), closely followed by metabolic-associated fatty liver disease (MAFLD) (24.6%). SARS-CoV-2 infection-related cholestasis was higher in patients with ACLD than in patients with NACLD (39.6% vs. 5.6%, p<0.001). No patient without CLD developed cholestasis. The incidence of decompensation episodes, such as ascites, hepatic encephalopathy and variceal bleeding was significantly higher in patients with cholestasis (32.4%, 32.4% and 17.6% vs. 0.3%, 0.3% and 0%, respectively; p<0.001).

Additionally, patients with cholestasis had a longer hospital stay (median/IQR 17/12 vs. 10.5/9 days, p=0.483) and a significantly higher mortality rate (23.0% vs. 0.6%, p<0.001) than those without cholestasis. Patients with ACLD (vs. NACLD) presented higher global mortality (10.7% vs. 0%, p<0.001) and liver-related mortality (10.1% vs. 0%, p<0.001). Multivariate logistic regression analysis showed that ACLD and decompensated disease were independent risk factors for cholestasis in patients with SARS-CoV-2 infection (p=0.031 and p<0.001, respectively).

Follow-up and clinical outcomes	No cholestasis (n=354)	Cholestasis (n=74)	p value
Sex, male/female (% male)	207/147 (58%)	53/21 (71.6%)	0.035
Age, years (IQR)	58 (23)	63 (20)	0.023
Median hospital stay, days (IQR)	10.5 (9)	17.0 (12)	0.483
ICU admission, n (%)	2 (0.6%)	7 (9.5%)	<0.001
Decompensated ACLD, n (%)	3 (0.8%)	51 (68.9%)	<0.001
Decompensation/further decompensation			
Ascites	1 (0.3%)	24 (32.4%)	<0.001
Hepatic encephalopathy	1 (0.3%)	24 (32.4%)	<0.001
Variceal hemorrhage	0 (-)	13 (17.6%)	<0.001
Death, n (%)	2 (0.6%)	17 (23.0%)	<0.001
COVID-19-related death, n (%)	2 (0.6%)	3 (4.1%)	0.038
Liver-related death, n (%)	0 (-)	16 (21.6%)	<0.001

Conclusion: Our study suggests that SARS-CoV-2 infection is a risk factor for cholestasis in patients with CLD, especially in those with ACLD or decompensated disease. Clinicians should be aware of the potential for cholestasis in these patients with underlying liver disease and closely monitor liver function tests. Further studies are needed to investigate the underlying mechanisms of SARS-CoV-2-induced cholestasis and develop appropriate management strategies for these patients.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is the most common cause of chronic liver disease worldwide, with a prevalence of 25% in the adult population. NAFLD encompasses a wide spectrum of histological conditions, from simple steatosis to nonalcoholic steatohepatitis (NASH), fibrosis and cirrhosis. Inflammation is one of the principal hallmarks of NAFLD. Polyclonal free light chains (FLCs) λ and κ reflect B-cell activation and high serum levels of FLCs are observed in a variety of inflammatory conditions.

Aims & Methods: The aim of this study is to evaluate the potential role of FLCs as biomarkers of inflammation and fibrosis in NAFLD/NASH patients. 254 patients with metabolic liver disease were consecutively enrolled in the study. 89 patients had simple steatosis, 88 had NASH, 77 had liver cirrhosis (45 with clinically significant portal hypertension [CSPH]). Diagnosis of NASH was histologically assessed. 101 patients had compensated advanced chronic liver disease (cACLD) based on histology (F>3) or elastography (liver stiffness measurement>15 kPa). Medical and pharmacological anamnesis, anthropometric measurements and laboratory tests (included λ and κ FLCs) were obtained for all patients.

Results: The concentration of total FLCs levels in patients with cirrhosis were higher compared with patients with NAFLD/NASH (p<0.01), while no significant difference in λ and κ FLCs levels were observed between NASH and NAFLD patients. Among patients who underwent biopsy, λFLCs tended to increase gradually with lobular inflammation severity, and patients with advanced fibrosis (F3-4) had a significantly higher FLCs compared with patients with mild-to-moderate fibrosis (F<3; p<0.05). Patients with clinically significant portal hypertension (CSPH) showed higher levels of FLCs compared to patients without CSPH (p<0.01).

At multivariate logistic analysis both kFLCs and λFLCs are significantly associated with diagnosis of CSPH and cACLD, independently from age, sex, diabetes, dyslipidemia and obesity. Diagnostic performance of cACLD and CSPH were high for both kFLCs (AUC 0.79 and 0.87 respectively) and λFLCs (AUC 0.81 and 0.89 respectively).

Conclusion: This study highlights the role of adaptive immune system in the pathogenesis of NAFLD. FLCs may be considered useful biomarkers of advanced liver disease (cACLD and CSPH) in patients with NAFLD.

Disclosure: Nothing to disclose.

NUTRITIONAL STATUS, MUSCLE QUALITY, SARCOPENIA AND QUALITY OF LIFE IN LIVER CIRRHOSIS

R. Saeidi[1,2], N. McGettigan[1,2], M. Morrin[3,1], J. Ryan[2,1], K. Boland[1,2]

Introduction: Sarcopenia defined as having low muscle mass, muscle strength and if combined with low performance indicate severe sarcopenia[1]. It is associated with adverse outcomes in cirrhosis, including hepatic encephalopathy, ascites, infection, and increased hospitalisation. Prevalence of sarcopenia has been reported between 40 to 70% and are more common with alcoholic liver disease[2].

Aims & Methods: We aim to assess relationship between nutritional status/assessment, muscle quality and sarcopenia. Cirrhotic patients were recruited from a tertiary-hepatology-clinic for this prospective cross-sectional study. BIA was performed as the standard (SECA mBCA-525) for nutritional status and sarcopenia assessment. Appendicular skeletal muscle mass (ASM) calculated through sum of limb muscle masses in kg. sarcopenia was diagnosed with ASM/height^2<7.0 kg/m^2 and <5.5 kg/m^2 for male and female respectively. Muscle quality was measured by mean handgrip strength in kg divided by ASM (HGS/ASM). Validated functional muscle metrics (handgrip and sit-to-stand), liver-frailty-index (LFI)[3], Chronic Liver Disease Questionnaire (CLD-Q)[4] and food-frequency-questionnaire (FFQ) were also analysed.

Results: 49 patients, 57% (28) alcohol-liver-disease, 18% (9) non-alcoholic steatohepatitis, 5% (4) viral, 4% (3) autoimmune and 7% (5) mixed aetiologies, were included. 44 healthy controls (HC) were recruited as well. Most patients were male (n=28, 57%), with mean age 56yrs (SD=9), mean Child-Pugh score 6 (IQR= 5-7) and MELD 10 (IQR= 7-12). 35% (n=17) were actively drinking alcohol. 9 (18%) of patients were frail and 34 (69%) were pre-frail. 25 (89%) cirrhotic male and 14 (66%) cirrhotic female had sarcopenia diagnosed via BIA. 24/42 (57%) had lower total daily energy intake than is recommended by EASL guidelines[5]. Of those, 11 (44%) male and 6 (42%) had diagnosis of sarcopenia.

There was positive correlation between nutritional status measured with BIA as Phase angle analysis (PhA) with total skeletal muscle mass adjusted for height, SMM/H^2, (r=0.51, p<0.0001) and ASM/H^2 (r=0.04,p=0.7). There was strong correlation between PhA and HGS (r=0.71, p=<0.001). Higher PhA score predicts lower MELD score therefore longer survivals (β = -0.092, p=0.004).

Healthy control has significantly better muscle quality (HGS/ASM) compared to cirrhotic patient (mean 2.52 vs 1.85 kg, SD 0.6 and 0.4 respectively, p<0.001).

Using functional testing, sit-to-stand time was lower in HCs (13.35 vs 8.94 secs, p=0.0001) and hand-grip strength higher in HC (p< 0.001). QoL was negatively correlate with sarcopenia (r=-0.06,p=0.6), LFI (r=-0.2,p=0.1), MELD (r=-0.15,p=0.3) and Child-Pugh score (r= -0.08, p=0.6) although they were not statically significant.

Conclusion: Cirrhotic patients had lower muscle quality and functional status compared to HC. FFQ and PhA are good assessment tool to establish nutritional status. PhA correlated much better with SMM/H2 than ASM/H2 and is a good predictor for disease severity. QoL is multifactorial and couldn't be explained with frailty scores or clinical severity scores.

POST BANDING ULCER BLEEDING IN CIRRHOTIC PATIENTS: WHAT ARE THE RISK FACTORS?

M. Mohamed[1], F. Saidani[1], M. Ben Abdelwahed[1], B. Raoua[1], N. Ben Chaabane[1], L. Safer Ep Saad[1]
[1]Fattouma Bourguiba Hospital of Monastir, Depatment of Gastro-Enterology, Monastir, Tunisia

Introduction: Endoscopic variceal ligation (EVL) is an effective treatment, whether in primary or secondary prevention of digestive bleeding due to esophageal varices (EV) rupture. However, this technique is not without risks, mainly post-banding ulcer bleeding (PBUB).

Aims & Methods: The aim of this study is to identify the risk factors contributing to PBUB.

This is a retrospective descriptive study including cirrhotic patients treated with EVL between January 2008 and December 2020.

Results: A total of 254 patients with a mean age of 57 years (35-81) and a sex ratio M/F 1.11 were included. The etiology of cirrhosis was viral in 95 patients (37.4%), post NASH in 53 (20.3%), dysimmune in 36 (14.2%), ethylic in 33 (13%) and in 37 cases (14.6%) it remained undetermined.

Post-banding ulcer bleeding was observed, on average, 6.04 days (3-10) after treatment in 28 patients (11%), of whom 7 (25%) presented with a state of shock and 3 (10.7%) died.

In univariate analysis, factors associated with a high risk of post-banding ulcer bleeding were a platelet count less than 60,000 (p=0.000), emergency treatment or treatment in the presence of ascites, hepatic encephalopathy or Child >/= B9 (p=0.000, p=0.000, p=0.043 and p=0.05), presence of red signs or hypertensive gastropathy (p=0.01 and 0.017), 6 or more treatment sessions, and the placement of 5 or more elastic rings (p=0.000, p=0.000).

In multivariate analysis, only two factors were associated with a higher risk of post-banding ulcer bleeding: a platelet count < 60,000 (p=0.009) and the presence of ascites (p=0.038).

Age, sex, duration of cirrhosis, and etiology were not associated with an increased risk of post-banding ulcer bleeding.

The occurrence of hemodynamic instability was associated with the presence of hepatic encephalopathy during the EVL procedure (p=0.004).

Conclusion: Post-banding ulcer bleeding is a dreaded complication of EVL, responsible for a high mortality rate. Knowledge of its risk factors, namely severe thrombocytopenia or the presence of massive ascites, is crucial in its prevention strategy.

Disclosure: Nothing to disclose.

PP1341

THE EFFECT OF RIFAXIMIN-A ON THE DEVELOPMENT OF COMPLICATIONS IN PATIENTS WITH MINIMAL HEPATIC ENCEPHALOPATHY AND LIVER CIRRHOSIS, DURING 3 MONTHS OF OBSERVATION

K. Ivanova[1], I. Bakulin[1]
[1]Mechnikov North-Western State Medical University, Propedeutics of Internal Diseases, Gastroenterology and Dietology n.a. S.M. Riss, Saint Petersburg, Russia

Contact E-Mail Address: napoleonovna20@gmail.com

Introduction: Minimal hepatic encephalopathy (MHE) represents the earliest and mildest form of hepatic encephalopathy. MHE does not represent clinically significant neurological and psychiatric abnormalities, and cognitive dysfunction is detected only with neuropsychological testing. Early diagnosis of HE is a prerequisite for maintaining the quality of life of patients and preventing overt HE.

Aims & Methods: Purpose of the study.To compare the dynamics of clinical and laboratory data and evaluate the incidence of complications during 3 months of follow-up with or without rifaximin-α therapy in patients with MHE associated with liver cirrhosis (LC).

Materials and research methods. Patients were selected according to the inclusion criteria: age from 18 to 75 years, the presence of cirrhosis (regardless of severity on the Child-Pugh scale), the presence of MHE, and signed voluntary informed consent.

In total, the study included 40 patients with MHE against the background of cirrhosis of various etiology and severity according to the Child-Pugh scale (A-C). Depending on the MHE treatment regimen, patients were randomly divided into groups: group 1 (n=14; 35%) - permanent therapy with rifaximin-α at a dose of 1200 mg/day, group 2 (n=12; 30%) - course rifaximin-α therapy at a dose of 1200 mg/day in courses (7 days of each month), group 3 (n=14; 35%) - without rifaximin-α therapy. Patients underwent an analysis of clinical (assessment of the severity of hepatic encephalopathy according to the results of psychometric tests: a number connection test, an animal name test-ANT, a short scale for assessing mental status-MMSE) and laboratory data (clinical and biochemical analysis, blood, coagulogram, capillary blood ammonia level), and also assessment of the quality of life (questionnaire-SF36) at the beginning of the study and after 3 months of observation.

Results: According to the results of the study, in group 1, against the background of constant therapy with rifaximin-α, 85.7% (n=12) showed a decrease in the level of ammonia in capillary blood, 28.5% (n=4) showed regression of MHE according to the results of psychometric tests, 71.4% (n=10) improved their quality of life. At the same time, 21.4% (n=3) had progression of MHE to overt HE, 21.4% (n=3) had an increase in the level of ammonia in capillary blood, 14,2% (n=2) had infectious complications (sinusitis, otitis media, ARI). In group 2, with the course use of rifaximin-α, 100% (n=12) showed a decrease in the level of ammonia in capillary blood, 16,6% (n=2) showed regression of MHE in the form of an improvement in psychometric tests, and 58,3% (n=7) showed an improvement in the quality of life. It should be noted that 8,3% (n=1) were diagnosed with the addition of a new coronavirus infection, as well as 8,3% (n=1) had bleeding from the esophageal varices. In group 3, 42.8% (n=6) showed a deterioration in the course of MHE, in the form of its progression to overt HE, 50% (n=7) showed an increase in ammonia levels, 64.2% (n=9) deteriorating quality of life indicators. In addition, 14,2% (n=2) were diagnosed with bleeding from the esophageal varices with a fatal outcome.

Conclusion: The study found that rifaximin-α reduces the progression of MHE to overt HE, the progression of portal hypertension, and also improves the quality of life in patients of this category. When comparing the effectiveness of continuous and course therapy with rifaximin-α, the results did not show significant differences, so further studies are needed in patients with cirrhosis and MHE to improve diagnostic and treatment approaches in patients of this category.

THE UTILITY OF THE MEAN PLATELET VOLUME/PLATELET RATIO IN THE ASSESSMENT OF FIBROSIS DURING METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE (MAFLD)

O. Alaya[1], R. Tababi[2], H. Kchir[3]
[1]Monastir Faculty, Kebilli, Tunisia, [2]Monastir Faculty, Gafsa, Tunisia, [3]Tunis Faculty, Tunis, Tunisia

Contact E-Mail Address: loufa.the.tulip@gmail.com

Introduction: The mean platelet volume (MPV) is an index that evaluates the size and the function of platelets. Many studies have shown that an increase in MPV is correlated with the severity of certain liver diseases.

Aims & Methods: The aim of this work is to identify the performance of the MPV/platelet ratio as a predicting factor of fibrosis among patients with MAFLD).

This is a retrospective study of 70 patients treated in our department for MAFLD over a one-year period (October 2021 - October 2022). A pulse elastometry (E) by Fibroscan was practiced on our patients as well as a blood count. A threshold E > 9.6 Kpa was deemed to be advanced fibrosis and E < 7.9 Kpa was deemed to be the absence of significant fibrosis. The fib-4 score was computed by online calculators. The specificity and sensitivity of the MPV/platelet ratio were studied by the ROC curve.

Results: Seventy patients were enrolled with a mean age of 57 years (+10 years), predominantly female with a sex ratio of 0.27. The median Body Mass (BMI) was 30.3 kg/m2 with a standard deviation of 5.5kg/m2. Fifty-five benefited from a Fibroscan and all of them had steatosis. The median elasticity was 5.8 kpa with a standard deviation of 6.3 Kpa and the median Controlled Attenuation Parameter (CAP) was 291 dB/m with a standard deviation of 38 dB/m. In this sample, 78.4% had no significant fibrosis, whereas 11.8% had significant fibrosis. The median Fib-4 scores and the MPV/platelet ratio were 1.37 and 0.051 with a standard deviation of 1.29 and 0.037, respectively. The MPV/platelet index was significantly correlated with the Fib-4 score (r=0.797 p < 0.001).

ROC curve analysis revealed that the MPV/platelet score predicted significant fibrosis with 100% sensitivity and 85% specificity (area under the curve=0.94 and p=0.04) and the absence of significant fibrosis with 87% sensitivity and 63% specificity (area under the curve=0.73 and p=0.047).

Conclusion: Our study shows that the MPV/platelet ratio highly predicts the severity of fibrosis among patients with MAFLD. Nevertheless, these results should be confirmed by other studies on a larger scale.

Disclosure: Nothing to disclose.

PP1343

DIFFERENCES IN CLINICAL HISTORY AND PRESENTATION IN PATIENTS WITH CHRONIC LIVER DISEASE UNDERGOING INPATIENT VERSUS OUTPATIENT LIVER TRANSPLANT EVALUATION

K. Cooper[1], D. Devuni[2]
[1]UMass Chan Medical School, Medicine, Worcester, United States, [2]UMass Chan Medical School, Medicine, Division of Gastroenterology, Worcester, United States

Contact E-Mail Address: katherine.cooper@umassmed.edu

Introduction: Liver transplant is the only definitive treatment for chronic liver disease (CLD). Referral to a hepatologist for consideration for liver transplant should be made when a patient with CLD experiences a hepatic decompensation or has a MELD score ≥ 15.

Failure to refer in a timely manner can result needing a liver transplant evaluation (LTE) in the inpatient setting while a patient is experiencing acute decompensation.

Aims & Methods: We aimed to compare the clinical presentation of patients undergoing LTE in the inpatient setting versus the outpatient setting to identify potential risk factors for requiring urgent evaluation. A list of all LTEs performed at our institution between 10/2017-8/2021 was obtained. Medical records were preliminarily reviewed for evaluation setting (Inpatient vs. Outpatients); evaluations for re-transplantation and acute liver failure were excluded. After all Inpatients (n=159) were identified, Outpatients (n=159) were selected at random to create a sample matched for age, gender, race, and ethnicity (n=318). Data were collected using our institutions electronic medical record and outside health records as obtained during LTE process. "Prior decompensations" refers to the number of the following clinical decompensations experienced *prior* to the time of LTE: ascites, hepatic encephalopathy (HE), variceal/acute UGIB, SBP and HRS. Categorical variables and continuous were compared between using Fisher's Exact test, and student's T test, respectively.

Results: Alcohol was the most common CLD etiology (42.1% Inpatient, 48.4% Outpatient). Inpatients tended to live further from our center than Outpatients (p=0.079). Inpatients had significantly higher MELD-Na scores (27.1 ± 8 vs. 13.3 ± 6; p<0.0001). Malnutrition was more common in 5.6 times more common in inpatients than outpatients (OR 5.6, 95% CI 2.9-10.8, p<0.001).

A similar proportion of patients had 1 hospitalization. But inpatients were 3 times as likely to have had ≥ 1 liver-related hospital admission prior to LTE (p<0.0001). Inpatients had significantly more prior decompensations than Outpatients prior to inpatient LTE (3.2 ± 1.4 vs. 1.8 ± 1.1, p<0.001), with the greatest differences in SBP and HRS.

Variable		Outpatient	Inpatient	p
Nutritional status (%)	Malnutrition	8.2	33.5	<0.0001
Previous hospital admissions (%)	0 admissions	23.9	11.4	<0.0001
	1 admissions	36.5	22.8	
	>1 admissions	39.6	65.8	
History of Decompensation (%)	Ascites	71.1	91.8	<0.0001
	HE	50.3	71.1	0.0002
	UGIB	23.3	32.1	0.1029
	SBP	3.8	22.0	<0.0001
	HRS	3.8	32.7	<0.0001

Conclusion: Multiple liver-related hospitalizations and malnutrition may be considered a risk factor for ultimately needing inpatient LTE and should be taken seriously by health care providers caring for patients with CLD. Episodes of SBP and HRS should prompt providers to consider immediate or urgent LTE referral regardless of other factors.

References: Multiple liver-related hospitalizations may be considered a risk factor for ultimately needing inpatient LTE and should be taken seriously by health care providers caring for patients with CLD. Episodes of SBP and HRS should prompt providers to consider immediate or urgent LTE referral regardless of other factors.

HEPATITIS C MICRO-ELIMINATION PROGRAMS, A GOOD SOLUTION FOR ACHIEVING THE ERADICATION

C.N. Oancea[1], C.T. Streba[1], V.-M. Sacerdotianu[1], I.P. Doica[1], I. Rogoveanu[1], T. Ciurea[1], D.I. Gheonea[1]
[1]University of Medicine and Pharmacy of Craiova, Research Center of Gastroenterology and Hepatology, Craiova, Romania

Contact E-Mail Address: Sacerdotianumihai@gmail.com

Introduction: Hepatitis C virus infection remains an important global burden despite the efficient DAA treatment available at this moment. A major goal was proposed by WHO in 2019 – elimination of HCV infection until 2030. One of the most important problems is the identification of infected persons in this relatively short time. Due to time and cost impact, a global and even a national screening program for all individuals is a method hard to be achieved. A solution is micro-elimination programs, that are focused on a limited area and a target population.

These programs can be implemented much easier, and faster and can be ruled at the same time, with experienced teams that already know all the necessary information and fully optimize resources.

Aims & Methods: This study aims to identify and eliminate HCV infection with micro-elimination programs in targeted areas with a population that has a clear indication for screening, due to the socioeconomic and habitual features. The micro-elimination program started with awareness campaigns.

After signing an informed consent form, persons over 40 years old completed a screening questionnaire and were given rapid Anti-HCV Test. Statistical analysis was performed based on the regional register created for these programs. All the positive patients were investigated and treated if they were eligible.

Results: Five micro-elimination programs were conducted from September 2020 to July 2022, and 42,976 persons from 6 counties were included in the screening. The prevalence ranged from 0.52 to 1.58 in the screened population, with predominance among the female sex. We also found statistically significant differences in HCV prevalence between urban and rural areas, industrial and residential settings (p<0.05), but none between age and HCV prevalence. The risk questionnaire revealed an increase risk of HCV infection in persons who required blood transfusions, shared use of personal hygene products, had dental interventions or surgery.

Conclusion: Micro-elimination programs represent important steps in HCV chronic hepatitis elimination and can be implemented with success in disadvantaged populations with limited access to medical care and can be a sustainable complementary action when national screening programs are overwhelmed or delayed in the aim of HCV elimination.

Disclosure: This study was supported by AbbVie SRL, Bucharest, Romania.

PP1345

ELIMINATING HEPATITIS C IN PEOPLE WHO USE DRUGS (PWUD) BY IMPLEMENTING HEPATITIS CARE WITH ADDICTION CARE, A MIXED-METHOD STUDY

D. Von den Hoff[1], F. Berden[2], J.P.H. Drenth[3], A. Schellekens[4]
[1]Radboud University Medical Center, Gastroenterology and Hepatology, Nijmegen, Netherlands, [2]Jeroen Bosch Ziekenhuis, Gastroenterology and Hepatology, Nijmegen, Netherlands, [3]Radboudumc University Nijmegen Medical Centre, Gastroenterology and Hepatology, Nijmegen, Netherlands, [4]Radboud University Medical Center, Psychiatry, Nijmegen, Netherlands

Contact E-Mail Address: daan.vondenhoff@radboudumc.nl

Introduction: People who use drugs (PWUD) are an important target population for hepatitis C virus (HCV) elimination in the World Health Organization (WHO) goals, because the PWUD population contains one of the largest clusters of residual HCV infections. Case-finding and treatment of these patients in hospitals is considered a challenge, while low threshold on-site screening and therapy in addiction care might facilitate viral elimination. We studied implementation of a decentralized PWUD-HCV care model, by exploring 1) viral elimination rates, and 2) facilitators and barriers for implementation.

Aims & Methods: In a multicenter mixed-method study in addiction care centers in the Netherlands we examined HCV-related outcomes in PWUD receiving HCV treatment within addiction care. The primary outcome was viral elimination, defined as percentage of identified HCV positive patients achieving sustained virologic response (SVR). Using semi-structured interviews barriers and facilitators for implementation were identified among health professionals and policy makers of addiction care and hospitals.

Theme	Facilitators	Barriers
Care chain agreements	Positive hospital attitudes and willingness Low-threshold communication channel	Lack of support in some hospitals Halt of previous infectious disease collaboration
Expertise	Most felt comfortable enough with their knowledge Not much expertise needed in most cases	*None*
Nurse as the mediator	Schooled in motivational interviewing Most intensive relationship with patients	*None*
Perceived problem scope	Establishing a network is also relevant to detect other infectious diseases	HCV is perceived as a closed chapter Challenging to gain experience in managing the disease
Treatment outcomes	Elimination is beneficial even if not all consequences are treated HCV treatment can motivate patients to change life Treatment can also enhance addiction treatment	*None*
Patient profile	*None*	Difficult to plan and keep appointments More psychological comorbidity in patients with addiction. Intellectual disabilities are more common
Stigma	Addiction care more accepting and understanding	Low-threshold treatment may lead to an underestimation of the severity Patients feel ashamed about having infectious disease
Hierarchical decision making	Variation in expertise and opinions among managements where HCV care should be centered	Variation in expertise and opinions among managements where HCV care should be centered Communication from management is poor Bureaucracy and slow decision-making

Table.

Results: We found 33 PWUD HCV RNA positive. Four patients were referred to the hospital for treatment due to hepatitis B virus or HIV co-infection or other reasons. Two patients currently receive treatment, three patients were not yet fit for treatment and two were lost to follow-up before treatment could be started. On-site treatment was initiated in 22 patients. Of these patients 91% was male, mean age was 50 years (SD=13) and 36% was born in the Netherlands. All patients completed treatment with glecaprevir/pibrentasvir (n=9) or sofosbuvir/velpatasvir (n=13). All on-site and hospital treated patients reached SVR and there were no reinfections. The viral elimination rate was 79% (26/33). Themes on facilitators and barriers for implementation collected in the interviews are shown in the table.

Conclusion: This study shows the high viral elimination (79%) of decentralized care of HCV infections within addiction care and provides insight in facilitators and barriers for on-site HCV treatment.

Based on these findings we recommend implementation and maintenance of decentralized HCV-addiction care models worldwide. This will lead to HCV elimination scaling-up in the Netherlands and abroad, furthering WHO goals.

ANTI-HDV REFLEX TESTING IN HBSAG-POSITIVE SUBJECTS: THE BEST STRATEGY TO IDENTIFY HDV INFECTION

V. Cossiga[1], S. Brusa[2], R. Montalti[3], A. De Conte[1], G. Jannuzzi[2], L. Ranieri[1], R. Sorrentino[2], L. Vallefuoco[2], L. Pignata[1], M. Capasso[1], M. Guarino[1], G. Portella[2], F. Morisco[1]

Contact E-Mail Address: mario.capa05@gmail.com

Introduction: In Italy, the prevalence of HDV infection in HBsAg carriers is about 9.9% (6.4% in Italian natives and 26.4% in immigrants). However, the actual prevalence is underestimated because the anti-HDV test is not performed routinely in all HBsAg carriers.

Aims & Methods: The aim of this study was to compare the prevalence and the absolute number of HDV infection identified in HBsAg-positive subjects tested at University Hospital Federico II before and after the introduction of anti-HDV reflex testing.

From January to December 2022, reflex test for the detection of total HDV antibodies was performed in all HBsAg positive subjects observed at AOU Federico II. We used as control group the HBsAg-positive subjects tested at the same laboratory between January and December 2019, before the implementation of anti-HDV reflex testing. Sera were evaluated with AD-VIA Centaur HBsAgII Qualitative, Liaison Murex HBsAg Quantitative and Liaison Murex Total Anti-HDV Qualitative.

Results: Before reflex testing, anti-HDV had been tested in 16.4% (84/512) of HBsAg positive subjects, while after its implementation, 100% (484/484) of HBsAg positive patients was tested for anti-HDV. The anti-HDV positive prevalence was lower than before the introduction of reflex test (10.7% vs 16.6%), but the absolute number of anti-HDV positive patients increased (14 vs 52 subjects). HDV-RNA was detectable in 26 (53%) of 49 subjects tested.

Conclusion: Our data showed that the implementation of anti-HDV reflex testing increased the number of diagnosis of HDV infection. In this setting, due to the forthcoming approval of specific anti-HDV drugs, a reflex test for anti-HDV should be implemented, in clinical practice, to early identify patients with HBV/HDV infection.

Disclosure: Nothing to disclose.

Introduction: Hepatitis C is a major global health problem caused by the hepatitis C virus, which can result in mild to severe symptoms, including liver cirrhosis and cancer. Unsafe medical practices, lack of awareness, poverty, intravenous drug abuse and limited access to healthcare facilities contribute to the high prevalence of this disease. An estimated 58 million people are effected with hepatitis c worldwide and every year 1.5 million are adding to burden (1).

Pakistan is one of the countries with the highest burden of hepatitis C, affecting around 12 million people having 4.2 % prevalence (2).

While the Pakistani government and international organizations have taken steps to eliminate hepatitis C, challenges remain, such as the stigma attached to the disease, limited access to screening and treatment in remote areas, and inadequate funding for hepatitis control program (3).

Aims & Methods: To address the issue of hepatitis C elimination in rural Pakistan, a cross-sectional observational study was conducted from January 2021 to December 2022 at the MTI Gajju khan Medical College Swabi. All patients above 18 years of age who visited the gastroenterology OPD were screened for Hepatitis C. Patients who were positive for Anti HCV antibody and had detectable HCV RNA were enrolled in the study.

Patients were divided into four groups: Chronic hepatitis C non cirrhotic treatment naïve and treatment experienced, Compensated Cirrhosis naïve and experienced. Sofosbuvir and Daclatasvir for 12 or 24 weeks were given, and Ribavirin was given to treatment-experienced and cirrhotic patients. Prevalence , efficacy of available free DAAs , recommendation to achieve elimination goal were discussed at end of study.

Results: Out of 10,240 patients screened for hepatitis C during their first visit to the gastroenterology OPD, 420 patients with a mean age of 36+16 having positive HCVRNA were enrolled. Almost 90% of the patients were non-affordable. After initial evaluations, the patients were separated into four groups. Chronic hepatitis C without cirrhosis was present in 287 patients, while cirrhotic were 137. Treatment-naïve patients were 307, and 113 patients were treatment-experienced. ETR was achieved in 403 (96%) patients, and SVR was achieved in 413 (91.5%) patients.

Conclusion: To achieve the hepatitis elimination goal 2030 in countries with low human development indexes, chronic hepatitis C screening, diagnosis, and management must be sponsored by national and international organizations. One-time screening should be offered for every patient above 18 years on first contact with healthcare workers. Unsafe medical practices should be strongly discouraged. The freely available drugs Sofosbuvir and Daclatasvir, with or without RBV, are highly effective treatment options for chronic HCV and the most adaptable strategy to eliminate hepatitis C. This regimen has produced excellent results in our country, influenced mainly by the presence or absence of cirrhosis and the easy and free availability of drugs.

Introduction: Opportunistic hepatitis C virus (HCV) screening, taking advantage of laboratory analysis requested to patients for another clinical reasons, has shown to increase HCV detection. Here, we present the results for HCV detection from "Sureste sin C" microelimination program, which is run within Hospital Universitario del Sureste sanitary area in Madrid (Spain). This program includes HCV training at hospital level at different services and in primary care, advertisement on informative panels, automation of preoperative protocol and search of lost to follow-up patients.

Aims & Methods: In July 2021, this HCV micro-elimination program began in our sanitary area. This program was supported by Gilead (within Hospitals without C program). A key point was to favor HCV opportunistic screening at different hospital services, both medical surgical (preoperatory) and Emergency departments. Moreover, systematic HCV serology screening (automatization) was included in the surgical preoperative service. The effectiveness of the program was measured in terms of number

of HCV-screening requests made between January-October 2019 (prior to the pandemic, first period) and January-October 2022 (second period).
Results: There were 3,709 requests for HCV serology (3,313 individual patients) in the first period, compared with 7,743 (6,902 individual patients) in the second period (109% increase). Divided by services, this increase was mainly due to the surgical services (251% increase), as a result of the automatic inclusion of HCV serology in the preoperative protocols, and in psychiatry (558% increase). In the medical area, the increase in the second period was 42%, being Gastroenterology, Internal Medicine, Pneumology and Oncology the services with greatest increase in requests.
Regarding Emergency department, an increase in requests of 101% was observed. In total, 145 Anti-HCV positive patients were detected in the first period (prevalence 4.37%), 48 being viremic (1.44%), compared to 130 patients in the second period (prevalence 1.88%), 29 viremics (0.42%).
Regarding only surgical services, there was a very significant increase in the number of positive serology in the second period (8 vs 45, 462% increase, prevalence 1.14%), as well as in the number of viremics (0 vs 5 patients, prevalence 0.12 %).
Conclusion: HCV serology automatization in the surgical preoperative protocol and the awareness and collaboration with other services to support opportunistic HCV screening, is an effective mechanism to achieve the objective of detecting infected patients within a hepatitis C microelimination program. Automatization in surgical preoperatory service has demonstrated to increase the detection of occult HCV infected patients.
Disclosure: This program was supported by Gilead (within Hospitals without C program).

Contact E-Mail Address: l.kupcinskas@gmail.com
Introduction: Lithuanian program for hepatitis C screening started on May, 2022. Based on results of our pilot study conducted in Klaipeda city (1) Lithuanian health authorities decided to pay general practitioners (GPs) a special fee for a service of promoting and performing serological tests for hepatitis C virus (HCV) antibodies:
1. For the population born in 1945-1994 (once per life) and
2. For people who inject drugs (PWID) or are HIV-infected (annual HCV testing).
Such an initiative is the first in Central and Eastern Europe.
This study aimed to evaluate the first results of the HCV screening program and develop different scenarios to achieve WHO targets to eliminate viral hepatitis C by 2030.
Aims & Methods: Patients were invited to participate in the HCV screening by GPs during the visits. Screening included a serum blood test for the presence of HCV antibodies. Patients who tested positive were referred to a gastroenterologist or infectious disease doctor. HCV RNA testing was used to identify the current infection. If the test result was positive, the doctor prescribed direct-acting antiviral (DAA) therapy. Information about screened and treated patients was obtained from the database of the National Health Insurance Fund. The Markov disease progression model elaborated by the CDA Foundation was used to assess HCV elimination progress in Lithuania. The data from the 2022 screening and previously published data were used as inputs. Three scenarios were developed: the 'Base' scenario - return to pre-screening program level in 2023 and 2 scenarios with different extents of treatment.
Results: Results: At the beginning of 2022, about 1.8 million people born in 1945-1994 lived in Lithuania. Between May 5, 2022 and January 31, 2023, population of 547627 people (58.9% women) were tested for HCV antibodies. Positive test results were found in 1.3% people. Seroprevalence of HCV antibodies was higher among men than women, 1.6% and 1.1%, respectively. In the risk group, 5345 PWID and HIV-infected people were screened, of whom 31,7% were seropositive. All seropositive patients were referred to specialists. Viremia was detected in 58 % of patients. In 2022, 1586 patients were treated with DAA. Treatment delay was related to organizational problems (specialist consultation waiting line, formal treatment restrictions, delay in drugs supply), but the number of treated patients during last two months of the program (December 2022- January 31, 2023) increased by 330 % in comparison to the same period of previous year before starting of program. If the number of tested patients remains the same as in the last three months in 2022, HCV antibody testing will be completed in 2023/2024. The Markov disease progression model to assess HCV elimination progress in Lithuania showed the following scenarios:
Scenario 1: if the same number of patients are treated as before the screening, the WHO targets will not be reached.
Scenario 2: treating 70% of infected patients (13000 in 2023/2024) will meet most but not all WHO targets. Scenario 3: by treating all infected patients by 2030, the WHO target will be met by saving 150 lives and preventing 90 new cases of decompensated cirrhosis and 120 cases of hepatocellular carcinoma.
Conclusion: In the Lithuanian screening program, HCV antibody testing by GPs is active; however, the number of patients treated needs to be increased to reach the WHO targets.

ISOLATED VIRAL LOAD INCREASE IN PATIENTS WITH HBEAG-NEGATIVE CHRONIC HEPATITIS B VIRUS INFECTION: CLOSE MONITORING OR ANTIVIRAL THERAPY?

C. Hsain[1], M. Kadiri[1], F.-Z. Chabib[1], C. Berhili[1], N. Lagdali[1], M. Borahma[1], I. Benelbarhdadi[1], F.Z. Ajana[1]
[1]Ibn Sina Hospital, Department of Hepato-Gastroenterology C, Rabat, Morocco

Contact E-Mail Address: ajafatimz@yahoo.fr
Introduction: HBeAg-negative chronic hepatitis B virus (HBV) infection (inactive carriers) is defined by: Normal ALT levels, minimal Fibrosis and/or low necrotic-inflammatory activity assessed by Fibroscan/Liver Biopsy and a Viral load (VL) <2000 ui/ml. An increase in VL in inactive carriers remains common.
Aims & Methods: The objective of our study is to determine the importance of regular VL monitoring in untreated inactive carriers with VL fluctuations between 2000 and 20000 ui/ml, and to evaluate the effectiveness of antiviral treatment.

This is a prospective, descriptive study conducted from 2018 to 2023, covering a 5-year period. The study involved all patients who were monitored in our gastroenterology department for chronic hepatitis B virus infection with negative Hbe Ag, and whose viral load (VL) fluctuated between 2000 and 20000ui/ml without cytolysis or worsening of fibrosis, and without any underlying cause identified.

Patients who had hepatitis D virus superinfection, those who were scheduled for immunosuppressive treatment, and pregnant patients were excluded from the study.

Results: A total of 64 patients with HBeAg-negative chronic HBV infection were followed up, median age was 47 years with extremes of 20 - 75 years and a sex ratio M /F of 1.

Initially, all patients were provided with a monitoring control. During the follow-up period, 21 patients showed an increase in VL, ranging from 2000 to 20000 ui /ml. These patients were divided into 2 groups: The 1st group representing 28.5% of the patients (n = 6) were treated with nucleotide analogues (Tenofovir 300mg/day), while the 2nd group represents 71.4% of the patients (n =15) remained under monitoring alone.

During 2 year follow-up, 83% of patients in the first group (n=5) achieved a negative VL, while only one patient had a decrease in VL after antiviral treatment. None of these patients showed seroconversion.

In the 2nd group, the VL remained fluctuating without exceeding 20000ui/ml and there was no evidence of clinical worsening or abnormal liver function tests during the follow up period.

Conclusion: Increased VL in inactive carriers is far from rare; there is no clear consensus on the required monitoring. However, the results of our study suggest that antiviral treatment may be effective in suppressing viral replication. These results also highlight the importance of close monitoring of VL in untreated patients. Despite the promising results of our study, it is essential to conduct a larger and more comprehensive study to further validate and confirm our findings.

Disclosure: Nothing to disclose.

Contact E-Mail Address: huiban.laura@yahoo.com

Introduction: The overall burden of B / D and C viral hepatitis remains substantial, despite the major advances in the prevention and treatment of patients in recent years, due to comorbidities and complications associated with liver disease. In this context, the national screening program LIVE (RO) 2 aims to further assess all patients identified as positive for one of the hepatitis B / D / C viruses.

Aims & Methods: The study aimed to identify fortuitous pathologies discovered in patients with chronic viral B / D / C infection diagnosed in the LIVE (RO) screening program 2. We conducted a prospective study that included people from vulnerable groups (poor, uninsured, rural people, people in foster care, homeless, Roma population, people with disabilities, and suffering from alcohol or drug addiction) in different areas of North-Eastern Romania, between July 2021 - April 2023, during the national screening program LIVE (RO) 2-EAST.

We also investigated the presence of newly discovered conditions in patients who tested positive and directed to the Institute of Gastroenterology and Hepatology in Iasi for the staging of liver disease and the establishment of antiviral treatment.

Results: The study group included 1176 patients, of which 422 men (35.8%) and 754 women (64.1%), aged between 35 and 83 years, with a mean age of 56.32 years. The predominant source of origin was rural (73.1%). Of the patients with positive RDTs, 635 (53.9%) patients were detected with HBsAg, 521 (44.3%) patients with anti-HCV antibodies, and 20 (1.7%) patients with anti-HVD antibodies. Of these, 215 patients (18.2%) were diagnosed with a new pathology associated with B / D / C viral infection.

The most common pathologies discovered incidentally were liver cirrhosis (94, 43.7%), liver cysts (35, 16.2%), liver hemangiomas (29, 13.4%), gallstones (24, 11.1%), type II diabetes mellitus (T2DM) (15, 6.9%), uterine fibroids (9, 4.1%), hepatocellular carcinoma (7, 3.2%), choledochal lithiasis (2, 0.9%). In addition, the presence of fortuitous pathologies was higher among patients with HBV infection than in those with HCV infection (65.3% vs. 42.1%, p = 0.012).

Among the risk factors associated with hepatocellular carcinoma (HCC) are chronic alcohol consumption (43%, compared to 19% in the group of patients without HCC), and the association of T2DM in 3 patients (31%, compared to 10% in the group of patients with HCC).

Conclusion: Patients with chronic B / D / C viral infection had a high prevalence of incidentally detected comorbidities, which necessitates the need for public health policies in vulnerable groups to promote access to existing health services to reduce the future burden of chronic diseases but also secondary complications of chronic liver disease.

Disclosure: Nothing to disclose.

PP1352

EPIDEMIOLOGY OF CHRONIC VIRAL HEPATITIS B/D AND C IN THE VULNERABLE POPULATION IN THE NORTH-EAST AND SOUTH-EAST REGIONS OF ROMANIA – INTERMEDIATE STAGE RESULTS IN THE LIVE(RO)2 - EAST SCREENING

A.-V. Trifan[1,2], L. Huiban[2,1], C.M. Muzica[1,2], R. Nastasa[1,2], S. Zenovia[2,1], R. Stafie[1,2], E. Stratina[2,1], A. Rotaru[1,2], A.M. Singeap[1,2], C. Cojocariu[1,2], C. Sfarti[2], I. Girleanu[2,1], S. Chiriac[1,2], H.-O. Minea[1,2], T. Cuciureanu[1,2], C. Stanciu[1,2]

[1]"Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania, [2]"St. Spiridon" Hospital, Institute of Gastroenterology and Hepatology, Iasi, Romania

Contact E-Mail Address: huiban.laura@yahoo.com

Introduction: In order to meet the requirements of the WHO, namely - the eradication of viral hepatitis by 2030, UMF "Grigore T. Popa" from Iasi together with ARAS and the Hospital "St. Spiridon" from Iasi, carries out since 2020 the project "LIVE(RO) 2 - Integrated regional program for prevention, early detection (screening), diagnosis and targeting treatment of patients with chronic liver disease secondary to viral infections with liver viruses B/D and C in the North-East and South-East regions".

Aims & Methods: This study aimed to assess the epidemiological characteristics of the vulnerable population in the eastern part of the country diagnosed with chronic B/D and C viral infection. Between July 2021 and April 2023, we performed a prospective screening of chronic viral hepatitis B/D and C in vulnerable people in the counties of North-East and South-East of Romania, within the national program LIVE(RO) 2 - EST. Rapid diagnostic tests were used to detect HBs antigen (HBsAg) and anti-HCV antibodies (HCVA): HBV (Wama Immuno-Rapid HBV®) and HCV (Wama Immuno-Rapid HCV®). Rapid test-positive patients were tested for HBV DNA and HCV RNA and those eligible under the national protocol were treated with antivirals.

Results: The study included 55593 individuals tested rapidly, of which 2160 (3.8%) patients were tested positive (1120 women, 1040 men, mean age 55.86 ± 6.023 years, predominantly rural background - 76.19%). Of these, 1077 (49.8%) were HBsAg positive, 918 (42.5%) with HCV positive needle, 37 (1.7%) HBV/HCV coinfection and 128 (5.9%) HBV/VHD coinfection. HBV-DNA was performed in 724 (67.3%) individuals, of which 452 (62.5%) subjects > 2,000 children/ml. Also, 518 (54.3%) patients with HCV-positive Ac had detectable HCV RNA, of which 375 (72.3%) received antiviral treatment. Depending on the ethnicity, the prevalence of viral infection was 4.29% in Roma people and 3.23% in Romanian people. Among the vulnerable groups determined by work, inactive people (27.7%), uninsured people (11.2%), unskilled people (1.87%), unemployed people (0.6%) and people working in agriculture (0.59%) were predominantly tested. Among the special vulnerable groups, people with disabilities (3.99%), people addicted to alcohol (2.43%) and people with a minimum income (1.21%) were predominantly tested.

Conclusion: The high prevalence of B/D and C viral infection in the vulnerable population tested in the North-East and South-East Region of Romania compared to the rest of the population, indicates the significant viral spread of the infection in these people, a condition that requires further testing and the need for policies public health in vulnerable groups to promote access to existing health services and early initiation of optimal antiviral treatment.

NONTUMORAL PORTAL VEIN THROMBOSIS IN PATIENTS WITH HEPATITIS C VIRUS AND SUSTAINED VIROLOGICAL RESPONSE - A FURTHER CHALLENGING CONSEQUENCE OF LIVER CIRRHOSIS

L. Huiban[1,2], C. Stanciu[1,2], C.M. Muzica[1,2], R. Nastasa[1,2], S. Zenovia[1,2], R. Stafie[1,2], E. Stratina[1,2], A. Rotaru[1,2], A.M. Singeap[1,2], C. Cojocariu[1,2], C. Sfarti[1,2], I. Girleanu[1,2], O. Stoica[1,2], S. Chiriac[1,2], T. Cuciureanu[1,2], A.-V. Trifan[1,2]

[1]"St. Spiridon" Emergency Hospital Iasi, Gastroenterology, Iasi, Romania, [2]"Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania

Contact E-Mail Address: huiban.laura@yahoo.com

Introduction: The advent of direct-acting antivirals (DAAs) is a major breakthrough in hepatology representing the therapeutical standard of care in patients with chronic hepatitis C virus infection. Despite high rates of sustained virological response (SVR), DAAs therapy doesn't eliminate the risk of thrombotic events.

Aims & Methods: We aimed to assess the prevalence of nontumoral portal vein thrombosis (PVT) after SVR.We prospectively analyzed a cohort of patients with HCV-related liver cirrhosis treated with paritaprevir/ritonavir, ombitasvir and dasabuvir (PrOD) ± ribavirin and ledipasvir/sofosbuvir (LED/SOF) ± ribavirin for 12/24 weeks, in a gastroenterology center from Romania, between January 1st 2016 and July 1st 2021. All patients with presumption of thrombosis were evaluated by vascular Doppler, abdominal ultrasound and confirmed by CT scan.

Results: The study included 730 patients treated with DAAs, of which 35 were diagnosed with non-malignant PVT after-SVR (15 men and 20 women, mean age 57.86 ± 7,068 years), corresponding to a prevalence of 4.8%. The mean time from SVR to complication was 290.00 ± 116.639 days. Most patients with nontumoral PVT received LED/SOF (71.4%), while the rest received PrOD (28.6%).

During the study, an improvement in the Child-Pugh and MELD score was observed at the SVR. The evolution changes slightly at the 48-week assessment, with a slight increase in the proportion of patients in the Child B class and MELD ≥ 15. The pro- and anticoagulant factors evaluated reflect the classic hemostatic profile of patients with liver cirrhosis and PVT, characterized by increased FII, FVIII and FvW and decreased anticoagulant factors (PC, PS, ATIII).

Conclusion: The study included 730 patients treated with DAAs, of which 35 were diagnosed with non-malignant PVT after-SVR (15 men and 20 women, mean age 57.86 ± 7,068 years), corresponding to a prevalence of 4.8%. The mean time from SVR to complication was 290.00 ± 116.639 days. Most patients with nontumoral PVT received LED/SOF (71.4%), while the rest received PrOD (28.6%). During the study, an improvement in the Child-Pugh and MELD score was observed at the SVR. The evolution changes slightly at the 48-week assessment, with a slight increase in the proportion of patients in the Child B class and MELD ≥ 15. The pro- and anticoagulant factors evaluated reflect the classic hemostatic profile of patients with liver cirrhosis and PVT, characterized by increased FII, FVIII and FvW and decreased anticoagulant factors (PC, PS, ATIII).

Introduction: Hepatitis C has an important global impact in terms of morbidity, mortality and economic costs, being a real public health problem worldwide. The efficacy of the new direct-acting antivirals treatment determined the World Health Organization (WHO) to adopt the ambitious strategy for Global Health Sector on Viral Hepatitis in 2016, having as main objective to eliminate hepatitis C virus (HCV) by 2030. In response to this challenge, several countries have already initiated the micro-elimination strategy as part of the global C virus eradication program.

Aims & Methods: We aimed to evaluate the prevalence of HCV infection and risk factors in a Romanian village population-based screening and link these data to the antiviral treatment.We conducted a prospective study from 1 March 2022 to 28 February 2023, based on a strategy as part of a project designed to educate, screen, treat and eliminate HCV infection in all adults, in a village located in Northeastern Romania. All demographic data and risk factors for HCV infection were collected through a questionnaire.

Results: In total, 3507 subjects were invited to be screened by rapid diagnostic orientation tests. Overall, 2945 (84%) subjects were tested, out of whom 78 (2.64%) were found with positive HCV antibodies and were scheduled for further evaluation in tertiary center of gastroenterology/hepatology, in order to be linked to care. A number of 66 (85%) subjects presented for evaluation and 55 (83%) had HCV RNA detectable. Of these, 54 (98%) completed antiviral treatment and 53 (99%) obtained sustained virological response. The main risk factors associated with chronic HCV infection were family history of HCV (OR=2.23, 95%CI=1.37–3.5, p<0.0001), professional exposure to blood products (OR=0.25, 95%CI=0.11-0.53, p<0.0001), blood transfusions performed before 1992 (OR=3.21, 95%CI=2.25-4.52, p<0.0001), abortions undergone before 1990 (OR=1.35, 95%CI=1.02-1.9, p<0.023), multiple surgical interventions (OR=1.32, 95%CI=1.05-1.72, p<0.038) and sharing personal hygiene objects (OR=1.45, 95%CI=1.12-1.73, p<0.002).

Conclusion: The elimination of hepatitis C worldwide has become a reality, with higher chances of success if micro-elimination strategies based on mass screening are adopted. At the same time, sustained effort it required from all. The development of screening programs can facilitate the cascade of care from diagnosis to treatment of all patients and the achievement of WHO objectives.

PREDICTORS OF RESPONSE TO SOFOSBUVIR-CONTAINING REGIMENS FOR CHRONIC HEPATITIS C IN INDIVIDUALS WITH CHRONIC KIDNEY DISEASE

I. Algohary[1], R. Gaweesh[1], M. Tahoun[2], M. Elkaraly[1], A. Kamal[3]
[1]Alexandria University, Faculty of Medicine, Internal Medicine, Nephrology, Alexandria, Egypt, [2]Alexandria University, Faculty of Medicine, Clinical Pathology, Alexandria, Egypt, [3]Alexandria University, Faculty of Medicine, Internal Medicine, Hepatology, Alexandria, Egypt

Contact E-Mail Address: ahmed.kamal.med.scientific@gmail.com
Introduction: Globally, hepatitis C virus (HCV) infection is still common among chronic kidney disease (CKD) patients despite the advent of serologic screening of blood by enzyme-linked immunoassays, routine use of erythropoietin for patients with anemia and CKD, and better adherence to infection control procedures to prevent the spread of HCV within dialysis units. A large body of epidemiological evidence regarding HCV infection among patients undergoing maintenance dialysis in the developed world has accumulated. prevalence rates have been shown to range between 1.4% and 28.3%. The prevalence rates observed in developing countries remain much higher with prevalence rates between 4.7% and 41.9%. Treatment of CKD patients with pegylated interferon plus ribavirin was challenging and with low response rates.
On its approval, sofosbuvir was not used among CKD patients with creatinine clearance < 30 ml/min, but recently its usage was approved after demonstrating its safety among these patients.
Aims & Methods: Our aim was to determine the response rate of sofosbuvir based regimens in CKD stage 4/5 and end stage renal disease (ESRD) patients on maintenance hemodialysis and to determine the predictors of treatment failure, including (IFNL4) SS469415590 gene polymorphism.
The study included 55 HCV pateints CKD stage 4/5 and ESRD on MHD. The sample size was calculated using G Power 3.1.9.4, 2018. Based on an effect size of direct acting antiviral therapy of HCV among patients with ESRD of 0.4, alpha error of 0.05, power of 80%, the minimum required sample size was calculated to be 52 patients.
Results: Sustained virologic response was achieved in 52.7% of cases. Among those who failed to achieve SVR, platelets and albumin was significantly lower ($p < 0.001$), INR and total bilirubin was significantly higher ($p < 0.001$). Both APRI and FIB-4 scores were significantly higher among those who failed to achieve SVR ($p < 0.001$). The favorable IFNL4 genotype (TT/TT) was present in 36.4% of the 55 patients. 58.6% of the TT/TT genotype patients achieved SVR compared to 41.4% of the non-TT/TT genotype patients ($p= 0.001$). On multivariate logistic regression analysis, higher FIB-4 Score was significantly associated with failure to achieve SVR. ROC curve analysis revealed that at a cut-off ≥ 2.63, pretreatment FIB-4 had a sensitivity of 88.46%, and negative predictive value (NPV) of 90%.
Conclusion: In CKD patients with stage 4 or stage 5, greater FIB-4 scores are linked to a higher chance of failing to achieve SVR after receiving sofosbuvir-containing regimens for chronic HCV infection.
Disclosure: Nothing to disclose.

Contact E-Mail Address: andy.j.walker@gsk.com
Introduction: GLIMMER (NCT02966834) was a Phase 2b study of the ileal bile acid transport (IBAT) inhibitor, linerixibat, for treatment of cholestatic pruritus in primary biliary cholangitis (PBC). The study included 147 patients: the largest trial in this population to date. GLIMMER had few restrictions on concomitant medications with the exceptions of other IBAT inhibitors, bile acid sequestrants and obeticholic acid; stable doses of other treatments were permitted.
Aims & Methods: In this analysis we explore the pruritus treatment history of patients entering GLIMMER. Investigators recorded details of prior and concomitant use of itch medications on the electronic case report form. For categorisation of prior and/or concomitant itch medication: prior only included patients who had tried and stopped at ≥1 pruritus medication before first study treatment and were not using anything else during treatment with linerixibat/placebo; concomitant only included patients who had used ≥1 pruritus medication in the past, which they continued to use during treatment; prior and concomitant included patients who had tried and stopped ≥1 pruritus medication prior to the study and, continued to use ≥1 pruritus medication during treatment with linerixibat/placebo. This post hoc analysis included all treatments prescribed for itch; guideline treatments were defined as bile acid sequestrants, naloxone, naltrexone, nalmefene, nalfurafine, sertraline, rifampicin or gabapentin. Pruritus severity was defined using worst itch numeric rating scale (NRS).
Results: At baseline, 24% of patients had mild (NRS <4), 52% moderate (NRS ≥4–<7) and 25% severe (NRS ≥7–10) pruritus. Mean age at baseline was 55.8 years but varied by itch severity, with mild patients being older (60.1 years) than those with moderate and severe pruritus (56.8 and 49.6 years, respectively). Median duration of pruritus at baseline was 6.3 years and those with mild pruritus tended to have a longer history than those with moderate or severe itch. Overall, a large proportion of patients were never previously treated: 37% (n = 55) had no prior/concomitant itch medications. Similar proportions of patients, 24% (n = 36) and 26% (n = 38), had received only prior itch medications or received prior and concomitant treatment for pruritus, respectively; 12% (n = 18) of patients were using only concomitant itch medications. Only 25% of patients were treated with cholestyramine, despite it being the guideline-recommended first-line therapy.
Treatment history differed by baseline itch severity: 43% of mild patients had no prior or concomitant treatment versus 28% of severe patients. However, differences were less marked for concomitant pruritus therapy use: 43%, 36% and 39% of mild, moderate and severe patients, respectively, continued concomitant itch medicines in GLIMMER. The majority of concomitant itch treatments were non-guideline recommended, with only 39% receiving guideline treatments.
Conclusion: Consistent with the literature, increased itch severity is associated with younger age. Many patients do not receive treatment despite lengthy history of pruritus, while prior use of cholestyramine is limited despite its position in treatment guidelines.

ALBI AND PALBI SCORES ARE PREDICTORS OF PROGNOSIS IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

R. Tababi[1], S. Mrabet[1], I. Akkari[1], E. Ben Jazia[1]
[1]Farhat Hached University Hospital, Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: ramzi.tababi@gmail.com

Introduction: ALBI and PALBI scores are simple biomarkers developed to evaluate liver function. They are calculated using albumin and bilirubin levels (and platelet count for PALBI score) which are considered ones of the main prognostic hallmarks in primary biliary cholangitis (PBC).

Aims & Methods: This study aimed to determine the prognostic value of ALBI and PALBI scores in PBC patients. We retrospectively included patients followed-up for PBC in our centre from 2000 to 2021, all treated with ursodeoxycholic acid (UDCA) for at least 12 months. Clinical and biological data were collected. Treatment biochemical response was defined according to Paris II criteria.

Liver complications occurring during follow-up were noted; namely ascites, variceal haemorrhage, hepatic encephalopathy and hepatocellular carcinoma. ALBI score /grade as well as PALBI score were determined via online calculators.

Survival analysis was made using Kaplan-Meier model. Diagnostic performance was assessed using ROC-curve analysis and area under the curve (AUROC).

Results: There were 50 patients of mean age 55 ±11 years old and 98% female. Nineteen patients (38%) were cirrhotic at diagnosis. Baseline median (and interquartile range: IQR) of ALBI and PALBI scores were -2.17 [-2.78; -1.60] and -5.31 [-5.99; -4.15].

Patients' distribution according to ALBI grades was as follows: grade 1 (n=22), grade 2 (n=20) and grade 3 (n=8).

At 12 months of UDCA treatment, 32 patients (64%) had biochemical response. During a median follow-up of 75,5 months [30; 110 months], thirteen patients (26%) had at least one liver-associated complication at 5 years.

Median liver related event-free survival was higher in ALBI-grade 1 patients (191 months [IC95%: 173-210 months] than in those with ALBI-grade 2 (84 months [IC95%: 51-117 months]) and ALBI-grade 3 (25 months [11-39 months]). The statistical difference using Log-rank test was significant: grade 1 vs grade 2 (p=0.002), grade 1 vs grade 3 (p<0.001) and grade 2 vs grade 3 (p=0.002).

ALBI score could predict liver complication at 5 years with an AUROC of 0.85 (p<0.001). A cut-off value of -2.07 or greater had a sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy (DA) of 92%, 72%, 57%, 96% and 78% respectively.

PALBI score was also a good predictor of liver complication at 5 years (AUROC: 0.88, p<0.001). A cut-off value of -4.91 or greater had respective values of sensitivity, specificity, PPV, NPV and DA of 92%, 81%, 67%, 96% and 84%.

Both scores could predict treatment response as well. ALBI score had an AUROC of 0.84 (cut-off <= -2.24, sensitivity: 71%, specificity: 88%, PPV: 91%, NPV: 65%, DA: 78%, p<0,001). The AUROC of PALBI score was 0.88 (cut-off <= -4.91, sensitivity: 89%, specificity: 88%, PPV: 93%, NPV: 83%, DA: 89%, p<0,001).

Conclusion: ALBI and PALBI scores were good prognostic biomarkers as they were highly performant in predicting treatment response along with identifying patients at risk of developing liver complications. These scores could help stratify patients eligible for more intensive therapy.

Disclosure: Nothing to disclose.

THE DEVASTATING IMPACT OF SEVERE PRURITUS IN PRIMARY BILIARY CHOLANGITIS (PBC)

H.T. Smith[1], M.M. McLaughlin[2], S. Das[3], A. Ribiero[4], P. Troke[5], A.J. Kremer[6], D. Jones[7]
[1]GSK, Value Evidence and Outcomes, London, United Kingdom, [2]GSK, Medicine Development, Collegeville, PA, United States, [3]GSK, Biostatistics, Hyderabad, India, [4]GSK, GI/Hepatology, Madrid, Spain, [5]GSK, Global Medical Affairs, London, United Kingdom, [6]University of Zürich, Department of Gastroenterology and Hepatology, Zürich, Switzerland, [7]Newcastle University, Liver Immunology, Newcastle, United Kingdom

Contact E-Mail Address: phil.j.troke@gsk.com

Introduction: Pruritus associated with primary biliary cholangitis (PBC) affects sleep and, social and emotional wellbeing. The impact of itch severity on quality of life (QoL) using the EuroQol-5-Dimension 5-Level (EQ-5D-5L) health utility score was explored and quantified in a post hoc analysis of the Phase 2b GLIMMER study of linerixibat for the treatment of pruritus in PBC (NCT02966834). Pruritus (particularly severe pruritus) was previously found to have a significant negative impact on QoL and health utility: mean (standard deviation [SD]) baseline utility was 0.69 (0.23); patients with mild or moderate pruritus at baseline had similar utilities (0.75 [0.17] and 0.76 [0.17], respectively) whereas patients with severe pruritus at baseline had notably worse utility (0.49 [0.28]).

Aims & Methods: Here we look in detail at factors impacting QoL in patients with PBC and pruritus. Patients in GLIMMER completed the EQ-5D-5L and Beck Depression Inventory (BDI-II) at baseline, which followed a 4-week single-blind placebo run-in period. EQ-5D-5L is a generic, standardised and simple health-related QoL instrument. Scores range from 1 "perfect health" to 0 "death". BDI is a 21-item, self-rated scale that evaluates key symptoms of depression. An overall score of 0–9 is classed as minimal depression, 10–18 mild, 19–29 moderate, and 30–63 severe depression. Patients were classified as having mild (<4, at baseline all mild were ≥3 to <4), moderate (≥4 to <7) or severe pruritus (≥7 to 10) using the mean worst daily itch score. Sleep disturbance severity was based on the same numerical rating scale thresholds as those used for pruritus.

Results: There were striking associations between itch severity, sleep disturbance and health utility, and between itch severity, depression and health utility. Overall mean (SD) health utility was highest in those with mild sleep disturbance 0.83 (0.126). Those with severe sleep disturbance had a much lower score and those with severe itch and severe sleep disturbance even lower (0.52 [0.30] and 0.47 [0.31], respectively). For patients with mild itch, 60% had mild sleep disturbance; the remaining 40% of patients had moderate sleep disturbance. In patients with severe itch, 34% experienced moderate sleep disturbance, while 66% had severe sleep disturbance. Thus, no patients with mild itch had severe sleep disturbance and no patients with severe itch had mild sleep disturbance. As might be expected, health utility was lower with worse depression; from 0.81 (0.18) with minimal depression to 0.39 (0.31) for those with severe depression; amongst those with moderate or severe depression the incremental impact of severe pruritus on health utility was striking, with utilities of 0.32 and 0.26, respectively. In mild and moderate itch, the distribution of depression severity was similar, with over 80% having minimal or mild depression. However, in the group with severe itch, 49% had moderate or severe depression.

Conclusion: Pruritus in PBC significantly impacts QoL. Severe sleep disturbance and moderate and severe depression were far more common in patients with severe pruritus. In patients suffering with both severe pruritus and moderate to severe depression, health utility was severely impaired.

Contact E-Mail Address: raniahalloul23@gmail.com

Introduction: Gastro-oesophageal varices (GOV) can occur in early stage primary biliary cholangitis (PBC), making it difficult to identify the appropriate time to begin screening with oesophageo-gastro-duodenoscopy (OGD). This proves the utility of a clinical tool to predict the probability of finding GOV in PBC patients such as the Newcastle Varices in PBC (NVP) Score.

Aims & Methods: Our aim was to assess the performance of this score in predicting GOV in PBC patients. We conducted a retrospective study analyzing clinical data of 72 PBC patients treated with Ursodeoxycholic acid (UDCA). The presence of GOV was noted as well as the occurrence of variceal bleeding. The NVP score was calculated for all the patients who underwent OGD. The performance of the score was assessed using ROC curves.

Results: Seventy-two patients were included with a mean age of 53.5 years. UDCA at the dose of 13-15 mg/kg/day was prescribed for all the patients. The median follow-up time was 9 years. An OGD was done for 69 patients (95.8%). Esophageal varices were found in 34 patients (47.2%). They were grade 1, 2 and 3 in respectively 12.5%, 29.2% et 5.6% of the patients. Gastric varices were present in 5 patients (6.9%). A quarter (25%) of the patients had a variceal bleeding during the follow-up time. The analysis of ROC curves showed that the NVP score had a good performance to predict the development of GOV in PBC patients (AUC=0.914, p<0.001).

Conclusion: According to our study, the NVP score is an inexpensive and non-invasive tool that accurately predicts GOV in PBC. Thus, it can be considered a substitute for OGD for GOV screening in PBC patients. Further studies are warranted to confirm these results.

Disclosure: Nothing to disclose.

PP1360

THE PREVALENCE AND RISK FACTORS FOR GALLSTONES IN AUTOIMMUNE LIVER DISEASES

Y. Hu[1], M. Liu[1], L. Zhou[1]

[1]Tianjin Medical University, Department of Gastroenterology and Hepatology, General Hospital, Tianjin, China

Contact E-Mail Address: 1035856587@qq.com

Introduction: Autoimmune liver diseases (AILDs) includes primary biliary cholangitis (PBC), autoimmune hepatitis (AIH) and primary sclerosing cholangitis (PSC), in which the immune system produces an inappropriate response to self-antigens leading to chronic liver disease. Gallstone disease is one of the most commonly occurring gastrointestinal disorders. The prevalence of gallbladder stones in patients with chronic liver disease is 22%-54%, higher than the general population[1].

Chronic liver disease in most studies mainly refers to viral hepatitis and alcoholic liver disease, and there are no studies on AILDs complicating gallstones. Previous studies have shown that gallstones were associated with autoimmune disease[2] and were a common cause of secondary sclerosing cholangitis[3], but the association between AIH, PBC and gallstones has not been reported yet.

We have observed that the combination of AILDs and gallstones are a common phenomenon in clinical practice. Therefore, our study was intended to analyze the proportion and the clinical characteristics of gallstones in patients with AILDs as a reference for clinical decision making in patients with AILDs complicated by gallstones.

Aims & Methods: We investigated the comorbidity of gallstones and risk factors associated with gallstones in patients with AILDs. AILDs patients attending the General Hospital of Tianjin Medical University from November 2012 to October 2022 were retrospectively included. Analysis of the proportion of AILDs patients with gallstones (including patients who underwent cholecystectomy for gallstones), clinical characteristics, and laboratory test. Logistic regression analysis was used to assess the risk factors for the combination of gallstones in patients with AILDs.

Results: A total of 560 patients with AILDs were enrolled, including 207 patients with PBC, 289 with AIH and 64 with PBC-AIH overlap syndrome (PBC-AIH). The proportion of patients with AILDs, PBC, AIH and PBC-AIH complicated by gallstones was 32.50%, 35.75%, 28.37% and 40.63%, respectively. Multiple stones predominate in patients with AILDs complicated by gallstones (43.41%), followed by single stones (32.42%) and sludge (6.04%). Age at first visit (p=0.007) and serum biochemical markers associated with bile duct injury such as GGT (p=0.003) and ALP (p=0.001) were significantly higher in patients with AILDs complicated by gallstones compared to those without gallstones. Age (odd ratio [OR] = 1.024; 95% confidence interval [CI] =1.006-1.042 and serum ALP levels (OR = 1.001; 95% CI = 1-1.002) were independent risk factors for patients with AILDs complicated by gallstones, while serum GGT levels (OR = 1.002; 95% CI = 1-1.003) were independent risk factors for patients with AIH complicated by gallstones. Significantly higher prevalence of gallstones in patients with AILDs older than 61.5 years (p=0.003).

Conclusion: Gallstones are more common comorbidity in AILDs patients, predominantly multiple stones. Age and serum ALP levels were independent risk factors for patients with AILDs complicated by gallstones. Patients with AILDs complicated by gallstones present with significantly elevated serum biochemical parameters associated with bile duct injury. The comorbidity of gallstones tends to delay the initial diagnosis of patients with AILDs.

PP1361

DEPRESSION AS A RISK FACTOR FOR CIRRHOSIS IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: A DECISION TREE-BASED RETROSPECTIVE COHORT STUDY

L. Guo[1], S. Zhou[1], L. Zhou[1]
[1]Tianjin Medical University General Hospital, Tianjin, China

Contact E-Mail Address: glp0626@163.com
Introduction: Primary biliary cholangitis (PBC) is an immune-mediated cholestatic liver disease characterized by progressive destruction of the small intrahepatic bile ducts, leading to fibrosis and eventually cirrhosis. Previous studies demonstrated a high proportion of depression in patients with PBC. Accumulating evidences have shown that depression is associated with the severity of liver diseases and some extrahepatic autoimmune diseases (EHAIDs). Compared to general population, the prevalence of depressive symptoms in patients with cirrhosis is higher (18-58% vs. 10%).
Moreover, cirrhotic patients with depression experience worse clinical outcomes. A diagnosis of depression before liver transplantation is related to reduced survival after transplantation. Antidepressant mirtazapine correlated with the reduced incidence of decompensated cirrhosis, liver transplantation and decreased mortality in patients with PBC. Therefore, it is important to screen for depression, and the effect of depression on patients with PBC remains to be fully elucidated.
Previous studies demonstrated that HLA alleles were closely related to PBC susceptibility. DRB1*08:03, DRB1*07:01, and DPB1*17:01 conferred an increased risk to PBC among Chinese populations. In another study, DRB1*07:01, 14:01 and 14:05 were the major predisposing alleles for PBC in China. Among Europeans, DRB1*08 was demonstrated to be a risk factor for PBC. HLA-DRB1 alleles were also associated with cirrhosis in patients with autoimmune hepatitis (AIH), autoimmune sclerosing cholangitis (ASC), and chronic hepatitis C. However, DRB1*11 and DRB1*13 were associated with a reduced risk of developing PBC. DRB1*11:01 was also demonstrated to be protective in post-traumatic stress disorder, bipolar affective disorders, and depression of early undifferentiated arthritis. In summary, it is helpful to explore the effect of HLA-DRB1 alleles on depression and further cirrhosis in patients with PBC.
Aims & Methods: A comorbid depression is common in patients with primary biliary cholangitis (PBC), of which the role in disease progression remains unclear. Genetic predisposition such as human leukocyte antigen (HLA)-DRB1 alleles are reported to be linked with both depression and PBC. For better management of PBC, it is pivotal to establish a risk model for cirrhosis that takes depression and HLA-DRB1 alleles into account. In this study, patients with PBC and healthy controls were evaluated for depressive symptoms using the Patient Health Questionnaire-9 (PHQ-9). Patients with PBC were divided into a model (n = 141) and validation cohort (n = 51). Further, we designed our study to determine the role of depression in treatment response, as well as the effect of depression and HLA-DRB1 alleles on cirrhosis.
Results: In detail, depression was observed to be a common phenomenon in patients with PBC (76/141, 53.9%), and positively associated with levels of alkaline phosphatase (ALP), ɣ-glutamyl transpeptidase (GGT), and Immunoglobulin (Ig)M in serum. HLA-DRB1*03:01 allele, which was more common in PBC patients with depression than those without, increased the risk of cirrhosis in patients with PBC (odds ratio [OR], 5.676; p < 0.001). Importantly, our study showed that PHQ-9 score, HLA-DRB1*03:01 allele, and other factors (age and level of ALP), were determined as risk factors for cirrhosis in patients with PBC by logistic analysis. Consistent with the logistic regression model, the elevated PHQ-9 score (>= 3.5) was calculated as a discriminating risk factor for cirrhosis in decision tree model.
Conclusion: In conclusion, the depressive symptom was associated with poor treatment response and was a risk factor for cirrhosis in patients with PBC. These results highlight the important clinical significance of the identification and management of depression in patients with PBC.

Introduction: Ursodeoxycholic acid (UDCA) is often used to treat patients with autoimmune hepatitis (AIH), although the immunomodulatory effects remain unclear. In this study, we investigated the effect of UDCA in patients with AIH and a mouse model of immune-mediated hepatitis (IMH).
Aims & Methods: We performed a retrospective cohort study by collecting patient data from 75 adults with AIH. A mouse model of immune hepatitis induced by concanavalin A (ConA) was established in C57BL/6J mice. The expression of hepatic inflammatory factors and immune cells in the liver and spleen was analyzed by real-time quantitative polymerase chain reaction and flow cytometry.

	UDCA group n = 26	Prednisone group n = 30	Combination Therapy group n = 19	Total n = 75
Female, n (%)	26 (100)	29 (96)	19 (100)	74 (98.67)
Age at diagnosis, years[a]	57.5±11.26	56.57±9.84	56.68±10.68	56.92±10.45
ALT (U/L)[b]	69.50 (93.95)	209.50 (202.76)	247.00 (106.00)	157.00 (216.5)
AST (U/L)[b]	60.50 (67.00)	200.00 (171.20)	224.00 (139.00)	167.00 (143.00)
IgG (g/L)[b]	1800.00 (400.00)	1850.00 (515.00)	1900.00 (630.00)	1850.00 (550.00)

Liver cirrhosis, n(%)	4 (15.38)	6 (20.00)	6 (31.58)	16 (21.33)

Note: Data represent the number (percentage), mean ± SD or median (interquartile range, IQR). a, mean ± SD; b, median (IQR).
Abbreviations: ALT: alanine aminotransferase; AST: aspartate aminotransferase; IgG: immunoglobulin G; ANA: antinuclear antibody; HAI: histologic activity index; HFI: histologic fibrosis index.
Table.

Results: During the 24-month follow-up, 34.7% of patients with AIH received UDCA monotherapy. The mean levels of biochemical markers in the UDCA monotherapy group were significantly decreased. An additional use of UDCA improved the clinical remission and reduced the required dosage of immunosuppressants. In the mouse model of immune hepatitis, UDCA downregulated expression of cytokine tumor necrosis factor-α(TNF-α)

and necroptosis markers in the liver. UDCA pretreatment upregulated the proportion of immunomodulatory myeloid-derived suppressor cells, and downregulated the accumulation of liver macrophages.

Conclusion: UDCA monotherapy is effective in AIH patients, and the additional use of UDCA improves clinical remission. UDCA pretreatment exhibits immunomodulatory activity against ConA-induced IMH.

Introduction: Autoimmune hepatitis (AIH) is a rare chronic liver disease. Assessment of Health-Related Quality of Life (HRQoL) in this field has emerged as a novel method to evaluate the well-being of patients and their therapeutic management. The aim of this study was to evaluate the health-related quality of life in patients with autoimmune hepatitis by comparing it to that of patients with chronic hepatitis C and healthy subjects.

Aims & Methods: We conducted a single centre study enrolling patients followed in our department for AIH between 2010 and 2023. Thirty patients followed for hepatitis C in our center et forty healthy subjects were selected as a control group. We assessed health related quality of life in these patients using the chronic liver disease questionnaire which is a specific tool used in liver disease to appreciate the HRQoL. Patients with decompensed cirrhosis were excluded.

Results: A total of 100 patients were enrolled: 30 patients with AIH, 30 patients with chronic hepatitis C and 40 healthy subjects. The median age was 51 (50-, 64- and 45-year-old respectively in AIH, chronic hepatitis C and healthy subjects) and the sex-ratio was 0,4. The overall Chronic Liver Disease Questionnaire scores (82 vs. 190, P<0.001), the worry domain (8 vs 30, P<0.001), the systemic symptom domain (14 vs 35, P<0.001) and the fatigue domain (10 vs 25, P<0.005) were significantly inferior in patients with autoimmune hepatitis compared to healthy subjects. Similarly, these scores were significantly worst in AIH patients compared to hepatitis c patients: overall Chronic Liver Disease Questionnaire scores (82 vs. 138, P < 0.001), the worry domain (8 vs 30, P<0.001), the systemic symptoms domain (14 vs 35, P<0.001) and the fatigue domain (10 vs 25, P<0.001). In AIH patients, the univariate analysis showed that cirrhosis was associated with lower overall score (99 vs 145, P<0.01) and lower score on the worry domain (7 vs 27, P<0.002) and the use of prednisolone was associated with lower scores on the worry domain (7 vs 8, P<0.05).

Conclusion: Patients with autoimmune hepatitis show a significant impairment of health-related quality of life compared to hepatitis c patients and healthy subjects. Therefore, focusing on the quality of life in these patients is important in order to provide an optimum medical care.

SINGLE ORIFICE OUTFLOW RECONSTRUCTION IN RIGHT LOBE GRAFT LIVING DONOR LIVER TRANSPLANTATION: A PRELIMINARY VIETNAMESE STUDY

H. Le Trung[1], T. Le Van[1], N. Nguyen Quang[2]
[1]Central Military Hospital 108, Department of HBP Surgery and Liver Transplant, Hanoi, Vietnam, [2]Vietduc University Hospital, Organ Transplantation, Hanoi, Vietnam

Contact E-Mail Address: liversurg108@gmail.com

Introduction: Outflow reconstruction is one of the key requirements of a successful living donor liver transplantation. The aim of study is to evaluate the technical characteristics and outcomes of single orifice outflow reconstruction in living donor liver transplantation using right lobe graft in a center in Vietnam.

Aims & Methods: The prospective study was performed on 52 cases of living donor liver transplantation using right lobe graft at 108 Military Central Hospital from January 2019 to December 2020. Polyester prostheses were used in reconstructing the MHV when the remnant liver volume was less than 35% of the donor liver volume. Venous branches with diameter ≥ 5mm were preserved and anastomosed to the prosthesis.

Results: There were 42 cases of using the extended lobe living donor liver transplant including the middle hepatic vein (HV) (80.8%) and 10 cases of the modified right lobe graft with the middle HV reconstructed from the V5 and/ or V8 branches (19.2%) by using polytetrafluoroethylene artificial vessels. We conjoined the middle hepatic vein and right hepatic vein as a single orifice anastomosis. The right hepatic vein of recipient were enlarged to the left and downwards at the orifice, with a mean incision length of 14 mm and 9.7 mm, respectively.

A total of 15 accessory right inferior hepatic veins with diameter > 5 mm were anastomosed directly to inferior vena cava (IVC) in an end-to-side fashion in recipient (28.8%). There were 3 cases of middle hepatic vein obstruction (2 stenoses, 1 occlusion) (5.7%).

The mortality rate of hepatic venous outflow obstruction was 1,9%. The caliber of HV anastomosis (< 30 mm) was an independent risk factor for hepatic venous outflow obstruction (p = 0,01).

Conclusion: The single orifice hepatic vein reconstruction in living donor liver transplantation using a right lobe graft is a simple and feasible surgical technique, and it does not require cadaveric vessels.

Disclosure: No Conflict of Interest.

Introduction: Acute-on-chronic liver failure (ACLF) is a critical syndrome occurring in individuals with acutely decompensated cirrhosis, characterised by high short-term mortality and multiorgan failure. Accurate prognostic scores are essential to support ICU treatment and outcomes. Socioeconomic status (SES) is a known, independent contributor to ill health and mortality.

This study aims to determine if incorporating SES into the CLIF-C ACLF score, a prognostic tool for ACLF outcomes, adds value in predicting in-hospital mortality in patients with ACLF.

Aims & Methods: Data from consecutive patients admitted to the Royal Free London ICU with a complication of cirrhosis, between 2016 and 2017, were obtained from the Royal Free NHS Trust database. CLIF-C ACLF scores were calculated at day 0 and 2 of ICU admission and in-hospital survival was assessed. SES was determined using the English Indices of Deprivation, a validated government tool that utilises individual postcodes to infer a deprivation decile. A higher decile indicates a higher SES and vice versa. Multiple logistic regression was used to examine the joint association between both CLIF-C ACLF and SES upon in-hospital mortality.

Results: The cohort comprised of 851 patients, of which 131 patients have been analysed thus far. There is no significant difference in age or sex between mortality groups (Table 1).

Regression analysis showed that SES proves a statistically significant improvement to the CLIF-C ACLF score in predicting in-hospital mortality at day 0 and 2 of ICU admission (p-value = 0.048 and p-value = 0.041, respectively). Additionally, the odds ratios demonstrated a significant inverse relationship between SES and in-hospital mortality, with an odds ratio of 0.847 (95% CI: 0.718 to 0.999) at day 0 and 0.821 (95% CI: 0.664 to 0.992) at day 2.

		Dead		Alive		
	n	Mean ± SD	n	Mean ± SD	Test used	p-value
Age	48	55.8 ± 12.3	83	53.3 ± 15.0	Independent T-Test	0.317
CLIF-C ACLF D0	48	59.9 ± 11.2	83	50.1 ± 9.74	Independent T-Test	<0.001
CLIF-C ACLF D2	32	64.9 ± 10.2	55	50.5 ± 11.3	Independent T-Test	<0.001
Delta (D0 to 2)	32	0.125 ± 9.36	55	-2.49 ± 7.61	Independent T-Test	0.163
	n	Median (IQR)	n	Median (IQR)	Test used	p-value
Deprivation Decile	48	3.5 (2 - 6.25)	83	5 (3 - 7)	Mann-Whitney U Test	0.054
	n	Male/Female	n	Male/Female	Test used	p-value
Sex	48	27/21	83	54/29	Chi-Squared Test	0.317

Table 1: Multiple analyses comparing in-hospital mortality groups.

Conclusion: Our findings suggest SES can add predictive value to the CLIF-C ACLF score with regards to in-patient mortality, allowing acute care clinicians to more accurately risk stratify patients in ICU. These findings may also have implications for public health strategies for targeting primary and secondary prevention schemes. Validation in larger cohorts is justified.

PREGNANCY OUTCOMES AND MATERNAL RISKS AFTER LIVER TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

L. Bannon[1,2], N. Zmora[3,2], M. Dishi -Galitzky[4,2], H. Katchman[1,2], S. Levy[1,2]

[1]Tel Aviv Sourasky Medical Center, Gastroenterology and Hepatology, Tel Aviv, Israel, [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [4]Tel Aviv Sourasky Medical Center, Department of Obstetrics and Gynecology, Tel Aviv, Israel

Contact E-Mail Address: sharonl@tlvmc.gov.il

Introduction: Pregnancy after liver transplantation (LT) is rising in prevalence. Although recent studies have shown an overall favorable outcome in post-LT pregnancies, there is still an increased risk of complications. Current recommendations suggest postponing pregnancy for at least one year after transplantation, yet the optimal timing of conception is a matter of debate. Since LT is still uncommon in fertile women, a multicenter and international effort is required to accumulate sufficient data to improve outcomes.

Aims & Methods: Our aim was to explore maternal and perinatal outcomes in post-LT pregnancies in a single tertiary referral medical center.

Data on pregnancies and deliveries in LT recipients a single tertiary center (Tel-Aviv Sourasky Medical Center, Israel) from 2013 through 2022 was retrospectively collected and analyzed.

Demographics, clinical data and laboratory tests throughout the course of pregnancy, delivery and perinatal period was retrieved from medical records and reviewed. Birth weight percentile was determined using the Dollberg curve.

Results: During study period we identified a total of 21 pregnancies in nine patients. Mean age at conception was 32 ± 4.8 years and mean time interval between LT and pregnancy was 5.9 ± 3.5 years. The indications for LT in 5 women (56%) were acute liver failure (due to autoimmune hepatitis, paracetamol toxicity and an unknown etiology).

Four other women were transplanted for chronic liver disease (HBV, PSC, Willson's disease and secondary sclerosing cholangitis after Kassai procedure), two of whom had portal hypertension complications (variceal bleeding and ascites).

Seven (33%) out of the pregnancies ended in miscarriages in the first trimester and 14 (67%) in viable newborn deliveries. Mean birth week was 36 ± 3.3 and the mean birth weight was 2640 ± 717.3 grams with mean weight percentile of 41 ± 24. Out of 14 living births only six (42.8%) reached term, seven (50%) were late preterm, of whom one was diagnosed with intrauterine growth retardation, and one (7%) baby was an early preterm (week 25, weight 750) and died shortly after birth.

Maternal outcomes were favorable, with only two (14%) pregnancies complicated by intrahepatic cholestasis of pregnancy (ICP) with full resolution after delivery, and two (14%) by acute rejection episode with good response to medical treatment. All women received calcineurin inhibitor-based immunosuppression either as monotherapy (2 women) or combined with azathioprine (7 women).

Conclusion: Despite improvement in LT outcomes and post-transplant care, pregnancy in LT recipients is still challenging with a high rate of miscarriage, pre-term delivery and low birth weight. There is a need for further data collection and analysis, which may assist in better risk stratification and improving patients care

MACROPHAGE ACTIVATION SYNDROM, RARE CAUSE OF ACUTE LIVER FAILURE WITH POOR PROGNOSIS

J. Brezina[1], L. Bajer[2], M. Hlavatý[1], P. Wohl[1], J. Spicak[1], P. Drastich[1]
[1]Institute for Clinical and Experimental Medicine, Hepatogastroenterology, Prague, Czech Republic, [2]IKEM, Hepatogastroenterology, Prague, Czech Republic

Contact E-Mail Address: lukasbajer1@gmail.com

Introduction: Macrophage activation syndrome (MAS), also known as secondary hemophagocytic lymfohistiocytosis (HLH) is poorly described life-threatening condition. It is caused by excessive activation of immune system with subsequent proinflammatory state resulting in multiorgan involvement. Clinically, MAS is characterized by fever, cytopenia, hepatosplenomegaly and elevated circulating ferritin. MAS can develop into acute liver failure (ALF) with poor prognosis.

Aims & Methods: We retrospectively analysed patients referred to our transplantation centre for ALF in whom the diagnosis of MAS was confirmed by histology. We focused on diagnosis leading to MAS, survival, transplantation outcome and clinical, laboratory and histological findings.

Results: From January 2005 to November 2022, we found eight patients with MAS referred to our centre for ALF. The underlying condition was EBV infection in five cases and adult Still disease in three cases. All eight patients had strongly elevated circulating ferritin (in average 19321 µg/l), leukocytosis and thrombocytopenia.

All patients except one had at least one negative bone marrow or lymph node examination prior to definitive diagnosis of MAS. Seven patients were treated with high-dose corticosteroids. Four patients met King's College criteria for urgent liver transplantation. Two of them were transplanted. Despite intensive therapy based on mechanical ventilation, continuous renal replacement therapy and circulation support, their clinical condition further deteriorated and all four patients died on average 34 days after symptom onset of multiorgan failure. At the autopsy, hemophagocytic macrophages have been described in multiple organs. Four patients who responded to corticosteroid therapy are in long-term remission after specialized haematological treatment with etoposide.

Conclusion: Macrophage activation syndrome represents rare cause of acute liver failure with high mortality, it is difficult to diagnose and even harder to treat. Our case series suggests that when the patients meet King's College criteria, they die despite the successful liver transplant. Therefore, it is important to carefully consider liver transplantation in these patients.

Contact E-Mail Address: luispedroasantos@gmail.com

Introduction: Liver transplantation (LT) is a potentially life-saving treatment for patients with end-stage liver disease, particularly acute-on-chronic liver failure (ACLF) patients due to high mortality rates.

Aims & Methods: Aims: This study aimed to characterize the population and outcomes of patients with ACLF undergoing LT, as well as to identify factors associated with worse prognostic.

Methods: Retrospective cohort study including 155 consecutive LTs performed in a Tertiary Center, between January 2020 and December 2022. ACLF was defined according to the EASL-CLIF consortium definitions. The statistical analysis was performed with the SPSS software v28.

Results: A total of 155 patients received a LT, including 25 with ACLF (16.1%). Of these, 16 (64%) had ACLF-1, 3 (12%) ACLF-2, and 6 (24%) ACLF-3, with renal dysfunction being the most common organ failure (27%). Mean age 55 years (80% male). The most frequent etiology of cirrhosis was alcohol (80%). In 68% of patients, at least 1 precipitating event was identified, with infections being the most frequent one (56%). The 1-year mortality rate after LT was 22%. No statistically significant factors associated with mortality were identified, however, spontaneous bacterial peritonitis as a precipitating event of ACLF showed a strong association with death (p=0.08).

Conclusion: ACLF is a growing indication for LT, comprising 1 in every 6 patients transplanted in this cohort. Our results suggest that renal failure and infections should be carefully managed in cirrhotic patients to avoid progression to ACFL. No predictors of post-LT mortality were identified.

PP1369

SHEAR WAVE ELASTOGRAPHY IS A RELIABLE NON-INVASIVE METHOD FOR THE ASSESMENT OF PORTAL HYPERTENSION IN NAFLD PATIENTS

P. Kikovic[1], M. Stulic[1], S. Stojkovic[1], J. Martinov Nestorov[1], N. Pejic[1], D. Culafic[1], M. Stojkovic Lalosevic[1]
[1]Clinical Center of Serbia, Gastroenterology and Hepatology, Belgrade, Serbia

Contact E-Mail Address: drmilicastojkovic@gmail.com

Introduction: Shear wave elastography is a non-invasive method for the assessment of liver fibrosis in patients with chronic liver diseases. Portal hypertension occurs as a result of increased blood flow and resistance due to liver liver fibrosis.

Furthermore, portal hypertension can lead to development of complications such as variceal bleeding, which significantly affects morbidity and mortality.

Aims & Methods: Aim of this study was to investigate correlation of liver tissue stiffness, measured with shear wave elastography, with the presence of esophageal varices found on upper endoscopy. This cross-sectional study included patients treated at the Gastroenterohepatology Clinic of the University Clinical Centre of Serbia, diagnosed with non-alcoholic fatty liver disease. Demographic, etiological, biochemical, clinical, ultrasonographic, and endoscopic features were analyzed in all patients.

The tissue stiffness was measured and expressed in kilopascals (KPa) using the S-Shear wave feature of the SAMSUNG RS80A device with a convex probe. The measurement reliability was determined using the Reliable Measurement Index (RMI) and Interquartile Range (IQR).

Results: Our study included 51 patients, among them 51% were male gender, while 49% were female gender, average age of 48 years, diagnosed with non-alcoholic fatty liver disease. In our cohort 22% of the patients were found to have esophageal varices, while 78% had no evidence of varices. Our results have demonstrated that there was statistically significant difference in values of liver stiffness between the patients with and without esophageal varices (17.7±8.94 vs 8.08±4.04, p<0.05). There was a statistically significant positive correlation between the existence of esophageal varices and the degree of fibrosis (R=0.82, P<0.05).

Conclusion: Our results support the usage of shear wave elastography as a non-invasive method for predicting the presence of portal hypertension in patients with liver diseases.

Disclosure: Nothing to disclose.

COMPARISON BETWEEN TRANSIENT ELASTOGRAPHY AND POINT-SHEAR WAVE IN NON-ALCOHOLIC STEATOHEPATITS PATIENTS: A PROSPECTIVE STUDY

G. Losurdo[1], A. Continisio[1], M. De Bellis[1], I. Ditonno[1], D. Novielli[1], M. Rendina[1], A. Castellaneta[1], A. Di Leo[1], M. Barone[1]
[1]University of Bari, Section of Gastroenterology, DIMEPREJ, University of Bari, Bari, Italy

Contact E-Mail Address: a.continisio2@gmail.com

Introduction: Transient elastography (TE) by Fibroscan® is a widespread method for non-invasive evaluation of liver stiffness measurement (LSM). Point-shear wave elastography (pSWE) is an alternative non-invasive method for this type of assessment. Transient elastography is also able to evaluate hepatic steatosis by the function Controlled Attenuation Parameter (CAP).

Aims & Methods: We aimed to compare the results of TE and pSWE for fibrosis assessment in patients with non-alcoholic steatohepatitis (NASH), stratified by the degree of steatosis.

Consecutive patients with established diagnosis of NASH attending our Gaastroenterology Unit underwent liver stiffness measurement (LSM) by both TE and pSWE. Liver steatosis was measured by CAP and the severity was graded into S0-S3. At least 10 measurements were performed and results were expressed as median with interquartile range. Statistical analysis was conducted by Pearson's test for correlation and linear regression. Bland-Altman graphs with bias and ROC curves with estimation of sensitivity, specificity, and area under the curve (AUC) were drawn.

Results: Seventy-seven patients were recruited (17 females, 60 males, aging 54.1 ± 13.9). The overall correlation between TE and pSWE was moderate (r=0,63, p < 0.001). Linear regression showed a "b" coefficient of 0.99 ± 0.033. The Bland-Altman plot found a bias of -0,52 and only six valued exceeded the 95% CI limits. When considering patients with mild steatosis (S1), we found a strong correlation (r=0.81, 95% CI 0.39-0.95, p=0.003). The highest correlation between TE and pSWE was recorded for S2 subjects: r=0.90 (95% CI, 0.64-0.98, p<0.001). The correlation was low in S3 patients (r=0.42, 95% CI, 0.09-0.67, p=0.001). A cut-off of 11.15 kPa of pSWE had sensitivity=87,50 % and specificity=97,10% to detect relevant fibrosis, with an AUC=0.98 compared to TE.

Conclusion: pSWE and TE showed comparable LSM in NASH. A good concordance was observed in patients with mild or moderate liver steatosis, while in S3 patients we observed a weaker agreement between the two techniques.

Disclosure: Nothing to disclose.

Contact E-Mail Address: cmcho@knu.ac.kr

Introduction: Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) for hepatic solid lesions has emerged as a safe technique to obtain an adequate liver tissue for diagnosis of parenchymal liver disease. However, the optimal FNB techniques have not been evaluated. Out study aimed to compare the diagnostic yield and specimen adequacy for EUS-FNB in hepatic solid lesions using different FNB techniques.

Aims & Methods: This is a single center retrospective study of EUS-FNB for hepatic solid lesions between Mar. 2015 and Jun. 2022. Each one needle pass of suction and slow-pull suction was applied for the same hepatic lesions and the sequence was randomly assigned. The primary outcomes were diagnostic yield to attain a histological diagnosis and rate of adequate specimen acquisition.

Results: A total of 119 patients (40 female, median age 70 years) underwent EUS-FNB for hepatic solid lesions. The mean size of hepatic solid lesion was 34.9+27.3 mm (range 7-150). Solid live lesions were located at S1 in 5 (4.2%), S2/3 in 97 (81.5%), S4 in 13 (10.9%), and S5/6/7/8 in 4 (3.3%). Needle puncture was approached at esophagus in 5 (4.2%), stomach in 108 (90.8%), and duodenum in 6 (5.0%). The use of needle was 20G Pro-Core in 44 (37.0%) and 22G in 75 (63.0%). The final diagnosis of solid liver lesions was benign in 3 (2.5%) and malignancy in 116 (97.5%) including cholangiocarcinoma (49, 41.2%), metastasis (63, 52.9%), hepatocellular carcinoma (2, 1.7%), and lymphoma (2, 1.7%). The overall diagnostic yield to obtain a tissue diagnosis was 90.8%. There was statistically no difference in diagnostic accuracy between suction and slow-pull suction (79.8% vs. 84.9%, P=0.308). Slow-pull suction obtained more adequate specimen comparing to suction (95.0% vs. 87.4%, P=0.040).

	Slow-pull suction, n (%)	Suction, n (%)	P value
Histologic diagnosis			
- Malignancy	91 (76.5)	86 (72.3)	
- Suspicious for malignancy	7 (5.9)	6 (5.0)	0.203
- Atypical	11 (9.2)	6 (5.0)	
- Benign	4 (3.4)	6 (5.0)	
Inadequate specimen	9 (5.0)	15 (12.3)	0.040
Diagnostic accuracy	101 (84.9)	95 (79.8)	0.308
Grossly core tissue acquisition	111 (93.3)	103 (86.6)	0.085

Table 1. Comparison of specimen adequacy and diagnostic performances according to EUS-FNB techniques.

Conclusion: The use of slow-pull suction EUS-FNB demonstrated improved specimen adequacy compared with suction technique with no difference in diagnostic accuracy.

Introduction: Hepatocellular carcinoma (HCC) is the most frequent primary liver tumor, emerging on the background of cirrhosis in the vast majority of cases. It is characterized by high vascularization and recent evidence showed a derangement in the metabolism of nitrogen substrates in HCC. Antiangiogenic therapy is the standard of care for patients with advanced HCC or intermediate HCC ineligible to locoregional treatments (1).

However, these therapies are burdened by significant toxicity and high costs. Hence, it is important to early identify responders who can benefit from these agents and non-responders who can be candidate to alternative treatments (2). 13N-ammonia is a PET perfusion tracer that is mainly metabolized in the liver (3).

Aims & Methods: The aim of the present study was to assess the potential role of PET-CT with 13N-ammonia to evaluate early response to antiangiogenic agents in advanced HCC patients, correlating 13N-ammonia PET-CT response with CT mRECIST response. Secondary aims of the study were to evaluate 13N-ammonia PET-CT perfusion parameters (K1 and k2) in HCC lesions, non-neoplastic liver and the liver of patients without liver diseases undergoing PET-CT for cardiologic indications and to correlate HCC perfusion parameters with outcomes of response to treatment.

Eighteen consecutive patients (mean age: 67.3 ± 9.0 years) with advanced HCC underwent contrast-enhanced CT and dynamic PET-CT with 13N-ammonia (acquisition time 20 minutes; 370 mBq) before (baseline) and 8-10 weeks after (post-therapy) the start of antiangiogenic treatment. For each patient, quantitative analysis was performed: volumes of interest (VOIs) were drawn on the descending aorta, on up to five HCC lesions and on two non-neoplastic liver areas using baseline and follow-up contrast-enhanced CT, and transferred on baseline and follow-up PET-CT, respectively. K1 (ml/cm3/min), k2 (min-1) and K1/k2 parameters were estimated using one-tissue compartment model. For each patient, percentage changes in K1 and k2 parameters in HCC lesions (ΔK1, Δk2, ΔK1/k2) between baseline and follow-up PET-CT were correlated to mRECIST response criteria, used as standard reference.

Results: The comparison between CT mRECIST and PET-CT response demonstrated significant concordance (p=0.044).

At baseline, HCC lesions showed higher median K1 values than non-neoplastic liver (0.94 (IQR 0.67) vs. 0.42 (IQR 0.34), p=0.0003) and liver of patients without liver diseases (0.94 (IQR 0.67) vs. 0.44 (IQR 0.13), p=0.001). Median k2 values were also higher in HCC lesions compared with non-neoplastic liver (0.17 (IQR 0.14) vs. 0.07 (IQR 0.06), p=0.0006) and liver of patients without liver diseases (0.17 (IQR 0.14) vs. 0.04 (IQR 0.07), p<0.0001) at baseline.

The comparison of perfusion parameters between responders and non-responders according to mRECIST criteria showed no significant difference at both baseline and follow-up PET-CT.

Early progressors after treatment had higher baseline K1 values compared with early non-progressors (median 1.45 (IQR 0.78) vs. 0.68 (IQR 0.46), p=0.03). Similarly, median k2 values were inversely associated with early progression (early progressors 0.22 (IQR 0.13) vs. early non-progressors 0.14 (IQR 0.11)) with a trend towards statistical significance (p=0.07).

Conclusion: Dynamic 13N-ammonia PET-CT may be a promising metabolic tool to predict response to antiangiogenic therapy in patients with advanced HCC. Particularly, values of PET perfusion parameters may help to evaluate the response of antiangiogenic therapy and predict liver decompensation and death in patients with advanced HCC.

ASSESSMENT OF LIVER STIFFNESS IN SUBJECTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE WITH ILIVTOUCH AND FIBROSCAN: RESULTS OF PROSPECTIVE TRIAL

S. Morozov[1], V. Isakov[1]
[1]Federal Research Center of Nutrition and Biotechnology, Gastroenterology & Hepatology, Moscow, Russia

Contact E-Mail Address: morosoffsv@mail.ru

Introduction: Liver stiffness measurements has become a "gold standard" for liver fibrosis assessment. New techniques based on the same physical principles have become available, but little is known about their comparative efficacy, especially in subjects with non-alcoholic fatty liver disease.

Aims & Methods: Aim: to compare the data of liver stiffness measurement with the use of FibroScan 502 (EchoSens, France) and iLivTouch FT200 (Wuxi Hisky Medical Technologies Co., China) devices.

Method: Subjects with non-alcoholic fatty liver disease (per EASL guidelines) who gave informed consent were eligible for the study (NCT05224037 at clinicaltrials.gov). All participants were examined on the same day with the use of both, iLivTouch FT200 (Wuxi Hisky Medical Technologies Co., China) (data are marked as LT) with a standard sensor, and Fibroscan 502 (EchoSens, France) with M or XL sensors depending on the patient's characteristics (FS). We compared the efficacy of examination and analyzed the results obtained with both devices depending on the stage of liver fibrosis. The null hypothesis was the absence of differences between the data obtained using both devices.

Results: The data of 105 people (58 women, mean age per group 52.8±12.6 years, BMI: 32.3±9.48 kg/m^2) were available. Success rate for FS was 68.7 ± 29% compared to LT: 86.9±19%; p<0.001. In 5 patients, it was impossible to conduct examination with FS, while it was possible to obtained at least 10 measurements using LT (in all cases BMI was >35 kg/m^2). In 1 case, it was not possible to obtain sufficient number of measurements with LT, although FS gave successful result.

There was significant direct correlation between the data of liver stiffness measurements obtained with both devices: Spearman rank R=0.56. However, comparison revealed significant difference in values: 9.6±6.6 kPa with LT vs 6.9±4.5 kPa using FS, p<0.0001.

In patients with NAFLD with advanced stages of liver fibrosis (F2+, n=29) the values of FS and LT were similar: 11.8±5.9 kPa for FS vs 13.9±7.9 kPa for LT, p=0.2. However, the values of liver stiffness differed significantly when subjects had milder stages (F0-1, n=71,) of liver fibrosis: 4.9±1.0 kPa for FS

vs 7.4±3.0 kPa, p<0.001. The agreement in liver fibrosis stage assessment (using cut-off values provided by the manufacturers) were as follows: for F0 - 56.9%, for F1-42.9%, F2-43.8%, F3-66.7%, and F4-70% of cases.
Conclusion: The results of liver stiffness obtained with Fibroscan and iLivTouch correlate closely. However, the agreement between studied techniques in subjects with non-alcoholic fatty liver disease is low.To make the measurements obtained with iLivTouch more accurate it may be necessary to develop new cut-off values that corresponds with different stages of liver fibrosis.

Introduction: Currently, we can reliably and non-invasively determine steatosis and liver fibrosis by CAP/ATI/PDFF and ET/2D-SWE/MRE, respectively. However, it is not possible to accurately determine the inflammatory component without biopsy. In addition to 2D-SWE and Attenuation Imaging, some new multiparametric US devices incorporate the tissue viscosity-dependent 2D-SWD dispersion slope parameter. The liver is not a purely elastic but a viscoelastic organ, so that 2D-SWD measurement could be useful in the determination of necroinflammation. Our aim was to evaluate the correlation of SWD with the inflammatory component of MAFLD.
Aims & Methods: Prospective study. Immediately prior to liver biopsy (Tru-Cut 16G) in patients with suspected MAFLD, SWD (Canon Aplio i800) was performed. Exclusion criteria were: liver biopsy length <1.5 cm/<11 portal tracts, absence of MAFLD on final biopsy result (steatosis <5%). MAFLD was classified according to NASH-CRN. Normally distributed quantitative variables were described using the mean; otherwise, the median was calculated.
Results: 112 patients were included: age 53 years, women 55%, BMI 30.9 kg/m^2, diabetes 39%, GPT 62 U/L. Biopsy: 2.5 cm, 14 portal spaces. Fibrosis distribution was: F0 53 (46%), F1/F2 37 (32%), F3/F4 25 (22%). Steatosis distribution was: S1 35 (34%), S2 30 (29%), S3 39 (37%). Steatohepatitis: definite 52 (45%), absent 47 (41%), indeterminate 16 (14%). SWD values showed statistically significant differences between patients without steatohepatitis/indeterminate vs. steatohepatitis (13 (m/s)/KHz vs. 13.750 (m/s)/KHz; p=0.015). A positive linear correlation was also observed between SWD and NAS score (rho = 0.216; p=0.028). For the lobular inflammation component, a value of 14.5 (m/s)/KHz had Esp 89.5%, PPV 93.1%, while 10.5 (m/s)/KHz had Sens 90.5%, NPV 80.9%.
Conclusion: The SWD dispersion parameter determined by mulparametric ultrasound could be useful in the non-invasive assessment of liver inflammation and the diagnosis of steatohepatitis in MAFLD patients.
Disclosure: Nothing to disclose.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is currently the most common chronic liver disease. NAFLD may lead to the development of non-alcoholic steatohepatitis, which further may progress to fibrosis, cirrhosis and hepatocellular carcinoma. Quantitative ultrasonography (QUS) has been recently introduced in to clinical settings as a method for the assessment of hepatic steatosis.
Aims & Methods: To investigate correlation of tissue attenuation imaging and tissue scatter distribution imaging with biochemical markers of NAFLD. This cross-sectional study included patients treated at the Gastroenterohepatology Clinic of the University Clinical Centre of Serbia, diagnosed with NAFLD. Demographic, etiological, biochemical, clinical, ultrasonographic, and endoscopic features were analyzed in all patients. Tissue attenuation imaging and tissue scatter distribution imaging was assessed using the QUS feature of the SAMSUNG RS80A device with a convex probe. The measurement reliability was determined using the Reliable Measurement Index (RMI) and Interquartile Range (IQR).
Results: Our study included 50 patients, among them 51% were male gender, while 49% were female gender, average age of 48 years. Mean TAI values were 0.65±0.16, mean TSI values were 94.01±12.8. There was statistically significant positive correlation between the values of cholesterol levels and these two scores (R=0.732, P<0.05). Furthermore there was statistically significant positive correlation between the values of HOMA IR with these two scores (R=0.866, P<0.05). Moreover these score were in positive correlation with GGT levels (R=0.669, P<0.05).
Conclusion: Our results support the usage of quantitative ultrasonography as a tool for the assessment and diagnosis establishment of NAFLD.
Disclosure: No conflict of interest to disclose.

Introduction: Non-invasive assessment of liver structure is an invaluable current practice of hepatology.

The rate of obesity is increasing globally. Africa is not an exception as obesity has become quite prevalent in many parts of Africa like Nigeria.

Steatosis (excessive fat in the liver) can be assayed in the liver using a controlled attenuation parameter (CAP) during transient elastography (TE).

Aims & Methods: All patients fasted for at least 3 hours prior to carrying out a Fibroscan. The level of fibrosis was recorded in kPa and the CAP in dB/m. The machine (Fibroscan Expert 630) also recorded the Shear wave speed (SWS) in meters per second. Height and weight were obtained using a Stadiometer and BMI was extrapolated. Biodata was obtained using a questionnaire

Results: One thousand four hundred and nine participants (1,409) were studied. The mean age was 43.84 (sd=14.27) years. About Sixty-five percent (64.84%) were males. The commonest (57.5%) indication for Fibroscan was Chronic Hepatitis B (CHBVI). Alcohol consumption and or suspicions of fatty liver disease made up about Nine percent (8.93%) of the indications. About 48% had higher-than-normal BMI.

About 81% had steatosis stage S0 (<248 dB/m). Nineteen percent had different degrees of steatosis. The largest group was S3 (280dB /m and above) with 9.6 %. Stage S1 (2458-267dB/m) was 5.7%. About 20% had significant fibrosis (14.0kPa and above) via TE measurement.

Age had a weak positive correlation (+0.185) with TE scores while BMI had a weak negative correlation (-0.162) with TE scores. On the other hand, the CAP score was strongly and positively (+0.461) correlated with BMI but negatively (-0.073) with SWS. P=0.001

On multiple regression, only BMI (B =4.09) significantly predicts CAP score by about 4 folds, p=0.0001.

Conclusion: The rate of obesity is increasing among adults in North-central Nigeria. Among this cohort, it's clear that as BMI increases, the degree (Stage) of steatosis also increases.

Disclosure: Nothing to disclose.

Introduction: The **aim** of this study was to evaluate and to establish cut-off values for two new quantitative ultrasound (QUS) parameters, TSI (tissue scatter-distribution imaging) and TAI (tissue attenuation imaging) in early diagnosis of liver steatosis (LS), as compared to controlled attenuation parameter (CAP).

Aims & Methods: A prospective study was conducted in which LS was assessed in the same session by QUS (Samsung Medison RS85,CA1-7A probe) and CAP (FibroScan Compact M530, M/XL probes). Reliable measurements were defined for CAP the median value of 10 measurements with IQR/M<0.3, and for QUS, five consecutive measurements of TAI and TSI acquired by a color-coded map. TAI and TSI were automatically calculated and considered reliable when reliability index, R^2>0.6. The CAP cut-off value used for the whole cohort for at least mild steatosis (S1) were 248 dB/m[1]; for ALD (alcoholic liver disease) cohort, 268 dB/mm[2]; for NAFLD(non-alcoholic liver disease) cohort 294dB/m[2]. Demographic and health related datas were recorded.

Results: A total of 285 patients, with a mean age of 56.1±12.4, 114 female and 171 male, were included in the study. According to aetiology, 164 (57.5%) patients had NAFLD, 61(21.4%) ALD, and 60 (21.1%) were other etiologies (viral, cardiac, autoimmune). The obtained TSI and TAI cut-off values for the diagnosis of at least mild steatosis (S1) are presented in Table 1.

Variable		Overall	NAFLD	ALD
TSI	S1	**>96.2** AUC=0.74,p<0.0001, Se=87.9%,Sp=53.0%;	**>96.5** AUC=0.73, p<0.0001, Se=90.9%, Sp=47.9%;	**>94.9** AUC=0.70, p=0.003 Se=72.9%,Sp=75.0%;
TAI	S1	**>0.73** AUC=0.82,p<0.0001, Se=78.3%,Sp=71.6%;	**>0.75** AUC=0.81, p<0.0001, Se=57.5%, Sp=90.8%;	**>0.66** AUC=0.74, p<0.0001, Se=84.8%,Sp=57.1%;

Table 1. Cut-off values of TAI and TSI for S1

There were no differences between the performance of TAI and TSI according to the DeLong test, p=0.18 and p=0.24. A strong direct correlation was observed between TAI and CAP r=0.701, moderate between TSI and CAP r=0.56 for the all cohort, but for NAFLD and ALD subgroups moderate correlations were found between TAI and CAP r=0.66, and r=0.66 respectively and TSI and CAP r=0.56 and 0.66, respectively.

In univariate regression analysis, the factors associated with TSI were hypertension, Diabettes mellitus(DM), and obesity, and all p-values were <0.0001, but in multivariate analysis, only hypertension(p=0.001) and obesity(p=0.0005) were associated. For TAI, in univariate analysis, the same factors: hypertension(p=0.004), obesity(p=0.0006) and DM (p=0.002) were associated, but in multivariate analysis, DM was the only factor associated, p=0.02. Age and gender were not correlated with any method, TSI or TAI.

Conclusion: TAI and TSI are feasible non-invasive methods for screening and diagnosis of liver steatosis, with good accuracy. Patients with NAFLD presented highest cut-off values, probably by the presence of DM and obesity, conditions independently associated with TAI and TSI values.

Introduction: Liver biopsy (LB) remains essential for the diagnosis and staging of parenchymal liver diseases. Endoscopic ultrasound-guided LB (EUS-LB) has emerged as an attractive alternative to percutaneous and transjugular routes.

Aims & Methods: Our aim is to compare the sample adequacy of EUS-LB with percutaneous LB.

Methods: A single-centre, randomized, controlled clinical trial was designed. Patients undergoing LB were randomly assigned to EUS-LB or percutaneous LB. EUS-LB was performed with a 19-gauge Franseen core needle through transduodenal and transgastric route. Percutaneous LB was done with a 16-gauge Tru-cut needle.

Main outcome was the percentage of adequate samples obtained.

Secondary outcomes were the percentage of accurate histological diagnosis, number of complete portal tracts (CPT), total and longest specimen length (TSL, LSL), sample fragmentation, adverse events (AE), and patients' satisfaction. An adequate specimen was defined as TSL≥20 mm and including ≥11 CPT.

Results: 90 patients were randomized (44 to EUS-LB and 46 to percutaneous LB) and included in the analysis. Percentage of adequate tissue samples was 32.6% and 70.4% for percutaneous LB and EUS-LB respectively (p<0.001). A final histological diagnosis was provided in all cases but one. TSL was longer after EUS-LB (23.5 mm vs 17.5 mm, p=0.01), while number of CPT was similar in both groups. Sample fragmentation occurred more often after EUS-LB (p<0.001). No differences in AE were found. Satisfaction reported with both procedures was high

Conclusion: EUS-LB is safe and accurate, and may be considered as an alternative to percutaneous LB for the evaluation of parenchymal liver diseases.

Disclosure: Nothing to disclose.

POLYCOMB PROTEIN SUZ12 PREDICTS POOR SURVIVAL OF HEPATOCELLULAR CARCINOMA AND PROMOTES INVASION POTENTIAL VIA ACTIVATING CXCR7 TRANSCRIPTION

L. Xia[1], T. Zheng[2], T. Xue[2]

[1]Shenzhen University, Shenzhen, China, [2]Fudan University, Shanghai, China

Contact E-Mail Address: xialixin@126.com

Introduction: Hepatocellular carcinoma (HCC) is a well-known deadly malignancy, accounting for about 8.2% cancer-related death worldwide. Particularly, invasion and metastasis is still the main obstacle to improve the survival of advanced HCC patients. Although high-throughout screen, such as GWAS, whole exon-sequencing, RNA sequencing has uncovered some genetics changes, the driver genes are relatively low mutation ratio in HCC. On the other hand, accumulated evidence suggests that cancer cells can use the similar regulation mechanisms in mammalian development. Our previous work revealed that goosecoid, which plays critical roles in gastrulation and neural crest development could promote the metastasis of HCC by modulating the epithelial-mesenchymal transition. However, the underlying development-related mechanisms utilized by HCC cells remain largely unknown, particularly genes involving epigenetic changes.

Aims & Methods: Aims: Polycomb proteins, such as EZH2 and EED, have been widely revealed involving in development and cancer. However, the roles of another development-related polycomb protein suppressor of zeste 12 (SUZ12) in cancer remains largely unknown. Here, we investigated the roles of SUZ12 in hepatocellular carcinoma (HCC) and the underlyling mechanisms.

Methods: Tissue microarray based on 88 tumor tissues and 27 normal liver tissues was used to examine the expression level of SUZ12. The gain- and loss- of function analysis was conducted to evaluate the effects of SUZ12 on the proliferation, migration and invasion of HCC cells. Meanwhile, luciferase reporter assay and RT-PCR assay were conducted to examine the effect of SUZ12 on the transcriptional activity of chemokine receptors 7 (CXCR7).

Results: High frequency of 17q amplification including SUZ12 locus in HCC was revealed through genome sequencing. Further, SUZ12 expressed relatively higher in tumor tissues and HCC cell lines, particularly in HCC cells with highly metastatic potential. Clinically, high SUZ12 expression was an independent prognostic factor for poor overall survival (hazard ratio =2.540, p = 0.002) of HCC patients, which was further confirmed by analyses of TCGA based database. Functionally, in vitro assays revealed that up-regulation of SUZ12 promoted the migration and invasion of HCC cells, whereas down-regulation of SUZ12 inhibited the migration and invasion potentials.

Furthermore, we found SUZ12 strongly upregulated the transcriptional level of CXCR7 screened from chemokine receptors family. Also, CXCR7 was revealed to contribute to the tumor-promoting roles of SUZ12.

Of interest, luciferase reporter assay revealed SUZ12 positively controlled the CXCR7 via direct promoter combination but not epigenetic suppression. Moreover, high SUZ12 expression was positively correlated with CXCR7 in advanced patients with portal vein invasion.

Conclusion: These findings indicate that SUZ12 is associated with the poor survival of HCC, and promotes the invasion potential of HCC cells partially by activating CXCR7 transcription. This non-classical transcriptional control of SUZ12 in HCC warrants future exploration.

ALTERED ANNEXIN EXPRESSION PROFILES IN HEPATOCARCINOGENESIS: INSIGHTS FROM AN EXPERIMENTAL MODEL

E.E. Herrera-Lopez[1], D. Guerrero-Escalera[2], J. Arellanes-Robledo[2], J. Camacho[1], J.I. Perez-Carreon[2]

Introduction: Hepatocellular carcinoma (HCC) is one of the most common and second most lethal liver cancer in the world (1). Unfortunately, only 18% of patients bearing HCC have a 5-year survival rate, which places it as the second most lethal cancer, preceded only pancreatic cancer (2).
Therefore, a strategy that could reduce mortality from HCC is to develop an early diagnosis approach based on identifying new biomarkers. Based on a previous transcriptomic study in our lab, which revealed that annexins gene expression was modified in microdissected HCC nodules (3).
Annexins A1, A2, A5, A8, and A10 belong to the A family of annexins that are Ca^{2+}-regulated phospholipid-binding proteins. Members of this family can be peripherally coupled to the surface of negatively charged membranes when they are calcium-linked. This capability provides them with membrane-bound functions, such as organization, transport, and interaction with the actin cytoskeleton (4). The rat hepatocarcinogenesis model, induced with diethylnitrosamine (DEN), has proven to be highly effective in replicating the development of cirrhosis and heterogeneous multinodular HCC within 18 weeks. DEN's alkylating properties induce chronic liver damage, leading to inflammation and fibrosis that are associated with cirrhosis and HCC. This closely resembles the development of HCC in humans (5, 6).
Aims & Methods: We aimed to further investigate the expression profile of five annexin genes in a well-established animal model of hepatocarcinogenesis associated with cirrhosis and to identify potential serological markers for early HCC. The gene expression products of annexin were analyzed by RT-qPCR and western blots. Both mRNA and proteins were extracted from rat liver tissue at preneoplastic stages at 6 and 12 weeks and neoplasia at 18 and 22 weeks.
Also, immunofluorescence was performed on rat liver samples and compared to HCC of clinical origin. Plasma samples were collected from the experimental model, and we used the ELISA technique to measure the serum levels of Annexin A1, A2, and A5.
Results: A gradual increase of annexin A1, A2, A5, and A10 was observed in liver of hepatocarcinogenesis-induced animals compared to normal liver both at mRNA and protein levels, being a statistically significant increase for annexin A1 and A5 since week 6 of the hepatocarcinogenesis model. In contrast, annexin A8 showed a significant decrease in protein levels. The histological location of annexin A1, A2, and A5 was in the tumor cells. The cellular location for annexin A1 and A5 observed in the cytoplasm and membrane of normal hepatocytes showed a re-localization to the nucleus of neoplastic cells. Notably, a significant increase in the plasma level of annexin A5 from week 12 was detected, with a gradual increase until week 22 in the hepatocarcinogenesis model.
Moreover, the plasmatic level of annexin A5 significantly correlated (r^2 = 0.8203) with the hepatic Annexin A5 level. Using the TCGA database, we found that the expression of ANXA2 (HR = 1.7, p = 0.0046) and ANXA5 (HR = 1.8, p = 0.00077) was associated with poor survival in HCC patients.
Conclusion: The results suggest that the expression profile of annexin A1, A5, and A10 may serve as early tumor markers, whereas annexin A2 and A8 could be used as markers of hepatocellular carcinoma progression, given their expression changes during advanced stages of hepatocarcinogenesis. Significantly, the presence of annexin A5 in the plasma of model animals suggests its potential as a biomarker for hepatocarcinogenesis.

Introduction: Genetic predisposition to accumulate fat by carrying risk alleles of PNPLA3, TM6SF2 and HSD17B13, has been shown to influence the probability of developing cirrhosis and hepatocellular carcinoma (HCC) in several liver diseases characterized by hepatic steatosis including non-alcoholic steatohepatitis, chronic hepatitis C and alcoholic liver disease. Whether these variants have any role in the progression of chronic hepatitis B (CHB) disease, without hepatic steatosis, remains unknown.
Aims & Methods: In this cross-sectional case-control study, we determined PNPLA3 rs738409, TM6SF2 rs58542926, and HSD17B13 rs72613567 variants in a cohort of 148 healthy controls, 91 CHB (57 cirrhotic and 34 non-cirrhotic), and 84 CHB-related HCC patients from a tertiary center. Associations between control and case groups with the alleles and geno-

types were investigated using logistic regression analyses, and adjustment for age and sex was applied. Survival analyses were performed using Kaplan-Meier Curves with the log-rank test in the CHB-related HCC cohort.

Results: The genotype and allelic distribution of PNPLA3, TM6SF2 and HSD17B13 were not different between healthy controls, CHB, cirrhosis and HCC groups. No genotype or allele, including the haplotype analysis, was found to be associated with susceptibility to CHB and increased risk for cirrhosis or HCC. Survival analysis revealed that none of the three variants has any influence on overall survival in patients with CHB-related HCC.

Conclusion: Our findings demonstrated that PNPLA3, TM6SF2, and HSD17B13 genetic variants, known for modulating liver fat and disease progression in hepatic steatosis, have no association with disease progression in patients with CHB and survival in CHB-related HCC.

Introduction: Hepatocellular carcinoma (HCC) is still an extremely poor prognostic cancer that remains one of the most common and aggressive human malignancies worldwide. The long noncoding RNAs (lncRNAs) have a wide range of functions, including gene transcription, epigenomic regulation, translation of protein-coding genes, RNA turnover, chromatin organization, and genome defense. LncRNAs provide the basis and justification to further develop applications of lncRNA as disease markers and therapeutic targets. LncRNA NPTN-IT1 plays a decisive role in hypoxia-induced metastasis in HCC, and when NPTN-IT1 is downregulated, patients usually face a poor prognosis.

Aims & Methods: In this study, a new therapeutic modality using lncRNA NPTN-IT1 was designed to control HCC progression. Sixty mice were included and categorized into three groups.

The 1st group acted as a normal control group, whereas the 2nd group acted as a pathological control group and was injected with N-Nitrosodiethylamine (DEN) weekly for 16 weeks. The 3rd Group was injected intrahepatically with lncRNA NPTN-IT1 once/week for four weeks starting from the 12th week after initiating the DEN injection. After 16 weeks, animals were euthanized, and liver specimens and blood samples were collected for pathological and biochemical assessment.

Results: Our results showed that lncRNA NPTN-IT1 administration showed regression of HCC with the restoration of normal architecture. The levels of AFP, VEGF, and TNF-α decreased significantly ($P< 0.001$), and the Relative expression of cyclin-D1 and TGF-b1 was significantly down-regulated ($P< 0.001$) after NPTN-IT1 administration.

Conclusion: LncRNA NPTN-IT1 can be considered a new therapeutic modality for Hepatocellular carcinoma.

Introduction: Biliary cirrhosis is inevitably accompanied by liver fibrosis, which is characterized by an increase in extracellular matrix (ECM) in the liver along with continuous destruction of liver cells. Until now, many studies have been conducted on the theory of secretion of ECM components by activation of hepatic stellate cells. Ursodeoxycholic acid (UDCA) is a representative hydrophilic endogenous bile acid and has been approved by the FDA. Epithelial-Mesenchymal Transition (EMT) means that epithelial cells lose their cell adhesion and polarity maintenance and are converted into mesenchymal cells. The EMT phenomenon is recognized as a very important molecular/cell physiological factor that causes fibrosis of various organs.

Aims & Methods: We investigated whether UDCA regulates fibrosis-related gene expression and EMT-related protein expression in hepatic stellate cells and conducted an experiment to confirm this in an animal model of biliary cirrhosis.

First, to analyze the regulation of fibrosis-related gene expression in hepatic stellate cells by UDCA, quantitative RT-PCR was performed for α-SMA, Collagen-I, vimentin, and TGF-β1 gene expression in LCX2cells.

Second, the level of phosphorylation of Smad3 in the same cells was quantitatively analyzed by WesternBlot method to measure the regulation of EMT-related protein expression.

Thirdly, the regulation of EMT-related gene and protein expression by UDCA was tested in the same way in the rat common bile duct ligation-model.

Results: As a result, UDCA induces a decrease in target protein expression by reducing the expression of genes related to fibrosis in hepatic stellate cells, which is accompanied by inactivation of the TGF-β 1/Smad3 signaling system, which is an upstream regulator of fibrosis and an EMT-related protein. identified. This effect of UDCA was confirmed to be reproduced in an animal model of biliary cirrhosis.

Conclusion: Through this, the researcher identified that UDCA functions to down-regulate EMT and eventually delay liver fibrosis.

PREDICTIVE FACTORS OF SURVIVAL IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH TRANSARTERIAL CHEMOEMBOLIZATION

Z. Benzarti[1], B. Bouchabou[1], A. Nakhli[1], N. Hemdani[1], R. Ennaifer[1]
[1]*Mongi Slim Hospital, Department of Hepatology, Tunis, Tunisia*

Contact E-Mail Address: zeinebbenzarti9@gmail.com

Introduction: Transarterial chemoembolization (TACE) is the first-line treatment for hepatocellular carcinoma (HCC) that cannot be treated with curative methods. It has been shown to be effective in improving radiological response rate and progression-free survival. However, the success of the treatment depends on the appropriate selection of patients.

Aims & Methods: The aim of our study was to identify predictive factors for overall survival (OS) following the first TACE session in patients with HCC on a cirrhotic liver.

We conducted a retrospective study including all patients followed for HCC complicating liver cirrhosis in the general surgery and gastroenterology departments of our Hospital treated by chemoembolization, during the period from January 2011 to December 2020. Median OS was estimated using Kaplan – Meier curves. Univariate and multivariate Cox regression analyses were applied to identify prognostic factors. Differences were considered statistically significant when corresponding p values were less than 0.05 (SPSS software version 26.0).

Results: Fifty-five patients with a mean age of 60±12 years were included in the study. The mean follow-up duration was 16.9 months. Technical aspects of TACE were reported in 48 out of 55 sessions, and radiological response was evaluated in 43 patients. Conventional TACE was performed in 18 cases (37.5%), and TACE with Drug Eluting Beads (DEBs) was performed in 30 cases (62.5%). Cisplatin was used in 9 cases (18.8%), and doxorubicin was used in 39 cases (81.2%). Out of the 43 patients evaluated, 10 (23.3%) showed a complete response, 10 (23.3%) showed a partial response, 6 (13.9%) showed stable disease, and 17 patients (39.5%) showed progression. The median survival was 10 months (range: 6.4-13.26). The survival rates at 3, 12, and 18 months were 81.3%, 33.5%, and 5%, respectively.

Univariate analysis showed that factors associated with significantly shorter survival were age ≥ 60 years (p = 0.04), lack of prior HCC treatment (p = 0.012), a size of the main lesion exceeding 20 mm (p = 0.042), a number of nodules of more than 4 (p = 0.047), the BCLC B stage (p = 0.039), conventional TACE (p = 0.023), the use of cisplatin as a chemotherapy molecule (p = 0.008), and an advanced CHILD score after the 1st TACE session (p = 0.001).

Multivariate analysis identified the absence of previous treatment for HCC (0,044 ; OR = 0,3), a size of the main lesion ≥ 20 mm (0,029 ; OR = 4,6), BCLC stage B (0,016 ; OR = 5,27), the use of cisplatin (0,046 ; OR = 3,24), and an advanced Child score (B or C) after the 1st TACE (0,029 ; OR = 5) session as independent predictors of mortality.

Conclusion: Our study demonstrated that the prognosis of HCC patients treated with TACE depends on various factors, including tumoral characteristics, technique procedure, and liver function. These variables are widely incorporated into prognostic scores such as NIACE, Six and Twelve, STATE, and HAP. Identifying predictive factors for survival can aid in therapeutic decision-making due to the large number of patients affected by this procedure and the heterogeneity of HCC.

Disclosure: Nothing to disclose.

ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE ASPIRATION IN THE DIAGNOSTIC VALUE OF FOCAL LIVER LESIONS: A SYSTEMATIC ANALYSIS OF 88 CASES

X. Kong[1], Z. Fan[1], D. Hu[1], G. Cheng[1]
[1]*The Second Affiliated Hospital of Soochow University, Department of Gastroenterology, Soochow, China*

Contact E-Mail Address: duanminhu@163.com

Introduction: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is an important diagnostic tool for suspected parenchymal lesions within the gastrointestinal tract and adjacent organs. However, the amount of literature on EUS-FNA for sampling focal liver lesions (FLLs) is limited.

Aims & Methods: This study aims at evaluating the safety and effectiveness of EUS-FNA in FLLs. Data from 88 patients who were diagnosed with FLLs by imaging and underwent EUS-FNA was reviewed in this retrospective study at the Second Affiliated Hospital of Soochow University and Ruijin Hospital of School of Medicine of Shanghai Jiao Tong University from 1 January 2017 to 31 August 2022.The EUS-FNA biopsy results were compared with the final diagnosis to evaluate the diagnostic value. Meanwhile, the relevant factors were analyzed to determine their influences on the EUS-FNA biopsy results.

Results: A final diagnosis was obtained (86 malignant and 2 benign) from the 88 cases. The overall diagnostic accuracy of EUS-FNA in FLLs was 93.18% (82／88; 95% confidence interval [CI],87.9–98.5), with a sensitivity, specificity, positive predictive value, and negative predictive value of 93.02% (80／86; 95%CI, 87.6–98.4), 100% (2／2; 95%CI, 100–100), 100% (80／80; 95%CI, 100–100), and 25% (2／8; 95%CI, -5–55.0), respectively . The parameters related to lesion and procedure were not statistically significant between these two groups (p> 0.05) (Table 1). The number of puncture needles in the groups showed a statistically significant difference between multiple and single punctures (p = 0.001).

Conclusion: It is revealed in this study that EUS-FNA is a safe and excellent diagnostic method for FLLs with high accuracy.

Disclosure: Nothing to disclose.

RELIABILITY OF THE TORONTO HCC RISK INDEX IN PREDICTING THE OCCURRENCE OF HEPATOCELLULAR CARCINOMA

M. Mtir[1], D. Cherif[1], H. Debbabi[1], H. Hassine[1], H. Yacoub[1], H. Kchir[1], N. Maamouri[1]
[1]*La Rabta Hospital, Gastroenterology B, Tunis, Tunisia*

Contact E-Mail Address: mtirmaha@gmail.com

Introduction: Hepatocellular carcinoma (HCC) is the leading cause of death in patients with cirrhosis. Indeed, several risk stratification scores have been developed to anticipate early detection in order to better codify their management, including the Toronto Hepatocellular Carcinoma Risk Index (THRI). It is a simple and validated tool that has been developed to predict the risk of HCC in patients with cirrhosis and is mainly based on the following parameters: etiology, age, sex and platelet count.

The objective of this study was to evaluate the reliability of the THRI score in predicting the occurrence of hepatocellular carcinoma.

Aims & Methods: We conducted a monocentric retrospective study collecting all cirrhotic patients over an 8-year period [2008-2015]. Clinico-biological data, disease severity, and long-term outcomes were collected. THRI was calculated for all patients, and were classified according to HCC risk into three levels : low HCC risk (<120), intermediate HCC risk (between 120 and 240), and those with high HCC risk (>240).

A statistical study using the SPSS tool was carried out. The performance of this score was evaluated with the area under the receiver operating characteristics curve (AUROC).

Results: We included 120 cirrhotic patients with an M/F sex ratio equal to 0.5. The mean age was 57 years [14-85]. The most frequent aetiology of cirrhosis were viral C (49%) and viral B (31%). The mean overall survival was approximately 6 years after diagnosis.

Twenty-five patients developed HCC during follow-up (20.8%). Patients who developed HCC had a higher THRI score than those who did not develop HCC : 264.8 ± 48.6 versus 232.3 ± 64.8, respectively with p-value = 0.008

Patients with a low risk of HCC were 5 (4.2%), none of whom had developed HCC. Fifty-eight patients (48.3%) were at intermediate risk, 12% of them (N=7) had developed HCC. The remaining 57 patients (47.5%) were at a high risk and 31.6% of them (N=18) developed HCC during their follow-up.

The AUROC for the THRI to predict HCC was 0.649 ([95% CI 0.533–0.765]. The cutoff THRI value in predicting the occurrence of HCC was 235.5 with a sensitivity of 72% and a specificity of 50%.

Conclusion: According to our study, the THRI score appears to be an effective tool for predicting the occurrence of HCC in cirrhotic patients. Its good sensitivity allows to identify the high-risk HCC population for early screening.

THE UNEXPECTED LACK OF NEGATIVE IMPACT OF THE COVID-19 PANDEMIC ON HEPATOCELLULAR CARCINOMA SURVEILLANCE

M. Majerovic[1], J. Prejac[2], A. Ladic[1], I. Knezevic Stromar[1], M. Kalauz[1], R. Ostojic[1], Z. Krznaric[1]

[1]University Hospital Centre Zagreb, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Zagreb, Croatia, [2]University Hospital Centre Zagreb, Department of Oncology, Zagreb, Croatia

Contact E-Mail Address: matea.majerovic@gmail.com

Introduction: The COVID-19 pandemic negatively affected cancer patients' care in many ways, including the timely diagnosis of malignancies.[1,2] Hepatocellular carcinoma is a tumor with well-defined risk factors that is potentially curable if detected in the early phase. Biannual ultrasound in high-risk patients has proven to be a valuable tool for accomplishing this goal and has therefore long been recommended.[3] However, in Western countries, the reported adherence to surveillance protocols was low in pre-pandemic years.[4] Since the declaration of the pandemic, primarily during the lockdown, but also in the post-lockdown period, many patients missed their regular check-ups, and physicians feared a further fall in surveillance adherence and a rise in the proportion of patients presenting with advanced disease.

Aims & Methods: The aim of this study was to assess whether the pandemic influenced the hepatocellular carcinoma (HCC) surveillance program. 350 patients (80.9% male, median age 66.9 years) treated at our Department between October 2010 and February 2023 due to newly diagnosed HCC were included in the analysis. The ongoing COVID-19 pandemic was declared in March 2020. Patients were divided into groups according to the time of HCC diagnosis (pre-pandemic and during the pandemic) and into surveillance and non-surveillance groups. Chi-square test was used to analyze the results. The level of statistical significance was set at $p < 0.05$.

Results: The number of newly diagnosed HCC cases was 28.4/year pre-pandemic and 27.7/year during the pandemic. There was no statistically significant difference between surveillance rates pre-pandemic (21.8%) and during the pandemic period (27.0%, P=0.385), nor in the proportion of patients that presented with symptomatic disease (P=0.314). During the pandemic, patients were more likely to be diagnosed in the potentially curative stage of the disease (BCLC 0 and BCLC A) (20.9% vs. 36.1%; OR 2.13, 95% CI:1.25-3.65; P=0.005).

Conclusion: Surprisingly, the pandemic did not influence HCC surveillance rates. Moreover, in this period, patients were more likely to be diagnosed in the potentially curative stage of the disease. Even though the benefits of HCC surveillance are well known and its implementation widely encouraged, the rates have been stably low over the last decade.

Introduction: Hepatocellular carcinoma (HCC) is a common malignancy worldwide. A tumor suppressor gene called PRDM1 is necessary for plasma cell development and T cell activity control. Different types of cancers have been linked to polymorphisms in the vitamin D receptor (VDR) gene.

Aims & Methods: This study was conducted to determine whether there may be a link between the polymorphisms in the VDR and PRDM1 genes and the development of HCC in patients with chronic hepatitis C.130 participants in this study were divided into three groups. 30 healthy individuals made up Group 1's control group. 70 chronic hepatitis C patients with HCC were in group 2. Group 3 contains 30 patients with post hepatitis C liver cirrhosis without HCC. Estimation of PDRM1 gene and Apa-1 VDR gene polymorphisms was done using the polymerase chain reaction- restriction fragment length polymorphism.

Results: As regard PDMR1 gene, In comparison to the HCC and cirrhosis group, the rates of the G allele and the GG phenotype in the control group were significantly higher. However, compared to cirrhosis and controls, the rates of the GA genotype and the A allele were considerably higher in the HCC patients. Additionally, the people with AA or GA genotypes have a 2-fold higher chance of developing HCC than those with GG genotypes when comparing the HCC group with the non-HCC group (controls and

cirrhotic patients) (odd ratio = 2.045% and 95% confidence interval are (1.123–3.722) (*P* = 0.019).As regard VDR gene, In comparison to the HCC and cirrhosis group, the rates of the A allele and the AA phenotype in the control group were significantly higher. However, compared to cirrhosis and controls, the rates of the CC genotype and the C allele were considerably higher in the HCC patients.

Conclusion: In patients with chronic hepatitis C, there is association between VDR Apa-1 polymorphism and RDM1 gene polymorphism with the development of HCC.

Disclosure: Nothing to disclose.

PP1390

RISK ASSESSMENT OF HEPATOCELLULAR CARCINOMA BY ELASTOGRAPHYHY: A SYSTEMIC REVIEW

R. El-Sayed[1,2], M. Diaa-Eldeen[1], M. Saif-Al-Islam[3]

Introduction: HCC is the sixth most common malignancy worldwide and a major cause of death in patients with CLD and cirrhosis. it accounts for 90% of primary liver cancer.

it is important to detect patient with high risk to develop HCC. Liver fibrosis (LF) is a major risk factor regardless of its etiology.

Using of liver biopsy is limited by its invasiveness, poor acceptance, cost, intra and interobserver errors. TE for liver can rapidly measure liver stiffness and also can predict the absence or presence of significant fibrosis as well as advanced cirrhosis.

Aims & Methods: To assess the ability of TE for detection of LF and HCC in patients with CLD. we searched MEDLINE, Cochrane, EMBASE database until 2019, using the following search items: TE, fibroscan, HCC and hepatoma. Each title and abstract was reviewed to make sure it is relevant. The full text was studied if the abstract indicated that the paper reported HCC risk by fibroscan. sensitivity analysis and assessment of publication bias were performed.

Results: Forty-six studies were included, 18 studies evaluated the role of LSM in predicting HCC in CLDs patients, 6 studies evaluated the role of LSM in predicting hepatic decompensation, 1 study reported a composite outcome of HCC and hepatic decompensation, and 4 studies evaluated the role of LSM in predicting mortality.

Conclusion: HCC is associated with increased LS. Each unit increase in LSM was associated with an 11% higher risk of HCC. LSM may be a useful method to identify patients with CLD at risk for HCC.

Disclosure: Nothing to disclose.

Introduction: Hepatocellular carcinoma (HCC) is a leading cause of mortality among patients with liver cirrhosis. Per the current practice guidelines different ablations are used either as curative or palliative therapies. The current study aimed at determining bacterial infections as causes of fever and the predictive role of procalcitonin (PCT) among patients with HCC who had ablation therapy.

Aims & Methods: This cross sectional study carried out on 100 patients with HCC during the period from November 2019 to December 2021. All patients were evaluated by full history taking, clinical examination, CBC, liver biochemistry, coagulation profile, kidney function, C-reactive protein (CRP), serum PCT and blood cultures. All were done for all participants at 4th day follow up after the procedures of ablation. HCC were treated according to the guidelines.

Results: The frequency of fever after HCC ablation was 64% with variable intensities. Bacterial cultures were positive in 20 patients (20%). Twenty four out of 100 patients had abnormally high PCT level. There was highly statistically significant increase of PCT level in patients with high CRP count and positive blood culture, P<0.05. There was statistically significant correlation between increased levels of PCT and levels of CRP, WBCs, Albumin, AST, ALT, degree of fever, Creatinine and BUN.

Variable	AUC	p-value	Cut off	Sensitivity	Specificity	PPV	NPV	Accuracy
CRP	0.965	<0.001*	>28	90.0	92.5	75.0	97.4	92.0
Procalcitonin	1.0	<0.001*	>0.66	100.0	100.0	100.0	100.0	100.0

Abbreviations: AUC, area under the curve; NPV: Negative predictive value;
PPV: Positive predictive value ; *: Statistically significant at p ≤ 0.05 #Cut off was chosen according to Youden index.

Conclusion: Bacterial infection accounts for 20% of fever among HCC patients after ablation therapy. PCT is 100% sensitive and specific for detection of the bacterial causes of fever among those patients.

Disclosure: None

Introduction: Hepatocellular carcinoma (HCC) is a global problem being fourth in terms of cancer-related deaths[1]. Contrast-enhanced ultrasound (CEUS) is used as an add-on test to confirm focal liver lesions suspected as HCC at prior diagnostic tests such as ultrasound or alpha-foetoprotein, or both[2,3].

According to guidelines[4,5,6,] a single contrast-enhanced imaging techniques, with either computed tomography (CT) or magnetic resonance imaging (MRI) showing the typical hallmarks is sufficient to diagnose HCC in cirrhotic patients. However, a significant number of HCC show atypical imaging features, and therefore, are missed at imaging.

The advantages of CEUS over CT and MRI is the use of contrast agents not containing iodine and that are not nephrotoxic, and quick image acquisition. Despite the advantages, the use of CEUS in the diagnostic algorithm for HCC remains controversial, with disagreement on relevant guidelines.

Aims & Methods: The aim was to assess the diagnostic accuracy of CEUS for the diagnosis of HCC of any size and at any stage in adults with chronic liver disease, in a surveillance programme or in a clinical setting and to assess the diagnostic accuracy of CEUS for the diagnosis of resectable HCC in people with chronic liver disease and identify potential sources of heterogeneity in the results.

We included studies assessing the diagnostic accuracy of CEUS for the diagnosis of HCC in adults with chronic liver disease, with cross-sectional designs, using one of the acceptable reference standards, such as pathology of the explanted liver, and histology of resected or biopsied focal liver lesion with at least a six-month follow-up.

Standard Cochrane methods [7] were used to screen studies, extract data, and assess the risk of bias and applicability concerns, using the QUADAS-2 checklist[8]. We used the bivariate model and provided estimates of summary sensitivity and specificity. We assessed the certainty of the evidence using GRADE[9,10]. We presented uncertainty-of-the-accuracy estimates using 95% confidence intervals (CIs).

Results: We included 23 studies with 6546 participants. Studies were published between 2001 and 2021. We judged all 23 studies at high-risk of bias in at least one domain, and 13/23 studies at high concern for applicability. Most studies used different reference standards to exclude the presence of the target condition. The time interval between the index test and the reference standard was rarely defined. We also had major concerns on their applicability due to the participant characteristics.

CEUS for HCC of any size and stage: sensitivity 77.8% (95% CI 69.4% to 84.4%) and specificity 93.8% (95% CI 89.1% to 96.6%) (23 studies, 6546 participants; very low-certainty evidence).

CEUS for resectable HCC: sensitivity 77.5% (95% CI 62.9% to 87.6%) and specificity 92.7% (95% CI 86.8% to 96.1%) (13 studies, 1257 participants; low-certainty evidence).

The observed heterogeneity in the results remains unexplained.

Conclusion: Using CEUS, as an add-on test following abdominal ultrasound, to diagnose HCC of any size and stage, 22% of people with the tumor would be missed, and 6% of people without would unnecessarily undergo further testing or inappropriate treatment. As to resectable HCC, we found that 23% of people with resectable tumor would incorrectly be unresected, while 8% of people without HCC would undergo further inappropriate testing or treatment. The uncertainty resulting from the high risk of bias of the included studies, heterogeneity, and imprecision of the results and concerns on their applicability limit our ability to draw confident conclusions.

EFFECT OF COVID-19 PANDEMIC ON HEPATOCELLULAR CARCINOMA DIAGNOSIS: RESULTS FROM A SINGLE CENTER STUDY FROM TURKEY

G. Bilican[1], M. Kekilli[1]

[1]Gazi University School of Medicine, Gastroenterology, Ankara, Turkey

Contact E-Mail Address: guldenbilican@gmail.com

Introduction: One of the most frequently diagnosed cancers in the world is liver cancer , it is the sixth most frequently detected tumor, approximately 905.677 new cases were reported in 2020 . In addition, liver cancer is the third most common cause of cancer-related mortality worldwide, with over 830.180 deaths in 2020 [1].

During the coronavirus disease 2019 (COVID-19) pandemic, suspension of elective non-emergency medical services was imposed all over the world. As a result of this, many patients couldn't get access to medical services which led to the delay in the diagnosis and treatment of various diseases. Cancer screening program have been temporarily interrupted worldwide

during the pandemic. These measures may have led to a reduction in COVID-19 transmission but it is thought that the delayed diagnoses of cancer patients will put an additional burden on the global health system.The aim of this study was to reveal whether restrictions during the COVID-19 pandemic lead to reductions or delays in the diagnosis of hepatocellular cancer (HCC).

Aims & Methods: This study was designed as a single center,cross-sectional and retrospective,study including adult patinet with a new diagnosis of HCC. Date of diagnosis, general demographics, main tumour size, extrahepatic disease, Barcelona Clinic Liver Cancer (BCLC) stage, serum alpha-fetoprotein level, adherence to surveillance, underlying disease aetiology, presence of tumour thrombosis and treatment were recorded.Patients were divided into two groups; patients with a new diagnosis of HCC during pre-COVID-19 period (March 2017 – February 2020) and patients with a new diagnosis of HCC during the COVID-19 period (March 2020 - March 2023).

Results: A total of 72 patients with de-novo HCC diagnosis were collected. During the pre-COVID-19 period there were 46 new HCC diagnoses compared with 26 new HCC diagnoses in the COVID-19 period.The largest tumor diameter and serum AFP levels were found to be statistically significantly higher in the COVID-19 period than in the pre-COVID- 19 groups (p=0.009; 0.005 , respectively).In the pre-COVID-19 period 8.7% (n=4) patients and in the COVID-19 period 30.7% (n=8) were diagnosed with portal vein thrombosis,the diffrence was statistically significant (p=0.042).There were no significant differences in sex distribution (p=0.179) or median age (p=0.495) between the two groups. When cases were analyzed according to etiology, there were no significant differences overall.In terms of etiology, the most common etiologic cause was chronic viral hepatitis B infection in both groups [pre-COVID-19 and COVID-19 period, respectively 60.9% (n=28); 56.9% (n=13)].

Variable	Pre-COVİD-19 n=46	COVİD-19 n=26	P
MELD score	10 (7-31)	11 (7-27)	0.165
Child-Turcotte-Pugh score	6 (5-13)	6 (5-14)	0.799
Largest tumor diameter	3.90 (1.10-20.0)	6.75 (1.50-20.0)	**0.009**
AFP	11.81 (1.51-14290.0)	90.0 (2.10-629495.0)	**0.005**
Albumin	3.3 (3.0-4.5)	3.6 (4.0-4.8)	0.302

AFP: *Alpha-fetoprotein,;MELD:* Model for End-stage Liver Disease

Table 1. Comparison of clinical and laboratory parameters between the two groups.

Conclusion: Current study showed that with the strict measures taken to keep the COVID-19 pandemic under control, we can encounter hepatocellular cancer patients at more advanced stages and complications in long-term follow-ups[2].

To minimize the negative impact of the pandemy such as an increase of avoidable advanced cancers and cancer-related deaths, post-pandemic management should focus on improving the number of screening programs and encouraging patients to strictly obey visits in the follow-up.

TIMING OF SURGERY AND CLINICAL OUTCOMES IN PATIENTS WITH SYNCHRONOUS COLON CANCER LIVER METASTASES UNDERGOING NEOADJUVANT CHEMOTHERAPY: A PROPENSITY SCORE ANALYSIS

N. Wen[1], Y. Wang[1], B. Li[1], J. Lu[1]

[1]West China Hospital, Sichuan University, Chengdu, China

Contact E-Mail Address: wenningyuan611@hotmail.com

Introduction: The optimal time for surgery after NAC for patients with SLM is still controversial. We plan to analyze whether the selection of different surgical timing will have different effects on the short-term clinical outcomes and long-term prognosis of patients.

Aims & Methods: We retrospectively collected all patients who met the inclusion and exclusion criteria from 2015 to 2020. Patients were grouped according to Time interval (TI) after NAC to surgery. The short-term and long-term clinical outcomes of the two groups were compared after propensity score matching. Univariate and multivariate analyzes were used to identify factors associated with patient prognosis.

Results: Among 152 enrolled patients, 98 were matched with comparable baseline (48 each group). In the matched cohort, postoperative ascites (8.3% vs. 22.9% , p = 0.049)
and bile leakage (4.2% vs. 16.7%, p = 0.045) occurred significantly more frequently in patients who underwent surgical resection 8~12 weeks after NAC than in patients who underwent surgery 4~8 weeks after NAC. Pleural effusion (31.3% vs. 12.5%, p = 0.026) occurred significantly more frequently in patients who underwent surgery 4~8 weeks after NAC. Although OS and DFS were not significantly different between the two groups, 13 factors were identified to be associated with patients’ OS and DFS by multivariate analysis.

Conclusion: Although our study did not reveal a significant effect of timing of surgery after NAC on patient prognosis, there was a difference in the risk of certain postoperative complications between the two groups that warrants clinical attention. Randomized controlled trials are needed in the future to confirm these findings.

Contact E-Mail Address: francescofrigo94@gmail.com

Introduction: Nivolumab is an anti-programmed death receptor-1 monoclonal antibody, evaluated as monotherapy for advanced HCC in two trials (Checkmate 040[1] and Checkmate 459[2]). It showed promising results with durable response, good tolerability and a favourable safety profile but failed to demonstrate a statistically significant benefit in overall survival (OS) benefit over sorafenib, the first-line therapy at the time.

Aims & Methods: The objective of this study was to evaluate the efficacy and OS of nivolumab as monotherapy in cirrhotic patients with advanced HCC ineligible for other treatments.

Approval for off-label use was obtained from the hospital committee for each patient based on literature review and personal medical history.

We conducted a retrospective, single-centre study of 22 cirrhotic patients with intermediate or advanced HCC treated off-label with nivolumab between September 2019 and April 2023. Enrolled patients were ineligible for local or surgical therapy, had disease progression or intolerance to prior tyrosine kinase inhibitor (TKI) therapy, and were not eligible for other systemic therapies.

All patients received intravenous nivolumab 3 mg/kg once every two weeks for the first 6 months and then 6 mg/kg once every 4 weeks. Treatment was continued until disease progression, serious adverse events, impaired performance status or death.

Outcomes measured were overall survival, radiological response (RR), defined as stable disease, complete or partial response at quarterly abdominal and thoracic CT scans, and biological response (BR), defined as a decrease in alpha-fetoprotein (AFP) blood level of ≥ 25% from baseline after 3 months of therapy. Safety profile of nivolumab was also assessed.

Results: Twenty-two patients were included: 73% male, median age 64.5 years (range: 30-80), 91% Barcelona Clinic Liver Cancer score C, 82% Child-Pugh A. One patient received nivolumab as I-line, 11 as II-line, 8 as III-line and 2 as IV-line. AFP at baseline was available in 19/22 patients and was elevated in 16/19 patients (median 259.9 ng/ml; IQR 26.7-1752). Median time of treatment was 3.5 months (range: 0.4-36.9). OS was 7.8 months (95%CI 4.7-14.2; range 1.1-34.1). RR (defined as partial response or stable disease) at 3 months was achieved in 8 patients and 6 patients maintained it at 6 months. BR at 3 months was achieved in 6 patients.

OS was significantly associated with RR (p 0.002) and BR (p 0.0001) at 3 months. Median OS in patients with RR at 3 months was 27.7 months (95%CI 4.7-27.7) versus 6.4 months (95%CI 3.2-9.1) in patients with disease progression (p 0.0003).

At baseline, better performance status (ECOG 0 vs 1-2) (p 0.031), presence of metastatic lymph nodes (p 0.040) and lower disease burden (monolobar vs bilobar involvement) (p 0.009) were associated with a better OS.

Grade 3-4 adverse events occurred in 5 patients (2 pulmonary thromboembolism, 1 variceal bleeding, 1 autoimmune colitis, 1 severe asthenia).

Conclusion: Nivolumab monotherapy in non-responder or intolerant to TKI patients without any other therapeutic option could represent an acceptable treatment, showing an OS greater than 6 months in 68% of patients (median 7.8 months). RR at 3 months predicts long survivors (median OS 27.7 months), as does BR at 3 months (median OS 27.9 months). Overall, nivolumab was well tolerated.

Contact E-Mail Address: ctw3170304140@outlook.com

Introduction: The incidence of liver cancer has shown different temporal trends across regions around the world. The incidence of liver cancer has shown an increasing trend in many western populations, while it has shown a decreasing trend in some Asian countries, while the underlying reasons remain unclear.

Aims & Methods: Using data from population-based cancer registries, we examined temporal trends in the incidence of liver cancer in the United States, Hong Kong, and Sweden since the 1970s through 2021, using joinpoint regression. We further performed an age-period-cohort analysis to address possible underlying causes for the observed temporal trends.

Results: The age-standardized incidence rate of primary liver cancer in the United States increased on average by 2.4% (95% confidence interval [CI] 1.7% to 3.1%) per year in men and by 2.2% (95% CI 1.7% to 2.6%) in women during the period 1975-2019, but decreasing trends were noted in 2015-2019 in both sexes (annual percent change [APC] -5.9%, 95% CI -8.1% to -3.6% in men; APC -4.9%, 95% CI -9.4% to -0.1% in women). The rate in Hong Kong steadily decreased in men (APC -2.1%, 95% CI -2.5% to -1.8%) and in women (APC -2.2%, 95% CI -3.2% to -1.1%) during the period 1983-2020. The rate in Sweden increased on average by 0.8% (95% CI 0.2% to 1.4%) per year in men and was generally stable in women (APC 0.2%, 95% CI -0.9% to 1.4%) per year in 1970-2021.We observed distinct changes in trends across age groups in the three populations and different trends across generations (birth cohorts).

Conclusion: The incidence of liver cancer has shown increasing trends in the United States and Sweden, while the incidence has decreased in Hong Kong population. Such disparities across populations may be explained by different etiology and implementation of preventive measures, such as vaccination against hepatitis virus infection, in different populations.

PP1397

THE EFFECT OF SARCOPENIA AT THE TIME OF DIAGNOSIS ON MORTALITY IN HEPATOCELLULAR CANCER PATIENTS

D. Turan Gökçe[1], A. Terlemezoğlu[2], D. Arı[2], M. Dağlı[3], M. Akdogan Kayhan[1]
[1]Ankara Bilkent City Hospital, University of Health Sciences, Department of Gastroenterology, Ankara, Turkey, [2]Ankara Bilkent City Hospital, Department of Gastroenterology, Ankara, Turkey, [3]Ankara Bilkent City Hospital, Department of Radiology, Ankara, Turkey

Contact E-Mail Address: dilaraturan89@yahoo.com

Introduction: Sarcopenia, defined as the loss of skeletal muscle mass, quality, and function, is an important metabolic disorder associated with malignancies and is an independent predictive factor for mortality in malignant patients [1].

Hepatocellular carcinoma (HCC) is the most common type of malignant liver cancer, and sarcopenia has been associated with a higher rate of complications and recurrences in patients with cirrhosis and HCC [1].

The assessment of patient general status before HCC treatment, including the presence of sarcopenia, is a key-point for achieving therapy tolerability and to avoid short- and long-term complications.

Aims & Methods: In this study, the material and methods involved the inclusion of 101 patients who were diagnosed with HCC and had admission CT images in the system between February 2019 and October 2021. The study evaluated the effect of admission Visceral-Subcutaneous Fat Ratio (VSR) indicating visceral adiposity and Intramuscular Adipose Tissue Content Ratio (IMAC) on mortality in patients with HCC . The VSR and IMAC were calculated for each patient using CT image analysis. The study did not involve any interventions or treatments, and all data were collected retrospectively. The study was approved by the institutional review board, and all patients provided informed consent for the use of their medical records for research purposes.

We aim to evaluate the effect of admission VSR indicating visceral adiposity and IMAC on mortality in patients with HCC.

Results: The median age of the patients was 61.4 (21-77) years, and 77 (76.2%) of the patients were male. Sixty-two of the patients (62%) had Child Pugh Score (CPS) A, and the 12-month transplant-free survival rate was 78.2%. The study found that there was a positive correlation between age and diagnosis time IMAC (R= 0.337, p=0.045) and a weak positive correlation with VSR (R= 0.223 and p= 0.045). Fourteen patients were excluded from the mortality analysis because they had undergone transplantation during this period.

The study found that the percentage of patients with HCC in Milan criteria was 44.9% (n:44).In an analysis of 87 patients, IMAC and VSR were associated with mortality independently of CPS (p=0.017 and p=0.048, respectively).

Conclusion: In conclusion, sarcopenia is an important indicator in predicting mortality and morbidity in patients with HCC independent of CPS. Nevertheless, the concurrent evaluation of radiological and clinical sarcopenia must be evaluated to determine the relationship between sarcopenia and mortality in HCC patients. The large population studies provide more accurate results.

Introduction: It is proven that platelets play an important role in growth, invasion, and angiogenesis of a variety of tumors. The mean platelet volume (MPV) indicates platelet activation and is altered in malignancies such as hepatocellular carcinoma (HCC).

Aims & Methods: The aim of this study was to explore the association between MPV and prognosis in HCC according to the Barcelona-Clinic Liver Cancer (BCLC) Staging Classification. This retrospective study performed between January 2020 and December 2021 included 92 patients with HCC who did not receive antiplatelet therapy. The overall survival was compared, and the predictors of overall survival were analyzed. High mean platelet volume (MPV) was defined as ≥median value of the cohort (≥ 8 fL). All the patients were divided into the normal and lower MPV groups according to the median MPV. We used receiver operating characteristic (ROC) curves to assess the prognostic value of MPV.

Results: Among 92 patients, high MPV was present in 50 (54.3%) and was associated with favorable baseline tumor characteristics: diameter of the largest nodule less than 3 cm (77.4 vs. 22.6%, p=0,01), less extrahepatic spread (16.7 vs. 83.3%, p=0.004), less macrovascular invasion (2 vs. 52.4%, p < 0.001), and lower BCLC stages (2 vs. 100% BCLC C/D; p< 0.001) as compared to patients with normal MPV. In receiver operating characteristic (ROC) curve analysis, MPV presented 93.3% of sensitivity and 69.4% of specificity at the criterion <8.5 fL (area under the curve (AUC) = 0.706) to predict higher BCLC stages (C/D).

Conclusion: Higher MPV is associated with better outcome in patients with advanced HCC. These findings may prompt further clinical research on additive antiplatelet therapy in the prevention and management of HCC.

Disclosure: Nothing to disclose.

Introduction: Platelets play an important role in inflammation, immunity, malignancy, and organ regeneration [1, 2]. Tumour cells use them for protection from immune-cell-mediated clearance [3].

Platelets may also promote formation of metastasis [4].

However, there is limited knowledge on the impact of platelet indices on HCC tumour biology [5].

Aims & Methods: The aim of the study was to explore the association between platelet count, mean platelet volume (MPV) & platelet distribution width (PDW) and tumour behaviour of HCV related HCC & their predictive power.

The study was conducted on two groups of patients, group 1which included patients with naive HCV related HCC and group 2 which included patients with chronic HCV cirrhosis. Liver function tests, AFP, serum creatinine, multi-phasic abdominal CT and or MRI were done at baseline for all

cases. In Group 1, non invasive diagnosis of HCC in cirrhotic patients according to the EASL guidelines was done. CBC was done using automated hematology analyzer with reporting of platelet count, MPV& PDW.

Results: Group 1 included 144 patients, 120 males &24 females, while group 2 included 116 patients, 52 males &64 females. In group 1, the age was significantly older (62.11±7.32 Vs 56.53 ± 9.23, p =0.000) &males were significantly more (120 Vs 52 , p=0.000). The MPV was 10.34±1.74 fl in group 1, while it was 10.21±1.19 fl in group 2, without significant difference (p=0.507). The PDW was 15.43±2.22% in group 1, while it was 15.14±1.52% in group 2, without significant difference (p=0.254). Also, the PLT count was significantly lower in group 1 (127080 ± 78101 Vs 156674 ± 80613, p=0.000).In group 1, platelet count was ≤150×109/L (thrombocytopenia) in 102 cases (71.8%) while it was >150×109/L in 40 (28.2%).

The median HCC diameter was significantly larger in patients with normal PLT count than thrombocytopenic patients (6.5 cm versus 5 cm, p= 0.025). There was no significant difference regarding BCLC,TNM stage, presence of malignant PVT or distant metastasis between group 1 cases with normal and low platelet count (p=.197,.169,.189 &.305 respectively).

There was significant positive correlation between PLT count & both BCLC and TNM tumor stage (r =0.185, 0.226 & p=0.027,0.007 respectively) but the correlation was insignificant regarding serum AFP level (r =0.118 & p=0.182). In group 1, MPV was ≥10.4 fl in 67 (52.3%) & <10.4 in 61cases (47.7%) while the PDW was ≥14.5% in 94 (79%) &<14.5 in 25 cases (21%).

There was no significant correlation between both MPV and PDW & both BCLC and TNM stage (r = -.035, -.037, p=0 .679,0 .679 & r = -.131 , -.154, p = .157, .095 respectively) but there was significant negative correlation between the MPV and serum AFP level (r = -.195 & p=0 .034).PDW at cut off value of 15.05% can significantly predicts HCC with sensitivity = 62,2%. specificity = 58,1%, AUC = 57,8%, P=0.043, 95% CI=0.503-0.654).

Conclusion: PLT count positively correlates with BCLC &TNM stage of HCV related HCC with larger tumor size in presence of normal platelet count. MPV negatively correlates with serum AFP level. PDW at cut off value of 15.05% can significantly predict HCV related HCC.

Contact E-Mail Address: ehab_abdelatty@hotmail.com

Introduction: Portal vein thrombosis (PVT) is common in cirrhotic patients. The prevalence ranges from 1%, at earlier stages to 30% in candidates for liver transplantation. The ADAM (a disintegrin-like and metalloproteinase) proteins, with their subfamily of ADAMTS -13 (A Disintegrin and Metalloprotease with Thrombospondin-13) are produced exclusively by hepatic stellate cells and play an important regulatory role in coagulation. The ADAMTS-13 protein is an enzyme, Willebrand factor cleaving protease. In vascular injury, von Willebrand factor (VWF) together with platelets initiates formation of thrombus.

Functional deficiency of ADAMTS-13 results in presence of unusually large VWF multimers in plasma, which promotes platelet aggregation and thrombus formation.

Aims & Methods: The aim was to investigate the relation of serum level of ADAMTS -13 and portal vein thrombosis in patients with HCV related liver cirrhosis. The study was carried out on 56 Egyptian patients with HCV related liver cirrhosis (LC) (LC group: 28 cirrhotic patient without PVT and LC+PVT group: 28 cirrhotic patient with cirrhosis and PVT) and 28 healthy volunteers as controls from Menoufia University Hospitals (Egypt).

The study was conducted in period from March 2020 to April 2021. They underwent history taking, physical examination and laboratory investigations (CBC, liver profile {ALT, AST, serum albumin, bilirubin, INR}, urea, creatinine, HBsAg, HCV Ab and serum ADAMTS-13 assay). Abdominal ultrasound with Doppler of portal vein (PV) was done for all patients and controls. Triphasic CT of the liver was done for patients with PVT to exclude hepatocellular carcinoma (HCC). Child-Pugh score, MELD score, AST/Platelet ratio index (APRI score) and FIB-4 were calculated for all patients.

Patients on anticoagulant therapy, age less than 18 years, inflammatory or bleeding events in previous 2 months, history of personal unprovoked thromboembolism (familial in first-degree relatives), etiology of liver cirrhosis other than HCV and HCC are excluded from the study.

Results: Serum ADAMTS-13 (ng/ml) was significantly lower in LC+PVT group (0.66±0.44) than in LC (0.92±0.99) and control group (0.96±0.92) (P=0.0001 for both) but there was no significant difference between LC group and controls (P=0.2). ADAMTS13 at cutoff level 1.62 ng/ml have 71.4% sensitivity and 62.5% specificity for prediction of PVT. In LC+PVT group, level of serum creatinine (mg/dl) (1.5±0.5) and INR (1.7±0.6) were significantly higher than LC group (creatinine 1.28±0.37) (INR 1.29±0.34) (P=0.03 and 0.001 respectively).

There was no significant difference between LC+PVT group and LC group as regard, history of encephalopathy, history of gastrointestinal bleeding, presence of ascites, CBC, liver profile (ALT, AST, serum albumin, bilirubin), urea, APRI score, FIB-4, and MELD score (P>0.05).

Regression analysis showed that ADAMTS 13 level and advanced degree of Child-Pugh score predict occurrence of PVT by 1.26 and 4.66 fold respectively. In LC+PVT group, there was a positive correlation between ADAMTS 13 level and INR (r=0.41, P=0.03) but there was no correlation with other parameters (age, platelet count, Hb, albumin, AST, ALT, bilirubin,

urea, creatinine and INR, APRI score, FIB-4, MELD score and Child-Pugh score (P>0.05). In LC group, there was a positive correlation between ADAMTS 13 and Child-Pugh score (r=0.41, P=0.03) and MELD score (r=0.46, P=0.02).

Conclusion: Low levels of ADAMTS-13 are associated with pathogenesis of PVT in liver cirrhosis. ADAMTS-13 concentration is potential biochemical marker in diagnostic strategy of PVT in patients with cirrhosis.

Introduction: Liver cirrhosis has been considered historically a hypocoagulant disease. However, currently its association with hypercoagulable states, mainly when liver function is impaired, is well established. The presence of a procoagulant phenotype has been suggested for development of spleno-porto-mesenteric axis thrombosis; however, there are no standardized data and no definitive recommendations have been reported in clinical guidelines regarding the screening of mutations related to thrombophilia in these patients.

Aims & Methods: The primary outcome of our study is to analyse the prevalence of inherited mutations associated with thrombophilia in patients with liver cirrhosis and non-tumor splenic portal axis thrombosis in our center. We analyze demographics, clinical features, and disease characteristics. We retrospectively included all patients with liver cirrhosis and non-tumoral thrombosis of the spleno-porto-mesenteric axis who underwent a thrombophilia study between January 2015- September 2022 in our center. As a thrombophilia study, factor V Leyden mutation, 20210A mutation of the prothrombin gene, proteins C and S, antithrombin, plasmatic homocysteine, and antiphospholipid antibodies were analysed. Data were analysed with SPPS (version 27).

Results: A total of 75 cases were enrolled (61.33 % male; median age: 64.8 ± 12.5 years). At the time of thrombosis patients belonged to Child-Pugh classes A: 64 % (n = 48); B: 29.3 % (n = 22) and C: 6.6 % (n = 5). Etiologies of cirrhosis included: Chronic HCV infection 36 % (n = 27), followed by alcohol-related liver disease 34.6 % (n = 26), indeterminate 9.33 % (n = 7) and MAFLD 6.6 % (n = 5). Most common sites of thrombosis were the portal vein 58.6 % (n = 44), followed by portal branches 10.6 % (n = 10), and 9.3 % (n = 7) in both territories. Regarding the thrombophilia study (Table 1), protein C, S, or antithrombin deficiency were observed in 60 cases (80%). However, mutations related to thrombophilia were detected only in 10.6% of cases (Factor V Leyden: n = 5; 20210A prothrombin mutations: n = 3), lupus anticoagulant in 0.75 % (n = 1) and hyperhomocysteinemia in 4 % (n = 3). Univariate and multivariate analysis did not show statistically significant association between presence of thrombophilia and baseline patient variables such as etiology, Child-Pugh class, MELD score, or thrombosis extent.

Non detected	63	84 %
Hiperhomocisteinemia	3	4 %
G20210A (Heterozygous)	3	4 %
Factor V Leiden (Heterozygous)	5	6.6 %
Lupus anticoagulant	1	1.3 %

Table 1. Thrombophilia study.

Conclusion: Most of the patients in our series presented protein C and S deficiency, probably secondary to their liver disease. However, the prevalence of other mutations related to thrombophilia were very low, like that usually observed in general population, so their screening in cirrhotic patients with thrombosis may be futile in most cases.

Disclosure: Nothing to disclose.

ENDOSCOPIC ULTRASOUND DIRECT PORTAL PRESSURE MEASUREMENT IS MORE RELIABLE THAN HEPATIC VENOUS PRESSURE GRADIENT MEASUREMENT IN PATIENTS WITH PRE-SINUSOIDAL FORMS OF PORTAL HYPERTENSION

L. Giuli[1], G. Rizzatti[1], F. Santopaolo[1], F.R. Ponziani[1], A. Contegiacomo[1], G. Tripodi[1], G. Venturini[1], B. Annicchiarico[1], C. Spada[1], A. Gasbarrini[1], A. Larghi[1]

Contact E-Mail Address: lucia.giuli92@gmail.com

Introduction: Hepatic venous pressure gradient (HVPG) represents the gold standard for the evaluation of portal hypertension (PH). HVPG > 10 mmHg defines clinically significant portal hypertension (CSPH), a condition that is independently associated with the occurrence of decompensation events. Portal pressure measurement is of fundamental importance for prognostic stratification and assessment of response to therapies. Indeed, a decrement of HVPG by 20% and/or < 10 mmHg reduces the decompensation risk. HVPG, however, indirectly measures PH and it may underestimate portal pressure gradient (PPG) in patients with pre-sinusoidal forms or with a pre-sinusoidal component of PH such in the case of initial stages of primary biliary cholangitis (PBC), non-alcoholic fatty liver disease (NAFLD), porto-sinusoidal vascular disorder (PSVD).

Moreover, HVPG procedure is invasive, involves radiographic exposure, and requires use of intravenous contrast media. Endoscopic ultrasound (EUS)-guided PPG measurement has recently become available. This technique allows measurement of portal pressure directly in the portal vein system and theoretically overcomes HVPG limitations.

Aims & Methods: We investigated the safety and accuracy of EUS measurements as compared to HVPG in evaluating PPG in a cohort of patients with CSPH. In patients naïve to non-selective beta-blockers (NSBBs) hemodynamic response to therapy was also evaluated.

Consecutive outpatients with liver disease characterized by pre-sinusoidal forms of PH who presented specific sign(s) of CSPH (gastro-oesophageal varices and/or portosystemic collaterals) underwent HVPG and EUS-guided PPG measurements with Echotip Insight 25G device (Cook Ireland Ltd.). In patients naive to NSBBs, treatment was started and after its titration EUS-PPG measurement was repeated. Definition and severity of adverse events (AEs) were based on classification of Cotton et al.

Results: Between March 2022 and December 2022, fourteen patients (mean age 58 ± 15; 57% males; etiology NAFLD related-cirrhosis 21.4%, PBC 7.2%, PSVD 71.4%) were enrolled. Mean platelet count was 71.000 U/microliter with 21% of patients having platelet count < 50.000 U/microliter. A total of 18 EUS-guided PPG and 14 HVPG measurements were performed. EUS-PPG was technically successful in all cases, without any AEs and requirement for platelet transfusion. EUS-PPG mean value was 18.7 ± 3.4 mmHg versus 9 ± 4.4 mmHg of HVPG (p<0.0001). In four patients naive to NSBBs we repeated a new EUS-PPG measurement after drug titration. The average PPG value in these patients before and after NSBBs titration was respectively 19.7 (± 3.4) and 17 (± 2.7) mmHg, with one patient out of four who achieved a decrement of PPG > 20 %.

Conclusion: Direct EUS-guided PPG measurement is safe and significantly more reliable than HVPG in the evaluation of PH in patients with pre-sinusoidal forms of PH. This technique could be also used to assess hemodynamic response to therapy in these patients.

Disclosure: N/A.

Contact E-Mail Address: julianaserrazina@gmail.com

Introduction: Previously known as idiopathic non-cirrhotic portal hypertension (PHT), porto-sinsuoidal vascular disorder (PSVD) has been recently introduced as a clinical entity with a spectrum of clinical presentations ranging from mild liver enzyme changes to clinically significant portal hypertension(CSPH). PSVD has well-established diagnostic criteria[1] requiring histologic evaluation of liver. Splenic stiffness evaluation with transient elastography is a non-invasive method to evaluate signs of portal hypertension in patients with chronic liver disease

Aims & Methods: We aimed to evaluate the correlation between clinical evidence of CSPH (ascites, and varices) with HVPG and liver and spleen elastography. We performed a retrospective analysis of 17 consecutive patients with histological evidence of PSVD on transjugular liver biopsy performed during liver hemodynamic assessment. Clinical charts were evaluated for evidence of PHT including ascites, splenomegaly (spleen diameter >13cm)and esophageal or gastric varices. Patients underwent liver and spleen transient elastography evaluation. The hepatic venous pressure gradient(HVPG) was evaluated during liver hemodynamic study and the presence of vena-vena communicants was noted.

Descriptive statistical analysis was performed. Quantitave variables with non-normal distribution were expressed as median (min-max). A p-value <0.05 was considered significant. Data analysis was performed with SPSS IBM 28.

Results: The median age was 44 (19-71) years and 15(88%) patients were male. Mild liver enzyme elevation and esophageal varices were the first presentation in 47% (n=8) and 41% (n=7) patients, respectively. Additionally, splenomegaly 76% (n=13) and ascites in 12% (n=2) were noted. Possible underlying etiology for PSVD included common variable immunodeficiency in 35% (n=6) patients, azathioprine use in 12% (n=2) and autoimmune disease: antiphospholipid syndromein 12% (n=2).

Concomitant partial or complete portal vein thrombosis was noted in 18% (n=3). Median spleen stiffness was 74.1kPA (23.3-75) and median hepatic stiffness was 9.6 (4.9-22.5 kPA). Spleen stiffness was significantly associated with the presence of varices (p=0.03) but not with ascites (p=0.32). There were 3 patients (18%) with spleen stiffness <40kPA , 33%(n=1) presenting with ascites and none with varices.

Median hepatic venous pressure gradient (HVPG) was 11(4-15)mmHg with presence of vein-to-vein communicant vessels in 35%(n=6) patients thus underestimating the HVPG. Considering 71%(n=12) patients with clinical evidence of portal hypertension (ascites/varices), 33%(n=4) had HVPG <10mmHg with vena-vena communicants detected in 75%(3/4). There was no association between HVPG and presence of varices (p=0.171), ascites (p=0.05) or splenomegaly (p=0.441)

Conclusion: Spleen transient elastography rather than HVPG is significantly associated with presence of varices in patients with PSVD.

LOCAL CAUSES OF PORTAL CAVERNOMA: ABOUT A UNIVERSITY SERIE

S. Sabbah[1], M. Kadiri[1], I. Benelbarhdadi[1], N. Lagdali[1], C. Berhili[1], F.-Z. Chabib[1], M. Borahma[1], F.Z. Ajana[1]
[1]Ibn Sina Hospital, Médecine C, Service d'Hépato Gastroentérologie, Rabat, Morocco

Contact E-Mail Address: sabbahselma@gmail.com

Introduction: Chronic portal thrombosis and/or portal cavernoma is a cavo-portal collateral venous pathway secondary to chronic thrombotic obstruction. The etiologies are numerous and must be systematically investigated. Our work aimed to study the profile of patients with portal cavernoma secondary to a local cause.

Aims & Methods: We conducted a 6-year retrospective, descriptive and monocentric study (2016-2022) including all patients followed for portal cavernoma and who have in their history a notion of abdominopelvic surgery or local non-surgical cause. All patients underwent a comprehensive etiologic workup for thrombosis.

Results: Out of the 56 patients diagnosed with portal cavernoma, 20 had a history of surgery or a local cause, indicating a prevalence of 35.71%. The mean age of the patients was 43.68 years with a range of 20 to 69 years and there was a clear female predominance with a sex ratio F/M of 19.

The clinical presentation of patients with portal cavernoma included acute abdominal pain in 83.3% of cases, digestive haemorrhage in 33.3%,

ascites in 33.3% and asthenia in 16.7%. Biologically, cholestasis was observed in 40% of cases, cytolysis in 26.6%, hepatocellular insufficiency in 6.6%, and pancytopenia in 6.6%. Abdominal ultrasound coupled with Doppler was performed in all patients, revealing a dysmorphic liver in 40% and heterogeneous liver in 26.6%.

Furthermore, angiography demonstrated extensive portal thrombosis in 20% of patients, and upper endoscopy found esophageal varices in 60%, gastroesophageal varices in 26.6%, and congestive gastropathy in 16.6% of patients.

Local causes of portal thrombosis included abdominal surgery (50%), pelvic surgery (25%), and non-surgical causes (25%). The abdominal surgeries included cholecystectomy (30%), appendectomy (30%), Porto-azygos shunt (20%), cholecystectomy followed by splenectomy (10%), and cholecystectomy followed by liver surgery: resection of the protruding dome for a hydatid cyst (10%).

An exhaustive etiological work-up was performed in all patients, revealing various underlying prothrombotic causes such as protein C and/or S deficiency (25%), celiac disease (10%), polycythemia vera (10%), chronic inflammatory bowel diseases (5%), Biermer disease (5%), and Paroxysmal Nocturnal Hemoglobinuria clone mutation (5%). whereas no associated prothrombotic pathology was found in 40% of the patients.

In the 40% where no underlying prothrombotic cause was found, the only cause of portal thrombosis was local: pelvic surgery in 20% of all cases, two abdominal surgeries in 10%, and main bile duct stent in 10% of patients.

As for the complications, 4 patients were complicated by portal biliopathy objectified by Cholangio-MRI and one patient died of hepatorenal syndrome.

Conclusion: The local cause of portal cavernoma is rare in the literature and is 4 % in our series. The most frequent surgery found in history is cholecystectomy, but these patients often have another associated prothrombotic factor. In the rare cases where no underlying prothrombotic factor was found, it was most often pelvic surgery followed by the association of 2 abdominal surgeries and a main bile duct stent.

PREDICTING VARICEAL BLEEDING IN NON-CIRRHOTIC PORTAL VEIN THROMBOSIS

N. Elleuch[1], W. Dahmani[1], A. Youssfi[1], A. Hammami[1], A. Braham Ep Krifa[1,1], A. Ben Slama[1], M. Ksiaa[1], H. Jaziri[1], A. Jmaa[1]

[1]Sahloul University Hospital, Gastroenterology, Sousse, Tunisia

Contact E-Mail Address: wafadh115@gmail.com

Introduction: Non-cirrhotic portal vein thrombosis (NCPVT) is a rare pathology of the liver characterized by the formation of a network of porto-portal collateral veins occurring after obstruction of the portal trunk in the absence of underlying liver disease. The long-term consequences of NCPVT are poorly understood. Published data regarding portal hypertension (PH) complications notably variceal bleeding in this context are scarce.

Aims & Methods: The aim of this study is to identify factors associated with the occurrence of variceal bleeding in patients with NCPVT.

Methods: We conducted a single-center retrospective cross-sectional study in the gastroenterology department of Sahloul University Hospital, over a period of 10 years, from January 2010 to December 2019.

Were included all non-cirrhotic patients over 18 years old, with chronic portal vein thrombosis. The diagnosis of NCPVT was retained based on the absence of flow in the portal vein and the visualization of a network of porto-portal collateral shunts on abdominal Doppler ultrasound or on 4-phase CT with contrast injection. We compared the 2 groups of patients: with (Group 1) and without (Group 2) variceal bleeding in order to identify the factors associated with its occurrence.

Results: Forty seven patients were included. The mean age was 40.7 years with a sex ratio (male/female) of 0.95. Variceal bleeding occured in 16 cases (34%) with a mean delay of 22.3 months, among which, 9 were on anticoagulants.

The factors associated with the occurrence of variceal bleeding in univariate analysis were: GI bleeding as the circumstance of discovery of portal thrombosis (22.2% in group 1 Vs 77.8% in group 2 with a p=0.004),the presence of clinical signs of PH (37.5% in group 1 Vs 62.5% in group 2 with a p <10-3), the presence of anemia (p=0, 014) or hyperleukocytosis on biology (p=0.023), the presence of signs of portal hypertension on follow-up imaging (37.5% in group 1 Vs 62.5% in group 2 with a p<10-3) and the presence of endoscopic signs of PH (48.3% in group 1 Vs 51.7% in group 2 with a p=0.001).

In multivariate analysis, the presence of endoscopic signs of portal hypertension (p=0.002) and the presence of collateral venous circulation on imaging (p=0.014) were independent factors associated with the occurrence of variceal hemorrhage during follow-up. Anticoagulant therapy was not associated with an increased risk of bleeding during follow-up.

Conclusion: This study emphasizes the importance of effective management of portal hypertension during non-cirrhotic portal cavernoma, especially when the manifestations of PH are in the foreground without delaying the possible initiation of anticoagulants.

Disclosure: Nothing to disclose.

INCREASE IN POINT-PREVALENCE AND COSTS OF LIVER CIRRHOSIS IN THE NETHERLANDS – A NATIONWIDE HEALTH CLAIMS DATA ANALYSIS

K. de Wit[1], G.M.C. Masclee[1], M.J. Coenraad[2], F. Cuperus[3], M. Kramer[4], R. Maan[5], R.B. Takkenberg[1], M.A. Lantinga[1]

Contact E-Mail Address: m.a.lantinga@amsterdamumc.nl

Introduction: Chronic liver injury ultimately progresses to the development of cirrhosis. Patients with cirrhosis can be in a compensated or decompensated phase, the latter marked by clinical events such as ascites, hepatic encephalopathy and variceal bleeding. These events are associated with significant morbidity and mortality and the management is challenging and labor-intensive. Due to ongoing unhealthy lifestyle factors resulting in chronic liver injury, the burden of cirrhosis on healthcare systems in Europe is increasing. There is however limited data on the impact of cirrhosis on Dutch healthcare resources.

Aims & Methods: We aimed to determine the point-prevalence and claimed health costs of adults (≥ 18 years) registered as patients with cirrhosis at Dutch hospitals. To this end we extracted health claims data (timeframe 2017-2021) from the records of the Dutch health claims database (Vektis), which covers almost all inhabitants of the Netherlands. We used diagnosis codes ‘compensated cirrhosis’ and ‘decompensated cirrhosis’ to identify patients.

Results: The point prevalence of patients with cirrhosis increased from 48,7 patients per 100.000 adult Dutch inhabitants in 2017 to 75,2 per 100.000 in 2021 (+54%). The point-prevalence for cirrhosis was highest in the province of Limburg with 105,6 patients per 100.000 adult Dutch inhabitants. The annual increase in unique new patients for which hospitals claimed costs was n=3.725 in 2018, n=3.840 in 2019 (+3%), n=3.749 in 2020 (-2%) and n=3.695 in 2021 (-1%). The largest increase was observed in the province of Zuid-Holland (approximately 5 new patients per 100.000 adult Dutch inhabitants per year). Total number of hospital admissions increased with 19% from 2.443 admissions in 2017 to 2.899 admissions in 2021. The median length of stay for admitted patients with cirrhosis in 2017-2021 was four days [IQR 2-7 days]. The annual reported costs for patients with cirrhosis increased from €35 million in 2017 to €78 million in 2021 (+120%).

Conclusion: The point-prevalence of Dutch adults registered as a patient with cirrhosis in Dutch hospitals increased by more than fifty percent, with remarkable regional differences. Consequently, the total healthcare costs claimed for these patients more than doubled in less than five years.

Disclosure: Nothing to disclose.

Introduction: In spite of its high prevalence and impact on health, non-alcoholic fatty liver disease (NAFLD) is not sufficiently addressed in European primary care (PC), with a large proportion of cases going undiagnosed or receiving late diagnosis. An international project was developed to design and evaluate an integrated, multidisciplinary, patient-centered model for NAFLD screening, diagnosis and linkage to specialty care and translate learnings into PC practice guidance.

Aims & Methods: Based on learning from this project, latest research evidence and existing guidelines for the management of NAFLD, we sought to develop a set of practice recommendations for screening, referral and management of NAFLD in PC.

The Rand/UCLA modified Delphi panel methods with 2 rounds was used to reach consensus on pre-defined statements. The international panel consisted of 15 experts from 6 countries, representing family medicine, gastroenterology, hepatology, cardiology and public health. Initially, 15 statements were drafted based on a synthesis of evidence from the literature and findings of this project. Prior to the consensus meeting, statements were rated by the experts in a first round. Subsequently, during a hybrid meeting of eight hours, experts discussed findings of round one, modified statements and rescored the updated recommendations in a second round.

Results: In round one, 10 of the 15 statements received high level of agreement (75% or greater). During the consensus process, 14 of 15 statements were considered appropriate and consensus was reached for all, with high agreement (>90%). The approved list included recommendations from several domains, including NAFLD risk assessment. diagnosis, referral to specialists, management, treatment, surgical management and integrated care.

Conclusion: The final set of 14 recommendations seeks to increase the comprehensive care for NAFLD in PC. We anticipate these recommendations to contribute to the ongoing discussion on systematic approaches to tackle NAFLD and support European PC providers through the integration of latest evidence into practice.

Contact E-Mail Address: clombo1149@gmail.com

Introduction: A large number of patients with autoimmune hepatitis (AH) seek information about their disease on the internet. The reliability, comprehensiveness, and quality of said information in Spanish has not been studied.

Aims & Methods: Our aim was to describe the characteristics of the information about AH on YouTube®. Methods: An analytic observational study evaluated videos in Spanish about AH available on YouTube®, describing their general characteristics, viewer engagement, and information sources. Standardized tools were utilized to analyze reliability (DISCERN), comprehensiveness, and overall quality (Global Quality Score [GQS]).

Results: One hundred videos were included, 93% of which provided information from healthcare professionals (group 1), and 7% of which reflected patient opinions (group 2).

There were differences in the median reliability (DISCERN: 4 vs 2, P ≤ .05) and comprehensiveness (4 vs 2, P ≤ .05) scores between groups, but equal overall quality (GQS 3 vs 2, P = .2). Reliability (DISCERN: 4; IQR: 3-4) and comprehensiveness (4.5; IQR: 3-5) were higher in videos by professional organizations, compared with those by independent users, healthcare information websites, and for-profit organizations (DISCERN: 3; IQR: 2.5-3.5; P < .001). Reliability (DISCERN: 2; IQR: 1.5-3), comprehensiveness (2; IQR; 1.5-2.5), and quality (GQS: 2.5; IQR: 1.5-3.5) were lower for videos made by for-profit organizations.

Conclusion: The majority of videos about AH in Spanish on YouTube® have good reliability, comprehensiveness, and quality. Videos created by academic organizations had higher scores, thus their collaboration, with respect to patient opinion videos, is suggested.

DISEASE PATTERNS AND ENTITIES IN CONSULT MEDICAL LIVER BIOPSIES HIGHLIGHT CHALLENGING DIAGNOSTIC AREAS IN HEPATOPATHOLOGY

I.-M. Grypari[1], I. Vlachos[1], E. Stoupi[1], D. Myoteri[1], D. Tiniakos[1]
[1]Aretaieion Hospital, Medical School, National and Kapodistrian University of Athens, Dept of Pathology, Athens, Greece

Contact E-Mail Address: dmyoteri@med.uoa.gr

Introduction: Difficult liver pathology cases often require expert review for optimal patient care. We reviewed consult cases received in our reference centre aiming to highlight challenging areas in hepatopathology that may benefit from consultation and focused educational activities.

Aims & Methods: We included all medical liver biopsies received for primary consultation in our Department between October 2016 and December 2022. Data on the sender (clinician/pathologist/patient) and the reason for consultation were collected. Initial and consult reports were screened for adequacy of clinical/laboratory/imaging information received, stains performed, initial and final diagnosis, disease grading/staging and comment on aetiology with suggestions to the clinician, where appropriate. Statistical analysis was performed using one sample t tests and descriptive statistics.

Results: We retrieved 147 consult cases (84 female-57.1%, median age 51, range 13-86 years), 135 (92.5%) submitted by hepatologists, 10 (6.9%) by pathologists and 1 (0.6%) by a patient. Adequate clinical/biochemical/imaging information was available in only 35/131 (26.7%) initial reports, while 51 (38.9%) did not have any information. Additional data was available with the consult in 122/147 (83%) cases but in 38 (25.8%) this was acquired by the consultant pathologist. Additional histochemical stains and immunostains were performed in 111 (78.7%) consult cases, while unnecessary stains had been initially performed in 30 (23.1%) cases. Most common reasons for consultation were confirmation of initial diagnosis 74 (50.3%), autoimmune hepatitis-AIH? 17 (11.6%), nonalcoholic steatohepatitis-NASH? 11 (7.5%) and primary biliary cholangitis-PBC? 11 (7.5%). Most common initial diagnoses were non-specific changes, chronic hepatitis, NASH and drug induced liver injury-DILI while most common consult diagnoses were vascular diseases, PBC, AIH, NASH and DILI (p<0.001, more details in Table 1).

Major changes in the initial diagnosis occurred in 73 (54.9%), minor changes in 37 (27.8%) and no change in 23 (17.3%) consults. Absence of adequate liver special stains, disease aetiology, grading/staging and comments/suggestions was recorded in 100 (76.9%), 71 (55.5%), 51 (45.1%) and 65 (49.6%) of initial reports, respectively (p<0.001compared to consults).

Diagnosis	Initial Report n (%)	Consult Report n (%)
Non specific changes	37 (27.8%)	7 (4.8%)
Chronic hepatitis	17 (12.8%)	1 (0.7%)
NASH	10 (7.5%)	14 (9.6%)
DILI	8 (6%)	12 (8.2%)
AIH	8 (6%)	17 (11.6%)
PBC	6 (4.5%)	19 (13%)
Vascular diseases	3 (2.3%)	22 (15.1%)

Table 1.

Conclusion: Study of consult medical liver biopsy patterns provides useful information on areas of hepatopathology posing diagnostic difficulty. The majority of consult cases in our Department are submitted by hepatologists. The most common diagnostic challenges in medical liver biopsies are vascular liver disease, interpretation of hepatitic pattern of injury, and recognition of primary cholangiopathy. These areas can be the subject of future continuing medical educational activities in hepatopathology.

Introduction: Chronic liver disease (CLD) causes 1.8% of all deaths in Europe. Without policies to mitigate harmful alcohol consumption and obesity, that proportion will continue to increase.

This study aims to estimate the impact of policy interventions targeting alcohol and obesity on the incidence of CLD and primary liver cancer in France, the Netherlands, and Romania.

Aims & Methods: A validated and peer-reviewed microsimulation model was employed using data from online databases and published literature. Static and dynamic trends in alcohol consumption and body mass index (BMI) respectively were projected from 2022 to 2030.

We modeled the incidence of CLD and liver cancer under three policy scenarios versus an inaction scenario. The policies were 1€ minimum unit pricing (MUP) on alcohol; a combination of 0.7€ MUP and a sugar sweetened beverage (SSB) tax; and a combination of 0.7€ MUP, SSB tax, and a volumetric tax on alcohol.

Results: All policies had an important impact ranging from a 2% to 7% reduction in annual incidence of chronic liver disease and liver cancer by 2030. The 1€ MUP policy had the largest predicted impact: In the three countries combined, that policy would result in 11,550 fewer cases of CLD and 7,921 fewer cases of liver cancer by 2030. Policy interventions combining a €0.7 MUP, an SSB tax, and a volumetric tax on alcohol would prevent nearly as many cases: 7,317 cases of CLD and 5,390 cases of liver cancer by 2030 compared with the inaction scenario.

Conclusion: In conclusion, we can reduce the number of Europeans who develop chronic liver disease or liver cancer by up to 7% before 2030 if we introduce a €1 MUP on alcohol, or we introduce complementary public health policies targeting alcohol consumption and obesity.

Disclosure: Financial support statement: This research was carried out as part of the HEPAHEALTH II project, commissioned by the European Association for the Study of the Liver (EASL), a non-profit medical association and has been supported by grants from Gilead Sciences Europe Ltd and Bristol-Myers Squibb. Nine EASL members co-authored this study.

LONG-TERM FOLLOW-UP OF LIVING LIVER DONORS: A SINGLE-CENTER EXPERIENCE

A. Shehta[1], E.E. Abdel-Khalek[2], M. Abdel Wahab[1]
[1]Mansoura University, Department of Surgery, Mansoura, Egypt, [2]Mansoura University, Department of Hepatology, Mansoura, Egypt

Contact E-Mail Address: ahmedshehta@mans.edu.eg

Introduction: Living donors are healthy individuals who are exposed to a major surgical procedure during which a major part of their liver is resected. Data on the long-term consequences of living liver donation are scarce.

Aims & Methods: This study examined clinical, laboratory, and long-term health-related quality of life (HRQoL) in 237 living liver donors and 239 matched controls during 48–168 months of postdonation follow-up. We used the 36-item short-form health survey (SF-36), version 1.

Results: The scores for the four following subscales were higher in nondonors than in donors: physical functioning ($p = 0.009$), role limitations due to physical health ($p = 0.002$), energy/fatigue ($p < 0.001$), and bodily pain ($p < 0.001$). The scores on the eight subscales of the SF-36
were higher in donors with living recipients than in donors whose recipients died ($p < 0.001$).

Conclusion: Our results suggest that living donor right hepatectomy is safe and results in a postdonation HRQoL similar to that of nondonors in those donors whose recipients are healthy, whereas donors whose recipients die have a lower HRQoL that is significantly negatively correlated with the time since recipient death and improves over time.

Disclosure: Nothing to disclose.

PP1412

PREDICITVE FACTORS OF SEVERITY IN ACUTE CHOLANGITIS. WHO SHOULD BE PRIORITIZED FOR URGENT BILIARY DRAINAGE? A RETROSPECTIVE STUDY

G. Font[1], D. Larrea[1], L. Ilzarbe Sanchez[1], C. Alvarez Urturi[1], L. Márquez Mosquera[1], G. Suris Marin[1], A. Seoane Urgorri[1], L. Barranco Priego[1], X. Bessa Caserras[1], L. Carot[1], M. González-Vivó[1]
[1]Hospital del Mar, Gastroenterology and Hepatology, Barcelona, Spain

Contact E-Mail Address: delarrea@psmar.cat

Introduction: According to guidelines for acute cholangitis management (Tokyo 2018), urgent drainage of the biliary tract is indicated in moderate and severe cases. However, it does not consider factors such as bacteraemia or comorbidities. In addition, the availability of immediate biliary drainage may be limited in some centres.

Aims & Methods: Aims: To evaluate the clinical characteristics of acute cholangitis in our environment and to identify predictive factors of severity.

Methods: A retrospective study of clinical and analytical variables at admission of 331 patients diagnosed with acute cholangitis at Hospital del Mar (2018-2021). Analysis of predictive factors for mortality during admission and at 30 days from discharge. Severty was assessed as association of mortality with clinical, haemodynamic and analytical variables analyzed via logistic regression. Analysis of differences in mortality between early drainage (before 48 hours) and late drainage through Pearson Chi squared test.

Results: The average age was 78 years, 53% were men, 35% had a smoking habit and 17.5% had a Charlson index of high morbidity (>5p). As relevant antecedents they had: diabetes (32.1%), COPD (11.48%), heart failure (16.92%) and ischaemic heart disease (10.3%). The causes of cholangitis were: choledocholithiasis (48.33%) and both benign and malignant strictures (24.92%), 26.75% of cholangitis did not have a clear cause. Choledocholithiasis was diagnosed by endoscopic ultrasound (41.67%), CT scan (23.72%), magnetic ressonance (19.87%) or abdominal ultrasound (14.74%). 197 patients required biliary drainage, median time to drainage of 5 days. The median hospital stay was 9 days and 6.65% of patients needed intensive care unit (ICU) admission.

Mortality was 4.23% during admission and 3.34% at 30 days from discharge. Intra-hospital mortality was related to high morbidity ($p<0,002$), a malignant aetiology of the cholangitis ($p<0,026$), alkaline phosphatase (AP) >300UI/L ($p<0,005$), CRP (C reactive protein) >8mg/dl ($p<0,006$), low albumin <3,3g/dl ($p<0,007$) and high leukocytes >12x10^3/uL ($p<0,022$).

Mortality at 30 days was associated with low levels of albumin, high levels of AP and CRP, high morbidity and a malignant origin of the cholangitis. In the multivariate analysis for intrahospital mortality, having high morbidity, AP>300 U/L and CRP>8mg/dl, were predictors of intra-hospital mortality (OR 2,34, IC 95% 1,19-4,16; OR 6,37 IC 95% 1,20-31,01; OR 5,10 IC95% 1,05-24,68; respectively). A malignant origin of a biliary stenosis was significantly associated with higher risk of mortality at 30 days after discharge (OR 12,57 IC 95% 1,58-100,17).

There were no differences in mortality of moderate and severe cholangitis between those drained before 48h of admission and those drained after 48h ($p=0,571$). In those patients who had the risk factors for mortality we identified, no differences in mortality were found between drainage before and after 48h of admission.

Conclusion: Patients with a high Charlson score, initial PA >300 U/L or initial CRP >8 mg/dL have a higher risk of mortality and therefore, should be considered as useful factors to prioritize those patients who need urgent drainage.

Disclosure: Nothing to disclose.

PP1413

THE EFFICACY OF BILIARY COVERED METAL STENT OVER CONVENTIONAL TREATMENT IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY RELATED TYPE II RETROPERITONEAL PERFORATION

M.K. Jung[1], J. Heo[1], C.-M. Cho[1], D.W. Lee[1], J.H. Lee[1]
[1]Kyungpook National University School of Medicine, Internal Medicine, Daegu, South Korea

Contact E-Mail Address: hero797@hanmail.net

Introduction: Perforation is one of the most serious complications in endoscopic retrograde cholangiopancreatography (ERCP). Conventional non-surgical treatment, including intravenous antibiotics with nothing per oral(NPO) and traditional bile drainage (plastic ERBD, PTGBD, PTBD), is generally approved treatment for the ERCP-related Stapfer's type ll perforation (perivaterian type). The biliary covered metal stent placement has recently been reported to have favorable outcomes in ERCP-related type ll perforation.

Aims & Methods: We aimed to compare the outcomes of conventional treatment and biliary covered metal stent insertion in patients with Stapfer's type II perforation. The medical records of patients who underwent ERCP at Kyungpook National University Hospital in Daegu from 2011 through 2022 were retrospectively reviewed.

Results: 8,402 ERCP procedures were conducted in our hospital. 66 ERCP-related perforations (0.78%) were identified with 47 patients (71.2%) had type II perforations. 34 patients received conventional treatments, 13 patients received biliary covered metal stent insertions. There were also no significant differences in clinical success rate (97.1% vs 92.3%, p=0.481), hospital stay (15.53±11.35 vs. 9.46±5.97 days, p=0.227), and NPO times (3.79±3.00 vs. 5.42±3.40 days, p=0.127). The conventional bile drainage group took shorter time for ERCP than SEMS group (12.62±6.315 vs. 18.46±11.16 minutes, p=0.028).

Conclusion: The biliary covered metal stent insertion did not improve patient' outcomes when compared with the conventional treatment method in ERCP-related type II perforations. Conventional treatment is sufficient for management of ERCP-related type II small sized perforations.

Disclosure: Nothing to disclose.

PP1414

DEVELOPMENT OF PREOPERATIVE ENDOSCOPIC ULTRASOUND-GUIDED GALLBLADDER DRAINAGE KIT FOR ACUTE CHOLECYSTITIS

S. Ito[1], T. Okuzono[1]
[1]Sendai Kousei Hospital, Department of gastroenterology, Sendai, Japan

Contact E-Mail Address: tabletennis2775@yahoo.co.jp

Introduction: Laparoscopic cholecystectomy (LC) remains the standard treatment for acute cholecystitis; however, it is not always suitable for patients who are poor candidates for surgery. Moreover, the rate of complications is approximately 10-30% and the mortality rate is approximately 1-2 %, which is not low. Percutaneous transhepatic gallbladder drainage (PTGBD) is recommended as conservative treatment, but the average hospital stay for PTGBD is considerably longer than that for LC especially in Japan. Recently, endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) has been reported as an alternative treatment for inoperable cholecystitis.

However, it has rarely been reported as a preoperative gallbladder drainage because the stent is commonly placed between the gallbladder and duodenum. We have developed an EUS-GBD kit for preoperative gallbladder drainage and have verified the function of it in live pigs for clinical introduction. This kit consists of anchors to fix between the gallbladder and stomach walls and the drainage tube.

Aims & Methods: The purpose of this study is to investigate the feasibility of LC after EUS-GBD with our novel drainage kit. Between May 2019 and March 2023, EUS-GBD with the novel drainage kit was performed on 38 live pigs. In six of them, LC was performed 2-9 weeks after EUS-GBD. We investigated the feasibility of LC, the rate of conversion to open cholecystectomy, and the complications.

Results: LC was successfully performed in all cases. In four cases, the anchors and drainage tube were endoscopically removed just before LC. In two cases, they were not removed before LC, and the gallbladder was removed along with the fistula including a part of the stomach. In all cases, there were no conversion to open cholecystectomy and no complications.

Conclusion: Laparoscopic cholecystectomy after EUS-GBD using our novel drainage kit is feasible in live pigs, and we will verify it though clinical trials involving humans in the future.

Disclosure: Nothing to disclose.

Introduction: Biliary diseases are an important source of morbimortality for patients, as well as a burden for the healthcare system. In Spain they represent the main cause of hospitalization (2018: 104551 admissions, 81400 cholecystectomies). The genetic syndrome LPAC (low phospholipid-associated cholelithiasis) is a poorly known and considered as infrequent condition,

that involves the development of hepatolithiasis due to mutations in the ABCB4 gene, which encodes the MDR3 protein that functions as a biliary transporter. Its treatment with bile salts avoids symptoms, admissions and the need for surgery. Our aim is to determine its incidence and characteristics in our center.

Aims & Methods: We conducted an ambispective study between February 2021 and September 2022. To be eligible, the patients had to fulfil at least two of the following: onset of biliary symptoms before the age of 40 years; recurrence of symptoms after cholecystectomy; image of intrahepatic macro- or microlithiasis (hyperechoic foci, comet-tail images, biliary sludge alongside intrahepatic bile ducts).

Demographic, clinical, ultrasound and genetic characteristics (analysis of MDR3 gene mutations) were analyzed, as well as their incidence among hospital admissions.

Results: 36 patients with LPAC were enrolled (Table 1). 6 of them were identified among 237 patients admitted to the for biliary causes in the last 9 months, which represents an incidence of 2.5% (95% CI: 1.17-5.41). By age subgroup, the incidence was 16.7% among those admitted <40 years and 9.1% among those <50 years. Considering only women, the incidence was 21% among those admitted <40 years and 15.8% among those <50 years.

The ultrasound characteristics were also analyzed. A trend was found between macrolithiasis with acoustic shadowing and presence of MDR3 mutations (42.9% vs 14.3%), although the differences were not statistically significant.

All patients remained asymptomatic and with no need of hospital readmissions after treatment with ursodeoxycholic acid was initiated.

Mean age at first symptoms (years)	27.5
Female gender	69.44% (25)
Hispanic origin	33.33% (12)
History of biliary diseases in first-degree relatives	58.82% (20)
BMI at diagnosis (kg/m^2)	22.2
Comorbidities	
- Hypertension	0.03% (1)
- Hypercholesterolemia	13.89% (5)
- Diabetes	0.03% (1)
Intrahepatic cholestasis of pregnancy in women with a history of pregnancy	14.29%(2)
Clinical and imaging features	
- Acute cholecystitis	19.44% (7)
- Acute pancreatitis	22.22% (8)
- Acute cholangitis	0.03% (1)
- Gallbladder lithiasis	80.56% (29)
- Common bile duct lithiasis	25% (9)
- Intrahepatic lithiasis:	88.89% (32)
· Hyperecoic foci	38.9% (14)
· Comet-tail images	27.8% (10)
· Intrahepatic lithiasis with acoustic shadow	22.2% (8)
Cholecystectomy	77.78% (28)
Recurrence after cholecystectomy	60.71% (17)
Genetic confirmation	
- among the total number of patients	28%
- among those who fulfil 3/3 criteria	40%

Table 1. Demographic, clinical, ultrasound and genetic characteristics of LPAC patients.

Conclusion: LPAC syndrome is not as uncommon as it might seem, especially among individuals younger than 40 years old admitted for biliary diseases, and mostly women. Its correct diagnosis based on simple criteria would avoid a large number of hospital admissions and unnecessary cholecystectomies.

Introduction: Primary choledocholithiasis is a common digestive disease that is closely related to biliary bacterial infection and host metabolic dysregulation. However, the compositions and functions of the bile microbial ecosystem and the pathogenesis of microfloral regulation of host metabolism resulting in stone formation are poorly understood.

Aims & Methods: To explore the orchestrated function of the bile microbial ecosystem and metabolite changes, biliary samples collected from patients with acute cholangitis induced by benign biliary stricture (n = 17) and primary choledocholithiasis (n = 33) were subjected to multiomics analyses.

Furthermore, clinicopathological features collected over a 24-month follow-up period were examined to evaluate the predictive value of candidate microbes.

Results: Compared with that in the nonlithiasis group, bile microbiome and metabolome analyses indicated that the diversity and composition of the microbiome were reduced and the microbial and metabolic functions changed greatly in the lithiasis group. Five alpha diversity indices of the bile microbiome were significantly decreased in the lithiasis group. Furthermore, we identified 49 differential bile flora between the two groups, and the relative abundances of 6 bacteria were associated with primary choledocholithiasis relapse conditions. Multiomics analyses showed that specific changes in disease-related bacterial taxa were closely related to metabolite variation, which might reflect disease prognosis.

According to pathway analyses, we revealed that bacterial infections, microbiota-derived amino acid metabolites and secondary bile acid-related pathways were significantly enriched in the stone-formation group, suggesting a novel host-microbial metabolic mechanism of primary choledocholithiasis.

Conclusion: Our study first indicates that bile host-microbial dysbiosis modulates the abnormal accumulation of metabolites might further disrupt calcium homeostasis and generate insoluble saponification. Meanwhile, bile bacterial infection inhibits the function of bile duct epithelial cells and eventually synergistically promotes stone formation. Finally, we determined the predictive value of Actinomycetes phylum reduction for recurrence in primary common bile duct stone patients.

Disclosure: Nothing to disclose.

ERCP-BASED TRANSCYSTIC DUCT GALLBLADDER-PRESERVING CHOLECYSTOLITHOTOM FOR CHOLECYSTOLITHIASIS PATIENTS WITH OR WITHOUT COMMON BILE DUCT STONES

J. Du[1], Y. Qian[1], L. Xu[1]
[1]Shenzhen University General Hospital, Department of Gastroenterology and Hepatology, Shenzhen, China

Contact E-Mail Address: dlxulong@aliyun.com

Introduction: Cholecystolithiasis is a common digestive disorder worldwide, affecting about 7% of adults aged 20-74 years. Laparoscopic cholecystectomy (LC) is considered as a safe and preferred surgical treatment for gallstone. Here, we assessed performance of ERCP-based transcystic duct gallbladder-preserving cholecystolithotom for patients having cholecystolithiasis with or without common bile duct stones.

Aims & Methods: A total of 41 patients having cholecystolithiasis with or without common bile duct stones (CBDS) and treated with ERCP-based transcystic duct gallbladder-preserving cholecystolithotom were enrolled in this study from March 2021 to April 2023 at the endoscopy center, Shenzhen University General Hospital.

Results: Of the 41 patients, 26 (63.4 %) had cholecystolithiasis without CBDS, while the rest 15 (36.6%) had concomitant cholecystolithiasis and CBDS. Among them, 33 (80.5%) patients had their gallbladder stones successfully removed by ERCP. The success rate of stone removal, operation time, and the full-covering metal stent (FCMS) implantation time were similar between patients with cholecystolithiasis only or with concomitant CBDS. The reported adverse events include post-ERCP pancreatitis (n=1), postoperative peritonitis (n=1), and postoperative acute cholecystitis (n=1), which were all resolved by subsequent intervention. Patients (n=33) who underwent this operation were followed up for 1 to 24 months, and none of them reported residue nor recurrence of gallbladder stones.

Conclusion: Cholecystolithiasis removal by ERCP-based transcystic duct gallbladder-preserving cholecystolithotom is a safe and effective treatment for cholecystolithiasis, and it preserves gallbladder function without incisions to abdominal wall or gastrointestinal tract. ERCP-based transcystic duct gallbladder-preserving cholecystolithotomis equally effective for cholecystolithiasis with or without CBDS.

EXTRACORPOREAL SHOCK WAVE LITHOTRIPSY VERSUS SPYGLASS-GUIDED LITHOTRIPSY FOR THE REMOVAL OF DIFFICULT BILIARY STONES

H. Khizar[1], J. Yang[2], X. Zhang[2]
[1]Hangzhou First People Hospital, Hangzhou, China, [2]Hangzhou First People Hospital, Gastroentrology, Hangzhou, China

Contact E-Mail Address: drxiaofeng_zhang@126.com

Introduction: ERCP is the conventional therapy for removing bile duct stones (BDS). Some large, impacted stones cannot be removed, and such patients need other advanced endoscopic lithotripsy procedures to remove these stones.

This study compares the safety and efficacy of extracorporeal shock wave lithotripsy (ESWL) and spyglass-guided lithotripsy.

Aims & Methods: Patients at our hospital diagnosed with complex large BDS between January 2021 and June 2022 were randomly assigned to the ESWL group or a spyglass group for lithotripsy. Our results include clinical and technical success, the mean number of ERCP sessions, the hospital stay, and any complications from the procedure.

Results: A total of 78 patients were included and randomly assigned to two groups (32 ESWL group and 46 Spyglass group). There was no significant difference in the characteristics of the two groups. Technical success was 93.5% for the ESWL group and 100% for the spyglass group (P = 0.019), whereas clinical success was 62% and 87%, respectively (P = 0.011). The EWSL group had 2.32±0.98 ERCPs, and the spyglass group had 1.13±0.36 (P = 0.000). The mean hospital stay was 13.25±6.39 and 9.80±5.85 days, respectively (P = 0.001). The mean lithotripsy sessions for ESWL were 2.3±0.63 and 1.13±0.36 for spyglass (P = 0.000). All groups had similar adverse effects, except for skin issues.

Conclusion: Compared to ESWL, spyglass-guided lithotripsy provides a safe and effective treatment for large and complex BDSs

A TWO-YEAR SINGLE CENTER RETROSPECTIVE ANALYSIS OF THE EFFICACY AND POTENTIAL COMPLICATIONS OF BILIARY PLASTIC STENTS

T.V. Moga[1], B. Miutescu[1], R. Bende[1], C. Burciu[1], D. Vuletici[1], C.G. Foncea[1], A. Popescu[1], R. Sirli[1], I.M. Ratiu[1]
[1]University of Medicine and Pharmacy "Victor Babes" Timisoara, Gastroenterology and Hepatology, Timisoara, Romania

Contact E-Mail Address: moga.tudor@yahoo.com

Introduction: Although biliary plastic stents (BPS) are frequently utilized in ERCP procedures, their effectiveness and associated complications can vary significantly.

This study aimed to determine the risk factors associated with BPS patency within our patient population.

Aims & Methods: We conducted a retrospective analysis of patients who underwent endoscopic cholangiopancreatography (ERCP) at our facility from January 2021 to December 2022, excluding those with a malignant cause. The study included patients who underwent at least one ERCP re-intervention within the past 23 months and received a biliary plastic stent during their initial ERCP

Results: Over a period of two years, our Gastroenterology department performed a total of 1354 procedures, with 1077 of these being for benign conditions. Of the 1077 benign cases, 212 (19.7%) required reintervention due to their etiology, and therefore had biliary plastic stents placed previously.

Out of a total of 212 subjects, 45% were male and had a mean age of 68.36±14.96 years. Among these subjects, choledocholithiasis was found to be the cause of obstruction in 81.1% of cases, common biliary duct stenosis in 9.5% of cases, chronic pancreatitis in 7% of cases, and other causes in 2.4% of cases.

The median interval between the initial procedure and the reintervention was 90 (1-1095) days. Acute cholangitis was the reason for reintervention in 32% (68/212) of the subjects, with 34% of them having Tokyo grade 3 cholangitis. In univariate regression analysis, the following factors were identified as independent predictors of cholangitis in patients with biliary plastic stents: total bilirubin levels, AST levels, ALT levels, number of days until reintervention, and CRP levels ($p<0.05$)

Conclusion: Within our cohort, 19.7% of patients required a reintervention for a benign condition following the initial placement of a biliary plastic stent. Of these patients, 32% experienced acute cholangitis as a reason for the reintervention. Our findings revealed that acute cholangitis in patients with biliary plastic stents was associated with days until reintervention, TGO levels, TGP levels, total bilirubin levels, and CRP levels.

Disclosure: Nothing to disclose.

PP1421

INCIDENCE AND RISK FACTORS FOR RESIDUAL COMMON BILE DUCT STONES IN CHOLEDOCHOLITHIASIS COMBINED WITH CHOLELITHIASIS AFTER ERCP EXTRACTION AND SUBSEQUENT CHOLECYSTECTOMY

J. Yang[1], Y. Wu[1]

[1]Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Hangzhou, China

Contact E-Mail Address: yjf3303@zju.edu.cn

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) with sequential cholecystectomy is the preferred treatment for patients with choledocholithiasis and cholecystolithiasis.

Aims & Methods: Aims: To investigate the incidence of residual common bile duct (CBD) stones in choledocholithiasis combined with cholelithiasis patients who undergoing ERCP and subsequent cholecystectomy, and analysis the related factors of postoperative residual stones.

Methods A retrospective analysis was performed for the clinical data of a total of 301 patients who underwent endoscopic removal of CBD stones via ERCP followed by cholecystectomy in Hangzhou First People's Hospital from January , 2017 to July, 2022. Endoscopic nasobiliary drainage tube was placed after clearance of CBD stones by ERCP in all people until cholecystectomy. Postoperative residual common bile duct stone were detected by nasobiliary cholangiography after cholecystectomy or found in follow-up within 6 months after cholecystectomy, which were confirmed and removed by ERCP. All patients were divided into residual group and non-residual group. Possible factors associated with postoperative residual CBD stones were collected and statistically analyzed, including clinical characteristics, test indices, bile duct anatomical factors, CBD stones and gallbladder stone characteristics, endoscopic factor.

Results: 1. According to the inclusion and exclusion criteria, a total of 301 patients underwent cholecystectomy after endoscopic extraction in this study. 54 patients discovered suspicious residual CBD stones by nasobiliary cholangiography, of which 50 patients were confirmed to have residual stones by ERCP. 5 patients were found and removed residual CBD stones within 6 months follow-up by ERCP. The incidence of postoperative residual CBD stones was 18.3%(55/301), and nasobiliary cholangiography had a positive predictive value of 92.6%(50/54).

2. The results of univariate analysis showed that there were significant differences between the two groups in gallbladder triangle adhesion, cystic duct diameter≥5mm, CBD diameter ≥15mm, multiple CBD stones, CBD stones diameter≥10mm, and applying of endoscopic mechanical lithotripsy (EML) ($P<0.05$). The multivariate logistic regression analysis showed that cystic duct diameter ≥5mm (OR=2.297, 95% CI:1.193–4.421, P=0.013), and multiple CBD stones (OR = 2.613, 95% CI:1.017–6.717, P=0.046) were the independent risk factors for postoperative residual CBD stones.

Conclusion: There was a high incidence of residual CBD stones in patients with CBD stones combined with gall blader stones who underwent endoscopic stones extraction and subsequent cholecystectomy. Cystic duct diameter≥5mm and multiple CBD stones were independent risk factors for postoperative residual CBD stones. Patients with high-risk factors should be followed-up carefully for early detection of postoperative residual CBD stones.

Disclosure: Nothing to disclose.

Introduction: Cholangiocarcinoma (CCA) constitutes a heterogeneous group of epithelial malignancies that arise in the biliary tree. CCA is a very aggressive cancer and carries a poor prognosis[1].

Furthermore, in view of the constant increase in its incidence and mortality in recent decades throughout the world, it represents a growing global health problem[1,2].

CCAs are divided into three subtypes according to their anatomical site of origin: intrahepatic CCA (iCCA), perihilar (pCCA), and distal (dCCA). Specifically, iCCA is characterize by high intertumoral clinical-pathological and molecular heterogeneity, leading to an innovative histological classification approved by WHO (ICD-O-3.2), into small bile duct iCCA and large bile duct iCCA[3].

The molecular pathogenesis of iCCA is very intricate and involves multiple molecular networks: among them, the Hedgehog (Hh)[4,6] signaling pathway. Indeed, the Hh pathway plays an important role in many aspects of iCCA, such as tumor survival, proliferation, migration and EMT reprogramming[5]. The impact of innovative therapies on the survival of patients with iCCA is an ongoing area of investigation. Evidence on the pathogenetic role of Hh in iCCA implies the possibility of targeting this signaling pathway for therapeutic purposes in iCCA subtypes.

Aims & Methods: The aim of this study is to demonstrate the antitumor efficacy of a natural therapeutic compound, from an in-house library, that inhibits the Hh pathway in experimental models of human iCCA, in vitro, in established iCCA cell lines (CCLP1) and primary cell lines derived from small or large bile duct iCCA.

The iCCA samples from resected specimens have been processed by mechanical and enzymatic digestion to obtain patient-derived primary cell lines. The effect of Glabrescione B (GlaB), a selective inhibitor of GLI1 (Hh downstream transcriptional factor), has been evaluated. The dose-dependent efficacy of GlaB [0, 1, 5, 10, 20, 50 µM] or hyaluronic acid (HA) nano-

hydrogel-encapsulated Glab [0, 0.5, 1, 5, 10 µM], have been evaluated by Trypan Blue Exclusion Test and MTS assay (cell viability), at different time points (24h, 48h, 72h, 96h). Its ability as inhibitor of Hh signaling pathway has been evaluated by Western Blot analysis. All experiments have been conducted in N.3 experimental replicates.

Results: Our research shows a dose-dependent and time-dependent reduction of cell proliferation by Trypan Blue Exclusion Test in all cell lines ($p<0.05$). The decrease already occurs at low concentrations and at 24-hour incubation (40-50%) and becomes more evident at higher concentrations and at 96-hour incubation (80-90%) ($p<0.05$). Likewise, at the protein level, Gli1 knockdown, in a dose and time-dependent manner, is demonstrated ($p<0.05$). MTS assays confirmed the cytotoxicity effect of GlaB at 20 µM and 50 µM ($p<0.05$). Therefore, we decided to pursue the study with lower concentrations (from 1 µM to 10 µM) capable of knocking down the cell viability by 50%.

Thereafter, successful, and stable encapsulation of GlaB [0.5-10 µM] in HA nanohydrogel has been accomplished. Data showed a dose-dependent and time-dependent inhibitory activity of HA-encapsuled GlaB [0.5-10 µM] in all cell lines ($p<0.05$).

Conclusion: Aberrant Hh pathway activation is widely known to be closely related with the development and malignant progression of various human cancers. Preclinical experimental data denote that dysregulation of this pathway is a determinant of cholangiocarcinoma progression and invasiveness. The achievements of this study could lay the groundwork for pre-clinical studies of HA-encapsuled Glab in iCCA.

Introduction: Cholangiocarcinoma (CCA) comprises a heterogeneous group of malignant tumors with dismal prognosis. Alterations in post-translational modifications (PTMs), including SUMOylation, result in abnormal protein dynamics, cell disturbances and disease. Here, we investigate the role of SUMOylation in CCA development and progression.

Aims & Methods: Levels and function of SUMOylation, together with response to S-adenosylmethionine (SAMe) and ML792 (SUMOylation inhibitors) or CRISPR/Cas9 against UBE2I were evaluated in vitro, in vivo and/or in patients with CCA. The impact of SUMOylation in CCA cells on tumor-stroma crosstalk was assessed performing co-culture experiments with CCA-derived cancer-associated fibroblasts (CAFs), human endothelial cells and monocytes. Proteomic analyses were carried out by mass spectrometry.

Results: The SUMOylation machinery was found overexpressed and over-activated in human CCA cells and tumors, correlating with poor prognosis. Most SUMOylated proteins found upregulated in CCA cells, after SUMO1-immunoprecipitation and further proteomics, participate in cell proliferation, survival or cell homeostasis. Genetic (CRISPR/Cas9-UBE2I) and pharmacological (SAMe and ML792) inhibition of SUMOylation reduced CCA cell proliferation and impeded colony formation in vitro. Moreover, both SAMe and ML792 induced apoptotic cell death in CCA cells in vitro. SUMOylation depletion (SAMe, ML792 or CRISPR/Cas9-UBE2I) halted tu-

morigenesis in subcutaneous models of CCA in vivo. Furthermore, SUMOylation deficiency in CCA cells reduced cancer-associated fibroblast and endothelial cell proliferation and impaired macrophage polarization towards an anti-inflammatory M2-like phenotype.

Conclusion: Aberrant protein SUMOylation contributes to cholangiocarcinogenesis by promoting cell survival and proliferation. Moreover, SUMOylation impacts the CCA-stroma crosstalk. Impaired SUMOylation halts CCA growth and, thus, may represent a potential new therapeutic strategy for patients with CCA.

Introduction: Cholangiocarcinoma (CCA) comprises a heterogeneous group of biliary malignant tumors characterized by dismal prognosis. The first-line treatment for advanced CCA [cisplatin (CisPt) and gemcitabine] is considered palliative due to the high chemoresistance of this cancer, barely impacting on patients' overall survival.

Here, we aimed to design, synthesize and study a new generation of platinum (Pt)-derived chemotherapeutic drugs that produce double-strand DNA breaks (vs classical single-strand breaks induced by CisPt and related compounds) and thus, prevent the development of DNA repair mechanisms in cancer cells.

Aims & Methods: Ten Pt-derivatives (Aurki-Pt#s) were designed and synthesized. Atomic Force Microscopy (AFM) and Transmission Electron Microscopy (TEM) were used to characterize the binding of Aurki-Pt#s to DNA. The antitumoral effect of the two best candidates (Aurki-Pt#1 and #2) was evaluated by measuring the viability of human CCA cells (EGI-1 and HUCCT1), newly generated CisPt-resistant EGI-1 CCA cells, normal human cholangiocytes (NHC) and cancer-associated fibroblasts (CAFs). The DNA damage induced by Aurki-Pt#1 and #2 was assessed using the comet assay.

To ascertain the internalization mechanism of Aurki-Pt#1 and #2, substrate competition studies through flow cytometry and accumulation studies using HPLC-MS/MS were carried out. Finally, the effect of Aurki-Pt#1 and #2 was also tested in vivo on a subcutaneous xenograft model of CCA.

Results: Aurki-Pt#s induced double-strand DNA breaks, and the subsequent DNA fragmentation, contrary to CisPt. Aurki-Pt#1 and #2 significantly reduced CCA cell viability. Both compounds triggered increased DNA damage in CCA cells when compared to CisPt, augmenting the reactive oxygen species levels and being more effective when inducing apoptosis in vitro.

Additionally, Aurki-Pt#1 and #2 decreased the proliferative capacity of those CCA cells that survived. Importantly, Aurki-Pt#1 and #2 also promoted cell death in CisPt-resistant CCA cells. Moreover, Aurki-Pt#1 and Aurki-Pt#2 caused CCA spheroid shrinkage.

On the contrary, Aurki-Pt#1 and #2 did not induce a lethal effect in NHC in culture, but promoted cell cycle arrest. Besides, Aurki-Pt#1 and Aurki-Pt#2 had an impact on the survival of CAFs. Aurki-Pt#1 and #2 were transported into cells through OCT1, OCT3, CTR1 and OATP1A2, which did not transport CisPt. Finally, Aurki-Pt markedly hampered tumor growth on a subcutaneous xenograft model of CCA in comparison with CisPt or vehicle control.

Conclusion: This new generation of Pt-derived chemotherapeutic drugs selectively diminishes CCA cell viability through the induction of double-strand DNA breaks, and has an impact on its tumor microenvironment, representing a promising therapeutic tool for naïve or CisPt-resistant CCA tumors.

Introduction: Cholangiocarcinoma continues to exhibit a high mortality rate despite advancements in diagnostic and therapeutic approaches. The contribution of the human microbiota to cholangiocarcinoma remains inadequately elucidated, with recent metagenomic analyses revealing a significant association between microbiota-driven carcinogenesis and cholangiocarcinoma.

This investigation seeks to explore alterations in microbiota composition in relation to cholangiocarcinoma and their metabolic signatures by integrating taxonomic and functional data with metabolomic findings and in vitro experiments.

Aims & Methods: The study included patients with and without cholangiocarcinoma who underwent endoscopic retrograde cholangiopancreatography (ERCP) between February 2019 and January 2021. Bile samples were procured through endoscopic nasobiliary drainage, followed by DNA extraction, PCR amplification of the bacterial 16S rRNA gene V3-V4 region, and data analysis utilizing QIIME2. In vitro CFSE proliferation and Annexin V/PI apoptosis assays were conducted to examine the effects of metabolites on cholangiocarcinoma cells.

Results: The study encompassed a total of 24 patients. Analysis of bile fluid indicated a significantly increased abundance of Escherichia coli in the cholangiocarcinoma group. Alpha diversity analysis demonstrated a marked difference between cholangiocarcinoma and non-cholangiocarcinoma cohorts.

NMR metabolic profiling identified 15 metabolites with significant concentration disparities, among which isoleucine exhibited the most pronounced variation. In vitro assays revealed that isoleucine inhibited cholangiocarcinoma cell proliferation without inducing apoptosis.

Conclusion: This study underscores the significance of biliary dysbiosis and bile metabolites, particularly isoleucine, in the development and progression of cholangiocarcinoma.

Disclosure: Nothing to disclose.

Introduction: Despite the use of various multidisciplinary diagnostic tools, early differentiation between benign and malignant biliary strictures remains challenging. BILEMUT consists of a mutational analysis of bile cfDNA collected at the time of first ERCP using a next-generation sequencing (NGS) panel of 52 genes (1).

It has demonstrated a sensitivity and specificity of 96.4% and 69.2%, respectively, for malignancy in biliary strictures. While genetic analyses were once very expensive, they have become more affordable nowadays. When evaluating new diagnostic techniques, it is crucial to consider not only their accuracy but also their cost, adverse events, and potential for early diagnosis.

Aims & Methods: Prospective observational descriptive pilot study in a cohort of patients diagnosed with non-malignant biliary strictures after the first ERCP recruited in a tertiary hospital between 2017-2020. The aim of this study is to compare the differences in diagnostic costs in euros between performing BILEMUT and repeating tests to achieve a diagnosis according to current clinical practice in biliary strictures. Moreover, adverse events and time required for diagnosis were evaluated.

Results: From the cohort of 68 patients with biliary stricture, 35 received a non-malignant diagnosis after undergoing the first ERCP. Of those patients, 12 were directly referred to surgery, 7 were considered for a wait and see or palliative care approach due to age and/or comorbidity, and 16 required further diagnostic tests to confirm the diagnosis.

In these 16 patients, the median cost of the different endoscopic procedures, radiological techniques, hospital admissions and consultations performed was 8641.52 euros (895.9 – 31704.4). The cost of BILEMUT was 1223 euros per patient. BILEMUT assay had a S=100%, E= 62.5%, NPV=100%, PPV=72,7%. Repeating tests to achieve a definitive diagnosis according to current clinical practice in biliary strictures yield a S = 62.5%, E=100%, PPV=100% and NPV=62.5%.

Both strategies had the same diagnostic accuracy in this cohort, 81.3% (57-93.4%). Among the 8 patients who were diagnosed with malignant biliary stricture, the median time to reach the final diagnosis in real clinical practice was 43 days (range 10-930).

In contrast, BILEMUT analysis was obtained much faster, with a median turnaround time of 10 days (range 7-14 days). BILEMUT does not pose any additional risks to patients. Furthermore, no complications occurred in the current clinical practice strategy in this cohort despite the extra invasive tests.

Conclusion: This pilot study suggests that the BILEMUT approach in patients with indeterminate biliary strictures after the first ERCP could reduce costs without impairing diagnostic accuracy compared to the current clinical practice approach.

In addition, BILEMUT reduced the time and number of diagnostic tests needed to achieve a final diagnosis. There could be a lower theoretical risk of complications associated with the BILEMUT approach due to its ability to reduce the need for invasive tests. However, this study did not demonstrate such a risk reduction.

Introduction: Digital single-operator cholangioscopy (DSOC) allows an accurate diagnosis of biliary strictures. Two DSOC-based artificial intelligence (AI) models trained to identify neoplasia were proposed. DSOC-guided pCLE biliary strictures direct visualization, using the Miami and Paris classifications has demonstrated high diagnostic accuracy for neoplasia (higher than expert endoscopists at times). To date, there are no head-to-head studies comparing DSOC-AI vs DSOC-pCLE.

Aims & Methods: We aim to compare the diagnostic accuracy for identifying neoplasia in indeterminate biliary lesions using a novel DSOC-AI model against DSOC-pCLE. Historic cohort-based diagnostic accuracy study in agreement with STARD initiative including patients ≥18 years old who underwent DSOC-pCLE (06/2014 to 11/2021). Patients without available DSOC videos, biopsy, or impossibility for 12-month follow-up were excluded. For DSOC direct visualization, neovasculature constituted neoplasia. For DSOC-pCLE, a higher presence of the Miami classification's malignancy criteria (thick white and dark bands, dark clumps, epithelium) than the Paris classification's inflammatory criteria (vascular congestion, roughness aspect, increased inter-glandular space, and thickened reticular structure) constituted neoplasia. For DSOC and pCLE-guided biopsy, corresponding histological findings constituted neoplasia. An offline DSOC-based AI model analysis was performed using the DSOC recorded videos from the selected cases. The DSOC-AI model considered neovasculature as the criterion for neoplasia. The gold standard for neoplasia was based on further clinical evolution, imaging, or surgical specimen findings during a 12-month follow-up. Accuracy of DSOC direct visualization, DSOC-pCLE, DSOC and pCLE-guided biopsy, and DSOC-AI model was calculated in terms of sensitivity, specificity, positive and negative predictive values (PPV and NPV), observed agreement, and area under the curve (AUC). Comparison of obtained diagnostic accuracies were defined through DeLong's test for two ROC curves.

Results: Ninety patients were selected, median age was 66.4 ± 13.7 years, 56.7% female. Tumour suspicion was the most common indication (55.6%) (Table 1). DSOC-AI reached a 97.7% sensitivity, 75% specificity,

98.8% PPV, 60% NPV and 96.7% observed agreement; whereas, DSOC-pCLE had a 94.2% sensitivity, a 100% specificity, 100% PPV, 44.4% NPV, and 94.4% observed agreement (Table 2). AUC for DSOC-AI was 0.79; for DSOC direct visualization (0.74; P=.763), DSOC-pCLE (0.72; P=.634), and DSOC and pCLE-guided biopsy (0.83; P=.809).

	Sensitivity	Specificity	PPV	NPV	OA
DSOC direct visualization	83/86; 96.51 (90.14 - 99.27)	3/4; 75 (19.41 - 99.37)	83/84; 98.81 (93.54 – 99.97)	3/ 6; 50 (11.81 – 88.19)	86/90; 95.56 (89.01 – 98.78)
DSOC-guided pCLE	81/86; 94.19 (86.95 – 98.09)	4/4; 100 (39.76 – 100)	81/81; 100 (95.55 – 100)	4/ 9; 44.44 (13.7 - 78.8)	85/90; 94.44 (87.51 - 98.17)
DSOC and pCLE-guided biopsy	84/86; 97.67 (91.85 - 99.72)	4/4; 100 (39.76 - 100)	84/84; 100 (95.7 – 100)	4/ 6; 66.67 (22.28 – 95.67)	88/90; 97.78 (92.2 – 99.73)
DSOC-based AI model	84/86; 97.67 (91.85 – 99.72)	3/4; 75 (19.41 – 99.37)	84/85; 98.82 (93.62 - 99.97)	3/ 5; 60 (14.66 - 94.73)	87/90; 96.67 (90.57 - 99.31)

PPV: Positive predictive value; NPV: negative predictive value; OA: observed agreement; pCLE: probed-based confocal laser endomicroscopy.

Conclusion: The DSOC-AI model demonstrated an offline diagnostic accuracy similar to DSOC-pCLE. Larger multicentric head-to-head trials with a proportional sample among neoplastic and non-neoplastic cases are advisable for best estimation of obtained results.

Introduction: There were lots of previous references showed cholecystectomy (CCY) can increase the incidence of hepatobiliary and pancreatic cancers, while CCY can reduce the probability of recurrent biliary events in patients after endoscopic retrograde cholangiopancreatography (ERCP) intervention for choledocholithiasis. Chronic inflammatory environments could promote the risk of malignancy, but the current evidence showed in a different way. We need to know the true risk of hepatobiliary cancers in patients, who underwent CCY after choledocholithiasis managed with ERCP.

Aims & Methods: We selected all the patients who underwent first time endoscopic sphincterotomy and endoscopic papillary balloon dilatation in their life time for choledocholithiasis or cholangitis management from 2011 to 2017 in Taiwan. After exclusion the patients had missing data, age under 18, CCY before admission, relevant cancer diagnosed before index date, we collected 13413 patients who accepted CCY after ERCP intervention.

We used propensity score matching to get 13330 patients in both CCY and non-CCY group after ERCP intervention. Each specific cancer incidence and mortality were compared between CCY and non-CCY group.

Results: In the CCY group, 60 patients had cholangiocarcinoma and 15 patients had Ampulla Vater cancer (AVC). In the non-CCY group, 168 cases had cholangiocarcinoma and 49 patients had AVC. The incidence rates of cholangiocarcinoma and AVC were 1.19, and 0.3 per 1,000 person-years in the CCY group, all significantly lower than 3.52 ($P < 0.0001$) and 1.02 ($P < 0.0001$) per 1,000 person-years, respectively, in the non-CCY group.

Conclusion: CCY is a definite treatment after ERCP intervention for choledocholithiasis or cholangitis, not only reduce the future recurrent biliary events, but also decreased the incidence risks of hepatobiliary cancers.

Introduction: Recent genomic analysis of biliary tract carcinoma has revealed the distinct genetic features based on their primary sites and is expected to help develop primary site-specific treatments. However, the exact primary site of perihilar cholangiocarcinoma (phCCA), which is located between the intrahepatic and extrahepatic bile ducts, is virtually unknown. A precise diagnosis of the primary tumor site of phCCA is urgently necessary to select appropriate treatment and improve prognosis.

Aims & Methods: This study aims to identify the primary site of phCCA by molecular pathological analysis. We analyzed a total of 358 surgically treated invasive CCA operated at the National Cancer Centre Central Hospital Tokyo, Japan from 1990 to 2013. The primary site of the tumor was evaluated based on bile duct stenosis location on preoperative image findings, detailed macroscopic observation in the resected specimen and histological tumor localization using elastic fiber staining. Hilar CCA (hCCA) was defined as a tumor originating in the upper common, right or left hepatic duct without macroscopic mass formation in liver.

The analysis set included 39 cases of mass-forming type intrahepatic CCA (iCCA-MF) and 9 cases of extrahepatic CCA (eCCA) in which both frozen and formalin-fixed paraffin-embedded specimens were available. The validation set included 60, 100, 85, 14, 36, and 15 cases of iCCA-MF, eCCA, hCCA, periductal infiltrating intrahepatic CCA (iCCA-PI), periductal infiltrating plus mass-forming intrahepatic CCA (iCCA-PI+Mass), and iCCA-MF with perihilar invasion, respectively.

First, transcriptome analysis was performed using the analysis set to identify candidate genes differentially expressed between eCCA and iCCA-MF. Second, immunohistochemical staining of the candidate genes was performed on the analysis set to determine the evaluation criteria.

Finally, immunostaining of the candidate markers was performed on the validation set to evaluate the expression levels of each CCA subtype and statistically analyze the comparison between hCCA and the other CCA subtypes.

Results: Candidate genes included Serpin Family A Member 1 (SEPRINA1), Claudin18 (CLDN18), and Mesothelin (MSLN) as positive cases, with their immunohistochemical staining evaluation criteria of ≥33%, ≥5%, and ≥1+ (positive intensity), respectively. The immunohistochemical expression of each three molecules in the analysis set between eCCA and iCCA-MF revealed SERPINA1 at 0% vs. 82% ($P < 0.01$), CLDN18 at 100% vs. 41% ($P < 0.01$), and MSLN at 100% vs. 48% ($P < 0.01$).

Similarly, a statistically significant difference was observed in the expression of each of the three molecules in the validation set. However, no significant difference was found in the immunohistochemical expression of the three molecules between eCCA and hCCA. Conversely, SERPINA1 expression in iCCA-MF cases with perihilar invasion was significantly different from that in cases of hCCA with microscopic hepatic parenchyma invasion, but not significantly different from that in cases of iCCA-PI+Mass. Furthermore, clustering analysis of the combination of three molecule expressions revealed that CCA was divided into three subgroups, consisting of iCCA-MF, iCCA-PI+Mass and iCCA-PI, and hCCA and eCCA.

Conclusion: We demonstrated molecular pathologically that the primary tumor site of phCCA can be identified and clinicopathologically classified in detail. In particular, we succeeded in showing that hCCA is classified into the same group as eCCA.

OVERALL SURVIVAL AND ASSOCIATION OF PRE-CHEMOTHERAPY ALBUMIN BILIRUBIN (ALBI) PROGNOSIS SCORE IN UNRESECTABLE CHOLANGIOCARCINOMA RECEIVED SYSTEMIC CHEMOTHERAPY

P. Poonyam[1], K. Pattamasirikun[1], P. Chonmaitree[1], A. Soodcharoen[1]
[1]Srinakharinwirot Uninversity, Medicine, Nakorn Nayok, Thailand

Contact E-Mail Address: piyakorn@g.swu.ac.th

Introduction: Cholangiocarcinoma (CCA) prevalence is high in East and Southeast Asia, especially in northeast Thailand. The first line of treatment for unresectable CCA is systemic chemotherapy which a median OS of less than 1 year under palliative systemic therapy. Albumin-Bilirubin (ALBI) prognosis score is the new method for the evaluation of liver performance status and prediction of treatment outcome but there is a lack of data in CCA patients.

Aims & Methods: Aim: To study the association of overall survival and ALBI prognostic score in unresectable CCA patients who received systemic chemotherapy.

Methods: This retrospective cohort study was conducted in Maha Chakri Sirindhorn Medical Center, Thailand. Demographic data, Clinical information, Laboratory profile, and survival analysis were extensively reviewed in the patient who received systemic chemotherapy from 2012 - 2022. All patients were monitored for at least 1 year after initial treatment with chemotherapy or until death.

Results: 69 patients of Unresectable CCA received systemic chemotherapy enrolled in this study. Most of the patients were men (45/69, 65.22%) and Intrahepatic type CCA (55/69, 79.71%). 17 patients (24.6%) need Biliary drainage before systemic chemotherapy which median pre-drainage TB was 11.35 mg/dL (10.7 – 20.6). Most ALBI prognostic score were group 2 (37/69, 53.6%) and anemia was significantly in ALBI 2 group (81.08%, $P <0.001$). The median overall survival was 10.23 months and the median progression-free survival was 5.77 months.

Significantly better overall survival of the ALBI 1 group compared with the ALBI 2 group (ALBI 1, 13.76 months; ALBI 2, 6.33 months; log-rank test, $P <0.001$). The estimated 6, 12, 18, and 24-month survival rates were 72.46%, 40.58%, 18.84%, and 8.70%, respectively, whereas the estimated progression-free survival rate at 6, 12, 18, and 24 months were 47.83% and 10.14%, respectively.

Conclusion: ALBI prognosis score may serve as a surrogate marker in predicting the overall survival and progression-free survival of CCA patients who received Systemic chemotherapy.

Disclosure: Nothing to disclose.

Contact E-Mail Address: d.m.dejong@erasmusmc.nl

Introduction: It is often difficult to correctly diagnose a suspicious biliary stricture. Biliary brushes and biopsies usually yield low cellularity and when cytopathological assessment is indecisive, additional sensitive diagnostic tests are lacking. Next generation sequencing (NGS) is an adjunctive diagnostic tool that may improve the diagnostic sensitivity. The aim of this study is to assess the added value of NGS for morphological classification of biliary brushes and biopsies in patients with suspicious biliary strictures.

Aims & Methods: In this retrospective single-center cohort study between 2019-2022, patients with suspicious biliary strictures of which biliary specimens by brush or intraductal biopsy were obtained and on which NGS (Ion Torrent) was performed, were included. Targeted NGS panels covering 40 (v5.1) and 59 genes (v6.1) were used for analysis of biopsies whereas brushes were analysed using the Oncomine™ Colon cfDNA Assay covering 14 genes with >240 hotspots. NGS was classified as malignant by an expert cytopathologist whenever one or more pathogenic mutations were identified. Sensitivity and specificity of NGS were calculated in general and in addition to type of morphology; i.e. benign, atypical, suspicious for malignancy and malignant.

Final diagnosis of the suspicious biliary strictures was defined on surgical resection specimens and autopsy, other endoscopic or percutaneous biopsies and/or clinical follow-up (>1 year). In addition, the changes in clinical decision making (CDM) after NGS outcome were evaluated retrospectively by an expert treatment panel. CDM was defined as a change in the course of treatment or the decisive factor to continue current treatment, without the need of additional imaging or pathology material.

Results: A total of 109 samples in 106 patients were included (94 brushes, 15 biopsies). Without taking into account initial morphology/histology, NGS had an overall sensitivity of 65% for brushes and 58% for biopsies, and specificity of 100% for both. Whenever taking initial morphology and histology into account, this resulted in an 85% sensitivity and 93% specificity. Whenever the initial morphology was described as atypical, NGS was able to correctly classify 54% of malignant cases, with a 64% sensitivity and 100% specificity.

Overall, NGS was able to identify 42 of the 75 (56%) malignancies correctly. There were no false positive results. Table 1 shows the sensitivities and specificities for both the brush and biopsy groups, stratified by initial morphology. The outcome of NGS resulted in a change of CDM in 8% of the patients.

Suspicious for malignancy	0.67 [0.46 – 0.83]	1.00 [0.16 – 1.00]	0.88 [0.47-0.99]	1.00 [0.03 – 1.00]
Malignancy	0.60 [0.15 – 0.95]	NA	-	-

Table 1.

Conclusion: There is a significant additional yield of NGS in the setting of biliary strictures. Nevertheless, NGS has a limited impact on clinical decision making and for now should only be used in patients in which the outcome is most valuable. This could be to differentiate between different causes of cancer to determine the optimal chemotherapy regimen, or in patients with a clinical suspicion of malignancy but without any mass on cross-sectional imaging. With more sensitive NGS panels for cholangiocarcinoma and more targeted therapy options, in the future the clinical impact will likely increase.

THE USEFULNESS OF DETECTIVE FLOW IMAGING (DFI) FOR MALIGNANT BILIARY TRACT LESIONS

S. Omoto[1], M. Takenaka[1], M. Kudo[1]
[1]Kindai University, Gastroenterology and Hepatology, Osakasayama, Japan

Contact E-Mail Address: shunsuke.oomoto@gmail.com

Introduction: Detective flow imaging (DFI) is a novel technology that enables the evaluation of low-speed blood flow signal that is difficult to visualize with conventional Doppler techniques[1)-3)].

This technique allows for evaluating microvascular signals within tumors in endoscopic ultrasound (EUS) without using contrast agents. In this study, we aimed to investigate the usefulness of DFI for the diagnosis of biliary tract lesions.

Aims & Methods: A retrospective study was conducted of patients who underwent DFI with EUS between September 2019 and December 2022 at our institution. Patients with biliary tract lesions diagnosed by either endoscopy or pathology were included. Malignant biliary tract lesions were defined as those with histopathological diagnoses of non-invasive or invasive carcinoma.

To evaluate the diagnostic ability of DFI for malignant biliary tract lesions, we assessed the presence of tortuous or variable caliber vessels in DFI findings.

Inter-observer agreement and the diagnostic ability of DFI in identifying malignant biliary tract lesions were also assessed. Additionally, the DFI findings of intraductal papillary neoplasms (IPNB) and cholangiocarcinoma in patients who underwent surgical resection.

Results: There were 17 cases of cholangiocarcinoma, 9 cases of IPNB, 3 cases of bile duct stone, and 3 other cases. The final diagnosis of biliary tract lesion was made by surgery in 20 cases and by EUS-FNA or biopsy in 9 cases.

In the first analysis, the sensitivity and specificity for the presence of tortuous or variable caliber vessels for the diagnosis of malignancy were 80% and 43% for tortuous vessels and 68% and 100% for variable caliber vessels, respectively. Interobserver agreement was k=0.63 for tortuous vessels and k=0.75 for variable caliber vessels.

In the second analysis, DFI identified stalk vessels in 7 of 8 cases (87.5%) of IPNB and in only 1 of 10 cases (10%) of invasive cholangiocarcinoma. The rate of concomitant stalk vessels was significantly higher in IPNB than in invasive cholangiocarcinoma (P<0.01).

Conclusion: DFI is a simple and easy-to-use technique that allows for the evaluation of blood flow in biliary tract lesions without the use of contrast agents. It has the potential to be a useful tool for the differential diagnosis of malignant biliary tract lesions.

Introduction: Therapeutic options in the management of inoperable perihilar cholangiocarcinoma (pCCA) patients are very limited and include palliative chemotherapy and endoscopic drainage procedures. Recently, ERCP-guided intraductal radiofrequency ablation (RFA) has been proposed as a potential adjuvant therapy in these cases.
Aims & Methods: We aimed to evaluate the feasibility, clinical success rates and safety profile of an endoscopic treatment protocol including RFA and biliary stenting in inoperable pCCA patients.
We performed an interim analysis of a single center, randomized control trial of native papilla cases of pCCA patients with ECOG 0-2 performance status and localized disease who required endoscopic biliary drainage (NCT05563870). Patients in the control arm underwent palliative stenting with plastic stents while patients in the active arm received RFA ablation with the Habib probe and plastic stenting. Treatment in both arms was planned based on preprocedural CT and MRCP, with the aim of draining as much of the viable liver volume. All patients were referred for palliative chemotherapy according to the current standard of care. Technical and clinical success rates and procedure-related adverse event (AE) rates were evaluated prospectively at 30 days.
Results: We included 15 patients (6 in the RFA arm, 9 in the control arm) between April 2022-April 2023. Patients were predominantly female (9/15), mean age was 72 years and most cases were classified as Bismuth IV strictures (7/15). Median ECOG status was 1 (range 0-2) and mean bilirubin level prior to endoscopy was 15.9 mg/dL (range 1.8-36.8).
Technical success was achieved in 14/15 patients and clinical success in 13/15 patients. Notably, there were 4 cases of cholangitis in the control arm compared to only 1 case in the active arm, 1 case of bleeding (control arm), 2 cases of cholecystitis (1 in each arm) and 1 perforation (active arm) and 1 case of severe pancreatitis requiring percutaneous drainage (control arm). There was no difference in the advent of moderate and severe AEs following the procedure (4 in the active arm vs. 7 in the control arm, p=0.64) and most cases were successfully managed by endoscopy, with only 1 case requiring surgery and 1 death recorded at 30 days after the procedure. 5 patients underwent systemic chemotherapy after endoscopic drainage.
Conclusion: Our preliminary data suggests that RFA followed by adequate biliary drainage is technically feasible even in difficult-to-treat cases such as high-grade hilar stricture, with no additional increase in complication rate in patients receiving ablation therapy.
Disclosure: Nothing to disclose.

Introduction: Endoscopic or percutaneous bile duct brushing is often performed as first step to differentiate between benign and malignant biliary strictures. Although brush cytology has a high specificity (95-100%), the sensitivity for detection of malignancy has been reported to be poor (41-67%).(1-4) This results in repeated diagnostic procedures with potential treatment delay, adverse events, and additional costs.
Aims & Methods: Aim of this study was to evaluate a change in protocol for brush cytology with optimization of handling and rating, Next Generation Sequencing (NGS), and the use of two brushes plus intraductal biopsies in patients with suspected perihilar or intrahepatic cholangiocarcinoma (pCCA/iCCA). Patients with suspicion of pCCA or iCCA were prospectively included between June 2021 and December 2023. Preferably two brushes and 2-4 intraductal fluoroscopy guided biopsies were taken during the initial procedure. Cells were dislodged in a Cytolyt container within 30 seconds of which two 'thin prep' slides were prepared. Double reading was routinely performed by at least two expert cytopathologists. NGS was performed in samples with an uncertain diagnosis of atypia.
A historical cohort (January 2017-June 2021) was used as control. In this cohort a single brush was performed without intraductal biopsies. The obtained cells were preserved in a Roswell Park Memorial Institute (RPMI)

1640 medium of which four cytospins were done. Double reading and NGS were not routinely performed. In both cohorts morphological diagnosis was assessed according to the Papanicolau society of cytopathology system for reporting pancreatobiliary cytology. Both the diagnostic category 'suspicious for malignancy' and 'malignant' were classified as results compatible with malignant disease. Final diagnosis was confirmed by either histological proof of malignancy or in case unavailable, follow-up compatible with malignant disease. Primary endpoint was the sensitivity before and after implementation of the protocol; secondary endpoints were the sensitivity of the individual steps of the modified protocol in the prospective cohort e.g. the sensitivity of only the first brush and additional value of NGS, the second brush, and intraductal biopsies.

Results: In this study, a total of 167 patients were evaluated (51 prospectively and 116 historical controls). The final diagnosis was malignant disease in 153 patients (91.6%). After implementation of the protocol, the sensitivity rose to 86% (95%CI, 72.6-93.7%) versus 48.5% (95%CI, 38.7-58.5%) prior to implementation (difference 37.5%; 95%CI, 22.3-52.6%). Specificity was 100% in both groups (1/1 vs 13/13). Sensitivity of the first brush in the prospective cohort was 76% (95%CI, 61.5-86.5%). NGS was of additional diagnostic value in 3 patients with uncertain brush cytology results, increasing the sensitivity to 82% (95%CI, 68.1-91%). A second brush was performed in 37 patients; in one of these patients, the second brush had additional diagnostic value over the first brush. Intraductal biopsies were performed in 26 patients (4 benign, 9 suspicious of malignancy, 13 malignant), leading to a malignant diagnosis in 2 out of 12 patients with false-negative brush cytology.

Conclusion: A modification in the handling of cytopathology, led to a significant improvement in the sensitivity of bile duct brushes to 76% for patients with suspected pCCA or iCCA. Furthermore, adding NGS, use of two brushes, and intraductal biopsies in the initial procedure could further increase sensitivity to 86%.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) with endoscopic sphincterotomy (EST) is an established endoscopic treatment for common bile duct stones and acute cholangitis. Due to its less invasiveness compared to surgery, it has been accepted as a first choice even for the elderly receiving anticoagulants.

However, there is only a limited number of reports of the safety of EST after minimal cessation of anticoagulant based upon the Japan Gastroenterological Endoscopy Society (JGES)guideline.

Aims & Methods: To evaluate the safety, we aimed to clarify the bleeding risk in patients taking anticoagulants in our institute. Patients who underwent ERCP at double institutes from January 2018 to December 2021. Among them, we compared the rate of bleeding after EST and bleeding requiring blood transfusion in anticoagulant patients and non-administrators. Patients taking anticoagulants were allowed to discontinue the direct oral anticoagulant (DOAC) on the day before or the day of ERCP, and those who followed the JGES guideline for warfarin were included.

Results: ERCP was performed in 1616 patients and an analysis of a total of 882 patients of EST including 69 patients taking anticoagulants revealed that there were no significant differences in the bleeding rate although the blood transfusion rate was significantly higher in the DOAC group (2/52 3.9%) and antiplatelet drug combination cases (1/15 6.7%) compared to other cases (5/805 0.6%).

Univariate and multivariate analyzes were performed according to background age, sex, hypertension, diabetes mellitus, heart disease, cerebrovascular disease, hemodialysis, platelet count decreased (less than $10x10^4/\mu L$), and urgency (within 24 hours after consultation). In the univariate analysis for EST bleeding, cerebrovascular disease, hemodialysis, and thrombocytopenia were significant risk factors($p<0.05$).

As a result of the multivariate analysis of these, only cerebrovascular disease was a significant risk factor (OR=2.11, 95%CI: 1.21-3.68, p=0.0086). In the univariate analysis for blood transfusion, DOAC users, cerebrovascular disease, and hemodialysis patients were significant risk factors($p<0.05$). A multivariate analysis that added EST bleeding to these results also found significant risk factors for similar items. DOAC (OR=6.89, 95%CI: 1.06-44.65, p=0.043) and cerebrovascular disease (OR=18.85, 95%CI: 3.01-117.93, p=0.0017), hemodialysis (OR=55.68, 95%CI: 6.51-475.99, p=0.00024) were significant risk factors for severe bleeding requiring blood transfusion.

Conclusion: Although there were no significant differences between the bleeding rates of EST for those taking anticoagulants and those not taking anticoagulants, it was suggested that there is a possibility of serious bleeding requiring blood transfusion in patients receiving anticoagulants, especially DOAC.

Disclosure: None.

Introduction: Advanced cannulation technique has transformed the management of difficult selective biliary cannulation (DSBC), which is associated with an increased risk of post-ERCP pancreatitis (PEP). However, Periampullary diverticula (PAD) was not sufficient for DSBC on its own and the role of different types in cannulation may be ambivalent.

Aims & Methods: In this study, we developed DeepDV, a novel artificial-intelligence-based diagnostic identification system to advance using of rescue technique for DSBC with PAD. DeepDV is trained using a large-scale multimodal dataset that includes Electronic Health Record (EHR) and duodenoscope images. For training DeepDV, a total of 1704 patients with native papilla and PAD who underwent ERCP from January 2016 to June 2022 were retrospectively collected.

Results: In a retrospective, multicenter testing cohort of patients with PAD (n=325), who underwent ERCP, we demonstrate that DeepDV can predict the cases needed advanced cannulation technique used by the ESGE to define the difficult cannulation (after 5minutes, 5 attempts, or more than 1 unintended pancreatic duct cannulation).

Outcome/ n, (%)	Type I	Type II	Type III	Type IV
Pancreatitis post ERCP	2(0.83)	3(11.11)	1(1.40)	5(2.32)
Successful cannulation rate	11(91.67)	23(85.19)	70(98.59)	213(99.07)
Difficulty at cannulation	7(58.33)	23(85.19)	6(8.85)	98(45.58)

Conclusion: Our results represent how artificial intelligence and multimodal dataset may be used to provide a more accurate prognostication for the advanced cannulation technique and may help to avoid unintentionally and repeatedly attempts.

Contact E-Mail Address: edina.tari@gmail.com

Introduction: Endoscopic Retrograde Cholangiopancreatography (ERCP) is the most commonly used therapeutic procedure for pancreaticobiliary disorders. However, how to best achieve safe and effective bile duct cannulation is still debated. Endoscopists doing ERCP routinely recognize the differences in the macroscopic appearance of the major papilla. This has led to a conception that certain appearances of the papilla are more difficult to cannulate and, therefore, more prone to adverse events.

Aims & Methods: We aimed to assess the influence of papilla morphology on ERCP outcomes and adverse events.

PROSPERO registration number: CRD42022360894. Three medical databases (MEDLINE via Pubmed, Embase, CENTRAL) were systematically searched from inception to 29/09/2022. Studies detailing the cannulation process or the rate of adverse events in the context of papilla morphology were included. For the primary classification of the papilla, the Haraldsson system was used.

Additional analyses were conducted including further studies comparable to the Haraldsson classification. A pooled event rate with a 95% confidence interval (CI) was used for the effect size measure. The risk of bias assessment was performed using the Joanna Briggs Institute Critical Appraisal tool for studies reporting prevalence.

Results: A total of 17 studies were eligible, and 14 of them were included in the quantitative synthesis. In studies using the Haraldsson classification, the rate of difficult cannulation was the lowest in type I ("regular") papilla (26%; CI: 18–37), followed by type III ("protruding/bulging") (35%; CI: 25–48) and type II ("small") papilla (39%; CI: 28–52). The highest rate was observed in the case of type IV ("creased/ridged") papilla (41%; CI: 28–55). For post-ERCP pancreatitis, the event rate was the highest in type II ("small") papilla (11%; CI: 8–15), and the lowest in type I ("regular") (6%; CI: 5–8) and III ("protruding/bulging") papilla (6%; CI: 4–8). In the case of both outcomes, similar results were observed including also the studies with different classifications. There was no difference in the event rate of cannulation failure and post-ERCP bleeding between the different papilla types. Most studies carried a low risk of bias.

Conclusion: Compared to the regular papilla type, other types are associated with a higher rate of difficult cannulation. Small papilla is associated with a higher rate of post-ERCP pancreatitis.

Disclosure: Nothing to disclose.

AGGRESSIVE HYDRATION WITH LACTATED RINGERS FOR REDUCING POST-ERCP PANCREATITIS: A SYSTEMATIC REVIEW AND META ANALYSIS

T.G. Uy[1], M.E. Pe Benito[1], A. Masbang[1], V. Porciuncula II[1]
[1]St. Luke's Medical Center, Department of Medicine, Quezon City, Philippines

Contact E-Mail Address: tiffanygraceuymd@gmail.com

Introduction: The most common complication of Endoscopic Retrograde Cholangiopancreatography (ERCP) is post-ERCP Pancreatitis (PEP). Aggressive periprocedural hydration with PLR has been shown to reduce incidence of PEP, but the evidence is still lacking. This meta-analysis aims to determine if aggressive hydration with Lactated Ringer Solution reduces the incidence of PEP.

Aims & Methods: RCTs studying the effect of aggressive PLR hydration on the incidence of PEP were retrieved from Pubmed, Cochrane and OVID databases using the following key terms and their equivalents: ERCP, pancreatitis, hydration. Nonrandomized studies and studies that included other interventions were excluded. Quality assessment was done using the Cochrane risk of bias tool. Pooled odds ratio (OR) at 95% confidence intervals were computed to generate forest plots. Data synthesis and analysis were performed using Revman 5.4 for Mac. A p-value <0.05 was considered as statistically significant.

Results: Six RCTs with 1516 patients were included in this meta-analysis. The incidence of PEP was significantly lower in the aggressive hydration group overall 5.6% (43/765) compared to 13.4% (101/751) in the standard (OR=0.37, CI= 0.23 - 0.60, P<0.0001, I^2=34%). This effect was maintained re-

gardless of timing of onset of hydration, with decreased risk of PEP seen in the aggressive hydration group, given hydration pre-procedure (OR =0.51, CI= 0.28 - 0.93, P=0.03, I^2=41%) and those that only started hydration peri-procedure (OR =0.22, CI= 0.11 - 0.44, P<0.00001, I^2=0%).

Conclusion: Aggressive hydration with Lactated Ringer Solution in patients undergoing ERCP can prevent PEP.

Disclosure: Nothing to disclose.

RESCUE NEEDLE KNIFE PAPILLOTOMY AND CONVENTIONAL SPHINCTEROTOMY IN THE ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY (ERCP) CANNULATION: A COMPARISON OF SUCCESS AND ADVERSE RATE BY USING PROCEDURE TIME MATCHED COHORT

B.H. Cha[1]
[1]*The View Hospital, Gastroenterology, Doha, Qatar*

Contact E-Mail Address: doctorhyo@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is a minimally invasive endoscopic procedure that is crucial for pancreato-biliary diseases and selective cannulation is the most important step. However, even an experienced endoscopist can face cannulation failure in up to 15-30% of cases in the first ERCP when standard methods alone are used.[1]

Many studies suggested the various needle knife fistulotomy or papillotomy as an alternative technique in difficult cannulation cases.[2,3]

However, needle knife papillotomy (NKP), which is modified technique with needle knife has not been evaluated well.

Aims & Methods: To evaluate the clinical outcomes and adverse events of bile duct cannulation by NKP, we performed a retrospective review on medical records of all ERCP cases in Sheikh Khalfia Specialty Hospital, UAE. For six years, Sphincterotomy (SPT) naïve patients except altered-anatomy cases were enrolled and their procedure times, cannulation success rates, radiation exposures, and adverse events were measured between the procedure time matched two cohort group of SPT only and rescue NKP.

Results: In total 416 ERCP cases, 43 procedure time matched cases were selected among 352 (84.7%) SPT only cohort and 43 cases from 64 rescue NKP cohort. Biliary cannulation was succeeded in all cases (100%) by using SPT cannulation with rescue NKP technique without failure. There was no differences in cumulative radiation doses, cannulation time, and adverse event rates in rescue NKP group compared to SPT only group: Post-ERCP hyperamylasemia/hyperlipasemia (16.5% vs. 34.8%, p=0.080), pancreatitis (3.9% vs. 4.3%, p=0.883), cholangitis (4.7% vs. 4.3%, p=0.695), and no perforation case was noticed in both groups.

Conclusion: The SPT with rescue NKP technique can be used in the difficult biliary cannulation cases during ERCP safely and effectively.

Introduction: Recent reports have evaluated the difficult biliary cannulation (DBC) during endoscopic retrograde cholangiopancreatography (ERCP) based on the shape of the papilla [1)2)].

However, it is more important to elucidate how the difficulty of biliary cannulation changes depending on the morphology of the papilla. We performed a morphological evaluation to investigate the causes of DBC during ERCP, including the relationship between the shapes of the papilla and intra-ampullary pancreaticobiliary bifurcations (IAPBs).

Aims & Methods: We prospectively established a database and retrospectively assessed the difficulty of selective biliary cannulation (SBC) with contrast-assisted cannulation (CAC) during ERCP, in which any morphological IAPBs are visualized. In all cases, both the bile and pancreatic ducts were cannulated or imaged in a naïve major duodenal papilla. The database included papilla shapes with Haraldsson’s classification of Type 1-Type 3, the number of papillary orifices classified as Mono or Dual. The IAPBs were classified into four types based on their branching angle (Figure V for acute branching, Figure T for perpendicular branching, Figure X for orifice of bile duct located just above the papillary orifice inside, and pancreaticobiliary maljunction classified as Figure I). In addition, small intra-ampullary cysts (choledochocele, IAC) were classified into three types based on their location: the common channel (Ac) type, equivalent to Elton’s dilated common channel syndrome [3)];, the bile duct (Ab) type, including a cyst within the papilla; and the common bile duct (CBD) type, corresponding to Alonso Lej type III. DBC was defined as cannulation longer than 5 minutes, and when guidewire placement in the pancreatic duct (P-GW) was attempted to facilitate SBC. We conducted a logistic regression analysis to investigate the association among the anatomical morphology of the papilla, the variation of IAPBs, and the presence of IAC.

Results: We analyzed a database of 1,700 consecutive cases. The shape of papilla Type 1 was found in 621 (36.5%), Type 2 in 82 (4.8%), and Type 3 in 997 cases (58.6%). Mono orifice was confirmed in 1,192 cases (70.1%), and P-GW was performed in 709 cases (41.7%). IAC was observed in 203 cases (11.9%). The odds ratio (OR) for DBC in relation to papilla morphology was analyzed with Type 1 as the reference. The OR for Type 2 was 1.9 (95% confidence interval [CI], 1.5-3.0) (p=0.07), and for Type 3, it was 1.7 (95% CI, 1.3-2.1) (p<0.01). In the analysis of the number of orifices, the OR was calculated with Dual as the reference. Mono was 2.5 (95% CI, 2.0-3.2) (p<0.01). In the analysis of IAPBs, the ORs were calculated with Dual as the reference. The ORs for Figures V, T, X and I were 1.6 (95% CI, 1.2–2.1) (p<0.01), 2.4 (95% CI, 1.7–3.2) (p<0.01), 5.1 (95% CI, 3.8–7.0) (p<0.01) and 0.6 (95% CI, 0.3–1.4) (p=0.39), respectively. In the analysis of IAC, the ORs were calculated with the absence of IAC as the reference. The ORs for Ac, Ab and CBD were 1.3 (95% CI, 0.9–2.0) (p=0.17), 1.5 (95% CI, 0.9–2.6) (p=0.14), and 0.6 (95% CI, 0.3–1.4) (p=0.23), respectively. When the shape of papilla was Type 3 and had a Mono orifice with IAPBs of Figures V, T, or X, the difficulty of SBC significantly increased.

Conclusion: Our study suggests that morphological DBC depends not only on the shape of the major duodenal papilla, but also on the number of orifices, the type of IAPBs, and the presence of IAC. Sometimes, IAPBs can exhibit unexpected bifurcations that make SBC difficult. To overcome this difficulty, it is important to perform SBC using CAC to confirm IAPBs.

THE IMPACT OF PERIAMPULLARY DIVERTICULUM ON CANNULATION RATE AND ADVERSE EVENTS IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

A. Gustafsson[1,2], B. Tingstedt[2], G. Olsson[1]
[1]Region Kronoberg, Department of Research and Development and Department of Surgery, Central Hospital, Vaxjo, Sweden, [2]Lund University, Department of Clinical Sciences Lund, Surgery and Department of Surgery, Skåne University Hospital, Lund, Sweden

Contact E-Mail Address: arvid.gustafsson@gmail.com
Introduction: A common finding in patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) is periampullary diverticulum (PAD). It is more prevalent in females and elderly patients but is also linked to cholangitis and common bile duct stones. The anatomy may be distorted by PAD, possibly making papilla cannulation challenging. Whether PAD increases the difficulty of cannulation and whether it is linked to a higher incidence of adverse events has been debated.
To provide further insights into this scenario, we conducted a nationwide registry-based study.
Aims & Methods: Our objective was to determine the impact of PAD on the cannulation rate, adverse events, and ERCP duration. We collected data on ERCP procedures performed between 2006 and 2021 from the Swedish Registry for Gallstone Surgery and ERCP (GallRiks). The 125,558 ERCPs that were registered in the registry during the study period were reduced to 73,937 after we excluded rendezvous procedures, previous sphincterotomies, previous stenting, and procedures with missing follow-up data.
Results: PAD was discovered in 12,782 (10.2%) ERCPs, with data recorded in the registry, and was present in 8,589 (11.6%) ERCPs in the study population. For 2,796 (3.8%) of the patients in the study group had the papilla inside the PAD (Boix Type 1), while 5,793 (7.8%) of the patients had a papilla on the edge of the PAD (Boix Type 2) or immediately next to it (Boix Type 3).
The probability of successful cannulation was greater in non-PAD patients (89.7% vs. 88.6%; P=.002), whereas successful cannulation was reduced to only 81.1% if the papilla was located within the PAD (Type 1) (P<.001). The procedure time did not differ between the PAD (37.4 min) and non-PAD (37.5 min) groups (P=.73).
There were no differences in intraprocedural complications (3.1%) or adverse events (16.4% vs. 15.5%; P=.05), whether PAD was present or not. In the PAD group, the risk of bleeding increased (1.8% vs. 1.3; P=.001). The perforation risk did not differ across the groups (PAD 0.8% vs. 0.7% non-PAD; P=.22), however PAD had a reduced incidence of cholangitis (1.8% vs. 2.3%; P=.01) and pancreatitis (4.5% vs. 5.2%; P=.008).
Conclusion: The cannulation rate is slightly reduced in the presence of PAD, and this effect is more pronounced and particularly apparent in patients with Type 1 PAD. The safety of ERCP is unaffected by the presence of PAD.

THE UK NATIONAL ERCP SURVEY: ADHERENCE TO GUIDANCE AND ACCESS TO ACUTE CARE

W. Ahmed[1], B. Kluettgens[2], C. Stockman[2], C. Dobson[3], B. Oates[4], I. Penman[5], C.J. Rees[3], L. Sharp[6], K. Oppong[7], S.M. Everett[1]

Contact E-Mail Address: wafaa.ahmed@nhs.net
Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is a high-risk procedure. There are multiple clinical guidelines yet practice varies. As part of an on-going BSG Endoscopy Quality Improvement Programme, we aim to describe current ERCP practice in the UK and benchmark this against published guidelines.
Aims & Methods: An anonymised survey link was emailed to all independent ERCP practitioners in the UK and a further survey was sent to all organisations in the UK in which ERCP is carried out. Multiple reminders and individual contacts were used to maximise response rate. Clinical questions covering a range of scenarios were aligned with published guidelines and quality standards including the UK National Institute for Health and Care Excellence (NICE).
Results: 171 organisations providing ERCP were identified with a 100% response rate. 491 ERCP practitioners were identified with 78% (n= 386) response rate. In patients with an intermediate likelihood of common bile duct stones (CBDS), 9% of responders would proceed directly to ERCP, 76% would request MRCP or EUS first and 11% would arrange same session EUS +/- ERCP.
In patients with normal anatomy and large or difficult to extract stones, 68% would perform sphincterotomy followed by sphincteroplasty and further attempts at duct clearance at the index procedure. After two or more inadvertent guidewire into the pancreatic duct (PD), 25% of individual

practitioners always and 51% usually place a PD stent, whereas 19% rarely and 5% never do. In 10% of organisations standard practice is usually not to insert a PD stent.

NICE quality standard in the management of gallstone disease (QS104) stipulate that adults with CBDS causing jaundice have ERCP within 72 hours of diagnosis; 86% of organisations are compliant with this all or most of the time. In patients who need emergency ERCP for CBDS, 66% of organisations are compliant all or most of the time with having an ERCP within 24 hours (QS104).

In 29% of organisations, access to same-day ERCP 5 days a week was not available all/ most of the time. Out of hours ERCP (1800-0800) was not available all or most of the time in 63%, and over weekends it was not available all or most of the time in 59%.ERCP was available out of hours within the hospital in 33% of organisations during weekdays and 36% over the weekends as an unpaid, ad-hoc or goodwill arrangement.

In 26% of organisations there is regular weekly access to a deep sedation / general anaesthetic (DS/GA) list and 60% have access to a DS/GA list on an ad hoc basis or through referral to a different hospital. 55% of ERCPists were aware of the quality of therapeutic intent of any ERCP procedure being affected by suboptimal patient tolerance with endoscopist administered conscious sedation in the past month and 62% would prefer to perform all ERCPs under DS/ GA.

Conclusion: Despite clear guidance, variation in the management of CBDS and placement of pancreatic stents persists. Access to out-of-hours and weekend ERCP is sparse in the UK, and there is a reliance on goodwill to facilitate these cases. The availability of DS/GA is limited and there is a clear desire for improved access to optimise patient tolerance and ERCP outcomes.

Introduction: Prone is a common position for endoscopic retrograde cholangiopancreatography (ERCP). However, patients need to rotate their neck up to 90^{o} to the right along the procedure time, which might cause post-procedure neck sprain. Furthermore, patients with limited neck rotation may have difficulty during intubation of the endoscope. We designed a pillow to have only one elevated corner, this was put under the right shoulder, and the height of the pillow gradually sloped down to the other 3 corners. We hypothesize that the elevation of the right shoulder by the pillow makes thoracic rotation to compensate the cervical rotation and this would reduce neck sprain, from overstretching neck muscle, and facilitate endoscope intubation.

Aims & Methods: This randomized, controlled study aimed to evaluate the efficacy of the ergonomic wedge pillow for patients undergoing prone ERCP. Patients aged between 18-80 years who were indicated for ERCP at King Chulalongkorn Memorial Hospital were recruited. Patients with limited neck rotation less than 30-degree, severe cervical spine diseases, endotracheal intubated, or informed consent could not be obtained were excluded. The patients were randomized to undergo ERCP using pillow (study group) or without pillow (control group), in 1:1 fashion. Neck pain was reported by patients at baseline (before ERCP), and 1 hour, 1 day, and 7 days after ERCP. Scope intubation difficulty was rated by endoscopists. Patients' and endoscopists' satisfaction scores were recorded by using scales of 0-10.

Results: A total of 256 patients (122 women and 134 men) were randomized to study (128 patients), and control (128 patients) groups. The baseline characteristics and base-line neck pain scores were not different between two groups. The pillow group required less assisting shoulder lift during scope intubation (9% vs 22%, respectively) (p = 0.002). The requirement of nasopharyngeal airway insertion was not different between the two groups (13% vs 17%, respectively) (p = 0.385). After ERCP, neck pain was reported at 1 hour, 1 day, and 7 days after ERCP in 25%, 20%, and 0% in study group, and 31%, 31%, and 0% in control group, respectively. The incidence of neck pain at 1 day was significantly lower in pillow group than control group (p = 0.044), especially for moderate to severe neck pain (4% vs 11%, respectively) (p = 0.032). Endoscopists' satisfaction scores were significantly higher in pillow group than control group (9.6 vs 8.9, respectively) (p < 0.001). There was a trend of higher patients' satisfaction scores in pillow than control groups, 9.7 vs 9.5, respectively, however, this did not reach a statistical significance (p = 0.081).

	Pillow (n = 128)	Control (n = 128)	p-value
Age (years)	59.48±15.603	60.82±13.45	0.775
BMI (kg/m^2)	22.99±3.82	22.49±3.81	0.193
Indication			0.566
Biliary Stone	83 (65%)	87 (68%)	
Benign stricture	17 (13%)	17 (13%)	
Malignant stricture	25 (20%)	21 (16%)	
Pancreatic therapy	3 (2%)	3 (2%)	
Maximum active neck rotation to the right (degree)	68.64±14.08	67.23±14.39	0.342
Procedure time (minutes)	40.55±25.05	35.85±18.09	0.152
Sedative medications			
Midazolam (mg)	1.98±2.35	1.86±1.11	0.537
Meperidine (mg)	15.59±13.42	15.39±13.11	0.776
Propofol (mg)	282.82±184.04	275.64±150.21	0.905
Baseline score of neck pain score	0.43±1.25	0.45±1.25	0.816
Neck pain after ERCP (n, %)			
1. 1-hour	32 (25%)	39 (31%)	0.329
2. 1-day	25 (20%)	30 (31%)	0.044
3. 7-day	0 (0%)	0 (0%)	1.000
Assisted shoulder lifting during scope intubation (n, %)	12 (9%)	28 (22%)	0.002

Conclusion: The ergonomic, wedge-shaped pillow reduced the difficulty score of scope intubation and required less assisting shoulder lifting during scope intubation when compared with control. This pillow significantly reduced the incidence of neck sprain, especially for moderate-to-severe pain, at 1 day after prone ERCP. The pillow had a higher endoscopist's satisfaction score and a trend toward higher patients' satisfaction score.

USEFULNESS OF E-LEARNING TO IMPROVE BILIARY CANNULATION TECHNIQUE FOR TRAINEES: A MULTICENTER PROSPECTIVE STUDY

J. Kaneko[1], Y. Kobayashi[2], T. Yamada[1]
[1]Iwata City Hospital, Division of Gastroenterology, Iwata-shi, Japan, [2]Seirei Hamamatsu General Hospital, Department of Gastroenterology, Hamamatsu-shi, Japan

Contact E-Mail Address: meganerock10@gmail.com

Introduction: Improving the biliary cannulation technique in endoscopic retrograde cholangiopancreatography (ERCP), especially for native papilla, is challenging for trainees. Several previous studies have shown that improving it required a large caseload, usually 350–400 cases, or a special education program. Therefore, we created an e-learning educational video series system to allow trainees to learn biliary cannulation anywhere with ease and conducted a multicenter prospective study to evaluate it.

Aims & Methods: We created 27 educational videos containing biliary cannulation for native papilla with explanations. Twelve endoscopists with less than 6 years of ERCP experience at two general hospitals in Shizuoka, Japan, participated in this educational program using an e-learning system. First, each participant performed 10 biliary cannulations of native papillae with a preceptor, followed by e-learning and additional 10 biliary cannulations of native papillae. Data from 120 biliary cannulations each for pre-e-learning (PR) and pro-e-learning (PO) were compared according to comprehension score (CS), difficult cannulation (DC), failed biliary cannulation (FB), and adverse events (AE). CS was given by the preceptor-to-trainee oral test before biliary cannulation (maximum of six points). DC was defined as biliary cannulation time >300 sec, >5 biliary cannulation attempts, and ≥2 unintended pancreatic duct cannulation. The correlation between CS and DC was analyzed using the Cochran-Armitage test for trends, and receiver-operating characteristic (ROC) curves were used to determine CS's cut-off value.

Results: There were no significant differences in age, gender, and benign/malignant status of patients undergoing biliary cannulation between PR and PO groups. The outcomes are shown in the table. CS was higher in the PR group than in the PR group; however, no significant differences in DC, FB, and AE rates were observed between the two groups. There was a negative correlation between CS and DC (P<0.01), and the cut-off value and area under the ROC curve for CS for DC were scored 4 and 0.72 (95% confidence interval: 0.66–0.78), respectively. On per-participant comparison, CS≥4 became higher after e-learning (P=0.04); however, there were no significant differences in DC, FB, and AE rates.

		Pre-e-learning group	Pro-e-learning group	P-value
comprehension score	Median [IQR]	4 [3–5]	5 [4–6]	<0.01
difficult cannulation	% [n/N]	54 [65/120]	45 [54/120]	0.20
failed biliary cannulation	% [n/N]	37 [44/120]	28 [34/120]	0.21
adverse events	% [n/N]	9 [11/120]	11 [15/120]	0.53
PEP		5 [6/120]	11 [13/120]	0.15

IQR; interquartile range, PEP; post-endoscopic retrograde cholangiopancreatography pancreatitis

Conclusion: Our e-learning system could help deepen comprehension of papilla but did not significantly reduce DC, UBC, and AEs. E-learning and technical acquisition may be needed to improve biliary cannulation.

CLINICAL EVALUATION OF 22G NEEDLE WITH NOVEL 0.018-INCH GUIDEWIRE AND NOVEL DILATION DEVICES DURING EUS-GUIDED TRANSHEPATIC BILIARY DRAINAGE

T. Ogura[1], S. Ueno[1], H. Nishikawa[1]
[1]Osaka Medical and Pharmaceutical University, Endoscopy Center, Takatsukishi, Japan

Contact E-Mail Address: oguratakeshi0411@yahoo.co.jp

Introduction: If the diameter of the intrahepatic bile duct is much less dilated, bile duct puncture with a 19G needle can be challenging during EUS-guided transhepatic biliary drainage (EUS-THBD). These characteristics can decrease the difficulty of bile duct puncture, but use of a 22G needle is less feasible because of poor visibility, maneuverability, and stiffness of conventional 0.018-inch guidewire. A novel, improved 0.018-inch guidewire and dilation devices have recently become available.

Aims & Methods: We conducted a prospective study to evaluate the technical feasibility and safety of EUS-BD in patients with insufficient bile duct dilatation using a 22G needle and the new 0.018-inch guidewire. A 22G needle is used as the puncture needle for intrahepatic bile ducts of diameter <1.5 mm, and a 19G needle is selected for diameters ³1.5 mm.

As the primary endpoint of the study, the technical success rate of EUS-THBD using a 22G needle with the novel 0.018-inch guidewire was evaluated in patients with insufficient dilation of the intrahepatic bile duct.

Results: A total of 63 patients who required EUS-THBD were enrolled (22G needle group, n=30; 19G needle group, n=33). Technical success was obtained in all patients in the 19G needle group. In the 22G needle group, technical failure occurred in two patients due to non-identification of the intrahepatic bile duct on EUS (technical success rate, 93.1%), and puncture of the bile duct itself was not performed in these patients. Mean procedure time was similar between the groups. Adverse events were observed in 10.3% (3/30) of patients in the 22G needle group, and in 24.2% (8/33) in the 19G needle group.

Conclusion: In conclusion, use of a 22G needle with a novel 0.018-inch guidewire was comparable to a 19G needle with 0.025-inch guidewire, even in the case of insufficient intrahepatic bile duct dilatation.

Disclosure: None

PP1446

ENDOSCOPIC ULTRASONOGRAPHY–GUIDED RENDEZVOUS TECHNIQUE VERSUS PRECUT METHOD AS A SALVAGE TECHNIQUE FOR DIFFICULT BILIARY CANNULATION IN PATIENTS WITH BILIARY STONES

T. Okuzono[1], S. Ito[1], D. Togo[1], D. Hirasawa[1]
[1]*Sendai Kousei Hospital, Department of Gastroenterology, Sendai, Japan*

Contact E-Mail Address: okuzonotoru@gmail.com

Introduction: Endoscopic ultrasonography–guided rendezvous technique (EUS-RV) has been reported to be useful as a salvage method in cases of difficult biliary cannulation during endoscopic retrograde cholangiopancreatography (ERCP). Having said that, needle-knife precut (including transpancreatic sphincterotomy) is often selected over EUS-RV. However, it is associated with adverse events such as retroperitoneal perforation, retroperitonitis, and papillary hemorrhage.

On the other hand, EUS-RV has been reported to afford a higher success rate and lower incidence of adverse events. Nevertheless, few studies have compared the effectiveness of EUS-RV and the precut method.

Aims & Methods: To compare the outcomes of EUS-RV and the precut method in cases of difficult cannulation of the common bile duct due to stones.

From January 2018 to September 2022, 735 patients with a naive papilla with common bile duct stones underwent ERCP excluding post-reconstruction intestinal tract (excluding the Billroth-I method). Forty-three patients underwent salvage cannulation. EUS-RV and the precut method were attempted in 14 and 29 cases, respectively. There was no case in which the precut method and EUS-RV were performed in a single session. All patients received standard post-ERCP pancreatitis prophylaxis, and the success rates of the technique, adverse event rates, and procedure time were documented.

Results: The technical success rates of biliary cannulation via EUS-RV and the precut method were 83% and 79%, respectively. The corresponding adverse event rates were 13% and 28%. The adverse events noted were as follows: two cases of posterior hemorrhage and one of pancreatitis in patients who underwent EUS-RV and three cases of pancreatitis and one of posterior hemorrhage among patients in whom the precut method was performed. The median times from starting the usual cannulation technique to the decision to switch to the salvage method were 17 and 20 min, respectively, among patients in whom EUS-RV and precut method were attempted. The corresponding median times from the decision to switch to the salvage method to successful biliary cannulation (or quitting in cases of failure) were 20 and 26 min (p = 0.02).

Conclusion: EUS-RV tended to have a higher success rate and cause fewer adverse events than the precut method. However, the associated procedure time was significantly longer, partly because it included the time required to replace the endoscope twice. The findings suggest that EUS-RV can be an option in cases in which the usual cannulation technique has failed, because the associated technical success and adverse event rates are similar.

IMPACT OF INTRA- OR PERI-DIVERTICULAR PAPILLA LOCATION ON EFFICACY AND COMPLICATIONS OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN THE TREATMENT OF COMMON BILE DUCT STONES

M.M. Estevinho[1], R. Pinho[1], L. Proença[1], J.P. Laranjeira Correia[1], P. Mesquita[1], T. Freitas[1]
[1]*Centro Hospitalar Vila Nova de Gaia Espinho, Vila Nova de Gaia, Gastrenterology, Porto, Portugal*

Contact E-Mail Address: mmestevinho@gmail.com

Introduction: Several factors affect the difficulty of endoscopic retrograde cholangiopancreatography (ERCP) (Facciorusso et al.). This study aimed to evaluate whether the intra- and peri-diverticular location of the papilla has an impact on the results of ERCP for common bile duct stones.

Aims & Methods: Retrospective evaluation of patients without previous sphincterotomy undergoing ERCP for common bile duct stones between August 2020 and February 2023. Data on the patient (age, sex, comorbidities), procedure (elective/urgent, location and type of papilla, techniques used, successful cannulation, diagnosis, immediate complications), and outcomes (complications at 3, 30, and 90 days, need for repeating ERCP) were collected.

Results: Of the 769 patients undergoing ERCP during this period, 224 met the inclusion criteria (median age 76 years, 58% female). The papilla had an intra-diverticular location in 20 and a peri-diverticular location in 45, while it was not dependent on the diverticula in the remaining 159. Regarding the endoscopic classification (SADE; Haraldsson et al.), most were type 1 (55%) or type 2 (20%). The cannulation rate was 93%, with precut being used in 18% (fistulotomy/papillotomy n=22; transpancreatic precut n=14). The cannulation rate was significantly lower in patients with intra-diverticular and peri-diverticular papilla (75% and 87%, respectively, versus 97%; p<0.01), being the precut use also higher (20% and 31%, p=0.038). The ability to completely remove stones in the index ERCP (efficacy) was lower in patients with intra- or peri-diverticular papilla (71% and 70% versus 85%, p=0.04).

There were no differences in intraprocedural complications (n=8, p=0.42), at 3 (n=20, p>0.05), 30, and 90 days (n=1). However, the need for repeating ERCP was different between groups (38% peri-diverticular, 25% intra-diverticular, versus 15%; p<0.01).

Conclusion: The intra- or peri-diverticular location of the papilla limits the cannulation rate and efficacy of ERCP, requiring more frequent use of advanced cannulation techniques and repeat procedures. However, it should be noted that no more complications occurred in these locations.

TRENDS IN THE USE OF BIODEGRADABLE PANCREATICOBILIARY STENTS IN LARGE UK HOSPITAL TRUST

T. Riley[1], Z. Wilson[1], C. Moret[1], S. Mahmood[1], J. Iqbal[1], H. Kaltsidis[2]
[1]Manchester Foundation Trust, Gastroenterology, Manchester, United Kingdom, [2]Northern Care Alliance, Gastroenterology, Manchester, United Kingdom

Contact E-Mail Address: thomas.riley@doctors.org.uk

Introduction: Biodegradable pancreaticobiliary stents provide an alternative to conventional stents and avoid the need for a repeat procedure for endoscopic removal. While use is not currently widespread in the United Kingdom, accepted indications for insertion include bile leaks, prophylaxis of post-ERCP pancreatitis and as a bridge to cholecystectomy after bile duct clearance. Evidence from small studies suggest biodegradable stents are safe and cost effective, however there are few prospective studies to guide best practice. Complications of biodegradable stents are also not well understood with limited, if any, data describing issues specific to these types of stent.

In our hospital trust, biodegradable stents have been in use since 2019 and this study aims to describe trends in use including complications and provide a comprehensive summary experience to date.

Aims & Methods: The electronic record of all patients in two hospitals within Manchester foundation trust who underwent insertion of a biodegradable pancreaticobiliary stent were reviewed. The study period was between March 2019 and April 2023. Patient demographics, type of stent, indication for stent insertion, readmissions and repeat ERCP data was collected on review of each patient's record.

Results: During the study period 66 Biodegradable stents were inserted in 63 patients of which 48 were pancreatic and 18 biliary. All pancreatic stents were inserted for post-ERCP pancreatitis prophylaxis, whilst 5 biliary stents were performed for bile leaks and 13 for biliary drainage post-ERCP. A total of 9 patients were readmitted within 6 months for a pancreaticobiliary related complications including cholangitis (n=3), cholecystitis (n=2), post-ERCP pancreatitis (n=2), biliary obstruction (n=1) and persistent bile leak (n=1). In total, 10 patients underwent repat ERCP within 6 months. In one patient, the biodegradable stent was noted at ERCP to be in situ ERCP 5 months after insertion. Over 94% (n=17) of all biliary stents were performed in the first year of study, although the majority of these were inserted in 1 of the 2 study centres.

Conclusion: To our knowledge this is the largest series of patients undergoing biodegradable stent insertion in the United Kingdom. In this study, the most common indication for the insertion of a biodegradable stent was post-ERCP pancreatitis prophylaxis. As the study period progressed pancreatic stents became by far the most commonly inserted stent. In fact, only 1 biliary stent was placed in the final 3 years of the study period, demonstrating a trend towards the use of pancreatic biodegradable stents versus biliary stents. This may represent differences in clinical practice, services provided over time (e.g Spyglass or 'hot' cholecystectomies) or simply endoscopist preference.

The study suggests that biodegradable stents are safe and effective with only 10 patients undergoing a further ERCP in 6 months. Therefore, a significant proportion of patients were able to avoid a second procedure thus providing a benefit in both risk and cost.

Contact E-Mail Address: sinpesan@gmail.com

Introduction: With the diversification of ERCP procedures, higher torquable guidewire and techniques are required. We developed a bile duct simulator model that enables guidewire manipulation in an environment similar to the human body, and evaluated its usefulness.

Aims & Methods: A bile duct model was created by 3D printing based on real DIC-CT/MRCP image data. Epoxy resin was used as the material, and bile ducts from B2 to B8, excluding B1, were reproduced. By fixing the bile duct section in a water immersion tank, operations can be performed while the duct is filled with water and contrast medium, enabling guidewire operations similar to those in the actual bile duct. As a bench evaluation, three different thicknesses of guidewires (0.018 inch, 0.025, and 0.035 inch) were used for comparison and verification. The time required for the guidewire tip to reach all bile ducts from B2-8 was measured (terminated if not completed within 120 seconds), and a clinical engineer (CE) with more than 500 cases of experience as an ERCP assistant and a physician (DR) with more than 5000 cases of experience as an ERCP assistant made five alternating attempts per 3 different guidewires, 30 times in total. The endpoints were the percentage of complete bile ducts reached and the time required, and comparisons were made by guidewire diameter and job category.

Results: The complete reach rate was 40% for 0.018 inch (DR 60%/CE 20%) and 100% for both 0.025 inch and 0.035 inch. DR 86.7% and CE 73.3%, with no significant difference between job categories. The failure to complete reach the bile ducts was because all of them were difficult to insert into B7, but the other bile ducts were reachable. The median time required for complete reach was 120 (51-120) seconds for 0.018 inch, 56 (24-84) seconds for 0.025 inch, and 40.5 (23-51) seconds for 0.035 inch, with larger diameters requiring significantly shorter access times ($P < 0.01$).

Conclusion: The simulator demonstrated that the torque performance improved as the guidewire diameter increased, and guidewires larger than 0.025 inch could be inserted stably into all bile ducts.

The results of this study suggest that reaching all bile duct branches within 60 seconds can be used as a guideline for product development and training goals.

Contact E-Mail Address: pecsi.daniel@pte.hu

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is essential in the minimally invasive management of biliary and pancreatic disorders. In certain indications, not delaying and carrying out ERCP during the weekend can be important to improve outcomes.

Aims & Methods: We aimed to analyze the outcomes of ERCP performed during weekends and holidays with regular weekday ERCPs. 3260 ERCP cases from 7 tertiary centers were analyzed from the Hungarian ERCP Registry database. 116 ERCPs were performed during weekends or holidays, and 3144 during weekday working hours.

The main outcomes were successful biliary cannulation, difficult biliary cannulation, and adverse event rates. Chi-square and Fisher's exact tests were performed as appropriate. Propensity score matching was also performed and the comparisons were also performed in the matched groups.

Results: Weekend ERCPs were mostly carried out for the indication of acute cholangitis and acute biliary pancreatitis (70% of weekend cases), while in the weekday group, only 32% of cases were done for these indications. No difference was found between weekday and weekend ERCPs in the rate of successful biliary cannulation (2891/3144, 92.0% vs. 106/116, 91.4%), difficult biliary cannulation (32.0% vs. 33.6%), and advanced cannulation method use (26.2% vs. 31.0%) ($p>0.05$).

There was a significantly higher number of ASGE grade 3 difficulty cases when ERCP was carried out urgently (30.3% vs. 56.0%, $p<0.01$), but we found no increase in the number of adverse events (post-ERCP pancreatitis, bleeding, perforations) in the ERCPs carried out during weekends. Additionally, no significant differences were detected between the propensity-matched groups in the outcomes above.

Conclusion: ERCPs carried out during the weekend, no difference was found regarding outcomes compared to weekday ERCPs despite having more difficult procedures.

ENDOBILIARY RADIOFREQUENCY ABLATION IN THE MANAGEMENT OF MALIGNANT BILIARY OBSTRUCTION – SINGLE CENTER EXPERIENCE

Y. Petkova[1], P. Karagyozov[2], I. Tishkov[3]

[1]Acibadem City Clinic University Hospital Tokuda, Department of Interventional Gastroenterology, Sofia, Bulgaria, [2]Acibadem City Clinic Tokuda University Hospital, Department of Interventional Gastroenterology, Sofia, Bulgaria, [3]Acibadem City Clinic Tokuda Hospital, Department of Interventional Gastroenterology, Sofia, Bulgaria

Contact E-Mail Address: yoanapetkova89@gmail.com

Introduction: Malignant biliary obstruction/MBO/is generally managed by biliary stenting however major following problem is stent patency. Recent studies show the advantages of endoscopic retrograde cholangiopancreatography-guided intraductal radiofrequency ablation/ ERCP ID-RFA/ as adjunctive therapeutic modality.

Aims & Methods: Aims: To evaluate the efficacy and safety of ID-RFA in terms of stent patency,symptom–free survival and adverse events/ AE/.Primary endpoints–evaluating the period of stent patency and survival;secondary endpoints-assessing AE.

Methods: We performed retrospective analysis of a prospective database including all consecutive patients who underwent ID-RFA for the period July 2021 – December 2022.17 procedures in 16 patients who were unresectable or poor surgical candidates were performed followed by stenting in the study period.

Results: Endobiliary RFA/EB-RFA /catheter (ELRA, STARmed, Taewoong Medical) and RF generator system (VIVA combo, STARmed) were used in 15 of the procedures. In two cases ID-RFA was performed with Habib EndoHPB catheter/Boston Scientific.

After passing a guidewire the catheter was positioned at the targeted lesion, followed by 120 s of ablation (target temperature 80°C, 7–10 W,temperature control mode)–in two to three sessions,unilaterally or bilaterally depending on the type and lenght of the stenosis verified by the proceding cholangiogram.

The mean period of stent patency defined as time between the date of the procedure and the last follow up of the patient without signs of stent occlusion was 144,36 ± 89.3 days. In this period all of the patients were symptom–free with good quality of life and without any signs of cholangitis.

The indications were:10 patients with CCA,two patients/n=2-12.5%/ with intraductal extension of papillary adenoma-both poor surgical candidates -one with HGD;one with HGD with intramucosal carcinoma who underwent endoscopic snare papillectomy /ESP/ followed by endoscopic ID-RFA and placement of stents,2 patients with gallbladder cancer, 2 patients with bile duct occlusion due to metastasis.

In 9 of the patients with CCA /90% of patients with CCA ;56,25 % of the total number/chemotherapy with Cisplatina/Gemcitabine followed with no interruption of the courses during the period of treatment; one refused chemotherapy.

In three of the patients/18.75%/ we performed ID RFA in order to prolong stent patency in occluded by tumor ingrowth metal stents. The rate of the AE was 18.75%/n=3/ - 1 patient with self-limited bleeding;1 patient with postprocedural cholangitis and 1 patient with liver abcess – managed percutaneously.

There were no deaths or ICU admissions. We experienced two stent occlusions – in one in patient with papillary adenoma with HGD–on day 169– managed with second session of ID- RFA followed by metal stent placement - asymptomatic up to the last follow up,the second with tumor ingrowth from endobiliary metastasis in previously placed metal stent -the patency after RFA was 116 days – managed with metal stent in stent placement.

Ethiology N = 16	Cholangiocarcinoma N=10/62.5%/	Gallbladder cancer N=2/12,5%/	Ampullary adenoma with intraductal ingrowth N=2/12.5%/	Metastasis from extrahepatic cancer N=2/12.5%/
Stent placed after RFA	Bilaterally metal stents N=6/37,5%/ One metal stent N=4/25%/	Metal stent in stent N=1/6.25%/	Plastic stent in previously placed metal stent N=1/6,25%/	Plastic stents bilaterally N=3/18,75%/ One plastic stent N=1/6,25%/
Type of stenosis	Bismuth type 1 N=1/6.25%/	Bismuth type 3A N=4/25%/ Bismuth type 3B N=1/6,25%/	Bismuth type 4 N=8/50%/	Distal stenosis due to intraductal ingrowth of papillary adenoma N=2/12,5%/
Number of session Total number of procedures N=17	Two sessions N=5/29,41%/	Three sessions N=8/47,06%/	Four sessions N=4/23,53%/	

Conclusion: ID-RFA is a promising new tool which provides improved outcomes in patients with MBO both in stent patency and symptom free survival.It has many advantages – easy delivery of controlled temperature application and good safety profile.Therefore ID-RFA can be proposed as adjunctive treatment in patients with MBO although more randomized studies are needed.

RAMAN SPECTROSCOPY IN THE DIAGNOSIS OF MALIGNANT BILIARY STRICTURE – A FEASIBILITY STUDY

P. Slodicka[1], P. Falt[1], V. Ranc[2], O. Urban[1]
[1]University Hospital Olomouc, 2nd Department of Internal Medicine, Gastroenterology and Geriatrics, Olomouc, Czech Republic, [2]Institute of Molecular and Translational Medicine, Faculty of Medicine, Palacky University, Olomouc, Czech Republic

Contact E-Mail Address: peter.slodicka@fnol.cz

Introduction: Biliary stricture (BS) diagnosis is challenging with limited diagnostic yields from imaging and tissue sampling. Raman spectroscopy (RS) is an optical method based on analysis of scattered monochromatic light. RS is able to provide tissue molecular "fingerprinting".

Aims & Methods: The aim of this pilot study was to develop a methodology for in vivo RS in patients with BS. During ERCP, a fibre Raman probe (Endoscopic Fiber-Optic Raman Probe Bundle Fiber, Uni-Export Instruments, USA) was introduced transpapillary into the suspected malignant BS using an 8.5 Fr metal sheath. The Raman probe was placed in an adequate position under fluoroscopy control. Spectral BS measurements were performed (without fluoroscopy) 10-20 times for each patient (laser wavelength 785 nm, duration of each measurement 0.001-0.150 s). RS of normal bile duct and duodenal mucosa of each patient was subsequently performed.

The final BS diagnosis was verified using brush cytology. The attained data was saved and analysed by a specialised biophysicist. All patients provided informed consent.

Results: A total of 20 patients (mean age 71, range 38 to 89, 45% males) with suspected malignant biliary stricture indicated for ERCP were measured, of which 11 had a final diagnosis of cholangiocarcinoma (CC). A total of 815 measurements were performed, of which 466 were subsequently analysed. In 5 (25%) cases, transpapillary insertion of an RS probe was not possible. No procedure-related complications were reported and no mechanical damage to the probe was observed.

On visual analysis, the duodenal RS pattern differed from both normal bile duct and CC (Figure 1 and 2).

Nevertheless, further data processing will be required to develop a discernible method to discriminate between CC and normal bile duct with a suitable level of selectivity and specificity.

Conclusion: Transpapillary Raman spectroscopy of biliary stricture is feasible. Although duodenal and biliary RS patterns were different, current data does not allow to fully discriminate between CC and normal bile duct.

Disclosure: The authors declare that there is no conflict of interest.

Contact E-Mail Address: nobuhero222@yahoo.co.jp

Introduction: Recently, a novel self-assembling peptide hemostatic gel has become available in Japan. However, the safety and efficacy of this novel self-assembling peptide hemostatic gel remain unclear for bleeding after EST.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of a novel self-assembling peptide hemostatic gel for bleeding after EST, and compared to conventional endoscopic hemostasis technique.

This retrospective study was carried out between January 2019 and October 2022. Patients who developed bleeding associated with EST were enrolled. The patients were divided into two groups based on the hemostasis techniqueused: a conventional hemostasis technique (Group A) or a novel self-assembling peptide hemostatic gel hemostasis technique (Group B).

Results: A total of 62 patients (Group A, n=36; Group B, n=26)were included. Endoscopic hemostasis was initially obtained in 72.2% (26/32) of patients in Group A and in 88.4% (23/26) of patients in Group B, with no significant difference (P=0.1211).

However, the procedure time was significantly shorter in Group B (mean, 9.38 min) compared with Group A (mean, 15.4 min) (P=0.0103).There were no significant differences in the severity of bleeding between the two groups (P=0.4468). post-EST bleeding was observed in 6 patients (Group A, n=4; Group B, n=2). although there was no significant difference (P=0.6532), adverse events were more frequently observed in Group A (n=12) than in Group B (n=1).

Conclusion: PuraStat application for EST bleeding might be safe and effective, and comparable to the conventional endoscopichemostasis technique, although further prospectiverandomized trial is needed.

ENDOSCOPIC TRANSPAPILLARY GALLBLADDER DRAINAGE FOR ACUTE CHOLECYSTITIS: TECHNICAL RECOMMENDATIONS FOR DIFFICULT INTUBATION OF THE CHOLECYSTIC DUCT

K. Takahashi[1], A. Shimakura[1], T. Mori[1], E. Ozawa[1], K. Nakao[1]
[1]Nagasaki University Hospital, Nagasaki, Japan

Contact E-Mail Address: takapochi0809@nagasaki-u.ac.jp

Introduction: Endoscopic transpapillary gallbladder drainage (ETGBD) for acute cholecystitis has been effective for patients with ascites and bleeding tendencies. However, the success rate of ETGBD is lower than that of other endoscopic retrograde cholangiopancreatography-related procedures, and it is often difficult to complete the procedure.

Aims & Methods: This study aimed to investigate the outcomes of ETGBD in the management of acute cholecystitis at our hospital while offering some technical recommendations for the procedure. This was a retrospective study of 41 patients who had undergone ETGBD for acute cholecystitis at our hospital between January 2015 and July 2021.

Results: There were 28 males and 13 females, with a median age of 80 years (range, 58–91). Of these patients, 27 (65.9%) had mild ETGBD, 13 (31.7%) had moderate ETGBD, and one (2.4%) had severe ETGBD. The cases of intra-gallbladder, cholecystic duct, and common bile duct stones were found in 30 (73.2%), 13 (31.7%), and 16 (39.0%) patients, respectively. The types of cystic duct branching were merging of the upper (n = 36) and lower sides (n = 5), toward the head (n = 35) and foot sides (n = 6), and merging of the right (n = 34) and left sides (n = 7). The technical success rate was 95.1% (39 out of 41) (endoscopic nasobiliary stenting [n = 34] and endoscopic nasobiliary gallbladder drainage [n = 5]), and the clinical success rate was 100% (n = 39). The median treatment time was 30 minutes (range, 11–72).

In the present study, difficult intubation was defined as failure to intubate the gallbladder using conventional devices. Among the 12 patients who experienced intrabiliary intubation difficulties, seven of them were able to be cannulated into the gallbladder with the SwingTip™ cannula (Olympus, Tokyo, Japan), which features a controllable catheter tip angle. In two patients whose bile duct stenosis was still difficult even with the SwingTip™ cannula, the long-tapered cannula (StarTipV™, Olympus) was used to break through the stenosis. In one patient whose cholecystogram could not be obtained, a retrieval balloon for the above contrast was used to obtain a cholecystogram, and endoscopic transpapillary balloon sphincteroplasty was finally performed.

Regarding factors influencing the difficulty of intubation of the gallbladder, multivariate analysis showed that “dilation of the common bile ducts (>10 mm)” was a significantly difficult factor.

Conclusion: Even though ETGBD is difficult in patients with dilated common bile ducts (≥10 mm), it could be performed relatively safely and effectively by using dedicated devices.

Disclosure: Nothing to disclose.

PREDICTIVE FACTORS OF POST-ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY PANCREATITIS FOR BILIARY COMPLICATIONS IN LIVING-DONOR LIVER TRANSPLANTATION RECIPIENTS

A. Shehta[1], M. Elshobari[1], T. Salah[1], A. Sultan[1], M. Abdel Wahab[1], M. Samy[2]

[1]Mansoura University, Department of Surgery, Mansoura, Egypt, [2]Mansoura University, Department of Hepatology, Mansoura, Egypt

Contact E-Mail Address: ahmedshehta@mans.edu.eg

Introduction: Endoscopic retro-grade cholangiopancreatography (ERCP) has shown great safety and efficacy in the management of post- living-donor liver transplantation (LDLT) biliary complications. Pancreatitis is the commonest and the most feared complication after ERCP.

Aims & Methods: We reviewed the data of liver transplant recipients who underwent ERCP for biliary complications after LDLT between 2011 & 2022.

Results: 63 patients underwent ERCP after LDLT. They were targeted to 134 set of ERCP. Pancreatitis occurred in 52 sets (38.8%). We subclassified the patients into 2 groups, Without Pancreatitis: 31 patients (49.2%) and With Pancreatitis 32 patients (50.8%).

Higher incidence of pancreatitis was noticed with the first ERCP set (p = 0.04). Biliary strictures were more noted in Pancreatitis group (p = 0.025). Difficult cannulation requiring precut was more observed in pancreatitis group (p = 0.007). Also, more frequent sphincterotomy was observed in pancreatitis group (p = 0.003). Longer hospital stay, more fever, abdominal pain and vomiting were noted in Pancreatitis group (p = 0.001). Higher post-ERCP serum amylase (p = 0.001) and creatinine (p = 0.021), while lower serum calcium (p = 0.21) were noticed in pancreatitis group.

On multivariate analysis, preoperative diabetes mellitus, number of biliary anastomoses (single/multiple), and difficult cannulation requiring precut were significant predictors of post-ERCP pancreatitis.

Conclusion: Patient-related bedside procedure-related risk factors play essential role in the development of pancreatitis after ERCP for LDLT recipients. Endoscopists should be mindful by those high-risk patients during ERCP to apply appropriate techniques to prevent the development of this serious complication.

Disclosure: Nothing to disclose.

PP1456

ENDOSCOPIC PAPILLECTOMY FOR THE SUBMUCOSAL LESIONS OF THE MAJOR DUODENAL PAPILLA

E. Ozawa[1], T. Yamao[2], K. Nakao[1]

[1]Nagasaki university hospital, Gastroenterology And Hepatology, Nagasaki, Japan, [2]Sasebo City General Hospital, Sasebo, Japan

Contact E-Mail Address: eisukeozawa@nifty.com

Introduction: Endoscopic papillectomy (EP) has been established for the management of epithelial tumors such as adenomas and T1a carcinomas in the papilla of Vater. However, the indications and techniques for EP of submucosal lesions have not been established, and determining the appropriate treatment strategy can be challenging. Therefore, we present our experience with EP for submucosal lesions of the duodenum in this report.

Aims & Methods: The subjects were five cases of submucosal tumors of the major duodenal papilla and two cases of papillary bile duct cysts with repeated pancreatitis, out of 130 cases who underwent endoscopic papillectomy (EP) at each related facility between January 2000 and September 2019. In all cases, endoscopic ultrasonography (EUS) and intraductal ultrasound examination (IDUS) were performed to confirm that there was no invasion into the duodenal muscularis propria or progression into the bile duct or pancreatic duct, and that the size of the lesion was basically 1 cm or less for enhancing lesions. Lymph node metastasis was also ruled out before performing the resection. There were four male cases, with a median age of 72 (39-77) years, and a median tumor size of 11 (9-30) mm. The observation period was 1251 (54-2385) days.

Results: In the solid lesions, the histopathological examination showed four cases of NET-G1 and one case of paraganglioma. Complete resection was possible in all cases, with four cases having undergone complete resection and one case with unclear margins. In the cystic lesions, no clear tumor lesions were found in the resected specimens, and there was no recurrence of pancreatitis after resection. No metastasis, recurrence, or serious complications have been observed in the above cases.

Conclusion: Duodenal NETs are known to frequently occur in the duodenal papilla, and the current standard treatment is pancreaticoduodenectomy, which is a highly invasive procedure. For duodenal NETs measuring 1 cm or less, which are indicated for endoscopic resection according to the pancreatic and gastrointestinal neuroendocrine tumor guidelines, EP may be a safe and effective diagnostic treatment. EP may also be effective as a symptomatic treatment for papillary bile duct cysts with repeated pancreatitis, and further studies are necessary to accumulate cases and investigate the complete resection rate, risk of metastasis or recurrence, and risk of complications.

Disclosure: Nothing to disclose.

PP1457

ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY BY CONVENTIONAL DUODENOSCOPE WITH COLONOSCOPY-ASSISTED PRE-PLACEMENT OF A LONG GUIDE TUBE IN PATIENTS WITH COMPLEX SURGICALLY ALTERED ANATOMY

H. Jin[1], X. Zhang[1], J. Yang[1], L. Lu[2], H. Shen[3], Z. Jin[1]
[1]Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Gastroenterology, Hangzhou, China, [2]Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Department of Gastroenterology, Hangzhou, China, [3]Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Gastroenterology Internal Medicine, Hangzhou, China

Contact E-Mail Address: lbjhb2013@163.com

Introduction: The success rate of endoscopic retrograde cholangiopancreatography (ERCP) is suboptimal in patients with complex surgically altered anatomy (e.g. Roux-en-Y anastomosis, pancreaticoduodenectomy) due to difficulty in advancement of scope to the target site and selective biliopancreatic duct cannulation. Although balloon-assisted enteroscopy can achieve a higher rate of intubation, its clinical application is limited by its small working channel and few compatible accessories.

Aims & Methods: We aimed to explore the feasibility and effectiveness of a novel endoscopic approach in patients with complex surgically altered anatomy.

This is a retrospective study of patients who underwent ERCP with complex surgically altered anatomy at our center with an annual ERCP volume of approximately 3000, between January 2018 and November 2022. The endoscopic procedures were performed by three senior endoscopists who had ERCP experience for at least 5 years. Long colonoscopy (measuring 168cm)-assisted ERCP was adopted as a first-line intervention, and selective biliopancreatic duct cannulation was performed after the target site (native papilla or the surgical anastomosis) was reached.

For patients with failed cannulation, a plastic guide tube measuring 250 cm was inserted via the working channel of the colonoscope and its distal end was placed near the target site. The colonoscope was then withdrawn while the guide tube was left in-situ. By following the guide tube, a conventional side-viewing duodenoscope was cautiously advanced to the target site and biliopancreatic duct cannulation re-attempted.

Results: A total of 58 patients were recruited (mean age:56.7 years [standard deviation [SD]:14.4; male:36 [62.1%]]. The reconstruction methods were as follows – Roux-en-Y hepaticojejunostomy:32 (55.2%), Billroth-II gastrectomy with Braun anastomosis:11 (19.0%), pancreaticoduodenectomy:10 (17.2%) and Roux-en Y gastrectomy:5 (8.6%). Common bile duct stone was the most common indication for ERCP (n=30; 51.7%), followed by bilioenteric anastomotic stenosis (n=15; 25.9%), pancreaticojejunal anastomotic stenosis (n=7; 12.1%) and chronic pancreatitis (n=6; 10.3%). 55 (94.8%) of 58 had successful intubation by long colonoscope with a mean procedure time of 57.7minutes (SD:23.4). The mean time to reach target site was 19.1minutes (SD:9.0). The target site could not be identified in two patients and intestinal perforation occurred during endoscopic intubation in one patient.

Among those with successful endoscopic intubation, biliopancreatic duct cannulation was achieved in 35 (63.6%) patients. For the remaining 20 patients with initial failure of biliopancreatic duct cannulation, intubation rate by duodenoscope was 100% by tracing the guide tube to target site. The success rate of biliopancreatic duct cannulation by duodenoscope was 85% (17/20) with a mean procedure time of 83.5 minutes (SD:21.1). The mean time to reach target site was 17.0minutes (SD:6.1). Notably, 90% (18/20) had either native papilla or pancreaticojejunostomy, in which selective biliopancreatic duct cannulation is known to be technically difficult with any type of forward-viewing scope due to unfavorable cannulation trajectory. For those with failed cannulation, two had anatomical stricture and one had impacted pancreatic stone.

Conclusion: ERCP by conventional duodenoscope with colonoscopy-assisted pre-placement of guide tube is a feasible, effective and safe alternative for patients with complex surgically altered anatomy in experienced endoscopists.

Disclosure: Nothing to disclose.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) techniques have advanced exponentially in recent years. However, ERCP is often challenging to complete, and one factor is the difficulty of the selective approach to the bile ducts, including the cystic duct, biliary stenosis, or postoperative anastomosis. We newly developed and commercialized a wire-driven bidirectional steerable catheter using artificial blood vessel material for ERCP, including these difficult cases.

In this study, we evaluated its usefulness and safety in approaching the biliary tract using a desktop phantom in patients with surgically altered anatomy of Roux-en-Y hepaticojejunostomy.

Aims & Methods: The developed novel catheter uses a seamless tube that comprises a body part with polytetrafluoroethylene (PTFE) and a 15mm long distal part with porous expanded PTFE. The minimum tube diameter is 2.1 mm, and the distal tip diameter is 1.4 mm. Two loop-formed control wires are installed into the tube for bidirectional bending. A desktop experiment compared the bending performance via a balloon-assist enteroscopy and the trackability with a conventional catheter with a steerable tip.

In addition, we clinically evaluated the success rate and duration of selective cannulation for the biliary branch and the frequency of complications in the four patients who underwent intestinal tract reconstruction by Roux-en-Y cholangiojejunostomy and required endoscopic treatment for symptoms such as acute cholangitis.

Results: The developed steerable catheter could bend over 90 degrees in both directions, and the minimum bending radius was about 4 mm, approximately five times smaller than the conventional steerable catheter.

The desktop phantom trackability tests showed that using the developed steerable catheter and a guidewire enabled physicians to select bile duct branches with complex and steep angles easily and quickly. In the clinical evaluation, the insertion of the guide wire and the developed steerable catheter was swiftly completed in the bile ducts bilaterally in the patients, which was impossible with the conventional steerable catheter.

The mean time required for guide wire insertion in the unilateral bile duct was 18.8 ± 10.1 seconds with the steerable catheter and 94.1± 42.1 seconds with the conventional catheter ($p < 0.05$). No catheter-related complications occurred.

Conclusion: The newly developed catheter with a steerable tip showed high bending performance compared to the conventional catheter. It was applied to complex diversion of the biliary branch for ERCP, especially in patients with surgically altered anatomy.

DOES WIRE-GUIDED CYSTOTOME DILATION FOR DIFFICULT BENIGN BILIO-PANCREATIC STRICTURES GUARANTEE LONG-TERM PATENCY?

E. Palmeri[1], L. Dioscoridi[1], E. Forti[1], F. Pugliese[1], M. Cintolo[1], G. Bonato[1], C. Panetta[1], F. Fimiano[1], M. Bravo[1], D. Donnarumma[1], M. Capasso[1], A. Palermo[1], M. Mutignani[1]
[1]*ASST Grande Ospedale Metropolitano Niguarda, Digestive and Interventional Endoscopy Unit, Milano, Italy*

Contact E-Mail Address: epalmeri94@gmail.com
Introduction: Difficult benign biliary and pancreatic strictures are generally managed by Soehendra screw or cystotome. Many studies described the techniques without information even of mid -term follow-up.
Aims & Methods: The main aim of the study is to verify the long-term patency of the dilated strictures after the use of cystotome. Data were retrospectively collected from October 2018 to September 2021 and all consecutive patients affected by difficult biliary or pancreatic strictures treated using cystotome were included.
Technical success was considered the ability to overpass the stricture.
Clinical success was defined as drainage of biliary or pancreatic strictures and symptoms resolution. Patients were evaluated at median follow-up of 28 months since the index procedure.
Results: Of the 13 patients included in the study (5 males, 8 females; mean age: 53 years old), 8 had biliary and 5 pancreatic strictures. Technical success was obtained in 12 patients. Only minor adverse events were reported in three patients. At follow-up, 7 patients presented stable resolution of the stricture, 4 recurrence of stricture and 2 showed persistence of the stricture.
Conclusion: The use of a cystotome can be considered an alternative method for dilation of difficult pancreatic and biliary strictures, after the failure of conventional modalities. According to follow-up, this alternative approach allows 54% of long-term stricture resolution.
Disclosure: Nothing to disclose.

Contact E-Mail Address: tommaso.schepis@gmail.com
Introduction: Endoscopic Retrograde Cholangiopancreatography (ERCP) is performed with reusable duodenoscopes and, infections due to colonization of the endoscope are an increasing problem. The single-use EXALT Model D duodenoscope (Boston Scientific Corporation, USA) has been recently developed to avoid the risk of cross-transmission and the need for endoscope reprocessing.
The aim of this study is to report the experience of a high-volume endoscopy center in the use of this new device.
Aims & Methods: This is a retrospective observational study performed at a single high-volume endoscopy center. All consecutive patients undergoing ERCP performed with EXALT single-use duodenoscope by expert endoscopists from April 2010 to November 2022 were reviewed from a prospectively maintained ERCP database. Demographic and technical data, indications, AEs, and ERCP success rate were recorded. Statistical analysis was performed with SPSS 20 software. Descriptive data are reported as mean/median ± standard deviation/range, or percentage.
Results: Nineteen patients were included (4 children with an age of 7, 7, 11, 17). Patients' characteristics are summarized in Table 1. Post-Liver transplantation immunodeficiency was the most common indication for the use of disposable duodenoscope (9, 47.3%), followed by SARS-CoV2 infection (6, 31.5%) (cases performed during the weekend with difficult access to reprocessing) and immunodeficiency (4, 21%). Twelve native papillae were recorded (63.1%) undergoing biliary sphincterotomy in 10 cases (52.6%) and pancreatic sphincterotomy in 1 case (5.2%). In 1 case (5.2%) precut was needed after cross-over to reusable duodenoscope. Seven cases of non-native papilla were recorded (36.8%). ERCP was completed with the single use duodenoscope in 17 cases (87.4%).
In two cases a cross-over to standard duodenoscope was needed for technical failure of the insufflation valve and for the impossibility to achieve a long-route position in the second case, to approach a papilla at the inferior duodenal genu. One case of delayed bleeding (5.2%) managed endoscopically, and 1 case of post-ERCP pancreatitis (5.2%) managed conservatively, were recorded.

Demographics:	
No. of patients, *n*	19
Age (years), *mean ± SD (range)*	49.2 ± 23.9 (7-84)
Sex (men), *n (%)*	13 (68.4)
Indication for disposable scope use:	
LT related immunodeficiency, *n (%)*	9 (47.3)
SARS-CoV2 infection, *n (%)*	6 (31.5)
Congenital immunodeficiency, *n (%)*	2 (10.5)
Acquired immunodeficiency, *n (%)*	2 (10.5)
Technical data:	
Native papillas, *n (%)*	12 (63.1)
Biliary sphincterotomy, *n (%)*	11 (57.8)
Pancreatic sphincterotomy, *n (%)*	1 (5.2)
Precut, *n (%)*	1 (5.2)
Biliary plastic stent placement, *n (%)*	10 (52.6)
Biliary metal stent placement, *n (%)*	1 (5.2)
Pancreatic stent placement, *n (%)*	3 (15.7)
Naso-biliary drainage, *n (%)*	4 (21)
Cholangioscopy, *n (%)*	2 (10.5)
AEs:	
Bleeding, *n (%)*	2 (5.2)
Perforation, *n (%)*	0
PEP, *n (%)*	1 (5.26)

Table 1: Patients characteristics (n: number, LT: liver transplantation, AEs: adverse events).

Conclusion: EXALT single use duodenoscope resulted efficient and safe in the management of bilio-pancreatic diseases, also in children. However, the scope leads to some difficulties when used in non-standard anatomical scenarios. The real advantages of disposable duodenoscope and the environmental/cost impact are still controversial issues, and more studies are need for conclusive data.
Disclosure: Nothing to disclose.

PP1461

CONTRIBUTION OF MACRODILATATION OF THE SPHINCTER OF ODDI IN THE TREATMENT OF LARGE BILE DUCT STONES

S. Mrabti[1], A. Benhamdane[1], T. Addajou[1], R. Berrida[1], S. Sentissi[1], I. El Koti[1], F. Rouibaa[1], A. Benkirane[1], H. Seddik[1]
[1]Military instruction hospital Mohammed V, Gastroenterology II, Rabat, Morocco

Contact E-Mail Address: doc.mrabti@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography is the treatment of choice for common bile duct stones. Nevertheless, it turns out to be difficult when it comes to a large bile duct stones. The macrodilatation of the sphincter of Oddi was developed in order to face this problem, it consists of a hydrostatic dilation of the sphincter of Oddi, after the endoscopic sphincterotomy.

Aims & Methods: The objective is to evaluate the effectiveness of sphincteroplasty and to analyze the factors associated with the success of this technique in patients with large bile duct stones.

This is a descriptive and analytical retrospective study conducted in our department between April 2002 and April 2023, including 52 patients who underwent sphincteroplasty for the extraction of a large bile duct stone. The success of the endoscopic treatment was defined by the complete emptiness of the common bile duct at the end of the procedure. Statistical analysis was performed using SPSS version 24.0 software. The study of the factors associated with the success of endoscopic treatment was carried out using a logistic regression model.

Results: The average age of our patients was 65.37+/-17.46 years with a female predominance of 56.9%. The mean common bile duct diameter was 16mm+/-2.97 [8-24mm]. 16.51% of patients were cholecystectomized, 2% of patients had acute pancreatitis, on the other hand acute cholangitis was objectified in 9.8% of patients. 7.8% of patients had biliary stenosis and only one patient had periampullary diverticulum. The success rate of sphincteroplasty was 96.1% with no notable complications. In univariate and multivariate analysis and adjusting for the factors studied (age, sex, history, presence of acute pancreatitis or acute cholangitis, main bile duct diameter, presence of periampullary diverticula, presence of main bile duct stenosis), no of these factors appeared to be associated with the success or failure of sphincteroplasty.

Conclusion: Macrodilation of the sphincter of oddi is a safe and effective technique in the treatment of large bile duct stones. In our study, the success rate was 96.1%, however none of the factors studied was associated with the success or failure of sphincteroplasty.

Disclosure: No conflict of interest.

COMPARISON OF DIFFERENT ERCP TECHNIQUES FOLLOWING ROUX-EN-Y GASTRIC BYPASS: A SYSTEMATIC REVIEW AND META-ANALYSIS

B. Gellért[1,2], J. Hoferica[1], A. Rancz[1], B. Eross[1], P. Hegyi[3,4,5], D.S. Veres[1], I. Hritz[2]
[1]Centre For Translational Medicine, Semmelweis University, Budapest, Hungary, [2]Semmelweis University, Department of Surgery, Transplantation and Gastroenterology, Budapest, Hungary, [3]Institute of Pancreatic Diseases, Semmelweis University, Budapest, Hungary, [4]Centre for Translational Medicine, Semmelweis University, Budapest, Hungary, [5]Institute for Translational Medicine, Medical School, University of Pécs, Pécs, Hungary

Contact E-Mail Address: gellert.balint@icloud.com

Introduction: Performing endoscopic retrograde cholangiopancreatography (ERCP) in patients with Roux-en-Y gastric bypass (RYGB) anatomy represents a real challenge for endoscopists. The most widely used options for ERCP in these cases are enteroscopy-assisted ERCP (EA-ERCP), laparoscopy-assisted ERCP (LA-ERCP), and endoscopic ultrasound-directed ERCP (EDGE).

Aims & Methods: Our aim is to compare EA-ERCP, LA-ERCP, and EDGE in terms of safety and efficacy by performing a systematic review and meta-analysis. The protocol was registered beforehand with PROSPERO (ID: CRD42022368788). We systematically searched three medical databases, namely MEDLINE (via PubMed), Embase, and Cochrane CENTRAL, to look for studies investigating EA-ERCP, LA-ERCP, or EDGE.

We performed indirect comparison to compare the interventions based on comparative and single-arm studies. Proportions were calculated by pooling together event rates with 95% confidence intervals (CI). Differences between interventions were considered significant if $p<0.05$. Random-effect model was used to pool effect sizes.

Results: In total, 67 studies were included (2,714 patients). The technical success rate was 78% (CI: 0.71-0.83) for EA-ERCP, 93% (CI: 0.9-0.95) for LA-ERCP, and 96% (CI: 0.92-0.98) for EDGE with total heterogeneity (I^2) 0%. Subgroup differences were significant between EA-ERCP and EDGE or LA-ERCP groups, $p < 0.05$.

The clinical success rate was 65% (CI: 0.58-0.73) for EA-ERCP, 92% (CI: 0.89-0.94) for LA-ERCP, and 93% (CI: 0.88-0.97) for EDGE, I^2: 18%, $p< 0.05$. Overall adverse event rates were 12% (CI: 0.7-0.21), 19% (CI: 0.14-0.24), and 20% (CI: 0.12-0.31), respectively with I^2: 60%, $p= 0.343$.

Conclusion: EA-ERCP performed poorly compared to LA-ERCP and EDGE regarding technical and clinical success rates, with no significant difference in adverse event rates. Our results question he role of EA-ERCP in the RYGB population.

PP1463

EFFICACY AND SAFETY OF EMERGENT ENDOSCOPIC GALLBLADDER DRAINAGE

H. Nishikiori[1], R. Sagami[1,2], T. Sato[1], K. Mizukami[2], K. Murakami[2]
[1]Oita San-ai Medical Center, Department of Gastroenterology, Oita, Japan, [2]Oita University, Faculty of Medicine, Department of Gastroenterology, Yufu, Japan

Contact E-Mail Address: nikki@san-ai-group.org

Introduction: Endoscopic transpapillary gallbladder drainage (ETGBD) is recommended for patients with acute cholecystitis at high risk of surgery/percutaneous drainage. Endoscopic ultrasound-guided gallbladder drain-

age (EUS-GBD) has a higher success rate than ETGBD but has a higher mortality rate as well. Therefore, the more appropriate procedure as emergent endoscopic drainage remains controversial.

Aims & Methods: This study aimed to evaluate the efficacy of endoscopic gallbladder drainage (EGBD); ETGBD and EUS-GBD for patients with technical failure of ETGBD in the same session.

Patients with moderate/severe acute cholecystitis at high risk of surgery who underwent ETGBD alone or EGBD were enrolled. In the EGBD group, patients underwent EUS-GBD after technical failure of ETGBD in the same session. The primary outcome was technical/clinical success rate and procedure-related adverse events by comparing ETGBD and EGBD.

Results: We enrolled 40 ETGBD and 41 EGBD patients. The overall technical success rate was significantly higher in the EGBD group than in the ETGBD group (97.6% vs. 82.5%, P=0.023). No significant difference was in clinical success rates and adverse event rates between both groups (P=0.858 and 0.665, respectively). The length of hospitalization was significantly shorter in the EGBD group (6.5 vs. 10.1 days, P<0.001).

Conclusion: EGBD contributed to higher technical/clinical success rate, and shorter length of hospitalization, with similar incidence rate of adverse events, than ETGBD alone. Thus, this rescue strategy of ETGBD with EUS-GBD having a higher global success rate may be ideal for emergency endoscopic gallbladder drainage.

PP1464

REMIMAZOLAM VERSUS PROPOFOL FOR SEDATION IN ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY: A NON-INFERIORITY STUDY

J. Lee[1], J.-S. Park[2]

[1]Inha University College of Medicine, Digestive Disease Center, Department of Internal Medicine, Incheon, South Korea, [2]Inha university School of Medicine, Gastroenterology, Incheon, South Korea

Contact E-Mail Address: pjsinha@naver.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is a frequently employed procedure for diagnosing and treating pancreaticobiliary diseases. The selection of an appropriate sedative agent is crucial for ensuring patient comfort and procedural success. An optimal sedative should offer a predictable duration of action and a high safety profile. This study aimed to compare the efficacy and safety of remimazolam and propofol in patients undergoing ERCP procedures.

Aims & Methods: A randomized, single-blind, single center study was conducted comparing remimazolam and propofol for inpatient ERCP sedation. The study medications were administered under the supervision of the endoscopist. A total of 110 patients scheduled for ERCP were randomly assigned to receive either remimazolam or propofol.

The primary endpoint was a composite of successful procedure completion and no requirement for rescue medication.

Secondary endpoints included sedation efficacy, recovery time, and adverse events.

Results: Of the 110 patients randomized, 108 underwent sedation and ERCP (53 received remimazolam, 55 propofol). The primary endpoint was achieved for 100% of patients in both groups. The incidence and frequency of treatment-emergent adverse events, including desaturation, were comparable between the two groups. ERCP initiation occurred sooner in the propofol group (mean, 63.18 ± 16.56 seconds) compared to the remimazolam group (75.23 ± 32.27 seconds; p-value=0.02). Additionally, the time to full alertness after ERCP completion was significantly shorter in the propofol group than the remimazolam group (304.18 ± 146.25 vs. 448.34 ± 224.09 seconds; p-value<0.001).

Conclusion: This trial demonstrated non-inferiority of remimazolam to propofol in achieving the primary endpoint of successful ERCP completion without the need for rescue medication. The incidence and frequency of adverse events were comparable between the two groups. However, our study also revealed that propofol had a faster onset and recovery time compared to remimazolam. Although this difference may not be clinically significant, it could have practical implications in certain cases. Consequently, remimazolam can be considered a safe and effective alternative to propofol for ERCP sedation, potentially expanding clinicians' options and improving patient outcomes. Further research is warranted to determine the optimal choice of sedative agents for various patient populations and procedures.

Disclosure: Nothing to disclose.

Contact E-Mail Address: doc.mrabti@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography is the treatment for choice of lithiasis of the common bile duct . It allows the extraction of calculations either by the use of standard maneuvers in particular the biliary extraction balloon or the basket of Dormia, or if necessary by additional maneuvers.

Aims & Methods: Our objective is to study the predictive factors of failure of the vacuity rate primary of common bile duct during endoscopic retrograde cholangiopancreatography in lithiasic pathology. This is a descriptive and analytical retrospective study including all patients with benefited from an Endoscopic retrograde cholangiopancreatography for lithiasic pathology, between September 2003 and August 2022. All patients underwent Endoscopic retrograde cholangiopancreatography with endoscopic biliary sphincterotomy and extraction of stones by standard maneuvers (Biliary extraction balloon or Dormia basket). The factors associated with the failure of the primary vacuity rate of common bile duct have been studied by the logistic regression. Statistical analysis was performed using Jamovi software.

Results: Among 1080 patients who underwent endoscopic retrograde cholangiopancreatography for lithiasis pathology, 606 (54.2%) had simple lithiasis, 315 (29.2%) had bile duct stones and 179 (16.6%) had large stones. The average age of the patients was 58.9 +/- 14.4 years with extremes ranging from 19 to 98 years. The sex ratio (M/F) was 0.67 with a female predominance in 59.5%. 18.2% of patients had acute cholangitis and 9.2% had acute pancreatitis.

355 patients were cholecystectomized (32.9%), 67 patients had an antecedent of endoscopic biliary sphincterotomy (6.2%) and 5 patients had an history of common bile duct surgery (0.4%). Periampullary diverticulum was found in 9.1% of cases (n=98). The mean common bile duct diameter was 13.4 mm +/- 4.31.

Common bile duct stenosis was present in 6.3% of patients (n=68). The primary vacuity rate was 75.1%. Additional maneuvers were used in 22.7% of cases.

After univariate analysis, the predictors of failure after using the standard maneuvers were: age (OR: 0.9; 95% CI: [-0.03- -0.01]; p<0.001); gender (OR: 0.7; 95% CI: [-0.5- -0.02]; p=0.036); history of cholecystectomy (OR: 1.3, 95% CI: [0.02-0.6]; p=0.035); the presence of cholangitis (OR: 0.4; 95% CI: [-1.1- -0.4]; p<0.001); significant dilation of the common bile duct >15mm

(OR: 0.8, 95% CI: [-0.2- -0.1]; p<;0.001), common bile duct stenosis (OR: 0.3; 95% CI: [-1.7- -0.7]; p<;0.001) and the presence of stone formation and/ or large calculus (OR: 0.1; 95% CI: [-2--1]; p<;0.001).

After multivariate analysis, and adjusting for the factors studied, only the presence of cholangitis (OR: 1.9; 95% CI: [0.2-1]; p=0.001), stone formation and/or large stones (OR: 2.5; 95% CI: [0.5-1.3]; p<0.001), significant dilation of the common bile ducte > 15mm (OR: 0.88; 95% CI: [-0.17- -0.07]; p<0.001), and common bile duct stenosis (OR: 2.9; 95% CI: [0.4-1 .7]; p=0.002) were significantly associated with failure of the primary vacuity rate of the common bile duct.

The overall vacuity rate after using the additional maneuvers was 92.4%.

Conclusion: In our study, the primary common bile duct vacuity rate was 75.1%. The predictors of failure of the primary vacuity rate of common bile duct were the presence cholangitis, stones and/or large stones, significant dilation of the common bile duct (>15mm) and common bile duct stenosis.

Disclosure: Nothing to disclose.

COMPARISON OF EFFICACY AND SAFETY BETWEEN ERCP AND PTGBD AS PRIMARY DRAINAGE IN ELDERLY PATIENTS WITH ACUTE CHOLANGITIS: A SINGLE-CENTER OBSERVATIONAL STUDY

H. Kurebayashi[1], T. Ishida[1], S. Ujihara[1], K. Yamamoto[1], Y. Yokotani[1], T. Adachi[1], N. Yonekura[1], M. Katayama[1], M. Tanaka[1], H. Yasuda[1], T. Shigematsu[1]

[1]*Saiseikai Shiga Hospital, Gastro Enterology, Ritto, Japan*

Contact E-Mail Address: kurebarr.h@gmail.com

Introduction: Early drainage of the biliary tract is significant in managing patients with acute cholangitis. In cases where endoscopic retrograde cholangiopancreatography (ERCP) is not feasible, percutaneous transhepatic gallbladder drainage (PTGBD) is considered as an alternative treatment.

Several studies indicate that PTGBD is a well-established treatment as well as ERCP, however there is limited literature of evaluation and comparison of these procedures in elderly people.

Aims & Methods: This study aimed to compare the clinical outcomes of ERCP and PTGBD in elderly patients with acute cholangitis. We retrospectively compared patients aged 70 years or older who underwent ERCP or PTGBD between 2019 and 2022.

Results: Among 129 cases of acute cholangitis, 101 patients underwent ERCP, while 28 patients underwent PTGBD. Benign and malignant biliary obstruction were present in 76% (98/129) and 24% (31/129), respectively. The mean age was 84.2 years in ERCP and 84.5 years in PTGBD. Main reasons for performing PTGBD were postoperative stomach in 21% (6/28), unstable vital signs in 46% (13/28), full-stomach in 25% (7/28), and failure to perform ERCP in 14% (4/28).

The overall technical success rate was 91% (92/101) in ERCP and 100% (28/28) in PTGBD. Senior residents performed the entire PTGBD procedure, while only 63% (64/101) of ERCP cases were performed by senior residents. Both ERCP and PTGBD showed improvement in jaundice (T-Bil -0.72 vs. -0.45, P>0.05), liver dysfunction (AST -178.7 vs. -206.6, P>0.05; ALT -57.4 vs. -77.4, P>0.05), and inflammatory response (white blood cell count -5.4x103 vs. -7.4x103, P>0.05) in blood tests after the procedure. However, acute pancreatitis occurred in 5% (5/101) after ERCP, leading to mortality in 2% (2/101).

Other complications were observed in 19% (19/101), including bleeding after endoscopic sphincterotomy (EST) in 4% (4/101). In contrast, PTGBD caused no major complications or drainage failure, although tube dislocation occurred in 18% (5/28). The median length of stay was longer in PTGBD (25 days) compared to ERCP (15.2 days).

Conclusion: Both ERCP and PTGBD are effective treatments for acute cholangitis in elderly patients. Besides, PTGBD has an advantage of a higher technical success rate and fewer procedure-related complications compared to ERCP.

Introduction: The endoscopic transpapillary bile duct brushing cytology and biliary forceps biopsy with endoscopic retrograde cholangiopancreatography are generally performed for pathological diagnosis of biliary strictures. The sensitivity of the conventional cytology and biopsy was reported to be 30% to 81%. The diagnosis of biliary strictures may not be reached, especially of those caused by pancreatic cancer.

Aims & Methods: The Trefle (Piolax Medical Devices, Yokohama, Japan) is a new device that consists of looped metallic wires to scrape and aspirate the tissue along with bile juice.

The aim of the study was to compare the diagnostic performance of the new device with that of conventional cytology and biopsy. A total of 264 cases with biliary stricture underwent transpapillary biopsy and cytology between 2012 and 2021, of which 124 were diagnosed using the new device. We retrospectively analyzed the diagnostic utility of the new device compared with that of conventional cytology and biopsy.

Results: The locations of biliary strictures were perihilar in 73 cases and distal in 191 cases. Of the 264 cases, 195 were diagnosed with a malignant stricture. 122 cases had biliary cancer, whereas 72 had pancreatic cancer. The sensitivity of the new device and the conventional cytology and biopsy was 61% and 55%, respectively. Adding a biopsy to the new device increases the sensitivity to 89%. In the cases with biliary strictures caused by pancreatic cancer, the sensitivity of the new device and the conventional cytology and biopsy was 49% and 39%, respectively.

Conclusion: Our study suggests that the new device was more useful than conventional cytology and biopsy for the pathological diagnosis of biliary strictures, especially those caused by pancreatic cancer. Adding a biopsy to the new device to the new device is expected to increase sensitivity.

MOTORIZED SPIRAL ENTEROSCOPY-ASSISTED THERAPEUTIC ERCP IN PATIENTS WITH ROUX-EN-Y BILIOENTERIC RESCONSTRUCTION

S. Nennstiel[1], R. Fried[1], A. Herner[1], C. Schlag[1]
[1]University hospital Zurich, Department of Gastroenterology and Hepatology, Zurich, Switzerland

Contact E-Mail Address: ron.fried@usz.ch

Introduction: Postsurgical upper gastrointestinal anatomy impedes access to the biliary system in case an appropriate intervention is needed. Motorized spiral enteroscopy (MSE) was shown feasible in patients with altered anatomy and has the advantage that standard ERCP instruments can be used.

Therefore, MSE-ERCP appears to be the optimal solution for postsurgical patients, especially with long limb anatomy.

Aims & Methods: We retrospectively analyzed all MSE-ERCP procedures performed in patients with Roux-en-Y reconstruction between September 2021 and October 2022 in our hospital.

Results: We identified 18 MSE-ERCP procedures (9 in long afferent limb situation – e.g. after gastrectomy or hepaticojejunostomy; 9 in very long limb situation – e.g. gastric bypass) in a total of 14 patients. In 14/18 MSE-ERCPs (78%) the papilla/hepatico-jejunostomy was reached and in 12/14 MSE-ERCPs (86%) the intended "standard" ERCP-interventions (e.g. cholangiography, endoscopic papillotomy, biopsy, balloon-dilation, stone-removal, plastic as well as fully covered metal stent-insertion) were successfully performed.

Success of reaching the biliary entry was lower in very long limb-situations (66% vs 89%), success of interventions was comparable in both limb situations. Observed complications were caused either by enteroscopy in one patient or by the biliary intervention inanother patient. Mean procedure time for successful interventions was 93 minutes. In 60% of patients MSE-ERCP was carried out on an outpatient basis.

Conclusion: MSE-ERCP is a promising technique for patients with Roux-en-Y reconstructions with good success and acceptable complication rates. Prolonged examination times have to be taken into account and outpatient application is possible in the majority of cases.

LONG-TERM OUTCOMES OF A LONG, PARTIALLY COVERED METAL STENT FOR EUS-GUIDED HEPATICOGASTROSTOMY IN PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION

A. Hedjoudje[1], J. Pokossy[1], E. Perez-Cuadrado-Robles[2], R. Coriat[3], S. Koch[4], F. Prat[1]
[1]Hopital Beaujon, Department of Endoscopy, Clichy, France, [2]Georges-Pompidou European Hospital, Department of Gastroenterology, Paris, France, [3]Cochin University Hospital, Gastroenterology Unit, Paris, France, [4]Chru Minjoz Besançon, Gastroenterology Unit, Besancon, France

Contact E-Mail Address: abdellah.hedjoudje@gmail.com

Introduction: The first line treatment for biliary obstruction is endoscopic retrograde cholangiopancreatography (ERCP). However, in some situations such as duodenal obstruction or hilar obstruction or surgically altered anatomy, conventional endoscopic management fail. Hepaticogastristomy drainage (HGS) through endoscopic ultrasound has emerged as a new technique for biliary decompression in case of ERCP failure. We hereby aim to evaluate long-term efficacy of EUS-HGS.

Aims & Methods: One hundred ninety-eight patients undergoing EUS-HGS using long partially covered metallic stent in 3 academic centers from January 2010 to January 2022 were retrospectively studied. Technical and functional success, adverse events, recurrent biliary obstruction (RBO), and reinterventions were evaluated.

Results: The principal cause of malignant biliary obstruction was pancreatic cancer in 47,6 %. Patients were metastatic at the time of HGS in 65,2% of cases. Patients were male in 53,8% with mean bilirubin of 58.74 mg/dL. The main reason for HGS was duodenal obstruction (30,9%) followed by failed biliary cannulation (30,4%). The median overall survival rate was 3.1 months [IC 95%; 2.2 - 3.97]. In the entire cohort 35 patients / 198 had recurrent biliary obstruction (17,7%) with median stent patency of 448 days.

On multivariate analysis, age was associated with lower chance of stent dysfunction (HR = 0.97 [0.95-0.99], p=0.028). Stent type, stent diameter, stent size, size of puncture, ascites and cause of malignant obstruction were not associated with stent patency. Reintervention through the EUS-HGS route was technically possible in most cases.

Conclusion: EUS-HGS using for unresectable malignant biliary obstruction was safe and effective on the long term with low rate of stent dysfunction and recurrent biliary obstruction. Patient's prognosis was primarily determined by the underlying disease.

Introduction: Cholangioscopy-assisted intraductal lithotripsy is a first-line option in the treatment of complex gallstones. Its effectiveness and safety are demonstrated in the literature by multiple studies published after 2017.

However, there are no published studies about the long-term recurrence of choledocholithiasis in patients treated by these techniques.

With this study we intend to answer this question, evaluating the long-term recurrence of choledocholithiasis in patients with complex choledocholithiasis treated with intraductal lithotripsy techniques.

Aims & Methods: Retrospective cohort study of 62 consecutive patients who underwent cholangioscopy-guided intraductal lithotripsy between 2017 and 2022 at our center. Data were collected from a dedicated prospectively maintained database.

Primary outcome: recurrence of choledocholithiasis.

Follow-up time: 5 years.

Survival analysis was performed using Kaplan-Meyer curves and Cox regression (Statistical software STATA 17 (StataCorp, TEXAS).

Results: Of the 62 patients, 35 (56.5%) were women, mean age 72 years (min. 28, max. 96), 20 of whom had previously undergone cholecystectomy and with a mean follow-up time after lithotripsy of 28.21 months. 88.7% of patients achieved complete stone removal in the 1st session, with a rate of 100% at the second procedure. The mean number of stones was 2.02 with a size of 18.74mm. There was recurrence of choledocholithiasis in 9 patients, of which 77.8% had cholangitis, with a mean time of

13.33 months after lithotripsy. In patients with recurrence of choledocholithiasis, 22.2% had gallbladder. None of the patients required surgery to explore the biliary tract.

Conclusion: Cholangioscopy-guided lithotripsy is associated with a high success rate in difficult gallstones, with a safety profile similar to conventional techniques and lower rates of choledocholithiasis during follow-up.

EXPERIENCE WITH THE USE OF SINGLE USE DUODENOSCOPY FOR ERCP IN A TERTIARY CARE CENTER

K. Balendran[1], M. Abdellah Ahmed[1], T. Karunakaran[1], G. Corbett[1]
[1]Cambridge University Hospitals, Department of Gastroenterology, Cambridge, United Kingdom

Contact E-Mail Address: m.abdellah@azhar.edu.eg

Introduction: Infection related morbidity and mortality is still a major hazard associated with the standard re-usable duodenoscopes used for endoscopic retrograde cholangiopancreatography (ERCP). The single use duodenoscope (SUD) has been developed as a potential disposable instrument for preventing cross-transmission of infections via contaminated devices in high-risk patients. However, data for the use of SUD in real-world practice is very scarce.

Aims & Methods: In this study we aimed to assess our single centre experience with SUDs in patients underwent ERCPs, in terms of performance and safety. We included all the patients who underwent ERCP with the use SUD (Boston Scientific designed EXALT Model D) between October 2020 and February 2023 at Cambridge University Hospitals. Based on the retrospective review of procedure notes, outcomes were analysed with regards to procedure indication, success rate for the intended clinical indication, interventions performed, and adverse events. The SUD was used when prespecified institutional criteria (immunocompromised patient, multi drug resistant infection or failed procedure with standard re-usable duodenoscopes) were met or when there was no reusable duodenoscopes available at the time of procedure.

Results: The SUD was used in total of 34 patients during the study period. Baseline patient characteristics and procedure details are shown in Table 1. 59% of the patients were females. The median age was 64.5 years. Nineteen patients (56%) had a native papilla. The most common indication for the ERCP was choledocholithiasis (12, 35%) followed by benign biliary stricture (11,32%), head of pancreas tumor (6, 18%) and cholangiocarcinoma (4,12%).

28 out of 34 (82%) procedures achieved technical success. 20 procedures (59%) had the SUD used as the primary endoscope and 19 were successful (95%). In the other 14 cases (41%) SUD was used after the standard re-usable duodenoscopes due to anatomical problems encountered preventing progression of the procedure and of these 9 (64%) were completed successfully. In 5 of these (83%), failure occurred due to distorted duodenal anatomy which did not allow the scope to reach a favorable position.

Regarding the post procedure adverse events, 5 patients (15%) developed post procedure pancreatitis, two (5%) developed cholangitis and one patient (2%) had post sphincterotomy bleeding .

Conclusion: The SUD may be an effective tool in patients with distorted gastro-duodenal anatomy with failure when using a re-usable duodenoscopes. The reason for this may be due to the diameter and stiffness of the SUD. It was observed that SUDs are associated with comparably higher rates of adverse events in this study group due to the technical difficulty of the procedures. In addition to the fact that SUD eliminates the risk of device-related infection transmission, it appears to represent a reliable and effective alternative to standard re-usable duodenoscopes for a variety of indications and levels of difficulty.

	ERCP with SUDs
Age (Median, Range)	64.5 (28-84)
Gender- Female	20 (59%)
Native papilla	19 (56%)
Indication for the ERCP	
-Choledocholithiasis	12 (35%)
-Benign biliary stricture	11 (32%)
-Head of pancreas tumor	06 (18%)
-Cholangiocarcinoma	04(12%)
-Others	01 (3%)
Indication for SUD use	
-Immunosuppression	05 (15%)
-Failed procedure with standard re-usable scope	14 (41%)
-Unavailability of the re-usable standard scope at the time of the procedure	15 (44%)
Maneuverers performed using SUD (can be >one per case)	
-Successful biliary cannulation	29(85%)
-Sphincterotomy	21(62%)
-Sphincteroplasty	05(15%)
-Balloon trawl	16(47%)
-Controlled radial expansion(CRE) balloon dilatation of the biliary stricture	04(12%)
-Mechanical lithotripsy	02(6%)
-Brushings for cytology	06(18%)
-Biliary stent removal	02(6%)
-Biliary (plastic) stent placement	02(6%)
-Biliary(metal) stent placement	11(32%)
-Spy glass	02(6%)
Completion of ERCP for intended clinical reasons	28(82%)
Reasons for failure with SUD	
-Distorted gastro-duodenal anatomy	05(15%)
-Unstable patient	01(3%)
Adverse events	
-Pancreatitis	05(15%)
-Cholangitis	02(6%)
-Post sphincterotomy bleeding	01(3%)

Introduction: Hydatid cyst of the liver is a parasitic disease caused by the development of the taenia Echinococcus Granulosus. Fistulization in the bile duct is one of the most frequent complications. Endoscopic treatment is necessary because of the risks associated with surgery.

Aims & Methods: Aims: To evaluate the impact of endoscopic ERCP in the diagnosis and Therapeutic management of ruptured liver hydatid cysts in the bile ducts.

Methods: 60 patients with a hydatid cyst fistulized in the bile ducts were included retrospectively over a period of 20 years, from January 2002 to September 2022. Overall success was defined by definitive vacuity of the main bile duct.

The results were analysed by JAMOVI 2.0

Results: Among the ERCPs performed in our department during the study period, 4.6%(n=60) were for a hepatic hydatid cyst communicating with the bile ducts.

Median age of our patients was 46.1±14.8 with a sex ratio of 2.

ERCP was indicated for acute cholangitis in 44.9% and persistent external biliary fistula in 34%. Median bile duct diameter was 10[7-14]mm and median cyst diameter was 35[27-47]. Sphincterotomy was performed in 96% of patients allowing extraction of hydatid fluid by balloon or Dormia in 87.8%.

Nevertheless, 24% required naso-biliary drainage and 8% benefited from biliary prosthesis placement. Overall success rate was 93,3% (n=56) while 4 patients (6,7%) developed some complications.

This technique helped with the disappearance of jaundice after 5 to 10 days.

Conclusion: Our study confirms that endoscopic treatment of ruptured hydatid cyst in the bile ducts is an effective therapeutic alternative, with a low rate of immediate complications and a good long-term evolution.

Disclosure: Nothing to disclose.

EARLY NEEDLE KNIFE FISTULOTOMY IS SAFE AND EFFECTIVE

W.L. Lam[1], R. Prawiradiradja[1], M. Ding[1], C.C. Yau[1], S. Hebbar[1]
[1]University Hospital North Midlands, Gastroenterology/Endoscopy, Stoke-on-Trent, United Kingdom

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is an endoscopic procedure that carries risks of post ERCP pancreatitis (PEP), perforation and bleeding. Extensive studies have been carried out in a bid to reduce these risks and to modify procedural related risk factors to minimise the risk of PEP. One of these methods is utilising the needle knife fistulotomy (NKF) early into gaining biliary access.

Aims & Methods: We aim to study the effectiveness and safety of utilising NKF early in ERCP, both as a primary means of gaining biliary access and a salvage method in difficult biliary cannulation. Papillary morphology which has been thought to contribute to its effectiveness and safety is also studied. All the cases with NKF, either early NKF or primary, during ERCP by a single operator over a ten year period from 2013 to 2022 were identified. Early NKF has been defined as proceeding to the technique within 5 minutes of attempting biliary cannulation, less than 5 contacts with the papilla or after one pancreatic duct (PD) cannulation.

Primary NKF has been defined as NKF prior to attempted cannulation. The notes and endoscopy reports of these patients who had undergone the procedure were reviewed for:

1. Success rate on first ERCP and the follow up managements for unsuccessful cases.
2. Success rate on reattempt ERCP cases following an unsuccessful first ERCP after NKF.
3. Success rate with various papillary morphology (classified according to the Haraldsson classification).
4. Complication rate of ERCP where NKF was attempted.
5. The rate of PD cannulation, PD stent insertion and its associated rate of PEP.
6. The rate of biliary cannulation and complications in patient who had undergone primary NKF.

Results: There were 289 cases of ERCP that had early NKF by a single operator. The biliary cannulation rate was 88.9% (n=257) on first attempt ERCP. For the failed first attempt ERCPs, 15 patients were brought back for re-attempt at ERCP and the success rate was 93.3% (n=14). Cumulatively, the successful biliary cannulation is 93.8% (n=271).

Successful cannulation was 95% in protruding papillas (Haraldsson Type 3), 89% for creased or ridge papillas (Haraldsson Type 4), 81.3% in the regular papilla (Haraldsson Type 1) and 66.7% in papillas within a diverticulum. The overall complication rate for early NKF was 3.1% (n=9). The mortality rate in this study was 0.3% (n=1) from severe pancreatitis.

The rate of post-procedure bleeding was at 0.3% (n=1). There was a rate of 0.3% (n=1) for perforation caused by needle knife incision, which was managed with endoscopic clipping intraprocedurally. The rate of pancreatitis was 2.4% (n=7). There were 38 patients who underwent PD cannulation, of which 5.3% (n=2) suffered from PEP and did not have a PD stent inserted.

Out of 38 patients, there were 5 patients who had PD stent inserted and none had pancreatitis. For the 251 patients who had not undergone PD cannulation, 2% (n=5) had PEP. There were 16 cases of primary NKF and 100% was successful with biliary cannulation. There were no complications.

Conclusion: Early NKF is an effective method of gaining biliary access in ERCP in experienced hands. In our experience, primary NKF has been highly successful with no complications.

Additionally, a second attempt at ERCP should be considered ahead of more invasive interventions such as percutaneous transhepatic cholangiogram (PTC) if the clinical situation allows after an initial failed attempt at ERCP with NKF. Early NKF is also safe in experienced hands, as evidenced by low rates of complications.

PP1474

EFFICACY OF COMBINED PER-ORAL CHOLANGIOSCOPY-TARGETED BIOPSIES WITH FROZEN SECTIONS IN THE DIAGNOSIS OF PATIENTS WITH BILE DUCT NODULAR TUMORS

W.-H. Huang[1], C.-Y. Yang[1], S.-C. Chuang[1], H.-H. Cheng[1], C.-Y. Peng[1]
[1]China Medical University Hospital, China Medical University, Taichung, Taiwan

Contact E-Mail Address: u97766.huang@msa.hinet.net

Introduction: Per-oral cholangioscopy (POC)-targeted biopsies, potential to overcome the problems associated with inadequate tissue sampling and increase the diagnostic sensitivity of bile duct nodular tumors.

The utility of frozen section analysis, able to detect malignancy immediately and allows the early surgery in patients with invasive carcinoma.

Aims & Methods: To evaluate the diagnostic yield and efficiency of POC-targeted biopsies combined with frozen section histopathology.

From Oct. 2017 to Dec. 2021, consecutive patients with biliary nodular tumors were included in this study. The cholangioscope (SpyGlass DS, Boston Scientific Co., Natick, MA, USA) was advanced through a standard therapeutic duodenoscope (Olympus). All procedures were performed under moderate sedation or general anesthesia. Before POC, a standard endoscopic retrograde cholangiogram (ERC) with biliary sphincterotomy was performed to localize the bile duct nodular tumor and to facilitate ductal access and therapy. The cholangioscope was introduced into the bile duct through a guidewire via the working channel. The biliary trees were inspected, and suspicious lesions are biopsied. No more than nine biopsies per lesion were taken for histological examination. The specimens of endoscopic biopsies were then sent to the frozen section laboratory for freezing and staining. The slides were read immediately, and a preliminary report was conveyed to the clinician. The pathologist would then assess for the presence or absence of dysplasia or invasive cancer in the specimen.

Results: A total of 8 patients (7 male and 1 female; mean age 65 years) with bile duct nodular tumors undergoing cholangioscopy-targeted biopsies with frozen sections were included. The clinical presentations of

the patients were obstructive jaundice 2, abdominal pain 2, and imaging findings 4. Seven of the 8 patients had undergone ERC and ductal biopsies without definite diagnosis. The nodular tumors in the bile ducts, average size 1.5 cm (range 0.8-2.0), were located in proximal (4), middle (1) and distal (3) extrahepatic duct respectively. Among 8 patients with biopsy-proved malignancy, 3.5 times (range 2-9) biopsies were needed to be taken. All except one frozen section histopathology (adenocarcinoma in situ) was not compatible with surgical pathology (high grade dysplasia). Hilar invasion was observed in one patient during cholangioscopy, and subsequently surgery was not performed. One patient developed severe complication associated with acute cholangitis.

Conclusion: In this case series study, combined POC-targeted biopsies with frozen section histopathology provides an immediate and efficient diagnosis and allows an early surgery for patients with bile duct tumors. More patients are need to be included in the further study.

Disclosure: Nothing to disclose.

PP1475

A MULTICENTER STUDY OF FACTORS INFLUENCING THE DIFFICULTY OF SELECTIVE BILIARY CANNULATION USING NEW TEXTURE AND COLOR ENHANCEMENT IMAGING (TXI)

M. Takenaka[1], Y. Tanisaka[2], A. Fujita[2], M. Mizuide[2], Y. Otshuka[1], Y. Masuda[1], K. Takashima[1], H. Tanaka[1], T. Fukunaga[1], A. Yoshida[1], T. Yamazaki[1], S. Omoto[1], K. Minaga[1], K. Kamata[1], S. Ryozawa[2], M. Kudo[1]

[1]Kindai University, Department of Gastroentelorogy, Osaka-sayama, Japan, [2]Saitama Medical University International Medical Center, Saitama, Japan

Contact E-Mail Address: mamoxyo45@gmail.com

Introduction: In endoscopic retrograde cholangiopancreatography (ERCP)-related procedures, selective biliary cannulation is the most basic procedure and the most difficult to master. The device to improve the success rate of selective biliary cannulation is one of the most awaited innovations in the field of biliopancreatic diseases.

Texture and Color Enhanced Imaging (TXI) is a novel imaging technique that can create enhanced endoscopy images. TXI mode optimizes image structure, brightness, and tonality, the factors that construct and delineate mucosal surface images.

In this study, we aimed to reveal the factors using TXI influencing the difficulty of selective biliary cannulation.

Aims & Methods: This was a multicenter, retrospective study conducted at Kindai University Faculty of Medicine and Saitama International Medical Center.

Patients with naïve papilla for whom selective biliary cannulation was attempted between June and October 2022 were included in this study. A duodenoscope (TJF290V, Olympus Medical Systems, Tokyo, Japan) and EVIS X1 system (Olympus Corporation) were used for ERCP.

Papillary morphology evaluation was performed first with white light imaging (WLI) and then with TXI in all cases, and each evaluation was documented. TXI and WLI were used alternately in each case as the imaging mode during biliary cannulation.

The primary endpoint was the success rate of selective biliary cannulation.

Secondary endpoints included the ability to assess the morphological classification of the papilla, the time required for selective biliary cannulation, and the rate of first-touch cannulation (FTC).

For the morphological classification of the papilla, the agreement rate between the gold standard, as judged by three experienced endoscopists after ERCP, and the evaluation with WLI alone and with TXI were analyzed, respectively.

For the time required for selective biliary cannulation, it was defined as the time from the time the catheter was removed from the scope to the time of successful biliary cannulation. FTC was defined as the first attempt that led to successful biliary cannulation.

Results: Between the two groups of 57 patients in the TXI group and 56 patients in the WLI group, the concordance rate for the morphological classification of the papilla was 0.87 for TXI, better than 0.71 for WLI.

There was no difference between the two groups (TXI vs. WLI) in either the success rate of biliary cannulation (98.3 vs. 98.2%) or time required for biliary cannulation (median) (7.5 vs. 7.0 min), but the rate of FTC tended to be higher in TXI (42.1 vs. 25.0%).

Multivariate analysis (OR (95%CI), p-value) revealed the following characteristics: non-separate type papilla (0.25 (012-0.49), 0.0002), smaller papilla (0.43 (0.18-1.02), 0.083), longer oral protrusion (0.51 (0.35-0.80), 0.0024), and the presence of diverticula (0.52 (0.31-0.86), 0.0071) were factors contributing to a longer time required for biliary cannulation.

In trainee-specific analysis, the overall success rate of biliary cannulation was 69.7% (62/89), whereas the factors contributing to biliary cannulation failure were a long oral protrusion (0.21 (0.07-0.58), 0.0024) and the presence of a diverticulum (0.31 (0.09-1.02), 0.054) in multivariate analysis.

Conclusion: The factors affecting the difficulty of selective biliary cannulation were the non-separate type of papilla, the longer oral protrusion, and the presence of a diverticulum. TXI is expected to contribute to selective biliary cannulation by allowing the endoscopist to more accurately determine whether the papilla is a separate type or not than WLI.

Disclosure: There is no conflict of interest regarding this study.

TOTALLY RETROGRADE ENDOSCOPIC THERAPY TO TREAT STRASBERG TYPE C BILE LEAKS: A RETROSPECTIVE SINGLE CENTER EXPERIENCE

A. Palermo[1], L. Dioscoridi[1], E. Palmeri[1], M. Capasso[1], D. Donnarumma[1], F. Fimiano[1], C. Panetta[1], F. Pugliese[1], M. Cintolo[1], G. Bonato[1], M. Bravo[1], E. Forti[1], M. Mutignani[1]

[1]ASST Grande Ospedale Metropolitano Niguarda, Digestive and Interventional Endoscopy Unit, Milano, Italy

Contact E-Mail Address: a.palermo21@campus.unimib.it

Introduction: Endoscopic therapy is the treatment of choice for most external biliary fistulas except for those originating from isolated/disconnected ducts as in Strasberg type C lesions after laparoscopic cholecystectomy. The failure in opacifying during cholangiography and in accessing the isolated duct with the usual endoscopic methods made the endoscopic intervention not an available treatment option.

We propose a totally retrograde endoscopic access to treat Strasberg type C bile leaks.

Aims & Methods: The aim of this study is to evaluate technical and clinical success of totally retrograde endoscopic access to treat Strasberg type C bile leaks.

The proposed endoscopic intervention consists in cannulating the isolated duct by passing from the cystic duct or from the bile duct stump/leak using a hydrophilic guidewire and subsequent placing fully covered self-expandable metal stents (fc-SEMS) or plastic stents across the level of transection.

Before stenting, a mechanical or pneumatic dilation is performed using a 4 mm balloon or a 7/8,5 Fr Soehendra boogie. If cannulating the isolated duct is not technically possible ("single-step direct cannulation"), a "step-up approach" is used: a fc-SEMS or a plastic stent is placed with the distal edge in the subhepatic intrabdominal space as nearest as possible to the transected duct and the proximal edge transpapillary into the duodenum, by-passing the residual biliary tree.

After 4-6 weeks, a second ERCP is performed to directly stent the transected duct searching the path with a hydrophilic 0.035 angled guidewire. A plastic or fc-SEMS is placed to drain the biliary tree in all the cases.
This is a retrospective study of consecutive patients who underwent endoscopic treatment from March 2012 to March 2023
Results: Twenty-eight consecutive patients (12 M, 16 F; mean age: 55.4 y.o.) were retrospectively enrolled.
The access to the transected biliary radicle was obtained by opening the cystic stump using a 0.035 hydrophilic guidewire in 21 cases and from a common bile duct stump in 7 cases, passing through the intraperitoneal cavity.
In 19 cases, we performed direct cannulation of the isolated cut duct, while in 9 cases we performed an endoscopic step-up approach.
Technical success rate was 100%. Clinical success was obtained in 26 patients (93%): in one case, four days after the endoscopic procedure the patient underwent partial right hepatectomy due to an infected hepatic iatrogenic hematoma; in the other patient, a successful treatment of the biliary leak was not possible since the stent and the isolated duct were not in the same anatomical line, hence the patients underwent liver resection. Mean time of fistula's closure was 36 hours.
No major adverse events were reported. In two cases we observed a stent displacement, that in one case led to recurrence; in both cases, the patient was re-treated endoscopically. Acute cholangitis requiring endoscopic treatment was observed in one case.
Conclusion: The proposed endoscopic treatment is innovative, safe, and effective, but is applicable in tertiary level endoscopic centres and requires considerable expertise. This minimally invasive procedure can increase the rate of fistula healing and will eventually decrease the need for more aggressive and risky operative procedures.
Disclosure: Nothing to disclose.

SAFETY AND EFFICACY OF ENDO- BILIARY RADIOFREQUENCY ABLATION FOR STENT OCCLUSION: A CASE SERIES

G. Sismey[1], T. Wong[1], P. Berry[1], S. Kotha[1]
[1]*Guy's and St Thomas Hospital, Gastroenterology, London, United Kingdom*

Contact E-Mail Address: george.sismey@nhs.net
Introduction: Endo-biliary radiofrequency ablation (RFA) is a novel minimally invasive intervention to treat stent occlusion in malignant biliary strictures1. Advances in oncological therapies have improved survival and tumour ingrowth into uncovered self-expanding metal stents (UcSEMS) is common and strategies to manage this are limited2.
We aimed to determine the clinical outcomes of endo-biliary RFA using ELRATM probe (Taewoong) in patients with UcSEMS occlusion.
Aims & Methods: Retrospective data was collected from February 2020 to March 2023 at St Thomas' Hospital.
Results: 28 endo-biliary RFA's were performed in 12 patients for occluded UcSEMS over this period, delivered by 3 operators. Demographics are shown in table 1.
Excluding two recent cases, 60% required multiple RFA interventions. The median number of RFA's was 2, with one patient requiring 9 sessions. One patient was excluded as there was significant parenchymal disease in addition to UcSEMS occlusion and despite RFA, there was progression in liver metastasis. For patients with bilirubin monitoring post RFA, 11 (100%) procedures resulted in a reduction in bilirubin between 1-4 weeks.
The average reduction in bilirubin was 61.4% (6/11 patients) at week 1 and 77.4% (9/11 patients) at week 2-4. Excluding 2 recent cases, survival was 90 % at 30 days post procedure, and 70% at 90 days. Survival was 100% at 90 days for cholangiocarcinoma. The patient requiring 9 sessions (not on chemotherapy), survived for 18 months with significantly improved quality of life. There were no recorded complications. Technical difficulties were encountered in 2 cases due to impedance in bilobar stents with a Y configuration due to contact of the probe with metal at the hilum.

M:F	7:5
Mean age	71
Performance status	0-2
Malignancy Cholangiocarcinoma	5
Pancreatic cancer	4
gall bladder	1
Hepatocellular carcinoma	1
metastatic breast cancer	1

Table 1: Demographics

Conclusion: Endo-biliary RFA had good technical and clinical success with measurable reduction in bilirubin in patients with UcSEMS occlusion without any complications in our cohort. It is difficult to say if survival is purely due to biliary drainage or if there is an anti-tumour effect with RFA, especially given the 100% survival at 3 months in patients with cholangiocarcinoma. Additional data from randomised controlled trials is required to assess the role of RFA in malignant strictures.

PREDICTING DIFFICULT BILIARY CANNULATION IN ERCP – DEVELOPMENT OF AN INNOVATIVE MODEL

I. Tarrio[1], A. Andrade[1], M. Moreira[1], T. Araújo[1], L. Lopes[1]
[1]*Unidade Local de Saúde do Alto Minho, Gastrenterology, Viana do Castelo, Portugal*

Contact E-Mail Address: isatarrio@gmail.com
Introduction: Biliary cannulation is a key parameter in any training program and is pivotal in post-ERCP pancreatitis (PEP). The development of a simple and reliable model to predict a difficult cannulation ex-ante would allow us to develop better training programs and potentially decrease PEP, by matching difficult cases with more experienced endoscopists. However, there is no model published that allows to predict a difficult biliary cannulation (DBC).
Aims & Methods: We aimed to develop of a model to predict a DBC - defined as:
i. Taking longer than 5 minutes,
ii. With at least 5 attempts for BC or;
iii. With at least one pancreatic duct cannulation -, but before biliary cannulation.
A prospective cohort study was carried out in a large volume center for ERCP between January 2021 and March 2022. All patients with naïve papilla for biliary ERCP were enrolled (n=278). Two explained variables were evaluated:
i. Time to achieve biliary cannulation and;
ii. DBC.
Several predictors were evaluated including Viana's classification of the papilla and a new 5 dimensions framework for assessing the maneuverability of the scope by the endoscopist in the duodenum. A linear regression model and a qualitative response probit model were developed.

Results: Among the 278 patients, 196 (43.4%) were male, with a mean age of 73 years (range 19-107). The most frequent indication was biochemical/imaging suggested biliary disease without jaundice (45.2%; n=122). Three expert endoscopists supervised and performed all ERCPs; in 30.9% of the cases (n=85) a trainee began the procedure. The rate of successful cannulation was 100%. Standard methods alone were used in 66.4% (n=178) and needle-knife fistulotomy was performed in 29.9% (n=80) as a rescue technique. The median overall duration of ERCP was 18 minutes and 47 seconds; biliary cannulation was achieved with a median of 3 minutes and 38 seconds. Eighty patients (28.8%) had the a prominent tubular non-pleated papilla, followed by flat type (20.1%, n=56) and prominent tubular (19.8%, n=55). Regarding cannulation time, when a trainee started ERCP, the cannulation time lasts on average 4 more minutes compared with no presence of trainee (p<0.000) and when the endoscopist could not move duodenoscope to the desired position in D2, cannulation time was 3 minutes and 36 seconds longer than when the scope could be moved to the desired position in D2 (p=0.004).

When the endoscopist cannot get the papilla in the desired position for cannulation, the probability of having a DBC is 21.63 percentage points higher (p=0.015). Additionally, if the endoscopist cannot move the duodenoscope in the desired position, the probability of having a DBC is 24.05 percentage points higher (p=0.002). If a short position is not possible to achieve, the probability of having a DBC is 53.81 percentage points higher (p=0.018).

Furthermore, for each millimeter longer increase of the longitudinal axis of the papilla, the probability of having a DBC increases by 1.63 percentage points (p=0.020). When a trainee starts an ERCP, the probability of the cannulation to be difficult is 22.87 percentage points higher compared with an ERCP without the participation of a trainee (p<0.000).

Conclusion: We have demonstrated that it is possible for an endoscopist to predict a DBC prior to attempting it. This may possibly be useful for the future design of new training programs in ERCP and the development of measures to decrease the rate of PEP.

THE EFFICACY OF DISPOSABLE ELEVATOR CAP DUODENOSCOPE IN PREVENTION OF INFECTION TRANSMISSION: PILOT STUDY

W.H. Paik[1], M.H. Lee[1], S.H. Lee[1], J.-K. Ryu[1], Y.-T. Kim[1]
[1]Seoul National University Hospital, Dept. of Internal Medicine, Seoul, South Korea

Contact E-Mail Address: iatrus@hanmail.net

Introduction: Insufficient disinfection of duodenoscopes, particularly the elevator site, can cause ERCP-related infections and serve as a significant source of multidrug-resistant (MDR) infection. To address this issue, a disposable elevator cap (DEC) was developed, and a recent randomized clinical trial demonstrated its effectiveness in reducing contamination following high-level disinfection. However, there is limited evidence in actual clinical practice to reduce cholangitis caused by MDR pathogens.

This study aimed to compare the efficacy of the novel DEC duodenoscope with the standard duodenoscope in preventing infection transmission.

Aims & Methods: We conducted a prospective non-randomized cohort study in a single institution comparing baseline characteristics, technical performance, and incidence of acute cholangitis, including MDR pathogen, in 95 patients using a standard duodenoscope and 101 patients using a DEC duodenoscope.

Results: Age, sex, comorbidities, and indication for ERCP were similar between the two groups. However, the standard duodenoscope group had a higher proportion of naïve papilla (51% vs. 34%, p = 0.04), while the technical success rate was slightly higher in the DEC duodenoscope group (95% vs. 85%, p = 0.15). The rates of procedure-related adverse events were similar between the two groups (16% for DEC vs. 15% for standard). The incidence of post-ERCP cholangitis was also similar (10% for DEC vs. 11% for standard, p = 0.90). The proportion of post-ERCP cholangitis caused by MDR pathogens was similar in the two groups (1% for DEC vs. 2% for standard, p = 0.39).

Conclusion: This study suggests that the technical performance of the DEC duodenoscope is similar to that of the standard duodenoscope. However, more clinical data are needed to confirm the efficacy of the DEC duodenoscope in preventing ERCP-related infection transmission.

DUODENAL MAJOR PAPILLA MORPHOLOGY CAN PREDICT ERCP PROCEDURAL OUTCOMES AND ADVERSE EVENTS, A PROSPECTIVE STUDY

K. Amalou[1], F. Belghanem[1], M. Medkour[1], M. Youcef Achira[1]
[1]HCA, Gastroenterology, Alger, Algeria

Contact E-Mail Address: amalou_kh@yahoo.fr

Introduction: The morphology of the major papilla could be a risk factor for failure of selective biliary cannulation (SBC) and post endoscopic retrograde cholangiography and pancreatography (ERCP) complications. We aimed to assess whether papillary morphology predicts ERCP procedural outcomes and adverse events.

Aims & Methods: We aimed to assess whether papillary morphology predicts ERCP procedural outcomes and adverse events.

A prospective analysis was performed of patients undergoing ERCP for biliary indications. Patients were included if they received therapeutic ERCP and had naïve major duodenal papilla.

We used Haraldsson's classification for papilla morphology, as follows: Regular (Type 1), Small (Type 2), Protruding or Pendulous (Type 3) and Creased or Ridged (Type 4).

The primary outcome was failing SBC and post-ERCP pancreatitis (PEP), with secondary outcomes including other adverse events and procedural outcomes such as inadvertent pancreatic duct cannulation, cannulation time, and attempts.

Results: A total of 246 cases were included. Age, gender, indications and therapeutic procedures were not different among the four types of papillae. The failure rates of SBC with Type 3 papilla and Type 4 papilla were 9.61% and 5.25%, respectively. In the multivariate analysis, Type 2 papilla (odd ratio 6.78, p = 0.031) and Type 3 papilla (odd ratio 6.84, p = 0.016) were associated with greater SBC failure compared with Type 1 papilla. Malignant obstruction compared to stone (odds ratio 6.35, p = 0.011) and age (odd ratio = 2.11, p = 0.021) were also risk factors for cannulation failure. Type 2 papilla was correlated with a higher rate of post-ERCP pancreatitis (20%, p = 0.012) compared to the other types of papilla However, papilla morphology was not a significant risk factor for any complications in the multivariate analysis.

Conclusion: Small papilla and protruding or pendulous papilla are more difficult to cannulate compared to regular papilla. Small papilla is associated with a higher rate of post-ERCP pancreatitis. Understanding this is key for managing intraprocedural approaches and minimizing adverse events.

NEEDLE KNIFE PAPILLOTOMY AND FISTULOTOMY IN SUPER-ELDERLY (> 90 YEARS OF AGE): SAFETY AND OUTCOMES

H. Hisai[1], T. Sakurai[1], Y. Koshiba[1], S. Ameda[1], N. Suzuki[1]
[1]Japanese Red Cross Date Hospital, Department of Gastroenterology, Date, Japan

Contact E-Mail Address: hisai.hiroyuki@gray.plala.or.jp

Introduction: Needle knife papillotomy (NKP) and needle knife fistulotomy (NKF) are often used to facilitate biliary access in failed standard biliary cannulation and are associated with post-ERCP complications. However, data specifically evaluating NKP and NKF in patients older than 90 years is lacking.

Aims & Methods: The main objective of this study was to access the safety and efficacy of NKP and NKF in patients 90 years of age and older. Medical records of 249 patients with difficult biliary cannulation who underwent NKP and NKF from September 2000 and February 2023 were enrolled in this study. Patients were divided into two groups: 90 years age and older (Group A: n=34, 8 men, 26 women; mean age, 92.8 years; range 90-101 years) and less than 90 years old (Group B: n=215, 102 men, 113 women; mean age, 75.7 years; range 41-89 years). Patient characteristics, indications for ERCP, technical success and complications were retrospectively evaluated. Success was defined as deep placement of a catheter into the common bile duct. A diagnosis and severity of ERCP complications was made according to ASGE classification.

Results: Choledocholithiasis (57.0%) was the most frequent indication followed by malignant biliary obstruction (36.9%). Periampullary diverticulum was found 10 patients (29.4%) in Group A and 49 (22.7%) in Group B. The number of patients with American Society of Anesthesiologists (ASA) physical status class ≥ 3 was significantly larger in Group A than in Group B (47.1% vs 27.9%, P=0.029). Twelve patients (35.3%) in Group A and 89 (41.3%) in Group B underwent prior placement of a pancreatic stent.

There was no significant difference in the success rates of cannulation in the first session (67.6% vs 69.3%, P=0.844) and in the final session (97.1% vs 97.2%, P>0.999) between the two groups. Mean time to NKP/NKF and mean procedure durations were not significant between the two groups. Four complications (11.8%) occurred in Group A (pancreatitis 1, perforation 1, cholecystitis 2) and 35 (16.3%) in Group B (pancreatitis 19, bleeding 7, perforation 3, cholecystitis 6).

Complication rates was not significantly different. The use of a pancreatic stent was not related to complication rate. Early mortality rate was significantly higher in Group A than in Group B (17.2% vs 2.8%, P=0.009). There were no procedure-related deaths.

Conclusion: With adequate timing and experience, NKP and NKF are considered as safe and effective procedures in super-elderly.

Disclosure: Nothing to disclose.

Introduction: The benign papillary stenosis (BPS) leads to obstruction of the outflow of bile. The importance as an incidental finding has been insufficiently characterised. In particular, it is unclear whether endoscopic retrograde cholangiopancreatography (ERCP) with endoscopic papillotomy (EPT) and the resulting risk of adverse events should be performed in asymptomatic BPS.

Aims & Methods: Hence, the primary objectives were to evaluate the risk of adverse events (i.e. overall, bleeding, perforation, cholangitis, post-ERCP-pancreatitis, and death) after endoscopic retrograde cholangiopankreaticography (ERCP) with endoscopic papillotomy (EPT) in patients with benign papillary stenosis (BPS) and the course after EPT in comparison to patients with EPT for other reasons than BPS.

Secondary objectives included the characterisation of clinical features of BPS and the evaluation of particular risk factors for adverse events in this group.

In a retrospective case-control study 92 BPS patients (age: 77.0 (68.3; 83.8) years, women: 64 (69.6 %)) who had undergone ERCP with EPT from 2010 to 2019 were assigned to a control group matched for gender, age and year of procedure that had undergone ERCP with EPT for other reasons than BPS. Statistics were realised using analysis of variance (ANOVA), Pearson's chi-squared test, Fisher's exact test, paired t-test and Mann-Whitney-U-test. Within the BPS group risk factor analysis was accomplished via binary logistic regression.

Results: Jaundice before ERCP with EPT occurred less frequently in patients with BPS (14,4% vs. 33,0%, p = 0,003). The laboratory tests before the intervention showed that both the cholestasis parameters (AP [U/l]: 118.0 (80.0; 213.0) vs. 244.0 (119.0; 395.0), p < .001; gamma-GT [U/l]: 249.0 (68.8; 626.8) vs. 508.0 (290.0; 820.0), p < .001; total bilirubin [mg/dl]: 1.3 (0.7; 3,5) vs. 2.8 (1.3; 6.5), p < .001) and the transaminases (ALT [U/l]: 58.0 (24.0; 150.0) vs. 158.5 (76.5; 275.3), p < 0.001; AST [U/l]: 55.0 (22.5; 202.5) vs. 129.0 (61.5; 275.8), p = .002) were significantly lower in patients with BPS. The bile duct as measured by ultrasound before the EPT was nominally wider in patients with BPS (11.0 (9.0; 14.0) mm vs. 9.5 (7.0; 13.0) mm, p = 0.055). The ERCP revealed that BPS was moderate in 29.8 % and high in 70.2 %; the median length was 4.0 mm (IQR 3.0; 5.0). The EPT successfully drained the bile drainage in the majority of cases in both groups (100 % and 97.8 %, p = .497).

After the intervention the size of the bile duct decreased tendentially more in the BPS group (-6.5 (-9.7; -3.2) mm vs. -3.5 (-6.7; 0.0) mm, p = .381 and -50.0 (-59.5; -24.7) % vs. -38.7 (-53.4; 0.0) %), p = .198). The overall rate of adverse events tended to be higher in patients with BPS (20.7 % vs. 10.9 %, p = .069). The applied for both bleeding (12.0 % vs. 5.4 %, p = .116) and post-ERCP-pancreatitis (10.1 % vs. 4.4 %, p = .144).

Significantly more patients with BPS died after ERCP with EPT (9.8% vs. 2.2%, p = .030); the deceased presented a reduced state of health (ASA 3: 22.2 % or ASA 4: 77.8 %). Two out of nine BPS patients died from direct complications of ERCP with EPT. Within the BPS group no risk factors for adverse events or death could be detected.

Conclusion: The EPT in BPS is associated to an increased risk of adverse events, in particular increased deaths, although the majority of patients did not die from procedural adverse events. Further studies on the natural course of BPS and the effect of elective EPT in this patient group are mandatory.

Disclosure: Nothing to disclose.

FULLY COVERED SELF-EXPANDABLE METAL STENTS FOR THE TREATMENT OF POST-SPHINCTEROTOMY BLEEDING: SYSTEMATIC LITERATURE REVIEW AND META ANALYSIS

G. Kakked[1,2], M. Kozyk[1], K. Strubchevska[1], N. Mehta[2], C. Chapman[2], I. Waxman[2], A. Singh[2]

[1]Beaumont Hospital Royal Oak, Gastroenterology, Royal Oak, United States, [2]Rush University Medical Center, Gastroenterology, Chicago, United States

Contact E-Mail Address: drkakked1@gmail.com

Introduction: Self-expandable metallic stents are increasingly being considered when managing patients with post-endoscopic sphincterotomy (post-ES) bleeding, either as a primary intervention or in cases where other interventions fail to achieve hemostasis. However, safety and efficacy data is still scarce.

This study evaluates the literature on using fully covered self-expandable metallic stents (FCSEMS) for managing post-ES bleeding and describes their safety and efficacy.

Aims & Methods: A systematic literature search was conducted on Wiley Online Library and PubMed databases covering the period of 2010 to 2022 to identify relevant studies. Data were extracted, and hemostasis success, rebleeding, and complication rates were defined as outcomes of interest.

The summarized data were combined using the DerSimonian-Laird model with a Freeman-Tukey double arcsine transformation. Because of the heterogeneity of the data, we used a random-effects model. The chi-squared (Chi2) and I-squared statistic (I2) was used to assess the level of heterogeneity. All analysis was performed in Stata version 18.0

Results: We included ten studies in the meta-analysis (201 patients). The FCSEMS was deployed successfully in 100% of the patients. The hemostasis success rate was 95%, polled in all the studies (95% CI 86-100), while the rebleeding rate was 9% (95% CI 3-18). No death was reported in any of the ten studies related to the insertion of FCSEMS.

The complication rate was 10% (95% CI 5-16, I2= 26%), with stent migration being the most typical complication at 56% (95% CI 32-78) of all complications.

Conclusion: Fully covered self-expandable metal stents are effective and generally safe for managing post-ES hemorrhage, with a high initial hemostasis success rate, low rebleeding rates, and acceptable complications rate. FCSEMS can also be deployed with a high technical success rate.

Thus, FCSEMS can be part of the primary mitigation measures for post-ES bleeding.

Introduction: The evaluation of intraductal extension of perihilar cholangiocarcinoma (pCCA) is extremely challenging and affects the resectability of the disease. Digital Single-Operator Cholangioscopy (D-SOC) and D-SOC-guided biopsies are frequently used for diagnostic assessment of indeterminate biliary strictures.

Aims & Methods: In this study, we evaluated the role of D-SOC and D-SOC-guided biopsies in the pre-operative evaluation of intraductal extension of pCCA. We retrospectively analysed pCCA patients who underwent D-SOC and D-SOC-guided biopsies to assess the intraductal extension of the tumor prior to surgery for potentially resectable disease in our center between 2017 and 2021.

The accuracy of endoscopic appearance and histological sampling were compared to surgical samples obtained at surgery.

Results: Among 48 patients who underwent surgery for pCCA, after multidisciplinary discussion, D-SOC and D-SOC-guided biopsies were performed for proximal biliary staging in 6 patients (M:F 5:1, mean age at diagnosis 67 y.o.), which had an unclear ductal extension. A total of 12 D-SOC -guided biopsies were performed (7 from common duct, 2 from right duct and 3 from left duct). Concordance between CS-guided biopsies and surgical samples histological evaluation was 83% (10/12), with 6/6 true positives, 4/6 true negatives and 2/6 false negatives.

Among the histological false negatives, the first case had a cholangioscopic appearance compatible with CCA extension, thus the result of D-SOC-guided biopsies did not influence the therapeutic choice. In the second histological false negative, the evaluation of the surgical specimen showed perineural invasion and periductal tumor development. Radical surgery was achieved in all 6 patients.

Conclusion: Despite limited sample size, our preliminary data suggest a very high specificity of D-SOC and D-SOC -guided biopsies in the pre-operative evaluation of intraductal extension of potentially resectable pCCA patients.

A multidisciplinary approach and an accurate pre-operative assessment of pCCA remain of paramount importance to correctly diagnose and stage the disease before surgery.

Disclosure: Nothing to disclose.

Introduction: Accurate distinction between benign and malignant biliary strictures (BS) is challenging. The use of bile duct biopsies and brush cytology via endoscopic retrograde cholangiopancreatography (ERCP) remains suboptimal. Single-operator cholangioscopy increases the diagnostic yield in BS but has limited availability and high costs. Convolutional neural network (CNN)-based systems have the potential to assist in the diagnostic process and improve reproducibility. Thus, we assessed the feasibility of using deep learning to differentiate BS out of fluoroscopy images during ERCP.

Aims & Methods: We conducted a retrospective review of adult patients (n=251) from three university centers in Germany (Leipzig, Dresden, Halle) who underwent an ERCP. We developed and evaluated a deep learning-based model (DenseNet) by means of fluoroscopy images. We measured the area under the receiver operating characteristic curve (AUROC) to evaluate the performance of the classifier and used saliency maps analyses to understand the decision-making process of the model.

Results: In cross-validation (Leipzig cohort), malignant BS were detected with a mean AUROC of 0.88 ± 0.02. On two independent external validation cohorts (Dresden, Halle), the of the deep learned based classifier reached a mean AUROC of 0.71 ± 0.04 and 0.74 ± 0.07, respectively. The artificial intelligence model's predictions identify plausible characteristics within the fluoroscopy images.

Conclusion: By using a deep learning model, we were able to discriminate malignant BS from benign biliary conditions. Artificial intelligence improves the diagnostic yield of malignant BS and needs to be validated in prospective design.

Disclosure: Nothing to disclose.

Introduction: The biliary tree has traditionally been considered sterile under normal conditions[1].

Recent evidence has revealed rich microbial communities in the biliary tract of patients affected by biliary tract disorders, supposing that biliary microbiota could play a significant role in the development of several biliary diseases, namely gallstones, autoimmune cholangiopathies, and cancer[2,3].

However, while possible connections between gut micro-organisms and biliary diseases has been studied more extensively, to date few evidences are available on how the microbiological composition may change disease's progression[4].

Not least it is still unclear how the modification of Oddi's sphincter function after endoscopic sphincterotomy performed during an endoscopic retrograde cholangiopancreatography (ERCP) may represent a favorable environment for ascending bacterial colonization[5,6].

Aims & Methods: We performed a prospective observational study aimed to evaluate the prevalence of biliary pathogens of the bile in various disorders and to identify a microbial fingerprint for each disease. 162 consecutive patients with native papilla undergoing to ERCP for any indication were prospectively enrolled from July 2022 to April 2023.

One bile sampling was performed after bile duct cannulation, before contrast injection and sphincterotomy, while a second one was done at the end of the procedure. Pre procedural clinical data, bile cultures and clinical follow-up were collected and analyzed.

Results: Biliary culture was obtained in 100% of patients. 52% of bile cultures were positive for at least 1 bacterium. No differences were found in microbial community before and after sphincterotomy. Out of 78 patients with positive bile cultures, 46 (59%) had cholangitis, all of them were under antibiotic therapy. Patients treated with immunomodulant agents did not have an increased risk of positive bile cultures.

Multidrug-resistant bacteria were detected in pre-sphincterotomy bile cultures in 9 (5%) patients, of which 7 were extended-spectrum beta-lactamase (ESBL),1 Methicillin-resistant Staphylococcus aureus (MRSA) and 1 Vancomycin-Resistant Enterococci (VRE).

No significant correlations were found between the presence of multidrug-resistant bacteria and underlying diseases, systemic cholangitis or immunomodulant exposure.

Characteristic	N	%
Patients	162	
Age (mean)	71 (27-97)	
Gender		
Male	82	51
Female	80	49
Indications		
Choledocolithiasis	95	58.6
PDAC	28	17.3
CCA	6	3.7
Acute cholangitis	23	14.3
PSC	1	0.6
Papillary tumours	6	3.7
Others	3	1.8
Drug-induced immunosuppression	11	6
Proton pump inhibitors	102	63
Antibiotic therapy over last 3 months	29	18

Table 1. Baseline characteristics of our population study. PDAC: Pancreatic Ductal Adenocarcinoma. CCA: Cholangiocarcinoma. PSC: Primary sclerosing cholangitis.

Conclusion: Our preliminary results showed how the biliary tree in patients with biliary diseases may not be sterile, even when Oddi' s sphincter is intact. The presence of neoplastic diseases or immunosuppression therapy does not seem to correlate with an increase in positive bile cultures nor in multidrug resistant bacteria. Further analysis may be needed to assess the correlation between bile cultures and long-term outcomes.

EUS PRIOR TO ERCP IN CASES WITH DILATED CBD ON OTHER IMAGING WITH NORMAL OR BORDERLINE DERANGED LFT- IS IT REALLY WORTH?

P.N. Desai[1], M.V. Kabrawala[1], C. Patel[1], R. Prajapati[1], R. Kakadiya[1]
[1]SIDS Hospital & Research Centre, Endoscopy, Surat, India

Contact E-Mail Address: drp_desai@hotmail.com

Introduction: Dilated CBD on non-invasive imaging with normal or borderline derangement of LFT and unremarkable physical signs has been always a diagnostic dilemma. In the clinical setting, however, to determine the presence of ductal calculi or importantly a tumor remains a significant dilemma; a balance must be struck between invasive ERCP, associated complications and potential inaccurate diagnosis. We made a protocol to do EUS prior to ERCP in all such cases, where the previous investigations did not give a conclusive evidence of the pathology. We studied the efficacy of EUS in such cases for reaching a conclusive diagnosis and avoid unnecessary ERCP and its incipient complications.

Aims & Methods: To evaluate the efficacy of EUS prior to ERCP for patients with dilated CBD and other inconclusive imaging with normal or borderline derangement of LFT.

A total of 900 patients were referred for ERCP in last 6 years with inconclusive imaging study for dilated CBD and normal to borderline deranged LFT's.

Results: 482 - CBD stones
08 - Pancreatic Malignancy
12 - Distal Cholangiocarcinoma
04 - CBD Sludge
34 - Ampullary Tumor
30 - Impacted Stone at ampulla
12 - Distal CBD polyps
06 - WON Compression
12 - Chronic Pancreatitis Related Stricture
86 - Presumed Spontaneous passage of stones,
44 - Type 1 Choledochal cyst,
60 - Periampullary diverticulum,
40 - Stones in Hartman's pouch,
34 - Small ampullary adenoma,
16 - Duodenal ulcers with scarring
20 - Post cholecystectomy dilatation

ERCP was performed in 557 cases (61.9%) and avoided in 38.1%).
In the cases of pancreatic malignancy, distal cholangiocarcinoma, ampullary tumors, FNA was done and patients without cholangitis were not offered ERCP but subjected to surgery. Two patients with CBD sludge had cholangitis so ERC was done. Distal CBD polyps were removed at ERCP and two had intraductal ductal extensions so surgery was offered. Only two patients each with choledochal cyst and post duodenal ulcer scarring underwent ERC as they had cholangitis.

Conclusion: EUS has remarkable diagnostic yield in detecting etiology of dilated CBD and avoids unnecessary ERCP's in patients with unidentified cause on other imaging modality.

Disclosure: The authors have nothing to disclose.

THE CLINICAL UTILITY OF ENDOSCOPIC ULTRASOUND IN INVESTIGATING BILIARY PAIN

T. Keen[1,2], L. Ayres[1], R. Mccrudden[1], G. Elsayed[1], J.M. Franklin[1,2]

Introduction: Biliary pain is a common cause of morbidity both before and after cholecystectomy. Endoscopic ultrasonography (EUS) is sensitive for the diagnosis of biliary pathology and can identify disease that is occult on other imaging modalities. The aim of this study is to determine the diagnostic yield of EUS when performed for biliary pain.

Aims & Methods: This was a retrospective service evaluation of EUS referrals to a regional referral centre in the UK. All local patients who were referred for EUS for suspected biliary pain between January 2015 to December 2019 were included. Demographics, symptoms, liver function tests (LFTs), non-invasive imaging, EUS reports and clinical outcomes were reviewed. Biliary dilatation was defined as greater than 7mm pre-cholecystectomy and greater than 10 mm post-cholecystectomy. A EUS was considered as diagnostic for a cause of biliary pain if findings were identi-

fied which explained symptoms. Symptom resolution was defined as no further investigation, review or imaging performed for biliary symptoms in secondary care during the follow-up period. Statistical significance for proportions was calculated using chi-squared tests.

Results: 565 patients were included in the study. The median age of the cohort was 55 (range 17-89) years. 161 (28%) patients were male. 241 (43%) patients had previously had a cholecystectomy. The study participants had been extensively investigated with previous imaging which was non-diagnostic; in total the patients had 500 trans-abdominal ultrasound scans, 316 CT scans, 315 MRCPs and 77 previous EUS.

334 (59%) EUS were considered diagnostic. Patients who had previously had a cholecystectomy were less likely to have a diagnostic EUS compared to those who had a gallbladder ((99/241 (41%) vs 235/324 (73%); p<0.01). The diagnostic yield of EUS was higher in patients with abnormal LFTs or a dilated biliary tree and in those with both abnormal LFTs and biliary tree dilatation (table 1).

	Normal LFTs, non-dilated biliary tree	Abnormal LFTs, non-dilated biliary tree	Normal LFT, dilated biliary tree	Abnormal LFTs, dilated biliary tree	Total
Diagnostic EUS/ Total number of patients. N (%)	69/150 (46)	161/270 (60) (p<0.01)	38/60 (63) (p=0.02)	66/85 (78) (p<0.01)	335/565 (59)
Previous cholecystectomy. Diagnostic EUS/ Total number of patients. N (%)	25/74 (32)	49/121 (39) (p=0.35)	9/21 (43) (p=0.44)	16/25 (60) (p<0.01)	99/241 (41)

Table 1.

Positive findings included gallstones (n=92), gallbladder microlithiasis/ sludge (n=181), bile duct stones (n=85), bile duct microlithiasis/sludge (n=108), chronic pancreatitis (n=21) and mass lesions (n=4) which were later diagnosed as metastatic renal cell cancer, pancreatic cancer and two ampullary adenomas.

311 patients had a diagnostic EUS with a biliary aetiology for their pain which was amenable to treatment. Symptom resolution occurred in 85/136 (63%) who had ERCP, 21/24 (83%) who had both cholecystectomy and ERCP, 63/94 (67%) who had a cholecystectomy and in 19/57 (33%) who were managed conservatively. Patients with a diagnostic EUS were more likely to have resolution of their symptoms compared to those with no cause identified ((207/334 (62%) vs 81/231 (35%); p<0.05). Median duration of follow-up was 54 months (range 32-81 months).

Conclusion:

In our cohort of patients with biliary pain who have been previously investigated, EUS is associated with a high diagnostic yield across all groups, although this yield increases in patients with abnormal LFTs, a dilated biliary tree, or both. A diagnostic EUS leads to biliary intervention in a high proportion of patients, and patients who have EUS-guided intervention appear have a greater chance of becoming symptom free than those without a diagnostic EUS. This supports investigation of patients with suspected biliary pain with EUS, regardless of whether their liver blood tests are abnormal or their bile ducts are dilated.

Contact E-Mail Address: m-kida@kitasato-u.ac.jp

Introduction: Endoscopic ultrasonography-guided fine-needle aspiration (EUS-FNA) has become an indispensable examination in the clinical fields. Recently therapeutic EUS such as pseudocyst drainage, EUS-biliary drainage, and EUS-pancreatic duct drainage, etc. have become popular. In order to become a good endosonographer, it has been believed that the learning of EUS-FNA takes long time and certain number of case experiences are essential. And it is also difficult to learn EUS/EUS-FNA without instructors.

Furthermore, clinical cases are not enough for training young endosonographer. Then hands-on training with models are able to reduce the number of performing clinical Therapeutic EUS on training program.

Aims & Methods: Therefore, we have developed newly designed model for training therapeutic EUS procedure such as EUS-HGS and PFC drainage, conducted the trial of these models with trainees, and investigated its usefulness and limitations.

We have collaborated with Olympus Co. and made model for EUS-HGS by special plastic material (Century medical Co., Tokyo) and pseudocyst model by non-rupture-balloon (SB Kawasumi Co., Tokyo) which is 8cm in diameter. This balloon is filled by lubricant, and these models are put into water tank. We have tried this model at Kitasato Train-The-Trainer (TTT) and Changhai TTT with 26 trainees (11 for HGS and 15 for PFC). We have investigated whether all trainees can complete HGS and PFC drainage procedure (each 5 steps; identify target, needle puncture), GW insertion, dilation, and stenting) and measured these procedure step times. At first each trainee tried these models after simple explanation and they tried it as 2ndtime after teaching tips and tricks. We have employed UCT-260 (Olympus Co., Tokyo) ,19G EUS-FNA needles and 7Fr plastic stent as a drainage tube.

Results: Concerning about PFC drainage, trainees completed the procedure 11/15(73%) at first try and 11/15(73%) at second time. At first try, 3 trainees completed up to 3rd step, not to 4th, 5thsteps, and at second try, 1 trainee still completed up to 3rd step, but 3 up to 4th step. Averaged time of 1st try and 2nd try is 780s vs 594s (p<0.001), respectively.

Concerning about HGS model, trainees completed the procedure 11/11(100%) at first try and 11/11(100%) at second time. Averaged time of 1st try and 2nd try is 712s vs 490s (p<0.001), respectively.

According to their impression, resistance of puncture and putting in a stent is less, compared with clinical cases, even though this model has resistance to pass through the gastric wall, PFC wall, and hepatic parenchyma. Trainees with less experience improved apparently, compared with trainees with more experience. However, it is very useful to understand the procedure of EUS-HGS and EUS-guided PFC drainage for the biggner of therapeutic EUS.

Conclusion: We concluded that newly designed EUS-HGS and pseudocyst model is useful to train the beginner, in order to understand the procedure. Furthermore, using these models, we can brush up their skill by repeating hands-on training.

APPLICATION OF QUANTITATIVE CONTRAST-ENHANCED HARMONIC EUS ON DIFFERENTIAL DIAGNOSIS OF GALLBLADDER POLYPOID LESIONS

M.-L. Han[1], K.-C. Chen[2,3], P.-C. Li[2], H.-P. Wang[4], Taiwan Contrast Enhanced Study Group (T-CESG)
[1]National Taiwan University Hospital, Division of Endoscopy, Department of Integrated Diagnostics & Therapeutics, Taipei, Taiwan, [2]Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, [3]Far Eastern Memorial Hospital, Division of Gastroenterology and Hepatology, New Taipei, Taiwan, [4]National Taiwan University Hospital, Devision of Gastroenterology and Hepatology, Department of Internal Medicine, Taipei, Taiwan

Contact E-Mail Address: minglun@ms18.hinet.net

Introduction: Contrast-enhanced harmonic endoscopic ultrasound (CEH-EUS) can demonstrate microvascularization of the tumors. However, most images acquired from CEH-EUS are interpreted subjectively without quantification by time-intensity curves (TICs) analysis. The role of quantitative CEH-EUS through time-intensity curve (TIC) has not been explored in differential diagnosis of gallbladder(GB) polypoid lesions.

Aims & Methods: In this study, we used a handcrafted software to quantify TIC curve of CEH-EUS images to differentiate malignant gallbladder polypoid lesions from benign ones.

We analyzed the videos of CEH-EUS for GB polypoid lesions from the patients in National Taiwan University Hospital. The convex-type echoendoscope (GF-UCT260; Olympus, Tokyo, Japan) equipped with ultrasound (US) systems (EU-ME2) was used for the procedures. The second generation of US contrast agent with Sonazoid (GE Healthcare, Oslo, Norway), which contains perfluorobutane microbubbles with a median diameter of 2–3 μm, was administered bolus and intravenously with a dosage of 0.015 ml encapsulated gas per kilogram body weight. The videos were recorded in AVI formats with 30 frames/second.

The algorithm for getting TICs includes the following steps:

1. Circling the region of interest(ROI) in the B-mode
2. Performing speckle tracking of the ROI in the B-mode
3. Simultaneously obtaining the intensity of ROI (the mean pixel values in the ROI) in the corresponding contrast-enhanced harmonic image
4. Outputting TICs after subtracting the baseline intensity (for eliminating the different baseline intensities caused by other settings).
5. Outputting histogram of pixel values and excel file containing all pixel values from the frame with the highest mean pixel value automatically.
6. Calculating the standard variance of (5) to represent the heterogeneity inside the ROI.

The speckling tracking composes of searching and matching processes. We used full search for the searching process and normalization cross-correlation for the matching process. By using the hardware of CPU with Intel i7-8750H and GPU with Nvidia GTX 1050 Ti, the computation time was 0.7 ms/frame. Based on this algorithm, we designed a graphical user interface of this model.

Results: A total of 30 eligible videos were enrolled for analysis. Fourteen lesions were pathologically proven of malignancies (including 11 adenocarcinomas, two neuroendocrine tumors, one B-cell lymphoma) and the other 16 lesions were benign cases. Among 16 benign lesions, 6 were chronic cholecystitis, 4 were adenomyoma, 2 were intracholecystic papillary neoplasm, one was xanthogranulomatous cholecystitis, one was cholesterol polyps, one was hyperplastic polyp and one was Mycobacterium tuberculosis. The lesion size ranged from 8.1 to 90mm in malignant group and from 4.4 to 29mm in benign group. The mean peak intensity was 46.36 dB (SD=31.77) in malignant group and 55.94 dB (SD=44.59) in benign group respectively (p=.509). The mean time to peak was 30.14 s (SD=10.00) in malignant group and 20.50 s (SD=6.70) in benign group respectively (p=.004).

Conclusion: This preliminary report of using TIC of CEH-EUS images for differential diagnosis of GB polypoid lesions showed significant difference in time to peak between malignant group and benign group. Further large scale of studies are needed for comfirming the application of this novel technique.

Disclosure: Nothing to disclose.

A NOVEL DRILL AS THE TRACT DILATION TECHNIQUE DURING EUS-GUIDED BILIARY DRAINAGE BY NON-EXPERT HANDS (WITH VIDEO)

M. Yamamaura[1], T. Ogura[2], S. Ueno[1], A. Okuda[1], N. Nishioka[1], N. Hattori[1], K. Bessho[1], H. Nishikawa[1]
[1]Osaka Medical and Pharmaceutical University, Osaka, Japan, [2]Osaka Medical and Pharmacetuical University, Oasaka, Japan

Contact E-Mail Address: shancunchangda@gmail.com

Introduction: In the case that tract dilation fails using the initially selected dilation device during EUS-guided hepaticogastrostomy (HGS), it should be re-attempted using another device. However, switching the device has the disadvantages of prolonged procedure time and sudden loss of the correct axis, and it is therefore highly desirable that the initial tract dilation is successful. Recently, a novel drill dilator has recently become available in Japan. However, comparison study between this device and other has been not reported as initial dilation technique. Here we describe the technical feasibility of this device for use during EUS-HGS, and compared with balloon catheter.

Aims & Methods: This retrospective study included patients who underwent EUS-HGS using SEMS between October 2021 and October 2022. Patients who developed bleeding associated with EST were enrolled. Excluded from the study were patients who underwent EUS-HGS using a plastic stent or stent deployment without tract dilation.

Results: A total of 49 patients were enrolled, of whom 19 underwent EUS-HGS using the drill dilator and 30 underwent EUS-HGS using a balloon catheter. EUS-HGS using the drill dilator initially was performed mainly by non-expert hands (n=19), whereas non-expert hands performed few procedures in the balloon catheter group (n=2) (P<0.0001). The initial tract dilation was successful in all patients in the drill dilator group (19/19, 100%) and in 29/30 (97%) in the balloon catheter group (P=0.4214). However, to insert stent delivery system, additional tract dilation was needed in 73.7% (14/19) of the drill dilator group.

On the other hand, stent delivery system insertion was successful in all patients of the balloon catheter group.

Conclusion: The novel drill dilator shows promise for initial dilation during EUS-BD. However, balloon dilation technique should be attempted first when deploying a dedicated metal stent using an 8.5Fr stent delivery system.

Disclosure: Nothing to disclose.

Introduction: Balloon dilation and plastic stent deployment have been performed as hepaticojejunostomy stricture (HJS) treatment techniques by PTBD or under DB-ERCP guidance. Although these techniques have shown favorable clinical results, the treatment period can be long because stent deployment is required.

In addition, HJS may recur even after treatment because the scar tissue itself remains. To overcome these challenges, we developed an transluminal antegrade piecemeal dilation technique (TAPD) for treating HJS.

The aim of this study was to evaluate the technical feasibility and safety of this technique in terms of the pre- and post-cholangioscopic findings.

Aims & Methods: This retrospective study included consecutive patients who were complicated with symptomatic HJS between November and February 2022. The primary outcome of this study was the technical success rate of TAPD using a drill dilator. Technical success was defined as resolution of the HJS, based on the cholangioscopic findings. The secondary outcome was adverse events associated with TAPD such as bleeding or perforation.

Results: TAPD was attempted at around 11 days after EUS-HGS in 19 patients. Among the 19 patients, passage of the guidewire across the HJS into the intestine was unsuccessful in 4 patients, and the technical success rate of this procedure was 78.9%. TAPD was successful in all 15 patients in whom passage of the guidewire was achieved. After TAPD, cholangioscopy identified no bleeding or perforation in any patient. During the follow-up period, no recurrence of HJS was observed in any patient who underwent TAPD.

Conclusion: In conclusion, TAPD appears to be technically feasible and safe. Although it is necessary to conduct a randomized trial in comparison with other methods, with long-term follow up, TAPD may be a useful option for the treatment of HJS.

Disclosure: Nothing to disclose.

Contact E-Mail Address: delsa.hanane@gmail.com

Introduction: The concept of Macroscopic on-site evaluation (MOSE) was introduced in 2015 when the endoscopist observed better diagnostic yield when the macroscopically visible core on MOSE was superior to 4 mm.

Few studies have assessed the adequacy of histologic cores in MOSE during endoscopic ultrasound-guided fine-needle aspiration/biopsy (EUS-FNA/FNB). Recently, some classifications were published.

Aims & Methods: Our study aimed to evaluate the MOSE of EUS-FNA/FNB using 2 classifications to determine the adequacy of the histologic core specimens.

This multicentric prospective study conducted in 5 centers in 2 countries (Egypt and Morocco) included 312 patients with pancreatic, biliary, or gastrointestinal pathology who were referred for EUS examination. Data from patients with MOSE evaluation of the specimen were collected.

Results: The mean age of the 312 patients was 60 ± 12 years and 172 patients (55%) were males. The mean lesion size was 38.2 ± 18.7 mm. 323 lesions were biopsied, of which 213 were pancreatic lesions (62%). Needle types used were Franseen (Acquire) (n=258, 82.7%) and Procore (n=6, 2%) needles for EUS-FNB and Expect (n=28, 9%) and Echotip (n=20, 6.4%) needles for EUS-FNA. The needle sizes used during the procedures were 22G (95.8%), 20G (2%), and 19G (2.2%).

The median number of needle passes was 1.76 [1, 4]. 305 of 312 samples (97.8%) were considered adequate for histological evaluation by the endoscopist. 3 patients presented small blood collection (1%).

The overall diagnostic yield of cytopathology was 95%. The cytological examination confirmed the diagnosis of adenocarcinoma in 147 patients (64.2%).

Conclusion: MOSE in EUS-FNA/FNB sampling showed high diagnostic yield and accuracy using different needle sizes. In our study, MOSE helped the endoscopist to improve the quality of the core and, if necessary, to multiply the needle passes. This resulted in a high diagnostic yield for cytopathology.

Introduction: Recently, in endoscopic ultrasound-guided biliary drainage (EUS-BD), combinations of a 22-gauge (G) needle and a 0.018-inch guidewire (GW) has been used for small diameter duct. However, the 0.018-inch GW has low stiffness, which sometimes makes subsequent procedures difficult.

Aims & Methods: The aim of this study was to investigate the efficacy of a new 3F dilator in EUS-BD with a 22-G needle. Between December 2021 and March 2023, the 3F dilator was used in five patients, who underwent EUS-BD with a 22-G needle at our institution. EUS-rendezvous technique was used in four patients, and the puncture site was the extrahepatic bile duct via the second portion of the duodenum in pull position in 1 patient, the extrahepatic bile duct via the first portion of the duodenum in push position in 1 patient, and the left intrahepatic duct via stomach in 2 patients. In one patient, EUS-hepaticogastrostomy was performed. The purpose of the use and its success or failure were examined.

Results: In four patients with EUS-rendezvous technique, a 0.018-inch GW could not pass through the papilla due to low stiffness of the GW, and insertion of a 3F dilator was attempted to reinforce the GW stiffness. The 3F dilator was successfully inserted and it required dilation of puncture route by repeated needle pass under GW placement. Of four patients, insertion of the 3F dilator increased the stiffness of the GW and resulted in successful passage of the papilla in 3 patients; one patient required replacement with a 0.025-inch GW. No biliary peritonitis from puncture route was observed. In one patient with EUS-hepaticogastrostomy, insertion of the 3F dilator to replace a 0.025-inch GW failed to pass through the rigid bile duct wall despite repeated needle pass of bile duct under GW placement. After dilation with a spiral dilater, a 3F dilater could be inserted and successfully replaced with a 0.025-inch GW.

Conclusion: In EUS-BD with a 22-G needle, a 3F dilator is effective for reinforcement of a 0.018-inch GW stiffness and replacement with a 0.025-inch GW.

Disclosure: Nothing to disclose.

Introduction: EUS-guided choledochoduodenostomy (EUS-CDS) is a minimally invasive procedure used to treat malignant biliary obstruction (MBO) by the transduodenal placement of a lumen-apposing metal stent (LAMS) into the extrahepatic bile duct. In order to identify the factors that contribute to safe and effective EUS-CDS procedures using LAMS we performed a systematic review of the literature with meta-analysis.

Aims & Methods: The methodology of our analysis was based on PRISMA recommendations. Electronic databases (Medline, Scopus, EMBASE) were searched up to November 2022. Full articles including patients with distal malignant biliary obstruction who underwent EUS-CDS using LAMS after failed ERCP were eligible. Technical success, clinical success, and adverse events were pooled by means of a random model. Multivariate meta-regression and subgroup analysis were performed to assess the correlation between outcomes and different variables.

Results: Twelve studies with 845 patients were included in the meta-analysis. Pooled technical and clinical success rates were 96% (95%CI: 94%-98%; I2=52.29%) and 96% (95%CI: 95%-98%), respectively, with no significant association with baseline characteristics, such are sex, age, common bile duct (CBD) diameter and stent size. The pooled AE rate was 12% (95%CI: 8%-16%; I2=71.62%). The AE rate was significantly lower when using an 8x8mm stent as compared to a 6x8 mm LAMS (OR 0.59, 0.35-0.99; p=0.04), with no evidence of heterogeneity (I2=0%).

Conclusion: EUS-CDS with LAMS is confirmed to be a safe and effective option for relief of MBO. The selection of appropriate stent size is crucial for achieving optimal outcomes.

Disclosure: Nothing to disclose.

Contact E-Mail Address: ai.voferreira@gmail.com
Introduction: Endoscopic ultrasound (EUS) is an important tool for the evaluation of patients with common bile duct (CBD) dilation without obvious identified aetiology after ultrasonography (US), computed tomography (CT) and/or magnetic resonance cholangiopancreatography (MRCP).
Aims & Methods: The aim of this study was to evaluate the diagnostic performance of EUS for CBD dilation in patients with a negative initial study.
Retrospective, unicentric and cohort study including patients who underwent EUS for CBD dilation (diameter ≥7mm if intact anatomy or ≥10mm if prior cholecystectomy) in the absence of obvious pathology on prior imaging, including US, CT and/or MRCP, from January 2016 until June 2022. All EUS procedures were performed with a linear echoendoscope.
Results: Totally, 109 patients were included, 50 patients without symptoms or altered liver biochemistry (45.9%). Among the 41 patients with positive EUS, 33 patients had choledocholithiasis (30.3%), 6 chronic pancreatitis (5.5%) and 2 had ampullary cancer (1.8%). Older age was associated with positive EUS (median 79 vs 71 years, p=0.030). Patients with jaundice, cholelithiasis and altered liver biochemistry were 16.2 (p=0.002), 3.1 (p=0.024) and 2.9 (p=0.009) times more likely to have positive EUS, respectively.
A total of 53 patients underwent MRCP with a negative result (48.6%). In this group, 12 patients had a positive EUS, 10 had choledocholithiasis (18.9%) and 2 had chronic pancreatitis (3.8%). Of those, patients with abdominal pain and jaundice were 15.4 (p<0.001) and 20.0 (p=0.007) times more likely to have positive EUS, respectively. CBD diameter in MRCP was not associated with finding a causative lesion (p=0.473).
Considering only asymptomatic patients without altered liver biochemistry, CBD diameter ≥8.5mm, evaluated by CT, had a sensibility of 100% and specificity of 75% in predicting a positive EUS (AUC 0.734, p=0.048).
Conclusion: EUS is a useful diagnostic method for patients with unexplained CBD dilation, with a higher yield, even in patients with negative MRCP, and especially in patients with older age, symptoms such as abdominal pain and jaundice, cholelithiasis and/or altered liver biochemistry. CBD diameter evaluated by CT had a moderate discriminative ability in predicting a positive EUS in asymptomatic patients without altered liver biochemistry.
Disclosure: Nothing to disclose.

Introduction: EUS-guided gallbladder drainage (EUS-GBD) is superior to the percutaneous route for patients at high surgical risk with acute cholecystitis, but no data is available outside the acute setting. Our aim was to evaluate safety and effectiveness of elective endoscopic gallbladder treatment (EEGBT) in patients at high surgical risk with benign gallbladder diseases.
Aims & Methods: We retrospectively analyzed consecutive cases of EEGBT performed with EC-LAMS in 9 tertiary care centers over 24-months, in patients indicated for cholecystectomy with benign gallbladder diseases at high surgical risk. Study outcomes were adverse event(AE) rates, technical and clinical success rate and need for additional intracholecystic procedures.
Results: Overall, 44 patients were included in the study. Mean age was 76.4±12.3 (years, SD), male/female ratio 21/23, Charlson Comorbidity Index ≥5 in 68% of patients. The most frequent indication to EEGBT was gallstone related biliary cholic (43.2%). Technical and clinical success were both obtained in 100% of cases. EUS-guided LAMS implantation was achieved more frequently from the duodenum (72.7%), and the Hot-Axios was the preferred utilized stent (77.3%). AEs were observed in 3/44 patients (6.8%). No EEGBT-related deaths were observed. Intracholecystic litothripsy was required in 6 patients (13.9%). Mean hospital stay was 5 days (SD±12).
Conclusion: EEGBT has high technical and clinical success rates and a high safety profile. Prospective studies to standardize procedural protocol are needed.
Disclosure: Nothing to disclose.

IS THE ANESTHESIOLOGIST STILL NEEDED FOR ENDOSCOPIC ULTRASOUND-GUIDED GALLBLADDER DRAINAGE?

A. Cominardi[1], G. Comparato[1], C. Gaetano[2], G. Aragona[1]
[1]Ospedale Guglielmo da Saliceto di Piacenza, Gastroenterology and Digestive Endoscopy Unit, Piacenza, Italy, [2]Ospedale Guglielmo da Saliceto di Piacenza, General Surgery Unit, Piacenza, Italy

Contact E-Mail Address: annacomi26@gmail.com
Introduction: Endoscopic ultrasound-guided gallbladder drainage is usually reserved for high surgical risk patients. The procedure was usually performed under deep sedation to ensure the best tolerability for the patient and facilitate the endoscopist's performance.
However, many of them showed a high-risk even for deep sedation.

Aims & Methods: Our aim was to evaluate the safety and efficacy of EUS-GBD under conscious sedation (CS).

All consecutive EUS-GBD under CS performed in our hospital were prospectively enrolled from January 2020 to December 2022.

Patient characteristics, type and dosage of anesthetic drug administered (Fentanyl (FNT), Pethidine (PTD) or Benzodiazepine (BZD)), size of lumen-apposing-metal-stent (LAMS), gallbladder (GB) access, technical success, clinical success, early and late adverse events (AEs) rate were evaluated. Safety was defined as AEs occurrence. The efficacy of EUS-GBD was expressed as technical and clinical success. We defined as "conscious sedation" a drug-induced depression of consciousness during which patients respond to verbal commands or react to touch. Breathing remains intact and no support is needed.

Results: A total of 49 patients (41.7% male, mean age 82,9±10 years-old) underwent EUS-GBD under in our Unit. Among all the 49 EUS-GBD in CS, 47 (95.9%) were indicated as treatment for acute cholecystitis in high-surgical-risk patients and 2 (4.1%) as rescue-strategy after ERCP fail.

In 45 (91.8%) EUS-GBD a 10x10mm LAMS was deployed, in 3 (6.2%) procedures a 15x10mm and in 1 (2%) an 8x8mm LAMS. GB was accessed from the duodenum in 68.8% of cases.

A combination of PTD+BZD was administered in 29 (59.2%) EUS-GBD, while 18 (36.7%) procedures were performed under FNT+BZD. Only 2 (4.1%) EUS-GBD were performed only under BZD.

Mean FNT, PTD, BZD dose were 50(±11.5) mcg, 38.4(±25.6) mg and 4(±1.5) mg, respectively.

Technical success of EUS-GBD under CS was 97.9%. In one procedure the distal flange of the LAMS did not open due to LAMS malfunction. The clinical success of EUS-GBD under CS was 97.9% since in one procedure there was not a decrease of inflammatory, cytolysis and cholestasis indices. Only in 1 (2%) EUS-GBD an early AE was reported. No late AEs were described.

The statistical analysis showed that the administration of a combination of fentanyl and benzodiazepine or a combination of pethidine and benzodiazepines or the administration of only benzodiazepines affected neither technical nor clinical success, nor AEs rate (Table 1).

	PTD+BZD	FNT+BZD	BZD
Technical success	*p*=0.4014	*p*=0.4413	*p*=0.8349
Clinical success	*p*=0.3930	*p*=0.4337	*p*=0.8331
Adverse events	*p*= 0.2237	*p*=0.1846	*p*=0.8349

Conclusion: EUS-GBD under CS was a safe procedure with a low AEs rate. The administration of FNT+BZD, PTD+BZD or BZD alone did not affect procedure outcome.

Disclosure: Nothing to disclose.

Introduction: Endoscopic ultrasound-guided gallbladder drainage (EUS-GBD) was not always technically feasible. The distance between the gallbladder (GB) and the gastrointestinal wall and the GB distension were some of the limiting factors to the EUS-GBD.

Aims & Methods: Our study aim was to evaluate abdomen computed tomography (CT) predictors of EUS-GBD technical success (TS).

The CT images of all consecutive patients that underwent EUS-GBD from January 2020 to December 2022 in our hospital were retrospectively evaluated.

CT data collected were: artifacts presence, days between CT and EUS-GBD, slice thickness, region of interest (ROI) density, GB morphology, GB long and short axis, sludge, stones presence, size, location and density, distance between GB and antrum or duodenal bulb, GB wall thickness and peri-GB fluid presence.

EUS-GBD data evaluated were: type and size of stent, TS and clinical success.

Results: We evaluated 45 abdomen CTs of patients that underwent EUS-GBD (male 60%, mean age 81.3±10.5 years old).

The mean time between CT and EUS-GBD was 4±4 days. EUS-GBD was performed via duodenal bulb in 29 (64.4%) cases.

Mean GB short and long axis length were 42.1±11.4 and 103.4±28.7 mm, respectively.

Mean CT distance between GB and stomach or duodenal bulb were 14.8±12.9 and 10.8±10.6 mm, respectively. Stones were found in 22 (48.9%) GB with mean size of 14.9±4.5 mm. Sludge was described in 23 (51.1%) cases. On univariate analysis, CT distance between GB and duodenal bulb, GB wall thickness and GB short axis length were significantly related to EUS-GB TS, but only CT distance between GB and duodenal bulb and GB wall thickness were an independent predictor of EUS-GBD TS at multivariate analysis.

	UNIVARIATE ANALYSIS			MULTIVARIATE ANALYSIS		
	Odds Ratio	95% CI	P value	Odds Ratio	95% CI	P value
Min distance gastric antrum-GB (mm)	0.94	0.88-1.00	0.089	-	-	-
Min distance duodenal bulb-GB (mm)	0.83	0.70-0.97	0.027	0.70	0.49-0.99	0.046
GB wall thickness (mm)	0.67	0.44-1.02	0.048	0.28	0.09-0.86	0.027
GB long axis (mm)	1.03	0.98-1.08	0.122			
GB short axis (mm)	1.12	0.99-1.28	0.069	1.38	0.97-1.96	0.070
Duodenal access vs gastric (n)	9.45	0.94-94.48	0.055	-	-	-
Stones presence (n)	3.78	0.38-37.2	0.253	-	-	-
Perivisceral fluid (n)	1.14	0.17-7.66	0.890	-	-	-

Conclusion: Pre-EUS-GBD CT may be a useful tool to predict EUS-GBD TS, especially the TC measurement of the distance between the GB and the duodenal bulb and GB wall thickness.

Disclosure: Nothing to disclose.

PP1500

USEFULNESS OF DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING FOR DIAGNOSING GALLBLADDER MALIGNANCY

S. Nihei[1], K. Hosono[2], A. Nakajima[3]
[1]Yokohama City University, Yokoyama, Japan, [2]Yokohama City University Hospital, Department of Gastroenterology and Hepatology, Yokohama, Japan, [3]Yokohama City University Hosp. Dept. of Gastroenterology, Dept. of Gastroenterology, Yokohama, Japan

Contact E-Mail Address: helshin64@gmail.com

Introduction: Ultrasonography (US), computed tomography (CT), magnetic resonance imaging (MRI), endoscopic ultrasonography (EUS), and fluorine-18 fluorodeoxyglucose positron emission tomography (FDG-PET) are widely used to evaluate gallbladder disease.

However, there are some cases difficult to diagnose even with those modalities. In recent years, the image quality of diffusion-weighted imaging (DWI) has improved with the development of MRI systems. The usefulness of DWI for gallbladder disease has been reported in several studies. PET has some limitations, such as high cost, radiation exposure, and influence by blood glucose levels. The purpose of this study was to compare the usefulness of DWI with PET in the diagnosis of gallbladder disease.

Aims & Methods: Forty-two patients who underwent preoperative DWI and PET for gallbladder disease were included. The final diagnosis was made histologically on excised specimens. Of the 42 patients, 24 had malignant conditions (23 had gallbladder cancer, and 1 had neuroendocrine cancer), and 18 had benign conditions (9 had chronic cholecystitis, 3 had adenomyomatosis, 4 had polyps, 1 had gallbladder adenoma, and 1 had xanthogranulomatous cholecystitis). We evaluated the accuracy of DWI and the apparent diffusion coefficient (ADC) value of each disease.

Results: The sensitivity of DWI and PET was 88% vs 88% ($p = 1.0$), the specificity was 61% vs 56% ($p = 0.56$), and the accuracy was 76% vs 74% ($p = 0.56$), showing no significant difference. The mean ADC value of malignant diseases was (1.71±0.29) × 10-3mm2/s, and that of benign diseases was (2.33±0.36) × 10-3mm2/s ($p < 0.001$). The mean ADC value of malignant diseases was significantly lower than that of benign diseases.

Conclusion: In this study, DWI had a similar accuracy compared to PET. DWI compensates for the limitations of PET and can be performed in a more noninvasive manner. The combined use of DWI and ADC was suggested to contribute to the improvement of the diagnostic capability for gallbladder diseases.

Contact E-Mail Address: yamaguchi.atsushi.uc@mail.hosp.go.jp

Introduction: Endoscopic nasobiliary drainage is accompanied by a risk of accidental removal of the nasobiliary drainage (NBD) tube, especially through self-removal in elderly patients. UMIDAS NB stent (Olympus, Tokyo, Japan), hereafter referred to as UMIDAS, is an integrated plastic stent (PS) and NBD catheter system. In UMIDAS, the PS stays in the same place to maintain biliary drainage when the NBD tube is removed. Thus, UMIDAS has been developed to reduce endoscopic procedures following biliary drainage.

We speculated that UMIDAS can be a safety net in accidental NBD tube deviation for acute cholangitis and obstructive jaundice. Therefore, we prospectively observed and reported the efficacy and disadvantages of UMIDAS (UMIN000047515).

Aims & Methods: From April to November 2022, we placed a UMIDAS NB stent in 30 patients with acute cholangitis or obstructive jaundice. We evaluated the plastic stent (PS) position at the time of accidental stent removal and before the planned endoscopic procedure. In addition, we studied the ratio of successful biliary drainage and complications based on the usage of UMIDAS.

Results: In this study, 19 planned NBD tube removals and 11 accidental removals were included. Among the 11 accidental removals, 4 were self-removal, 2 were accidental deviation to the intestine, and 5 were long period to next procedure. All 11 patients with accidental NBD tube removal showed a correct PS position after NBD tube removal.

Of the 19 patients with planned NBD tube removal, 15 had a correct PS position, 2 had complete migrations into the common bile duct (Figure 5a), and 2 had incomplete migrations (the migration of the duodenal side flap only) before NBD tube removal.

After removal, 13 patients had a correct PS position, 3 had complete migration of PS, and 3 had incomplete migration of PS. Of the 30 patients with UMIDAS, 24 (80%) had a correct PS position after NBD tube removal (27 (90%) if including incomplete migration). All patients with UMIDAS had successful biliary drainage, including patients with accidental removal of NBD, and had no complications.

Conclusion: The UMIDAS NB stent might be useful for biliary drainage in patients with a high risk of NBD tube self-removal.

Disclosure: Nothing to disclose.

SAFETY AND EFFICACY OF ANTIMIGRATION FULLY COVERED METAL STENT IN DIFFICULT COMMON BILE DUCT STONE: A RETROSPECTIVE STUDY

M. Dalla Libera[1], M. Valvano[1], M. Campanale[1], E. Giambruno[1], A. Montale[1], G. Stefanelli[1], A. Allegretti[1], P. Romagnoli[1], M. Oppezzi[1]
[1]*Ente Ospedaliero - Ospedali Galliera, Genova, Italy*

Contact E-Mail Address: mauro.dalla.libera@galliera.it

Introduction: The endoscopic retrograde cholnagio-pancreatography (ERCP) with endoscopic sphincterotomy results in a complete bile duct stones (CBDSs) clearance in about 80-90%. However, in case of incomplete CBDSs clearance, an endoprosthesis could be placed. A plastic stent is commonly used, with a success rate after a previous ERCP, ranging from 44% to 96%.

However, there are no comparative studies between plastic and metal stent. Moreover, data concerning the safety and efficacy of antimigration Fully covered Metal stents – flare type (aFCMS) are lacking.

Aims & Methods: In this single-center retrospective study we collected data concerning all patients who underwent ERCP with antimigration metal stent placement for incomplete removal of CBDSs between January 2021 to January 2023. All patients were contacted in order to program stent remotion within 3-6 months (considering their general clinical condition) or to evaluate their clinical status. We aim to estimate the incidence of migration rate, and adverse events, and complete biliary clearance after 3-6 months from the index ERCP.

Results: Out of 34 patients included patients, 20 underwent a second ERCP after a median of 164 (±78) days. The reasons for the lack of a second ERCP evaluation are reported in the table. In 11/20 (55%) a distal migration occurred.

Only one proximal migration was reported. Among the 34 included patients only one presented a clinical recurrence linked to the proximal migration of aFCMS. 19/20 patients achieved a complete clearance after the second ERCP. No serious adverse events were reported.

Conclusion: The aFCMS represents an effective and safe therapeutic chance in case of incomplete CBDSc clearance in particular in case of difficult CBDSs. Moreover, the very low incidence of stent proximal migration makes this device particularly useful in the case of this clinical condition.

PROPENSITY SCORE MATCHING ANALYSIS FOR CLINICAL IMPACT OF BRAIDED- VERSUS LASER-CUT-TYPE COVERED SELF-EXPANDABLE METAL STENTS FOR EUS-GUIDED HEPATICOGASTROSTOMY

S. Ueno[1], T. Ogura[1], H. Nishikawa[1]
[1]*Osaka Medical and Pharmaceutical University, Endoscopy Center, Takatsukishi, Japan*

Contact E-Mail Address: onchannopasocon@yahoo.co.jp

Introduction: To prevent stent migration during EUS-HGS, intra-scope channel release technique is important, but are unfamiliar to non-expert hands. The self-expandable metal stent (SEMS) is an additional factor to prevent stent migration. However, no comparative studies of laser-cut and braided types during EUS-HGS have been reported.

Aims & Methods: The aim of this study was to compare the distance between the intrahepatic bile duct and stomach wall after EUS-HGS among laser-cut- and braided-type SEMS. To evaluate stent anchoring function, we measured the distance between the hepatic parenchyma and stomach wall before EUS-HGS, one day after EUS-HGS, and 7 days after EUS-HGS. Also, propensity score matching was performed to create a propensity score for using Laser cut type group and Braided group with a logistic regression model.

Results: A total 144 patients were enrolled in this study. Among them, 24 patients underwent EUS-HGS using a laser-cut-type SEMS, and 118 patients underwent EUS-HGS using a braided-type SEMS. EUS-HGS using the laser-cut-type SEMS was mainly performed by non-expert endoscopists (n=21).

However, EUS-HGS using braided-type SEMS was mainly performed by expert endoscopists (n=98), showing a significant difference. The distance after 1 day was significantly shorter with the laser-cut-type group (2.91 ± 1.88 mm) compared with the braided-type group (8.19 ± 6.07 mm). In addition, this distance remained significantly shorter in the laser-cut type group compared with the braided-type group after 7 days.

Although these results were similar after propensity score matching analysis, the distance between hepatic parenchyma and stomach after 7 days was increased 4mm compared with the distance after 1 day in Braided group. On the other hand, in Laser cut type group, the distance after 1 day and 7 days was almost same.

Conclusion: In conclusion, EUS-HGS using a laser-cut-type SEMS may be safe to prevent stent migration, even in non-expert hands, compared with a braided-type SEMS, although a randomized trial is warranted.

PALLIATIVE TREATMENT WITH STENTS IN PATIENTS WITH UNRESECTABLE TYPE III AND IV MALIGNANT HILAR BILIARY OBSTRUCTION: A PERCUTANEOUS VERSUS ENDOSCOPIC APPROACH

G. Wang[1], X. Fu[2], H. Shan[1], F. Gao[2]
[1]*Sun Yat-sen University Cancer Center, Endoscopy, Guangzhou, China,* [2]*Sun Yat-sen University Cancer Center, Minimally Invasive & Interventional Radiology, Guangzhou, China*

Contact E-Mail Address: wanggb@sysucc.org.cn

Introduction: Various types of cancer can cause malignant hilar biliary obstruction(MHBO) by direct infiltration or external compression of the biliary tract, mainly including cholangiocarcinoma, hepatocellular carcinoma, pancreatic carcinoma et.al. At the time of the onset of clinical performance, only 10%-20 % are suitable candidates for surgical resection or liver transplant. For inoperable cases complicated with jaundice, biliary drainage has been accepted as the preferred palliative modality. Endoscopic biliary drainage may be more suitable for bismuth type I and II (tumour below or confined to the hilum) MHBO based on its less invasive than percutaneous approach. However, for bismuth type III and IV (tumour extension into the right and left hepatic) tumours, the preferred approach remains uncertain.

Although most existing observational data indicated that percutaneous drainage might be easier to achieve effective drainage outcome without increasing procedure-related complications, an RCT compared the above two approaches in perihilar CCA was terminated due to higher mortality in the percutaneous group. A recent RCT also failed to compare the two approaches as the primary intervention in patients with MHBO. This fundamental question remains uncertain in clinical practice. Most of the existing studies included type II hilar stricture cases. Studies mainly focusing on type III and type IV cases are rare. Thus, the purpose of the current study was to compare these two approaches in terms of the short and long-term clinical outcomes of biliary decompression in unresectable cancer patients with type III and IV MHBO.

Aims & Methods: A comprehensive search was conducted in our database between January 1, 2014, and October 31, 2021. A total of 365 inoperable cancer patients with biliary obstruction who received biliary stent implan-

tation percutaneously or via endoscopic retrograde cholangiopancreatography (ERCP) as primary biliary intervention were reviewed. Eventually, Sixty-six unresectable cancer patients with bismuth type III and IV MHBO were retrospectively included in this study. The clinical outcomes of the included patients were compared concerning their effective drainage and complications. Both clinical and treatment factors that affect median overall survival (mOS) were analyzed.

Results: Successful biliary drainage was achieved in 44 patients (66.7%), and the successful drainage rate was significantly higher in the percutaneous group than in the endoscopic group (80% vs 55.5%, respectively, p = 0.036). Patients who received successful biliary drainage had a longer mOS than those who received unsuccessful biliary drainage (8.9 months vs. 2.3 months, p =0.025). Patients who received sequential anticancer therapy had a longer mOS than those who only received the best supportive care (11.6 months vs. 2.3 months, p <0.001). In the multivariate analysis, successful biliary drainage (p =0.023), and anticancer treatment (p <0.001) were significant favorable prognostic factors that affected patients' survival.

Conclusion: In summary, for inoperable cancer patients with bismuth III or IV MHBO, the percutaneous method seemed safe and effective in decreasing bilirubin in this study, although it might be hard to conclude that percutaneous stent implantation should be recommended as the first intervention in cancer patients with type III and IV MHBO cases. Effective drainage may create chances for unresectable cancer patients to receive anticancer treatment which may help to prolong survival. More well-designed randomized controlled trials are needed to verify our results.

Introduction: Hemobilia can be caused by various reasons and can cause lethality in case of unsuccessful hemostasis. The management of hemobilia is often cumbersome and there were few effective treatment modalities for hemobilia from above papilla.

Recently, endoscopic hemostasis showed promising efficacy with the advent of hemostatic modalities including self-expandable metal stent (SEMS).

Aims & Methods: In this study, we tried to evaluate the association between successful endoscopic hemostasis for hemobilia from above papilla and other clinical factors. Patients who underwent CT angiography, diagnostic or therapeutic angiography in addition to ERCP in Seoul National University Hospital from July 2008 to May 2022 were included. Patients with extra-biliary origin bleeding and post-endoscopic sphincterotomy bleeding were excluded. The primary outcome was successful endoscopic hemostasis, and the secondary outcome were delayed bleeding, 28-day mortality, amount of blood transfusion and hypovolemic shock.

Results: A total of 28 patients were include. A total of 21 patients received endoscopic hemostasis procedure as initial hemostasis, 7 patients received arterial embolization as initial hemostasis. In initial endoscopic hemostasis group, plastic stent, fully covered SEMS, and uncovered SEMS were used in 11, 8, and 2 patients, respectively. The overall success rate of primary endoscopic hemostasis was 85.7% (18 of 21).

The success rate of endoscopic hemostasis were 80% (8 of 10) for SEMS, 90.9% (10 of 11) for plastic stent. Among 3 patients who failed endoscopic hemostasis, 2 patients had become hemodynamically unstable in endoscopy room and underwent successful rescue transarterial embolization without delay. In initial arterial embolization group, the success rate of hemostasis was 100% (7 of 7).

	Overall (n=28)	Endoscopic Hemostasis (n=21)	Embolization (n=7)	P value
1st Hemostasis success	25 (89.3%)	18 (85.7%)	7 (100%)	0.551
1st Hemostasis method	-	fc-SEMS : 8 uc-SEMS: 2 Plastic stent : 11	Coil and glue : 2 Glue and PVA : 1 Coil : 2 Glue : 1 PVA : 1	-
Delyed bleeding	9 (32.1%)	7/18 (38.9%)	1/7 (14.3%)	0.362
RBC transfusion (Pack, mean, SD)	4.86 (4.704)	4.19 (4.045)	6.86 (6.230)	0.199
Hypovolemic shock (Vasoactive drugs)	8 (28.6%)	5 (23.8%)	3 (42.9%)	0.371

fc-SEMS: fully covered-Self expandable metal stent, uc-SEMS: uncovered-Self expandable metal stent , PVA: Polyvinyl alcohol
SD: standard deviation

Conclusion: Endoscopic hemostasis using SEMS may allow patients with hemobilia from above papilla to receive transarterial embolization under more stable status while ensuring a certain level of successful hemostasis for selected patients and by experienced endoscopists.

Disclosure: Nothing to disclose.

OUTCOMES OF ENDOSCOPIC GALLBLADDER DRAINAGE IN HIGH-RISK PATIENTS WITH ACUTE CHOLECYSTITIS: ENDOSCOPIC GALLBLADDER STENTING VERSUS ENDOSCOPIC ULTRASOUND-GUIDED GALLBLADDER DRAINAGE

Y. Kawakami[1], Y. Masaki[1], A. Takizawa[2], T. Nakamura[1], T. Hirano[1], K. Wagatsuma[1], H. Nasuno[2], K. Ishigami[1], A. Murota[1], H. Wakasugi[2], K. Suzuki[2], H. Nakase[1]

Introduction: Emergent cholecystectomy is recommended for acute cholecystitis (AC). However, cholecystectomy is occasionally difficult in high-risk surgical patients with any comorbidities. Therefore, endoscopic gallbladder drainage is a promising alternative to cholecystostomy. There are two methods for endoscopic gallbladder drainage as follows: endoscopic gallbladder stenting (EGBS) and endoscopic ultrasound-guided gallbladder drainage (EUS-GBD). However, there are limited data comparing the clinical outcomes of treatment with EGBS and EUS-GBD.

Aims & Methods: This study aims to compare the efficacy and safety of EGBS and EUS-GBD in high-risk surgical patients with AC. We retrospectively reviewed high-risk surgical patients with AC who underwent EGBS or EUS-GBD between April 2012 and March 2022 at two centers. 41 patients (22 men and 19 women; mean age, 82±8 years) underwent EGBS, and 13 patients (6 men and 7 women; mean age, 83±8 years) underwent EUS-GBD.

The primary endpoints were technical and clinical success for both methods of endoscopic gallbladder drainage. The secondary endpoints were the rate of recurrent cholecystitis and adverse events (AEs).

Results: The technical success rates in the EGBS group and the EUS-GBD group were 93% (38/41) and 100% (13/13), respectively (p = 0.32). The conversion of EGBS to percutaneous transhepatic gallbladder drainage or EUS-GBD was performed in three patients.

The clinical success rates in the EGBS group and the EUS-GBD group were 100% (38/38) and 92% (12/13), respectively (p = 0.08). The median stent patency durations in clinically successful cases in the EGBS group and the EUS-GBD group were 597 days (range, 28-2251 days) and 345 days (range, 36-907 days), respectively (p = 0.377).

The recurrence rate in the EGBS group was 21% (8/41; cholecystitis in 3 cases and cholangitis in 5 cases) with the successful management of these eight cases by endoscopic re-intervention, while the recurrence rate in the EUS-GBD group was 0% (0/13). AEs in the EGBS group and the EUS-GBD group were 10% (4/41; mild pancreatitis in 3 cases and cystic duct injury in 1 case) and 8% (1/13; suffocation due to aspiration), respectively (p = 0.82).

Conclusion: Both EGBS and EUS-GBD were useful as permanent drainage in high-risk surgical patients with AC, although there was a tendency that patients treated with EGBS had a higher recurrence rate of cholecystitis than those treated with EUS-GBD.

PORTAL VEIN FLOW BY DOPPLER ULTRASONOGRAPHY AS A PREDICTOR FOR SUCCESSFUL ENDOSCOPIC BILIARY DRAINAGE IN MALIGNANT

Y. Myung[1]

[1]Catholic Kwandong University International St. Mary's Hospital, Gastroenterology, Incheon, South Korea

Contact E-Mail Address: dittomyung@gmail.com

Introduction: Hilar cholangiocarcinoma patients often require biliary drainage, but objective tools for assessing the effectiveness of endoscopic biliary drainage are unsatisfactory. Studies have shown that biliary obstruction can reduce hepatic blood flow.

Aims & Methods: The aim of this study was to analyze changes in portal vein flow after endoscopic biliary drainage and evaluate the correlation between portal vein flow and liver function.

A prospective study enrolled 14 patients who underwent endoscopic stenting for hilar cholangiocarcinoma between September 2021 and June 2022. Portal vein velocity (Vmax) by Doppler ultrasonography and bilirubin level were assessed on all patients before and on the 1st, 3rd, and 14th days after endoscopic drainage. The patients were divided into two groups based on the success of drainage, with 11 patients in Group A (successful) and 3 in Group B (unsuccessful).

Results: The mean Vmax was 14.3 ± 2.5 cm/s before endoscopic drainage and 16.4 ± 3.3 cm/s, 18.0 ± 3.6 cm/s, and 20.8 ± 5.5 cm/s on the 1st, 3rd, and 14th day after drainage, respectively. The Vmax was significantly higher on each day following drainage compared to before (p<0.001). The rate of increase in Vmax was significantly higher in Group A than Group B on the 14th day (1.6 ± 0.48 vs 1.1 ± 0.13, P=0.03). The rate of increased Vmax correlated significantly with the rate of decreased serum bilirubin levels (r^2 = 0.407, P < 0.001).

Conclusion: Successful endoscopic biliary drainage in hilar cholangiocarcinoma significantly increased portal vein velocity (Vmax). Vmax assessment by Doppler ultrasonography may be a useful tool for evaluating the effectiveness of endoscopic biliary drainage in malignant hilar biliary obstruction.

Introduction: Stent placement by endoscopic retrograde cholangiopancreatography (ERCP) is one of the preferred methods for biliary drainage in unresectable malignant biliary obstruction. Nevertheless, clinical success of palliative drainage is not easy to predict, especially at the time of ERCP.

Aims & Methods: We conducted a multicentre retrospective cohort study in 3 centres in Portugal, involving patients with unresectable malignant biliary obstruction (UMBO) submitted to palliative ERCP-guided biliary stenting between 2015 and 2022.

This study aimed to evaluate clinical success of biliary drainage in our population, as well as to evaluate the performance of two recently developed and internally validated risk scores for predicting successful biliary drainage after ERCP-guided endobiliary stenting in UMBO, created by the group of Pausawasdi N. et al.

This group developed a first score for predicting early clinical success of biliary drainage (decrease ≥50% in total bilirubin (TB) levels within 2 weeks after stenting), using as variables the presence/absence of extrahepatic biliary obstruction, peritoneal carcinomatosis, the type of biliary stent (plastic or metallic) and pre-endoscopic alkaline phosphatase level.

The second score was developed to predict complete clinical success of biliary drainage (normalization of TB levels within 6 weeks after stenting) including pre-endoscopic TB levels, presence/absence of extrahepatic biliary obstruction and type of stent as variables. We included 217 patients for this study.

However, due to the limitations of a retrospective analysis, we could not evaluate the performance of these scores for all the patients of our cohort. Statistical analysis was performed using SPSS v.29.

Results: In our cohort, a decrease in total bilirubin (TB) levels ≥50% within 2 weeks after biliary stenting was reached in 81.9%(N=113) of the patients of a subpopulation of 138 patients in which these TB levels were available. TB normalization in 6 weeks after stenting occurred in 55%(N=72) of the cases from a subpopulation of 131 patients in which this TB level was measured. In our population, the predictive scores for early and complete clinical success had an AUROC of 0.597 (95% CI, 0.471-0.723; p = 0.13) and of 0.737 (95% CI, 0.650-0.825; p <0.001), respectively.

Conclusion: In our cohort, the predictive score for complete clinical success of biliary stenting in UMBO (at 6 weeks) had a good accuracy (AUROC 0.74), similar to the AUROC reported by this study group (AUROC 0.76 in the validation cohort).

The main advantage of this score relies on the fact that it can be applied before ERCP, since its variables can all be determined pre-endoscopically or, at the most, by the time of ERCP (type of stent), possibly allowing the definition of a better strategy for the management and follow-up of these patients.

Introduction: Anastomotic biliary strictures represent a significant burden after orthotopic liver transplantation, with challenging endoscopic treatment. The selection of the optimal approach regarding type of stents remains controversial due to the absence of strong evidence. The European Society of Gastrointestinal Endoscopy recommends stricture remodeling using multiple plastic stents (MPS),[1] whereas the American College of Gastroenterology supports the use of fully covered self-expandable metal stents (FC-SEMS),[2] as for every benign biliary stricture.

In the absence of cumulative comparisons and considering the development of intraductal SEMS (ID-SEMS), which are promising for this type of strictures, this systematic review with meta-analysis aimed to evaluate the potential differences in the performance of the available stents in post-transplant anastomotic biliary strictures management.

Aims & Methods: The systematic research was performed in MEDLINE, Cochrane, and Scopus databases until April 2023 for comparative studies evaluating the successful stricture management using MPS and SEMS, including FC-SEMS and ID-SEMS.

The primary outcome was stricture resolution after completion of therapy, documented by cholangiogram or cross-sectional imaging. Secondary outcomes included stricture recurrence (clinical and biochemical relapse with imaging confirmation) during the follow-up period, stent migration and adverse events.

Quality assessment was based on the Newcastle-Ottawa scale. Meta-analyses were based on random effects model and the results were reported as odds ratios (OR), with 95% Confidence Intervals (95%CI). Subgroup analyses by type of metal stent were performed to explore the diversity among the results of different studies.

Results: Nine studies with an overall number of 687 patients were included in our analysis, with three of them being randomized controlled trials. Metal stents were placed in 251 cases (82 ID-SEMS and 169 FC-SEMS) and MPS in 436. Considering the primary outcome, metal and plastic stents did not differ significantly in stricture resolution with OR: 0.99 (95%CI: 0.48-2.01; I^2=35%). Stricture recurrence and migration rates were also comparable between the two arms [OR: 1.71 (95%CI: 0.87-3.38; I^2=55%) and OR: 0.73 (95%CI: 0.32-1.68; I^2=56%) respectively].

All of these outcomes presented with moderate heterogeneity. Finally, the difference between adverse events rates was non-significant [OR: 1.47 (95%CI: 0.89-2.43; I^2=24%)]. Interestingly, in the subgroup analysis ID-SEMS provided significantly higher complete resolution rates with low heterogeneity compared to the MPS [OR: 3.48 (95%CI: 0.89-13.62; I^2=5%)], whereas the comparison between FC-SEMS and MPS did not reach significance [OR: 0.76 (95%CI: 0.42-1.39; I^2=11%)]. Relative recurrence rates did not differ between subgroups [for ID-SEMS vs MPS, OR: 1.01 (95%CI: 0.51-2.03; I^2=0%; for FC-SEMS vs MPS, OR:2.39 (95%CI: 0.87-6.56; I^2=66%)]. On the other hand, migration rates were significantly lower for ID-SEMS compared to MPS, with OR: 0.28 (95%CI: 0.11-0.70; I^2=0%), and equivalent for FC-SEMS and MPS [OR: 1.25 (95%CI: 0.54-2.88; I^2=40%)]. Complication rates were similar for ID-SEMS and MPS [OR: 0.90 (90%CI: 0.28-2.84; I^2=47%)], but their prevalence after FC-SEMS were significantly higher compared to MPS [OR: 1.76 (95%CI: 1.06-2.93; I^2=0%)].

Conclusion: The comparison between metal stents and MPS did not result to significant differences in any outcome. However, ID-SEMS appeared superior to MPS in stricture resolution and migration rates, whereas FC-SEMS provided comparable outcomes to MPS.

Introduction: Post-endoscopic sphincterotomy bleeding is an adverse event of endoscopic retrograde cholangiopancreatography (ERCP). In some patients, the hemorrhage can be severe, occurring during ERCP, and difficult to resolve by standard endoscopic techniques (e.g., injection, thermals or clips). Fully covered self-expandable metal stents (FC-SEMS) have been used to treat this complication. However, the studies are scarce, mostly with few patients, evaluating the efficacy and safety of these stents as a primary technique.

Aims & Methods: We aimed to evaluate the technical, clinical and safety success of using FCSEMS in the treatment of post-endoscopic sphincterotomy bleeding.

This was a retrospective cohort study, between September/2016 and April/2023, including all consecutive patients undergoing ERCP in which intra-procedural post-sphincterotomy bleeding occurred at our center. In all consecutive patients in whom active bleeding occurred FCSEMS were placed as primary therapy.

Outcomes:

1. Ttechnical success;
2. Clinical success (bleeding control);
3. Recurrence of bleeding (up to 7 days);
4. Adverse events. Descriptive and inferential exploratory analysis.

Results: FCSEMS were placed in 52 patients (38.5% male; median age 73 years (minimum 41-maximum 104), in a total of 3483 ERCP performed (2189 biliary sphincterotomy). Of the patients with bleeding, 21.2% (n= 11) were taking anticoagulants and 23.1% (n=12) were taking antiplatelet agents. The main indication for ERCP was lithiasis in 80.8% (n=42). Technical success and clinical success were 100%.

In 4 patients there was recurrence of bleeding after ERCP (7.7%); new ERCP was performed in 3 of these, and a new FCSEMS was placed in 1 patient. No patient died or required surgical or interventional radiology treatment. In 13 patients it was found that FCSEMS had migrated (25%) at the time of scheduled removal.

Conclusion: The placement of fully covered self-expandable metal stents during ERCP is an effective and safe treatment for the control of post-sphincterotomy bleeding, with a low recurrence rate.

PERCUTANEOUS CHOLECYSTOSTOMY AS A DEFINITIVE TREATMENT VERSUS BRIDGING TREATMENT BEFORE CHOLECYSTECTOMY FOR ACUTE CHOLECYSTITIS: A RETROSPECTIVE OBSERVATIONAL STUDY

J. Lau[1], S. Sinha[1], S. Andrews[1], K. Bowling[1], T. Platt[1], M. Kostalas[1], P. Christopoulos[1]

[1]Torbay Hospital, Upper Gastrointestinal Department, Torbay, United Kingdom

Contact E-Mail Address: joshua.lau@nhs.net

Introduction: Percutaneous Cholecystostomy (PC) is an effective treatment option for patients with acute cholecystitis (AC) who are too unwell, or too comorbid for surgery. However, guidelines and evidence for drain management and outcomes following PC insertion are limited. The aim of this study is to investigate the efficacy and mortality of PC in treating AC as a definitive treatment versus a bridging treatment before laparoscopic cholecystectomy (LC).

The study also aims to assess if certain patient factors including background comorbidity and presenting signs of organ dysfunction are predictive of PC outcomes at a district general hospital.

Aims & Methods: We retrospectively reviewed all patients that had been treated with PC for AC from February 2019 to November 2022. Data collected included patient demographics, Charlson comorbidity index (CCI), American Society of Anaesthesiology (ASA) score, liver function blood tests, admission respiratory rate and oxygen saturations, progression to LC, 30-day, 3 month, and 12 month mortality, as well as the recurrence rate of AC, and PC complication rate.

Results: 50 Patients underwent PC for AC in Torbay Hospital between 2019 and 2022, with 48 patients having long-term data for suitable review. In this cohort, 68.8% of the patients were male, with a mean age of 76 ± 9. The overall mean CCI was 4.96 ± 1.12, and the average ASA was 2.83 ± 0.36. 6 patients (12.5%) had recurrence of AC with a mean of 57 ± 56 days onset after PC insertion. 12 patients (25%) had PC complications; 11 (23%) were minor with pain/dislodged tube and 1 (2%) major with a subhepatic abscess.

22 patients (46%) progressed to LC following PC, and 26 patients (54%) had PC as definitive treatment. The LC progression cohort had a 30-day and 12-month mortality of 0%, whilst the definitive PC cohort had a 30-day mortality of 30.8% (8 patients), and 12-month mortality of 46.1% (12 patients) (fig 1). The LC progression cohort compared to the definitive PC cohort had a significantly lower CCI (4.39 vs 5.57 p<0.05), and a significantly lower ASA (2.61 vs 3.04 p<0.05) (fig 2).

The 12-month survival cohort compared to the 30-day mortality cohort had significantly lower ASA (2.71 vs 3.25 p<0.05), a non-significantly lower CCI (4.66 vs 5.86 p=0.094), and a lower rate of respiratory dysfunction (9.4% vs 31.3%), but no significant difference in the presence of raised bilirubin > 34µmol/L (17.5% vs 12.5%).

Conclusion: Our results demonstrate PC as an effective and safe technique to use in critically ill and comorbid patients suffering from AC. In addition, we show that PC is a highly effective treatment option for bridging a select cohort of patients to receive a delayed LC.

Furthermore, the data suggest ASA and CCI scoring can be used as adjuncts to assess whether bridging patients from PC to LC is appropriate. Finally, ASA and respiratory dysfunction can also be used as significant negative predictors of post-PC mortality.

Introduction: Treatment and follow-up strategies for silent gallbladder (GB) stones in patients prior to kidney transplantation (KT) have not been established.

Aims & Methods: We performed a retrospective cohort analysis comparing the risk of gallstone-related biliary complications and complications after cholecystectomy in KT recipients. By obtaining this information, we expected to evaluate the role of prophylactic cholecystectomy in KT recipients. A total of 2,295 KT recipients at Seoul National University Hospital from January 2005 to July 2022 were evaluated. Silent gallstones were identified from abdominal images (US, CT or MRI) 3 years before and 1

year after KT. The main outcome was the incidence of biliary complication and post-cholecystectomy complications and their severity in KT recipients.

Secondary outcomes included death-censored graft failure (DCGF), graft failure (GF), and all-cause mortality. The Fisher exact test was used to assess the significance of the incidence of postoperative complications. The Kaplan-Meier (KM) curve was plotted for biliary complication-free survival in the observation group. The Cox proportional hazards model was used to identify risk factors associated with biliary complications in the observation group. A P<0.05 was considered indicative of statistical significance. All analyses were performed using the IBM SPSS Statistics 27.

Results: A total of 230 patients with gallstones were enrolled in this study. Among them, 16 underwent cholecystectomy prior to KT and 214 were followed without any intervention or surgery. Of the 214 patients observed, the median follow-up was 73.8 months and biliary complications occurred in 20 patients, with an incidence rate of biliary complications of 9.3%. 20 had acute cholecystitis, 2 had acute cholangitis, and 3 had gallstone pancreatitis. When cholecystectomy was performed, the incidence rates of postoperative complications were 6.3% in the pre-KT cholecystectomy group and 38.8% in the post-KT cholecystectomy group, respectively (p = 0.04). The severity of postoperative complications was based on the Clavien-Dindo classification, and the post-KT cholecystectomy group had a higher incidence of fatal complications greater than grade 4 compared to the pre-KT cholecystectomy group. Patients with multiple GB stones (adjusted hazard ratio [aHR] 2.46, 95% CI 1.56-8.30, p = 0.04), GB wall thickening ([aHR] 5.41, 95% CI 1.63-17.91, p = 0.006) and large GB stones greater than 1 cm ([aHR] 5.55, 95% CI 2.02-15.23, p = 0.001) were more likely to have biliary complications.

	Post cholecystectomy Complication	Severity Grade	Treatment
Pre-KT cholecystectomy			
1	Operation bed fluid collection	IIIa	PCD
Post-KT cholecystectomy			
1	Abdominal wall bleeding	II	Transfusion, conservative care
2	Liver abcess	II	Antibiotics
3	Operation bed fluid collection	IIIa	PCD
4	Operation bed fluid collection, perihepatic abcess	IIIa	PCD, Antibiotics
5	Aspiration pneumonia, septic shock	IVb	Antibiotics, ICU care
6	Cystic duct stump leakage, biliary septic shock, pleural effusion	IVb	ERCP and ERBD, ICU care, Thoracentesis
7	Hemoperitoneum, Biloma, Bile leakage	IVb	PCD, ERBD, Antibiotics

PCD : Percutaneous drainage

Table 4. List of postoperative complications in pre-KT and post-KT cholecystectomy group

Conclusion: Gallstone-related biliary complications and subsequent cholecystectomy after kidney transplantation results in more serious complications and worse treatment outcomes. Therefore, it may be helpful to recommend prophylactic cholecystectomy for KT candidate with significant risk factors for biliary complications, such as multiple gallstones, large gallbladder stone greater than 1cm or Gallbladder wall thickening.

COMPARISON OF ONCOLOGICAL OUTCOMES AFTER IMMEDIATE AND DELAYED RE-RESECTION OF INCIDENTAL GALLBLADDER CARCINOMA

B. Li[1]

[1]Sichuan University, West China Hospital, Division of Biliary Surgery, Chengdu, China

Contact E-Mail Address: libei@scu.edu.cn

Introduction: Gallbladder carcinoma (GBC) is the most common malignant tumor of the biliary tract and the sixth malignancy of the gastrointestinal tract[1,2]. It is frequently diagnosed at an advanced stage due to nonspecific symptoms and aggressive biological behavior[3]. Radical resection is the most effective treatment, yet reported 5-year survival rates following operation vary greatly, from 10% to 100%[4-6].

Indeed, long-term survival appears in patients with early-stage tumors. These patients are usually diagnosed incidentally, after cholecystectomy for presumed benign gallbladder disease. As the growing number of laparoscopic cholecystectomies executed, incidental gallbladder carcinoma (iGBC) is a progressively relevant clinical issue[7,8].

Re-exploration and re-resection are currently recommended for T1b, T2, and T3 iGBC patients without definite distant metastasis[9]. The extent of re-resection involves a partial hepatectomy of segment IVB+V, either as wedge resection or multi-segments resection and hepatoduodenal lymph nodes dissection[10]. However, there are few data on the timing of re-resection, especially immediate re-resection and delayed re-resection.

In this study, we compared the outcomes of immediate and delayed re-resection in iGBC patients, and to define optimal re-resection time that may improve prognosis.

Aims & Methods: For incidental gallbladder carcinoma (iGBC) patients with T1b and higher tumors are recommended to undergo radical re-resection, it is not clear whether immediate re-resection is more beneficial to long-term survival compared with delayed re-resection. To assess whether immediate re-resection is more beneficial to long-term survival compared with delayed re-resection.

This single centre retrospective observational cohort study of patients with iGBC was conduct from June 2006 and February 2015. Patients who underwent radical re-resection for T1b or higher iGBC were enrolled.

The oncological outcomes of patients who underwent immediate re-resection were compared with those of patients treated with delayed re-resection.

Results: A total of 78 patients were included. 31 patients underwent immediate re-resection and 47 patients underwent delayed re-resection. The baseline demography, extent of resection, resection margin, T stage, lymph node involvement and postoperative complications were similar between the two groups. Patients in immediate re-resection group had less intraoperative blood loss and shorter hospital stay compared with those in delayed re-resection group.

Kaplan-Meier analysis indicates that the overall survival rate of patients with delayed re-resection significantly decreased than those with immediate re-resection. Multivariate analysis showed that delayed re-resection (HR = 5.110, 95%CI: 1.595-16.371, P = 0.006), R1 resection (HR = 4.502, 95%CI: 1.345-15.070, P = 0.015) and lymph node positivity (HR = 6.025, 95%CI: 1.286-28.220, P = 0.023) were adverse prognostic factors for overall survival.

Conclusion: Immediate re-resection for selected patients with incidental gallbladder carcinoma is oncologically superior to delayed approach. To improve iGBC detection and timely referral of iGBC patients to immediate re-resection may allow more patients to benefit from this operation.

Introduction: The clinical value of combined resection of important hepatic vessels in hilar cholangiocarcinoma remains controversial. We aimed to compare the short-term and long-term outcome of combined versus non-combined major vessel resection in patients undergoing radical resection for hilar cholangiocarcinoma.

Aims & Methods: This single centre retrospective cohort study of patients with hilar cholangiocarcinoma was conduct from January 2007 to December 2018. Patients who underwent radical re-resection were enrolled. The short-term and long-term clinical outcomes of the groups were compared after propensity score matching.

Results: A total of 310 patients were included. There was no statistically significant difference in perioperative clinical outcomes between VR group (PVR and AVR) and non-VR group after 1:2 PSM. Patients who received PVR had significantly longer OS (p=0.023) and DFS (p=0.010) compared to those in the non-PVR group. AVR group was associated with improved OS (p=0.036) and DFS (p=0.029) compared with non-AVR group following the curative-intent resection. The postoperative complications of combined VR would not worsen long-term survival for patients (OS: p=0.159; DFS: p=0.112).

Conclusion: Combined vascular resection (VR) would improve the long-term survival for patients with hilar cholangiocarcinoma. The postoperative complications of combined VR would not worsen long-term survival. Therefore, radical surgical resection should be actively performed in these patients.

COMPARATIVE STUDY OF THREE COMMON BILE DUCT CLOSURE TECHNIQUES AFTER CHOLEDOCHOLITHOTOMY: SAFETY AND EFFICACY

M. Omar[1], A. Redwan[2], M. Alansary[3]

[1]South Valley University, General Surgery, Qena, Egypt, [2]Sohag University, General Surgery, Sohag, Egypt, [3]South Valley University, Anasthesia and Intensive Care, Qena, Egypt

Contact E-Mail Address: elqefty@yahoo.com

Introduction: T-tube drainage, primary closure, and biliary stenting are the common bile duct closure methods. There is great debate on the optimal duct closure technique after common bile duct exploration.

This study aimed to assess the safety and efficacy of the three commonest common bile duct closure methods after common bile duct exploration for common bile duct stone for future generalization.

Aims & Methods: In this analysis, 211 patients with common bile duct stone underwent common bile duct exploration from January 2016 to December 2020. The patients were divided according to common bile duct closure techniques into three groups, including the T-tube drainage group (63 patients), primary duct closure group (61 patients), and antegrade biliary stenting group (87 patients).

Results: The incidence of overall biliary complications and bile leak were statistically significantly lower in the biliary stenting group than in the other two groups. Also, Hospital stays, drain carried time, return to normal activity, re-intervention, and re-admission rates were statistically significantly lower in the biliary stenting group than in the other two groups. There were no statistically significant differences regarding operative and choledochotomy time, retained and recurrent stone, stricture, biliary peritonitis, cholangitis, and the cost among the three groups.

Conclusion: We state that the biliary stenting procedure should be the preferred first option for common bile duct closure after common bile duct exploration when compared with T-tube drainage and primary duct closure.

POST-CHOLECYSTECTOMY MAJOR BILE DUCT INJURY: IDEAL TIME TO REPAIR BASED ON A MULTI-CENTER RANDOMIZED CONTROLLED TRIAL WITH PROMISING RESULTS

M. Omar[1], A. Redwan[2], E. Ali[2], M. Alansary[3], A. Kamal[4]
[1]South Valley University, General Surgery, Qena, Egypt, [2]Sohag University, General Surgery, Sohag, Egypt, [3]South Valley University, Anasthesia and Intensive Care, Qena, Egypt, [4]Helwan University, General Surgery, Helwan, Egypt

Contact E-Mail Address: elqefty@yahoo.com

Introduction: Bile duct injury (BDI) is one of the serious complications of cholecystectomy procedures, which has a disastrous impact on long-term survival, health-related quality of life (QoL), health-care costs as well as high rates of litigation. The standard treatment of major BDI is hepaticojejunostomy (HJ). Surgical outcomes depend on many factors, including the severity of the injury, the surgeons' experiences, the patient's condition, and the reconstruction time.

We aimed to assess the impact of reconstruction time and abdominal sepsis control on the reconstruction success rate.

Aims & Methods: This is a multicenter, multi-arm, parallel-group, randomized trial that included all consecutive patients treated with HJ for major post-cholecystectomy BDI from February 2014 to January 2022.

Patients were randomized according to the time of reconstruction by HJ and abdominal sepsis control into group A (early reconstruction without sepsis control), group B (early reconstruction with sepsis control), and group C (delayed reconstruction).

The primary outcome was successful reconstruction rate, while blood loss, HJ diameter, operative time, drainage amount, drain and stent duration, postoperative liver function tests, morbidity and mortality, number of admissions and interventions, hospital stay, total cost, and patient QoL were considered secondary outcomes.

Results: Three hundred twenty one patients from 3 centers were randomized into three groups. 44 patients were excluded from the analysis, leaving 277 patients for intention to treat analysis. With univariate analysis, older age, male gender, laparoscopic cholecystectomy, conversion to open cholecystectomy, failure of intraoperative BDI recognition, Strasberg E4 classification, uncontrolled abdominal sepsis, secondary repair, end-to-side anastomosis, diameter of HJ (< 8 mm), non-stented anastomosis, and major complications were risk factors for successful reconstruction.

With multivariate analysis, conversion to open cholecystectomy, uncontrolled sepsis, secondary repair, the small diameter of HJ, and non-stented anastomosis were the independent risk factors for the successful reconstruction. Also, group B patients showed decreased admission and intervention rates, decreased hospital stay, decreased total cost, and early improved patient QoL.

Conclusion: Early reconstruction after abdominal sepsis control can be done safely at any time with comparable results for delayed reconstruction in addition to decreased total cost and improved patient QoL.

Disclosure: Nothing to disclose.

CHOLECYSTECTOMY DOES NOT INCREASE THE RISK OF THE METABOLIC SYNDROME

Z. Orzeszko[1], T. Gach[2], K. Gałązka[3], N. Kantor[1], B. Markowska[2], M. Szura[2]
[1]Hospital of Saint John of God in Cracow, Department of General and Oncologycal Surgery, Kraków, Poland, [2]Jagiellonian University, Faculty of Health Sciences, Cracow, Poland, [3]Hospital of Saint John of God in Cracow, Department of Anesthesiology and Intensive Care, Kraków, Poland

Contact E-Mail Address: zosia.orzeszko@icloud.com

Introduction: Laparoscopic cholecystectomy is well known as a gold standard of treatment for gallstone disease. It has been implied that cholecystectomy is an independent risk factor for metabolic syndrome.

Nevertheless, evidence on metabolic outcomes of cholecystectomy is based chiefly on population-based retrospective research and remains inconclusive.

Aims & Methods: The study aims to assess the risk of metabolic syndrome after laparoscopic cholecystectomy prospectively and evaluate the change in serum lipid levels associated with gallbladder removal. The study included individuals undergoing laparoscopic cholecystectomy due to gallstones. The exclusion criteria covered all previous metabolic disorders and influencing drugs. The changes in all metabolic syndrome criteria were evaluated before and three months after the laparoscopic cholecystectomy.

The blood evaluation contained serum glucose, total serum cholesterol (TC), low-density (LDL) and high-density lipoprotein cholesterol (HDL), and triglyceride levels (TG). The medical examination evaluated blood pressure (BP), heart rate (HR), weight, and waist circumference.

The study was approved by the local ethics committee and was registered on ClinicalTrails.gov. (NCT05557669).

Results: 85 participants were enrolled. There were no statistically significant differences postoperatively in weight, body mass index, BP, HR, serum glucose, and TG. Although, there was a remarkable decrease in both TC and LDL levels. HDL increased notably. The prevalence of the MetS changed insignificantly after surgery.

The notably lower percentage of individuals after surgery fulfilled the fasting plasma glucose criterion, but other criteria changed unremarkably. The relative risk of developing MetS after laparoscopic cholecystectomy was 0,87 (0.64-1.19; CI 95%).

Criteria	RR	CI 95%
Fasting plasma glucose	0.83	0.61-1.11
Waist circumference	0.98	0.71-1.33
TG	1.12	0.75-1.66
HDL	0.89	0.62-1.28
BP	1.00	0.72-1.38

Table 1. Relative risk (CI 95%) of developing different metabolic syndrome criteria after laparoscopic cholecystectomy.

Conclusion: In contrast to retrospective studies, the prospective evaluation indicated no evidence of increased risk of metabolic syndrome after laparoscopic cholecystectomy.

However, further investigation regarding the metabolic consequences of this procedure is required.

ENDOSCOPIC MANAGEMENT OF BILIARY COMPLICATIONS AFTER LIVER TRANSPLANTATION

M.I. Canha[1], R. Prata[1], P. Lages Martins[1], R. Vasconcelos Loureiro[1], M.J. Silva[1], T. Capela[1], G. Oliveira Ramos[1], A. Mateus Dias[1], H. Pinto Marques[2], R. Perdigoto[2], J. Coimbra[1]
[1]Centro Hospitalar Universitário de Lisboa Central, Department of Gastroenterology, Lisbon, Portugal, [2]Centro Hospitalar Universitário de Lisboa Central, Hepatobiliopancreatic and Transplantation Center, Lisbon, Portugal

Contact E-Mail Address: m.inescanha@gmail.com
Introduction: Biliary complications are estimated to occur in 5-32% of patients undergoing liver transplantation (LT) and are an important source of morbimortality, with mortality and retransplantation rates up to 20% and 13%, respectively. Their early recognition and multidisciplinary management are critical in improving outcomes.
Aims & Methods: Our aim was to evaluate post LT biliary complications, their endoscopic management, and clinical outcomes.
We conducted a retrospective study of a prospectively maintained database of LT adult patients who underwent endoscopic retrograde cholangiopancreatography (ERCP) at a transplantation center between July 2020 - December 2022. Demographic, clinical, surgical, and endoscopic data were collected and analyzed in Stata®V17 (p<0,05). The outcomes assessed were ERCP's technical success, procedure-related complications, complete resolution of the biliary complication, need for surgical reintervention, and mortality.
Results: We performed 166 ERCPs in 64 patients (2,6±1,3 ERCPs/patient), 86% males, mean-aged 56±11 years. The median interval between LT and first ERCP was 10 [2;46] months. The most frequent indications for ERCP were radiological documentation of biliary stenosis (BS) (33%) and cholangitis (27%). All patients had prophylactic antibiotic treatment and rectal indomethacin.
The most common biliary complication was anastomotic BS (75%), followed by bile leakage (14%), non-anastomotic BS (5%) and choledocholithiasis without BS (5%). 56% of anastomotic BS presented in the first year, whereas all the non-anastomotic BS were diagnosed after the first year. The bile leaks were detected from the fourth week following LT, 67% were high-output leaks and 67% associated with a BS.
Biliary cannulation ± sphincterotomy was achieved in 100% of the procedures, with a 97% technical success rate (4 BS were not traversed by the guidewire and 1 high output leakage was considered not amenable to endoscopic treatment).
We performed dilation in 28% of the procedures, plastic stent placement in 62% (mean number of 2±1 stents with a total caliber of 15±6Fr per procedure) and fully covered self-expandable metal stent in 5% of the cases.
There were 4.8% procedure-related complications (4 intraprocedural bleedings treated endoscopically, 2 post-ERCP cholangitis, 1 mild pancreatitis and 1 delayed bleeding requiring blood transfusion), with no associated deaths.
Median follow-up was 10 [4;21] months. From the initial 64 patients, 16 patients are still under treatment, 4 were retransplanted for unrelated reasons, 3 died of other causes and 1 abandoned follow-up.
Our clinical success rate was 77.5% (31/40), achieving complete endoscopic resolution of the biliary complication within 3,2±1,3 ERCPs during a median of 196 days of treatment. Success rates per diagnosis were 100% in isolated choledocholithiasis, 79% in anastomotic BS, 67% in bile leaks and 50% in non-anastomotic BS.
Among the 9 patients with treatment failure (22.5%), 5 had presented with cholangitis, 3 of whom with multiple liver abscesses. Seven underwent surgical reintervention and 4 died of complications related to the post-LT biliary condition (mortality rate: 4/40, 10%). We did not find statistically significant associations of age, number of index surgeries, T tube placement, and indication for ERCP with clinical failure in multivariable logistic regression analysis.
Conclusion: The endoscopic management of biliary complications after LT had a high success rate in our patients, with few associated complications and an important contribution to decreasing the need for surgical reinterventions.

ABLATION USING PAPILLOTOME AND BIPOLAR HEMOSTATIC FORCEPS FOR PATIENTS WITH INTRADUCTAL RESIDUAL TUMOR EXTENDING INTO THE PANCREATIC OR COMMON BILE DUCT AFTER ENDOSCOPIC PAPILLECTOMY

Y. Sumida[1], K. Maehara[1], T. Inada[1], A. Hirotada[1], N. Harada[2]
[1]Kitakyushu Municipal Medical Center, Dept. of Gastroenterology, Kitakyushu, Japan, [2]Kyushu Medical Center, National Hospital Organization, Dept. of Gastroenterology, Fukuoka, Japan

Contact E-Mail Address: y.raisin@gmail.com

Introduction: In recent years, the indications for endoscopic papillectomy (EP) have expanded, and additional ablation such as radiofrequency ablation (RFA) have been reported for residual tumors that have extended into the pancreatic duct or common bile duct after EP. However, RFA may cause adverse events due to excessive heat, highlighting the need for safe and reliable methods to manage intraductal lesions.

Aims & Methods: This study aimed to assess the efficacy and safety of additional ablation using a papillotome and bipolar hemostatic forceps for residual neoplasms in the pancreaticobiliary tract following EP of ampullary tumors. We retrospectively reviewed patients who underwent ablation for residual pancreaticobiliary lesions following endoscopic papillectomy (EP) between January 2017 and March 2023. Intraductal ablation was performed using a papillotome for endoscopic sphincterotomy in Spray Coagulation mode (VIO 3; Elbe) and bipolar hemostatic forceps (Hemostat-Y: PENTAX). Clinical data, including adverse events, were collected retrospectively. After EP, endoscopic papillotomy and endoscopic pancreatic ductotomy were performed either on the same day or within seven days as needed to expose intraductal lesions. The bipolar forceps were energized with the forceps open without grasping the tissue. The tube stent was removed during treatment, and a guidewire was inserted to stabilize the procedure and facilitate sequent stent replacement. This approach prevents excessive thermal damage to deeper tissue layers by applying heat to the targeted tumor tissue with the Bipolar forceps cup open. While the sparks from the papillotome reach the upper left half of the duct, they do not extend to the lower right half; therefore, bipolar hemostatic forceps were applied to address this problem in the lower right half of the pancreatic or common bile duct.

Results: The median lesion size was 18 mm (interquartile range: 13-21 mm). Residual pancreaticobiliary extension lesions had a median size of 13 mm (interquartile range: 8-15 mm) in the common bile duct and 7 mm (interquartile range: 6-10 mm) in the pancreatic duct. Adverse events were observed in 3 patients (11.5%), with one experiencing delayed bleeding and three developing symptomatic biliary stricture. The median follow-up period was 311 days. During the follow-up, one patient with T1 carcinoma that invaded the sphincter of Oddi experienced recurrence in the pancreatic duct. No local recurrence was detected in the other patients via endoscopy or computed tomography.

Conclusion: Ablation using a papillotome and bipolar hemostatic is a safe and effective method to treat residual intraductal pancreaticobiliary extension lesions after EP. However, more studies are needed to confirm these findings.

Introduction: Malignant distal biliary obstruction is a common complication in the progression of pancreatic tumors. Endoscopic ultrasound (EUS) guided drainage can provide effective biliary drainage when not achieved by endoscopic retrograde cholangiopancreatography (ERCP) and can be performed by hepaticogastrostomy or choledocoduodenostomy (CDD). Gallbladder drainage by cholecystogastrostomy (GBD) has been described in small uncontrolled series and could be effective. The objective of this study was to compare the clinical efficacy of CGD vs CDD in distal biliary tract obstruction (DBTO).

Aims & Methods: This was a retrospective, multicenter study (four tertiary centers) including all consecutive patients with DBTO and jaundice who underwent CDD or GBD with a lumen-apposing metal stent (LAMS). The primary outcome was to compare the clinical success rate defined as a decrease of total bilirubin by 50% in 14 days and/or a decrease in total bilirubin below 51 µmol/L after 30 days. Secondary outcomes were technical success, overall survival, survival without biliary reintervention, immediate (within 24 hours) and delayed (>24 hours) morbidity.

Results: 78 patients were included between July 2018 and September 2022, 41 GBD and 37 CDD. The mean age was 71 years, and 82% had pancreatic adenocarcinoma, 55% had metastatic disease at diagnosis, and 45% had duodenal stenosis. Most patients (N=59; 76%) had undergone EUS-guided drainage after ERCP failure.

The mean diameter of the main bile duct was significantly smaller in the CGD group (13 mm vs. 18 mm; p=0.001). The total bilirubin mean was 196 µmol/L in the GBD group vs. 241 µmol/L in the CDD group; p=0.149. Clinical success was comparable between the two groups: 88% (36/41 - CGD) vs. 89.2% (33/37 - CDD); p=0.848.

There was no difference in overall survival (log-rank p=0.727) or survival without biliary obstruction (log-rank p=0.725) between the two groups. Immediate morbidity was comparable: 7% (3/41 - GBD) vs. 13% (5/37 - CDD); p=0.368. The rate of significant immediate complications tended to be lower in the GBD group (5% (2/41 - CGD) vs. 8% (3/37 - CDD); p=0.093). Delayed morbidity (mainly LAMS obstruction) (>24 hours) was lower in the GBD group 7.3% (3/41 - CGD) vs. 27% (10/37 - CDD); p=0.022. There were no biliary complications after the 26th day in the GBD group. The LAMS dimensions did not have an impact on biliary complications in the CGD group (6x8mm vs. 10x10mm vs. 15x10mm).

Conclusion: Biliary drainage of tumoral obstruction of the distal biliary tract by GBD had comparable clinical efficacy and was associated with reduced delayed morbidity compared to CDD. This type of drainage is feasible, especially when the main bile duct is not dilated enough to consider CDD.

A SINGLE CENTRE ANALYSIS OF AMBULATORY HOT CHOLECYSTECTOMY IN A DISTRICT GENERAL HOSPITAL IN THE UK

M.I. Hussain[1], J. Bird[2], M. Hamid[2], C. Sellahewa[2]
[1]Portsmouth Hospitals University NHS Trust, General Surgery, Portsmouth, United Kingdom, [2]The Dudley Group NHS Foundation Trust, General Surgery, Dudley, United Kingdom

Contact E-Mail Address: mihussain@nhs.net
Introduction: The COVID-19 pandemic has created a backlog of around 7 million patients waiting for an operation in NHS England. A significant proportion of the waiting list included patients waiting for Laparoscopic Cholecystectomy. This is partly due to a lack of awareness and intent leading to non-compliance with the Hot Gall Bladder Pathway. NICE recommends 80% of qualifying acute biliary diseases must be dealt with cholecystectomy within 5 days of diagnosis. The issue of the rising number of patients waiting for elective cholecystectomies is prevalent across Europe.
Aims & Methods: A thrice-weekly ambulatory service aimed at reducing the burden of gallstone disease was initiated in our hospital.
This study evaluated a consecutive series of hot laparoscopic cholecystectomies performed between December 2021 and January 2023. Statistical analysis was performed using Statistical Package for Social Science (SPSS) version 27.0 for Windows (SPSS Inc., Chicago, IL, USA).
Results: Overall, 264 (females: 189, males: 75) hot cholecystectomies were performed with a median age of 47 years. The median BMI and ASA were 32 and 2 respectively. 210 patients presented for the first time. 139 patients had Grade I while 90 patients had Grade II acute cholecystitis as per Tokyo Guidelines 2018.
All cases were completed laparoscopically. 29 patients had a subtotal cholecystectomy. Patients with Tokyo Grade II had 6.9 times higher odds of subtotal cholecystectomy than Grade I. Median postoperative stay was zero. 49 patients encountered complications (Clavien-Dindo Grade I: 17; Grade II: 9; Grade III: 23). Increased BMI was linked to an increased risk of complications.
Conclusion: A dedicated ambulatory service for hot cholecystectomies can be employed to resolve the mounting waiting lists not only in England but also across Europe whilst at the same time providing high-quality care.

FEASIBILITY AND SAFETY OF SPYGLASS DS CHOLEDOCHOSCOPE AND ENDOSCOPIC RADIOFREQUENCY ABLATION IN THE DIAGNOSIS AND TREATMENT OF UNRESECTABLE EXTRAHEPATIC CHOLANGIOCARCINOMA

J. Yang[1], X. Zhang[1]
[1]Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Hangzhou, China

Contact E-Mail Address: yjf3303@zju.edu.cn
Introduction: The sensitivity and accuracy of diagnosis for extrahepatic cholangiocarcinoma (EHCC) can be greatly improved by Spyglass DS choledochoscope, which can realize direct observation and biopsy . Studies have shown that endoscopic radiofrequency ablation (RFA) could prolong stent patency and survival in patients with unresectable extrahepatic cholangiocarcinoma (EHCC). However, there are few reports about Spyglass DS choledochoscopy and endoscopic RFA therapy in the same stage of diagnosis and treatmen for unresectable EHCC.
Aims & Methods: Aim: To investigate the feasibility and safety of Spyglass DS combined with endoscopic RFA)for unresectable EHCC on the same stage.
Methods A total of 90 patients with extrahepatic bile duct obstruction treated in Hangzhou First People's Hospital from January 2013 to January 2022 were divided into two groups according to the diagnosis and treatment process: conventional group: ERCP + cytobrush/ Spyglass DS cholangioscopy first, and ERCP + RFA again when the pathological results were positive; simultaneous group: ERCP was performed via Spyglass DS cholangioscopy to examine the bile duct and biopsy the lesion under direct vision, and RFA was performed on the same stage for patients identified as malignant tumor. The success rate of procedure, recovery of liver function, the number of ERCPs and the incidence of postoperative adverse events were compared between the two groups.
Results: The sensitivity of Spyglass DS choledochoscope biopsy for EHCC was 87.5% (35/40) significantly higher than that of the cell brush group (38.9% (14/36), and the difference was statistically significant (P<0.05); All patients in both groups successfully completed endoscopic RFA with a 100% of procedure success rate; there was no statistically significant difference in the improvement of bilirubin between the two groups (P>0.05); the mean number of ERCPs in simultaneous group was significantly less than that in conventional group (1.00 vs. 2.59, P<0.001), which was statistically different; the incidence of postoperative adverse events between the two groups was 14.7% (5/34) vs. 14.3% (5/35), with no statistical significance (P=0.889).
Conclusion: Spyglass direct vision diagnosis + biopsy combined with RFA for unresectable extrahepatic cholangiocarcinoma can significantly improve the diagnostic sensitivity, reduce the number of ERCPs, and not increase the incidence of postoperative adverse events, which is a safe and effective diagnosis and treatment method with a high cost-benefit ratio.

RELATIONSHIP AND CELLULAR LOCALIZATION OF AHR AND ELAVL1 IN PANCREATIC CANCER, *IN VITRO*

D. Stukas[1], A. Jasukaitiene[1], J. Matthews[2], A. Gulbinas[1], Z. Dambrauskas[1]

Introduction: Pancreatic cancer (PC) is emerging as one the most lethal types of cancer with only a 10% five-year survival rate[1].

Pancreatic ductal adenocarcinoma (PDAC) being the most common among PC. Low survival rate is attributed to the fact that most incidences of PDACs are diagnosed in advanced or metastatic stages [2].

In such cases, gemcitabine remains one the first-line drugs used for treatment [2] but the efficacy of the treatment can fall short due to PDAC tumour heterogeneity and its acquired resistance to said chemotherapy [3].

The aryl hydrocarbon receptor (AHR) is a transcription factor that is commonly upregulated in pancreatic ductal adenocarcinoma [4].

AHR can be linked to Human antigen R (ELAVL1) whose expression in cell cytoplasm is positively associated with PDAC response to gemcitabine [5].

AHR can block ELAVL1 from shuttling from nucleus to cytoplasm [6] where it stabilizes its target messenger RNAs (mRNAs) and increases protein expression of said mRNAs.

Among those target mRNAs are those induced by gemcitabine treatment. Frequently with upregulated AHR expression, ELAVL1 would be sequestered in the nucleus which would lead to increased chemoresistance, however the relationship between AHR and ELAVL1 in PDAC is still poorly understood.

Aims & Methods: The aim of the study was to investigate how AHR and ELAVL1 genes and proteins interacts with each other and change their cellular localization in PDAC cells.

Two PDAC cell lines were used (BxPC-3, Su.86.86). AHR and ELAVL1 genes were silenced for 24-hours by lipofectamine mediated siRNA transfection. Cellular localization change of AHR and ELAVL1 proteins was illucidated by fluorescent microscopy. After silencing of AHR or ELAVL1 genes, RNA and proteins were extracted and real-time polymerase chain reaction (RT-PCR) and Western Blot (WB) analysis were performed. Direct binding between ELAVL1 protein and AHR mRNA was investigated by immunoprecipitation assay followed by RT-PCR and WB assays.

Results: The results of gene silencing showed that silencing of AHR can increase ELAVL1 mRNA and protein and silencing of ELAVL1 can decrease AHR mRNA and protein expression. The results of immunoprecipitation assay showed that ELAVL1 protein binds AHR mRNA resulting in mRNA stabilization. This shows a direct link between these two molecules. Moreover, silencing of AHR resulted in increased ELAVL1 protein concentration in cytoplasm which indicates that AHR blocks ELAVL1 shuttling from nucleus to cytoplasm. Silencing of ELAVL1 did not alter the cellular localization of AHR protein.

Conclusion: A direct relationship between AHR and ELAVL1 can be seen in PDAC. Moreover, by decreasing AHR expression it is possible to increase ELAVL1 shuttling from nucleus to cytoplasm which might contribute to PDAC cells responding better to chemotherapy.

GLP1 AND ANALOG ROSE-010 BIND GLP1 RECEPTOR AT AN NNOS-/FOX3+ SUBSET OF MYENTERIC NEURONS

D.-L. Webb[1], M.u. Din[1], R. Arturson[1], C. Wrede[1], E. Carroll Hayes[1], S. Sarrafzadeh[1], E. Kenny[2], P.M. Hellström[1]

Introduction: We earlier published evidence of relaxation of human gut muscle contraction by GLP1 and analog ROSE-010 in surgically isolated biopsies (1).

Pharmacological experiments pointed to dependency on functional nerves. Immunohistochemistry (IHC) revealed presence of GLP1 receptor (GLP1R) in a subset of cells within myenteric plexus. Exact cell types were not established. A hypothetical model was proposed in which GLP1R activation at nNOS expressing nitrergic myenteric neurons triggers NO production, then driving muscle relaxation.

Aims & Methods: This hypothesis was pursued by identifying FOX3 and nNOS expressing myenteric plexus neurons relative GLP1 and ROSE-010 binding. Paraffin sections from human gut transmural biopsies were, by segment (n): cardia (6), fundus (2), corpus (6), jejunum (2), ileum (5), unspecified small intestine (6), colon (7), sigmoid (2), rectum (3). GLP1R was first mapped using a new antibody (clone D-6, sc-390774, Santa Cruz Biotech, USA) by ordinary IHC with DAB. This targets amino acids 91-145 of N-terminal extracellular domain of human GLP-1R. Mapping was verified in serial sections using biotinylated GLP1 (B-GLP1, 1 µM) or ROSE-010 (B-ROSE, 5 µM) synthesized with biotinyl-AEEAc tag at amino terminal histidine.

To visualize this 1:1 stoichiometry, a signal amplification system was developed using streptavidin-HRP, biotinylated goat anti-streptavidin antibody and a second round of streptavidin-HRP followed by DAB staining. For triple labelling on other slides, streptavidin tagged fluorophores were instead used after FOX3 staining of neuronal nuclei using monoclonal an-

tibody (Biolegend, USA) and HRP-DAB; nNOS was visualized by antibodies (mouse sc-5302 FITC, Santa Cruz Biotech or goat NB100-858, Novus Biologicals). Although unusual, amplification and triple labelling only required off-the-shelf reagents (Vector Labs, USA).

Results: Across the gut, approx. half of myenteric plexus cells were positive using GLP1R antibody; this number being variable. Many had clear neuronal morphology. Intensity was scored between 2 and 3 (max was 4). The amplification system introduced a small background, but B-GLP1, B-ROSE and nNOS stained far above this. Myenteric plexus cells most strongly staining for B-GLP1 and B-ROSE were in some cases negative for nNOS. Triple labelling further revealed peptide positive cells within myenteric plexus that were nNOS- with FOX3+ nuclei. Myenteric plexus GLP1R and nNOS distribution was confirmed by ordinary IHC of serial sections.

Conclusion: This arrives at the existence of GLP1R+ myenteric neurons that are not nitrergic as well as GLP1R- nitrergic neurons. Support was found for the hypothesis in which GLP-1 and ROSE-010 act on nitrergic neurons (i.e., GLP1R+/nNOS+/FOX3+).

However, the other permutations of GLP1R relative nNOS expressing neurons indicate that GLP1 and ROSE010 act simultaneously on other types of neurons (as of now undefined), whereas not all nitrergic neurons are equipped to respond to these peptides. The net effect of these peptides to induce muscle relaxation arises from selective signaling at a distinct subset of neurons that collectively are only definable as "GLP1R+".

Introduction: Type 1 diabetes is a disease of the endocrine pancreas, but it also affects the exocrine part, especially the ductal cells. Several studies have shown that secretin-induced ductal HCO_3^- secretion is reduced in diabetes, however, the underlying mechanism and the effect of diabetes on basal secretion is less known.

Aims & Methods: Our aim is to investigate the effect of diabetes on pancreatic exocrine function. Diabetes was induced in wild type and cystic fibrosis transmembrane conductance regulator (CFTR) knock out mice by i.p. administration of streptozotocin and disease development was confirmed by fasting blood glucose level measurement. Pancreatic ductal fluid and HCO_3^- secretion were measured by fluid secretion measurements and fluorescence microscopy, respectively. Expression of ion transporters were investigated by real-time PCR and immunohistochemistry, whereas TEM was used for the morphological characterization of the pancreas.

Results: Basal fluid and HCO_3^- secretion are significantly elevated in diabetes. Acute or chronic glucose treatment did not affect HCO_3^- secretion, but inhibition of CFTR significantly reduced it in both normal and diabetic mice. Cl^- efflux and the expression of CFTR, ANO1, NHE-1 and AQP1 increased in diabetes. Secretin-stimulated fluid secretion was also significantly higher in diabetic mice.

Conclusion: Our results show that diabetes increases fluid and HCO_3^- secretion in ductal cells both under basal and stimulated conditions in which the increased function of ion and water transporters, especially CFTR, plays central role.

This study was supported by the National Research, Development and Innovation Office Grant (SNN134497 to VV) and the CFRD-SRC Grant (No.: SRC 007).

Introduction: Excessive lipid accumulation in the pancreas is known as pancreatic steatosis (PS). PS is an entity whose clinical significance has not been understood until recently. However, recent studies have shown that PS may be a pathology associated with metabolic syndrome (MS), insulin resistance (IR), and diabetes mellitus (DM), which can disruptthe endocrine and exocrine functions of the pancreas.

In our previous study, we showed that ultrasonographic PS and its grade were associated with MS and its components, fatty liver and pancreatic tissue stiffness that we determined by shearwave elastography.

Aims & Methods: Unfortunately, data on the frequency of PS are very limited. There is no data on its frequency in Turkey. Therefore, as the Turkish Pancreas Study Group, we aimed to evaluate the frequency of PS detected by transabdominal ultrasonography (TAU) in gastroenterology clinics located in different geographical regions of Turkey and the factors associated with PS and its degree. Volunteers were evaluated by TAU whether theyhad PS, or not, also the degree of PS, at their study centers.

In order to eliminate the differences between the researchers on PS diagnosis by TAU, the researchers in the centers participating in the study were trained for ultrasonographic evaluation, method and common nomenclature, and the kappa score was calculated statistically in terms of compliance. Also if possible, pancreatic stifness was evaluated by means of SWE by ultrasonography. All demographic, antropometric and biochemical parametres, and arterial blood pressures were measured and the diagnosis of MS established by these measurements. During TAU examination, hepatosteatosis (HS) state and its degree evaluated and recorded.

Results: A total of 1700 volunteers from 13 centersthroughout Turkey were included in the study, prospectively. Mean age was 48.03± 20.86 years (56.9% female, 43.1% male), no significant difference was found between

both genders (p=0.176). BMI mean was 27.22 ± 5.00 kg/m^2. PS pevalance was detected in 68.9% all study population (Mild PS in 32%, moderate PS in 28.8%, severe PS in 8.1%). There was a correlation between PS and ultrasonographic grade and age, BMI, waist circumference, SBP, fasting blood glucose, lipid levels, IR, DM, Hypertension and MS frequency, fecal elastase level, pancreatic shearwave elastography score (kP).

The frequency of HS was 55.5%, the Positive Predictive Value of HS for PS was 87.58%, the Positive Predictive Value of PS for HS was 68.55%, and the Relative Risk of HS for PS was 6.734. Positive Predictive Value of PS for MS was 88%.

Conclusion: In this comprehensive multicenter study conducted in Turkey, the frequency of PS was found70%, its relationship was determined with HS, MS (and it'scomponents).

Furthermore, there was a relationship betweenPS (also PS stage) and pancreatic stiffness, as well as, PS and Fecal Elastase Level (pancreatic exocrine functions).

Introduction: Severe acute respiratory syndrome coronavirus 2 (SARS-COV-2), the causative virus for coronavirus disease-2019 (COVID-19), primarily affects lung tissues causing severe acute respiratory distress syndrome. SARS-CoV-2 is believed to cause acute pancreatitis (AP) through direct viral invasion (through ACE2 receptors) or the systemic inflammatory immune response (SIIR) through cytokine storm.

This study was conducted to assess the impact of COVID-19 infection on clinical outcomes, including mortality, in patients admitted with acute pancreatitis.

Aims & Methods: The national inpatient sample (NIS) 2020 was queries for hospitalizations with the discharge diagnosis of acute pancreatitis. Patients who were diagnosed with COVID-19 infection upon hospitalization were identified. Their baseline characteristics and clinical outcomes were compared to patients with AP and no COVID-19 infection. Chi-square and the student's t-test were used for the statistical analysis.

Multivariate analysis to assess mortality predictors in patients with AP was then performed.

Results: Out of 258965 AP hospitalizations included in the analysis, 2725 patients had COVID-19 infection. There was a higher percentage of Hispanics in the COVID-19 AP compared to the non-COVID-19 AP group. Peripheral vascular disease, chronic pulmonary disease, alcohol use, drug use, and smoking were more prevalent in the non-COVID group.

There was no difference in the burden of comorbidity between the two groups, as estimated by Carlson's comorbidity index (p 0.7597) (Table 1).

In-hospital mortality was higher in the COVID-19 AP group compared to the non-COVID-19 AP group (2.2% vs. 0.6%, p <0.0001). The multivariate logistic regression analysis showed higher odds of mortality in patients with COVID-19 infection (OR 3.97, CI 2.17-7.26. p <0.0001).

Table 1.

Conclusion: COVID-19 clinical course varies individually from asymptomatic to severe multiorgan failure and death. A meta-analysis of 2419 patients concluded that COVID-19 significantly increased the odds of mortality in AP. It also showed that COVID-19 was associated with an increased incidence of severe pancreatitis, necrotizing pancreatitis, and a longer length of stay in AP.

Another study showed that COVID-19 virus had been isolated in stool samples and pancreatic pseudocysts in patients with AP, which further supports the morbid effect of the virus on AP. A meta-analysis of 19 studies has shown a similar pattern of cytokine levels alteration in both severe AP and COVID-19, which leads to further exacerbation in the cytokine storm leading to multi-organ failure and death.

Our study showed that COVID-19 infection is independently associated with increased mortality among patients admitted with acute pancreatitis.

Disclosure: Nothing to disclose.

Introduction: Infected necrotizing pancreatitis (INP) is associated with an increased risk of organ failure and mortality. In a previous meta-analysis, procalcitonin (PCT) was found to have the most robust connection to INP. Herein, we aimed to identify early predictors for INP.

Aims & Methods: A systematic search was conducted in Medline (via Pubmed), Embase, and Central databases on 27.10.2022 (PROSPERO no.: CRD42022370672). The selected studies confirmed infection by computed tomography imaging with the presence of gas in the necrotic collection or by examination of the sample acquired by an intervention using Gram staining or culture. Any laboratory biomarkers were included for the index test that were compared between sterile necrotizing pancreatitis and INP. The random effect model was used to gain pooled estimates with 95% CI, and we fitted the SROC curve. Heterogeneity among the studies was evaluated.

Results: We included 14 observational studies involving 1,591 patients, in the analysis 9 studies with 758 patients were included. In the disease's early phase, within the first 72 hours after admission, the pooled area under the ROC curve (AUC) of C-reactive protein (CRP) was 0.70 (95% confidence interval (CI) = 0.63, 0.77), and for PCT, it was 0.70 (95% CI = 0.57, 0.83), and for white blood cell count (WBC), it was 0.61 (95% CI = 0.47, 0.75). After the first 72 hours, in the late phase, the pooled AUC of CRP showed an elevated level of 0.88 (95% CI = 0.75, 1.00), and for PCT, it was 0.86 (95% CI = 0.60, 1.00). No significant heterogeneity was observed.

Conclusion: The predictive value of CRP and PCT for infection is intermediate in the early phase but very good in the late phase of the disease. Based on these results, in case of persistently high CRP and PCT, infection is likely, and initiation of antibiotics is recommended.

Disclosure: The authors declare no conflict of interest.

Introduction: Acute pancreatitis (AP) is an acute disease of the pancreas with several serum indicators of the disease severity (C-reactive protein (CRP), procalcitonin (PCT)), but none of them are accurate. YKL-40 (chitinase-3-like-1 protein) is a glycoprotein that plays a mayor role in the inflammation and angiogenesis. Development of peripancreatic fluid collections (PFC) in the AP complicates the clinical course of the disease and often requires advanced endoscopic or surgical treatment. Early recognition of PFCs could lead to new therapeutic options and their improved management.

Aims & Methods: The aim of our study was to compare the diagnostic yield of YKL-40 and interleukin 6 (IL-6) versus routine laboratory markers in prediction of PFCs in AP. This prospective study recruited 57 patients (23 male, 34 female) with AP at the University Hospital Center Sestre Milosrdnice, Zagreb, from June 2020 until December 2021. After obtaining informed consent, patients had blood drawn for routine laboratory studies (including CRP and PCT) with additional 7 milliliters of blood for determining serum concentrations of YKL-40 and IL-6 on admission and 48 hours after admission. Presence of PFCs was determined with a computer tomography scan carried out 72-96 hours after admission.

Analysis were performed using enzyme-linked immunosorbent assay (ELISA). Receiver operating characteristic curve was calculated, confidence intervals were obtained using bootstrap method with 1000 iterations, and areas under the curve (AUCs) were compared using Kruskal-Wallis, Dunn, and Mann-Whitney tests.

Results: The AUC values are presented in Table 1. Post-hoc Dunn test with Bonferroni correcton indicated that there is a statistical difference between all pairwise comparisons in AUC scores for PFC predicton of investigated biomarkers both on admission and 48 hours after admission ($P < 0.05$). Both YKL-40 and IL-6 had an order of magnitude better AUC scores than CRP and PCT. At 48 hours after admission, CRP AUC scores improved drastically, reaching AUC scores comparable with YKL-40 and IL-6, with all of the biomarkers having AUC scores in range of moderately good predictors. IL-6 had the best AUC scores overall in both groups.

	On admission (AUC [95%CI])	48 hours after admission (AUC [95%CI])	Mann-Whitney U between measurements *P*
CRP	0.55 [0.25-0.83]	0.82 [0.61-1.0]	<<0.05
PCT	0.57 [0.03-0.89]	0.61 [0.12-0.97]	0.06
YKL-40	0.70 [0.38-0.86]	0.81 [0.51- 0.97]	<<0.05
IL-6	0.8 [0.6-0.96]	0.85 [0.63-1.0]	<<0.05
Kruskall wallis test *P*	<<0.05	<<0.05	

Table 1.

Conclusion: Results demonstrated that IL-6 on admission and YKL-40 (alongside CRP) 48 hours after admission may be good early predictors for PFCs and the need for future invasive treatments, but due to small sample size and low study power further measurements are needed to confirm these preliminary results.

Contact E-Mail Address: ctgkelu@nju.edu.cn

Introduction: Patients with severe acute pancreatitis (SAP) had different types and duration of organ failure (OF), which was not taken into account in the current classifications. There is a lack of research on early progression patterns of multiple OF to further develop clinical subphenotypes of SAP.

Aims & Methods: This study aimed to develop and validate potential subphenotypes of SAP based on multiple OF trajectories. Patients with SAP admitted to Jinling Hospital between 2012-2016 (development) and patients with predicted SAP participating in a randomized controlled trial (the TRACE trial, NCT02473406) between 2017-2020 (validation)were included. A group-based multi-trajectory model was performed to identify subphenotypes using consecutive OF data assessed by the sequential organ failure assessment (SOFA) score. The worst SOFA sub-scores (respiration, renal and cardiovascular) for every 3 days during the first 15 days of hospital admission/enrollment were used to develop trajectories. The primary outcome was infected pancreatic necrosis (IPN) at 90 days. The association between subphenotypes and outcomes were evaluated in the two cohorts. The heterogeneity of treatment effects for immune enhancement was investigated in the validation cohort.

Results: There were 258 SAP patients in the development cohort and 504 predicted SAP patients in the validation cohort, with respiratory failure (79.8%) being the most common OF type. Four subphenotypes were identified in development cohort, Rapidly Improving (RI, n=41, 15.9%) presented with rapidly improved respiratory failure. Single Delayed Improving (SDI, n=98, 38%) had delayed improvement in respiratory failure without renal and cardiovascular failure. Multiple Delayed Improving (MDI, n=55, 21.3%) was characterized by delayed improvement in both respiratory and renal failure but no cardiovascular failure. Persistent Worsening (PW, n=64, 24.8%) was persistent respiration, renal and cardiovascular failure. The incidence of 90-day IPN for the subphenotypes in development cohort was 5% for RI, 31% SDI, 42% MDI, and 72% PW, which were replicated in the validation cohort ($p<0.01$).

In multivariate Cox model of the validation cohort, SDI, MDI and PW were associated with an increased risk of 90-day IPN in reference of RI ($p<0.05$). Subphenotypes significantly modified treatment efficacy ($p=0.048$), the incidence of IPN was lower in SDI using thymosin alpha 1 compared to placebo (HR 0.62, 95%CI 0.39 to 0.99, $p=0.049$).

Conclusion: Four novel multiple OF trajectory-based subphenotypes for SAP patients associated with IPN risk stratification were identified. The heterogeneous immune-enhancing treatment effects among subpheonotypes could contribute to individualized management.

SIX-FOLD INCREASED RISK OF ACUTE PANCREATITIS IN ALCOHOL RELATED LIVER DISEASE COMPARED TO MATCHED CONTROLS: A NATIONWIDE POPULATION-BASED COHORT STUDY

A. Dugic[1,2], L. Widman[1], H. Hagström[1,3]
[1]Karolinska Institute, Department of Medicine, Huddinge, Stockholm, Sweden, [2]Heidelberg University Hospital, Department of Internal Medicine IV, Heidelberg, Germany, [3]Karolinska University Hospital Huddinge, Division of Hepatology, Department of Upper GI, Stockholm, Sweden

Contact E-Mail Address: dugica@gmail.com

Introduction: Excessive alcohol consumption is a significant global health concern. Alcohol-related liver disease (ALD) and pancreatitis are two common digestive diseases caused by alcohol. The coexistence of ALD with acute or chronic pancreatitis is common, but with wide prevalence estimates of pancreatitis ranging from 1.4% to 70% in alcohol-related cirrhosis. Due to high variability, a better understanding of the overlap between these diseases is necessary.

This nationwide study aims to estimate the incidence of acute pancreatitis (AP) in patients with ALD compared to the general population and identify risk factors for developing AP.

Aims & Methods: This was a nationwide population-based cohort study using data from the Swedish National Patient Register on 37,062 patients with ALD from 1969 to 2020. Patients were matched for sex, age, and municipality with 352,931 reference individuals from the general population. The diagnosis of AP and mortality data were derived from the National Patient Register and the Cause of Death Register, respectively.

Logistic regression was employed to estimate the risk of ever having pancreatitis (either acute or chronic) at or prior to ALD diagnosis, and Cox regression was used to estimate rates for hospitalization related to AP after ALD diagnosis.

Results: A total of 389,993 persons were included in the study (median age at entry, interquartile range [IQR], 59 [56–67]; 72.1% male). Of patients with ALD, 7% have experienced at least one episode of pancreatitis before being diagnosed with ALD, which corresponded to 9-fold higher odds of pancreatitis (either acute or chronic) in ALD than in controls. During follow-up, 1,049 patients with ALD developed AP (4.3/1000 person-years) compared with 3,979 reference individuals (0.8/1000 person-years). The 10-year cumulative incidence of AP was 2.7% (95%CI=2.5–2.8) for patients with ALD and 0.6% [95%CI=0.58–0.63) for reference individuals.

This corresponded to an adjusted HR of 6.3 (95%CI=5.8–6.9). The rate of AP was highest within the first year after ALD diagnosis (aHR 13.0, 95%CI=10.6–15.9) and was thereafter decreasing during follow up, but was always higher than in reference individuals, e.g., after 10 years (aHR 3.1, 95%CI=2.5–3.8). After excluding patients with gallstone related AP, the results did not change materially.

Overall mortality was 74.7% in ALD comparing to 43.1% in the general population. Younger age, male sex, history of alcohol and tobacco consumption were independent risk factors for developing AP in ALD. In particular, drinking after ALD diagnosis was strongly associated with risk of future AP (aHR 8.6, 95%CI=6.7–11.2).

Conclusion: ALD diagnosis is associated with 9-fold increased odds of prior history of pancreatitis compared to the general population. The rate of AP following a diagnosis of ALD is 6-fold higher than in the general popula-

tion, however only around 2.7% of patients with ALD develop AP within ten years. We identified possible risk factors that could be of clinical interest when trying to estimate AP risk in patients with ALD.

ENDOSCOPIC ULTRASOUND IN ACUTE PANCREATITIS: CAN WE REDUCE RECURRENCE?

T. Keen[1,2], L. Ayres[1], R. Mccrudden[1], G. Elsayed[1], J.M. Franklin[1,2]
[1]University Hospital Dorset, Gastroenterology, Bournemouth, United Kingdom, [2]Bournemouth University, Institute of Medical Imaging and Visualisation, Bournemouth, United Kingdom

Contact E-Mail Address: tkeen@doctors.org.uk

Introduction: Acute pancreatitis (AP) is a common cause of acute hospital admissions, with the potential for severe acute complications, progression to chronic pancreatitis and recurrent episodes. A first presentation leads to investigations to identify a cause, including serum blood tests and transabdominal ultrasound.

Following these investigations, a significant minority of patients have no clear cause for pancreatitis. Endoscopic ultrasonography (EUS) can identify aetiologies of AP, and direct intervention to reduce recurrence.

The goal of this study was to determine the diagnostic yield of EUS and the impact of subsequent biliary intervention on recurrence of AP.

Aims & Methods: This was a retrospective service evaluation of EUS referrals to a regional referral centre in the UK from January 2015 to December 2019. Demographics, symptoms, liver blood tests, non-invasive imaging, EUS records and outcomes were reviewed. A EUS was labelled as diagnostic if findings were identified which explained the cause for pancreatitis that had not been explained with other investigations.

Symptom resolution was defined as no further episodes of acute pancreatitis or abdominal pain requiring investigation, imaging, or presentation to secondary care during the follow-up period. Statistical significance for the difference between proportions was calculated using chi-squared tests.

Results: Ninety-seven patients were included in the study. The median age of the cohort was 58 (range 18-88) years. 55 (57%) patients were male. 22/97 (23%) patients had previously had a cholecystectomy. 41/97 (42%) had abnormal liver blood tests at the time of referral. Three patients had no non-invasive imaging. 27/97 (28%) had one of either transabdominal ultrasound, MRCP or CT, 63/97 (65%) had two tests and 4/97 (4%) had all three. 5 (5%) patients previously had a non-diagnostic EUS.

72/97 (74%) EUS were diagnostic. Findings included gallstones (n=15), gallbladder microlithiasis/sludge (n=51), bile duct stones (n=13), bile duct microlithiasis/sludge (n=11), chronic pancreatitis (n=7) and a pancreatic mass (n=1) which was later diagnosed as a pancreatic adenocarcinoma.

65 patients had a biliary aetiology for their pancreatitis which was amenable to treatment. Of these, 12 had subsequent ERCP, 7 had ERCP and cholecystectomy, 33 had a cholecystectomy and 13 were treated conservatively. Recurrent pancreatitis occurred in 12/52 (23%) patients who had treatment for a biliary aetiology of their pancreatitis compared with 8/13 (75%; p<0.01) of patients who were managed conservatively despite a biliary aetiology for pancreatitis, 8/32 (25%; p=0.84) of patients with a diagnostic EUS with a finding not amenable to treatment or a non-diagnostic EUS experienced further episodes.

One patient died from complications related to acute pancreatitis and was not included in this analysis. Median duration of follow-up was 51 months (range 32-80 months).

Conclusion: In our cohort of patients referred for EUS for unexplained acute pancreatitis, EUS had a high diagnostic yield. A lower proportion of patients had a biliary aetiology for their pancreatitis that was amenable to intervention with either ERCP, cholecystectomy or both procedures; these patients experienced fewer episodes of recurrent acute pancreatitis than those managed conservatively. This supports the use of EUS in patients with acute pancreatitis with no cause identified with non-invasive imaging.

Disclosure: Nothing to disclose.

HOW USEFUL ARE THE ESGE AND ASGE GUIDELINES FOR ESTIMATING COMMON BILE DUCT STONES IN ACUTE BILIARY PANCREATITIS PATIENTS?

E.S. Çetin Karabacak[1], S. Acar[2], A.T. Eminler[2], M. Tozlu[2], b. toka[2], M.I. Uslan[2], A.S. Koksal[2], E. Parlak[3]
[1]Sakarya University, Internal Medicine, Sakarya, Turkey, [2]Sakarya University, Gastroenterology, Sakarya, Turkey, [3]Hacettepe University, Gastroenterology, Ankara, Turkey

Contact E-Mail Address: eminler77@gmail.com

Introduction: In cases of acute biliary pancreatitis, ERCP is typically used to treat choledocholithiasis. There is currently no consensus on the indications and timing of ERCP in the treatment of acute biliary pancreatitis (1). The classification of patients based on their risk groups is a key aspect of the guidelines published by American and European associations for assessing the indications for ERCP in patients with gallbladder stones and identifying those who require further investigation (2,3).

Aims & Methods: This study aims to determine how well ASGE and ESGE guidelines predict choledocholithiasis among patients who have been hospitalized with a diagnosis of biliary pancreatitis. The demographic, clinical, and laboratory parameters of cases admitted with a diagnosis of acute biliary pancreatitis between January 2014 and December 2018 at the Gastroenterology Clinic of Sakarya University Education and Research Hospital were retrospectively examined in our study.

The patient groups that underwent ERCP and those that did not were compared in terms of the criteria included in ESGE and ASGE among these patients.

Results: The data of 1538 patients was analyzed in the study. According to the ASGE and ESGE criteria, the specificity of indicating the presence of choledocholithiasis was 96% and 97.5%, respectively, and the positive predictive value (PPV) of ESGE was slightly higher than that of ASGE (83.9% and 79.5%, respectively). Adding the criteria of T. bilirubin >4 mg/dl and choledochal dilatation in ultrasonography (USG) to the ASGE criteria increased the specificity to >99% and was identified as the criterion with the highest positive likelihood ratio (LR+) (22.26). The specificity of the moderate probability of presence according to the ASGE and ESGE criteria was around 40%.

However, the presence of abnormal liver function tests (LFT) and choledochal dilatation together in the moderate probability criteria doubled the specificity in both ASGE and ESGE (98.6% and 95.4%, respectively).

Conclusion: In conclusion, it was determined that the use of high-probability ASGE and ESGE criteria is helpful for selecting appropriate patients for elective ERCP in patients with biliary pancreatitis. Especially, the presence of bilirubin and/or an elevated LFT in addition to choledochal dilatation detected by USG has a high predictive value for choledocholithiasis.

EARLY PREDICTION MODELS FOR ESTIMATING THE NEED FOR INTERVENTION AND MORTALITY OF ACUTE PANCREATITIS: A MULTICENTER COHORT STUDY

H. Kang[1], K.J. Lee[2], S.I. Jang[3], S. Bang[4], J.H. Cho[3]
[1]Gil Medical Center, Gachon University College of Medicine, Department of Internal Medicine, Incheon, South Korea, [2]Hallym University Dongtan Sacred Heart Hospital, Hallym University College of Medicine, Department of Internal Medicine, Hwaseong, South Korea, [3]Gangnam Severance Hospital, Yonsei University College of Medicine, Department of Internal Medicine, Seoul, South Korea, [4]Severance Hospital, Yonsei University College of Medicine, Department of Internal Medicine, Seoul, South Korea

Contact E-Mail Address: rabbit9644@gmail.com
Introduction: The incidence of acute pancreatitis (AP) has been steadily increasing worldwide and the burden of disease can become greater if severe late phase complications occur. However, there is currently no prediction tool available in early phase for this specific clinical situation. We aimed to establish a prediction model with early phase parameters to estimate the need for intervention and late phase mortality.
Aims & Methods: We selected patients from a retrospectively collected AP cohort of five university hospitals that contained data of patient with AP from 2010 to 2022. The endpoint was defined as late phase pancreatitis-related mortality or endoscopic, percutaneous, vascular, or surgical intervention for complications within six months after admission. We randomly split the cohort into development and validation sets with a ratio of 7:3. The model was developed by logistic regression, and the diagnostic performance was analyzed using area under the curve (AUC).
Results: We identified 2,497 patients with AP (1,748 in the training set; 749 in the validation set) with a total endpoint rate of 3.1%. Two models were established using four variables at admission (Systemic Inflammatory Response Syndrome, organ failure, calcium <8.5 mg/dL, albumin <3.45 g/dL) and four variables after 48 hours of admission (Fever, organ failure, CRP ≥200 mg/L, CT Severity Index (CTSI) ≥5). Model #1 consists of variables at admission only, and Model #2 consists of all eight admission and 48hr variables. Model #2 had an AUC of 0.835 and 0.790 in the development and validation set, respectively. Model #2 showed significantly higher AUC to predict late-phase severe complications compared to Model #1 and other systems such as Ranson's criteria, BISAP score, and CTSI. Using two established models sequentially, patients can be classified into four groups with different rates of late phase severe complications (15.2% vs. 9.5% vs. 2.8% vs. 0.9%; P<.001).
Conclusion: We developed a set of early prediction models to predict the likelihood of eventual mortality or intervention in the late phase of AP within 6 months. These models can stratify the long-term prognosis of AP and help with appropriate allocation of medical resources for intensive care and interventional procedures.

THE NATURAL COURSE OF ASYMPTOMATIC PANCREATIC WALLED-OFF NECROSIS

M. Bektaş[1], S. Acar[2], A.T. Eminler[2], M. Tozlu[2], B. Toka[2], M.I. Uslan[2], E. Parlak[3], A.S. Koksal[2]
[1]Sakarya University, Internal Medicine, Sakarya, Turkey, [2]Sakarya University, Gastroenterology, Sakarya, Turkey, [3]Hacettepe University, Gastroenterology, Ankara, Turkey

Contact E-Mail Address: eminler77@gmail.com
Introduction: Walled-off necrosis (WON) may develop in the long-term follow-up after acute pancreatitis due to acute inflammation of the pancreas. It can be managed through endoscopic, percutaneous, or surgical drainage, depending on its clinical condition. The methodology is a topic of debate due to the scarcity of data regarding the progression of asymptomatic WON in patients (1).
Aims & Methods: The aim of this study is to determine the course of asymptomatic individuals who have developed walled-off necrosis (WON) following to an episode of acute pancreatitis over a long time of observation. A retrospective evaluation was conducted on 46 (3.9%) out of 1173 patients diagnosed with acute pancreatitis between June 2016 and December 2019, who developed WON during the follow-up period. Individuals who exhibited symptoms either at the point of diagnosis or during subsequent monitoring had been determined. An analysis was made between the clinical and WON characteristics at baseline of patients who required drainage during follow-up and those who did not.
Results: Out of the total of 46 patients who developed WON, 4 individuals were excluded due to inadequate follow-up data, 9 patients underwent drainage at the time of diagnosis, and 2 patients lost without receiving any form of drainage intervention. During the course of the study, a total of 31 patients were followed up for a mean duration of 25.20±17.40 months. Out of these patients, 10 (32.3%) required interventional intervention within a mean duration of 122.5±152.5 days (Group 1), while the remaining 21 patients (67.7%) were monitored without any intervention.
Embolization was executed on a single patient owing to the presence of a splenic artery aneurysm identified in WON, however, drainage was not carried out. Endoscopic drainage was employed in five patients, percutaneous drainage in three patients, and surgical drainage in one patient. The prevalence of biliary etiology was found to be significantly higher in Group 1 compared to Group 2 (90.0% vs 47.6%, p<0.050).
The study revealed that the Intra-WON necrosis rate and initial WON size were significantly higher in patients who required drainage at follow-up. The Intra-WON necrosis rate was 68.50±28.50% compared to 38.10±26.90% in the non-drainage group (p<0.05).
Similarly, the initial WON size was 125.90±46.60 mm in the drainage group compared to 89.30±45.00 mm in the non-drainage group (p<0.05).
Conclusion: Asymptomatic patients with walled-off necrosis (WON) ought to be managed conservatively through careful ongoing monitoring. It is recommended that the results obtained be validated through extensive longitudinal research.

Introduction: Surgery has been the conventional treatment for symptomatic Disconnected pancreatic duct syndrome (DPDS). The advent of therapeutic endoscopic ultrasound (EUS) has brought a paradigm shift in endoscopic management of DPDS. However, data on long-term outcomes of various interventions especially endoscopic interventions in DPDS is lacking.

Aims & Methods: A prospectively maintained database of patients with acute necrotizing pancreatitis (ANP) having DPDS and undergoing endoscopic interventions over the last ten years was analyzed. All included patients had proven duct disruption documented either on Magnetic resonance cholangiopancreatography or endoscopic retrograde cholangiopancreatography. Patient demographics, etiology of pancreatitis, extent of pancreatic necrosis, site of duct disruption, details of interventions and their outcome along with long-term follow-up data were analyzed.

Results: 68 patients with DPDS (mean age: 38 ± 8.16 years, male to female ratio: 5.8) were included. Alcohol was the commonest etiology of ANP [45/68 (66.2%)]. The site of duct disruption was neck in 23 (33.8%), body in 43 (63.2%) and tail in 2 (2.9%) patients. 42 (61.76%) patients had >30% parenchymal necrosis on imaging at day 5 of onset of ANP. 53 (77.94%) patients with DPDS had an external pancreatic fistula (EPF) consequent to percutaneous drainage while 3 (4.41%) developed EPF post-surgery.

Other presentations included recurrent pancreatic fluid collection(PFC) following successful transmural drainage of walled off necrosis in 5 (7.3%) patients and percutaneous drainage in 1 patient (1.4%) respectively and recurrent pain/pancreatitis in 6 (8.8%) patients. EPF healed by medical therapy including subcutaneous Octreotide in 23 (33.8%) patients whereas EUS-guided transmural drainage (ETD) of fistula tract/coexistent fluid collection resulted in successful closure of EPF in 25 (36.8%) patients. Surgical closure of EPF was done in 8 (11.8%) patients. Recurrent PFCs (n=6) were successfully managed by ETD and permanent indwelling transmural plastic stents.

Patients with recurrent pain were successfully managed with EUS-guided pancreatic duct drainage of the disconnected segment followed by regular stent exchange. Over a mean follow-up period of 54.43 ± 29.46 months, 3 patients developed recurrent PFC that was successfully managed with ETD. All these 3 patients had initially presented with EPF (2 managed conservatively and 1 surgically). None of the patients treated endoscopically had recurrent pain/PFC. 18 (26.5%) patients developed diabetes mellitus (DM) with 14 patients requiring insulin.

Conclusion: DPDS results in a prolonged and complicated clinical course in patients with AP. EUS-guided interventions seem to be safe and effective for the management of various clinical consequences of DPDS. Despite successful drainage of the disconnected segment, one-third of patients develop DM.

Disclosure: Nothing to disclose.

Introduction: Acute pancreatitis (AP) can progress to recurrent acute pancreatitis (RAP) or chronic pancreatitis (CP).

Aims & Methods: This systematic review and meta-analysis aimed to identify risk factors associated with this progression. The protocol was registered on PROSPERO (CRD42022368931). A comprehensive search was conducted in three (Medline, Embase, Cochrane) databases on October 25th, 2022. Articles reporting and risk factors associated with AP progression into RAP or CP were included. Pooled odds ratios (OR) with 95% confidence intervals (CI) were calculated using the random effects model. Heterogeneity was evaluated using the I^2 statistic. The risk of bias assessment was performed using the Quality in Prognostic Studies (QUIPS) tool.

Results: A total of 71 articles were included in the meta–analysis, and several risk factors were identified for the progression of AP into RAP and CP. We found the following risk factors of AP recurrence: younger age, male gender, smoking, alcoholic etiology, hypertriglyceridemia, diabetes mellitus, pseudocyst, etc. The pooled OR for the male gender was 1.45 (95% CI: 1.29-1.64, I^2=24%), for smoking was 1.45 (95% CI: 1.16-1.81, I^2=62%), for alcoholic etiology was 1.76 (95% CI: 1.38-2.25, I^2=81%), for hypertriglyceridemia was 2.45 (95% CI: 2.07-2.90, I^2=9%), for diabetes mellitus was 1.49 (95% CI: 1.24-1.80, I^2=0%), for pseudocyst was 2.19 (95% CI: 1.52-3.15, I^2=0%). We also found risk factors of RAP progression into CP. The risk of bias was moderate in the majority of the included studies.

Conclusion: Our study identified multiple modifiable risk factors which can be treated to prevent the progression of pancreatitis.

Disclosure: Nothing to disclose.

Contact E-Mail Address: federicocaldart94@gmail.com

Introduction: Acute pancreatitis (AP) can be associated with CFTR gene mutations. Several mutations have been described and classified based on the type of protein changes. The CFTR-France database classifies variants in disease-causing (DC), variants of unknown significance (VUS) and no-disease-causing (NDC), according to their clinical consequences. The role of VUS and NDC mutations in AP patients was not clearly defined.

Aims & Methods: The aim of this study is to determine the role of VUS and NDC mutations in patients suffering from AP. We enrolled retrospectively patients with AP observed in our Centre between 2013 and 2020 and tested for CFTR gene mutations. Patients were divided in CFTR wild type, DC, VUS and NDC. We evaluated epidemiological, clinical, and instrumental characteristics at the disease onset and the clinical outcome in terms of progression to chronic pancreatitis, onset of pancreatic calcifications, development of exocrine and endocrine pancreatic insufficiency.

Results: We tested 322 patients (199 males and 123 females, age at onset 35.4±15.8 years). We compared 99 patients with CFTR mutations (65 males and 34 females, age at onset 29±13 years) with 223 wild type patients (134 males and 89 females, age at onset 38.2±15.7 years), showing significant differences in terms of age at onset, BMI, smoking and drinking habits, chronic pancreatitis, and pancreatic calcifications at the onset of the disease. The clinical course of the wild type patients was characterized by an earlier progression to chronic pancreatitis, onset of calcifications and exocrine pancreatic insufficiency. VUS and DC patients had a similar clinical outcome of the disease. NDC group was excluded from the analysis due to the low number of patients.

Conclusion: Patients carrying VUS mutations of the CFTR gene have a clinical outcome similar to patients carrying DC mutations.

Disclosure: Nothing to disclose.

Introduction: Pancreatic fluid collections (PFCs) resulting from acute pancreatitis (AP) that are persistently symptomatic can be associated with infections and mass effect.

Aims & Methods: Aim: The aim of the study was to evaluate the clinical characteristics and natural history of PFCs in AP.

Methods: In this study, we recruited a total of 378 patients includes 253 (66.93%) prospective hospitalized patients and 125 (33.06%) retrospective patients who had presented with documented AP at the Pancreas Clinic. In this abstract, we present prospective data. Patients underwent a thorough demographic and clinical history. We also recorded data on PFC morphology, presence of venous thrombosis, the need for interventions and outcomes of PFCs at baseline and each follow-up visit. Continuous data were expressed in median with interquartile range (IQR) and categorical data as proportions.

Results: A total of 253 prospective hospitalized patients were included with median (interquartile range, IQR) age in years of 34.56 (27–43) and a higher prevalence of males 217 (81.5%) than females 36 (14.2%) were observed. The most common etiology was idiopathic 71 (28.1%) followed by alcohol 70 (27.7%), alcohol with smoking 5 (2.0%) and cholelithiasis 37 (14.6%). Most patients had moderately severe and severe AP were 214 (84.6%) and 39 (15.4%) respectively with the index episode observed in 175 (69.2%), recurrent in 75 (29.6%) and acute on chronic in 3 (1.2%). The most common type of fluid collection was acute necrotic collection 230 (90.9%) followed by walled-off necrosis 20 (7.9%), pseudocyst 4 (6.2%) and acute peripancreatic fluid collection 3 (1.2%).

In terms of fluid collection, During the first three months, the volume and maximum size were 83.60 (26.3–383.20) cubic centimeters (cc) and 8.90 (5.47–12.42) diameter, respectively. Venous thrombosis was the most common complication in 172 (68%) patients and was observed in the retropancreatic splenic vein in 38 (15.2%). 18 (14.4%) patients required interventions in the first 3 months, while 14 (11.2%) in the next 3 months. Venous thrombosis developed in 15 (5.9%) additional patients during the next 3 months. The most common intervention was EUS-guided cystogastrostomy (CG) with SEMS or plastic placement in 49 (19.6%) in the first 3 months, followed by PCD alone in 29 (11.5%), PCD followed by EUS drainage in 16 (6.4%), and combined procedures in 15 (6%). Complete resolution was observed in 52 (20.6%) patients among those who did not undergo intervention within the first three months, while a reduction and increase in size were seen in 60 (23.7%) and 65 (25.7%) patients respectively. Among the patients who did not undergo intervention between third and sixth months, complete resolution was observed in 72 (28.5%) patients, while a decrease and increase in size were seen in 31 (12.3%) and 26 (10.3%) patients respectively. Among the patients who underwent interventions during the first and next 3 months, PFC relapse and increase in size were observed in 8.90 (5.47–12.42) and 4.4 (0.0–10.9) of the patients who underwent interventions in the first and following three months, respectively. The mortality rate was observed in 21 (8.4%) patients.

Conclusion: 75% of PFCs undergo spontaneous resolution within 6 months, while most relapses and venous thrombosis occur within the first 3 months. These findings highlight the importance of closely monitoring patients during the early stages of PFC development, as this period may present a heightened risk for complications that require medical intervention.

Introduction: Etiology of acute pancreatitis can be established in the majority of patients. However, in 25 % of cases it remains elusive. Biliary microlithiasis/sludge is detected in up to 75% of patients with idiopathic acute pancreatitis (IAP). As recurrent biliary pancreatitis can be prevented, the underlying etiology of IAP should be established. The aim of this multicentre retrospective study was to develop a machine learning-aided non-invasive prediction tool to guide clinicians in the selection of idiopathic acute pancreatitis patients to be referred to endosonography to establish etiology and allow treatment.

Aims & Methods: We retrospectively used routinely recorded clinical and laboratory parameters of 218 consecutive patients with confirmed acute pancreatitis admitted to our tertiary care hospital between 2015 and 2020. Patients who did not receive endosonography as part of the diagnostic work-up and whose pancreatitis episode could be adequately explained by other causes than biliary sludge and microlithiasis were excluded. We trained supervised machine learning classifiers using H2O.ai automatically selecting the best suitable predictor model to predict microlithiasis/sludge. The predictor model was validated in two independent retrospective cohorts from two tertiary care centers (TU Munich & University Medical Center Göttingen).

Results: 28 categorized patients' variables recorded at admission were identified to compute the predictor model with an accuracy of 0.84 [95% CI 0.791, 0.9185], positive predictive value of 0.84 and negative predictive value 0.80 in the identification cohort (218 patients). In the validation cohort, the robustness of the prediction model was confirmed with an accuracy of 0.76 [95% CI 0.673, 0.8347], positive predictive value of 0.76 and negative predictive value of 0.78 (117 patients).

Conclusion: We present a robust and validated machine learning-based predictor model consisting of routinely recorded lab work at admission that can predict biliary sludge and microlithiasis as cause of acute pancreatitis and select patients for EUS.

Disclosure: Nothing to disclose.

Introduction: Microlithiasis and sludge have been considered the largest aetiological drivers within the cohort of idiopathic acute pancreatitis for decades. Subsuming microlithiasis and sludge-induced pancreatitis patients into the idiopathic or gallstone-induced pancreatitis cohorts has so far made adequate risk assessment regarding pancreatitis outcome impossible. It is therefore still unclear whether different therapeutic approaches are needed for microlithiasis and sludge than for gallstone-induced pancreatitis.

Aims & Methods: 348 patients with acute biliary pancreatitis treated at a high-volume pancreas centre from 2005 to 2021 were stratified into a total of 7 concrement groups using the new consensus definition for microlithiasis and sludge. The gallstone-pancreatitis cohort was compared with the microlithiasis and sludge cohort and all possible combination concrement groups with regard to pancreatitis disease progression (cholestasis pattern, EUS/ERCP results).

Results: Microlithiasis and sludge-induced pancreatitis as well as combination concrement groups classified according to the revised Atlanta classification did not show a milder course than gallstone-induced pancreatitis (p = 0.63). Microlithiasis (3.6 mg/dl; mean) and sludge (2.6 mg/dl; mean) showed an increase in bilirubin on the day of admission to hospital due to pancreatitis, which was not significantly different from gallstone-induced pancreatitis (3.5 mg/dl mean, normal range < 1.2 mg/dl; p = 0.067). The highest EUS concrement detection and ERCP concrement extraction rate occurred on the day of admission and day 1, respectively. EUS detection rate (day 1): Gallstone AP 44.82 % (n = 13/29), Microlithiasis AP 46 % (n= 7/15), Sludge AP 40.7 % (n = 11/27), p = 0.98; ERCP extraction rate (admission day): Gallstone AP 39.1 % (n = 18/46), Microlithiasis AP 25 % (n = 5/20),Sludge AP 38.8 % (n = 7/18); p = 0.49).

Conclusion: Microlithiasis and sludge achieve a gallstone-equivalent cholestasis pattern and also do not differ in pancreatitis outcome from gallstone-induced acute biliary pancreatitis. In the case of EUS detection of microlithiasis and sludge in the early phase of acute pancreatitis, the concrement should be considered as a trigger rather than a cause of pancreatitis (unless another aetiology can be detected).

Introduction: Within five years of having acute pancreatitis (AP), three in five people develop prediabetes (PD) or diabetes mellitus (DM). However, information on risk factors is limited.

Aims & Methods: We aimed to identify risk factors for developing PD or DM following AP. We systematically searched three databases up to 2021.11.18 extracting direct, within-study comparisons of risk factors on the rate of new-onset PD, DM or PD/DM in AP patients. Meta-analysis was performed using the random-effects model to calculate pooled odds ratios (OR) with 95% confidence intervals (CI).

Results: Of the 45 studies identified, 36 were included in the meta-analysis, covering 71,367 participants. The odds of developing DM was significantly higher after severe AP (OR: 2.65; CI: 1.23-5.71) than non-severe, alcoholic AP (OR: 1.95; CI: 1.03-3.67) compared to other aetiologies and if pseudocysts developed (OR: 2.50; CI: 1.00-6.28) versus their absence. The odds of developing PD/DM was significantly higher after severe AP (OR: 3.16; CI: 1.13-8.83) than non-severe, severe and moderate AP (OR: 4.66; CI: 2.24-9.68) versus mild and presence of necrosis (OR: 5.53; CI: 1.59-19.21) versus its absence. Compared to other aetiologies there was a tendency for PD/DM development in hypertriglyceridaemic AP (OR: 3.27; CI: 0.84-12.67) and significantly lower odds of developing DM (OR: 0.61; CI: 0.44-0.85) and PD/DM (OR: 0.72; CI: 0.55-0.94) with idiopathic and biliary aetiology, respectively.

Conclusion: Severe and moderately severe AP, local complications, alcoholic and hypertriglyceridaemic aetiologies may be linked to a higher odds of developing PD or DM.

Disclosure: No conflict of interest.

Introduction: Splanchnic vein thrombosis (SVT) is a local complication of acute pancreatitis (AP) that may lead to subsequent complications such as portal hypertension, gastrointestinal bleeding, and mesenteric ischemia.[1,2] Despite its clinical significance, there is limited data in the literature concerning the temporal development and associated risk factors of SVT.

Aims & Methods: Our aim was to understand the time course and risk factors of SVT in the early phase of AP. To identify relevant studies we conducted a systematic search across four major medical databases (Embase, MEDLINE via PubMed, Scopus, and Cochrane Central Register of Controlled Trials) on 27th of October 2022. We included studies that employed appropriate imaging techniques in adult patients with AP, reported SVT data from the early phase of AP, and provided reliable information about the timing of imaging relative to AP symptom onset or hospital admission. We excluded studies that reported data on patients with a recent history of malignant disease or recent surgical procedures. We calculated the proportion of patients affected by SVT with 95% confidence intervals (CI). We conducted subgroup analyses based on diagnostic timing and disease characteristics. To assess the risk of bias we used the Joanna Briggs Institute Critical Appraisal Checklist for Prevalence Studies and the GRADEpro tool to determine the level of evidence. The protocol for this method was registered prospectively in the PROSPERO database, with registration number CRD42022367578.

Results: Data from 14 eligible studies and 1,951 patients was pooled; the proportion of patients with SVT in the early phase of AP (within 11 days after symptom onset or 5 days after hospital admission) was 0.13 (CI 0.07-0.23). The occurrence was lowest 0-3 days after symptom onset at 0.06 (CI 0.03-0.1), it increased to 0.23 (CI 0.16-0.31) between 3-11 days. Disease factors influencing SVT occurrence were severity (mild: 0.14 (CI 0.04-0.39), moderate: 0.23 (CI 0.09-0.47), severe: 0.31 (CI 0.15-0.54), p=0.21), etiology (alcoholic 0.31 (CI 0.13-0.58), biliary 0.12 (CI 0.04-0.3), p=0.03), and pancreatic necrosis (absent 0.10 (CI 0.04-0.25), under 30% 0.25 (CI 0.1-0.5), over 30% 0.55 (CI 0.29-0.78), p= 0.01).

Conclusion: One in eight patients develops SVT in the early phase of AP. Alcoholic etiology and pancreatic necrosis increase the risk of SVT. In addition, this risk seems to increase with the duration of AP; therefore, looking for and diagnosing SVT with imaging is important in the management of AP.

NEUTROPHIL-LYMPHOCYTE RATIO (NLR) AS PROGNOSTIC MARKER IN ASSESSING ACUTE PANCREATITIS OUTCOME

R. Garlapati[1], V.R.R. Valluru[1], G Mohan Reddy[1]
[1]Kurnool Medical College, Gastroenterology, Kurnool, India

Contact E-Mail Address: rakeshreddy117@gmail.com
Introduction: Acute pancreatitis is one of the most common cause of emergency hospital admissions in India. The neutrophil–lymphocyte ratio (NLR), calculated from the white cell differential count, provides a rapid indication of the extent of an inflammatory process and helpful categorizing the patients.
Aims & Methods: To determine an optimal ratio of NLR for severity prediction.
Prospective cross-sectional study was done in department of gastroenterology, Kurnool medical college in 100 consecutive acute pancreatitis (according revised Atlanta criteria) patients visiting gastroenterology OPD. Blood samples were collected immediately on admission and end of 48 hours. Relevant radiological investigations were done.
Results: Alcohol etiology was common cause of pancreatitis.
The mean NLR on admission in Mild group was 6.2±1.2 and the moderate group was 9.1± 1.6. The mean NLR of severe group was 13.6±2.5. The differences between the severity were statistically significant (P <0.001).
The mean NLR at end of 48 hours in Mild was 4.7± 0.7, The moderate group was 8.3± 1.2 and the mean NLR of severe group was 14.8±1.6. The differences between the severity were statistically very highly significant (P <0.001).
Conclusion: NLR can be done at the time of admission and can be serially monitored which can act as a guide to detect those patients progressing to severe pancreatitis.

Introduction: Acute pancreatitis is the most common and serious complication of endoscopic retrograde cholangiopancreatography (ERCP). Risk factors for PEP are classified as patient-related and endoscopist- or technique- related factors. However, patient-related factors focused on the pancreatic volume and intrapancreatic fat content have not been investigated previously.
In this study, we used 3- dimensional (3D) volumetry, and histogram investigated the potential association of pancreatic head volume and fat content with the incidence of PEP.
Aims & Methods: We retrospectively analyzed 157 patients who underwent ERCP for diagnostic or therapeutic purposes.Pancreatic volume was measured by using contrast-enhanced images obtained by continuous 5.0-mm, 320-, 64-row detector CT before ERCP. Computed tomography scan images of precontrast and venous phase were used for evaluation. Pancreatic volume was determined by using 3D analysis software.
The pancreas was divided into the head and body/tail using the left edge of the superior mesenteric-portal vein confluence, and the volume of each part was calculated separately. Hounsfield unit histogram analysis (HUHA) was performed by using precontrast images. The percentage of HUHA ≤0 Hounsfield unit (HU) in pancreatic parenchyma represented the fat content. Multivariate analysis was performed to identify risk factors for PEP.
Results: PEP occurred in 35 patients (PEP group) and the incident rate was 22.3%. The mean volume of the whole pancreas was significantly larger in the PEP group (p<0.001). The mean volume of the pancreatic head was significantly larger in the PEP group (p<0.0001), but there were no significant differences in those of the pancreatic body and tail. Fat content of the pancreatic head was significantly higher in the PEP group (p<0.01), but there were no significant differences in fat content of the pancreatic body and tail. Multivariate analysis revealed that the pancreatic guidewire placement (hazard ratio [HR], 4.7; p < 0.01), the pancreatic head volume (HR, 7.1; p < 0.01), and fat content of the pancreatic head (HR, 5.1; p < 0.01) were independent risk factors for PEP.
Conclusion: The volume and fat content of the pancreatic head were independent predicting factors for PEP. Quantitative assessment of the pancreas using multislice CT imaging may contribute to the prediction of the onset of PEP.

Contact E-Mail Address: sebastian.rasch@tum.de

Introduction: Incidence and mortality rates of acute pancreatitis (AP) vary and often rely on old surveys. Likewise, the type of organ failure and consequent interventions have only been reported in a few recent reports. [1-3] We thus compiled German-wide data on morbidity and mortality of AP using the Diagnosis-related group (DRG) coding system.

Aims & Methods: All German hospitals have to report DRG codes to the federal statistical office. We analysed this database of the years 2018 and 2019 for selected DRG Codes.[4] The derived information was classified as reliable, acceptable or prone to bias depending on the reported code (e.g. mandatory information or not).

Results: In 2018 and 2019 109.064 patients with the main diagnosis AP were treated in German hospitals. This corresponds to an incidence of 65.5/100.00 person-years. The median age was 57 (IQR 45-71), 60.8% were male and 22.0% had an acute on chronic pancreatitis. The median hospital stay was 6 days (IQR 4-10), while 5.2% were discharged within 1 day. According to the DRG codes, 7.3% suffered respiratory failure, 6.4% renal failure (acceptable information), 1.6% circulatory failure and 0.6% liver failure (information prone to bias). 1.3% of the patients received renal replacement therapy and 0.06% ECMO therapy. A pancreatic drainage was performed in 1.8 % of the patients. In 73% of these cases an internal drainage was applied. A necrosectomy was performed in 1.1% of the patients and 0.8% received therapy with Caspofungin (reliable information). In total, 3.5% of the patients were admitted to an intensive care unit , 3.6% were put on ventilation, and 3.1% on invasive ventilation. According to the revised Atlanta classification 86.8% of the patients had a mild pancreatitis while 13.2% suffered at least one coded organ failure or local complication (moderately severe and sever AP). Overall mortality was 2.4% (1.6/100.000 persons, reliable information). Patients with at least one coded organ failure or local complication suffered a mortality rate of 14.9 %, in patients that were either treated for local complications, ventilated or dialysed (5.5% of the patients, corresponding to a severe AP) the mortality rate was 24.9% (reliable information).

Conclusion: The incidence of AP is notably higher than previously reported and patients with systemic or local complications still suffer a substantial mortality. However, recent mortality rates in Germany appear to be on the lower side of the reported range.

Introduction: Recent advancement in endoscopic ultrasonography (EUS)-guided treatment has improved clinical outcomes of patients with pancreatic fluid collections (PFCs). However, there is still a debate on preventive effect of long-term placement of a transmural plastic stent (PS) on recurrence after successful resolution of PFC. We conducted a systematic review and meta-analysis evaluating PFC recurrence rates with and without a transmural PS after EUS-guided treatment.

Aims & Methods: We conducted a systematic literature search using PubMed, Web of Science, Embase, and the Cochrane database to identify clinical studies comparing outcomes with and without transmural PS published until September 2022. We pooled data on PFC recurrence and adverse events using the random-effects model.

Results: Seven studies (randomized controlled trial, 2; prospective study, 1; retrospective study, 4), including 333 patients with long-term transmural PS and 289 patients without PS, were identified. The rate of PFC recurrence was significantly lower in patients with transmural PS (pooled odds ratio [OR] 0.24, 95% confidence interval [CI] 0.06-0.95; P = 0.042). A similar trend was observed when analyzing three prospective studies (OR 0.14, 95% CI 0.02-0.85; P = 0.033). In a subgroup analysis limited to studies focusing on patients with disconnected pancreatic duct syndrome that has been reported to be a risk factor for PFC recurrence, the odds ratio was numerically lower than that for the entire cohort (OR 0.14, 95% CI 0.04-0.46). Adverse events associated with long-term transmural PS placement were reported in four studies. The rate of adverse events was 4.1%, whereas asymptomatic stent migration was observed in 22.3%. We conducted a meta-regression analysis, which suggested that the types of stents utilized for the initial EUS-guided drainage (lumen-apposing metal stent vs. PS) had no significant influence on the association between long-term transmural PS and PFC recurrence.

Conclusion: In this meta-analysis, long-term PS placement could reduce the risk of PFC recurrence. Given the potential adverse events of indwelling PS, such as stent obstruction or bleeding, our results should be confirmed in prospective comparative studies.

Contact E-Mail Address: mihai.pahomeanu@drd.umfcd.ro

Introduction: Updated population-based studies on acute pancreatitis (AP) in Romania are lacking. Our aim was to evaluate the current data for AP in a tertiary center in Bucharest.

Aims & Methods: We performed an electronic health care records (EHRs) search ICD-10 codes: K85, B25.2, B26.3) for AP cases treated at University Emergency Hospital of Bucharest between 2015 and 2022. Aim of this study was to estimate the daily cost of AP and its probable correlation in regard to: type of case (gastroenterological or surgical), sex, age, ICU, outcome, etiology, severity, morphology (assessed as stated in Revised Atlanta Classsification (RAC). All costs reported in EUR by conversion from RON at the date of submission (28 april 2023).

Results: 1503 episodes of AP (942 gastroenterological, 561 surgical) in 1314 unique patients were analysed, data about costs being found in 1246 episodes. Median daily cost (MDC) estimated at 170.91. Higher MDC was related to surgical AP, F(1,1244)=7,05, p<0,01. The Kruskal-Wallis analysis showed significant diferences in regard to: severity H(2)=85,20, p<0,01 with the highest cost in severe AP (Md=229.23) and the lowest in mild AP (Md=162.26); outcome H(4)=105,22, p<0,01 the deceased having the highest MDC (Md=204.84) and the one healed the lowest (Md=118.57).

Significant differences H(6)=17,22, p<0,01 were found between Acute Necrotic Collection (Md=123.29) and Interstitial AP (Md=84.80) and between the biliary H(15)=203,96, p<0,01 (Md=139.34), hypertrigliceridemic (Md=97.45) and alchoolic etiology (Md=79.31). Pearson Correlation found a weak and unsignificant correlation with older age, r(1244)=0,25, p=0,373. No significant differences were found regarding sex, F(1,1244)=2,73, p=0,09, and admission in ICU F(1,1229)=1,46, p=0,23.

Conclusion: In this large retrospective study higher costs of AP correlate to hospitalization in surgical wards, severity, developement of local complications and biliary etiology. No correlations were found to age or ICU admission. Median daily cost (MDC) estimated at 170.91. This is the first report of AP related costs in Romania.

Introduction: Nearly all patients with Acute Pancreatitis (AP) experience abdominal pain which warrants prompt analgesia, and this is one of the main management priorities in the early management of AP (1). With some recent studies suggesting that EA might be a safe procedure and a promising therapeutic approach in AP (2,3,4), we sought to assess the benefit of EA over IV analgesia on pain control in patients of AP with moderate to severe pain.

Apart from analgesia efficacy we also checked for improvement in organ failure, morbidity and mortality in patients of AP.

Aims & Methods: This study was conducted over a period of one and a half years. All consecutive patients of AP were prospectively included in the study with moderate to severe pain based on a numerical rating scale (NRS ≥4), irrespective of the severity of pancreatitis. Patients were sequentially allocated into 2 groups- Epidural Patient-controlled analgesia (PCA) group (Ropivacaine 0.2% + Fentanyl 2 mcg/ml) and Intravenous (IV) PCA group (Fentanyl 10 mcg/ml) + IV Paracetamol 1 gm Thrice daily and medications were given for a period of 5 days. In both groups, morphine was used as rescue analgesia at times when NRS ≥4.

The primary objective was to assess pain control and the Secondary objectives were to assess the efficacy of epidural and IV analgesia on organ failure, morbidity and mortality in patients of AP. Standard statistical analysis was done and the comparison of quantitative variables with or without normal distribution was analysed using Independent t-test and Mann-Whitney test respectively. The Qualitative variables were analysed with the Chi-square and Fisher's exact tests. P value <0.05 was considered statistically significant.

Results: We enrolled 36 patients with AP, 18 patients in each group. All baseline characteristics were comparable between the two groups. The mean age of subjects was 45.2 ± 13.3 years. The mean time of admission from the onset of pain in our study subjects was 2.56 ± 1.2 days. The mean number of days with adequate pain control was 3.28 ± 0.75 days in the epidural versus 3.11 ± 0.76 days in the IV group with no observed statistically significant difference (p = 0.496). Adequate pain control was achieved at day 3 in both groups as per NRS which was not statistically significant. The total Patients who required rescue analgesia were 16

(44.4%). Almost half of the patients 9 (50%) in the IV group required rescue analgesia in comparison to 7 (38.9%) in the epidural group, and the cumulative dose of rescue analgesia (morphine) required was 60 mg in the epidural group, which was lower than the dose required (76 mg) in the IV group though not statistically significant (p = 0.83). Organ failure was seen in a total of 9 (25%) patients (4 patients in the epidural versus 5 patients in the IV group).

The most common observed organ failure was acute lung injury in 6 (16.7%), 3 in each group followed by acute kidney injury in 3 (8.3%) patients, 2 in IV and 1 in the epidural group (p = 1.0). The resolution of SIRS at day 3 in comparison to baseline was better in the epidural group as compared to the IV group (70% vs 27.7%) though statistically not significant (p = 0.089). There was no mortality in either group.

Conclusion: We concluded that thoracic epidural PCA and IV PCA were equally efficacious in pain control in acute pancreatitis. However, the need for rescue analgesia was lower in the thoracic epidural group than in the IV group, though statistically not significant. Moreover, thoracic epidural analgesia was safe, feasible, and showed an insignificant clinical trend towards early SIRS resolution.

Introduction: Hypertriglyceridemia is a well-established cause of acute pancreatitis, representing up to 35% of all etiologies. The risk of developing acute pancreatitis increases progressively with serum triglyceride (TG) levels over 500 mg/dL. The degree of TG elevation is also associated to the severity of hypertriglyceridemia-induced pancreatitis (HTGP).

Besides general measures, it has been suggested from observation studies that, in selected patients, insulin and plasmapheresis may have a role in the management of this condition.

Aims & Methods: We present an observational retrospective study of patients diagnosed with severe HTGP treated with plasmapheresis (PX) in an Intensive Care Unit (ICU) between January 2013 and March 2023.

Results: Of the 19 patients included in this study, 89% were men (n=17) and the mean age of presentation was 41 ± 7 years. Around 90% of patients were obese with a mean body mass index (BMI) of 29 ± 3 kg/m^2. The average APACHE II score was 9±7 and most patients did not require organ support (n=16, 84%). All the selected patients had severe hypertriglyceridemia at admission (1225 to 4700 mg/dL) and underwent PX within 48h of ICU admission. Levels of TG were measured before and after each plasmapheresis. 68% of patients needed only one treatment to reduce TG to a value below 500 mg/dL (n=13), 26% needed two treatments (n=5) and 5% needed four (n=1). A total of 27 PX were conducted. The average decrease in TG levels per treatment was 67% and 74% with the first treatment. The mean volume exchanged was 3683 mL ± 859 mL, and the most used replacement solutions were albumin/crystalloid (n=12, 44%) and albumin alone (n=11, 41%). The technique was interrupted mainly due to elevated transmembrane pressure (n=11, 40%). There were no PX interruptions due to complications related to the patient. Although heparin was used in all patients for anticoagulation, no hemorrhagic complications were associated to the technique. Hypotension occurred in 7% of plasmapheresis and was solved with crystalloid administration . The mean ICU length of stay was 7+11 days and the mean hospital length of stay was 17+21 days. The hospital mortality was 5% (n=1).

Conclusion: PX proved to be successful in lowering TG levels in HTGP. One to two plasma exchanges effectively reduced the serum TG level. There was a low rate of procedure-related complications. However, having no comparison with standard treatments, the impact of this technique on the patients' clinical outcomes is still uncertain. Further prospective randomized clinical studies are needed to outline an efficient treatment for the management of HTGP.

Introduction: Multidisciplinary team meetings (MTM) have been adopted widely to ensure that oncological patients receive an optimal diagnosis, staging and treatment, especially in tertiary referral centers. The relevance of MTM on acute and chronic pancreatitis is unexplored.

Aims & Methods: The aim of this study is to describe the experience of a tertiary referral center MTM for pancreatic diseases in the management of patients with acute and chronic pancreatitis (AP/CP).

A prospectively maintained database of patients with AP/CP discussed in MTM from 10/2020 to 01/2023 was queried and patients analyzed according with the subsequent clinical problems: etiology of AP (EAP), treatment of AP complications (TAP), etiology of chronic pancreatitis (ECP) and treatment of chronic pancreatitis complications (TCP).

Results: Globally 143 patients were included for a total of 201 discussions. 94 were AP and 49 CP (median/IQR age 55/43-68 years; males 58.3%). According with the established clinical questions:

- EAP (67 patients): the hypothesized etiology before MTM discussion was in most cases autoimmune (64%) or idiopathic (18%). Imaging revision alone at the MTM changed the suspicious etiology in 28%. After performing further investigations suggested by the MTM the final diagnosis was changed in additional 39% (3 overlooked cancers diagnosed).
- TAP (27 patients): mostly referred for pseudocysts (37%), management of complications in anatomical variants (17%), walled-off necrosis (13%). The problem was solved in 100% of cases, mostly by surgical (33%) or endoscopic (48%) treatments.
- ECP (14 patients): MTM changed the initial suspicion in 50% of cases, with previously unexplored genetic etiology in 64% of cases. 50% of initially idiopathic CP cases had a definite etiology.
- TCP (35 patients): mostly referred for appearance of focal lesion in CP (22%), pancreatic duct obstruction/stenosis (28%) or abdominal pain (28%) with resolution of the problem in 98% of cases by surgical (53%) or endoscopic (17%) treatments. Three malignant lesions were diagnosed.

Conclusion: Our observational study shows that a MTM conducted in tertiary referral center for pancreatic diseases allows to correctly establish etiology and treat complications in AP and CP. A high rate of previously overlooked malignancies were diagnosed and genetic defects identified.

VIRAL ETIOLOGY IN PATIENTS WITH IDIOPATHIC ACUTE PANCREATITIS

A. Abu-Elfatth[1], A. Osman[1], M. Mekky[1], M.A. El-Mokhtar[2], S. Mohammed[1]

[1]Assiut University Hospital, Assiut University, Assiut, Egypt, [2]Assiut University, Medical Microbiology and Immunology, Faculty of Medicine, Assiut, Egypt

Contact E-Mail Address: ahmed111@aun.edu.eg

Introduction: Acute pancreatitis (AP) is the most common gastrointestinal disease requiring hospitalization, and is associated with high morbidity and mortality. Despite the improvement of diagnostic technologies, and the availability of endoscopic ultrasound and sophisticated radiological imaging techniques, the etiology of AP remains unclear in 10–30% of patients and is defined as idiopathic AP (IAP). Overall incidence of infectious etiologies causing AP is not known given the lack of population studies reporting on the topic.

Aims & Methods: We aimed to assess the frequency of viral etiology in patients with IAP. A prospective study recruited patients age 18 years or older who were diagnosed with AP (ClinicalTrials.gov ID: NCT03601325) admitted to the hospital in period between 2018 and 2022. IAP was defined as an episode with AP with etiological cause of an AP is not detectable after an accurate anamnesis excluding drug abuse, alcohol abuse, history of infection, an evaluation of metabolic disorder, including hypertriglyceridemia and hypercalcemia and at least two second-level imaging techniques including EUS and/or MRCP to exclude abnormality of pancreatic gland, pancreatic or biliary and gallbladder lithiasis. In cases with IAP; One serum sample for virus serology was collected from each patient. Acute viral infection was diagnosed by serological detection of IgM in the initial sample using ELISA and /or detection of viral nucleic acid using PCR.ELISA kits for the detection of IgG/IgM Coxackie B virus, and antibodies against viral capsid antigens of Epstein-Barr virus (EBV), anti-human herpes virus 1/2/6, Cytomegalovirus (CMV) IgM, HIV and Adenovirus IgM/IgG were purchased from SERION ELISA classic (Germany). All assays were carried out according to the manufacturer's instructions.

Results: A total of 300 patients were enrolled in the study with mean age was 49.50 years. Majority (66.7%) of patients was males. Gall stone pancreatitis was found in 190 (63.3%) patients. One third of cases had severe acute pancreatitis. In a total of 60 (20%) patients, the etiology of AP wasn't detected and were defined as IAP. Viral serology was positive 11/60 (18.3%) patients with IAP (Coxackie B virus in 9 cases and CMV in two cases). A total of 15 (5%) patients were died; two of them had CMV induced pancreatitis.

Conclusion: In patients with IAP, viral induced acute pancreatitis may be present in a considerable number of patients. So, viral serology should be done in cases with IAP.

Disclosure: None

Introduction: Sarcopenia is a progressive skeletal muscle disorder characterized by a loss of muscle mass, as well as strength and function. The presence of sarcopenia in acute pancreatitis (AP), a disease with potentially marked catabolism and impaired food intake, could further affect the course and outcome of the disease.

Aims & Methods: The aim of our study is to determine the prevalence of sarcopenia in patients with AP based on computed tomography (CT) and its association with disease severity and clinical outcomes. We retrospectively analyzed patients hospitalized for AP in 2020, regardless of etiology. Predictors of disease severity, the APACHE II index, and the BISAP index were determined on admission. To assess pancreatic necrosis and local complications, contrast-enhanced CT of the abdomen with CT Severity Index (CTSI) was performed between days 3 and 5. Assessment of sarcopenia was recorded by determining the psoas muscle index (PMI) and the Hounsfield Unit average calculation (HUAC) at the level of the L3 vertebra. Thresholds for PMI were set at 6.36 cm2/m2 for men and 3.92 cm2/m2 for women, whereas HUAC values were determined at the level of the 25% quartile of values measured in our patients. Local and systemic complications of AP were defined using the revised Atlanta criteria, whereas the impact of comorbidities was assessed by determining the Charlson comorbidity index (CCI).

Results: We analyzed 50 patients, of whom 32% were women. The mean age was 67 years (IQR 52-73), and the mean body mass index (BMI) was 27.88 ± 4.72 kg/m2. The mean length of hospital stay was 11.82 ± 7.68 days. The prevalence of sarcopenia was 16% by PMI and 26% by HUAC. There was no difference in the prevalence of sarcopenia between the sexes. We found significant negative correlations of PMI with APACHE II (r=-0.38; P=0.006), BISAP (r=-0.32; P=0.02), CCI (r=-0.43; P=0.002), and age (r=-0.35 ; P=0.01) but no significant correlation with CTSI, BMI, and length of hospital stay. HUAC is significantly negatively correlated with APACHE II (r=-0.73; P<0.0001), BISAP (r=-0.58; P<0.0001), BMI (r=-0.39; P=0.005), CCI (r=-0.68; P<0.0001), age (r=-0.58; P<0.0001) and length of hospital stay (r=-0.32; P=0.02) but with no correlation with CTSI.

According to the PMI criteria, no significant difference was found between the group of subjects with marked sarcopenia and the group without sarcopenia in all analyzed outcomes. Using HUAC criteria, patients with sarcopenia were significantly older (76±7.23 vs 59.22±14.12; P=0.0001) and had significantly higher BMI (30.85±3.77 vs 26.84±4.62; P=0.007). The same group had significantly higher values of APACHE II (10.92±20.74 vs 6.32±8.28; P=0.0001) and CCI index (5±2.48 vs 2.19±1.81; P=0.0001). No differences were observed in other outcomes. Mortality analysis was not possible because no deaths occurred.

Conclusion: Sarcopenia is quite common in patients with AP already on admission. As expected, sarcopenia in this group is also associated with older age and a greater number of concomitant diseases, but it also seems to be associated with higher BMI values. There are indications that sarcopenia is associated with potentially more severe forms of the disease, but this has not been confirmed in terms of the frequency of specific clinical outcomes. This is likely a consequence of the relatively small number of patients studied with a rather limited number of observed complications and a very low proportion of patients with a severe AP. Further studies in a larger number of subjects with a higher proportion of severe forms of AP are needed for more reliable results.

Introduction: Chronic pancreatitis is one of the well-known risk factors of pancreatic adenocarcinoma, the 4th leading cause of cancer mortality. Excessive chronic alcohol consumption is the first cause leading to chronic pancreatic and hepatic inflammation. The intestinal microbiota plays a role in the pathogenesis of these two diseases and patients with chronic alcoholic pancreatitis (CAP) or alcoholic hepatitis (AH) display altered and specific gut dysbiosis, with a higher relative abundance of Enterococcus in patients with CAP compared to AH(1).

A recent study identified strains of E. faecalis able to produce a toxin, called cytolysin, responsible for liver lesions in chronic liver diseases. Its presence was associated with the worst clinical outcomes(2). It is yet unknown whether patients with CAP also exhibit an elevated relative abundance of cytolysin-producing E. faecalis strains.

Aims & Methods: The objectives of this study were 1/ to assess the presence of E. faecalis strains expressing or not cytolysin, in the intestinal microbiota of patients with CAP (n = 24) compared to patients with AH (n = 27) and to healthy controls (HC, n = 28), 2/ to evaluate the role of E. faecalis strains (isolated from the patients), in the genesis and potentiation of pancreatitis lesions and early precancerous lesions (acinar-to-ductal metaplasia), in a murine model of pancreatitis induced by cerulein, and 3/ to assess the presence of Enterococcus in surgical specimens of patients who went under pancreatic resection for CAP, (n = 6) compared to controls (normal pancreatic parenchyma apart of benign tumors n = 4).

Results: Our data showed that the relative abundance of cytolysin-positive E. faecalis in the intestinal microbiota is elevated in patients with AH and even more in patients with CAP. Genomic DNA of E. faecalis was detected in 96% of CAP patients, and 85% of AH patients. CAP patients were more frequently cytolysin-positive (96%) than HC (39%, p < 0.001) or AH patients (48%, p < 0.001). The relative abundance of cytolysin-positive E. faecalis was elevated in CAP and AH patients (p = 0.0006 and p= 0.0067) but not HC. In our murine model of cerulein-induced chronic pancreatitis, E. faecalis tend to increase the rate of pancreatitis lesions, as well as the number of acinar-to-ductal metaplasia lesions, specifically when pancreatitis is triggered. We used two different anti-Enterococcus antibodies

with concordant results, showing that Enterococcus is present in the pancreatic parenchyma of patients with CAP, but not in the healthy pancreas of controls.

Conclusion: These results support a potentially detrimental role of Enterococcus, and especially E. faecalis, in the evolution of pancreatic inflammation. This study opens new research perspectives to investigate the pathophysiological mechanisms of intestinal microbiota species in the pancreatic exocrine tissue. Microbiota and metabolites produced by these microorganisms (like cytolysin) are probably key actors in the pancreatic inflammation process, involved in the cross-talk between the gut and pancreas. It could lead to consider potential new therapeutic targets in patients with chronic pancreatitis at risk of developing aggressive pancreatic cancers.

Introduction: Liver and pancreas are target organs of an increased alcohol intake or impaired metabolic asset. While the correlation between liver cirrhosis and exocrine pancreatic insufficiency (EPI) is better known from literature and clinical practice, the relationship between non-cirrhotic chronic liver damage and EPI is less clear. Although studies show the role of alcohol-related hepatic steatosis and NAFLD as precursors of chronic pancreatic damage, literature is heterogeneous, discordant and lacking.

Aims & Methods: The aim of our study is to verify the frequency of EPI in patients (pts) with known diagnosis of hepatic steatosis. This is a prospective, observational, monocentric, not randomized study. Pts with known diagnosis of alcohol-related hepatic steatosis (alcohol intake > 2-3 AU/day - Group A) and non-alcoholic-related (alcohol intake < 2-3 AU/day, insulin resistance with Homa Index > 2.5, Diabetes type II - Group B) were included. All pts were submitted to a clinical questionnaire (mini nutritional assesment - MNA), clinical and biochemical evaluation (nutritional and metabolic profile), ultrasound and hepatic elastometry; evaluation of exocrine pancreatic function was made by faecal elastase (FE-1) value (EPI < 200 µg/g). Pts with known diagnoses of chronic liver damage (liver cirrhosis, viral hepatitis, autoimmune), and known diagnoses of chronic pancreatitis and/or PEI were excluded.

Results: This study included 37 pts in total, of whom 22 (59.4%) men and 15 (40.5%) women (median age of 57 yrs). Pts with alcohol intake > 2-3 AU/day (Group A) were 10 (27.2%), those with insulin resistance and type II Diabetes in oral hypoglycemic therapy (Group B) were 27 (72.9%). They were also divided according to the degree of hepatic steatosis evaluated ecographically (mild: 7 (18.9%), moderate: 15 (40.5%), severe: 5 (13.5%) and hepatic elastometry according to Metavir score (F0-F1:10 (27%), F2:25 (67.5%), F3:2 (5.4%). No pts had a nutritional and vitamin profile change, except 3 (8.1%) women with vitamin D values < 30 ng/ml. 34 (91.9%) pts had FE-1 value > 500 µg/g compatible with preserved pancreatic exocrine functionality while 3 pts (8.1%) from Group B had FE-1 value < 200 µg/g, of which only one with symptoms. There was no correlation between steatosis and hepatic fibrosis with exocrine pancreatic function.

Conclusion: In conclusion, only 8.1% of patients with hepatic steatosis had a condition of EPI. These data, despite the presence of recent studies confident in the increased frequency of EPI in patients with mainly non-alcohol-related hepatic steatosis, although still preliminary, do not show a significant relationship between hepatic steatosis and EPI. Therefore, it will be necessary to increase the study population and it will be meritorious secondary integration through radiological study with pancreatic MRI and Elasto-MRI.

Disclosure: Nothing to disclose.

Introduction: Several biomarkers including adipokines have been investigated in chronic pancreatitis (CP). Nevertheless, the current results are inconclusive with conflicting results.

Aims & Methods: Therefore, we aimed to evaluate the levels of major adipokines including adiponectin, leptin, and resistin in CP patients. A systematic electronic search using Pubmed, Embase, and Scopus was conducted, evaluating observational studies published till November 2022. Quality assessment of the included studies was performed using the Newcastle-Ottawa Scale (NOS). The principal summary outcome was the mean difference (MD). Results were reported as MD (95% confidence interval [CI]).

Results: A total of 14 studies were included in our qualitative synthesis, out of which, 9 were evaluated in our quantitative synthesis. A significant MD in leptin levels was found in CP patients vs. controls (-1.299 [95% CI -2.493 – 0.105]), resistin levels in CP patients vs. controls (10.129 [95% CI 6.735 – 13.524]), and adiponectin levels in pancreatic cancer (PC) patients vs. controls (11.240 [95% CI 5.872 – 16.60]). Nevertheless, no significant MD was observed in leptin levels between CP vs. PC patients (-1.299 [95% CI -2.493 – 0.105]), in addition to adiponectin levels in CP patients vs. controls (0.422 [95% CI -5.651 – 6.535]) and CP vs. PC patients (-6.252 [95% CI -13.269 – 0.766]).

Conclusion: We reported significantly decreased leptin and increased resistin levels in CP patients. Moreover, PC patients present increased levels of adiponectin. However, leptin and adiponectin levels did not significantly differ between CP and PC patients, as well as adiponectin levels between CP patients and controls.

Introduction: Segmental portal hypertension (SPH) is a rare complication of benign or malignant pancreatic pathology caused by thrombosis or compression of the splenic vein or mesenteric confluent. The main clinical presentation is upper bleeding.

Aims & Methods: our study aimed of this study is to investigate the characteristics of SPH in pancreatic diseases. This is was a retrospective, descriptive study conducted over 6 years and 4 months, from January 2017 to April 2023. All patients with SPH related to a pancreatic pathology were included.

Results: Out of 162 patients with pancreatic pathology, 17 patients (8.2%) presented with SPH. The average age of the patients was 60.8 years [35-76 years], and there was a clear male predominance with a male-to-female ratio of 7.6H/F.

Clinical symptoms were mainly related to the underlying pancreatic pathology, and only 3 patients (17%) had clinical signs suggestive of portal hypertension (such as ascites, splenomegaly, collateral venous circulation, and digestive hemorrhage).

The pancreatic pathology responsible for SPH was a tumor of the head of the pancreas in 9 patients (52.9%), a compressive pancreatic necrotic collection (type WON) in 2 patients (11.7%), neuroendocrine tumor in 1 patient (5.8%), TIPMP in 1 patient (5.8%), chronic calcifying pancreatitis in 2 patients (11.7%), and IgG4 autoimmune pancreatitis in 2 patients (11.7%).

Imaging studies, including ultrasound and abdominal CT, showed collateral venous circulation in 10 patients (58.8%), splenic thrombosis in 4 patients (23.5%), superior mesenteric vein thrombosis in 1 patient (5.8%), and splenic vein compression in 4 patients (23.5%).

Upper endoscopy was performed in 9 patients, and isolated gastric varices (IGV) were found in 6 patients (35.2%), esophageal varices (VO) in 4 patients (23.5%), and normal findings in 2 patients (11.7%).

Conclusion: Segmental portal hypertension is a rare complication in pancreatic diseases with a prevalence of 8.2%. Clinical symptoms are nonspecific, and the prognosis is closely related to the underlying pancreatic pathology. Tumor pathology appears to be the most common cause of SPH in this study.

Introduction: Paraduodenal pancreatitis (PP) is a particular form of chronic pancreatitis that affects an area, defined by some authors as "groove", between the head of the pancreas, the duodenum and the main biliary tract. [1]

The two forms of PP, the cystic and the "solid" form, [2] may extend to the adjacent pancreatic tissue and the entire main pancreatic duct, causing chronic obstructive pancreatitis ("diffuse" form), leading to heterogeneous clinical presentations.[3,4]

Pathogenesis and natural history is still unclear, even if it has been linked to exogenous factors, especially alcohol and smoking, and the treatment include both medical therapy and surgery [5].

Aims & Methods: We performed a multicentre retrospective observational study to explore the burden of the disease, and its evolution towards exocrine pancreatic insufficiency(EPI) considering also the risk of neoplastic evolution. We collected data from both academic and non-academic Italian centers. All patients with diagnosis of PP were included in the registry. Data were extracted at the time of diagnosis and during follow-up. Univariate and multivariate analysis were performed to explore the relations between variables and outcomes of interest.

Results: 208 patients(87.5% male) from 16 centres were collected into our national registry. Mean age at diagnosis was 51(± 11) years and mean time from clinical presentation to diagnosis was 18(±29) months. 88.4% had history of alcohol abuse and 89% of smoking. 36 patients(17.9%) had diabetes at diagnosis, while 80 patients (41.5%) had chronic pancreatitis. Clinical presentation included abdominal pain(89.1%), jaundice(18.5%),

nausea(47.1%) and vomiting(32.6%). Initial laboratory tests showed a mean increase of bilirubin of 1.62(±1.7) times upper limit of normal(ULN), Amylase 2.9(±2.5) times ULN, Lipase 3.2(±3.1) times ULN. 6(3%) patients developed pancreatic cancer after a mean time of 10.3(±10.8) months from PP diagnosis. 49 patients(23.6%) had EPI at diagnosis , while further 49 patients developed it during follow up.

Among patients with EPI at diagnosis, 19(38.8%) recovered with no more signs of EPI at the last follow up. Preliminary analyses showed that EPI at diagnosis was associated to EPI at the last follow up(OR 2.6, p=0.012). Mean time to develop EPI was 17.1(±23.5) months. Conservative treatment was the treatment of choice in 54.3% cases, surgery in 17.3% and endoscopic therapy in 16.35% cases. Over a median follow-up of 36 (range, 1-168) months, mortality was 4.8%.

Conclusion: Paraduodenal pancreatitis is an uncommon disease, mainly diagnosed in male patients with history of alcohol and smoking. Moreover, conservative strategy was the treatment of choice in our cohort of patients.

Introduction: Basic science results suggest that abnormalities of the endocrine pancreas in cystic fibrosis (CF) occur earlier than hitherto estimated (1).

All stages of the abnormal glucose tolerance (AGT) spectrum are associated with declining pulmonary function and increased mortality which could be reduced by early recognition and treatment (2-4).

Despite, screening for AGT is recommended only from 10 years of age (yoa) according to the current guidelines (5,6).

Accurate knowledge of the prevalence of AGT and its subtypes is essential to develop a better screening strategy, therefore we conducted a systematic review and meta-analysis in the topic.

Aims & Methods: Our systematic review and meta-analysis (PROSPERO number: CRD42021282516) was conducted on studies that reported data on the prevalence of AGT or its subtypes in CF populations. Literature search was conducted in MEDLINE (via PubMed), Embase and Cochrane Register of Controlled Trials (CENTRAL). General and superselected populations (e.g.: pancreas exocrine insufficient, ΔF508 homozygous) were separately analyzed. Pooled proportions, risk and odds ratios with 95% confidence intervals (CI) were calculated in at least three age subgroups (pediatric, adult, mixed/unknown). One-stage dose-response random effect meta-analysis was used to assess the effect of age on CF- related diabetes (CFRD).

Results: The quantitative analysis included 457 studies and data from 520,544 patients. More than one third of children with CF (chwCF) were affected by AGT (0.31 [95% CI 0.25-0.37]), even under 10 yoa 0.33 [95% CI 0.23-0.44], and half of the adults with CF (awCF) had AGT (0.51 [95% CI 0.45-0.57]). The prevalence of prediabetes remained unchanged (impaired glucose tolerance in chwCF: 0.14 [95% CI 0.10-0.18]) vs. awCF: 0.19 [95% CI 0.14-0.25]), while the proportion of CFRD increased by age (<5 yoa: 0.005 [95% CI 0.0001-0.15]; 5-10 yoa: 0.05 [95% CI 0.01-0.27]; 10-18 yoa: 0.11 [95% CI 0.08-0.14]; >18 yoa: 0.27 [95% CI 0.24-0.30]).

Conclusion: CF-related AGT is common under 10 years of age. Reconsideration of the current guidelines and better awareness are needed for screening and treating AGT in CF, especially under 10 yoa, to delay the disease progression and maintain a better life quality.

Introduction: Pancreatic fibrosis (PF) is a major component of chronic pancreatitis (CP) pathogenesis. Besides, PF affects different pancreatic disorders. So, pancreatic fibrosis precise diagnosis gives a great opportunity to be a part of the strategy for preventing disease progression.
Hence, non-invasive pancreatic fibrosis evaluation based on pathologically approved data are perspective.
Aims & Methods: The aim of this study was to find out the relationship between the histological assessment of the degree of pancreatic fibrosis according to G. Klöppel & B. Maillet's scale, supplemented by histochemical methods, and non-invasive method - multidetector computed tomography (MDCT).
The study was performed on 58 patients underwent surgery for pancreatic diseases from April to December 2022, mean age 60.5±15 (35-80).
We assessed the degree of perilobular and intralobular fibrosis, their integrative index according to G. Klöppel & B. Maillet's scale [1], as well as the percentage of collagen fibers in fibrosis using Van Gieson's stain.
Results: Fibrosis assessment using G. Kloppel's 6-point grading system has revealed data: perilobular and intralobular fibrosis by 1 point, respectively, - 29.3% and 41.4%, by 2 points - 17.3% and 13.8%, 3 points - 5.2% and 3.4%, 4 points - 13.8% and 18.9%, 5 points - 20.7% and 13.8%, 6 points - 12.0% and 7.0%, 0 points - 1.7% each.
Integral index of pancreatic tissue fibrosis with a weak degree was detected in 58.6%, moderate - in 17.2%, severe - in 22.5%; fibrotic changes were absent in 1.7%, that positively correlated with the results of proportion of collagen fibers measurement according to Van Gieson's stain: 0 - 2.6%, 1-10 - 30.8%, 11-50 - 48.7% and more than 50% - 17.9% (p=0.03). The indicators of the four selected groups were compared with data of multidetector computed tomography.
Analyzing MDCT-results, we received significant intergroup differences between mean values of normalized contrast enhancement ratios in portal vein phase of contrast enhancement and enhancement ratio in groups with mild and moderate fibrosis (p=0.05), as well as moderate and severe fibrosis (p=0.04).
Conclusion: Non-invasive methods for diagnosis of pancreatic tissue fibrosis may be an alternative approach for assessment diseases which are associated with pancreatic fibrosis, especially in moderate and severe degree.

Introduction: Chronic pancreatitis (CP) is a persistent inflammation of the pancreatic parenchyma that can lead to irreversible endocrine and exocrine dysfunction as well as pancreatic cancer. As the disease progresses, the pancreatic parenchyma becomes irregularly fibrotic and atrophic, resulting in the formation of the so-called "hard pancreas".
Although endoscopic ultrasound (EUS) has been widely used for diagnosing CP, the assessment of fibrosis using the Rosemont criteria (RC) is generally subjective.
Shear wave elastography using EUS (EUS-SWE) has been advocated as an objective approach to evaluating pancreatic fibrosis; however, the diagnostic accuracy and the optimal pancreatic region or the number for the measures are still unknown.it is unknown which pancreatic region is taken measurement.
This study compares the measurement site diagnostic accuracy in diagnosing CP and its correlation with RC.
Aims & Methods: Fifty patients with CP or suspected CP who underwent EUS-SWE were analyzed retrospectively. As per the RC, they were classified into two groups: CP and non-CP. The pancreatic stiffness was evaluated by measuring the velocities of the shear wave (Vs) and determining the relevant cutoff value of Vs for diagnosing CP. In addition, the correlation between Vs and RC, and the factors of the RC affecting pancreatic stiffness were evaluated.
Results: We finally analyzed 34 CP group cases and 16 non-CP group cases. Vs values were significantly higher for the CP group in all regions (p<0.001). Vs values by region for diagnostic accuracy of chronic pancreatitis were highest in the body (cut off, 2.33, AUC 0.87, 95%CI 0.76-0.98). The number of EUS criteria and Vs values were significantly correlated in all regions, but the correlation coefficient was highest in the pancreatic body (rs=0.55).
Multivariate analysis revealed that lobularity with honeycombing was an independent factor for EUS criteria affecting pancreatic stiffness (p=0.02).

	Univariate analysis			Multivariate analysis		
	OR	95%CI	P value	OR	95% CI	P value
Hyperechoic foci with shadowing	2.94	1.09–2.7	0.006	4.5	0.40–50.7	0.22
Hyperechoic foci without shadowing	1.26	0.38–4.2	0.71			
Lobularity with honeycomb	11.8	2.3–60.0	0.003	11.1	1.4–88.1	0.02
Lobularity without honeycomb	2.4	0.57–10.4	0.23			
Irregular MPD contour	7.4	1.78–30.8	0.005	6.6	0.73–58.9	0.09
Dilated side branches	5.4	1.58–18.7	0.007	0.93	0.14–6.17	0.94
Hyperechoic MPD margin	29.0	3.29–256.0	0.002	4.18	0.37–1.37	0.25
MPD dilation	3.1	0.58–16.5	0.19			

Table. Endoscopic ultrasonography findings by Rosemont criteria related to Vs values of the pancreatic body by univariate and multivariate analysis

Conclusion: Quantifying pancreatic hardness by EUS-SWE is useful as an objective indicator in diagnosing CP. In addition, the SWE measurement in the pancreatic body is suitable for pancreatic hardness evaluation and correlates well with the Rosemont criteria.

Introduction: Chronic pancreatitis (CP) is a fibroinflammatory syndrome with reduced quality of life (QOL) and shortened life expectancy. Population-based estimates of the incidence and prevalence of CP are scarce in China.

Aims & Methods: Aims: To evaluate the incidence and prevalence of CP and describe the disease burden of CP in Sichuan Province, China.

Methods: Hospital admissions (HA) data for CP from 1 January 2015 to 31 December 2021 were obtained from the Health Information Center of Sichuan Province (HIC-SC). During the study period, 38,086 individuals were diagnosed with CP in Sichuan Province. The yearly incidence rate and point prevalence rate (31 December 2021) of CP were calculated. Disease burden of CP were evaluated. Yearly incidence rates were standardized for age by the direct method using the permanent population of Sichuan Province in the 2020 census as the standard population. Costs for CP were adjusted by the consumer price index (CPI) every year to 2021 costs.

Results: The 38,086 CP patients consisted of 23,278 males and 14,808 females. The mean age at diagnosis of CP was 57.83 years. The mean incidence rate of CP during the study period was 6.81 per 100,000 person-years, and the incidence of CP increased each year. The point prevalence rate of CP in 2021 was 45.52 per 100,000 people for the total population, 55.04 per 100,000 people for men, and 35.78 per 100,000 people for women. The number of CP-related hospitalizations increased from 3,734 in 2015 to 11,009 in 2021. The total costs for CP-related hospitalizations for CP patients over the study period were US$ 103.54 million, with an average of US$ 2718 per patient.

Conclusion: We conducted a population-based epidemiological study of CP in Sichuan Province, China, from 2015 to 2021. During the study period, the annual incidence of CP in Sichuan Province increased, and by 2021, the prevalence of CP was 45.52 cases per 100,000 person-years for the total population. The number of CP patients and CP-related hospitalization costs increased. Therefore, prevention and treatment of CP are of great importance.

Introduction: Pancreatic exocrine insufficiency (PEI) has been recently defined as a reduction of pancreatic exocrine secretion and/or intraluminal activity of pancreatic enzymes below a level that prevents normal digestion of nutrients. For diagnosis, quantification of the coefficient of fat absorption (CFA) is considered the gold standard. Faecal elastase-1 test (FE-1) is the most widely used pancreatic function test in clinical practice. However, the efficacy of this test for the diagnosis of PEI is debatable.

Aims & Methods: Aim of our study was to evaluate the accuracy of FE-1 test for the diagnosis of PEI using CFA or 72-h faecal fat quantification as reference methods.

Methods: A systematic review and meta-analysis was performed. Major databases were searched for studies reporting accuracy of FE-1 test using the above mentioned reference methods for the diagnosis of PEI. Sensitivity (S), Specificity (E), Positive Predictive Value (PPV) and Negative Predictive Value (NPV) were calculated globally and individually for cystic fibrosis (CF) and chronic pancreatitis (CP) based on cut-off points of 200 µg/g and 100 µg/g. Results are shown with 95% confidence interval.

Results: 19 studies (948 patients) were included (8 studies in CF, 5 in CP, 2 after pancreatic surgery, 2 in pancreatic cancer, 1 in diabetes mellitus and 1 in neuroendocrine tumours). The overall S, E, PPV, and NPV of FE-1 test for PEI were 86% (76-94), 55% (36-73), 72% (55-86) and 44% (21-67), respectively, for a cut-off point of 200 µg/g. In the studies that used a cut-off point of 100 µg/g, values were 92% (87-96), 65% (52-76), 55% (22-85) and 59% (31-84), respectively. In CF, the studies using the cut-off point of 200 µg/g showed S and E of 88% (73-98) and 65% (31-93). In CP, with the same cut-off point, results of S and E were 83% (63-96) and 54% (18-88).

Conclusion: Independently of the cut-off used for diagnosis, FE-1 test is a rather sensitive but nonspecific method for PEI. A low FE-1 result supports the diagnosis of PEI in just 55-72% of the patients with pancreatic disease, whereas a normal FE-1 result does not rule out PEI.

EARLY RESULTS FROM THE HUNGARIAN CYSTIC FIBROSIS RELATED PANCREATIC DISORDER REGISTRY DATA

A. F.Kéri[1,2], R. Nagy[1,2,3], Z. Vajda[1], K. Ocskay[1], A. Párniczky[1,2,3]

Introduction: All stages of the cystic fibrosis-related abnormal glucose tolerance (CF-AGT) spectrum are associated with increased morbidity and mortality which could be reduced by early detection and treatment (1-4). Despite, the oral glucose tolerance test (OGTT) with two blood glucose measurement time points from 10 years of age (yoa) is still the gold standard method according to current guidelines (5,6).

Aims & Methods: Our aim is to provide data on the usability and diagnostic value of a hybrid protocol for the detection of early AGT in children with CF (chwCF).

The Cystic Fibrosis Related Pancreatic Disorder Registry (CFRPDR) is a prospective registry involving chwCF (<18 yoa) undergoing our hybrid AGT-screening protocol. The screening protocol consists of a frequently-sampled three-hour OGTT with blood sampling in every 30 minutes. Those chwCF with more than two interim blood glucose levels higher than 11 mmol/l are further examined with postprandial capillary glucose monitoring. Screening is started as early as possible, in most cases before 10 yoa and repeated yearly.

Results: Currently 121 chwCF are involved in the registry from which we have analyzed the baseline data of the first 79. 74% of the chwCF were diagnosed with normal glucose tolerance (NGT) (0-18 yoa: 58, 0-6 yoa: 18, 7-12 yoa: 22, 13-18 yoa: 18), 15% with impaired glucose tolerance (IGT) (0-18 yoa: 12, 0-6 yoa: 3, 7-12 yoa: 5, 13-18 yoa: 4) and 11% with CF-related diabetes (CFRD) (0-18 yoa: 9, 0-6 yoa: 0, 7-12 yoa: 1, 13-18 yoa: 8) according to the current gold standard method. 60% of the chwCF were diagnosed with NGT (0-18 yoa: 47, 0-6 yoa: 14, 7-12 yoa: 17, 13-18 yoa: 16), 14% with indeterminate glycaemia (INDET) (0-18 yoa: 11, 0-6 yoa: 4, 7-12 yoa: 5, 13-18 yoa: 2), 15% with IGT (0-18 yoa: 12, 0-6 yoa: 3, 7-12 yoa: 5, 13-18 yoa: 4), and 11% with CFRD (0-18 yoa: 9, 0-6 yoa: 0, 7-12 yoa: 1, 13-18 yoa: 8) by frequently-sampled OGTT.

After the postprandial capillary glucose monitoring 4 more diabetic chwCF were diagnosed, 3 of them had IGT and 1 of them had INDET according to their OGTT measurements. 39% (12 chwCF) of the AGT cases was diagnosed under 10 yoa with frequently sampled OGTT.

Conclusion: In our cohort CF-AGT is common even under 10 yoa, and 44% of the AGT cases would have been missed with current standard screening method. Therefore, guidelines need to be revised, and our hybrid AGT-screening protocol could be a potent alternative especially in low- and middle income countries where continuous glucose monitoring is less available.

Introduction: With disease progression, patients with chronic pancreatitis experience pancreatic exocrine insufficiency (PEI), nutritional deficiencies with associated bone complications and impaired quality of life.

Aims & Methods: The aim of this study was to investigate risk factors in patients with chronic pancreatitis and to evaluate their relation to bone density complications. The severity of CP was assessed by the M-ANNHEIM classification. Nutritional status was evaluated by fat-soluble vitamins D (CMIA method) and K (K1 and K2 by High-Performance Liquid Chromatography); magnesium and BMI in addition to routine biochemical markers; PEI was assessed by fecal-elastase-1, and imaging morphological data by Cambridge classification for CT/MRCP (grade I-IV). Bone densitometry was performed by Dual-energy X-ray absorptiometry. For statistical analysis was used SPSS v22.

Results: The study enrolled 45 patients with chronic pancreatitis (29 males, 52,01 ± 14,42). Patients with severe morphological changes (25 patients) were evaluated with lower vitamin D ($p = 0,04$) and K1 levels ($p = 0,027$). PEI with fecal elastase-1 values below 200 µg / g feces was found in 17 patients. The mean levels of vitamin D, K1, and K2 were 37.85 nmol/L 0.21 µg / L, and 0.15 µg / L, respectively. Vitamin D deficiency was found in 10 patients and insufficiency in 22 patients. 11 patients had low vitamin K levels. Significantly higher vitamin D values were observed with increasing BMI ($r = 0.39$, $p = 0.001$). Disease progression by M-ANNHEIM classification was associated with lower vitamin D and K levels. Osteopenia was observed in 10 patients and osteoporosis in 6 patients. Bone density was affected and significantly decreased in patients with vitamin D deficiency or severe insufficiency, PEI, and morphological changes grade Cambridge IV ($p < 0.05$).

Conclusion: An effort should be the point of a multidisciplinary approach for an up-to-date strategy for patients with pancreatic disorders. Proper patients follow-up and monitoring of complications of chronic pancreatitis might reduce the associated morbidity and mortality and ensures a better quality of life.

Disclosure: Nothing to disclose.

PP1569

SUBCLINICAL COGNITIVE IMPAIRMENT IN CHRONIC PANCREATITIS IS ASSOCIATED WITH REDUCED MOBILITY AND QUALITY OF LIFE

M. Damm[1], K. George[1], J. Rosendahl[1], R. Greinert[1]
[1]University Hospital Halle, Department of Internal Medicine I, Halle, Germany

Contact E-Mail Address: marko.damm@uk-halle.de

Introduction: Chronic pancreatitis (CP) is a chronic inflammatory disease of the pancreas that can lead to a wide range of complications. Previous studies have reported that CP may also be associated with subclinical cognitive impairment (SCI).

Aims & Methods: The aim of this study was to prospectively determine the prevalence, characteristics and causes of SCI and to assess its impact on quality of life and physical performance in patients with CP.

Patients with fulfilled criteria in imaging for CP were prospectively enrolled. Patients with any form of overt metabolic (e.g. hepatic, uremic) encephalopathy, neurodegenerative disorders (e.g. dementia, Parkinson's disease), decompensated cirrhosis or sepsis were excluded. All patients underwent psychometric testing (Psychometric Hepatic Encephalopathy Score (PHES) test battery, animal naming test (ANT)), assessment of health-related quality of life (QoL; EORTC C30 PAN28), such as mobility and strength (timed "up-and-go" test (TUG), chair rising test (CRT), tandem gait test, hand grip strength). SCI was diagnosed when at least one test of the PHES was pathological. Possible risk factors described previously (e.g. malnutrition, pancreatic exocrine insufficiency (PEI), pain, alcohol abuse, sleep disturbance, opioid use) were prospectively assessed.

Results: Seventy-one patients with a median age of 58 years were enrolled, and 23% were female. According to the TIGAR-O classification, the etiology was toxic (alcohol/ smoking) in most (49%) of the cases. 69% had a history of pain due to CP and 37% reported suffering from sleep disturbances.

SCI was prevalent in 41% of the patients, while 25% had only one and 16% had two or more pathological tests. Interestingly, only 3 patients showed a pathological ANT. Patients with SCI had lower overall QoL scores (p=0.048). Regarding QoL, it was mainly physical functionality that was impaired (p<0.001). Consistent with these data, patients with SCI took significantly longer to complete the TUG (p=0.008) and had more frequent pathologic CRT (p=0.004). However, while approximately 16% of the patients reported injury from a fall in the past 12 months, there was no significant association with SCI in the present study.

In addition, surrogate parameters for malnutrition, such as serum prealbumin (p=0.01), magnesium (p<0.001) and iron (p=0.02) were decreased in patients with SCI.

Among all possible risk factors analyzed, only a history of alcohol abuse was significantly associated with SCI in univariable analysis. In addition, alcohol abuse was also an independent risk factor of SCI (odds ratio (OR) 3.46; p=0.02) in a multivariable regression model together with the variables age, gender, education and cirrhosis.

Despite SCI affecting global QoL, sleep disturbance appeared to be the strongest variable independently associated with impaired QoL in multivariable analysis (OR 9.9; p=0.001).

Conclusion: We show that subclinical cognitive impairment (SCI) is prevalent in patients with CP and can impact quality of life and physical performance. Alcohol abuse was found to be a significant risk factor for SCI, while sleep disturbance was the strongest variable affecting global quality of life. These findings suggest the need for addressing modifiable risk factors in CP patients to improve outcomes.

Introduction: Complete removal of pancreatic duct stones is the goal of endoscopic treatment for chronic pancreatitis (CP), which is mainly performed by endoscopic retrograde cholangiopancreatography (ERCP), and is completed with either a basket or a balloon catheter. However, choosing which catheter primarily depends on the operators' preference, and the evidence is still scarce. Thus, this study compared the efficacy and safety of these two devices for pancreatic duct stone extraction.

Aims & Methods: This single center retrospective cohort study reviewed the records of 452 consecutive CP patients who underwent ERCP for the first time, from February 2012 to December 2021. A propensity score-matched analysis (1:1) was performed using age, sex, diabetes mellitus, steatorrhea, pancreatic duct stricture, pancreas divisum, ESWL prior to stone extraction, number of stones, size and location of stones as variables. Finally, 101 patients with basket and 101 with balloon catheter were analyzed. The primary outcome was the clearance rate of pancreatic stones; the secondary outcomes were ERCP peri-procedural outcomes and complications.

	All patients			Propensity score-matched patients		
Variables	Basket catheter, % (n = 101)	Balloon catheter, % (n = 351)	P value	Basket catheter, % (n = 101)	Balloon catheter, % (n = 101)	P value
Total complete clearance, n (%)	86.1 (87/101)	88.3 (310/351)	0.5547	86.1 (87/101)	84.2 (85/101)	0.6923
Size of Stones, n (%)						
<2.0cm	90.1 (73/81)	87.6 (276/315)	0.5342	90.1 (73/81)	80.5 (66/82)	0.0826
≥2.0cm	70.0 (14/20)	94.3 (33/35)	0.0394	70.0 (14/20)	100.0 (19/19)	0.0314
Pancreatic duct stricture, n (%)						
Yes	83.3 (35/42)	87.7 (142/162)	0.4615	83.3 (35/42)	86.8 (46/53)	0.6367
No	88.1 (52/59)	88.9 (168/189)	0.8732	88.1 (52/59)	81.3 (39/48)	0.3205

Table. The Impact Factors for Rate of Complete Clearance Between Basket and Balloon Catheter Groups

Results: The rate of complete clearance was comparable between two groups (86.1% [87/101] vs 84.2% [85/101], P = 0.692). In patients with stones ≥ 2cm before extracorporeal shock wave lithotripsy (ESWL), the rate of complete clearance was significantly higher in balloon than in basket group (100% [19/19] vs 70.0% [14/20], P = 0.031). No significant difference was found in partial (odds ratio [OR] 0.8; 95% confidence interval [CI], 0.3-2.1; P = 0.603) and unsuccessful clearance (OR 1.9; 95% CI, 0.6-5.8;

P = 0.274). In multivariate analysis, ESWL prior to stone extraction was the only independent predictor of complete clearance (OR, 2.3; 95% CI, 1.2-4.3; P = 0.013). In ERCP peri-procedural outcomes analysis, no significant difference were found in rates of difficult cannulation (1.0% vs 3.0%, P = 0.614), endoscopic sphincterotomy (53.5% vs 49.5%, P = 0.573), dilation of stenosis (26.7% vs 32.7%, P = 0.357), and extraction through the minor papilla (13.9% vs 10.9%, P = 0.522) between basket and balloon catheter groups.

For patients with pancreatic duct stenosis, the rates of clearance were comparable between two groups. The rates of complications were also similar in pancreatitis (6 [5.9%]/9 [8.9%], P = 0.421), infection (0 [0.0%]/1 [1.0%], P = 1.000), and perforation (0 [0.0%]/2 [2.0%], P = 0.477) between the two groups; no bleeding or basket impaction was detected.

Conclusion: Basket and balloon catheters showed similar efficacy and safety for pancreatic stone extraction, while the balloon catheter was superior to the basket if the stone size was ≥ 2cm before ESWL. ESWL prior to stone extraction was an independent predictor for pancreatic stone extraction.

Introduction: Nutritional deficiencies, including fat-soluble vitamins, water-soluble vitamins and minerals have been studied in the setting many autoimmune diseases, including those involving the digestive system. However, despite the well-known pancreatic involvement in IgG4-related diseases, nutritional deficiencies in autoimmune pancreatitis (AIP) have not been examined so far.

Aims & Methods: The aim of the present study was to determine the prevalence of micronutrient deficiencies in patients with AIP as well as to investigate their relationship with relapse. We retrospectively analysed medical records of patients followed up for AIP at our Pancreas Outpatient Clinic between January 2001 and March 2022. Demographic and clinical data were collected. The primary outcome was the prevalence of micronutrient deficiencies during AIP follow-up. The secondary outcome was the prevalence of AIP relapse, with exposure defined as micronutrient deficiency occurring at any time during follow-up. Micronutrient variables were solely described categorically as deficient or normal, according to the reference values at the time of each test. However, the cut-off value for vitamin D deficiency was set to below 25 nmol/L since levels between 25-50 nmol/L solely indicate an insufficiency.

Results: One hundred patients were included in the final analysis. The male-to-female ratio was 2.5:1; median age at diagnosis was 57 years (range 19-85). Median follow-up was 53 months, and during this time, 38% of patients suffered from at least one micronutrient deficiency. The most prevalent micronutrient deficiencies were vitamin D (16.1%) and zinc (25.5%). There were no statistically significant differences in prevalence of micronutrient deficiency stratified by AIP subtype. The prevalence of PEI and of at least one relapse were significantly higher in patients with micronutrient deficiencies than in those without (92.1% vs 69.4%, p = 0.01 for PEI, and 52.6% versus 27.4%, p = 0.02 for relapse). Interestingly, the prevalence of pancreatic enzyme replacement therapy (PERT) was also higher in patients with any micronutrient deficiency compared to in patients with no deficiencies 34 (89.5%) vs 40 (64.5%), p=0.01. Relapse was observed in 37% of the AIP patients. The odds for relapse were 2.9 (1.26-6.86, p=0.02), 2.71(1.36-5.41, p=0.006) and 3.38 (1.09-10.55, p=0.04) times higher in patients with any deficiency, zinc deficiency and vitamin D deficiency, respectively, compared to in non-deficient patients. However, after stratifying for AIP type 1 and adjusting for PEI and elevated IgG4 levels, this association ceased to be statistically significant.

Conclusion: Zinc and vitamin D deficiencies may be common in patients with AIP indicating that these micronutrients might play a role in the natural course of AIP probably as a result of delicate interplay between disease burden, disease severity and the consequent destruction of the gland. Importantly, any micronutrient deficiency may be prevalent even in the light of treated PEI which emphasizes the potential of micronutrients as an additional tool in the workup and follow-up of AIP patients. More studies are warranted to ascertain our findings.

Introduction: Type 2 is a less frequent and known form compared to type 1 autoimmune pancreatitis (AIP). Despite considered as a benign form, only few studies with a short follow-up have been published on type 2 AIP.

Aims & Methods: Patients with definitive or probable diagnosis of type 2 AIP by International Consensus Diagnostic Criteria (ICDC) present in our prospectively maintained database since 1995 were identified.

All patients were contacted and clinically evaluated during the year 2022. Uncontactable patients and patients refusing clinical evaluation were considered as lost at follow-up. Clinical, radiological, serological, and pathological reports were evaluated.

Results: Eighty-eight patient out of 420 AIP patients present in the database (21%) were diagnosed as type 2 AIP (55 males, 33 females, mean age at clinical onset 33.5±13.5 years, range 16-71). According to the ICDC, 21 patients (23.8%) had a definitive and 67 a probable diagnosis of type 2 AIP. Mean follow-up time was 9.2±7.1 years (range 1-27 years). No differences were observed comparing patients with definitive and probable type 2 AIP diagnosis. Concomitant IBD was reported in 77 patients (87.5%), mostly diagnosed before or at the same time of type 2 AIP. Nine patients were drop out (10.2%). Survival curve evaluated a probability of ralapse of 27% at 5 years and 29% at 10 years. Risk of endocrine or severe exocrine insufficiency were relatively low, 5% and 25% respectively. Four extra-pancreatic malignancies (5%) were diagnosed (1 renal, 1 breast, 1 rectum and 1 prostate cancer), none pancreatic. 1 patient died for car accident.

Conclusion: Patients affected by type 2 AIP have a benign long-term clinical outcome. Mortality rate was low, as well as extra-pancreatic and pancreatic malignancies.

Disclosure: Nothing to disclose.

Introduction: Autoimmune pancreatitis (AIP) is a steroid responsive fibroinflammatory disease of the pancreas, classified as type 1, type 2 or not otherwise specified, based on clinical, radiological and serological features. Few studies have investigated the pancreatic exocrine function (PEF) in patients suffering from AIP. Moreover, no definitive data are available on the role of steroids in recovering PEF.

Aims & Methods: Patients with diagnosis of AIP between January 1 st 2010 and December 31 st 2020 present in our prospectively maintained database were identified (312 patients). Patients with a pre-steroid treatment fecal elastase (FE) were included. Moreover, in patients with available pre- and post-treatment FE (between 3 a 12 months after steroid initiation), changes in PEF were evaluated.

Results: One-hundred-twenty-four patients were included, with a median FE of 122 ug/g (IQR 15-379). Fifty-nine (47.6%) had severe pancreatic exocrine insufficiency (sPEI) (FE < 100 ug/g). At univariate analysis, type 1 AIP, radiological involvement of the head of the pancreas (diffuse involvement of the pancreas or focal involvement of the head), specific symptoms (jaundice and weight loss), age and diabetes were significantly related to lower FE and higher risk of sPEI. However, at multivariable analysis, only the involvement of the head of the pancreas was identified as risk factor for both, lower FE and risk of sPEI. After steroids, median FE changed form 64 (IQR 15-340) to 202 (IQR 40-387) ug/g (p=0.058) and head involvement was the only predictor of PEF recovery, even after adjustment for other variables interaction.

Conclusion: The inflammatory involvement of the head of the pancreas is the only factor associated to PEF and PEF recovery after steroids in patients with AIP.

GLUCOMETRY TO GLUCOMETRY CYST RATIO: A NOVEL DIAGNOSTIC APPROACH FOR MUCINOUS AND NON-MUCINOUS PANCREATIC CYSTS

O.D. Borjas Almaguer[1], J.D. Marroquin Reyes[2], O. Aguijar Najera[3], H.A. Díaz Hernández[2], A. Saul Perez[2], M.A. Ramirez Luna[2]
[1]Universidad de Monterrey / Christus Muguerza Sur, Gastroenterología y endoscopia digestiva, Monterrey, Mexico, [2]INCMNSZ, Endoscopy, Ciudad de Mexico, Mexico, [3]Hospital Juarez, Endoscopy, Ciudad de Mexico, Mexico

Contact E-Mail Address: omarborjas@hotmail.com

Introduction: Pancreatic cyst prevalence is about 2% to 3% in the general population (1,2). It is important to classify them accurately, given the fact that in premalignant lesions surgery could be curative. On the other hand, unnecessary pancreatic surgery could be associated with significant morbidity. The mucinous cysts are considered the premalignant types, traditionally the carcinoembryonic antigen (CEA) has been described as the analysis of cyst fluid to discern them from the non-mucinous.

Recently, the cyst glucose value has been described as a better discriminant, however, there are different cut-off levels founds across the studies (3).

The distribution of glucose in the body is almost uniform (4), a higher metabolic rate within a cyst translates into lower intracystic glucose, which correlates with high-grade injury (3). Therefore, we decided to explore the diagnostic performance of the glucometry-to-glucometry cyst ratio.

Aims & Methods: We conducted a prospective cohort from January 2021 to October 2022 at the endoscopy department at the National Institute of Medical Sciences and Nutrition “Salvador Zubiran” (INCMNSZ) in Mexico City. We included patients older than 18 years who underwent endoscopic ultrasound with FNA of a pancreatic cyst and had a fluid analysis of glucose, CEA, and amylase. We performed glucometry on-site on the patient and the cyst fluid with a FreeStyle Optium Neo glucometer. Glucometry to glucometry cyst ratio (glucometry patient/glucometry cyst) was calculated for each patient.

Follow-up was performed and a final diagnosis was established by a multidisciplinary team, biopsy or surgical specimen. Finally, we performed a 2x2 table and a ROC curve with Youden index to establish the best cut off for diagnostic performance of glucometry-to-glucometry cyst ratio.

Results: 24 patients were included 14 with mucinous cyst diagnosis and 10 with non-mucinous diagnosis, the median age was 58.5 (25-84), and 83% were female. CEA mean was 2331.7± 3359.3 ng/mL for mucinous vs 23.8± 62.6 ng/mL for non-mucinous (p= <0.001). The on-site cyst glucometry was 39.3± 22.1mgdL vs 112± 42.9 for the mucinous and non-mucinous respectively (p= 0.001).

The glucometry/cyst glucometry relation was 3.30± 0.84 (mucinous) vs 1.13± 0.69 (non-mucinous), p= 0.001. The AUC was 0.971 (0.915 -1.000), 0.948 (0.853 – 1.00), and 0.964 (0.900 – 1.000) for glucose relation, glucometry, and CEA respectively. The sensitivity, specificity, PPV, NPV, and precision for CEA (192ng/dL) was 70%, 92.8%, 87.5%, 81.2%, and 83.3% while glucometry (<50mg/dL) was 80%, 85.7%, 83.3%, 85.7%, and 83.3%. Notably, the glucometry relation (>2.45) found a 90%, 92.8%, 90%, 92.8%, and 91.6% for the same parameters.

Conclusion: The glucometry-to-glucometry cyst relation is a novel, cheap, accessible, and superior diagnostic approach for the classification of mucinous and non-mucinous pancreatic cysts. Further studies with bigger sample sizes are needed to confirm these findings.

Contact E-Mail Address: nirb@tlvmc.gov.il

Introduction: Intraductal papillary mucinous neoplasms (IPMN) have a potential to evolve into pancreatic adenocarcinomas. While main-duct IPMN (MD-IPMN), involving the main pancreatic duct (MPD), are less common than side-branch IPMN (SB-IPMN) or mixed-type IPMN (mixed-IPMN), their malignant transformation potential is far greater. Current guidelines refer to worrisome radiological features and high-risk stigmata of IPMN in dictating recommended management strategies, whether surgical resection, endoscopic ultrasound (EUS) with fine-needle aspiration (FNA) or long-term radiological follow-up. However, controversy exists between different guidelines in terms of recommended follow up duration.

Aims & Methods: To assess the utility of radiological follow up of MD-IPMN and mixed-IPMN, including prevalence of worrisome radiological findings and their correlation to development of progression or pancreatic adenocarcinoma.

Eighty-four patients with MD-IPMN or mixed-IPMN who underwent at least one magnetic resonance cholangiopancreatography (MRCP) at our medical center were included. Clinical and laboratory data were obtained retrospectively from their medical records, and imaging tests were revised. A cross-sectional analysis was aimed to point clinical and laboratory parameters associated with development of pancreatic adenocarcinomas. A retrospective cohort study was performed on 44 patients of the study population, who had at least six months of follow up (mean follow up time 26.51±18.75 months), trying to point factors correlating with worrisome radiological features.

Results: Nine cases of pancreatic adenocarcinoma were recorded in the cohort (10.7%). These were diagnosed in 7 patients at presentation, whereas 2 patients developed them during follow up period. Factors associated with cyst progression greater than 5 mm during follow up were alanine aminotransferase (ALT) levels (p=0.007), maximal cyst size (p=0.02), MPD diameter (p=0.01) and the presence of jaundice (p=0.04) or a sense of abdominal fullness (p=0.008).

The cross-sectional analysis indicated that pancreatic adenocarcinoma was associated with complaints of nausea (p=0.01), as well as elevation of aspartate aminotransferase (AST) (p=0.05), gamma glutamyl transpeptidase (GGT) (p=0.01) and alkaline phosphatase (ALP) (p=0.01).

Conclusion: This study demonstrates the association between clinical findings and elevated liver enzymes and the risk of IPMN malignant transformation. Although further studies are needed, these data may aid in risk stratifying patients when determining the duration and mode of follow up for IPMN.

Disclosure: Nothing to disclose.

CLINICAL CHARACTERISTICS AND PREOPERATIVE DIAGNOSIS OF SOLID-PSEUDOPAPILLARY NEOPLASM: A SINGLE-CENTER EXPERIENCE OF 18 PATIENTS

Y. Sakata[1], H. Nebiki[1], S. Sugimori[1], T. Yamasaki[1]

[1]Osaka City General Hospital, Dept. of Gastroenterology, Osaka, Japan

Contact E-Mail Address: saka_t.med@icloud.com

Introduction: Solid-pseudopapillary neoplasm (SPN) is a rare tumor of low malignancy that occurs predominantly in young females. Imaging of SPN is often described as a well-defined and heterogeneous tumor with calcifications or cysts, otherwise small size SPN often shows a homogeneously solid tumor.

However, the differential diagnosis between SPN and other cystic tumors is often difficult due to the variety of imaging findings. In this report, we describe the clinical features and preoperative diagnosis of SPN we experienced at our hospital.

Aims & Methods: We studied 18 cases of SPN that were pathologically diagnosed by surgical resection at our hospital between 1997 and 2022.

Results: There were 12 female and 6 male patients, with a median age of 39.5 years (range: 9-67) and a median tumor size of 23 mm (range: 9-66). The tumor location was in the pancreatic head in 4 cases, body in 6 cases, and tail in 8 cases. The median follow-up period was 89.5 months (range: 8-265), and recurrence-free survival was achieved in all cases during the follow-up period.

The tumors were incidentally detected in 15 cases during health check-ups (mainly by ultrasonography) or other medical examinations, while the other 3 cases were detected due to subjective symptoms that were thought to be caused by SPN. SPN could be diagnosed by contrast-enhanced CT in 10 of 18 cases (56%) and by EUS in 7 of 12 cases (58%).

Contrast-enhanced CT showed enhancing mass in 10 cases, cystic component in 9 cases (50%), and calcification in 8 cases (44%). Among the 8 cases in which SPN could not be diagnosed by contrast-enhanced CT, EUS was performed in 7 cases, and we could diagnose SPN in 2 cases.

Both cases had small lesions of less than 13 mm without cystic components, which made the differentiation from other tumors difficult on contrast-enhanced CT, however EUS showed well-circumscribed, well-defined, and homogeneously hypoechogenic tumors. MRI was performed in 12 cases, and could diagnose SPN in 5 cases, but MRI did not improve the diagnostic accuracy compared to contrast-enhanced CT. The diagnostic accuracy of EUS-guided fine needle aspiration (EUS-FNA) was 89% (8/9 cases).

There were 5 cases in which SPN could not be diagnosed preoperatively. Among them, 3 cases had small tumor sizes (12-16 mm), and 4 cases lacked calcification, making it difficult to differentiate them from neuroendocrine tumors or solid-cystic neoplasms.

Conclusion: Most cases of SPN are detected incidentally, and regular abdominal ultrasonography during medical check-ups is important for early detection. Diagnosis can be more difficult in cases with small tumor diameter, and no cystic component or calcification. However adding EUS to contrast-enhanced CT imaging may improve accuracy. Furthermore, EUS-FNA contributes to preoperative diagnosis with a high diagnostic accuracy.

Disclosure: Nothing to disclose.

Contact E-Mail Address: hkatsuda0112@gmail.com

Introduction: Pancreatic solid pseudopapillary neoplasm (SPN) is a rare tumor of low malignant potential that predominantly affects young women and is characterized pathologically by a pseudopapillary structure. Surgical resection is the only curative treatment for SPN, and there are few effective treatment options for patients with metastasis. However, the natural history of SPN, their molecular biological characteristics, and the factors that determine its malignant potential have not been clarified. Recently, organoid culture technology has enabled more specific and precise analyses using only cultured tumor cells. In this study, we aimed to clarify the molecular biological mechanisms that define the origin of SPN, what genetic factors define the malignant transformation of SPN by combining advanced high throughput technology and organoid technology, and examined its correlation with clinical findings.

Aims & Methods: Age, gender, tumor diameter, and presence or absence of malignant pathological findings were extracted from six SPN cases resected from December 2019 to April 2021 at our hospital. In addition, organoids were derived from tumor and normal pancreatic tissues. Gene expression of the organoids and surgical samples were analyzed by RNA-seq.

Results: The median age of the patients was 41 years (IQR: 38-49 years) with a male-to-female ratio of 1:7. The median tumor diameter was 34 mm (IQR: 18-101 mm). Three patients had nerve plexus or vascular invasion, and one of them had liver metastasis. SPN with malignant findings showed significantly increased nucleus diameter (mean 5.8 μm vs. 8.1 μm, $p<0.001$). The results suggest molecular biological differences associated with malignant transformation. RNA-Seq was performed using normal and tumor surgical tissues, as well as normal and tumor organoids generated from the surgical samples. Comparison of tumor and normal tissue from surgical specimens showed marked changes in gene expression related to cellular localization, and this feature was even more pronounced in tumors with higher grades of malignancy. A similar trend was observed using organoids.

Conclusion: We examined clinical features and performed RNA-seq using surgical tissues and organoids to elucidate the gene expression patterns that characterize SPN. We found that SPN showed a significant enlargement of cell nuclei in high-grade cases, and that there were clear differences in gene expression related to cellular localization and extracellular matrix. Based on the findings of this study, we hope to elucidate the molecular biological mechanisms leading to the development of novel therapies for SPN.

Contact E-Mail Address: mvujas@gmail.com

Introduction: Intraductal papillary mucinous neoplasm (IPMN) of the pancreas is a precursor of pancreatic cancer. While earlier research has shown a high prevalence of synchronous/metachronous extrapancreatic tumors in IPMN patients, these studies have often been small with retrospective data collection.

Aims & Methods: Through the Epidemiology Strengthened by histoPathology Reports in Sweden (ESPRESSO) cohort, consisting of computerized histopathology data from all 28 pathology departments in Sweden during the period 1965-2017, we retrieved data on IPMN.

Each index case was matched to ≤5 general population controls.

Through Cox proportional hazards regression models, we estimated hazard ratios (HRs) for future gastrointestinal (GI) cancer precursors and death. In secondary analyses, full siblings were used as comparators.

We excluded IPMN patients with high-grade dysplasia (HGD) to avoid the risk of misclassification.

Outcome topography included esophagus, stomach, colon and rectum and outcome morphology included Barrett's esophagus, gastric metaplasia, mucosa type 1-3, tubulous adenoma, sessile serrated polyp, tubulovillous adenoma and villous adenoma.

Results: A total of 117 patients with IPMN, 539 age- and sex-matched controls, and 122 siblings were included. Among patients with IPMN, the mean age at diagnosis was 68.3 years and 48% were female.

Compared to IPMN patients, sibling controls were slightly younger (mean 65.5 years).

Patients with IPMN were also more likely to have prior diabetes, chronic obstructive pulmonary disease, obesity, dyslipidemia, and alcohol-related disease.

Almost all IPMN cases (97%) had ≥3 healthcare visits within the last year before diagnosis.

A Charlson Comorbidity Index score of ≥3 was seen in 28% of IPMN cases, compared to in 11% of controls and 9% of siblings.

IPMN cases were at increased risk of earlier GI cancer precursors compared to controls from the general population (OR=6.67; 95%CI=3.45-14.29), but

the association failed to reach statistical significance when we compared with siblings (OR=2.00; 95%CI=0.92-4.35).
Over a median of 2.1 years of follow up, we confirmed two (1.7%) incident GI cancer precursors in IPMN vs. four (0.7%) in controls, corresponding to an HR of 1.89 (95%CI=0.34-10.55).
By contrast, IPMN patients were at increased risk of death (HR 3.61 (95%CI=1.79-7.27)).
The most common cause of death in IPMN was pancreatic cancer (n=14; 45.2% of all deaths).
Pancreatic cancer was the cause of death in only two (2.7%) controls and one (7.7%) sibling.
Extrapancreatic cancers were found in eight (6.8%) IPMN patients, 21 (3.9%) controls and four (3.3%) siblings.
Conclusion: We found no association between IPMN and other GI cancer precursors. This argues against comprehensive routine surveillance for other GI cancer precursors in IPMN patients.
Mortality was increased in IPMN with pancreatic cancer being the most common cause of death, indicating the need for lifelong follow up in all resected and non-resected patients with IPMN.
Disclosure: Dr Ludvigsson is coordinating a study on behalf of the Swedish IBD quality register (SWIBREG). This study has received funding from the Janssen corporation. Dr Ludvigsson has also received financial support from MSD to develop a paper reviewing national healthcare registers in China. Contact E-Mail Address: linamarcelaaguilera@gmail.com
Introduction: Pancreatic acinar cystic transformation (ACT) was first described in 2000. Its initially supposed pre-neoplastic nature was reconsidered in the WHO Classification 2019. Its current management prone to a non-surgical approach, and so rare cases of histopathological diagnosis have been obtained since. Radiological diagnostic criteria have been proposed to differentiate ACT from Branch-duct Intraductal Papillary Mucinous Neoplasms (BD-IPMN) (Delavaud et al., 2014): 1) ≥ 5 cysts, 2) clustered peripheral small cysts, 3) cyst calcifications and 4) no communication with the main pancreatic duct.
Aims & Methods: The aims of this study were to describe the clinical and radiological characteristics of patients with a presumed diagnosis of ACT in imaging and to assess the role of these known radiological criteria in case of possible differential diagnoses.
In this single-centre retrospective study (2003-2021), consecutive patients with a presumed diagnosis of ACT in the coding database were included. Patients without an available imaging (CT or MRI) for expert radiological centralized review were excluded. A group of "typical" diagnosis of ACT was defined as the absence of differential diagnosis to be evoked. A group of "uncertain" diagnosis of ACT was defined as other possible differential diagnoses.
Results: A total of 64 patients were included (35 male patients [55%]). Median age of diagnosis was of 60 (IQR 47-67) years. ACT diagnosis was "typical" for 35 (55%) patients and was "uncertain" for 29 (45%) patients. In the "typical" group, 91.4% of patients presented ≥3 radiological criteria versus 96.6% in the "uncertain" group (p=0.61). There were more calcifications and <10 cysts in the "uncertain" group compared to the "typical" group (86% versus 66%, p = 0.041 et 24% versus 6%, p = 0.06, respectively).
In the "uncertain" group, the main differential diagnoses suggested were: 16 (55%) BD-IPMN and 7 (24%) calcified chronic pancreatitis (CCP). A pathological confirmation of ACT was obtained for three patients from which two were in the "uncertain" group.
Conclusion: ACT displays an heterogenous morphological imaging presentation reflecting a challenge for accurate non-invasive diagnosis. The published diagnostic radiological criteria seem not to be sufficient, especially in case of calcifications or/and <10 cysts.

Introduction: Mucinous cysts of the pancreas are known precursors of pancreatic ductal adenocarcinoma. International guidelines for management and surveillance of pancreatic cysts advise surgical resection of high-risk lesions - mucinous cystic neoplasms (MCNs) and main duct intraductal papillary neoplasms (IPMNs), especially in those with worrisome clinicopathological stigmata. For low-risk cysts, lifelong radiographic surveillance is the standard approach, which can be psychologically distressing for patients and burdensome for healthcare systems. Endoscopic ultrasound (EUS)-guided radiofrequency ablation (RFA) of high-risk cystic lesions of the pancreas is increasingly being used as a minimally invasive alternative in patients who are unfit for or who decline surgery (1). We assessed the safety and efficacy of EUS-guided RFA in the management of low-risk cystic lesions of the pancreas.
Aims & Methods: 68 patients (29M, 39F; mean age 63, range 33-82 years) with low-risk mucinous cystic neoplasms of the pancreas (branch-duct IPMN/mucinous cystadenomas, 0.7-4cm in size) were recruited for treatment by EUS-RFA. The primary endpoint was change in size of the pancreatic cyst on cross-sectional imaging (MRI) at one year after treatment (efficacy). Secondary endpoints included progression following treatment, procedure related morbidity and local complication rate (safety).

Results: 68 patients were recruited of whom 55 completed RFA ablation of their cyst. Anatomical concerns (i.e., blood vessel, main duct proximity) precluded RFA in 12 patients. 18/55 patients (33%) underwent a second ablation. Follow up imaging data were available for 46 (84%) patients and showed a <20% reduction in cyst size in 18 patients, 20-49% in 4 patients, 50-79% in 5 and 80-100% size reduction in 18 patients. For one patient, doubling in cyst size was recorded at the 12-month follow-up. Excluding one case of scope-induced small bowel perforation (Clavien-Dindo; ClvD grade 3), other adverse events were mild (ClvD 0-2) and expected (transient abdominal pain, bloating, sore throat, nausea/vomiting). One patient experienced a self-limiting, post procedure grand mal seizure on a background of epilepsy.

Conclusion: EUS-RFA was well tolerated in most cases. Our data indicate that the procedure is relatively safe. The response ranged from a <20% reduction in size to complete cyst resolution.

Introduction: IPMNs are mucin-producing subtypes of pancreatic cysts considered a potential precursors of pancreatic cancer accounting for 8% of all pancreatic malignancies. The molecular mechanisms and biological factors involved in the progression of IPMN are still unknown. In previous studies, modifiable risk factors (e.g., smoking) and protective factors (e.g., ACE inhibitors) have been investigated to slow down or prevent the IPMN progression.

The aim of this study is to investigate the association between modifiable lifestyle factors (smoking and alcohol consumption) and the use of commonly prescribed medications (aspirin, ACE -inhibitors, angiotensin- II -receptor antagonists, and statins) and the progression of IPMN.

Aims & Methods: This was a monocentric retrospective cohort study. The study included patients who underwent radiological and clinical examinations at time 0 and at the 3-year follow-up visits. Demographic data (sex, age, weight, and height), IPMN characteristics (type of IPMN and radiological characteristics at baseline), lifestyle factors (smoking and alcohol consumption), and medication use (aspirin, ACE -I, ARBs, and statins) were recorded.

Clinical and radiological characteristics were recorded at the 3-year follow-up to detect progression of IPMN (defined as the presence of high-risk stigmata and/or features of concern). Statistical analysis was performed using SPSS 20. Descriptive data are presented as mean±standard deviation and median with range or percentage.

Categorical data were compared using the χ_2 test. Multivariate logistic regression analysis was performed to adjust for confounding factors (age, sex, and IPMN subtype). A p value < 0.05 was considered statistically significant.

Results: 126 patients were included in the study. Patient characteristics are summarized in Table 1. Smoking (p 0.036; OR 5.7, IC95% 1.11-29.04), heavy alcohol use (p 0.027; OR 4.8, IC95% 1.10-9.50), and use of ARB (p 0.048; OR 3.52, IC95% 1.85-14.50) were associated with progression of IPMN. Statin use was associated with a lower risk of IPMN progression (p 0.043; OR 0.154, IC95% 0.021-0.978). Body weight, aspirin, ACEi, and low alcohol intake were not statistically associated with IPMN natural history.

Demographics:	
No. of patients, n	126
Age (years), mean ± SD	65 ± 11
Sex (men), n (%)	46 (36,5%)
Type of IPMN:	
Main duct-IPMN, n (%)	106 (84%)
Side Branches-IPMN, n (%)	7 (5.5%)
Mixed type-IPMN, n (%)	13 (10,5%)
BMI:	
18-25	65 (56%)
25-30	40 (34,5%)
30-35	7 (6%)
35-40	4 (3,5%)
>40	0
Alcohol intake:	
Low-dose (<2 units/day)	88 (69,8%)
High-dose (>2 units/day)	17 (13,5%)
Smoking habit:	24 (19%)
Drugs intake:	
ACE-I	21 (16,5%)
Aspirin	26 (20,5%)
Sartans	34 (26,9%)
ARB	34 (26,9%)

Table 1. Patients' characteristics.

Conclusion: With the limitations resulting from the small sample size and retrospective design of the study, smoking, heavy alcohol consumption, and ARBi use appear to be risk factors for progression of IPMN. In contrast, statin use was found to be a protective factor for IPMN progression. Prospective studies are needed to confirm these preliminary data.

COMPARATIVE ANALYSIS OF GLUCOSE AND CEA LEVELS FOR THE DIAGNOSIS OF PANCREATIC CYSTS: INSIGHTS FROM EUS-FNA

N. Shumka[1], P. Karagyozov[1], I. Tishkov[1]

[1]Acibadem City Clinic Tokuda University Hospital, Department of Interventional Gastroenterology, Sofia, Bulgaria

Contact E-Mail Address: shumkanadica97@gmail.com

Introduction: Pancreatic cysts are a common finding in imaging studies, and, considering the different malignant potentials of mucinous and non-mucinous cysts, it is necessary to develop accurate methods and algorithms to differentiate between them. We conducted this study to compare the diagnostic performance of glucose levels and CEA levels in the diagnosis of mucinous pancreatic cysts.

Aims & Methods: We conducted a retrospective study of patients who underwent EUS-FNA of pancreatic cystic lesions between September 2020 and March 2023 at a tertiary referral center. We included patients whose glucose and CEA levels had been measured. Indicators of mucinous cysts include glucose levels less than 2.7 mmol/l and CEA levels greater than 192 ng/ml. It was compared to the final pathology (obtained after surgery or by EUS-FNB) result to determine their accuracy.

Results: A total of 31 patients were included in the study, 13 males and 18 females. The mean age was 55.7 years. Of the 31 patients, 12 (38.7%)

were diagnosed with mucinous cysts (6 mucinous cystic neoplasms, 6 intraductal papillary mucinous neoplasms), and 19 (61.2%) were diagnosed with non-mucinous cysts (9 serous cystic neoplasm, 8 pseudocysts, 1 solid pseudopapillary neoplasm, and 1 lymphoepithelial cyst). There was a female prevalence in patients with mucinous cysts (8 females and 4 males) with a mean age of 59,6 years. From the cyst fluid analysis, the sensitivity, specificity, and accuracy of glucose in diagnosing mucinous cysts were 91.7%, 89.5%, and 90.3%, respectively. CEA's sensitivity, specificity, and accuracy were 81.8%, 85.0%, and 83.9%, respectively.

	Non-mucinous	Mucinous
Gender (%male)	47.3%	33.3%
Age (Median)	50.2	58.3
Cyst location		
head	9	3
body	2	5
tail	8	4

Conclusion: In the diagnosis of pancreatic cystic lesions, glucose levels have high diagnostic performance with high sensitivity and accuracy. In contrast, CEA levels have a lower diagnostic performance. The findings of our study support the use of EUS-FNA and glucose levels in the diagnosis of pancreatic cystic lesions, as well as EUS-FNB to obtain histological specimens for a more accurate diagnosis of pancreatic cysts.
Further studies are needed to validate these findings and explore the potential of other biomarkers in diagnosing and managing pancreatic cystic lesions.
Disclosure: Nothing to disclose.

PERFORMANCE OF INTRA-CYSTIC GLUCOSE MEASUREMENT FOR THE CHARACTERIZATION OF PANCREATIC CYSTIC LESIONS

T. Ribeiro[1], S. Lopes[1], P. Moutinho-Ribeiro[1], F. Vilas-Boas[1], G. Macedo[1]
[1]University Hospital Center of São João, Gastroenterology, Porto, Portugal

Contact E-Mail Address: tiagofcribeiro@outlook.com
Introduction: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is essential for the classification of pancreatic cystic lesions (PCLs). Recently, glucose measurement in pancreatic cystic fluid (PCF) has been suggested as an alternative to PCF carcinoembryonic antigen (CEA) level as a predictor of mucinous cystic lesions (MCLs) [1].
An accurate detection and differentiation of MCLs versus non-mucinous cystic lesions (NMCLs) is highly important due to the distinctive malignant potential of each type of PCLs.
Aims & Methods: This study aims to evaluate the diagnostic performance of intra-cystic glucose in distinguishing between MCLs and NMCLs and to analyze the possibility of on-site glucose measurement with a standard glucometer.
Patients with PCLs who underwent EUS-FNA with intra-cystic glucose measurement between 2017 and 2022 were included. Final diagnosis of MCL or NMCL was based on the operative specimen, intra-cystic biopsy or, if this data was unavailable, final diagnosis was based on multidisciplinary evaluation. The diagnostic performance of glucose versus CEA in PCF for the differentiation between MCLs and NMCLs was compared. A cut-off of <50 mg/dL was used for the diagnosis of MCLs.
Additionally, the agreement between on-site glucose determination with a standard glucometer and laboratory glucose measurement was assessed.
Results: A total of 78 patients were included, of which 48 were female (61.5%). The median age of 64 years (IQR 52-72). MCLs accounted for 56.4% (n=44) of all PCLs, which were predominantly located in the head of the pancreas (n=25, 32%). The median diameter of the PCLs were 31 mm (IQR 26-43). The median values of glucose and CEA were 20 mg/dL (IQR 20-94) and 39 ng/mL (IQR 2-439), respectively.
Intra-cystic glucose had a sensitivity and specificity of 93.2% and 76.5%, respectively for the diagnosis of MCLs (versus 55.6% and 87.5%, respectively, for CEA). The area under the curve was 0.870 for glucose (versus 0.806 for CEA). An excellent correlation was observed between on-site and laboratory glucose measurement (Intraclass correlation coefficient: 0.947).
Conclusion: The measurement of intra-cystic glucose in PCF showed superior performance to CEA in distinguishing between MCLs and NMCLs, with excellent correlation between on-site and laboratory glucose measurement. Thus, on-site intra-cystic glucose appears to be an excellent biomarker for the characterization of PCLs due to its low cost, high availability, and the need for a minimal volume of PCF for its determination.

Introduction: The undetermined pancreatic cystic neoplasms represent 20-30% of the total number of pancreatic cystic lesions(PCL). The diagnostic accuracy of endoscopic ultrasound (EUS) morphology is 51%. Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) should be performed for differentiating between mucinous and non-mucinous pancreatic cysts when the characterization of the cyst cannot be made on the basis of non invasive imaging techniques.

Aims & Methods: Our aim was to assess the utility of the Neutrophil gelatinase-associated lipocalin(Ngal) concentration alone or combined with glucose level in cyst fluid obtained by EUS with EUS-FNA for discriminating between mucinous and non-mucinous PCL's.

This prospective study was performed between april 2018 and may 2020 at one tertiary referral hospital and included 63 patients , 30 with undetermined pancreatic cysts (group A) and the controlled group was represented by 33 patients with pancreatic pseudocysts after acute pancreatitis drained by EUS (group B). The patients from group A underwent EUS-FNA for liquid analysis and the patients from group B had liquid collection during the drainage of pseudocysts. The final diagnosis was based on surgery or EUS results (morphology, cytology, glucose and carcinoembryonic antigen(CEA) intracystic level) or on imaging during follow-up (24 month). We performed sandwich enzyme-linked immunosorbent assays (ELISA) for cystic and serum Ngal determination and measured glucose levels by a hand glucometer.

Results: The final diagnosis was pseudocyst in 33 patients, serous cystadenoma in 6, mucinous cystadenoma in 3, intraductal papillary mucinous neoplasms in 19 patients, and ductal adenocarcinoma in 2 patients. The cystic fluid analysis of these patients showed that the mean Ngal value for the serous cystic adenomas was 336ng/dl, 728ng/dl for the mucinous lesions and 1116ng/dl for the pseudocysts. The intracystic Ngal concentration (cut-off ≥ 500 and ≤ 800ng/dl) had diagnsotic sensitivity 70.8%, and specificity 92.3% for mucinous cysts. Serum Ngal concentration had no diagnostic contribution. The cystic glucose levels (cut-off ≤ 22mg/dl) had sensitivity 83.3% and specificity 82.1% for mucinous lesions. Combined glucose(cut-off ≤ 22mg/dl) and Ngal(cut-off ≥ 500 and ≤ 800ng/dl) testing showed sensitivity of 58,3 and specificity 100% for mucinous cysts. Wheras either positive Ngal (cut-off ≥ 500 and ≤ 800ng/dl) or glucose (cut-off ≤ 22mg/dl) testing showed sensitivity 95.8% and specificity 74.4%.

Conclusion: Pancreatic cyst fluid NGAL concentration alone and combined with glucose level appeared to be useful in discriminating mucinous cysts.

PANCREATIC BIOPSY EVALUATION WITH A "SMART ROSE" DEVICE FOR IMMEDIATE FEEDBACK ON SAMPLE ADEQUACY AND CANCER PRESENCE IN ENDOSCOPIC BIOPSIES: INITIAL HUMAN CLINICAL TRIAL RESULTS

L. Bogdanowicz[1], O. Fidaner[1], M. Guidetti[1], F. Dibennardo[1], A. Grycuk[1], D. Gehrke[1], D. Ceres[1], M. John[1], C. Bovalis[1], E. Kundro[1], I. Raijman[2]

[1]NovaScan Inc., Chicago, United States, [2]Greater Houston Gastroenterology, Gastroenterology, Houston, United States

Contact E-Mail Address: les@novascanllc.com

Introduction: Pancreatic cancer (PC) accounts for 0.5 million new cases and 4.7% of the world's cancer-related deaths in 2020[1,2].

Endoscopic ultrasound (EUS) guided Fine Needle Biopsies (FNB) are the current standard of care for confirming suspicious lesions, however the diagnostic accuracy is reported below 70%[3-5].

Rapid on-site evaluation (ROSE) improves the diagnostic performances of biopsies via an on-site pathological assessment to reduce the number of needle passes, complication rates, and the need for additional procedures[6]. However, availability of an on-site pathologist is often not feasible. NovaScan has pioneered the use of an impedance spectroscopy biomarker for cancer detection in different tissues based on the Cole Relaxation Frequency (CRF).

NovaScan has developed a "smart ROSE" device that assesses PC presence in FNBs obtained during endoscopic procedures ex vivo, in real-time and on-site, without altering the tissue sample or affecting the workflow.

Aims & Methods: Data were collected in a double-blind, IRB approved study from a cohort of 21 patients (9 males, 12 females) undergoing EUS procedures for suspected pancreatic lesions at the Texas International Endoscopy Center. FNBs were performed with a 22 gauge biopsy from a transduodenal approach. Each biopsy sample was transferred onto a disposable strainer allowing for any excess fluid to drain. An electrode for scanning was placed onto the core samples for data collection with the "smart ROSE," a low cost, portable device that can be used in the operating room. The device measures impedance spectroscopy in the 1 kHz - 10 MHz frequency range and derives a bio impedance biomarker via custom-designed hardware. The assessment of the sample is completed in a few seconds and subsequently, the sample is flushed into a pathology jar to undergo the standard workflow for cytology. The algorithm for extracting the bioimpedance biomarker from the measurement was developed based on our previous preclinical study with transgenic (KPC) mice[7]; pancreas samples with a CRF biomarker below 1 MHz were considered noncancerous, while biomarker values above 1MHz or the absence of a biomarker reading were considered cancerous.

Results: PC assessment provided by nsCanary was validated against pathology outcomes for each biopsy sample. Findings showing a sensitivity of 80% and a specificity of 87.5% are reported in Table 1.

		Pathology Outcome	
		CA	NC
nsCanary Assessment	CA	4	2
	NC	1	14

Table 1. Confusion matrix for asessments and pathology outcomes. CA indicates cancerous outcome, NC indicates noncancerous outcome.

Conclusion: We believe the "smart ROSE" device will provide immediate feedback to the endoscopist on cancer presence and on sample adequacy. This device is intended to support the decision-making process by enabling clinicians to overcome the challenge of proving cancer presence during the first biopsy procedure, ultimately avoiding revisits and unnecessary trauma.

Introduction: Pancreatic ductal carcinoma (PDAC) is characterized by a highly aggressive phenotype and resistance to chemotherapy. Both features are promoted by a hypoxic and nutrient-poor tumor microenvironment. However, the mechanisms by which these conditions support tumor progression and the involvement of nuclear factor of activated T cells (NFATc1) are largely unknown.

Aims & Methods: Aims: Our aim was to define the adaptive role of NFATc1 in metabolic reprogramming and survival mechanisms of PDAC in nutrient and oxygen poor environment.

Methods: PDAC-Cells with transient NFATc1 knockdown or CRISP-Cas9-mediated knockout were examined following deprivation of either oxygen or essential nutrients, e.g. glutamine. The role of NFATc1 in glutamine dependent cell viability and growth was determined in various human and murine PDAC cell lines, as well as patient-derived cells, using MTT and colony formation assays. Metabolic reprogramming was measured by HPLC/MS, RNA-Seq, qPCR and seahorse analysis. Involvement of NFATc1 in nutrient-dependent metabolic and transcriptional effects were confirmed in patients' tumor samples and in patient derived organoids.

Results: Our ongoing study reveals a close link between hypoxic and nutrient deficient tumor environment dependent regulation of glycolysis, integrated stress responses and activation of NFATc1.

Moreover, the activity and expression of key metabolic enzymes and transporters are hooked to NFATc1 in concert with ATF4 and HIF1α. We are currently investigating the potential of targeted inhibition of NFATc1-mediated metabolic reprogramming in the context of hypoxia and glutamine-deficient environment.

Conclusion: We postulate a central role of NFATc1 in the adaptive metabolic reprogramming of PDAC cells, which may provide the framework for new therapeutic strategies, especially in hypoxic and nutrient-deficient tumors.

Introduction: Metastatic involvement of the pancreas is rare, incidence is between 2-5% of all pancreatic malignancies in living patients. Renal cell carcinoma (RCC), lung carcinoma, breast carcinoma and melanoma belong to the most common secondary malignancies of the pancreas. Clinical history, imaging (CT, MRI, PET CT), endoscopic ultrasound (EUS) guided biopsy (FNB), histology and immunohistochemical methods are key for a precise diagnosis which allows tailored therapeutical approach.

Aims & Methods: The aim of the study was to evaluate incidence of metastasis to the pancreas in a centre highly specialized for treatment of cancer. We performed a retrospective evaluation of a prospectively maintained database and reviewed all patients who have been referred for an EUS within the last 24 months to our tertiary centre, where around 400 specialized EUSs are carried out annually. Demographic data, imaging, findings on EUS, histology, immunohistochemistry and treatment were reviewed.

Case	Primary tumour	Age (years)	Sex	Location within the pancreas	Size (mm)	Extra-pancreatic metastasis	Time: original diagnosis – pancreatic metastasis (years)	Treatment	Lenght of survival since EUS (months)
1	RCC: left kidney	69	F	Head Body	15 11	No (Note: 16mm NET– pancr. tail)	9	Active surveillance	16
2	RCC: right kidney	60	M	Body	47	No	7	Robotic distal pancreatectomy	13
3	RCC: right kidney	80	F	Head	25	No	8	Active surveillance	13
4	Rectal adenocarcinoma	75	F	Head	30	Yes (peripancreatic perit. deposits)	12	Chemotherapy (FOLFIRI)	12
5	Non-small cell lung adenocarcinoma	76	M	Body	25	No	Synchronous	Chemotherapy/ Immunotherapy (Carboplatin/ Pametrexed / Pembrolizumab)	6
6	RCC: right kidney	70	M	Tail	50	No	13	Immunotherapy (Avelumab) + TKI (axetinib)	6
7	Non-small cell lung adenocarcinoma	64	F	Head	11	Yes (brain)	4	Radiotherapy (IMRT) followed by EGFRi (osimertinib)	5
8	Leiomyosarcoma (left thigh)	74	M	Head	35	Yes (right lung hilum, liver)	39	None (doxorubicin planned)	2 (died)
9	High-grade tubo-ovarian carcinoma	62	F	Tail	35	No	4	Chemotherapy (Carboplatin, Caelyx); robotic distal pancreatectomy; PARPi (Olaparib)	29

Results: Nine patients with metastatic involvement of the pancreas were diagnosed. Mean age was 70 years (min: 62, max. 80); five were females (5/9: 56 %). The primary tumour included RCC (4/9; 44 %), lung adenocarcinoma (2/9; 21 %), rectal adenocarcinoma (1/9; 11 %), leiomyosarcoma (1/9; 11 %) and tubo-ovarian carcinoma (1/9; 11 %). Metastasis was localised in the head of the pancreas in four patients (45 %), in the body in two individuals (22 %) and in the tail in two patients (22 %). One patient (11

%) had RCC metastasis in the head and body of the pancreas. The mean tumour size was 28mm (min: 11mm, max: 50mm). Three patients (33 %) had synchronous extra-pancreatic metastases. Median time between the primary diagnosis and EUS for pancreatic metastasis was 8 years (0-39 years). One patient underwent surgery (distal pancreatectomy), two have been surveilled actively, one died before treatment was commenced; five patients (56 %) have been treated with combinations of systemic treatments (including chemotherapy, immunotherapy, TKI, PARPi, EGFRi) and/or radiotherapy and/or surgery. The mean survival time since EUS-FNB diagnosis has been 11 months. One patient died.

Conclusion: Despite metastatic pancreatic involvement is rare, attention to (even non-recent) clinical history is crucial. EUS guided biopsy is safe and allows precise histological and immunohistochemical diagnosis. Treatment options include excellent systemic tailored treatment approaches as well as surgery in selected individuals.

CONSIDERATION OF WHETHER SCREENING FOR EARLY DETECTION OF PANCREATIC CANCER SHOULD BE CONTINUED EVEN IN SUPER-ELDERLY INDIVIDUALS

R. Kodama[1], Y. Oka[1], Y. Kobayashi[1], Y. Yokota[1], H. Saegusa[1], H. Ushimaru[1]
[1]Minaminagano Medical Center, Shinonoi General Hospital, Department of Gastroenterology, Nagano, Japan

Contact E-Mail Address: kodryo@grn.janis.or.jp

Introduction: With the increase in the opportunity to follow up patients with risk factors for pancreatic cancer, such as IPMN, using imaging tests, it is generally considered to discontinue follow-up for those who are elderly and not eligible for surgery.

There are few studies comparing the group of patients who underwent surgery with those who did not undergo surgery among super-elderly individuals aged 80 years or older.

Aims & Methods: This was a retrospective, single-center study aimed at examining the extension of survival by surgery in healthy super-elderly patients aged 80 years and over with pancreatic cancer. Among the 183 patients diagnosed with histologically confirmed conventional ductal adenocarcinoma of the pancreas at our hospital between April 2011 and March 2021, we targeted 20 cases aged 80 years or older, whose clinical courses were available, and who were considered to be resectable or borderline resectable with an ECOG Performance Status of 0. Of the 20 cases, 11 underwent surgery and 9 did not, and we retrospectively compared the surgery group and non-surgery group.

Results: The age of the surgery group was 83±5 years, while that of the non-surgery group was 88±6 years, which was significantly higher in the non-surgery group. However, there was no significant difference in gender, symptom rate, abdominal pain rate, or blood test results for Alb, AMY, CEA, or CA19-9 levels.

Tumor localization was pancreatic head (64%), pancreatic body (18%), and pancreatic tail (18%) in the surgery group, while all cases in the non-surgery group were located in the pancreatic head. All cases in the surgery group were Resectable on CT imaging, and they underwent pancreaticoduodenectomy (73%), distal pancreatectomy (18%), or total pancreatectomy (9%) without NeoAdjuvant Chemotherapy.

In the non-surgery group, 89% were Resectable and 11% were Borderline on CT imaging, and the reasons for non-resection were age (45%), patient preference (33%), past medical history (11%), and surgeon's judgment (11%). Chemotherapy was administered in 64% of the surgery group and 67% of the non-surgery group, and second-line or later treatment was administered in 27% of the surgery group and 22% of the non-surgery group. In addition, radiation therapy was administered in 18% of the surgery group. The median survival time (IQR) was 333 (251-426.5) days in the surgery group and 226 (137-728) days in the non-surgery group, which was significantly longer in the surgery group. All cases in the surgery group died of the original disease, while 78% of the non-surgery group died of the original disease and 22% died of cerebral infarction.

Conclusion: Surgery is expected to prolong the survival period even in super-elderly individuals, and imaging follow-up for early detection of pancreatic cancer is important even in super-elderly individuals if they have a surgical tolerance.

Disclosure: Nothing to disclose.

PANCREATIC DUCTAL ADENOCARCINOMA WITH STRONG EXPRESSION OF INTERLEUKIN-13 RECEPTOR A2 SHOWS A POOR RESPONSE TO GEMCITABINE-BASED CHEMOTHERAPY

Introduction: Interleukin-13 receptor α2 (IL-13Rα2) is a single-transmembrane protein consisting of 380 amino acids. It is a subunit of the IL-13 receptor family. IL-13Rα2 has high affinity for IL-13, and IL-13 binding has complex internal effects and functions. Pancreatic ductal adenocarcinoma (PDAC) with strong expression of IL-13Rα2 has a poor prognosis and is associated with gemcitabine resistance in an orthotopic mouse model of PDAC.

Aims & Methods: We evaluated the influence of IL-13Rα2 expression on patients with PDAC undergoing gemcitabine-based chemotherapy. We included patients with PDAC, as diagnosed by endoscopic ultrasound-fine needle aspiration (EUS-FNA), who received systemic chemotherapy from March 2014 to March 2019. Tumor expression of IL-13Rα2 was assessed by immunohistochemistry and classified using a three-point scale [0 (negative), 1 (weak), or 2 (strong)] in a blinded fashion. The IL-13Rα2-high group comprised patients with strong expression.

Overall survival (OS) and progression-free survival (PFS) were analyzed from initiation of chemotherapy or chemoradiotherapy to death, and from treatment to the date of local progression > 20% or distant metastasis. The primary tumor reduction rate was compared between the high and low IL-13Rα2 expression groups. The effect of chemotherapy was assessed by computed tomography after 3 months. Additionally, in surgical samples, we evaluated the relationship between IL-13Rα2 and gemcitabine resistance genes (hENT, dCK, RRM1, RRM2, and CDA) by quantitative PCR.

Results: A total of 95 patients were enrolled. High and low IL-13Rα2 expression was detected in 63 and 32 cases, respectively. The IL-13Rα2-high group showed significantly poorer progression-free and overall survival rates than the IL-13Rα2-low group ($p = 0.0191$ and $p = 0.0062$, respectively). The factor of IL-13Rα2 expression was associated with progression disease after 3 months of the first gemcitabine-based chemotherapy (odds ratio = 13.72, $p = 0.0143$).

In univariate analyses, PS of 0–1 or 2 ($p < 0.01$), mGPS of 0-1 or 2 ($p < 0.01$), tumor size < 32 or ≥ 32 mm ($p = 0.02$), surgery, ($p < 0.01$), radiation ($p < 0.01$), and tumoral IL-13Rα2 expression ($p < 0.01$) were associated with OS.

In multivariate analysis, no surgery, no radiation, and positive IL-13Rα2 expression of the tumor were associated with a poorer prognosis (HR = 0.31, 95% CI: 0.12–0.81, p = 0.02; HR = 0.35, 95% CI: 0.17–0.73, p = 0.01; and HR = 1.81, 95% CI: 1.02–3.22, p = 0.04, respectively).

As for gemcitabine resistance genes by quantitative PCR, the expression of hENT1 was significantly lower in the IL-13Rα2-high group (p = 0.01); dCK, RRM1, RRM2 and CDA expression levels were not significantly related to IL-13Rα2 expression (p = 0.14, 0.06, 0.97, and 0.13 respectively).

Conclusion: The evaluation of EUS-FNA specimens for tumoral IL-13Rα2 expression at the time of diagnosis enables prediction of prognosis. Strong expression of IL-13Rα2 in EUS-FNA specimens decreases gemcitabine-based chemotherapy effectiveness in PDAC.

Evaluation of IL-13Rα2 expression in EUS-FNA specimens prior to chemotherapy may facilitate selection of the most suitable chemotherapeutic agent.

Disclosure: Nothing to disclose.

UTILIZATION OF HANDCRAFTED SOFTWARE FOR QUANTITATIVE CONTRAST-ENHANCED HARMONIC EUS-FOCUSING ON DIFFERENTIAL DIAGNOSIS OF PANCREATIC TUMORS

K.C. Chen[1,2,3], P.C. Li[2], Y.T. Kuo[3,4,5], H.P. Wang[3,5,6]

[1]Far Eastern Memorial Hospital, Internal Medicine, New Taipei City, Taiwan, [2]Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, [3]Taiwan Contrast EUS Study Group, Taipei, Taiwan, [4]National Taiwan University Hospital, Integrated Diagnostics & Therapeutics, Taipei, Taiwan, [5]National Taiwan University, Internal Medicine, Taipei, Taiwan, [6]National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan

Contact E-Mail Address: timothychen921@gmail.com

Introduction: Contrast-enhanced harmonic endoscopic ultrasound (CEH-EUS) can demonstrate microvascularization of the tumors. However, most images acquired from CEH-EUS are interpreted subjectively without quantification by time-intensity curves (TICs) analysis.

Aims & Methods: In this study, we used handcrafted software to quantify CEH-EUS images for objective interpretation of tumor microvascularization to make differential diagnosis of pancreatic tumors feasible.

We analyzed the videos of CEH-EUS for pancreatic tumors from the patients in National Taiwan University Hospital and Far Eastern Memorial Hospital. The convex-type echoendoscope (GF-UCT260; Olympus, Tokyo, Japan) equipped with ultrasound (US) systems (EU-ME2) was used for the procedures.

The second generation of US contrast agent with Sonazoid (GE Healthcare, Milwaukee,Wisc), which contains perfluorobutane microbubbles with a median diameter of 2–3 μm, was administered bolus and intravenously with a dosage of 0.015 ml encapsulated gas per kilogram body weight. The videos were recorded in AVI formats with 30 frames/second.

The algorithm for getting TICs includes the following steps:

1. Circling the region of interest(ROI) in the B-mode
2. Performing speckle tracking of the ROI in the B-mode
3. Simultaneously obtaining the intensity of ROI (the mean pixel values in the ROI) in the corresponding contrast-enhanced harmonic image
4. Outputting TICs after subtracting the baseline intensity (defined as mean TIC in the first 10 s for eliminating the different baseline intensities caused by other settings).
5. Outputting histogram of pixel values and excel file containing all pixel values from the frame with the highest mean pixel value automatically.
6. Calculating the standard variance of (5) to represent the heterogeneity inside the ROI.

The speckling tracking composes of searching and matching processes. We used full search for the searching process and normalization cross-correlation for the matching process. By using the hardware of CPU with Intel i7-8750H and GPU with Nvidia GTX 1050 Ti, the computation time was 0.7 ms/frame.

Results: The detailed results were shown in Table 1. We collected 10 and 7 videos of CEH-EUS for pancreatic tumors from NTUH and FEMH respectively in this study. Among them, 9 were diagnosed of pancreatic ductal adenocarcinoma (PDAC), 6 were pancreatic neuroendocrine tumors (PNET), and 2 were autoimmune pancreatitis (AIP). The TICs were obtained through our proposed model. Briefly, there were no significant differences in times to peak, the mean peak intensity, the in-slope tangent and standard deviation of pixel value in ROI (from the frame with the highest mean pixel value) among PDAC, PNET, and AIP. However, there was significant difference in the mean peak intensities of PDAC and non-PDAC (37.88 vs 63.12, p=.031).

	PDAC	PNET	AIP	Non-PDAC (NET & AIP)	P value (PDAC vs PNET vs AIP)	P value (PDAC vs non-PDAC)
Number	9	6	2	8		
Times to peak(SD), seconds	27.50 (7.98)	26.76 (8.56)	21.5 (5.94)	25.45 (7.65)	0.632	0.598
The mean peak intensity(SD), dB	37.88 (18.58)	66.10 (28.91)	54.2 (3.96)	63.12 (25.09)	0.087	0.031
In slope(SD)	2.90 (2.34)	5.07 (3.87)	5.34 (2.41)	5.14 (3.40)	0.331	0.131
SD of pixel value in ROI (the highest mean pixel value)(SD)	34.77 (9.14)	35.47 (10.44)	33.94 (0.08)	35.09 (8.86)	0.977	0.942

Table 1. The results from three kinds of pancreatic tumors based on the proposed model.

Conclusion: In this study, there were no significant differences in times to peak, the mean peak intensity, and SD of pixel value in ROI (from the frame with the highest mean pixel value) among PDAC, PNET, and AIP, however there was significant difference in the mean peak intensity between PDAC and non-PDAC group. A study with larger test number is needed in the future for further application.

Contact E-Mail Address: smpark@chungbuk.ac.kr

Introduction: Chronic pancreatitis (CP) and acute pancreatitis (AP) are known risk factors for pancreatic cancer (PC), but the incidence and risk of PC vary depending on the subtype of pancreatitis.

Aims & Methods: We conducted a population-based cohort study to evaluate the incidence and risk of PC in patients with different subtypes of pancreatitis. We identified patients with AP (n=225,811, 50.0%) and CP (n=225,685, 50.0%) from Korean population-based data and matched them with age- and sex-matched controls (n=4,514,960). We analyzed the

incidence and adjusted hazard ratios (aHRs) of PC among patients followed for more than 2 years or 5 years, and annual interval risks in each group, including single AP (SAP), recurrent AP (RAP), CP with AP, and CP without AP. We also performed subgroup analysis for both sexes and adjusted for confounding factors associated with PC.

Results: The incidences (per 10^5) and risks (aHR) of PC were higher in RAP (12.69, 5.00) or CP with AP (12.12, 5.74) groups compared to SAP (2.31, 1.32) or CP without AP (2.28, 1.57) groups. The annual interval risks of PC decreased over time, with SAP and CP without AP groups showing no increased risk of PC after 3 or 4 years, respectively. However, the risk of PC remained elevated in the RAP and CP with AP groups for more than 8 years. Women with RAP, SAP, and CP with AP had higher risks of PC than men.

Conclusion: Our findings suggest that the risk of PC is higher in patients with RAP and CP with AP than in those with SAP or CP without AP. The risk of PC also persists for a longer time in patients with RAP and CP with AP. Our study provides insights into the incidence and risk of PC in patients with different subtypes of pancreatitis, which can help in the development of effective prevention and screening strategies for PC in this high-risk population.

Contact E-Mail Address: J.Meziani@erasmusmc.nl

Introduction: Several studies suggest that new-onset diabetes mellitus (NOD) may be an early manifestation of pancreatic ductal adenocarcinoma (PDAC). Therefore, the international CAncer of the Pancreas Screening (CAPS) Consortium recommends glucose and HbA1c monitoring in high-risk individuals (HRIs) for PDAC. However, evidence that such monitoring improves the detection of PDAC is lacking.

Aims & Methods: The aim of this study was to investigate NOD, glucose and HbA1c values in relation to the development of PDAC in a screening program for HRIs. Analysis was performed on individuals participating in the Familial Pancreatic Cancer (FPC) surveillance study, in which HRIs with a hereditary predisposition for PDAC are followed yearly by MRI and/or EUS and blood sampling. Individuals who underwent fasting glucose and/or HbA1c monitoring at least once were included.

Results: In October 2021, the FPC cohort consisted of 463 HRIs, of which 404 had undergone at least one glucose or HbA1c measurement. Of these, 9 individuals developed PDAC and 4 non-PDAC individuals were diagnosed with NOD. Glucose levels ranged between 3.4-10.7 mmol/L (mean 5.4 ± 0.7), and HbA1c levels between 25-68 mmol/mol (mean 37.3 ± 3.6). The percentage of cases with at least one elevated value was comparable between the PDAC and non-PDAC group for glucose (33% and 27%, p=0.707) and HbA1c (22% and 14%, p=0.623).

Conclusion: In this large HRI surveillance cohort, measuring glucose and HbA1c values did not contribute to PDAC detection. Larger and longer term studies are needed to determine the final role of glucose and HbA1c monitoring in PDAC surveillance.

Disclosure: Nothing to disclose.

EPIDEMIOLOGICAL, CLINICAL AND DIAGNOSTIC ASPECTS OF PANCREATIC CANCER: THE EXPERIENCE OF A UNIVERSITY HOSPITAL IN AN EMERGING COUNTRY

F. Amri[1], C. Belkhayat[1], H. Koulali[1], A. Zazour[1], Z. Ismaili[1], G. Kharrasse[1]

[1]Mohammed VI University Hospital, Department of Hepato-Gastroenterology, Digestive Diseases Research Laboratory (DSRL), Faculty of Medicine and Pharmacy, Mohammed First University, Oujda, Morocco

Contact E-Mail Address: fakh.amr@gmail.com

Introduction: Pancreatic cancer (PC) is the 12th most common cancer in the world and the 7th leading cause of cancer death (Globocan 2020), and its incidence is higher in developed countries. Early diagnosis and surgical resection offer the best chance of potential remission, unfortunately, the majority of patients are diagnosed at an advanced stage due to the non-specific nature of symptoms.

Aims & Methods: This retrospective descriptive study aims to investigate the epidemiological and clinical aspects of pancreatic cancer in an emerging country.

Pancreatic cancer cases, diagnosed and treated at a University Hospital between January 2018 and December 2022, were analyzed using the SPSS Statistics version 20 program for data analysis

Results: A total of 197 new cases of pancreatic cancer were identified, with a mean age of 64.6 +/- 11.5 years, and a range of 33-91 years. The majority of patients (90.9%) were over 50 years old, and there was no significant difference in sex ratio (male 50.3%, female 49.7%). Diabetes was identified in 38.1% of cases, with 42.7% of these cases having new-onset diabetes, and 90.6% having uncontrolled diabetes at the time of diagnosis. Only 7.6% of cases were obese, while 22.8% reported chronic tobacco smoking, and 12.7% reported chronic alcohol consumption. The most frequent digestive symptoms reported by patients were abdominal pain (88.8%), jaundice (56.3%), vomiting (28.4%), constipation (7.1%), and diarrhea (3%). More than half of the patients (53.2%) had a score of 2 or more on the ECOG performance scale, and there was a significant association between ECOG score and cancer stage, with 65% of metastatic cancers having an ECOG score of 2 or more (p=0.02). 24% had a BMI of less than 18 kg/m2. Head cancer accounted for 80.7% of all cases, with corporal and caudal location accounting for 19.3%. 19.8% of cancers were resectable, 4.1% were borderline, 43.7% were locally advanced, and 32.5% were metastatic. CA 19-9 level was correlated with tumor stage, with 71.9% of metastatic tumors having a level greater than 100 U/ml (P=0.025). The predominant histological type was adenocarcinoma (96.4% of cases).

Conclusion: The study highlights the challenge of diagnosing pancreatic cancer at an early stage due to the nonspecificity of symptoms. The results highlight also that the recent onset of diabetes or the uncontrolled state of long-standing diabetes in elderly patients should raise suspicion for pancreatic cancer

Disclosure: None.

PP1597

THE IMPACT OF EUSFNB USING PROCORE NEEDLES FOR MICROSATELLITE INSTABILITY ASSESSMENT IN UNRESECTABLE PANCREATIC ADENOCARCINOMA

F. Teh[1], L.M. Wang[2], B.E.A. Kwek[1], J. Li[1], W.C.K. Lin[1], C.H.N. Tee[1], T.-L. Ang[1]
[1]Changi General Hospital, Gastroenterology and Hepatology, Singapore, Singapore, [2]Changi General Hospital, SingHealth, Department of Laboratory Medicine, Pathology Section, Singapore, Singapore

Contact E-Mail Address: francisdaban@gmail.com

Introduction: Pancreatic adenocarcinoma has a poor prognosis with an overall 5-year survival rate of 10% as most patients present with unresectable or metastatic disease. Evaluation of microsatellite instability (MSI) or deficient DNA mismatch repair (dMMR) status can tailor treatment to increase the efficacy of systematic therapy. However, the adequacy of tissue samples obtained by routine endoscopic ultrasound-guided fine needle biopsy (EUSFNB) of pancreatic adenocarcinoma for MSI/dMMR assessment remains unclear. This study evaluated the role of EUSFNB using the Procore (Cook Medical) biopsy needles for MSI/dMMR assessment. In recent years, a new 20G Procore needle has been developed to overcome the limitations of tissue acquisition of the smaller needles (22G,25G) and the rigidity of the larger one (19G). We also aimed to study the performance assessment between Procore 20G vs 22G needles in tissue acquisition for MSI/dMMR assessment.

Aims & Methods: This was a single-centre study reviewed patients with suspected pancreatic adenocarcinoma who underwent diagnostic EUS-FNB in a tertiary referral centre using either 20G or 22G Procore needles from January 2022 to March 2023. The newer 20G Procore needle was designed with a forward side-bevel, whereas the 22G needle had a reverse side-bevel, for tissue core acquisition. Clinical data and characteristics of lesions in all patients undergoing EUSFNB in the participating site are prospectively maintained in a registry for quality control and audit purposes. All cases of adenocarcinoma were tested for MSI/dMMR status by immunochemistry (MLH1, MSH2, MSH6 & PMS2). The primary study outcome measure was the adequacy of tissue samples for MSI/dMMR testing. Secondary outcomes were the rate of histological core tissue acquisition, the difference in the adequacy of tissue for MSI/dMMR testing between 20G and 22G Procore needles and the rate of MSI-high pancreatic adenocarcinoma. The impact of the use of these needles in obtaining adequate tissue on patient management was also evaluated.

Results: A total of 31 patients (mean age 68.2 SD± 8.17; 51% male) with pancreatic adenocarcinoma were included in the study. The mean size for the pancreatic mass was 33.17 SD±20.4 with most of the pancreatic mass located at the pancreatic head, uncinate, and neck region 70% (21/31). The histological yield of EUSFNB was 100%. Overall tissue adequacy rate for MSI/dMMR assessment was 80% (25/31), which was higher with 20G compared to 22G Procore needles (88.8%;16/18 vs 69.2%;9/13, p-value = 0.207). Two of the 23 patients with successful MSI/dMMR testing (8.7%) had MSI-high status. One received second-line treatment with pembrolizumab, and the other received the best supportive care due to worsening liver function and poor functional status.

Conclusion: This study affirmed the feasibility of routine MSI testing from specimens acquired by EUSFNB using the Procore EUSFNB needles. Our results also suggested that the larger 20G Procore needle with forward side-bevel had a higher yield for MSI testing than the 22G needle with reverse side-bevel, even though both needle types could obtain tissue cores for histology, and this should be reassessed by a further study with larger sample size that is adequately powered.

Disclosure: None.

Introduction: Inflammation-based prognostic indicators have been developed to predict the prognosis in patients with pancreatic cancer. Neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR) and C-Reactive Protein/Albumin Ratio (CAR) have shown to be predictors of poor outcomes in various malignancies.

Aims & Methods: The aim of our study was to assess the role of NLR, PLR and CAR in predicting prognosis and sarcopenia in pancreatic cancer. We conducted a retrospective single-center study, including all patients diagnosed with pancreatic adenocarcinoma between 2014 and 2022.

Patient characteristics, inflammatory markers, tumor status and outcomes were collected. Baseline NLR, PLR and CAR were calculated for each patients. Radiologic sarcopenia was assessed by calculating the total psoas area index.

Results: In total, thirty patients were enrolled with a mean age of 61 ± 11 years and a sex ratio M/F of 4. The tumor was predominantly located at the head (66.6%). Regarding staging, the tumor was resectable in 11 patients (36%), locally advanced in 10 patients (33%) and metastatic in 9 patients (9%). Mortality rates at 6 months, 12 months and 36 months were 50%, 63.3% and 75% respectively. All the analyzed ratios were not associated to tumor locations or stages (p>0.05). High NLR was significantly higher in patients with sarcopenia compared to those without sarcopenia (4.7 ± 2.6 vs 2.9 ± 1.62 respectively, p = 0.02), Difference not found with PLR or CAR. When analyzing the receiver operating characteristic (ROC) curve, AUC of NLR, PLR and CAR in predicting 12 months survival were [0.838 (95% CI: 0.683–0.992, p=0.004)], [0.831 (95% CI: 0.671–0.992, p=0.005)] and [0.781 (95% CI: 0.601–0.961, p=0.018)], respectively.

Conclusion: In our study, pre-therapeutic NLR was significantly correlated with sarcopenia and showed better prediction of 12 months survival and thus associated to a poor prognosis. It is a simple, easly to calculate and valuable tool for assessment of prognosis in pancreatic cancer.

Disclosure: Nothing to disclose.

Introduction: The benefits of neoadjuvant therapy for patients with pancreatic cancer (PC) with portal venous involvement are still a matter of debate.

The aim of this study is to compare the short- and long-term outcomes of surgery with or without neoadjuvant therapy (NAT) in patients with PC with suspicion of venous involvement.

Aims & Methods: A multicenter retrospective cohort study was conducted to compare patients who underwent upfront surgery (US) vs patients who underwent surgery after NAT for PC with suspicion of venous involvement between 2007 and 2017. The primary endpoints were short-term morbidity and mortality, overall survival and disease-free survival.

Results: We included 690 patients who underwent US and 361 patients with NAT from 9 centers. Patients with NAT had more suspicion of radiological SMV-PV involvement(83.6% vs 96.9%, p<0.001), but received fewer SMV-PV resections (79.3% vs 53.7%, p<0.001) and in the final pathology had less SMV-PV infiltration (65.9% vs 52.3%, p<0.001), perineural invasion (90.1% vs 75.2%, p<0.001), angioinvasion (76.7% vs 59.9%, p<0.001), lymph node involvement (83.6% vs 60.6%, p<0.001) and R1 resections (67.2% vs 44.7%, p<0.001).

In patients undergoing venous resection, there were no differences between the US and NAT patients in major postoperative complications (20.0% vs 22.8%, p<0.50) and reoperations (10.2% vs 11.4%, p<0,66). When venous resection was not performed, patients with NAT had significantly fewer (Clavien-Dindo ≥IIIb) postoperative complications (24.4% vs 10.8%, p=0.02), fewer reoperations (11.2% vs 3.0%, p=0.006), and less 90-day mortality (7.7% vs 2.4%, p=0.03). Furthermore, patients with NAT had a significantly better survival of 27.3 compared to 21.2 months in patients with US (p = 0.003).

	No venous resection			Venous resection		
	Upfront surgery (US)	Neoadjuvant therapy (NAT)	P value*	Upfront surgery (US)	Neoadjuvant therapy (NAT)	P value*
Total, n	143	167		547	194	
Complications, n (%)	78 (54.6)	83 (49.7)	0.39	341 (62.3)	137 (71.0)	0.03
Clavien dindo			0.02			0.50
I-IIIa	59 (75.6)	74 (89.2)		268 (80.0)	105 (77.2)	
IIIb-V	19 (24.4)	9 (10.8)		67 (20.0)	31 (22.8)	
Reoperation	16 (11.2)	5 (3.0)	0.006	53 (10.2)	21 (11.4)	0.66
Readmission	11 (7.7)	13 (7.8)	0.98	79 (15.9)	22 (12.2)	0.23
90-day mortality	11 (7.7)	4 (2.4)	0.03	27 (4.9)	6 (3.1)	0.28

Table. Short-term morbidity and mortality

Data are missing for some patients: complications (n=1), Clavien dindo (n=7), reoperation (n=36), readmission (n=62)

Conclusion: NAT should be considered in patients with PC with venous involvement, since it might allow a better selection of patients and is associated with less degree of major postoperative complications and better overall survival.

Disclosure: Nothing to disclose.

Introduction: Single-molecule fluorescence microscopy has been researched for diagnosis of disease and detecting drugs or substances at the molecular level. It is known to detect the target proteins more precisely than ELISA and has a higher multiple detection rate, with small sample volume and at low cost. Pancreatic cancer often presents at an advanced stage. So there is a demand for early detection.

Aims & Methods: The aim of this pilot study is to check the feasibility of this technique to diagnose the pancreatic cancer. From April 2016 to June 2021, 16 pancreatic cancer patients and 21 non-pancreatic cancer patients were enrolled in the study at Seoul National University of Bundang Hospital. 15 markers (CA19-9, CRP, CA-125, D-dimer, Lumican, Cathepsin-D, IL-6, LRG-1, IFN-r, Beta-2, CEA, Clusterin, TTR, IL-4, and C5a) were detected from blood sample using single-molecule fluorescence microscopy. To create a train and test set for our research, we split the enrolled patients into halves.

The primary outcome of the study is the accuracy, which is defined as the number of correct predictions, where patients are predicted as patients and controls are predicted as controls, divided by the total count. We analyzed the classification accuracy of each group and examined the accuracy based on the combination and number of markers used.

Although the sizes of the training set and the testing set were equal, we randomly split each sample into either the training or testing set, and repeated this process 1,000 times.

Results: Eight out of 16 pancreatic cancer patients were used for training and the remaining 8 for testing. For the non-pancreatic cancer patients, 11 of the 21 blood samples were used for training, and the other 10 for testing.

In the classification accuracy of diagnosis, we tested the accuracy by utilizing Gaussian Naïve Bayes and Support Vector Machine. In case of Gaussian Naive Bayes for the train set, the average accuracy was 99.2%, the standard deviation was 0.019. When applied to the test set, the accuracy was 86.3%, with a standard deviation of 0.074. In case of Support Vector Machine for the train set, the average accuracy was 75.6%, the standard deviation was 0.004. When tested on the test set, the accuracy was 77.6% with a standard deviation of 0.076.

For the accuracy according to the number of biomarkers used, the accuracy was calculated by adding one biomarker at a time in the order previously listed. Accuracy tended to increase as markers were added, the highest accuracy was achieved when using 10 biomarkers (88.4%), and adding more biomarkers from the 11th to 15th actually decreased the accuracy (lowest 85.5% to highest 87.8%).

Conclusion: In this pilot study, we identified that single molecule counting technology showed a feasibility for the new technique to differentiate the patients with pancreatic cancer from healthy control. Further studies with more samples and appropriate selection of biomarkers, and optimization of classification model are necessary to fit the best performance of this novel technique. Utilizing this novel technique with multiple biomarkers in combination is expect to enable low-cost, small-sample volume, and high- accuracy diagnosis in pancreatic cancer.

Disclosure: Nothing to disclose.

Introduction: Pancreatic cancer (PC) is one of the fatal malignant tumors, with a 5-year survival rate is approximately 6%, and is expected to become the second leading cause of cancer deaths by 2030. The poor prognosis of PC is associated with the tumour microenvironment, characterized by excessive fibrosis and extracellular matrix deposition, known as desmoplasia. PC's highly desmoplastic property not only increases the malignancy of the tumor but also inhibits the penetration and diffusion of anti-cancer drugs, related to drug resistance. Chauhan et al. demonstrated that the angiotensin inhibitor (ASI), losartan reduced stromal collagen and hyaluronan production, thus improving the efficacy of chemotherapy in PC models. Several retrospective studies have reported that the ASI usage group showed higher overall survival (OS) and progression-free survival compared to the non-ASI usage group in PC patients. However, most of the previous studies on ASI in PC patients were based on retrospective data from single institutions. Recently, real-world big data study could explain this subject.

Aims & Methods: In this study, we aimed to conduct whether ASI use in PC patients improve OS using National Health Information Database of the National Health Insurance Service, which represents the entire Korean population. We assessed 209,723 participants for eligibility, diagnosed with pancreatic cancer between 2002 and 2020. A total of 64,219 PC patients were enrolled and divided into 3 groups [chronic ASI users with hypertension (HTN), n=13,239; non-ASI users with HTN, n=5,963; non-HTN group, n=45,017]. We performed propensity score matching to balance the baseline characteristics of the 3 groups and to reduce potential confounders using a logistic regression model with adjustment for the following: age; sex; region of residence (urban or rural); household income; underlying disease of HTN, diabetes mellitus, cardiovascular disease, cerebrovascular disease, chronic kidney disease or chronic pancreatitis; Charlson Comorbidity Index (0, 1 or ≥2); concurrent use of aspirin, metformin, statin; PC surgery type; radiotherapy; and chemotherapy.

Results: Multivariate analysis using Cox regression analysis for matched cohort presented ASI usage, female, younger, history of chronic pancreatitis, CCI ≥2, concurrent use of statin, and receiving distal pancreatectomy were significantly associated with longer OS. In addition, Kaplan-Meier curve for OS of 3 groups according to ASI usage showed that chronic ASI users presented significantly longer OS than non-ASI users and non-HTN group [Hazard ratio, chronic ASI users (control) versus non-ASI users 1.447; chronic ASI users (control) versus non-HTN group 1.518; P value < 0.001].

Conclusion: We found that the use of ASI after PC diagnosis is associated with longer survival in PC patients. Additional well-designed randomized controlled studies are needed to confirm these findings in the future.

Introduction: Two pancreatic cancer(PDAC) transcriptome subtypes have been defined (basal-like and classical) that seem related to different prognosis. Nevertheless, RNA-extraction from pancreatic tissue is cumbersome and has been performed mainly on surgical samples, representative of <20% of cases. Most PDAC patients undergo Endoscopic-UltraSound(EUS)-guided tissue acquisition(EUS-TA), but RNA-sequencing on such samples has been rarely performed or limited to paraffin-embedded samples with low RNA quality.

Furthermore, the association between molecular subtype and patient-related factors such as BMI, smoking, drug use, tumor location and Ca19.9 expression is uninvestigated.

Aims & Methods: The aim was to correlate PDAC molecular subtypes identified by RNA-sequencing on EUS-TA samples with prognosis and evaluate whether they are associated to patients' factors.

Consecutive patients with non-metastatic PDAC who underwent EUS-TA at diagnosis were enrolled in a prospective biobanking study with snap-frozen samples. Those with adequate quantity and quality of RNA underwent RNA-sequencing with Illumina Nova-Seq. PURIST score was applied to define transcriptional subtype and association with patient-related factors and overall survival (OS) investigated. Categorical and continuous variables were investigated by Fisher's exact test or Mann-Whitney test, correlation analyses with Pearson test

Results: In 44/45 samples, RNA was of quantity and integrity allowing successful RNA-sequencing. According with PURIST score 3 patients were classified as basal-like (6.8%) and the other 41 as classical. Basal-like patients had a significantly lower median OS compared to classical (3 vs 16 months; p=0.01) and a basal-like phenotype was associated to increased risk of death (HR 7.79; p=0.006). PURIST score also significantly correlated inversely with OS (r=-0.6; p=0.0007). Concerning patients' variables, patients with basal-like tumors were more frequently current smokers (66.6% vs 12.2%; p=0.05) and had a lower baseline Ca19.9 (80 vs 1243 IU/ml; p=0.001). No differences were found concerning age, gender, BMI, diabetes history, disease stage, tumor location, use of aspirin or statins.

Conclusion: Molecular subtype identification on EUS-TA PDAC cases at diagnosis is feasible and a basal-like phenotype is rare but associated to worse prognosis. Furthermore, current smoking seems to be associated to a more aggressive molecular subtype, which in turn does not seem to express a high Ca19.9. Further studies on a larger cohort are needed to confirm such findings.

Disclosure: Nothing to disclose.

Introduction:

Systemic inflammation and nutritional parameters have been studied as possible prognostic factors in advanced pancreatic cancer (APC) treatment results predictors.

Aims & Methods: The study aimed to analyze the correlation between nutritional status parameters and indices and the number of multi-agent treatment courses received at the inpatient chemotherapy department. Pre-treatment parameters (Charlson comocrbidity index (CCI), complete blood count, total protein, albumin, bilirubin) were collected and nutritional ratios and indices (neutrophil-to-lymphocyte (NLR), platelete-to-lymphocyte (PLR), lymphocyte-to-monocyte (LMR), prognostic nutritional index (PNI), nutritional risk index (NRI), HALP (hemoglobin, albumin, lymphocyte, protein), prognostic immune nutritional index (PINI), systemic inflammation score (SIS), systemic immune-inflammation index (SII)), were calculated in 158 patients with APC. We used Kendall rank correlation coefficient test to assess the correlation between the aforementioned parameters and the amount of treatment courses received.

Results: Out of 158 patients, 72 were men (45.5%) and 89 had with metastatic disease (56.3%). Mean number of inpatient received courses was 7. Kendall rank correlation coefficient test was statistically significant for CCI (-0.15), hemoglobin (0.129), erythrocyte (0.129), total protein (0.174), and albumin levels (0.178) as well as for PNI (0.179), NRI (0.150), HALP (0.145), PINI (0.187), and SII (-0.13) (p<0.05). There was a trend to statistical significance also in neutrophil (-0.1, p=0.052) and lymphocyte counts (0.104, p=0.06) and LMR (0.101, p=0.067).

Conclusion: In advanced pancreatic cancer, nutritional and systemic inflammation indices may serve as a predictor of the number of multi-agent chemotherapy treatment courses received at the inpatient chemotherapy department.

Introduction: Sarcopenia can be considered a prognostic factor for the occurrence of postoperative pancreatic fistula, other postoperative complications and mortality after pancreatoduodenectomy in patients with pancreatic adenocarcinoma.

Aims & Methods: The aim of our study was to determine the impact of sarcopenia on the occurrence of postoperative pancreatic fistula, other complications and mortality after pancreatoduodenectomy in patients with pancreatic cancer. Retrospective study of treatment of 152 patients with pancreatic cancer, who underwent pancreaticoduodenectomy in our Institution in the period from 2017 till 2019, was performed. Preoperative computed tomography (CT) was performed for all patients. Sarcopenia was quantified using two approaches: the Total Psoas Index (TPI) and the Hounsfield Unit Average Calculation (HUAC). The measurements were conducted at the level of the third lumbar vertebral body (L3).

Results: In 66 (43.4%) patients sarcopenia was diagnosed using HUAC. Postoperative complications occurred in 41 (62.1%) patients in the group with sarcopenia and in 29 (33.7%) patients in the group without sarcopenia (c^2 = 12.1, p=0.0005). Mortality was 4 (6.1%) and 2 (2.3%) respectively (c^2= 1.3, p=0.24).

In patients with sarcopenia determing by HUAC infections complications occurred in 8 patients, pancreatic fistula Grade B or C in – 24 patients, haemorrhage – in 5, delayed gastric emptying – in 3 patients, chyle leak – in 1. In patients without sarcopenia infections complications occurred in 7 patients, pancreatic fistula Grade B or C in – 10 patients, haemorrhage – in 5, delayed gastric emptying – in 3 patients, chyle leak – in 4 patient. We didn't find any significant difference in the number of infections complications (c^2=0.04, p=0.8) and haemorrhage (c^2 = 1.6, p=0.2). The level of pancreatic fistula Grade B or C was significant higher in patients with sarcopenia (c^2= 3.9, p=0.04).

Sarcopenia was diagnosed in 78 (51.3%) patients using TPI, postoperative complications occurred in 53 (67.9%) patients, in patients without sarcopenia postoperative complications occurred in 17 (23.0%) patients (c^2=30.9, p=0.0001). Mortality was 5 (6.4%) and 1 (1.4%) respectively (c^2=2.6, p=0.1).

In patients with sarcopenia determing by TPI infections complications occurred in 10 patients, pancreatic fistula Grade B or C in – 26 patients, haemorrhage – in 5, delayed gastric emptying – in 6, chyle leak – in 6 patients. In patients without sarcopenia infections complications occurred in 5 patients, pancreatic fistula Grade B or C in – 8 patients, haemorrhage – in 3, delayed gastric emptying – in 1. The level of pancreatic fistula Grade B or C was higher (c^2 = 0.02, p=0.8) in patients with sarcopenia. We didn't find any significant difference in the number of infections complications (c^2 = 0.8, p=0.3) and haemorrhage (c^2 = 0.8, p=0.3).

Conclusion: Present results suggest that sarcopenia, determined by HUAC and TPI, is a reliable indicator of the level of postoperative complications. Patients with sarcopenia, determined by HUAC, had higher level of postoperative pancreatic fistula after pancreaticoduodenectomy.

Calculation of sarcopenia using HUAC can be used to predict the occurrence of postoperative pancreatic fistula before pancreatoduodenectomy in patients with pancreatic cancer and help surgeons to guide preoperative and intraoperative clinical tactics.

Disclosure: Nothing to disclose.

Introduction: Pancreatic cancer (PC) is one of the most lethal cancers in the world, and by 2050, it is expected to become the leading cause of cancer-related deaths. Fatty pancreas (FP) is defined by significant fatty infiltration of the pancreatic parenchyma in the absence of chronic, excessive alcohol intake. The link between FP and PC is not fully understood; however, as a possible modifiable risk factor, FP is suspected of contributing to PC development. The aim was to assess the association between PC and FP by conducting a systematic review and meta-analysis.

Aims & Methods: We systematically searched three databases on 21.10.2022: MEDLINE (via PubMed), Embase, and CENTRAL (PROSPERO no.: CRD42022369017). Case-control and cross-sectional studies reporting on patients where the intra-pancreatic fat deposition was determined based on modern radiology or histology were included. We investigated patients with PC and without PC. As primary outcome parameters, FP in PC patients and non-PC patients, and PC in FP and non-FP patients were measured. Proportion and odds ratio (OR) with a 95% confidence interval (CI) was used for the effect size measure.

Results: In total, 17 articles were identified, including 2,956 patients. The possibility of having FP among patients with PC was more than six times higher (OR 6.13; 95% CI 2.61-14.42) than in patients without PC. The presence of PC among patients with FP was 32% (OR 1.32; 95% CI 0.42-4.16). The proportion of FP among PC patients was higher (0.62; 95% CI 0.42-0.79) than in non-PC patients.

Conclusion: In conclusion, FP was identified six times more in PC patients. Among patients with identified predisposing factors for PC, proper patient management can result in better survival rates. The last two authors contributed equally.

Disclosure: None.

Introduction: Recent studies propose that pancreatic ductal adenocarcinoma (PDAC) can be morphologically classified into biologically relevant categories each associated with known molecular subtypes with prognostic and possibly predictive significance (1).

Two distinct morphological PDAC categories ('gland forming' and 'non-gland forming') and four morphological patterns were thus recognized. We aimed to validate the prognostic significance of the newly proposed morpho-molecular classification of PDAC.

Aims & Methods: We reviewed all tumour containing histological slides from 50 chemotherapy-naive PDAC resection specimens from 50 patients (32 male, median age 71, range 30-97) treated in our centre between 2016-2019 and followed up for up to 85 months (mean follow up 35.1 months, mean time to death 23 months). Cases were assessed for the presence of four morphological patterns (conventional, tubulopapillary, squamous and composite) that grouped into two categories "gland forming" and "non-gland forming" according to the presence of well or not of well-formed tubular or compact structures. Tumour histological grading and TNM staging according to WHO 2019 and AJCC 2017, respectively, was performed. Morphological patterns and tumour categories were correlated with clinical-pathological variables and patient overall survival. Statistical analysis was performed using Pearson correlation coefficient and chi-squared test and overall survival analysis was conducted using the log rank test and Kaplan Meier curves. The level of significance was set at p=0.05.

Results: Our PDAC cohort included 9(19.6%) grade 1, 17(37%) grade 2, 20(43.5%) grade 3 and 12(24.5%) pT1, 25(51%) pT2, 10(20.4%) pT3 and 2(4.1%) pT4 cases. There were 31(62%) gland forming and 19(38%) non-gland forming PDAC, subclassified in 21(42%) with conventional, 10(20%) with tubulopapillary, 2(4%) with squamous and 17(34%) composite pattern. Morphological patterns were positively correlated with lymph node status (r=0.384, p=0.008). The non-gland forming category was positively correlated with higher tumour grade (r=0.435, p=0.003) and inversely correlated with the presence of pancreatic intraepithelial neoplasia-PanIN (r=-0.394, p=0.006). A weak negative association was observed between vascular invasion and female sex (r=-0.301, p=0.034) and perineural invasion with increasing age (r=-0.328, p=0.021). There were no other significant correlations observed. At the end of follow up 12/44 (27.3%) patients were alive. The two morphological categories and four morphological patterns did not correlate with overall survival (log rank test p=0.732 and p=0.843, respectively).

Conclusion: We have confirmed the applicability of the newly proposed binary morphological classification in PDAC. In our cohort the most common morphological category is "gland forming" with the majority of PDAC showing conventional pattern while "non-gland forming" PDAC are of higher histological grade. The recently proposed prognostic significance of the binary morphological classification has not been confirmed. Further studies in cohorts with larger number of cases with molecular subtyping are required to further assess the prognostic implications of the morphomolecular classification in PDAC.

Contact E-Mail Address: federica.bda@gmail.com

Introduction: Insulinomas are rare, functioning pancreatic neuroendocrine neoplasms (pNEN), whose gold standard therapy is surgical resection. Endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA) has emerged as a minimally invasive therapeutic option for pancreatic lesions. This study aims at describing a series of patients with pancreatic insulinoma treated with EUS-RFA.

Aims & Methods: This single-center, retrospective study includes all consecutive patients with pancreatic insulinoma undergoing EUS-RFA because unfit for surgery or refusing surgery. EUS-RFA was performed by using a 19G RFA needle, and a dedicated current generator system with a RFA energy of 20 to 50W. Technical success (i.e., the achievement of complete ablation), adverse events rate, and radiologic response within 3 months after EUS-RFA (i.e., complete tumor necrosis) were evaluated. Follow-up was assessed by clinical monitoring and blood test evaluation at least every 6 months for the first year after the procedure. A descriptive statistical analysis was performed for all the variables.

Results: From March 2017 to September 2022, 10 patients (mean age: 67.1 ± 10.1 years; F:M 7:3) were included. The mean size of insulinomas was 11.9 ± 3.3mm. The median number of passes was 6 (1-14) with a median ablation duration of 15 (6-20) seconds per pass. Technical success, immediate post-procedural euglycemia, and complete radiological response by abdominal CT scan were achieved in all cases (100%). Mild procedure-related early adverse are shown in Table 1. Persistent euglycemia was assessed at 6 and 12 months for each treated patient.

Patients, n	10
Technical success, n (%)	10 (100)
Early adverse events, n (%)	
Mild abdominal pain	2 (20)
Bleeding	1 (10)
Late adverse events, n (%)	0 (0)
Euglycaemia within 24 hours	10 (100)
Radiologic complete response within 90 days, n (%)	10 (100)
Clinical remission at 6 months, n (%)	10 (100)
Clinical remission at 12 months, n (%)	9/9 (100)

Table 1.

Conclusion: Data from this case series suggest that EUS-RFA is a feasible and safe therapeutic approach for pancreatic insulinomas with mid-term efficacy.

EFFICACY AND SAFETY OF CAPECITABINE AND TEMOZOLOMIDE (CAPTEM) IN ADVANCED GASTRO-ENTERO-PANCREATIC NEUROENDOCRINE NEOPLASMS (GEP-NEN): A SYSTEMATIC REVIEW AND METANALYSIS

M. Tacelli[1], S. Massironi[2], C. Gallo[2], N. Bina[1], C. Stornello[1], P.G. Arcidiacono[1], G. Capurso[1]

Contact E-Mail Address: matteo.tacelli@gmail.com

Introduction: Gastro-entero-pancreatic neuroendocrine neoplasms (GEP-NEN) are heterogeneous tumors, with multiple therapeutic options for advanced stages. The combination of capecitabine and temozolomide (CAPTEM) is increasingly used for advanced GEP-NEN, but evidence on results is sparse.

Aims & Methods: We conducted a systematic review and meta-analysis to assess efficacy and safety of CAPTEM in advanced GEP-NEN. We included studies enrolling patients with any grade GEP-NENs undergoing CAPTEM. A meta-analysis with random effects model, progression-free survival (PFS) as primary endpoint and severe adverse events (SAEs) rate as secondary endpoint was performed. Different treatment schedules were considered. The heterogeneity (I^2) was interpreted by metaregression analysis considering the following covariates: study type and design, sample size, metastatic disease rate, rate of primary pancreatic NENs, previous treatments, and study quality.

Results: A total of 22 studies with 788 patients (age range 29-64 years; male proportion range 46.9-65%, primary pancreatic site range 14-100%) were included. All but 1 study, being a RCT, were retrospective. The median CAPTEM cycles number was 6.9 (IQR 4.5-8). The cumulative PFS was 14.7 months (12.9-16.5), with high heterogeneity (I^2=99%). Study type and design, previous treatments, and quality of the studies did not affect PFS. Although not significant, PFS was higher in patients with nonpancreatic primary tumors and in post-2017 trials. The pooled SAEs rate was 17.6% (10.1-25). There was no publication bias.

Conclusion: CAPTEM is an effective combination, with similar PFS and a safety profile compared to other agents. Further investigation in RCTs or in sequence studies is advisable.

Disclosure: Nothing to disclose.

[1]Università degli Studi di Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy, [2]Azienda Ospedale-Università di Padova, Radiology, Padova, Italy

Contact E-Mail Address: acmilanetto@unipd.it

Introduction: Pancreatic Neuroendocrine Neoplasms (pNEN) often have a good prognosis in terms of survival. We evaluated health-related quality of life (HRQoL) after a pancreatic resection in open surgery for a pNEN.

Aims & Methods: 104 patients who underwent a pancreatic resection for a pNEN between May 1990 and April 2022 in our Center were enrolled. Clinical data (i.e. surgery, histology, comorbidity, and pancreatic function) were retrieved from clinical charts, while the QoL data were collected prospectively. The EORTC QoL questionnaires QLQ-C30, QLQ-GI.NET21 and QLQ-PAN26 were filled by the patients from September 2021 to December 2022 (at least six months after surgery).

Results were analyzed as suggested by the EORTC Group: in a scale from 0 to 100 (in percentage values), higher scores represent a better outcome in case of functional scales and a worse outcome for symptomatic scales. The results of each questionnaire, divided into common domains, were considered together as a final raw score. Six major clinical domains were selected as outcome variables: global QoL, physical function (PF2), social function (SF), disease related worries (DRW), pain and upper-GI symptoms. These domains were evaluated in relation to seven clinical variables: gender (male, female), age (<65 yrs, ≥65 yrs), comorbidities (no, single, multiple), type of pNEN (functioning, nonfunctioning), histological grade (1, 2), type of surgical resection (limited, standard), and pancreatic function (normal, diabetes mellitus, exocrine insufficiency). Wilcoxon and Kruskal-Wallis test were used for data analysis.

Results: There were 41 M/63 F, mean age 63 yrs (SD 13.5 yrs). 63.5% were affected by multiple comorbidities. 57% were non-functioning and 70% were G1 tumors. 54% underwent standard resection, 83% maintained a normal (or not impaired) pancreatic function after surgery. Data show good global HRQoL results (median 83.3%; IQR 58.3-100%). Regarding DRW, a good outcome with low concerns about their health status (median 26.7; IQR 13.3-33.3), while their physical (median 94.4; IQR 77.8-100) and social (median 88.9; IQR 77.8-94.4) functions were modestly affected. Pain (median 9.5; IQR 0-19.1) and upper GI symptoms (median 3.9; IQR 0-9.1) were rarely reported. We observed statistically significant results for QoL (worse in women, p=0.04, and in elderly, p<0.001), PF2 (worse in women, p<0.001, and in elderly, p<0.001), pain (worse in women, p=0.02, and in elderly, p=0.002); upper-GI symptoms were worse in elderly (p=0.016), and standard surgery affected both SF and DRW (p=0.03 and p=0.04, respectively).

Conclusion: In patients who underwent a pNEN resection, gender, age and type of surgery seem to slightly affect HRQoL; however, a good HRQoL was generally reported.

EVALUATION OF TRANS-PANCREATIC SPHINCTEROTOMY COMPARED WITH DOUBLE GUIDEWIRE AND PRE-CUT TECHNIQUES DURING ERCP FAILURES: A SINGLE-CENTER RETROSPECTIVE STUDY OF EFFICACY AND SAFETY

T.-T. Longin[1], J. Winkler[1], M. Barraud-Blanc[1], L. Heyries[1], P. Grandval[1]
[1]Aix-Marseille University, Gastroenterology and Endoscopy, Marseille, France

Contact E-Mail Address: philippe.grandval@ap-hm.fr

Introduction: ERCP fails for anatomical, surgical or neoplastic reasons. Apart from these situations, the risk of failed cannulation is 10%. Double guidewire (DGW) or precut papillotomy (PC) techniques are necessary and allow ERCP to be continued. However, these techniques are associated with higher complication rates and require expertise. Transpancreatic sphincterotomy (TPS) was described in 1999 but rarely used until 2018 in our center. Recent articles suggest superiority of this technique. Our team decided to introduce it as a first-line procedure when the pancreatic duct was cannulated twice instead of the common bile duct.

The aim of the study was to compare two successive periods without and with trans-pancreatic sphincterotomy in ERPC failures.

Aims & Methods: A single-center retrospective study was conducted in our endoscopy center. The procedures were performed by three experienced operators. All successive patients referred for biliary ERCP were reviewed and a selection of difficult ERCPs was made, according to ESGE criteria. Two inclusion periods were defined. In the first, between 2014 and 2018, PC and DGW were used for difficult cannulation. In the second period, between 2018 and 2021, TPS was preferred and other techniques were used only when necessary. The primary endpoint was the success rate of biliary cannulation. Post-RCP complications were also analyzed.

Results: One hundred patients were included (50% male, mean age 69.7 years). PC, DGW, and TPS were used in 28, 37, and 35 patients. The overall success rate for biliary cannulation was 77%. The specific rates for PC, DGW and TPS were 78%, 70% and 83% with no statistical difference (p=0.34). The overall complication rate was 16% (PC 14%, DGW 19%, TPS 14%) with no difference. Post-ERCP pancreatitis occurred in 8% (moderate pancreatitis) with no difference between groups. When the first technique failed (22/100), a second technique allowed 100% success with 5% complications.

Conclusion: Transpancreatic sphincterotomy in an expert center, allows 83% success in case of biliary cannulation failure, without significant difference with PC and DGW techniques. These techniques, in our study, have identical adverse event rates. Regarding the ease of use of TPS, this technique easily followed by prophylactic pancreatic stenting, should be preferred when the pancreatic duct is cannulated instead of the bile duct.

SAME-SESSION ENDOSCOPIC DIAGNOSIS AND SYMPTOMS' PALLIATION IN PANCREATOBILIARY MALIGNANCIES: CLINICAL IMPACT OF RAPID-ON-SITE EVALUATION

G. Vanella[1], G. Dell'Anna[1], A. Cosenza[1], R. Leone[1], M.C. Petrone[1], A. Mariani[1], L. Archibugi[1], G. Rossi[1], M. Tacelli[1], P. Zaccari[1], C. Doglioni[2], G. Capurso[1], P.G. Arcidiacono[1]
[1]IRCCS San Raffaele Institute, Pancreatobiliary Endoscopy and Endosonography Division, Milan, Italy, [2]IRCCS San Raffaele Institute, Pathology Unit, Milan, Italy

Contact E-Mail Address: g.e.vanella@gmail.com

Introduction: Besides increasing adequacy, Rapid-on-Site Evaluation (ROSE) during Endoscopic Ultrasound (EUS) or Endoscopic Retrograde Cholangiopancreatography (ERCP) may have an impact on choices and timing of subsequent therapeutic procedures, yet unexplored.

Aims & Methods: We conducted a retrospective evaluation of a prospectively maintained database of a tertiary, academic centre with availability of ROSE and hybrid EUS-ERCP suites.

All consecutive patients referred for pathological confirmation of suspected malignancy and Jaundice or Gastric Outlet Obstruction (GOO) between Jan-2020 and Sep-2022 were included.

Results: Of 541 patients with underlying malignancy, 323 (59.7%) required same-session pathological confirmation (male: 54.5%; age 70 [62-77]; pancreatic cancer: 76.8%, cholangiocarcinoma 16.4%). ROSE adequacy was 98.9% for EUS and 50% for ERCP-guided sampling.

Amongst 302 patients with Jaundice, ERCP cannulation was successful in 83.7%, but final drainage was completed in 97.4% thanks to 37 EUS-CholedochoDuodenostomies and 5 EUS-HepaticoGastrostomies. Amongst 21 patients requiring GOO palliation, EUS-GastroEnterostomy was performed in 15 and duodenal stenting in 6. All 53 therapeutic EUS procedures occurred after adequate ROSE.

Amongst ERCP-guided placement of stents, the use of plastic stents was significantly higher amongst patients with inadequate ROSE (10/11 [90.9%] versus 14/240 [5.8%], p<0.0001, OR=161 [19-1352]).

Median hospital stay for diagnosis and palliation was 3 [2-7] days and median time to chemotherapy was 33 [24-47] days.

Conclusion: Nearly two-thirds of oncological candidates to endoscopic symptoms palliation requires contemporary pathological diagnosis. An adequate ROSE allows same-session state-of-the-art therapeutics standardly restricted to pathologically confirmed malignancies (e.g. uncovered SEMS or therapeutic EUS), potentially leading to shorter hospital stay and time to chemotherapy.

MANAGEMENT OF MALIGNANT GASTRIC OUTLET OBSTRUCTION DUE TO PANCREATIC CANCER IN THE ERA OF EUS-GASTROENTEROSTOMY: AN INTERNATIONAL PRACTICE SURVEY AND CASE VIGNETTE STUDY

C. De Ponthaud[1], B. Bozkırlı[2], G. Capurso[3], S. Gaujoux[1], G.E.M. Rizzo[4], S. Robinson[5], F. Vilas Boas Silva[6], G. Vanella[3]
[1]Hôpital la pitié salpêtrière, APHP, Department of HPB and Endocrine Surgery, Paris, France, [2]Acibadem Maslak Hospital, Department of General Surgery, Intabul, Italy, [3]IRCCS San Raffaele Institute, Pancreatobiliary Endoscopy and Endosonography Division, Milan, Italy, [4]ISMETT - University of Palermo, Gastroenterology, Palermo, Italy, [5]Freeman Hospital, Newcastle upon Tyne, United Kingdom, [6]São João University Hospital, Department of Gastroenterology, Porto, Portugal

Contact E-Mail Address: g.e.vanella@gmail.com

Introduction: Malignant Gastric Outlet Obstruction (mGOO) has been standardly treated by surgical GastroEnterostomy (S-GE) or Endoscopic Stenting (ES). More recently, EUS GastroEnterostomy (EUS-GE) has emerged as a low-invasive alternative with surgical-range efficacy, supported by guidelines. Nevertheless, its worldwide diffusion is heterogeneous and advantages/disadvantages debated.

The aim of this survey is to assess clinical decision-making of international specialists regarding mGOO and to explore current opinion regarding EUS-GE use.

Aims & Methods: An online survey was created exploring centers' experiences and physicians' opinions regarding indications, contraindications, benefits and risks of available treatments; 2 case vignettes explored clinical decision-making in different scenarios. The survey was spread through social networks and the EPC newsletter.

Results: Overall, 290 pancreatologists from 44 countries (5 continents) responded, of whom 35% surgeons and 65% gastroenterologists, 44% from centers managing > 20 mGOO/year. The most frequently available treatment for mGOO was ES (91%), followed by S-GE, while EUS-GE was only available to 59% of responders, and only 10% declared proficiency in this technique.

68% referred an established gold-standard in their centers, but this differed by specialty, with ES, EUS-GE and S-GE being advised by 45%, 20% and 10% of gastroenterologists and 24%, 8% and 25% of surgeons.

For 51% of responders, EUS-GE will become the primary treatment for mGOO. This percentage increases among gastroenterologists and high-volume centers. For 14%, EUS-GE spread will be limited in the future, or used only when ES fails (19%), with higher rates among surgeons.

When choosing between alternatives, the main decision driver is life expectancy, followed by disease stage and patient's frailty, whereas potential future surgical resectability does not contraindicate any treatment for 3/4 of responders. The main perceived advantages of EUS-GE were minimally invasiveness and high clinical efficacy, while the learning curve remains its main disadvantage.

Conclusion: This survey revealed significant differences in the management of mGOO, depending on specialties, local expertise and treatment volume, suggesting the lack of standardized algorithms.

Despite great enthusiasm around EUS-GE, its availability remains suboptimal, with learning curve as the main barrier. Life expectancy and patients' frailty are likely to remain the main decision factors.

Disclosure: Nothing to disclose.

Contact E-Mail Address: fatemehhassani2001@gmail.com

Introduction: There were conflicting results on the association between Vater ampulla type, success rate, and incidence of pancreatitis after Endoscopic Retrograde Cholangiopancreatography (ERCP). The objective of this investigation was to examine the frequency of pancreatitis characterized by ampulla of Vater type in patients undergoing endoscopic retrograde cholangiopancreatography (ERCP), as well as to assess the rate of success in treating such cases.

Aims & Methods: Between January 2021 to December 2022, a total of 517 ERCP-associated procedures were conducted in Sayyad Shirazi Hospital, Gorgan, Iran. Prior to the procedure as well as at 6-, and 24-hours post-procedure, levels of serum amylase were assessed.

Furthermore, the patient underwent an assessment to detect any indications of pancreatitis. Of all 517 individuals underwent ERCP, 69 patients were excluded due to a history of endoscopic sphincterotomy or papillary balloon dilatation in the past or who exhibited hyperamylasemia. Written informed consent was obtained from all included patients.

Results: A total of 448 patients with a mean (SD) age of 59.90 (16.03), and 57.1% being female met the inclusion criteria of the study (Table 1). The incidence of pancreatitis after ERCP in type 1, type 2, and type 3b Vater ampulla was 2.6% (5/191), 3.6% (1/28), and 12.5% (1/8), respectively. Post-ERCP pancreatitis was not observed in type 3a, type 4, and type D Vater ampulla. There was no statistically significant relationship between the type of Vater ampullar and the occurrence of post-ERCP pancreatitis (P-value= 0.259).

Moreover, the success rate of the procedure in type 1, type 2, type 3a, type 3b, type 4, and type D Vater ampulla was 90.1, 69.0%, 79.7%, 55.6%, 90.9%, and 88.9%, respectively (P-value < 0.005).The result of the final diagnosis based on the Vater Ampulla type is shown in Table 2.

Conclusion: There was a significant relationship between Vater ampulla type and ERCP success rate, while the Vater ampulla type was not associated with the incidence of post-ERCP pancreatitis.

Disclosure: Nothing to disclose.

Introduction: Ampullary lesions (AL) of the minor duodenal papilla are extremely rare. Endoscopic papillectomy (EP) is a routinely used treatment for AL of the major duodenal papilla but the role of EP for minor AL has not been elucidated yet.

Aims & Methods: We identified 20 patients with AL of minor duodenal papilla out of the multicentric database from the ESAP study that included 1422 EPs (prevalence of minor papillary lesions: 1.4%). We evaluated the procedural outcomes and safety of EP for minor AL.

Results: All patients with an AL of the minor duodenal papilla received an EP. The most common histological subtype was an ampullary adenoma in 12 Patients (3 low-grade dysplasia and 9 high-grad dysplasia). Five patients revealed non-neoplastic lesions. Invasive cancer (T1a), adenomyoma and neuroendocrine neoplasia each were found in one case. The rate of complete resection (R0) was 90%. There were no severe complications. After EP one patient had a bleeding that required an intervention and two patients had a recurrence that was detected in follow-up endoscopy. After EP the median follow up was 27.7 months (0-70).

Conclusion: EP is safe and effective in AL of the minor duodenal papilla. The management of these lesion seems to be similar to AL of the major duodenal papilla.

Disclosure: Nothing to disclose.

Introduction: In the context of pancreatic ductal adenocarcinoma (PDAC) ≤ 10 mm in diameter, the diagnostic performance of endoscopic ultrasound-guided fine needle aspiration/biopsy (EUS-FNAB) is relatively low. Pancreatic juice cytology (PJC) has recently gained attention because of its high sensitivity for small PDAC. However, the appropriateness of EUS-FNAB/PJC for small PDAC is still controversial.

Aims & Methods: This study aimed to clarify the true diagnostic ability of EUS-FNAB and the salvage ability of PJC in PDAC ≤ 10 mm. A retrospective analysis was conducted on 271 patients with pancreatic tumors ≤ 10 mm confirmed by EUS, who were undergoing attempted EUS-FNAB. For accurate evaluation of the ability of EUS-FNAB to distinguish PDAC, pancreatic metastasis/malignant lymphoma were excluded. The technical success of EUS-FNAB was defined as the possibility of needle puncture and the ability to obtain adequate specimens for cytological/histological assessment. The diagnostic ability of EUS-FNAB was analyzed using technical success cases. A positive cytological diagnosis was defined as cells with highly suspected adenocarcinoma/definite adenocarcinoma based on the Bethesda system in both EUS-FNAB and PJC examinations. EUS-FNAB histological diagnosis was considered negative if only atypical cells existed. The diagnoses made with EUS-FNAB were determined based on cytology and/or histological findings.

After eliminating technical failure or negative results by EUS-FNAB, patients with a strong likelihood of having PDAC from imaging characteristics underwent salvage PJC. The primary endpoint was clarifying the technical success rate/diagnostic ability of EUS-FNAB for PDAC ≤ 10 mm. In addition, the salvage ability of PJC for false-negative/technical failure EUS-FNAB cases was also examined.

Results: EUS-FNAB procedures were attempted for 271 patients with pancreatic tumors ≤ 10 mm. Overall, 80.8% of patients with pancreatic tumors (median lesion size of 8 mm [range, 3–10 mm]) achieved technical success. The reasons for technical failure were the inability to puncture due to anatomical inaccessibility (3.3%), unclear visibility for a puncture (5.2%), and inadequate specimen retrieval for cyto-histological analysis (10.7%). Actual diagnostic ability of EUS-FNAB in the diagnosis of PDAC ≤ 10 mm. In patients who achieved EUS-FNAB technical success, PDAC ≤ 10 mm was detected in 28.3% (62/219) of the patients with surgical resection/clinical follow-up.

The sensitivity, specificity, and accuracy of comprehensive EUS-FNAB was 82.3%, 94.9%, and 91.3%, respectively. In the diagnostic ability comparison using AUC, comprehensive EUS-FNAB had naturally higher diagnostic ability than EUS-FNAB cytology alone/EUS-FNAB histology alone ($P = 0.002$, $P < 0.001$, respectively).

In addition, EUS-FNAB cytology had higher diagnostic capability than EUS-FNAB histology alone (P = 0.034). Thirty-five patients were diagnosed with PDAC ≤ 10 mm from among the 212 patients who encountered technical failure/negative diagnosis by EUS-FNAB. Among these patients with PDAC ≤ 10 mm, 74.3% were additionally diagnosed by salvage PJC accurately (PJC positive and final diagnosis of PDAC ≤ 10 mm). The overall accuracy of PJC was 81.6% in this study. The other nine patients with PDAC ≤ 10 mm, who had not been accurately diagnosed by EUS-FNAB/PJC, were finally diagnosed by surgical resection/clinical follow-up based on their imaging findings.

Conclusion: The true technical success rate/sensitivity of EUS-FNAB for PDAC ≤ 10 mm was relatively low. EUS-FNAB followed by PJC may be ideal for diagnosing PDACs ≤ 10 mm in diameter.

Introduction: The retroperitoneal location of the pancreas represents a challenge for the early identification of chronic pancreatitis (CP) and pancreas neoplasms (PN). Imaging and endoscopic ultrasound (EUS) with elastography are helpful resources with variable accuracy. EUS-guided shear wave elastography (EUS-SW) measures tissue elasticity by shear waves inside the organ through acoustic radiation force impulse. Its accuracy has not been assessed for CP and solid PN.

Aims & Methods: We aim to estimate the diagnostic accuracy of EUS-SW for CP and solid PN. Cases with a recently confirmed diagnosis of CP or PN who underwent EUS-SW (12/2020-11/2022) were included. Cases that required EUS for subepithelial lesion assessment comprised a third study group (controls, CG). Age, gender, body mass index (BMI), diabetes, fatty liver disease, alcohol, and tobacco consumption were recorded. An expert endoscopist (RVZ) performed EUS, assessed fatty pancreas score, strain ratio (SR), histogram (SH), and ten measurements of EUS-SW elasticity (SWE) and dispersion (SWD) per case. SWE and SWD variation were based on quotient among interquartile range (IQR) and median.

In cases with <30% variation, the association of SWE and SWD was estimated with study groups, baseline and EUS data through multivariate ANOVA regression. SWE and SWD cut-off values were calculated with Youden's index. Data was analysed in R v4.0.

Results: 88 cases were enrolled (37 CG, 14 CP, 37 PN), median age of 62.5 (IQR 53-70), 47.7% female. The proportion of fatty pancreas score II and III was similar in CG (37.8% and 56.8%) and CP (57.1% and 42.9%); there was a significant difference in PN, with a score II, III, and IV of 24.3%, 40.5%, and 29.7%, respectively (p<.001). Median SR was also similar among CG (3.6; IQR 2.9 - 4.3) and CP (3.9; IQR 3.6 - 4.7) but significantly different compared with PN (7.6; IQR 5.3 - 11.1; p<.001). Median SWE and SWD were 10.5 kPa (7.3 - 16.6) and 1.9 [m/s]/kHz (1.6 - 2.4), with a <30% variation in 27 (30.7%) and 57 (64.8%), respectively (Table 1).

Study groups (CG/CP/PN) and diabetes were associated to a higher SWE and SWD (p<.05). Predicted SWE were significantly different among PN vs CG (-13.1; -24.4 to -1.7; p=.0242) (figure 1). An SWE ≥17.4 diagnosed PN with a sensitivity, specificity, positive and negative predictive values of 75% (19-99), 91% (72-99), 60% (27-99) and 95% (63-99); while an SWD ≥2.31 predicted PN with a diagnostic accuracy of 54% (25-81), 70% (55-83), 35% (21-66), 84% (60-91), respectively.

Conclusion: EUS-SW constitutes an objectively valuable measuring tool for CP and PN diagnostic workups. Larger multicentric diagnostic trials are needed to confirm these findings. NCT05095831.

COMPARISON OF FORK-TIP AND FRANSEEN NEEDLES FOR ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE BIOPSY

A. Fujita[1], M. Mizuide[1], Y. Tanisaka[1], T. Shin[1], K. Sugimoto[1], R. Jinushi[1], S. Ryozawa[1]

Introduction: There is no unanimity regarding the most appropriate needle to use for endoscopic ultrasound-guided fine needle biopsy (EUS-FNB). To date, new types of FNB needles have been designed, including the Fork-tip and Franseen needles. The Fork-tip is characterized by two sharp tips on opposite sides of the lumen, and the Franseen needles are characterized by three symmetric cutting tips. This study primarily aimed to compare the diagnostic utility and histological quality between the use of the Fork-tip and Franseen neesles in EUS-FNB for solid pancreatic lesions.

Aims & Methods: We retrospectively analyzed 187 patients at our center for solid pancreatic lesions, 75 of whom underwent EUS-FNB using a 22 G Franseen needle and 112 using a 22 G Fork-tip needle, from December 2019 to October 2022.

Results: After propensity-matched analysis, each group was adjusted to 66 cases. The results revealed that sex, age, route for puncture, and tumor size, site, and tumor type were not different between the Franseen and Fork-tip groups. Both groups were not significantly different in terms of number of punctures, procedure time, core tissue score, blood score, and technical success rate. From the histological findings, the most common final diagnosis was adenocarcinoma (107 patients), which was followed

by a benign lesion (19 patients), and finally, the NET (6 patients). In this study, no adverse events during the procedure were encountered. The diagnostic accuracy of the Fork-tip group (92.4%; 61/66) was similar to that of the Franseen group (90.9%; 60/66) (P >0.99). The outcomes of the two groups were similar for the distinction between benign and malignant lesions.

The rate of changes of operators from a trainee was significantly less in the Fork-tip group (9.1%, 6/66) than in the Franseen group (24.2%, 16/66) (P = 0.03). The reasons for operator changes were as follows: In the Franseen group, there were ten cases of difficulty in adjusting the puncture route from the second part of the duodenum, six cases of difficulty in penetrating the gastric wall from the stomach.

In contrast, in the Fork-tip group, there were two cases of difficulty in adjusting the puncture route from the second part of the duodenum, two cases of difficulty in penetrating the gastric wall from the stomach, two cases of difficulty in avoiding vessels. All cases were successfully punctured after an expert took over.

	Propensity-matched patients		
	Franseen group	Fork-tip group	*P*
Number of punctures, median (IQR)	2 (2–2)	2 (2–2)	0.85
Change from trainee to expert	16/66 (24.2%)	6/66 (9.1%)	0.03
Diagnostic accuracy, n (%)	60/66 (90.9%)	61/66 (92.4%)	>0.99
Sensitivity	89.3% (50/56)	91.2% (52/57)	0.76
Specificity	100% (10/10)	100% (9/9)	
Positive predictive value	100% (50/50)	100% (52/52)	
Negative predictive value	62.5% (10/16)	64.3% (9/14)	

Table 1. Comparison of procedure outcome and histological material between Franseen and Fork-tip groups

Conclusion: Although in both groups, the diagnostic accuracy and other outcomes of procedures conducted, were not significantly different, the rate of changes of operator from a trainee to an expert was significantly less in the Fork-tip group than in the Franseen group. Thus, the Fork-tip needle was observed as good choice for trainees and the appropriate needle must be selected according to the situation.

EUS-GUIDED FINE-NEEDLE BIOPSY VERSUS FINE-NEEDLE ASPIRATION WITH WET SUCTION IN THE DIAGNOSIS OF SOLID LESIONS

R. Ortigão[1], J. Chaves[2], M. Dinis-Ribeiro[3], D. Libânio[4], R.P. Bastos[5]
[1]Institute Portuguese of Oncology, Gastrenterology, Porto, Portugal, [2]IPO Porto, Porto, Portugal, [3]IPO Porto, Dept. of Gastroenterology, Porto, Portugal, [4]Instituto Português de Oncologia do Porto, Gastroenterology Department, Porto, Portugal, [5]Gastrenterologia, Dr., Porto, Portugal

Contact E-Mail Address: raquel.ortigao@hotmail.com

Introduction: Endoscopic ultrasound (EUS) guided fine-needle biopsy (FNB) seems to have a greater diagnostic capacity when compared with needle aspiration biopsy (FNA), but whether it has advantages over FNA using wet suction (WS) is uncertain.

Our aim was to compare FNA-WS technique wit FNB-WS in solid lesions and to identify predictors associated with inadequate samples.

Aims & Methods: Retrospective study including all patients with solid lesions submitted to EUS-FNA or EUS-FNB between 01/2020 and 12/2022.

Results: A total of 227 patients were included (271 biopsies – 131 FNA-WS and 140 FNB-WS). 132 (49%) lesions corresponded to adjacent organ lesions (pancreas, liver and adrenal gland), 70 (26%) to subepithelial lesions (SLE) of the digestive tract and 69 (26%) to adenopathies. The mean number of needle passes was similar between FNA and FNB (2.66 vs 2.73, p=0.637).

Diagnostic samples were adequate in 236 procedures (87% - 89% in FNA vs 86% in FNB, p=0.487). Younger age, 25G (vs 22G) needle and non-malignant lesions were associated with inadequate sampling (p<0.05), with diagnosis of non-malignant lesion (p<0.001) and younger age (p<0.041) identified as independent risk factors for inadequate sampling. Lesion size, needle type (FNA vs FNB), number of needle passes and lesion type (organ lesion vs adenopathies vs LSE) had no influence.

EUS-guided FNA and FNB (22G) were adequate in 93% and 86% respectively (p=0.063). For adenopathies FNA-WS was superior (93% vs 84%, p=0.026), while in pancreatic lesions and SLE, the diagnostic capacity of FNA and FNB was similar (91% vs 84% p=0.273 and 86% vs 88% p=0.771).

Conclusion: With the use of the WS technique there were no differences in the diagnostic capacity of the biopsy with FNA and FNB.

Disclosure: Nothing to disclose.

INTRATUMORAL VASCULAR ENHANCEMENT PATTERN AND DOPPLER IMAGE ON CEH-EUS IN PREDICTION OF CHEMOTHERAPY RESPONSE OF ADVANCED PANCREATIC CANCER PATIENTS

J.K. Park[1], H. Chung[1], J.K. Lee[2], J. Park[2], K.-H. Lee[2], K.-T. Lee[2]
[1]Hallym University Kangnam Sacred Heart Hospital, Medicine, Seoul, South Korea, [2]Samsung Medical Center, Gastroenterology, Seoul, South Korea

Contact E-Mail Address: hanyangjj@gmail.com

Introduction: Contrast-enhanced harmonic endoscopic ultrasonography (CEH-EUS) has been a widely used imaging modality to characterize, differentiate, and stage pancreatic cancer. A previous study reported that avascular areas on contrast-enhanced ultrasonography (CE-US) are associated with fibrosis and necrosis within pancreatic cancer.

In this study, we examined the usefulness of CEH-EUS for evaluating therapeutic responses in PC by analyzing the relation between intra-tumoral vascular enhancement and Doppler image on the CE-EUS and the response of chemotherapy in advanced pancreatic cancer.

Aims & Methods: This is the retrospective study of Samsung Medical Center and Hallym University Kangnam Sacred Heart Hospital in Seoul, South Korea from Mar. 2015 to DEC. 2023. A total of 150 patients with unresectable advanced pancreatic cancer underwent CE-EUS. Patients were treated with gemcitabine-based chemotherapy. Three months after the completion of chemotherapy, the responsiveness of chemotherapy was assessed by Computed Tomography.

The aim of this study is to evaluate therapeutic responses in PC by analyzing the relation between intra-tumoral vascular enhancement and Doppler image on the CE-EUS and the response of chemotherapy in advanced pancreatic cancer.

Results: CEH-EUS showed an enhanced (with vascular) group in 73 patients, and a non-enhanced group in 77 patients. The response of the 3 months of chemotherapy was associated with the contrast enhancement of the EUS (p < 0.05). The response rate of the enhanced group (84.7%) was higher than the non-enhanced group (69.2%) in pancreatic cancer chemotherapy.

Conclusion: The current results demonstrate that CEH-EUS may be useful in assess the prognosis of patients with unresectable advanced pancreatic cancer who receive systemic che- motherapy.

Evaluation of intratumoral collateral vessel flow by doppler image could be useful for predicting chemotherapy response in patients with pancreatic cancer. Thus, CEH-EUS combined with doppler image may be useful

for evaluating therapeutic responses in pancreatic cancer. Further clinical study should be performed to target larger number of patients.
Disclosure: Nothing to disclose.

COULD FROZEN SECTION EVALUATION INCREASE PREDICTIVE DIAGNOSTIC YIELD OF ENDOSCOPIC ULTRASONOGRAPHY GUIDED FINE NEEDLE BIOPSY (EUS FNB) FOR PANCREATIC SOLID LESION?

H.Y. Shih[1], Y.H. Chen[2], C.C. Wu[3], L.T. Chen[2], K.C. Chang[4]
[1]Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung Medical University/Taiwan Contrast Enhanced Endoscopic Ultrasound Study Group(T-CESG), Gastroenterology, Kaohsiung, Taiwan, [2]Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung Medical University, Gastroenterology, Kaohsiung, Taiwan, [3]Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung Medical University, Pathology, Kaohsiung, Taiwan, [4]National Cheng Kung University Hospital, Pathology, Tainan, Taiwan

Contact E-Mail Address: vulgaristw@gmail.com
Introduction: The prediction of positive results of endoscopic ultrasonography guided tissue acquisition (EUS TA), including EUS fine needle aspiration(EUS FNA) and EUS fine needle biopsy (EUS FNB), has changed from rapid on-site evaluation(ROSE) to macroscopic on-site evaluation (MOSE). The average predictive positive rate is about eighties percent under MOSE. The intraoperative frozen section evaluation has been widely used by the surgeons. We conducted the study to evaluate if there is any benefit of intraoperative frozen section evaluation for increasing the predictive diagnostic yield of EUS FNB.
Aims & Methods: Aims: We compared the yield rate of EUS FNB for pancreatic solid lesions between MOSE and intraoperative frozen section evaluation and MOSE only.
Methods: The study was conducted at a single tertiary referral center from Aug. 2021 to Mar. 2023.
The patients who were indicated for EUS FNB were enrolled into the study. During EUS FNB we sent the specimens from the first two passes for the frozen section after we considered adequate macroscopic visible tissue core. Later we would obtain other specimens from later passes for the permanent section (MOSE + Frozen group (MF group)). As for the control group we sent the specimens for the permanent section only (MOSE only group (M group)).
We compared the histological results of frozen and permanent sections and divided them into three subgroups as the frozen section being equal, inferior and superior to the permanent one.
The p-value <0.05 was defined as statistically significant.
Results: Total one hundred ninety four patients were enrolled into the study and ninety seven patients were divided into each group equally. Demographic characters were as the followings with MOSE with frozen group versus MOSE only one:
age 62+-14 vs 63+-12 years old
gender male to female 1.6: 1 vs 1.6 : 1
diagnosis of pancreatic solid lesion adenocarcinoma : neuroendocrine tumor : chronic pancreatitis 71:5:2 vs 41:5:12
average size of lesion 37.2+-16 vs 34.3+-13 mm
location of lesion uncinate process: head: neck: body: tail 4:32:5:20:11 vs 5:22:0:16:13
the most common location of lesion was head of pancreas on both groups
As for the results of EUS FNB, the pass for permanent section was 5.5 versus 5.8 (MF group vs M group, p=0.018) and the transgastric puncture route was 51 versus 53 patients and transduodenal route was 46 vs 44 patients (MF group vs M group).
About the yield rate the MF group was 92.8% and the M group was 79.4% (p=0.006).
When comparing the histological results of frozen and permanent sections the frozen section was equal, inferior and superior to the permanent one as 63 (65%), 33 (34%) and 1 (1%) patient(s)(Table).

	MOSE + Frozen (n= 97)	MOSE only (n=97)	p value
EUS FNB			
pass for permanent section	5.5	5.8	
puncture route (%)			
transgastric	51 (53)	53 (55)	0.018
transduodenal	46 (47)	44 (45)	
Yield rate (%)	92.8	79.4	0.006
frozen vs permanent section (%)			
equal	63 (65)		
inferior	33 (34)		
superior	1 (1)		

Table.

Conclusion: When performing EUS FNB for pancreatic solid lesions, it seems to increase the predictive yield rate if we combine MOSE and intraoperative frozen section evaluation. There are some pitfalls about combined MOSE and intraoperative frozen section evaluation, such as prolonged procedure time and increased medical expenses due to frozen section evaluation.

NOVEL CATHETER DEDICATED FOR ENDOSCOPIC TRANSMURAL NECROSECTOMY OF PANCREATIC WALLED-OFF NECROSIS: EXPERIENCES FROM A TERTIARY REFERRAL CENTER

G.A. Olsen[1], S. Novovic[1,2], E. Feldager[1], P.N. Schmidt[1], J.G. Karstensen[1,2]
[1]Copenhagen University Hospital Hvidovre, Pancreatitis Centre East, Gastro Unit, Hvidovre, Denmark, [2]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Contact E-Mail Address: gitte.aabye.olsen@regionh.dk
Introduction: The need for endoscopic necrosectomy (EN) has increased dramatically, as endoscopic EUS-guided drainage has become gold standard for treatment of pancreatic walled-off-necrosis (WON)[1,2].
Although snares and baskets are commonly used in EN procedures, they can be ineffective and dedicated instruments specifically designed for EN are scarce. Recently, an innovative powered endoscopic debridement system (EndoRotor, Interscope Inc., Northbridge, MA, USA) designed to excise and remove necrotic tissue within the WON was introduced specifically for EN with promising results[3,4].
While the first generation EndoRotor catheter was limited to 3.2 mm diameter, a larger catheter that fits into a large-channel gastroscope with a working channel of 6.0 mm has now been introduced. This study evaluates the clinical outcomes, safety, and feasibility of the novel 6.0 catheter for EN of WON.
Aims & Methods: This retrospective study was performed using prospectively collected data from all patients who underwent EN with the 6.0 catheter between December 2021 and March 2023 at Gastro Unit, Copenhagen

University Hospital Hvidovre, a tertiary referral center in Denmark. All patients with symptomatic WON and need for necrosectomy were considered eligible for this study. Technical feasibility, safety, and clinical outcomes were evaluated.

Results: Sixteen patients underwent a total of 25 EN procedures with the 6.0 catheter. The mean age of the patients was 51.8 years (SD 17.7 years) and 11 (68.8%) were male. The etiology of the acute necrotizing pancreatitis was alcohol in 4 patients (25.0%), gall stones in 7 patients (43.8%), post-endoscopic retrograde cholangiopancreatography (ERCP) in 3 patients (18.8%), and idiopathic in 2 patients (12.5%). The mean size of the WON was 27.5 cm (SD 10.5 cm). The median computed tomography severity index (CTSI) was 8.5 (P25-P75: 6.0-9.0) and median modified CTSI (mCTSI) was 9.0 (P25-P75: 8.0-10). Two patients did not achieve clinical resolution (12.5%), as they died from multisystem organ failure before resolution of the WON was achieved. The median length of stay in hospital for the patients who achieved clinical resolution was 56.0 days (P25-P75: 36.5-96.0 days) and the median number of necrosectomy procedures performed to achieve clinical resolution was 5.0 (P25-P75: 2.0-8.5). All patients had EN procedures performed with snares in addition to the procedures with the powered debridement system. Five patients had necrosectomy performed with the 3.2 catheter (31.0%) as well as the 6.0 catheter. The median duration of EN with the 6.0 catheter was 60.0 minutes (P25-P75: 45.0-100 minutes) per procedure.

A device-related adverse event was noted in one instance (4.0%). The patient exhibited symptoms of peritoneal reaction in the hours following the procedure, which may have been caused by perforation of the WON into the peritoneal cavity. The patient was treated with laparoscopic peritoneal lavage and drainage and recovered without further interventions. No other procedure-related adverse events were identified. Malfunction of the catheter was observed in 7 procedures (28.0%).

Conclusion: To perform necrosectomy procedures optimally, dedicated endoscopic instruments designed for debridement of pancreatic WON are required. This study suggests that EN with the novel EndoRotor 6.0 catheter is safe and feasible with promising clinical results for EN of pancreatic WON. To assess the efficacy relative to standard techniques, comparative studies are warranted.

RAPID DIAGNOSIS BY A PATHOLOGIST USING HE STAINING DURING EUS-TA FOR PANCREATIC DISEASE ENABLE A RAPID AND HIGH ACCURACY, AND MAKE IT POSSIBLE TO DIAGNOSE NON-IDC AT THE STAGE OF RAPID DIAGNOSIS

S. Sugimori[1], H. Nebiki[1], T. Yamasaki[1], Y. Sakata[1]

[1]Osaka City General Hospital, Gastroenterology, Osaka, Japan

Contact E-Mail Address: ssugimori1020@gmail.com

Introduction: Rapid on-site evaluation at EUS-TA is often performed by a cytotechnologist. In our hospital, a pathologist makes a rapid diagnosis using HE staining during EUS-TA. It is unclear whether rapid diagnosis by a pathologist using HE staining is useful.

Aims & Methods: Aim: The aim of this study is to clarify the accuracy of rapid diagnosis performed by pathologists and whether non-IDC can be differentiated at the stage of rapid diagnosis. Design: A single center retrospective study. Method: Patients who underwent EUS-FNA for pancreatic disease at our hospital between 2020 and 2022 were included. When EUS-TA was performed, the slow-pull technique and standard suction technique were combined in all cases. Puncture was added when immunostaining was deemed necessary. IDCs include adenocarcinoma, adenosquamous carcinoma, mucinous carcinoma, anaplastic carcinoma, and IPMC, non-IDCs include NEN (neuroendocrine neoplasia), ACC (acinar cell carcinoma), SPN (solid-pseudopapillary neoplasm), GCT (granular cell tumor), and metastasis.

Results: Two hundred and thirty-nine patients were included, including 37 benign, 179 IDC, and 23 non-IDC cases. 25G needles were used for 178 cases (74.5%). There were 188 FNA needles and 51 FNB needles. The average number of punctures was 3.2. The accuracy for distinguishing between benign and malignancy was 96.7% for rapid diagnosis and 97.9% for final diagnosis of EUS-TA. Of the 77 surgical cases, 11 were non-IDC, and all were diagnosed as non-IDC at the rapid diagnosis stage. Discussion: At our hospital, it is extremely rare for the rapid diagnosis and the final diagnosis of EUS-TA to diverge. In the case of IDC, it is possible to hold an in-hospital conference when the results of rapid diagnosis are available and to start treatment early. Furthermore, since many cases of IDC or non-IDC can be diagnosed at the stage of rapid diagnosis,

Conclusion: Rapid diagnosis by pathologists using HE staining enabled a rapid and high accuracy rate, and made it possible to diagnose non-IDC at the stage of rapid diagnosis.

Disclosure: Nothing to disclose.

Introduction: Contrast enhanced endoscopic ultrasound (CE-EUS) has emerged as an invaluable real time tool in the characterisation and diagnosis of gastrointestinal(GI) lesions but application in therapeutic EUS (post tissue acquisition) remains under evaluated. Bleeding post EUS tissue acquisition(TA) is usually mild, self limiting though serious complications can still occur.

We aim to review if application of real time CE-EUS to assess and quantify severity of bleeding has any impact on the clinical outcome and need for intervention.

Aims & Methods: This was a retrospective study of 1597 consecutive patients who underwent tissue acquisition at a single tertiary centre between March 2018 to March 2023. Patients with new onset fluid collection/haemorrhage post tissue acquisition who underwent CE- EUS using Sonazoid contrast agent were included. Information on baseline demographics, pre/post laboratory tests, EUS procedural findings and clinical outcomes were collected. Video recordings of the CE-EUS were reviewed and graded according to the extent of perfusion with presence/absence of contrast extravasation and pseudo-aneurysm.

Severity EUS findings of the fluid/hematoma post CH-EUS injection (observed for at least 90s)

Grade 0 No perfusion noted

Grade 1 Perfusion noted < 50% of total area

Grade2 Perfusion noted > 50% of total area

Grade 3 100% perfusion of the area of concern

Results: 60/1597 (4.4%) patients had hematoma/new onset fluid collection post EUS-TA with CE-EUS performed. Overall intervention rate post EUS-TA was 5/1597 (0.31%). 29 patients were subsequently analysed based on video availability and divided into no leak(grade 0) and active leak group(grade1-3). There were no significant differences in the median age (53 vs 64, p = 0.13), Charlson Co-morbidity index (3.5 vs 3, p = 0.561) and antiplatelet usage. There were also no significant differences between lesion size (24.6 vs 31.6, p= 0.246), needle sizes and the number of passes(3 vs 2, p= 0.34). 53% (8/17) of the active leak group had final diagnosis of neuroendocrine/cystic lesions as compared to the non active leak 3/12(25%). Fisher's exact test used did not show any statistically significant association between haemoglobin drop, need for intervention and death (p=0.413) respectively with the CE-EUS results.

Conclusion: Post EUS Tissue acquisition bleeding is mostly mild and self-limiting. More studies are required to see if CE-EUS can play a objective role in predicting adverse outcomes.

Disclosure: Nothing to disclose.

Introduction: Endoscopic ultrasonography (EUS) is the most reliable and efficient diagnostic modality for pancreatobiliary disease owing to its high spatial resolution, which allows the detection of small lesions. There is difficulty in making differential diagnosis based on EUS imaging characteristics alone, however, because the majority of lesions are hypoechoic. Assessment of vascularity is another approach that can be used for differential diagnosis. Doppler imaging modalities, such as color-Doppler EUS, power Doppler EUS, and e-FLOW EUS, are used in real-time checking of vascularity. Of these methods, e-FLOW EUS is a directional power Doppler ultrasonography method that has better spatial and temporal resolutions than the others.

However, conventional EUS Doppler modes, including e-FLOW EUS, are not suited to visualization of fine vessels and slow flow. Contrast-enhanced EUS (CE-EUS) is better for detecting blood flow and does not have some of these limitations. Assessment of the utility of CE-EUS for detecting intraductal papillary mucinous neoplasms (IPMNs) and gallbladder lesions has been reported.

However, the use of contrast agents means that there are some caveats concerning its use, and recent advances in technology have led to the development of detective flow imaging EUS (DFI-EUS) to overcome the problems associated with conventional Doppler mode EUS. Few reports have examined its clinical utility because the method is so new.

Aims & Methods: We evaluate its utility for differential diagnosis of gallbladder lesions and intraductal papillary mucinous neoplasms (IPMNs). Enrolled were patients who underwent DFI-EUS, e-FLOW EUS, and contrast-enhanced EUS for gallbladder lesions or IPMNs. Detection of vessels on DFI-EUS and e-FLOW EUS was compared with that on contrast-enhanced EUS and pathological findings. The vessel pattern was also categorized as regular or irregular. Of the 33 lesions included, final diagnoses were 13 IPMNs and 20 gallbladder lesions.

Results: DFI-EUS was significantly superior to e-FLOW EUS for discriminating between mural nodules and mucous clots and between solid gallbladder lesions and sludge with presence or absence of vessel detection in lesions (P = 0.005). An irregular vessel pattern was a significant predictor of malignant gallbladder lesions (P = 0.002). DFI-EUS is more sensitive than e-FLOW-EUS for vessel detection and differential diagnosis of gallbladder lesions and IPMNs.

Conclusion: Vessel evaluation using DFI-EUS may be a useful and simple method for differentiating between mural nodules and mucous clots in IPMN, between solid gallbladder lesions and sludge, and between malignant and benign gallbladder lesions.

Disclosure: Nothing to disclose.

THE BIGGER, THE BETTER? – A PROSPECTIVE CONTROLLED TRIAL COMPARING THE DIAGNOSTIC ACCURACY OF 19G AND 22G FRANSEEN-TIP EUS-FNB NEEDLES IN SOLID PANCREATIC LESIONS

S. Klauss[1], E. Goni[1], M. Vornhülz[1], S. Sirtl[1], M. Zorniak[2], M. op den Winkel[1], C. Schulz[1], J. Schirra[1], S. Ormanns[3], J. Mayerle[1], G. Beyer[1]

Contact E-Mail Address: sarah.klauss@med.uni-muenchen.de

Introduction: Endoscopic ultrasound-guided fine-needle biopsy (EUS-FNB) is about to become the standard procedure to distinguish solid pancreatic lesions and is typically performed using a 22G needle. Although smaller needles may be more flexible for positioning, larger needle diameters might produce bigger tissue cores and thus improve histological and molecular analysis.

The aim of this single-institution, prospective, controlled study was to compare the sample adequacy and diagnostic yield of solid pancreatic lesions using the 19G and 22G Franseen-tip EUS-FNB devices (Boston Scientific Acquire™).

Aims & Methods: The study was approved by the LMU Munich IRB and registered to German Clinical Trial Registry (DRKS00021088). Adult patients with solid pancreatic lesions on imaging (CT, MRI or ultrasound) were prospectively recruited between April 2019 and April 2022. Diagnostic EUS-FNB was performed by experienced investigators utilizing both needle sizes with 1-2 needle passes each. A blinded pathologist graded the diagnostic quality of the samples and diagnostic accuracy was calculated.

Results: The mean age at presentation was 67 years (IQR: 59 -77.5) with a ratio of 1.2:1 of male to female. Of 119 included patients, 19 had to be excluded. In 85 out of the remaining 100 patients, only one needle could be used in the lesion due to technical difficulties or complications. The final diagnoses included pancreatic cancer (68.6%), neuroendocrine tumors (4.7%), lymphoma (1.2%), extrapancreatic malignancies (11.6%), chronic pancreatitis (7.0%), autoimmune pancreatitis (2.3%) and others (4.7%). The overall EUS-guided sampling sensitivity for the 22G-needle was 74.2% and for the 19G-needle 77.2%. The diagnostic sensitivity in malignant lesions was similar in both needles (22G: 78.9%, 19G: 79.1%) and was 82.0% (22G) and 78.6% (19G) when regarding only cases with pancreatic ductal adenocarcinoma (PDAC). Post-procedural bleeding occurred in 8 cases whereas in 3 patients' further intervention was necessary.

Conclusion: In this prospective, controlled study, the use of a 19G EUS-FNB needle did not result in a higher diagnostic accuracy of solid pancreatic lesions compared to the standard size 22G.

Disclosure: Nothing to disclose.

Introduction: Pancreatic cystic lesions (PCL) represent an increasingly diagnosed condition with significant burden to patients' lives and medical resources. Endoscopic ultrasound (EUS)-ablation techniques have been utilized to treat focal pancreatic lesions. This systematic review with meta-analysis aims to assess the efficacy of EUS-ablation on PCL in terms of complete or partial response and safety.

Aims & Methods: A systematic search in Medline, Cochrane and Scopus databases was performed until April 2023 for studies assessing the performance of the various EUS-ablation techniques. The primary outcome was complete cyst resolution, defined as cyst disappearance in follow-up imaging. Secondary outcomes included partial resolution (reduction in PCL size), and adverse events rate. A subgroup analysis was planned to evaluate the impact of the available ablation techniques (ethanol, ethanol/paclitaxel, radiofrequency ablation (RFA), lauromacrogol) on the results. Meta-analyses using a random effects model were conducted and the results were reported as percentages with 95% Confidence Intervals (95%CI).

Results: Fifteen studies (840 patients) were eligible for analysis. Complete cyst resolution after EUS-ablation was achieved in 44% (95%CI: 31-57; 352/767; I2=93.7%), and the respective partial response rate was 30% (95%CI:20-39; 206/767; I2=86.1%). Adverse events were recorded in 14% (95%CI: 8-20; 164/840; I2=87.2%) of cases, rated as mild in 10% [(95%CI: 5-15); 128/840; I2=86.7%]; and severe in 4% (95%CI: 3-5; 36/840; I2=0%). The subgroup analysis for the primary outcome revealed rates of 70% (95%CI: 64-76; I2=42.3%) for ethanol/paclitaxel, 44% (95%CI: 33-54; I2=0%) for lauromacrogol, 32% (95%CI: 27-36; I2=88.4%) for ethanol and 13% (95%CI: 4-22; I2=95.8%) for RFA. Considering adverse events, the ethanol-based sub-group rated the highest percentage [16% (95%CI: 13-20; I2:91.0%)].

Conclusion: EUS-ablation of pancreatic cysts provides acceptable rates of complete resolution and low incidence of severe adverse events, with chemoablative agents yielding higher performance rates.

Disclosure: Nothing to disclose.

Introduction: Endoscopic ultrasound (EUS) fusion imaging with cross sectional imaging (CT or MR) has been proposed as a method for co-registration of structures visible through different imaging techniques, with localization and tracking of the position of biopsy tools or therapeutic devices. Although initially developed for transabdominal [1] or endorectal [2] applications, the method seams feasible also for EUS [3], as tested with an initial prototype system [4].

The aim of our paper was to report on the testing of a second generation EUS fusion imaging based on electromagnetic (EM) navigation.

Aims & Methods: The equipment used consisted of Hitachi Noblus US system, Pentax linear scope, Custom made model and Aurora NDI magnetic-navigation. In order to create a porcine model we used an artificial "esophagus" and a porcine stomach. Beyond that, we attached to the model "gallbladder filled with stones" and a "pseudocyst" with the aim of simulating interventional procedures such as EUS-guided fine needle aspiration / biopsy (EUS-FNA/B) or EUS-guided pseudocyst / gallbladder drainage.

Additionally, one EM 6 degrees of freedom (DOF) positioning sensor was placed on the "patient" chest and scanned by CT. Furthermore, the 3D rendering of the model and registration with the pre-procedure data using the sensor have been performed.

The last step was placing a catheter with an EM 6DOF sensor mounted inside, in the working channel of the endoscope close to the distal tip in order to fuse live EUS images with the pre-procedure CT.

Results: The system displayed in real-time both EUS image and corresponding CT cross-section. Small registrations errors due to the differences between the pre-operative data and real model anatomy at the procedure time occurred but they have been overcome.

Thus, the rotation correction between EUS scan and corresponding CT cross section can be done by the doctor during endoscopic procedure operating a special designed catheter handle and adjusting the angle of the catheter tip inside the endoscope.

Conclusion: The purpose of incorporating image fusion into pancreaticobiliary pathology is to boost the quality of diagnostic and therapeutic strategies not only by improving and speeding up the learning curve of EUS, but also by enhancing the accuracy of preoperative assessment regarding tumor resectability or by increasing the safety of therapeutic EUS procedures.

Introduction: The incidence of pancreas cysts is increasing, and the use of EUS-guided through-the-needle-biopsy (EUS-TTNB) is gradually increasing for accurate diagnosis. However, studies including a large number of patients on clinical outcomes and safety of EUS-TTNB for pancreatic cysts are still lacking. In this study, we evaluated the diagnostic yield, adverse events(AE), and risk factors of AE related to EUS-TTNB in a large number of cohorts.

Aims & Methods: We reviewed the prospectively collected EUS-TTNB for pancreatic cysts database at Asan Medical Center, between January 2019 and December 2022. We analyzed technical success rate, diagnostic yield, AE, and risk factors for AE.

Results: A total of 248 patients were analyzed. Technical success could be achieved in 247 patients, except one patient (100%). Among them, 191 patients had a specific histologic diagnosis (diagnostic yield, 77.3%). There was no significant difference in diagnostic yield according to the number of biopsy specimen, the presence of septation in the cysts, the size of cysts, and location of cysts. AE occurred in 41 patients (16%), and there was no serious AE. Acute pancreatitis was the most common AE (12/248, 12%) following cyst hemorrhage (7/247, 3%). In univariate analysis on the risk factors of acute pancreatitis related to EUS-TTNB, male (HR 2.22, 95% CI: 1.02-4.83, P=0.045) and IPMN (HR 3.08, 95% CI: 1.35-7.03, P=0.01) were statistically significant. In multivariate analysis, IPMN (HR 2.75, 95% CI: 1.24-6.11, P=0.01) was the significant risk factor of acute pancreatitis after EUS-TTNB.

Characteristics	Univariate analysis			Multivariable analysis		
	OR	95% CI	P value	Adjusted OR	95% CI	P value
Age > 70 years	2.52	0.85 – 7.49	0.09			
Male sex	2.22	1.02 – 4.83	0.045			
Needling > 2	1.25	0.56 – 2.77	0.58			
Biopsy > 4	1.93	0.86 – 4.31	0.11	1.89	0.84 – 4.27	0.13
IPMN	3.08	1.35 – 7.03	0.01	2.75	1.24 – 6.11	0.01

Note. OR, odds ratio; CI, Confidence interval;

Table. Risk factors of acute pancreatitis after TTNB.

Conclusion: EUS-TTNB showed a relatively high technical success rate and diagnostic yield. IPMN was the most significant risk factor of AE related to EUS-TTNB.

Introduction: Differential diagnosis of solid pancreatic tumours (SPT) is a clinical challenge. Development of advanced imaging techniques associated with EUS, such as elastography and contrast enhancement, has been a step forward in this context. EUS-guided detective flow imaging (DFI) is a very recent technology allowing the evaluation of microvascularization and low-velocity blood flow without the need of contrast agents.
Aims & Methods: Aim of our study was to evaluate the findings obtained by EUS-DFI in SPT and compare them with contrast enhanced harmonic EUS (CEH-EUS).
Methods: A prospective, single-centre, observational study in patients who underwent EUS for the evaluation of SPT was designed. Procedures were performed with a linear echoendoscope (Fujifilm 740UT) attached to the ultrasound system Arietta 850. Lesions were characterized according to the vascularization pattern (hypervascular, isovascular and hypovascular) described with both methods. Final diagnosis was based on histology after EUS-guided biopsy. Data area shown as mean ± SD and percentage.
Results: 44 patients were included (mean age 67 years, range 24-88, 23 males). Mean tumour size was 26.1 ± 15.7 mm. Fourteen (31.8%) lesions were located in the head of the pancreas, 19 (43.2%) in the body, 9 (20.5%) in the tail and 2 (4.5%) in the uncinate process.
Final diagnosis was adenocarcinoma in 24 patients (54.5%), neuroendocrine tumour in 13 (29.5%), inflammatory mass in 3 (6.8%), autoimmune pancreatitis in 1 (2.3%), pancreatic necrosis in 1 (2.3%), accessory spleen in 1 (2.3%) and lipoma in 1 (2.3%).
Agreement regarding the vascular pattern of SPT between CEH-EUS and EUS-DFI was reached in 97.7% of the cases. All adenocarcinomas were hypovascular, inflammatory masses and autoimmune pancreatitis isovascular, pancreatic necrosis avascular, and accessory spleen and lipoma hypervascular at both CEH-EUS and EUS-DFI. All 13 neuroendocrine tumours were hypervascular at CEH-EUS, 12 of them (90%) at EUS-DFI.
Conclusion: EUS-DFI allows evaluating the microvascular pattern of SPT with a similar accuracy than CEH-EUS, but without the need of using contrast agents.

Introduction: Strain elastography (SE) allows quantifying the degree of pancreatic fibrosis in CP. Two methods of measuring pancreatic fibrosis by SE, the strain ratio (SR) and the strain histogram (SH) are available. No study has compared so far, these two methods for the diagnosis of CP.
Aims & Methods: Aim of our study was to evaluate the diagnostic yield of SR and SH for non-calcific CP.
Methods: A prospective, comparative study of the diagnostic accuracy of SR and SH for CP was designed. Patients undergoing EUS for the evaluation of CP were included. Patients with calcifying CP were excluded. Procedures were performed with linear echoendoscopes (Pentax 34J10, 38J10, and Fujifilm 740UT) and the ultrasound system Arietta 850. Rosemont EUS criteria for CP were evaluated. An area of the pancreatic body (A) was selected for SR and SH measurement.
A soft extrapancreatic area was additionally selected as reference area for SR (B), being the quotient B/A the SR result. Data are shown as percentages, mean (95%CI), and analyzed by ANOVA and linear regression. The diagnostic accuracy of SR and SH were evaluated using the Rosemont classification as the reference method. STARD criteria for studies of diagnostic accuracy were followed.
Results: 164 patients were included (mean age 48 years, range 17-85, 78 males). 27 (16.5%) patients presented a normal pancreas, 69 (42.1%) indeterminate findings for CP and 68 (41.5%) suggestive for CP. SR was 2.02 (1.89-2.15), 3.17 (3.02-3.32), and 4.46 (4.20-4.70), and SH 145.47 (136.25-154.69), 101.13 (96.31-105.96), and 80.04 (76.23-83.84) in normal pancreas, indeterminate and suggestive of CP, respectively ($p<0.0001$).
Number of EUS criteria correlated significantly with the degree of pancreatic fibrosis as evaluated by SR ($r=0.774$, $p<0.0001$) and SH ($r=0.770$, $p<0.0001$). A SR > 2.45 showed sensitivity of 92.0% and specificity of 92.3% for the diagnosis of CP, with an area under the ROC curve of 0.978.
Similarly, a SH <115 showed sensitivity of 87.7% and specificity of 100%, with area under the ROC curve of 0.967.
Conclusion: The quantification of pancreatic fibrosis by SR and SH during pancreatic EUS-SE show a very high and similar diagnostic accuracy in patients with suspected CP.

Introduction: It is sometimes difficult to distinguish between autoimmune pancreatitis (AIP) and pancreatic neoplasm. In imaging diagnostic examination, long or multiple strictures, or segmental/focal narrowing of pancreatic duct without marked upstream dilatation in endoscopic retrograde pancreatography is important finding to diagnose as AIP.

It has been speculated that the narrowing of pancreatic duct is attributed to periductal lymphoplasmacytic infiltration characteristic of histology in AIP. We reported a resected case of AIP in which branch pancreatic duct wall thickening demonstrated by endoscopic ultrasound (EUS) reflected periductal lymphoplasmacytic infiltration[1)].

EUS that provides high resolution image of pancreas can delineate periductal lymphoplasmacytic infiltration as pancreatic duct wall thickening.

Aims & Methods: The aim of this study is to determine whether pancreatic duct wall thickening on EUS contributes to the diagnosis of AIP. From March 2017, when we began focusing on pancreatic duct wall thickening in AIP, to March 2023, there were 24 consecutive patients diagnosed with AIP in our department.

EUS was performed in all of them, and the presence of pancreatic duct wall thickening was noted on the EUS report. Pancreatic duct wall thickening was focused on a thickened wall with symmetry, irregular luminal caliber, and a smooth hyperechoic layer covering the surface[1)].

The international consensus diagnostic criteria for AIP were applied. The detection rate of pancreatic duct wall thickening on EUS, characteristics according to pancreatic duct wall thickening, and the change of pancreatic duct wall thickening after steroid therapy were investigated.

Results: All patients were diagnosed with type 1 AIP (definitive type 19, probable type 2). Median age was 70 years (range: 55-82), and male was 18 patients. The median serum IgG4 level at diagnosis was 446 mg/dL (range: 147-2600). The detection rate of pancreatic duct wall thickening on EUS was 83.3% (20/24). Localization was diffuse in 12 patients and segmental/focal type in 12 patients.

Other organ involvement was observed in 13 patients. There was no difference in the above factors depending on the presence or absence of pancreatic duct wall thickening. Twenty patients underwent steroid trial. Among them, 7 patients who underwent EUS after steroid trial showed improvement in pancreatic duct wall thickening.

Conclusion: Pancreatic duct wall thickening on EUS was often seen in patients with AIP and improved with steroid therapy. Focusing on this imaging finding may be useful in the diagnosis of AIP.

Introduction: Endoscopic ultrasonography-guided gastroenterostomy (EUS-GE) is emerging as a new and minimally invasive endoscopic treatment method for gastric outlet obstruction (GOO). In EUS-GE, it is important that stents can be safely and reliably deployed and that there is no stent migration.

As the optimal method, we have developed the EUS-guided balloon-occluded gastrojejunostomy bypass (EPASS) and have performed it as a clinical study.

Aims & Methods: We retrospectively evaluated the results of EPASS including long-term outcomes. The EPASS procedure was performed under conscious sedation. The endoscope was used to reach the site of obstruction. The stricture was cannulated with a 0.025-inch guidewire and the guidewire was used to negotiate beyond the site of obstruction under endoscopic and fluoroscopic guidance. The double balloon tube was then inserted on the guidewire beyond the duodenal–jejunal flexure using an overtube. The two balloons of the occluder were inflated with 30–40 mL normal saline and constrast. 200–300 mL of methyleneblue-stained saline was then injected to distend the occluded segment of duodenum. A linear echoendoscope was then inserted into the stomach. A site in the posterior wall of the body of the stomach was punctured directly by the delivery system of the lumen apposing metal stent. A 20 x 10 or 15 x 10 mm stent was used.

The distal flange of the stent was deployed under EUS guidance, followed by deployment of the proximal flange under endoscopic or EUS guidance. Stent position was confirmed with the drainage of methylene-blue-stained saline, the endoscopic view of the proximal flange and also the fluoroscopic image. Thirty-six consecutive patients with symptomatic GOO who were not refractory to surgical gastrojejunostomy were enrolled in the study.

The primary endpoint was technical success rate. Secondary endpoints included procedure time, GOO scoring system (GOOSS) scores at 7 days and 1 month after EPASS, clinical success rate (improvement in GOOSS scores at 7 days after EPASS), procedure-related adverse events (AEs) rate, overall survival (OS) after EPASS in the 23 patients with long-term follow-up, and stent patency rate.

Results: The mean age was 70.6 years (range 47-91), 16 (44%) were female, and the underlying diseases were 18 pancreatic cancer, 9 gastric cancer, 3 duodenal cancer, 4 gallbladder cancer, 1 breast cancer, and 1 chondrosarcoma. The technical success rate was 94.4% (34/36), mean procedure time was 26.9 minutes (range 14-40), mean time to double-balloon tube insertion was 9.8 minutes (range 6-28), mean pre-GOOSS score was 0.42, mean GOOSS score was 2.08 and 2.21 at 7 days and 1 month after EPASS, and the clinical success rate was 88.9% (32/36).

The incidence of procedure-related AE was 16.7% (6/36), including 2 cases of fever, 2 cases of abdominal pain, and 2 cases of worsening ascites. The mean overall survival after EPASS was 183.8 days, all patients died of primary disease, and there were no events such as stent occlusion or stent deviation (stent patency was 100%).

Conclusion: EPASS is a safe and reliable EUS-GE method and may be a useful treatment for symptomatic malignant GOO.

Introduction: Differentiating pancreatic cystic lesions (PCLs) remains a diagnostic challenge. The use of high-definition imaging modalities which detect tumor microvasculature have been described in solid lesions.
We aim to evaluate the usefulness of cystic microvasculature when used in combination with cyst fluid biochemistry to differentiate PCLs.
Aims & Methods: We retrospectively analyzed 110 consecutive patients with PCLs from 2 Italian Hospitals who underwent EUS with HFlow and EUS fine needle aspiration to obtain cystic fluid. The accuracy of fluid biomarkers was evaluated against morphological features on radiology and EUS. Gold standard for diagnosis was surgical resection. All cysts fluid cutoff values were assigned from previous literature: CEA>192(ng/ml), CA19.9>37(U/L), amylase>250(U/L), lipase>336(U/L), glucose<50(mg/dl).
Results: Of 110 patients, 65 were diagnosed as mucinous, 41 as non-mucinous neoplasms (4 patients excluded). Fluid analysis alone yielded 76.7% sensitivity, 56.7% specificity, 77.8 positive predictive value (PPV), 55.3 negative predictive value (NPV) and 56% accuracy in diagnosing pancreatic cysts alone. Our composite method yielded 97.3% sensitivity, 77.1% specificity, 90.1% PPV, 93.1% NPV, 73.2% accuracy.
Conclusion: This new composite method which utilizes high-definition microvasculature imaging on EUS is superior to that of the stand-alone analysis of cyst fluid biochemistry. It can be applied to the holistic approach of combining cyst morphology, vascularity, and fluid analysis alongside endoscopist expertise.

DYNAMIC CONTRAST ENHANCED HARMONIC ENDOSCOPIC ULTRASOUND (CEH-EUS) FOR THE DIAGNOSIS OF FOCAL PANCREATIC MASSES. INFLOW-TIME MAPPING - A NOVEL SIMPLISTIC OBJECTIVE APPROACH: A PILOT STUDY

S. Badiu[1], A. Saftoiu[1], S.A. Coman[1], D. Tabacelia[1], A. Todiroaie[1]
[1]Elias Emergency University Hospital, Bucharest, Romania

Contact E-Mail Address: simona.badiu@yahoo.com
Introduction: Contrast-enhanced harmonic endoscopic ultrasound (CEH-EUS) is one of the best imaging modalities to visualize tumor blood flow, but conventional observation can sometimes be insufficient, particularly in lesions characterized by rapid changes in blood flow. Inflow-time mapping (ITM) is a colored parametric display of time-to-peak enhancement for each pixel in the display that allows a better differentiation of tissues by their speed of contrast agent uptake. ITM is a simple, easily reproducible computer-aided color parametric imaging (CPI) technique that can bring a more objective approach to CEH-EUS analysis and further improve the differential diagnosis of pancreatic masses.
Aims & Methods: To investigate the potential advantages and limitations of Inflow-time Mapping - a novel computer-aided color parametric imaging technique - in assessing focal pancreatic lesions using contrast-enhanced harmonic endoscopic ultrasound.
A total of 15 patients including 8 cases of pancreatic ductal adenocarcinomas (PDAC), 3 cases of chronic pancreatitis, 2 cases of pancreatic neuroendocrine tumors (NETs), one case of serous cystadenoma (SCA) and one case of intraductal papillary mucinous neoplasm (IPMN) were enrolled. CEH-EUS and ITM examinations were performed for the frames obtained during the arterial phase. All CEH-EUS and ITM images were retrospectively reviewed and two sets of criteria were assigned: (1) Routine CEH-EUS alone, focusing on the degree and pattern of enhancement, and (2) CEH-EUS and ITM, focusing on differentiating pancreatic lesions based on their speed of ultrasound contrast agent (UCA) uptake, compared to adjacent tissue. Final diagnosis was based on EUS-guided tissue fine needle aspiration biopsy (EUS-FNAB).
Results: Based on CEH-EUS, 11 pancreatic lesions were initially considered PDAC based on their hypoenhanced appearance. ITM analysis could not provide additional information in 8 patients due to insufficient vascularization. In 3 patients, by showing no difference in the speed of UCA uptake in the enhanced regions of the lesion compared to the surrounding parenchyma, ITM analysis was able to correctly identify chronic pancreatitis, as proven by histology. Among the 2 hyperenhanced pancreatic le-

sions described on CEH-EUS, ITM analysis was able not only to correctly diagnose but also to provide an extensive characterization of 2 pancreatic NETs by showing a greater speed of UCA uptake in the lesion and a typical pattern of the parametric map. ITM analysis also proved useful in objectively highlighting the speed and pattern of enhancement (septal/mural) of 2 included cystic lesions, IPMN and SCA.

Conclusion: ITM is a promising tool for an objective, simplistic approach, in the assessment of hypervascular pancreatic lesions, particularly pancreatic NETs. It can also become an important step in the evaluation of focal pancreatic masses in patients with chronic pancreatitis, where parenchymal inhomogeneity and altered local perfusion might influence the purely visual assessment of CEH-EUS.

Introduction: Pancreatic cancer (PC) is one of the most lethal tumors worldwide, and in 2030 it will become the second leading cause of cancer related death (1–3). Computed tomography (CT) and magnetic resonance imaging (MRI) are the gold standards to stage the disease (4). Nevertheless, these imaging modalities are unable to provide real-time information on biological characteristics of tumors, such as vascularity, which is proportional to angiogenesis, growth rate, and necrosis (5,6). Dynamic contrast-enhanced ultrasound (D-CEUS) allows qualitative and quantitative microvascular perfusion assessment in real-time (7).

Aims & Methods: This study aimed to evaluate the role of D-CEUS in the characterization of PC. Thirty-eight patients with suspected PC were prospectively enrolled between October 2022 and March 2023. All patients underwent endoscopic ultrasound guided biopsy for histological diagnosis and CT or MRI for staging. According to these modalities, patients were divided into three categories: resectable PC (R-PC), locally advanced PC (LA-PC), and metastatic PC (M-PC). D-CEUS was performed the same day of lesion biopsy and time-intensity parameters were compared among tumor categories. The diagnostic performances of selected parameters was evaluated by receiver operating characteristic (ROC) analysis.

Results: PC was diagnosed in 36 (94.7%) patients and classified as R-PC, LA-PC and M-PC in 5 (13.9%), 13 (36.1%) and 18 (50%) patients, respectively. Among perfusion parameters, time to peak (TTP) showed a trend to increase in LA-PC patients (median 18.03 sec, interquartile range [IQR] 14) compared to R-PC group (median 12.9 sec, IQR 3.05) ($p = 0.05$) and it was significantly higher in LA-PC group compared to M-PC group (median 12.35 sec, IQR 4.08) ($p = 0.03$). A cut-off value < 11.6 sec showed a good accuracy to distinguish LA-PC from M-PC (area under the ROC curve = 0.74) with maximal specificity (100%) but low sensitivity (50%).

Conclusion: Quantitative perfusion parameters extracted from D-CEUS seem to be useful in distinguishing the invasiveness of PC. In particular TTP, a parameter related to blood flow was higher in LA-PC compared to M-PC, suggesting different microvascular characteristics of the tumors. Further studies on larger population are needed to confirm these findings and to explore the biological basis for this phenomenon.

CLINICAL AND TECHNICAL SUCCESS OF EUS-GUIDED ANTEROGRADE DRAINAGE FOR NON-NEOPLASTIC OBSTRUCTED BILIARY AND PANCREATIC DUCTS: A SINGLE-CENTER EXPERIENCE

C. Robles-Medranda[1], D. Cunto[1], M. Puga-Tejada[1], J. Alcivar-Vasquez[1], M. Egas-Izquierdo[1], J. Baquerizo-Burgos[1], M. Arevalo-Mora[1], H. Alvarado-Escobar[1], R. Del Valle Zavala[1], H. Pitanga-Lukashok[1], IECED

[1]Instituto Ecuatoriano De Enfermedades Digestivas (IECED), Gastroenterology and Endoscopy Division, Guayaquil, Ecuador

Introduction: The first-line treatment for obstructed biliary or pancreatic ducts is endoscopic retrograde cholangiopancreatography (ERCP), yet access may fail (even in expert hands) in 10-15% of cases due to inability to cannulate the papilla or a challenging narrow anatomy. Endoscopic ultrasound-guided biliary drainage (EUS-BD) or EUS-guided pancreatic duct drainage (EUS-PDD) have emerged as direct duct accesses alternate to the percutaneous or surgical approach, both which carry high morbidity and mortality.

Aims & Methods: We aim to assess the anterograde's drainage clinical and technical success in non-neoplastic obstructed biliary and pancreatic ducts. Data from patients with a history of obstructed biliary or pancreatic ducts between January 2021 and October 2022 was analyzed retrospectively. Clinical and technical success were the primary endpoints. Adverse events, re-stenosis, and re-intervention were also evaluated.

Results: A total of twenty patients were included (15/20 EUS-BD and 5/20 EUS-PDD), median age of 46 (IQR 24-77), 70% female.

A) EUS-BD: inability to cannulate the papilla was due to stenosis secondary to: 6/15 laparoscopic cholecystectomy, 7/15 conventional cholecystectomy, 1/15 gallbladder neoplastic plastron, and 1/15 Y-Roux. In 4/15 a previous attempt was performed (1/4 balloon dilation, 1/4 percutaneous transhepatic biliary drainage, and 2/4 stenting). Anterograde drainage was

performed in 7/15 using a single pigtail stent, 5/15 double pigtail stents and 3/15 lumen-apposing metal stent (LAMS). Stomach puncture was the preferred approach site in 13/15. A 15/15 (100%) technical success was achieved, but a 9/15 (60%) clinical success based on bilirubin decrease. During follow-up, adverse events were documented in 3/15 cases: upper bleeding, cholangitis, and subhepatic fluid collection. Stent migrated in 3/15 cases. There was no restenosis, but reintervention was necessary on 8/15. One patient died.

B) EUS-PDD: anterograde drainage was decided due to acute or chronic pancreatitis and choledocholithiasis in 2/5, 1/5, and 2/5 cases, respectively; 2/5 patients were under non-opioids therapy before the procedure for pain management, and 4/5 were prescribed pancreatic enzyme supplementation. In 3/5 cautery-assisted dilation was required. In 1/5, balloon dilation was also necessary. Used stents included: single and double pigtail stents, LAMS, and self-expandable metal stents (SEMS). Technical and clinical success was achieved in 5/5 (100%), with no adverse events.

Conclusion: Anterograde EUS-BD and EUS-PDD for the management of non-neoplastic biliary and pancreatic duct drainage are valuable alternatives in patients where ERCP is not feasible. Further prospective studies are necessary to confirm the observed results.

Introduction: Post-operative pancreatic fluid collections (POPFCs) are common adverse events after pancreatic surgery and may need interventions. Endoscopic ultrasound (EUS)-guided drainage for POPFCs is increasingly reported, but its appropriate timing has not been fully elucidated.

Aims & Methods: The aim of this meta-analysis was to evaluate treatment outcomes of POPFCs according to the timing of EUS-guided drainage. Using PubMed, Embase, Web of Science, and the Cochrane database, we identified clinical studies published until December 2022 with data comparing outcomes of early and delayed EUS-guided drainage for POPFCs. We pooled data on adverse events (AEs), mortality, and technical and clinical success rates, using the random-effects model.

Results: From 1,415 papers identified in the initial literature search, we identified 6 retrospective studies, including 128 and 107 patients undergoing early and delayed EUS-guided drainage for POPFCs. The threshold of early and delayed drainage ranged from 14 to 30 days. Distal pancreatectomy was the major cause of POPFCs, ranging from 44 to 100%. Reported AE rates of EUS-guided drainage of POPFCs ranged from 4% to 46%, and the pooled odds ratio (OR) for adverse events was 0.81 (95% confidence interval [CI], 0.40-1.64, P = 0.55) comparing early to delayed drainage. There was no evidence on heterogeneity between the studies ($P_{heterogeneity}$ = 0.93 and I^2 = 0%). There was no procedure-related mortality, and technical success was achieved in all cases. Clinical success rates were reported as 90 to 97% and were comparable between early and delayed drainage groups with a pooled OR of 0.60 (95% CI, 0.20-1.83, P = 0.37).

Study	Early / Delayed, n	Technical success (%)	Clinical success (%)	Adverse event (%)	Bleeding (%)	Infection (%)	Stent migration (%)
Varadarajulu	4/6	100/100	100/83	0/0	0/0	0/0	0/17
Tilara	17/14	100/100	100/100	6/7	6/7	0/0	0/0
Caillol	22/19	100/100	86/100	45/47	27/16	14/21	0/11
Storm	42/33	100/100	93/94	21/30	5/6	0/3	0/3
Fujimori	14/16	100/100	93/100	7/6	7/6	0/0	0/0
Oh	29/19	100/100	97/95	7/0	7/0	0/0	0/0

Table. Clinical outcomes of early and delayed EUS-guided drainage for postoperative pancreatic fluid collection.

Conclusion: POPFCs can be managed by early EUS-guided drainage without an increase in AEs.

COMPARISON BETWEEN ENDOSCOPIC ULTRASOUND-GUIDED RADIOFREQUENCY ABLATION AND SURGICAL RESECTION FOR PANCREATIC INSULINOMA: A SINGLE-CENTER, RETROSPECTIVE ANALYSIS

F. Borrelli de Andreis[1], D. De Sio[2], G. Quero[2], P. Mascagni[2], I. Boskoski[1], S. Alfieri[2], C. Spada[1], F. Attili[1]

Contact E-Mail Address: federica.bda@gmail.com

Introduction: Insulinomas are rare, functioning neuroendocrine neoplasms that cause non-ketotic hypoglycemia due to hyperinsulinism. Surgery is considered the gold-standard treatment, although endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA) has been recently described as a less invasive, efficient therapeutic option for these tumors. In this study, we aim to compare post-procedural outcomes of surgical resection versus EUS-RFA for pancreatic insulinomas.

Aims & Methods: All patients who underwent surgical resection or EUS-RFA for pancreatic insulinoma in our Institution were included in the study, and data from all procedures were retrospectively recorded and statistically analyzed. EUS-RFA was indicated for all subjects either unfit for surgery or unwilling to undergo surgical treatment. Patients' baseline characteristics, location, size of insulinomas, procedural time, and intra- and postoperative outcomes were compared.

Results: From April 2012 to July 2022, 11 and 10 patients with pancreatic insulinoma underwent surgical resection and EUS-RFA, respectively. The median age was 65.5 (51-84) and 37 years (28-72, p<0.001) for the EUS-RFA and surgery cohorts, respectively. As a whole, 15 (71.4%) out of 21 were female. The median tumor size was 15mm (8-30) for the surgical group and 11mm (8-19) for the EUS-RFA group (p=0.17). The majority of the insulinomas were located in the pancreatic body (28.6%) and tail (28.6%), with no statistical difference between the two groups (p=0.16). Operative time was significantly longer in the surgical population (280min, 120-372) as compared to the endoscopic one (28min,18-40, p<0.001). Clinical success, defined as the normalization of glucose blood levels, was reached in all cases. The complication rate was significantly higher in the surgical group compared to the endoscopic group (7-63.6% vs 1-10%, p=0.01). Specifically, 7 patients in the surgical cohort developed a pancreatic fistula while one patient in the EUS-RFA population had self-limiting bleeding after the procedure. One patient of the surgical cohort underwent reoperation for an infected abdominal fluid collection.

Variable	EUS-RFA N=10	Surgical resection N=11	p value
Median age-adjusted CCI, points	4.5 (2-6)	2.0 (2-5)	0.002
MEN-1, n (%)	2 (20.0)	0 (0.0)	0.119
Hypoglycemic symptoms, n (%)	10 (100)	11 (100)	/
Positive fasting test, n (%)	9 (90.0)	10 (90.9)	0.943
Median operative time, min (range)	28 (18-40)	280 (120-372)	<0.001
Procedure-related AE, n (%)	1 (10.0)	7 (63.3)	<0.001
Postoperative euglycemia, n (%)	10 (100)	11 (100)	/
Median follow-up time, months (range)	15 (6-62)	51 (6-126)	0.670

Legend: AE: adverse events; EUS-RFA: endoscopic ultrasound-guided radiofrequency ablation; CCI: Charlson Comorbidity Index; MEN-1: multiple endocrine neoplasia type 1.

Table 1. Characteristics of patients classified by treatments.

Conclusion: As compared to surgical resection, EUS-RFA for pancreatic insulinomas may be considered a safe and efficient treatment option with a shorter operative time and a lower rate of related complications. Prospective comparative studies are needed to ascertain the role of EUS-RFA as a treatment of choice for selected patients with pancreatic insulinoma.

Introduction: Acute pancreatitis in 10%–20% of cases can be associated with necrosis of the pancreatic gland, peripancreatic tissue, or both. Expert multidisciplinary care by gastroenterologists, surgeons, interventional radiologists, and specialists in critical care medicine, infectious disease, and nutrition is required to successfully manage these patients.

The current accepted invasive treatment for patients with necrotizing pancreatitis is the so-called "step-up" approach, which includes an initial percutaneous catheter drainage (PCD) followed by endoscopic, surgical, or laparoscopic necrosectomy, if necessary.

We report a case series of a new endoscopic approach to treat infected pancreatic necrosis (IPN).

Aims & Methods: Consecutive patients with IPN, extended from perigastric area up to the paracolic gutters or into the pelvis, were prospectively studied from January 2017 and June 2022.

Treatment protocol was radiological percutaneous drainage as first step followed by fully covered metal stent placement (FC-SEMS) in the track of the catheter. Percutaneous endoscopic necrosectomy (PEN) was performed 2-4 days later using a flexible endoscope through the percutaneous tract.

About 2-4 weeks later when, a matured sac was visible, EUS-guided endoscopic transluminal drainage (ETD) with lumen-apposing metal stents (LAMS) was performed.

Control of sepsis with resolution of collection(s) was primary outcome measure.

Results: We included 18 patients, males in 50% of cases with age 60 ± 12 years old. The most frequent cause of pancreatitis was biliary (7 cases) followed by alcoholic in 6 cases; in 3 cases pancreatitis was caused by hyperlipemia and in 2 cases was idiopathic. The mean size of WON was 18 ± 2 cm. For PEN, the SEMSs used were oesophageal FC-SEMS. LAMS used for ETD were Hot Axios, Hot Spaxus, and Nagistent. The mean time of endoscopic intervention for PEN and ETD was 18 ± 3 days and 37 ± 4 days respectively. In 5 cases adverse events occurred: 3 cases of overinflations resolved with the introduction of Verres needles in the abdomen. In 2 cases post procedural GI bleeding required endoscopic intervention.

The median time of resolution of WON was 3.5 weeks (minimum 2, maximum 6 weeks), with a median of 2 sessions for PEN (minimum 2, maximum 3) and 2 sessions for ETD (minimum 2, maximum 4) at an interval of 7 days (range: 4-9 days) were needed to achieve resolution of fluid collection. In all cases control of sepsis was reached together with resolution of collections. No cases of deaths were observed.

Conclusion: The combined step-up dual approach of initial PCD after 2-3 weeks of illness followed by early PEN and delayed ETD is a safe and effective alternative treatment for patients with large size IPN, extended from the pancreatic lodge into paracolic gutters or the pelvis.

Introduction: Current endoscopic ultrasound technologies (EUS) are suboptimal in the assessment of pancreatic cystic lesions (PCLs). We developed a new through-the-needle brush, the “loop brush”, to improve the cellular yield, and thereby sensitivity, of EUS fine needle aspiration (EUS-FNA) of pancreatic cysts.

Aims & Methods: We aim to evaluate the “loop brush” safety, robustness, and efficacy.

We performed an in-vivo randomized controlled trial in pigs using artificial cysts. In one group, the loop brush was deployed through a 22G EUS-FNA needle into the cysts. In the control group, cystic punction was performed with standard EUS-FNA. Loop brushes were visually inspected post-procedure. Cytological assessment, cell counting, and hemoglobin analysis were performed in samples from both groups.

Results: Artificial cysts (n=114) were punctured in six pigs, 57 in each group. Neither adverse events nor significant device malfunction occurred during loop brushing. Samples collected with the brush had non-detectable concentrations of hemoglobin in 72% (41/57) of cases, and 26% (16/57) had less than 0.6 g/dL, with no significant difference to the controls (p=0.32). Brushing cell counts were associated with significantly increased cell counts (11.7× median difference, p<.0001). Cytological smears were diagnostic in 77% of cases in the brushing group, while 54% in the control group (p=0.01, Fisher’s exact test; p=0.006, Chi-square test).

Conclusion: The new loop brush procedure appears to be safe, causing neither significant bleeding nor device malfunction. Samples obtained with the loop brush were suitable for cytological analysis and showed significantly higher cell yield than controls. Further clinical studies are warranted.

Introduction: Pancreatic fluid collections (PFC) are debris or fluid of the pancreas that need to be drained out. This may result from surgery or necrotizing pancreatitis. This meta-analysis compared the outcomes of PFC through endoscopic and percutaneous interventions.
Aims & Methods: A medical database was searched up to June 2022, comparing the outcomes of endoscopic drainage (ED) and percutaneous drainage (PD) for the PFC. Eligible studies reporting clinical and technical success and adverse events were selected.
Results: Seventeen studies with 1170 patients were included for meta-analysis, of which 543 patients underwent ED and 627 underwent PD. Odd ratio (OR) of technical success was 0.81 (95% confidence interval (CI) 0.31, 2.1) and clinical success was in the favor of ED group at OR 2.23 (95% CI 1.45, 3.41). Adverse events OR 0.62 (95% CI 0.27, 1.39) and stent migration OR 0.61 (95% CI 0.10, 3.88) were the same in both groups, but hospital stay pooled mean difference of 15.02 days (95% CI 9.86, 20.18), mortality OR 0.24 (95% CI 0.09, 0.67), and re-interventions OR 0.25 (95% CI 0.16, 0.40) favored ED.
Conclusion: ED is safe and efficient for PFC with higher clinical success, lower mortality rate, hospital stay, and re-interventions compared with PD.

Introduction: Infection with SARS-CoV-2 leads to pronounced changes in the intestinal microbiome and also decay of tryptophan that are both related to disease severity. Supplementation of tryptophan metabolism using ileocolonic-release nicotinamide may stabilize the microbiome and alleviate COVID-19 symptoms.

Aims & Methods: This prospective, double-blind, randomized, placebo-controlled trial evaluated safety and efficacy of a 4-week intervention with a novel oral formulation of nicotinamide (1,000 mg/d) in symptomatic, unvaccinated, non-hospitalized outpatients with PCR-proven early COVID-19.

The primary outcome was full recovery from reduced physical performance after 2 weeks in the prespecified symptomatic primary analysis population with at least one risk factor for severe COVID-19. Stools from a part of the patients (4 timepoints) were submitted to 16S rRNA (n=70) and shotgun metagenomics (n=18) sequencing.

Results: Screening of 7,013 patients resulted in randomization of 900 participants (nicotinamide or placebo (1:1), from which 867 received the investigational product and 500 qualified for the acute disease analysis population. 110 of 191 patients (57.6%) receiving nicotinamide and 80 of 188 patients receiving placebo (42.6%) recovered from their performance drop at week 2 (absolute difference, 15.0 percentage points; odds ratio, 1.33; 95% confidence interval, 1.03 to 1.70; P=0.004).

Nicotinamide was also superior in the secondary endpoints ability to perform normal activities (P=0.009) and shortness of breath (P=0.012). Substantial effects on gut microbiome constitution were seen counteracting COVID-19 related changes.

Reduction of tryptophan biosynthesis in the microbiome in placebo patients was restored and NAD salvage pathways were activated in nicotinamide-treated individuals. No relevant safety signals were observed.

Conclusion: Oral treatment with nicotinamide stabilized the gut microbiome against COVID-19 related changes and led to faster recovery of physical performance in symptomatic patients at risk for severe Covid-19. (Funded by the German Research Foundation [DFG], the State of Schleswig-Holstein and the UEG Research Prize; ClinicalTrials.gov number: NCT04751604)

Introduction: Initial reports suggested a high mortality associated with peri-operative COVID-19 infection resulting in delayed surgery and a global change in surgical pathways. The impact of COVID-19 variants and vaccinations on surgical outcomes is yet to be described.

Aims & Methods: We aimed to define the risk of COVID-19 infection in the 30 days following surgery and the associated mortality. With the approval of NHS England we identified all registered adult patients in an OpenSAFELY-TPP primary care general practice within England whilst having an abdominal, obstetric, orthopaedic, thoracic or vascular procedure defined using OPCS codes between 01/02/2020 and 01/03/2022.COVID vaccinations and COVID waves were defined. Crude 30 day risks were calculated using Kaplan Meier curves.

A competing risks Cox proportional survival analysis was used to adjust the cumulative risk of COVID-19 infection by the competing risk of death and subsequent non COVID-19 emergency readmissions.

Primary care records managed by the GP software provider TPP were linked to ONS death data, Hospital Episodes Statistics, and Second Generation Surveillance System Public Health England test data through OpenSAFELY.

All data were linked, stored and analysed securely within the OpenSAFELY platform: https://opensafely.org/. Data include pseudonymised data such as coded diagnoses, medications and physiological parameters. No free text data are included. All code is shared openly for review and re-use

under MIT open license https://github.com/opensafely/PostOpCovid. Detailed pseudonymised patient data is potentially re-identifiable and therefore not shared.

This study was approved by the Health Research Authority [REC reference 21/EE/0278] by the East of England Research Ethics Committee.

Results: We identified 1,213,890 patients within the study period who underwent at least one surgical procedure. Following surgery 11,950 (0.9%) patients developed COVID-19 infection within 30 days. Post-operative COVID infections were greatest in wave 4 with 2.5% of patients having a post-operative infection. Adjusting for all factors post-operative COVID infection risk was 4.9 (aHR 4.88 95% CI 4.65-5.12) fold greater in the fourth wave compared to the first wave.

Within 90 days of surgery there were 820 (0.06%) deaths. A recent COVID infection increased crude morality to 1.42%, and a post-operative COVID infection increased crude mortality to 1.82%. The risk of death reduced following a first and second vaccination (aHR 0.11 95% CI 0.09-0.13). A recent COVID infection (7-42 days prior to admission) increased mortality 4 fold (aHR 3.84 95% CI 3.31-4.45) and a post-operative COVID infection increased mortality 8 fold (aHR 8.49 95% CI 7.6-9.48) compared to those without a COVID-19 infection. This increased 90 day mortality risk was highest in the second wave following a post-operative COVID infection, but then decreased to the non-covid baseline for both emergency and elective procedures in the 3rd and 4th waves.

Conclusion: The risk of post-operative COVID infection is low but has increased as strains have been become more transmissible. The absolute risk of death following peri-operative COVID-19 infection is greater than those who have not had infection however this risk has become attenuated during the latter waves of the pandemic.

Acknowledgements: We are very grateful for all the support received from the TPP Technical Operations team throughout this work, and for generous assistance from the information governance and database teams at NHS England and the NHS England Transformation Directorate.

Contact E-Mail Address: manolakis@uth.gr

Introduction: Among the constellation of symptoms attributed to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection, dysphagia emerged as a rather rare manifestation. This post-COVID-19 dysphagia seems to arise from esophago-gastric junction (EGJ) disorders either triggered or fueled by SARS-CoV-2 infection. New-onset dysphagia is associated with EGJ-outflow obstruction (EGJ-oo) whereas post-COVID-19 aggravation of dysphagia is associated with Achalasia. Available evidence to guide treatment for patients with post-COVID-19 dysphagia are currently lacking.

Aims & Methods: To offer an evidence-based therapeutic approach for patients presenting with post-COVID-19 dysphagia. Patients presenting with post-COVID-19 dysphagia between January 2021-December 2022, underwent esophagogastroduodenoscopy, esophagram, computed tomography and two esophageal high-resolution manometry (HRM) studies 4-8 months apart. The Chicago classification 4.0 was used for HRM diagnosis. SARS-CoV-2 infection was documented through at least one positive reverse transcriptase polymerase chain reaction (RT-PCR) test. Demographics, history of anti-SARS-CoV-2 vaccination, Eckardt scores (ES) were also recorded. A step-up therapeutic approach was applied and evaluated.

All patients received proton pump inhibitor (PPI-20mg rabeprazole od) therapy as a first step. If dysphagia and/or vomiting persisted or the patient experienced bolus impaction then pneumatic dilatation (PD) with a rigid 30mm balloon was applied. If dysphagia persisted despite PD then the patient underwent 35mm-PD or per-oral endoscopic myotomy (POEM), based on personal preference and anesthesia eligibility. In the occurrence of type III Achalasia, POEM was offered as second-line treatment. Informed consent was obtained from all patients.

Results: Thirty-two patients (23 females; mean age±SD: 61±8years) were included, eighteen with new-onset dysphagia (median ES:6) and fourteen with aggravation of pre-existing dysphagia (median ES:8 vs 3). All patients with new-onset dysphagia had EGJ-oo whereas those with pre-existing dysphagia exhibited either type II (N=13) or type III (N=1) Achalasia. A female predominance was evident in the EGJ-oo group (female:male ratio of 2.7:1). Achalasia patients exhibited higher median IRP values compared to the EGJ-oo group: 23.1(1.5) vs 17.4(1.7) (P<0.001). In patients with EGJ-oo, dysphagia resolved under PPI treatment over a median(IQR) of 4(2.2) months: IRP 13.4(1.2) vs 17.4(1.7) at baseline (P<0.05). PPI treatment was not effective in the group with pre-existing dysphagia (P=0.8) therefore PD at 30mm was applied in 13 patients and POEM in one patient with type III Achalasia.

Interestingly, all patients within the PD-treated Achalasia group required further treatment escalation either PD at 35mm (N=6) or POEM (N=7) for resolution of symptoms. In the 35mm-PD group ES dropped from 8 to 3 (P<0.05) whereas in the POEM-treated group ES dropped from 8 to 1 (P<0.05). POEM was more effective in reducing symptoms compared to 35mm-PD (P=0.003).

Conclusion: Based on HRM, two post-COVID-19 dysphagia phenotypes can be identified each requiring different management. New-onset dysphagia is associated with EGJ-oo and seems to resolve under PPI over time. On the contrary, post-COVID-19 aggravation of dysphagia corresponds to type II or III Achalasia and requires aggressive endoscopic treatment either PD with a larger caliber balloon or POEM, with the latter yielding more favorable results.

GUT MICROBIOTA IS ASSOCIATED WITH PERSISTENCE OF LONGER-TERM VACCINE IMMUNOGENICITY AFTER TWO DOSES OF BNT162B2

K.S. Cheung[1], H.Y. Ng[2], Y. Liao[3], R. Zhang[4], K.H. Chan[4], F. Li[3], W.-K. Seto[1], I.F. Hung[1], T.T. Lam[3], W.K. Leung[1]

Contact E-Mail Address: mongolhorse2002@gmail.com

Introduction: Gut dysbiosis reduces immunogenicity of non-COVID-19 vaccines. While immunogenicity of BNT162b2 wanes with time, factors influencing durability of vaccine immunogenicity are underinvestigated.

Aims & Methods: Aim: We aimed to investigate association between gut microbiota composition and longer-term immunogenicity of BNT162b2. Methods: This was a prospective cohort study recruiting adult BNT162b2 two-dose recipients from three vaccination centers in Hong Kong. Exclusion criteria included prior COVID-19, gastrointestinal surgery and immunocompromised status. Blood samples were collected at baseline and day180 after first dose, and tested for neutralising antibody (NAb) against receptor-binding domain (RBD) of wild type SARS-CoV-2 virus using chemiluminescence immunoassay. NAb seroconversion (defined as >=15 AU/mL) was determined at day180. Those with NAb 75th percentile and <75th percentile were classified as high- and low-responders, respectively. Stool samples were collected at baseline, followed by DNA extraction and shotgun metagenomic sequencing by Illumina NovaSeq 6000 platform. Relative abundances of microbial taxa were compared between high- and low-responders. Alpha-diversity was estimated by observed species, Shannon and Simpson indices, and compared between the two groups using Wilcoxon signed-rank test. Beta-diversity was compared by non-metric multidimensional scaling (NMDS). Linear discriminant analysis (LDA)-Effect Size (LEfSe) was performed to identify stool bacterial species and metabolic functional pathways with LDA score >=2. Multivariable logistic regression adjusting for clinical factors (including age, sex, diabetes mellitus, overweight/obese) was used to derive adjusted odds ratio (aOR) of persistently high vaccine response with bacterial species.

Results: Of 242 BNT162b2 recipients (median age:50.2 years [IQR:42.5-55.6];male:85 [35.1%]), 232 (95.9%) remained seropositive at day180. 61 (25.2%) of vaccine recipients were persistent high-responders (median NAb level:205.4 AU/mL; IQR:164.6-291.3) while 181 (74.8%) were low-responders (median NAb level:40.9 AU/mL; IQR:25.8-66.4). The baseline demographics were comparable between the two groups (all p>0.05). There was no difference in the alpha and beta diversity between the two gropus (all p>0.05). Ruminococcus bicirculans, Parasutterella excrementihominis, and Streptococcus salivarius were more abundant in high- than low-responders (0.9% vs 0.1%, 0.08% vs 0.02%, 0.06% vs 0.04%, respectively), while Bacteroides thetaiotaomicron was less abundant (1.1% vs 2.1%). Consistently, LEfSe showed that R. bicirculans (log_{10}LDA score=3.65), P. excrementihominis (score=2.82), and S. salivarius (score=2.31), were enriched in persistent high-responders, while B. thetaiotaomicron was enriched in low-responders (score= –3.70). On multivariable analysis, bacterial species including R. bicirculans (aOR:1.87;95% CI:1.02-3.51), P. excrementihominis (aOR:2.20;95% CI:1.18-4.18) and S. salivarius (aOR:2.09;95% CI:1.13-3.94), but not clinical factors, were associated with persistent high response. R. bicirculans positively correlated with metabolic pathways enriched in persistent high-responders, including superpathway of L-cysteine biosynthesis (score=2.25) and L-isoleucine biosynthesis I (score =2.16), which are known to benefit immune system.

Conclusion: Potential microbial markers for longer-term BNT162b2 immunogenicity were R. bicirculans, P. excrementihominis, S. salivarius and B. thetaiotaomicron. Quantitative polymerase chain reaction (qPCR) will be performed in a validation cohort.

Contact E-Mail Address: beyzasepin@gmail.com

Introduction: Non-alcoholic Fatty Liver Disease (NAFLD), is a state of hyperinflammation which is associated with release of pro-inflammatory cytokines. Obesity, diabetes and metabolic syndrome, which are usually accompanied by hepatosteatosis, are risk factors for severe Covid-19 infection.

Aims & Methods: We aimed to investigate the association of hepatosteatosis and liver fibrosis by non-invasive markers (FIB-4 and APRI) with the prognosis of Covid-19 disease among hospitalized patients. In this retrospective and observational study, 500 patients with the diagnosis of Covid-19 between March 2020 and March 2022 and underwent Thorax Computed Tomography (CT) were included. Demographics, clinical characteristics and laboratory data at admission were recorded. Liver-spleen attenuation value difference (CT_{L-S}) was obtained from CT images and non-invasive fibrosis markers as APRI and FIB-4 scores were calculated (1). Advanced fibrosis was defined as FIB-4>2.67, APRI≥1. Severe outcomes were defined as either intensive care unit (ICU) admission or mortality.

Results: Among the patients, 129 (25.8%) were admitted to the ICU, and mortality occurred in 53 (10.3%) cases. According to CT_{L-S} value, hepatosteatosis was in 32.6% of the cases. 82.8% of cases with hepatosteatosis were male, mean age was 52.6±13.5, 82% were overweight or obese. Hypertension and diabetes were the most common comorbidities. Among ICU patients, hepatosteatosis was found in 41.8% and ICU admission was associated with hepatosteatosis (p=0.002). Of the patients with hepatosteatosis, 58% of patients have FIB-4>1.3 and of these, FIB-4 and APRI score were significantly high in patients with ICU admission and mortality (p=0,001). Of the patients both with hepatosteatosis and advanced fibrosis, 71% were admitted to the ICU, mortality was seen in 32.5%. Mortality was significantly higher in patients with hepatosteatosis and advanced fibrosis according to the FIB-4 score (p=0.001). In the ROC analysis, combination of FIB-4 score and attenuation had highest sensitivity (sensitivity: 88.37%; Negative Predictive Value 90.85%; p=0.001) in determining the need for ICU need. The need for ICU follow-up was found to be 5 times higher in patients with a high FIB-4 score and low attenuation value [(Odds ratio (OR) 5.101; 95% Confidence Interval (CI): 2.865-9.083)]. The risk factors for the need for intensive care in patients with hepatosteatosis were advanced age, presence of fibrosis, high ferritin and IL-6 level in univariate analysis, whilst only high ferritin level was defined as a risk factor in multivariate analysis. Inflammation markers such as IL-6 and ferritin were significantly higher in patients with hepatosteatosis and fibrosis.

FIB-4		<1,30	1,30-2,67	>2,67	p
ICU follow up, n (%)	+	14 (20.3)	18 (28.6)	22 (71.0)	0,001 *(Fisher Freeman Halton Test)*
Mortality, n (%)	+	3 (4.3)	2 (3.2)	10 (32.3)	0,001 *(Fisher Freeman Halton Test)*
Duration of hospitalization, days	*Median*	8 (2-35)	10 (1-87)	24 (6-70)	0,001 *(Mann Whitney U Test)*

Table 1: Duration of hospitalization, ICU admission and mortality according to FIB-4 score in patients with hepatosteatosis.

Conclusion: Hepatosteatosis and fibrosis determined by non-invasive tests were found to be associated with severe Covid-19 infection. Hepatosteatosis and fibrosis may increase inflammation-related markers such as ferritin and IL-6 and may create a synergistic effect with infectious conditions. Likewise high ferritin level in Covid-19 patients with hepatosteatosis is a risk factor for severe disease. $CT_{L\text{-}S}$ and fibrosis scores have strong negative predictive value in the diagnostic evaluation for severity of Covid-19 disease.

LIVER AND COVID-19 - NEW INSIGHTS AND EARLY PROGNOSTIC MARKERS

L. Aratari[1], T. Schilling[2], L.U. Krauss[1], A. Mehrl[1], K. Gülow[1], V. Pavel[1], M. Müller-Schilling[1], S. Schmid[1]

[1]University Hospital Regensburg, Internal Medicine I, Regensburg, Germany, [2]Klinikum Stuttgart, Interdisziplinaere Notaufnahme, Intensivstation, Stuttgart, Germany

Contact E-Mail Address: Stephan.Schmid@ukr.de

Introduction: COVID-19, as a systemic disease, critically affects the liver and biliary system. Secondary sclerosing cholangitis (SSC) is an increasing complication in critically ill patients. After severe COVID-19 infection, the occurrence of bile duct changes resembling the picture of SSC has been increasingly observed. The early prognosis of COVID-19-associated SSC has not been adequately studied.

Aims & Methods: The aim of this study is to investigate the effects of COVID-19 on the liver in relation to previous hepatic disease, as well as to identify early prognostic markers for the course of disease in patients and the development of any complications. 261 patients treated in intensive care units of the University Hospital Regensburg and suffering from COVID-19 were analyzed in different groups. The classification was based on the presence and type of previous hepatic disease. Laboratory and clinical parameters collected during hospitalization included values at the time of admission and maximum values that developed during hospitalization. These were evaluated concerning mortality rates and the development of COVID-19-associated SSC in the different patient groups.

Results: Patients with pre-existing chronic liver disease had a hazard ratio for death of 2.045 (p=0.0446) compared to patients without chronic liver disease. The hazard ratio for death was higher for patients with pre-existing chronic liver disease than for patients with malignant disease (HR=1.986, p=0.0135) or dialysis requirement on ICU admission (HR=1.732, p=0.034). In all groups, mortality was also significantly correlated with an increase in liver enzymes during hospitalization. High bilirubin (p=0.002) or INR (p=0.018) levels on admission also correlated with increased mortality, independent of pre-existing hepatic disease. Among the entire cohort, the cause of death was associated with COVID-19 in 90.8%. In addition, the risk of developing COVID-19-associated SSC increased with the duration of ECMO therapy and correlated significantly (p=0.004) with high AP levels on admission.

Conclusion: This study demonstrates the potent effects of COVID-19 on the liver and biliary system and potential complications in patients with and without pre-existing chronic liver disease. Bilirubin and INR could serve as predictive factors for mortality. AP could be considered an early predictor for the development of COVID-19-associated SSC in patients with COVID-19. In the future, this will provide crucial clues for an optimized treatment strategy, including ventilation and sedation.

CHANGES IN THE MICROBIOME AND THE EFFECTS OF A SYNBIOTIC INTERVENTION IN HOME-QUARANTINED PATIENTS WITH MILD SARS-COV-2 INFECTION: A RANDOMIZED, DOUBLE-BLIND, PLACEBO CONTROLLED, TELEMEDICINE STUDY (SYNCOV STUDY)

A. Horvath[1,2], N. Feldbacher[1,2], K. Buchegger[1,2], V. Stadlbauer[1,2]

[1]Center for Biomarker Research in Medicine, Graz, Austria, [2]Medical University of Graz, Graz, Austria

Contact E-Mail Address: angela.horvath@cbmed.at

Introduction: The novel coronavirus (SARS-CoV-2) not only caused respiratory infections but led to gastrointestinal manifestations in a considerable amount of cases, with diarrhea being the most common symptom. Due to the intestinal involvement in the course of the disease, probiotics were suggested as potential adjuvant treatment.

Therefore, we conducted a totally remote telemedical study in patients with COVID-19 disease in home quarantine in order to investigate COVID-19-related microbiome changes and test the effect of a multispecies synbiotic on respiratory symptoms, gastrointestinal quality of life and the microbiome composition.

Aims & Methods: Thirty patients were randomized to a 30-day intervention with Ecologic AAD (Winclove, Amsterdam, The Netherlands) or a placebo in a 2:1 ratio. Respiratory and gastrointestinal symptoms were documented in 2-10 day intervals via an online survey tool using the acute respiratory tract infection questionnaire (ARTIQ) and the gastrointestinal quality of life index (GIQLI), respectively. Five stool samples were taken during the study period. Patients were asked to conserve the sample in provided DNA stabilizer tubes and return them via mail at the end of the study for 16S sequencing.

Results: Of 30 recruited patients, 26 finished the study per protocol, 10 of these patients were allocated to the placebo group (4 male/6 female; 34.1±9.6 years), and 16 patients to the synbiotics group (6 male/10 female; 39.4±13.1 years). Patients reported respiratory symptoms and a decreased in their gastrointestinal quality of life which both improved significantly during the study irrespective of the synbiotic intervention. The microbiome composition showed significant alterations in comparison to non-infected controls during the pandemic (p=0.002). These alterations were mainly characterized by an increase in Bacteroidetes and a decrease in Christensenellaceae, Ruminococcaceae and Gammaproteobacteria taxa. Although the synbiotic intervention showed a significant modulation of beta-diversity in treated patients (p=0.001) and a stable introduction of the probiotic strain E. faecium W54, COVID-19-related taxa were not affected.

Conclusion: Patients with mild COVID-19 disease in home quarantine showed respiratory symptoms, reduced gastrointestinal quality of life and changes in the microbiome, but did not benefit clinically from a synbiotic intervention in this phase of the disease.

SEVERE COVID-19 INFECTION CAUSES LONG-TERM ALTERATIONS OF THE GUT-LIVER AXIS

A. Horvath[1,2], A. Polyak[1,2], B. Prietl[1], V. Pfeifer[1], H. Habisch[2], I. Balazs[1,2], N. Feldbacher[1,2], S. Kofler[1,2], K. Buchegger[1,2], T. Madl[2], V. Stadlbauer[1,2]

[1]Center for Biomarker Research in Medicine, Graz, Austria, [2]Medical University of Graz, Graz, Austria

Contact E-Mail Address: angela.horvath@cbmed.at

Introduction: A proportion of patients who contracted a severe COVID-19 infection suffer from post-acute disease.

Aims & Methods: In order to understand the role of the gut-liver axis in this setting, we compared a large panel of patient reported outcomes and biomarkers related to respiratory symptoms, gastrointestinal and health-related quality of life, routine blood work, gut permeability, innate and adapted immune response as well as the intestinal microbiome and metabolome of patients who previously suffered from severe COVID-19 disease (sCOV, n=21) to patients after mild COVID-19 disease (mCOV, n=10) in a crosssectional study.

Results: sCOV patients were studied on average 318 days after the infection, mCOV patients after 221 days (p=0.013) and even after this period of recuperation, sCOV patients reported lower general health (p=0.026), physical functioning (p<0.01) and more lower-airways symptoms (p=0.031) in validated questionnaires compared to mCOV patients.

In general, sCOV patients were older (p=0.031), had more comorbidities (p=0.02), higher BMI (p<0.01), and higher rate of arterial hypertension (p=0.023) although being physically more active (p=0.035), had lower serum albumin (p<0.01), total protein (p<0.01), serum calcium (p=0.02), and estimated glomerular filtration rate (p=0.022), but higher fasting glucose levels (p<0.01) compared to mCOV patients.

Increased serum diamine oxidase levels (p=0.017) indicated increased intestinal permeability, impaired neutrophil function with impaired directedness of chemotaxis (p=0.035), and lower ROS production in response to E. coli (p<0.01) indicated a dysfunction of the innate immune system. Higher of effector memory cells (p=0.009), terminally differentiated effector memory cells (0.035), CD3+ CD4+ T - cells (p=0.013) and CD45RA negative memory cells (p=0.028) and on the other hand and lower marginal zone B cells (p=0.021), central memory cells (p=0.024), immature T helper cells (p=0.031) and CD161 positive cytotoxic T cells (p=0.04) in sCOV compared to mCOV patients indicated an altered adaptive immune response. Gut microbiome sequencing revealed lower microbial richness (p<0.01) and reorganization of Ruminococcaceae and Lachnospiraceae families, potentially a long-term sequelae of the acute disease.

Serum metabolome analysis showed higher glycoprotein to supramolecular phospholipid composite ratio (p<0.05), indicating inflammation, and lower levels of small-medium sized HDL particles (p<0.05) in sCOV patients. Stool metabolome analysis showed lower glycine and lactulose levels (p<0.05), and higher asparagine (p<0.001) and glycocholic acid (p<0.01) levels in sCOV patients. Multi-omics factor analysis showed higher VLDL particle number and predicted higher glucose and mannose metabolism capacity in sCOV patients.

Conclusion: This study highlights the differences in biomarkers of the gut-liver axis in patients who previously had severe COVID-19 disease. The gut-liver axis may be a potential source of biomarkers and a therapeutic target in COVID-19 disease.

Disclosure: AH and VS received speaker honoraria and research grants from Institut Allergosan.

HOW TO RAISE AWARENESS AND FIND OUR WAY TO MORE SUSTAINABLE GI ENDOSCOPY

M. Aerts[1], H. Reynaert[1], I. Colle[2]
[1]UZ-Brussel, Department of Gastroenterology and Hepatology, Jette, Belgium, [2]ASZ, Department of Hepatology and Gastroenterology, Aalst, Belgium

Contact E-Mail Address: maridi.aerts@uzbrussel.be

Introduction: The healthcare sector generates millions of tonnes of waste worldwide each year and GI endoscopy is one of the largest contributors (1).

Despite the proven negative health and environmental impacts of incineration, many European public health agencies and national governments still require incineration as the only safe waste management solution for hospitals' waste (2).

In November 2022, we started a project around waste management in our endoscopy unit. Until then we did not segregate any of our waste except dangerous medical material such as needles, medication and potentially infectious and toxic products. Moreover, even this segregation, seemed to have different interpretation rules in different hospital departments.

This lack of segregation and separate waste streams causes that the quantity of waste categorised as hazardous is unnecessarily much higher than it needs to be, increasing not only the environmental impact of disposal methods, but also the financial costs of disposal and treatment.

The large majority of waste produced by the healthcare sector (approximately 85%), however, is actually non-hazardous and similar to domestic waste i.e. much of it can be easily recycled. Over 50% of non-hazardous waste from hospitals is paper, cardboard, and plastics, while the rest comprises discarded food, metal, glass, textiles, and wood (3).

Aims & Methods: We want to raise awareness about the amount of waste produced in a GI endoscopy room and its environmental impact. Moreover, we want to investigate whether most non-hazardous waste from our department is potentially recyclable or compostable.

Finally, we would like to promote practices that reduce the volume of waste generated and ensure we can do a proper waste segregation in our endoscopy rooms.

We planned on measuring the amount of residual waste during 3 months in 3 different endoscopy rooms and kept track of the procedures that were done during that period. After these 3 months, we would start to segregate waste and measure again our different bins. To make this segregation possible we placed in every endoscopy room 3 different bins: 1 for residual waste, 1 for plastics and 1 for non-confidential paper and cardboard.

By measuring and calculating the difference, we would like to motivate our medical and nursing staff to continue doing this small effort with enormous results.

Results: In December 2022, January 2023 and February 2023 we collected 205,98 kg, 197,3 kg and 205,22 kg for 606, 583 and 545 endoscopies, respectively. We have now closed our first segregation month, March 2023 and we measured 190,8 kg for 565 endoscopies from which 144,78 kg was residual waste, 38,7 kg were plastics and 7,32 kg was non-confidential paper and cardboard.

The biggest problem we encountered was the training of our staff how to choose the right bin since there is a big difference between munipicial and hospital waste. We will continue to measure for another 3 months and provide training and workshops to our staff.

Conclusion: After one month of segregation, we found that we were able to lower residual waste by 24%. Problems we encountered during our process were the training of our staff and the different segregation policies we have, in combination with the fact that certain categories of waste require specific approaches. The current sustainability metrics and guidelines, though confusing sometimes, offer a unique opportunity to take the first step to the so needed sustainability transformation. Sustainability reporting allows a company to first observe its environmental footprint and then improve its business model and operations.

Introduction: As the demand for advanced endoscopy procedures grows worldwide, endoscopy units specializing in these procedures face significant challenges in meeting this demand with limited resources. Consequently, there is an urgent need to optimize endoscopy unit efficiency. Previous studies have highlighted non-procedural factors, including room turnover, as a key area to improve efficiency.

However, turnover time in advanced endoscopy units varies considerably across the world. To address this issue, our study aims to compare turnover time in different regions globally to identify best practices for enhancing endoscopy unit efficiency.

Aims & Methods: We conducted a retrospective chart review of endoscopic procedures performed between January 2022 and November 2022 in five centers (two in the US, one in Italy, and one in Ecuador) to collect data. Both inpatient and outpatient procedures were included. We categorized the procedures into three groups based on their regions: US, Europe, and Latin America.

Turnover time was defined as the time elapsed from one patient leaving the room until the next patient entering the room. Procedure time was defined as the duration from the first scope being inserted to the last scope being removed. We used t-tests to compare the turnover time between the different regions.

Results: Our study analyzed a total of 1,200 cases from three different regions: US (n=910), Italy (n=107), and Ecuador (n=183). Some patients underwent multiple procedures during the same session (Table 1).

Among the US group, 34% of procedures were ERCP, 23% were EUS, 23% were EGD, and 14% were colonoscopies. Out of the 910 cases, 655 (73%) were performed on an outpatient basis.

The average turnover time for the US group was 39.5 minutes, and the average procedure time was 45 minutes. In the Italy group, 35% of procedures were ERCP, 47% were EUS, and 8% were EGD. Out of the 107 cases, 61 (57%) were performed on an outpatient basis.

The average turnover time for the Italy group was 11.6 minutes, and the average procedure time was 42 minutes. Within the Ecuador group, 31% of procedures were ERCP, 32% were EUS, and 4% were EGD. Out of the 183 cases, 141 (77%) were performed on an outpatient basis.

The average turnover time for the Ecuador group was 15.7 minutes, and the average procedure time was 131 minutes. In 47 cases (25.7%), more than one endoscopy procedure was performed during the same session. Comparing the results, the US group had a significantly higher turnover time by over 20 minutes compared to the other regions ($p < .00001$). However, there was no significant difference in the number of EUS and ERCP procedures between the groups.

Country	US (N = 910)	Italy (N=107)	Ecuador (N = 183)
Advanced Endoscopy Procedures	884 (97%)	41 (38.3%)	119 (65%)
General Endoscopy Procedures	25 (3%)	66 (61.7%)	64 (35%)
Inpatient	246 (27%)	46 (43%)	42 (23%)
Outpatient	655 (73%)	61 (57%)	141 (77%)
ERCP (Including EUS/ERCP)	307 (34%)	37 (35%)	57 (31%)
EUS	212 (23%)	50 (47%)	58 (32%)
EGD	208 (23%)	8 (8%)	82 (45%)
Colonoscopy	125 (14%)	12 (11%)	72 (39%)
Other	58 (7%)	0	3 (2%)
Turnover time (min)	39.5	11.6	15.7
Scope in-out time (min)	45	42	131

Conclusion: The results of our study demonstrate a significant difference in turnover time between the US and Italy/Ecuador despite similar numbers of EUS and ERCP procedures and comparable or lower procedure times. With a difference of over 20 minutes, this highlights the urgent need for optimizing the efficiency of endoscopy units in the US. To achieve this, further comparative studies between the US and international centers are necessary.

Our findings provide a valuable starting point for developing best practices and strategies to enhance endoscopy unit efficiency and meet the growing demand for these procedures.

EXPLORING THE ASSOCIATION OF ANXIETY AND DEPRESSION WITH GASTROINTESTINAL DISEASES IN THE CONTEXT OF BEHAVIORAL TRAITS AND SOCIOECONOMIC STATUS

L. Huang[1], X. Tao[2], L. Wu[1]
[1]Renmin Hospital of Wuhan University, Wuhan, China, [2]Wuhan University, Wuhan, China

Contact E-Mail Address: wu_leanne@163.com

Introduction: Individuals affected by anxiety and depression are more likely to be affected by gastrointestinal (GI)diseases. Understanding the mechanisms underlying the association between mental and GI diseases can have critical translational implications across different scenarios.

In this study, we designed an observational trial to explore the association of anxiety and depression with gastrointestinal diseases in the context of behavioral traits and socioeconomic status.

Aims & Methods: We recruited patients undergoing screening GI endoscopy from September 22, 2022 in Renmin Hospital of Wuhan University, investigated their anxiety and depression level by questionnaires including Patient Health Questionaire-9 (PHQ-9) and Generalized Anxiety Disorder (GAD-7), and collect their baseline information, including behavioral traits, socioeconomic status, and H. pylori infection, etc.

The including criteria included:

1. Patients who can read, understand and sign informed consent forms;
2. Patients who receive gastrointestinal endoscopy examinations;
3. Patients who can understand the study, and are willing and able to complete all the procedures with follow-up visits.

The excluding criteria included:
1. Patients who have been diagnosed with gastrointestinal tumors before this endoscopy (esophagus, stomach: low grade neoplasia, high grade neoplasia, cancer; colorectal: high grade neoplasia, cancer);
2. Patients with other serious physical diseases (such as severe cardiovascular and cerebrovascular diseases, organ failure, etc.);
3. Patients who have had major stress incidents in the past two weeks;
4. People who are addicted to drugs, alcohol or drugs.
After GI endoscopy, all the endoscopic diagnosis of patients were collected. Finally, patients with different levels of anxiety and depression were compared according to their endoscopic diagnosis with behavioral traits and socioeconomic status using chi-square test and t-student test.

Results: From September 22, 2022 to March 23, 2023, 4947 patients who met the including criteria were recruited in Renmin Hospital of Wuhan University with 156 patients excluded according to the excluding criteria. Finally, 4791 patients were included for analysis. 3109 patients received upper GI endoscopy while 1682 patients received lower GI endoscopy. Patients with depression disorder were associated with higher incidence of gastric polyp (18.88% vs. 23.58%; PHQ-9≤4 vs. 4<PHQ-9≤9; p=0.030), colorectal polyp (52.78% vs. 65.79%; PHQ-9≤4 vs. 9<PHQ-9; p=0.027) and a higher body mass index (23.03 vs. 23.85; PHQ-9≤4 vs. 9<PHQ-9; p=0.009). Patients with anxiety disorder were associated with higher incidence of reflux esophagitis (16.20% vs. 27.78%; PHQ-9≤4 vs. 9<PHQ-9; p=0.023). Patients who suffering from colorectal polyps tended to be male (52.79% vs. 42.69, p=0.000) with obesity (BMI 23.89 vs. 22.99, p=0.000). And a relatively lower income was also associated with higher incidence of colorectal polyps (p=0.032).

Conclusion: Individuals affected by anxiety and depression are more likely to be affected by GI diseases like reflux esophagitis and colorectal polyps. And different socioeconomic status can also devote to several GI disease like colorectal polyps. Even though current evidence was dependent on endoscopy diagnosis, it helps us to understand the interplay among psychiatric disorders, behavioral traits, socioeconomic status in GI disorders and to develop more efficient programs to reduce the risk of GI diseases.

OPEN ACCESS UPPER GASTROINTESTINAL ENDOSCOPY: A 4-YEAR EXPERIENCE AT AN ACADEMIC MEDICAL CENTRE

Y.B. Tan[1], N.A. Binte Johari[1], C.H. Lim[1], J.P.E. Chang[1], M.T.K. Tan[1]
[1]*Singapore General Hospital, Singapore, Singapore*

Contact E-Mail Address: tanyubin89@gmail.com

Introduction: Open access oesophagogastrodudenoscopy (OAO) is defined as the performance of oesophagogastrodudenoscopy procedures requested by referring physicians without a prior gastroenterology clinic consultation. With the ever increasing demand for specialist outpatient clinic appointments, the use of OAO have increased to reflect the drive to reduce healthcare costs via decreasing potentially unnecessary clinic visits. This also allows endoscopy to be scheduled and performed in a more timely fashion.

Aims & Methods: The aim of this study is to highlight and evaluate our experience in providing OAO services to patients with non-alarming dyspepsia symptoms under the age of 60 years old.

The records of patients scheduled for OAO from Jan 2019 to Dec 2022 at Singapore General Hospital (SGH) Department of Gastroenterology & Hepatology were reviewed and analyzed.

The inclusion criteria for OAO included patients within the age of 21 to 60 years old with non alarming dyspepsia symptoms such as reflux, heartburn, recurrent abdominal pain and bloating. Exclusion criteria include patients who are physically unfit, patients at higher risk of endoscopy (severe ischemic heart disease/cardiac devices/heart valve replacements, severe pulmonary disease, poorly controlled hypertension or diabetes, acute coronary syndrome or stroke within the last 6 months, difficult airway issues, anticoagulation users) or those that require urgent endoscopy (signs of gastrointestinal bleeding).

Results: A total of 569 patients were scheduled for OAO and 436 patients underwent the procedure. The mean age of patients was 45.7 (SD = 10.9) years old. 36% were males while 64% were females and in terms of racial demographics, there were 82.9% Chinese, 4.3% Malay, 7.7% Indian and 5.1% Others.

The median waiting time to endoscopy was 23 days (IQR 16-36) and there were no major adverse events reported. More than half of the endoscopies were unremarkable (231, 53%). There were 25 (5.7%) patients with major findings, 3 had gastric/oesophageal adenocarcinoma, one had incidental varices and 21 had peptic ulcer disease. There were 180 minor findings which includes gastritis, hiatal hernias, esophagitis, polyps, duodenitis. Rapid urease test was conducted for 409 patients and 55 (13.4%) returned positive. One-fifth of the patients were given a Gastroenterology follow-up appointment (85, 19.5%) after the oesophagogastrodudenoscopy.

Fifteen patients, representing only 2.6% of the total patients referred, were rejected over the last 4 years as they did not meet the inclusion criteria for OAO.

Scheduled OAO	569
Actualized OAO	436
Median actual scope time (IQR)	23 (16-36) days
Normal Findings	231
Major Findings	25
Gastric/Oesophageal Adenocarcinoma	3
Varices	1
Peptic Ulcer Disease	21
Minor Findings	180
Adverse Events	0

Table 1: Outcome Measures & Findings.

Conclusion: OAO is a safe and effective strategy in providing timely oesophagogastrodudenoscopy to low risk patients at our centre. Of the 436 patients that underwent OAO, 5.7% had major findings. There were no major adverse events. Compliance to our inclusion and exclusion criteria was also good. Hence, polyclinics are encouraged to refer patients under 60 years with non-alarming dyspepsia to OAO.

Introduction: Propofol administration managed directly by the gastroenterologist is a sedation regimen, which is broadly spreading, in clinical practice in Endoscopy Units (EU) all over the world [1]. This is primarily due to a very high patient and endoscopist satisfaction. Moreover, fears associated with propofol use by non-anesthesia providers are based on sound theoretical principles. Non-anesthesiologist-administered-propofol (NAAPS) managed by the gastroenterologist is an issue still controversial for many anesthesiologist societies.

Aims & Methods: This study aims to analyze safety outcomes between NAAPS sedation and anesthesiologist-assisted deep sedation during endoscopic procedures for low-risk patients. We retrospectively assessed data from low anesthesiologist risk-patients (American Society of Anesthesiologists I-II), undergone esophagogastroduodenoscopies (EGDs) and colonoscopies under NAAPS sedation, and assisted anesthesiologist-deep sedation, between May 2019 and October 2021, in a tertiary center.

Primary outcome was to compare sedation related-adverse events rates between NAAPS and deep sedation. Propensity score matching analysis was performed using sex, age, Body Mass Index (BMI), smoking, comorbidities and time examination in order to standardize baseline variables.

Results: Overall, in colonoscopies subset, 2491 patients were managed under NAAPS and 257 patients under deep sedation, whereas in EGDs subset, 2439 patients were managed under NAAPS and 282 patients under deep sedation. In unmatched analysis, no difference was shown in terms of adverse events rates between NAAPS and deep sedation, both in EGDs and colonoscopies subsets (1.8% vs 3.5%; p=0.202 and 1 vs 0,4%, p=0.815, respectively).

After matching, EGDs subset analysis comprised 282 procedures in NAAPS group versus 188 in deep sedation group, whereas colonoscopies subset included 256 patients in NAAPS group and 174 in deep sedation group. Matched analysis revealed non-different adverse events rate between moderate and deep sedation groups (colonoscopies 3.5% vs 0.6%, p=0.249 and EGD 0.4% vs 1%, p=0.452, respectively).

Conclusion: NAAPS during endoscopy represents a safe sedation modality, comparable with safety outcomes of anesthesiologist-assisted deep sedation. Cost-efficacy analyses are needed, in order to highlight economic advantages of non-anesthesiologist management of propofol during endoscopy.

Introduction: Disorders of Gut-Brain Interactions (DGBIs), such as functional dyspepsia (FD) or Irritable Bowel Syndrome (IBS) are common in patients with Hypermobile Ehlers-Danlos Syndrome/Hypermobile Spectrum Disorder (hEDS/HSD)[1]. Healthcare utilisation (HCU) is high in DGBIs but no study to date has looked at HCU or healthcare costs (HCC) in patients with hEDS/HSD and these DGBIs.

Aims & Methods: To calculate the healthcare costs associated with patients with hEDS/HSD and FD and/or IBS.

A cross-sectional study was performed. Patients completed a ROME IV, SF6 (quality of life questionnaire) and HCU questionnaire. The latter was adapted from the IBD Boost study[2] and included consultations, admissions, clinically assisted nutrition and hydration (CANH), medications and personal expenses over 6 months. Costs were calculated based on the National Schedule of NHS Costs[3] and NHS Business Services Authority Prescription Cost Analysis[4]. Patients were grouped based on ROME IV diagnoses of FD and IBS. Chi-squared was used for categorical data. The Kruskal-Wallis test was used for continuous variables. A multivariate regression analysis was performed to see what healthcare characteristics were the strongest predictors of rising HCCs. In view of the multiple comparisons p<0.005 was considered significant.

Results: 660 hEDS/HSD patients completed the study; 92.9% were female, median age 39 years. 90(13.2%) had IBS only, 197(29.0%) had FD only, 212(31.2%) had both FD and IBS and 161(23.7%) had neither IBS nor FD. Table 1 describes and compares HCU across the 4 groups. There were significantly more outpatient visits, admissions and CANH use in patients

with FD±IBS. Total HCC per patient was significantly higher in patients with both FD and IBS (£3622.15) and FD only (£3782.82) compared to IBS only (£1610.12,p<0.001) and neither IBS nor FD (£1376.34,p<0.001). Consultations and admissions contributed to the majority of total HCC (31.3% and 27.4% respectively). Rheumatology and Gastroenterology were the commonest secondary/tertiary services used. CANH was used in 37.6% of patients with FD only and 29.2% of patients with both FD and IBS and accounted for 11% and 7% of total HCC in these DGBI groups respectively. The 10 highest HCCs (£21,653.80-£99,983.90) were in patients with FD±IBS, and they all required an inpatient admission.

The average SF6 in patients with FD±IBS (0.253) was significantly lower than in patients with IBS only (0.511,p<0.001) or those with neither IBS nor FD (0.519,p<0.001). 22.0% of the entire cohort had a score less than 0, which is a quality of life worse than death.

The adjusted R^2 value of the regression model used to determine what factors independently correlated with rising HCCs was 0.527. The variables significantly predicted rising HCCs, F(31,557)=3.775, p<0.001. ‚Polypharmacy' and ‚Employment Status' were the greatest predictors of rising healthcare costs (β=-0.209, p<0.001 and β=-0.121,p=0.003 respectively).

	Neither IBS nor FD (n=161)	IBS only (n=90)	FD only (n=197)	Both FD and IBS (n=212)	p-value (comparing differences across all groups)
Median number of outpatients visits per patient(range)	4(0-104)	7.5(0-84)	9(0-135)	9(0-102)	<0.001
Number(%) with ≥1 admission	8(5)	2(2.2)	33(16.8)	26(12.3)	<0.001
The median number of investigations per patient(range)	2(0-12)	3(0-8)	2(0-10)	2.5(0-11)	0.742
Number(%) on CANH	16(9.9)	8(8.9)	74(37.6)	62(29.2)	<0.001
The median number of medications per patient(range)	6(0-18)	7(1-17)	6(1-17)	7(1-23)	0.132

Table 1: Comparison of HCU in hEDS/HSD with and without FD and IBS over 6 months.

Conclusion: In hEDS/HSD patients, those with FD±IBS had the highest HCU and HCC highlighting the need to prioritise the development of cost-effective services for those with foregut disorders.

Introduction: Increasing infectious rate estimates and low microbiological surveillance affect safety of gastrointestinal endoscopy globally. Single use endoscopes and accessories have been claimed to improve safety, but there is lack of data on their indication and sustainability.

We aimed to identify a series of best practice recommendations for the use of single use endoscopes and accessories using a modified Delphi.

Aims & Methods: Consensus statements for the use of single use endoscopy and accessories were developed using a modified Delphi process, utilizing an international endoscopist expert panel of 62 experts from 33 nations. The main steps in the process were selecting the consensus group, conducting systematic literature reviews, developing statements, and anonymous voting on the statements until consensus was reached. High-risk patients were defined as those with multi-drug-resistant infections, immunosuppressive medication or chemotherapy, post-transplantation, or with severe neutropenia.

Results: Twenty-six statements were voted upon through two rounds, the statements were categorised as single use accessories, clinical indication for single use endoscopes, technical factors, environmental issues, and financial implications addressing relevant areas of patient safety, infection, climate change and cost. Of the 26 statements, 17 statements reached consensus.

Category 1: single use accessories (8 statements), related to defining recommendations for the use of single use accessories in all patient populations or high-risk patients.

Category 2: clinical indication for single use endoscopes (9 statements), including indications to high-risk patients, protecting the endoscope apparatus and contamination measures in endoscopy units.

Category 3: technical factors (4 statements), related to superior performance and technical specifications with the new innovation.

Category 4: environmental issues (2 statements), concerning mechanisms that reduce the detrimental burden to the environment.

Category 5: financial implications (3 statements), related to healthcare policies, cost neutrality and other financial associations of single use endoscopy.

Conclusion: This is the first international initiative in determining clinical indications for single use endoscopy and accessories.

The study's findings should serve as a framework for future physicians to guide future research and aid the proper evidence-based indications for the implementation of single use endoscopes in clinical practice.

DOES THE CLINICAL ASSESSMENT SERVICE HELP WITH OUTPATIENT CAPACITY AND PATIENT PATHWAY?

E. Brothwood[1], C. Tai[1], P. Giuffrida[1], K. Besherdas[1]
[1]Royal Free London, Gastroenterology, Enfield, United Kingdom

Contact E-Mail Address: besherdasdr@hotmail.com
Introduction: A clinical assessment service (CAS), was introduced replacing choose and book for primary care referrals. The CAS service involves assessment of referrals letters from primary care and triaging to see consultants in the outpatient department (OPD), or arranging diagnostic investigations and a virtual review of the investigations to decide on the management plan thereafter.
Aims & Methods: We describe the initial experience of this new service with aims to enhance the patient pathway, reduce unnecessary outpatient appointments and speed up diagnosis and treatment.
A single centre, retrospective analysis of all routine OPD referrals to the gastroenterology department at a district general hospital in North London triaged via CAS from January to end December 2022, were scrutinized. During this period, 1-2 CAS clinics (24 patients triaged per clinic)/week was undertaken. Triage outcomes included : straight to test (STT), clinic review, redirect to an alternative service or discharge back to GP. A template outcome letter was sent to GPs and patients.
Electronic Patient Record (EPR) was interrogated for : reason for referral, triaging outcome, investigations requested, and investigation outcomes.
Results: 2265 patients were assessed.
CAS triage outcomes were : 680 patients (30%) were triaged to receive an OPA; 68 patients (3%) were redirected to another service. 20 patients were discharged back to their GP, having already been investigated for the same indication by another department. The remainder were sent for an investigation.
The commonest investigations were : gastroscopy (684), colonoscopy (288), combined gastroscopy and colonoscopy (171), CT scan (198), MRI (45).
959 patients (42%) required a first OPA either from point of triage or after they have had an initial STT investigation.
973 patients (43%) were discharged from the pathway following STT without requiring a clinic appointment.
The most common reasons for referral were: abdominal pain, dyspepsia, reflux symptoms or diarrhoea.
Conclusion: From this study we conclude, CAS model helps streamline the patient pathway with nearly 70% of patient triaged STT without requiring an OPD appointment. 43% of patients were discharged back to care of their GP after investigations without the need for an OPD appointment increasing capacity for OPD appointments. We endorse the use of this model of care for gastroenterology patients referred within the routine pathway.

A DEEP LEARNING-BASED, REAL-TIME IMAGE REPORT SYSTEM DURING LINEAR ENDOSCOPIC ULTRASOUND

X. Li[1], L. Yao[1], H. Yu[1]
[1]Wuhan University, Department of Gastroenterology, Renmin Hospital of Wuhan University, Wuhan, China

Contact E-Mail Address: 2711523477@qq.com
Introduction: EUS is one of the most important tools for imaging and accessing the pancreatic biliary system. The followed endoscopic reports are essential but varied in quality, which impacted the diagnosis and the follow-up clinical decision. We aimed to construct a real-time endoscopic ultrasound automatic image report system (EUS-AIRS) for generating high-quality image reports.
Aims & Methods: Eight Deep Convolutional Neural Networks (DCNN) models were integrated to achieve four main functions for EUS-AIRS. The four models of standard station capture module are optimized on the basis of previous work. For lesion capture and Fine-Needle Aspiration (FNA) biopsy procedure capture function, 27807 images were used to train and test. 53344 image pairs from 80 patients were applied to trian and test the three-mode classification model to realize the differentiation of benign and malignant lesions.
Results: In video verification, EUS-AIRS achieved 86.40% accuracy and 79.55% coverage rate in capturing standard stations. In image verification, the accuracy of lesion capture model, FNA biopsy procedure capture model and were 91.4% and 79.8%, respectively. The accuracy of the three-mode differential model for benign and malignant lesions was 82.9%. The design diagram for the AI report is shown in Figure 1.
Conclusion: EUS-AIRS could generate qualified image reports in real-time. It could be a powerful tool to help ultrasonic endoscopists to generate high-quality endoscopic reports in real clinical practice.

AN IMPROVED MEASURE OF AUTOMATIC SPEECH RECOGNITION PERFORMANCE IN CLINICAL SETTINGS

J. Shor[1], R.A. Bi[2], S. Venugopalan[3], S. Ibara[1], R. Goldenberg[4], E. Rivlin[4]
[1]Verily Life Sciences, San Francisco, United States, [2]MIT, Cambridge, United States, [3]Google, Mountain View, United States, [4]Verily Life Sciences, Tel Aviv, Israel

Contact E-Mail Address: joelshor@google.com

Introduction: Clinicians in a number of disciplines work in an overburdened healthcare system that leads to difficult working environments and an epidemic of physician burnout [1].

AI-related technologies have the potential for improving efficiency on repetitive tasks, therefore increasing both patient throughput and decreasing physician burnout. For example, physicians often spend as much time doing paperwork as with patients [2].

Automatic Speech Recognition (ASR) could be leveraged to reduce the amount of the paperwork. However, the adoption of speech technology in the medical community has been slow [3].

The most common metric for measuring ASR performance, Word Error Rate (WER), has significant practical drawbacks.

First, all mistakes are treated equally. In clinical settings, however, medical words are more important (e.g. “had complete resection” -> “had complete c-section” is a worse mistake than -> “has complete resection”, but both have equal WER).

Second, some mistakes affect the overall intelligibility more than others (e.g. “was no perforation” -> “was no puffer age” vs “was not any perforation”). Although researchers have proposed alternatives to the WER, no metric combines medical domain knowledge with recent AI advances in language understanding.

In this work, we present a new metric for evaluating the usability of medical transcription and show that it outperforms existing metrics on clinically relevant sentences.

Aims & Methods: Our proposed metric, the Clinical BERTScore (CBERTScore), combines the BERTScore [5] and the medical subset of the Knowledge Graph in a novel way. We inject medical information into this metric in two ways. First, we compute a weighted score on a subset of words involving medical terms, as determined by the Knowledge Graph [4]. Second, we tune the weight of the clinical term penalty to best match a clinician transcript dataset (CTP) that we collected.

The CTP is a collection of 18 clinician preferences on 150 medical phrases. The phrases were derived from what gastroenterologists said when dictating their procedures (ex. “We see a sessile 3mm hyperplastic polyp.”). Clinicians were shown a ground truth phrase and two “transcripts,” both with different mistakes. In this initial study, two clinicians were each asked which transcript was more useful, or whether they were equally useful. We measure the performance of CBERTScore and other metrics by how well they agree with clinician preferences.

Results: CBERTScore agreed with clinician preferences the most (75.4% agreement), as compared to BERTScore (66.7%), METEOR (53.4%), BLEU (24.6), and WER (10.5%). Notably, WER is the worst at determining which transcript clinicians think will be more useful. In addition, CBERTScore was not worse on non-medical text, indicating that it is useful for evaluating transcripts in a general setting. We make the preference dataset publicly available.

Conclusion: CBERTScore, a novel metric that combines medical domain knowledge and recent advances in AI, may more closely indicate clinically relevant ASR accuracy than other existing metrics. This metric warrants further validation towards becoming the primary metric to train and evaluate speech features in clinical settings.

IS COMBINATION OF DEEP LEARNING AND ENDOSCOPIC ULTRASONOGRAPHY A VALID ADJUNCT TO THE DIAGNOSIS OF MEDIASTINAL AND INTRA-ABDOMINAL LYMPHADENOPATHY? A RETROSPECTIVE SINGLE-CENTER TRIAL

Z. Fan[1], G. Cheng[1], W. Wu[1], L. Xu[1], J. Li[2], D. Hu[1]

Introduction: The prediction of mediastinal and intra-abdominal lymphadenopathy poses a significant challenge, and definitive diagnosis is essential for treatment selection. Physicians performing endoscopic ultrasonography (EUS) can face difficulties in targetting suspicious lymph nodes, and lead unnecessary punctures when multiple lesions are present.

Aims & Methods: The aim of this study is to investigate the value of deep learning (DL) in aiding differentiating lymphadenopathy with EUS images. The retrospective single-center study included patients who underwent EUS for mediastinal or intra-abdominal lymphadenopathy from September 2016 to January 2023. Lymphadenopathy areas were outlined on EUS images for machine learning. UNet was selected for segmentation, and the classification was finished by k-Nearest-Neighbor approach and convolutional neural networks including ResNet 50, 101, 152 and DenseNet 121, 169, 201. Experts collected features of each lymph node for binary logistic regression analysis. The physician group, consisting of two experts and two beginners, reviewed EUS images from the validation set of the DL model and made respective diagnosis. Diagnostic efficacy was evaluated among these groups.

Results: A total of 200 suspicious lymph nodes with 630 EUS images from 93 patients were enrolled, and105 images were randomly selected as the validation set. ResNet 50 achieved a sensitivity of 95.38%, a specificity of 70.00%, an accuracy of 85.71%, and an area under the curve (AUC) of 0.827. The kappa statistic (kappa value=0.683) indicated substantial agreement compared to the final diagnosis. The logistic regression model

achieved a sensitivity of 81.54%, a specificity of 60.00%, an accuracy of 73.33%, and an AUC of 0.708. The kappa statistic (kappa value=0.424) indicated moderate agreement compared to the final diagnosis. The diagnosis by experts achieved a sensitivity of 73.85%, a specificity of 65.00%, an accuracy of 70.47%, and an AUC of 0.694. The kappa statistic (kappa value=0.383) indicated fair agreement compared to the final diagnosis. The diagnosis by beginners achieved a sensitivity of 58.46%, a specificity of 55.00%, an accuracy of 57.14%, and an AUC of 0.575. The kappa statistic (kappa value=0.129) indicated slight agreement compared to the final diagnosis. Paired sample comparisons of their receiver operating characteristic curves (ROC) showed that ResNet 50 outperformed the other three groups (P<0.05).

Conclusion: DL has certain reliability and feasibility in assisting differentiating mediastinal and intra-abdominal lymphadenopathy with EUS images, which effectively supplements the diagnosis from clinical experience and yields benefits.

Introduction: In recent years, various novel technologies have emerged to aid health care providers in optimizing patient management. Mixed Reality (MR) is an interactive, real-time processed, three-dimensional (3D) registered spatial computing technology that combines virtual (VR) and augmented reality (AR). Advantageous features of MR in endoscopy are the gesture operation and 3D spatial guidance, allowing more comfortable ergonomic interactions for GI endoscopists (translation and rotation) avoiding the need for touching monitors, increasing situational awareness, with a potential reduction or even replacement of monitors in the endoscopy suite.

Aims & Methods: We aim to evaluate the feasibility of mixed-reality holographic monitors in terms of interconnectivity and user's experience during endoscopic procedures. A non-blinded, non-randomized, interventional trial to assess the added utility and user's experience with MR was performed from November 2022 to March 2023 in a single tertiary center. The GI endoscopists used an MR system, a dedicated processor and software, paired with VR lenses during diagnostic procedures in adult patients. The primary outcomes were device technical assessment (interconnectivity and frame rate) and user's acceptance (comfort, functionality, and learnability), measured by the specialized platform and Likert scale, respectively.

Results: 30 operators used the dedicated software as replacement of the surgical monitors. 86.7% of the operators were males and the median age was 36 years (31 – 37). Fifteen esophagogastroduodenoscopies (50.0%), three cholangioscopies (10.0%), ten colonoscopies (33.3%), and two endoscopic ultrasounds (6.7%) were performed. One hologram was used in 90.0% of the procedures, two procedures used two holograms (6.7%), and one cholangioscopy used three holograms (3.3%). The operators' acceptance in terms of comfort, functionality, and learnability is summarized in table 1. The mean latency was 89.7 ± 2.87ms and the holograms performed at a 58.50 ± 1.11 frames per second (FPS).

	Very bad	Bad	Acceptable	Good	Very good
Gestures functionality	-	-	3/30 (10.0%)	18/30 (60.0%)	9/30 (30.0%)
Holographic Image Quality	-	3/30 (10.0%)	5/30 (16.7%)	16/30 (53.3%)	6/30 (20.0%)
Surgical field image through the lenses	-	-	4/30 (13.3%)	14/30 (46.7%)	12/30 (40.0%)
	Very bad	Hard	Acceptable	Easy	Very easy
Gestures learnability	-	-	3/30 (10.0%)	20/30 (66.7%)	7/30 (23.3%)
	Totally Disagree	Disagree	Neither agree nor disagree	Agree	Totally agree
Lenses Comfortability				22/30 (73.3%)	8/30 (26.7%)
Posture Comfortability		2/30 (6.7%)		23/30 (76.7%)	5/30 (16.7%)

Table 1. Summary of the Likert scales evaluating the users' acceptance for Mixed-Reality Holographic Screens in terms of comfortability, functionality, learnability, and image quality.

Conclusion: This dedicated system can replace surgical monitors within endoscopy units with good interconnectivity and FPS rate. Operators indicated that the software and hardware were comfortable and easy to use. Prospective studies assessing more cases with remote assistance and risk of potential complications should be performed for real-world evaluation of this MR system. NCT05640401.

Introduction: In recent years, there has been a surge in the development of artificial intelligence (AI) systems for endoscopic applications, such as Barrett's neoplasia detection and polyp characterization. While these systems have shown promising results, the vast majority is trained and validated on small, retrospective, single-center or expert-acquired data sets. Current AI systems are particularly prone to a so-called domain-shift: a system only performs well on data it has been trained on. As real-world scenarios in the endoscopy suite can be complex and diverse, the risk of poor generalization of AI should not be underestimated.

Aims & Methods: In this study we aim to provide a quantitative analysis of this domain shift and propose several strategies to improve generalization to clinical practice. We trained three AI systems for commonly used applications in gastrointestinal endoscopy, using publicly available data sets with high quality standards. In order to identify the limitations of these systems, all test sets were artificially degraded in a stepwise manner with clinically prevalent artifacts: blur, inadequate exposure and color variability. These degradations represent the heterogeneity of image quality in daily clinical practice. Severity of degradation was clinically calibrated by a panel of expert endoscopists.

Two levels of degradation were identified:

1. Mild degradation, still considered as high quality data;
2. Moderate degradation, considered as image quality that could still be encountered in daily clinical practice.

The trained models were subsequently evaluated for their appropriate performance metrics on the gradually degraded test sets. After implementation of several training strategies to mitigate potential performance loss, the models were re-evaluated on the same test sets.

Task (data set)	Training strategy	No degradation (AUC)	Mild degradation (AUC, percentage loss)	Moderate degradation (AUC, percentage loss)
Barrett neoplasia detection (in-house data set)	Standard training protocol	92.0%	87.4%, -4.6%	76.8%, -15.2%
	Domain-specific pretraining	95.1%	91.1%, -4%	80.9%, -14.2%
	Ensemble model	93.9%	89.9%, -4%	78.3%, -15,6%
Polyp detection (Kvasir)	Standard training protocol	84.9%	83.4%, -1.5%	74.5%, -10.4%
	Domain-specific pretraining	88.5%	87.6%, -0.9%	82.0%, -6.5%
	Ensemble model	85.9%	84.9%, -1.0%	77.3%, -8.6%
Polyp detection (Piccolo)	Standard training protocol	75.6%	59.4%, -16.2%	51.4%, -24.2%
	Domain-specific pretraining	81.3%	70.0%, -11.3%	63.4%, -17.9%
	Ensemble model	77.2%	72.6%, -4.6%	57.7%, -19.5%

Results: All three models display a considerable decrease in performance when exposed to various types of clinically relevant image degradation. Mean loss was 7.4% and 16.6% for respective mild and moderate degradation. Implementation of specific training strategies to improve robustness resulted in substantial reduction of performance loss on all degraded test sets.

Conclusion: This study highlights the potential limitations of current AI systems in endoscopic applications which may lead to poor generalization. Specific training strategies can mitigate this risk and improve robustness of these systems. Development of robust and reliable AI systems that deliver consistent and accurate performance is crucial to ensure safe implementation into daily clinical practice.

COSTS OF HOME-MONITORING BY TELEMEDICINE VERSUS STANDARD CARE MANAGEMENT OF INFLAMMATORY BOWEL DISEASE – A DANISH REGISTER-BASED FIVE-YEAR FOLLOW-UP STUDY

M. Al-sheikh[1], D.V. Ankersen[1], J. Olsen[2], M. Spanggaard[2], S. Stallknecht[2], C. Peters-Lehm[1], R. Naimi[1], M. Bennedsen[1], P. Munkholm[1], J. Burisch[3,1]

Contact E-Mail Address: Mette.bennedsen@dadlnet.dk

Introduction: Within Inflammatory bowel disease (IBD), cost-utility of telemedicine have only been evaluated in few short-term studies compared to standard care. Constant Care (CC) is a telemonitoring web app which has been implemented in North Zealand Hospital in Denmark since 2015. The aim of this study was to assess long-term cost effectiveness of remote telemedicine services (eCare) compared to standard care (sCare) for IBD patients during five years.

Aims & Methods: A retrospective register-based study was carried out among patients with ulcerative colitis (UC) and Crohn's disease (CD) continuously included in the telemedicine service CC in 2015-2020. Direct and indirect healthcare costs over a 5-year period were obtained from Danish registers and compared to a control group of IBD patients from all five regions in Denmark. Patients were matched 1:5 on year of birth, gender, education, income, disease, use of any biologics, duration of disease and Charlson Comorbidity index. These patients were divided into cohort 1: not recieving biologics and cohort 2: receiving biologics, on which direct and indirect costs were estimated on yearly basis from two years before inclusion in CC (the index year) and five years after using a linear regression model.

Results: A total of 572 IBD patients were included in the study and followed up in 5 years. In cohort 1 (62%), average total direct costs and total earnings were 14,703€ and 310,877€ in eCare compared to 17,119€ and 290,916€ in sCare.While in cohort 2, average total direct costs and total earnings were 76,366€ and 225,769€ compared to 31,456€ and 214,952€ in sCare. Analysis of PROs data of patients in CC through 5 years showed increasing QoL and was higher in cohort 1 than in cohort 2. While disease activity in CD patients, i.e. HBI was shown to be increasing after year 3 and 4 in cohort 1 and 2, respectively. Cohort 1 in CC were more adherent to medication compared to cohort 2.

Conclusion: Telehealth is cost-effective approach for patients not receiving biologics compared to sCare. However, biologics remain more expensive for patients in eCare. Remote tight control in terms of PRO measures in eCare improves quality of life and adherence to medication and possibly prolong time to relapse.

Introduction: Social media (SM) are part of our daily lives they allow experience exchange between doctors and offer new training perspectives. A large number of users, including endoscopists, are present daily on the SM.
Aims & Methods: Aim of the study:
Primary: Assess the use of SM by Gastro-enterologists (GE)
Secondary : Assess the impact of SM on learning and training.
Method: We led an international descriptive prospective study over 10 months using a self-administered form of 28 questions via Google Forms sent to Residents and specialists in GE
We collected data on Demographics, qualitative and quantitative data on the use of SM, appreciation of practitioners.
Data analysis was done by Jamovi software 2.2.5.
Results: We included 521 participants, all were using SM.
the median age was 35years [32; 48], The majority of participants were specialists 427(82%), 94(18%) residents.
514(98,7%) of the participants reported using SM also for learning purposes.
The average time spent on SM was 4.39±1.56 hours/day, of which median 2 H is devoted to learning.
YouTube was the most used SM for this purpose 431(82.7%), followed by WhatsApp 373(71,5%), Facebook 371(71.2%) and Instagram of 221(42.4%).
Social media were mostly used for Reviewing the details of an endoscopic technique 404 (77.5%) Searching for an image 361(69.2%) Searching for a guideline.
108 (20.72%)
472(90,5%) think that SM can improve their knowledge; however, 368(70,6%) of the participants think that they cannot evaluate the reliability of information through SM.
The advantages of SM use are complimentary access according to 47% of participants availability of information for 19% of participants and anonymity 9%.
Main limits were reliability of information 42% multiplicity of information 39% and distraction on SM 19%.
Conclusion: Most people are connected to SM. They became a learning channel making access to knowledge easier.
Our study shows the evolution of the use of SM, and its impact on training. Careful attention should be made on how to improve contents authenticity and reliability.
Disclosure: Nothing to disclose.

DISCRIMINATION OF THE DIFFERENTIAL EFFECTS OF SELECTIVE SUPPRESSION OF IL-6 TRANS-SIGNALING BY OLAMKICEPT IN MODERATE-TO-SEVERE ULCERATIVE COLITIS

O. Sternebring[1], N. Patidar[2], A. Ravi[1], R. Carcillo[2], A. Rivollier[1], M. Behar[2], S. Read[1], R. Szabady[3], J. Sørensen[4], P. D'Alessandro[2], P. Pinton[1]

Contact E-Mail Address: ola.sternebring@ferring.com
Introduction: IL-6 is implicated in the pathogenesis of ulcerative colitis (UC), however no IL-6 inhibitor has been approved for UC to date. Selective inhibition of IL-6 trans-signaling could ameliorate the deleterious, pro-inflammatory effects of IL-6[1], while preserving the homeostatic, tissue reparative activity of classical IL-6 signaling.
Olamkicept [2], a fusion protein consisting of two complete extracellular domains of gp130 attached to the Fc-region of an IgG_1 antibody, neutralizes IL-6 trans-signaling in vitro and has shown promising clinical effects in a recent randomized, double-blind, placebo-controlled phase II trial in moderate to severe UC (NCT03235752)[3].
Aims & Methods: The objective of this study was to characterize the biological effects resulting from selective inhibition of IL-6 trans-signaling using an in silico model of colonic inflammation.
A hybrid mechanistic-statistical computational model of colonic inflammation in UC was developed using published pre-clinical and clinical studies as well as internally generated in vitro pharmacology data[2-4]. The output of the model included changes in IL-6 signaling pathway components (IL-6, soluble IL-6 receptor, membrane-bound IL-6 receptor, soluble gp130, and STAT-3 phosphorylation), C-reactive protein (CRP), fecal calprotectin, adaptive immune cell (CD4+ T lymphocyte) sub-populations, cytokines, and chemokines. States of tissue damage and repair (healing) were estimated.
The performance of the model was tested against clinical data generated in NCT03235752[3] in which patients had been allocated to receive intravenous (IV) administration of 300 mg or 600 mg olamkicept or placebo every two weeks for 12 weeks.
Simulations assessing the differential effects of modulating trans- and cis-signaling were probed using pharmacological inhibitors of trans- (olamkicept, 300-1800 mg administered IV every 2 weeks) and pan-IL-6 signaling (IL-6 receptor inhibitor and a STAT-3 phosphorylation inhibitor).
Changes in concentrations of IL-6 signaling species and down-stream effects on immune cell sub-population levels were compared both in the systemic circulation and locally in the gut tissue.
The initial concentrations of the signaling species were based on those typically observed in UC patients[5].
Results: Based on the simulations, concentrations of free IL-6 in the systemic circulation were minimally impacted by exposure to olamkicept. In gut tissue, IL-6 concentrations decreased by approximately 10% at the highest olamkicept dose tested, returning to pre-treatment levels within a day post dose.
Suppression of IL-6 trans-signaling by olamkicept caused a transition away from aT_h17-rich state in gut tissue and attenuated inflammatory chemotactic signals in a dose-dependent manner. In comparison, the pan-inhibition of IL-6 signaling reduced T_h17 mediated inflammatory activity, however tissue healing pathways dependent on IL-6 cis-signaling were also suppressed.

Conclusion: In the developed in silico model of colonic inflammation, inhibition of IL-6 signaling was associated with attenuation of T_h17 mediated inflammation in the gut. Pan-inhibition of IL-6 signaling was associated with impaired tissue healing, however this was not observed for olamkicept, where homeostatic, classical IL-6 signaling was preserved.

This study provides quantitative support to therapeutic strategies targeting IL-6 trans-signaling in UC to reduce the cytokine's undesirable effects while preserving its beneficial functions.

TELEMEDICINE FOR SUSTAINABLE POSTOPERATIVE FOLLOW-UP: A PILOT STUDY EVALUATING THE HYBRID LIFE-CYCLE ASSESSMENT APPROACH TO CARBON FOOTPRINT ANALYSIS

J. Walshaw[1], R. Lathan[1], L. Hitchman[1], I. Chetter[1], M. Yiasemidou[2]
[1]Hull University Teaching Hospitals, Hull, United Kingdom, [2]Oxford University Teaching Hospital, Leeds, United Kingdom

Contact E-Mail Address: marinayiasemidou@gmail.com

Introduction: Surgical site infections (SSI) are the most common healthcare-associated infection however access to healthcare services, lack of patient awareness of signs, and inadequate wound surveillance may limit timely diagnosis. Telemedicine as a method for postoperative follow-up has been shown to reduce time, travel, and cost, without compromising clinical outcomes.

Furthermore, a significant contributor of CO_2e is attributable to patient travel, therefore the NHS must adopt innovative approaches to meet its net zero target by 2024.

Aims & Methods: This study aimed to provide a comprehensive analysis of the feasibility and sustainability of telemedicine post-operative follow-up for remote diagnosis of SSI.

Patients were reviewed remotely at 30 days with a combined outcome measure (photographs and validated questionnaire). A hybrid life-cycle assessment approach to carbon footprint analysis was used. The $kgCO_2e$ associated with remote methods was mapped prospectively.

A simple outpatient clinic review, i.e. no further investigations or management required, was modelled for comparison. DEFRA conversion factors amongst healthcare specific sources were used to ascertain $kgCO_2e$. Patient postcodes were applied to conversion factors based upon mode of travel to calculate $kgCO_2e$ for patient travel. Total and Median (IQR) carbon emissions saved were presented for both patients with and without SSI.

Results: 31 patients (M:F 2.4, 66.7±11.7 years) agreed to participate. The median return distance for patient travel was 42.5 (7.2 to 58.7) km. Median reduction in emissions using remote follow-up was 41.2 (24.5 to 80.3) $kgCO_2e$ per patient (P<0.001). The carbon offsetting value of this method is planting 1 tree for every 6.9 patients.

Total carbon footprint of face-to-face follow-up was 2895.3 $kgCO_2e$, compared to 1301.3 $kgCO_2e$ when using a remote first approach (P<0.001). Carbon emissions in participants without wound complications was 700.2 $kgCO_2e$ for clinic method and 28.8 $kgCO_2e$ for remote follow-up.

Conclusion: This model shows that the hybrid life-cycle assessment approach is achievable and reproducible. Implementation of an asynchronous digital follow-up model is effective in substantially reducing the carbon footprint of a tertiary surgical centre.

Further work is needed to corroborate these findings on a larger scale, quantify the impact of telemedicine on patient's quality of life and incorporating $kgCO_2e$ into the cost analysis of potential SSI monitoring strategies.

Disclosure: No conflict of interest.

PP1668

USEFULNESS OF VIRTUAL SCALE ENDOSCOPE FOR EARLY GASTROINTESTINAL LESIONS

N. Minakata[1], H. Ikematsu[1], F. Kiyomi[2], S. Inoue[3], T. Akutagawa[4], T. Watanabe[1], T. Yano[1], R. Shimoda[4]
[1]National Cancer Center Hospital East, Department of Gastroenterology and Endoscopy, Kashiwa, Japan, [2]Clinical Research Support Center Kyushu, Department of Statistics and Data Center, Fukuoka, Japan, [3]Saga University, Division of Gastroenterology, Department of Internal Medicine, Saga, Japan, [4]Saga University Hospital, Department of Endoscopic Diagnostics and Therapeutics, Saga, Japan

Contact E-Mail Address: nminakat@east.ncc.go.jp

Introduction: For early gastrointestinal lesions, size is one of the most important factors in the selection of treatment. Lesion size is generally estimated visually, but there are errors in the size estimated visually, which may cause problems in reproducibility and objectivity. Virtual Scale Endoscope (VSE) is newly developed endoscope that displays a virtual scale using the principle of triangulation, and has been reported to measure the size of polyps in a simulated colorectal phantom more accurately than visual estimate.

However, it is unknown whether VSE can accurately measure the size of the actual gastrointestinal lesions with various sizes and macroscopic types.

Aims & Methods: The aim of this study was to investigate whether the size of the resected lesion measured by VSE is close to the true size. We prospectively enrolled patients who had early gastrointestinal lesions of 20 mm or less visually at the preoperative endoscopic examination. Finally, all lesions were performed en bloc resection endoscopically. "The size of the lesion visually estimated in vivo through endoscopy before treatment in real time (visual size)", "The size of the resected lesion measured by VSE (VSE size)", and "The size of the resected lesion measured by ruler (ruler size)" were evaluated for each lesion.

The primary endpoint was the difference between "VSE size" and the true size, which was defined as "VSE error". The secondary endpoints were the difference between "visual size" and the true size, which was defined as "visual error", and the comparison of the variation between "VSE error" and "visual error".

The difference between the two groups was calculated as [100 x (estimated or measured size - true size) / true size] (%). The true size was defined as "ruler size". Variation between "VSE error" and "visual error" was analyzed by the F-test.

Results: 60 lesions were enrolled at two centers from April 2022 to December 2022. There were 20 lesions each in the esophagus, stomach, and colon. The mean lesion size ± standard deviation (SD) was 14.0 ± 6.3 mm. Macroscopic types were protruded type in 8 (13.3%) lesions, slightly elevated type in 24 (40.0%), and flat or slightly depressed type in 28(46.7%). 21 (35%) lesions were measured by expert and 39 (65%) were measured by non-expert before treatment. The mean "VSE error" ± SD was 0.3 ± 8.8 % and the mean "visual error" ± SD was -1.7 ± 29.3 %. And, "VSE error" were significantly less variable than "visual error" (p<0.001).

Conclusion: The measurement of lesion size by VSE is accurate and acceptable because it is closer to the true size and has less variation than visual estimation by endoscopists.

Disclosure: Virtual Scale Endoscope is provided by FUJIFILM for this study.

AN ASSESSMENT OF PATIENT READINESS TO ENGAGE IN DIGITAL PATIENT REPORTED OUTCOMES IN AN AUSTRALIAN INFLAMMATORY BOWEL DISEASE COHORT

T.H. Yiu[1], S. Rouse[1], C. Hausler[2], K. Curin[1], N. McGuinn[1], J. Petrunic[1], A.S. Nielsen[3], B. Rasmussen[4], E. Chow[1]

[1]Western Health, Gastroenterology, Footscray, Australia, [2]Monash University, Melbourne, Australia, [3]Deakin University, Melbourne, Australia, [4]Western Health, School of Nursing and Midwifery, Faculty of Health, Footscray, Australia

Contact E-Mail Address: elizabethchow@yahoo.com

Introduction: Studies have indicated Digitalized Patient Reported Outcome (PRO) can improve patients' health and well-being[1-2] with cost effective advantages compared with conventional disease surveillance[3]. To improve patient acceptance of digital PRO, health professionals need to achieve better understanding of factors that contribute to patients' readiness to interact with digital PRO systems.

These factors have been measured previously by a validated questionnaire developed by Kayser et al[4]- The ReadHy (Readiness and enablement index for Health technology).

Aims & Methods: The aim of this study is to use the ReadHy questionnaire to assess readiness of Western Health IBD patients to engage in digital PRO.

A descriptive, questionnaire-based, cross-sectional study was performed at Western Health IBD outpatient clinic between Nov – Dec 2022. IBD patients were recruited at the clinic in voluntary bases with readiness assessed via ReadHy questionnaire. Results were compared with AS Nielsen et al 2022[5], a Denmark study assessing readiness of PRO and non-PRO users. Domains examined included self-monitoring and insight, constructive attitudes and approaches, Skills and technique acquisition, emotional distress, feeling understood and supported by healthcare providers, social support for health, using technology to process health information, understanding of health concepts and language, ability to actively engage with digital services, feel safe and in control, motivated to engage with digital services, access to digital services that work and digital services that suit individual needs. K-means clustering was also performed to determine readiness profiles of patients.

Results: Western Health IBD cohort scored higher in most domains in compared to both PRO and non-PRO users in Nielsen et al cohort. According to Nielsen et al, a higher score correlates to PRO-readiness and the PRO user group scored higher on average than the non-PRO user group.

There is a statistically difference in "heiQ8 Emotional distress" domain of which patients in the PRO users scored higher than the non-users in Nielsen et al cohort. Western Health cohort had a mean score of 2.74 (SD 0.59), statistically lower than the PRO user group's mean of 3.06 ($p < 0.005$) but with no difference in compared with the non-PRO user group's mean of 2.77 ($p= 0.724$). The causation remained unclear as it could be that implementation of digital PRO resulted in reduction of emotional distress or patients with less emotional distress were more likely to participate in digital PRO.

Western Health IBD cohort is a younger population with higher rate of daily usage of information technology. As per findings of Nielsen et al and our k-mean clustering, younger participants with higher education level, higher use of electronic device in daily life and using search engine for health-related issues had higher readiness to engage in PRO.

Conclusion: Western Health IBD cohort had shown similar or higher readiness to digital PRO compared to the Nielsen et al PRO and non-PRO users' cohorts, suggesting Western Health IBD patients are ready for the implementation of digital PRO. Future research can be conducted in other Australian IBD centres to further assess digital PRO readiness in a national level.

EVALUATING THE IMPACT OF A GI GUIDELINES APP ON HEALTHCARE PROVIDER AWARENESS AND ADHERENCE: INSIGHTS FROM A SURVEY

A. Balduzzi[1], R. Pancheva[2], M. Te Groen[3], I.M. Gralnek[4], W. Khannoussi[5], G. Marchegiani[6]
[1]University of Verona, Unit of Surgery and Dentistry, Paediatrics and Gynaecology, Verona, Italy, [2]Medical University Prof Dr Paraskev Stoyanov, Hygiene and Epidemiology, Varna, Bulgaria, [3]Radboudumc, Department of Gastroenterology and Hepatology, Nijmegen, Netherlands, [4]Ha'Emek Medical Center, Gastroenterology, Haifa, Israel, [5]Mohammed VI University Hospital, Hepato Gastroenterology, Oujda, Morocco, [6]University of Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy

Contact E-Mail Address: giovanni.marchegiani@aovr.veneto.it

Introduction: The Quality of Care Taskforce of the United European Gastroenterology developed a GI Guidelines app to address the issue of healthcare providers struggling to keep track of the numerous available guidelines. The app provides easy access to updated guidelines on different fields of gastroenterology. This study aims to evaluate the app's impact on healthcare providers' awareness and adherence to guidelines through a survey

Aims & Methods: This study aims to evaluate the app's impact on healthcare providers' awareness and adherence to guidelines through a survey. The survey was disseminated to both app users and non-users, with 1377 responses collected. The questions were designed to provide valuable insights into the user base of the GI Guidelines app and the potential gap to be filled to improve current clinical practice. The participants' demographic information, including their sex, age, training status, years of practice, and geographic distribution, was collected. The survey also asked app users about their familiarity with the guidelines, their usage of the app, and its usability. Moreover, the survey solicited suggestions from app users on how to improve the app and what guidelines they would like to see included. Non-app users were asked about their use of guidelines in clinical practice and their reasons for not using the app.

Results: The survey results showed that the app was widely used by clinicians, with 975 out of 1377 app users reporting daily use. App users were most familiar with endoscopy, inflammatory bowel disease, and liver content guidelines. The app was perceived as user-friendly and easy to navigate, with a mean rating of 76.56 and a median of 80 (out of a max of 100). App users provided valuable feedback on how to improve the app, including content-related and technical improvements. Most non-app users still reported using guidelines in their clinical practice, emphasizing the importance of guidelines in healthcare.

Conclusion: The GI Guidelines app developed by the UEG QOC taskforce is a valuable tool for healthcare providers in their day-to-day practice. The survey results provide insights into the app's usage, its impact on healthcare providers' awareness and adherence to guidelines, and suggestions for its improvement. These insights can help the taskforce improve the app and increase awareness and adherence to guidelines, ultimately leading to better outcomes for patients with gastrointestinal disorders.

Disclosure: Nothing to disclose.

IMPROVING INNOVATION IN HEALTHCARE USING LOW-CODE/NO-CODE TECHNOLOGY: WAIKATO HOSPITALS ACUTE ELECTRONIC ENDOSCOPY TRIAGE AND REFERRAL SYSTEM, A SINGLE TERTIARY HOSPITAL EXPERIENCE

C. Kerrison[1], E. Zheng[1], A. De Souza[1], H. Johnston[2], J. Wong[1], F. Weilert[1]
[1]Waikato Hospital - Te Whatu Ora, Gastroenterology, Hamilton, New Zealand, [2]Waikato Hospital - Te Whatu Ora, IS Department, Hamilton, New Zealand

Contact E-Mail Address: clarence.kerrison@gmail.com

Introduction: Low-code/no-code (LCNC) applications are under-utilised as clinician-built solutions for daily hospital-based tasks. Waikato Hospitals endoscopy unit in Hamilton, New Zealand, on average receives five to twelve acute endoscopy requests per day. Prior to December 2021 all inpatient endoscopy requests for conditions such as gastrointestinal bleeding, were made on handwritten paper and faxed to the endoscopy unit. Following this the co-ordination and triage of multiple referrals occurred onsite from a single physical board. This created problems such as forms being lost, handwriting illegible and co-ordination and communication inefficient. Environmental sustainability was also a major concern regarding paper wastage.

Aims & Methods: We aimed to develop a referral and management system for acute endoscopy requests using LCNC technology. This would be built and maintained by the endoscopy staff and tailored to clinical and administrative needs. We used the Microsoft Power Platform, Power Automate and Power Apps, to develop this clinician-built triage and management system, alongside an electronic referral request for acute endoscopy from Clinical Work Station™ (Waikato Hospitals electronic medical records system). The system was developed by a Gastroenterology Trainee with experience in LCNC systems, and was developed with the endoscopy staff. The electronic referral system went live on 6th of December 2021.

Results: From December 2021 to August 2022, our clinician-built system had 4512 visits with up to 44 unique users monthly using the Microsoft PowerApp through mobile and desktop, either directly or through Microsoft Teams. The Microsoft Power App recorded 1201 new endoscopy referrals, of which 1007 (84%) endoscopies were completed, 56 (5%) duplicate referrals, 17 (1%) triaged to outpatient endoscopy and 111 (10%) declined or cancelled back to the referrer. 1177 (98%) referrals utilised the electronic notifications setting between clinicians, nursing and administration staff using push notifications, minimising the need for face-to-face contact and physically meeting.

The system eliminated paper waste, while also optimised patient care by real time co-ordination of referrals and improved documentation when making or changing triage decisions. Prior to December 2021 there were 15 steps from the patient presenting to hospital with a gastrointestinal bleed to having their endoscopy completed, now the process is shortened to seven steps, with instant upload of requests upon submission of an endoscopy request and real-time tracking. 10 endoscopy staff including 2 doctors and 6 endoscopy nurse co-ordinators provided positive feedback and support for its ongoing use during staff surveys.

Conclusion: The LCNC system we have developed is clinician focused, modified for our needs and is built on current Microsoft 365™ licencing, which does not incur extra costs to our hospital, and allows integration into Microsoft Outlook™ and Microsoft Teams™. In the short time our system has been online, it has demonstrated efficiency, sustainability, and safety for patient care with high levels of clinician satisfaction and has potential to be integrated to other hospitals with similar Microsoft 365™ licencing.

Disclosure: Nothing to disclose.

PP1672

AN AUTOMATED VIDEO ANALYSIS SYSTEM FOR RETROSPECTIVE ASSESSMENT AND REAL-TIME MONITORING OF ENDOSCOPIC PROCEDURES

Y. Zhu[1], P.-H. Zhou[2]
[1]Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Shanghai, China, [2]Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Fudan University, Shanghai, China

Contact E-Mail Address: zhuyan1992521@163.com

Introduction: Accurate recognition of endoscopic instruments facilitates quantitative evaluation and quality control of endoscopic procedures. However, no relevant research has been reported. In this study, we aimed to develop a computer-assisted system, EndoAdd, for automated endoscopic surgical video analysis based on our dataset of endoscopic instrument images.

Aims & Methods: Large training and validation datasets containing 45,143 images of 10 different endoscopic instruments and a test dataset of 18,375 images collected from several medical centers were used in this research. Annotated image frames were used to train the state-of-the-art object detection model YOLO-v5 to identify the instruments. Based on the frame-level prediction results, we further developed a hidden Markov model to perform video analysis and generate heatmaps to summarize the videos.

Results: After approximately 2,000,000 iterations on the training dataset, the performance of YOLO-v5 on the validation dataset was saturated. The model achieved high accuracy (>97%) on the test dataset for all 10 instrument types. The mean average accuracy, precision, recall, and F1-score were 99.1%, 92.0%, 88.8%, and 89.8%, respectively.

The receiver operating characteristic (ROC) curveshows that the detection module achieved satisfactory performance with an area under the curve (AUC) exceeding 0.94 for all instrument types. Among the endoscopic instruments, EndoAdd achieved the best discriminative results for the snare, hybrid knife, dual knife, IT knife, and APC (AUC=1.00) and performed worst for the injection needle (AUC=0.94).

Notably, 199 of the 703 injection needle images (28%) in the test dataset were misclassified as hybrid knives. We used EndoAdd in offline mode to generate heatmaps for the 6 POEM videos in the test dataset. The heatmaps shows the operating patterns by the senior and junior endoscopists. The heatmaps shows that the junior endoscopists used hot biopsy forceps more frequently, whereas the senior endoscopists often used them at the end of myotomy.

Moreover, the heatmap shows a longer background period for the junior endoscopists, reflecting that they may have spent more time changing the surgical instruments or adjusting the endoscopy during the procedure.

Conclusion: We successfully developed an automated endoscopic video analysis system, EndoAdd, which supports retrospective assessment and real-time monitoring. It can be used for data analysis and quality control of endoscopic procedures in clinical practice.

PP1673

HAND IN HAND COLON - GUIDANCE FROM A COORDINATING CARE NURSE

O. Kalnizki[1], N. Kizner[1], R. Gross[1]
[1]Assuta Medical Center, Gastroenterology, Ra'anana, Israel

Contact E-Mail Address: nofarki@assuta.co.il

Introduction: Hand in Hand Colon was founded to mitigate, expedite, streamline and optimize a patient's journey after undergoing a colonoscopy that unearthed a potential carcinoma. The project bridges the gaps prompted by the involvement of interdisciplinary fields from colonoscopy to diagnosis, surgery, oncological treatment and ultimately, recovery. The project, spearheaded and managed by coordinating care nurses, guides patients through the thicket of uncertainty, both bureaucratic; "where do I go now?" and emotional as patients take on the role of "cancer patient".

Services require a maze of services which can lead to miscommunications and trouble understanding and navigating through the medical system. Patients will need to wait for their biopsy results, meet with a surgeon, oncologist, or both, undergo medical imaging as well as understand what is going on around them, medical terms why they are meeting with specialists, why are they getting tests done and where all this will lead them.

Each of these steps presents the patient with obstacles: Israel's imaging availability is one of the lowest in the OECD, backed up labs, doctors work with different HMOs and available and short-wait appointments are hard to come by.

The project offers one-one-one guidance to each patient following colonoscopy with a suspicious finding by a coordinating care nurse. The nurse will guide patients through medical necessities while also presenting availability and information, supporting and easing on the overwhelmed patient.

Aims & Methods: The project is a centralizing source for the patient, working as a one stop shop: expediting results and appointments, prioritizing and clarifying medical requirements and lowering anxiety levels.

Ultimately, our goal is to achieve diagnosis early as to move forward with treatment and increase the chance of a favorable prognosis while also providing patients with the option to ask questions, understand what's going on and feel, somewhat, at ease, therefore also increasing patient responsiveness.

Results: The project began taking on patients in March 2022. The following only relates to the project at Assuta Raanana. As of January 2023, 72 patients have been referred to the site's coordinating care nurse, of them 92% have undergone expedited imagery, 46% have already undergone surgery, chemotherapy or both, 100% of biopsy analyses were submitted within two weeks and 100% of patients were contacted and offered service by the appointed nurse.

Since the project began, coordinating care nurses have participated in group sessions with expert clinicians receiving training and support on dealing with distraught patients given life changing news. Soon, nurses will also receive group sessions to work through their own emotions regarding their exposure and day-to-day work with cancer patients to manage stress, burn-out, tension and sorrow.

The nursing team works under the belief that a gastroenterological nurse's job does not begin and end with their accumulated knowledge, nursing skills, technical abilities but that these can work to adhere to the 6 C's of nursing as put forth by the NHS: care, compassion, communication, competence, courage and commitment that all come together to provide patients with the best and highest level of care possible.

Conclusion: Following our experiences during the project's first year of operation, we believe that a patient's success and overall experience can be bettered through this project.

Disclosure: Nothing to disclose.

PP1674

G-PLAY - DEVELOPMENT OF A GUIDELINE-BASED ONLINE-PLATFORM TO LEARN AND DISCUSS PERI-INTERVENTIONAL MANAGEMENT OF ANTICOAGULANTS IN COLONOSCOPY

T.J. Lux[1], A. Meining[1], A. Hann[2]
[1]University Hospital Würzburg, Internal Medicine II, Gastroenterology, Würzburg, Germany, [2]University Hospital Wuerzburg, Internal Medicine II, Wuerzburg, Germany

Contact E-Mail Address: lux_t1@ukw.de

Introduction: The continuous advancement of medical research has led to an increase in the number and extent of guidelines. However, adherence to these guidelines varies significantly, which may be attributed to individualized treatment, impracticality, lack of clinical impact, or insufficient information. The G-PLAY platform aims to generate reports linked to corresponding guideline recommendations and questions, enabling inexperienced users to learn and experienced users to identify discrepancies between theory and practice.

Aims & Methods: Our aim was to identify pertinent guidelines and gather the requisite information for developing a guideline-based quiz application specifically designed for peri-interventional management of anticoagulants in colonoscopy. To achieve this, we closely analysed the S2k guideline for quality standards in gastroenterology (preprint) and subsequently designed a Python-based web application in alignment with these guidelines. In addition to generating reports, the application captures user demographics, such as profession, experience, and location, enabling further subanalyses. We also incorporated a queuing algorithm to allocate questions based on the user's prior performance and the current distribution of answers for each question.

Results: Given the highly individualised nature of peri-interventional management of anticoagulants, we have formulated a structured report template that accommodates the most prevalent use-cases. The template encompasses various attributes, such as patient bleeding history, intake of relevant medication along with the indication, risk of thrombosis, and detailed information on the indication/planned procedures, including specifics about the size, location, and morphology of polyps. Users are prompted to specify whether and for how long anticoagulants should be paused. The automatically generated reports are tied to corresponding guideline excerpts. Upon answering a question, users can review the guideline excerpts related to the question, view answer statistics, and engage in discussions in the comment section.

Conclusion: G-PLAY is a free, modular, and open-source platform designed to enhance guideline knowledge among trainees and facilitate the identification of discrepancies between theory and practice among experts. The application has the potential to improve adherence to guidelines, ultimately leading to better patient care and outcomes. Visit info.coloreg.de/g-play for further information and beta access to the platform (starting 1st of June 2023).

Disclosure: Nothing to disclose.

Contact E-Mail Address: lynn_debels@hotmail.com

Introduction: Operator dexterity is recognised as a critical determinant of outcomes after surgery (1,2). No objective metric exists for the quality of endoscope tip manipulation (tip-control). We aimed to validate a tip control score in-vivo, using post endoscopic mucosal resection (EMR) snare tip soft coagulation (STSC) of the defect margin.

Aims & Methods: A web application containing a timed-score was used to record correct and incorrect applications (=hits) of STSC to the margin of defects after piecemeal EMR. Correct hits were visualised diathermy applications touching the defect margin.

2 blinded endoscopists scored sequential videos of STSC performed by consenting endoscopists. Correct hits/incorrect hits (=accuracy) and correct hits/second (=speed) were determined. Results were stratified by polypectomy complexity (SMSA[+] score)(3,4), difficulty of STSC application (independent movement of the colonic wall not explained by the movements of the endoscope [=movement artefact]) and experience of the endoscopist (expert vs fellows in endoscopy).

			Median Accuracy % (IQR) [95% CI]			Median Correct Hits/s (IQR) [95% CI]		
			Fellow	Expert	p	Fellow	Expert	p

		p	0.111	0.405		0.540	0.768	

*Table 1 Median accuracy and speed for fellows vs experts stratified by SMSA level and difficulty. IQR, Interquartile Range; CI, Confidence Interval; *Easy, no movement artefact; **difficult, movement artefact; SMSA, Size-Morphology-Site-Access score.*

Results: 39 STSC procedures performed by 10 endoscopists (3 experts, 7 fellows) were rated. 12 (30.8%) polyps were SMSA 2 or 3, 3 (7.7%) were SMSA 4, and 24 (61.5%) were SMSA+. 24 (61.5%) STSC procedures were categorised as difficult.

Median accuracy of STSC was 86.0% (interquartile range [IQR] 19.5, 95% confidence interval [CI] 77.0-91.0) and median speed was 0.175 (IQR 0.113, 95%CI 0.130-0.210). Accuracy strongly correlated with blinded expert im-

pression of the tip-control demonstrated in the video (correlation coefficient=0.81, P<.001). Movement artefact significantly adversely impacted both overall accuracy (P=.06) and speed (P=.05). Increasing SMSA score adversely impacted overall accuracy (SMSA 4 vs SMSA+, P=.04), but not speed (P=.61).

Fellows were significantly less accurate (76.5% vs 92.0%, P<.001) and slower (0.155 vs 0.202 hits/s, P=.02) vs experts in applying STSC. Movement artefact significantly impacted the performance of fellows (accuracy 68% vs 88%, P=.036, 0.151 vs 0.213 hits/s, P=.07) but not experts (P=.281 and P=.483). In procedures without movement artefact, performance of fellows and experts were similar (accuracy P=.106, speed P=.148). In SMSA+ polyp observations with movement artefact fellows were significantly less accurate than experts (80.0% vs 92.0%, P=.045) (table 1).

Conclusion: This is the first in-vivo description of a score for the quality of endoscope tip manipulation. Endoscopist accuracy and correct hits/second were inversely related to training status, polypectomy difficulty and degree of movement artefact when applying STSC.

The score ranges presented here could be used to benchmark endoscopists and fellows with respect to SMSA scores, guide progression through SMSA levels and correct tip-control scores for movement artefact due to patient breathing.

ONLINE EDUCATION SIGNIFICANTLY IMPROVED GASTROENTEROLOGISTS' UNDERSTANDING OF THE USE OF ULTRASOUND IN THE MANAGEMENT OF INFLAMMATORY BOWEL DISEASE

E. Bell[1], M. Calle[1]

[1]Medscape Global, London, United Kingdom

Contact E-Mail Address: ebell@webmd.net

Introduction: Intestinal ultrasound (IUS) offers a number of advantages over endoscopy in monitoring and managing patients with inflammatory bowel disease (IBD) but despite the wide availability of IUS, it remains underused to support decision-making in clinical practice.

Aims & Methods: We aimed to determine whether online accredited education could improve gastroenterologists' knowledge of best practice in the use of IUS to monitor and manage patients with IBD, and could enhance their confidence in using IUS in clinical practice.

Gastroenterologists participated in a 30-minute video lecture with synchronized slides and embedded IUS videos entitled 'Gastrointestinal Ultrasound in the Management of IBD'. Responses to 3 multiple-choice, knowledge questions and 1 self-efficacy, 5-point Likert scale confidence question were analyzed. Educational effect was assessed using a repeated-pair design, pre-/post-assessment. A paired samples t-test was conducted for significance testing on overall average number of correct responses and for confidence rating. A series of McNemar's tests were conducted at the question level (5% significance level, P <.05).

Cohen's d with correction for paired samples estimated the effect size of the education on number of correct responses (<.20 modest, .20-.49 small, .59-.79 moderate, ≥.80 large). The activity launched on 1 February 2021 with data collection through 12 April 2021.

Results: Gastroenterologists (n=195) significantly improved their knowledge of the ECCO-ESGAR guideline recommendations on the use of IUS in IBD (54% correct responses at baseline rising to 65% post-activity; P <.01), that stool content going in both directions in IUS is indicative of stricture (55% correct responses at baseline rising to 70% post-activity; P <.001), and that bowel wall thickness >4mm in a patient with Crohn Disease is the most sensitive IUS parameter indicating active disease i.e. treatment failure. (28% correct responses at baseline rising to 58% post-activity; P <.001)

The proportion of gastroenterologists answering all 3 questions correctly rose from 9% at baseline to 35% post-activity.

The average percentage of correct responses increased from 46% at baseline to 64% post-activity (P <.001), and there was a moderate educational impact (Cohen's d=0.60).

After completing the activity, 44% of gastroenterologists reported improved confidence in in interpreting IUS images to support the management of patients with IBD, resulting in a notable confidence shift of 79%.

92% of gastroenterologist responders felt the education would improve their performance, resulting in improved patient outcomes.

Conclusion: This online activity significantly improved gastroenterologists' knowledge and confidence in the use of IUS in IBD management. Gastroenterologists would likely benefit from additional education to embed their knowledge on the use of IUS and improve their confidence in interpreting IUS images to support decision-making in clinical practice.

Disclosure: Nothing to disclose.

Introduction: Endoscopic sphincterotomy (EST) is a critical procedure in cholangiopancreatic endoscopic practice. However, learning opportunities outside of actual patients are limited, and effective learning methods are needed to understand complications and ensure the correct flow of procedures. To address this, we developed EST simulator with a duodenal papilla composed of soft material and pseudo-vessel that mimics the bleeding complication under abnormal incision: other than the 11-12 o'clock direction or over cutting with the appropriate direction.

Aims & Methods: The aim of this study was to evaluate the effectiveness of the EST learning program which included hands-on training using this simulator.

First, trainees filled out pre-program questionnaire including the self-confidence and understanding of EST, and expectation for simulator learning. Before hands-on training with the simulator, trainees watched the instruction video. The video contained basic flow of EST procedure, how to control the duodenoscope, overview of EST devices such as guidewire/ cannula/ sphincterotomy knife/ a basket catheter, and introducing the simulator model. Then trainees freely attempted EST with the simulator once. After 1st trial, expert endoscopists gave the trainees feedback and 6 tips based on Bethesda ERCP Skill Assessment Tool (BESAT). Afterwards, trainees tried second EST procedure.

Finally, participants filled out post-program questionnaire. A successful EST was defined as a medium incision made in the 11-12 o'clock direction. Too small incision or causing bleeding complication was defined as fault. Primary outcomes were subjective score using the Visual Analogue Scale (VAS) between before and after the training program.

The evaluation of simulator training with feedback was compared the success rates of EST between 1st and 2nd trials. Statistical differences between the two groups were analyzed by the McNemar's Chi-square test for categorical variables. Wilcoxon signed-rank test for comparing VAS scores. A p value <0.05 was considered statistically significant. This study is registered as UMIN000044823 in UMIN Clinical Trials Registry.

Results: Thirty gastroenterology-related physicians completed the program, with a median age of 32 years, a median year of graduation of 6.5 years, and a median duration of endoscopic training of 57.5 months. Self-confidence in performing EST without the assistance of a senior physician also increased significantly from a median score of 24 before training to a median score of 53 after training. Furthermore, understanding of the procedures and devices increased significantly from a median score of 42.5 before training to a median score of 65 after training. The level of expectation for simulator learning using this model also increased significantly from a median score of 69.5 before training to a median score of 85.5 after training. The success rate of EST improved significantly from 43% on 1st trial to 77% on 2nd trial.

Conclusion: Education program with a novel EST simulator reproducing bleeding complication that combined with video learning of knowledge and the procedural flow, possibly contributes to improvement of skills and self-confidence.

USEFULNESS AND SATISFACTION OF THE THEORETICAL AND PRACTICAL COURSE ON BOWEL ULTRASOUND AT UEG SUMMER SCHOOL 2022

A. Costantino[1,2], C.-G. Af Björkesten[3], N. Zignani[4], F. Santagata[4], R. Penagini[2]

[1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Gastroenterology, Milano, Italy, [2]Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milan, Italy, [3]Helsinki University Hospital, Abdominal Centre, Hus, Finland, [4]University of Milan, Milan, Italy

Contact E-Mail Address: andreascostantino@gmail.com

Introduction: Bowel ultrasound is a cost-effective, non-invasive, and readily available tool for the clinical management of patients with inflammatory bowel diseases. Moreover, it can be an accurate tool for the assessment of patients with chronic and acute gastrointestinal (GI) disorders (e.g., abdominal pain and diarrhoea) in order to rule in and out organic causes. It is presently unknown how many GI residents have the opportunity of an ultrasound training period during their residency.

Aims & Methods: Aim of this study was to evaluate how a two-hour theoretical and hands-on learning course on bowel ultrasound has affected the ability of GI residents to correctly identify some basic physiological and pathological ultrasound findings.

The participants were GI residents from different Countries, who voluntarily chose to take part to the intestinal ultrasound course, one of twelve optional courses held during the two-day UEG Summer School in Prague in June 2022. The bowel ultrasound course, consisting of a 0.5-hour theoretical and a 1.5-hour hands-on part with bowel ultrasound performed on healthy volunteers ran eight times during the Summer School, with a maximal number of twelve participants per session.

Participants performed an initial test, consisting of answering ten questions contained in a digital anonymous questionnaire with Google Form (Google, Mountain View, USA) to recognize some basic anatomical structures and/or pathological ultrasound images of the enteric system. At the end of the two-hour course, participants completed a final test with the same initial questions and images.

Answers to each single question before and after the course were compared, by calculating the percentage difference in the number of correct answers.

A hypothesis test (McNemar's test) was then conducted to assess the statistical significance of the difference between the percentage of correct answers before and after the course.

Results: Among the 70 participants in the course, 48 answered all the questions and results refer to this group. Respondents were from 14 European and Mediterranean area Countries (56.3% women, 43.8% in their 4th year of residency); 60.4% of respondents stated they had an ultrasound training period during their residency.

Participants improved significantly after the course: differences between the percentage of correct answers before and after the test were significant (α = 5%) for seven out of ten questions (e.g., normal and thickened colon).

Eleven trainees had previous experience of performing bowel ultrasound or had previously taken part in a similar course. Answers given by the subgroup of participants (n = 37) who had never taken part in a bowel ultrasound course or performed a bowel ultrasound were similar: six answers out of ten showed a significant improvement.

Among the 48 residents, 95.8% self-reported to have improved their capabilities after the course, and every respondent (100%) would have recommended this course to a friend colleague.

Conclusion: Our data show a strong impact on the ability to identify basic anatomical structures and pathological images, such as thickened bowel wall, using bowel ultrasound after a brief theoretical and practical course. Although test and post-test surveys may have potential biases [1], the number of participants who responded appropriately to the questionnaire is greater or comparable to previous studies on ultrasound training. [2-5] Further studies should evaluate if the benefit of a brief course apply to practical examinations and is maintained in residents who do not actively perform intestinal ultrasound over time.

Contact E-Mail Address: fabiocortellini@yahoo.it

Introduction: In European Countries, abdominal ultrasound (US) is often considered a first-line diagnostic technique and an extension of clinical examination [1]. The interpretation of US and its accuracy is operator dependent and, in the absence of adequate training and continuous medical education, US probes may be a useless tool [2,3]. To fill this gap, The European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB) has developed guidelines to identify minimum training requirements for US examinations [4], with 300 exams needed to be a Level 1 sonographer.

In Italy, gastroenterologists have the possibility to learn abdominal US during medical residency or while attending private dedicated training courses. Nonetheless, there is no standardized training among Italian universities and many gastroenterologists acquire US skills only after their residency. This evidence points out the pitfalls of our educational system.

Aims & Methods: The aim of our survey was to identify the overall education and knowledge of abdominal US among young Italian gastroenterologists (<40 years old). For this purpose, we sent a questionnaire to young Italian gastroenterologists and residents in Gastroenterology (GI).

The Ultrasound Committee of the Italian Young Gastroenterologist and Endoscopist Association (Associazione Giovani Gastroenterologi ed Endoscopisti Italiani- AGGEI) distributed via e-mail to all its members (348) a web-based survey and multiple-choice test with images, based on the EFSUMB recommendations about minimum training requirements for a US examination [4].

The answers were collected anonymously and analyzed for distribution and correlations.

Statistical analysis was performed with STATA 13.0 (College Station, TX: StataCorp LP).

Results: The questionnaire was filled out by 110 participants (60 males, 54.5% aged <30) from all over Italy with a response rate of 31.6% Most of the respondents worked in Academic Hospitals and were GI residents or PhD students.

Among the participants, 58.9% learned US during their GI residency by other skilled residents and only 8.2% attended specific US courses. The great majority (90%) of respondents were currently working in a Unit with a US service. During their training participants performed a median number of 320 (IQR 20-1280) upper abdomen and 240 (IQR 20-640) bowel ultrasound examinations. A total of 39 did not perform any bowel US. More than half (55%) completed independently >300 abdominal US (Level 1 EFSUMB sonographer).

Seventy-four point five percent of respondents believe in the value of US education for their future clinical practice. At the univariate logistic regression, being >30 years old and working in a non-academic hospital were factors associated with a positive result in the questionnaire, with a statistically significant association (OR 2.406; 1.142–5.168, p<0.05). Multivariate analysis showed that the respondents who stated to feel confident in performing abdominal US independently had higher points on the test (OR 0.370; 0.161-0.850, p<0.05 at the multivariate logistic regression) (Table).

Factors associated with high scores (>14/22) in the test	n of respondents with high scores (%)	Univariate logistic regression (OR 95% CI)	p	Multivariate logistic regression (OR 95% CI)	p
Age					
<30	29/60 (48%)	0.970 (0.588-1.600)	0.906		
<40	36/50 (72%)	2.406 (1.142–5.168)	0.021		
Workplace					
Academic	44/82 (54%)	1.157 (0.750-1.787)	0.508	2.409	0.079
Not Academic	21/28 (75%)	2.590 (0.992-6.761)	0.052	(0.902-6.434)	
Clinical role					
GI Resident	43/79 (54%)	1.194 (0.767-1.859)	0.432		
Consultant	22/31 (71%)	2.046 (0.837-4.998)	0.116		
Do you feel confident in performing GIUS/UAUS independently? Yes	33/45 (73%)	0.352 (0.155-0.800)	0.013	0.370 (0.161-0.850)	0.019
US service in the GI unit	58/99 (59%)	1.237 (0.339-4.502)	0.747		
Do you believe that it is useful to perform UAUS or GIUS independently for a young GI specialist? Yes	24/28 (85%)	6 (1.912-18.82)	0.002		

Table. Uni and multivariate logistic regression for the evaluation of factors associated with higher scores in the multiple-choice test with images.

Conclusion: Most young Italian gastroenterologists believe US training has an important role for their education. However, their competence suffers from heterogeneous teaching.

GI Schools should provide standardized theoretical and practical (hands-on training and learning by doing) education for this essential examination.

Introduction: As a chronic condition, eosinophilic oesophagitis (EoE) requires lifelong therapeutic management and multidisciplinary care. Reports suggest clinicians managing EoE have gaps in knowledge and competence, which may lead to suboptimal patient outcomes. We aimed to assess whether a purpose-specific curriculum comprising a series of continuing medical education (CME) activities addressed these gaps.
Aims & Methods: Four faculty-led, CME-accredited activities on EoE were hosted on two free-to-access online medical education websites. Each activity provided 30–60 minutes of education in short videos and addressed learning objectives based on a review of published literature and expert insights. Educational outcomes were assessed using Moore's expanded outcomes framework Levels 1–4 (participation, satisfaction, knowledge, and competence, respectively). Intent to change practice and need for further education were also assessed. Level 1 data were captured using Google Analytics; Level 2–4 data were captured using pre- and post-activity questionnaires administered by an independent third party and analysed by the authors. Across the curriculum 21,032 participants engaged with the content, with a sample size of 800 available for the Level 2–4 analysis; the margin of error was calculated as ~3% based on a standard confidence interval of 95%.
Results: Within 12 weeks of launch, a mean of 5,258 participants engaged with each curriculum activity (Moore's Level 1). Mean satisfaction (Moore's Level 2) was high (87.3%) across the curriculum. From baseline to follow-up, significant average increases in declarative knowledge (24%, p=0.012), procedural knowledge (18%, p<0.001), and competence (16%, p=0.004) were observed (Moore's Levels 3a, 3b, and 4, respectively) (Table). Gastroenterologists had the highest proportion of correct answers at follow-up across all activities (86–95%). Allergists/immunologists had the largest increase in knowledge from baseline to follow-up (51%, activity 1); the smallest increase was seen for gastroenterologists (7%, activity 2). For all specialities, the lowest proportion of correct answers at follow-up was for questions on pathophysiology/causes of EoE (Table). Overall, 64% of learners would change their practice following participation in ≥1 curriculum activity and ~20% indicated further education would be beneficial.

			Baseline	Follow-up	P-value
Average proportion of clinicians answering questions correctly across the curriculum by Moore's level (%)	Level 3a (declarative knowledge)		63	87	0.012
	Level 3b (procedural knowledge)		74	92	<0.001
	Level 4 (competence)		75	91	0.004
Average proportion of clinicians answering questions correctly across the curriculum by speciality and question theme (%)	Pathophysiology of EoE	Immunologists/allergists	56	85	0.011
		Gastroenterologists	61	86	
	Chronic nature of EoE / need for long-term management	Immunologists/allergists	92	94	
		Gastroenterologists	87	97	
	Biologic treatments	Immunologists/allergists	79	92	
		Gastroenterologists	77	95	

Conclusion: This expert-led, CME curriculum led to significant improvements in clinician knowledge and competence surrounding the latest research and best practices in the pathophysiology, diagnosis, and management of EoE, which may lead to improvements in patient care and outcomes. Findings support further development of online, multiformat educational activities to address clinical knowledge and competence gaps. Future programs should focus on the underlying pathophysiology of EoE and how this may inform practice.

ADVANCING TREATMENTS FOR NON-ALCOHOLIC STEATOHEPATITIS (NASH) AND NON-ALCOHOLIC FATTY LIVER DISEASE (NAFLD): TRENDS AND OPPORTUNITIES

A. Bevan[1], A. Vignola[2], P. Figueroa[3], S. Blacoe[4], I. Facchini[5]
[1]PPD Part of Thermo Fisher Scientific, Peri-and Post-approval Studies and Real-world Evidence, Cambridge, United Kingdom, [2]PPD Part of Thermo Fisher Scientific, General Medicine, Wilmington, United States, [3]PPD Part of Thermo Fisher Scientific, Medical and Scientific Group, Pharmacovigilance Regulatory Affairs and Medical Writing, Austin, United States, [4]PPD Part of Thermo Fisher Scientific, General Medicine, Bellshill, United Kingdom, [5]PPD Part of Thermo Fisher Scientific, General Medicine, Munchen, Germany

Contact E-Mail Address: isabella.facchini@ppd.com

Introduction: Several factors, including increasing disease prevalence, high unmet need and growing understanding of the diverse mechanisms underlying disease pathogenesis are contributing to an increased interest in clinical research in NASH and NAFLD.

Aims & Methods: We undertook an analysis of metadata from Clinicaltrials.gov (CT.gov) to characterize trends over the last 10 years and what this may tell us about the future trajectory for treatment development. CT.gov was searched for studies containing the terms “NASH” or “Nonalcoholic Steatohepatitis” or “Nonalcoholic Fatty Liver Disease” or “NAFLD” or “NASH Cirrhosis” or “Fatty Liver Disease” or “Metabolic Steatosis” posted from 01-Jan-2013 and 31-Dec-2022. Expanded access programs were excluded as these were not considered research studies. 1095 records were returned, of which 32 were excluded as their focus was on conditions other than those of interest. 1063 studies in the analysis were divided into two equal periods: P1 - 2013 to 2017, and P2 - 2018 to 2022, and analyzed by study type, study phase, intervention type and funding.

Results: Studies increased 100% in P2 vs P1, with the most marked increase in early phase studies (108%). The majority of studies were interventional (798 [75%]), which increased by 91% in P2. Observational studies also increased markedly in P2 (131%). Drugs were the most common study intervention (39%), increasing by 98% in P2. There was also a notable increase in the number of diagnostic studies in P2 (871%), the majority of which were studies of non-invasive methods for staging liver fibrosis. 64% of studies were non-industry funded, which increased by 82% in P2. Industry funded studies increased by 140%, with the largest increase in the biotech sector (174%).

Conclusion: Our data provides evidence of a marked increase in clinical research activity in NASH and NAFLD in the last 5 years, particularly in early phase drug development and non-invasive diagnostic methods as an alternative to liver biopsy for staging fibrosis. This combined with the finding that most research has been non-industry funded suggests a growth in basic science that may translate into an increase in industry research in the future. This is supported by the finding that industry funded studies have increased more sharply than non-industry in the last 5 years.

ENDOSCOPIC TIP CONTROL - A SIMPLE, EX-VIVO MODEL WITH POTENTIAL FOR ENDOSCOPIST BENCHMARKING AND TRACKING OF PROGRESS OVER TIME

L. Debels[1], S. Smeets[1], P.J. Poortmans[1], M.E. Argenziano[1], L. Desomer[2], R. Valori[3], J. Anderson[3], D.J. Tate[1]

Contact E-Mail Address: lynn_debels@hotmail.com

Introduction: Operator dexterity is recognised as a critical determinant of outcomes after surgery (1-2). No such recognition exists for the quality of endoscope tip manipulation (tip-control) and no objective measurement scale exists.

Aims & Methods: The aim of this study was to develop and validate a score for tip-control in an ex-vivo setting.

A web application containing a timed-score with clickable buttons to indicate correct and incorrect application of snare tip soft coagulation (STSC) was developed. The score was tested on a training model containing 4 shapes constructed from 1-4 identical circles (radius 1.4cm) connected at their mid-points drawn onto a single piece of cooked ham.

Endoscopists with varied profiles consented to video recording of their timed complete application of STSC (hits) to sequential circles using a gastroscope.

Correct application was defined as any visualised diathermy application touching the marked lines. Median correct-hits/incorrect-hits (accuracy) and correct hits/second (speed) were determined by a single rater over the 4 recordings and stratified by shape and endoscopist demographics.

Results: 22 endoscopists (8[36.4%] trainees, 6[27.3%] non-interventional consultant gastroenterologists and 8[36.4%] interventional endoscopists) participated.

Participant median accuracy was 82.0% (IQR17.5, 95%CI 77.0-85.0) and correct hits/second 0.141 (IQR0.095, 95%CI 0.120-0.160). Accuracy strongly correlated with blinded rater opinion of the macroscopic ham appearance (correlation coefficient=0.78, P<.001).

	Median Accuracy Group of Interest (IQR) [95%CI]	Median Accuracy Remaining population (IQR) [95%CI]	P	On Target Hits / second Group of Interest (IQR) [95%CI]	On Target Hits / second Remaining population (IQR) [95%CI]	P
Overall	82.0 (17.5) [77.0-85.0]	-	-	0.141 (0.095) [0.120-0.160]	-	-
Trainee	73.6% (8.1) [67.6-79.6]	85.5 (16.9) [79.6-91.4]	0.25	0.114 (0.046) [0.078-0.150]	0.153 (0.078) [0.097-0.209]	0.03
Consultant - not interventionalist	69.0% (15.8) [59.0-79.0]	81.8 (15.0) [77.2-86.3]	0.15	0.138 (0.028) [0.113-0.162]	0.135 (0.110) [0.081-0.190]	0.97
Consultant - interventionalist	88.0% (5.8) [83.9-92.1]	72.1 (14.7) [66.8-77.4]	0.01	0.191 (0.128) [0.102-0.280]	0.125 (0.07) [0.102-0.147]	0.04
>1000 colonoscopies	85.5% (10.8) [79.6-91.4]	72.5 (9.3) [66.8-78.2]	0.09	0.157 (0.092) [0.097-0.217]	0.114 (0.056) [0.082-0.146]	0.04
>5 years experience	88.0% (5.19) [79.9-96.1]	76.0 (14.5) [71.2-80.8]	0.07	0.151 (0.077) [0.070-0.232]	0.132 (0.061) [0.085-0.178]	0.36

Table 1. Comparison of the median tip-control accuracy and the on target per second per participants groups. CI, Confidence Interval; IQR, Interquartile Range; P, P-value; SMSA, size-morphology-site-access score for determining level of complexity of polypectomy; pEMR, piecemeal endoscopic mucosal resection.

A scatter plot of endoscopist accuracy versus correct hits/second categorized endoscopists into 4 groups (combinations of accurate/inaccurate, fast/slow)(Figure 1). Interventional endoscopists were commonly fast and accurate (accuracy 88.0%[P=.001], correct hits 0.191/s[P=.04]) versus other participants. Non-interventional consultants had the lowest accuracy numerically and statistically similar tip-control to other participants (accuracy 69.0%[P=.15], correct hits 0.135/s[P=.97])(inaccurate). Trainees had similar accuracy to non-trainees but lower correct hits/second (accuracy 73.6%[P=.25], correct hits 0.153/s [P=.03])(slow). Endoscopists with >5 years experience did not have better tip-control (accuracy 88.0%[P=.07], correct hits 0.132/s[P=.36]) when compared to the rest of the participants (table 1).

Conclusion: This is the first demonstration of an ex-vivo objective tool to assess the quality of endoscopic tip manipulation. Tip-control reliably stratifies endoscopists by important demographics including interventional profile, number of polypectomies performed and those performing difficult polypectomy but does not correlate with years of endoscopy experience.

If tip-control can be linked to established performance indicators it may provide an objective benchmark for endoscopy and interventional procedures allowing tracking of progress over time.

PERCEPTIONS AND PRACTICES ON CLINICAL USE OF PROBIOTICS: A NATIONAL SURVEY OF HEALTHCARE PRACTITIONERS

Introduction: Probiotics have the potential to be used for the prevention and treatment of various medical conditions. In Greece, perceptions and practices concerning the clinical use of probiotics remain uncertain.

Aims & Methods: This study is an initiative of the Hellenic Society for the study of Helicobacter Pylori and Other Gastrointestinal Infections (EEMELOP) aiming to evaluate how healthcare practitioners (HCPs) perceive and use probiotics in clinical practice. A closed-ended, 20-item, online questionnaire was distributed via email to HCPs throughout Greece. The questionnaire was based predominantly on multiple-choice questions, focusing on perceptions of HCPs regarding the appropriate indications of probiotics, timing of administration and safety.

Results: From 725 questionnaires sent, 185 (25.5%) HCPs provided feedback. The majority (97.5%) were gastroenterologists, most (60%) running their practice in the private sector, whilst 41.6% reported >20 years of practice. Fifty-one percent considered probiotics "definitively safe" and 31% "probably safe".

The most commonly recognized therapeutic indications were irritable bowel syndrome (IBS; 87.6%), prevention of antibiotic-associated diarrhea (84.3%), pouchitis (55.1%), prevention of Clostridiodes difficile infection (50.3%) and acute diarrhea (41.1%). HCPs recognized as most commonly prescribed strains of Saccharomyces boulardii (69.2%), Lactobacillus acidophilus (68.1%), and Bifidobacterium bifidum (57.8%).

Thirty-one percent reported to "always" prescribe probiotics in association to antibiotics, 25.9% "only during protracted antibiotic courses" and 17.3% "only in patients with a history of gastrointestinal symptoms". Forty-six percent reported to "always" prescribe probiotics during Helicobacter pylori eradication and 22.3% "frequently".

However, practices were heterogeneous, with 38.1% reporting that the length of probiotic supplementation should be "equal to" and 44.5% that it should be "extended beyond" the duration of the eradication regimen. Concerning IBS, 24.9% reported to "frequently" prescribe probiotics as first-line treatment and 23.2% "sometimes", most commonly for the IBS-diarrhea (78.4%) and mixed IBS (38.9%) subtypes. Most HCPs (69%) choose a multi-strain probiotic formulation for IBS therapy; however, their attitude was not similar regarding the optimal timing of response assessment, broadly ranging from 7 days to 3 months.

Regarding the optimal administration of probiotics in relation to meals, 50.8% agreed that "it depends on the formulation of the probiotic product", 18.9% responded "before meals", 15.7% claimed that "this is irrelevant" and 11.4% responded "after meals". Medical conferences (73.5%), pharmaceutical representatives (65.5%) and scientific journals (64.9%) were the most common sources of information on probiotics.

Conclusion: HCPs are familiar with probiotics, recommend them for a wide range of gastrointestinal conditions and consider them safe. However, apparent discrepancies in practice patterns underscore the need for continuous medical education and development of consensus recommendations, aiming to guide rationale use of probiotics in clinical practice.

ASSESSING THE IMPACT OF PPI DEPRESCRIPTION EDUCATION METHODS IN THE ENGLISH PRIMARY CARE NETWORK

K. Plehhova[1], J. Wray[1], S. Sutton[2], J. McArdle[3], A. Dawson[1], C. Coyle[1]

[1]Reckitt, Global Medical Affairs, Hull, United Kingdom, [2]Interface Clinical Services, Hinstock, United Kingdom, [3]IQVIA, Upton, United Kingdom

Contact E-Mail Address: joshua.wray@rb.com

Introduction: There is evidence that suggests proton pump inhibitors (PPIs) are overprescribed across UK Primary Care Networks (PCNs) and that this places a high burden on the NHS[1].

This study looked to implement a pilot system to support physicians in identifying inappropriate PPI therapy alongside promoting guideline-appropriate management[2].

Previous data published from this study[3] suggests that PPI overprescribing in English PCNs is prevalent with little evidence of structured follow-ups.

Aims & Methods: A system was designed and deployed in 62 surgeries across England, by Interface Clinical Services. Three deployment approaches were trialled: Tier (1) – data platform with resource materials, Tier (2) – Tier 1 and online support, Tier (3) – Tier 2 and pharmacist led mentorship supporting audit. The data platform uses data from the practice clinical system to assess prescribing practice. Patients were stratified according to demographics, PPI dosage, treatment duration and indication. To date, 80,218 patients have been identified of which 77,356 (96.4%) patients were eligible for consideration of PPI dose reduction or deprescribing.

Results: There were ~42,800 patient prescriptions reviewed in Tier 1&2 where it was assumed that 1666 (3.89%) patients were eligible for step down and 41,038 (95.83%) patients were eligible for step off. the remaining 0.28% were ineligible for step down or step off. In Tier 3, there were ~34,500 patients prescriptions reviewed. It was assumed that 1266 (3.67%) patients were eligible for step down and 33,103 (95.86%) patients were eligible for step off. When it came to assessing actual recommendations, 1031 (2.99%) of patients were stepped down, with 7890 (22.85%) patients stepped off.

Conclusion: When a deprescribing specialized pharmacist was deployed in the English PCN to support with medicines audit, an approximate 26% decrease in PPI prescriptions were observed. This data proves that this 'hands on' approach to deprescribing is an effect method.

PSYCHOLOGICAL INTERVENTION IMPROVES QUALITY OF LIFE, BUT SURVIVAL IN PATIENTS WITH EARLY-STAGE CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

A.S. Bognár[1], B. Teutsch[2], S. Bunduc[3], B. Fogarasi[1], D. Gergo[1], O. Almog[1], Y. Hadani[1], K. Márta[4], P. Hegyi[5]

Contact E-Mail Address: bognar.sara@gmail.com

Introduction: Psychological interventions (PI) are rapidly increasing in every disorder, but their effectiveness, particularly in malignant diseases, is still debated. Here we aimed to investigate the effect of PI on survival and quality of life (QoL) in patientswith cancer.

Aims & Methods: The systematic search was performed in MEDLINE, Cochrane and Embase databases from inception until 18th October 2021 to identify randomized controlled trials comparing PI to standard care. Outcomes were overall survival (OS), recurrence-free survival (RFS) and different domains of QoL: global, emotional, social and physical. Subgroup analysis was performed based on intervention provider, -type, -environment, -duration and cancer stage. Pooled hazard ratios (HR) and standardized mean difference (SMD) with 95% confidence intervals (CI) were calculated with a random effect model.

Results: 129 articles were eligible for data analysis. The OS and RFS did not differ significantly between the groups (OS: HR=1.01; CI: 0.95,1.07; RFS: HR=0.99; CI: 0.84,1.16). However, our analysis showed significant improvements in the intervention group in all the analyzed domains of QoL; the global (SMD=0.84; CI: 0.37,1.31), emotional (SMD=0.52; CI: 0.20,0.83), physical (SMD=0.45; CI: 0.11,0.79) and in the social (SMD=0.34; CI: 0.08,0.60). Importantly, the effect of PI on QoL was positive immediately, 12 and 24 weeks after intervention, but not at 48 weeks. The effect was mainly observed in early-stage cancer patients.

Conclusion: Even though PIs do not prolong survival, they significantly improve the QoL. PI should be implemented 3-4 times per year as standard care at least for patients with early-stage cancer.

Disclosure: No conflict of interest.

IMPROVING TRAINING IN ENDOSCOPIC MANAGEMENT OF UPPER GI BLEEDS (UGIB)

F. Betteridge[1], M. O-Flaherty[2], S. Dixon[2], S. Murray[1]

[1]North Bristol Trust, Bristol, United Kingdom, [2]University Hospitals Bristol, Bristol, United Kingdom

Contact E-Mail Address: sam.murray@nbt.nhs.uk

Introduction: Contributing to the on-call Upper Gastrointestinal Bleed (UGIB) rota is a crucial part of a consultant gastroenterologist's role. There is no standardised training in managing UGIB as part of the gastroenterology curriculum in the UK, with wide variation in experience amongst registrars by completion of training. Furthermore, with UK Gastroenterology training now reduced to four years, there are fewer opportunities for trainees to gain experience in UGIB. The Bristol Endoscopy Training Collaborative (BETC) developed an Upper Gastrointestinal Haemostasis Course to provide delegates with formal upper gastrointestinal bleeding training. The JAG pilot Upper GI Haemostasis course developed by BSG EQIP initiative was used as template (1)

Aims & Methods: We ran four 1-day courses at Vesalius Clinical Training Centre, Bristol, between November 2021 and November 2022, with 8 delegates & 4 faculty per course. Each course cost approximately £3000 to deliver, including venue hire and porcine models, and was fully funded by the Southwest Endoscopy Training Academy & Health Education England. The course programme included small group, hands-on training for use of adrenaline injection, heater probe, clip placement, haemostatic powder, variceal banding and sclerotherapy. Porcine models (MedMeats) with simulated bleeds were used with accessory & equipment support from industry partners. Hands-on training for Sengstaken Tube (Steris) insertion and oesophageal stent (Danis) placement was demonstrated with plastic models.

Non-technical skills were taught using small group discussions covering topics including on-call role play, prioritisation in UGIB, pathology recognition, and report writing. Pre- and post- course confidence surveys were sent to delegates, and comparisons were made with the Mann-Whitney-U test. If quoting a company specific product need to reference company e.g. Hemospray (Cook Medical, Indiana, USA).

Results: 31 delegates attended the four courses, with fully completed questionnaires obtained from 23 delegates. Most (21 of 23) participants were gastroenterology registrars; urgical registrars, consultant gastroenterologists and clinical endoscopists also attended.

All delegates stated they would recommend the course to a colleague. Self-reported improvements were seen for all learning objectives:recognising pathology, technical skills and report writing. Most notably, confidence in holding the out of hours on call phone for UGIBs improved from an average of 4/10 to 8/10, (p value < 0.005).

Conclusion: We describe a cost-effective single-day course to improve training in management of UGIB. This course can be reproduced at other regional centres. Those looking to refresh or up-skill UGIB management would also benefit.

LEARNING OF DIGESTIVE ENDOSCOPY IN TUNISIA: ARE THE PRINCIPLES OF MEDICAL ETHICS RESPECTED?

C. Makni[1], S. Souissi[1], Y. Zaaimi[1], M. Shimi[1], S. Ayadi[1], E. Belhaj Mabrouk[1], A. Mensi[1], Y. Said[1], L. Mouelhi[1], R. Debbeche[1]
[1]University of Tunis El Manar/STGE, Ariana, Tunisia

Contact E-Mail Address: cyrinemakni.mehrez@gmail.com

Introduction: The education of gastroenterologists in training must include training and practical application in order to acquire expertise and independence as an endoscopist. This raises important ethical questions. Nevertheless, there is a conflict between our ethical duty to respect the autonomy, dignity, information and consent of the patient on the one hand, and the technical and practical aspect of the training of future specialists on the specialists on the other hand. The objective of our work was to evaluate the attitudes and general knowledge of gastroenterologists in the field of medical ethics from their learning stage.

Aims & Methods: We conducted a prospective and evaluative cross-sectional and evaluative study, using a questionnaire. We interviewed 162 physicians, concerning their training period : 134 specialists in gastroenterology, divided into 69 hospital doctors and 65 private doctors. The remaining 28 were residents in their third and fourth year of training.

Results: One hundred and sixty-two physicians participated in our study and completed the questionnaire. The sex ratio M/F was 0.51 and the mean age was 35 +/- 5.4 years.

Before performing their first endoscopic procedures on patients, 76.5% of the gastroenterologists had no prior practical training.

Under the supervision of the senior, the majority (72.8%) performed the gastroscopy during the first semester of training (first internship), while the majority (46.3%) performed colonoscopy after the first year of training. In the absence of a supervisor, the majority of proctological examinations were performed In the absence of a supervisor, the majority of proctological examinations were performed during the first trimester of training (57.4% of operators). The gastroscopy and colonoscopy were mostly performed after the first year of training (65.4% and 91.3% respectively).

In response to the patient's question: Who is going to perform the endoscopic procedure on me? The majority of gastrologists, 76.6% (n=124) would have given the correct information and 23.4% would have given false or unclear answers. Simple, fair and clear information on the different aspects of the care was often given to the patient; the indication for the examination was explained by 85.8% of the respondents (n=139), the procedure and the discomfort by 79.6% of the respondents (n=129). On the other hand, information about possible side effects and complications was not given in the majority of cases (82.7% of gastrologists, n=134).

A minimum of two minutes was dedicated to the explanation of the endoscopic examination: 35.8% of the learners gave the patients two minutes (n=58), almost half, i.e. 51.9%, gave them between two and five minutes (n=84), 11.7% gave them between five and ten minutes, and only one gave them more than ten minutes.

Only 22.2% of participants introduced themselves to patients as the physician in training and 17.9% introduced the nurse in the endoscopy room.

A minority of gastroenterologists in training, 19.1% (n=31), required an informed consent signed by the patient before performing the endoscopic procedure (gastroscopy and colonoscopy). All respondents gave patients time to reflect before the endoscopy, mostly between two and five minutes (52.5%).

Conclusion: Our study showed that there are clear gaps in medical ethics in digestive endoscopy training. Therefore, better supervision and training programs in medical ethics should be offered to hepatogastroenterology residents in their first year of training to ensure skill development on the one hand and patient safety on the other.

AWARENESS AND PERCEPTIONS ABOUT PROTON PUMP INHIBITORS USAGE AMONG PHYSICIANS IN INDIA: A SURVEY

R. Reddy Gundam[1], A. Lavekar[2]
[1]Asian Institute of Gastroenterology, Medical Gastroenterology, Hyderabad, India, [2]Triveni Hospital, Medical Gastroenterology, Nanded, India

Contact E-Mail Address: drriteshreddygastro@gmail.com

Introduction: Proton pump inhibitors (PPIs) are commonly prescribed drugs in preventing and treating certain conditions for definite time periods. However, evidence suggests an association of wide range of adverse effects with unwarranted and incongruous sustained PPI use. Discrepancies in prescribing PPIs appears to revolve around physician attitudes and self-justified perceptions. This survey was conducted to evaluate the knowledge and perceptions of PPI-related adverse events among physicians, and subsequent change in behaviour associated with the use of PPIs.

Aims & Methods: This was a prospective, questionnaire-based, multicentric survey with data collected from physicians across India who have volunteered to participate in periodic surveys.

Respondent's familiarity on adverse effects with PPI use				
	Not at all	Slightly	Somewhat	Very much
Familiarity with published scientific data on possible adverse effects from PPI use	64 (13.76%)	233 (50.11%)	139 (29.89%)	29 (6.24%)
Has recent evidence about adverse effects of PPIs changed prescribing habits?	62 (13.33%)	224 (48.17%)	176 (37.85%)	3 (0.65%)
How concerned are you about adverse effects when prescribing PPIs?	59 (12.69%)	264 (56.77%)	140 (30.11%)	2 (0.43%)
Frequency of discussing risks of adverse effects with patients before starting PPI	75 (16.13%)	233 (50.11%)	154 (33.12%)	3 (0.65%)
Frequency of patients on PPI therapy to bring up concerns about the risk of adverse effects?	80 (17.20%)	240 (51.61%)	144 (30.97%)	1 (0.22%)

Table: Respondent's familiarity on adverse effects with PPI use

Results: The survey was completed by a total of 465 physicians. The survey comprised of questions, with multiple choice answers, about general familiarity with concern about possible PPI adverse effects, awareness and beliefs about adverse effects, when to continue and deprescribe PPI. The physicians were also questioned regarding the extent to which they changed their prescribing habits as a result of studies of adverse effects. A significant proportion of physicians were unaware of the specific adverse

effects with PPI use. Most were slightly concerned about adverse effects when prescribing PPIs; nearly 48% physicians somewhat changed their prescribing practices for PPIs on account of these adverse effects. More than half (55%) survey responders perceived the PPI to be moderately effective at reducing the risk of upper gastrointestinal bleeding, whereas 26% believed it was slightly effective, 17% as very effective, while 2% felt it was not effective at all.

Conclusion: There is a need for strategies to alter behaviour based on a physicians' awareness of NSAID risks, indications for PPIs, besides prescribing approaches in hospitals. Healthcare practitioners could benefit from explicit guidance about scenarios in which patients can safely discontinue the use of PPIs, and regarding strategies for de-escalation that are most likely to succeed. There should be a strong foundation for prescribing PPIs, and a balanced regime to be followed for only as long as essential, at the lowest effective dose avoiding avertible prescriptions.

Disclosure: Nothing to disclose.

PP1689

DEVELOPING A REGIONAL SIMULATION FACULTY TO DELIVER ENDOSCOPIC NON-TECHNICAL SKILLS TRAINING

S. Murray[1], P. Dunckley[2], H. Tierney[3], K. Richardson[3]
[1]North Bristol NHS Trust, Gastroenterology, Bristol, United Kingdom, [2]Gloucestershire Hospitals NHS Foundation Trust, Gastroenterology, Cheltenham, United Kingdom, [3]North Bristol NHS Trust, Postgraduate Medical Education, Bristol, United Kingdom

Contact E-Mail Address: murray.sam@gmail.com

Introduction: Non-technical skills training is a key component to developing an effective endoscopy workforce. The South-West Endoscopy Training Academy (SWETA), set out to train faculty to deliver this training across multiple endoscopy units throughout our region. This initiative is fully funded by Health Education England (HEE) via SWETA.

Aims & Methods: Enthusiastic endoscopy educators were sought to attend an adapted one-day train the simulation trainers course. They learned educational theory, debriefing skills and ran their own simulation scenarios. Each participating unit received simulation equipment including a simulated vital signs monitor and manikin to be able to deliver in-situ simulation sessions on their own endoscopy units. A portfolio of endoscopy-based scenarios was made available online. A pre-intervention centralised confidence survey was used to identify areas of perceived strengths and weaknesses within the endoscopy workforce to help focus training. This will be repeated after the study period so any improvements in staff confidence can be demonstrated. Post training feedback was collected online from participants following each sim session delivered locally.

The endoscopy simulation faculty attend a quarterly network meeting online to share feedback and discuss training delivery. They are encouraged to develop their own scenarios, often based on real life events, and share any latent errors they have identified so learning can be disseminated across the region's endoscopy units.

Results: To date, 27 endoscopy staff including consultants, clinical endoscopists and endoscopy nurses from 10 endoscopy units have been trained as faculty between Mar-Nov 2022.

Pre-training confidence surveys from 49 endoscopy staff across 3 trusts have been collected highlighting perceived anxieties e.g. acting as a team leader and initiating management in a medical emergency. There was good knowledge of where emergency drugs and equipment were located and who to call in a medical emergency.

Eleven in-situ simulation sessions have been delivered in 3 units with feedback collected from 63 endoscopy staff. Example scenarios delivered included upper GI bleeding, over sedation and an acute asthma attack. Feedback has been universally positive. Participants described a renewed confidence to deal with medical emergencies, they appreciated the opportunity to receive feedback from their colleagues and were able to practice key communication and leadership skills. Latent errors were identified such as a faulty call bell in one endoscopy room and the lack of certain equipment e.g. rebreathe mask in recovery.

Conclusion: In-situ simulation is an effective method of delivering non-technical skills training to a regional multidisciplinary endoscopy workforce.

Disclosure: Nothing to disclose.

DIGESTIVE ENDOSCOPY PERFORMED BY A RESIDENT IN TRAINING: PATIENT ACCEPTABILITY ASSESSMENT

C. Makni[1], S. Souissi[1], Y. Zaaimi[1], M. Shimi[1], S. Ayadi[1], E. Bel Hadj Mabrouk[1], A. Mensi[1], Y. Said[1], L. Mouelhi[1], R. Dabbeche[1]
[1]University of Tunis El Manar/STGE, Ariana, Tunisia

Contact E-Mail Address: cyrinemakni.mehrez@gmail.com

Introduction: The learning process of digestive endoscopy appears to conflict with the physician-gastroenterologist-patient contract. It is clear that the patient's rights clash with the duties of the endoscopist and learners.

The objective of our study was to evaluate the acceptability and experience of patients who underwent an endoscopic procedure performed by a resident in training.

Aims & Methods: We administered a questionnaire over a period of six months to 146 patients who underwent a diagnostic endoscopic exploration, Esophagogastroduodenoscopy (EGD) or Colonoscopy, 30 minutes after the examination, which was performed by a resident in training. The form was manually filled out by the resident operator. Patients were not informed of the level of training of the operator.

The questionnaire included demographic data of the patient (age and gender), the type of examination undergone, as well as 20 closed-ended questions grouped into four domains (Information provided to the patient, Conduct of the endoscopic procedure, Patient's estimation of the operator, Patient's trust in the operator).

Results: We surveyed 146 patients who had undergone a diagnostic endoscopic examination (esophagogastroduodenoscopy or colonoscopy) performed by a resident in training, 30 minutes after the procedure. Of the 146 patients, 91 had undergone esophagogastroduodenoscopy (62.3%) and 55 had undergone a scheduled colonoscopy (37.7%). The sex ratio was 1.17, and the average age was 50 years. The indications for the procedure were diverse, such as epigastric pain, iron deficiency anemia, abdominal pain, and constipation. The average duration of the symptoms was 17.75 months (range: four days to 84 months).

Before the endoscopic examination, the majority of patients (79%) had received a clear and correct explanation of the indicated examination, mainly on the day of the appointment. The time dedicated to this explanation was less than two minutes in 55% of cases.

None of the patients had signed an informed consent before the start of the endoscopic examination. During the endoscopic examination performed without sedation, all patients felt discomfort, which was moderate for most of them (52.7%).

The same was true for the colonoscopy, with discomfort felt by all patients, which was moderate for most of them (47.3%). According to the patients, the average age of the operator was 29 years (range: 20-50). The scientific level was overestimated by the majority of patients (69.9%), with 62.3% thinking that the operator was a qualified specialist and 7.6% thinking that he was a professor.

The majority of patients (90.4%) already knew that they could be treated by a resident in training when seeking care at a university hospital center. The level of trust was on average 8.29 on a scale of 0 to 10 (4-10). All patients agreed to be examined by the endoscopist present in the room before his or her presentation. However, 26.7% would have refused to be examined by a resident if they had known in advance.

A minority of patients would have preferred to be examined by an older physician (16.4%) or a physician of the opposite gender (5.5%).

Conclusion: Our study has shown that even though the principles of medical ethics appear to be addressed in our daily practice of digestive endoscopy, there are obvious shortcomings and gaps. Therefore, additional efforts should be made by the endoscopist to ensure the patient's right to information, respect for their dignity, autonomy, and consent.

Disclosure: Nothing to disclose.

Introduction: Auditing processes and outcomes is essential for the quality of healthcare services. Performance metrics for small bowel capsule endoscopy (SBCE) were defined by the European (ESGE) and American (ASGE) Societies in 2018 and 2022, respectively. This study aimed to evaluate compliance with these parameters in the periods following their publication.

Aims & Methods: Patients who underwent SBCE in two periods (2018-2019 and 2022-2023) in a tertiary Portuguese hospital were retrospectively evaluated. The bowel preparation protocols and the gastroenterologists responsible for video evaluation were the same in both periods. Clinical and procedure-related data were collected.

Results: A total of 348 capsule enteroscopies were included, 241 performed in the first period (2018-2019) and 107 in the second (2022-2023). All ESGE criteria were met in 63.9% of cases in the first period, and in 84.1% in the second. ASGE parameters were met in 59.8% and 73.8%, respectively. The indication was appropriate in 93.7%, with no difference between periods (p=0.180). In cases of overt bleeding, the timing was appropriate in 62.5% (considering 48 hours) or 84.4% (14 days), with a trend towards performing SBCE earlier in the second period. Patency testing was performed in 85.9% of patients with risk factors for retention, with significant improvement in the second period (80.1 versus 99.0%, p<0.01). Intestinal preparation was performed in 90.8% and was classified as adequate in 82.2% (p=0.132). Documentation of transit time was higher in the second period (74.3% versus 88.8%, p=0.04), while percentages of incomplete small bowel study (3.7%) or retention (0.9%), description of complications (97.1%), and written post-procedure recommendations (94.5%) did not differ. The overall diagnostic yield was 51.7% (p=0.536), with the use of standardized terminology being higher in the second period (71.7% versus 98.1%, p<0.01).

Conclusion: Significant improvement was observed in quality metrics between periods. However, there is room for improvement in the selection of patients for patency testing, timely placement in cases of bleeding (target >90%), and description of transit times (target >98%).

TRAINING IN EUS: CURRENT STATE OF TRAINING MODALITIES FROM A WORLDWIDE SURVEY

L. Archibugi[1], M. Tacelli[1], M.C. Petrone[1], M. Kahaleh[2], P. Fusaroli[3], J. Iglesias-Garcia[4], G. Capurso[1], P.G. Arcidiacono[1]
[1]San Raffaele Scientific Institute IRCCS, Pancreato-biliary Endoscopy and EUS Division, Pancreas Translational and Clinical Research Center, Milano, Italy, [2]Robert Wood Johnson Medical School Rutgers University, Gastroenterology, New Brunswick, United States, [3]University of Bologna / Hospital of Imola, Gastroenterology Unit, Imola, Italy, [4]University Hospital of Santiago de Compostela, Department of Gastroenterology and Hepatology, Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain

Contact E-Mail Address: matteo.tacelli@gmail.com

Introduction: Endoscopic Ultrasound (EUS) is an advanced procedure requiring a formal and specific training. Currently position papers by American and European societies for endoscopy (ASGE and ESGE) have been published on required training modalities, but data on the adoption of such standards lack.

Aims & Methods: The aims of this study are to describe the current state of training in EUS around the world, investigate educational lacks and clarify expectations of trainees for their training period. A survey was administered to Next-Generation EUS Pre-Course 2023 participants, all EUS trainees<40 years of age. This comprehended 66 questions evaluating 5 topics: trainees demographic data and basic competences, training centers characteristics, training modalities adopted, activities after the end of training period, trainees expectations and opinions. Survey responses were analyzed using descriptive statistics.

Results: 114 EUS trainees replied from 5 continents (mostly from Europe); 59.9% males, 89.5% gastroenterologists (10.5% surgeons or internists). All trainees satisfied the basic requirements for endoscopic and ultrasonographic skills. 29.5% of trainees were trained in centers with EUS volumes<10/week. In the majority of cases training was performed adopting mostly or only linear probes (67.9%), 79.5% of training were in centers were same-session EUS-ERCP could be performed and 67.3% of trainees believed that the same person should be trained in both procedures.

In contrast to books, videos or conferences, phantom models and in-vivo/ex-vivo models were very rarely used during training, and also considered not very useful as learning opportunities. 61.1% of trainees aimed to achieve during training a complete autonomy in diagnostic EUS+FNA/FNB for all stations,plus at least an initial approach to therapeutic EUS. Most trainees affirmed that during training they expected more hands-on, therapeutic-EUS, FNA/FNB teaching on ultrasound machine and more focus on contrast/elastography skills.

Conclusion: EUS training around the world is variable and does not always respond to basic ASGE/ESGE suggestions. A higher volume of hands-on procedures with FNA/FNB should be guaranteed during training.It should be discussed whether a basic training period in EUS should include also an initial approach in therapeutic EUS, as expected by trainees.

MANAGEMENT OF INTENTIONAL FOREIGN BODY INGESTION: EXPERIENCE FROM A UAE CENTRE

A. Alali[1], K. Altenaji[2], M. Alzaabi[2], M. Wallace[3], M. Karajeh[1]
[1]SSMC, Gastroenterology, Abudhabi, United Arab Emirates, [2]SSMC, Abudhabi, United Arab Emirates, [3]SSMC/Mayo Clinic, Gastroenterology, Abudhabi, United Arab Emirates

Contact E-Mail Address: ameirahbadr@gmail.com

Introduction: Intentional foreign body ingestion (iFoBI) is seen mainly among prisoners for secondary gains and in patients with psychiatric illness. European Society of Gastrointestinal Endoscopy (ESGE) guideline suggests that endoscopic removal is preferred for objects retained in the esophagus, large (≥2.5 cm in diameter) objects retained in the stomach, or long (≥ 5-6cm) or sharp objects in the stomach and proximal duodenum. We have seen a surge in the number of admissions with iFoBI at our hospital related to a change in pain medication policy at a local prison, with ensuing protests action. This presented an opportunity to study the outcomes and certain aspects of management in this group of patients. There is limited data on the outcome of non-endoscopic management of sharp ingested foreign bodies and the impact on length of stay.

The aim of this study was to describe our experience and outcomes of patients admitted with iFoBI at our centre.

Aims & Methods: We performed an observational retrospective study of all patients presenting with iFoBI at our hospital between October 2021 and December 2022 during which time we had a surge of admissions with iFoBI related to a change in pain medication policy at a local prison, with ensuing protests action. The nature, number, and location of ingested foreign body on imaging, outcomes as well as the management method including conservative, endoscopic removal and surgical treatment were analysed. We also analysed timing of endoscopy, impact of diet and laxatives and length of stay.

Results: A total of 49 episodes of iFoBI in 25 patients presented during the study period. All patients were male prisoners with a median age 33 years and 59% of UAE nationality. None of the episodes of iFoBI presented with oesophageal impaction. Ingested objects were variable in number and type, but they were mostly metallic, and 11 objects were regarded as high-risk objects such as sharp metal objects ≥ 5cm. Upper endoscopy was carried out in 11/49 based on ESGE guidelines of which 55% were after working hours which imposed a significant impact on the service. Most objects were not within endoscopic reach on presentation and patients were managed conservatively. Only one patient required surgical intervention to remove a 9 cm sharp metallic object that became impacted at the ileocecal junction and was causing significant edema and peri-terminal ileum inflammation as seen on cross sectional imaging. There was no relationship between the timing of endoscopy and complications such as perforation or obstruction (p value 0.035) or length of stay (p value 0.036). However, length of stay was prolonged while waiting for psychiatric evaluation (p value 0.056).

Conclusion: The majority of ingested foreign bodies, including sharp metallic objects, pass through the gastrointestinal tract spontaneously and without complications. Middle of the night endoscopy, which has significant impact on staff and resources, can be avoided in most cases of iFoBI except those with esophageal impaction. Most patients can be managed with watchful waiting and serial exams. Effective management strategy requires multidisciplinary approach to address the root causes for this behaviour with the aim of reducing future admissions with iFoBI.

WILL USE OF VIDEO GAMES HELP IN AVOIDING ERGONOMIC RELATED INJURIES IN ENDOSCOPIC PROCEDURES; A STUDY FROM PAKISTAN

F. Kayani[1]
[1]Bolan University of Medical and Health Sciences, Gastroenterology, Quetta, Pakistan

Contact E-Mail Address: farhana_kayani@hotmail.com

Introduction: Endoscopy is a complex competence which requires educative training and practice to ensure the procedure is performed correctly. Recently, the awareness of work-related musculoskeletal injuries (MSIs) among gastro- intestinal endoscopists has increased because of their ef- fect on the private and work life of clinicians as well as on the health care system. So the burning issue of avoiding ergonomic related injuries is emerging . in this aspect we are looking into how use of video games can help , asstudies shows the Video game users acquire endoscopic but not robotic techniques quicker, and training on video games appears to improve performance.

Aims & Methods: Thirty Gastroenterology residents (18 male, 12 female) volunteered to participate. The students were then randomized to control (group A) or ‚training' (i.e., video game practicing; group B) arms.In group B, each resident played three commercially available video games for 30 min on an X-box (Microsoft, Seattle, WA) for 8 weeks. 8 weeks later, all residents were allocated in endoscopy unit for 8 weeks and were given 5 cases / day and 5 days per week.A 22-question survey about ergonomics and work-related musculoskeletal injuries was sent to both arms.Responses were collected, and data were analyzed

Results: Of the total study population, 95.08% of Arm A were observed to have ergonomic injuries, whereas only 54.83% of ARM B had ergonomic injuries ($p<0.00$). Spearman correlation coefficients demonstrated a significant relation between many of the parameters, particularly right wrist and left thumb injury . Group B subjects improved significantly over those in group A . female gastroenterologists were more likely than were their male colleagues to have experienced injuries involving the upper back, by a margin of 49% to 36%.($p<0.007$) .Ergonomics training was highly desirable among respondents, particularly among those with previous injuries ($P = 0.0030$).

Conclusion: Correct ergonomics is a learned and practiced behavior. We believe that videogame use is a useful way to facilitate improvement in eendoscopic ergonomic behaviors. Simulation models can prove to be an important addition to the training arsenal.

We suggest that consideration of endoscopic setup, proper posture, and practice of postural resets along with incorporation of a user-centered design that accommodates the breadth of its users, rather than employing a onesize-fits-all approach are necessary components for a longer, healthier, and pain-free career.

CLINICAL, ENDOSCOPIC, AND HISTOPATHOLOGIC FINDINGS IN GASTROINTESTINAL AMYLOIDOSIS

L.U. Krauss[1], S. Schmid[1], P. Mester[1], K. Utpatel[2], C. Kunst[1], M. Müller-Schilling[1], V. Pavel[1]
[1]University Hospital Regensburg, Department of Internal Medicine I, Gastroenterology, Hepatology, Endocrinology, Rheumatology and Infectious Diseases, Regensburg, Germany, [2]University of Regensburg, Institute of Pathology, Regensburg, Germany

Contact E-Mail Address: pavel_vlad2008@yahoo.com

Introduction: Amyloidosis describes a group of diseases caused by the extracellular accumulation of misfolded serum proteins. Amyloidosis can affect all organs including the gastrointestinal (GI) tract. Symptoms like nausea, vomiting, diarrhoea, and abdominal pain suggest GI involvement of amyloidosis.

Furthermore, GI amyloidosis is associated with a higher risk of gastrointestinal bleeding, especially when mucosal lesions are present.

Aims & Methods: Our study aimed to evaluate the frequency of GI manifestations in patients with amyloidosis, characterize these patients clinically, and describe the endoscopic and histopathologic findings in GI amyloidosis.

A retrospective study was conducted at a German University Hospital, including a cohort of 61 patients with different types of amyloidosis between January 2004 and June 2022. Clinical, endoscopic, and histopathological data were retrieved from medical records and analysed.

Results: 61 Patients with different types of amyloidosis were included in the study cohort. 23 (37.7%) displayed GI involvement. The median age of the patients with amyloidosis and gastrointestinal manifestation at diagnosis was 62 ± 18.28 years. 60.9% were male. Among the amyloidosis types, 52.5% were amyloid light chain (AL), 21.7% were transthyretin (TTR), 13.0% showed amyloid A (AA), and in 18% of the cases, the type was unknown. The gastrointestinal organs affected were mainly the colon (65.22%), stomach (30.4%), rectum (30.4%), duodenum (26.1%), and ileum (21.7%).

Initial gastrointestinal symptoms were present in 78.3% of the patients and included mainly diarrhoea (34.8%), abdominal pain (30.4%), weight loss (26.1%), nausea/vomiting (21.7%), and loss of appetite (17.4%). Endoscopic findings were ulcerations (47.8%), mucosal inflammation (43.5%), polyps (26.1%), erosions (13.0%), vascular malformation, polypoid protrusion, submucosal haematoma, erythema, metaplasia, and diverticulum.

Histopathological findings included thickening of the vessel walls, (peri-) vascular and interstitial amyloid deposits, and in one patient, a polyp with amyloid deposits. GI bleeding occurred in 39.1 % of the patients during the course of the disease. The mortality rate 5 years after diagnosis was 30.4%.

Conclusion: Amyloid tends to deposit in the gastrointestinal tract, which, being easily accessible, is often the target organ for a pathological diagnostic examination. However, amyloidosis of the gastrointestinal tract, with biopsy-proven disease, is rare. Due to the low incidence of this disease, the diagnosis of gastrointestinal amyloidosis may be overlooked. Furthermore, considering the existing literature, there is a paucity of data on GI amyloidosis.

Therefore, clinicians must be aware of this manifestation when treating patients with amyloidosis, and if suspected, endoscopy with biopsy and histopathological examination should be performed.

Disclosure: Nothing to disclose.

PREVALENCE OF BURNOUT SYNDROME IN A TERTIARY UNIVERSITY CENTRE IN ROMANIA

M. Dranga[1], S. Chiriac[1], C. Stanciu[2], I. Girleanu[1], C. Cojocariu[1], A.-M. Singeap[1], C. Cijevschi Prelipcean[2], A.-V. Trifan[1]
[1]"Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania, [2]"St. Spiridon" Emergency Hospital, Gastroenterology, Iasi, Romania

Contact E-Mail Address: mihaela_dra@yahoo.com

Introduction: Burnout syndrome is a commonly seen in healthcare professionals, particularly in physicians who are exposed to a high level of stress at work and has a negative impact on the medical activity. The physicians who had have high burnout levels have been shown to commit more medical errors.

Aims & Methods: Aim: To assess the level of the burnout syndrome in a tertiary university centre of gastroenterology in Romania.

Methods. This observational study involved physicians from a tertiary gastroenterology university centre. An online questionnaire assessed the presence of burnout using the Maslach Burnout Inventory (MBI).

Results: A total of 64 physicians responded to the questionnaire. In terms of high burnout, 11 doctors (17.18%) had emotional exhaustion, 13 doctors (20.3%) had depersonalization, and 58 doctors (90.62%) scored low for personal achievement. There were statistically significant correlations between the personal accomplishment and exhausting scores and between the personal accomplishment and depersonalization scores, respectively (P=0.007, and P<0.001, respectively).

Conclusion: Physicians present an increased risk for burnout relative to workers in other fields. The high rate of burnout among physicians found by our study requires careful attention. Further studies aiming to identify other factors that contribute to burnout as well as measures to combat burnout are necessary. Professional societies should get involved in studying the factors that generate burnout among physicians as well as to find solutions to reduce them.

CAN A GREEN SHOEBOX IMPROVE RESIDENT DOCTORS ENDOSCOPIC DEVELOPMENT - YES IT CAN

É. Gáspár[1], A.G. Moraru[2], A.-M. Boțianu[2,3], I. Avram[2], D. Ciubotaru[2]
[1]Regina Maria Hospital Brasov, Dep. of General Surgery, Brasov, Romania, [2]SCJUBV, Dep. of Gastroenterology, Brasov, Romania, [3]Transilvania University, Dep. of Internal Medicine & Gastroenterology, Brasov, Romania

Contact E-Mail Address: illyes.i.eva@gmail.com

Introduction: The training of gastroenterology residents in machine augmentd-simulated enviroment in Romania is a very limited feature and only available in the major university centers. The goal of this pilot study was to determine if a green designed simulator(Shoebox based endoscopic simulator-SBES) can mimic diagnostic endoscopy setting and thus improve endoscopy training for residents gaining dexterity and confidence.

Aims & Methods: A low-cost gastroscopy training model was created utilizing a budget of less than 10 Euro(gastroscope not included). Afterward, a training curriculum consisting of a sequence of tasks was designed to mimic standard techniques frequently utilized in gastroscopy. This curriculum was tested on the gastroenterology residents and nurses.

Development of competency in endoscopy among two gastroenterology first year resident with endoscopy naive skills was assessed during a month time while comparing it to two endoscopy naive nureses(having

only visual experience of 25 years) and an endoscopy naive first year resident with gaming/instrumental background(25 years of gaming and 20 years of guitar playing skills). Baseline was assessed by performance of a consultant.

Measurement of development were rendered by supervising faculty by recording “insertion time”,”depth of unassisted insertion”,”independent procedure completion”,”ability to identify endoscopic landmarks” and “level of confidence”.

Results: Simulator vs real life gastroscopy was assessed gaining 8/9 out of 10 points. Simulator trained residents outperformed endoscopy naive nurses by the end of the pilot study in all performance aspects(p=0.05). One however must mention that endoscopy naive nurses had a start baseline much nearer the consultant level in comparison to the residents.

Endoscopy naive resident with gaming/instrumental background held initialy a shorter “insertion time” in comparison to non gamer/instrumental counterparts.

All the assessed parameters improved gradually however the episodic assessment revealed induction reluctancy and by the end of the pilot study a steep lerning curve could be observed during thise training episodes. Confidence levels raised by the end of the study, reaching a medium level(scale 5 of 10)-consultant performace level was not reached(blinded subjects).

Conclusion: In this pilot study a month of SBES was utilized along with the GATE(gastroenterological education-training endoscopy)concept. The goal was to determine if SBES training can mimic in vivo training while enhancing competecy, dexterity and most of all self confidence. The subjective conclusion/wish of residents was to be able to continue with the simulated training. SBES training allows a wider accesability to train ex vivo and enhances faculty to be more efficient with their endoscopy practice while putting focus on sustainable care and being greener as well.

HOW IS IT TO BE AN ENDOSCOPIC NURSE IN SWEDEN? A NATIONAL SURVEY INCLUDING 67 NURSES PERFORMING ENDOSCOPY

F. Swahn[1], C. Wallenkampf[1]

[1]Karolinska Universitetssjukhuset Huddinge, Sektion GI Endoskopi, Stockholm, Sweden

Contact E-Mail Address: catharina.wallenkampf@regionstockholm.se

Introduction: There have been endoscopy nurses in Sweden for more than 2 decades. At least in the start, there were doubts and skepticism about their professional status.

We wanted to investigate, by survey, how Swedish endoscopy nurses experience their professional role today.

Aims & Methods: A written questionnaire comprising 44 questions were sent to all registered (n=70) endoscopic nurses in. Sweden. The issues included: education, work load, medical responsibility, medical support, education of other professional categories, further education, research and salary.

Results: Responses were received by 67/70 (96%); 55F/12M; median age 50 [range 33-64]. Number of years in healthcare: median 25 years [range 10-45]. Number of years performing endoscopy: median 5 years [range 0,5-20]. Dedicated time for endoscopy: n=26 100%; n=20 70-99%; n=18 50-69%; n=3 20-49%. Annual number of gastroenteroscopy: median 350 [range 20-1400]; colonoscopy: median 600 [range 150-1500]. The doctors assess referrals in 100%. During endoscopy, consultation by physician is rare and support is usually provided within 2-5 minutes (90%) and is seldomly perceived as an inconvenience and the reason is usually related to large polyps, cancer and difficult bleeding. Taking over the endoscopic procedure by the doctor - happens rarely. Appraisal of PAD-results is performed by almost all nurses, n=66 (98%). Two-thirds n= 41 (62%) of nurses are involved in endoscopic education and mentorship, which of 80% include residents. One n=1 nurse has an ongoing doctorial project.

A majority finds their professional role as positive, but n=23 (34%) have on various occasions felt opposed (82% by doctors; 18% by other nurses), however n=46 (69%) experiences strong positive support from the entire medical team. The median salary is approximately 4120 € [range 2900 – 5870] and n=40 (60%) find it not satisfactorily.

Conclusion: Endoscopy nurses in Sweden have over time been established as an important professional and educational contributor within endoscopy. The vast majority of endoscopic nurses find their job inspiring and rewarding, but there is still space for improvement.

Disclosure: Nothing to disclose.

PP1699

UNVEILING GENDER DISPARITIES IN NATIONAL GASTROENTEROLOGY CONFERENCES IN PAKISTAN: THE JOURNEY TOWARDS EQUALITY

J. Devi[1], A. Subhan Butt[2], J. Kumar[3], M.S. Memon[1], L. Rai[4]

[1]Asian Institute of Medical Sciences, Gastroenterology, Hyderabad, Pakistan, [2]Aga Khan University, Gastroenterology, Karachi, Pakistan, [3]Liaquat University of medical and health sciences, mbbs 2nd year, Hyderabad, Pakistan, [4]JPMC Karachi, Gastroenterology Ward 23, Karachi, Pakistan

Contact E-Mail Address: vikas_seetlani@yahoo.com

Introduction: The phenomena of the “glass ceiling” and “sticky floor” persist for women in academic medicine, despite ongoing efforts to address gender disparities. The lack of gender diversity in scientific conferences can lead to unconscious bias and discourage women from pursuing careers in gastroenterology.

No data exists on this issue in Pakistan, making it crucial to assess gender representation in the field.

This study aims to investigate gender dynamics in invited faculty and conference committee leadership in three major gastroenterology, and hepatology societies in Pakistan over the last 5 years.

Aims & Methods: In this cross-sectional study, the annual scientific programs from 2018-2022 of three major gastroenterology, and hepatology societies in Pakistan were reviewed. The gender makeup of the faculty invited as speakers, chairs, moderators, leadership (president), and program committee (chair organizing/scientific committee) was recorded and compared. Regression analysis was used to evaluate the trends for female representation over time for each role.

Results: The proportion of women faculty invited to all conferences was extremely low ranging between 7-20%. A subtle increase in women speakers and moderators was observed in PSSLD and PSG however, there was considerable variability in PSH.

There was no significant difference in the proportion of women in various roles. The trend of women’s representation across all three societies remained almost unchanged over time (slope=0.08, R2=-0.078, p-value=0.875). All program committee leadership roles were held by men, except in PSSLD (2021,2022) where a woman held a committee leadership position and more women were invited as speakers.

Conclusion: There was considerable variability in the representation of women across different roles in the conferences held by all three societies. While there was some improvement observed in the number of female speakers in certain conferences, there was no significant difference in the overall representation of women across all conferences and roles. Moreover, leadership positions were predominantly held by men.

THE ROLE OF SEX HORMONES IN THE DEVELOPMENT OF CONSTIPATION. A CLINICAL PROSPECTIVE STUDY IN SUBJECTS WITH GENDER INCONGRUENCE ASSIGNED MALE AT BIRTH AND ASSIGNED FEMALE AT BIRTH DURING GENDER AFFIRMING HORMONE THERAPY

A. Tesi[1], F. Pallotti[1], S. Di Chiano[1], E. Delli Paoli[1], F. Lombardo[1], D. Badiali[1]
[1]La Sapienza University of Rome, Experimental Medicine, Rome, Italy

Contact E-Mail Address: ariannatesi@hotmail.com
Introduction: Functional constipation represents a common disorder, burdened by a significant impact on the patient's quality of life and a difficult clinical management, due to the absence of a known pathophysiological model. Considering that functional constipation predominantly affects females, many studies evaluated the role of sex hormones in development of this condition.
However, the literature limits are represented by the lack of in vivo studies and by the heterogeneity of the clinical and experimental characteristics of the study groups. Persons with gender incongruence (Assigned Male at Birth, AMAB, and Assigned Female at Birth, AFAB) that are undergoing Gender Affirming Hormone Therapy (GAHT) represent an interesting model for the study of sex hormones action in vivo.
Aims & Methods: This study aims to investigate the effects of oestrogens and testosterone on stool frequency and consistency; abdominal symptoms (pain, bloating); symptoms related to constipation (pain during defecation and difficulty in evacuation), defecation urgency.
Twenty-two subjects undergoing GAHT have been evaluated before and after 24 weeks of hormonal therapy based on oestradiol valerate gel (AMAB persons) or testosterone (AFAB persons) (1).
All subjects underwent clinical history, physical examination, and filled in the Patient Assessment of Constipation-Symptoms (PAC-SYM) questionnaire, which assesses the severity of symptoms related to constipation using a score (higher the score, higher the symptoms severity).
The subjects compiled a two-week daily diary, reporting frequency of evacuations, stool consistency according to the Bristol Stool Form Scale (BSFS), presence of pain related to evacuation, defecation urgency and other abdominal GI symptoms.
Blood samples were taken to assess the levels of β-estradiol and testosterone during therapy period. In AMAB, serum estradiol <200 pg/ml and testosterone <55 ng/dl were considered as therapy target levels. In AFAB, the target level of testosterone was 400-700 ng/dL (2). Statistical significance (p value <0.05) has been assessed using the chi-square test for categorical variables.
Results: A higher PAC-SYM score in all subscales was observed in AMAB persons. These subjects also reported more frequently stools type 1, 2 and 3 according to the BSFS.
On the contrary, AFAB persons reported a decrease in all subscales of the PAC-SYM score and softer stool consistency. No significant association was observed between hormonal levels and variation of the PAC-SYM score (all subscales) or the stool consistency.

		AMAB	AFAB	p- value
Number of subjects		10	12	-
Achievement of hormonal target levels (Number of subjects)	Yes No	7 (70%) 3 (30%)	7 (58,3%) 5 (41,7%)	-
PAC-SYM score (abdominal subscale)	Increase No variation or decrease	9 (90%) 1 (10%)	5 (41,7%) 7 (58,3%)	0,01
PAC-SYM score (rectal subscale)	Increase No variation or decrease	10 (100%) 0 (0%)	7 (58,3%) 5 (41,7%)	0,02
PAC-SYM score (stool subscale)	Increase No variation or decrease	10 (100%) 0 (0%)	6 (50%) 6 (50%)	0,01
Stool consistency according to the BSFS	Increased consistency (type 1, 2, 3) Soft stools (type 4, 5, 6, 7)	6 (60%) 4 (40%)	0 (0%) 12 (100%)	0,01

Conclusion: The results of this study suggest that sex hormones could play a role in the development of gastrointestinal functional symptoms. Therapy with oestrogens seems to cause the onset of constipation symptoms and the change of stools from normal to hard consistency suggests a possible slowdown of colonic transit. On the contrary, therapy with testosterone seems to relate with an improvement of constipation symptoms and stool consistency.

Introduction: Qualitative research in healthcare consists of studies using a variety of methodological approaches to gain in-depth insights into patients' and practitioners' experiences, perceptions, and social dynamics, particularly in relation to clinical interventions and their real-world acceptability and efficacy.
There is growing concern regarding the underrepresentation of qualitative research in clinical journals,[1] including Gastroenterology with less than 0.1% of published articles in the top 10 Gastroenterology journals classed as utilising qualitative methods.[2]
Aims & Methods: In this piece of research, we seek to gain a deeper understanding of the nature of qualitative research published in the top 20 Gastroenterology and Hepatology journals, and identify if there is a relationship between journals' SCImago journal rank indicator, a measure of scientific influence that accounts for both citations and the prestige of the journals where the citations originate, and the number of qualitative

articles published in these journals over a 20-year period. We conducted a comprehensive PubMed search in April 2023, using a validated search strategy[3] that encompassed a combination of terms, including "interview," "qualitative," and "experience," to identify qualitative studies, including those employing mixed methods, excluding reviews, published between 2002 and 2022 in the top 20 GI journals ranked according to their SCImago score.

We used simple descriptive statistics to quantify the scope of the included articles, their provenance and the types of qualitative analytical methods used. We used Pearson's correlation coefficient to calculate the existence of any relationship between SCImago Journal rank indicator and the number of qualitative articles published per journal.

Results: We identified 68 journal articles (median 1 per journal, Q1=0, Q3=5, range = 0-17) that used qualitative methods for both data collection and, published in the top 20 GI journals over a 20 year period, making up less than 0.0008% of all published primary studies in these journals. Most focused on inflammatory bowel disease (n=30,44%) and liver transplant (n=16,24%), and were conducted in the USA (n=33, 49%) and the UK (n=12,18%). Most participants in the qualitative studies were patients (n=49,72%) and clinicians (n=25,37%).

The main methods used for data collection were semi-structured interviews (n=51,75%) and focus groups (n=17,25%). Thematic analysis was the most common qualitative data analytical method used (n=36, 53%). There was a weak, non-significant correlation (r(18)=-0.19, p=0.43) between SCImago journal rank indicator and the percentage of published qualitative articles.

Conclusion: Our analysis indicates that qualitative research remains notably underrepresented in the top 20 GI journals in the last two decades. A majority of the published qualitative studies centred on inflammatory bowel disease and liver transplant, were primarily from the USA and the UK, and frequently used similar qualitative data collection and analytical methods.

Although no apparent relationship between SCImago rank, and percentage of articles published that used qualitative methods was found, the lack of such articles in the top 20 GI journals suggests a potential bias against qualitative research by reviewers and editors or reluctance by researchers to submit qualitative articles to clinical GI journals.

Expanding the visibility of qualitative research in GI journals can enhance our understanding of patients' and practitioners' experiences and contribute to more comprehensive and patient-centred care in GI medicine.

ASSOCIATION OF ENDOSCOPIST-PATIENT SEX CONCORDANCE AND COLONOSCOPY OUTCOME

F. Theunissen[1], D.M. de Jong[1], R.J.T. Ouwendijk[2], P. ter Borg[2], L.M.J.W. van Driel[1], M.J. Bruno[1], P.D. Siersema[1], M.C.W. Spaander[1]

Contact E-Mail Address: f.theunissen@erasmusmc.nl

Introduction: Recent data has suggested that discordance between surgeon sex and patient sex is associated with a negative postoperative outcome (1). It is as yet unknown whether this is also true for endoscopists' performance in relation to endoscopist and patient sex. We aimed to assess if there is an association between endoscopist-patient sex discordance and colonoscopy outcome.

Aims & Methods: In a multicenter retrospective study all colonoscopy procedures performed between 2016 and 2020 in 17 hospitals were collected from a prospective endoscopy database. Coloscopies were categorized into colorectal cancer screening procedures and colonoscopies performed for other indications. Concordance sex was defined if endoscopist and patient had the same sex, discordance was defined if endoscopist and patient did not have the same sex. For each colonoscopy, patient discomfort (Gloucester comfort scale >4), cecal intubation, adenoma detection rate (ADR), and polyp detection rate (PDR) was recorded.

We used generalized estimating equations accounting for endoscopist age and experience (years of experience), patient age, year of procedure, ASA classification, adequate bowel preparation (Boston bowel preparation score ≥6), type of hospital (academic vs. non-academic) and type of sedation. Random effects incorporated were patient ID, hospital and endoscopist.

Results: Out of 235,101 colonoscopies, 44,944 screening procedures were performed by 103 endoscopists, of which 23,990 were sex concordant and 20,954 were sex discordant. The other 190,157 colonoscopies were performed by 196 endoscopists, of which 95.662 were sex concordant and 94.495 were sex discordant. In screening colonoscopies, sex discordance was associated with significantly more discomfort (aOR: 1.19; 95%CI, 1.04-1.37), lower ADR (aOR: 0.86; 95%CI, 0.82-0.90), and lower PDR (adjusted Odds Ratio (aOR): 0.84; 95%CI, 0.80-0.88) but not with cecal intubation (aOR: 0.9; 95%CI, 0.76-1.07).

In non-screening colonoscopies ,sex discordance was significantly associated with lower PDR (aOR: 0.95; 95%CI, 0.92-0.98) but not with discomfort (aOR: 0.99; 95%CI, 0.92-1.07), cecal intubation (aOR: 1.00; 95%CI, 0.94-1.06) and ADR (aOR: 1.00; 95% CI, 0.96-1.05). Subgroup analyses revealed no specific subgroup, and endoscopists' sex and patients' sex did not change this association (Table 1).

		Colorectal Cancer Screening colonoscopies	Non-screening colonoscopy
	Outcome	OR (95% CI)	OR (95% CI)
Female patients	Significant discomfort	0.685 [0.446 – 1.052]	0.815 [0.604 – 1.100]
	Caecal intubation	0.992 [0.607 – 1.620]	1.219 [0.740 – 2.008]
	ADR	1.020 [0.875 – 1.188]	1.037 [0.742 – 1.450]
	PDR	1.040 [0.879 – 1.231]	0.916 [0.789 – 1.062]
Male patients	Significant discomfort	0.721 [0.441 – 1.177]	0.952 [0.673 – 1.348]
	Caecal intubation	0.965 [0.652 – 1.428]	1.250 [0.711 – 2.196]
	ADR	0.938 [0.804 – 1.095]	1.018 [0.696 – 1.488]
	PDR	0.976 [0.829 – 1.150]	0.870 [0.729 – 1.039]

Table 1. Discordance vs concordance.

Conclusion: Sex discordance between endoscopists and patients was associated with more discomfort, lower ADR, and lower PDR in screening colonoscopies, and lower PDR in non-screening colonoscopies. These findings do not seem to be driven by a specific subgroup or endoscopists' sex, such as the case was in the study on the observed discordance between surgeon sex and patient sex and its associated negative postoperative outcome. Further studies are needed to confirm or invalidate these findings, as well as the clinical relevance.

Introduction: Sustainability is a major issue that doesn't spare the field of digestive endoscopy. Bearing that in mind, the French Society of Digestive Endoscopy (SFED) created the Eco-responsibility and Sustainability Commission in 2021 and conducted a survey on green endoscopy practices throughout France.

Aims & Methods: Two digital forms (Google® Mountain View California, USA) were created and sent via the SFED mailing list (doctors and nurses). Data collection took place from January to April 2022.

The first questionnaire included 32 questions, regarding participants, their sensitivity to the ecological cause (using a numerical scale up to 10, the highest sensitivity) their use of small devices, the type of water used, their knowledge of biomedical waste (BMW), the clothing worn in the endoscopy room (ER) and recycling loops.

The second questionnaire consisted of 31 questions, concerning the participants, whether they had already taken ecological action on a personal level, their data storage systems and their means of transportation.

Results: First questionnaire: 707 people from all over France responded out of 9911 recipients of the SFED mailing list. Average environmental sensitivity was 7.5/10.

- Regarding the use of small devices : 88.4% of the participants use reusable valves. 49.5% use reusable bite blocks. 94.3% use single use hemostatic clips.
- Regarding the type of water used according to the endoscope use : for the aspiration tests, 32.6% use filtered tap water; for the insufflation and endoscope lens wash jar, 24.9% use filtered tap water; and for the irrigation pump, 71.9% % use filtered tap water.
- 96.5% of participants knew that BMW should be incinerated, but only 5.4% knew that for every ton of BMW incinerated, approximately 1 ton of CO2 is produced.
- Regarding he clothing worn in the endoscopy room : 71.2% of the participants wear fabric scrubs washed within the hospital, most of the surgical cap (87.6%) are use single use, but theatre clogs are mainly reusable (88.7%). When the participants are cold in the ER, in 63.4% they wear single use over shirt.
- Regarding recycling loops : there is a glass recycling loop in 73.1% ER, a plastic recycling loop in 59.3% and a paper recycling loop in 38.3%.

Second questionnaire: 385 people from all over France responded out of 9969 recipients of the SFED mailing list.

Average environmental sensitivity was 7.7/10. 90% of the participants have personally undertaken ecological actions, such as sorting waste, recycling, composting, buying less, cycling.

Storage : 24.6% of pictures are stored on a server, 35.1% are stored and printed, 30.1% are printed only.

Transportation : 21.6% of the participants go to work by bike, 60.3% by car, 8.1% by foot, 3.9% use public transportation.

Conclusion: To conclude, this practice survey is a global reflection of green endoscopy in France and allows us to have concrete results to base our efforts on to reduce the carbon impact of digestive endoscopy. To help us, the ESGE recently published its recommendations, and we can use the 3Rs rule: Reduce, Reuse, Recycle.

WHAT CAN PATIENTS TELL US ABOUT SAFETY IN THE ENDOSCOPY UNIT? THE 'PATIENT REPORTED INCIDENTS OF SAFETY IN ENDOSCOPY (PRISE)' STUDY

S. Ravindran[1,2,3], R. Sikafi[4], P. Datt[5], C. Tolosa[2], C. Tapec McLachlan[2], S. Marshall[6], K. Flott[7], H. Ashrafian[3,7], A. Darzi[3,7], S. Thomas-Gibson[2,8]

Introduction: Safety in endoscopy is of paramount importance with increasingly therapeutic and complex procedures. Despite safety initiatives, incidents still occur. In order to learn from these, we need to be able to better detect issues. The patient voice has been crucial in understanding healthcare from a different perspective. Specifically, patient reporting has been able to detect safety-related issues, which may not have been identified through other means [1, 2]. This is an area not previously explored in endoscopy.

Aims & Methods: Our aims were to develop a novel tool for patient reporting of safety incidents in endoscopy (PRISE), co-designed with patients. Secondary aims were to identify safety incidents, factors and perceptions. This study was split into two phases. Phase one involved a literature review of articles related to patient reported incidents, followed by patient focus groups to identify key topic areas to address and survey design

ideas. These findings informed development of the PRISE survey tool. A patient panel was created and, through regular refinement meetings with the research team, question items were created.

Phase two was a prospective pilot of the PRISE tool in a single academic centre. The survey was disseminated over an 8 month period through physical and electronic media. Patients were asked to complete this within 2 weeks of their procedure. Outcome measures included the percentage of positive responses (PPR) across question item domains, safety perception scores and number of safety incidents detected. Descriptive and comparative analyses were performed.

Results: In phase one, over 1600 articles were identified from search criteria. Following title, abstract and full text screens, 17 full text articles were included in the literature review. A total of 24 incident topic areas were identified. Three focus groups were conducted with 22 participants. Outcomes were focussed around five themes: question style, content, question items, timing, and dissemination. The PRISE co-design process was conducted over ten sessions. The final survey consists of the following sections: demographics, safety incidents and factors – 24 items, grouped into domains (pre-procedure, post-procedure, unit and staff), safety concerns – a qualitative section, and safety perceptions – a quantitative score. In phase two, 596 patients responded to the survey. Perceptions of safety were overwhelmingly high (mean rating 9.7/10). The PPR for all domains was > 90%, with the staff domain (items on staff characteristics) rated significantly higher than all others (96.7% PPR; $p < 0.001$). Four clear PSIs were identified - three related to equipment failure and one regarding wrong bowel preparation. Six patients (1.0%) declared safety concerns. Two patients felt they suffered from a mistake. The five highest negatively rated question items were related to information handover, management of patient concerns during procedure, physical space in the unit, equipment faults during procedure, and unnecessary delays in care respectively. Thematic analysis of comments identified negative themes related to bowel preparation, care process issues, communication, constraints on service, environment, equipment, procedures, and staff.

Conclusion: A patient co-designed pilot prospective survey identified high perceived safety in the endoscopy unit. Staff characteristics were rated highly. Safety incidents were detected as well as areas to focus on for safety improvement.

SAFETY OF ENDOSCOPIST-DIRECTED NURSE-ADMINISTERED SEDATION IN AN ITALIAN REFERRAL HOSPITAL: RETROSPECTIVE AUDIT ON 2 YEARS AND 19.407 PATIENTS

R. Conigliaro[1], F. Pigò[1], M. Gottin[2], G. Grande[1], S. Russo[1], S. Cocca[1], M. Lupo[1], M. Marocchi[1], H. Bertani[1]

Contact E-Mail Address: bertani.helga@aou.mo.it

Introduction: Balanced propofol sedation administered by adequately trained non-anesthesiologist personnel has gained popularity in GI endoscopy because of its shorter procedure and recovery time, high patient satisfaction, and low rate of adverse events (AEs), even if it's still considered controversial. We reported data from a retrospective audit of Endoscopist directed nurse administered sedation (ED-NAAS) over a 2-year period in an Italian referral hospital.

Aims & Methods: Consecutive endoscopic procedures performed between October 2020 and October 2022 were considered. Under the guidance of the endoscopist, the nurse administered 1 to 2mg of midazolam, followed by a progressive top-up dosages of 10-20mg bolus of propofol to achieve moderate to deep sedation. Fentanyl was administred based on the patient's weight if indicated. Endoscopists and nurses were all certified in our hospital with a continuous and scheduled training from 2006. The patients' characteristics, dosage of administered drugs, AEs during and after the examination, were all investigated. The following AEs were deemed minor but significant: bradycardia (≤50 beats/min ≥10 seconds), hypoxia (SaO2 ≤ 90% ≥10 seconds) and hypotension (systolic BP ≤100 mmHg with a drop ≥ 20 mmHg). Major consequences included death, a persistently low state of awareness, permanent harm, the need for an emergency anaesthetist evaluation, the need for hospitalization or endotracheal intubation.

To increase the sensitivity of AEs detection, reports were reviewed in these cases:

1. AEs declared in the report,
2. Search by string "desaturation" "hypotension" "bradycardia" "apnoea" "hypoxia" in the report,
3. Oxygen saturation level, systolic BP and heart rate ≤50 bpm annotated during the intra-procedural monitoring compared to parameters measured before sedation,
4. Patients administered flumazenil, naloxone, etilephrine, atropine.

Results: A total of 19407 examinations (7803 EGDS, 10439 colonoscopies, 77 PEG, 697 EUS and 365 ERCP) and 14415 patients were enrolled. 29.4% of patients were classified as ASA I, 66.5% as ASA II and 5.1% as ASA III. Balanced sedation with propofol was administered in 86% of EGDS, 94% of colonoscopies, 92% of EUS, 94% of ERCP and in 72% of PEG. Hypotension was recorded in 1293 (6%) examination, which required fluid infusion in 330 cases (26%) and in 8 cases etilephrine to restore blood pressure. Bradycardia was recorded in 176 (0.9%) patients, which required atropine in 134 (72.8%) cases. 11 patients (0.06 %) had a minor respiratory adverse event.

The mean age of patients of hypotension, bradycardia and respiratory adverse event was respectively 61.1±15 years, 64.3±15.3 and 55.6±16.2. ASA III patients were respectively 4.1%, 2.8% and 27.2% in the three groups of AEs.

The mean SD/median (25^{th}-75^{th} percentil) dosage of medications were respectively 2.0±0.7mg, 2.0±0.7mg, 1.8±0.3mg of midazolam, 71.0±34.5mcg, 68.0±31.0mcg and 62.5±9.5mcg of fentanyl, 94.0±74.3mg, 77.0±61.7mg and 120 (70-190)mg of propofol. BMI and Mallampati score of II were re-

spectively 23.0±4.5 and 72.8% in patients with respiratory AEs. 1 patient (0.001%) had a major AE, needing oro-tracheal intubation. He was 63 years old with unknown diagnosis of amyotrophic lateral sclerosis, with normal BMI, Mallampati score I, sedated with 2mg of midazolam + 80mg of propofol. Limits of the study include recall bias (missed cases of AEs not caused by sedation but because of examination itself, e.g., bradycardia or laryngospasm).

Conclusion: Balanced propofol ED-NAAS is safe in low-risk patients. Major adverse events occurred in 0.001% procedures.

Disclosure: Nothing to disclose.

Introduction: Recently, various electrosurgical knives with water-jet functions are available worldwide. However, their injection performances using water-jet functions have not been objectively evaluated thus far.

Aims & Methods: This study aimed to objectively evaluate the water-jet-functioned electrosurgical knife injection performances in a desktop experiment.

Five types of water-jet-functioned electrosurgical knives, including two injection styles of sheath-type (A: DualKnife J, KD-655L; B: FlushKnife, DK2620-J-B20S; C: Splash M-Knife, DN-D2718B; D: ISSEN, SN1650-20) and tip-type (E: ORISE ProKnife, M00519361) were evaluated. These knives were compared with an injection needle (Control: SuperGrip 25G) as a control. The injection speed under constant pressure and the injection efficiency for each knife against prepared porcine stomach mucosa were evaluated. The additional clear gel injections using an injection needle were observed using an indigo blue-colored gel to evaluate the difference between the locations of water-jet holes.

Results: Four types of knives, except for A, showed significantly higher water-jet speeds (A: 0.79 ± 0.03 g/20 sec, B: 2.56 ± 0.05 g/20 sec, C: 3.09 ± 0.06 g/20 sec, D: 2.86 ± 0.05 g/20sec, E: 1.79 ± 0.03 g/20 sec) compared to that of the control (1.21 ± 0.03 g/20 sec).

Meanwhile, significantly higher efficacy of injection was found in the tip-type water-jet function knife, second to the injection needle (Control: 37.2% ± 35.5%, A: 20.9% ± 20.2%, B: 1.1% ± 2.2%, C: 6.2% ± 12.6%, D: 12.5% ± 15.6%, E: 33.3% ± 32.2%).

An additional injection experiment revealed that the injection with a piercing tip into the gel could achieve sufficient additional injection inside the stacked clear gel.

Conclusion: The tip-type water-jet function electrosurgical knife is preferable for effective submucosal injection during endoscopic treatments.

SINGLE-USE GASTROSCOPE REDUCES ENDOSCOPIST MUSCLE LOAD COMPARED TO REUSABLE GASTROSCOPE

V. Bessone[1], S. Adamsen[2,3]

[1]Ambu Innovation GmbH, Augsburg, Germany, [2]Ambu A/S, Ballerup, Denmark, [3]Bispebjerg Hospital, Digestive Disease Center, Vedbæk, Denmark

Contact E-Mail Address: vebe@ambu.com

Introduction: As for any hand tool, the weight of the endoscope influences user comfort and the risk of developing musculoskeletal injuries, frequently occurring among gastrointestinal endoscopists [1; 2]. As a result, the endoscope weight reduction has been recommended to optimize the ergonomics of the endoscopes [3]. Because of the constituent material, single-use endoscopes are lighter than reusable ones, with a possible reduction of the muscle activation needed to hold and operate the endoscope.

Aims & Methods: The aim of the study was to compare the muscle activation while holding and operating two different gastroscopes with different weights. The activation of the forearm muscles using a single-use and a reusable gastroscope was measured using wearable superficial electromyogram (sEMG) sensors while holding the endoscopes and performing a set of standardized manoeuvres. 14 subjects (six females; median age 34 years; range 25-65 years) participated. The gastroscopes were a single-use (aScope Gastro, Ambu A/S, Denmark; weight: 0.6 kg) and a reusable gastroscope (GIF-1TH190, Olympus, Japan; 1.4 kg). The set of exercises included an initial 30-second rest position holding the endoscope statically; followed by two left-hand wheel rotations reaching a 90° tip up and down bend, respectively, and maintaining these positions for 10 seconds. Finally, the valves were pressed for 10 seconds each. The exercises were repeated three times with a 30-second rest position in between. The two gastroscopes were used in randomized order. A sleeve with embedded sEMG electrodes (ErgoSleeve, Myontec Ltd., Finland) was worn by the participants on the left arm to detect activation of the wrist flexor and extensor muscles. Before starting, the maximal voluntary contraction (MVC) was measured. sEMG data were processed using the connected software (Ergolink, Myontec Ltd., Finland), reported as muscle load (%MVC) i.e., the percentage of sEMG data normalized to MVC and displayed as average and standard deviation of the muscle load. Data were compared with paired t-test with statistical significance set at $p<0.05$ and calculated using Excel (Microsoft Corporation, USA).

Results: The muscle load was higher with the reusable gastroscope in the rest positions and during all manoeuvres (flexors [%MVC]: 6±2 vs. 5±2; extensors [%MVC]: 7±3 vs. 6±3; all $p<0.001$). We deduced that the gastroscopes' weight difference played a major role. In fact, also during the rest position during which no manipulation of wheels or valves was required, the muscle load was higher when the reusable gastroscope was used (flexors [%MVC]: 4±2 vs. 3±2; extensors [%MVC]: 3±1 vs. 2±1; all $p<0.001$). In a previous study regarding hand tool weight and its relationship with the development of postural tremor [4], the authors demonstrated that the heavier the tool, the shorter the time before detecting postural tremor (as example, 9 minutes for tools weighing 0.8 kg, 12 min for 0.4 kg). Considering that the majority of diagnostic gastroscopies last a minimum of 10 min [1], tremor is assumed to be inevitable when using reusable endoscopes. In fact, despite the weight is partially distributed on the insertion tube and the connection cord, the total weight of reusable gastroscopes is higher than 1.2 kg, while the one of single-use gastroscopes less than 0.6 kg.

Conclusion: Holding and operating a single-use gastroscope reduces the load on the left wrist muscles compared to a heavier reusable gastroscope. This benefits the user ergonomics, and may prevent or delay the development of tremor, fatigue, and musculoskeletal injuries.

PP1708

DEVELOPMENT OF A GASTROINTESTINAL SYMPTOM SCALE FOR THE STANDARDIZED ASSESSMENT AND FOLLOW-UP OF PEDIATRIC PATIENTS

K. Hammer[1], G.J. Holtmann[2], J. Hammer[3]
[1]St. Anna Kinderspital, Vienna, Austria, [2]Princess Alexandra Hospital, Gastroenterology & Hepatology, Brisbane, Australia, [3]Medical University Vienna, Vienna, Austria

Contact E-Mail Address: karin.hammer@stanna.at
Introduction: Accurate symptom assessment and monitoring over time is critical for effective patient management and research. Standard history taking is unavoidably influenced by both patient-related and physician-related factors. Patient reported outcome measures (PROMs) facilitate evaluation of patients and allow to better assess treatment effects. Validated tools are lacking for paediatric gastroenterological patients.
Aims & Methods: We aimed to adapt and validate for paediatric populations a self-administered Structured Assessment of Gastrointestinal Symptoms (SAGIS) tool that previously has been validated in adult cohorts. Each item of the original SAGIS instrument was thoroughly reviewed for its relevance in the paediatric population. The resulting paediatric (p) SAGIS was utilized over a 35 months' period in consecutive patients in a paediatric outpatient GI-clinic. Principal components analysis (PCA) followed by Varimax rotation and confirmatory factor analysis (CFA) was performed in derivation and validation samples. Responsiveness to change was assessed in 32 children with inflammatory bowel disease (IBD) after 12 months of therapy.

Children with IBD (n=32)	Initial Visit	After 1 year of therapy	p-value
Mean total GI-symptom score	0.41 ± 0.49	0.14 ± 0.33	<0.01
Abdominal pain	0.49 ± 0.66	0.19 ± 0.44	<0.01
Dyspepsia	0.42 ± 0.56	0.24 ± 0.54	<0.05
Diarrhea	0.37 ± 0.60	0.13 ± 0.49	<0.05
Constipation	0.57 ± 0.74	0.14 ± 0.35	<0.001
Dysphagia/Nausea	0.25 ± 0.39	0.14 ± 0.29	=0.09

Results: The final paediatric SAGIS consisted of 21 GI-related Likert-type questions, 8 dichotomous questions assessing extra-intestinal symptoms and two most bothersome symptoms. 1153 children/adolescents completed a total of 2647 questionnaires. Cronbach's alpha was 0.89, indicating good internal consistency. PCA supported a five-factor model (symptom groups: abdominal pain, dyspepsia, diarrhoea, constipation, dysphagia/nausea), CFA showed good model fit (CFI:0.96, RMSEA:0.075). The initial mean total GI-symptom score in IBD-patients (8.7±10.3) decreased to 3.6±7.7 after 1 year of therapy (p<0.01), and four of five symptom group scores decreased significantly upon treatment (p<0.05). The table shows responsiveness of p-SAGIS in children with IBD, total GI-symptom scores and symptom scores of pSAGIS-domains at the initial visit and after 1 year of therapy (data are given as mean±standard deviation).
Conclusion: The pSAGIS is a novel, easy to use, self-administered instrument for GI-symptom assessment in children/adolescents with excellent psychometric properties. It may standardize GI-symptom assessment and may enable uniform clinical analysis of treatment outcomes.

Introduction: Musculoskeletal disorders (MSDs) are disorders of the musculoskeletal system (muscles, tendons, skeleton, etc.). Work-related MSDs are MSDs caused or aggravated by working conditions.
Endoscopic activity is known for the non-ergonomic positions it imposes on the practitioner, responsible for joint constraints and a physical and mental workload.
Aims & Methods: The aim of our work is to measure the prevalence of MSDs among hepato-gastroenterologists (HGE) and to evaluate the risk factors.
This is an international multicenter observational, descriptive and analytical study from 04/01/2022 to 18/10/22, conducted among digestive endoscopy practitioners who voluntarily responded to a self-administered questionnaire via Google Form containing three parts: socio-professional characteristics of the surveyed HGEs, questions for the evaluation of MSDs and treatments taken and questions for the evaluation of the psychosocial environment and workload.
Data analysis was done by Jamovi 2.2.5 software.
Results: We recruited 417 participants with a median age of 37 [32; 48] with female predominance 250(60%) and a mean BMI of 24.9 (±3.44).
A participation of 79(19%) Residents, 246(59%) specialists and 92(22%) professors in HGE. The median endoscopic practice time was 84 months [84; 196].
Regarding MSDs, 171 (41%) of the participants had a history of muscular and joint disorders, the incidence of MSDs in the 12 months preceding the study was 120 (28.7%) and in the last 7 days 183 (43.88%).
The lower back 130(71%), neck 120(65.5%) and right wrist 75(41%) were the most affected areas. The least affected areas were the hips 20(11%) and the elbows 12(6.5%).
MSDs were found in 101 (43.7%) of the participants with a BMI > 24 kg/m2 against 53 (23.2%) who had a BMI < 18 kg/m2.
Practitioners with a long history of muscular and joint disorders had a higher risk of MSDs in the year compared to practitioners without a history of MSDs, with a statistically significant p value of p< 0.003 (52.6% vs 37.8%); there was also a statistically significant relationship between age;

length of time practicing endoscopy; practice of therapeutic endoscopy and the presence of MSDs in our participants, with respective p values of p<. 001(40-60years 61.2% vs <40years 30.5%); p=0.024; p<.001.
There was also a statistically significant relationship between the practice of advanced endoscopy (EE+ ERCP) and the presence of MSD in our participants with a p value p<.001.
Conclusion: Work-related MSDs remain a neglected subject, yet according to our study one practitioner out of 3 suffers from them. Age, overweight, length of time in endoscopic practice, and the number of endoscopies performed are the main risk factors for MSD.
Our results underline the importance of a rigorous and adequate prevention, by an adaptation of the work ergonomics and physical exercise to reduce the incidence of this professional pathology.
Disclosure: no conflicts of interest.

EFFECTIVENESS OF ERGONOMICS PROGRAM BASED ON MOVEMENT ANALYSIS FOR EXPERIENCED ENDOSCOPISTS: A PILOT STUDY

H.-S. Kim[1], H. Kim[1], J.W. Kim[1], H.J. Park[1], O.-y. Kwon[2]
[1]Yonsei Univ. Wonju College of Medicine, Internal Medicine, Wonju, South Korea, [2]Yonsei University, Physical Therapy, Wonju, South Korea

Contact E-Mail Address: hyskim@yonsei.ac.kr
Introduction: Though the burden of musculoskeletal injury(MSI) by long-term accumulation of endoscopy procedures is well known, there is little data on the techniques that can reduce or prevent MSI.
Aims & Methods: The purpose of this study is to develop a new method for MSI assessment in long-term endoscopy practitioners and to establish an individualized MSI restoration plan through the special 16-week intervention of Kinetic Ergonomics based on Movement Analysis(KEMA) program by physical therapists.
Fifteen volunteer endoscopists practicing more than 10 years from 4 tertiary medical centers, were evaluated by demographics, endoscopy burden, location and degree of pain, and endoscopy posture. A comprehensive functional evaluations of ergonomic position, posture, and MSI and load during endoscopy was made by the physical therapist and self-perception questionnaire for involved joints was also evaluated. Then personalized KEMA program (musculoskeletal function evaluation and customized exercise program based on ergonomics) was delivered for 16 weeks by physical therapists on a one to one basis. KEMA program included recommendations for individualized exercises, static and dynamic posture re-education during and between procedures, optimization of procedure suite set-up and pain education. The endoscopists were re-evaluated regarding their perception and adherence to ergonomics and subjective symptoms at the end of the program.
Results: Various ergonomic problems were found to varying degrees in all 15 long-term endoscopy practioners including ergonomic inefficiencies and suboptimal movement patterns. Among 12 areas evaluated, pain areas were most commonly found in the order of the low back, neck, shoulder, wrist, and thumb. In addition, cumulative endoscopy time and neck and thumb pain, cumulative number of endoscopy cases and neck, back, and hip pain scores, neck and shoulder pain, and wrist and elbow pain showed positive correlations with each other. After 16-weeks KEMA program, among these 5 main painful joints, the remaining 4 joints (80%) showed improvement in the intensity and frequency of pain, except for the shoulder.
Before and after the program, the level of understanding of knowledge about ergonomics increased from an average of 28 points to 33.6 (5-point scale of 10 items), but unfortunately, ergonomic attitudes and performance did not show significant changes.
Conclusion: The evaluation of MSI based on kinetic ergonomics for endoscopists and customized exercise program helped to recognize one's own body condition and relieve pain and recovery of the MSI even with a relatively short-term management of 16 weeks. These ergonomic interventions used here could potentially contribute to career longevity, decreased burnout, reduce lost days of work and most importantly reduction in pain and fatigue among practitioners.

Contact E-Mail Address: kumarl@tcd.ie
Introduction: Gastrointestinal (GI) bleeding poses a significant burden on inpatient care and significant in-patient mortality. Previous audits have demonstrated variation in practice, with patchy adherence to guidelines. In Ireland, information regarding patient outcomes from GI bleeding is scarce.
Aims & Methods: To follow the outcomes of patients admitted with gastrointestinal bleeding in Ireland, monitor trends in patient activity and to identify factors associated with adverse outcomes. A retrospective review of all acute admissions in Ireland between 2017 and 2022 with GI bleeding as the principal diagnosis was performed using the National Quality Assurance and Improvement System Application, an online tool that analyses patient data from discharge summaries. Demographics such as age, gender, admission source was recorded. GI bleeding was stratified into upper GI bleeds (UGIB) and lower GI bleeds (LGIB), with UGIB further classified as variceal and non-variceal GI bleeding based on relevant logged terms. Outcomes including mortality, readmission rates (7-day and 30-day), and hospital length of stay (LOS) were analysed. Regression analysis was performed to identify factors associated with adverse outcomes.
Results: Data from 16,456 emergency admissions was analysed. The median age was 70.5 years (IQR 53-81), 57.2% were male. Median LOS was 4 days (IQR 2-7). Overall mortality was 3.8% (n=625), 6.5% (n=1076) of admissions required high-dependency care and readmission rates within 7- and 30-days were 5% (n=818) and 12.2% (n=2013) respectively. Patient admissions were under a general medical team in 43.8%, a surgical team in 42.4% and gastroenterology in 12.9%.
Weekend admissions (Friday-Sunday) were associated with an increased median LOS (4.0 days vs 3.0 days, p<0.001). Patients admitted under Gastroenterology had a longer average LOS (6.9 days vs 6.3 days, p<0.001) compared to other services but had an overall lower mortality (2.8% vs 4.1%, p=0.013). No significant difference was observed in admission rates, LOS, mortality, 7- and 30-day readmission during the COVID pandemic.
UGIB (n=9546) data demonstrated an overall mortality of 4.0% (n=378) with significantly higher mortality (7.6% vs 3.7% p<0.001), ICU requirements (25.4% vs 7.1%, p<0.001), and 7-day (6.6% vs 4.8%, p=0.039) and 30-day (17.9% vs 12.3%, p<0.001) readmission rates seen in variceal bleeds vs non-variceal bleeds. LGIB (n=1842) admissions had a mortality of 2.1% (n=38), a median LOS of 4 days (IQR2-8) with majority (58.5%) of admissions being under a surgical team.

Older age (overall OR 1.054 [95% CI 1.045-1.062, p<0.001]) and an intensive care unit admission (overall OR 12.8 [95% CI 10.5-15.5, p<0.001]) were found to be independent variables predicting mortality across all types of GI bleed admissions. Older age also predicted 7-day and 30-day readmissions to hospital.

Conclusion: This is the first study to report national outcomes of patients admitted with GI bleeding and highlights variations which could be addressed by a GI bleeding care bundle. Patients with GI bleeding admitted at the weekend have a longer average LOS and suggest potential value of weekend endoscopy.

WASTE AUDIT IN A LARGE SWISS ENDOSCOPY CENTER - FIRST STEP TO A GREENER ENDOSCOPY UNIT

F. Rybinski[1], M. Winters[2], M. Zimmerli[1], C. Abshagen[2], J.H. Niess[1], H.S. Heinrich[1]
[1]Clarunis- Universitäres Bauchzentrum Basel, Gastroenterology, Basel, Switzerland, [2]Universitätsspital Basel, Sustainability, Basel, Switzerland

Contact E-Mail Address: henriettesophie.heinrich@clarunis.ch

Introduction: Climate change is a major challenge to our future generations and environment, and limiting its effects is necessary in every aspect of our daily lives. Endoscopy units are one of the most resource-intensive hospital departments, producing large amounts of contaminated waste, mostly disposed of by incineration, generating large quantities of CO_2. The environmental impact of endoscopy needs to be better investigated as current ESGE/ ESGENA guidelines propose reducing waste by first creating awareness via implementing audits to assess waste production[1]. We sought to investigate the feasibility of an audit procedure assessing waste production and mechanisms of disposal to understand where to reduce, reuse or recycle the waste.

Aims & Methods: During one working week in March 2023, we performed a structured waste audit in collaboration with the department for environmental sustainability in the endoscopy department of the university hospital of Basel, a tertiary referral center in northwestern Switzerland, performing >6000 endoscopic procedures per year. Waste was collected separately in patient-specific bags for each procedure, from the preparation of the patient to discharge by two investigators. The use of sharps and reusable equipment (e.g., tubing, etc.) was included in the calculation of the waste generated per procedure.

Results: During the study period,the normal running of the endoscopy unit was not disrupted. Waste produced by 75 examinations was analyzed. Median waste production was 910 g/ Gastroscopy, 1060g/ Colonoscopy, 1110g/ Gastro-and Colonoscopy, 1240 g/ Sigmoidoscopy and 1823 g/ ERCP or EUS. This adds up to 26 kg of waste per day or 52 t of CO_2 generated by incineration per year in our endoscopy unit.

Conclusion: A structured waste audit can easily be incorporated into the daily practice of an endoscopy unit without impacting patient care and using few resources. Creating awareness of waste generation and composition is a crucial first step toward creating sustainable endoscopy practice. The amount of $C0_2$ generated by our endoscopy unit in a year equals driving eight times around the world. Gastroscopy and colonoscopy should be combined in one procedure when possible.

USE OF A HANDHELD METAL DETECTOR FOR MANAGEMENT OF METALLIC FOREIGN BODY INGESTION IN CHILDREN

T. Krencnik[1], T. Jalsovec[1], M. Klemenak[1], P. Riznik[1], J. Dolinsek[1]
[1]UKC Maribor, Clinic for Pediatrics, Maribor, Slovenia

Contact E-Mail Address: tkrencnik@gmail.com

Introduction: Foreign body ingestion is nowadays still an important and common cause of referral of children to the emergency department. The most common ingested objects are coins. Some ingested foreign objects (e.g., button batteries, sharp objects) can lead to life-threatening complications. The golden standard for determining the presence and the location of ingested objects is still the X-ray examination of the whole digestive tract. A handheld metal detector is a portable device that by measuring changes in the inductance of a coil determines that a metallic object is near. The presence of such an object is presented as an audio and/or visual signal. With changing the sensitivity of the detector and repeated screenings of different areas it is possible to determine a possible location of a metal foreign object in the body.

Aims & Methods: The aim of our study was to determine if the use of a handheld metal detector could determine the presence and the location of an ingested metal foreign object to a degree that a supplementary X-ray examination would not be necessary.

We collected the medical data from the children with suspected metal object ingestion who were referred to our emergency department from October 2017 until March 2023. We focused on the type of ingested object and on the correlation between metal detector signal and x-ray image in detecting the presence and location of the presumably ingested foreign object.

Results: The data from 43 children (39.5% female; average age 50 months; min 3 months, max 11 years 4 months) that were treated at our emergency department was available for the analysis. Approximately two thirds (65%) of children were referred on the same day of suspected metal object ingestion and almost all (92.5%) were referred in 7 days after suspected ingestion. The most common ingested objects were coins (32.6%), followed by button batteries (18.6%) and hair pins (11.6%).

All the children were first checked using the metal detector placed on the different parts of the body (neck, chest, abdomen) and in 35 children (81.4%) the signal was detected.

Subsequently, x-ray was performed in 40 children. The most common location of the foreign object was the stomach (42.5%), followed by large bowel (27.5%) and oesophagus (15.0%).

The signal from the metal detector matched the x-ray object location in 90,0% of cases (N=36). For the objects, that were not detected by the metal detector, mean delay from ingestion to referral was 7 days (min 0, max 17 days), whereas for the others mean delay was 1 day (min 0, max 7 days).

Endoscopic removal was performed in 25.4% of cases (N=11), mostly for button batteries (N=4) and sharp objects (hairpins, screw, wires) where the location of the object was still in the reach of an endoscope.

Conclusion: Handheld metal detectors in majority of cases show a good correlation with the results of x-ray examinations. However, in cases where metal detectors don't confirm the presence of a metal foreign object, an x-ray is needed to confirm this. Smaller objects and low sensitivity of the detector could present a problem for the detection.

SEDATION LEVEL AND ITS FACTORS IN ENDOSCOPIC PROCEDURES WITH MODERATE SEDATION BY GASTROENTEROLOGISTS (GISED)

A. Craciun[1,2], I. Rodrigues[1,2], J. Serrazina[1,2], S. Bronze[1,2], I. Botto[1,2], F. Faustino[1], F. Capinha[1], R. Tavares Fernandes[1], D. Sousa[1], F. Damião[1], L.C.R. Freitas[1], A.I. Valente[1], A.R. Gonçalves[1], C. Noronha Ferreira[1,2], R. Tato Marinho[1,2], L. Correia[1,2]

[1]Hospital de Santa Maria, Serviço de Gastroenterologia e Hepatologia, Lisbon, Portugal, [2]Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Contact E-Mail Address: aanacraciun@gmail.com

Introduction: Combination of benzodiazepines and opioids are effective for achieving moderate sedation for endoscopic procedures and can be delivered safely by endoscopists in patients with ASA Class I–III. Non-anaesthesiologist administration of propofol (NAAP) is only available in a few European countries and there is evidence that low-risk procedures can presumably be done with conventional moderate sedation regimens.[1,2]

Aims & Methods: This study aimed to evaluate the factors influencing efficacy and safety and satisfaction of patients undergoing low risk endoscopic procedures under moderate sedation by gastroenterologists(GIs). A single-centre prospective study was carried out between April 2021 and February 2023, wherein 317 consecutive patients with indication for endoscopic procedure with sedation by GIs were evaluated and finally 264 included. Fifty-three patients were excluded due to refusal of informed consent 38%(n=20), cognitive/hearing impairment 19%(n=10), ASA-IV or V 11%(n=6), presence of stoma 11%(n=6), absence of assistance after sedation 8%(n=4), intolerance to sedatives 4%(n=2), predicted difficult airway and ventilation 4%(n=2), poor bowel preparation impairing performance of colonoscopy 4%(n=2). Midazolam induction dose was 0.05mg/kg, plus analgesia with pethidine at initial dose of 25mg (maximum 50mg) and titrated to achieve a score of 3 or 4 on the Ramsay scale. Nurse-assessed Gloucester comfort scale was used for patient comfort during procedures. Patients' satisfaction was evaluated based on a final self-completion survey. Statistical analysis was performed using SPSS v27 (SPSS Inc., Chicago, IL, USA).

Results: The 264 patients had a mean age 64±13 years with 53%(n=139) men. The mean BMI was 27.1±5.3 kg/m^2.In total, 309 endoscopic procedures were performed: 28%(n=87) gastroscopies and 72%(n=222) colonoscopies. When considering efficacy of sedation based on patient reported consciousness during endoscopy in 56%(n=148) (Table 1), factors independently associated with inadequate sedation were BMI (OR 1.1; 95% CI 1.01-1.2), midazolam induction dose compliance (OR 0.1; 95% CI 0.06-0.3), achieving Ramsay score ≤4 (OR 0.4; 95% CI 0.2-0.9), pain during procedure (OR 1.6; 95% CI 1.3-2.1) and remembering the start of procedure (OR 4.1; 95% CI 1.6-10.7). Twenty-two adverse events were reported and only one serious requiring hospitalization for 24 hours due to chemical cardioversion of atrial fibrillation. Most patients were at least satisfied with their procedures 82,5%(n=189/229). On univariate analysis, inadequately sedated patients were significantly more likely to remember the start of the procedure, experience pain and less likely to repeat the procedure.

Conclusion: The BMI, midazolam induction dose noncompliance, Ramsay scale score ≥5 and pain during procedure are independently associated with inadequate sedation which consequently results in poor patient satisfaction. The achievement of the adequate sedation target is essential for patient satisfaction.

Introduction: Several therapeutics are in development for familial adenomatous polyposis (FAP) to reduce polyp burden, the incidence of cancer and prevent or postpone intestinal surgery. However, there is limited consensus on the optimal method for measuring intestinal disease activity in FAP.

Aims & Methods: We aimed to systematically review existing endoscopic severity indices for FAP.

We searched MEDLINE, EMBASE and the Cochrane Library from inception to February 2023 to identify studies that evaluated endoscopic disease activity and severity in children and adults with FAP.

Results: A total of 94 studies were included. We evaluated component items of scoring indices, such as polyp count, polyp size and histology, and the scoring indices for the upper- and lower gastrointestinal tract . Partial validation was observed for polyp count and size.

The most common reported scoring index was the Spigelman classification system, which was used for assessing the severity of duodenal disease.

A single study reported an almost perfect inter- and intra-observer agreement for this system.

The InSIGHT polyposis staging system, which was used for assessing colorectal polyp burden has been partially validated. It showed substantial inter-observer agreement, however it lacked the analysis of the intra-observer agreement.

The SPACE criteria is a novel system to identify high-risk gastric polyps and was assessed for the inter-observer agreement; however it showed a moderate level of inter-observer agreement.

Conclusion: There are no fully validated endoscopic disease severity indices for FAP. Development and validation of reliable and responsive endoscopic disease severity instrument will be useful for clinical care, research and to assess the impact of pharmacological therapies on polyp burden in FAP.

A RETROSPECTIVE AUDIT OF END-TO-END QUALITY MEASURES IN ENDOSCOPY: INTERDEPENDENCE OF DETECTION RATES FOR ADENOMA AND SESSILE SERRATED ADENOMA OF ENDOSCOPISTS AND PATHOLOGISTS

N. Moy[1,2], L.F. Hourigan[3,1], G.J. Holtmann[1,3,4]
[1]Princess Alexandra Hospital, Queensland Health, Department of Gastroenterology & Hepatology, Brisbane, Australia, [2]Queensland University of Technology, Centre for Behavioural Economics, Society and Technology, Brisbane, Australia, [3]University of Queensland, Faculty of Medicine, Brisbane, Australia, [4]Translational Research Institute, Brisbane, Australia

Contact E-Mail Address: naomi.moy@health.qld.gov.au
Introduction: Detection rates of adenoma (ADR) and sessile serrated adenoma (SSRA) during colonoscopy are key quality indicators linked to the reduction of post-procedure colorectal cancer rates. The detection rate of for sessile serrated adenomas and adenomas can vary by endoscopist gender, experience and can be improved by the monitoring of key procedural metrics and education (1-3).
In addition, variation of ADR and SSRA can occur among pathologists (4,5). This variation among pathologists can potentially explain variation in ADR and SSRA of endoscopists. As part of routine end-to-end quality assurance, we identified significant variation among pathologists in relation to ADR and SSRA. Subsequently feedback was provided to the pathologists and an education program initiated.
This research examines whether these measures reduced the variation in pathologist detection rates for ADR and SSRA and if there is a subsequent impact on rates of detection of endoscopist. This requires determining if detection rates were linked to pathologists, if pathologist rates were linked to endoscopists and whether any detectable differences were maintained over time.
Aims & Methods: This retrospective quality improvement project reviewed the pathology results of all patients who underwent a colonoscopy procedure during three periods at a single tertiary site servicing a diverse population in Brisbane, Australia (HREC EX/2023/QMS/95516). Data was collected via the Endoscopy Services Information System Solution database and pathology results were collated from Pathology Queensland, Australia. The three periods examined were Quarter 3 (Jul-Sep) in 2020, 2021 and 2022.
Pearson Chi^2 test was used to determine if ADR and SSADR for pathologists were independent, and if endoscopists and pathologists are independent. Finally, one-way ANOVA, factorial ANOVA and t-tests were used to determine if there was a change in detection rates for pathologists and endoscopists over time. In all tests, a $p \leq 0.05$ is significant.
Results: A total of 3,813 colonoscopies were analysed during the three periods, of which 2,972 were had submitted material for histologic assessment. Procedures were performed by 25 endoscopists and a total of 16 pathologists examined the biopsied samples across the three periods. 17 endoscopists and 11 pathologists were involved in all three periods.
Significant variation in ADR was observed in Period 1 ($p < 0.05$). However, for subsequent time periods (after the variation was identified as part of our quality assurance measures), no significant relationship was observed between the pathologist and ADR and SSRA in subsequent years. Furthermore, in subsequent years there was a significant increase ($p<0.05$) of the rate of SSRA but not ADR.
Conclusion: This study suggests that not only the ADR and SSAR of endoscopists should be monitored but monitoring of variation in ADR and SSAR between pathologists can reveal substantial variations. With appropriate measures this unwarranted variation in key quality indicators of colonoscopy can be avoided.

Introduction: PuraStat is a novel hemostatic self-assembling matrix that seems promising both for the control of active bleeding and for the prevention of bleeding after operative endoscopy procedures.

Aims & Methods: The aim of this registry was to evaluate the safety and efficacy of PuraStat for the control of active bleeding and for the primary and secondary prevention of bleeding after different operative endoscopy procedures. A specific database was created and used to collect anonymous data from different Italian centers. Data on type of application (bleeding control vs prophylaxis, site and type of procedure in case of prophylaxis), amount of gel used, outcomes and safety of the application were systematically prospectively collected and analyzed.

Results: PuraStat was used on 401 patients that were treated for an active gastrointestinal bleeding or as a preventive measure after an operative endoscopy procedure in 10 Italian centers. 91 treatments for active bleeding and 310 preventive applications were included; 130 (32.4%), 44 (11%) and 227 (56.6%) were upper (ie. varices, ulcers, gastric antral vascular ectasia (GAVE), post endoscopic resection), biliopancreatic (ie. post sphincterotomy, post papillectomy, walled-off pancreatic necrosis (WOPN) drainage) and lower GI procedures (ie. post endoscopic resection, post pneumatic anastomotic dilation, radiation proctopathy) respectively. In 174/401 (43.4%) PuraStat was the primary treatment modality. The median coverage of the area treated with PuraStat was 97.9%, with difficulty in the application in 7/401 (1.7%) due to endoscope position. Hemostasis of active bleedings was achieved in 90/91 patients (98.9%).

In the follow-up 7/91 patients (7.7%) in whom PuraStat was used for hemostasis had a bleeding event as compared with 12/310 patients (3.9%) after prophylactic PuraStat application. No complication related to the use of PuraStat occurred.

Conclusion: PuraStat is a safe and feasible hemostat both for bleeding control and for bleeding prevention after different operative endoscopy procedures. For the first time we explored and evaluated the use of PuraStat in upper GI and Biliopancreatic procedures, demonstrating also in these cases an excellent profile in bleeding treatments as well as in bleeding prevention. Our results show that the possible application for the use of PuraStat may be wider compared to current indications.

Introduction: Acute perforations during endoscopic procedures are an emergency and need immediate closure to prevent abdominal cavity contamination and its fraught complications. Mucosal defect closure by loop-Clip method and its modifications have been successfully used to close perforations. We assessed the effectiveness of loop-clip method by a single channel endoscope.

Aims & Methods: The study aims at studying the effectiveness of Loop-clip method by a single channel endoscope in closure of acute iatrogenic perforations.

On recognition of a perforation, a predetached endoloop (LeClamp ligation device; Leo Medical Co Ltd, Changzhou, China) fixed to the hemoclip (Resolution clip, Boston Scientific, Boston, Mass, USA) was delivered using a single-channel endoscope (GIF-HQ190 Olympus, Tokyo, Japan) and anchored near the proximal margin of the defect, followed by deployment of consecutive hemoclips to anchor the endoloop along the margins of the defect. The endoloop was then tightened slowly by reattaching it to a hooking device (endoloop delivery system) resulting in an approximation of the borders of the perforation and closing it in a purse-string fashion. The parameters observed were the size, complete closure of the defect, closure time, Post closure Clinical spectrum, peritonitis, need for surgery, and hospital stay.

Results: A total of 24 cases of iatrogenic perforations were closed using the loop-clip method at our institution (the biggest endoscopic center in the country). The site of perforations was 1 oesophageal, 6 Gastric, 3 duodenal, 1 jejunal, and 13 colonic. 19 patients had perforations during therapeutic procedures (Oesophageal dilatation, Gastric ESD, SEMS deployment of a jejunal anastomotic leak, Colonic EMR/ESD). All the perforations during diagnostic procedures were during colonoscopy and the site was rectosigmoid.

To the best of our knowledge, endoscopic closure of a jejunal perforation in altered anatomy using loop and clips has not been described in the literature.

The mean size of the defect was 2.1 cms. The mean closure time was 12.7 minutes. 23(95%) of the patients complained of abdominal pain, 16(67%) patients developed fever mostly on day 2 of admission which settled with iv antibiotics. All the defects (100%) were closed successfully. None of the patients required surgery.

Mean age (years)	64.4 [41,83]
Size of Perforation (cms):	2.125 [1.5,2.5]
Successful closure	24[100%]
Mean procedure time (minutes)	12.70
Mean Hospital stay (days)	5[3,9]
Need of Surgery	0%
Mortality	0%

Conclusion: Early recognition and closure of endoscopic perforations is very essential for decreasing the morbidity and mortality. We found Loop-Clip method a very effective method for closure of large sized iatrogenic perforations with complete closure in all cases.

Disclosure: NONE

PROSPECTIVE STUDY OF WASTE GENERATION AND ENERGY CONSUMPTION FROM A LARGE ACADEMIC GI ENDOSCOPY CENTER: TIME TO TURN TO GREEN ENDOSCOPY

H. Patel[1], M. Desai[2], S. Srinivasan[1], C. Campbell[2], A. Higbee[2], P. Nathani[1], D. Radadiya[1], A. Perisetti[2], P. Sharma[3]
[1]University of Kansas Medical Center, Gastroenterology, Kansas City, United States, [2]Kansas City VA Medical Center, Kansas City, United States, [3]University of Kansas School of Medicine, Gastroenterology, Leawood, United States

Contact E-Mail Address: patelhk.md@gmail.com

Introduction: While GI endoscopy units serve an integral role in screening and diagnosis of a plethora of clinical conditions but could also be a source of environmental waste generation and energy consumption in form of plastic, sharps, personal protective equipment (PPE), cleaning supplies and energy. Evaluation of large data from one endoscopy center could serve as an actionable model for other centers in the health-system for environmentally sustainable endoscopy units.

Aims & Methods: We prospectively collected data on total waste generation of a single large academic VA based endoscopy unit (average 3500 procedures per year) over May-June 2022. We stratified the waste generated from esophagogastro-duodenoscopy and colonoscopy into biohazardous, non-biohazardous, or recyclable items to determine opportunities to improve/maximize the recycling of waste.

Data on each item used for each patient since entry to the endoscopy unit and discharge including the endoscopy procedure, amount of waste generation per day for the entire unit, type of waste, energy utilization for each day, and reprocessing related waste generation for each procedure were analyzed.

We also performed a review of endoscopy inventory utilized and audit of items utilized in each procedure. No patient information was collected, and study was approved by the local institutional review board.

Results: Data of 400 procedures collected over the study period was analyzed providing total waste generation of 1010.65 kg which include sharps (51.57 kg) and biohazard waste (336.34 kg). Average per day land-fill waste generation was 30.63 kg which approximates to 9,189 kg for an entire year. Despite 44% of items taken out from the inventory being recyclable, only 28% of them were used in the procedure per audit adding to the 8.6 kg. waste per day. Thus, intra-procedure inventory audit could reduce landfill waste by 20% per day (Figure 1). By scope cleaning and reprocessing, additional 194 gallon of liquids waste (=735.26 kg.) per day was generated. Two football field sized landfill waste is generated this way when total annual waste generation is considered. On average 277.1 kW hour energy was utilized for endoscopy unit alone per day which equals to 8.2 gallons of gasoline use per day.

Conclusion: Measures to reduce waste generation in form of reducing landfill and water waste are needed. Auditing and only using the inventory absolutely needed in a case could reduce the landfill waste by 20%. Improvement in methods aimed at environmentally effective scope reprocessing measures are immediately needed since this contributes to a significant source of total waste generation from the GI endoscopy as well.

Disclosure: Nothing to disclose.

PROSPECTIVE EVALUATION OF EFFICACY, SAFETY AND PATIENT SATISFACTION IN ENDOSCOPIC PROCEDURES WITH MODERATE SEDATION BY GASTROENTEROLOGISTS (GISED)

A. Craciun[1,2], I. Rodrigues[1,2], J. Serrazina[1,2], S. Bronze[1,2], I. Botto[1,2], F. Faustino[1], F. Capinha[1], D. Sousa[1], R. Tavares Fernandes[1], F. Damião[1], L.C.R. Freitas[1], A.I. Valente[1], A.R. Gonçalves[1], C.N. Ferreira[1,2], R.T. Marinho[1,2], L. Correia[1,2]
[1]Hospital de Santa Maria, Serviço de Gastroenterologia e Hepatologia, Lisbon, Portugal, [2]Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Contact E-Mail Address: aanacraciun@gmail.com

Introduction: Combination of benzodiazepines and opioids are effective for achieving moderate sedation for endoscopic procedures and can be delivered safely by endoscopists in patients with ASA Class I–III. Non-anaesthesiologist administration of propofol (NAAP)is only available in a few European countries and there is evidence that low-risk procedures can presumably be done with conventional moderate sedation regimens.[1,2]

Aims & Methods: This study aimed to evaluate efficacy, safety and patient overall satisfaction in endoscopic procedures with moderate sedation by gastroenterologists (GIs).

A single-centre prospective study was carried out between April 2021 and February 2023, where 317 patients with indication for endoscopic procedure with sedation by GIs were evaluated and finally 264 included. Fifty-three patients were excluded for failure to obtain informed consent 38%(n=20), cognitive or hearing impairment 19% (n=10), ASA-IV or V 11%(n=6), presence of stoma 11%(n=6), absence of assistance after sedation 8%(n=4), anticipated intolerance or reaction to sedatives 4%(n=2), predicted difficult airway and ventilation 4%(n=2), poor bowel preparation unable to perform the exam 4%(n=2). Midazolam induction dose started at 0.05mg/kg, plus analgesia with pethidine at initial dose of 25 mg (maximum 50 mg), titrated until achieving score 3 or 4 in Ramsay scale. Nurse-assessed Gloucester comfort scale was used for patient comfort during procedures. Patients' satisfaction was evaluated based on a final self-completion survey: satisfaction (5 levels); remembering the start of procedure (yes/no); remembering staying awake during procedure (yes/

no), pain scale (0 to 10) and repeating the procedures under the same conditions (yes/no/maybe). Statistical analysis was performed using SPSS v27 (SPSS Inc., Chicago, IL, USA).

Results: The 264 patients included had mean age 64±13 years with 53%(n=139) men. The mean BMI was 27.1±5.3 kg/m^2. ASA classification: Class II 58%(n=156) and class III 20.8%(n=56). Anxiety or depression disorder was noted in 21%(n=54) and obstructive sleep apnea syndrome in 6%(n=16). Use of benzodiazepines was noted in 21%(n=58) and opioids in 5%(n=14).

In total, 309 endoscopic procedures were performed: 28%(n=87) gastroscopies and 72%(n=222) colonoscopies. Midazolam induction dose per protocol was met in 59% patients (n=156). Median midazolam dose at gastroscopy was 3.0 (3.0-5.0)mg and colonoscopy 5.0 (3.0-6.0)mg; median dose of pethidine was 25mg (0-50). Sedation target (Ramsay score ≤4) was reached in 44%(n=140) and absence or slight pain was verified in 74%(n=236) cases. Adverse events were noted in 8%(n=22), the majority mild, characterized by hypotension and/or transient hypoxemia rectified with oxygen therapy; one patient needed 24 hours hospitalization due to atrial fibrillation requiring chemical cardioversion. Most patients were at least satisfied with their procedures 82,5%(n=189/229), with no pain experienced in 53% cases (n=128/240). Among those who referred pain (0 to 10), the median was 3.0 (2.0-5.0). Even though the majority did remember the start 72%(n=191) or the course 56%(n=148) of the procedures, 82%(n=216) would repeat it under the same conditions.

Conclusion: Moderate sedation by gastroenterologists is safe and effective and should be implemented in low-risk procedures with patients ASA I-III, especially in countries where NAAP is unavailable. Compliance with midazolam induction dose to achieve the sedation target is important for patient satisfaction.
