CANCER GENETICS

P01.001.A Hypoxia-mimetic agent DFO inhibits cancer cell proliferation and induces DNA damage

David Diez-Castro[1;2], *Luis Perez-Romasanta*[3], *Rogelio González-Sarmiento*[1;2;4], *Ana-Belén Herrero*[1;2;4]

[1]*Institute of Biomedical Research of Salamanca, Institute of Biomedical Research of Salamanca, Salamanca;* [2]*Faculty of Medicine, Departament of Medicine, Salamanca;* [3]*Hospital University of Salamanca, Oncology service, Salamanca;* [4]*Institute of Molecular and Cellular Biology of Cancer (IBMCC), University-CSIC, Salamanca*

Background/Objectives: Hypoxia is common in solid tumour microenvironments and has been associated with radiotherapy resistance and poor clinical outcomes. Replicating hypoxic conditions in vitro requires incubation at 1% O_2, 5% CO_2 and 94% N_2. This nitrogen-induced hypoxia is costly and time-consuming since it needs 24 hours to establish hypoxia. An alternative technique to replicate hypoxic conditions is the use of mimetics like deferoxamine (DFO). This molecule is an iron chelating agent that facilitates the accumulation of hypoxia-inducible factors and has been shown to induce apoptosis in breast tumor cell lines[1].

Methods: MCF7 (breast), VCAP (prostate), CAL33 (head and neck) and OVCAR-8 (ovarian) cancer cell lines were used to test the effect of DFO on proliferation using MTT and annexin-V/propidium iodide assays. DNA damage, specifically double strand break (DSB) formation, was tested by γH2AX foci quantification via immunofluorescence assays.

Results: DFO inhibited cell proliferation and apoptosis in a dose- and time-dependent manner. These effects were more marked than the one achieved through nitrogen-induced hypoxia. Additionally, DFO induces DNA damage through DSB formation.

Conclusion: Although DFO is usually used as a hypoxia-mimetic agent because it is cheaper and less time-consuming than nitrogen-induced hypoxia, our results show that it decreases cell proliferation and induces DNA damage through DSB formation. Therefore, its antitumoral effect should be further explored.

Grants: Study was financed by Gerencia Regional de Salud, JCyL (GRS2171/A/2020)

Valladolid (CSIC-UVa), Splicing and Genetic Susceptibility to Cancer Laboratory, Valladolid, Spain

Background/Objectives: Alternative splicing regulates gene expression patterns and is controlled by splicing regulatory elements (SRE). Mutations in SREs might affect splicing and be involved in disease susceptibility. Our purpose was to study the alternatively spliced exon 7 of the breast cancer susceptibility gene *ATM*.

Methods: A minigene with exons 4 to 9 of *ATM* (MG_ATM_4-9) was used in this work. The enhancer/silencer profile in *ATM* exon 7 was bioinformatically analysed by HexPlorer to identify the potential regions to study. Selected sequences were deleted in MG_ATM_4-9 by site-directed mutagenesis. In the region with more impact on exon 7 inclusion, we introduced 3 internal overlapping microdeletions. Additionally, we tested all possible variants localised in critical SRE intervals and variants with HexPlorer score below -40 were selected. Thus, 19 variants were introduced into the minigene and functionally tested.

Results: We identified two minimal regions (12/13-nt) involved in exon recognition, located in the 3'-end exon [△(E7): 50-75%]. Of the 19 variants analysed, seventeen (89%) impaired splicing, seven of which had strong impact on splicing, producing exon 7 skipping (59-69%) and <30% of the minigene full-length transcript.

Conclusion: The functional SRE mapping by exonic microdeletions was a useful approach to identify enhancer-rich sequences and SRE variants that impair splicing. The identification of spliceogenic variants is a helpful tool in the genetic counselling consultation, facilitating the early detection and diagnostic of diseases.

Grants: Predoctoral fellowship from the *Junta de Castilla y León* (2022-2025); ISCIII (PI20/00225 and PI23/00047).

P01.003.C Rare Germline Variants in glioma: A genomic analysis of 125 individuals from Northern Sweden

Adam Rosenbaum[1], *Anna Dahlin*[1], *Carl Wibom*[1], *Beatrice Melin*[1]

[1]*Umeå universitet, Department of Diagnostics and Intervention, Umeå, Sweden*

Background/Objectives: The etiology of glioma, the most common malignant CNS tumor, remains inadequately understood. Although germline predisposition, including common and rare variants, have been studied, the role of rare germline variants to glioma predisposition remains insufficiently explored.

Methods: We conducted whole genome sequencing on germline samples from 125 individuals from Northern Sweden, diagnosed with various subtypes of glioma. Of these, 46 were diagnosed before 40 years of age, and 12 familial gliomas from 5 families. We studied rare variants in established cancer predisposition genes, as well as a broader investigation of other genes with rare likely pathogenic variants.

Results: Our study reveals 20 rare coding variants in 18 genes, including *TP53*. Several are likely pathogenic and reside within known cancer predisposition genes, suggesting a link to glioma development. We identified rare variants in genes not previously associated with glioma, providing possible new insights into the etiology of glioma. Comparing the frequency of rare coding mutation among our cases and 300 individuals of similar lineage 7 genes have a significantly increased burden of rare coding variants. These genes are awaiting validation.

Conclusion: Our findings show that the germline genetic predisposition to glioma still holds some explanatory potential to the development of the disease. Continuing studying this aspect of predisposition may unlock new understanding of glioma development.

P01.007.C Large genomic rearrangement: tandem duplication and triplication in *BRCA1* gene causative for hereditary breast and ovarian cancer

Bernardus Aldrige Allister[1], *Jonathan Lühmann*[1], *Lena Wendeburg*[1], *Tim Ripperger*[1], *Bernd Auber*[1], *Frank Dechend*[2], *Carmela Beger*[3], *Stefanie Tölle*[3], *Julia von Ehr*[4], *Nataliya Di Donato*[1], *Doris Steinemann*[1]

[1]*Hannover medical school (MHH), Department of Human Genetics, Hannover, Germany;* [2]*MVZ Reproduction Medicine and Human Genetics, Hildesheim, Germany;* [3]*MVZ Labor Krone GbR, Bad Salzuflen / Bielefeld, Germany;* [4]*Frauenärzte am Schloss, Wolfenbüttel, Germany*

Background/Objectives: Large genomic rearrangements (LGRs) include copy number variations like duplications or triplications of coding or non-coding genomic regions within the human genome. Here, we report on two LGRs in two families with the suspicion of hereditary breast and/or ovarian cancer (HBOC) syndrome, a pathogenic *BRCA1* tandem duplication targeting exon 18-19 and a for the first time a pathogenic *BRCA1* tandem triplication of exon 2.

Methods: MLPA, Optical Genome Mapping (OGM), cDNA analysis and Sanger sequencing have been performed to identify these rearrangements and to characterize their localization and orientation as well as to predict their pathogenicity for HBOC development.

Results: We show that the duplication of exon 18-19 in *BRCA1*, is a tandem duplication: ogm[GRCh38] dup(17)(q21.31q21.31)(43057052_43063373). Validation by sanger sequencing of the cDNA shows that this tandem duplication of exon 18-19 generate a premature termination codon at the second codon of the duplicated exon 18. In the second index patient, four copies of the *BRCA1* promotor region, exon 1a,1b and exon 2 were detected via MLPA and OGM enabled us to resolve this LGR as a *BRCA1* exon 2 tandem triplication: ogm[GRCh38] trip(17)(q21.31q21.31)(43117155_43124115). cDNA analysis shows that this LGR causes an inclusion of a portion of intron 2 sequence and provokes a premature termination codon exactly at the junction between exon 2 and the intronic sequence of intron 2.

Conclusion: Due to a predicted premature termination codon we classify both LGRs as pathogenic variants. This signifies that LGRs such as tandem duplications and triplications can be causative for HBOC.

Background/Objectives: *BRCA1*:c.5017_5019del(p.His1673del) is a founder variant relatively frequent in Northern Italy. Despite previous suggestion of pathogenicity, variant classification in public databases is still conflicting, needing additional evidence.

Methods: Maximum likelihood penetrance of breast/ovarian and other cancer types was estimated using full pedigree data from 53 informative Italian families. The effect of the variant on BRCA1-ABRAXAS1 interaction was assessed using a GFP-fragment reassembly-based PPI assay. Results were combined with additional data from multiple sources to classify the variant according to ACMG/AMP classification rules specified for *BRCA1/2*.

Results: Variant-carriers displayed increased risk for ovarian cancer (HR = 33.0, 95%CI = 7.0-155.0; cumulative risk at age 70 = 27.6%, 95%CI = 12.6-40.0%) but not for breast cancer (HR = 0.7, 95%CI = 0.2-2.2). An increased risk of uterine cancer (HR = 8.0, 95%CI = 1.03-61.6) emerged, warranting further evaluation. Likelihood ratio in favor of pathogenicity was 98898642.82 under assumption of standard *BRCA1* breast and ovarian penetrance, and 104240832.84 after excluding breast cancer diagnoses (based on penetrance results). Functional analysis demonstrated that the variant abrogates the BRCA1-ABRAXAS1 binding, supporting the PS3 code assignment within the ACMG/AMP rule-based model. Collectively, these findings allowed to classify the variant as pathogenic.

Conclusion: Pathogenicity of *BRCA1*:c.5017_5019del(p.His1673del) has been confirmed; however, breast cancer risk in Italian families is not increased, unlike in families from other countries and in carriers of most *BRCA1* pathogenic variants. Haplotype analysis is underway to explore the hypothesis of potential in-cis modifiers. Nevertheless, the knowledge of atypical risk profiles for this and other variants will pave the way for personalized management based on specific genotype.

Background/Objectives: Familial occurrence of glioma, the most common type of malignant brain tumor, is observed in about 5% of cases. Studies on the genetic landscape of glioma predisposition are still scarce.

Methods: Leukocyte DNA of 122 glioma patients from 115 tumor families with at least one glioma patient each were analyzed by whole-exome sequencing. Data were analyzed using two approaches: (1) variants in established cancer predisposition genes (CPGs) or suspected glioma risk genes (n = 154) were extracted and classified, (2) the frequency of rare (MAF < 0.01%) or deleterious variants in all genes in the glioma cohort was compared with that in a control cohort (n = 257 families). Exome data of >70 additional patients are pending and will be included in our analysis.

Results: Both approaches associated *BRCA2* variants, including the pathogenic variants c.316+5G > C, p.(K944*), p.(I1470Kfs*11), most strongly with familial glioma. *BRCA2* variants were significantly more frequent in the glioma than in the control cohort ($P = 0.0088$). In addition, rare deleterious variants in *APC, ATM*, and *EGFR* were recurrently observed in the glioma cohort. In agreement with Choi et al., Sci. Adv., 2023, our familial glioma

cases carried rare deleterious variants in known CPGs, e.g. *ATM*, *PMS2*, and *POLE*, and novel CPGs, e.g. *SLC4A7* and *WDR7*. Furthermore, we identified 31 genes, not previously associated with cancer predisposition, that were recurrently affected in the glioma but not at all in the control cohort.

Conclusion: Our study on a large European familial glioma cohort implicates known CPGs, particularly *BRCA2* and *ATM*, and novel CPGs in glioma risk.

P01.010.B Analysis of aberrant splicing in capture RNA-seq data as a supplement to DNA germline testing to increase diagnostic yield

*Florentine Scharf[1], Thomas Keßler[1], **Evgenia Vibe**[1], Oliver Klaas[1], Jonas Ingermann[1], Caroline Heintz[1], Anna Benet-Pages[1;2], Sabrina Angerbauer[1], Martin Wendlandt[1], Tobias Wohlfrom[1], Verena Steinke-Lange[1;3], Andreas Laner[1], Ariane Hallermayr[1;3], Julia Romic-Pickl[1;3], Morghan Lucas[1;3], Elke Holinski-Feder[1;3]*

[1]MGZ – Medizinisch Genetisches Zentrum, Munich, Germany; [2]Institute of Neurogenomics, Helmholtz Research Center, München, Germany; [3]Medizinische Klinik und Poliklinik IV, Campus Innenstadt, Klinikum der Universität München

Background/Objectives: Hereditary tumor syndromes comprise 5-10% of cancer cases, necessitating accurate identification of causal genetic variants for effective patient management. The diagnostic yield of whole-exome sequencing (WES), the gold standard for molecular diagnostics, ranges from 15-25% in these syndromes. High-throughput functional studies, such as RNA sequencing (RNA-seq), play a crucial role in reclassifying variants of uncertain significance (VUS) and unveiling pathomechanisms like aberrant splicing, particularly when initial variant detection fails.

Methods: We developed a cost-efficient, high-throughput RNA-seq approach to analyze RNA phenotypes where we complement polyA mRNA or hexamer capture with enrichment of 49 cancer-associated genes from PAXgene-derived RNA samples.

Results: We achieved ultra-high coverage sequencing data of ~3,500X mean target coverage and, on average, 80% of exons covered with >50 read depth using hexamer capture and target enrichment. In almost 80% of positive controls for aberrant splicing, we detected a difference of >20% in the PSI (percent-spliced in) score compared to negative controls.

Conclusion: Our workflow provides high-quality RNA-seq data, which allows the assessment of splicing events. Our data on the comparisons between positive and negative controls substantiate the possibility of an automated high throughput pipeline. This work represents the basis for implementing targeted RNA-seq in cancer diagnostics, in which we want to establish the parallel analysis of WES and RNA-seq to increase the diagnostic yield and turnaround time for patients with hereditary tumor syndromes.

P01.011.C Identification of shared genetic variants among different cancers and between adenomyosis and cancer utilizing members of the same family

Sevcan Aydın[1], *nura fitnat topbas selcuki[2], pinar yalcin bahat[3], engin oral[4], Feyza Tuncer[5]*

[1]Istanbul University, Graduate School of Health Sciences, Istanbul, Türkyie; [2]University of Health Sciences Turkey, Istanbul Sisli Hamidiye Etfal Training and Research Hospital, Obstetrics and Gynecology, Istanbul, Türkyie; [3]University of Health Sciences Turkey, Istanbul Kanuni Sultan Suleyman Training and Research Hospital, Department, Obstetrics and Gynecology, Istanbul, Türkyie; [4]Biruni University Faculty of Medicine, Obstetrics and Gynecology, Istanbul, Türkyie; [5]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Genetics, Istanbul, Türkyie

Background/Objectıves: Adenomyosis is a benign uterine condition characterized by the localization of endometrial-like tissue in myometrium. Its pathogenesis remains elusive, but it carries cancer-like characteristics. We aimed to identify shared genetic variants both between different cancers and adenomyosis and cancer, utilizing a family having women affected by both conditions.

Methods: Five women from the same family were subjected to gynecological examinations via transvaginal ultrasonography, amongst two receieved pathologically confirmed diagnosis of ovarian mucinous adenocarcinoma and clear cell renal cell carcinoma (ccRCC). Whole exome sequencing was performed on all women utilizing Illumina NextSeq550. Bioinformatic analyses were performed on Genomize SEQ and Pairend platforms, MAF < %1 was applied to identify rare and novel variants. Cases with cancer versus all cases were evaluated in parallel, for which one member was utilized as a control, who manifested neither of the conditions.

Result: Pathological evaluations excluded adenomyosis in the case diagnosed with ovarian mucinous adenocarcinoma, while the case with ccRCC received adenomyosis diagnosis. A novel genetic variant in *NTN1* gene was identified across all cases, in addition to rare variants in 10 genes shared among cases with cancers.

Conclusıon: *NTN1* gene might be one of the many links between the pathogenesis of cancer and adenomyosis, fitting in with its attributed roles in cell migration and angiogenesis. The impact of the novel variant in *NTN1* merits clarification functionally. Further studies are in need to elucidate the diversifying mechanisms among two similar conditions evolving towards either malignity or benignity.

P01.012.D Reproductive factors and sex hormones levels on differentiated thyroid cancer risk: A Mendelian Randomization study

See Hyun PARK[1;2], *Mojgan Karimi[2], Cloe Domenighetti[2], Thérèse Truong[2]*

[1]Paris Saclay Universite, Gif-sur-Yvette, France; [2]INSERM, Exposome and Heredity, Villejuif

Consortium: EPITHYR consortium, and The European Prospective Investigation into Cancer and Nutrition (EPIC-Europe)

Background: Differentiated thyroid carcinoma (DTC) is the most common type of thyroid cancer, occurring three times more frequently in women than in men. However, the underlying biological mechanisms driving this sex-specific discrepancy remain poorly understood. To analyze the causal role of sex hormones and reproductive factors in the risk of DTC, we implemented a two-sample Mendelian Randomization (MR) analysis using genome-wide association studies (GWAS) summary statistics.

Methods: GWAS on DTC were derived from a meta-analysis of 6 studies including 7,705 cases and 963,612 controls of European population, while GWAS summary statistics on sex hormones, reproductive factors, and gynecological factors related to hysterectomy were retrieved from publicly available literature. We used the inverse-variance weighted method to estimate odds ratio,

with additional multiple sensitivity analyses to ensure the suitability of the MR analysis, and conducted multivariable MR to account for potential confounding variables.

Results: We showed that endometrial cancer was associated with DTC (OR = 1.15, $p = 9 \times 10^{-3}$). We also observed an association between SHBG levels and increased risk of DTC, however this association lost significance upon adjustment for obesity-related factors. Putative causal associations was observed with uterine fibroids; nonetheless, this association was not supported by additional sensitivity analyses. No significant associations were found for levels of sex hormones, age at menopause, menarche and first birth, nor with endometriosis.

Conclusion: Using the largest GWAS on DTC to date, our findings do not support a significant influence of sex hormones and reproductive factors in the observed differences in DTC risk between women and men.

P01.013.A Evolution of genomic profiles in primary and recurrent astrocytic gliomas

Libuse Lizcova[1], *Halka Lhotska*[1], *Karolina Janeckova*[1], *Lucie Hodanova*[1], *Karla Svobodova*[1], *Hana Cechova*[2], *Tatiana Aghova*[1], *Sarka Ransdorfova*[2], *Lenka Pavlistova*[1], *Filip Kramar*[3], *David Netuka*[3], *Zuzana Zemanova*[1]

[1]*General University Hospital and First Faculty of Medicine, Charles University in Prague, Center of Oncocytogenomics,Institute of Medical Biochemistry and Laboratory Diagnostics, Prague, Czech Republic;* [2]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic;* [3]*First Faculty of Medicine of Charles University and Military University Hospital Prague, Department of Neurosurgery and Neurooncology, Prague*

Background/Objectives: Astrocytic gliomas, including grades 2-4 astrocytoma and grade 4 glioblastoma, are characterized by diverse biological behaviors and recurrent lesions. During disease progression, these tumors undergo genomic evolution with newly acquired genetic properties. However, the mechanisms and evolutionary dynamics underlying tumor progression and relapse remain poorly understood.

Methods: Genomic profiles of 35 paired glioma samples (primary and recurrent; 15x astrocytoma, 20x glioblastoma) were analyzed using combination of cytogenomic methods: I-FISH (Abbott Molecular, MetaSystems), aCGH/SNP (Agilent), MLPA, MS-MLPA (MRC-Holland) and targeted NGS panel (Invitae).

Results: Primary tumors displayed common aberrations like *IDH1/IDH2* and *TERT* mutations, CNAs of chromosome 7, 10, and *CDKN2A/2B* and *EGFR* genes, persisting in recurrent lesions. All but two patients experienced recurrences with newly acquired genetic/epigenetic changes with a high frequency of CNAs leading to complex rearrangements. Divergent clonal evolution was observed in 22 cases, while 11 cases displayed linear evolution. Aberrations of chromosomal regions 4p, 6p, 8q, 9q, 11p and 11q were recurrently identified in recurrences. cnLOH was proved in 22 cases, mainly on 7p and 17p. Disease progression occurred in 28 patients.

Conclusions: This study highlights heterogeneity in tumor evolution driven by genomic/microenvironmental imbalances or treatment. Recurrence may arise from major tumor clone or multiple subclones within the primary tumor. Cytogenomic analyses of recurrent tissues contribute to understanding these processes and identification of alterations associated with glioma progression. These biomarkers could subsequently serve as resource for precision oncology targeting cancer dynamics in astrocytic gliomas.

P01.014.B PAX5 alterations in a consecutive childhood B-ALL cohort treated on ALL IC-BFM 2009 protocol

Klementina Črepinšek[1;2], *Janez Jazbec*[2;3], *Marko Kavčič*[2;3], *Tomaž Prelog*[3], *Tine Tesovnik*[1;2], *Barbara Jenko Bizjan*[1;2], *Robert Sket*[1;2], *Jernej Kovač*[1;2], *Marusa Debeljak*[1;2]

[1]*University Children's Hospital, UMC Ljubljana, Clinical Institute for Special Laboratory Diagnostics, Ljubljana, Slovenia;* [2]*University of Ljubljana, Faculty of Medicine, Ljubljana;* [3]*University Children's Hospital, UMC Ljubljana, Department of Oncology and Haematology, Ljubljana*

Background/Objectives: In this study, we aimed to identify patients within our B-ALL cohort with altered *PAX5*. Our objective was to characterize the types of genetic changes, determine their origin (somatic/germline), and analyze the clinical outcomes associated with them.

Methods: A consecutive cohort of 99 patients with B-ALL treated at the Children's Hospital of the UMC Ljubljana according to the ALL IC-BFM 2009 protocol was included in our study. We used RNA sequencing data for gene expression analysis, fusion gene detection and variant identification, multiplex-ligation dependent probe amplification for copy number variation assessment, and Sanger sequencing to detect germline variants.

Results: *PAX5* was impacted in a 33.3% of our patients, with the genetic alterations ranging from CNVs and rearrangements to SNVs. The most common were CNVs, which were found in 33.7% of patients, followed by point mutations in 5.2% and gene rearrangements in 4.1%. We identified 8 patients with a *PAX5*-associated genetic subtypes that were previously classified as "B-other", and they showed intermediate outcomes. We showed a trend of poorer survival in hyperdiploid cases carrying duplications in *PAX5* compared to other hyperdiploid cases. We also report an interesting case of a patient with *PAX5::FKBP15* and a pathogenic variant in *PTPN11* who underwent an early relapse with a monocytic switch.

Conclusion: In conclusion, this study provides valuable insights into the presence, frequency, and prognostic significance of diverse *PAX5* alterations in B-ALL patients, highlighting the complexity of genetic factors and their impact on patient outcomes.

P01.015.C Rare mutations in FH and POLE genes in a patient with Ewing sarcoma and familial cancer burden

Dimitar Bakalov[1], *Svilen Maslyankov*[2], *Kalina Belemezova*[3], *Radka Tafradjiiska-Hadjiolova*[1], *Zafer Sabit*[1], *Ivanka Dimova*[4]

[1]*Medical University of Sofia, Department of Physiology and Pathophysiology, Sofia, Bulgaria;* [2]*Medical University of Sofia, Department of Surgery, Sofia, Bulgaria;* [3]*Medical University of Sofia, Department of Medical Biology, Sofia, Bulgaria;* [4]*Medical University of Sofia, Department of Medical Genetics, Sofia, Bulgaria*

Background/objectives: Ewing sarcoma is a rare and aggressive form of bone and soft tissue cancer, predominantly affecting young individuals. We explore the underlying genetic factors contributing to Ewing sarcoma in a 22-year-old patient, having familial cancer burden (colon, kidney, breast, bladder, melanoma).

Methods: Whole exome sequencing was performed on genomic DNA from the affected individual. Comprehensive bioinformatic analyses were employed to prioritize and validate variants, with a particular focus on genes implicated in cancer susceptibility.

Results: The analysis revealed two very rare heterozygous missense variants of unknown significance: c.809 A > G (p.Tyr270Cys) in the *FH* gene (frequency of 3e-5) and c.1015 G > A (p.Asp339Asn) in *POLE* gene (frequency of 8e-5) in the patient's germline. *FH* encodes fumarate hydratase, a key enzyme in the tricarboxylic acid cycle, which is associated with autosomal dominant "Leiomyomatosis and renal cancer" phenotype. *POLE* is essential for DNA replication and repair, and is associated with autosomal dominant "Colorectal cancer, succeptibility to, 12" phenotype.

Conclusion: This study contributes to the growing body of knowledge surrounding the genetic landscape of Ewing sarcoma, highlighting the role of *FH* and *POLE* gene variants. Additionally, the severe family history of colon, urothelial, breast and skin cancers in first- and second-degree relatives raises intriguing questions about shared genetic predisposition. Further investigations into the potential synergistic effects of these variants and their implications for familial cancer risk are warranted. This case underscores the importance of genetic counseling in individuals with Ewing sarcoma and multidisciplinary approach to personalized cancer care.

Background/Objectives: Early-stage cancer manifests with minimal or no noticeable symptoms, leading to a diagnostic delay and subsequent less effective treatment. Since analysis of cell-free DNA (cfDNA) may serve to identify early neoplastic changes, liquid biopsy-based tests hold potential for non-invasive cancer screening.

Methods: The plasma of 60 prostate cancer patients and 369 control individuals were collected to analyze cfDNA by low-coverage whole-genome next-generation sequencing. Data were processed using an in-house bioinformatics pipeline to detect genetic variability and characterize qualitative and quantitative sequencing metrics. A total of 379 samples (49 patients, 330 controls) were used to train the model from decision trees using gradient boosting to facilitate prostate cancer prediction. Subsequently, a testing set of 50 samples (11 patients, 39 control) was used to assess the accuracy of the model.

Results: The robust combination and evaluation of 671 attributes, including genomic variability and sequencing metrics, by ensemble learning model, have shown a sensitivity of 81.8% and specificity of 100.0% on the testing dataset. The ROC AUC of 97.4% suggests a high prediction capability of the test.

Conclusion: Here, we emphasize the decent potential of liquid biopsy test enhanced by artificial intelligence to evaluate an extensive set of cfDNA sequencing metrics and genomic attributes for non-invasive prostate cancer screening.

Grants: The work was supported by the OPII project ITMS: 313010Q927 (GenoScan LBquant), co-financed by ERDF. P01.017.A Development and validation of an expanded comprehensive genomic profiling assay with enhanced variant sensitivity for tumor biopsies

Stephanie Constantinou[1], *Alexia Eliades*[1], *Kyriakos Tsangaras*[1], *Chrysa Soteriou*[1], *chrystalla lazarou*[1], *Achilleas Achilleos*[1], *charalambos loizides*[1], *Christos Lemesios*[1], *Chrystalla Havadjia*[1], *sarah barbour*[1], *aris pallaris*[1], *chrysovalando soteriou*[1], *Louisa Constantinou*[1], *Haris Kkoufou*[1], *Michalis Spyrou*[1], *antonis antoniou*[1], *Antonia Matsentidou*[1], *Melina Vaki*[1], *george manoli*[1], *Christos Prokopi*[1], *Styliana Georgiou*[1], *Elena Kypri*[1], *Marios Ioannides*[1], *George Koumbaris*[1], *Philippos Patsalis*[1;2]

[1]*Medicover Genetics, Nicosia, Cyprus;* [2]*University of Nicosia Medical School, Department of Basic and Clinical Sciences, Nicosia, Cyprus*

Background/Objectives: Comprehensive genomic profiling using next-generation sequencing (NGS) has become increasingly important in the classification and management of cancer, enabling a growing number of patients to benefit from targeted therapies. Such approved therapies include ones developed for less prevalent gene alterations, thus emphasising the need for assessing a broader panel of genes for multiple alteration classes with an enhanced sensitivity. Herein, we describe the development of an expanded 392-gene panel, offering high analytical performance.

Methods: DNA isolated from a set of formalin-fixed, paraffin-embedded (FFPE) tissue samples comprising reference materials, non-malignant and tumor samples was subjected to library preparation and hybrid capture enrichment with our expanded 392-gene panel. Enriched libraries were subsequently sequenced by NGS on a NovaSeq platform and data was analysed using proprietary bioinformatic pipelines.

Results: A set of FFPE samples comprising benign, malignant and reference material samples, was used to evaluate the assay's analytical performance. The assay demonstrated high sensitivity and specificity for all classes of genomic alterations, including single nucleotide variants (SNVs), small insertions and deletions (Indels), copy number alterations (CNAs), translocations, as well as the immuno-oncology biomarkers, microsatellite instability (MSI) and tumor mutational burden (TMB). Notably, the developed assay can detect mutations down to 1% variant allele frequency (VAF).

Conclusion: Validation results demonstrate the development of a tissue-based NGS assay for the assessment of an expanded panel of genomic alterations and therapy-associated biomarkers that can detect less prevalent variants with enhanced sensitivity.

P01.019.C Increased prevalence of pathogenic and likely pathogenic *CHEK2* variants in the Balearic Islands Hereditary Cancer cohorts.

Maria Antònia Caro-Miró[1], *Catalina Lladó-Sampol*[2], *Antònia Perelló-Martorell*[2], *Evelin Horvath*[2], *Paloma de la Torre-Rubio*[3], *DAMIAN HEINE SUÑER*[1], *Victor Asensio-Landa*[1], *Laura Torres-Juan*[1], *María Carmen Prado-Farnos*[1], *Susana Renee Avella-Klaassen*[1], *Iciar Martínez*[1], *Jesús Alarcón Company*[2], *Antonia Obrador-Hevia*[1]

[1]*Hospital Universitari Son Espases, Molecular Diagnosis and Clinical Genetics Unit, Palma, Spain;* [2]*Hospital Universitari Son Espases, Oncology, Palma, Spain;* [3]*Hospital Universitari Son Espases, Digestology, Palma, Spain*

Background/Objectives: *CHEK2* has been identified as an intermediate-risk gene associated with breast, prostate, and colon cancer (OMIM: 609265).

In this study, we examined the frequency and mutational spectrum of *CHEK2* variants within the Balearic Islands' hereditary cancer (HC) cohort, comparing it to the Catalonian population databases in order to investigate potential founder mutations.

Methods: The research assessed the prevalence of pathogenic/likely pathogenic (P/LP) *CHEK2* variants and included two Balearic Island cohorts: 1559 patients from the HC cohort sequenced by the TruSight Hereditary Cancer panel (Illumina®) between 2016 and 2022, and 3352 non-HC patients sequenced via Whole Exome Sequencing (WES) (Illumina®). Frequencies from the genetically closest population, Catalonia, were used for comparison.

Results:

Group	Patients	Patients (%) with P/LP variants in *CHEK2**
Breast, ovarian and prostate (BOP) cancer	1101	24 (2.2%)
Colorectal cancer	368	9 (2.4%)
Other cancer conditions	130	2 (1.5%)
Total Balearic Islands HC	1599	35 (2.2%)
Non-HC	3352	20 (0.6%)
Catalonian HC (Vargas-Parra 2022)	1848	14 (0.8%)

*Variants analysed (NM_007194): c.1427C > T, c.279G > A, c.349A > G, c.433C > T, c.1100del, c.591del, c.319+2T > A.

CHEK2 variants	% BOP cancer	% Colorectal cancer	% Other cancer conditions	% Non-HC
c.1427C > T	0.82	2.17	0.00	0.39
c.279G > A	0.73	0.27	0.77	0.21

Conclusion: The prevalence of P/LP variants in the HC cohort was found to be 2.2% (2.2% in BOP cancer patients and 2.4% in colorectal cancer patients), significantly higher than the genetically closest population of Catalonia. This possibly suggests the

presence of a founder effect of c.1427C > T and c.279G > A variants, enriched in Mallorca and Ibiza patients, respectively.

Consortium: ICGC-MMML-Seq Consortium

Background/Objectives: The 5th edition of the WHO Classification of Haematolymphoid Tumours describe disease entities defined by genetic abnormalities. For instance, the diagnosis of Burkitt lymphoma (BL) requires an *IG::MYC* juxtaposition, e.g. due to t(8;14)(q24;q32). Some high-grade B-cell lymphomas (HGBL) lacking the *MYC* translocation exhibit immunophenotypic similarities to BL but share similarities at the mutational level with diffuse large B-cell lymphomas (DLBCL). A subset of these HGBL (HGBL-11q) show characteristic chromosomal aberration defined by gains in 11q23.2-11q23.3 and losses in the 11q24.1-qter region. Here, we identify differential transcriptomic features of such HGBL-11q relative to BL and DLBCL.

Methods: Gene expression profiling was conducted using the HTG EdgeSeq Pan B-Cell Lymphoma Panel using RNA obtained from formal-fixed paraffin-embedded (FFPE) tissues of 7 BL, 26 HGBL-11q, 132 DLBCL, and two reactive tonsils. The panel was verified against RNAseq data available from overlapping samples of the ICGC-MMML-Seq cohort, leaving 206 genes for subsequent clustering and DESeq2 analyses. A two-step cumulative gene expression classifier was developed to segregate HGBL-11q from BL and DLBCL.

Results: Using unsupervised UMAP analysis of the 206 genes, we observed that HGBL-11q clustered apart from BLs and DLBCLs. DESeq2 revealed 48 and 38 genes differentially expressed between HGBL-11q and DLBCL or BL, respectively. A two-step classifier was trained to distinguish HGBL-11q from DLBCLs and BLs, respectively. PostHoc genomic analyses of cases classified as HGBL-11q showed two cases not yet assigned to this entity to carry typical 11q aberrations.

Conclusion: Gene expression profiling of FFPE tissues was effective in identifying HGBL-11q among other mature aggressive lymphomas.

P01.021.A Germline ESR1 variants may be causative of juvenile papillomatosis of the breast

Zahra Firoozfar[1], *Shahryar Alavi*[1], *Mohammadreza Dehghani*[2], *Mohammad Yahya Vahidi Mehrjardi*[3]

[1]*Palindrome, Isfahan, Iran;* [2]*Yazd Reproductive Sciences Institute, Shahid Sadoughi University of Medical Sciences, Yazd, Iran;* [3]*Diabetes Research Center, Shahid Sadoughi University of Medical Sciences, Yazd, Iran*

Objectives: Germline variants are causative of 10% of cancer incidences. Juvenile papillomatosis of the breast (JPB), also known as Swiss cheese disease, is a benign condition occurs in individuals with a family history of breast carcinoma and its incidence in males is rare. Here, we report a case with several affected males by JPB or gynecomastia, harbouring a significant germline mutation in the ESR1 gene.

Methods: WES was performed on 200 Iranian individuals with hereditary cancers. Sequence raw data was analysed using GATK, and GRCh38 as reference genome. We also called copy number variations using PalinDepth, our proprietary algorithm. Variants were filtered based on the ACMG guideline, then were manually curated to find the best match with the patients' phenotype.

Results: Germline ESR1 D538G mutation (chr6:g.152098791A > G) was detected in heterozygous state in a 5 years old boy suffering from JPB, with several males in the pedigree are affected with gynecomastia. No other significant exome variant was detected. Sanger sequencing showed that another affected family member is heterozygous for the ESR1 variant.

Conclusion: ESR1 D538G mutant is well described in sporadic breast cancer where ESR1 somatic mutations lead to malignancies. Recently it has been shown that ESR1 variants could increase the risk of hereditary breast cancer. Interestingly, we detected D538G mutation in a patient with familial breast anomalies in males. Further experiments could validate plausible effects of germline D538G mutation, investigating if this could trigger hereditary breast cancer in females.

P01.022.B Cascade testing for hereditary breast cancer: what is achievable in a South African clinical service?

Tabitha Osler[1], *Mardelle Schoeman*[2], *Jennifer Edge*[3], *Willem Pretorius*[2], *Felix Rabe*[4], *Christopher Mathew*[5], **Michael Urban**[6,7]

[1]*Sydney Brenner Institute for Molecular Bioscience, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa;* [2]*Division of Molecular Biology and Human Genetics, University of Stellenbosch, Cape Town, South Africa;* [3]*Department of Surgery, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa;* [4]*Faculty of Medicine and Health*

Sciences, University of Stellenbosch, Cape Town, South Africa; [5]Sydney Brenner Institute for Molecular Bioscience, University of the Witwatersrand, Johannesburg, South Africa; [6]Division of Human Genetics, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa; [7]Department of Obstetrics and Gynaecology, Faculty of Medicine and Health Sciences, University of Stellenbosch, Cape Town, South Africa

Background/Objectives: A main reason for genetic counselling and testing people with possible hereditary breast cancer is to identify probands and their asymptomatic family members who carry pathogenic variants, by the process of cascade testing. This allows prevention by radiographic screening and risk-reducing surgery, especially in female relatives. We investigated uptake in a South African regional breast cancer service.

Methods: Pedigrees and laboratory electronic records in 83 consecutive female breast cancer patients with pathogenic variants associated with high or moderate penetrance of hereditary breast cancer were used to assess family member testing. Electronic appointment, clinical and radiology records were used in test-positive relatives to identify preventive interventions conducted by a year later.

Results: 1173 family members were considered eligible for testing, 55% female. Relatives of 39/83 (47%) probands took up testing, with 111 tested and 40 testing positive (3 in ATM, 17 in BRCA1, 17 in BRCA2, 3 in PALB2), including 31 females. Family member testing was associated with gender and degree of relationship. In female relatives, the proportion tested dropped from 25% in first degree to 8% in second degree relatives, and in males from 14% to 0.8%. Prophylactic measures undertaken in guideline-eligible asymptomatic female relatives included radiographic screening in 5/20 (25%), risk-reducing mastectomy in 9/19 (47%), and bilateral salpingo-oophorectomy in 3/13 (23%).

Conclusion: Compared to international evidence uptake of presymptomatic testing is low; in test-positive female relatives, uptake of screening is low but of risk-reducing surgery appears similar. We will explore further with a qualitative study.

P01.023.C Piperine exerts antitumor effects in head and neck cancer

Juliana Prado Gusson-Zanetoni[1], Luana Cardoso[1], Stefanie Oliveira de Sousa[1], Laura Luciana De Melo Moreira Silva[1], Tiago Henrique[2], Eloiza Tajara[2], Claudia Regina Bonini Domingos[1], Sonia Maria Oliani[1], Eny Maria Goloni-Bertollo[2], **Flavia Cristina Rodrigues-Lisoni**[1]

[1]*São Paulo State University (UNESP), Institute of Biosciences, Humanities and Exact Science, Department of Biological Science, São José do Rio Preto; [2]School of Medicine of São José do Rio Preto (FAMERP), Molecular Biology Department, São José do Rio Preto, Brazil*

Background/Objectives: Head and neck cancer (HNC) is promoted by genomic instability that affects cell growth, metabolism and inflammation. Treatments for patients with this cancer are generally very invasive and the use of natural products has been used as an adjuvant. Among these, piperine (1-piperoylpiperidine) stands out, which can be isolated from the fruits or roots of black pepper (*Piper nigrum*), as it has pharmacological effects such as antioxidants, anti-inflammatory and immunomodulatory. Therefore, the aim of the present study was to investigate the molecular mechanisms of action of piperine in relation to its potential antitumor effect on head and neck squamous cells carcinoma (HNSCC).

Methods: Parameters related to neoplastic potential including proliferation, cytotoxicity, migration, apoptosis, cell cycle, clonogenicity, genotoxicity were verified in HNSCC (HEp-2 and SCC-25) treated with piperine. Furthermore, molecular analysis of the cytokines, proteins and genes were investigated to understand how piperine modulates the inflammatory pathways.

Results: The results of the tests indicated that piperine modified the morphology, inhibited growth/viability and the formation of cell colonies, promoted genotoxicity by triggering apoptosis and cell cycle arrest in G2/M and S. The decrease in cell migration also was observed, probably due to the decrease in the expression of *MMP2/9* genes. Furthermore, piperine reduced the expression of molecules related to inflammation such as PTGS2, PTGER4, ERK, p38 and cytokines.

Conclusion: These results suggest that piperine exerts antitumor effects on HNSCC and may be a promising natural treatment by regulating signaling pathways associated with inflammation and cancer.

P01.024.D Germline Pathogenic Variants In Pakistani Patients Evaluated At A Hereditary Breast Cancer Clinic

Fizza Akbar[1], *Shamila Ladak[2], aushna saleem[3], alizeh fatimi[2], bassim zahid[2], zahraa siddiqui[2], uzair ansari[4], Salman Kirmani[1]*

[1]*Aga Khan University Hospital, Division of women and child health, Karachi, Pakistan; [2]Aga Khan University Hospital, Medical College, Karachi, Pakistan; [3]Albert Einstein College of Medicine, United States; [4]Aga Khan University Hospital, Paediatrics and Child Health, Karachi, Pakistan*

Background/Objectives: Hereditary breast cancer (HBC) accounts for 5-15% of all breast cancer cases. These are attributed to pathogenic (P) and likely pathogenic (LP) germline variants in breast cancer predisposition genes. This study describes the spectrum of germline variants causing HBC in Pakistan and explores clinical correlations with P/LP variants.

Methods: Retrospective chart review of 751 patients from HBC clinic who proceeded with multi-gene panel testing between 2017 and 2023. Descriptive and inferential statistical analyses were done.

Results: Eighteen percent (137/751) tested positive, 36% (273/751) had a VUS and 45% (341/751) had a negative result. Sixty percent of positive patients had P/LP variants in *BRCA1/2*, while the other 40% were attributed to other genes. Six recurrent *BRCA1* variants reported were in 20 unrelated patients, with *BRCA1* c.1961dup (p.Y655Vfs*18) being the most common, present in eight patients. *CHEK2 (5.4%), FANCM (5.4%), PALB2 (4.7%)* were the next most prominent genes. Patients with positive results had a younger age at diagnosis at 42, IQR (34-50). Having a positive result showed a positive association with triple-negative breast cancer (TNBC). Of the patients who tested positive for *BRCA1/2*, 84% had a diagnosis of TNBC. Of all patients with positive results, 12% of patients had a negative family history of cancer.

Conclusion: Our findings give unique insights into the genetic factors causing HBC in the Pakistani population. As more patients are tested and protocol-driven referrals are made across the country, our insight into the genetic architecture of hereditary breast cancer in our population will continue to increase.

P01.025.A Recurrent variant in the 3'UTR of the MSH6 gene in four unrelated Italian families with Lynch syndrome phenotype

Domizia Pasquetti[1], *Federica Francesca L'Erario*[2], *Roberta Pietrobono*[1], *Maria Grazia Pomponi*[2], *Arianna Panfili*[3], *Emanuela Lucci Cordisco*[1;2], *Maurizio Genuardi*[1;2]

[1]*Section of Genomic Medicine, Department of Life Sciences and Public Health, Catholic University of Sacred Heart and Unit of Medical, Rome, Italy;* [2]*UOC Genetica Medica, Fondazione Policlinico Universitario "A.Gemelli" IRCCS, Rome, Italy;* [3]*Direzione Scientifica, Fondazione Policlinico Universitario "A.Gemelli" IRCCS, Roma*

Background/Objectives: Pathogenic variants in MSH6 account for 12%-35% of Lynch syndrome (LS). Despite classification guidelines, variants of uncertain significance (VUS) in MMR genes represents a diagnostic dilemma. We discuss here the c.*23_*26dup *MSH6* variant, that is reported as a VUS in ClinVar but considered as pathogenic in a previous published study.

Methods: Genetic counseling involved four unrelated Italian families, with germline NGS analysis performed in four subjects and targeted variant analysis in two. IHC of MMR proteins was conducted on four endometrial tumors (EC) and one colorectal cancer (CRC); MSI was performed on one of two CRCs.

Results: All the six individuals were heterozygotes for *MSH6* c.*23_*26dup. EC was diagnosed in all four female carriers (median age: 45.7 years), showing no MSH2 and MSH6 protein expression. CRC occurred in two male carriers at ages 62 and 32; IHC and MSI revealed no MSH2 and MSH6 expression, with MSI-H status in one tested CRC.

Conclusion: The clinical phenotypes of c.*23_*26dup *MSH6* carriers are highly suggestive of LS, with significantly high penetrance for early-onset gynecological tumors. The *MSH6* variant could be pathogenic and cause LS in these families. However, the lack of MSH2 expression suggests involvement of the *MSH2* gene. Under this assumption, the *MSH6* c.*23_*26dup variant could be a linked marker of an undetected *MSH2* alteration. The previously reported families were from Northern Italy, while our families are from Central Italy. The geographic origin and the phenotypic similarities across the families suggest that they might derive from a common founder.

Conflict of Interest: None declared

P01.026.B A case of *MYC* and *BCL2*- positive high-grade B-cell lymphoma with concurrent 11q gain-loss aberration

Gulleyla Kilic[1], *Olga Meltem Akay*[2], *Emre Osmanbasoglu*[2], *Dicle Ballikaya*[1], *Tuba Akan*[3], *İbrahim Öner Doğan*[4], *Hülya Kayserili*[1;5]

[1]*Koc University Hospital, Genetic Diseases Evaluation Center, Istanbul, Türkyie;* [2]*Koc University Medical School, Hematology, Istanbul, Türkyie;* [3]*Koc University Hospital, Flow Cytometry, Istanbul, Türkyie;* [4]*Koc University Medical School, Pathology, Istanbul, Türkyie;* [5]*Koc University Medical School, Medical Genetics, Istanbul, Türkyie*

Background/Objectives: High-grade B-cell lymphoma (HGBCL, previously known as double-hit lymphoma) is an aggressive type of B-cell non-Hodgkin lymphoma characterized by rearrangements in *MYC* and *BCL2*, or/and less commonly, *BCL6* gene. Rare cases of HGBCL with concurrent *MYC* rearrangement and 11q aberrations have been described[1]. In this study we provide further evidence that 11q aberrations can also be found in HGBCL with *MYC* and *BCL2* rearrangements (HGBCL-MYC-BCL2-11q)[2]. Clinical, immunohistochemical and detailed cytogenetic characterization of the case is discussed.

Methods:A 36-year-old woman with three-month history of cervical lymphadenopathy,

pancytopenia and elevated LDH was referred to our hospital. The diagnosis of HGBCL-MYC-BCL2-11q was established based on histopathologic/immunohistochemical examination of the bone marrow sample with flow cytometry, classical cytogenetic and interphase/metaphase fluorescence in situ hybridization analyses.

Results: A bone marrow examination showed diffuse infiltration of neoplastic B-cells with CD19 +, HLA-DR +, CD10 +, CD38 +, CD20 +, CD22 +, TdT- and kappa light chain expression. iFISH analysis showed abnormal *BCL2*, *cMYC*, *IGH*, *MLL (KMT2A*) and *TEL/AML1* signals. Conventional cytogenetic analysis defined a highly complex karyotype with a derivative chromosome 1, trisomy 7, t(8;14), triplication 11q, deletion 11q, partial trisomy 12p, t(14;18), trisomy 18 and monosomy X. The complex karyotype was further clarified by additional selected FISH probes for chromosomes 1,8,11,14,18 and X. She received GMALL-B-ALL 2002 protocol treatment and expired 7 months after the diagnosis.

Conclusion: Our findings highlight the importance of clarifying the complex karyotype in HGBCL patients. Future studies are needed to define the prognosis, treatment response and survival of *MYC* and *BCL2*-positive HGBCL patients with 11q aberrations.

Background/Objectives: The outcome of pilocytic astrocytoma depends heavily on the success of surgery. In the cases where surgery alone is not curative, next generation sequencing approaches can be used to identify treatment targets for precision medicine. Here we report a pediatric pilocytic astrocytoma case that underwent incomplete surgical resection due to the location of the tumor.

Clinical genetics analyses demonstrated that the tumor did not carry a *BRAF* fusion or a *BRAF* mutation. After post-operative surveillance according to the low-grade glioma protocol, recurrent tumor progressions resulted in multiple chemotherapy regimens.

Methods: RNA sequencing by an open-ended targeted approach was performed and detected the presence of a novel *ATG16L1::NTRK2* fusion gene. The rearrangement was subsequently confirmed by interphase fluorescent in situ hybridization

Italiadomani PIANO NAZIONALE DI RIPRESA E RESILIENZA

in tumor cells. Functional analysis of the fusion was performed by in-vitro transient transfection of HEK293 cells. The ATG16L1::TRKB fusion protein was found to activate both the MAPK-pathway, and the PI3K-pathway, through increased phosphorylation of ERK, AKT and S6.

Results: As a result of the identification of a NTRK fusion, the patient was enrolled in a phase I/II clinical trial of the nonselective TRK inhibitor larotrectinib. The patient responded well without significant side-effects. Eight months after start of treatment, tumor lesions were no longer detectable consistent with complete response. Presently, 14 months later, complete remission is sustained.

Conclusion: Our findings highlight the importance of screening for other MAPK-drivers in *BRAF*-negative low-grade gliomas, since rare fusion genes may serve as targets for precision oncology therapy.

P01.028.D The neurofibromin-lysosome axis in breast cancer

Antonella Delicato[1;2], Pilar Chacon Millan[1;2], Bruno Achutti Duso[3], Alessia Castiglioni[3], Eleonora Messuti[3], Sara Galavotti[3], Diego Medina[2;4], Luca Mazzarella[3], **Manuela Morleo**[1;2]

[1]University of Campania "Luigi Vanvitelli", Department of Precision Medicine, Naples, Italy; [2]Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli, Italy; [3]IEO European Institute of Oncology - IRCCS, Department of Experimental Oncology, Milan, Italy; [4]University of Naples 'Federico II', Department of Medical and Translational Science, Naples, Italy

Background/Objectives: Breast cancer is the most frequent cancer in women. Neurofibromin (NF1) loss-of-function mutations are associated with poor breast cancer survival. Loss of NF1 (a negative regulator of the Ras-MAPK pathway) leads to constitutive mTORC1 signaling by activation of the Ras-MAPK pathway contributing to neoplastic transformation. NF1 interacts with LAMTOR1, a lysosomal protein crucial for mTORC1 activation on lysosomes, while changes in lysosome function and spatial distribution are closely related to cancer development and progression. We hypothesize that neurofibromin has a direct functional role in lysosomal metabolism and mTOR activation in breast cancer.

Methods: We generated NF1 knockout (NF1-KO) human breast cancer cells (SKBR3, BT474, HCC1954) using CRISPR-Cas technology and developed cell-based assays by high-content imaging approaches for lysosomal phenotype screening. mTOR signaling was analyzed by Western blot upon nutrient deprivation and then upon refeeding.

Results: mTOR activity decreases under nutrient deprivation and is reactivated under nutrient refeeding in the three breast cancer cell lines. However, loss of NF1 abrogates the decrease in mTOR signaling under nutrient deprivation. Moreover, lysosomes appear more condensed and increase in number in NF1-KO cells.

Conclusions: These results demonstrate that mTOR is constitutively active and lysosomal activity is altered in three different NF1-KO breast cancer cell models. In-depth investigation of specific lysosomal changes and NF1-dependent molecular mechanisms will provide a deeper understanding of the dynamic changes in cancer development, providing more opportunities for cancer diagnosis and treatment.

P01.029.A Treatment-related clonal competition and disrupted molecular processes in chronic lymphocytic leukemia

Kristyna Zavacka[1;2], *Jakub Porc[1;3], Petr Taus[1], Karol Pál[1], Sarka Pavlova[1;2;3], Jitka Malcikova[1;2;3], Kamila Stranska[1;2;3], Marcela Zenatova[2], Boris Tichy[1], Anna Panovska[2], Michael Doubek[1;2;3], Sarka Pospisilova[1;2;3], Karla Plevova[1;2;3]*

[1]Central European Institute of Technology, Masaryk University, Center of Molecular Medicine, Brno, Czech Republic; [2]University Hospital Brno, Department of Internal Medicine – Hematology and Oncology, Brno, Czech Republic; [3]Medical faculty, Masaryk University, Institute of Medical Genetics and Genomics, Brno, Czech Republic

Background/Objectives: Chronic lymphocytic leukemia (CLL), the most common adult leukemia in Western countries, is characterized by a highly variable clinical course, which is closely related to dynamic changes in leukemic cell clones over time. The expansion of subclones with different gene mutations, many of which are non-recurrent, makes CLL challenging to treat. We aimed to describe the clonal evolution in CLL, focusing on specific treatments and different stages of the disease. We particularly studied factors influencing the clonal development of *TP53*-mutated subclones, as defects in the *TP53* gene are the strongest predictive and prognostic marker in CLL and drive chemoimmunotherapy resistance.

Methods: We investigated a cohort of 62 CLL patients with detailed clinical characterization and known patterns of *TP53* mutation evolution. Whole-exome sequencing was employed to identify somatic variants at two to six different timepoints during the disease course of each patient. Subsequently, we analyzed abnormal molecular pathways and mutational signatures in defined patient groups and tracked their changes over time.

Results: Our analysis revealed striking competition among co-existing CLL subclones of individual patients. We observed progressive evolution of specific gene mutations, highlighting both their mutual exclusivity and co-occurrence. Moreover, we observed several impaired pathways and mutational signatures associated with different disease stages, treatment outcomes, and *TP53* status.

Conclusion: Our study provides insights into the molecular aspects underlying clonal evolution in CLL. These findings enhance our understanding of distinct disease phenotypes and suggest potential targets for personalized treatment strategies in CLL.

Consortium: NASGE - Nationale Allianz für seltene genetische Erkrankungen

Background/Objectives: Although there are recommendations at national and international level as to which genes should be analyzed in the context of a hereditary breast and ovarian cancer (HBOC), the individual composition of the corresponding gene panels varies, resulting in a different diagnostic yield.

Methods: We performed a retrospective NGS dataset analysis of suspected HBOC patients who had been tested at different German diagnostic laboratories that are part of the NASGE network. These results were compared with the most common panel recommendations and an internal HBOC core gene panel. Additionally, we analyzed the data concerning other potential tumor risk syndromes (TRS) not caused by pathogenic variants in the core panel genes.

Results: We collected 29,317 HBOC datasets and at least one pathogenic variant (class 4/5) was reported in about 4250 datasets, resulting in an overall diagnostic yield of 14.5%. The diagnostic yield of pathogenic variants (class 4/5) varied depending on the analyzed panel (between 5 and 26 genes) from 9.0% to 13.8% with the internal panel having a yield of 12.7%. Notably, in about 1% of cases, a pathogenic variant outside the established HBOC core genes was identified, potentially indicating the presence of other TRS.

Conclusion: These results are consistent with previous observations that a significant proportion of patients with HBOC predisposition were not detected by the guideline-based gene panels and suggest that expanded diagnostics compared to currently recommended multigene panels may identify additional patients at high risk for developing cancer.

P01.031.C RNA-seq of a cohort of cancer patients demonstrates its capacity to reclassify uncertain variants by unveiling aberrant splicing events

*Florentine Scharf[1], Thomas Keßler[1], Evgenia Vibe[1], Oliver Klaas[1], Jonas Ingermann[1], Caroline Heintz[1], Sabrina Angerbauer[1], Tobias Wohlfram[1], Andreas Laner[1], Ariane Hallermayr[1;2], Julia Romic-Pickl[1;2], Morghan Lucas[1;2], **Verena Steinke-Lange**[1;2], Elke Holinski-Feder[1;2]*

[1]MGZ – Medizinisch Genetisches Zentrum, Munich, Germany; [2]Medizinische Klinik und Poliklinik IV, Campus Innenstadt, Klinikum der Universität München, Munich, Germany

Background/Objectives: Around 5-10% of cancers are caused by hereditary tumor syndromes. For the current state-of-the-art method of gene panel testing via whole-exome sequencing (WES), the diagnostic yield ranges between 15-25% for these syndromes. Additional high-throughput methods are therefore required to increase the diagnostic yield. RNA-seq can guide the reclassification of variants of unclear significance (VUS) and detect previously unknown causative variants by revealing aberrant splicing at the RNA level.

Methods: We developed a cost-efficient, high-throughput targeted RNA-seq approach to analyze aberrant splicing events.

Results: Over 100 cases underwent RNA-seq, previously examined by NGS exome sequencing without revealing a clear pathogenic variant. Of these, 144 had a VUS, while 4 showed no initial concerning variants. RNA-seq led to the reclassification of 4 variants as likely benign and 8 as (likely) pathogenic, an increase in diagnostic yield by 8%. Of the 8 (likely) pathogenic reclassified variants, 2 were in *BRCA*1/2 genes. Among reclassified cases, 9 variants affected an intronic splice site, and 3 were outside of obvious splice-relevant regions. For one case with no initially reported variants, RNA-seq identified the use of a cryptic exon in the *APC* gene, guiding subsequent intronic region analysis.

Conclusion: RNA-seq offers clinically relevant insights on VUS and cases where no variant was detected, aiding clear diagnoses for unresolved cases. Overall, ~8% of cases previously unsolved by DNA exome sequencing were successfully reclassified by our RNA-seq approach, significantly improving diagnostic yield and optimizing patient care for hereditary cancer syndromes.

P01.032.D The role of liquid biopsy by rapid NGS in cancer management

Mustafa Ozen[1], *Serhat Seyhan[2], Emre Ilhan[2], Rabia Aksoy[2]*

[1]Istanbul University-Cerrahpasa, Medical Genetics, Istanbul, Türkyie; [2]Medroyal Genetic Assessment Center, Medical Genetics, Istanbul, Türkyie

Background/Objectives: Liquid biopsy (LB) is a promising technique for early detecting and monitoring cancer; however, there are still room to improve in sensitivity and duration of the test. Here, we report data in 20 cancer patients referred to us for LB. We propose that LB by rapid NGS technique is crucial for cancer management.

Methods: At least 10 ml of whole blood is collected in EDTA containing vacutainers. Plasma is seperated immediately and stored in -80 until further use. Total nucleic acid (TNA) is isolated from the plasma samples using MagMAX ™ Cell-Free TNA isolation kit. Total of 10 ng TNA is subjected to Genexus NGS platform where library preperation and sequencing are done automatically in 24 hours by using Oncomine Precision assay. This assay detects actionable mutations in 50 genes in DNA and RNA level. The data is analysed initially by Genexus platform and further analysed by Oncomine software.

Results: Out of 20 patients analysed, 10 patients are dignosed with Lung cancer, 3 had suspicion for lung cancer, 2 had pancreas cancer, 1 patient in each cancer type of breast, bronchial, hepatocellular and colon cancers. We were able to detect

actionable mutations in 70 % of our patients. Most of the mutations were SNV in the following genes analyzed: EGFR, p53, KRAS, PTEN and BRAF. One patient had EML4-ALK fusion and one AR amplification.

Conclusion: LB by rapid NGS is an important tool for cancer management. İt is critical to include DNA and RNA in the analysis to precisely detect mutations.

P01.033.A Meta-analysis of *GRIN2A* variants contradicts a role in tumorigenesis

Robin-Tobias Jauss[1], *Johannes Lemke*[1;2], *Vincent Strehlow*[1]

[1]*Institute of Human Genetics, University of Leipzig Medical Center, Leipzig;* [2]*Center for Rare Diseases, University of Leipzig Medical Center, Leipzig*

Background/Objectives: *GRIN2A* has previously been identified as frequently mutated in tumor samples, leading to a hypothesised involvement of *GRIN2A* in tumorigenesis. Pathogenic *GRIN2A* germline variants on the other hand lead to neurodevelopmental disorders, and extensive phenotyping of affected individuals revealed no evidence for tumor burden.

Methods: All publicly available *GRIN2A* variants were obtained from ClinVar, Cosmic and gnomAD to account for germline variation, somatic variation and variants identified in the general population, respectively. Functional consequences, mutational hotspots and gene expression were assessed for each dataset to draw conclusions on potential pathomechanisms of tumorigenesis.

Results: Pathogenic germline variants in *GRIN2A* expose a genotype-phenotype correlation with distinct clustering in functionally relevant domains. Somatic *GRIN2A* variants are indeed unique when compared to pathogenic germline variants, but exhibit a homogeneous distribution and no enriched functional consequences in specific domains of *GRIN2A*. Expression of *GRIN2A* is lower in tumor samples compared to non-diseased tissues.

Conclusion: The homogeneous distribution and low expression of somatic variants implies a lack of mutational clustering and functional relevance, which refutes the hypothesised major role of *GRIN2A* in tumorigenesis.

P01.036.D First mutational analysis of TERT promoter and CTNNB1 in hepatocellular carcinoma, cirrhotic, and non-cirrhotic liver tissues from Brazilian patients.

Mariana Leonardo Terra[1], *José Junior Barros*[1], *Antônio Hugo José Fróes Marques Campos*[2;3], *Vera Pannain*[4], **Natalia Araujo**[1]

[1]*Oswaldo Cruz Institute - FIOCRUZ, Laboratory of Molecular Virology and Parasitology, Rio de Janeiro, Brazil;* [2]*A.C.Camargo Cancer Center, Department of Anatomic Pathology, São Paulo, Brazil;* [3]*Rede D'Or São Luiz, Division of Pathology, São Paulo, Brazil;* [4]*Federal University of Rio de Janeiro, Clementino Fraga Filho University Hospital, Rio de Janeiro, Brazil*

Background/Objectives: Hepatocellular carcinoma (HCC) is a major global health burden, with poor prognosis especially at later stages. HCC often arises in cirrhotic livers due to specific risk factors. Its development involves complex genetic mutations. TERT and CTNNB1 somatic mutations are prevalent in HCC but unexplored in Brazilian patients. This study aims to investigate the association of TERT promoter mutations (C228T and C250T) and CTNNB1 exon 3 mutations with HCC development in Brazil.

Methods: Eighty-five liver tissue samples, comprising 26 tumor/surrounding tissue pairs, and 16 HCC, 9 cirrhotic and 8 non-cirrhotic unpaired samples, were analyzed. DNA extracted from cryopreserved or formalin-fixed tissues underwent mutation analysis through Sanger sequencing of PCR fragments.

Results: C250T frequency in HCC tissues was notably low (2.4%) and absent in cirrhotic and non-cirrhotic tissues. C228T was more prevalent in HCC (45.2%) and cirrhotic tissues (19%) than non-cirrhotic (0%) tissues, exhibiting a gradual increase with liver disease progression. Significantly different C228T frequencies were observed in HCC vs. non-cirrhotic ($P = 0.0001$) and cirrhotic vs. non-cirrhotic ($P = 0.0485$) tissues. Paired analysis demonstrated exclusive C228T presence in HCC in 46.2% of pairs. While C228T showed higher prevalence in HCCs linked to HCV infection (66.7%), statistical significance was not reached. Preliminary CTNNB1 analysis showed mutations occurred more frequently in HCC (23.8%) than cirrhotic (9.1%) and non-cirrhotic (0%) tissues, with concordance observed with C228T mutation in 66.7% of cases.

Conclusion: TERT promoter mutation C228T, and potentially CTNNB1 mutations, emerge as promising biomarkers for HCC in Brazilian patients, facilitating early detection, risk stratification, and offering potential therapeutic targets for this aggressive cancer.

Conflict of Interest: None declared

P01.039.C Importance of detecting mosaic variants in a case suggestive of Gardner's syndrome.

Jesús Cabanes Madrid[1], *Blanca Luis Sánchez*[2], **José Manuel Sánchez Zapardiel**[1], *Beatriz Hidalgo Calero*[1], *Montserrat de Miguel*[1], *Ricardo Blázquez Martín*[1], *Marina Ibáñez Vizcaíno*[1], *Francisca Luengo Sainz de Baranda*[1], *Victoria Carrero Blázquez*[1], *Luis Robles Díaz*[3]

[1]*Hereditary Cancer Unit, Hospital 12 de Octubre. Madrid, Department of Clinical Analysis-Clinical Biochemestry, Madrid, Spain;* [2]*Hospital Puerta del Mar, Cádiz, Department of Clinical Analysis-Clinical Biochemestry, Cádiz;* [3]*Familiar Cancer Unit, Hospital 12 de Octubre, Madrid, Department of Medical Oncology, Madrid, Spain*

Background/Objectives: A 19-year-old male was found to have 14 adenomatous polyps and was diagnosed with multiple osteomas in the left ethmoid sinus and frontal sinus. These findings pointed to Gardner's syndrome and the patient was referred to the Family Cancer Unit.

Methods: Next Generation sequencing (Illumina) was carried out using the Hereditary Cancer Solution kit (Sophia Genetics). The results were analyzed with Sophia-DDM and the variant allele frequency (VAF) detected were confirmed from different tissues by high depth NGS and Sanger sequencing.The segregation was carried out in both parents.

Results: The variant c.4537G > T p.(Glu1513*) in the *APC* gene are located on mutation cluster region (MCR) and generates a premature stop codon which causes a truncated protein. According to American College of Medical Genetics (ACMG) criteria it was classified as pathogenic. The variant has been identified by high depth NGS in blood and buccal swab at a VAF 10% an 9% respectively, and by sanger sequencing in different sections of colon biopsy at a VAF mean of 10-30%. The results obtained confirm the presence of this variant in mosaicism and "de novo" origin.

Conclusion: Unusual percentage of allele frequencies may be due to artefacts or false positives from sequencing errors. However, mosaic variants are also found in this range and it's important screening them, paying special attention to genes

related to the patient's phenotype. Otherwise, it would result in inadequate genetic counselling for the patient and their relatives.

Grants: Project "PI19/00340" to L.R., funded by Instituto de Salud Carlos III (ISCIII) and co-funded by the European Union.

P01.040.D Germline predisposition in paediatric melanoma patients undergoing matched tumor-normal sequencing

Alexandra Liebmann[1], *Jakob Admard*[1], *Hannah Wild*[2], *Michael Abele*[2], *Irina Bonzheim*[3], *Ewa Bien*[4], *Stephan Forchhammer*[5], *Dominik Schneider*[6], *Christopher Schroeder*[1], *Stephan Ossowski*[1], *Ines Brecht*[2]

[1]*University Hospital Tübingen, Institute of Medical Genetics and Applied Genomics, Tübingen, Germany;* [2]*University Children's Hospital Tübingen, Paediatric Hematology and Oncology, Tübingen, Germany;* [3]*University Hospital Tübingen, Institute of Pathology and Neuropathology, Tübingen, Germany;* [4]*Medical University of Gdansk, Poland, Department of Paediatrics, Hematology, Oncology, Gdansk, Poland;* [5]*University Hospital Tübingen, Center for Dermatooncology, Department of Dermatology, Tübingen, Germany;* [6]*Dortmund Municipal Hospital, Dortmund, Clinic of Paediatrics, Dortmund, Germany*

Background/Objectives: Genomic characterisation has led to an improved understanding of adult melanoma. However, the aetiology of melanoma in children is still unclear. The aim of this study was to further characterize paediatric melanoma and to identify putative causative germline alterations possibly relevant for prevention and surveillance.

Methods: The cohort of 26 paediatric melanoma patients was grouped into different categories: spitzoid melanoma (SM), conventional melanoma (CM) and others (OT). Tumor-normal exome sequencing was performed and analyzed using an in-house bioinformatics pipeline (megSAP). Germline variants were called with freebayes and annotated with VEP.

Results: No (likely) pathogenic variants were found in the high-risk melanoma genes *CDK4* and *CDKN2A*. In all patients with CM (n = 10) germline variants were found in low to moderate melanoma risk genes: 8 CM patients carried at least one *MC1R* variant, one patient carried the *MITF* E318K variant, another patient carried variants in *PTEN* (c.800del, p.Lys267Arg*9) and in *BRCA2* (c.9253dup, p.Thr3085Asn*26). In the SM group (n = 12), 41.7% (n = 5) patients carried at least one *MC1R* variant. In the OT (n = 4) group, 2 patients carried a *MC1R* variant. The *MC1R* variants detected were V92M (n = 6), R151C (n = 5), R160W (n = 4), V60L (n = 4), D84E (n = 1), R163Q (n = 1), K278E (n = 1).

Conclusion: Genetic risk factors may play a more important role in paediatric melanoma than previously anticipated. It can be envisioned to develop combinatorial risk models including genetic and environmental factors to identify individuals at risk and to establish prevention measures.

Grants: Fortüne (2529-0-0), German Childhood Cancer Foundation (DKS 2013/18 DKS 2018/37), DFG (Project-ID286/2020B01-428994620)

P01.041.A Validation of the BOADICEA model for epithelial tubo-ovarian cancer risk prediction in the UK Biobank

Xin Yang[1], *yujia wu*[1], *Lorenzo Ficorella*[1], *naomi wilcox*[1], *Joe Dennis*[1], *jonathan tyrer*[1], *Timothy Carver*[1], *nora pashayan*[1], *marc tischkowitz*[2], *paul pharoah*[3], *Douglas F. Easton*[1;4], *Antonis C. Antoniou*[1]

[1]*University of Cambridge, Department of Public Health and Primary Care, Cambridge, United Kingdom;* [2]*University of Cambridge, Department of Medical Genetics, Cambridge, United Kingdom;* [3]*Cedars-Sinai Medical Center, Department of Computational Biomedicine, Los Angeles, United States;* [4]*University of Cambridge, Department of Oncology, Cambridge, United Kingdom*

Background/Objectives: To assess the clinical validity of the multifactorial BOADICEA model for predicting 10-year epithelial tubo-ovarian cancer (EOC) risk in a large, independent prospective cohort.

Methods: We evaluated the model discrimination and calibration in the prospective UK Biobank cohort comprising 199,429 women (733 incident EOCs) of European ancestry without previous cancer history. We predicted 10-year EOC risk incorporating data on questionnaire-based risk factors (QRFs), family history, a 36-SNP polygenic risk score (PRS) and pathogenic variants (PV) in six EOC susceptibility genes (*BRCA1*, *BRCA2*, *RAD51C*, *RAD51D*, *BRIP1* and *PALB2*).

Results: Individually, QRFs, the PRS and PVs (each combined with age), gave similar discrimination (AUC~0.64-0.65). Discrimination was considerably greater using the multifactorial model that included the PRS, QRFs, FH and PV status (AUC = 0.68, 95%CI:0.66-0.70). This model was well calibrated in deciles of predicted risk with calibration slope = 0.99 (95%CI:0.98-1.01). The model had similar discriminative ability in women younger or older than 60 years. The AUC was higher when analyses were restricted to PV carriers (0.76, 95%CI:0.69-0.82); the model remained well calibrated in all risk groups. Using relative risk (RR) thresholds, the full model classified 97.7%, 1.7%, 0.4% and 0.2% women in the RR < 2.0, 2.0≤ RR < 2.9, 2.9 ≤ RR < 6.0 and RR ≥ 6.0 categories respectively, identifying 9.1% of incident EOC among those with RR ≥ 2.0.

Conclusion: BOADICEA, implemented in CanRisk (www.canrisk.org), provides a valid individualized 10-year EOC risks which can facilitate decision making in clinical EOC risk management.

Grants: Cancer Research UK (PPRPGM-Nov20\100002).

Consortium: PTEN Study Group

Background/Objectives: PTEN Hamartoma Tumor Syndrome (PHTS) has a broad clinical spectrum including benign and malignant tumors with varying age of onset. Many patients remain unrecognized, unaware of their increased cancer risk. We assessed the cancer spectrum and histopathological cancer characteristics to determine whether this could improve PHTS recognition.

Methods: Genetic testing results and pathology reports were collected for patients tested for germline *PTEN* variants between 1997-2020 from the diagnostic laboratory and the Dutch nationwide pathology databank (Palga). Cancer spectrum and age of onset were assessed in patients with (PTENpos) and without (PTENneg) a germline *PTEN* variant. Histopathological cancer characteristics were assessed in a nested cohort.

Results: 341 PTENpos patients (56% females) and 2,882 PTENneg patients (66% females) were included. PTENpos presented mostly with female breast (BC, 30%), endometrial (EC, 6%), thyroid (TC, 4%) or colorectal cancer (4%). Besides PHTS-related cancers, PTENpos had non-serous ovarian cancer (3%). PTENpos were significantly younger at cancer onset (43 vs. 47years) and developed more often (46% vs. 18%) a second BC. *PTEN* detection rates were highest for BC < 40 years (9%), TC < 20 years (15%) and EC < 50 years (28%). Histopathological characteristics were similar between groups.

Conclusion: No histopathological cancer characteristics were distinctive for PHTS. However, PTENpos were significantly younger at cancer onset. Therefore early-onset BC, EC or TC warrants consideration of PHTS diagnostics either by pre-screening for other PHTS features or direct germline testing.

Grants: This project has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie grant agreement No955534

P01.044.D Evaluation of the results of cytogenetic, molecular cytogenetic and molecular analysis in non-Hodgkin lymphoma

Can Berk Leblebici[1], *Nüket Yürür Kutlay*[1], *Arzu Vicdan*[1], *Sadiye Ekinci*[1], *Hatice Ilgın Ruhi*[1], *Timur Tuncalı*[1], *Halil Gürhan Karabulut*[1], *Şule Altıner*[1], *Ezgi Gökpınar İli*[1]

[1]*Ankara University Medical School, Medical Genetics, Turkiye*

Background/Objectives: Non-Hodgkin lymphomas (NHL) are the most common lymphoma type in adults. In this study, the results of cytogenetic, fluorescence in situ hybridization (FISH) and next generation sequencing (NGS) analysis of patients diagnosed with NHL is presented.

Methods: The results of genetic analysis performed on BM or PB samples of patients with NHL in our department between 2022-2023 were evaluated retrospectively.

Results: Sixty patients (28 women 32 men), their average age was 58, were included in the study. There were a total of 12 types of NHL and the most frequent one was diffuse large B-cell lymphoma. Loss-of-function changes in the *DNMT3A* gene in B-cell-derived lymphomas and gain-of-function changes in *STAT5B* and *STAT3* genes in T-cell-derived lymphomas were detected as the most common mutations.

The number of detected pathological findings by the method used is summarized in the table below:

Method	DLBCL[1]	MZL[2]	FL[3]	TCL[4]	MCL[5]	T-LGL[6]
NGS	8	7	5	3	4	2
Cytogenetics	4	1	0	2	2	0
FISH	0	1	1	1	1	0

[1]Diffuse large B-cell, [2]Marginal zone, [3]Follicular, [4]T-cell and [5]Mantle cell lymphoma. [6]T-cell large granular lymphocytic lymphoma/leukemia

Conclusion: Lymphoma pathogenesis is complex. Genetic test results make important contributions to the evaluation of parameters related to diagnosis, treatment and prognosis in cases with NHL. Pathological NGS findings may be related to the pathogenesis of lymphoma but the interpretation may be difficult. In this study, evaluation will be made regarding the genetic test results of NHL cases.

P01.045.A Utility of whole body MRI surveillance in children and adults with cancer predisposition syndromes

Frances Victoria Que[1], *Shao-Tzu Li*[1], *Jeanette Yuen*[1], *Tarryn Shaw*[1], *Hui Xuan Goh*[1], *Nur Diana Binte Ishak*[1], *Zewen Zhang*[1], *Jianbang Chiang*[1], *Lee Lian Chew*[2], *Choon Hua Thng*[2], *Joanne Ngeow*[1;3;4]

[1]*National Cancer Centre Singapore, Cancer Genetics Service, Division of Medical Oncology, Singapore, Singapore;* [2]*National Cancer Centre Singapore, Division of Oncologic Imaging, Singapore, Singapore;* [3]*Duke-NUS Medical School, Oncology Academic Clinical Program, Singapore, Singapore;* [4]*Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore*

Background/Objectives: Surveillance improves outcomes by detecting cancer early in individuals with cancer predisposition syndromes (CPS). Whole body MRI (WB-MRI) provides head-to-thigh imaging in one sitting without radiation exposure and is recommended for individuals with CPS associated with increased risk of multi-focal tumors/cancers and/or susceptibility to radiation. This study evaluated the diagnostic performance of WB-MRI as a screening tool for Li-Fraumeni syndrome, Constitutional Mismatch Repair Deficiency syndrome, Hereditary Paraganglioma-Pheochromocytoma syndrome and other CPS.

Methods: A review of patients with CPS seen at the Cancer Genetics Service, National Cancer Center Singapore was conducted. Patients who underwent screening WB-MRI from 2014 to 2022 were identified to determine the sensitivity and specificity of WB-MRI in detecting cancer early.

Results: Of 103 patients with CPS who were indicated to have WB-MRI surveillance, 54 underwent the procedure (52% uptake rate): 28 (52%) were female, median age was 41 years (range 1-65 years); 21 (39%) had Li-Fraumeni syndrome, six (11%) had Hereditary Paraganglioma-Pheochromocytoma syndrome, and seven (13%) had Von Hippel Lindau syndrome. WB-MRI screening led to a diagnosis of cancer in seven (13%) patients (renal cell carcinoma, prostate adenocarcinoma, osteosarcoma, neuroendocrine tumor); four of these seven patients (57%) were treated with curative intent. Twelve (22%) patients required additional investigations, with eight (15%) having benign findings. The sensitivity and specificity of WB-MRI in our cohort was 64% and 81% respectively, with a false-positive rate of 19% and false-negative rate of 36%.

Conclusion: WB-MRI is an effective screening tool in patients with specific CPS, demonstrating a high specificity and low false positive rate.

P01.046.B Targeted transcriptomics validates metastasis-relevant genes from case-case GWAS risk variants and functional annotation in sporadic colorectal carcinomas.

Peh Yean Cheah[1], *Kuen Kuen Lam*[1], *Lai Fun Thean*[1], *Michelle Su Mei Lo*[1], *Emile Tan*[1], *Choong Leong Tang*[1], *Iain Bee Huat Tan*[2]

[1]*Singapore General Hospital;* [2]*National Cancer Centre Singapore, Singapore*

Background/Objectives: Colorectal cancer (CRC) is the third highest incidence cancer and leading cause of cancer mortality worldwide. Metastasis to distal organ is the major cause of cancer mortality. Currently, the underlying genetic factors are unclear. This study aims to identify metastasis-relevant genes and pathways for better management of metastasis-prone patients.

Methods: A case-case genome-wide association study comprising 2677 sporadic Chinese CRC cases with clinically determined metastasis status (1282 metastasis-positive vs 1395 metastasis-negative) was performed using the Human SNP6 microarray platform and analyzed with the correlation/trend test based on the additive model. 647,545 single nucleotide polymorphism (SNP) variants with association testing -log10p-value ≥ 5 were imported into Functional Mapping and Annotation (FUMA) and Ingenuity (IPA) software for functional annotation and pathway analysis.

Results: About 196 candidate genes were identified for both overall and disease subtypes stratified by gender, tumor stage, site, and metastasis organs. Targeted high throughput transcriptomics was performed on 200 (100 metastasis-positive vs 100 metastasis-negative) left-sided stage III tumors using the Fluidigm platform. About a third of the candidate genes identified by the combined case-case GWAS and in silico analysis were validated; half of these are significant in the female subset only. This reaffirms that there is female-specific metastasis-relevant genes contributing to sexual dimorphism in CRC metastasis.

Conclusion: Combining genome-wide association testing with in silico functional annotation and wet-bench validation identified metastasis-relevant genes that could serve as features to develop subtype-specific metastasis-risk signatures for tailored management of CRC patients.

Background/Objectives: Approximately 10% of cancer patients harbour germline variations predisposing to cancer. Increased lymphoma development risk has been reported in several syndromes and patients with familial history. We aimed to investigate germline predisposition genes in paediatric lymphoma cases/families with at least one indication for genetic counselling.

Methods: Whole exome sequencing was performed in 22 paediatric lymphoma cases (Hodgkin's lymphoma (n = 13), diffuse large B-cell lymphoma (n = 3), Burkitt's lymphoma (n = 3), T-cell anaplastic lymphoma (n = 2), lymphoproliferation (n = 1)) with indications for genetic counselling. Segregation analyses were performed for candidate genes.

Results: Almost 60% of cases were associated with immunodeficiency without differential clinical diagnosis, and germline variations in genes related to primary immunodeficiency such as *CD70, RAG2, LRBA, NBN, ITK* and *TNFSF9*. In other lymphoma families, germline variations in inherited cancer susceptibility genes like *PRF1, BRIP1, SMAD4, KDR, ALK* have been observed. In addition to the major predisposition genes, each case was found to carry numerous heterozygous variants of germline cancer genes (*NOTCH1, FLT3, BCR, JAK2, CCDN1*,etc.). Two new candidate genes/variants thought to be responsible for germline predisposition to lymphoma have also been identified.

Conclusion: Implementation of next-generation sequencing has recently enabled discovering rare genetic variants predisposing paediatric patients to lymphoid neoplasms. It is valuable for identifying individuals at risk in families for early diagnosis, genetic counselling and follow-up. It is also important to evaluate patients for indications for genetic counselling in order not to miss rare hereditary cases in the clinic.

P01.048.D Barriers and facilitators to sustainment of the Tumor-First workflow for hereditary epithelial ovarian cancer detection

Vera M. Witjes[1], *Yvonne H.C.M. Smolders*[1], *Joanne A. De Hullu*[2], *Margreet G.E.M. Ausems*[3], *Marian J.E. Mourits*[4], *Marjolijn Ligtenberg*[1;5], *Nicoline Hoogerbrugge*[1], *Julie E.M. Swillens*[6]

[1]*Radboud university medical center, Department of Human Genetics, Nijmegen, Netherlands;* [2]*Radboud university medical center, Department of Obstetrics and Gynecology, Nijmegen, Netherlands;* [3]*University Medical Center Utrecht, Division Laboratories, Pharmacy and Biomedical Genetics, Department of Genetics, Utrecht, Netherlands;* [4]*University of Groningen, University Medical Center Groningen, Department of Obstetrics and Gynecology, Groningen, Netherlands;* [5]*Radboud university medical center, Department of Pathology, Nijmegen, Netherlands;* [6]*Radboud university medical center, Scientific Center for Quality of Healthcare (IQ Healthcare), Nijmegen, Netherlands*

Background/Objectives: Around 10-15% of women with epithelial ovarian cancer (OC) have a genetic predisposition, making genetic testing essential. To optimize detection of heredity, we have implemented the "Tumor-First" workflow nationwide. This workflow implies that OC tumor DNA is examined for presence of

pathogenic variants (e.g. in *BRCA1/2*) serving to stratify germline testing and to provide information on the effectiveness of PARP-inhibitors. Implementation was successful with the uptake of tumor DNA testing exceeding 80% and positive experiences. However, with the everchanging field of genetic testing, we aimed to determine the sustainability of the Tumor-First workflow.

Methods: We used a qualitative study design. 30 healthcare professionals from 7 medical disciplines were interviewed to discuss factors important for sustainment of the Tumor-First workflow. Barriers and facilitators of sustainment were analyzed using the framework of Flottorp.

Results: Main facilitators of sustainment were support, motivation, and awareness amongst healthcare professionals, presence of leading figures in the field, practical advantages of the workflow and (financial) embeddedness within the healthcare system. Main barriers were concerns about sustainment of nationwide uniformity considering ongoing developments in the field and the nearing end of project-related nationwide coordination. Without coordination, developments in tumor sequencing techniques and the rise of homologous-recombination-deficiency testing might lead to heterogeneity amongst laboratories in procedures and workflows.

Conclusion: As the field of genetic testing undergoes rapid developments, nationwide coordination is needed to sustain a uniform workflow. These results provide guidance on implementation and sustainment of innovations in the field of genetic testing.

Background/objectives: Women carrying germline pathogenic variants in *BRCA1* and *BRCA2* are offered surveillance, risk-reducing bilateral mastectomy (RRBM) and salpingoophorectomy (RRSO) to reduce cancer morbidity and mortality. The aim of this study is to evaluate cancer incidence and mortality in relation to risk-reducing surgery in a nationwide cohort of healthy *BRCA*-carriers.

Methods: The Swedish *BRCA*-cohort includes Swedish *BRCA*-carriers identified 1994-2018. Their data was linked with nationwide Cancer -, Patient-, and Cause of Death registers. Cancer-free women were followed from the date of testing, until death or end of follow-up (Aug 2022).

Results: The 837 women cumulated to 9329 person years, whereof 4972 before/never RRBM and 4357 after RRBM, 6102 before/never RRSO and 3227 after RRSO. Preliminary results indicate that at the end of follow-up, 74 (16%) developed breast cancer (median age 47, range 24-72), 16 (4%) ovarian cancer (median age 54, range 30-73), and 44 (median age 66, range 29-97) had died. In total, 386 carriers (46%) had undergone RRBM (median age 39, range 20-72) and 400 (48%) RRSO (median age 44, range 21-77).

Conclusions: This study will summarize cancer incidence and mortality and the effect of risk reducing interventions, on a national level in Sweden during the first 20 years of clinical *BRCA1* and *BRCA2* -testing. Updated data on age-dependent cancer incidence as well as the effect of risk reducing surgery on mortality will be presented.

P01.050.B Expression analysis of ultraconserved regions in childhood acute lymphoblastic leukemia

Maria Augusta Poersch[1], Gabriela Canalli Kretzschmar[2], Saloe Bispo[2], Daniela Fiori Gradia[1], Roberto Rosati[2], **Jaqueline Carvalho de Oliveira**[1]

[1]Federal University of Parana, Genetics, Curitiba - PR, Brazil; [2]Pelé Pequeno Príncipe Research Institute, Curitiba - PR, Brazil

Background/Objectives: The ultraconserved regions (UCRs) are genomic elements that exhibit complete sequence conservation across human, rat, and mouse genomes and are implicated in various cancers. However, their role in childhood acute lymphoblastic leukemia (ALL) remains underexplored. The present study aims to identify differentially expressed transcripts associated with UCRs across ALL subtypes.

Methods: Using RNA sequencing data from St. Jude Research Hospital (804 subjects aged 0-15), differential expression analysis was conducted with DESeq2, including 240 annotated transcripts. Comparisons spanned T-ALL versus B-ALL, high-risk versus low-risk subtypes, and distinct expression profiles of hypodiploid, high hyperdiploid, and recurrent genetic abnormalities: ETV6-RUNX1, rearrangement of KMT2A, iAMP21, BCR-ABL1, and TCF3-PBX.

Results: The differential expression analyses revealed 40 significantly deregulated transcripts, with the T-ALL vs. B-ALL comparison displaying the highest diversity (16 transcripts). Noteworthy oncogenes, including ZNF521, EBF1, EBF3, PBX1, and EPHA7, exhibit subtype-specific expression patterns. ZNF521 is more expressed in high-risk ALL, while EBF1 was found to be overexpressed in B-ALL. PBX1 shows increased expression in the TCF3-PBX1 subtype, and EPHA7 demonstrates higher expression in B vs. T ALL. Furthermore, regulatory genes such as HOXA2, HOXA3, and HOXA5 were found to be downregulated in BCR-ABL1 positive patients and upregulated in the KMT2A-rearrangement.

Conclusion: This comprehensive analysis identifies UCR-related transcripts deregulated in ALL subtypes, including critical oncogenes. In conclusion, our study sheds light on the crucial role of T-UCR-associated transcripts in childhood ALL, improving the understanding of the disease and offering valuable insights for personalized treatment approaches in the future.

P01.051.C Enhanced cytogenomic analysis of complex karyotype in myelodysplastic syndrome using optical genome mapping

Andriana Valkama[1], *Sandra Vorimo*[1], *Anna Tervasmäki*[1], *Hannele Räsänen*[2], *Eeva-Riitta Savolainen*[2], *Katri Pylkäs*[1;2], *Tuomo Mantere*[1]

[1]*Laboratory of Cancer Genetics and Tumor Biology, Translational Medicine Research Unit, Medical Research Center Oulu and Biocenter Oulu, University of Oulu, Oulu, Finland;* [2]*Northern Finland Laboratory Centre Nordlab, Oulu, Finland*

Background/Objectives: Myelodysplastic syndrome with complex karyotype (CK-MDS) is a clinically challenging disease. In the clinical workup of MDS, cytogenetic analyses detecting structural variants (SVs) are crucial for prognostication and guiding treatment decisions. However, the current standard of care (SOC) testing, relying on karyotyping, often yields ambiguous results in cases with a complex karyotype.

Methods: We evaluated the SV detection by optical genome mapping (OGM) for 15 CK-MDS cases compared with SOC and explored the use of OGM as a tool for novel discoveries in combination with exome and transcriptome sequencing.

Results: Abnormalities were reported in 73 chromosomes within the cohort using karyotyping. The concordance with OGM, defined as the presence of large SVs in the same chromosomes, was 89% (65/73). The concordance between OGM and FISH was 100% (20/20). Importantly, OGM provided additional important information for all the analyzed CK-MDS cases. This included the detection of SVs >5Mb in chromosomes that were not specified by karyotyping to harbor abnormalities (93% of cases) and smaller SVs overlapping with leukemia-associated genes (53% of cases). Our analysis also confirmed the presence of three in-frame gene-fusions, including *NUP98::PRRX2*, and two novel fusions.

Conclusion: This study supports the application of OGM for CK-MDS cases to enhance SV detection and acquiring gene-level information. OGM could be effective as either a first-tier test or in combination with karyotyping. Furthermore, our results underscore the utility of OGM as a research tool in cancer samples with complex genomic rearrangements.

Background/Objectives: Use of genomic technologies in the investigation of haematological malignancies has led to an increase in the identification of disease associated genetic variants which may also confer inherited susceptibility. We report a collaborative approach supported by the CanGene-CanVar research programme and UK Cancer Genetics Group to develop a clinical and educational infrastructure to improve clinical pathways for the assessment and management of germline predisposition to haematological malignancies across the UK National Health Service (NHS).

Methods:

1. An online National consensus group meeting was convened with stakeholders across clincial and laboratory services alongside policy makers from NHS England. Stakeholders completed pre-meeting questionnaires, followed by in-meeting polling on consensus statements. Consensus was deemed to be reached when ≥80% respondents selected 'Agree/Strongly Agree' or 'Yes' in response to the statement posed.
2. An online survey based gap and training needs analysis (TNA) was undertaken across the relevant healthcare workforce to identify and analyse related training needs mapped to clinical pathways.

Results: 146 stakeholders registered for participation in the consensus meeting. Consensus was reached on 28 statements across the whole clinical-laboratory pathway. 272 healthcare workers participated in the TNA. This showed significant variation across the workforce in knowledge and skills required to deliver these clinical pathways.

Conclusion: A national clinical/scientific collaboration enabled the publication of consensus guidelines. Identification of training needs highlighted a requirement for educational resources. We present updates on the UK national educational and clinical infrastructure to iteratively improve clinical care pathways for patients with germline predisposition to haematological malignancies.

P01.053.A Identifying genetic vulnerabilities and trascriptional programs in TERT-promoter-mutant glioblastoma

Kevin Tu[1;2], *Connor Stewart*[2;3], *Peter Hendrickson*[2], *Joshua Regal*[2;4], *So Young Kim*[2], *David Ashley*[2], *Matthew Waitkus*[2], *Zachary Reitman*[2]

[1]*Cancer Research UK Cambridge Institute, United Kingdom;* [2]*Duke University, Durham, United States;* [3]*Emory University, Atlanta, United States;* [4]*Roswell Park Comprehensive Cancer Center, Buffalo, United States*

Background/Objectives: Mutations in the promoter of the telomerase reverse transcriptase (TERT) gene are early somatic mutations that occur in >80% of glioblastomas (GBMs). TERT promoter mutations (TPMs) create a neomorphic E-twenty-six (ETS) transcription factor binding site which reactivates TERT expression and drives GBM immortality. Directly targeting TERT and transcription factors has historically proven challenging. Here, we seek to identify potential targets upstream of TPMs using pooled genetic screens.

Methods: We generated T98G-TERT-ON, a TPM + GBM cell line with inducible TERT expression. We performed a minature pooled CRISPR/Cas9 screen in T98G-TERT-ON against TERT and GABPB1L, a critical ETS subunit that binds to TPM+ promoters. We annotated TPM status for >400 cell lines and 500 primary GBMs, then conducted comparative analyses between TPM status using genetic dependency data and/or gene expression profiles.

Results: We did not detect a dependency for TERT or GABPB1L in the CRISPR/Cas9 screen in T98G-TERT-ON. Similarly, TERT was not a dependency in TPM + GBM cell lines within the computational cohort. The ETS subunits GABPB1 and GABPA were dependencies within both TPM+ and TPM- cell lines. TPM+ cell line expression profiles were regulated by multiple ETS transcription factors. Moreover, in primary GBMs, TERT expression was strongly associated with the expression of ETS transcription factors ELF5, ETV1, ETV5, ERF, ETV4, ETV2, ETS2, GABPB1, SPI1.

Conclusion: Our findings suggest multiple ETS-factor regulate TERT interchangeably and/or redundantly in a cellular context-dependent manner, posing challenges in targeting TPMs through upstream regulators. Approaches to target other aspects of TPM biology merit attention.

Background: Pathogenic variants in the *STK11* gene cause Peutz-Jeghers syndrome (PJS) (OMIM#175200). PJS-type hamartomatous polyps have been reported in only three newborns without genetic confirmation, with the youngest confirmed case documented at 6 months. Infant cases involved either the small bowel or stomach.

Methods: We present a 5-month-old male, second child of non-consanguineous parents, with an unremarkable familial history. Prenatal ultrasounds revealed an arachnoidal cyst and polyhydramnios. At birth, he presented marked abdominal distension. An abdominal ultrasound revealed diffuse thickening of the colon, a hepatic arteriovenous malformation, and multiple hepatic lesions suggesting hemangiomas. No mucocutaneous pigmentation was observed. After inconclusive studies, the condition worsened with subocclusion episodes, leading to subtotal colectomy at 2 months. Pathological study revealed diffuse colon involvement with hamartomatous polyposis.

Results: Clinical exome sequencing identified two heterozygous variants in *STK11*. First, an exon 1 deletion, further confirmed by MLPA, spanning at least 1300 bp and including the promoter region and start codon. This deletion, previously reported in PJS, was classified as pathogenic following ACMG criteria. Second, a missense variant of unknown significance (NM_000455.5:c.525G > C/p.Lys175Asn). Digital PCR and direct sequencing validated the patient's results and showed that the variants were absent in both parents. Microsatellite marker genotyping further supported declared paternity and maternity. Long-range PCR revealed a cis configuration. Array-CGH was normal.

Conclusion: This is the first case of congenital presentation of diffuse colonic hamartomatous polyposis, which was genetically confirmed as PJS. The codominant trans configuration hypothesis was ruled out, leaving other explanations for early onset severity under consideration.

P01.055.C Genetic and Epigenetic characterization of B-cell neoplasms with *IG* enhancer hijacking

Cosima Drewes[1], *Cristina López*[2], *Nnamdi Okeke*[1], *Sina Hillebrecht*[1], *Petra Schuetz*[1], *Anja Fischer*[1], *Anja Mottok*[1], *Susanne Bens*[1], *Christof Schneider*[3], *Stephan Stilgenbauer*[3], *Eugen Tausch*[3], *Reiner Siebert*[1]

[1]*Institute of Human Genetics, Ulm University and Ulm University Medical Center, Ulm, Germany;* [2]*Institut d'Investigaciones Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain;* [3]*Division of CLL, Department of Internal Medicine III, Ulm University Medical Center, Ulm, Germany*

Background/Objectives: Oncogene translocations leading to enhancer hijacking from one of the immunoglobulin (*IG*) loci, such as *IGH::MYC*, *IGH::BCL2*, or *IGH::CCND1*, are pathognomonic aberrations of several lymphoma entities. In Chronic Lymphocytic Leukemia (CLL), e.g. *BCL2* and *BCL3* are oncogenes recurrently targeted by *IG* translocations. We here aimed to comprehensively characterize CLL with *IG* translocations at the genetic and epigenetic level.

Methods: B-cell neoplasms with *IG* translocations and respective partner oncogenes as well as recurrent imbalances were

identified by FISH (n = 325). DNA methylation and CNV analyses were performed using Infinium® MethylationEPIC (EPIC) BeadChip arrays (n = 313). The IGHV mutation status was determined by Sanger Sequencing (n = 284).

Results: We investigated 313 B-cell neoplasms, including 305 CLLs, with *IG* translocation affecting various partners. (*IGH*::*BCL2*: n = 43, *IG*::*BCL3*: n = 89, *IG*::*MYC*: n = 41, *IGH*::unknown partner: n = 140). From the *IGH*::*BCL2*-translocated CLLs, 87% (33/38) carried a mutated IGHV, 37% (16/43) trisomy 12 and 35% (15/43) 13q deletion. In contrast, *IG*::*BCL3*-translocated CLLs exhibited in 96% (72/75) unmutated IGHV and in 59% (50/84) trisomy 12, whereas 13q deletion was rare (12%, 11/84). In unsupervised DNA methylation analyses, IGHV mutation status segregated subgroups of CLLs with best discrimination applying a threshold of ≥99% for unmutated IGHV. Moreover, despite confounding by the IGHV mutation status, also *IGH*::*BCL2* and *IG*::*BCL3*-translocated CLLs segregated between them and also from other CLLs. *IGH*::*MYC*-translocated CLL and *IGH*::unknown partner CLL built no specific groups.

Conclusions: Our genetic and epigenetic analyses suggest that *IGH*::*BCL2* and *IG*::*BCL3*-translocated CLLs form two distinct subgroups of CLL based on DNA methylation, IGHV mutation status, and CNVs.

P01.056.D Exome sequencing identified rare recurrent copy number variants and hereditary breast cancer susceptibility

Tuomo Mantere[1], *Timo Kumpula*[1], *Sandra Vorimo*[1], *Taneli Mattila*[2], *Luke O'Gorman*[3], *Galuh Astuti*[3], *Anna Tervasmäki*[1], *Susanna Koivuluoma*[1], *Tiina Mattila*[1], *Mervi Grip*[4], *Robert Winqvist*[1], *Outi Kuismin*[5], *Jukka Moilanen*[5], *Alexander Hoischen*[3], *Christian Gilissen*[3], *Katri Pylkäs*[1]

[1]*Laboratory of Cancer Genetics and Tumor Biology, Research Unit of Translational Medicine and Biocenter Oulu, University of Oulu, Oulu, Finland;* [2]*Department of Pathology, Oulu University Hospital and University of Oulu, Oulu, Finland;* [3]*Department of Human Genetics and Radboud Institute of Medical Life Sciences, Radboud University Medical Center, Nijmegen, Netherlands;* [4]*Department of Surgery, Oulu University Hospital and University of Oulu, Oulu, Finland;* [5]*Department of Clinical Genetics, Medical Research Center Oulu and PEDEGO Research Unit, Oulu University Hospital and University of Oulu, Oulu, Finland*

Background/Objectives: Copy number variants (CNVs) are a major source of genetic variation and can disrupt genes or affect gene dosage. They are known to cause or contribute to the predisposition to various diseases. However, the role of CNVs in inherited breast cancer (BC) susceptibility has not been thoroughly investigated.

Methods: We performed a whole-exome sequencing-based analysis of rare CNVs in 98 high-risk Northern Finnish BC cases. After filtering, selected candidate alleles were validated and characterized using a combination of orthogonal methods, including optical genome mapping and long-read sequencing. The variants were genotyped in geographically matched cases and controls, comprising 278 hereditary and 1983 unselected BC cases, as well as 1229 controls.

Results: Analysis revealed three recurrent alterations: a 31 kb deletion co-occurring with a retrotransposon insertion (delins) in *RAD52*, a 13.4 kb deletion in *HSD17B14* and a 64 kb partial duplication of *RAD51C*. The *RAD52* delins and *HSD17B14* deletion both showed significant enrichment among cases with indications of hereditary disease susceptibility. *RAD52* delins was identified in 7/278 cases (P = 0.034, OR = 2.86) and *HSD17B14* deletion in 8/278 cases (P = 0.014, OR = 3.28), the frequency of both variants in the controls being 11/1229. The *RAD51C* duplication was identified in 2/278 of hereditary cases and 2/1229 controls (P = 0.157, OR = 4.45).

Conclusion: This study suggests a role for *RAD52* and *HSD17B14* in hereditary BC susceptibility, highlighting the importance of studying CNVs alongside single nucleotide variants in the search for genetic factors underlying hereditary disease predisposition.

Background/Objectives: Very recent studies reported pathogenic germline variants in up to 10% of non-small cell lung cancer (NSCLC) patients. Possible implications are (experimental) targeted therapy or interventions, adjusted cancer surveillance, and predictive testing for family members. The "national Network Genomic Medicine (nNGM) Lung Cancer" offers multicentric somatic gene panel testing for patients with advanced NSCLC throughout Germany. Within this network the Task Force 5 "Genetic Tumor Risk" investigates pathogenic germline variants and further oncogenic somatic alterations by parallel whole-exome/ whole-genome sequencing.

Methods: Inclusion criteria favor never-smokers, young age of onset, multiple cancer diseases and a family cancer history. Whole-genome sequencing of control samples (University Hospital Dresden) and whole-exome sequencing of formalin-fixed paraffin-embedded lung cancer tissues (University Hospital Cologne) were performed. Germline variants were assessed in 141 cancer predisposition genes and somatic variants were evaluated to identify the relevance of germline variants for tumorigenesis and

alternative drivers. Clinical information and follow-up information were collected.

Results: 103 individuals have been included. Median age of onset was 57.5 years (IQR: 47.8;67.5), 30% (n = 31) were never-smokers, 43% (n = 44) had multiple tumor diseases, and 73% (n = 75) a positive family cancer history. Prospective germline sequencing of 72 individuals revealed 10 pathogenic heterozygous variants in two dominant (*BRCA2*, *RAD51D*) and six recessive cancer predisposition genes.

Conclusion: This ongoing prospective, multicentric study identifies pathogenic germline variants in selected NSCLC patients and investigates associations with clinical and molecular parameters. An increased cohort size and extended bioinformatic analysis will allow assessment of pathogenic germline variant yields and their clinical implications for NSCLC patients.

P01.058.B Whole exome sequencing revealed GATA2 rare mutations in Bulgarian patients with personal/family history of breast cancer

Svilen Maslyankov[1], *Kalina Belemezova*[2], *Tsvetan Popov*[2;3], *Dimitar Bakalov*[2], *Radka Tafradzhyiska*[2], *Irina Miteva*[3], *Ivanka Dimova*[2]

[1]*Second surgery clinic, Department of Surgery, Medical Faculty, Medical University Sofia, Sofia, Bulgaria;* [2]*Medical University Sofia;* [3]*Second surgery clinic, Department of Surgery, Medical Faculty, Medical University Sofia*

Background/Objectives: The significance of GATA2 mutations in cancer risk is an area of ongoing research, and our understanding of the role of this gene in cancer continues to evolve. While GATA2 mutations are associated with an increased risk of certain hematological malignancies, they are not as commonly implicated in solid tumors, such as breast or ovarian cancers. We aimed to characterize the GATA2 genetic variants, revealed in BRCA1/2 negative Bulgarian women with strong indications for familial breast cancer.

Methods: After DNA isolation from peripheral venous blood, whole exome sequencing was performed using Illumina technology.

Results: In two women rare genetic variants in GATA2 gene were discovered. The variant c.829A > G (p.Ser277Gly) was revealed in a woman with strong family history for breast cancer. The variant c.669G > A (p.Met223Ile) was found in 42-years old woman affected by bilateral invasive breast cancer from non-specific type (NST), which was Her2-positive; the woman had grand-mother and aunt affected by gynecological cancer. Both variants have been reported in patients with leukemia syndromes.

Conclusion: A comprehensive evaluation of the individual's personal and family history is essential in determining the most appropriate genetic testing strategy. The landscape of genetic testing for hereditary cancer is continually evolving, and new genes associated with breast cancer risk may be identified over time. GATA2 is a key transcriptional regulator of hematopoiesis involved in the development of monocytes, mast cells, NK cells, and megakaryocytes. Its deficiency could be predisposing factor to breast cancer development as well.

P01.059.C Comprehensive splicing analysis of the alternatively spliced *CHEK2* exons 8 and 10 by hybrid minigenes

Lara Sanoguera-Miralles[1], *Inés Llinares-Burguet*[1], *Elena Bueno-Martínez*[1], *Lobna Ramadane-Morchadi*[2], *Cristiana Stuani*[3], *Alberto Valenzuela-Palomo*[1], *Alicia García-Álvarez*[1], *Pedro Pérez-Segura*[2], *Emanuele Buratti*[3], *Miguel de la Hoya*[2], *Eladio A. Velasco-Sampedro*[1]

[1]*Instituto de Biomedicina y Genética Molecular de Valladolid (IBGM), Consejo Superior de Investigaciones Científicas – Universidad de Valladolid (CSIC-UVa), Splicing and Genetic Susceptibility to Cancer Laboratory, Valladolid, Spain;* [2]*Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Molecular Oncology Laboratory, Madrid, Spain;* [3]*International Centre of Genetic Engineering and Biotechnology (ICGEB), Molecular Pathology Laboratory, Trieste, Italy*

Background/Objectives: Exon recognition is controlled by a large set of splicing regulatory elements (SREs), such as splicing enhancers and silencers. Variants at these motifs may impair splicing and lead to disease-associated loss-of-function transcripts. Our aim was to investigate the alternatively spliced exons 8 and 10 of the breast cancer susceptibility gene *CHEK2* with a view to identifying spliceogenic SRE variants.

Methods: We used a *CHEK2* minigene with exons 6–10 that produced the expected minigene full-length transcript and replicated naturally occurring events, in particular the skipping of exons 8 and 10. By site-directed mutagenesis, 12 internal microdeletions were incorporated in order to map SRE-rich intervals of both exons by splicing assays in MCF-7 cells. Then, 87 variants located in critical SRE intervals were introduced into the wild-type minigene and functionally tested.

Results: We identified three minimal regions (10-, 11- and 15-nt) essential for exon recognition: c.863_877del [ex8, Δ(E8): 75%] and c.1073_1083del and c.1083_1092del [ex10, Δ(E10): 97% and 62%, respectively]. Of the 87 variants tested in these intervals, thirty-eight (44%) impaired splicing, four of which (c.883G > A, c.883G > T, c.884A > T, and c.1080G>T) induced negligible amounts (<5%) of the minigene full-length transcript.

Conclusion: Any exonic change is capable of disrupting splicing, since thirty-three out of the 38 spliceogenic variants were annotated as missense, three as nonsense and two as synonymous. Moreover, c.883G>A, c.883G>T and c.884A>T were classified as pathogenic/likely pathogenic variants according to ACMG/AMP-based criteria.

P01.060.D Molecular cytogenetic characterization of Polyploid Giant Cancer Cells (PGCCs) in cytarabine-resistant AML cells

Pei-Yi Chen[1;2], *Yu-Xuan Lin*[2], *Chia-Ling Wu*[1], *Jui-Hung Yen*[2]

[1]*Laboratory of Medical Genetics, Genetic counseling center, Hualien Tzu Chi Hospital, Hualien, Taiwan;* [2]*Department of Molecular Biology and Human Genetics, Tzu Chi University, Hualien, Taiwan*

Background/Objectives: Polyploid giant cancer cells (PGCCs) are cells with multiple nuclei or a single giant nucleus containing multiple sets of chromosomes. These cells exhibit cancer stem cell characteristics, regulate the cancer microenvironment, and are highly associated with drug resistance, metastasis, and cancer relapse. While PGCCs have been extensively studied in solid tumors, their role in liquid tumors remains unclear. We generated two AML PGCC cell lines derived from MV4-11 and MOLM13 cells through prolonged exposure to cytarabine. This study aims to

further investigate the cytogenetic characteristics of these AML PGCCs.

Methods: Cell viability was assessed using the MTT assay. Cell morphology was observed through cytospin/Giemsa staining and immunofluorescence analysis. The chromosomal polyploidy level was measured using karyotyping, FISH, and flow cytometry. Molecular characteristics of the PGCCs were assessed using microarray analysis, RT-q-PCR, and western blot analysis.

Results: Drug resistance was confirmed by a pronounced increase in cell viability in the derived cells after cytarabine treatment. Immunofluorescence staining revealed that a portion of the resistant cells displayed multiple nuclei and giant cell size, resembling the so-called PGCCs. Interphase FISH was conducted to demonstrate a significant increase in the polyploid cell population detected in these PGCC cell lines. Microarray analysis showed differential gene expression and signaling pathways associated with the PGCCs compared to the parent cells.

Conclusion: We successfully established AML PGCCs and assessed their biological features. Our data provide information to elucidate the characteristics of PGCCs in liquid tumors, including phenotypes, genotypes, and crucial molecular mechanisms.

P01.061.A Importance of a bioinformatics pipeline for the detection of Alu in the NGS panel of hereditary cancer genes

Ricardo Blázquez Martín[1], *José Manuel Sánchez Zapardiel*[1], *Celia Amil Manjón*[1], *Pilar Duarte García*[1], *Marina Ibáñez Vizcaíno*[1], *Francisca Luengo Sainz de Baranda*[1], *Victoria Carrero Blázquez*[1], *Beatriz Hidalgo Calero*[1], *Montserrat de Miguel*[1], *Juan de Dios García Díaz*[2]

[1]*Hereditary Cancer Unit, Hospital 12 de Octubre. Madrid, Department of Clinical Analysis-Clinical Biochemestry, Madrid, Spain;* [2]*Clinical Genetic Unit, Hospital Principe de Asturias, Madrid, Department Internal Medicine, Alcalá de Henares, Spain*

Background/Objectives: Alu elements are the most abundant transposable elements, they are short interspersed elements (SINEs) ~300 nucleotides in length. Transposable elements are rare sequences of DNA that can move themselves to new positions within the genome and may be linked to genetic diseases and susceptibility to certain disorders, including cancers. In our case, it is a case of a family with a multiple history of breast, ovarian, pancreatic and prostate cancer at an early age. After a non-informative study, it was reprocessed with the multigene panel we are currently working with.

Methods: Next-generation sequencing was performed using the Hereditary Cancer Solution kit (Sophia Genetics) and sequencing on the NextSeq platform (Illumina). Results were analyzed using Sophia-DDM software.

Results: The bioinformatic pipeline detected an Alu element in exon 5 of *PALB2* gene, likely resulting in a premature stop codon and subsequent production of a truncated or ausent protein by NMD mechanism. According to American College of Medical Genetics (ACMG) criteria it was classified as pathogenic. However, the exact location, the complete sequence and the generated break points of this Alu element could not be determined and an orthogonal method is required.

Conclusion: It is important to have a bioinformatics pipeline capable of identifying Alu elements in families with a long history of cancer and at very young ages that have been previously uninformative. An accurate characterisation of these elements and a correct genetic counselling is crucial for a correct clinical management for patients and their families.

Conflict of Interest: None declared

P01.062.B Rare genetic phenomena in *TP53* can lead to a misdiagnosis of Li-Fraumeni Syndrome

Vasiliki Dellatola[1], *Paraskevi Apostolou*[1], *Jan Traeger-Synodinos*[2], *MARIA TZETIS*[2], *DRAKOULIS YANNOUKAKOS*[1], *Irene Konstantopoulou*[1], *Florentia Fostira*[1]

[1]*Human Molecular Genetics Laboratory, Institute of Nuclear & Radiological Sciences and Technology, Energy & Safety, National Center for Scientific Research "Demokritos", Athens, Greece;* [2]*Laboratory of Medical Genetics, St. Sophia's Children's Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece*

Background/Objectives: Next-generation sequencing of germline DNA extracted from whole blood can reveal *TP53* Pathogenic/Likely Pathogenic (P/LP) variants in low Variant Allele Frequencies (VAF ≤30%). These might be attributed to mosaicism, circulating tumor DNA, or clonal hematopoiesis, a process induced by advanced age and chemotherapy. Herein, we aimed to differentiate these rare phenomena in a selected group of patients with cancer diagnoses focusing on association to Li-Fraumeni Syndrome (LFS).

Methods: This study included 14 patients with *TP53* P/LP variants of low VAF (7-30%) and a diagnosis of breast (5), ovarian (4), colorectal (3), endometrial (1), and prostate cancer (1). The mean age at diagnosis was 58.6 years (range:28-78 years). Re-sampling of blood/saliva (mesoderm) and re-analysis was performed >3 months after initial testing. If the *TP53* variant was still evident, DNA from hair follicles (ectoderm) was analyzed through Sanger sequencing. Parameters considered involved patient age, time at genetic testing, personal history, and disease burden.

Results: Through re-sampling, the *TP53* variant under investigation was not present in 85.7% (12/14) of patients, indicating either clonal hematopoiesis or the presence of circulating tumor DNA. Two patients (14.3%) proved to have the underlying *TP53* variant in mosaicism, predisposing for LFS, upon validation in both mesodermal and ectodermal tissues. Notably, both individuals had breast cancer and one met the genetic testing criteria for LFS.

Conclusion: Accurate delineation of *TP53* variants origin and their association with LFS is imperative for tailored clinical interventions. This is of high importance in regions lacking systematized genetic centers, such as Greece.

of Pediatric Endocrinology, Nijmegen, Netherlands; [4]Radboud University Medical Centre, Radboud Institute for Medical Innovation, Nijmegen, Netherlands; [5]Radboud University Medical Centre, Department of Medical Imaging, Nuclear Medicine, Nijmegen, Netherlands

Consortium: -

Background/Objectives: Children with PTEN hamartoma tumor syndrome (PHTS) are at increased risk for developing thyroid abnormalities, including differentiated thyroid carcinoma (DTC). The Dutch PHTS guideline recommends ultrasound surveillance starting from age 18. The literature describes PHTS patients who developed DTC before age 18, the Dutch PHTS expertise centre has initiated annual ultrasound surveillance starting from age 12. We describe the yield of thyroid ultrasound surveillance in these children with PHTS.

Methods: A retrospective single centre cohort study was conducted. Pediatric PHTS patients who received thyroid ultrasound surveillance before age 18 between 2016–2023 were included. Patients' medical records have been reviewed. Primary outcomes included prevalence and time to develop thyroid nodules ≥10mm, nodular growth, goiter, thyroiditis and DTC. Descriptive statistics and Kaplan-Meier analyses were performed.

Results: Forty-three patients were included. Two patients (5%) were diagnosed with DTC at ages 12 and 17. Both DTCs were identified as minimally invasive follicular carcinoma at stages pT3NxMx and pT1NxMx. A total of 84% were diagnosed with thyroid abnormalities at a median age of 12 years (range 9-18, table 1). Most common findings were benign, including nodular disease (74%), goiter (30%) and autoimmune thyroiditis (12%). Nodular growth was observed in 14 patients (33%) resulting in (hemi)thyroidectomy in 7 patients (16%).

Conclusion: Thyroid ultrasound surveillance resulted in the detection of DTC in 2/43 PHTS patients before age 18. These findings support the recommendation to initiate thyroid ultrasound surveillance in children from age 10 – 12 onwards, preferably within an expertise centre.

P01.064.D Chloroquine-induced DNA damage synergizes with DNA repair inhibition to cause head and neck cancer cell death

Diego Iglesias-Corral[1;2;3], *marta lópez alonso*[2], *Lucía garcía collado*[2], *Nuria Arroyo-Garrapucho*[1;2;3], *Juan-Luis García*[1;3], *Rogelio González-Sarmiento*[1;2;3], *Ana-Belén Herrero*[1;2;3]

[1]Biomedical Research Institute of Salamanca (IBSAL), IIMD-07, Salamanca, Spain; [2]University of Salamanca, Faculty of Medicine, Department of Medicine, Unit of Molecular Medicine, Salamanca, Spain; [3]Institute of Molecular and Cellular Biology of Cancer (IBMCC), University of Salamanca-CSIC, Salamanca, Spain

Background/Objectives: Head and neck cancer (HNC) is a heterogeneous group of malignancies that accounts for 450.000 deaths annually. Tumor heterogenicity, along with the emergence of resistances to conventional treatments highlight the necessity for new therapies. Chloroquine (CQ) is a well-known autophagy inhibitor that induces DNA double-strand breaks (DSBs) through reactive oxygen species (ROS) production. We have previously described in in vitro studies that the combination of CQ with inhibitors of homologous recombination (HR) and nonhomologous end-joining (NHEJ) DNA repair pathways is a promising approach for the treatment of different tumors.

Methods: HNC cell lines 32816 (generated in our laboratory) and CAL-33 were used. The combination of CQ with the HR inhibitor, Panobinostat (LBH) or NHEJ inhibitors (KU-57788, NU-7026) were tested. Antitumoral activity was evaluated by proliferation and apoptosis assays and synergistic interaction between the drugs was calculated using the Chou-Talalay method. DSB induction was tested by γH2AX foci quantification via immunofluorescence assays. To evaluate HR efficiency, cells were transfected with a GFP-reporter construct, then treated with LBH for 48 h. HR proficient cells (GFP +) were quantified by flow cytometry.

Results: All drugs tested inhibited cell proliferation and induced apoptosis in the studied cell lines. The combination of CQ with either HR or NHEJ inhibitors exhibited a synergistic effect on apoptosis induction that was largely prevented by antioxidant addition.

Conclusion: Our studies suggest that the combination of CQ and inhibitors of DNA-repair pathways could be a new therapeutic approach against HNC.

Grants: Study funded by PI20/01569.

P01.065.A A Canadian Lab's Experience Using Optical Genome Mapping To Clinically Genotype Hematological Neoplasms

Zeid Hamadeh[1;2], *Eric McGinnis*[1;2], *Tara Spence*[1;2]

[1]The University of British Columbia, Medicine, Vancouver, Canada; [2]Vancouver General Hospital, Cytogenomics, Vancouver, Canada

Background/Objectives: Diagnosis and management of hematologic malignancies relies on detection of acquired genetic abnormalities in cancer cells. We report the added yield of optical genome mapping (OGM) observed in our retrospectively selected clinical validation cohort of hematologic neoplasms.

Methods: We comprehensively assessed 83 patients by both standard-of-care (SOC) techniques and OGM to validate OGM as a routine clinical test for acute myeloid leukemia, myelodysplastic syndrome, acute lymphoblastic leukemia, and chronic lymphocytic leukemia. Samples included 61 bone marrow aspirates (BMAs) and 22 peripheral bloods received by our laboratory for routine karyotyping and/or FISH.

Results: We observed high concordance with SOC methods with a sensitivity of 97.6%, specificity of 100%, and accuracy of 98.6%. OGM identified or clarified findings either cryptic or not resolvable using SOC, decreasing the proportion of with normal karyotype by 23% of BMAs, identifying chromothripsis in 13% of all cases, identifying cytogenetically visible or recurring variants in 46% of BMAs, and generating prognostically or diagnostically relevant findings in 42% of BMAs. Additional findings included, but were not limited to, three KMT2A rearrangements, a KMT2A partial tandem duplication, a RUNX1::MECOM rearrangement, a NUP214::ABL1 fusion, and two submicroscopic TP53 deletions.

Conclusion: OGM shows significant power in detecting or resolving abnormalities previously inadequately characterized by SOC testing, permitting refinement of genomics-based diagnosis and risk stratification and potentially altering treatment and prognostication for a portion of patients. Future assessment will be needed in a prospective unselected cohort to definitively establish clinical utility of OGM.

P01.066.B Role of *ATG7* loss in taxane-resistant head and neck cancer

Nerea Gestoso-Uzal[1;2;3], *Laura Molinero-Sicilia*[2;3], *Mercedes León-López*[2;3], *Ana-Belén Herrero*[1;2;3], *Juan-Luis García*[2;3], *Juan Jesús Cruz-Hernández*[1;2;3], *Rogelio González-Sarmiento*[1;2;3]

[1]*Molecular Medicine Unit, Department of Medicine, University of Salamanca, Salamanca, Spain;* [2]*Biomedical Research Institute of Salamanca (IBSAL), University Hospital of Salamanca-USAL- CSIC, Salamanca, Spain;* [3]*Institute of Molecular and Cellular Biology of Cancer (IBMCC), University of Salamanca-CSIC, Salamanca, Spain*

Background/Objective: Head and neck squamous cell carcinomas (HNSCC) include heterogeneous tumours in the cervicofacial area. Combating therapy resistance is one of the main challenges in HNSCC. The main aim of this work was to characterize the molecular mechanisms underlying taxane resistance in HNSCC.

Methods: Taxane resistance was induced in two HNSCC cell lines, 32816 and 32860, by gradually increasing paclitaxel concentration. Cell lines were characterized by aCGH and expression microarrays. Autophagy was analyzed by western blot. CRISPR-Cas9 technology was used to generate *ATG7* knockout cell lines. The efficacy of its design was tested by Sanger sequencing, RT-qPCR and western blot.

Results: A 32816 taxane-resistant stable cell line was established, while 32860 cells remained sensitive to taxanes after twenty cycles of treatment. The aCGH study showed a differential deletion in 3p26.6-3p21.1 in 32860 cell line. Expression microarrays identified a significant underexpression of *ATG7*, a gene located in this region and involved in autophagy. Moreover, the study of the autophagy signalling pathway suggested a blockade of autophagy in 32860 cells, that may be responsible for the 32860 response to taxane resistance induction. To get a deeper understanding of the role of *ATG7*, we generated *ATG7* knockout cell lines from 32816 and confirmed the blockade of autophagy caused by *ATG7* loss in them. Further studies are being performed to establish the response of *ATG7* knockout cells to taxane resistance induction.

Conclusion: The loss of *ATG7* causes a blockade of autophagy in HNSCC that may be associated with the therapeutic response to taxanes.

Grants: This project was funded by FIS-FEDER:PI18/01476.

P01.067.C digitalMLPA: Multiplex NGS-based assays to detect a wide range of structural variants implicated in hereditary cancer predisposition syndromes

Sebastiaan Lamers[1], *Maria Giovanna Maturo*[2], *Janina Luitz*[2], *Jonas de Groot*[3], *Martin Loden*[4], *Lisette Stolk*[1]

[1]*MRC Holland, Cytogenetics, Amsterdam, Netherlands;* [2]*MRC Holland, IVD Development, Amsterdam, Netherlands;* [3]*MRC Holland, Genetic Disorders, Amsterdam, Netherlands;* [4]*MRC Holland, Oncogenetics, Amsterdam, Netherlands*

Background/Objectives: Hereditary cancer predisposition syndromes (HCPS) account for 5-10% of all cancers. Among these syndromes is Lynch syndrome, a disorder that predisposes carriers of DNA mismatch repair (MMR) gene sequence mutations and copy number variants (CNVs) to early-onset cancer. A recently identified paracentric inversion involving MMR gene *MSH2* exon 2-6 may account for a subset of unexplained Lynch syndrome cases.

Methods: An updated version of SALSA® digitalMLPA™ Probemix D001 Hereditary Cancer Panel 1 and an extended assay, SALSA® digitalMLPA™ Probemix D002 Hereditary Cancer Panel 2 are in development. The assays incorporate probes for the identification of CNVs and multiple targeted mutations in more than 50 genes linked to HCPS, of which 28 are targeted by both panels. Specifically, two probes were integrated in both panels detecting the 3′ and 5′ breakpoints of the *MSH2* exon 2-6 inversion. These probemixes were tested on more than 50 positive samples carrying aberrations in different target regions, including a sample carrying the *MSH2* exon 2-6 inversion.

Results: Both assays successfully identified CNVs and targeted mutations in all target regions in the tested samples. Additionally, the *MSH2* exon 2-6 inversion was detected with the two inversion-specific probes.

Conclusion: These assays are suitable for detection of a wide range of CNVs involved in HCPS. Furthermore, the integration of probes targeting mutations like the *MSH2* exon 2-6 inversion in SALSA® digitalMLPA™ assays underscores the potential of the digitalMLPA technique in uncovering a broad spectrum of genetic factors involved in HCPS.

P01.068.D Comprehensive molecular profiling of breast cancer subtypes in a Turkish population: Insights from next-generation sequencing analysis

Drenushe Zhuri[1], *Engin Atli*[1], *Hazal Sezginer Guler*[1], *Fulya Dusenkalkan*[1], *Nilay Ozupek*[1], *Selma Demir*[1], *Sinem YALÇINTEPE*[1], *HAKAN GURKAN*[1]

[1]*Trakya University, Medical Genetics, Edirne, Türkyie*

Background/Objectives: Breast cancer is a heterogeneous disease with diverse molecular subtypes that have implications for prognosis and treatment. The most commonly recognized immunohistochemical classification of breast cancer is based on the expression of the hormone receptors estrogen (ER), progesterone (PR), and human epidermal growth factor (HER2). As a result, the following four breast cancer subtypes are commonly recognized as luminal A, luminal B, HER2-positive, and triple-negative. This study presents the findings from a single-center experience of next-generation sequencing analysis of breast cancer subtypes in the Thrace region.

Methods: We retrospectively analyzed the NGS data of 397 patients with breast cancer who applied to our center between 2020 January-2023 December. After the isolation of DNA, the NextSeq550-Illumina system and the Qiaseq Targeted (Qiagen) Amplicon panel kit were used for molecular analysis. *BRCA1/BRCA2* deletion/duplications were evaluated with the Multiplex ligation-dependent probe amplification method.

Results: As a result of analysis for ninety-three targeted cancer genes, we detected eighty-three pathogenic/likely pathogenic (P/LP) variations in seventy-four cancer cases. Twenty-one P/LP variants (25%) in nineteen Luminal A breast cancer cases. Forty-four P/LP variants (53%) in thirty-nine Luminal B breast cancer cases and nineteen P/LP variants (22%) in HER2-positive cases. BRCA1/BRCA2 gene deletion was detected only in one HER2-positive case.

Conclusion: Clinical and pathological characteristics were correlated with molecular subtypes identified by NGS. The diagnosis rate was 18.63% in this study. Our results shed light on the distribution of breast cancer subtypes in the Thrace region and provide insights into the genomic landscape of these tumors in this population.

P01.069.A Prevalence and consequences of APC mosaicism in patients with colorectal adenomas

Diantha Terlouw[1], Manon Suerink[2], Monique van Leerdam[3], Frederik Hes[4], Demi van Egmond[2], Dina Ruano[2], Anja Wagner[5], Floris Groenendijk[6], Sanne ten Broeke[7], Arjen Mensenkamp[8], Iris Nagtegaal[9], Carli Tops[10], Alexandra Langers[3], Tom van Wezel[2], Hans Morreau[2], **Maartje Nielsen**[10]

[1]Lumc, Clinical genetics, Leiden, Netherlands; [2]Lumc, Pathology, Leiden, Netherlands; [3]Lumc, Gastroenterology and Hepatology, Leiden, Netherlands; [4]UZ Brussel, Clinical Genetics, Jette, Belgium; [5]Erasmus University Medical Center, Clinical Genetics, Rotterdam, Netherlands; [6]Erasmus University Medical Center, Pathology, Rotterdam, Netherlands; [7]University Medical Center Groningen, Clinical genetics, Groningen, Netherlands; [8]Radboud University Medical Center, Molecular genetics, Nijmegen, Netherlands; [9]Radboud University Medical Center, Pathology, Nijmegen, Netherlands; [10]Lumc, Clinical Genetics, Leiden, Netherlands*

Background/Objectives: Although germline pathogenic *APC* variants are detected in up to 80% of adenomatous polyposis patients, a substantial proportion remains unexplained

Methods: APC mosaicism was analyzed in 458 patients with a broad spectrum of phenotypes in three university medical centers in the Netherlands.

Results: The mosaicism detection rate was 11.1% (51 out of 458) in the entire cohort. This rate was 17.1% (46 out of 269) in patients with ≥10 adenomas before 60 years or with ≥20 adenomas before 70 years and 2.6% (5 out of 189) in patients falling outside Dutch polyposis testing guidelines. Overall, the odds of finding *APC* mosaicism increased significantly with adenoma count and a younger age at diagnosis. Interestingly, 28% (9 out of 32) of mosaic patients undergoing an esophagogastroduodenoscopy were diagnosed with gastroduodenal adenomas. Moreover, none of the children tested inherited the mosaic variant. In one patient without children, the mosaic variant was detected in semen. Patients having a recurrent colibactin-associated c.835-8A>G variant in some but not all lesions were phenotypically similar to non-mosaic patients.

Conclusion: APC mosaicism was found in over 10% of unexplained polyposis patients. We recommend testing in -at least- all patients with negative germline results with (1) multiple adenomas before 50 years, (2) ≥20 adenomas before 60 years, or (3) ≥30 adenomas before 70 years. Regular colonoscopy and at least one gastroduodenoscopy should be offered; the frequency of follow-up should depend on the findings. Furthermore, consider germline testing for offspring, especially when mosaicism exceeds the colon.

P01.070.B A Recurrent POT1 Founder Germline Variant Associated with Early Onset Melanoma, Various Malignancies and High Tumor Burden

Aasem Abu Shtaya[1,2], *Inbal Kedar[2], Lily Bazak[2], lina basel-salmon[2], Sarit Farage-Barhom[2], Ori Segol[1], Michal Naftali[3], Marina Eskin-Schwartz[4], Ohad Shmuel Birk[4], Shirley Polager-Modan[5], Nitzan Keidar[6], Gili Reznick Levi[7], Ahmad Mahamid[8], Noy Azulay[2], Yael Goldberg[2]*

[1]Carmel Medical Centre, Unit of Gastroenterology, Haifa, Israel; [2]Rabin Medical Center, Recanati Genetics Institute, Petah Tikva, Israel; [3]Clalit Genomic Center, Petach Tikba, Israel; [4]Soroka Medical Center, Genetics Institute, Be'er Sheva, Israel; [5]Carmel Medical Centre, Genetics Institute, Haifa, Israel; [6]Schneider- Children's Medical Center, Pediatric Genetic Unit, Petah Tikva, Israel; [7]Rambam Health Care Campus, Genetics Institute, Haifa, Israel; [8]Carmel Medical Centre, Department of Surgery, Haifa, Israel*

Background/Objectives: POT1 is a key component of the shelterin complex that plays a critical role in telomere protection and length regulation. Germline variants in the *POT1* gene have been implicated in predisposition primarily to malignant melanoma and chronic lymphocytic leukemia. This study reports the identification of *POT1* p.I78T, a founder variant among Ashkenazi Jews, and describes a unique clinical landscape in carriers.

Methods: A directed database search was conducted for individuals referred for genetic counselling in 2018 to 2023 who were found to carry the *POT1*(NM_015450.3) c.233T>C:p.(I78T) germline variant. Demographic, clinical, genetic, and pathology data of patients and family members were analyzed.

Results: Ten carriers of the *POT1*:p.(I78T) variant aged 25 to 67 years from ten unrelated families of AJ descent were identified. Carriers had a total of 28 primary malignancies (range 1-6); eight carriers aged 25-63 years had recurrent malignant melanoma, three carriers (30%) had desmoid tumors; three (30%) had Papillary thyroid cancer, and four women (57% of female carriers) had breast cancer. Additional tumors included CLL, sarcoma, endocrine tumors and colonic polyps. Review of a local genome database yielded an allelic frequency of the variant of 0.06% among all ethnicities and of 0.25% in Ashkenazi Jews. A shared haplotype was found in all probands carrying the variant, indicating that a common founder was likely in these families.

Conclusion: *POT1*:p.(I78T) is a recurrent, founder disease-causing variant associated with early-onset melanoma in addition to other solid malignancies, with a high tumor burden. Genetic testing of *POT1* should be included in germline panels for various cancer types.

Conflict of Interest: None declared

P01.071.C Analysis of molecular genetic testing yields for hereditary forms of cancer 2020-2023

Ilona Pirushka[1], *Baiba Lace[2], Ieva Mičule[3;4], Arvids Irmejs[5], Peteris Loža[5], jelena maksimenko[5]*

[1]Children's Clinical University Hospital, Clinic of Medical Genetics and Prenatal Diagnosis, Riga, Latvia; [2]Riga East Clinical University Hospital, Rīga, Latvia; [3]Riga Stradins University, Rīga, Latvia; [4]Children's Clinical University Hospital, Rīga, Latvia; [5]Pauls Stradiņš Clinical University Hospital, Rīga, Latvia*

Objectives: The aim of this study was to determine the clinical and molecular characteristics of patients from 2020 to 2023 who underwent hereditary cancer multigene panel testing.

Methods: The study enrolled 247 adults: 5% (n = 13) men and 95% (n = 234) women with: breast cancer 89% (n = 221), ovarian cancer 6% (n = 14), colorectal cancer 3% (n = 8), testicular cancer 0,8% (n = 2), melanoma 0,8% (n = 2). 17 adults underwent cascade testing. Patients with cancer (n = 247) were tested by gene panels, predictive testing for patients' relatives (n = 17) - by Sanger sequencing. All breast and ovarian cancer patients had initial testing for BRCA1/2 founder mutations before NGS testing.

Results: The mean age at the time of NGS was 46 years. Genetic testing identified a pathogenic/likely pathogenic variant in 32 % of patients ($n = 78$). Test result was negative in 64% ($n = 158$) of patients. 11 VUS were identified in 4% ($n = 9$) of patients.

The most identified germline mutations were in *BRCA1* ($n = 36$; 46%) *BRCA2*, ($n = 17$; 22%), *CHEK2*($n = 9$;12%). Pathogenic/likely pathogenic variants in *ATM*, *PALB2*, *RAD51C*, *FANCM*, *TP53*,*MLH1*, *PMS2* were also identified. 33% (n = 15) from all positive *BRCA1/2* variants were founder mutations. The cascade screening for the asymptomatic persons was positive in 88% (n = 15), negative in 12% (n = 2).

Conclusion: We propose that genetic testing in Latvia, utilizing a panel of 11 *BRCA1/BRCA2* gene founder mutations, provides an inexpensive, efficient platform for cancer prevention/treatment. This panel may be expanded or replaced by multigene hereditary cancer panel in the future.

P01.072.D Genome sequencing in patients with hereditary breast and ovarian cancer

Ulrike Faust[1], *Dennis Witt*[1], *Antje Stäbler*[1], *Silja Gauß*[1], *Marc Sturm*[1], *Benita Menden*[1], *Olga Kelemen*[1], *Leon Schütz*[1], *Ines Gruber*[2], *Kristin Bosse*[1], *Stephan Ossowski*[1], *Tobias Haack*[1], *Olaf Riess*[1], *Christopher Schroeder*[1]

[1]*Institute of Medical Genetics and Applied Genomics, Tübingen, Germany;* [2]*Department for Women's Health, Tübingen, Germany*

Background/Objectives: Multi-gene panel or exome sequencing are the current standard for hereditary breast and ovarian cancer (HBOC) testing. However, a pathogenic variant in the HBOC genes is only found in 15% to 25% of high-risk families. The implementation of genome sequencing (GS) has the potential to increase the diagnostic sensitivity through detection of structural variants, alterations in regulatory regions, as well as the integration of polygenic-risk-scores (PRS) and analysis of actionable genes.

Methods: The study involved 819 patients with breast and/or ovarian cancer, fulfilling criteria for HBOC testing and 4810 healthy controls. GS was performed and analyzed in our accredited diagnostic laboratory following standard procedures. Our pipeline was designed to incorporate the Breast Cancer PRS 313 (Mavaddat et al., 2019) and Ovarian Cancer PRS (OCAC 36 by canrisk.org).

Results: Causative variants were found in 12.8% of cases across 9 HBOC genes. The in-depth characterization of a complex *BARD1*-structural variant confirmed the advantages of GS over other methods. The raw PRS of our breast cancer cohort as well as of our ovarian cancer cohort was significantly higher than in our local controls. Additionally, 20 pathogenic variants in actionable genes were found in 18 patients.

Conclusion: GS offers advantages over current standard multi-gene panel or exome sequencing. We were able to benefit from additional structural variants and increased process standardization. PRS might explain up to an additional 20% of breast cancer cases. Finally, GS has a higher flexibility regarding re-analysis of candidate genes, regulatory regions, and structural variants.

P01.073.A Unique mutation spectrum in the Israeli Arab population suspected of Hereditary Breast and Ovarian Cancer or MUTYH Associated Polyposis syndrome

Gili Reznick Levi[1], *Elizabeth E Half*[2;3], *Tamar Paperna*[1], *Hanna Segev*[1], *Yael Goldberg*[4;5], *Karin Weiss*[1;3]

[1]*Rambam Health Care Campus, The Genetics Institute, Haifa, Israel;* [2]*Rambam Health Care Campus, Institute of Gastroenterology, Haifa, Israel;* [3]*The Rappaport Faculty of Medicine, Technion, Haifa, Israel;* [4]*Raphael Recanati Genetic Institute, Rabin Medical Center, Petach Tikva, Israel;* [5]*Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel*

Background/Objectives: Most of the Founder Pathogenic Variants (PVs) in genes related to cancer predisposition syndromes in Israel were described in the Jewish population.

This work aims to describe the mutation spectrum of Hereditary Breast and Ovarian Cancer (HBOC) in Christian Arabs and *MUTYH* associated polyposis (MAP) in Israeli Arabs.

Methods: Electronic records of all Arab patients presenting to the Oncogenetic clinic at Rambam Health Care Campus between 2013- 2020 were reviewed for personal or family history suspected of HBOC or polyposis syndromes.

Results: 35 unrelated Christian Arab patients, with a personal or family history of breast and\or ovarian cancer, underwent *BRCA1/BRCA2* (14/35) testing or multi-gene panel testing (21/35). A recurrent *BRCA2* exon 5-11 duplication was found in 5/33 (15.2%) patients for whom copy number variant (CNVs) analysis was performed. 37 Arab polyposis patients from 30 unrelated families underwent *APC* and *MUTYH* testing; 8(26.6%) carried bi-allelic *MUTYH* PVs. The major variant detected was p.(Glu452del) seen in 75% of positive cases. Interestingly, Druze and Muslims shared the same haplotype.

Conclusions: We identified a high prevalence of a *BRCA2* duplication among Christian Arabs with personal/ family history of HBOC in Israel, emphasizing the importance of CNV analysis in this sub-population. MAP is quite frequent (27%) among Arab polyposis cases in Northern Israel. PV spectrum is unique, with high frequency of the founder variant p.(Glu452del). Our results impact the genetic testing strategy in the Israeli Arab population suspected of HBOC or MAP.

Conflict of Interest: None declared

P01.074.B Compilation and reclassification of *BRCA2* VUS found in the Genetic Counselling Unit of Salamanca in the last 23 years

Paloma Martín-Bejarano Soto[1;2;3], *Eva María Sánchez-Tapia*[1;2;3], *Paula García-Vallés*[1;2;3], *Mercedes León-López*[1;2;3], *Teresa Martín-Gómez*[4], *emilio fonseca sánchez*[4], *Rogelio González-Sarmiento*[1;2;3], *Ana-Belén Herrero*[1;2;5]

[1]*Molecular Medicine Unit, Department of Medicine, University of Salamanca, Salamanca, Spain;* [2]*Biomedical Research Institute of Salamanca (IBSAL), Salamanca, Spain;* [3]*Institute of Molecular and Cellular Biology of Cancer (IBMCC), University of Salamanca-CSIC, Salamanc, Spain;* [4]*Medical Oncology Service, University Hospital of Salamanca, Salamanca, Spain;* [5]*Institute of Molecular and Cellular Biology of Cancer (IBMCC), University of Salamanca-CSIC, Salamanca, Spain*

Background/Objectives: BRCA1/2 genetic testing is key for improving clinical management and for patients with hereditary breast/ovarian cancer. Variants found in these genetic tests are classified according to their impact on the protein function and thus on the risk of developing breast cancer. However, the identification of variants of unknown significance (VUS) limits the clinical utility of genetic testing as the impact on protein function is unknown. VUS are mainly missense variants that cannot be classified due to insufficient experimental and clinical data.

Methods: The variants identified in the Genetic Counselling Unit (GCU) of the University Hospital of Salamanca between 2000-2023 have been compiled. They were searched for re-evaluation in the aggregators Varsome and ClinVar, which are based on the use of the classification guidelines specified by the ACMG/AMP.

Results: Of the 79 VUS detected in over 2000 studies performed in the last 23 years, 62 (76.4 %) were reclassified according to Varsome and 23 (26.6%) according to ClinVar (Table 1). Of the 79 variants, most (91.1%) are missense variants and belong to 94 families.

Table 1. Updated classification of the 79 VUS according to Varsome and ClinVar.

Clasification	Varsome	ClinVar
Bening	17	17
Likely bening	41	1
VUS	16	55
Likely pathogenic	1	0
Pathogenic	3	3
Not described	1	3

Conclusion: This study demonstrates the need for updating VUS detected in GCU due to their important clinical impact. Furthermore, it highlights the need to generate methods that allow the reclassification of these VUS as a priority.

Grants: This project was funded by IP20.

P01.075.C Investigation of variant distribution and frequency in triple negative breast cancer patients living in the Trakya Region of Turkey: A Single Center Experience

HAKAN GURKAN[1], *Engin Atli*[1], *Nilay Ozupek*[1], *Bilge Nihan Satkın*[2], *Drenusha Zhuri*[1], *Hazal Sezginer Guler*[1], *Selma Demir*[1], *Sernaz Topaloğlu*[3], *Atakan Sezer*[4], *Ebru Taştekin*[5], *Nermin Tunçbilek*[6]

[1]Trakya University Faculty of Medicine, Department of Medical Genetics, Edirne, Türkyie; [2]Trakya University Faculty of Engineering, Department of Genetics and Bioengineering, Edirne, Türkyie; [3]Trakya University Faculty of Medicine, Department of Medical Oncology, Edirne, Türkyie; [4]Trakya University Faculty of Medicine, Department of General Surgery, Edirne, Türkyie; [5]Trakya University Faculty of Medicine, Department of Medical Pathology, Edirne, Türkyie; [6]Trakya University Faculty of Medicine, Department of Radiology, Edirne, Türkyie

Background/Objectives: Approximately 15% to 20% of all breast cancers are triple negative breast cancers (TNBCs). TNBC is most common in premenopausal women aged < 40 years and is highly aggressive, and poorer clinical outcome than those of hormone receptor positive and HER2-enriched breast cancers. In fact, >85% of breast cancers developing in the context of BRCA1 germline pathogenic variant carriers display a triple-negative phenotype, and 11% to 19% of patients with triple-negative disease harbor BRCA1 germline or somatic mutations.

Methods: The aim of our study is to investigate the distribution and frequency of variants in TNBC patients living in the Trakya Region of Turkey. 45 patients who applied to our Genetic Diseases Evaluation Center with a diagnosis of TNBC between October 2019 and October 2023 were included in the study. The average age of the patients is 53.27 years. Targeted Breast NGS panel (94 genes) and BRCA1/2 MLPA were studied in patients using the NGS method.

Results: Pathogenic/likely pathogenic (P/LP) variant was detected in 16 patients (35.5%), and VUS variant was detected in 16 patients (35.5%). 10 of the 16 P/LP variants (62.5%) were located in BRCA1. NM_007294.3(BRCA1):c.5266dupC (p.Gln1756Profs) variant was detected in four patients (40%). Other P/LP variants were detected in the BRCA2 (2), CHEK2 (1), MUTYH (1), PALB2 (1) and MUC16 (1) genes.

Conclusion: Unlike the literature, we detected a higher rate (62.5%) of P/LP variants in the BRCA1 gene in our patients with triple-negative phenotype. This result may be related to ethnic stratification and/or variants with a founder effect.

P01.077.A Addressing the 'leaky pipe' in colorectal cancer genetics referrals: The critical need for optimization

Nur Diana Binte Ishak[1], *Shao-Tzu Li*[1], *jianglei wu*[1], *Jianbang Chiang*[1], *Joanne Ngeow*[1;2]

[1]National Cancer Centre Singapore, Cancer Genetics Service; [2]Lee Kong Chian School of Medicine, Nanyang Technological University

Background/Objectives: Colorectal cancer significantly burdens Singapore, with over 1,865 cases diagnosed annually. Lynch syndrome, the most common hereditary colorectal cancer, affects 1 in 300 Singaporeans. Despite high prevalence, referrals to Cancer Genetics Service (CGS) remain low, highlighting a gap in Lynch syndrome detection. This study delves into referral discrepancies and barriers to timely hereditary cancer syndrome diagnosis among colorectal cancer patients in Singapore.

Methods: We evaluated patients seen at the National Cancer Centre Singapore from 2017 to 2021, identifying 1,716 colorectal cancer cases diagnosed under age 50 or with a second Lynch syndrome-related cancer. Appropriate CGS referrals were determined based on age at cancer diagnosis, deficient mismatch repair protein expression, polyp pathology (adenomatous, hamartomatous, juvenile polyps), and presence of desmoid tumours.

Results: We found that only 15% of the 878 colorectal cancer patients under the age of 50 were referred to CGS, while the referral rate for patients with a second Lynch syndrome-associated cancer was even lower at 9.8%. While most non-referred cases had MMR evaluation, 20% were not referred in spite of tumour pathology, indicating missed opportunities for hereditary cancer risk detection.

Conclusion: This gap in referrals underscores the urgent need for increased awareness and improved referral practices among medical professionals. Prioritizing early detection through timely referrals is essential not only for initiating preventive strategies and enhancing patient outcomes but also for identifying at-risk relatives and substantially reducing the community's cancer burden. Proactively addressing these gaps is crucial, ensuring effective management of hereditary colorectal cancer syndromes towards a more preventive healthcare model.

P01.078.B An interdisciplinary approach to counsel children with cancer predisposition and their families for genetic testing and surveillance

Nicola Dikow[1], *Anna Lisa Nitschke*[1;2], *Steffen Hirsch*[1;2;3], *Joachim Kunz*[2;4;5], *Kerstin Grund*[1], *Peggy Lüttich*[6], *Christian Sutter*[1], *Katrin Hinderhofer*[1], *Cornelis M. van Tilburg*[2;4;6], *Olaf Witt*[2;4;6], *Andreas Kulozik*[2;4;6], *David Jones*[2;5], *Maja Hempel*[1], *Till Milde*[2;4;6], *Christian Schaaf*[1], *Stefan Pfister*[2;4;6], *Kristian Pajtler*[2;4;6]

[1]*Heidelberg University, Institute of Human Genetics, Heidelberg, Germany;* [2]*Hopp Children's Cancer Center Heidelberg (KiTZ), and National Center for Tumor Diseases (NCT), Heidelberg, Germany;* [3]*German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Division of Pediatric Neurooncology, Heidelberg, Germany;* [4]*German Cancer Research Center (DKFZ) and German Cancer Consortium (DKTK), Heidelberg, Germany, Clinical Cooperation Unit Pediatric Oncology, Heidelberg;* [5]*German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Heidelberg, Division of Pediatric Glioma Research, Heidelberg;* [6]*Heidelberg University Hospital, Heidelberg, Germany, Department of Pediatric Oncology, Hematology, Immunology & Pulmonology*

Background: The knowledge of cancer predisposition syndromes (CPS) is the prerequisite for surveillance programs, that have proven benefits in an increasing number of CPS. Our interdisciplinary expert panel discusses, evaluates and counsels children with suspected CPS and their families. Here, we report the diagnostic rates and surveillance recommendations.

Patients and Methods: All individuals seen in the interdisciplinary consultation (2018 - 2022) were included for retrospective analysis. Data on medical and family history, physical examination, molecular and histological tumor characteristics, diagnosis and surveillance recommendations were retrieved from medical records.

Results: Of 144 individuals (median age 9 years), 99 had symptoms of CPS (including 52 with a tumor diagnosis); 45 were clinically unaffected and presented for predictive genetic testing of familial genetic variants. A CPS was diagnosed prior to consultation in 33/99 patients and unknown in 66/99. For 57/66 patients, molecular analysis was performed. A CPS was detected in 26 patients (45,5%), and in 8/10 (80%) of those with more than one type of cancer. The most frequently affected genes were *NF1*, *TP53*, *MEN1*, *APC* and *PTEN*.

Surveillance recommendations could be given for almost all individuals with a CPS diagnosis.

Conclusion: Our interdisciplinary approach contributes to the identification of CPS in pediatric patients and families at risk and highlights the need for personalized surveillance recommendations established by an expert panel, especially in rare CPS. Our approach is intended to lay the foundation for more systematic CPS assessment and the establishment of standardized surveillance concepts.

P01.079.C Hematological malignancies as a secondary finding on diagnostic exome sequencing: should we consider reporting them?

Gaber Bergant[1], *Aleš Maver*[1], *Borut Peterlin*[1]

[1]*University Medical Center Ljubljana, Clinical Institute of Genomic Medicine, Ljubljana, Slovenia*

Background/Objectives: The detection of somatic secondary findings (SFs) during diagnostic next-generation sequencing presents significant challenges in the context of patients with suspected rare disorders with no existing international guidelines. The differentiation between somatic and germline variants is a complex aspect of genetic analysis, with implications for diagnostic accuracy and patient care.

Methods: We conducted a detailed analysis of four cases where patients underwent diagnostic exome sequencing for suspected rare disorders in which we detected somatic secondary findings associated with hematological malignancies.

Results: Our investigation revealed the presence of somatic SFs in the patient samples, which were associated with hematological malignancies. We found that these somatic SFs could potentially influence the primary diagnostic interpretation, underscoring the difficulty in distinguishing them from germline variants. The analysis highlights the complexity of interpreting exome sequencing data when somatic variants are present.

Conclusion: Our findings underscore the urgent need for clear guidelines on how to analyze and report somatic secondary findings in diagnostic exome sequencing. This work emphasizes the importance of increased awareness and a systematic approach to the reporting of SFs that are unrelated to germline genomic variations. The presence of somatic SFs has significant implications for patient care, and addressing this challenge is crucial for the advancement of precision medicine.

P01.080.D Differences in polygenic score distributions in European ancestry populations: implications for breast cancer risk prediction

Kristia Yiangou[1], *Nasim Mavaddat*[2], *Joe Dennis*[2], *Maria Zanti*[1], *Jacques Simard*[3], *Antonis C. Antoniou*[2], *Douglas F. Easton*[2;4], *Kyriaki Michailidou*[1]

[1]*The Cyprus Institute of Neurology and Genetics, Biostatistics Unit, Nicosia, Cyprus;* [2]*University of Cambridge, Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, Cambridge, United Kingdom;* [3]*Centre Hospitalier Universitaire de Québec – Université Laval Research Center, Genomics Center, Québec City, Québec, Canada;* [4]*University of Cambridge, Centre for Cancer Genetic Epidemiology, Department of Oncology, Cambridge, United Kingdom*

Consortium: Breast Cancer Association Consortium (BCAC)

Background/Objectives: Polygenic risk scores (PRSs) provide a promising tool for personalized breast cancer (BC) risk prediction. A 313-variant PRS (PRS-313) has been constructed and is being used in several clinical trials of risk-based screening. However, specific evaluation of its distribution across different European populations has not been performed which could be potentially important for accurate risk estimation.

Methods: We explored the distribution of PRS-313 across European ancestry populations, using data from 94,072 females without BC from 21 countries participating in the Breast Cancer Association Consortium (BCAC) and from 225,105 white females without BC participating in the UK Biobank. We calculated the mean PRS by country in BCAC and by country of birth in UK Biobank. We investigated the implications of PRS distribution variability across the countries in BC risk prediction and potential approaches to account for the observed distribution variability.

Results: The mean PRS differed markedly by country in both BCAC and UK Biobank; being highest in the south-east (e.g. Cyprus, Greece, Italy) and lowest in the north-west (e.g. Ireland). Using the PRS distribution to define risk categories leads to risks over- or underestimation in a proportion of individuals from south-eastern and north-western countries, respectively.

Adjustment for the leading ancestry informative principal components explained the differences in PRS distribution in both datasets.

Conclusion: PRS distributions differ across European ancestry populations. Country-specific distributions are required to provide well calibrated risk estimates. These approaches could also be used for the evaluation of PRSs for other diseases.

P01.081.A Stress granules: from rare disorder to potential novel cancer treatment

Johannes Lederbauer[1], *Davor Lessel*[1], *Prof. Dr. rer. nat. Hans-Jürgen Kreienkamp*[2]

[1]*University Hospital Salzburg, Institute of Human Genetics, Salzburg, Austria;* [2]*University Hospital Hamburg-Eppendorf, Institute of Human genetics, Hamburg, Germany*

Background/Objectives: Stress granules (SGs) are cytoplasmic aggregates that assemble upon stress to block the translation and thereby provide a protective mechanism. However, hyper-assembly of SGs is observed in many cancers and thought to cause chemotherapy resistance. Recently, we linked the RNA helicase DHX30 to a rare, neurodevelopmental syndrome, and found that underlying, heterozygous missense variants cause an increased propensity to trigger SG formation.

Methods: We utilized DHX30-deficient cellular and animal models, different SG inducing agents including different chemotherapeutics and analysis on protein and RNA level to further investigate the role of DHX30 in SG assembly.

Results: Our in depth analyses identified *DHX30* as the first essential gene for general SG assembly. Mechanistic analyses revealed that DHX30 interacts via RNA with two main nucleators of SGs, G3BP1 and Caprin1. Notably, expression of both proteins was significantly reduced in *DHX30* deficient models upon several stressors. Overexpression of both proteins in DHX30 deficient cells led to formation of SGs thus providing a mechanistic understanding. In addition, highly prevalent, somatic, *KRAS* missense variants (p.Gly12/Asp/Cys/Val) have been shown to enhance SG formation in pancreatic tumours. Interestingly, *DHX30* silencing mitigated SG hyper-assembly in *KRAS*-mutant cancer cells. Similar results were obtained when *KRAS*-mutant plasmid were overexpressed in *DHX30* deficient cell lines.

Conclusion: By analysing a rare Mendelian disorder, we identified *DHX30* as the first essential SG assembly gene. Furthermore, we show that molecular findings from such rare disorders can be translated to common diseases. Indeed, we identified a potential novel molecular target to treat *KRAS*-mutated cancers.

Consortium: PRiSma

Background/Objectives: BC risk is a multifactorial phenotype, and incorporation of PRS in risk estimation can lead to higher accuracy accounting for a bigger proportion of the genetic risk fraction. We aimed to explore the risk distribution in different populations of women at risk and investigate the effect of incorporating PRS in their risk estimation.

Methods: PRS genotyping was performed using the $PRISMA_{268}$ array. BC risk was estimated with the BOADICEA.v6 model using personal and family history, breast density (BD) and then compared to estimations including PRS in the same model.

We estimated the 10-year risk in two populations of healthy women: (1) 133 women carrying a germline PV in *ATM, BARD1, CHEK2, PALB2 or RAD51C/D* and (2) 593 women with a BC family history and negative genetic test. Patients were classified in average, moderate, or high risk following the NICE guidelines. t-test and X2 were used to assess differences in BC risk estimation between carriers and non-carriers and the change of distribution when adding PRS.

Results: There were no statistically significant differences in 10-year BC risk between carriers and non-carriers (7.43% vs 4.10%, $p = 0.55$). Adding PRS led to re-classification of 28% and 22% of carriers and non-carriers, respectively($p = 0.16$). Overall, 11-15% increased their risk group and 11-13% decreased their risk group.

Conclusion: Risk stratification for carriers of moderate penetrance variants is comparable to non-carriers with family history. Incorporation of PRS_{268} leads to change in risk group in 20-30% of healthy individuals with a family history, regardless of their carrier status.

P01.084.D Cytotoxic effect of thymoquinone with tamoxifen on hormone-positive breast cancer cells

Vildan Betul Yenigun[1], *Ebru Kanimdan*[1], *Ayfer Sendul*[2], *Abdurrahim Kocyigit*[2]

[1]*Bezmialem Vakıf University, Vocational School of Health Services, Istanbul, Türkyie;* [2]*Bezmialem Vakıf University, Medical Biochemistry, Istanbul, Türkyie*

Background/Objectives: Breast cancer is the most common cancer among women. Hormonal therapy is frequently used for hormone receptor-expressing breast cancers which is the most common form. Tamoxifen (TAM) is an estrogen receptor antagonist which competes with estrogen to bind to its receptor. Thymoquinone (TQ) is the main bioactive component of black cumin essential oil with anti-cancer properties. Recent studies have shown that using TQ alone or with other chemotherapeutics is effective on cancer cells. Therefore, this study aimed to examine the possible synergistic effect of the combined use of TAM and TQ on breast cancer.

Methods: ER+ breast cancer cells (MCF-7) were used in this study to investigate the combination effect of TAM and TQ. MTT cell viability test was used to calculate both drugs' half-maximal inhibitory concentrations (IC50) at 24 h and observe the cell viability after they were co-administered. Apoptosis was detected by Annexin V/PI in addition to Acridine Orange/Ethidium Bromide (AO/EB) staining.

Results: Statistical difference in cell death was observed starting from 25 µM TQ with an IC_{50} value of 74,7 µM in 24 hours. TAM induced statistical cell death starting from 10 µM concentration. Combining TQ with TAM showed apparent synergism, decreasing the IC_{50} value of TAM. Combination index analysis showed additive effect with CI values of 1,07. Apoptosis was also increased with a non-toxic dose of TAM (5 µM) and TQ combination.

Conclusion: The results of this study showed that TQ could synergistically increase the efficacy of TAM on ER+ breast cancer cells.

P01.085.A Towards characterizing the DNA methylome of classic Hodgkin lymphoma

Nadine Matscheko[1], *Anja Fischer*[1], *Selina Glaser*[1], *Cosima Drewes*[1], *Björn Brändl*[2;3], *Franz-Josef Müller*[3], *Helene Kretzmer*[2], *Ole Ammerpohl*[1], *Reiner Siebert*[1]

[1]*Institute of Human Genetics, Ulm University and Ulm University Medical Center, Ulm, Germany;* [2]*Max Planck Institute for Molecular Genetics, Department of Genome Regulation, Berlin, Germany;* [3]*Zentrum für Integrative Psychiatrie gGmbH, Universitätsklinikum Schleswig-Holstein Campus Kiel, Kiel, Germany*

Background/Objectives: Classic Hodgkin's lymphoma (cHL) is a B-cell tumor characterized by B-cell identity loss, chromosomal instability, and aberrant long tandem repeat expression. Malignant mono-nucleated Hodgkin and multi-nucleated Reed-Sternberg cells (HRS) constitute only minorities in tumor samples, making (epi-)genetic alteration screening challenging. Here, cHL cell lines offer promising alternatives and were examined for HRS-specific DNA methylation compared to B-cell lymphoma cell lines (BCL) and normal B-cell populations (BCs).

Methods: Bisulfite-converted DNA from 10 cHL, 45 BCL cell lines, and 110 BCs was investigated using Illumina HumanMethylation450K and EPIC BeadChips. Significantly differentially methylated cytosines (DMCs/CpGs) in cHL cell lines were identified (FDR ≤ 0.001, $\Delta\beta_{mean} \geq 0.4$). Moreover, 6 cHL and 10 BCL cell lines were sequenced with Oxford Nanopore (ONT), data was processed with ONT softwares dorado and modkit, and DMCs were identified (FDR ≤ 0.001).

Results: Array data-based analysis identified 4493 hyper- and 264 hypomethylated CpGs in cHL cell lines compared to BCL cell lines and BCs. Associated genes were enriched for B-cell receptor signaling, transcription, and cytoskeleton functions. Comparing ONT data of cHL and BCL cell lines, the former revealed 40,432 hypermethylated and 17,192 hypomethylated DMCs, with 10.08% and 1.22% overlap, respectively, with array-identified DMCs. Thereby, hypermethylated sites were enriched for promoter-sequences.

Conclusion: Compared to BCs and BCL cell lines, cHL cell lines predominantly exhibit hypermethylated, promoter-localized DMCs. However, the contribution of differentially methylated B-cell receptor signaling genes to B-cell identity loss is still unclear. Furthermore, investigating affected cytoskeleton functions would be worthwhile as they may affect cytokinesis, potentially leading to multi-nucleated HRS.

P01.086.B Assessment of pathogenic germline variants in patients with luminal B subtype breast cancer.

Andressa Almeida[1], *Karina Miranda Santiago*[1], *Fabiana Makdissi*[1], *José Rocha*[1], *Giovana Torrezan*[1], *Dirce Carraro*[1]

[1]*A.C. Camargo Cancer Center, Brazil*

Background/Objectives: This study aimed to examine the prevalence of germline pathogenic variants (GPVs) in luminal B breast cancer and correlate these with patient clinical data.

Methods:A retrospective study was conducted on an unselected series of 69 Brazilian women diagnosed with luminal B breast cancer, with samples available at the biobank of the A.C.Camargo Cancer Center. Participants underwent genetic sequencing of a 112-gene panel related to hereditary cancer predisposition, with clinical data from medical records review..

Results: Of the 69 patients, 20% (14/69) presented GPVs in the genes: *CHEK2* (4 patients), *BRCA2* (2), *TP53* (2), *ATM* (1*), BARD1 (*1), *BLM* (1), *BRIP1* (1), *LZTR1* (1), *MUTYH* (1) and *RAD51C* (1). GPVs carriers showed an earlier cancer diagnosis compared to non-carriers (p-value 0,021), ranging between 31 and 72 years, median of 39.5 years. 57% (8/14), were diagnosed before 45 years of age, 21% (3/14) between 46 and 60 years, and 14% (2/14) after 60 years. HER2 overexpression was observed in 64% (9/14) of cases, and the ductal histological subtype was predominant in 85% (12/14) of cases.

Conclusion: We identified a high incidence of GPVs in luminal B breast cancer, and an earlier onset of cancer in these patients.The research revealed genetic diversity, including a low incidence of variants in the *BRCA1* and *BRCA2* genes.Despite a small sample, variants in other genes and high HER2 overexpression offer new insights, highlighting the need for research on less studied breast cancer subtypes.Future research should delve into how genetic variants, HER2 overexpression, and histological subtypes interrelate to clarify hereditary breast cancer's origins.

P01.087.C miRNA Profiling Identifies Potential Risk Biomarkers in Familial Prostate Cancer Cases

Lucía Chica Redecillas[1;2], *Juan Miguel Guerrero-González*[2], *Sergio Cuenca López*[1], *Elena Arance*[2], *Fernando Marín-Benesiu*[1;2], *Carmen María Morales-Álvarez*[1;2], *Maria Jesus Alvarez Cubero*[1;2;3], *Luis Javier Martínez-González*[1;2]

[1]*Faculty of Medicine - University of Granada, Department of Biochemistry and Molecular Biology III and Immunology, Faculty of Medicine, Granada, Spain;* [2]*Centre for Genomics and Oncological Research: Pfizer, University of Granada, Andalusian Regional Government (GENYO), Granada, Spain;* [3]*Biosanitary Research Institute (ibs. GRANADA), University of Granada, Spain*

Background/Objectives: About 5-10% of prostate cancer (PC) cases have a hereditary component. Men with a family history of this disease face a twofold increased risk, with a tendency for more aggressive cancer. Current guidelines for early diagnosis and patient stratification are inadequate. Present study aims to identify potential miRNA biomarkers for the detection and stratification of high-risk familial PC.

Methods: We analysed miRNA expression in two PC multicase families. We used the edgeR package to study the transcriptome and only considered results with FDR < 0.05 as significant. To

ensure the validity of the results, we compared them with The Cancer Genome Atlas (TCGA) database.

Results: Eight miRNAs significantly expressed in hereditary PC patients were identified and validated by TCGA: hsa-miR-205-5p, hsa-miR-197-3p, hsa-miR-144-5p, hsa-miR-423-3p, hsa-miR-101-3p, hsa-miR-501-5p, hsa-miR-671-3p and hsa-miR-744-5p. Enrichment analysis revealed the involvement of target genes of identified miRNAs, such as *SOX9, ZEB2, FOXO3* and *LRRK2*, in crucial pathways related to cancer development, highlighting the Wnt signaling pathway. Construction of miRNA-mRNA network also revealed a high interconnection among identified miRNAs with genes involved in the Wnt pathway.

Conclusion: miRNAs have the potential to be significant cancer biomarkers. Specifically, hsa-miR-205-5p, hsa-miR-101-3p and hsa-miR-144-5p play important roles in crucial pathways in PC. Our study underscores the importance of the Wnt signaling pathway in the development of hereditary PC. These findings are consistent with our previous research on this disease.

Consortium: Cervigen consortium

Background/Objectives: While cervical cancer is associated with HPV infection, it appears to be influenced by genomic risk factors which have remained largely obscure. Pathogenic variants in genes of homology-directed repair (HDR) or mismatch repair (MMR) are known to predispose to diverse malignancies including breast and ovarian cancer (HDR) or colon and endometrial cancer (MMR). We here investigate the spectrum of HDR and MMR germline variants in cervical cancer, stratified by HPV status and histological subgroups.

Methods: We performed targeted next-generation sequencing of eleven HDR genes and five MMR genes on genomic DNA samples from 555 German patients with cervical dysplasia or invasive cancer. Variants were classified as pathogenic or likely pathogenic based on ClinVar categories and additional ESM1b and AlphaMissense prediction.

Results: 5 % of our patients carried a pathogenic or likely pathogenic germline variant. These included eight patients (1.4%) with truncating variants in BRCA1, BRCA2, BARD1 or BRIP1. While one patient with HPV-negative adenocarcinoma carried a pathogenic MMR gene variant (in MSH6), HDR germline variants were associated with HPV-positive squamous invasive cancer. Age at diagnosis of invasive cancer tended to be lower in HDR variant carriers (38.8 ys) compared to non-carriers (46.3 ys).

Conclusion: Our study indicates a potential risk-modifying role of HDR germline variants in a small fraction of cervical cancer patients but no association with HPV-negative status.

Grants: Supported by grants from the Bruno and Helene Jöster Foundation and the Comprehensive Cancer Center of Lower Saxony (CCC-N).

P01.089.C Comparative sequencing study of mismatch repair and homology-directed repair genes in endometrial cancer and breast cancer patients from Kazakhstan

Ying Zheng[1], **Natalia Vdovichenko**[1], *Peter Schürmann[1], Dhanya Ramachandran[1], Geffers Robert[2], Lisa-Marie Speith[1], Natalia Bogdanova[1;3], Julia Enßen[1], Natalia Dubrowinskaja[1], Tatyana Yugai[4], Zura Berkutovna Yessimsiitova[5], Nurzhan Turmanov[1], Peter Hillemanns[1], Thilo Dörk[1]*

[1]Hannover Medical School, Gynaecology Research Unit, Hannover; [2]Helmholtz Institute for Infection Research, Genome Analytics, Braunschweig; [3]Hannover Medical School, Radiation Oncology Research Unit, Hannover; [4]Rahat Clinics, Almaty, Kazakhstan; [5]al-Farabi Kazakh National University, Department of Biodiversity and Bioresources, Almaty, Kazakhstan

Background/Objectives: Endometrial cancer has been associated with pathogenic variants in mismatch repair (MMR) genes, especially in the context of the hereditary Lynch Syndrome. More recently, pathogenic variants in genes of homology-directed repair (HDR) have also been suggested to contribute to a subset of endometrial cancers although their causal role is debated.

Methods: In the presented targeted sequencing study, we investigated the relative distribution of pathogenic MMR or HDR gene variants in a hospital-based series of 351 endometrial cancer patients from the Oncology Clinic in Almaty, Kazakhstan. In a direct comparison, we also sequenced 179 breast cancer patients from the same population with the same panel of 16 genes. Identified variants were classified according to ClinVar, ESM1b and AlphaMissense prediction tools.

Results: We found 10 endometrial cancer patients (2.8 %) carrying pathogenic or likely pathogenic variants in MMR genes while 14 endometrial cancer patients (4.0 %) carried pathogenic variants in HDR genes. In the breast cancer series, we found nine carriers (4.8%) of pathogenic or likely pathogenic variants in MMR genes while 14 patients (7.4%) harbored pathogenic or likely pathogenic HDR gene variants. One patient who developed breast cancer first and endometrial cancer later carried a novel frameshift variant in *MSH6*.

Conclusion: Our results indicate that pathogenic MMR and HDR gene variants occur at substantial frequencies in both breast and endometrial cancer patients from the Kazakh population.

Grants: Funded by the Wilhelm Sander Foundation.

Consortium: Cervigen consortium

Background/Objectives: Human papillomavirus (HPV) infection triggers cervical cancer development, and genome-wide association studies have identified multiple genomic variants at the human leukocyte antigen (HLA) locus (6p21.32-33). The targets and mode of action at this locus are not well understood. We here aim to refine these associations in an independent case-control series and investigate their functional relevance by eQTL analysis in cervical specimens.

Methods: We genotyped candidate variants at the HLA locus in a German series of invasive cervical cancers, dysplasias, and healthy controls (n > 1,000 in each group). We then used stepwise conditional logistic regression analyses to identify independent signals and tested these variants for their impact on 36 HLA gene transcripts in 200 cervical tissue samples.

Results: The HLA region contained at least four independently associated risk variants for cervical cancer. In addition to previous findings from our cohort, rs17190106 associated with overall cervical disease and invasive cancer, and rs535777 associated with adenocarcinoma. We identified mRNA transcripts upregulated in HPV-positive samples. One variant, rs9272117, affected the expression of multiple genes across the HLA region.

Conclusion: We confirm the presence of independent cervical cancer risk signals at 6p21 in our hospital-based cohort. We identify genomic variants that modulate gene transcript levels together with HPV, indicating that highly controlled gene regulation underlies cervical cancer susceptibility at the HLA locus. These genes may act in concert to modulate the host immune response towards HPV infection.

Grants: Supported by the Bruno and Helene Jöster Foundation and the Comprehensive Cancer Center of Lower Saxony (CCC-N).

P01.091.B Germline PTEN pathogenic variant in a patient with Kaposiform haemangioendothelioma

Hannah Massey[1], *Jennie Murray*[1], *larry hayward*[1]

[1]*Western General Hospital, United Kingdom*

Background/Objectives: Kaposiform haemangioendothelioma (KHE) is a rare vascular neoplasm usually presenting in childhood. Its high morbidity and mortality is secondary to compression, invasion, and coagulopathy. The genetics of KHE remain poorly understood. Studies have detected somatic variants in GNA14 and germline variants in PIKC3A contributing to tumorigenesis via the Ras and mTOR pathways respectively. We present the first case of a germline change in PTEN identified in the context of Kaposiform haemangioendothelioma.

Methods: A 28-year-old female with metastatic KHE was enrolled in the IMAGINE study (Integrating Medically Actionable Genomics Into Early Phase Trials).

Results: A PTEN heterozygous c.277C>Tp.(His93Tyr) pathogenic variant was detected initially in tumour and subsequently saliva indicating a constitutional genetic change. Reverse phenotyping revealed the patient had a large head circumference, palmar keratosis and papillomas on the hand, feet, and gums, in keeping with PTEN-Hamartoma tumour syndrome (PHTS).

Conclusion: We report the first case of a constitutional PTEN pathogenic variant in association with a KHE. PHTS is a well characterised tumour predisposition syndrome with an 85% lifetime tumour risk. While over 50% of patients with pathogenic PTEN variants have vascular anomalies no malignant vascular tumours have previously been reported. Pathogenic variants in PTEN lead to loss of protein function with a subsequent upregulation of mTOR signalling. Upregulation of mTOR signalling is commonly observed in cancer. This raises the question as to whether mTOR inhibitors could be used in the treatment of KHE.

Consortium: Cervigen consortium

Background/Objectives: Persistent infection by high-risk human papillomavirus triggers the development of cervical cancer and dysplasia. Genome-wide association studies for cervical cancer have so far identified multiple genomic risk variants at the human leukocyte antigen (HLA) locus (6p21.32-33), as well as variants on chromosome 2 (PAX8), 5 (near CLPTM1L) and 17 (GSDMB).

Methods: We directly genotyped reported variants, as well as 15 novel variants derived from a HPV seropositivity GWAS, in a German case-control series of invasive cervical cancer, dysplasia, and healthy controls (N > 1,000 in each group). We performed unadjusted logistic regression analyses stratified by histology and HPV type. Selected variants were further investigated for their impact on RNA transcript levels in cervical specimens.

Results: We replicated risk loci in the HLA region as well as at PAX8 and GSDMB at $p < 0.05$ in our independent case-control series, although the GSDMB locus was only associated with cervical dysplasia. We found evidence that HPV16 and HPV18 seropositivity variants at chromosome 6 and 14 associate with cervical cancer risk in an HPV type-specific manner. rs9357152 may exert its effect through inducing HLA-DRB1 in the presence of HPV. Genotyping of further suggestive HPV-type specific signals from the seropositivity GWAS provided evidence of association at $p < 0.05$ for seven additional cervical cancer risk regions.

Conclusion: Our results support the view that several genomic risk loci exist for cervical dysplasia and cancer, and some of them may be HPV-type specific.

P01.093.D Precision medicine from the renal cancer genome

Yasser Riazalhosseini[1]

[1]*McGill University, Human Genetics, Montreal, Canada*

Background/Objectives: Renal cell carcinomas (RCC) are characterized by their inherent resistance to chemotherapy and radiation and their largely diverse clinical outcomes. Leveraging genomic diversity among individual tumors, our research during the past decade has concentrated on developing personalized medicine approaches for the most common and the most aggressive type of RCC, clear cell renal carcinoma (ccRCC).

Methods: We generated the largest dataset of ccRCC including somatic genomic and clinical annotations for over 940 ccRCC patients, and developed a genomic classifier, based on mutational status of 12 RCC-relevant genes, which is able to stratify patients according to their risk of relapse after nephrectomy and/or death due to RCC.

Results: The performance of this classifier, which is independent from tumor stage and patient age, is validated for 75% of ccRCC patients whose tumors are affected by mutations of *VHL* gene. We have expanded the application of our 12-gene RCC assay to liquid biopsy analysis, aiming at developing a non-invasive approach for the application of our classifier, and establishing early detection of relapse in high-risk patients. Additionally, we observe a different genomic evolution trajectory of disease progression in ccRCCs that do not harbor VHL mutations. Our ongoing research focuses on understanding the distinct biology of these tumors using single-cell and spatial genomics, and our cohort of patient-derived organoid models of aggressive ccRCCs to identify novel therapeutic targets.

Conclusion: At the conference, I will present this decade-long endeavor and will discuss how our Pan-Canadian 'Precision RCC' program leverages this legacy to establish personalized medicine in RCC.

P01.094.A Predicting mutation risk at nucleotide scale using transformer neural networks

Marcell Veiner[1,2], *Iván Galván-Femenía*[1], *Daniel Naro*[1,3], *Fran Supek*[1]

[1]*IRB Barcelona - Institute for Research in Biomedicine, Genome Data Science, Barcelona, Spain;* [2]*Universitat de Barcelona, Faculty of Medicine and Health Sciences, Barcelona, Spain;* [3]*Universitat Politècnica de Catalunya · Barcelona Tech - UPC, Barcelona, Spain*

Background/Objectives: Somatic mutation rates in cancer vary across the human genome at different scales. At the megabase- and gene-scale variation is well-studied, the mutation rate heterogeneity at sub-gene scales remains less explored. The aim of this contribution is to evaluate somatic mutation rates of Single Nucleotide Variants (SNV) in the human genome at base-pair resolution (1-300bp), and associate DNA sequence features to each mutational process.

Methods: We separated ~230M SNVs obtained from 12,166 pan-cancer whole-genome sequences into de novo mutational signatures using non-negative matrix factorisation, and fit to known COSMIC signatures. Subsequently, we trained a transformer neural network called MutFormer to differentiate between mutated vs trinucleotide-matched non-mutated sites on 18 SBS signatures, and to guide the discovery process of novel DNA determinants.

Results: Our models were validated on an independent cohort, achieving AUCs ranging from 0.55 on flat signatures (SBS5) to 0.86 on signatures dominated by a few mutation types (SBS17a/b), suggesting wider sequence context for these signatures (5-10bp on each side of the mutation). We found several DNA features shaping the mutational landscape, some as a wider sequence context (e.g. AAAKAATAAAW, SBS10a), while some by being in the vicinity of the mutation (CCWGG, SBS17b). Our method was also applied to model the germline mutation rate, achieving similarly high AUCs.

Conclusion: Overall, our transformers provide a state-of-the-art method for inferring the risk of SNVs occurring given the nearby DNA sequence, with implications to disease gene discovery and evolutionary biology.

P01.095.B Dyskeratosis congenita segregation in a large Middle Eastern family reveals a novel pathogenic *TERC* variant

Michal Barzily Rokni[1], *Chezi Ganzel*[2;3], *Malka BenUziyahu*[1], *Adi Zisman*[1], *Rachel Beeri*[1], *Ephrat Levy-Lahad*[1;3]

[1]*Shaare Zedek Medical Center, Medical Genetics Institute, Jerusalem, Israel;* [2]*Shaare Zedek Medical Center, Department of Hematology, Jerusalem, Israel;* [3]*Hebrew University of Jerusalem, Faculty of Medicine, Jerusalem, Israel*

Background: Dyskeratosis congenita (DC) is a rare, heterogeneous genetic disorder caused by defective telomere maintenance resulting in shortened telomeres. *TERC* pathogenic variants (PVs) (the telomerase RNA component) gene cause autosomal dominant DC. The highly variable expression of the disease, even in the same family, makes diagnosis and surveillance recommendations a challenge.

Objectives: To determine the pathogenicity of a *TERC* variant of unknown significance (VUS), using segregation in an extensive Muslim Arab family (over 100 members).

Results: A 50-year-old man with myelodysplastic syndrome (MDS) reported family history of four brothers and a sister who died of leukemia. Exome-based panel testing identified a *TERC* gene variant, n.97T>G (rs1777963567). This variant has been reported once in ClinVar, as a VUS. It is not present in any database, and is located within the template/pseudoknot domain of the *TERC* RNA component, which is required for RNA or RNP stability. We reclassified the VUS as a novel, likely pathogenic variant after: (1) Identifying clinical features of DC in the patient, including: dysplastic nails, oral leukoplakia, pulmonary fibrosis, prematurely gray hair and liver disease. (2) Determining shortened telomere length in the patient's blood. (3) Segregation analysis revealing all affected siblings (four) as heterozygous for the variant and non-affected siblings (five) as negative for the variant. Genetic counseling services and surveillance recommendations were offered to all at risk family members, of which only a few responded.

Conclusion: We report n.97T>G as a novel PV in the *TERC* gene causing DC, in order to further aid identification of and treatment for DC families.

Conflict of Interest: None declared

P01.096.C A rare homozygous germline missense variant of *TP53* causing Li-Fraumeni syndrome

Fuad Chowdhury[1], *Melanie Finkbeiner*[2], *Katie Girgulis*[2], *Ryan Lamont*[3], *Jillian Parboosingh*[3], *Lucie Pecheux*[4], *Renee Perrier*[1]

[1]*University of Calgary and Alberta Children's Hospital, Department of Medical Genetics, Calgary, Canada;* [2]*University of Calgary and Alberta Children's Hospital, Department of Pediatric Hematology-Oncology, Calgary, Canada;* [3]*Molecular Diagnostic Laboratory, Department of Medical Genetics, Calgary, Canada;* [4]*University of Alberta and Stollery Children's Hospital, Department of Pediatric Hematology-Oncology, Edmonton, Canada*

Background: Li-Fraumeni syndrome (LFS) is a cancer predisposition syndrome caused by heterozygous variants in *TP53* often through loss-of-function mechanisms. Subsequent somatic loss-of-heterozygosity is frequently observed in tumour samples of many cancer types, while bi-allelic germline variants are extremely rare in individuals with LFS. Most of these individuals are homozygous for the lowly-penetrant R337H founder variant.

Methods: Clinical panel or single-gene sequencing was performed on proband peripheral blood DNA to identify *TP53* variants. Subsequently, first-degree relatives were tested for inheritance of the *TP53* variant, when possible.

Results: We report two previously healthy and unrelated girls diagnosed with adrenocortical carcinoma (ACC). Both presented with several months of virilization and clinical evidence of androgen excess. The first patient is a 5-year-old girl of Pakistani ancestry with consanguineous parents who is homozygous for a NM_000546.6(*TP53*):c.328C>T (p.R110C) germline variant of uncertain significance (VUS). The second is a 2-year-old girl presenting additionally with hypercortisolism and she is heterozygous for the same *TP53* variant. Neither family had a history of LFS-spectrum cancers.

Conclusions: The presence of a germline R110C variant in two unrelated girls with a rare ACC provides strong clinical evidence that *TP53* p.R110C can cause LFS. Pathogenic variants affecting the same residue have been described. Furthermore, previous in vitro functional characterization of p53-R110C demonstrated reduced transcriptional activity, induction of apoptosis, and altered subcellular localization. Moreover, this report provides further clinical evidence of the pathogenicity of hypomorphic germline *TP53* variants when homozygous and supports surveillance for relatives with at least one R110C variant.

Consortium: ClinGen InSiGHT Hereditary Colorectal Cancer/Polyposis Variant Curation Expert Panel

Background/Objectives: To resolve the interpretative challenges of variants of uncertain significance (VUS), gene-specific ACMG/AMP variant classification criteria were developed and validated for the APC gene by the ClinGen-InSiGHT Hereditary Colorectal Cancer/Polyposis Variant Curation Expert Panel (VCEP) (https://cspec.genome.network/cspec/ui/svi/doc/GN089).

Methods: A streamlined algorithm using the APC-specific criteria was developed and applied to reassess all APC variants in ClinVar and the reference APC gene variant database in the Leiden Open Variation Database (LOVD).

Results: A total of 10,228 unique APC variants were analysed. 94% and 96% of the ClinVar and LOVD variants, respectively, with an initial classification of (Likely) Benign or (Likely) Pathogenic remained in their original categories. 41% of ClinVar and 61% of LOVD VUS were reclassified into clinically actionable classes, the vast majority as (Likely) Benign. The total number of VUS was reduced by 37% from 6142 to 3865. For 36 promising APC variants that remained VUS despite evidence for pathogenicity, a data mining-driven work-up was undertaken to curate additional evidence which allowed the further reclassification of 18 VUS as (Likely) Pathogenic.

Conclusion: The application of APC-specific classification criteria substantially reduced the number of VUS in ClinVar and LOVD. The study also demonstrates the feasibility of a systematic approach to variant classification with large datasets, which serves as a generalisable model for other gene-/disease-specific variant interpretation initiatives. It also allows for the prioritization of VUS that will benefit from in-depth evidence collection. The reclassified promising APC variants will be subjected to VCEP approval and made publicly available through ClinVar and LOVD for widespread clinical use.

P01.098.A Using the homologous recombination deficiency mutational signature to look for the missing heritability in breast cancer

Jose Camacho Valenzuela[1;2], *nancy hamel[2;3], Thibaut Matis[4;5], paz polak[6], Carla Daniela Robles Espinoza[7;8], William Foulkes[1;2;3]*

[1]McGill University, Human Genetics, Montréal, Canada; [2]MUHC Research Institute, Cancer Research Program, Montréal, Canada; [3]Lady Davis Institute at the Jewish General Hospital, Montréal, Canada; [4]Institute Bergonié, Cancer genetics unit, Bordeaux, France; [5]Bric Bordeaux Institute Of Oncology - Inserm U1312 University Bordeaux - Institute D'oncologie De Bordeaux., Bordeaux, France; [6]Icahn School of Medicine at Mount Sinai, Oncological sciences, New York, United States; [7]Laboratorio Internacional de Investigación sobre el Genoma Humano (LIIGH) UNAM, Juriquilla, Mexico; [8]Wellcome Sanger Institute, Experimental cancer genetics, Hinxton, United Kingdom

Background/Objectives: Approximately 50% of hereditary breast cancer is explained by germline variants in well-known Breast Cancer Susceptibility Genes (BCSGs), predominantly *BRCA1/2*. The remaining 50% remains unexplained. We hypothesized that analyzing DNA from normal tissue and breast tumor from the same patient would allow us to identify other Homologous Recombination Repair (HRD)-related BCSGs, should they exist.

Methods: Focusing on matched normal/tumor exome data of breast cancer patients from The Cancer Genome Atlas, we developed a combined multidimensional pipeline to correlate the presence of Mutational Signature 3 (Sig3) with germline cancer predisposition variants, accounting for secondary tumor events. We evaluated genes enriched with variants in patients with Sig3 in their tumors, including non-cancer genes.

Results: We confirmed a significant association of *BRCA1/2* with Sig3 ($p < 0.05$). We also observed an association for some HRD genes, specifically *RAD51C* ($p < 0.05$), *PALB2* and *RAD51D*, though the last two did not reach significance. We did not identify positive correlation with Sig3 for previously unrelated genes. Somatic biallelic loss of *BRCA1/2* (~70%) and methylation in *BRCA1/RAD51C* (~20%) explain most cases lacking germline *BRCA1/2* variants. *BARD1* and *PALB2* germline variants with somatic second hits explained some of the remaining non-*BRCA1/2* cases. We are further investigating the non-BRCA cases with Sig3.

Conclusion: Somatic and epigenetic events in well-known HRD genes appear to explain approximately 90% of HRD cases without *BRCA1/2* germline variants. Other non-*BRCA1/2* genes likely explain only a small proportion of cases. An integrated germline/tumor approach is a powerful genomic strategy to understand non-*BRCA1/2* cases.

Grants: CIHR (FDN-148390).

Conflict of Interest: None declared

P01.099.B Landscape of Germline Variants in Cases of Ovarian Cancer: Insights from a Single-Center Study

Ece ÇİÇEK[1], *Drenushe Zhuri[1], Nilay Ozupek[1], Hazal Sezginer Guler[1], umut çiçek[1], HAKAN GURKAN[1]*

[1]Trakya University, Medical Genetics, Edirne, Türkyie

Background/Objectives: Ovarian cancer stands as one of the predominant gynecological malignancies globally. Diverse risk

factors have been elucidated in connection with ovarian cancer, encompassing advanced age, genetic predisposition, familial history, nulliparity, and others. Existing research underscores that over 20% of ovarian cancer cases exhibit a hereditary genetic basis, with approximately 70% of these genetic anomalies manifesting as germline mutations in the *BRCA*1/2 genes. In this study, we aimed to investigate the mutational spectrum of ovarian cancer in a single-center patient group.

Methods: Between January 2022 and September 2023, our study enrolled 60 patients diagnosed with ovarian cancer who applied to our Genetic Diseases Evaluation Center. DNA samples extracted from the peripheral blood of patients underwent analysis utilizing the The QIAseq Human Breast Cancer Panel (93 genes, DHS-001Z; Qiagen).

Results: In fifteen cases, comprising 25% of the study cohort, sixteen pathogenic/likely pathogenic (P/LP) variants were identified, with one of them being novel. Additionally, seventeen cases presented 22 variants of unknown clinical significance (VUS). These cases were categorized into two groups: (1) carriers of *BRCA1/2* variant and (2) non-carriers of *BRCA1/2* variant, with 50% of the P/LP variants detected in *BRCA1/2* genes, primarily within group1.

Conclusion: The mutations most frequently observed in cases of ovarian cancer are typically found in the *BRCA* genes. However, our study's findings indicate a lack of correlation with previously reported mutation rates in genes other than *BRCA1/2*. This observation suggests the potential to offer novel insights into the mutational spectrum of ovarian cancer.

Conflict of Interest: None declared

P01.100.C Mutational landscape of glioblastoma tissue and derived tumoroid exomes

Vita Rovite[1], *Sigita Hasnere*[2], *Raitis Pečulis*[1], *Aija Gerina*[2], *Olesja Rogoza*[1], *Omkar Suhas Vinchure*[3], *Vaibhav Jadhav*[3], *Jay Gopalakrishnan*[3]

[1]*Latvian Biomedical Research and Study centre, Molecular and Functional Genomics, Riga, Latvia;* [2]*P. Stradins Clinical University Hospital, Oncology, Riga, Latvia;* [3]*Institute for Human Genetics Heinrich-Heine-Universität Universitätsklinikum Düsseldorf, Laboratory for Centrosome and Cytoskeleton Biology, Düsseldorf, Germany*

Background/Objectives: Glioblastoma (GB) is the most frequent malignant brain tumor. GB patients' median survival is <24 months, and there is no cure. Glioma-PerMed project is consortium based effort to establish rapid and efficient glioma invasion assays and machine learning algorithms for predicting the GB invasion in ex-vivo, personalized diagnostics, drug discovery, and patient follow-up in the clinics. Aim of this study was to charcterize mutational landscape of GB tissue and derived tumoroid models.

Methods: Five GB tissue and seven tumoroids was obtained at Jay Gopalakrishnan lab in University of Dusseldorf, Germany. Sequencing of the obtained biological samples was done at Latvian Biomedical Research and Study cente using MGIEasy Exome Capture V4 Probe Set and MGIEasy Exome Universal Library Prep Set on DNBSEQ-G400 sequencer. Exome sequencing reads were trimmed using fastp v0.23.4, afterwards reads were aligned to human genome reference GRCh38.p14 using bwa mem v0.7.17. Tumor tissue - tumoroid sample pair variant differences were detected with Strelka v2.9.10.

Results: GB tissue samples contained from 149124 to 209524 variants while tumoroids from 18169 to 186502 variants. Specifically, we assessed the presence of mutations in 79 genes realted to GB pathogenesis. In tumour tissue we found mutations in 34-30 genes, while tumoroids this varied from 16 - 45 genes.

Conclusion: In our sample set tumour tissues most often we detected mutations in known glioma associted genes, for example, TP53, PDGFRA, ATR, and less number of cases IDH1, EGFR and PTEN mutations.

P01.102.A Germline mutations in *HIC1* are associated with serrated polyposis syndrome

Xavier Domínguez-Rovira[1], *Coral Arnau-Collell*[1], *Gemma Gonfaus*[1], *Gemma Llargués-Sistac*[1], *Jenifer Muñoz*[1], *Ainara Llopis*[1], *Yasmin Soares de Lima*[1], *Cristina Herrera-Pariente*[1], *Leticia Moreira*[1], *Teresa Ocaña*[1], *Marcos Díaz-Gay*[2], *Miriam Cuatrecasas*[3], *Sabela Carballal*[1], *Anael Lopez-Novo*[4], *Guerau Fernandez*[5], *Antoni Castells*[1], *Luis Bujanda*[6], *Gabriel Capellá*[7], *Joaquin Cubiella*[8], *Daniel Rodriguez-Alcade*[9], *Laura Valle*[7], *Francesc Balaguer*[1], *Clara Ruiz-Ponte*[4], *Laia Bonjoch*[1], *Sergi Castellví-Bel*[1]

[1]*Hospital Clínic, FRCB-IDIBAPS, CIBEREHD, Gastroenterology, Barcelona, Spain;* [2]*Moores Cancer Center at UC San Diego, La Jolla, San Diego, United States;* [3]*Hospital Clínic de Barcelona, Pathology, Barcelona, Spain;* [4]*Fundación galega de medicina xenómica, Grupo de Medicina Xenómica-USC, IDIS, CIBERER, Santiago de Compostela, Spain;* [5]*Sant Joan de Déu Barcelona Hospital, Barcelona, Spain;* [6]*Donostia Hospital, CIBEREHD, Gastroenterology, San Sebastián, Spain;* [7]*Catalan Institute of Oncology, Barcelona, Spain;* [8]*Complexo Hospitalario Universitario de Ourense - CHUO, Gastroenterology, Ourense, Spain;* [9]*Hospital Universitario de Móstoles, Digestive diseases section, Móstoles, Spain*

Background/Objectives: Serrated polyposis syndrome (SPS) is characterized by multiple and/or large serrated polyps and colorectal cancer (CRC) risk. *HIC1* (*Hypermethylated in cancer 1*) is a transcriptional repressor that functions as a tumor suppressor gene, previously suggested as a new candidate gene to germline predisposition to SPS (1). We aimed to provide functional evidence to evaluate *HIC1* as a new hereditary gene for SPS.

Methods: Gene-panel sequencing of 211 SPS patients was performed to validate the findings in a discovery cohort of 39 patients from 16 SPS families. Two cellular models for *HIC1*, a CRISPR/Cas9 knock-out model and an overexpression model, were produced. We assessed the DNA damage response and the *SIRT1* regulatory pathway upon *HIC1* genetic variation.

Results: Three predicted pathogenic variants were identified within the *HIC1* gene (p.Ala37Val, p.Gln432Arg and p.Gly471Arg) in the discovery and validation cohorts. Functional characterization revealed higher p-H2AX levels (a marker for ongoing DNA damage) and impaired *HIC1* binding to the *SIRT1* promoter in cellular models carrying the identified genetic variants when compared with the wild-type sequence.

Conclusion: Our results indicate that *HIC1* genetic variants located in the zinc finger region can lead to disruption of protein function. Our results support *HIC1* as a new gene associated with SPS predisposition, although additional cohorts should be evaluated to further investigate its hereditary role.

Background/Objectives: Many Polygenic Scores (PGS) have been described for Breast Cancer (BC), differing by number and selection of SNPs. This variability leads to a wide range of estimated PGS in the same individual and therefore to inconsistent risk stratification. The aim of this study is to optimise the computation of BC risk scores by the selection of the variants involved.

Methods: Starting from the 100 PGSs available for BC on the PGS Catalog, we aligned all their variants to obtain the most represented SNPs associated to disease risk. TheSNPs selection approach was based on the association with Breast Cancer and on the concordance between the different PGSs. Standardization and embedding operations were performed on the effect weights to create a new PGS.

Results: The newly created PGS has 4,606 SNPs. We tested this PGS on Genomic England, UK Biobank and FinnGen data. In all the data sets tested the combined approach to estimate the effect weights shows the best performance, distributions between BC patients and controls were significantly different (Kolmogorov–Smirnov test p-value < 0.0001). Across cohorts, women in the highest 1% of the score had a two to three-fold increased risk of develop BC compared with women in the middle quintile Lifetime risk of BC for women in the lowest and highest quintiles of the PRS was 10% and more than 25%, respectively.

Conclusion: These finding and optimization approach strengthen the standardisation of PGS that could help clinicians to better stratify patients risk of developing BC.

Andalusian Research Institute in Data Science and Computational Intelligence (DaSCI). University of Granada, Granada, Spain;* [5]*IBS, Biosanitary Research Institute (ibs. GRANADA), University of Granada, Granada, Spain*

Background/Objectives: Although prostate cancer (PC) is the second most frequent tumour worldwide, its diagnosis focuses on inconclusive or not necessarily cancer-specific strategies. Therefore, a classifier is proposed to predict the occurrence of PC and to provide a tool to assist the pathologist in the decision-making process.

Methods: Different machine learning methods based on eXplainable Artificial Intelligence were trained using gene expression data from 550 samples available on 'The Cancer Genome Atlas' repository. Our model was validated in 463 samples from four external cohorts. Additionally, a set of SHapley Additive exPlanations was provided to help clinicians to understand each prediction. To analyze reliability and feasibility of applying the classifier in clinical practice, a gene expression analysis by qPCR was performed in 60 fresh prostate tissue samples (20 control individuals and 40 PC patients stratified by tumor aggressiveness).

Results: An in-depth analysis showed that the Random Forest algorithm combined with undersampling procedure was the best performing approach with robust statistical significance (sensitivity:0.90; specificity:0.8; AUC:0.84) across all databases. Classifier validation in prostate tissue samples revealed an increase in *DLX1, TDRD1, AMACR, HPN, HOXC6* and *OR51E2* expression when comparing high vs. low aggressive PC patients and PC patients vs. controls.

Conclusion: Proposed tool has shown good performance in 4 independent external cohorts of different ancestries and the explanations provided are consistent with the results obtained in the experimental validation with biological samples. In the near future, highlighted genes expression, in combination with our model, could be applied to liquid biopsy to improve PC screening.

P01.105.D Risk management for breast cancer in BRCA mutation carriers; compliance to the recommended surveillance.

Toine Werker[1], *Simone Salemink*[1], *Wendy Van Zelst-Stams*[1], *Arjen Mensenkamp*[1], *Angela van Remortele*[1], *Maaike Haadsma*[1]

[1]*Radboud University Medical Center, Human Genetics, Nijmegen, Netherlands*

Background/Objectives: Due to their highly increased risk of breast cancer, women with a pathogenic mutation in the BRCA1- or BRCA2-gene are eligible for preventive mastectomy or specific breast cancer surveillance protocols to warrant early detection. This study investigates the extent to which BRCA mutation carriers follow the Dutch breast cancer guideline recommendations.

Methods: We performed a cross-sectional study at the department of Human Genetics of the Radboud University Medical Center, Nijmegen, The Netherlands, among presymptomatic women aged 25 to 75 with a pathogenic mutation in the BRCA1- or BRCA2-gene, identified between 2012 and 2021. Women were asked about their current surveillance status through a survey.

Results: 256 out of 709 (36,1%) women responded and the 200 women without a history of breast cancer were included. In total, 86% (172/200) of them were compliant to the recommended guidelines. Of these women, 85 (42.5%) underwent preventive mastectomy. In the 115 other women, eligible for surveillance, in 75.7% (87/115) breast screening was performed according to the guideline. Women non-compliant to guideline surveillance were more often BRCA1 mutation carriers ($p = 0.045$), of older age ($p = 0.019$), and had a longer time since mutation detection ($p = 0.031$).

Conclusion: This study, not previously conducted among Dutch BRCA mutation carriers, reveals that the majority of women were compliant with recommendations concerning their breast cancer risk. However, nearly one-fourth of those eligible for surveillance

do not receive guideline-compliant breast screening. We believe that guideline compliance can be improved by closer collaboration between involved healthcare providers.

Grants: Not applicable.

P01.106.A Clinical and Molecular Characterization of Fumarate Hydratase (FH) germline carriers in Omani families.

Abeer Alsaegh[1], *Reem Abdulrahim*[1], *Chantel Van Wyk*[2], *Ilse Crous*[2], *Sara Al Kiyumi*[2], *Amira Al Balushi*[2], *Suad Al Malki*[2], *Bushra Al Muhairi*[2]

[1]*Sultan Qaboos Comprehensive Cancer Care and Research Center, Genomics, Oman;* [2]*Sultan Qaboos Comprehensive Cancer Care and Research Center*

Backgroud/Objecties: Although there are several families described with FH mutations associated with Hereditary Leiomyomatosis and Renal Cell Cancer, the prevalence and full spectrum of the phenotype is still unknown. The objective of this study is to collect and describe the clinical and molecular phenotype in Omani families with pathogenic mutations in FH gene.

Methods: Retrospective hospital chart review of individuals referred to clinical genetics service from 2021 to 2023 to Sultan Qaboos Comprehensive Cancer Care and Research Center.

Results: A total of 30 FH mutation carriers were identified in this cohort. The majority were diagnosed with renal cell carcinoma (19/30). There was also (2/30) patients diagnosed with Uterine leiomyosarcoma, (5/30) diagnosed with pre- menopausal young onset breast cancer, (2/30) diagnosed with bladder carcinoma and only 2/30 with the typical skin lesions for cutaneous leiomyomas. Uterine fibroids were only reported in (4/30).

Conclusion: In our cohort we seem to identify more carriers diagnosed with breast and bladder cancer and all have the common founder mutation in FH gene (c.698G>T). In view of these results, patients with this mutation may benefit from early breast cancer screening in addition to other common cancers associated with this syndrome.

Grant: no grant was obtained to do this study

P01.107.B *ATM* c.7475T>G, p.(Leu2492Arg) variant confers a moderate risk for breast cancer

Ivana Maleva Kostovska[1], *Predrag Noveski*[1], *Sanja Kiprijanovska*[1], *Simona Jakovchevska*[1], *Dijana Plaseska-Karanfilska*[1]

[1]*Macedonian Academy of Sciences & Arts, Research Center for Genetic Engineering and Biotechnology "Georgi D. Efremov", Skopje, Macedonia*

Background/Objectives: Case-control and family-based studies have identified *ATM* as a moderate breast cancer (BC) susceptibility gene. While germline protein truncating variants (PTVs) in *ATM* are linked to a 2-4 fold elevated BC risk, the risk posed by missense variants remains uncertain, with the majority classified as variants of uncertain significance (VUS). Our study aimed to comprehensively evaluate the prevalence of *ATM* variants among BC cases and general population.

Methods: Sequencing of BC cases ($n = 971$) was performed using TruSight Cancer NGS sequencing panel, while *ATM* variants in the control samples ($n = 871$) were derived from WES conducted in our laboratory. Additionally, 280 BC cases were screened for the *ATM* c.7475T>G variant with allele specific PCR.

Results: The observed *ATM* mutation rate was 1.9% (18/971) in BC cases and 0.5% (4/871) in the control cohort, with the majority of pathogenic variants (80%, 12/15) being PTVs. VUS variants were identified in 53 BC cases (5.5%) and 41 controls (4.7%). The most common VUS c.7475T>G, p.(Leu2492Arg) was identified in 1.6% of the BC patients and 0.6% of the controls (20/1251 vs. 5/871), thus carrying a moderate increased risk for BC (OR 2.8; 95%CI 1.05-7.52, $p = 0.03$). This variant has higher allele frequency in our population compared to gnomAD (0.59% vs. 0.01%), is located in the FAT domain, has CADD score of 26.7 and is classified as VUS in ClinVar.

Conclusion: This is the first study to demonstrate moderate BC risk in *ATM* c.7475T>G carriers, emphasizing the importance of studying *ATM* VUS in different populations where some VUS exhibit higher frequencies.

Conflict of Interest: None declared

P01.108.C Investigating the Impact of IDH1 Mutation on Monocyte Differentiation Transcriptome in Early Glioma Development

Ebru BAKIR[1], *Yavuz Oktay*[1]

[1]*izmir Biomedicine and Genome Center, Molecular Biology and Genetics, İzmir, Türkyie*

Background/Objectives: Gliomas, the most prevalent primary brain tumors, often harbor IDH1 mutations, notably the R132H alteration, leading to the production of the oncometabolite 2-hydroxyglutarate (2-HG). This study aims to investigate the effects of secreted factors from astrocytes mimicking early IDH1 R132H gliomas on monocyte differentiation, shedding light on the molecular mechanisms underlying glioma development.

Methods: Immortal human astrocytes expressing IDH1 R132H were utilized to generate conditioned media (CM) mimicking early glioma stages. Primary monocytes were exposed to these CM during differentiation to macrophages. Transcriptome-wide analysis of differentiated macrophages was conducted via RNA sequencing to identify differentially expressed genes in response to the IDH1 mutation.

Results: RNA sequencing revealed 124 differentially expressed genes associated with the IDH1 mutation. Gene ontology analysis indicated interference with the p53 signaling pathway and elevated signatures related to negative regulation of complement activation in IDH1 R132H-exposed cases. Additionally, pathways associated with Th1 and Th2 cell differentiation, as well as cytotoxic T cell homeostasis, were significantly enriched.

Conclusion: Secreted factors from astrocytes in early glioma formation significantly impact monocyte differentiation transcriptome, potentially shaping the tumor microenvironment. The findings underscore the role of IDH1 mutation in modulating immune responses and highlight potential therapeutic targets for glioma treatment.

P01.109.D Characterization of the transgenic animal models *Danio Rerio* and *Caenorhabditis Elegans* to examine pathophysiology associated with SMARCB1 variants

Elena Tacchetto[1;2], *Lisa Buson*[2], *valeria morbidoni*[1], *Cristina Cerqua*[1], *Valerio Magnaghi*[3], *Laura Papi*[4], **Eva Trevisson**[1;2]

[1]*IRP – Istituto di Ricerca Pediatrica Città della Speranza, Padova, Italy;* [2]*Università degli Studi di Padova, Salute della Donna e del Bambino, Roma, Italy;* [3]*Università degli Studi di Milano, Dipartimento di scienze farmaceutiche e molecolari, Milano, Italy;* [4]*Università di Firenze, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", Firenze, Italy*

Background/ Objectives: SMARCB1 is a nuclear protein and core subunit of the BAF chromatin-remodeling complex. SMARCB1 variants are associated with tumor predisposition syndromes and developmental disorders. We developed and characterized two transgenic models, *C.elegans* and zebrafish, to examine the pathophysiology associated with SMARCB1.

Methods: We analyzed the expression of SMARCB1 orthologues. In *C.elegans*, *snfc-5* was analyzed by q-RT PCR. In *D.rerio* there are two paralogs: *smarcb1a* and *smarcb1b*, whose spatial and temporal expression was analyzed. We employed CRISPR/Cas9 to obtain our transgenic animals: we generated *smarcb1a-/-*, *smarcb1b-/-* and *smarcb1ab* + /- lines in *D. rerio*. In *C. elegans*, we modeled mutations associated with distinct human phenotypes. We performed a series of experiments to characterize the transgenic lines, as brood size and longevity and we are studying nociception. In zebrafish, we are performing phenotypical observation, survival curves and histological analysis.

Results: In zebrafish the two isoforms were detected from the first stages of embryonic development and ubiquitously. With an in-vivo analysis, we observed that *smarcb1* reaches the highest levels of expression in the central nervous system. In *C. elegans*, the single isoform *snfc-5* is expressed from the egg stage to the adulthood. Our data suggest that *smarcb1* is a maternal determinant. The phenotypical analysis of our transgenic lines, suggest that SMARCB1 plays an important role in survival, embryonic development and tissue maintenance.

Conclusion: Our findings indicate that SMARCB1 plays key roles in different pathways and developmental stages. The integration of this multidisciplinary approach could help to identify novel therapeutic targets.

P01.110.A KMT2C mutations associated with colorectal and lung cancer development

Dimitar Dimitrov[1], *Nelly Miteva-Marcheva*[1], *Hristo Ivanov*[1], *Aleksandar Linev*[1], *Vili Stoyanova*[1]

[1]*Medical University of Plovdiv, Department of Pediatrics and Medical Genetics, Plovdiv, Bulgaria*

Background: Worldwide, cancer is a leading cause of death. We conducted a study which aim was to investigate mutations associated with tumorigenesis in patients with colorectal and lung cancer.

Methods: A total of 31 cancer patients (12 with lung cancer, 19 with colorectal carcinoma) were enrolled, from whom ctDNA samples were collected by liquid biopsy and subjected to targeted sequencing with a panel of 484 cancer-related genes followed by bioinformatic analysis.

Results: Sequencing revealed diverse genetic variants, and pathogenic or likely pathogenic variant were found in the KMT2C gene in 100% of the patients (KMT2C c.2961C>G, KMT2C c.8390del, KMT2C c.2578C>T, KMT2C c.2573G>T and KMT2C c.2917A>G).

Discussion: The KMT2C gene is part of the KMT2 family. Dysregulation or mutation of KMT2 family have been observed frequently in various types of human cancers including lung and colorectal cancers. Most KMT2C mutations lead to protein reduction, promoting tumorigenesis by dysregulating enhancer activity. Similar to our study, a research by Chatarina Larsson et al. found that the KMT2C variant c.8390del occurs in 25-48% of MSI CRC cases, also this variant leads to inactivation of KMT2C, promoting the development of colorectal cancer through transcriptional dysregulation in several pathways known to be involved to cancer.

Conclusion: Our findings underscore the potential of KMT2C mutations as significant contributors to cancer development and as promising targets for future therapeutic strategies. Further research is needed to fully understand the implications of these mutations in cancer progression and treatment.

P01.111.B Parafibromin immunohistochemical staining of tumors from patients with hyperparathyroidism-jaw tumor syndrome

Ana Blatnik[1], *Olga Blatnik*[2], *Primož Drev*[2], *Vita Setrajcic Dragos*[3], *Anja Zagožen Klasinc*[3], *Iva Opalič*[1], *Srdjan Novaković*[3], *Mateja Krajc*[1]

[1]*Institute of Oncology Ljubljana, Department of Clinical Cancer Genetics, Ljubljana, Slovenia;* [2]*Institute of Oncology Ljubljana, Department of Pathology, Ljubljana, Slovenia;* [3]*Institute of Oncology Ljubljana, Department of Molecular Diagnostics, Ljubljana, Slovenia*

Background/Objectives: Germline pathogenic variants (PV) in CDC73 gene are associated with hyperparathyroidism-jaw tumor syndrome (HPT-JT), characterized by parathyroid adenomas/carcinomas, ossifying fibromas of the maxilla/mandible, renal lesions, and benign and malignant uterine tumors. CDC73 encodes a putative tumor suppressor parafibromin. In our study, we assessed the results of parafibromin immunostaining of tumors from HPT-JT patients.

Methods: We identified carriers of CDC73 PVs in the Slovenian National Registry of Tested Individuals from Families with Hereditary Cancer and obtained their tumor specimens. Nuclear expression of parafibromin was assessed in tumor tissue sections using a rabbit monoclonal antibody, according to standard operating procedures.

Results: Of 3283 cancer predisposition carriers, 6 (5 female, 1 male) were carriers of *CDC73* PVs. One was asymptomatic, 3 developed parathyroid adenomas, 4 had uterine tumors, and 2 were treated for breast ductal carcinoma in situ (DCIS). Notwithstanding technical difficulties, immunostaining was successful in 1 parathyroid adenoma, 3 uterine tumors and both DSICs. Loss of parafibromin was demonstrated in the parathyroid adenoma. All 3 uterine tumors (2 fibroepithelial polyps and 1 atypical adenomyoma/adenosarcoma) showed loss of parafibromin in the mesenchymal component and normal staining in the epithelial component. Both DCIS samples had normal parafibromin expression.

Conclusion: Our parafibromin immunostaining results are compatible with what is currently known about HPT-JT tumor spectrum. Breast cancers in our patients do not appear to be associated with germline *CDC73* variants. Epithelial-mesenchymal uterine lesions displayed loss of parafibromin in the stromal component which metastasized to the lungs and proved to be fatal for one patient.

P01.112.C Functional analysis of genetic variants in genes involved in cancer helps establish pathogenicity and improves diagnostics for familial tumour syndromes.

Rick van Minkelen[1], *Mark Nellist*[1], *Marianne Hoogeveen-Westerveld*[1], *Hannie Douben*[1], *Leontine M A van Unen*[1], *Esmee Kasteleijn*[1], *Evelien Kroon*[1], *Heidi de Gruyter*[1], *Guido Breedveld*[1],

Margreethe van Vliet[1], Yvette Van Ierland[1], Berna Beverloo[1], Anja Wagner[1], Tjakko Van Ham[1]

[1]Erasmus Medical Centre, Clinical Genetics, Rotterdam, Netherlands

Background/Objectives: The identification of a pathogenic DNA variant in an individual with a genetic predisposition to cancer helps establish a diagnosis, enabling appropriate treatment and monitoring, and facilitating informed reproductive decision-making. However, in many individuals, variants of uncertain clinical significance (VUS) are identified. In these cases the genetic specialists are unable to provide the patient with certainty regarding their affection and/or carrier status.

Methods: To improve variant classification we apply in vitro functional testing to interrogate the effects of diagnostically relevant genetic variants on the expression and activity of components of the MTOR and RAS signalling pathways. Defects in MTOR or RAS signalling are common features of many sporadic tumours, and are associated with a diverse group of Mendelian disorders, particularly familial tumour syndromes such as tuberous sclerosis complex (*TSC1*, *TSC2*) and neurofibromatosis (*NF1*).

Results: Using our functional approach, we have so far been able to test >700 variants in genes involved in MTOR (AKT3, DEPDC5, MTOR, NPRL2, NPRL3, PIK3CA, PIK3R2, PTEN, TSC1 and TSC2) and RAS signalling (HRAS, NF1, SPRED1). Evidence to support pathogenicity was obtained for 73/114 clinically relevant variants in *NF1*, 63/197 in *TSC1* and 291/543 in *TSC2*.

Conclusion: Our work demonstrates that a range of specific biochemical assays can be applied in a diagnostic setting to help establish variant pathogenicity, and provide an accurate molecular diagnosis.

P01.114.A Pathogenic insertion of a mitochondrial DNA fragment in the *PALB2* gene associated with hereditary breast and ovarian cancer syndrome.

Alejandro Moles-Fernandez[1;2], *Miriam Masas[1;2], Jordi Leno[1;2], Eduard Perez[3;4], Berta Campos[1;2], Judith Balmaña[3;4], Orland Diez[1], Elena García-Arumí[1;2;5], Eduardo Tizzano[1;2]*

[1]Vall d'Hebron Barcelona Hospital Campus, Vall d'Hebron Hospital Universitari, Department of Clinical and Molecular Genetics, Barcelona, Spain; [2]Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Barcelona Hospital Campus, Vall d'Hebron Hospital Universitari, Medicine Genetics Group, Barcelona, Spain; [3]Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology, Medical Oncology Department, Barcelona, Spain; [4]Vall d'Hebron Institute of Oncology, Vall d'Hebron Barcelona Hospital Campus, Hereditary Cancer Genetics Group, Barcelona, Spain; [5]Vall d'Hebron Institut de Recerca (VHIR), Vall d'Hebron Barcelona Hospital Campus, Vall d'Hebron Hospital Universitari, Research Group on Neuromuscular and Mitochondrial Disorders, Barcelona, Spain

Background/Objectives: Hereditary breast and ovarian cancer syndrome (HBOCS) has been related to deleterious alterations in genes involved in homologous recombination, such as *BRCA1*, *BRCA2*, and *PALB2*. Point, copy number variants, and even the insertion of transposable elements, such as *Alu* sequences, have been identified as mechanisms of alteration of these, and others genes related to monogenic diseases. However, in very few cases, the insertion of mitochondrial DNA fragments (mtDNA) in coding sequences of disease-related nuclear genes has been described.

Methods: Massive parallel sequencing (MPS) of a gene panel associated with HBOCS in germline DNA was performed. The variant found was confirmed by PCR and sequencing of the DNA fragment of interest. The sequence was aligned with the nuclear and mitochondrial genome.

Results: The patient, with a family history compatible with suspected hereditary cancer, was diagnosed with invasive ductal carcinoma of the left breast at the age of 55 years. The pathogenic variant c.2515_2516ins70, p.(Thr839Ilefs*14), in the *PALB2* gene was detected in heterozygosity. This 70-nucleotide insertion was localized into exon 6 of *PALB2* and 65 nucleotides of this, were coincident with an mtDNA fragment comprising the sequence of the mitochondrial *MT-TA* gene, mitochondrial alanine tRNA.

No other pathogenic variants or variants of unknown significance were identified in the patient. Following the *ACMG* variant classification guidelines, this variant was classified as pathogenic.

Conclusion: To our knowledge, this is the first germline pathogenic variant caused by an mtDNA insertion in an HBOCS susceptibility gene.

Grants: FIS PI19/ 01772. La Marató TV3-Foundation (590/C/2020).

Conflict of Interest: None declared

P01.115.B *DDX41* germline predisposition to Myeloid Neoplasms: two siblings with the same double-hit germline/somatic non-canonical genomic constellation

Chiara Minotti[1;2], *Carmelo Gurnari[3], Giorgia Silvestrini[3], Enrico Attardi[1], Giorgia Ranucci[3], Camilla Page[3], Valentina Ferradini[1;2], Giuseppe Novelli[1;2], Maria Teresa Voso[3], Federica Sangiuolo[1;2], Enrica Marchionni[1;2]*

[1]Tor Vergata University of Rome, Medical Genetics Section, Dep. of Biomedicine and Prevention, Rome, Italy; [2]Tor Vergata Hospital, Medical Genetics Unit, Rome, Italy; [3]Tor Vergata University of Rome, Dep. of Biomedicine and Prevention, Rome, Italy

Up to 15% of Acute Myeloid Leukemia (AML) and Myelodysplastic Syndrome/Neoplasms (MDS) patients harbor inherited predisposition traits. Germline mutations of *DDX41* (MIM*608170), encoding for an RNA helicase, accounts for about 80% of MDS/AML with a documented germline predisposition. General disease ontogenesis encompasses the acquisition of a second somatic hit on the contralateral allele (most typically p.R525H). *DDX41*-mutant MDS/AML are characterized by male predominance, late onset, hypoplastic bone marrow, and indolent disease course.

We report on a 68-year old patient with an initial diagnosis of hypoplastic MDS (2% blasts). At the age of 76, he received a diagnosis of MDS-IB2 (10.5% blasts). At that time, a 94 myeloid genes NGS panel on his bone marrow aspirate detected the c.1547A>G [p.Tyr516Cys] heterozygous pathogenic variant in *DDX41* (NM_016222.4) at a Variant Allele Frequency (VAF) of 48%. Given the suspicion of a germline origin, Sanger sequencing confirmed the presence of this variants on fingernail DNA.

Notably, the patient's older brother received a diagnosis of MDS at 69 years of age. Segregation analysis, performed on DNA extracted from CD3+ lymphocytes used as a germline reference, disclosed the presence of the known heterozygous variant.

Interestingly, both siblings progressed to MDS upon acquisition of the same non-canonical *DDX41* somatic variant p.Thr227Met (VAF of 10% and 3.5%), whose functional characterization is ongoing.

Recognition of germline predisposition in MDS/AML is crucial for disease surveillance/therapy, and donor selection for hematopoietic stem cell transplantation. Genetic counselling of affected patients and their unaffected relatives is advisable to establish a proper multidisciplinary management.

P01.117.D Clinical utility of RNA-based targeted next-generation sequencing for the molecular diagnostics of non-small cell lung cancer

Magdalena Pelc[1], *Urszula Lechowicz*[1], *Joanna Moes-Sosnowska*[1], *Adam Szpechcinski*[1], *Paulina Skronska*[1], *Aneta Zdral*[1], *Adriana Rozy*[1], *Emil Wojda*[2], *Mateusz Polaczek*[2], *Małgorzata Szołkowska*[3], *Tadeusz Orłowski*[4], *Pawel Sliwinski*[5], *Reanata Langfort*[3], *Joanna Chorostowska-Wynimko*[1]

[1]*Institute of Tuberculosis and Lung Diseases, Department of Genetics and Clinical Immunology, Warsaw, Poland;* [2]*Institute of Tuberculosis and Lung Diseases, III Department of Lung Diseases and Oncology, Warsaw, Poland;* [3]*Institute of Tuberculosis and Lung Diseases, Department of Pathology, Warsaw, Poland;* [4]*Institute of Tuberculosis and Lung Diseases, Department of Surgery, Warsaw, Poland;* [5]*Institute of Tuberculosis and Lung Diseases, II Department of Lung Diseases, Warsaw, Poland*

Background/Objectives: In recent years, the number of druggable somatic alterations with relevant targeted therapeutic agents has significantly increased in non-small cell lung cancer (NSCLC). Therefore, a robust, time- and cost-effective testing methods should be applied in molecular diagnostics of NSCLC. We evaluated the utility of RNA-based targeted next-generation sequencing (NGS) for the detection of clinically significant genetic variants in NSCLC patients.

Methods: RNA-based targeted NGS (FusionPlex_Lung assay, Archer) was performed in 312 tumor specimens (~75% adenocarcinoma; mainly advanced) from 309 NSCLC patients (mean age of 71 ± 8.4 years) in search of pathogenic single nucleotide molecular variants (SNVs, including indels) and/or actionable gene fusions.

Results: Genetic changes were detected in 171 NSCLC samples (~55%) from 169 patients. Sequencing results from 14 samples (~4,5%) did not meet quality criteria for further analysis. Pathogenic SNVs were detected in 160 tumor specimens from 158 patients, including single nucleotide changes or small deletions/insertions in *KRAS* (n = 106 samples, 105 patients), *EGFR* (n = 31 samples, 30 patients), *BRAF* (n = 14), *MET* (n = 1), *RET* (n = 1) genes and splicing mutations resulting in *MET* exon 14 skipping (n = 8). In four cases a co-occurrence of two molecular variants was noted. Actionable gene fusions occurred in 11 patients, comprising *EML4::ALK* (n = 7), *CD74::ROS1* (n = 2), *SDC4::ROS1* (n = 1), *KIF5B::RET* (n = 1).

Conclusion: Targeted RNA-based NGS assay enables robust, specific and sensitive detection of the clinically relevant molecular alterations essential to predict the potential benefit of NSCLC patients from targeted therapies, as it simultaneously tests for both SNVs and gene fusions within single analysis.

Grants: IGICHP 3.3/22

P01.118.A Validation of RNA-based targeted next-generation sequencing assay for molecular variants detection in non-small cell lung cancer

Urszula Lechowicz[1], *Magdalena Pelc*[1], *Adam Szpechcinski*[1], *Joanna Moes-Sosnowska*[1], *Paulina Skronska*[1], *Adriana Rozy*[1], *Aneta Zdral*[1], *Mateusz Polaczek*[2], *Emil Wojda*[2], *Małgorzata Szołkowska*[3], *Tadeusz Orłowski*[4], *Pawel Sliwinski*[5], *Reanata Langfort*[3], *Joanna Chorostowska-Wynimko*[1]

[1]*The Institute of Tuberculosis and Lung Diseases, Department of Genetics and Clinical Immunology, Warsaw, Poland;* [2]*The Institute of Tuberculosis and Lung Diseases, III Department of Lung Diseases and Oncology, Warsaw, Poland;* [3]*The Institute of Tuberculosis and Lung Diseases, Department of Pathology, Warsaw, Poland;* [4]*The Institute of Tuberculosis and Lung Diseases, Department of Surgery, Warsaw, Poland;* [5]*The Institute of Tuberculosis and Lung Diseases, II Department of Lung Diseases, Warsaw, Poland*

Background/Objectives: The accurate molecular characterization of non-small cell lung cancer (NSCLC) is mandatory for the optimal care of patients. We have validated RNA-based targeted next-generation sequencing (NGS) assay for the detection of important genetic variants in different types of NSCLC specimens.

Methods: 379 tumor specimens from 372 patients were analyzed using the Archer FusionPlexLung (AFPL) with reference to conventional IVD qPCR and fluorescence in situ hybridization (FISH) tests and DNA-based targeted NGS assay (TruSight_Tumor15, Illumina). A minimum required number of reads per sample was 0.5 million and an Internal Sample Quality Control index ≥10.

Results: Valid molecular results were obtained in 312 NSCLC samples; 17.8% specimens did not meet the acceptance criteria either for NGS procedure or data analysis. Actionable variants were detected in 171 (54.8%) samples. Concentrations ≥10ng of RNA and Cp at PreSeq <29 were established as borderline values allowing a sample to be qualified for further NGS analyses. The validation process allowed to set the reporting thresholds for SNVs at the lowest allele frequency of ≥4,9%, with at least 10 altered reads at ≥100 reads coverage. The reporting a gene fusion at ≥10% fusion site reads and supporting reads ≥5, with unique origins ≥3 in NGS resulted in very good concordance with FISH and qPCR. The median values for Total Fragments, RNA QC and RNA fragment length were 1371234, 194 and 123, respectively.

Conclusion: RNA-based NGS offers a diagnostic solution ensuring precise identification of variants across numerous genes that hold therapeutic significance in NSCLC.

P01.119.B POU5F1B is a human-restricted ROCK inhibitor-sensitive oncoprotein that restructures membrane nanodomains to increase cell adhesion.

Laia Simó Riudalbas[1], *Sandra Offner*[2], *Abrami Laurence*[2], *Eduard Unterauer*[3], *Julien Duc*[2], *Evarist Planet*[2], *Ralf Jungmann*[3], *Alexandre Reymond*[1], *Gisou van der Goot*[2], *Didier Trono*[2]

[1]*Center for Integrative Genomics, Lausanne, Switzerland;* [2]*École polytechnique fédérale de Lausanne, Lausanne, Switzerland;* [3]*Max Planck Institute of Biochemistry, Planegg, Germany*

Background/Objectives: *POU5F1B* arose by retrotransposition of *POU5F1/OCT4* in the last common ancestor of modern hominidae. In human the encoded protein is endowed with oncogenic properties. It promotes colorectal cancer growth and metastasis. Here, we aim at investigating the molecular mechanisms by which *POU5F1B* exerts its pro-oncogenic effect.

Methods: Detergent resistant membranes (DRMs) were isolated from colorectal cancer cell lines to study cholesterol-rich nanodomains. Acyl-RAC capture assay and radiolabeling 3H-palmitic acid incorporation were used to study protein S-acylation. We used LC-MS/MS and high-resolution microscopy to investigate protein composition and cell focal adhesions, respectively.

Results: We found that the oncogenic action of POU5F1B requires ubiquitination of lysine residues present only in the human isoform. This post-translational modification is essential for POU5F1B to localize to the cytoplasm and become S-acylated by the DHHC17 S-acyltransferase. This leads to POU5F1B association with DRMs, where it triggers the accumulation of signaling molecules and integrins, thereby stimulating cell focal adhesion

and modifying the mechanic properties of cancer cells and their interactions with the extracellular matrix. The stability of POU5F1B depends on Rho-associated protein kinase (ROCK), a regulator of cytoskeletal dynamics and cell motility. Consistently, we identified ROCK inhibitors as POU5F1B destabilizers in a high-throughput drug screening.

Conclusion: We identified POU5F1B as the first ever described human-lineage specific cancer-promoting protein. It acts by an unprecedented mechanism, the remodeling of membrane nanodomains. Its action can be blocked by ROCK inhibitors. These results have interesting evolutionary and therapeutic implications.

P01.121.D DNA methylation biomarkers of thymomas and thymic carcinomas

Vanessa Nicoli[1], Marianna Giangreco[1], Eleonora Pardini[1], Iacopo Petrini[1], Diana Bacchin[2], Vittorio Aprile[2], Franca Melfi[3], Marco Lucchi[2], Roberta Ricciardi[4], michelangelo maestri[4], Andrea Stoccoro[1], Lucia Migliore[1], **Fabio Coppedè**[1]

[1]University of Pisa, Translational Research and of New Surgical and Medical Technologies, Pisa, Italy; [2]University of Pisa, Division of Thoracic Surgery, Dept. of Surgical, Medical and Molecular Pathology and Critical Care Medicine, Italy; [3]University Hospital of Pisa, Minimally Invasive and Robotic Thoracic Surgery, Robotic Multispecialty Center of Surgery, Italy; [4]University of Pisa, Neurology Unit., Dept. of Clinical and Experimental Medicine, Italy

Background/object: Thymic epithelial tumors (TETs) are the most frequent neoplasms of the anterior mediastinum and include thymomas (TMs), thymic carcinomas (TCs), and rare neuroendocrine tumors. Epigenetic modifications are increasingly observed in these tumors, indicating the need for further characterization of their distribution among different subtypes, stages and histotypes.

Methods: We reviewed the literature related to DNA methylation studies in TETs, including candidate gene association studies and genome-wide investigations. We then designed a panel of genes among the most promising epigenetic biomarkers of TETs and evaluated their methylation levels in 71 bioptic TET samples consecutively collected over a 3-year period, including 64 TMs and 7 TCs. Blood samples were collected at thymectomy from each patient and screened for peripheral epigenetic biomarkers of TET subtypes.

Results: TCs showed hypermethylation of *GHSR* and *ELF3* genes and reduced *IL1RN* methylation levels compared to TMs. We also observed a significant hypomethylation of the *RAG1* promoter region in TMs, but not in TCs, compared to healthy thymic tissues. No difference in the methylation levels of the investigated genes was seen among TM stages and subtypes. No changes in the blood methylation levels of the investigated genes were seen among TET subtypes.

Conclusion: The present study revealed TET methylation biomarkers and a set of genes that can discriminate between TMs and TCs.

P01.123.B Identification and validation of new DNA methylation panels for the differentiation between hepatocellular carcinoma and cholangiocarcinoma

Tina Draškovič[1], *Nina Hauptman[1]*

[1]Institute of Pathology, Faculty of Medicine, University of Ljubljana, Department of Molecular Genetics, Ljubljana, Slovenia

Background/Objectives: Differentiating between hepatocellular carcinoma (HCC) and cholangiocarcinoma (CCA) is sometimes challenging. The aim of our study was to identify and validate novel DNA methylation biomarkers and to develop panels that can differentiate between HCC, CCA and their paired normal tissue.

Methods: Using bioinformatics, we identified new differentially methylated promoter regions and designed panels for the diagnosis and differentiation between HCC and CCA. DNA was isolated from formalin-fixed, paraffin-embedded tissue samples of 15 HCC, 15 CCA and their paired normal tissue. After DNA isolation and DNA bisulfite conversion, the methylation status of the selected regions was determined by dPCR. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated based on the hyper- or hypomethylation of each sample.

Results: The design panel for HCC includes the promoter regions of the genes RNF135 and EFNB2, which successfully differentiate HCC from CCA with a sensitivity of 87%, a specificity of 100%, a PPV of 1 and an NPV of 0.88. The design panel for CCA includes the promoter regions of the genes RNF125, HOXC4 and ABLIM1, which differentiate CCA from HCC with a sensitivity of 67%, a specificity of 100%, a PPV of 1 and an NPV of 0.75. Both panels are 100% cancer specific.

Conclusion: Our results show that the DNA methylation status of the selected promoter regions and the designed panels successfully diagnose and differentiate HCC and CCA with high sensitivity, specificity, PV and NPV and are cancer specific.

Grants: Slovenian Research and Innovation Agency (P3-0054, J3-3070 and PhD research funding).

P01.124.C Genetic landscape of hereditary hematological malignancies (HHM) in adults

Dora Csaban[1], *Livia Varga[1], Zoltan Orfi[1], Lenke Tanko[1], Nora Kondor[1], Andras Bors[1], Jozsef Harasztdombi[1], János Dolgos[1], Judit Reichardt[1], Beata Koller[1], János Fábián[1], Andrea Varkonyi[1], Viktor Lakatos[1], Laszlo Gopcsa[1], Valyi-Nagy Istvan[1], Peter Remenyi[1], Hajnalka Andrikovics[1]*

[1]Central Hospital of Southern Pest, National Institute of Hematology and Infectious Diseases, Budapest, Hungary

Background: Due to advancements in sequencing technologies, more insights are gained in the background of hereditary hematological malignancies (HHM), which were recently recognized as novel clinical entity in WHO and European LeukemiaNet Classifications.

Methods: Peripheral blood or bone marrow samples were used for isolation of tumour derived DNA from 455 patients with haematological malignancy (ALL, AML, MDS, MPN). Next generation sequencing (NGS) targeted panel contained genes associated with somatic and germline hematologic malignancies. The

presumed germline pathogenic variants were confirmed by Sanger sequencing from independent samples (hair follicles or potential hematopoietic stem cell donor family members).

Results: In our study with 'tumour only' testing strategy, 58 variants were presumed to be hereditary pathogenic alterations, of which were confirmed in 9 cases (1.98%): DDX41 (n = 3), RUNX1 (n = 3), TP53 (n = 1), TERT (n = 1), PTPN11 (n = 1). With the exception of DDX41 (age at diagnosis: 60-69 year), HMM patients were younger than average patients with haematological malignancies (17-49 years). All patients showed unobtrusive personal and family history without any malignancies. Cascade screening of family members identified carrier status in 16 out of 50 cases, and no clinical symptoms were observed in several older relatives.

Conclusion: Our results highlight that HHM occurs not only in young individuals. The prevalence of HMM might be underestimated due to its low penetrance. Germline genetic information influence the choice of targeted therapy and the selection of hematopoietic stem cell donor from the family. Additionally, it draws attention to the inclusion of asymptomatic carrier relatives in hematological/oncological care.

P01.125.D A Novel Association Of *CHEK2* Splice Site Mutation With Early Onset Gastric Cancer

AHMED AL-OMAR[1], Süleyman Alıcı[2], **İlknur Sunar**[1]*, Ayse Busra Akalin[3], Ibrahim Akalin[1]*

[1]Metagentech Center for Genetic Diseases, istanbul, Türkyie; [2]Hisar Intercontinental Hospital, Medical Oncology, istanbul, Türkyie; [3]Bahcesehir University, Faculty of Medicine, istanbul, Türkyie

Background/Objectives: *CHEK2* is a tumor suppressor gene that arrests cell cycles and leads to apoptosis after DNA damage. Germline mutations in *CHEK2* gene increase risk for breast and other types of cancer. There are different types of pathogenic variants such as short insertions/deletions, single nucleotide variations, large genomic rearrangements, and splicing variants.

Methods: A 31-year-old female patient with a history of gastric cancer was admitted to the hospital and operated for total gastrectomy. Pathological evaluation revealed T4N3 MSI stabile, lymph node and extra peritoneal metastatic adenocarcinoma. Biochemistry laboratory results showed elevated levels of ALT, AST, GGT and alkaline phosphatase. The patient received 6 cycle FLOT chemotherapy. External radiotherapy was applied with capecitabine. The patient was referred for genetic testing for hereditary cancer genes.

Result: Exome sequencing analysis revealed unknown significance of c.-185-6del heterozygous splice site mutation in *CHEK2* gene, responsible for autosomal dominantly inherited "Cancer Predisposition Syndrome, *CHEK2*-related, Li-Fraumeni Syndrome 2, AD(?) [MIM#609265]".

Conclusion: The mutation was identified in gnomAD database and splice site *CHEK2* mutations were attributed to be responsible for gastric cancer development under 55-year-old patients. Here we for the first time report a *CHEK2* splice site variation (c.-185-6del) supposed to be pathogenic in gastric cancer patients up to date.

P01.126.A Harnessing cDNA analysis to enhance variant classification in cancer predisposition genes

Liesbeth Claeys[1;2]*, Suzanne Vanhauwaert[1;2;3], Annelies De Jaegher[1;2], Kim De Leeneer[1;2;3], Bram Parton[1;2], Ilse Coene[1;2], Martine De Bleeckere[1;2], Katia De Pauw[1;2], Arne De Visscher[1;2], Elke D'Haese[1;2], Tjoïlina Reyniers[1;2], Hélène Verhaeghe[1;2], Bruce Poppe[1;2;3], Robin de Putter[1;2;3], Kathleen Claes[1;2;3]*

[1]Ghent University Hospital, Center for Medical Genetics Ghent, Ghent, Belgium; [2]Ghent University, Department of Biomolecular Medicine, Ghent, Belgium; [3]Ghent University and Ghent University Hospital, Cancer Research Institute Ghent (CRIG), Ghent, Belgium

Background/Objectives: In clinical practice a panel of 107 genes linked to familial cancer syndromes, comprising various subpanels tailored to clinical requests, is routinely employed. This study aims to assess the utility of cDNA analysis in enhancing molecular diagnostics.

Methods: SeqCap EZ HyperCap technology was applied for target enrichment, followed by NovaSeq6000 sequencing. Digital MLPA and ExomeDepth were utilized for exon-level CNV detection. RNA extraction from short term lymphocyte cultures, supplemented with puromycin as an NMD inhibitor, enabled RT-PCR and Sanger sequencing. A total of 44 cases spanning 16 genes were investigated.

Results: Among 9871 patients screened, (likely) pathogenic variants (class 4/5) were detected in 10% (n = 1038), with 6% (n = 585) harboring variants of unknown clinical significance (VUS, class 3).

Algorithms predicted aberrant splicing for 25 variants, with 12 corroborated by cDNA-analysis, upgrading them to class 4. Nine variants were downgraded to class 2 while 4 others remained class 3. Notably, an aberrant transcript was confirmed in 4 cases with an SVA element insertion in *PMS2*. Twelve exon CNVs were further investigated by cDNA testing. Only one of five affecting PMS2 exons 13-15 was confirmed. Four exon-CNVs in other genes were confirmed. In three other cases cDNA analysis discerned disease relevant from pseudogene artifacts.

Conclusion: We demonstrate the multifaceted benefits of cDNA analysis in familial cancer syndrome diagnostics: it enhances variant classification, validates exon CNVs, and distinguishes gene sequences from (non-expressed) pseudogenes. The integration of cDNA analysis enriches the molecular diagnostic arsenal, refining patient management strategies.

Background/Objectives: Lynch Syndrome is the most common form of hereditary colon cancer, caused by germline mutations in four genes of the DNA-mismatch repair pathway (*MLH1*, *MSH2*, *MSH6* and *PMS2*). Current diagnostic approaches identify causative genetic variants in less than 50% of cases. We present an unsolved case from an Equatorian family with Lynch-like syndrome, with tumor loss of *MLH1* and *PMS2* expression and *BRAF* wild-type, and a familial history of colorectal and stomach cancer, but no underlying genetic variants detected through standard diagnostic tests.

Methods: We performed germline whole-genome sequencing (WGS) of DNA from blood samples of two siblings to identify the causative mutational event. To further underpin the molecular mechanism involved, subsequent transcriptome sequencing (RNA-seq) and quantitative PCR in one of the siblings was performed.

Results: In both siblings, a tandem duplication of 37 kilobases was found in the *LRRFIP2* gene, contiguous to *MLH1*. RNA-seq data confirmed an altered expression of *LRRFIP2* and *MLH1*. Results were validated with a quantitative PCR for both genes.

Conclusions: WGS allowed the identification of a duplication in the *LRRFIP2* gene that affects the expression of *MLH1*, explaining the clinical presentation of the patient and their family. This case highlights the added value of using WGS and RNA-seq to current standard diagnostic approaches to help solve cases that present with complex genomic rearrangements that otherwise would have not been detected with current genetic testing.

Background/Objectives: Glioblastoma (GBM) represents the most aggressive form of nervous system cancer. The objectives of this pilot study were to characterize the genomic profile of GBM tumor tissue samples and to investigate the potential of liquid biopsies for diagnosing and monitoring patients.

Methods: A total of 110 samples of plasma were collected from 45 GBM patients before and during treatment. Plasma samples from 10 controls were also collected. After isolating cfDNA, concentrations were determined, compared between patients and controls, and monitored throughout the patients' clinical course. Tumor tissue samples were analyzed using array Comparative Genomic Hybridization (aCGH).

Results: aCGH analysis showed frequent gains and losses of chromosomes 1, 4, 5, 6, 7, 8, 9, 10, 12, 15, 16, 17, 20, 21, 22, and Y. Amplifications involving the *EGFR* and *MET* genes and deletions of *CDKN2A*, *PTEN*, *RB1* and *NF1* were common alterations observed in our cohort. The levels of plasma cfDNA revealed that GBM patients have higher plasma baseline cfDNA levels than healthy controls. In some of the patients a substantial increase in plasma cfDNA levels was observed during follow up, which is being correlating with clinical events.

Conclusion: Our findings demonstrate the feasibility of isolating cfDNA from the plasma of GBM patients. Furthermore, monitoring cfDNA levels during treatment may provide valuable insights into disease progression and treatment response. Integrating the analysis of liquid and tissue biopsies enables a comprehensive characterization of the tumor profile. A larger cohort and an extended follow-up period are required for further validation.

P01.129.D Rare variants modulate phenotype in NF1 carriers'

Elena Pasquinelli[1;2], **Chiara Fallerini**[2;3]*, Samantha Minetto[2;3], Giulia Rollo[2;3], Margherita Baldassarri[2;3;4], Alessandra Renieri[2;3;4]*

[1]Medical Genetics, University of Siena, Italy, Department of Medical Biotechnologies, Siena; [2]Med Biotech Hub and Competence Center, Department of Medical Biotechnologies, University of Siena, Siena, Italy, Department of Medical Biotechnologies, Siena, Italy; [3]Medical Genetics, University of Siena, Italy, Department of Medical Biotechnologies, Siena, Italy; [4]Genetica Medica, Azienda Ospedaliera Universitaria Senese, Siena, Italy, Siena, Italy

Background/Objectives: Neurofibromatosis type 1, is a rare genetic disorder predisposing to a pleiotropic phenotype ranging from psychosocial issues, congenital malformations, benign tumors of the nervous systems or aggressive solid cancer. We hypothesize that this phenotypic variability is due to additional rare variants in other genes, acting as an oligogenic threshold model.

Methods: Clinical and Exome sequencing data were retrieved in a retrospective nested-study from 32 patients with pathogenic/like pathogenic NF1 variants.

Results: NF1 carriers with solid cancers show a mean of 4.12 variants in cancer driver genes per subject while NF1 carriers without solid cancers have 2.16 variants per subject with Mann-Whitney test significant at $p < 0.05$. Furthermore, we present that less frequently (macrocephaly or cognitive disorder) or rarely (connective disorder or polydactyly) ancillary characteristics could be linked to rare variants in additional genes. NF1 carriers with cognitive impairment have a mean of 2.7 additional variants, with at least one of them being a P/LP variant in a well known dominant neurodevelopmental disorder gene. In inherited cases, we detect in probands that NF1 inherited variant combined with other rare variants inherited from both parents act reinforcing the NF1 susceptibility with an additive trend.

Conclusion: In conclusion, we have highlighted that rare variants may modulate phenotypic outcome in neurofibromatosis. These results are relevant for both clinical policy and clinical practice: we propose to use the rare variant capture for amelioration screening program in NF1 carriers and identification of specific gene cards for personalized treatment.

Conflict of Interest: None declared

P01.130.A Germline testing for patients with pancreatic adenocarcinoma: a retrospective study in the department of genetics at Amiens University Hospital, France

Luana Giovannangeli[1]*, Emilie Lacot-Leriche[1], Gilles Morin[1], Bénédicte Bonte[1], Florence Amram[1], Florence Jobic[1], Emma Lachaier[1]*

[1]CHU Amiens-Picardie, Genetics, Amiens, France

Background/Objectives: In 2019, the American Guidelines recommended universal germline testing for patients with Pancreatic Cancer (PC). Literature reports pathogenic variations in 10-15% of PC. In France, due to limited access to oncogenetics, germline testing is usually restricted to patients with familial history, age under 50 years or somatic alteration in *BRCA* which can lead to PARP-inhibitor therapy. In our department, we applied universal testing. This study aimed to determine the benefit of universal germline testing compared to French practices.

Methods: We conducted a retrospective study (2022-2023) in our department of genetics in Amiens, France. Patients with pancreatic adenocarcinoma (locally advanced or metastatic) regardless of familial history or age were included. The analyzed genes were, at least: *EPCAM, ATM, BRCA1, BRCA2, TP53, PALB2, CDKN2A/p14, CDKN2A/p16*, and MMR ones.

Results: Among 45 patients, one was excluded (neuroendocrine cancer). According to American Guidelines: 5 had pathogenic variations (1 *BRCA1*, 3 *BRCA2, 1 ATM*), 11 had variants of unknown significance (VUS) and 28 had negative testing. According to French practices, 8 had criteria for germline testing. Among them, 1 had pathogenic variation (*BRCA2*), 3 VUS, and 4 negative results.

Conclusion: According to French practices, 4 pathogenic variations would not have been highlighted. Despite a restricted panel of genes with follow-up recommendation compared to the American panel, the rates of pathogenic variants and VUS remain high. Our study confirms the relevance of universal testing for PC. Universal testing improves analytical performance but also increase consultation activity, approximatively 20 per year in our department.

Conflict of Interest: None declared

P01.132.C The advantage of targeted next-generation sequencing over qPCR in testing for druggable *EGFR* variants in non-small cell lung cancer

Adam Szpechcinski[1], *Joanna Moes-Sosnowska[1], Urszula Lechowicz[1], Paulina Skronska[1], Magdalena Pelc[1], Małgorzata Szołkowska[2], Emil Wojda[3], Piotr Rudzinski[4], Krystyna Maszkowska-Kopij[5], Mateusz Polaczek[3], Renata Langfort[2], Pawel Sliwinski[6], Tadeusz Orłowski[4], Joanna Chorostowska-Wynimko[1]*

[1]The Institute of Tuberculosis and Lung Diseases, Department of Genetics and Clinical Immunology, Warszawa, Poland; [2]The Institute of Tuberculosis and Lung Diseases, Department of Pathology, Warszawa, Poland; [3]The Institute of Tuberculosis and Lung Diseases, III Department of Lung Diseases and Oncology, Warszawa, Poland; [4]The Institute of Tuberculosis and Lung Diseases, Department of Thoracic Surgery, Warszawa, Poland; [5]The Institute of Tuberculosis and Lung Diseases, Outpatient Clinic, Warszawa, Poland; [6]The Institute of Tuberculosis and Lung Diseases, II Department of Lung Diseases, Warszawa, Poland

Background/Objectives: Targeted therapies in non-small cell lung cancer (NSCLC) are dedicated to patients with tumors exhibiting features of oncogene addiction, including activation of epidermal growth factor receptor (EGFR) by SNVs/indels in exons 18-21 of the gene. Nowadays, diagnostic techniques based on qPCR and direct DNA sequencing are being replaced by next-generation sequencing (NGS) for actionable variants detection. In this study, we evaluated the diagnostic usefulness of targeted NGS panel for druggable EGFR variants testing in clinical NSCLC material previously analyzed by IVD-certified qPCR test with respect to DNA reference material.

Methods: The *EGFR* variants were tested in tumor tissue specimens from 59 NSCLC patients by the NGS 'TruSight Tumor 15' assay (Illumina) and the qPCR 'Cobas EGFR mutation test' (Roche Diagnostics). The sensitivity and specificity of NGS assay were evaluated using the biosynthetic and biological DNA reference material with known allelic frequencies (VAF) of *EGFR* variants.

Results: In DNA reference material, NGS assay demonstrated sufficient lower detection limit for diagnostic applications (VAF < 5%); all *EGFR* variants were correctly identified. NGS showed high repeatability of VAF assessment between runs (CV% from 0.02 to 3.98). In clinical material, the overall concordance between NGS and qPCR was 59%. The majority of discordant results concerned false-positive detection of *EGFR* exon 20 insertions by qPCR. *TP53* was frequently co-mutated gene in *EGFR*-positive NSCLC patients.

Conclusion: The NGS showed a number of superior features over the qPCR in *EGFR* variant detection (exact identification of *EGFR* variants, calculation of allelic frequency, high analytical sensitivity) which might enhance the basic diagnostic report.

Conflict of Interest: None declared

P01.134.A Exome sequencing identifies candidate genes for platinum response in ovarian cancer patients

Lisa-Marie Speith[1], *Lara Thomys[1], Donna-Lucil Sperber[1], Peter Schürmann[1], Dhanya Ramachandran[1], Robert Geffers[2], Britta Wieland[1], Mu Yang[1], Kristine Bousset[1], Clemens Liebrich[3], Tjoung-Won Park-Simon[1], Peter Hillemanns[1], Thilo Dörk[1]*

[1]Hannover Medical School, Gynaecology Research Unit, Hannover; [2]Helmholtz Institute for Infection Research, Genome Analytics, Braunschweig, Germany; [3]Wolfsburg Clinics, Gynaecology and Obstetrics, Wolfsburg, Germany

Background/Objectives: Carriers of pathogenic germline variants in BRCA1 or BRCA2 have an improved response after standard platinum treatment for ovarian cancer. In the present study we used genomic DNA from long-term survivors to identify and characterize additional genes that may be involved in the development of an extraordinary platinum response.

Methods: We performed exome sequencing in 30 selected patients with high-grade serous ovarian cancer who responded particularly well to carboplatin chemotherapy and were alive and tumor-free more than two years after the end of therapy. Candidate genes harboring truncating variants were ranked through pathway enrichment analyses and literature search. Selected candidate genes were further investigated through silencing or inhibitor studies in different ovarian cell lines using flow cytometry and survival assays.

Results: We identified truncating germline variants in nine genes associated with DNA replication in 7/30 patients (23%). Four of the nine genes were also known to be involved in R-loop suppression. Analyses of large case-control sequencing data sets indicated that none of them was associated with overall risk for ovarian cancer. In functional studies using a pair of platinum-sensitive and platinum-resistant A2780 cell lines, the inhibition or down-regulation of two of the candidate genes modulated platinum response and differentially induced cell death.

Conclusion: Germline variants in replication-associated genes may contribute to the platinum sensitivity of tumors in long-survivors. Inhibition of such genes may open an avenue for improving platinum therapy in patients with resistant tumors.

Grants: Supported by the German Research Foundation (Do761/15-1).

[1]*University of Cagliari, Medical Genetics, Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy;* [2]*University of Cagliari, Centre for Research University Services (CeSAR, Centro Servizi di Ateneo per la Ricerca), University of Cagliari, Monserrato (CA), Italy;* [3]*University of Cagliari, Unit of Oncology and Molecular Pathology, Department of Biomedical Sciences, University of Cagliari, Cagliari, Italy;* [4]*Medical Genetics, R. Binaghi Hospital, Local Public Health and Social Care Unit (ASSL) of Cagliari, Cagliari, Italy;* [5]*UO of Hematology and Bone Marrow Transplant Centre, A. Businco Hospital, Cagliari, Italy*

Background/Objectives: multiple myeloma (MM) is a hematologic disease caused by clonal proliferation of plasma cells. We examined the genetic aspects of MM, including sequence-related genetic alterations and genomic instability, to demonstrate the superiority of sWGS, a high-throughput technology, as a valid alternative compared to classical cytogenetics. Indeed, although FISH is the current gold standard to detect cytogenetic events in MM, it is costly, labor-intensive and does not show the exact genomic background of this disorder.

Methods: we analyzed 100 patients at various stages of MM. We performed SNP-array and FISH to detection of copy number aberrations (CNA) and balanced translocations, respectively. Additionally, we performed sWGS (0.1X) and WES on each sample.

Results: SNP-arrays suggested genomic instability in approximately 30% of patients, often associated with gain-of-function variants in several oncogenes (*NRAS, KRAS, BRAF*) and loss-of-function variants in *TP53*, directly related to the risk of progression, survival, and resistance to therapy. Moreover, we detected variants in *DNMT3A* gene correlated with tumor progression. Furthermore, sWGS detected CNA and LOH with superior sensitivity compared to array and, with a specific bioinformatic pipeline, was able to identify balanced translocations, demonstrating sWGS is superior to FISH, which is not able to identify all CNA and LOH.

Conclusion: sWGS has proven to be a superior method for identifying biallelic events and rearrangements with heterogeneous breakpoints. WES and sWGS, to be used as a first diagnostic approach, can be helpful in addressing various aspects related to targeted therapy, therapy failure and relapse, providing crucial information on clinical decision-making.

Conflict of Interest: None declared

P01.136.C Whole Exome Sequencing (WES) and Shallow Whole Genome Sequencing (sWGS) of tissue and Cell-Free DNA (cf-DNA) for the assessment of Homologous Recombination Deficiency (HRD) in Ovarian Cancer

[1]*University of Cagliari, Medical Genetics, Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy;* [2]*University of Cagliari, Centre for Research University Services (CeSAR, Centro Servizi di Ateneo per la Ricerca), University of Cagliari, Monserrato (CA), Italy;* [3]*Medical Genetics, R. Binaghi Hospital, Local Public Health and Social Care Unit (ASSL) of Cagliari, Cagliari, Italy;* [4]*Unit of Oncology and Molecular Pathology, Department of Biomedical Sciences, University of Cagliari, Cagliari, Italy*

Background/Objectives: pathogenetic variants in the genes *BRCA1/BRCA2* have a significant role in developing ovarian cancer (OC) and are essential for genome integrity by repairing double-stranded DNA breaks via the homologous recombination repair (HRR) pathway. Our aim is to identify whether the HR disruption correlates with oncogene alterations and, ideally, with therapy responses.

Methods: a total of 96 women affected by OC (13 in paclitaxel-platinum with or without bevacizumab, 3 in PARP-inhibitors) were enrolled. We performed: on 66 samples a multigene panel on FFPE tissue and HRS-test to identify HRD; on 30 samples WES (germinal and somatic) and SNP-array; on all 96 samples shallow whole-genome sequencing (sWGS), which results were compared to the reference assay SOPHiA. Furthermore, sWGS was also performed on cf-DNA in 50 cases.

Results: we found germinal variants in *BRCA1/BRCA2* on 5.21% and 6.25% of subjects, respectively. Moreover, we detected several variants in suppressor genes and oncogenes, including mismatch repair (MMR) genes, likewise causative variants in HRR-related genes like *BARD1* (2,08%), *ATM* (2,08%), *CHEK2* (1,04%). Somatic pathogenic variants were: 71,88% in *TP53*, 16,67% in *BRCA1* and 11,46% in *BRCA2*. Almost all cases (98%) presented genomic instability highlighted both on tissue and cf-DNA.

Conclusion: *BRCA1/BRCA2* mutation status is the main genetic biomarker of HRD but is not sufficient to describe the total HRD status, which can be driven by somatic events and further genetic alterations. Therefore, a bioinformatics pipeline to evaluate the HRR system status in OC has been set, based on sWGS, to support therapeutics and follow-up strategies.

P01.137.D Rare Capillary Malformation-Arteriovenous Malformation Syndrome (CM-AVM): Intrafamilial phenotypic heterogeneity

stavroula psoni[1], *STYLIANI AMENTA*[2], *Emmanouel Manolakos*[3], **Eirini Tsoutsou**[4], *Christina Kanaka-Gantenbein*[5], *HELEN FRYSSIRA*[6]

[1]*Pediatrician-Medical Geneticist, Private Practice;* [2]*MITERA Maternity Hospital, Clinical Genetics;* [3]*ATG-Access to Genome Labs, Athens, Greece;* [4]*General Hospital of Athens "G. Gennimatas", Thalassemia Unit;* [5]*"Aghia Sofia" Children's Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece, Pediatrics-Pediatric Endocrinology, First Pediatric Clinic;* [6]*Medical School, National and Kapodistrian University of Athens, Greece, Medical Genetics*

Background/Objectives: Capillary Malformation-Arteriovenous Malformation Syndrome (CM-AVM) (OMIM:608354) syndrome is a rare autosomal dominant genetic disease characterized by broad phenotypic variability and caused by mutations in the *RASA1* gene (p210RasGAP-protein-activator-1). CM-AVM comprises a wide phenotypic spectrum with atypical capillary and fast-flow vascular malformations being the most prominent clinical features. The CMs are usually multifocal and surrounded by pale halo with central red dot and can be observed in the brain, face or extremities. We describe a new CM-AVM case.

Methods: The 3.5 year-old female proband was offspring of non-consaguineous parents and presented with short stature, lordosis, genu valgum, macrocephaly and multiple nodular macule like café-au-lait skin lesions on the trunk and extremities. The family history revealed propensity for malignancies on the maternal ancestors. Hormonal, biochemical testing and internal organs imaging were normal. The karyotype was 46, XX.

Whole Exome Sequencing (WES) was subsequently performed on DNA extracted from the proband and her parents after obtaining signed informed consent, using standard procedures.

Results: WES identified in heterozygous state the *RASA1* mutation c.261_262del (p.Gly89ArgfsTer22) which comprises a 2bp deletion at exon-1 leading to frameshift and premature stop codon. The proband's mother was a carrier, although not presenting any skin lesions.

Conclusion: Upregulation of the Ras/MAPK signaling pathway, caused by haploinsufficiency of the Ras21-protein-activator-1, disrupts the normal growth regulation, cell differentiation and proliferation which in turn leads to angiogenesis overdrive. Given the CM-AVM phenotypic variability, clinical genetic evaluation and testing is essential for the diagnosis, follow-up and counseling of the patients and their families.

Background/Objectives: We previously demonstrated that carriers of *CTNNA1*-truncating variants present increased lifetime-risk of developing diffuse gastric cancer (DGC). These carriers are 14-fold more likely to develop DGC than carriers of *CTNNA1*-missense variants. Herein, we aim at understanding if *CTNNA1* germline transcripts bearing premature termination codons (PTC) are targeted for nonsense-mediated mRNA decay (NMD), and to disclose the transcriptomic profile of CTNNA1-deficient tumors.

Methods: We CRISPR/Cas9 edited gastric cancer cell lines mimicking CTNNA1 truncating variants (CTNNA1-PTC) and assessed whether NMD is triggered, and obtained the transcriptomic profile of CTNNA1-deficient DGC tumors using RNA-seq from CTNNA1 germline carriers.

Results: CTNNA1-PTC cells lose CTNNA1/ αE-catenin mRNA/ protein expression. NMD blockade significantly increased (~13-fold) their CTNNA1 mRNA expression, compared to untreated cells. As CTNNA1 expression recovered wild-type mRNA levels, NMD is likely the mechanism responsible for CTNNA1 mRNA decay. Immunohistochemistry showed αE-catenin protein loss in DGC tumors, but not in normal tissue. Transcriptome analysis of 11 DGC tumors revealed 14 significantly downregulated and 940 upregulated genes in comparison to matched normal tissue ($p < 0.01$; differential expression: 2-fold increase/decrease in tumors *vs* normal). Upregulated signaling pathways involve cell adhesion, actin cytoskeleton, cell migration, angiogenesis and

immune response, as well as JAK/STAT, EGFR or TGF-β oncogenic pathways.

Conclusion: We demonstrated that NMD acts over CTNNA1 PTC-bearing transcripts, being responsible for mRNA decay of germline mutant alleles. CTNNA1-mutant tumors present a transcriptional landscape recapitulating the behavior of poorly cohesive, invasive, proliferative and migratory cancers. *CTNNA1*-deficient DGC overexpress molecules and pathways worth exploring as therapy targets.

P01.139.B Challenges of multigene panel testing of breast cancer patients in Turkey

Deniz Agirbasli[1], *Mehmet Erinc Onal*[2], *Didem Gulhan*[2], *Aysel Kalayci*[1]

[1]*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Medical Genetics, Istanbul, Türkyie;* [2]*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, Türkyie*

Background/Objectives: Hereditary breast cancer represents 5-10% of all breast cancer cases. Germline pathogenic/likely pathogenic (P/LP) variants in *BRCA1/2* genes are responsible for only 15% of the familial cases. Next-generation sequencing (NGS) based-multigene panels for detecting germline variants have emerged as a valuable tool in genetic assessment.

Methods: The multigene NGS panel results of 207 women with breast cancer who applied to our center between 2021-2022 were analyzed retrospectively.

Results: The mean age of cases at diagnosis was 45,93 ± 9,98. Out of 180 patients, the most common histologic types were ductal (n = 150, 83%) and lobular carcinoma, respectively (n = 15, 8,3%), followed by mixed type (n = 8, 4,4%), tubular (n = 4, 2,2%), mucinous (n = 2, 1,1%), metastatic spindle cell carcinoma (n = 1, 0,5%). No identifiable variants were detected in 110 patients (53%). Number of pathogenic variants detected were 24 (11,5%), variants of uncertain significance (VUS) were 61 (29,5%), and likely pathogenic variants were 14 (%6,7). 19 patients carried multiple variants (9,1%). Most common P/LP mutations were detected in *CHEK2* (n = 8, 3.8%), *BRCA1* (n = 6, 2,8%), *BRCA2* (n = 6, 2.8%), *ATM* (n = 4, 1.9%), *PALB2* (n = 3, 1,4%) genes followed by *BARD1, BRIP1, XRCC2, RAD50, NBN, BLM*.

Conclusion: The results of multigene panels will diversify genetic counseling as well as prevention and treatment selection. Although no clinical decisions can be made on the basis of variants of uncertain significance, genetic re-evaluation should be performed at regular intervals, and functional studies should be performed. Current family history risk assessment tools must be improved for patients with a strong family history of cancer as in our cohort.

Background/Objectives: The *CDKN2A/2B* gene is a tumor suppressor and its deletion is one of the most frequent events in acute lymphoblastic leukemia (ALL), acting as a secondary cooperating factor and playing a critical role in cell cycle regulation and chemosensitivity. *CDKN2A/B* deletions are detected in approximately 20-25% of pediatric B-cell precursor ALL cases and 40-50% of T-cell precursor ALL patients. It is indicative of poor prognosis in pediatric and adult B-ALL. We present the incidence of deletions in *CDKN2A/2B* and other specific genetic alterations in ALL key-genes in a Portuguese cohort of pediatric ALL used for risk stratification.

Methods: 105 ALL samples were analyzed by Array Comparative Genomic Hybridization combined with Single Nucleotide Polymorphism array (SNPa). The analysis included the evaluation of ploidy, whole-genome alterations, loss of heterozygosity and copy number alterations affecting ALL critical genes, including *CDKN2A/B*.

Results: The results of our study demonstrate that the most frequent genetic alteration was the deletion of the *CDKN2A/B* gene, present in 34% of the samples, followed by deletions in *ETV6*, *PAX5* and *EGR*. *CDKN2A/B* homozygous deletion is more prevalent than heterozygous deletion present in 23% of the cases. On the other hand, is relevant that in 64% of the cases in which the *CDKN2A/B* deletion was found, another genetic alteration was present (*PAX5* or *ETV6* deletion).

Conclusion: The presence of *CDKN2A/2B* homozygous deletions can represent a new ALL subgroup, with different outcomes. Risk stratification considering new sub-groups of genetic alterations, can improve survival rates and therapeutic response.

P01.141.D Next generation sequencing results in acute myeloid leukemia diagnostics

Zoltan Orfi[1], Dora Csaban[1], Andras Bors[1], Livia Varga[1], Nora Meggyesi[1], Lenke Tanko[1], Adrienn Borsy[1], Andras Kozma[1], Nora Kondor[1], János Dolgos[1], Laszlo Gopcsa[1], Jozsef Harasztdombi[1], Viktor Lakatos[1], Gabor Mikala[1], Judit Reichardt[1], János Fábián[1], Peter Remenyi[1], Valyi-Nagy Istvan[1], Hajnalka Andrikovics[1]

[1]Central Hospital of Southern Pest, National Institute of Hematology and Infectious Diseases, Budapest, Hungary

Background/Objectives: Acute myeloid leukemia (AML) is a genetically heterogeneous clonal disorder of myeloid stem cells. In favor of increasing the precision of diagnosis, prognosis and in order to select most suitable targeted therapy, a comprehensive genetic mutation screening for acquired genetic abnormalities is necessary. Massively parallel sequencing effectively enables the identification of measurable residual disease marker(s). According to international recommendations (ELN, NCCN) more than 30 genes should be screened besides recurrent cytogenetic abnormalities.

Methods: At our institute, 175 bone marrow samples from AML patients were analyzed by cytogenetics and next-generation sequencing (NGS targeted panel of 23-68 genes or WES).

Results: Recurrent cytogenetic abnormalities were detected in 20 cases [t(15;17)(q24.1;q21.2)/PML::RARA; t(8;21)(q22;q22.1)/RUNX1::RUNX1T1; inv(16)(p13.1q22)/CBFB::MYH11; t(11q23;v)/KMT2A; inv(3)(q21.3q26.2)/MECOM]. Recurrent WHO defining genetic mutations were found in CEBPA (n = 6; 3%), NPM1 (n = 67; 38%) in normal karyotype AML. Mutations in TP53 (n = 10; 6%), in MDS related mutations (n = 48; 27%) or MDS type cytogenetics (n = 4; 2%) were also observed. No WHO defining category were identified in 20 cases (11%). In the NPM1 group the following frequent mutation associations were observed: DNMT3A, FLT3, IDH1/2, NRAS, PTPN11, RAD21 and WT1.

Conclusion: The frequency of identified gene mutations in our study group is in agreement with the international literature. Genetic profiling with NGS facilitates and complements the diagnosis, prognosis of complex disease clusters and provides valuable information about targeted therapeutic possibilities and significantly enhances the identification of hereditary malignancies as well. Thus, NGS combined with cytogenetics is now an indispensable tool for patients with curative myeloid malignancies.

P01.142.A BRG1 and HIF1A functional crosstalk defines transcription of ABC transporters in paclitaxel resistantcancer cells

Karolina Gronkowska[1], Sylwia Michlewska[2], Tomasz Płoszaj[3], Kinga Kołacz[1], Agnieszka Robaszkiewicz[1]

[1]University of Lodz, Department of General Biophysics, Lodz; [2]University of Lodz, Laboratory of Microscopic Imaging and Specialized Biological Techniques, Lodz; [3]Medical University of Lodz, Department of Clinical Genetics, Lodz

Background/Objectives: Cancer drug irresponsiveness to chemotherapy is followed by substantial chromatin remodeling at the regulatory elements of genes, which confer drug resistance. Based on TCGA database we delineated strong correlation between mRNA level of SWI/SNF subunit BRG1 encoded by frequently mutated SMARCA4 and ABC transporters, which remove or sequester anticancer drugs inside cancer cell organelles. Therefore, we asked if overexpression of BRG1 is responsible for the limited drug responsiveness of cancers, which developed resistance during paclitaxel therapy.

Methods: ChIP- and RNA-Seq samples were sequenced with Illumina550, data analysis and integration were performed in Galaxy, gene mutations were detected with Sanger sequencing, genes were silenced with siRNA, co-immunoprecitpiated proteins were detected by western blot, colocalization was quantified by confocal microscopy.

Results: The tested *SMARCA4*$^{+/+}$ TNBC samples showed redistribution of BRG1 around TSS of ABC genes responsible for anticancer drug detoxication in paclitaxel-resistant phenotypes without substantial enrichment of the enzyme, whereas mutations gained during the therapy reverted BRG1 truncation caused by pre-existed deletions in *SMARCA4*$^{del/del}$ in non-small lung cancer cells, thereby causing recruitment of BRG1 to ABCC5 and ABCC10 gene promoters. Motif spacing analysis of BRG1 binding sites allowed to identify inter alia HIF1A as possible co-factor of BRG1-based SWI/SNF complex. This transcription factor co-occurred in the nucleus and formed immunoprecipitable complex with BRG1 and p300 acetyltransferase in paclitaxel resistant cancer phenotypes. The deficiency of BRG1 or HIF1A declined ABC gene overexpression and restored paclitaxel-resistant cancer cell responsiveness to numerous chemotherapeutics.

Conclusion: HIF1A defines BRG1-SWI/SNF activity in paclitaxel-resistant cancer cells.

P01.143.B Analysis of aberrantly expressed microRNAs in advanced laryngeal carcinoma showed most targetable pathways

Silva Kyurkchiyan[1], Veronika Petkova[1], Gergana Stancheva[1], Diana Popova[2], Radka Kaneva[1], Todor Popov[2]

[1]Medical University - Sofia, Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria; [2]Medical University - Sofia, UMHAT "Tsaritsa Yoanna – ISUL", Department of ENT, Sofia, Bulgaria

Background/Objectives: Advance laryngeal squamous cell carcinoma (LSCC) is still tumor burden, associated with poor survival. miRNAs were known regulatory molecules. They were suggested as biomarkers to seek new treatments. The aim of our study is to evaluate miRNAs, which were deeply and significantly involved in deregulation of major pathways in advanced LSCC.

Methods: In total 131 patients, diagnosed with advanced LSCC were enrolled. The patients were separated in two: training (n = 60) and validation (n = 71) groups. Global microRNA profiling was done, and most significantly miRNAs were analyzed additionally in patient cohort via RT-qPCR. Promising miRNA results were used in in silico, validation and correlation analysis. SPSSv.27 and data bases were used in statistical and bioinformatic analysis. P-value <0.05 was taken as appropriate.

Results: Several miRNAs were most often co-expressed, namely miR-93-5p, miR-145-5p and miR-210-3p. Their expressions were validated in in vivo advanced LSCC samples and further used in bioinformatic and enrichment analysis. Our results highlight the significant roles played by miR-93-5p, miR-145-5p, and miR-210-3p in the processes, regulating pathways linked to cell cycle, hypoxia,

metabolism, apoptosis, angiogenesis, and metastasis. miR-93-5p/miR-145-5p/miR-210-3p appear to correlate with biomarkers of those pathways: three HIFα isoforms, VEGFA, VEGFR1, VEGFR2, TP53, BCL-2. Moreover, these miRNAs are actively involved in regulating processes that affect currently used chemo- and target therapies.

Conclusion: Our findings suggest that investigating key regulators of hypoxia, apoptosis, autophagy, and metabolic deregulations could be essential in the management of LSCC.

P01.144.C Incidental detection of acquired cryptic chromosomal rearrangements (CCRs) in patients who underwent germline genomic testing.

Moneeb Othman[1], *Peter Bauer*[1], *Boodor Al-Kawlani*[1], *Uros Hladnik*[1], *Omid Paknia*[1]

[1]*Centogene AG, Rostock, Germany*

Background/Objectives: Acquired genetic changes contributing to cancer, such as complex genomic rearrangements and cryptic copy number abnormalities (CNAs) can be incidentally detected by NGS-based copy number variant (CNV) analysis. We report here two cases referred to our laboratory. First case is a 13-year-old girl with abnormalities in bone marrow cell morphology, acute leukemia, and pancytopenia. The second case is a 12-year-old boy abnormalities in multiple cell lineages in the bone marrow, hepatosplenomegaly, leukocytosis, eosinophilia, monocytosis and myelofibrosis.

Methods:WES-based CNV analysis was performed for both cases, and the results were confirmed by chromosomal microarray analysis.

Results: In the first case, a terminal pathogenic gain of 7.3 Mb within the 9q34.12q34.3 chromosomal cytobands, encompassing the *ABL1* gene and a proximal pathogenic gain of 7.5 Mb within the 22q11.1q11.23 chromosomal cytobands, encompassing the *BCR* gene, have been detected. The unbalanced rearrangement results in the gain of a second copy of the Philadelphia chromosome and is predicted to lead to an abnormal *BCR-ABL1* fusion. In the second case, an interstitial deletion of 876 kb encompassing partially *FIP1L1* and *PDGFRA* genes and the entire *CHIC2* gene was identified within the 4q12 chromosomal cytoband was detected. The deletion was predicted to result in an abnormal *FIP1L1-PDGFRA* fusion. A *FIP1L1-PDGFRA* fusion gene usually results from a cryptic interstitial deletion in 4q12.

Conclusion: The incidental detection of acquired genetic alterations in patients undergoing germline genomic testing highlights the potential of NGS-based CNV analysis in uncovering unsuspected genomic rearrangements. Therefore, detecting gene fusions in leukemia is significantly valuable for diagnosis, prognosis and potential treatment strategies.

P01.145.D RNA-based gene alteration and expression analysis in NSCLC with known KRAS G12C status

Joanna Moes-Sosnowska[1;1], *Urszula Lechowicz*[1], *Magdalena Pelc*[1], *Adam Szpechcinski*[1], *Paulina Skronska*[1], *Adriana Rozy*[1], *Aneta Zdral*[1], *Mateusz Polaczek*[2], *Emil Wojda*[2], *Małgorzata Szołkowska*[3], *Tadeusz Orłowski*[4], *Pawel Sliwinski*[5], *Renata Langfort*[3], *Joanna Chorostowska-Wynimko*[1]

[1]*The Institute of Tuberculosis and Lung Diseases, Department of Genetics and Clinical Immunology, Warsaw, Poland;* [2]*The Institute of Tuberculosis and Lung Diseases, III Department of Lung Diseases and Oncology, Warsaw, Poland;* [3]*The Institute of Tuberculosis and Lung Diseases, Department of Pathology, Warsaw, Poland;* [4]*The Institute of Tuberculosis and Lung Diseases, Department of Surgery, Warsaw, Poland;* [5]*The Institute of Tuberculosis and Lung Diseases, II Department of Lung Diseases, Warsaw, Poland*

Background/Objectives: The *KRAS* c.34G>T, p.(Gly12Cys) (G12C) variant is frequently present in non-small cell lung cancer (NSCLC) targeted with KRAS inhibitors. However, the reliability of that treatment is not satisfactory. To better understand NSCLC biology and identify potential biomarkers, it is important to analyze the prevalence of KRAS variants and their relationship to other oncogenesis-related genes. Therefore, we aimed to compare the expression of 14genes among *KRAS*-positive and negative tumors using RNA-based next-generation sequencing (NGS).

Methods: *KRAS* variants and expression levels of 14genes (*ALK*,*BRAF*,*EGFR*,*FGFR1-3*,*KRAS*,*MET*,*NRG1*,*NTRK1-3*,*RET*, and *ROS1*) were evaluated in 160 tumors (formalin-fixed, paraffin-embedded(FFPE) biopsies and surgically resected tissues) including 126(79%) adenocarcinomas, 24(15%) large cell lung cancer and 10(6%) not otherwise specified (NOS) with the use of RNA-FusionPlex Lung panel(Archer).

Results: Overall, 58(17.4%) of the 160 samples harbored 58 clinically significant *KRAS* variants, of which 95% were found in adenocarcinomas. The G12C was the most frequent variant among all *KRAS*-positive tumors(36%). *KRAS*-negative tumors characterized with variants: *EGFR* ($n = 13$); *BRAF*($n = 7$); CD74::ROS1($n = 1$); EML4::ALK($n = 3$) and METex14 skipping($n = 6$). The gene expression analysis revealed significantly higher median expression of the *NTRK2*(*TrkB*) in tumors with the G12C variant ($p = 0.016$) and significantly lower median expression of the *KRAS* in tumors carrying the c.37G>T, p.(Gly13Cys) variant ($p = 0.011$).

Conclusion: This study adds new data to the genomic characterization of *KRAS*-positive tumors, especially those with G12C variants. Our study revealed higher levels of *NTRK2* in G12C-positive tumors which can be associated with unfavorable prognosis since *NTRK2* signaling may contribute to metastasis, and is associated with intratumoral hypoxia. Further research is needed to confirm these observations.

P01.146.A deepHRD, a clinically validated NGS- and AI-based method for detection of genomic instability in ovarian cancer

Juliette Albuisson[1], *Gwladys Le Dain*[2], *Sandy Chevrier*[1], *Anthony Comte*[1], *Romain Boidot*[1], *Valentin Derangère*[1], *Vincent Goussot*[1], *Caroline Truntzer*[2]

[1]*Centre Georges François Leclerc, Département de Biologie et Pathologie des Tumeurs, DIJON, France;* [2]*Centre Georges François Leclerc, Plateforme de transfert en Biologie Cancérologique, DIJON, France*

Homologous Recombination Repair Deficiency (HRD) leads to tumor genomic instability (GIS) and sensitivity to PARP inhibitors in ovarian cancers (OC), and the identification of HRD status is considered a major therapeutic issue.

We developed an NGS- and AI-based HRD detection tool that allows the detection of GIS in tumor samples. First, sequencing of a SNP and CNV containing genomic backbone (2.8 Mb size) is performed in a standard Illumina NGS platform. Second an AI-based algorithm analyzes NGS results in tumor sample is applied.

We performed several steps of validation: technical validation was done comparing Myriad Mychoice GIS score/class and our own GIS score/class in 177 tumor samples analyzed in our Centre. Second, technical sensitivity was assessed using a tumor sample with GIS score just above threshold and decreasing tumor purity. Third, clinical validation was done in 360 tumor samples from PAOLA-2 study.

Our method showed very good technical performance (sensitivity and specificity 0.94 and 0.95 respectively). Clinical performance was good (Sensitivity 0.93, specificity 0.84, using combined BRCA sequencing results and deepHRD scoring, PFS 54.3 [40.2-60.6] vs 18.7 [14.3-24.7] in GIS+ vs GIS- respectively). In all 43 Myriad Mychoice inconclusive results, deepHRD showed a similar performance. Technical sensitivity could be confirmed with GIS detection in samples with as less as 20% of tumor purity.

Technology transfer is currently under progress in our centre and will be soon available either through collaboration or commercial use.

P01.148.C Impact of rare and low-frequency genetic variants in pleural mesothelioma

Elisabetta Casalone[1], *elton jalis herman*[1], *Cecilia Di Primio*[1], *Carla Debernardi*[1], *Rebecca Filomena*[1], *ANGELO SAVOCA*[1], *Miriam Rosselli*[1], *Dario Mirabelli*[2], *Giuseppe Matullo*[1;3]

[1]*University of Turin, Medical Sciences, Turin, Italy;* [2]*University-Hospital and Center for Cancer Prevention, Cancer Epidemiology, Turin, Italy;* [3]*AOU Città della Salute e della Scienza, Medical Genetics, Turin, Italy*

Consortium: EPIC network

Background: Previous Genome Wide Association Studies (GWASs) in pleural mesothelioma (PM) identified low risk genetic variants conferring a limited increase risk of the diseases and showing evidence of interaction with asbestos exposure. Other sequencing studies on cancer gene panels in PM cases identified 5-10% of germline mutations increasing susceptibility to PM even at low levels of asbestos exposure. Here, we conducted a whole exome sequencing (WES) analysis aimed at identifying genes with rare variants contributing to PM risk.

Methods: WES screening was performed on DNA isolated from blood of 129 pre-clinical PM and 129 non-cancer individuals. Alignment of the sequencing reads, variant calling and annotation were performed using JuliaOmixTM software (GenomeUp, Italy). SNVs with a read depth > 20X and a m.a.f. < 0.01 in GnomAD database, were taken into account for downstream analyses.

Results: In the group of cases we identified pathogenic rare variants in cancer predisposing genes such as *ACVR1B, B2M, DNMT3A, HRAS, NPM1, PTPN11, STAG2*. Sequence Kernel association test performed in about 1 million of rare variants across 17758 genes showed a significant enrichment in genes involved in DNA methylation, chromosome replication and segregation.

Conclusion: WES sequencing technologies allowed us to identify rare germline mutations in novel genes potentially contributing, together with asbestos exposure, to increase risk of PM development. Functional analysis will be performed to test pathogenic effects and the potential impact of the mutational processes in somatic cells.

P01.149.D Major impact on modifiable colo-rectal cancer risk factors on at risk individuals through personalised prevention in clinical genetics practice

marie-gabrielle delorme guinand[1], *anna serova-erard*[1], *laury nicolas*[1], *noemie demare*[2], *simon rey*[1], *martine duclos*[3], **François Cornélis**[1]

[1]*CHU Clermont-Ferrand, 63000, Clermont-Ferrand, France;* [2]*Avicenne Hopital, Assistance Publique des Hopitaux de Paris, Paris, France;* [3]*CHU Observatoire National de l'Activité Physique et de la Sédentarité, 63000, Clermont-Ferrand, France*

Introduction : In EU-27 countries in 2020, colorectal cancer (CCR) was the 2nd cause of cancer death. Major modifiable risk factors are the lack of physical activity (PA) and of dietary fiber intake (DFI). The majority of outpatients in clinical genetics showing no germline pathogenic variants are affected with a multifactorial disease, for which correction of risk factors is essential. Our aim was to evaluate the impact of personalised advice following standardized evaluation of PA and DFI.

Patients & Methods : Genetics adult outpatients were systematically evaluated using the International PA Questionnaire short form and a in-house questionnaire for DFI, taking 5 minutes on average. At high CCR risk individuals had personal or familial history of CCR or colon adenomas.

Results : Evaluation of PA and FDI revealed 51.3% (n = 559, since 2018) and 74.5% (n = 212, since 2021), respectively, of individuals below the OMS recommendation, who were given personalised advice. At the second evaluation, 9 months later (in mean, range 3-12 months), out of those, 42.7% and 24.1%, respectively, had corrected to meet the OMS target. For the subgroup of individuals at high CCR risk (n = 92), 48.9% and 81.6% were below the targets at the first evaluation and, out of those, 35.6% and 24.1%, respectively, had corrected at the second evaluation.

Conclusion : Systematic personalised prevention in clinical genetics practice has a major impact on modifiable colo-rectal cancer risk factors such as PA and, to a lesser extents, DFI, with a similar magnitude on individuals at high or low CCR risk.

P01.150.A Assessment of cancer predisposition syndromes in a pediatric oncology center from Midwest-Brazil

Flávia Delgado Martins[1], *Renata Sandoval*[2]

[1]*Hospital da Criança de Brasília José Alencar, Pediatric oncology, Brasília;* [2]*Hospital da Criança de Brasília José Alencar, Genetic service, Brasília*

Background/Objectives: Pediatric cancer can be a sentinel for cancer predisposition syndromes (CPS). Understanding the association of specific tumor subtypes with recognizable clinical patterns may help to identify carriers, and to inform care. Here we provide descriptive data from pediatric cancer patients with referral for genetic evaluation.

Methods: We retrospectively reviewed medical charts of childhood cancer patients who were referred to the oncogenetics

service between January 2018 and July 2023. Cases without pathology and/or imaging reports supporting a malignancy diagnosis were excluded. Referral indications, clinical data and germline genetic tests results (when available) were assessed.

Results: Among 129 patients who were referred to genetic evaluation, 96 met study criteria. A suspicious family history of cancer was a recurrent referral indication (n = 47). Phenotypic-driven diagnosis was possible for 37 cases (38.5%): 14 Neurofibromatosis type 1, 12 Tuberous Sclerosis Complex and 11 polyposis syndromes. Among patients who performed germline testing, 85% (17/21) harbored a pathogenic/likely pathogenic germline variant in a CPS gene.

Conclusion: In this highly selected cohort we found almost 40% of CPSs identified by a phenotype-driven approach and among those who performed germline testing 85% of positive results. This preliminary data allowed the creation of an institutional registry of CPSs and future prospective studies.

P01.151.B Reflex CRC Initiative - Advancing Colorectal Cancer Care through Comprehensive Genetic Testing

Christoforos Pappas[1], *Hannes Olauson*[2], *Felix Haglund*[3], *Johan Lindberg*[4], *Caroline Beergrehn*[5], *Emma Tham*[1], *Annika Sjövall*[1]

[1]*Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden;* [2]*Karolinska Institute, Department of Laboratory Medicine, Stockholm, Sweden;* [3]*Karolinska Institute, Department of Oncology-Pathology, Stockholm, Sweden;* [4]*Karolinska Institute, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden;* [5]*Capio St Göran Hospital, Department of Surgery, Stockholm, Sweden*

Background/Objectives: Colorectal cancer management is evolving towards personalized medicine, with genetic testing playing a crucial role in treatment decisions. The Reflex Testing for Colorectal Cancer initiative aimed to integrate comprehensive genetic testing into routine care. Specifically, the aim was to promptly determine treatment predictive genetic factors and hereditary cancer risk syndromes that would lead to potential prophylactic surgery as well as identify DPYD deficiency that affects oncological treatment.

Methods: The study, conducted from October 2021 to December 2023, included 370 patients diagnosed with colorectal cancer. Genetic analysis was performed on DNA extracted from blood and from tumor tissue taken from biopsy during endoscopy, using a gene panel of 385 genes (GMCK panel) designed to identify variants relevant to treatment prediction, prognosis, and heredity for all solid tumors.

Results: In the first 100 cases (48 females, 52 males), 7% were diagnosed before 50 years and 18% between 50 and 60 years of age. The tumor localization varied, with 23% in the right colon, 9% in the transverse colon, 27% in the left colon and 41% in the rectum.15% showed high microsatellite instability. Additionally, four patients (4%) were identified with Lynch syndrome (disease-associated variants in *MLH1*(x2) or *MSH6*(x2)). Regarding treatment-predictive biomarkers, pathogenic variants were found in *KRAS* in 44% and in *BRAF* in 20%.

Conclusion: The analysis of paired tumor and blood data can identify both somatic and germline aberrations that are of clinical significance and thus enable personalized therapeutic decisions at diagnosis.

Background: Constitutional heterozygous pathogenic variants in the exonuclease domain of *POLE* and *POLD1*, which affect the proofreading activity of corresponding polymerases, cause a cancer predisposition syndrome (polymerase proofreading-associated polyposis), characterized by increased risk of gastrointestinal polyposis, colorectal cancer, endometrial cancer and other tumour types. The connection between the disruption of polymerase proofreading activity and cancer development is through an increase in the somatic mutation rate.

Methods: We studied an extended family with multiple members heterozygous for the pathogenic *POLD1* variant c.1421T>C p.(Leu474Pro). Genome sequencing was performed to evaluate mutational patterns of patient-derived fibroblasts colonies and of de novo mutations obtained by parent-offspring comparisons. Exome sequencing data from tumours developed by patients with the hereditary cancer syndrome were also analysed.

Results: Heterozygous *POLD1* L474P just subtly increases somatic and germline mutation burden in non-tumour tissues. In contrast, tumours developed in individuals with a heterozygous mutation of the exonuclease domain of *POLD1*, including L474P, have extremely high mutation rates (>100 mut/Mb) associated with tumour mutational signature SBS10d. To explain these observations, also common to other *POLD1* exonuclease domain pathogenic variants, we show, for the first time, that *POLD1* proofreading deficient tumours developed in the context of the hereditary cancer syndrome require somatic inactivation of the wildtype allele in the target tissue (e.g. colon or endometrial epithelium), usually through loss of heterozygosity, resulting in the elimination of all exonuclease-proficient copies of the gene.

Conclusion: These results provide strong evidence that *POLD1* pathogenic variants have a recessive effect on mutation rate in somatic cells.

P01.154.A Germline testing in routine care of ovarian cancer patients in Estonia 2009-2023

Mikk Tooming[1;2], *Kadri Rekker*[2], *Kadri Toome*[2], *Olga Fjodorova*[2], *Hanno Roomere*[2], *Ülle Murumets*[2], *Piret Laidre*[2], *Katrin Ounap*[1;2], *Tiina Kahre*[1;2]

[1]*Institute of Clinical Medicine, Department of Clinical Genetics, Tartu, Estonia;* [2]*Genetics and Personalized Medicine Clinic, Tartu University Hospital, Tartu, Estonia*

Background/Objectives: Germline testing in routine care of ovarian cancer (OC) patients in Estonia has evolved from single-gene testing to targeted NGS gene panels during the years 2009 to 2023. This study aimed to investigate the prevalence of (likely) pathogenic variants (PV) in Estonian OC patients.

Methods: The study included 761 OC patients referred from tertiary hospitals between 2009 and 2023 to the Genetics and Personalized Medicine Clinic at Tartu University Hospital for genetic testing. Individuals were analyzed using either APEX microarray, *BRCA1/2* Sanger sequencing, *BRCA1/2* multiplex ligation-dependent probe amplification analysis or Illumina TruSight Cancer/Hereditary Cancer (94 or 113 genes) gene panels.

Results: Most common histological OC type was serous carcinoma 559/761 (73%). The mean age of OC onset was 56 years (4-91y), and the mean age of testing was 60 years (10-91y). Bilateral OC occurred in 42/761 (5.5%) patients. Overall, 207/761 (27%) OC patients carried PV. *BRCA1/2* PV was found in 158/761 (21%) patients. Additionally, 49/761 (6.4%) patients had PV in non-BRCA genes associated with OC, including *ATM*, *BRIP1*, *DICER1*, *PALB2*, *PMS2*, *RAD51C* 25/761 (3.3%), and secondary findings in *BARD1*, *CHEK2*, *FANCM*, *MITF*, *MUTYH*, *PPM1D*, *TP53* 24/761 (3.1%). *BRCA1* was the most prevalently mutated gene, PV detected in 123/207 (59%) of patients, followed by *BRCA2* 35/207 (17%), *CHEK2* 13/207 (6.2%), and *BRIP1* 11/207 (5.3%).

Conclusion: The diagnostic efficacy of OC patients in Estonia was ~27%. The detection rate with the NGS gene panel is ~6% higher than focusing on *BRCA1/2* gene testing alone.

P01.155.B The co-regulation of circular RNAs and messenger RNAs in colorectal cancer: the fate of an unbalanced couple?

Corentin Levacher[1], *Philippe Ruminy*[2], *Camille Charbonnier*[3], *Joanna Delfosse*[1], *Edwige Kasper*[4], *Charbonnier Françoise*[1], *Mathieu Viennot*[2], *Jacques Mauillon*[5], *Nathalie Parodi*[5], *Stéphanie Baert-Desurmont*[4], **Claude Houdayer**[4]

[1]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, F-76000 Rouen, France;* [2]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, Centre Henri Becquerel, F-76000 Rouen, France;* [3]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, CHU Rouen, Department of Biostatitics, F-76000 Rouen, France;* [4]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, CHU Rouen, Department of Genetics, F-76000 Rouen, France;* [5]*Univ Rouen Normandie, Normandie Univ, CHU Rouen, Department of Genetics, F-76000 Rouen, France*

Background/Objectives: Circular RNAs (circRNAs) are emerging players in human diseases, with plausible function as part of competing endogenous networks. We hypothesized that circRNAs and mRNAs are co-regulated with a mandatory balance which, when broken, may favor disease development.

Methods: This hypothesis was tested in colorectal cancer (CRC) patients, thanks to the French multicenter Oligogenic Determinism of Colorectal Cancer collection (Baert-Desurmont et al., 2016) which contains whole blood RNA samples from 716 patients suspected of CRC predisposition excluding Lynch syndromes and polyposis, and 249 matched controls. The circRNA-mRNA couple was studied by SEALigHTS (Splice and Expression Analyses by exon Ligation and High-Throughput Sequencing) (Levacher et al., 2023) using a panel of 23 genes involved in CRC predisposition, i.e. 935 probes designed at exon ends, enabling the exploration of all exon-exon junctions. Following reverse transcription and probing on cDNA, nearby probes are ligated and the number of ligations quantified using unique molecular identifiers and sequencing.

Results: We described the landscape of circRNAs for these 23 genes i.e. 258 circular junctions, including 64 novel ones. The circRNA/mRNA ratios were calculated for each gene and ranged from 0.5% to 17% for *MLH1* and *POLD1*, respectively. The circRNA/mRNA ratio was 1.5-fold higher in patients compared to controls ($p < 2 \times 10\text{-}16$), irrespective of age of cancer onset or gender. This increase was mainly driven by *POLD1* ($p = 5.2 \times 10\text{-}8$) and did not reflect a competitive mechanism.

Conclusion: Overall, the unbalanced circRNA/mRNA couple observed in this large cohort opens new avenues in circRNA importance and CRC genetics.

P01.156.C Empowering Hereditary Cancer risk assessment: an unforeseen local geographic pattern revealed by Copy Number Variation analysis

Lia Bonamici[1], *Marco Marino*[2], *Lucia Artuso*[2], *Enrico Tagliafico*[2;3], *Elena Tenedini*[2;3]

[1]*University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy;* [2]*Modena University Hospital, Department of Laboratory Medicine and Pathology, Modena, Italy;* [3]*University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences, Modena, Italy*

Background/Objectives: Next Generation Sequencing (NGS) multi-gene panels (MGP) are extensively employed in molecular oncology and recommended for individuals with personal or familial criteria for hereditary cancer testing. Analysis algorithms for NGS data, which allow the simultaneous detection of sequence (SNV) and copy number variants (CNVs), have significantly increased the detection rates and cost-effectiveness of the tests, while maintaining high accuracy and reliability. CNVs, consisting of large deletions or duplications, potentially occur in all the genes currently examined for SNVs and may play an important role in tumor development. Despite this, they remain less characterized.

Methods: In this study, we analyzed results from 2989 patients affected mainly by breast or ovarian cancer, who underwent testing with a 26-gene panel for hereditary cancer.

Results: The cohort carried either variants of undetermined significance (42%) or Pathogenic/Likely Pathogenic (13.3%). According to previous studies, SNVs were ubiquitous across all tested genes, with pathogenic variants being more frequent in *BRCA1*, *BRCA2*, *CHEK2*, and *MUTYH*. Conversely, CNVs, observed in 1.8% of the patients, affected only ten genes. Among these, *PALB2* showed over 50% of the total variants. Moreover, the pathogenic deletion of exon 11, accounted for the 85.7% of the *PALB2* CNVs. The identification of a common place of origin for patients with exon 11 deletion, suggests a potential geographic effect contributing to this phenomenon.

Conclusion: These data provide insights into the relevance of CNVs detection, which can reveal valuable information in variant-associated cancer risk assessment and reveal unforeseen prevalence and distributions of variants across different regions and ethnic groups.

P01.157.D Homozygous substitution of threonine 191 by proline in polymerase η causes Xeroderma pigmentosum variant

Roberto Ricciardiello[1], Giulia Forleo[1], Lina Cipolla[1], Geraldine Van Winckel[2], Caterina Marconi[2], Thierry Nouspikel[2], Thanos Halazonetis[3], **Omar Zgheib**[2]*, Simone Sabbioneda[1]*

[1]Istituto di Genetica Molecolare "Luigi Luca Cavalli-Sforza", CNR, Pavia, Italy; [2]Geneva University Hospitals, Division of Genetic Medicine, Geneva, Switzerland; [3]University of Geneva, Department of Molecular and Cellular Biology, Geneva, Switzerland

Consortium: The submitted abstract has not yet been presented at a conference, but was recently published in:

Ricciardiello, R., Forleo, G., Cipolla, L. et al. Homozygous substitution of threonine 191 by proline in polymerase η causes Xeroderma pigmentosum variant. Sci Rep 14, 1117 (2024). https://doi.org/10.1038/s41598-023-51120-1

Background/Objectives: DNA polymerase eta (Polη) is the only translesion synthesis polymerase capable of error-free bypass of UV-induced cyclobutane pyrimidine dimers. A deficiency in Polη function is associated with the human disease Xeroderma pigmentosum variant (XPV). To date, no missense variant has been reported as being pathogenic or likely pathogenic, owing to the lack of functional studies adhering to ACMG guidelines for variant interpretation.

Methods: We hereby report the case of a 60-year-old woman known for XPV and carrying a Polη Thr191Pro variant in homozygosity. We further characterize the variant in vitro by primer extension assays and in vivo by UV survival assays and cell cycle analysis.

Results: We provide evidence that the substitution abrogates polymerase activity and results in UV sensitivity through deficient damage bypass. This is the first functional molecular characterization of a missense variant of Polη, whose reported pathogenic variants have thus far been loss of function truncation or frameshift mutations.

Conclusion: Our work allows the upgrading of Polη Thr191Pro from 'variant of uncertain significance' to 'likely pathogenic mutant', bearing direct impact on molecular diagnosis and genetic counseling. Furthermore, we have established a robust experimental approach that will allow a precise molecular analysis of further missense mutations possibly linked to XPV. Finally, our work provides insight into critical Polη residues that may be targeted to develop small molecule inhibitors for cancer therapeutics.

P01.158.A CRISPR/Cas9-mediated Generation of reference iPSCs expressing the Philadelphia translocation

Md Faruq Hossain[1]*, Lisa Hagenau[1], Lars Jensen[1], Anna-Maria Pielka[2], Susanne Thümecke[2], Björn Nowack[2], Andreas Kuß[1]*

[1]Interfaculty Institute for Genetics and Functional Genomics, Department of Functional Genomics, Greifswald, Germany; [2]SensID GmbH, Rostock, Germany

Background/Objectives: Next Generation Sequencing (NGS), particularly RNA-sequencing (RNAseq), has become vital for research and diagnostics. Reliable reference materials are essential for ensuring comparability in results. Here CRISPR/Cas9 technology was used to develop reference cell lines, including a human iPSC line, expressing the well-studied BCR-ABL1 fusion transcript. This fusion arises from a chromosomal translocation involving the ABL and BCR proto-oncogenes.

Methods: CRISPR/Cas9 technology was employed to create a fusion gene in different cell types including human iPSCs, blood and bladder cancer cells by targeting the breakpoint region of two introns associated with the rearrangement. Co-transfection of CRISPR guide RNAs and Cas9 induced double-strand breaks within both genes, leading to DNA misrepair and subsequent gene fusion.

Results: The BCR-ABL1 fusion gene was successfully incorporated into the wildtype human iPSC line MHHi001-A, confirmed by sequencing. Notably, the pluripotency and differentiation capabilities of the genetically modified iPSCs into the three germ layers remained uncompromised with no observed genomic aberrations or off-target modifications. Further cell lines that were modified in this fashion include the Jurkat cell line and human bladder cancer cells with a pre-existing FGFR3-TACC3 fusion on chromosome 4. The latter results in a cell line with two distinct fusion transcripts per cell.

Conclusions: The newly created genetically modified cell lines, particularly the human iPSC featuring the BCR-ABL1 fusion gene, can serve as valuable reference materials for NGS-based RNA analysis. Their utilization significantly improves the precision and reliability of NGS applications, addressing a crucial need in research and diagnostics.

P01.159.B Systematic review of multiple primary renal tumours (MPRT)

Huairen Zhang[1]*, Avgi Andreou[1], Rupesh Bhatt[2], James Whitworth[1], Bryndis Yngvadottir[1], Eamonn Maher[1;3]*

[1]School of Clinical Medicine, University of Cambridge, Department of Medical Genetics, Cambridge, United Kingdom; [2]Queen Elizabeth Hospital Birmingham, Department of Urology, Birmingham, United Kingdom; [3]Aston Medical School, Birmingham, United Kingdom

Background: In a subset of patients with renal tumours, multiple primary lesions may occur. Predisposition to multiple primary renal tumours (MPRT) is a well-recognised feature of some inherited renal cancer syndromes. The diagnosis of MPRT should therefore provoke a thorough assessment for clinical and genetic evidence of disorders associated with predisposition to renal tumourigenesis.

Method: To define the clinical and genetic characteristics of MPRT, a systematic literature review was undertaken.

Result: A total of 7562 patients from 448 articles were identified with MPRT. Compared to all patients with renal cell carcinoma (RCC), people with MPRT were more likely to be male (63% versus 71.7%) and have an earlier age at diagnosis (< 46 years, 19%

versus 34.5%). In 60.1% of cases MPRT were synchronous, and MPRT lesions had similar histology in 78.9% of individuals enrichment of multiple papillary RCC (16.8%). 10.2% of patients with MPRT had a family history of cancer or were diagnosed with a hereditary RCC associated syndrome with von Hippel Lindau (VHL) disease being the most common one (71.3%), followed by Birt Hogg Dube syndrome (14.6%). Individuals with a known or likely genetic cause were, on average, younger (43.3 years versus 56.7 years). In rare cases intrarenal metastatic RCC can phenocopy MPRT.

Conclusion: Based on these findings we suggest an investigative pathway for individuals with MPRT and approaches to cases in which routine germline genetic testing does not provide a diagnosis.

P01.160.C Deciphering copy number variations within the complex genomic region of the *PMS2* gene using Optical Genome Mapping

*Anne Holtorf[1], **Jasmin Maier**[1], Wilena Telman[1], Charlotte Singruen[1], Sarah Heinrich[1], Nina Wohlrab[1], Sophie Stoesslein[1], Siegel Corinna[1], Konstanze Hörtnagel[1]*

[1]Medicover Genetics, MVZ Martinsried GmbH, Martinsried, Germany

Background/Objectives: The *PMS2* gene is one of four DNA mismatch repair (MMR) genes and is critical for correcting errors after DNA replication and homologous recombination. Inactivation of *PMS2* leads to the accumulation of mutations, predisposing carriers to cancer and causing constitutional mismatch repair deficiency syndrome (CMMRDS). However, *PMS2* sequence analysis is complicated because the gene is located within a complex genomic region on chromosome 7, which contains a pseudogene with almost 100% sequence homology (*PMS2CL*). Particularly challenging is the identification of copy number variations (CNVs) within this genomic region, with the added complexity of the inability to distinguish between *PMS2* and *PMS2CL* using conventional laboratory techniques such as MLPA. Here we report on the possibility of using Optical Genome Mapping (OGM) as a new tool for detecting CNVs in this complex region of the genome.

Methods: One colon cancer patient (MSI-H, loss of PMS2) consented to germline testing. Next-generation sequencing was performed, including CNV analysis and additional MLPA. Subsequently, OGM was done to follow up on MLPA results.

Results: MLPA results suggested a deletion on chromosome 7, possibly encompassing *PMS2* exons 12-15. However, further investigation using long-range PCR to determine whether this deletion was in *PMS2* or its pseudogene remained inconclusive. Fortunately, OGM results revealed a heterozygous deletion of 77 kb including exons 12-15 of the coding *PMS2* gene, confirming Lynch syndrome.

Conclusion: OGM is a promising tool for identifying and deciphering structural variants in complex genomic regions, enabling diagnosis for patients and their families.

P01.161.D DNA methylation patterns in families with rhabdoid tumor predisposition syndrome (RTPS)

Matej Boros[1], *Karolina Nemes[2;3], Sebastian Bühner[2;3], Susanne Bens[1], Nnamdi Okeke[1], Sonja Dahlum[1], Selina Glaser[1], Nadine Matscheko[1], Anja Fischer[1], Britt König[1], Ole Ammerpohl[1], Pascal Johann[2;3], Martin Hasselblatt[4], Michael C. Frühwald[2;3], Reiner Siebert[1]*

[1]Institute of Human Genetics, Ulm University & Ulm University Medical Center, Ulm, Germany, Ulm, Germany; [2]Pediatrics and Adolescent Medicine, Swabian Children's Cancer Center, University Medical Center Augsburg, Augsburg, Germany; [3]Bavarian Cancer Research Center (BZKF), Augsburg, Germany; [4]Institute of Neuropathology, University Hospital Münster, Münster, Germany

Background/Objectives: Rhabdoid Tumor Predisposition Syndrome (RTPS) is due to germline *SMARCB1* or *SMARCA4* pathogenic variants. It confers a high risk for malignant rhabdoid tumors in early childhood. Despite a grim prognosis with 5-year overall survival rates of around 40%, the molecular mechanisms underlying mutation origin, tumor penetrance,or unfavorable prognosis are incompletely understood. We investigated familial DNA methylation patterns in RTPS.

Methods: 90 children with RTPS from 16 countries were identified in the EU-RHAB database (01/2004 - 01/2021). We analyzed a subcohort of 49 well-characterized RTPS1 and 2 RTPS2 patients, along with 44 mutation-negative parents and 4 mutation-negative siblings. DNA methylation was assessed in blood DNA using the Infinium MethylationEPIC v1.0 array and analyzed using ANOVA (limma R package) as well as UMAP- and PCA-based clustering.

Results: Comparing patients with parents or siblings group identified 12,238 CpGs (4,662 genes) and 355 CpGs (214 genes) differentially methylated CpGs, respectively, with 128 CpGs and 72 genes shared among these analyses. Only 1 CpG was differently methylated between parent and sibling controls. Sibling samples clustered with RTPS patients and both segregated apart from parents. Age was a predominant driver of variability between the observed clusters whereas sex, type of *SMARCB1/SMARCA4* mutation, or tumor DNA methylation subtype were unrelated to the observed clusters.

Conclusion: DNA methylation analyses of patients and relatives did not show a specific blood-born epigenotype of RTPS patients. DNA methylation heterogeneity in the families was strongly confounded by age, emphasizing the need for age-matched control populations.

Background/Objectives: PTEN Hamartoma Tumor Syndrome (PHTS) patients have hereditary cancer risks reaching 76% for breast cancer (BC), comparable to *BRCA1/2*, 22% for endometrial cancer (EC), and 21% for thyroid cancer (TC). Cancer prognosis in PHTS is unknown, and we aimed to provide this for PHTS-associated cancers.

Methods: This European cohort study included adult PHTS patients with data from medical files, registries, and/or questionnaires. Survival and risk factors were assessed using Kaplan-Meier and Cox regression analyses and were compared with sporadic cancer and population mortality using standardized mortality (SMR) and relative survival rates (RSR). Survival bias was addressed using left-truncation.

Results: Overall, 147 female BC patients were included (73% PHTS-indexes), median age of 41 years(IQR:35-49). The 10y-OS was 77%(95%CI:66-90), decreasing per increasing stages 0-IV: 90%(95% CI:73-100), 83%(95%CI:64-100), 74%(95%CI:48-100), 51%(95% CI:26-100) and 0%(95%CI:0-0). Relative survival after BC was comparable to sporadic BC until 2 years (2y-RSR = 1.1;95% CI = 1.1-1.1), gradually increasing to 5y-RSR = 1.7(95%CI = 1.6-1.7). For TC (N = 56, median age of 37(IQR:26-46)) and EC patients (N = 35, median age of 46(IQR:36-55)), the 10y-OS was 87%(95% CI:74-100) and 64%(95%CI:38-100). Overall and cancer-specific mortality in female patients was increased compared to the general population (SMR = 3.7;95%CI:2.6-5.0 and SMR = 2.7;95% CI:1.6-4.4).

Conclusion: This study showed comparable cancer prognosis in PHTS to the general population. The increased overall mortality in the total PHTS population was presumably related to higher cancer incidence. These results, together with the high survival observed in early-stage cancer, emphasize the importance of early PHTS recognition for the potential benefit of early cancer detection in patients with high hereditary cancer risks.

P01.163.B Deciphering the molecular complexity of the IKZF1plus profile using Optical Genome Mapping

Jonathan Lühmann[1], *Winfried Hofmann*[1], *Anke Katharina Bergmann*[1], *Anja Möricke*[2], *Gunnar Cario*[2], *Martin Schrappe*[2], *Brigitte Schlegelberger*[1], *Martin Zimmermann*[3], *Martin Stanulla*[3], *Doris Steinemann*[1]

[1]*Hannover Medical School, Department of Human Genetics, Hannover, Germany;* [2]*ALL-BFM Study Group, Christian-Albrechts University Kiel and University Medical Center Schleswig-Holstein, Department of Pediatrics, Kiel, Germany;* [3]*Hannover Medical School, Pediatric Hematology and Oncology, Hannover, Germany*

Background/Objectives: Acute lymphoblastic leukemia (ALL), the most frequent pediatric cancer, has witnessed improved survival rates exceeding 90% through genetic marker-based stratification and novel therapies. The IKZF1^{plus} profile, characterized by *IKZF1* deletion (IKZF1^{del}) alongside additional deletions, emerged as a poor prognostic marker in retrospective analyses of AIEOP-BFM ALL 2000/2009 trials and is used for high-risk stratification in the ongoing AIEOP-BFM ALL 2017 trial. A deeper genome-wide characterization of leukemic cells is necessary for a better understanding of the molecular response.

Methods: In total, 142 patients with *IKZF1* deletion from the AIEOP-BFM ALL 2000/2009 trial were re-analyzed by means of Optical Genome Mapping (OGM) enabling the simultaneous detection of structural variants and aneuploidies. Genomic profiles were correlated with patient outcome with respect to event-free survival (EFS), cumulative incidence of relapse (CIR) and overall survival (OS).

Results: About half of the patients in this study exhibited well-known and new genomic alterations in addition to IKZF1$^{del/plus}$. In 53 patients gene fusions (*ABL*-class, *CRLF2*, *PAX5*, *JAK2*, *ZNF384*) have been detected. Eighteen patients displayed established prognostic markers namely high hyperdiploidy, *ETV6::RUNX1*, or iAMP21. Our data demonstrate the genomic complexity and heterogeneity of the IKZF1$^{del/plus}$ patient group. In this cohort EFS, CIR and OS are similar in IKZF1^{del} and IKZF1^{plus} patients and mainly dependent on the accompanying good or poor prognostic markers.

Conclusion: Through the utilization of OGM, we reveal the complex genomic landscape in ALL and demonstrate that the significance of the IKZF1^{plus} profile is not as prominent as previously anticipated.

P01.164.C Functional assessment of variants of uncertain significance in *PTEN* with a predicted effect on splicing

Elke van Veen[1], *Arjen Mensenkamp*[1], *Janneke Schuurs-Hoeijmakers*[1], *Nicoline Hoogerbrugge*[1], *Richarda de Voer*[1]

[1]*Radboud University Medical Center, Department of Human Genetics, Nijmegen, Netherlands*

Background: Pathogenic variants in *PTEN* are associated with PTEN hamartoma tumour syndrome (PHTS). However, in a number of patients variants of uncertain significance (VUSs) are identified. To assign these VUSs a meaningful pathogenicity classification, the functional effect of these variants needs to be assessed. Here, we selected *PTEN* VUSs identified in PHTS-like patients with a predicted effect on splicing to assess their functional effect.

Methods: VUSs were identified in an ERN-GENTURIS PHTS cohort ($n = 510$). All variants were classified as a VUS using the *PTEN*-specific ACMG guidelines and had a spliceAI score of >0.1, with no published functional data to date were included. Amplicons spanning one or two exons that harboured the identified VUSs were designed and cloned into a minigene vector using gateway cloning. Site-directed mutagenesis was used to generate the variants of interest and splice assays with mutant and wild type constructs were performed.

Results: Eight *PTEN* VUSs were identified for further functional testing. We identified five missense variants (c.77C>A, p.(Thr26Asn); c.89C>A, p.(Pro30Gln); c.94A>T, p.(Ile32Phe); c.801G>T, p.(Lys267Asn); c.929A>G, p.(Asp310Gly)) and three intronic variants (c.80-1G>C; c.165-18T>A; c.253+5G>C). One additional variant (c.334C>G, p.(Leu112Val)) was included in the assay as a positive control. These nine variants were distributed over seven exon-intron regions, captured in five amplicons ranging between ~2.5-5.2 kb in size.

Conclusion: Upon assessment, coding variants may also exert an effect on splicing and thus impact the function of PTEN. Splice effect analysis will help to further classify the pathogenicity of *PTEN* VUSs.

Grants: This work is funded by HORIZON-MSCA-2021-PF-01.

P01.165.D Complex translocation leading to13q interstitial deletion in a Moroccan child with retinoblastoma and intellectual disability

ZHOUR EL AMRANI[1], *siham chafai elalaouia*[2], *Wafaa Jdioui*[3], *aziza sbiti*[4], *ilham ratbi*[5], *Thomas Liehr*[6], *abdelaziz sefiani*[7], *Abdelhafid Natiq*[8]

[1]*Research team in genomics and molecular epidemiology of genetic diseases, Genomics Center of Human Pathologies, Faculty of Medicine and Pharmacy, Medical Genetics, RABAT, Morocco;* [2]*Faculty Of Medicine And Pharmacy Of Rabat, Medical Genetics, Rabat, Morocco;* [3]*Centre des consultations et des explorations externes, Hopital d'enfants, CHU Ibn SinaConsultation de génétique, Rabat, Medical Genetics, Morocco;* [4]*National Institute D'hygiène Du Maroc, Medical Genetics, Rabat, Morocco;* [5]*Faculty Of Medicine And Pharmacy Of Rabat, Rabat, Morocco;* [6]*Institute of Human Genetics, Jena University Hospital, Friedrich Schiller University, Germany;* [7]*National Institute D'hygiène, Medical Genetics, Morocco;* [8]*Faculty Of Medicine And Pharmacy Of Rabat, Medical Genetics, Morocco*

Background/Objectives: Retinoblastoma (RB) is the most common malignant intraocular tumor in children; it affects their eyes often even prenatally. RB may be sporadic or familial, due to germinal mutation in *RB1* gene or by abnormal chromosomal abnormalities involving *RB1* gene, located in 13q14. Monosomy of subband 13q14 as a partial deletion can also be responsible for RB with additional symptoms. The latter may be RB associated with psychomotor retardation, macrocephaly, broad forehead, thick earlobes, and bulbous nose.

Methods: We present here the case of a boy from a consanguineous marriage with bilateral retinoblastoma, intellectual disability and facial dysmorphic features. Classical and molecular cytogenetics(FISH) were used to recognize genotype-phenotype association.

Results: The karyotype showed a three way translocation involving chromosomes 5, 12 and 13. Further molecular cytogenetics analysis revealed a deletion of 13q14 involving the tumor suppressor gene *RB1*.

Conclusion: This case highlights the impact of classical and molecular cytogenetics in diagnosis of rare genetic syndromes and for the genetic counselling of patients and their families. Pure molecular karyotyping analyses would miss the underlying chromosomal mechanism leading to the rearrangement.

Grants: this work does not receive any funding, and I would like to apply for a fellowship to attend the European Human Genetics Conference.

Conflict of Interest: None declared

P01.166.A Deep intronic insertions in patients at high risk for hereditary breast and ovarian cancer

*Bernardus Aldrige Allister[1], **Winfried Hofmann**[1], Jonathan Lühmann[1], Bernd Auber[1], Nataliya Di Donato[1], Monika M. Golas[2;2;3], Doris Steinemann[1]*

[1]Hannover medical school (MHH), Department of Human Genetics, Hannover, Germany; [2]University of Augsburg, Human Genetics, Faculty of Medicine, Augsburg, Germany; [3]University Hospital Augsburg, Comprehensive Cancer Center Augsburg, Augsburg, Germany

Background/Objectives: 13 core genes (*ATM*, *BARD1*, *BRCA1*, *BRCA2*, *BRIP1*, *CDH1*, *CHEK2*, *PALB2*, *PTEN*, *RAD51C*, *RAD51D*, *STK11*, and *TP53*) are routinely tested in patients with the suspicion of the hereditary breast and ovarian cancer (HBOC). Non-coding variants such as Alu-elements, the most prevalent mobile-element insertion (MEI) in the human genome are increasingly recognized as a cause of the genetic disorders. However, their relevance in HBOC predisposition may be underestimated.

Methods: We perform whole genome and whole transcriptome sequencing on 134 high risk HBOC patients (Asian:9, European:125), who are tested negative for pathogenic variants in HBOC core genes. The data was analyzed using an in-house-NGS-megSAP-pipeline coupled with the MEI detection tool Mobster.

Results: We detected eight deep intronic Alu-element insertions in eight different European patients: 7 in *BRCA2*, 1 in *PTEN*. The Alu-element insertion in *BRCA2* intron 13 (NC_000013.11:g.32348295_32348296insAluYa5) was annotated in seven unrelated patients by Mobster. This Alu-element insertion is present within the International Genome Sample Resource with different population frequencies: European:4/628 = 0,64%, Asian:56/1172 = 4,78%, African:12/885 = 1,36%, American:13/485 = 2,68%. cDNA analysis, showed that this AluYa5 insertion causes *BRCA2* in-frame exon 12 skipping.

Conclusion: High population frequency of the insertion suggests that the possible hypomorphic-effect of exon 12 deletion requires additional analysis of its pathogenicity. However, our findings suggested that deep intronic Alu-element insertion could play a role in causing disease in unresolved cases of HBOC.

REPRODUCTIVE GENETICS

P02.001.C Heterozygote missense variations in *PROKR2* present partial penetrance for causing Hypogonadotropic Hypogonadism

Florence Abou[1;2], *moran gershoni[3], Netanel Waldenberg[4], Naama Steiner[5], Noga Fuchs Weizman[6], Shimi Barda[6], Sandra Kleiman[6], Shlomi Barak[4;7], Ruti Parvari[1;2]*

[1]Ben-Gurion University of the Negev, National Institute of Biotechnology in the Negev, Be'er sheva, Israel; [2]Ben-Gurion University of the Negev, The Shraga Segal Department of Microbiology, Immunology and Genetics Faculty of Health Sciences, Be'er sheva, Israel; [3]Institute of Animal Science, Agricultural Research Organization, Volcani Center, Rishon LeZion, Israel; [4]The Multidisciplinary Center for Female and Male Infertility, Male fertility, Tel Aviv, Israel; [5]Soroka University Medical Center, Fertility and IVF Unit, Department of Obstetrics and Gynecology, Be'er Sheva, Israel; [6], Male Fertility Clinic and Sperm Bank, Lis Maternity Hospital, Tel Aviv Sourasky Medical Center, affiliated with the Sackler Faculty of Medicine, Tel Aviv, Israel; [7]Assuta Ashdod University Hospital, Reproductive Services, Ashdod, Israel

Background: Hypogonadotropic hypogonadism (HH), with a prevalence of 1–10 per 100,000 individuals, is characterized by reduced function of the gonads due to insufficient stimulation by the gonadotropin-releasing hormone (GnRH) from the hypothalamus. Kallman syndrome is a form of HH characterized by delayed or absent puberty and an impaired sense of smell.

Heterozygote mutations in the *PROKR2* (prokineticin receptor-2) gene were associated with HH. PROKR2 and its ligand PROK2 have a role in the cellular migration of both GnRH neurons and the Olfactory interneurons.

Objective: Identify the genetic causes of infertility in males.

Methods: Whole Exome Sequencing of peripheral blood DNA and bioinformatic analysis.

Results: In one infertile man not presenting HH, we identified a previously reported heterozygote variant in *PROKR2* (p.L173R) associated with Kallman syndrome, which was suggested to be a founder mutation. The variation occurs in up to 0.5% in various control populations (gnomAD). In a cohort of 83 individuals, none present with HH, we identified two additional missense variations (p.R286C and p.R85C) reported in the literature, each in a different infertile patient. The population frequencies of these variants are up to 4.6% and 0.27% respectively in specific control populations. Overall, 23 variations in *PROKR2* were reported to be associated with Kallman syndrome or HH, and six additional pathogenic variations appear in Clinvar. Most are more common in the population than the prevalence of HH.

Conclusion: Clinical manifestations of p.L173R, p.R286C, and p.R85C, together with other reported variations in *PROKR2* suggest complex inheritance and low penetrance in the disease phenotype.

Grants: ISF 2844/21.

P02.002.D Detection and interpretation of mosaicism in PGT-A programs

*Julia Gontar[1], Nadiya Kazachkova[1], Nataliia Buderatska[2], Ihor Ilyin[3], Olga Parnytska[2], Yuriy Herevych[3], Eduard Kapustin[3], Sergiy Lavrynenko[2], Yana Lakhno[1], **Olena Fedota**[4]*

[1]LLC "Medical Center IGR", Diagnostic Laboratory, Kyiv, Ukraine; [2]LLC "Medical Center IGR", Embriologic Laboratory, Kyiv, Ukraine; [3]LLC "Medical Center IGR", IVF Deparment, Kyiv, Ukraine; [4]LLC "AMS", Research Department, Kharkiv, Ukraine

Background/Objectives: Mosaicism interpretation is a PGT-A problem. Comprehensive chromosome screening methods differ in the results information. Genetic analysis methodology depends on the tasks, economic expediency and family features. The study

of approaches to optimizing mosaicism detection in PGT-A is relevant.

Methods: The study involved 3382 embryos samples obtained from 668 women (33.7 ± 5.4 years) treated with IVF/ICSI cycles. For PGT-A a trophectoderm biopsy was performed on the post-fertilization hours 120 or 144. 1134 samples were diagnosed by NGS, 2248 samples - using FISH in chromosomes 9, 13, 15, 16, 17, 18, 21, 22, X, Y, 70 samples - by both methods.

Results: According to NGS or FISH, variants were established: norma – 43.7% and 43.5% ($p > 0.05$), aneuploidy – 53.7% and 26.4%, mosaicism – 1.7% and 25.8%, polyploidy – 0 and 4.3%. Thus, the proportions of embryos with abnormalities show a difference ($p < 0.001$). After FISH-detected mosaicism, such combinations were established: diploidy/polyploidy – 13,4%, disomy/monosomy/trisomy – 1,6%, trisomy/monosomy – 1,2% on the same chromosome. These mosaicisms cannot be identified by NGS, but may have clinical implications. Disomy/monosomy and disomy/trisomy were detected by NGS – 1,1% and 0,6% and FISH – 5,7% and 4,0%.

Using both NGS/FISH, the same result was obtained for 78.6% of embryos: true match – 64.3%, N/N – 45.7%, An/An – 18.6%; formal – aneuploidy on different chromosomes, An/An – 7.1%, various combinations – An/mos 4.3%, An or mos/An+mos – 2.9%. 21.4% of samples were different: An/N – 8.6%, N/An – 1.4%, N/mos – 4.3%, N/mos or An – 5.7%, mos or An/N – 1.4%.

Conclusion: Optimizing of PGT-A, especially for families with biological limitations, may require a combination of several methods.

P02.003.A Characterisation of novel variants for endometriosis risk identified in participants within the genomics England database

*Elpida Fragouli[1], **Amelia Warren**[1], Demetra Andreou[1], Anna Mantzouratou[1]*

[1]Bournemouth University, Life and Environmental Sciences, Bournemouth, United Kingdom

Background/Objectives: Endometriosis, altough multifactorial, tends to affect women of the same family with heritability between 47-51%. Studies have identified 40+ single nucleotide polymorphisms (SNPs) mostly associated with advanced endometriosis. To date no variants have been associated with earlier endometriosis stages. Genomic England database (GED) cantains whole genomes information and medical records from thousands of participants. The aim of this is to identify endometriosis risk variants in selected populations within GED and investigate the pathways these variants could act on.

Methods: Previous studies identified genomic areas associated with an increased endometriosis risk. Of these, 5 genes were selected for furher invesigation, IDO1, IL6, CNR1, TACR3 and KISS1R. Participant data with endometriosis were extractred from selected participant panels, filtered according to specific inclusion criteria and classified to stages according to the degree of medical interventions presented in the clinical data. A database was created and populated with targeted genomic similarity queries within our participant cohorts.

Results: Fifty-seven patients were identified as appropriate candidates for the study. Deferential variant frequency in the GED endometriosis cohort was seen in 10 SNPs compared with that in the general GED population. Two variants were significanly increased in frequency in the endometriosis cohort and assosciatied with IDO1 and CNR1 genes. Both variants are not yet characterised, one is novel, and not previously associated with the condittion.

Conclusion: Targeted investigations in GED identified new variations for IDO1 and CNR1 genes with significantly increased frequency in endometriosis patients. Their further characterisation could reveal novel pathways about the onset of endometriosis.

P02.004.B The "Goldilocks" panel: Determining the optimal number of genes to include for equitable, pan-ancestry Carrier Screening.

Mia Gruzin[1;2], Matthew Hobbs[1], Sarah Poll[3], Jaysen Knezovich[4], Swaroop Aradhya[3], Leslie Burnett[1;2;5]

[1]Garvan Institute of Medical Research, Darlinghurst, Australia; [2]School of Clinical Medicine, UNSW Medicine and Health, St Vincent's Clinical Healthcare Campus, Darlinghurst, Australia; [3]Invitae Corporation, San Francisco, United States; [4]Blue Jay Consulting Services, Brisbane, Australia; [5]Northern Clinical School, Faculty of Medicine and Health, University of Sydney, St Leonards, Australia

Background/Objectives: Clinical utility of reproductive carrier screening varies across diverse populations because of the preponderance of genomic data from European individuals in public databases, and the heterogeneity of available carrier tests. We have defined the size and composition of an optimal ("Goldilocks") carrier panel with clinical utility across diverse populations, regardless of ancestry.

Methods: Using gnomAD (v4.0) and ClinVar data for ~1,300 serious, childhood-onset autosomal recessive (AR) and X-linked (XL) monogenic conditions, we modelled various in silico screening panels, validating with real-world data from >380,000 individuals. To compare targeted "hotspot" variant analysis against full gene sequencing, we studied differences in carrier yield between specific ancestry groups for *CFTR*.

Results: A gene panel of ~500 prioritised genes ("Goldilocks") achieved 99% of maximum possible carrier yield, irrespective of genetic ancestry. Smaller panels provided diminished carrier yield and inequitable benefit to specific ancestry groups. Real-world carrier screening data from >75 countries validated our model. Using *CFTR* as an example, compared to full gene sequencing, "hotspot" analysis provided unequal yield between specific ancestry groups, missing >10% of the most prevalent pathogenic variants for patients with self-reported Asian, Hispanic, and Middle Eastern ancestry.

Conclusion: An optimally-sized, globally equitable, pan-ancestry Goldilocks panel will identify carrier risk for 99% of most-severe AR/XL conditions. This panel may be analysed virtually from exome or genome sequencing, allowing for ongoing refinement based on emerging evidence. To maximise clinical utility across diverse ancestry groups, full gene sequencing approaches are preferred over targeted "hotspot" variant analyses.

Grants: Not applicable.

P02.005.C Copy number variation sequencing for the products of conception: what is the optimal testing strategy

1290

Shuyuan Li[1], *yiyao chen*[1]

[1]*Hengshan Road, Shanghai, China*

Background/Objectives: Copy number variation sequencing (CNV-seq) is crucial in prenatal diagnosis, but its limitations in detecting polyploidy, maternal cell contamination (MCC), and uniparental disomy (UPD) restrict its application in the analysis of products of conception (POCs). This study aimed to investigate an optimal genetic testing strategy for POCs in the era of CNV-seq.

Methods: CNV-seq and quantitative fluorescent polymerase chain reaction (QF-PCR) were performed in all 4,211 spontaneous miscarriage cases. Different testing strategies were compared and the optimal testing strategies were proposed.

Results: Of the 4211 cases, 2561 (60.82%) exhibited clinically significant chromosomal abnormalities. CNV-seq alone, without QF-PCR, might misdiagnose 311 (7.39%) cases, including 278 polyploidy, 13 UPD, and 20 MCC. In 20 MCC cases identified by QF-PCR, CNV-seq successfully pinpointed the cause of miscarriage in 13 cases. Furthermore, in cases where QF-PCR suggested polyploidy, CNV-seq improved the diagnostic accuracy in 54 (1.28%) hypo/hypertriploidy cases. After comparing four different strategies, the sequential approach (initiating with CNV-seq followed by QF-PCR if necessary) emerged as advantageous, reducing approximately 70% of the cost associated with QF-PCR while maintaining result accuracy.

Conclusion: We propose an initial CNV-seq followed by QF-PCR if needed—an efficient and cost-effective strategy for the genetic analysis of POCs.

Grants: This work was supported by the Shanghai Municipal Science and Technology Commission (22Y11906700) and Clinical Research Plan of IPMCH (IPMCH2022CR1-02).

P02.007.A A homozygous *HIPK4* variant causes a familial form of male infertility

Sophie Adina Koser[1], *Avinash S. Gaikwad*[1], *Andela Kovacevic*[2], *Isabella Aprea*[3], *Claudia Krallmann*[4], *Birgit Stallmeyer*[1], *Johanna Raidt*[3], *Heymut Omran*[3], *Sabine Kliesch*[4], *Hubert Schorle*[2], *Corinna Friedrich*[1], *Frank Tüttelmann*[1]

[1]*Institute of Reproductive Genetics (IRG), University of Münster, Münster, Germany;* [2]*Institute of Pathology, Department of Developmental Pathology, University of Bonn, Bonn, Germany;* [3]*Department of General Paediatrics, University of Münster, Münster, Germany;* [4]*Centre of Reproductive Medicine and Andrology (CeRA), Department of Clinical and Surgical Andrology, University of Münster, Münster, Germany*

Background/Objectives: Oligoasthenoteratozoospermia (OAT) is a highly variable phenotype of male infertility that is characterised by reduced sperm count and motility, and abnormal sperm morphology. Its genetic basis is not well understood. Exome sequencing in familial cases offers the opportunity to discover novel candidate genes also for this infertility phenotype.

Methods: Four infertile brothers with varying OAT were recruited at the CeRA. Exome sequencing including the parents and a fertile brother enabled segregation analysis expecting a shared autosomal recessive or X-linked cause. Candidate variants were validated by Sanger sequencing and further analysed via heterologous expression in HEK293T cells.

Results: Three infertile brothers were homozygous for a start loss variant (c.1A>G) in *HIPK4*, which is highly expressed in spermatids. Heterologous expression demonstrated that a downstream start codon in frame was used, likely resulting in an N-terminally truncated protein disrupting a part of HIPK4's kinase domain. Interestingly, the fourth brother carried compound heterozygous variants in *DNAH17* (c.[1076_1077dup];[7752 + 2T>A]) known to cause multiple morphological abnormalities of the sperm flagella (MMAF).

Conclusion: In contrast to previous studies reporting *HIPK4* as associated with azoospermia, we identify *HIPK4* as likely cause for familial OAT. Importantly, published male knockout mice mimic the patients' OAT phenotype with predominantly abnormal sperm heads in mice and men. Our work highlights the utility of exome-based segregation analysis and illustrates the possibility of different monogenic causes within the same family.

Grants: This work was supported by the DFG Clinical Research Unit 326 'Male Germ Cells' (CRU326) and the Medical Faculty Münster's 'CareerS' programme.

Conflict of Interest: None declared

P02.008.B Towards a diagnostic gene panel for impaired sperm morphology and motility causing male infertility

Clara Barkhaus[1], *Johanna Kuß*[1], *Birgit Stallmeyer*[1], *Frank Tüttelmann*[1]

[1]*Institute of Reproductive Genetics (IRG), University of Münster, Münster, Germany*

Background/Objectives: Male infertility is a clinically and genetically extremely heterogeneous disease affecting approximately 7% of men. Morphological defects of spermatozoa (teratozoospermia), often associated with impaired sperm motility (asthenozoospermia), are a common clinical phenotype. Several candidate genes have been described to cause the disorder. To establish a diagnostic gene panel for affected men, it is necessary to separate validated disease genes from genes with limited evidence.

Methods: To identify candidate genes for impaired sperm motility and morphology, we performed a Pubmed search using the terms, 'asthenozoospermia', 'teratozoospermia', 'multiple abnormalities of the sperm flagella' and 'disease gene', followed by a standardised evaluation of all described candidate genes based on the ClinGen gene-disease clinical validity curation.

Results: We identified 128 genes in which genetic variants were associated with teratozoospermia, asthenozoospermia or a combination of both. Of these, 50 genes were reported with autosomal recessive inheritance. For 41 genes, a gene-disease relationship was described in at least 2 independent reports and/or for more than 3 different variants. According to the ClinGen framework, more than 30 of these genes reached sufficient evidence to be included in a diagnostic gene panel.

Conclusion: Male infertility due to impaired sperm motility and/or morphology is a common and heterogeneous disease. Analysis of genes with a validated gene-disease correlation should be implemented in the diagnostic workflow of affected men.

Grants: This work was supported by the DFG Clinical Research Unit 326 'Male Germ Cells' (CRU326).

P02.010.D Expanded carrier screening for monogenic disorders as part of the preconception care

Martina Hajduskova[1], *Martina Hruba*[1], *Lucie Solcova*[1], *Anna Rykovska*[1], *Monika Pittrova*[1], *Petr Losan*[1]

[1]*Genetika Plzen, s.r.o., Laboratory of reproductive genetics, Plzeň*

Background/Objectives: Clinical genetics aims to minimize the risk of inheriting monogenic recessive disorders (MRDs). This is achieved by screening for multiple MRDs and identifying

asymptomatic carriers in a population. Such pan-ethnic expanded carrier screening (ECS) with follow-up care may improve preventive preconception measures.

Methods: A new ECS at Genetika Plzen targets 128 autosomal and 23 X-linked MRDs (103 genes), reflecting the international guidelines (ESHG, ACOG, ACMG). Our ECS employs an NGS panel with a hybridization enrichment using custom probes (Agilent Technologies), the MiSeq V3 Platform (Illumina), and the Varsome Clinical software (Saphetor SA). For all genes, the entire coding sequence including UTRs and exon-intron junctions are examined, both SNVs and CNVs are assessed. Only variants of pathogenicity classes 4 and 5 are reported.

Results: During 2021-2023, we screened 406 subjects, 198 couples and 10 individuals, mostly living in the Czech Republic. 238 individuals (59%) carried at least one class-4/-5 gene variant. We identified 16 couples (8%) with increased reproductive risk, i.e., either the female partner (for X-linked MRDs) or both partners (autosomal MRDs) carrying a clinically significant variant in the affected gene. As follow-up care, they were offered preimplantation/prenatal diagnostics.

Conclusion: Within preconception care, we have successfully established ECS to significantly reduce the risk of having a child suffering from a severe MRD (the ECS detection rate of up to 99% is achieved for most genes). Our results show that ECS detects significant percentage of couples at reproductive risk even in a population without high prevalence of particular MRDs.

P02.011.A Association of IL-6 polymorphism -174G>C with the Premature Ovarian Insufficiency in Bulgarian patients

*Ivelina Oprova[1], **Eliana Dimova**[2], Kalina Belemezova[2], Mariela Hristova-Savova[2], Petya Andreeva[1], Ivanka Dimova[3]*

[1]Shterev Hospital, Department of Infertility and IVF, Sofia, Bulgaria; [2]Shterev Hospital, Department of Medical genetics, Sofia, Bulgaria; [3]Medical University Sofia, Department of Medical genetics, Sofia, Bulgaria

Background/Objectives: Primary premature ovarian insufficiency (POI) represents the premature exhaustion of the ovarian reserve in women under the age of 40. Interleukin-6 is implicated in the pathophysiological characteristics associated with this condition. We explored the frequency in IL6 gene polymorphism -174 G>C among patients with POI, compared to non-selected European individuals (controls), with the aim of establishing a correlation between this genetic factor and the disease.

Methods: Twenty-four patients with POI (median age of 33.5 years) were subjected to our survey. IL 6 gene polymorphism -174 G>C was examined by Real-Time PCR Genotyping kit (DNA Technology LLC). The allele and genotype frequencies were compared to the data from 503 controls (data collected from ensembl.org). For the purpose of our study, we used the Chi-Square Test ($p < 0.05$ was considered significant).

Results: The genotype frequencies observed among the 24 cases and 503 controls were as follows: *G/G* - 62.5 % and 36 %, *G/C* - 33.3 % and 44,9 %, and *C/C* - 4.2 % and 19,1 %. The *G* and *C* allele frequencies were 79.2 % (cases) and 58,4 % (controls), and 20.8 % and 41,6 %, respectively. The genotype G/G and G allele distribution revealed significant differences between POI patients and controls (p values < 0.05).

Conclusion: We discovered an association of IL 6 –174 G/G genotype and G allele with POI in Bulgarian patients. IL-6 is involved in inflammation and apoptosis and dysregulation of these processes could contribute to the accelerated loss of ovarian follicles seen in POI.

P02.012.B Fractonation of high-quality spermatozoa promotes peripherial positioning of sex chromosomes

Zuzanna Graczyk[1], *Jagoda Kostyk[1], Julia Pospieszna[1,2], Zuzanna Myślicka[1], Marzena Kamieniczna[1], Marta Olszewska[1], Maciej Kurpisz[1]*

[1]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland; [2]Poznan University of Medical Sciences, Department of Toxicology, Collegium Pharmaceuticum, Poznan, Poland

Background/Objectives: Sperm chromosomes are non-randomly organized in three-dimensional nuclear space. This nuclear organization is one of the epigenetic mechanisms that can regulate genome functioning. After fertilization, chromosomes undergo chromatin remodeling, transcriptional activation and replication.

The aim of this study was to determine whether selection of spermatozoa with good motility or proper chromatin density, defines specific positioning of chromosomes.

Methods: Semen samples from 5 normozoospermic males were collected and processed for fractionation *via* swim up (to select viable and motile spermatozoa) or Percoll gradient (to select sperm with properly packed chromatin). Fluorescence in situ hybridization (FISH) was applied to analyse the positioning of chromosomes 4, 7, 8, 9, 18, X and Y. At least $n \geq 100$ of spermatozoa per subpopulation/chromosome were analysed (Leica DM5500 microscope, filter set: DAPI, SpG, SpO, SpAq, 630x magnification, motorized stage, LASX Navigator software).

Results: In spermatozoa with good motility or proper chromatin density, chromosome 4 moves towards the acrosome, compared to non-fractionated sperm. In motile sperm fraction chromosomes 18, X, and Y shift to the nuclear periphery, while in sperm with condensed chromatin, chromosomes 8, 9, and Y move to the nuclear periphery, compared to non-fractionated sperm.

Conclusion: High-quality sperm selectioning promotes repositioning of sex chromosomes towards nuclear periphery, which is the first region that interacts with the ooplasm during fertilization. Then, sex chromosomes must undergo remodelling of chromatin due to Meiotic Sex Chromosome Inactivation, which is crucial in the early stages of embryo development.

P02.013.C Genetic and functional evidence for *TDRD6* as male infertility-associated gene

Farah Ghieh[1], *Erik Schüftan[1], Sabine Kliesch[2], Frank Tüttelmann[1], Birgit Stallmeyer[1]*

[1]Institute of Reproductive Genetics (IRG), University of Münster, Münster, Germany; [2]Center of Reproductive Medicine and Andrology (CeRA), University Hospital Münster, Münster, Germany

Background/Objectives: Tudor domain-containing protein 6 (TDRD6) is essential for spermatogenesis and male fertility in mice. It localises to the chromatoid body (CB), a subcellular structure in round spermatids, and interacts with key proteins of the piRNA pathway. The function of TDRD6 in humans is unexplored warranting investigations whether *TDRD6* is also a disease gene for male infertility.

Methods: Exome/genome data of 2,362 infertile men with severe oligo- or azoospermia from the Male Reproductive Genomics (MERGE) study were screened for rare (MAF <0.01 in gnomAD) biallelic high impact variants in *TDRD6* (loss-of-function or missense with CADD >20). Compound heterozygosity was

established by segregation analysis or long-read sequencing. Testicular phenotypes and the impact of TDRD6 on the chromatoid body architecture were determined by immunohistochemical staining of marker proteins.

Results: We identified five infertile men with biallelic variants in *TDRD6* who shared a common reproductive phenotype of oligoasthenoteratozoospermia (OAT). One patient carried a homozygous missense variant and four patients were compound heterozygous for a loss-of-function variant and a missense variant. Two missense variants were predicted to destabilise TDRD6 protein structure. In two variant carriers, the subcellular localisation of CB marker protein DDX4 was impaired while the expression profile of piRNA pathway factors PIWIL1 and MAEL was unaffected.

Conclusion: This study establishes *TDRD6* as candidate gene for OAT-related human male infertility and provides functional evidence for a role of TDRD6 in CB formation during late spermatogenesis.

Grants: This work was supported by the IZKF Münster (Tüt4/011/23).

P02.014.D Gennet Endometrium Receptivity Test

Štěpán Chvojka[1], *Lucie Dohnalova*[1], *Romana Vlckova*[1], *Simona Suhajova*[1], *Hana Dvorackova*[1], *Martina Bittoova*[1], *Monika Koudová*[1]

[1]*GNTlabs by GENNET, Czech Republic*

Introduction: Nowadays in vitro fertilization treatment is a complex process which thanks to new knowledge and technological development is constantly being expanded to include additional examinations with one common goal - to increase the success of this treatment and thus enable the couple to have a healthy child. One of them is the examination of endometrial receptivity.

Methods: The endometrium is normally examined using ultrasound, with the development of Next Generation Sequencing (NGS) methods it is possible to assess the endometrium from another point of view, that of molecular genetics. The endometrium becomes receptive to the embryo only during a short period of time in the menstrual cycle. NGS techniques in combination with prediction algorithms make it possible to determine this period and determine the "implantation window", the time when the endometrium is most receptive to embryo transfer. This should ideally be between 19-21 day of the cycle for every fertile woman. However according to studies, up to 30% of women have a shifted implantation window.

Results: In cooperation with the Yikon company we have implemented the GERT (Gennet Endometrium Receptivity Test) in our laboratory which evaluates a total of 175 genes involved in the receptivity. Examination is indicated in women with repeated failure of euploid embryo implantation (after PGT-A). The result of the test is to determine whether the patient's endometrium is in the pre-, post- or receptive phase.

Conclusion: Based on the results the optimal time of the personalized embryo transfer is then recommended to the patients.

Conflict of Interest: None declared

P02.015.A Investigating the role of solute carrier family of genes in adenomyosis pathogenesis utilizing whole exome sequencing in a sporadic patient cohort

Nimet Eser[1], *nura fitnat topbas selcuki*[2], *Ipek Yildiz Ozaydin*[3], *engin oral*[4], **Feyza Tuncer**[5]

[1]*Istanbul University, Graduate School of Health Sciences, Istanbul, Türkyie;* [2]*Istanbul Sisli Hamidiye Etfal Training and Research Hospital, Department of Obstetrics and Gynecology, Istanbul, Türkyie;* [3]*Istanbul Kanuni Sultan Suleyman Training and Research Hospital, Department of Pathology, Istanbul, Türkyie;* [4]*Biruni University Faculty of Medicine, Department of Obstetrics and Gynaecology, Istanbul, Türkyie;* [5]*Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Genetics, Istanbul, Türkyie*

Background/Objectives: Adenomyosis and endometriosis are gynecological benign conditions characterized by the ectopic localization of endometrial tissue and stroma, which manifest with similar symptomology. Definite diagnosis is accomplished through histopathological confirmation of disease with surgical material. So far, genetic studies focused on endometriosis with limited attention to adenomyosis. We aimed to identify shared genetic variants among sporadic adenomyosis patients utilizing whole exome sequencing (WES).

Methods: Ten women, who received histopathological diagnosis of adenomyosis were recruited. Genomic DNA isolated from peripheral blood was subjected to WES on Illumina NovaSeq 6000 system. Pairend NGS Cloud platform was utilized in bioinformatic analysis, followed by filtering for MAF < 1%. Variants were prioritized in accordance with functional relevance and impact determined by in silico prediction tools.

Results: Remarkable accumulation of rare genetic variants in the members of the solute carrier family of genes (SLCs) were detected in our cohort. Among them, three of our patients carried rare variants of SLC12A1 and SLC12A2 which were prominent due to abnormal expression levels determined in a previous study. Moreover, nine of our patients harbored rare variants in genes (*SIX4, BSND, WNK2, SGK1, SLC12A9)* shown to influence the expression of *SLC12A1* and *SLC12A2*.

Conclusion: This is the first study to assert the importance of SLCs in the pathogenesis of adenomyosis through WES analysis. Prospective work includes assessing the expressions of *SLC12A1* and *SLC12A2* utilizing the genomic materials recovered from these patients' formalin-fixed paraffin-embedded hysterectomy tissues.

P02.016.B Estimation of carrier frequencies of autosomal recessive genetic conditions based on gnomAD v4.0 data

Ronja Hotakainen[1], *Timo Järvinen*[1], *Kaisa Kettunen*[1], *Anna-Kaisa Anttonen*[1;2;3], *Eveliina Salminen*[2;3]

[1]*University of Helsinki and Helsinki University Hospital, Laboratory of Genetics, Helsinki, Finland;* [2]*Helsinki University Hospital, Department of Clinical Genetics;* [3]*University of Helsinki, Department of Medical and Clinical Genetics, Helsinki, Finland*

Background/Objectives: A comprehensive strategy in the screening and prevention of rare diseases would benefit the current healthcare system. While monogenic rare diseases are relatively rare on their own, they contribute to around 10% of infant deaths and 20% of pediatric hospitalizations. The American College of Medical Genetics and Genomics recommends screening of autosomal recessive and X-linked conditions with a population frequency of ≥ 1/200, for all pregnant patients and those planning a pregnancy. Previous studies have used gnomAD v2.1.1 and v3.1.2 to estimate the gene carrier frequencies (GCF). In November 2023 gnomAD v4.0 was released, being nearly 5x larger than previous versions v2 and v3. The new 4.0 release provides added global diversity since it includes around 138 000 individuals of non-European ancestry.

Methods: We utilized the newest gnomAD v4.0 to calculate the GCF for gnomAD v4.0 populations. The analysis was performed for OMIM autosomal recessive genes utilizing ClinVar P/LP and

Conflicting variants with > 80% P and/or LP classifications. The gnomAD v4.0 data is available for download separately as exomes and genomes. We combined these data to calculate the combined GCF and at-risk couple rates (ACR) per population.

Results: The number of genes with GCF ≥ 1/200 varied greatly per population, whereas the at-risk couple rates were more similar between populations, Ashkenazi Jewish having the highest ACR of 6.16%.

Conclusion: This work highlights the effects of increased samples sizes in gnomAD v4.0 on GCFs.

Grants: This work was supported by Helsinki University Hospital Diagnostic Center Research fund.

P02.017.C Success rate of mosaic embryos in ART cycles

Jose A. Ortiz[1;1], Ruth Morales[1], Belen Lledó[1], Alba Cascales[1], Adoracion Rodriguez-Arnedo[2], Andrea Bernabeu[3], Rafael Bernabeu[3]

[1]Instituto Bernabeu, Molecular Biology and Genetics, Alicante; [2]Instituto Bernabeu, Reproductive Biology, Alicante; [3]Instituto Bernabeu, Reproductive Medicine, Alicante

Background/Objectives: After embryo biopsy and PGT-A analysis, embryos can be classified as euploid, aneuploid or mosaic in which normal and chromosomally altered cells are combined. The transfer of mosaic embryos has been controversial, but currently the recommendation of international scientific societies is to transfer them as they have been shown to result in healthy children and the risk of congenital anomaly is similar to spontaneous pregnancies. The aim of the study is to analyse the clinical outcomes of mosaic embryos compared to euploid embryos.

Methods: Observational and retrospective study. A total of 9385 embryos from 2899 PGT-A cycles were included (January-2017 to October-2023). The trophectoderm biopsies were analysed by NGS. Clinical data from euploid and mosaic embryos were compared using binary-logistic regression (Rv.4.3.1).

Results: The analysis of embryos through PGT-A revealed that 54.17% were aneuploid, and 9.97% showed mosaicism. A total of 2166 embryos were transferred, of which 274 showed mosaicisms. No differences were observed in the clinical outcomes between euploid and mosaic groups. The pregnancy, biochemical and clinical-pregnancy loss and ongoing-pregnancy rates were 54.3 vs. 51.8, 9.0 vs. 8.8, 14.0 vs. 11.2 and 38.8 vs. 37.9 percent, respectively. Furthermore, when data are analysed according to the percentage or type of mosaicism (segmental vs. whole chromosome) or the number of chromosomes involved, no differences in clinical outcomes are observed.

Conclusion: Mosaic embryos have a high implantation potential, comparable to that of euploid embryos. Non-transfer of these embryos would reduce the chances of successful ART.

Grants: Not applicable.

P02.018.D Possible exacerbation of semen phenotype in infertile men by an additive contribution of 2 genetic factors

Sandra Kleiman[1;2], Noga Weizman[1], Shimi Barda[1], Ofer Lehavi[1], Eli Arama[3], Shmuel Pietrokovski[3], moran gershoni[4]

[1]Tel Aviv Sourasky Medical Center; [2]Sackler Faculty of Medicine, Tel Aviv University; [3]Weizmann Institute of Science; [4]Institute of Animal Science, ARO-The Volcani Center

Background:

Patients with **c**omplete microdeletions of the **az**oospermia **f**actor-**c** region (c-AZFc) present with severe oligozoospermia (sO) or azoospermia. c-AZFc azoospermic men have a 75% chance of locating sperm cells in testicular extraction but have poorer ICSI-related outcomes than oligozoospermic men.

Objectives: To assess the involvement of additive genetic factors in the phenotype heterogeneity of c-AZFc patients.

Methods: Whole exome sequence analysis on three pairs of related male patients, Sanger sequencing, RFLP screening, scRNA-seq data analysis, microsatellites analysis, Y-chromosome micro-deletions, and karyotyping.

Results: In two brothers from a consanguineous family, one was azoospermic with c-AZFc microdeletion, and the other presented sO with no microdeletion; we identified a novel and likely pathogenic homozygous rare variant in a gene previously annotated in sO in humans and mice. The variant was absent in our cohort of fertile and infertile men.

The second pair was of a father and his son from a consanguineous family. The father has sO, and his son is azoospermic with a c-AZFc microdeletion and testicular maturation arrest. Six candidate pathogenic variants (CPV) are currently under assessment.

Lastly, a CPV in a testis exclusively expressed gene was detected in two remotely related infertile men. One was sO, and the second was azoospermic with c-AZFc microdeletion. In our cohort, this allele was detected only in infertile men in a heterozygote state.

Conclusion: An additive effect of two genetic factors on the semen phenotype is demonstrated for the first time. Additional CPV-causing sO that are likely exacerbated by c-AZFc microdeletion are currently being assessed.

P02.019.A Whole-genome sequencing for infertile couples: Moscow experience

Madina Kaplanova[1], Aleksandra Galaktionova[1], Alexander Potapov[1], Olesya Sagaidak[1], Ekaterina Kuznetsova[1], Maxim Belenikin[1], Anton Olenev[2]

[1]LLC Evogen, Moscow, Russian Federation; [2]Moscow State Budgetary Institution of Healthcare "G. M. Savelevoi City Clinical Hospital No.31", Moscow, Russian Federation

Background/Objectives: Infertility is defined by the failure to achieve a pregnancy after 1 year or more of regular unprotected sexual intercourse, it is affects an estimated 15% of couples globally. Whole-genome sequencing (WGS) may identify previously unknown infertility's causes and could be an effective method of identifying genetic variants causing reproductive loss.

Methods: WGS was performed for 192 infertile couples (384 persons: 192 males and 192 females) at Evogen lab using DNBseq-T7/G400 (MGI, China). The sequencing data were bioinformatically processed and interpreted by experts, the genetic variants were validated using Sanger sequencing.

Results: According to the results of sequencing 49 (12,8%) samples 71 genetic variants were defined, which could be considered as a cause of reproductive losses, including: 18 (25,4%) pathogenic variants, 9 (12,7%) likely pathogenic variants, 39 (54,9%) variants of uncertain significance and 5 (7,0%) structural anomalies. Among 192 males with diagnosis of infertility 20 (10,4%) variants were identified associated with spermatogenesis disorder. Among 192 females diagnosis of infertility 29 (15,1 %) variants were identified associated with pregnancy loss. Thus, among infertility couples 200 (10,4%) males and 29 (15,1%) females were found to have variants that were the probable cause of reproductive failure.

Conclusion: Pathogenic, likely pathogenic and variants of uncertain significance that could have been the cause of

reproductive failures were identified by WGS. These results helped couples and doctors to plan future pregnancies with the use of assisted reproductive technology.

Grants: The work was supported by the Moscow Department of Health grant.

P02.020.B Analysis of mitochondrial DNA variant segregation - a tool for implementing Preimplantation Genetic Testing for mitochondrial DNA-related disorders at the blastocyst stage

Paula Rubens[1;2], *Kalliopi Chatzovoulou*[1;2], *Anne Mayeur*[3;4], *Nadine Gigarel*[5], *sophie monnot*[5], *Agnès Rötig*[1;2], *nelly achour*[3;4], *Julie Steffann*[1;2;5]

[1]*Imagine Institute, Genetics of mitochondrial diseases, Paris, France;* [2]*Université Paris Cité, Paris, France;* [3]*Antoine Béclère Hospital, Reproductive Biology Unit CECOS, Clamart, France;* [4]*Université Paris-Saclay, Paris, France;* [5]*Necker Sick Children's Hospital, Genomic Medicine Unit, Paris, France*

Background/Objectives: Mitochondrial DNA (mtDNA) related diseases are severe, maternally inherited disorders. Their clinical heterogeneity is attributed to the coexistence of mutant and wild-type mtDNA molecules in the same cell, called heteroplasmy. Preimplantation genetic testing for mtDNA disorders (PGTmt) is challenging because it requires that the mutant load remain stable among the different cells and during development. Because data is scarce concerning mtDNA segregation at the blastocyst stage, we aimed to assess the reliability of trophectodem (TE) biopsy for PGTmt, by comparing it to the traditional blastomere results.

Methods: Among the 43 embryos studied, 28 carried pathogenic mtDNA variants (m.8344A>G n = 12, m.3243A>G n = 8, m.8993T>G n = 4, m.8993T>C n = 2, m.13094T>C n = 2) and 15 had mtDNA polymorphism (HV2). Heteroplasmy levels were determined by semiquantitative fluorescent PCR as described. Approval was granted by the French Biomedical Agency.

Results: A strong correlation was found between heteroplasmy levels of: i) blastomere and TE biopsies for both mutant load ($R^2 = 0.93$, $p < 0.0001$,$n = 14$) and the prevalent HV2 allele ($R^2 = 0.91$, $p < 0.0001$,$n = 20$); ii) TE biopsies and the rest of the blastocyst ($R^2 = 0.97$, $p < 0.0001$,$n = 12$), and iii) TE and inner cell mass samples ($R^2 = 0.93$, $p < 0.0004$,$n = 7$). A variation of up to 18% of the HV2 heteroplasmy level was observed among TE single-cells (n = 38) isolated from 6 embryos (mean SD = 2.6).

Conclusion: The strong correlation of mtDNA heteroplasmy levels between cleavage and blastocyst stage contributes to a potential shift to the desirably less invasive trophectoderm biopsy but must be considered with caution due to variability found among single TE cells.

P02.021.C Large copy number variants in infertile men

Triin Kikas[1], **Rain Inno**[1], *Avirup Dutta*[1], *Kristjan Pomm*[2], *Margus Punab*[2], *Maris Laan*[1]

[1]*Institute of Biomedicine and Translational Medicine, Chair of Human Genetics, Tartu, Estonia;* [2]*Tartu University Hospital, Andrology Clinic, Tartu, Estonia*

Background/Objectives: Spermatogenic failure (SPGF) affects ~10% of men. Our microarray based study in 215 SPGF patients identified a two-fold higher representation of > 1 Mb copy number variants (CNVs) in cases compared to fertile controls (13% vs 6.5%) (Kikas et al Sci Rep 2023). This study aimed to exploit whole exome (WES) data to map large CNVs and their clinical consequence in infertile men.

Methods: The study group comprised of 428 idiopathic azoo- or oligozoospermia patients recruited to the Estonian Andrology (ESTAND) cohort. WES was generated for DNA extracted from the whole blood using the FIMM NGS Sequencing service (Helsinki, Finland). Primary sequencing analysis and CNV calling were performed using the Illumina DRAGEN Bio-IT Platform (v3.9 and v3.10, GRCh38 assembly). CNV dataset was filtered for deletions or duplications > 500kb and a frequency of <1% in our study sample. All large CNVs were evaluated using VEP v105 to determine the likelihood of their pathogenicity. Prioritized CNVs were externally experimentally validated by arrayCGH or whole-genome sequencing (WGS).

Results: In total, 83 large CNVs with high confidence were identified in 64 patients. CNVs linked to known microdeletion and microduplication syndromes were identified in nine previously undiagnosed individuals (2.1%). Additional six large CNVs (0.5-2.5 Mb) included several haplo- and triplosensitive genes, some of which are implicated in genetic conditions and/or testicular function.

Conclusion: Among severe SPGF patients, 15% carried >500 kb CNVs. Clinically valid microdeletions or -duplications (15/428, 3.5%) were overrepresented compared to the general population.

P02.022.D Reverse phenotyping informing variant pathogenicity in reproductive carrier screening

Cara Beck[1], *Alison Archibald*[1;2;3], *Edwin Kirk*[4;5;6], *Nigel Laing*[7;8;9], *Martin Delatycki*[1;3;10]

[1]*Victorian Clinical Genetics Services, Parkville, Australia;* [2]*Murdoch Children's Research Institute, Parkville, Australia;* [3]*Department of Paediatrics, The University of Melbourne, Parkville, Australia;* [4]*School of Women's and Children's Health, University of New South Wales, Randwick, Australia;* [5]*NSW Health Pathology Randwick Genomics Laboratory, Randwick, Australia;* [6]*Centre for Clinical Genetics, Sydney Children's Hospital, Randwick, Australia;* [7]*Department of Diagnostic Genomics, PathWest Laboratory Medicine, Nedlands, Australia;* [8]*Centre for Medical Research, University of Western Australia, Nedlands, Australia;* [9]*Harry Perkins Institute of Medical Research, Nedlands, Australia;* [10]*Bruce Lefroy Centre, Murdoch Children's Research Institute, Parkville, Australia*

Consortium: The Mackenzie's Mission Study Team

Background/Objectives: A particular challenge of variant classification in reproductive carrier screening is the need to assess variants in the absence of a proband with a phenotype. Familial segregation can provide additional evidence for or against pathogenicity, particularly for X-linked variants. The Australian Reproductive Genetic Carrier Screening Project (Mackenzie's Mission) screened 9107 couples for >1300 genes that underlie ~750 serious childhood onset conditions. We report on three X-linked variants, initially classified as Likely Pathogenic, that were found to segregate in unaffected males.

Methods: Mackenzie's Mission methods and gene selection processes have been described previously. When a likely pathogenic variant was identified in an X-linked gene, genetic counselling included a discussion around testing male family members. If a male was identified with the variant, phenotypic assessment, including biomarker analysis where possible, was undertaken.

Results: Likely Pathogenic X-linked variants *IDS*, *COL4A5* and *F8* were identified in multiple couples. Males in the families were tested and some were found to carry the variant without a

significant phenotype. The male carrying the *IDS* variant had reduced iduronate-2-sulphatase levels with no clinical evidence of Hunter syndrome. Biomarker evaluation of males who carried the *COL4A5* and *F8* variants was normal, therefore ruling out Alport syndrome and haemophilia respectively.

Conclusion: Segregation and reverse phenotyping provided additional information, and in some cases, reproductive reassurance to the couples. This approach will become more important as increased numbers of genes are included in expanded reproductive carrier screening.

Grants: Funded by Australian Government Medical Research Future Fund (GHFM73390).

P02.023.A Polymorphisms of *ACE* and thrombophilic genes: risk for recurrent pregnancy loss

Olivera Miljanovic[1;2], *Vesna Ilic*[3], *Dragan Likic*[4], *Sladjana Teofilov*[1], *Bojana Cikota-Aleksić*[5], *Zvonko Magic*[6], *Jelena Jovanovic*[1]

[1]*Clinical Centre of Montenegro, Center for Medical Genetic and Immunology, Podgorica, Montenegro;* [2]*University of Montenegro, Faculty of Medicine, Podgorica, Montenegro;* [3]*Military Medical Academy, Institute of Medical Research, Belgrade, Serbia;* [4]*Institute for Public Health of Montenegro, Podgorica, Montenegro;* [5]*Military Medical Academy, Beograd, Serbia, Center of Clinical Pharmacology, Belgrade, Serbia;* [6]*Serbian Medical Society, Academy of Medical Sciences, Belgrade, Serbia*

Background/Objectives: The etiology of recurrent pregnancy loss (RPL) remains unclear in about 50% of cases. Polymorphisms in genes affecting coagulation and fibrinolysis have been postulated as a risk factor for RPL. We report the association between *SERPINE1* and *ACE* gene polymorphisms, and RPL in Montenegrin women.

Methods: Five gene polymorphisms, *F2* 20210G>A (rs1799963), *F5* 1691G>A (rs6025), *MTHFR* 677C>T (rs1801133), *SERPINE1* −675 4G/5G (rs1799762) and *ACE* I/D (rs1799752) were investigated in total of 224 women: 129 women with ≥2 early RPL or ≥1 late pregnancy loss, and 95 women with at least two normal life births and no history of pregnancy loss. Gene polymorphisms were genotyped by PCR-based methods.

Results: *SERPINE1* 4G/4G and *ACE* D/D gene polymorphisms are found significantly more prevalent among women with RPL ($p < 0.001$ both, OR 2.91 and 3.02, respectively). No association was found between *F2* 20210G>A, *F5* 1691G>A and *MTHFR* 677C>T polymorphisms and risk for RPL. A combination of *SERPINE1* 4G/4G + *ACE* D/D homozygotes was highly associated with RPL (Cochran-Armitage test, $p < 0.001$), and their strong independent association with RPL was confirmed by logistic regression analysis (both p values <0.001, OR 3.35 and 3.43, respectively).

Conclusion: This study demonstrated that impaired fibrinolysis, caused by the hypofibrinolytic polymorphisms in the *SERPINE*1 and *ACE* genes, may be a significant risk for RPL. The findings may add to the data on hereditary thrombophilia role in the pathogenesis of RPL and may address whether *SERPINE1* and *ACE* gene polymorphisms should be included in the diagnostic work-up of women with RPL.

P02.024.B Maternal whole blood transcriptomic signatures across 4 time points during pregnancy in 1,300 women

Sophie Hoffman[1], *Katie L Burnham*[1], *Emma Cook*[2], *D. Steve Charnock-Jones*[2;3], *Gordon Smith*[2;3], *Emma Davenport*[1]

[1]*Wellcome Sanger Institute, Hinxton, United Kingdom;* [2]*University of Cambridge, Department of Obstetrics and Gynaecology, Cambridge, United Kingdom;* [3]*University of Cambridge, Centre for Trophoblast Research, Department of Physiology, Development and Neuroscience, Cambridge, United Kingdom*

Background/Objectives: Pregnancy is a unique condition involving physiological and immunological changes in women throughout the three trimesters. Previously, transcriptomic studies performed on small cohorts have identified genes that are differentially expressed throughout pregnancy. However, lack of comprehensive descriptions of normal change in the maternal immune system during pregnancy precludes the identification and interpretation of abnormal changes and the subsequent development of measures to mitigate or prevent pregnancy complications.

Methods: In the Pregnancy Outcome Prediction Study (POPS2), we collected whole blood from pregnant women for genotyping ($n = 1,086$) and bulk RNA-seq ($n = 1,308$) at up to 4 time points (12, 20, 28 and 36 weeks). The resulting 3,781 RNA-seq samples make this the largest such cohort to date, with 887 individuals having ≥ 3 RNA-seq samples.

Results: Dream identifies differentially expressed genes (DEGs) between time points, both recapitulating findings from previous pregnancy transcriptome studies and introducing novel DEGs. DEG quantification (table) highlights time points between which the maternal immune system changes the most (12 vs. 36 weeks, $n = 3947$) and least (20 vs. 28 weeks, $n = 605$). CIBERSORTx analysis reveals imputed immune cell proportions vary by individual and time point.

Conclusion: Characterisation of normal variation in the maternal immune system during pregnancy will ultimately enable the identification and interpretation of biomarkers predictive of complications. Future work will incorporate genotyping data to identify regulatory variants contributing to transcriptomic variation in pregnancy.

Number of DEGs between timepoints	20wks.	28wks.	36wks.
12wks.	787	1875	3947
20wks.		605	2317

P02.025.C Contribution of *HLA-G* 14bp insertion/deletion polymorphism in the genesis recurrent pregnancy loss

Kateryna Sosnina[1], *Danuta Zastavna*[1], *Oresta Terpyliak*[1], *Bohdan Tretiak*[1]

[1]*State Institution «Institute of Hereditary Pathology of the National Academy of Medical Sciences of Ukraine», Diagnostics of hereditary pathology, Lviv, Ukraine*

Background/Objectives: HLA-G is a non-classical human leukocyte antigen expressed primarily in fetal tissues at the maternal–fetal interface and be involved in interactions that are critical in establishing and maintaining pregnancy. The specific polymorphisms found in coding and regulatory parts of *HLA-G* gene and associated with its different expression, might be important for pregnancy prolongation. In this study, we focused our attention on polymorphism insertion/deletion 14 base pairs at 3`UTR region of *HLA-G* gene, since it is known that this polymorphism directly affects the level of gene expression. The **aim** of our study was to analyze of the distribution of *HLA-G 14bp insertion/deletion* polymorphism among the woman with recurrent pregnancy loss (RPL) and in spontaneously aborted embryos.

Methods: DNA extraction from peripheral blood cells and chorionic villi, PCR, gel electrophoresis.

Results: Genotyping of *HLA-G 14bp insertion/deletion* polymorphism was performed in 86 women with RPL, 220 spontaneously aborted embryos and 55 control. The significantly higher *HLA-G 14bp insertion/insertion* genotype frequency was established in women with RPL and in spontaneously aborted embryos ($P < 0.05$) compared to the control. Calculation of odds ratio showed that the presence *14 bp insertion/insertion genotype* of the *HLA-G* gene in the embryo or in the woman increases the risk of recurrent pregnancy loss more than twice (OR = 2.34 and 2.65).

Conclusion: Considering the obtained results regarding the association of the homozygous genotype of 14 bp insertion of the *HLA-G* gene, we anticipate a specific role of the non-classical antigen HLA-G in the prolongation of human pregnancy.

P02.026.D Decoding the genetic links between endometriosis and its comorbidities: implications for disease risk and aetiology

Isabelle McGrath[1], *Grant W. Montgomery*[1], *Sally Mortlock*[1]

[1]*Institute for Molecular Bioscience, Saint Lucia, Australia*

Background/Objectives: Endometriosis is a poorly understood gynaecological disease with prolonged diagnostic delays, invasive diagnosis and ineffective treatment. The disease has diverse symptoms and there are multiple comorbidities. We aim to comprehensively characterise the comorbidities of endometriosis.

Methods: Comorbidities were identified by correlation with both endometriosis diagnosis and polygenic risk scores (PRS-PheWAS) in 5,432 endometriosis cases and 92,344 controls from the UK Biobank. Shared genetic architecture was explored with genetic correlation and causality investigated with Mendelian randomisation. The interplay between endometriosis PRS and comorbidities on endometriosis risk was examined.

Results: Endometriosis diagnosis correlated with 292 ICD10 codes, spanning gynaecological, immune, pain, psychiatric, gastrointestinal and urinary systems. PRS-PheWAS in males underscored the importance of female-specific pathways in the comorbid relationships. Most comorbidities could be attributed to shared genetics, with one novel causal effect discovered for testosterone levels. While cases harboured more comorbidities than controls, their comorbidity burden inversely correlated with PRS, indicating the contribution of comorbidities in addition to genetics for diagnosis. Furthermore, the impact of certain traits on endometriosis risk varied by endometriosis PRS, emphasising the nuanced relationship between comorbidities and genetic predisposition.

Conclusion: Endometriosis shares a genetic architecture with conditions across diverse biological systems. Despite limited evidence of individual traits causing endometriosis, overlapping biological pathways and the cumulative burden of conditions influence endometriosis risk. These findings offer valuable insights into the endometriosis aetiology and hold clinical implications for risk ascertainment.

P02.027.A Endometrial Fluid: a promising liquid biopsy to search for (epi)genomic-based diagnostic biomarkers of gynecological diseases

Bárbara P. González-García[1;2], *Aintzane Rabanal*[1;2;3], *Olaia Farto-Juaristi*[1], *Sofia g. Castresana*[1], *Elena Urquijo*[3], *Alba Hernangomez-Laderas*[1;2], *Ariadna Cilleros-Portet*[1;2], *Sergi Marí*[1;2], *Nora Fernandez-Jimenez*[1;2], *Amaia Irizar*[1;4;5], *Santiago Díez*[2;3], *Roberto Matorras*[1;2;3], *Jose Ramon Bilbao*[1;2;6], **Iraia García-Santisteban**[1;2]

[1]*University of the Basque Country (UPV/EHU), Leioa, Spain;* [2]*Biobizkaia Health Research Institute, Barakaldo, Spain;* [3]*Cruces University Hospital, Barakaldo, Spain;* [4]*Biogipuzkoa Health Research Institute, Donostia, Spain;* [5]*Center for Biomedical Research in Epidemiology and Public Health Network (CIBERESP), Madrid, Spain;* [6]*Center for Biomedical Research in Diabetes and Associated Metabolic Disorders (CIBERDEM), Madrid, Spain*

Background/Objectives: Gynecological diseases are posing a great burden on healthcare systems, due, in part, to the lack of minimally invasive diagnostic biomarkers. Endometrial fluid, a type of liquid biopsy that can be obtained in routine gynecological examinations, has proven promising for biomarker identification. Considering that part of the susceptibility to complex gynecological diseases is mediated by genetic variants that regulate DNA methylation (methylation Quantitative Trait *Loci*, mQTL), here we aim to identify (epi)genomic diagnostic biomarkers in endometrial fluid.

Methods: Endometrial fluid was collected from more than 200 women of reproductive age, together with more than 30 clinical parameters. DNA was isolated in order to obtain genotype and methylation data, using the Illumina GSA and EPIC arrays, respectively. After quality control (QC), (epi)genomics data were combined with TensorQTL to calculate endometrial fluid mQTLs. Finally, Summary data-based Mendelian Randomization (SMR) was used to integrate the identified mQTLs and public summary statistics of GWAS from several gynecological disease.

Results: In the first batch of DNA isolated from endometrial fluid, 103 samples passed genotyping and methylation QC, and were used to calculate 564,734 mQTL on endometrial fluid ($p < 5 \times 10^{-8}$). Integration of mQTL and GWAS of endometriosis, uterine leiomyoma, and ovarian, endometrial and cervical cancers, pinpointed several CpG sites that might be mediating disease etiology, and could serve as diagnostic biomarkers upon validation in independent case-control cohorts.

Conclusion: The combination of endometrial fluid mQTL with GWAS data enabled the identification of potential diagnostic biomarkers for gynecological disorders.

P02.028.B M1AP in meiotic recombination: genotype-specific differences in meiotic arrest

Nadja Rotte[1], Jessica Dunleavy[2], Michelle Diane Runkel[1], D. Fietz[3], Adrian Pilatz[4], Johanna Kuß[1], Dicke Ann-Kristin[1], Sofia Boeg Winge[5], Sara di Persio[6], Christian Ruckert[7], Verena Nordhoff[6], Hans-Christian Schuppe[4], Kristian Almstrup[5;8], Sabine Kliesch[6], Nina Neuhaus[6], Birgit Stallmeyer[1], Moira O'Bryan[2], Frank Tüttelmann[1], **Corinna Friedrich**[1]

[1]*Institute of Reproductive Genetics, University of Münster, Münster, Germany;* [2]*School of BioSciences and Bio21 Molecular Sciences and Biotechnology Institute, Faculty of Science, Melbourne, Australia;* [3]*Institute of Veterinary Anatomy, Histology and Embryology, University of Gießen, Gießen, Germany;* [4]*Clinic and Polyclinic for Urology, Paediatric Urology and Andrology, University Hospital Gießen, Gießen, Germany;* [5]*Department of Growth and Reproduction, University Hospital Copenhagen, Copenhagen, Denmark;* [6]*Centre of Reproductive Medicine and Andrology (CeRA), University of Münster, Münster, Germany;* [7]*Department of Medical Genetics, University Hospital Münster, Münster, Germany;* [8]*Department of Cellular and Molecular Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*

Background/Objectives: Meiosis is an indispensable process for generating spermatozoa. The meiosis-specific protein M1AP interacts with the ZZS (Zip2-Zip4-Spo16) proteins SHOC1-TEX11-SPO16 in mice, which are essential for meiotic recombination, especially crossover formation. *M1AP*, *TEX11*, and *SHOC1* represent validated disease genes for male infertility. However, little is known about the interplay of M1AP and ZZS in humans.

Methods: Infertile men with rare (MAF <0.01), biallelic/hemizygous loss-of-function (LoF) variants in *M1AP*, *SHOC1*, *TEX11*, and *SPO16* were queried from exome/genome data from the Male Reproductive Genomics (MERGE) study. Testicular phenotypes were determined by histological staining of marker proteins for different meiotic sub-stages. Using immunofluorescence staining of spermatocyte spreads, the impact on meiotic recombination in affected men was analysed.

Results: We identified the first homozygous LoF variant in *SPO16* in a man with complete meiotic arrest (MeiA). Men with assumed ZZS deficiency shared an early MeiA (*SHOC1* N = 3, *TEX11* N = 7, *SPO16* N = 1). In contrast, in men with *M1AP* LoF variants, haploid round (10 men) or elongated (6 men) spermatids were concordantly detected in testicular sections. Asynapsis of homologous chromosomes and unrepaired DNA double-strand breaks were specifically observed when the ZZS complex was disturbed, while impaired M1AP lead to decreased crossovers. Medically-assisted reproduction in a man homozygous for a *M1AP* LoF variant led to the birth of a healthy child.

Conclusion: While the ZZS proteins seem mandatory for meiotic recombination, it remains possible despite loss of M1AP. Future studies will elucidate the consequences for the offspring.

Grants: This work was supported by the DFG Clinical Research Unit 326 'Male Germ Cells'.

P02.029.C Children conceived using assisted reproductive technologies compared to spontaneous conception show sex differences in DNA methylation

Dana Kristjansson[1;2], *Yunsung Lee[1], Christian Magnus Page[1;3], Maria Christine Magnus[1], Astanand Jugessur[1], Robert Lyle[4], Siri Håberg[1]*

[1]*Norwegian Institute of Public Health, Center of Fertility and Health;* [2]*Norwegian Institute of Public Health, Department of Genetics and Bioinformatics;* [3]*Norwegian Institute of Public Health, Department of Physical Health and Ageing, Center of Fertility and Health;* [4]*Oslo University Hospital*

Background/Objectives: Previous studies have indicated differences in cord blood DNA methylation patterns according to conception by assisted reproductive technology (ART). Furthermore, studies have also shown sex differences in birth outcomes of infants conceived by ART. However, the extent and specific underpinnings of these differences require further exploration through comprehensive research.

Methods: We investigated sex differences in cord blood DNA methylation using the Illumina EPIC platform among 456 ART-conceived versus 507 naturally conceived girls and 503 ART-conceived and 473 naturally conceived boys.

Results: We found widespread differences in DNA methylation levels in ART-conceived newborns compared to those conceived naturally. Notably, we identified 37 differentially methylated CpGs for ART-conceived girls (FDR < 0.01), and 70 differentially methylated CpGs for ART-conceived boys, when compared to same sex naturally-conceived counterparts. Within these, ten CpGs were differentially methylated among the ART-conceived for both sexes.

Conclusions: These sex-specific epigenetic distinctions underscore the nuanced impact of ART on the fetal epigenome and prompt further exploration into the potential implications for developmental trajectories and health outcomes in ART-conceived individuals.

P02.030.D Celiac disease genetic markers in men as a genetic component of idiopathic infertility

Oresta Terpyliak[1], *Danuta Zastavna[1], Kateryna Sosnina[1]*

[1]*State Institution «Institute of Hereditary Pathology of the National Academy of Medical Sciences of Ukraine», Diagnostics of hereditary pathology, Lviv, Ukraine*

Background/Objectives: Celiac disease (CD) is an autoimmune disease triggered by dietary gluten and has been associated with several conditions influencing female and male reproduction. CD genetic components are *HLA-II* class genes known as *HLA-DQ2* and *DQ8*. The aim of study was to investigate distribution of *HLA-DQ2.5* (*HLA-DQA1*05:01* + *HLA-DQB1*02*) and *HLA-DQ8* (*HLA-DQB1*03:02*) genotypes among men from couples with idiopathic infertility (CII)

Methods: SSP-PCR for distribution of *HLA-DQ2.5* and *HLA-DQ8* genotypes. Pooled odds ratio (OR) and prevalence, with 95% confidence intervals were calculated.

Results: We did not establish a significant difference in the frequency of high (*DQ2.5* + *DQ8*) and low risk (*DQ8*) celiac genotypes (P > 0.05) in men from the CII group compared to the control group. As for the medium-high risk genotype (*DQ2.5*), statistical calculations showed a significant (P < 0.01) increase of the *DQ2.5*-genotype frequency in this group compared to the control, and the OR proves 5 times increases of idiopathic infertility risk. We did not establish a significant difference in the

presence of celiac markers in men with CII compared to women from the same couples, which may indicate the equal contribution of men with the celiac genotype as a possible cause of idiopathic infertility.

Conclusion: An increased risk of idiopathic infertility is associated with men carrying *DQ2.5*, a genotype predisposing to CD ($P < 0.01$). The OR proves 5 times increases of idiopathic infertility risk in the presence of the *DQ2.5* genotype in men. Our results indicate the equal contribution both men with celiac genotype and women as a possible cause of idiopathic infertility.

P02.031.A The effect of VitD on testicular tissue gene expression in metabolic syndrome induced endoplasmic reticulum stress

MERYEM SARIKAYA[1;2], *Betül Zorkaya*[2], *Tugce Ozbilenler*[3], *Ayse Evrim Bayrak*[1], *Fatma Kaya Dagistanli*[4], *Bilge Ozsait Selcuk*[1]

[1]*Istanbul Faculty of Medicine, Istanbul University, Medical Genetics, Istanbul, Türkyie;* [2]*Institute of Health Science, Istanbul University, Istanbul, Türkyie;* [3]*Institute of Graduate Studies, Istanbul University-Cerrahpasa, Istanbul, Türkyie;* [4]*Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Medical Biology, Istanbul, Türkyie*

Background/Objectives: Metabolic syndrome (MetS) is one of the prominent risk factors leading to cardiovascular diseases. In recent studies, MetS was associated with testicular dysfunction and male infertility. MetS induced endoplasmic reticulum stress (ERS) and cell death was also reported in testicular tissue. This study aims to investigate the possible effect of Vitamin D (VitD) on MetS induced ERS in testicular tissue.

Methods: A Sprague-Dawley rat MetS model was formed by a special diet. The study groups were consisted of control group ($n = 9$), VitD administrated (170 IU/week, orally) group (VitD; $n = 8$), MetS group ($n = 9$), and MetS+VitD group ($n = 8$). After 15 weeks, testicular tissues of the sacrificed rats were dissected. The gene expressions of ERS pathway *related PERK, IRE1, ATF6, ATF4, GRP78* and *CHOP*; VitD related *VDR* and *ERp57*; and male fertility related aromatase (*CYP19A1*) were analyzed qRT-PCR. Immunohistochemical analyses were performed for GRP78 and CHOP proteins. The statistical significance was analyzed by Student-T test and one-way ANOVA.

Results: The gene expressions of *ERP57* ($p = 0.004$) and *GRP78* ($p = 0.005$) was almost two fold higher in MetS than MetS+VitD group. *VDR* and *CYP19A1* expression was higher in MetS+VitD than MetS group ($p = 0.024$ and $p = 0.018$, respectively). The protein levels of GRP78 ($p < 0.0001$) and CHOP ($p < 0.0001$) was increased in MetS group when compared to other study groups.

Conclusion: The findings of this study suggest that MetS induced ERS pathway play an important role in testicular tissue and can be regulated by VitD.

Grants: This study was supported by the Scientific Research Projects Coordination Unit of Istanbul University (Project No: TYL-2022-39216).

P02.032.B Gender peculiarity of the material of reproductive losses

Iryna Tkach[1;2], *Nataliya Huleyuk*[1], *Danuta Zastavna*[1], *Thomas Liehr*[3], *Halyna Bezkorovaina*[1], *Oksana Lototska-Savchak*[1], *Olga Benko*[4]

[1]*State Institution Institute of Hereditary Pathology of the National Academy of Medical Sciences of Ukraine, Lviv, Ukraine;* [2]*Scientific Medical Genetic Center "LeoGENE", Lviv, Ukraine;* [3]*Institute of Human Genetics, Jena University Hospital, Jena, Germany, Jena, Germany;* [4]*Municipal non-profit enterprise Third Lviv territorial medical association, department of gynecology, Lviv, Ukraine*

Background/Objectives: The prognosis of the reproductive function of women with pregnancy loss is complex and partly based on the results of karyotyping of material of reproductive loss. According to the literature, during conception are formed the same number of male and female fetuses, but more boys are born. The purpose of this study was to evaluate the gender ratio and incidence of chromosomal anomalies in the products of conception (POC).

Methods: Banding cytogenetic and interphase mFISH with the centromeric probe panel for chromosomes 13, 14, 15, 16, 17, 18, 21, 22, X and Y were used.

Results: Were examined 2554 cases of material POC. Among all samples of POC, female karyotype was established in 1330 cases (52.1%), and male karyotype in 1224 cases (47.9%). Gender ratio of female to male in the POC, regardless of presence or absence of chromosomal anomalies (CA), is 1.09:1. Normal karyotype was established in 1638 cases (64.2%), abnormal karyotype in 916 (35.9%). Among the samples of POC with a normal karyotype, the female gender was determined in 801 cases (48.9%), and the male gender in 837 cases (51.1%). In samples with an abnormal karyotype, the female gender was established in 529 cases (57.8%), and the male gender in 387 cases (42.2%). The prevalence of female in POC with CA is due to monosomy X(18.4% of all pathology)

Conclusion: Depending on presence or absence of chromosomal anomalies in POC, the gender ratio differs: with a normal karyotype, female-to-male ratio is 1:1.05, and with an abnormal karyotype, it is 1.37:1 respectively.

P02.035.A Role of MUTYH gene variants in the etiology of recurrent pregnancy loss

Ceren Gezik[1;2], *Durmuş Durmaz*[1], *Cagri Gulec*[1], *Güven Toksoy*[1], *Ezgi Gizem Berkay*[3], *Seher Basaran*[1], *Bilge Ozsait Selcuk*[1]

[1]*Istanbul Faculty of Medicine, Istanbul University, Department of Medical Genetics, Istanbul, Türkyie;* [2]*Istanbul University Institute of Health Sciences, Department of Genetics, Istanbul, Türkyie;* [3]*Istanbul Kent University Taksim Campus, Department of Medical Biology and Genetics, Istanbul, Türkyie*

Background/Objectives: Recurrent pregnancy loss (RPL), is defined as the loss of two or more pregnancies before 24 weeks of gestation that affects 1-2% of pregnancies worldwide. The cause of RPL cannot be explained in about half of the cases. Recent studies suggest that mitochondrial dyshomeostasis and oxidative stress may play a role in RPL. The mutY DNA glycosylase *(MUTYH)* is a novel candidate gene in RPL involved in repair of oxidative stress induced DNA damage. This study aimed to investigate the association of *MUTYH* gene variants and RPL.

Methods: Variant analysis was performed on whole exome sequencing data from 10 couples and an additional 25 female patients examined due to the RPL in the first trimester.

Results: All patients had normal karyotypes and had no other causing factor related to infertility. In three female patients (8%), heterozygous pathogenic missense (rs143353451 and rs374950566) and nonsense (rs121908380) variants were detected in *MUTYH* gene. Protein modeling of these variants was performed by UniProt automated modeling and showed that mutated

MUTYH residues are located within conserved motifs at the surface of the molecule.

Conclusion: Findings of this study suggest that pathogenic variants of *MUTYH* gene might be crucial in the trigger of oxidative stress in human placenta and thus contribute to RPL etiology. Additive interaction of other heterozygous variants in RPL related genes should be explored and further functional studies should be conducted to explain the role of these variants in female infertility.

Grants: This study was supported by Turkish Health Institutes Presidency(No:28416) and Istanbul University Scientific Research Projects Unit(No:TYL-2022-39278).

Conflict of Interest: None declared

P02.036.B The molecular riddle of Endometriosis (EM) disorder: filling in the blanks between genetics, diet, and microbiome.

Aurora Santin[1], *Beatrice Spedicati*[1;2], *Anna Morgan*[2], *Stefania Lenarduzzi*[2], *Paola Tesolin*[2], *Alessandro Pecori*[2], *Giuseppe Giovanni Nardone*[1], *Silvia Camarda*[1], *Harry Stevens*[1], *Giulia Pianigiani*[2], *Lara Emily Rosso*[1], *Cristina Bon*[2], *Daniela Mazzà*[2], *Elena Vinerbi*[3], *Giovanni Di Lorenzo*[2], *Federico Romano*[2], *Francesca Buonomo*[2], *Alessandro Mangogna*[2], *Giuseppina Campisciano*[2], *Gabriella Zito*[2], *Serena Sanna*[3;4], *Maria Pina Concas*[2], *Giuseppe Ricci*[1;2], *Giorgia Girotto*[1;2]

[1]*University of Trieste, Department of Medicine, Surgery and Health Sciences, Trieste, Italy;* [2]*Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy;* [3]*Institute of Genetic and Biomedical Research (IRGB), National Research Council (CNR), Monserrato, Italy;* [4]*University Medical Center Groningen, Department of Genetics, Groningen, Netherlands*

Background/Objectives: EM is a multifactorial gynaecological disease, constituting the leading cause of infertility in affected patients. Little is known about EM aetiopathogenesis; however, genetics, diet and dysbiosis are involved in determining EM onset.

Methods: One-hundred and ten EM patients were enrolled at IRCCS "Burlo Garofolo" (Italy). Patients underwent a careful clinical examination; data regarding EM-symptoms severity, food preferences, and vaginal/rectal microbiome were collected. Whole-Exome Sequencing (WES) was conducted to identify rare damaging variants within a list of 47 EM-associated genes and new candidates. Regression models to investigate relationships between EM-symptoms, food preferences, microbiome, and logistic models to deepen EM-risk factors employing a control cohort (Women4Health) were performed.

Results: WES analysis detected >80 rare predicted damaging heterozygous variants within 26 genes, involved in cellular proliferation and immune response. A significant association between high-FODMAP food preference and dysmenorrhea severity ($p = 0.038$) was detected, in line with the known role of high-FODMAP foods in determining pain and inflammation (PMID:36424920). Moreover, gluten-containing foods preference was identified as an EM-risk factor ($p = 0.042$); indeed, 12 months of gluten-free diet have been proven to relieve EM-symptoms (PMID:23334113). Preliminary microbiome data confirmed vaginal and rectal dysbiosis; further, EM stage I-II was associated with an increased rectal colonization of *Prevotella* bacterium and dysmenorrhea.

Conclusion: This study provided novel glimpses into the role of genetics in EM development, the relation between EM-symptoms and food preferences, dysbiosis and EM-symptoms, thus supporting the hypothesis that genetics, diet, and microbiome act together in EM. Further analyses will deepen the relationships between all these causal factors.

P02.037.C Medicover Carrier Screening according to current guidelines

Melanie Isau[1], *Konstanze Hörtnagel*[2], *Elisabeth Gödde*[3], *Markus Stumm*[3]

[1]*Medicover Humangenetik Berlin-Lichtenberg MVZ, Molecularge-netics, Berlin, Germany;* [2]*Medicover MVZ Martinsried GmbH, Humangenetics, Martinsried, Germany;* [3]*Medicover Humangenetik Berlin-Mitte, Humangenetics, Berlin, Germany*

Background:

Carrier screening provides prospective parents information about their carrier status for autosomal recessive and X-linked conditions. If couples prove to be carriers, they have a 1 in 4 risk in each pregnancy of having a child with an autosomal recessive condition. For X-linked recessive conditions, there is a 50% risk for male offspring to be affected if the woman is found to be a carrier. It is estimated that approximately 1 in 100/125 couples have a risk of having a child affected with a serious recessive condition [1].

Methods: Based on ACMG guideline we established a tiered approach with which CS can be offered to all couples planning a pregnancy [2]. Our strategy supports a multi-sample CS workflow and is able to compare variants between samples and identify genes in which clinically relevant variants are present in both partners. We generate a combined report for the couple that includes reproductive risk.

Results: CS is a valuable tool in genetics and reproductive medicine that helps families to make informed choices about family planning and reduce the risk of passing autosomal recessive or X-linked genetic disorders to their children.

Conclusion: Since NGS offers an affordable, high-throughput solution, CS has become common practice in healthcare systems. The standardization of the screening approach will facilitate testing consistency and further it will be important that ACMG reevaluates the genes listed for screening and considers the need to modify criteria used to include and exclude genes.

P02.038.D Insights in the carrier screening for *CFTR* gene in the field of reproductive medicine

Andrea Domingo Gallego[1], **Sara Reyes**[1], *Lydia Madrid Cortés*[1], *Marta Carreño*[1], *Anna Borgia*[1], *Patricia Karrera*[1], *Paula Coleto*[1], *Raquel Muñoz Siles*[1], *Ester Olivé*[1], *Raquel Garcia*[1], *Lidia Carreño*[1], *Maria Segura-Puimedon*[1], *LLuís Armengol*[1]

[1]*qGenomics, Dry Lab, Esplugues de Llobregat*

Background/Objectives: Pathogenic variants in the *CFTR* gene are causative of classic cystic fibrosis (CF), as well as *CFTR*–related disorders. In 2023, the ACMG recommended a minimal set of 100 disease-causing variants to be studied. However, owing to the great diversity of variants in the *CFTR* gene, the effective detection of carriers with this approach is limited.

Methods: Observational retrospective study in 20,853 samples from gamete donors and patients undergoing assisted reproduction treatments referred to our laboratory from 2020 to 2023 for carrier screening using a NGS panel.

Results: Our data indicate that 27% (5,563/20,853) of the individuals were carriers of a disease-causing variant in the *CFTR* gene, with 143 different pathogenic variants detected. 73% of the

variants (105/143) were not included in the list proposed by ACMG. The top five most frequently identified were c.1210-34TG(12)T(5) (n = 648), p.Gly576Ala(;)Arg668Cys (n = 487), p.Phe508del (n = 385), p.Leu997Phe (n = 358) and p.Val754Met (n = 135). Only the p.Phe508del is considered to be causative of classic CF by CFTR2 database. A coincidence of variants in the *CFTR* gene has been identified in 6% (56/972) of the couples, of whom 57% (32/56) had an increased reproductive risk of having offspring with CF or *CFTR*-related disease.

Conclusion: This study provides data on the application of carrier screening of the *CFTR* gene in the field of assisted reproduction and highlights the relevance of performing broader NGS studies on all patients with reproductive desire.

Grants: not applicable.

P02.039.A GDF-15: A promising biomarker for identifying mitochondrial dysfunction in insulin resistance, polycystic ovary syndrome, and associated infertility

Vera Várhegyi[1;2], *Anna Módos*[1;2], *Domonkos Trager*[2], *Eszter Mária Horváth*[3], *Miklós Sipos*[1], *Maria Judit Molnár*[2], *Szabolcs Várbíró*[1;4], *Aniko Gal*[2]

[1]*Semmelweis University, Department of Obstetrics and Gynecology, Budapest, Hungary;* [2]*Semmelweis University, Institute of Genomic Medicine and Rare Disorders, Budapest, Hungary;* [3]*Semmelweis University, Department of Physiology, Budapest, Hungary;* [4]*University of Szeged, Albert Szent-Györgyi Health Centre, Department of Obstetrics and Gynecology, Szeged*

Background/Objectives: Recent research indicates that mitochondrial dysfunction plays a significant role in the underlying mechanisms of insulin resistance, polycystic ovary syndrome (PCOS), and associated infertility. GDF-15 (growth differentiation factor 15) is a stress-induced cytokine, with elevated plasma levels linked to mitochondrial dysfunction and various pathologies. This study aimed to investigate the role of GDF-15 as a biomarker in diagnosing IR and PCOS.

Methods: 81 female patients (mean age 35.43 ± 7.86 years) diagnosed with IR or PCOS and undergoing infertility treatment, displaying clinical features suggestive of mitochondrial dysfunction, were included. DNA isolation was performed from blood and urine epithelial cells. GDF-15 levels were measured using an ELISA kit, while mitochondrial DNA (mtDNA) deletions were assessed via long-range PCR.

Results: GDF-15 levels in the study cohort were slightly elevated compared to healthy controls (1213.58 vs. 818.68; Reference <2000). Abnormal GDF-15 levels were observed in 12 patients, with 11 having BMI values exceeding 25. Nine patients were undergoing metformin therapy. MtDNA deletion was confirmed in 8 cases (66.6%).

Conclusion: Elevated levels of GDF-15 were detected in 14.8% of patients, with 91.6% of this subgroup having a high BMI. MtDNA deletion was identified in 58% of cases, with 75% of them also undergoing metformin therapy. The degree of carbohydrate metabolism disturbance was more pronounced in high GDF-15 cases than in normal GDF-15 patients. These findings suggest that GDF-15 may be a predictive biomarker of abnormal metabolic processes in the background of IR, PCOS, and associated infertility.

P02.040.B Set of structural rearrangements of chromosome Y and their impact on male fertility

Lucie Liskova[1], *Vjaceslav Harmas*[1], *Vlasta Cejnova*[1], *Lenka Vancová*[1], *Lilly Dejová*[1], *Monika Stará*[2], *Marek Broul*[2;3], *Jana Lastuvkova*[1]

[1]*Krajská zdravotní, a.s. - Masaryk Hospital in Ústí nad Labem, o.z., Department of Medical Genetics, Ústí nad Labem, Czech Republic;* [2]*Krajská zdravotní, a.s. - Masaryk Hospital in Ústí nad Labem, o.z., Department of Sexology, Ústí nad Labem, Czech Republic;* [3]*Jan Evangelista Purkyně University, Faculty of Health Studies, Ústí nad Labem, Czech Republic*

Background/Objectives: Chromosome Y plays an important role in process of fertilization and development for males because it holds the SRY gene determining sex and numerous spermatogenesis genes, e.g. DAZ, AZF1/2. Various abnormalities can affect the Y chromosome; these are divided into numerical or structural abnormalities. Around 6% of infertile males have structural Y rearrangements (duplication, deletion, inversions, dicentrics, rings), in males with azoospermia, this number rises to 15% (Jiang, 2017).

Methods: Molecular diagnosis of Y-chromosomal microdeletions, microarray, karyotyping, FISH.

Results: We present 7 cases with structural rearrangements of chromosome Y detected by routine karyotyping and FISH analysis, further characterized by molecular diagnosis of Y microdeletion, and by microarray in some cases. We determinated three cases of partial deletion of Yq chromosome, mostly prenatally, when fertility of the male was not interrupted and the deleted Y chromosome was transmitted from father to the son. Two cases of isodicentric chromosomes were revealed in mosaic forms 45,X/46,X,idic(Y); the first in normal male with azoospermia, the second prenatally in amniotic fluid. One case of isochromosome i(Y)(p10) in nonmosaic form was detected in azoospermic male. The last case represents an inversion of Y(p11.2q11.2) in male with OAT syndrome.

Conclusion: The impact of genotype on male fertility is discussed, and depends on Y chromosome breakpoints, deleted genes and degree of 45,X line mosaicism. Cytogenetic analysis and molecular characterization of infertile men is very important to clarify a possible cause of infertility, and to establish the suitable subsequent medical therapy.

Background/Objectives: Cumulus cells (CCs) surround the oocyte and play an important role in oocyte development and maturation. CCs DNA damage has been associated with oocyte status; however, the existing studies present contradictory results. Considering the physical proximity to the oocyte, the aim of this study is to understand if CCs DNA damage, may serve as a biomarker for oocyte quality.

Methods: The alkaline comet assay was conducted on CCs obtained from 42 females undergoing intracytoplasmic sperm injection (ICSI). Among these, 20 exhibited ovulatory dysfunctions, while 22 were experiencing male-factor-related fertility issues. ICSI is an assisted reproductive technology which involves the injection of a single sperm into the cytoplasm of the oocyte. Prior to injection, the oocyte undergoes denudation, and CCs are usually rejected. Several reproductive parameters collected in the infertility context were evaluated.

Results: CCs DNA damage levels were significantly higher in females with ovulatory dysfunction when compared to those experiencing male-factor-related infertility ($p = 0.034$). A significant correlation was found between CCs DNA damage levels and the number of oocytes in 2PN stage ($p = 0.026$). Furthermore, females with a fertilization percentage above 50% exhibited increased levels of CCs DNA damage, greater number of oocytes in 2PN stage and a higher number of embryos obtained when compared to females with lower fertilization.

Conclusion: Overall, our findings led us to propose that higher CCs DNA damage may reflect the complete oocyte maturation (nuclear and cytoplasmatic), indicating an ideal stage for sperm reception, fecundation and, consequently, increased ICSI success.

P02.042.D Variant curation of the largest compendium of FOXL2 coding and non-coding sequence and structural variants to improve precision medicine in BPES

Charlotte Matton[1;2], *Julie Van De Velde[2], Miriam Bauwens[1;2], Eva D'haene[1;2], Sally Hooghe[2], Dave Bunyan[3;4], Hannah Verdin[2], Elfride De Baere[1;2]*

[1]Ghent University, Biomolecular medicine, Ghent, Belgium; [2]Ghent University Hospital, Center for Medical Genetics Ghent, Ghent, Belgium; [3]University of Southampton, Faculty of Medicine, Southampton, United Kingdom; [4]Salisbury District Hospital, Wessex Regional Genetics Laboratory, Wiltshire, United Kingdom

Background/Objectives: Monoallelic *FOXL2* coding and non-coding sequence and structural variants (SVs) lead to BPES (OMIM 10100), a rare, autosomal dominant developmental disorder characterized by a completely penetrant eyelid malformation and incompletely penetrant primary ovarian insufficiency (POI). As most variants have not been collected and classified systematically, we aimed to curate all reported and in-house constitutional *FOXL2* variants.

Methods: Here, we collected variants from our in-house database, generated via clinical genetic testing and downstream research testing in the Center for Medical Genetics Ghent, Belgium (2001-2024), and via literature and other resources in the same period. All retrieved variants were categorized using ACMG/AMP classifications to increase the knowledge of pathogenicity.

Results: We collected 405 unique genetic defects of the *FOXL2* region in 876 index patients. Of these, 88% are coding *FOXL2* variants, 52 of which are novel. The polyalanine tract is a known mutational hotspot of *FOXL2*, illustrated by the high percentage of pathogenic polyalanine expansions (27%). Furthermore, the molecular spectrum is characterized by 9% coding copy number variants (CNVs) and 2% non-coding CNVs, all but one located upstream of *FOXL2*. The remaining 1% are translocations along with chromosomal rearrangements of 3q23. In total, 98.4% variants were categorized as (Likely) Pathogenic, whereas 1.6% variants were categorized as Variant of Unknown Significance. All variants and corresponding classification will be uploaded in LOVD.

Conclusion: This uniform and structured reclassification, incorporating the largest dataset of variants implicated in *FOXL2*-associated disease so far, will improve both the diagnosis as well as genetic counselling for individuals with BPES.

P02.044.B Maternal genetic risk factors for spontaneous preterm birth: a systematic review and meta-analysis

Tea Mladenić[1], *ANITA BARIŠIĆ[2], Nina Pereza[1], Saša Ostojić[1], Borut Peterlin[3], Sanja Dević Pavlić[1]*

[1]Faculty of Medicine, University of Rijeka, Medial Biology and Genetics, Rijeka, Croatia; [2]University Hospital Rijeka, Gynecology and Obstetrics, Rijeka, Croatia; [3]Ljubljana, Clinical Institute of Medical Genetics, Ljubljana, Slovenia

Background/Objectives: A spontaneous preterm birth (sPTB) is any live birth completed before 37 weeks of gestation caused by the spontaneous onset of preterm labor. As there is ample evidence that the maternal genome plays a role in the occurrence of sPTB, we conducted a comprehensive systematic review of studies analysing the association between maternal genetic variants and sPTB using either a hypothesis-based or a hypothesis-free approach.

Methods: A literature search was conducted in PubMed, Scopus and PHGKB databases on the association between maternal genetic variants and sPTB. All included studies were categorised into two categories: hypothesis-based and hypothesis-free.

Results: The systematic review included 81 studies, of which 72 used a hypothesis-based approach and 9 used a hypothesis-free approach. Using additional criteria for hypothesis-based studies, a meta-analysis of 34 studies was performed for 133 variants in 49 genes. A significant association between the maternal genetic variant and sPTB was only found in the TNF-α (rs1800629) gene for both genotype ($P = 0.025$) and allele ($P = 0.038$). Moreover, in the hypothesis-free approach, 7 variants in 5 genes (EBF1, EESEC, HSPA1L, ASTN1, MAST1) reached global significance ($P < 5 \times 10\text{-}8$).

Conclusion: Despite numerous studies using both approaches, no specific genes or variants were clearly associated with the risk of sPTB. Due to the large differences in the definition of sPTB and the selection criteria for participants, standardization is required. Therefore, future genetic association studies should use a more precise description of subject groups and outcomes measured.

P02.045.C Characterization of somatic variants in placentas from pregnancies complicated by preeclampsia and other adverse outcomes

Gordon Ye[1], *Nathaniel Anderson*[1], *Thomas Oliver*[1;2], *Omar El-Tokhy*[1], *D. Steve Charnock-Jones*[3;4], *Gordon Smith*[2;3;4], *Sam Behjati*[1;2;5]

[1]*Wellcome Sanger Institute, Hinxton, United Kingdom;* [2]*Cambridge University Hospitals, United Kingdom;* [3]*NIHR Cambridge Biomedical Research Centre, Department of Obstetrics and Gynaecology, United Kingdom;* [4]*Centre for Trophoblast Research, Department of Physiology, Development and Neuroscience, Cambridge, United Kingdom;* [5]*University of Cambridge, Department of Paediatrics, United Kingdom*

Background/Objectives: The placenta is implicated in many adverse pregnancy outcomes. Past work has characterized the high mutation burden of normal placental tissue while identifying preliminary evidence of genomic signatures unique to those in pregnancies that experienced adverse outcomes including preeclampsia.

Methods: The Pregnancy Outcome Predicting Study was a prospective cohort study enrolling nulliparous women with ultrasound scans performed at the Rosie Hospital between January 2008 and July 2012. This work focuses on 150 pregnancies with maternal blood samples, clinical data, and placenta and cord tissue collected following birth. Samples underwent whole-genome sequencing and data were sorted into following groups based on clinical data: 1) healthy control; 2) preeclampsia 3) preeclampsia with other adverse pregnancy outcomes; and 4) other adverse pregnancy outcomes. Following sequencing quality-control, data from 453 placental samples and 149 cord samples (representing 149 pregnancies) were included for analysis. Somatic single nucleotide variants (SNV), copy number variants, structural variants, and insertion-deletion variants were called by CaVEMan, ASCAT/Battenberg, BRASS, and Pindel, respectively. Umbilical cord tissue served as the matched normal for our placental samples at the level of each pregnancy.

Results: Preliminary results suggest SNV burden does not differ substantially across our clinical groups, while tandem-duplications were observed more frequently in placentas from pregnancies experiencing preeclampsia (28.6% of preeclampsia cases vs. 13.6% of healthy controls).

Conclusion: We observe a potential relationship between structural variants and preeclampsia, particularly an enrichment of tandem duplications.

Grants: Gordon Ye: The Winston Churchill Foundation of the United States. The POPS cohort was supported by the NIHR Cambridge Biomedical Research Centre.

P02.046.D Use of array-CGH and NGS in etiological definition of idiopathic premature ovarian insufficiency: our recent experience in a sample of Italian women

Gaia Visani[1], *Silvia Kalantari*[1], *Laura Cucinella*[2], *Elena Rossi*[1;3], *Elisa Giorgio*[1], *Enza Maria Valente*[1;4], *Rossella Nappi*[2;5], *Fabio Sirchia*[1;6]

[1]*University of Pavia, Department of Molecular Medicine, Pavia, Italy;* [2]*IRCCS Policlinico San Matteo Foundation, Research Center for Reproductive Medicine and Gynecological Endocrinology - Menopause Unit, Pavia, Italy;* [3]*IRCCS Mondino Foundation, Neurogenetics Research Center, Pavia, Italy;* [4]*IRCCS Mondino Foundation, Medical Genetics Unit, Pavia, Italy;* [5]*University of Pavia, Department of Clinical, Surgical, Diagnostic and Pediatric Sciences, Pavia, Italy;* [6]*IRCCS Policlinico San Matteo Foundation, Department of Diagnostic Medicine, Medical Genetics Unit, Pavia, Italy*

Background/Objectives: Premature ovarian insufficiency (POI) has a strong genetic component, but etiology remains often unidentified. Historically, karyotype and *FMR1* analyses were the mainstay and sole genetic tests performed for POI patients. However, it was recently demonstrated that copy number (CNVs) and single nucleotide variants (SNVs) can contribute to the genetic landscape of the disease. Our objective is to perform array-CGH and Whole exome sequencing (WES) in women that had negative baseline genetic testing.

Methods: We included 63 women referred to the Menopause Clinic at our University Hospital for diagnosis and treatment of idiopathic POI during the last three years.

Results: The mean age at POI diagnosis in the cohort was 26.9 years (range 11-40 years), with 15 patients (22.7%) reporting primary amenorrhea. All women had normal karyotype, and *FMR1* gene testing resulted normal in all patients with secondary amenorrhea.

Array-CGH and WES identified a genetic cause of POI in 8 patients overall.

In particular, a genetic cause of POI was identified through Array-CGH and WES in 3 and 5 patients, respectively. Variants of unknown significance (VUS) were identified in 3 patients.

Conclusion: A genetic cause of POI was found thanks to Array-CGH and WES in 17.4% of our patients, playing a crucial role in the diagnosis of POI and providing relevant prognostic information to affected individuals and their families.

P02.047.A Analysis of human sperm DNA after cryopreservation

Sofia Coelho[1;2;3;4], *Carolina Almeida*[1], *Margarida Fonseca Cardoso*[3;5], *Sofia Lobo Xavier*[6], *Alberto Barros*[1;4;7], *Mário Sousa*[2;8], *Joana Marques*[1;4]

[1]*FMUP - Faculdade de Medicina, Universidade do Porto, Genetics Unit, Department of Patology, Porto, Portugal;* [2]*UMIB-Unit for Multidisciplinary Research in Biomedicine / ITR-Laboratory for Integrative and Translational Research in Population Health, Porto, Portugal;* [3]*ICBAS-Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Laboratory of Cell Biology, Department of Microscopy, Porto, Portugal;* [4]*RISE-Health, Porto, Portugal;* [5]*CIIMAR - Centro Interdisciplinar de Investigação Marinha e Ambiental, Universidade do Porto, Porto, Portugal;* [6]*Centro de Responsabilidade Integrada de Medicina da Reprodução, Unidade Local de Saúde de São João, Porto, Portugal;* [7]*Centro de Genética da Reprodução Professor Alberto Barros, Porto, Portugal;* [8]*ICBAS-Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Porto, Portugal*

Background/Objectives: Cryopreservation of human spermatozoa is widely used for fertility preservation, being generally considered a safe technique. However, a detailed analysis of DNA fragmentation and epigenetic modifications after cryopreservation is lacking.

Methods: Human spermatozoa samples (11) were collected from normozoospermic (NZ) individuals, after written informed consent, and were analysed before and after cryopreservation during 1 month. The TUNEL technique was used to evaluate sperm DNA fragmentation (SDF) and bisulphite-sequencing to analyse sperm DNA methylation (SDM) at two imprinted regions.

Results: Results evidenced a small but significant increase in SDF after sperm cryopreservation in 36.4% of the samples. The remaining 63.6% samples showed no significant changes. Regarding SDM, results showed no relevant changes in the methylation of the imprinted regions in either *H19* or *MEST/PEG1* genes. Correct imprinting marks, with no changes in the expected normal *H19* gene hypermethylation and *MEST* gene hypomethylation, were observed.

Conclusion: The present data gives important information regarding ensuring the safety of sperm cryopreservation in relation to imprinting marks. Especially because it was previously shown that imprinting errors occur in sperm from infertile patients, and reported an increased risk of imprinting syndromes, such as Beckwith-Wiedemann and Silver-Russell syndromes, in children born after assisted reproductive treatments. Although SDF was increased in a small fraction of samples, cryopreservation did not result in altered SDM patterns. To confirm these results, we are analysing longer periods of cryopreservation, with a higher number of NZ and non-NZ individuals.

Grants: FCT – Fundação para a Ciência e Tecnologia (2021.08252.BD, CEECIND/0037/2017 2022.09829.PTDC) (UIDB/00215/2020; UIDP/00215/2020;LA/P/0064/2020).

P02.048.B A large deletion of the androgen receptor (AR) gene in a patient with androgen insensitivity syndrome.

Leona Morožin Pohovski[1], *Adriana Bobinec*[1], *Ana-Maria Meašić*[1], *Ljubica Odak*[1,2]

[1]*Children's Hospital Zagreb, University of Zagreb, School of Medicine, Zagreb, Department of Medical and Laboratory Genetics, Endocrinology and Diabetology with daily care unit, Zagreb, Croatia;* [2]*European Reference Network –Intellectual disability, Tele Health, Autism and Congenital Anomalies*

Background/Objectives: Different genomic alterations affecting the androgen receptor gene (AR) located on chromosme Xq11-12 are associated with Androgen insensitivity syndrome (AIS). The AR is an important steroid hormone receptor that plays a critical role in male sexual differentiation, and development of secondary male characteristics. The most prominent molecular defects in the AR gene associated with AIS are missense variants. A eighteen-year-old girl was referred to our genetics clinic due to primary amenorrhea, absent uterus and ovaries, short and blind-ending vagina and presence of testis tissue in right ingvinal canal. External genitalia showed sparse pubic hair and normal breast development.

Methods: Chromosome analyses were performed by conventional highresolution cytogenetic technology. Clinical exome sequencing (CES) was performed using TruSightOne sequencing kit and NextSeq machine (Illumina, USA). Data analysis was carried out with BaseSpace Variant Interpreter (Illumina, USA) and curated online databases. Comparative genomic hybridization (CMA) was conducted using 8×60K oligonucleotide array (Agilent, Santa Clara, CA, USA).

Results: Chromosome analysis showed 46,XY karyotype. CES did not reveal any variants in genes known to be associated with proband's phenotype. Nevertheless, analysis in Integrative Genome Viewer (Broad Institute) showed a partial deletion of AR gene. Array-CGH revealed a 96 kb partial deletion of the AR gene, encompassing exons 2-8/8 (NM_001011645).

Conclusion: To our knowledge, this is the first patient described in the literature with large deletion in AG gene. The presented case emphasizes the use of molecular cytogenetics as an additional diagnostic tool for the detection of rare intragenic abnormalities.

P02.049.C Novel *STARD9* gene mutations identified in a patient with 46,XY gonadal dysgenesis, osteoporosis, and heart deficiency lend support to this gene as a syndromic DSD candidate

Dmytro Sirokha[1], *Alexey Rayevsky*[1], *Vitalii Kalynovskyi*[2], *Oksana Samson*[3], *Olexandra Gorodna*[1], *Jadwiga Jaruzelska*[4], *Kamila Kusz-Zamelczyk*[4], *Serge Nef*[5], *Ludmila Livshits*[1]

[1]*Institute of Molecular Biology and Genetics, National Academy of Sciences of Ukraine, Laboratory of Human Genomics;* [2]*Taras Shevchenko Kyiv National University, Kyiv, Ukraine;* [3]*Shupyk National Healthcare University of Ukraine, Department of Pediatric Endocrine Pathology of the Komisarenko Institute of Endocrinology and Metabolism, Endocrine Department;* [4]*Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland;* [5]*University of Geneva, Department of Genetic Medicine and Development, Faculty of Medicine, Geneva, Switzerland*

Objectives: Investigating gene mutations that affect gonad development is crucial for understanding the mechanisms behind Differences/Disorders in Sex Development (DSD). This research aims to identify novel DSD genetic variants using whole exome sequencing (WES) and genotype-phenotype correlation analysis.

Methods: WES was performed on a 46,XY SRY-positive patient with gonadal dysgenesis, osteoporosis, and heart deficiency. Bioinformatic analysis and simulation of mutant protein were conducted.

Results: Two different mutations in a compound heterozygous state were identified in the *STARD9* gene: NM_020759.3 c.5585_5590del (p.Ser1862_Thr1863del) (rs528276071) – an in-frame deletion (MAF = 0.0019); combined with NM_020759.3 c.3514 C>T (p.Arg1172Cys) (rs12594837) – a missense mutation (MAF = 0.00837). The patient's genetic background analysis did not reveal any pathogenic variants implicated in the DSD. Detected mutant variants were inherited from healthy parents — heterozygous carriers and were not previously implicated in the pathogenesis of any disease. It was shown that Stard9 is strongly expressed in Sertoli cells, some granulosa cells, late male interstitial progenitors, meiotic female germ cells, endothelium, and immune cells of mice. Bioinformatics analysis showed that STARD9 mutant protein's regions are conserved in primates only and have a disordered structure that probably affects some regulatory patterns responsible for the PPI interactions/interaction with specific interfaces.

Conclusion: Based on the results obtained in this study, previous reports concerning the expression pattern of the *STARD9* gene, and its cellular functions we suppose that *STARD9* can be considered as a candidate gene causing 46,XY syndromal DSD.

P02.051.A Genomic newborn screening, first clinical experience in Spain

Vincenzo Cirigliano[1;1], *Elena Ordonez*[1], *Bibiana Palao*[2], *Miriam Leon*[2], *Laura Garcia*[1], *Nerea Lobato*[2], *Irene Perea*[2], *Raquel Bernad*[2], *Enrique Fernandez*[2], *Mireia Lechuga*[1], *Isabel Castilla*[1], *Maria Moreno*[2], *Luis Izquierdo*[2]

[1]*Veritas Intercontinental, Barcelona, Spain;* [2]*Veritas Intercontinental, Madrid, Spain*

Background/Objectives: The advances in genomic sequencing and the growing knowledge in variant interpretation is facilitating the implementation of genomic screening in different medical areas. Genomic newborn screening is becoming a priority, with several countries implementing programs to evaluate the cost-effectiveness of integrating this determination. Here we present

the results of the first 800 newborn genomic screening test performed by a Spanish private laboratory.

Methods: Saliva, cord blood or venous blood sample was obtained from the newborn. Extracted genomic DNA is processed by a capture-based assay and sequenced on a next-generation sequencer (illumina). Exome sequencing data was processed using a proprietary bio-pipeline designed for this intended use. Only childhood onset diseases were analyzed.

Results: Around 8.6% of newborns presented variants in any of the genes included on the panel. The variants detected were related to hematological conditions (68.1%), syndromic (5.8%), Neurologic (5.8%), Cancer (5.8%), Musculoskeletal (4.4%), Metabolic (2.9%), Cardiovascular (2.9%), Immunological (1.5%), Endocrine (1.5%) and Urogenital (1.5%). More than 80% of the infants were newborns (0 months), the mean age was 3 month.

Conclusion: Even though the conditions included in the analysis are considered rare, the subset of pathologies tested affected more than 8% of newborns. Early detection lead to an adapted medical management that may involve symptoms prevention or the reduction of the impact of the condition in the child. Besides, rare conditions can take years before being diagnosed, this approach not only enables prevention in most of the cases, but also avoid diagnostic odyssey.

Grants: None significant to the purpose of this research

P02.056.B Loss-of-function variants in *NXT2* lead to male infertility due to non-obstructive azoospermia

Ann-Kristin Dicke[1], *Claudia Krallmann*[2], *Godfried van der Heijden*[3], *Miguel Xavier*[4], *Joris A. Veltman*[4], *Sabine Kliesch*[2], *Frank Tüttelmann*[1], *Birgit Stallmeyer*[1]

[1]*Institute of Reproductive Genetics, University of Münster, Münster, Germany;* [2]*Centre of Reproductive Medicine and Andrology, University Hospital Münster, Münster, Germany;* [3]*Department of Obstetrics and Gynecology, Radboud University Medical Center, Nijmegen, Netherlands;* [4]*Biosciences Institute, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background/Objectives: The nuclear export protein NXT1 ubiquitously facilitates the transport of a diverse spectrum of RNAs from the nucleus to the cytoplasm. In humans, the NXT1 paralogue NXT2 is specifically expressed in the testis, but little is known about its function.

Methods: From the Male Reproductive Genomics (MERGE) study, exome/genome data of >2,300 infertile men with severe oligo- or azoospermia was screened for rare (MAF <0.01 in gnomAD) variants in *NXT2*. Prioritised variants were validated and segregation analyses were performed. Reproductive phenotypes of variant carriers were evaluated and effects on subcellular localisation of NXT2 in patients' testicular tissue were determined.

Results: In a family with three infertile brothers, the hemizygous *NXT2* loss-of-function (LoF) variant c.354dup p.(Asp119*) co-segregates with the disease. The identification of a de novo deletion of the entire *NXT2* gene in an independent infertile man supports the association of LoF variants in *NXT2* with male infertility. Histological analysis of two patients' testicular tissue revealed a Sertoli cell-only phenotype (SCO) explaining the azoospermia. In testicular tissue with normal spermatogenesis, NXT2 is predominantly expressed in Sertoli cells according to immunohistochemical staining. In contrast, expression was lost in both *NXT2* variant carriers.

Conclusion: *NXT2* is a novel candidate gene for X-linked non-obstructive azoospermia. The concordant testicular phenotype of SCO points towards a role of NXT2 in germ cell formation or early maturation. Further studies need to clarify the pathomechanism of NXT2-related male infertility.

Grants: This work was supported by the DFG Clinical Research Unit 326 'Male Germ Cells'.

P02.057.C A novel digitalMLPA carrier screening assay for simultaneous detection of copy number variations and selected point mutations in challenging genomic regions

Romy Kuilboer[1], *Silvia Dyson Coral*[2], *Lisette Stolk*[1]

[1]*MRC Holland, Cytogenetics, Amsterdam, Netherlands;* [2]*MRC Holland, IVD Development, Amsterdam, Netherlands*

Background/Objectives: Carrier screening is crucial to identify those at risk of having children affected by genetic disorders. We present a novel multiplex carrier screening assay, designed for the simultaneous detection of copy number variations (CNVs) and selected point mutations in challenging genomic regions, including *CYP21A2*, *HBA1/HBA2*, *SMN1*, *CFTR*, *DMD*, *HBB*, *CLN3*, *CTNS*, and *GJB2/GJB6*.

Methods: A novel multiplex carrier screening assay is being developed that employs a targeted next-generation sequencing approach and is suitable for high throughput routine use: SALSA® digitalMLPA™ Probemix D028 Carrier Screening. Over 65 positive samples, for which independent confirmation was available, were tested with this assay.

Results: The results demonstrate the efficacy of the assay in accurately identifying aberrations in all targeted regions across a diverse sample set including 31 deletions, 6 duplications, 28 point mutations and 3 cases with both a CNV and a point mutation. Additionally, inclusion of a novel probe type allows the assay to detect not only *CYP21A2* deletions, but also a considerable percentage of the point mutations, showcasing its capability to navigate the challenges presented by complex genomic regions.

Conclusion: The development of this assay represents a significant advancement in addressing the challenges posed by complex genomic regions in carrier screening. By effectively detecting both CNVs and selected point mutations, this robust SALSA® digitalMLPA™ assay can complement sequence analysis for informed reproductive decision-making.

Grants: None.

P02.058.D 'Everyone is a carrier': A frame and content analysis of preconception expanded carrier screening (ECS) on social media

Kriss Fearon[1], *Cathy Herbrand*[1], *Lucina Wilde*[1], *Nicky Hudson*[1]

[1]*De Montfort University, Centre for Reproduction Research, Leicester, United Kingdom*

Background/Objectives: ECS is a preconception genetic test which informs prospective parents about recessive conditions they might transmit to their future children. Laboratories are increasingly marketing genetic testing through social media (Rose and Wick, 2018), yet no studies have analysed social media content on ECS, which is currently unregulated. Our study aims to

understand how this technology is framed on social media and the messages conveyed.

Methods: A systematic search strategy identified relevant posts across six social media platforms: X/Twitter, Instagram, Facebook, TikTok, Reddit and YouTube. 365 posts were analysed using Frame Analysis (Entman 1993) and inductive content analysis (Vears and Gillam, 2022), focussing on the origin of the post and the framing of ECS's aims, limitations and transmission risks.

Results: Most posters were test providers, fertility clinics, and clinicians with fewer posts from test takers. The content analysis highlighted five major themes: (1) informing about ECS and reproductive risks, (2) promoting ECS, (3) personal experiences of ECS, (4) pro-ECS advocacy, and (5) challenges and limitations of ECS. Commercial providers promoted uptake with frames like 'everyone is a carrier'. Test takers shared experiences and provided advice; they were broadly positive, framing ECS as 'science gives reassurance' and 'reproductive responsibility'.

Conclusion: Social media is used to raise awareness and provide information, as well as encourage wider adoption of ECS. This enables prospective users access to information, but the lack of regulation presents potential challenges for test takers to distinguish what constitutes reliable information.

PRENATAL GENETICS

P03.001.A Droplet digital PCR application for rapid aneuploidy and maternal cell contamination testing of invasive prenatal samples

Olga Mikhaylichenko[1], *Endre Hegedus*[2], *Vanessa Felice*[2], *Chenyu Li*[1], *Nathan Hendel*[1], *Eric Hall*[1], *Nyari Dzvova*[1], *Monica Herrera*[1], *Richard Dannebaum*[1], *Severine Margeridon*[1], *Ronald Wapner*[3], *Vaidehi Jobanputra*[2]

[1]*Bio Rad Laboratories;* [2]*New York Genome Center;* [3]*Columbia University Irving Medical Center*

Background/Objectives: Efficient aneuploidy screening and maternal cell contamination (MCC) control are essential in invasive sample analysis workflows, eliminating costs of whole genome sequencing for contaminated or aneuploid samples. This study introduces rapid aneuploidy screening using droplet digital PCR (ddPCR) on genomic DNA (gDNA) from fetal amniocytes or chorionic villi, requiring only 5 ng of gDNA per sample. The method reduces analysis time to 9 hours for a batch of 46 samples, eliminating the need for imaging or capillary electrophoresis. MCC estimation is performed alongside aneuploidy analysis in one test to assess sample quality and aneuploidy status.

Methods: gDNA from various sources underwent extraction using a standard column-based protocol. Multiplexed ddPCR assays targeted chromosomes 18, 13, 21, 3, X, and Y for aneuploidy detection, while the MCC assay focused on differentially methylated genomic regions between placental tissue and maternal cfDNA. Aneuploidy and MCC readouts were compared against QF PCR and NGS results.

Results: Evaluation involved 62 gDNA samples, demonstrating 100% concordance with QF PCR for fetal aneuploidy detection. MCC assay performance showed high reproducibility ($R2 = 0.98$) and correlation with QF PCR readout ($R2 = 0.78$) for amniotic fluid samples, with recommended optimization for chorionic villi.

Conclusion: In conclusion, ddPCR emerges as a fast, low-input, and cost-efficient alternative for rapid aneuploidy screening in invasive prenatal samples. Combining aneuploidy detection with MCC quality control in the same reaction plate using a methylation-based ddPCR approach reduces turnaround time and instrument costs, presenting a promising approach for invasive testing.

P03.002.B Optimized non-invasive prenatal diagnosis (NIPD) of monogenic disorders by mutation exclusion in real-life experience.

Nathalie Couque[1], *Ines Defer*[1], *Alexia Kinoo*[1], *Cédric Vignal*[1], *Hélène Cavé*[1], **severine drunat**[1]

[1]*CHU Robert-Debré, Molecular Genetics Unit, Paris, France*

Background/Objectives: The development of NIPD for monogenic disorders has increased the demand for prenatal diagnosis in families with a de novo mutation in a previous child. Importantly, the amount of circulating fetal DNA (cffDNA) analysed must be sufficient for reliable mutation exclusion, which requires accurate quantification.

Method: NIPD was performed using a variant-specific digital droplet PCR (ddPCR) assay. DNA was extracted from 10 ml plasma. Indel markers (DigitalTRACE®, Bionobis) were used for cffDNA quantification. Analyses were performed in four replicates.

Results: From mid 2022 to 2023, 61 NIPD (10-31 weeks of gestation; median:13.5 weeks) for 46 genes were performed. All assays were validated within a mean of 26 ± 8 days. The mean limit of detection (LOD) was 4.98 ± 0.9 droplet. Linearity assessment showed that for an average variant concentration of 0.85 copies/ul, the mean count of positive droplets was 13.8 ± 2.4. Accordingly, minimum levels for reliable reporting of negative results were defined as 1 copy/ul of cffDNA, i.e. 40 genomic equivalents (GE) of fetal DNA and 50 copies/ul of total DNA (i.e. 500 GE of DNA). The mean cffDNA concentration in each of the four replicate was 1.81 ± 1.32 copies/uL. Most NIPD (59/61) were related to previous occurrences of de novo variants. A positive result was found in 1 case, revealing *KIF1A* germinal mosaicism in an asymptomatic parent

Conclusion: The use of a panel of highly informative paternal indel polymorphic markers allowed accurate quantification of cffDNA. Furthermore, our data highlight the importance of offering NIPD in families with previous 'de novo' mutation

Conflict of Interest: None declared

P03.004.D Using low-coverage non-invasive prenatal screening data for polygenic risk score calculation

Sara Becelaere[1], *Simone Andrea Biagini*[1], *Ludovica Molinaro*[1], *Isabelle Cleynen*[1], *Toomas Kivisild*[1]

[1]*KU Leuven, Department of Human Genetics, Belgium*

Background/Objectives: Non-invasive prenatal screening (NIPS) samples derived from maternal blood contain cell free DNA (cfDNA) from fetus and mother. Investigating the maternal cfDNA provides opportunities for genetic analyses. However, calling genotypes directly from the low-coverage NIPS data is

challenging. We investigated the efficiency of using imputed low-coverage sequencing data from NIPS for polygenic risk score (PRS) calculations for height, preeclampsia and gestational diabetes mellitus (GDM).

Methods: NIPS samples were collected at UZ Leuven and imputed with QUILT. PRS for height were calculated for 2,057 NIPS samples using PRS-CS based on GWAS by Yengo (2022). The PRS for preeclampsia was calculated for 177 cases and 2,049 controls (Honigberg_2023). For GDM, GDM PRS and type-2 diabetes (T2D) PRS were calculated for 555 cases and 1,945 controls (Pervjakova_2022, and Mahajan_2022, respectively).

Results: The phenotypic variance in height explained by the PRS was 0.28, compared to 0.44 estimated from high quality genotype data. The variance in preeclampsia explained by the PRS was 0.029 (OR = 1.51(1.30-1.78);p-value = 2.23e-07) and the model had an area under the receiver operator curve (AUC) of 0.61(0.57-0.65), which is rather low but not unexpected given the low number of cases and the limited GWAS size. The phenotypic variance in GDM explained by the GDM PRS was 0.018 (OR = 1.32(1.19-1.46);p-value = 5.87e-08;AUC = 0.57(0.54-0.60)) and by the T2D PRS was 0.047 (OR = 1.55(1.40-1.71);p-value = 6.89e-18;AUC = 0.60(0.57-0.63)).

Conclusion: Height results indicate that imputed NIPS can be used for estimating PRS with sufficient accuracy. We show that PRS effectiveness in stratifying pregnancy-related complex diseases relies on the underlying genetic architecture and GWAS cohort sizes, expected to improve.

P03.005.A Outcome of genetic testing in fetal echogenic bowel

Ruxandra Nagy[1], *Ilse Feenstra*[2], *Dineke Westra*[3]

[1]*Maastricht UMC+, Clinical Genetics, Maastricht, Netherlands;* [2]*Radboudumc, Clinical Genetics, Nijmegen, Netherlands;* [3]*Radboudumc, Genetics, Nijmegen, Netherlands*

Consortium: n/a.

Background/Objectives: Fetal echogenic bowel (FEB) is detected in 0.2-1.8% of pregnancies during the second trimester. FEB is associated with fetal abnormality, including chromosomal anomalies, cystic fibrosis (CF), infection, and intra-amniotic haemorrhage. In the present study, we provide an overview of genetic testing in FEB.

Methods: We performed a retrospective observational study of all pregnancies with FEB referred to our center for genetic counseling between 2017 and 2022. Invasive genetic testing was performed via amniocentesis, including *CFTR* gene analysis, QF-PCR, copy number variant (CNV) analysis and whole exome sequencing. If parents opted out for invasive testing, parental *CFTR* carrier screening and noninvasive prenatal testing (NIPT) (if not previously executed) were performed.

Results: 268 pregnancies were included of which 183 (68.3%) with isolated FEB. NIPT excluded trisomy 13, 18 and 21 in 201 pregnancies (of which 104 isolated FEB). Invasive testing was performed in 49 fetuses [45 *CFTR* analysis, 28 CNV analysis, 11 SNV analysis (all with additional ultrasound findings)]. Parental *CFTR* carrier screening performed in 454 cases detected 27 carriers (5.9%), of which two couples. One fetus (isolated FEB; 0.4% of all pregnancies) had CF (homozygous pathogenic *CFTR* variant).

Conclusion: Genetic testing for FEB revealed a higher risk for CF than in the general Dutch population. This risk was, nonetheless, lower than previously reported in literature. The higher frequency of CF carriers in our cohort may be the result of a selection bias or could potentially be associated with FEB.

P03.006.B Diagnostic yield of prenatal genetic testing in pregnancies with cleft lip, alveolus and/or palate on fetal ultrasound

Maria Albers[1], *Marie-José Van den Boogaard*[1], *Judith Ummels*[2], *Aebele Barber Mink van der Molen*[3], *Mireille Bekker*[2], *Maarten Massink*[1], *Guus Lachmeijer*[1]

[1]*University Medical Center Utrecht, Department of Genetics, Utrecht, Netherlands;* [2]*University Medical Center Utrecht, Department of Obstetrics, Utrecht, Netherlands;* [3]*University Medical Center Utrecht, Department of Pediatric Plastic Surgery, Utrecht, Netherlands*

Background/Objectives: Differentiating prenatally between syndromic and non-syndromic cases of cleft lip, alveolus and/or palate (CLA/P) can be difficult since additional anomalies or developmental problems may only be recognizable after birth. A prenatal genetic diagnosis can aid in this distinction and improve prenatal counseling. The purpose of this study was to assess the yield of prenatal genetic testing in a retrospective cohort of fetuses with CLA/P detected by ultrasound imaging.

Methods: Between November 2020 and November 2022, 37 fetuses with CLA/P were prenatally detected by ultrasound, of which 11 with and 26 without additional anomalies. Prenatal genetic testing, including QF-PCR, SNP array or CNV analysis, gene panel testing of genes associated with CLA/P and/or trio whole exome sequencing (WES), was performed in 10 (38,5%) fetuses with CLA/P without additional anomalies and in all fetuses with CLA/P and additional anomalies. The outcomes were evaluated retrospectively.

Results: In 1 fetus (10%) with presumed isolated CLA/P a genetic diagnosis was identified with gene panel testing (Kallman syndrome, FGFR1). In 8 fetuses (72,7%) with CLA/P and additional anomalies a genetic diagnosis was established, of which 1 with QF-PCR (trisomy 13), 1 with chromosomal array (unbalanced translocation), 4 with gene panel testing (Kallman (FGFR1), Hartsfield (FGFR1), Baraitser-Winter (ACTG1) and CHARGE (CHD7) syndrome) and 2 with trio WES analysis (LMNB1-primary microcephaly and Neu-Laxova syndrome (PSPH)).

Conclusion: The results of this retrospective study suggest that prenatal gene panel and open exome testing increase the diagnostic yield in fetuses with cleft lip, alveolus and/or palate, both with or without additional anomalies.

P03.007.C Prenatal Diagnosis of SCN2A-related severe developmental and epileptic encephalopathy 11 by trio exome analysis

Uwe Ahting[1], *Siegel Corinna*[1], *Konrad Platzer*[2], *Johannes Lemke*[2;3], *Sophia Stoecklein*[4], *Christoph Hübener*[5], *Konstanze Hörtnagel*[1]

[1]*Medicover Genetics, MVZ Martinsried GmbH, Martinsried, Germany;* [2]*University of Leipzig Medical Center, Institute of Human Genetics, Leipzig, Germany;* [3]*University of Leipzig Medical Center, Center for Rare Diseases, Leipzig, Germany;* [4]*LMU University Hospital, Department of Radiology, München, Germany;* [5]*LMU University Hospital, Department of Obstetrics and Gynecology, München, Germany*

Background: Prenatal trio exome analysis can meet at least two major challenges: It can help find the correct genetic explanation

of fetal sonographic abnormalities and it can expand the prenatally manifesting phenotypic spectrum of diseases.

Method: Prenatal trio exome analysis.

Result: The fetus presented at 27 weeks of a so far uneventful pregnancy with polyhydramnios, small stomach bubble and fixed joints indicative of fetal arthrogryposis.

Trio exome analysis demonstrated a pathogenic heterozygous de novo missense variant in *SCN2A:* p.(Ala1329Asp). Pathogenic variants in *SCN2A* are associated with autosomal dominant neurologic diseases, ranging from benign familial seizures to severe developmental and epileptic encephalopathy 11 (EIEE11). The spectrum of symptoms primarily includes postnatal manifestations; little is known about prenatal onset. The found variant is not published as pathogenic yet. We classified the variant in accordance with ACMG-criteria to PS1, PM1, PM2, PM5, PP2, PP3 as pathogenic. However, the analog AS-change in evolutionary and functionally comparable SCN1A (Ala1339Asp) is associated with congenital arthrogryposis and perinatal seizures, so we suggested EIEE11 with prenatal onset in this case.

No relevant structural abnormalities of the brain were detected in the fetal MRI. After premature rupture of membranes the child was born at 29 weeks of gestation with fixed limb positions. The newborn showed seizures aggravating into status epilepticus, confirming the diagnosis of EIEE11 showing the severe end of the spectrum of this disease.

Conclusion: This case clearly exemplifies how prenatal trio exome analysis can help find the correct diagnosis and expand the prenatal phenotypic spectrum of diseases.

Conflict of Interest: None declared

P03.008.D Assessment of AION, an AI-based variant interpretation tool, for prenatal diagnostics in cases with fetal abnormalities

Rocio Acuna Hidalgo[1], *Maayke de Koning*[2], *Kristina Ibáñez Garikano*[1], *Andrea Bertana*[1], *Max Schelker*[1], *Ilona Lehtinen*[1], *Lourdes Rosano Gonzalez*[1], *Mariette Hoffer*[2], *Manon Suerink*[2], *Gijs Santen*[2]

[1]*Nostos Genomics GmbH, Computational Genomics, Berlin, Germany;* [2]*Leiden University Medical Center (LUMC), Department of Clinical Genetics, Leiden, Netherlands*

Background/Objectives: Interpretation of genetic variants using limited phenotypic data while maintaining a quick turnaround time for reporting complicates prenatal genetic testing. AION is an AI-based medical device software designed to classify and prioritize genetic variants for automated variant interpretation. This study retrospectively evaluates AION's clinical performance in identifying causative genetic variants in prenatal whole exome sequencing data, as well as in dealing with variants of unknown significance (VUS).

Methods: We analyzed 35 prenatal diagnostic cases with fetal abnormalities (including 10 positive cases and 25 with VUS). All cases were processed on AION, using trio SNV/indel VCF files and clinical phenotype information as input to generate a list of prioritized variants based on potential for disease causality. An exhaustive search to identify additional cases from published scientific literature supplemented our validation dataset.

Results: AION accurately identified the causative variants in all 10 positive cases, ranking 9 of these as the top variant. Among the 25 VUS cases, interpretation was complex due to incomplete or contradicting evidence. Here, the VUS was included in the prioritized list in 16 cases, with 12 identified as strong follow-up candidates based on pathogenicity evidence. The remaining 9 VUS cases were considered less likely to be disease-causing due to phenotype/segregation mismatches or limited pathogenicity evidence.

Conclusion: AION effectively prioritized confirmed disease-causing variants in all positive cases. AION also effectively distinguished strong follow-up candidates in VUS cases from those with weaker or conflicting evidence. The study demonstrates AION's potential in enhancing prenatal diagnostic accuracy and efficiency.

P03.009.A BASHer (BiAllelic SNP Haplotyper) Software: Streamlining SNP Haplotyping in Pre-Implantation Genetic Testing for Monogenic Disorders (PGT-M)

Graeme Smith[1], **Rebecca Haines**[1], *Heema Hewitson*[1;2], *Elaine Ronaldson*[1;2], *Pamela Renwick*[1;2]

[1]*Synnovis LLP, Genomics Laboratory, Guy's Hospital, London, United Kingdom;* [2]*Centre for Preimplantation Genetic Diagnosis, Genetics Department, Guys Hospital, London, United Kingdom*

Background/Objectives: For couples where one or both partners carry, or are affected by a genetic condition, pre-implantation genetic testing for monogenic disorders (PGT-M) can identify risk haplotypes inherited in embryos. These predict the genetic status, allowing embryos unaffected by the condition to be considered for transfer. Following the withdrawal of a previous genome wide next generation sequencing based assay and analysis platform, it was necessary to develop a solution using an existing in-house SNP array platform to enable the continued delivery of PGT-M for new conditions for our patients.

Methods: Biallelic SNP Haplotyper (BASHer) uses SNP array data (Thermo Fisher Scientific HT-CMA) from both partners and a related reference to automate the identification of SNPs associated with high or low risk haplotypes. The tool generates HTML reports with interactive tables and plots to assist users in identifying the risk haplotypes inherited in embryos. BASHer reports were validated by comparison with manual SNP case analysis where a spreadsheet filters SNPs using logic for the different inheritance modes.

Results: BASHer has been used to deliver the PGT-M service for the majority of new tests (80/104 cases). BASHer is enabling informative reporting to support decision making for clinicians and couples going through PGT-M. Clinical Scientist analysts report that it is a user-friendly service.

Conclusion: BASHer software provides a method for analysis of SNP array data to enable the reporting of PGT-M cases using existing laboratory workflows, and within required turn-around times.

P03.010.B Novel digital PCR assay utilizing in-droplet methylation-sensitive digestion for estimation of fetal cfDNA from plasma

Chenyu Li[1], *Olga Mikhaylichenko*[1], **Eric Hall**[1], *Thea Riel*[1], *Madhumita Ramesh*[1], *Maria Gencoglu*[1], *Nathan Hendel*[1], *Richard Dannebaum*[1],

Severine Margeridon[1], Monica Herrera[1], Xinhua Lin[2], Nazeeh Hanna[2], Martin Chavez[2]

[1]Bio Rad Laboratories, Hercules, United States; [2]NYU Langone Hospital Long Island, Mineola, United States

Background/Objectives: Accurate quantification of fetal fraction in cell-free DNA (cfDNA) is crucial for obtaining reliable non-invasive prenatal screening (NIPS) results. While next-generation sequencing (NGS) is presently the predominant NIPS method, its high cost and turnaround time impede universal and equitable NIPS implementation. We present a methylation-based approach for quantifying fetal fraction via droplet digital PCR (ddPCR) and methylation-sensitive restriction enzyme (MSRE) digestion, and demonstrate ddPCR as an attractive alternative to NGS for fetal fraction determination.

Methods: Assays for fetal DNA targeted regions with high levels of methylation in fetal cfDNA; assays for maternal DNA targeted regions with high levels of methylation in maternal cfDNA; universally hypo- or hypermethylated regions were included as controls. Proof of concept in-droplet MSRE-ddPCR workflow was established on Bio-Rad QX600 instrument. The ddPCR-derived fetal fraction values were compared against chromosome Y concentration values for male pregnancies, and against NGS annotated values for all pregnancies regardless of fetal sex.

Results: Fetal fraction assay multiplex was tested on a total of 130 prospective euploid (n = 125) and aneuploid (n = 5) clinical plasma samples from pregnant individuals. Methylation-based fetal fraction quantification demonstrated high concordance with NGS results and chromosome Y based calculation for male samples. Run to run reproducibility analysis demonstrated lower variability than previously reported for NGS (median SD 0.61% versus 1.3-3.4%).

Conclusion: Utilizing ddPCR allows for obtaining accurate fetal fraction readout in a more time- and cost-effective manner compared to NGS. By integrating methylation-based biomarker identification with ddPCR, we pave the way for compelling alternatives in a wide array of NIPS diagnostic applications.

P03.011.C Determining the origin of genome aberrations improves the positive predictive value of NIPT for 22q11.2 deletion syndrome

Jiale Xiang[1;2], Xiangzhong Sun[1], Jiguang Peng[1], Hongfu Zhang[1], Jiangkun Shen[1], Jingrou Li[1], Hongyu Li[2], Lanping Hu[2], Jingjing Zhang[2], Shihao Zhou[2], Sihu Xu[1], Yun Yang[1], Jun He[2], **Zhiyu Peng**[1;2]

[1]BGI Genomics, Shenzhen, China; [2]Changsha Hospital for Maternal & Child Health Care Affiliated to Hunan Normal University, Hunan Provincial Key Laboratory of Regional Hereditary Birth Defects Prevention and Control, Changsha, China

Background/Objectives: Non-invasive prenatal testing (NIPT) has been endorsed by the American College of Medical Genetics and Genomics as the preferred method for screening fetal 22q11.2 deletion syndrome (22q11.2 DS). Maternal genomic aberrations represent a significant source of false positives in NIPT, and there are currently no solutions that effectively address this challenge.

Methods: We have devised an innovative NIPT bioinformatics pipeline designed to discern the origins of copy number variations (CNVs). Then, we recruited a cohort of 22q11.2 DS cases to validate the effectiveness of our methodology. Follow-up tests including amniocentesis and genome sequencing of maternal leukocytes were conducted.

Results: Leveraging a dataset of over 900 CNVs, we developed a new pipeline that classifies CNVs into those of fetal, maternal, and maternal-fetal origin based on NIPT data. The use of our pipeline led to a notable increase in the positive predictive value of NIPT for detecting 22q11.2 DS from 87% (34/39) to 94% (34/36). Furthermore, our approach has the potential to reduce the number of invasive tests by 8% (3/39).

Conclusion: Our innovative and reliable bioinformatics pipeline has enabled the accurate differentiation of CNV origin into fetal, maternal, and maternal-fetal categories. Incorporating this pipeline into the analytical workflow could reduce false positives in NIPT results and minimize the need for invasive prenatal diagnoses.

P03.012.D Whole exome sequencing in recurrent cases of fetal sonographic anomalies

julia grinshpun-cohen[1], *Lena Sagi-Dain[2], Amihood Singer[1]*

[1]Israel Ministry of Health, Community Genetics, Ramat Gan, Israel; [2]Carmel Medical Center, Genetic Institute, Haifa, Israel

Background/Objectives: The evidence exploring the yield of whole exome sequencing (WES) in pregnancies with recurrent sonographic anomalies is scarce. In this study, we examine the yield of exome sequencing in a relatively large cohort.

Methods: in 2020, the Israeli Ministry of Health (MOH) introduced public funding of exome sequencing for cases of recurrent fetal sonographic anomalies. Pregnancies with recurrent (two or more pregnancies) anomaly in a specific anatomic system undergone trio exome sequencing following genetic counseling and normal microarray analysis. We retrospectively retrieved clinical data for this study from MOH electronic medical records.

Results: Until October 2023, 117 cases of WES due to recurrent similar sonographic anomalies were included in the study. Most commonly affected system was brain (37.6%), followed by hydrops (12%), KACUT (10.3%), cardiac anomalies (9.4%), and skeletal anomalies (8.5%). We detected pathogenic and likely pathogenic WES findings related to the phenotype in 33 cases (28.2%). The highest rates of abnormal genetic findings (P/LP) were for skeletal anomalies (40.0%), hydrops (35.7%), KACUT (33.3%), multiple anomalies (30.0%), brain anomalies (29.5%) and cardiac anomalies (27.3%).

Conclusions: The yield of WES in pregnancies with recurrent sonographic anomalies is appreciable (over 25% for most indications), reaching 40% in skeletal anomalies. Establishment of a specific genetic diagnosis in pregnancies with fetal anatomic

anomalies is of importance for exact estimation of prognosis and recurrence risk, allowing for prenatal or preimplantation genetic testing in future pregnancies. Thus, WES analysis in pregnancies with sonographic abnormalities is beneficial, especially in cases with recurrent anomalies.

Conflict of Interest: None declared

P03.013.A Extending the clinical spectrum of X-linked Tonne-Kalscheuer syndrome (TOKAS): new insights from the fetal perspective

Background/Objectives: Tonne-Kalscheuer syndrome (TOKAS) is a recessive X-linked multiple congenital anomaly disorder caused by *RLIM* variations. Of the 41 patients reported, only 7 antenatal cases were described.

Methods: After the antenatal diagnosis of TOKAS by exome analysis in a family that was followed for over 35 years because of multiple congenital anomalies in five male fetuses, a call for collaboration was made, resulting in a cohort of 11 previously unpublished cases.

Results: We present a TOKAS antenatal cohort, describing 11 new cases in 6 French families. We report a high frequency of diaphragmatic hernia (9/11), differences in sex development (10/11), and various visceral malformations. We report some recurrent dysmorphic features, but also pontocerebellar hypoplasia, preauricular skin tags and olfactory bulb abnormalities previously unreported in the literature. Although no clear genotype-phenotype correlation has yet emerged, we show that a recurrent p.(Arg611Cys) variant accounts for 66% of fetal TOKAS cases. We also report 2 new likely-pathogenic variants in *RLIM*, outside of the two previously known mutational hotspots.

Conclusion: Overall, we present the first fetal cohort of TOKAS, describe the clinical features that made it a recognizable syndrome at fetopathological examination, extend the phenotypic spectrum and the known genotype of this rare disorder.

P03.014.B Evaluation of PCR-based and isothermal whole genome amplification strategies for preimplantation genetic testing of repeat expansion and gene deletion disorders in combination with aneuploidy screening

*Vivienne Tan[1], Ying Liang[2], Arnold Tan[1], Simin Wong[3], Mulias Lian[3], Caroline Lee[4], Mahesh Choolani[3;5], Truong Dang[6], **Samuel Chong**[1;3;5;7]*

[1]National University of Singapore, Paediatrics, Singapore, Singapore; [2]Shijiazhuang Obstetrics and Gynaecology Hospital, Reproductive Medical Center, Shijiazhuang, China; [3]National University Health System, National University Centre for Women and Children, Singapore, Singapore; [4]National University of Singapore,

Biochemistry, Singapore, Singapore; [5]National University of Singapore, Obstetrics & Gynaecology, Singapore, Singapore; [6]Vietnam Military Medical University, Anatomy, Hanoi, Viet Nam; [7]National University Hospital, Laboratory Medicine, Singapore, Singapore

Background/Objectives: The isothermal multiple displacement amplification (MDA) whole genome amplification (WGA) method is commonly used for preimplantation genetic testing of monogenic disorders (PGT-M) utilizing short tandem repeat (STR) haplotyping. In contrast, PCR-based WGA methods such as multiple annealing and looping-based amplification cycles (MALBAC) are ideal for preimplantation genetic testing for aneuploidy or structural rearrangements (PGT-A/-SR). We compared the MDA and MALBAC WGA methods for PGT-M of repeat expansion or gene deletion disorders in conjunction with PGT-A aneuploidy screening.

Methods: Replicates of five-cell aliquots from cell lines of a Huntington disease (HD) case-parent trio and a spinal muscular atrophy (SMA) case-parent trio were subjected to MDA and MALBAC WGA. WGA products of the HD trio underwent fluorescent triplet-primed PCR (TP-PCR) of the *HTT* CAG repeat, while WGA products of the SMA trio underwent multiplex-PCR of three *SMN* gene fragments containing single nucleotide differences between *SMN1* and *SMN2*, followed by minisequencing. Amplified and minisequenced products were analysed using capillary electrophoresis.

Results: TP-PCR failed from MALBAC-amplified samples, regardless of WGA product input amount. Triplex PCR and minisequencing succeeded from MALBAC-amplified samples, but two of three amplicons consistently under-amplified. In contrast, both HD TP-PCR and SMN triplex PCR and minisequencing consistently succeeded from MDA WGA product. Both MDA and MALBAC products could also be used for PGT-A to detect whole chromosome or segmental aneuploidy.

Conclusion: Isothermal WGA is superior to PCR-based WGA when used for PGT-M of repeat expansion disorders and gene deletion disorders in conjunction with PGT-A aneuploidy screening.

P03.015.C Transcriptional networks in placenta and fetal brain reveal extensive sex differences in a mouse model of polychlorinated biphenyl mixture exposure and folate supplementation potentially counteracts the effects of prenatal PCB exposure

Kelly Chau[1], *Kari Neier*[1], *Anthony Valenzuela*[1], *Rebecca Schmidt*[1], *Pamela Lein*[1], *Janine LaSalle*[1]

[1]*UC Davis, Davis, United States*

Background: In a human study "Markers of Autism Risk in Babies: Learning Early Signs", detectable concentrations of polychlorinated biphenyls (PCB) in maternal blood were associated with NDDs and alterations to methylation patterns of neurodevelopmental genes. In a mouse model of prenatal exposure to this PCB mixture, there were enhanced repetitive behavior and deficits in sociability and vocalizations at the lowest dose (0.1 mg/kg) specifically in males.

Methods: To investigate sexual dimorphism, dosage effects, and nutrient supplementation, we exposed C57Bl/6J females to varying doses (0, 0.1, 1, 6 mg/kg) of the PCB mixture supplemented with folate prior to timed mating. At embryonic day 18, brain and placenta were collected for RNA-sequencing and Whole Genome Bisulfite Sequencing (WGBS).

Results: Differential expressed genes analysis showed sex-specific dose responses and non-monotonic responses at the 0.1 mg/kg dose. Weighted gene co-expression network analysis was applied to investigate groups of highly correlated genes affected by PCBs and revealed extensive sex differences, with male brains impacted more than female brains. Broad pathways are disrupted including DNA repair and folate supplementation counteracts the effects of PCBs in brain and placenta.

Conclusion: A weighted region correlation network analysis of WGBS data is in progress to identify comethylated regions correlated with PCB exposures. Integration of gene expression and DNA methylation will be performed to identify epigenomic signatures in placenta that will be compared to human NDDs for their predictive value.

P03.016.D The increased nuchal translucency paradox

Tanja Richter[1], *Ann-Kathrin Tschürtz*[1], *Karl Mehnert*[1]

[1]*MVZ genetikum, Neu-Ulm*

Background/Objectives: Nuchal translucency (NT) is defined as sonographic appearance of subcutaneous accumulation of liquid in the back of the fetal neck at 11-14 gestational week. Increased NT is defined as measurement above 99th percentil. Besides the association with chromosomal abnormalities, it is also known to be caused by monogenic conditions. Currently, increased NT is mostly associated with Noonan syndrome (NS). However, prenatal Whole Exome Sequencing (WES) reveals an increasingly number of monogenic syndromes which may also be associated with increased NT. Besides increased NT can be a variation without pathological significance.

Methods: In our laboratory we performe Trio-WES combined with a Noonan-Plus-panel. Alongside known NS genes, the panel includes RASopathy genes and genes reported with increased NT and/or hydrops fetalis. Furthermore it includes e. g. genes for Kabuki syndrome. We performed data analysis of prenatal WES with either isolated increased NT or combined with one or more of the following abnormalities: cystic hygroma, hydrops fetalis, ductus venosus abnormalities, congenital heart defects.

Results: Pathogenic variants were mostly detected in PTPN11 followed by LZTR1, BRAF, RIT1, SOS1, RAF1. With the Trio-WES apporach we also detected variants in genes not yet associated with increased NT like ARID1A, H1-4, KANSL1, NFIX.

Conclusion: Our results give rise to the question, if increased NT is caused by the underlying syndrome or if the detected syndrome may be an incidental finding based on a benign variation on ultrasound examination. To solve this „Increased nuchal translucency paradox"further evaluation of increased NT and its correlation with monogenic syndroms is needed.

P03.017.A Whole genome sequencing in prenatally detected congenital malformations

Eini Westenius[1;2], *Peter Conner*[3;4], *Maria Pettersson*[1;2], *Ellika Sahlin*[1;2], *Nikos Papadogiannakis*[5;6], *Anna Lindstrand*[1;2], *Erik Iwarsson*[1;2]

[1]*Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden;* [2]*Karolinska University Hospital,*

Department of Clinical Genetics and Genomics, Stockholm, Sweden; [3]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden; [4]Karolinska University Hospital, Center for Fetal Medicine, Stockholm, Sweden; [5]Karolinska Institutet, Department of Laboratory Medicine, Stockholm, Sweden; [6]Karolinska University Hospital, Department of Pathology, Stockholm, Sweden

Background/Objectives: This prospective cohort study investigated the diagnostic yield of short-read whole genome sequencing (WGS) in prenatally detected congenital malformations.

Methods: In this prospective study, 85 fetuses with different congenital malformations, negative for trisomies and causative copy number variants, were further analyzed with fetal-parental trio WGS analysis.

Results: A molecular diagnosis was achieved in 23/85 (27%) of cases. Causative variants were identified in 21 genes: *FGFR3* (n = 2), *L1CAM* (n = 2), *ACTA1* (n = 1), *CDH2* (n = 1), *CHD7* (n = 1), *COL1A1* (n = 1), *COL1A2* (n = 1), *DHCR7* (n = 1), *EYA1* (n = 1), *FBXO11* (n = 1), *FRAS1* (n = 1), *NIPBL* (n = 1), *OFD1* (n = 1), *PDHA1* (n = 1), *POMGNT1* (n = 1), *PTPN11* (n = 1), *RIT1* (n = 1), *SMARCC1* (n = 1), *SMC3* (n = 1), *SOX9* (n = 1) and *STAG2* (n = 1). The phenotypes of the cases were divided into different groups with the following diagnostic yields: multisystem 8/19 (42%), CNS 8/21 (38%), skeletal 4/12 (33%), thorax 2/16 (13%), abdominal 1/11 (9%) and other isolated anomalies 0/6 (0%). Additionally, five cases carried variants that were considered potentially clinically relevant.

Conclusion: We demonstrate a diagnostic yield of 27% with WGS in prenatally detected congenital malformations. Our study emphasizes the benefits that WGS can bring to the diagnosis of fetal structural anomalies. It is noteworthy that causative chromosome aberrations were excluded from our cohort before WGS. As chromosome aberrations are a well-known cause of prenatally detected congenital malformations, future studies using WGS as a primary diagnostic test, including assessment of chromosome aberrations, will most likely show that the detection rate will exceed the diagnostic yield of this study.

P03.018.B Report of PRKAG2-related lethal congenital glycogen storage disease of the heart as an ultra-rare cause of foetal hydrops mimicking RASopathies.

Alexandre White-Brown[1], Marilyn Richard[1], **Isabelle De Bie**[1]

[1]MUHC - McGill University Health Centre (Glen Site), Specialized Medicine, Division of Medical Genetics, Montréal, Canada

Background/Objectives: Non immune foetal hydrops (NIFH) has been associated with over 200 chromosomal and single gene conditions, RASopathies representing about a quarter of the underlying monogenic aetiologies. Lethal Congenital Glycogen Storage Disease of the Heart (LCGSDH) is an ultra-rare entity with less than 10 cases reported in the literature so far, for which prenatal features significantly overlap those of RASopathies. The majority of reported cases of LCGSDH harbor the recurring *PRKAG2* pathogenic variant NM_016203.4:c.1592G>A (p.Arg531Gln).

We report the clinical features of a pregnancy with Lethal Congenital Glycogen Storage Disease of the Heart (LCGSDH) associated with a novel likely pathogenic de novo *PRKAG2* variant.

Methods: Pregnancy was uneventful until 28 weeks gestation, where foetal bradycardia was noted. Follow up ultrasound at 32 weeks revealed bradycardia, hydrops, moderate biventricular hypertrophy, prominent tongue and polyhydramnios. The newborn, delivered prematurely at 35 weeks, passed away at 17 hours of life due to respiratory insufficiency.

Results: Trio exome sequencing uncovered a novel likely pathogenic de novo missense variant in *PRKAG2*, NM_016203.3:c.1150A>G, p.(Arg384Gly). Pathological examination revealed extensive cardiac glycogenosis and severe pulmonary hypoplasia.

Conclusion: This report expands on the phenotypic spectrum of *PRKAG2*-related LCGSDH and further supports the usefulness of genome-wide molecular studies in the clinical evaluation of NIFH.

P03.019.C Incidental findings of microdeletions/microduplications of mother and fetus through non-invasive prenatal testing (NIPT).

Minyeon Go[1,2], *Hyunjin Kim[1], Ji Eun Park[1], Kyung Min Kang[1], Hee Yeon Jang[1,2], So Hyun Yang[1], Jong Chul Kim[1], Dong Hyun Cha[1,3], Sung Han Shim[1,2]*

[1]Center for Genome Diagnostics, CHA Biotech Inc., Molecular Genetics Laboratory, Seoul, Korea, Rep. of South; [2]College of Life Science, CHA University, Department of Biomedical Science, Gyeonggi-do, Korea, Rep. of South; [3]CHA Gangnam Medical Center, CHA University, Department of Obstetrics and Gynecology, Seoul, Korea, Rep. of South

Background/Objectives: Non-invasive prenatal testing (NIPT) is a screening test with high sensitivity and specificity in confirming trisomy 21,18, and 13. Recently, NIPT has been expanded to the microdeletion/microduplication syndromes (MMSs). In this study, we described two incidental finding cases of MMSs found in NIPT.

Methods: NIPT and Chromosome microarray analysis (CMA) were conducted.

Results: A 37-year-old woman (G3P0) underwent NIPT at 11 + 1 weeks of gestation, and the results revealed a microdeletion of 1.42Mb in the 17p12 region. Karyotyping and CMA test were conducted. The karyotype analysis results showed that both mother and fetus have a balanced translocation between chromosome 6 and 16, 46,XXt(6;16)(q25.1;q22). As a result of CMA analysis, the1.4Mb deletion was confirmed in both mother and fetus. The deleted region contains the *PMP22* gene that known to be related to CMT1A. The mother did not show any symptoms and decided to maintain the pregnancy and is currently 33 weeks of gestation.

A 37-year-old woman (G2P1) with a natural pregnancy underwent NIPT at 14 + 0 weeks of gestation. As a result, a 33.9 Mb duplication on 7pter(p14.3p22.3) and a 22.1Mb deletion on Xqter (q26.3q28) were identified. Both genomic variations were confirmed in the fetal CMA result. Those variations are suspected in one of the parents so genetic counseling was conducted, but further follow-up was refused.

Conclusion: This study shows that NIPT can be a tool to reliably detect MMS, and if MMS is found in NIPT results, confirmation through diagnostic testing should be considered.

Consortium: the AChro-puce Consortium

Background/Objectives: Williams-Beuren syndrome (WBS) is a well known disorder often diagnosed before 6 years of life. However, its prenatal diagnosis remains challenging with only 30 scattered fetuses described to date. We aimed to gather fetal cases carrying a 7q11.23 copy number variation (CNV) and collect precise clinical data to broaden knowledge of antenatal features in these syndromes.

Methods: We retrospectively recruited unrelated cases with 7q11.23 deletion, known as WBS, or 7q11.23 duplication who had prenatal ultrasound findings. We collected laboratory and clinical data, fetal ultrasound and fetal autopsy reports from 18 prenatal diagnostic centers throughout France.

Results: Forty fetuses with WBS were collected and the most common features were intra-uterine growth retardation (IUGR) (70.0%, 28/40), cardiovascular defects (30.0%, 12/40), polyhydramnios (17.5%, 7/40) and protruding tongue (15.0%, 6/40). Cardiovascular defects were mostly associated with extra-cardiac features (83,3%, 10/12). Fetal autopsy reports were available for 11 cases and confirmed all features identified by prenatal ultrasound. Four fetuses with 7q11.23 microduplication were collected and prenatal ultrasound signs were moderate and often isolated.

Conclusion: This work strengthens the fact that 7q11.23 CNVs are associated with a broad spectrum of antenatal presentations. Early IUGR and cardiovascular defects were the most frequent ultrasound signs. Protruding tongue and premature ductus arteriosus closure could be emergent WBS specific prenatal signs. By reporting the biggest series of antenatal WBS, we aim to better delineate distinctive signs in fetuses with 7q11.23 CNVs. We also broaden the spectrum of 7q11.23 duplication as we describe milder phenotype than previously reported.

P03.022.B Diagnosis of tuberous sclerosis in the prenatal period: a retrospective study of 240 cases and review of the literature

Vincent Milon[1], *Marie-Claire Malinge*[1], *Maud Blanluet*[1], *Marine Tessarech*[1;2], *Clarisse Battault*[1], *Sarah Prestwich*[1], *Béatrice Vary*[1], *Pierre Gueracher*[1], *Louis Legoff*[1;2], *Magalie Barth*[1;2], *Clara Houdayer*[1;2], *Agnes Guichet*[1;2], *Audrey Rousseau*[3], *Dominique Bonneau*[1;2], *Vincent Procaccio*[1;2], *Céline Bris*[1;2], *Estelle Colin*[1;2]

Background/Objectives: Tuberous sclerosis complex (TSC) is a rare multisystemic disorder caused by a pathogenic variant in the *TSC1* or *TSC2* gene. During foetal life, TSC may be suspected by detecting cardiac rhabdomyomas (CRs), cortical tubers, or subependymal nodules. Multiple CRs are associated with a very high risk of TSC, but the CR could be single and isolated. Few data exist to estimate the risk of TSC in these cases.

Methods: We assessed the clinical and genetic diagnosis of TSC in a retrospective study of 240 fetuses tested for suggestive antenatal signs. We provide a review of the literature to specify the probability of TSC in case of detection of single or multiple CRs.

Results: In this series, a definite diagnosis was confirmed in 50% (41/82) of foetuses initially presenting with a single CR, and 80.3% (127/158) in case of multiple CRs. We detected 3 cases of parental germinal mosaicism and estimated the risk at 2.6% (3/115).

Conclusion: The initial detection of an isolated single CR was associated with a proven TSC in half of the cases. TSC's great phenotypic variability raises challenges for genetic counseling and variant interpretation.

P03.023.C A comprehensive analysis of rare chromosomal abnormalities for individual chromosomes based on 582,996 non-invasive prenatal test (NIPT) results: a systematic review and meta-analysis

Marton Konya[1;2;3], *Agnes Czimbalmos*[1], *Lotti Loczi*[1;4], *Tamas Koi*[1], *Caner Turan*[1;5], *Rita Nagy*[1;6], *Péter Hegyi*[1;7], *Szabolcs Varbiro*[4;8;9], **Aniko Gal**[2;3]

[1]*Semmelweis University, Centre for Translational Medicine, Budapest, Hungary;* [2]*Semmelweis University, Institute of Genomic Medicine and Rare Disorders, Budapest, Hungary;* [3]*Czeizel Institute, Budapest, Hungary;* [4]*Semmelweis University, Department of Obstetrics and Gynecology, Budapest, Hungary;* [5]*Semmelweis University, Department of Anesthesiology and Intensive Therapy, Budapest, Hungary;* [6]*Heim Pál National Pediatric Institute, Budapest, Hungary;* [7]*Semmelweis University, Institute of Pancreatic Diseases, Budapest, Hungary;* [8]*University of Szeged, Department of Obstetrics and Gynecology, Szeged, Hungary;* [9]*Semmelweis University, Workgroup for Science Management, Doctoral School, Budapest, Hungary*

Background/Objectives: Genome-Wide Non-Invasive Prenatal Testing (GW-NIPT) can provide positive results not only for common autosomal aneuploidies but also for rare autosomal trisomies (RATs) and structural chromosomal abnormalities (SCAs). Due to their rarity, there is currently insufficient information on the positive predictive values (PPV) of RAT and SCA-positive cases in the literature.

Methods: In this study, the screening accuracy and pregnancy outcomes of cases positive for RATs were examined based on publications where GW-NIPT testing was performed. True positive cases were determined using two different methodologies. One was a confirmed methodology where only cases validated by genetic testing were considered true positives, the other is an extended methodology in which, in addition to cases confirmed by genetic testing, intrauterine foetal death and abortion due to an ultrasound-confirmed abnormality were considered true positive cases where no diagnosis was made but the foetus was likely to be affected.

Results: 14 studies were analyzed, with a total GW-NIPT population of 582,996. Of these, 1,364 were RAT positive. Using a confirmed method, we found the highest rates of true positives in T16, followed by T22, and T2, with extended method, the highest rate of true positives in T22, followed by T16, and T15.

Conclusion: This is the first meta-analysis to determine with high precision the frequency of rare chromosomal abnormalities, test-positive rates, and the PPV of each chromosomal abnormality. Our results could help pre- and post-test genetic counseling and can help patients and clinicians in their decision-making.

P03.024.D Prenatal Exome Sequencing Implementation in Anomalous Fetuses; First Report from Turkey

*Ezgi Susam[1], **Beyhan Durak Aras**[1], Sinem Kocagil[1], Zafer Bütün[2], Melih Velipasaoglu[1], Hüseyin Mete Tanır[1], Sevilhan Artan[1]*

[1]Eskisehir Osmangazi University, Meselik Campus, Türkyie; [2]Eskişehir City Hospital, Eskişehir, Türkyie

Background/Objectives: Prenatal WES started to take place more frequently in the literature since 2016 and has been studied in cases with different numbers of participants and different phenotypic findings. The diagnostic yield ranges from 15% to 42% in several studies. Unlike other literature, our study was comprised of 20 cases, 50% of whom had parental consanguineous marriage and 25% had a positive family history due to population characteristics.

Methods: After excluding chromosomal aberrations by microarray analysis, WES (Twist Human Core Exome capture kit, MGI DNBSEQ-G40) analyses were studied in 20 fetuses with major or structural anomalies.

Results: In 9 of 20 cases, genetic etiology was found to explain the fetal phenotype, and the diagnosis yield was found as 45%. The highest diagnostic rate was obtained in fetuses with fetal akinesia (66%), central nervous system anomalies (50%), and skeletal system (40%) involvement, lowest yields were obtained from cardiac anomaly group (10%) and genitourinary anomalies (20%). It was thought that the diagnosis rate was higher than the literature, due to the high rate of inter-parental consanguinity and similarly affected individuals in families. In addition, in contrast to the high sporadic rates in the literature, it has been shown that all encephalocele cases are syndromic and caused by monogenic genetic etiologies.

Conclusion: Our study is one of the very first examples in the literature with high consanguinity rates and in which postnatal evaluations of the family members are made. The diagnostic yield was demonstrated with the results, and its applicability in our society has been questioned.

P03.025.A Characterization of a complex rearrangement between three chromosomes in a fetus with skeletal anomalies by optical genome mapping

Uwe Heinrich[1], *Wilena Telman[1], Aysegül Klapperich[2], Jenny Schiller[1], Konstanze Hörtnagel[1]*

[1]MVZ Martinsried GmbH, Planegg, Germany; [2]MVZ Humangenetik Köln GmbH, Köln, Germany

Background/Objectives: We present a prenatal case involving a 29-week-old fetus exhibiting ultrasound anomalies, notably hallux valgus on both sides, mild micromelia, and polysyndactyly. Previous chromosome, FISH, and microarray analyses initially showed a seemingly balanced complex rearrangement encompassing chromosomes 2, 7, and 14. This resulted in three derivative chromosomes with approximately five breakpoints.

Methods: Seeking further elucidation, we conducted optical genome mapping (OGM, Bionano Genomics) on ultrahigh molecular DNA extracted from amniotic fluid cells, revealing a more complex rearrangement than initially perceived.

Results: The refined characterization delineates 13 breakpoint regions with partially inverted chromosomal fragments, impacting a total of four protein-coding genes. Among the identified breakpoints, a significant finding emerged within an 8.24 kb region on chromosome 7 in band p14.1, specifically within intron 3 of the *GLI3* gene (gli-kruppel family member 3). Notably, loss-of-function variants in *GLI3* are causative for the autosomal-dominant "Greig cephalopolysyndactyly syndrome" (GCPS). GCPS is primarily characterized by finger duplication, polydactyly, syndactyly, and/or hyperphalangy. Postnatally, manifestations such as macrocephaly, hypertelorism, and developmental delay were reported with variable expressivity.

Conclusion: The implication of the disrupted *GLI3* gene as the potential genetic cause of the fetal ultrasound abnormalities is noteworthy. This case serves as a compelling illustration of the diagnostic efficacy of optical genome mapping in unraveling the genetic underpinnings behind diagnostic anomalies. The detailed insights gained from this approach not only contribute to our understanding of complex rearrangements but also hold significant implications for genetic counseling and prognosis in cases of congenital anomalies in the prenatal as well as postnatal setting.

P03.026.B Prenatal manifestation of a severe form of Mitochondrial Short-Chain Enoyl-CoA Hydratase 1 Deficiency

Jana Lastuvkova[1], *Marketa Tesarova[2], Blanka Vavrinkova[3], Pavel Gerych[3], Patrik Hitka[4], Mikulas Zich[1], Vlasta Cejnova[1]*

[1]Masaryk Hospital in Ústí nad Labem, o.z., Krajská zdravotní, a.s., Department od Medical Genetics, Ustí nad Labem, Czech Republic; [2]First Faculty of Medicine, Charles University and General University Hospital in Prague, Department of Paediatrics and Inherited Metabolic Disorders, Prague, Czech Republic; [3]Jan Evangelista Purkyne University and Masaryk Hospital in Ústí nad Labem, o.z., Krajská zdravotní, a.s., Department of Gynecology and Obstetrics, Ustí nad Labem, Czech Republic; [4]Jan Evangelista Purkyne University and Masaryk Hospital in Ústí nad Labem, o.z., Krajská zdravotní, a.s., Department of Neonatology, Ustí nad Labem, Czech Republic

Background/Objectives: Mitochondrial Short-Chain Enoyl-CoA Hydratase 1 Deficiency (ECHS1D) is a very rare autosomal recessive neurodegenerative disorder with a wide phenotypic spectrum. The patients most commonly present with severe encephalopathy and lactic acidosis in the neonatal period; later manifestations in infancy are rarer. So far, the only described prenatal signs have been intrauterine growth restriction and/or oligohydramnios.

Methods: Prenatal ultrasound, Sanger sequencing

Results: We present 3rd trimester prenatal ultrasound findings of foetal hydrocephalus in two consecutive pregnancies of a healthy young woman of Mongolian origin. In the 1st pregnancy, hydrocephalus and oligohydramnios were detected at the 39th week. After birth, the male newborn was hypotonic, had elevated serum lactate levels, developed metabolic acidosis and died 39 hours postpartum. During the 2nd pregnancy, the 20-week ultrasound finding was normal, the 33-week ultrasound showed a mild dilatation of cerebral ventricles and at the 35th week foetal hydrocephalus was confirmed. After birth, the female newborn had similar symptoms as her sibling and died 41 hours postpartum. A DNA analysis in both children revealed 2 heterozygous pathogenic variants of the *ECHS1* gene (NM_004092.4): c.712G>C(p.Ala238Pro) and c.814C>T(p.Arg272Trp). Each of the variants was subsequently detected in one of the parents.

Conclusion: To our knowledge, this is the first report of prenatal hydrocephalus in ECHS1D. An ultrasound finding of foetal hydrocephalus in the 3rd trimester can be the first manifestation of this severe metabolic disease. The aforementioned parents are planning another pregnancy with the use of preimplantation genetic testing.

P03.027.C Cell-based noninvasive prenatal test (cbNIPT) using whole-genome sequencing (WGS-cbNIPT)

*Maria Bach Laursen[1], **Maibritt Nørgaard Lauridsen**[1], Katarina Ravn[1], Line Dahl Jeppesen[1], Anne-Marie Bruun[1], Ripudaman Singh[1], Lars Henning Pedersen[2;3;4], Ida Vogel[2;5], Lotte Hatt[1]*

[1]Arcedi Biotech, Arcedi Biotech, Aarhus N, Denmark; [2]Aarhus University Hospital, Department of Gynecology and Obstetrics, Aarhus N; [3]Aarhus University, Department of Clinical Medicine, Aarhus N; [4]Aarhus University, Department of Biomedicine, Aarhus C; [5]Aarhus University, Center for Fetal Diagnostics, Aarhus N

Background/Objectives: We aimed to investigate the performance of cell-based noninvasive prenatal test (cbNIPT) using whole-genome sequencing (WGS-cbNIPT) for detection of genome-wide copy number variants (CNV) as compared to chromosomal microarray analysis on fetal cells (CMA-cbNIPT), and on chorionic villus sampling (CMA-CVS).

Methods: Pregnant women (N = 102) scheduled for CVS were recruited (gestational week 10 + 0-14 + 6). Intact fetal cells were isolated from peripheral blood and whole-genome amplified fetal DNA was used for WGS-cbNIPT. WGS (mean coverage: 5x) and CNV analysis (VarSeq) was performed on single cells or pools (2-3 cells). For 92 women, matching CMA-cbNIPT data was available.

Results: From a cohort of 102 pregnant women, WGS-cbNIPT results were compared to CMA-CVS (55 normals/47 anomalies). Detected aberrations included twenty aneuploidies (T21/T18/T13: 16/3/1), three cases with mosaicism (T16M/T8M: 2/1), and four cases with sex-chromosome anomalies. The WGS-cbNIPT detection rate for aneuploidies was 100% (27/27). In twenty pregnancies with clinically relevant non-mosaic CNVs, WGS-cbNIPT correctly identified all pathogenic deletions (range: 0.5–33Mb. 4/4 ≥5Mb, 5/5 ≤ 5Mb). For duplications ≤5Mb, 3/6 pathogenic duplications (range: 0.4–2.8Mb) and 5/5 duplications of unknown significance (range: 0.4–1.4Mb) were detected by WGS-cbNIPT. In total, 44/47 aberrations were detected by WGS-cbNIPT compared by CMA-CVS. All normal cases were correctly identified (55/55). The performance of WGS-cbNIPT was comparable to CMA-cbNIPT, however more sensitive in detecting duplications ≤5Mb with detection rates of 100% vs 25%, respectively.

Conclusion: WGS-cbNIPT is a comprehensive screening method showing results on-par-with CMA-CVS in 44/47 samples. The performance of WGS-cbNIPT is superior to CMA-cbNIPT for detection of duplications ≤5Mb.

P03.028.D The implementation of Whole Exome Sequencing in the molecular diagnosis of fetal structural anomalies: the experience of a referral Italian hospital

__Stefania Zampieri__[1], Agnese Feresin[2], Anna Morgan[1], Elisa Paccagnella[1], Elisa Rubinato[1], Daniela Mazzà[1], federica perino[2], Anna Samarin[2], Tamara Stampalija[2;3], Maurizio Pinamonti[4], Giovanni Turchetto[1], Rossana Bussani[2;4], Beatrice Spedicati[1;2], Flora Maria Murru[2;5], Giorgia Girotto[1;2]

[1]IRCCS Burlo Garofolo, Trieste, Italy, SC Genetica Medica, Trieste; [2]University of Trieste, Trieste, Italy, Department of Medicine, Surgery and Health Sciences, trieste, Italy; [3]IRCCS Burlo Garofolo, Trieste, Italy, Fetal Medicine and Prenatal Diagnosis Unit, Trieste; [4]Azienda Sanitaria Universitaria Giuliano-Isontina and University of Trieste, Pathology Department, Trieste, Italy; [5]IRCCS Burlo Garofolo, Trieste, Italy, Paediatric Radiology, Trieste, Italy

Background/Objectives: Fetal structural anomalies are responsible for ~3% of pregnancy complications, which are usually identified in the second trimester. Whole Exome Sequencing (WES) is recommended as a second-tier analysis after normal karyotype or chromosomal microarray analyses in the case of fetuses with a major malformation or multiple anomalies. This work aims to highlight the value of WES as an essential diagnostic technology in the prenatal setting by studying a deeply characterized cohort of fetuses with malformations.

Methods: A cohort of 68 fetuses with structural anomalies from 62 families, without aneuploidies or pathogenic copy number variants, and with a fulfilled post-mortem autopsy was selected for WES analysis. For all the fetuses, detailed phenotypic information (i.e., dysmorphology examination, histology, and imaging) and fetal tissue were available.

Results: In 24 cases (39.7%), we identified "likely pathogenic variants" or suggestive "variants of unknown significance" in genes with an already established genotype/phenotype association. Interestingly, in some cases, we also identified already-known pathogenic variants previously reported only in postnatal conditions, expanding their phenotypical spectrum in the prenatal setting. As an example, a female fetus with severe skeletal dysplasia carried a pathogenic variant in the *EBP* gene (c.364G>A,

p.(Glu122Lys)), which was first described in an adult woman affected by a rare X–linked dominant condition known as Conradi–Hünermann–Happle syndrome.

Conclusion: Our study demonstrated that WES can provide clinically relevant information for fetuses with malformation, allowing couples counseling, the estimation of recurrence risk, and the description of novel fetal genotype-phenotype associations.

P03.029.A Residual risks for chromosomal aberrations in patients with normal NIPS (non-invasive prenatal screening) – a retrospective study

Adriana Iglesias[1], *Diane Van Opstal*[1], *Florentine Thurik*[1], *Mark Drost*[1], *Marjolein Weerts*[1], *Marieke Joosten*[1], *Karin Diderich*[1], *Vyne van der Schoot*[1], *Myrthe van den Born*[1], *Robert-Jan Galjaard*[1], *Sabina de Weerd*[2], *Anneke Dijkman*[3], *Dimitri Papatsonis*[4], *Jerome Cornette*[5], *Sander Galjaard*[5], *Maarten Knapen*[5], *Krista Prinsen*[5], *Attie Go*[5], *Kyra Stuurman*[1], *Malgorzata Srebniak*[1]

[1]*Erasmus MC Sophia Children's Hospital, Clinical Genetics, Rotterdam, Netherlands;* [2]*Albert Schweitzer Hospital, Obstetrics and Gynecology, Dordrecht, Netherlands;* [3]*Reinier de Graaf Gasthuis Hospital, Obstetrics and Gynecology, Delft, Netherlands;* [4]*Amphia Hospital, Obstetrics and Gynecology, Breda, Netherlands;* [5]*Erasmus MC, Obstetrics and Gynecology, Rotterdam, Netherlands*

Background/Objective: Systematic follow-up of pregnancies with low-risk NIPS results in the general obstetric population is currently lacking. Here, we evaluated pregnancies with low-risk NIPS results which were later referred for chromosomal microarray analysis (CMA) testing. We aimed to assess the residual risk for chromosomal aberrations in pregnancies with normal NIPS results and to indicate potential causes of discordant negative NIPS results.

Methods: Between April 2017 and March 2021, 46,004 women received a low-risk NIPS result. Cytogenomic follow-up included prenatal (primarily due to ultrasound anomalies) or postnatal CMA data. The cohort was subdivided into women receiving NIPS results for only chromosomes 13, 18, and 21 (targeted NIPS = tNIPS) and for all autosomes (genome-wide NIPS = gwNIPS).

Results: 1.7% (789/46,004) of women with normal NIPS results were referred for CMA (146/9619 tNIPS and 643/36,388 gwNIPS). The residual risk for a pathogenic CNV (excluding susceptibility CNV) in the studied general population was 1:641 (0.20%) in the tNIPS group, and 1:888 (0.15%) in gwNIPS. Between 1% (tNIPS) and 1.1% (gwNIPS) of the fetuses were referred for CMA due to ultrasound anomalies. The residual risk for a pathogenic CNV in a fetus with ultrasound anomalies (excluding susceptibility CNV) was 1:8 (13%) in tNIPS group and 1:13 (7.7%) in gwNIPS group.

Conclusions: The residual risk for a pathogenic CNV after normal NIPS result is low in the general obstetric population. However, in pregnancies affected with ultrasound anomalies, the residual risk is notably increased justifying offering invasive testing. These findings are important for pre-and post-test counseling for NIPS and invasive testing.

P03.030.B Effect of Polygenic Scores of Telomere Length Alleles on Telomere Length in Newborns and Parents

Yunsung Lee[1], *Astanand Jugessur*[1;2], *Haakon Gjessing*[1;2], *Jennifer Ruth Harris*[1], *Ezra Susser*[3;4], *Per Magnus*[1], *Abraham Aviv*[5]

[1]*Norwegian Institute of Public Health, Centre for Fertility and Health, Oslo, Norway;* [2]*University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway;* [3]*Columbia University, Mailman School of Public Health, New York, United States;* [4]*New York State Psychiatric Institute, New York, United States;* [5]*Rutgers University, Center of Human Development and Aging, New Jersey Medical School, Newark, United States*

Background/Objectives: In adults, polygenic scores (PGSs) of telomere length (TL) alleles explain only about 4.5% of the variance in TL, as measured by quantitative polymerase chain reaction (qPCR). Yet, these PGSs infer a causal role of telomeres in aging-related diseases. TL is primarily established by birth, making it crucial to understand how these PGSs explain TL in newborns.

Methods: This study investigates the effect of PGSs on TL in both newborns and their parents, with TL measured by Southern blotting and expressed in base-pairs (bp), in the Norwegian Mother, Father, and Child Cohort Study. Additionally, it explores the impact of PGSs of transmitted or non-transmitted alleles on TL in newborns.

Results: For parents and newborns, the PGS effects on TL were 172 bp ($p = 2.03 \times 10^{-15}$) and 161 bp ($p = 3.06 \times 10^{-8}$), explaining 6.5% and 4.9% of the TL variance, respectively. The strongest PGS effect was observed from maternally transmitted alleles in newborn girls, amounting to 214 bp ($p = 3.77 \times 10^{-6}$) and explaining 7.2% of the TL variance. The PGS effect of non-transmitted alleles was 56 bp ($p = 0.0593$) explaining 0.4% of the TL variance.

Conclusion: Our findings emphasize the importance of TL genetics in understanding early-life determinants of TL. They point to the potential utility of PGSs composed of TL alleles in identifying susceptibility to aging-related diseases from birth and reveal the presence of sexual dimorphism in the effect of TL alleles on TL in newborns.

P03.031.C Development of a non-invasive prenatal diagnostic test for rare monogenic disorders.

Styliana Philippou[1], *Skevi Kyriakou[1], Michaella Georgiadou[1], Kyriakos Tsangaras[1], Achilleas Achilleos[1], charalambos loizides[1], Christos Lemesios[1], aris pallaris[1], Chrystalla Havadjia[1], sarah barbour[1], Gaetan Billioud[1], chrysovalando soteriou[1], Louisa Constantinou[1], Lygia Ioannou[1], Antonia Matsentidou[1], Christos Prokopi[1], Melina Vaki[1], Styliana Georgiou[1], george manoli[1], Elena Kypri[1], Marios Ioannides[1], George Koumbaris[1], Philippos Patsalis[1,2]*

[1]Medicover Genetics, Nicosia, Cyprus; [2]University of Nicosia Medical School, Department of Basic and Clinical Science, Nicosia, Cyprus

Background/Objectives: Non-invasive prenatal testing for monogenic disorders is of great clinical need. While nearly 75% of dominant single gene disorders arise from de novo mutations, limited next-generation sequencing (NGS) based tests are currently available for their detection. We aim to employ our proprietary targeted capture enrichment technology in developing a non-invasive prenatal test designed to identify the most severe de novo disorders.

Methods: A 34-gene panel was developed focused on the selection of genes leading to severe autosomal dominant or X-linked conditions. A total of 1900 probes were designed to encompass all coding regions of the genes of interest. DNA samples from both pregnant and non-pregnant women, as well as artificial samples were utilized. These samples were barcoded with unique molecular identifiers (UMIs), were subjected to a novel enrichment method, and were analyzed using NGS for the specific targeted regions.

Results: The assay yielded a high raw read depth per sample, facilitating efficient UMI error correction. Accurate detection of fetal fraction (FF) was achieved, and a background substitution-based error model was trained enabling a highly accurate fetal-specific variant calling in all tested samples. More than 97% of all targeted regions were covered at 200x read depth.

Conclusion: This work establishes the groundwork for the detection of monogenic disorders caused by de novo mutations. Future work will focus on the development of an accurate non-invasive screening test for rare monogenic disorders.

Background/Objectives: Exome sequencing (ES) is increasingly used in prenatal diagnosis. We report our experience with 411 consecutive prenatal cases through ES.

Methods: Step 1 of the computational analysis was limited to gene panels according to the fetal phenotype; step 2 consisted of examining all known mendelian genes (OMIM, CGD, and literature updates).

Results: After performing a-CGH, 30 cases had solo and 381 trio ES. In 56 cases (13.6%), we have identified a variant likely causative of the fetal phenotype. A total of 17 of 56 cases were solved in Step 2 analysis. In 54 of the solved cases, the pathogenic variants were SNVs, while 2 were structural variants (SV). There were 3 cases of uniparental disomies UPD6, UPD16 and UPD17, all including isodisomic segments with likely causative recessive genes. The diagnostic yield of the various gene panels ranged from 24% for Brain Malformations to 9% for Congenital Heart Disease. Only VUS+ with a substantial likelihood of contributing to the phenotype were disclosed (24 cases, 5.84%).

Conclusion: ES is a powerful method for diagnosing causative variants prenatally; trio sequencing reduces the turnaround time (median 16 days during 2023) and increases the diagnostic yield. The fetal phenotypes of many of postnatal diagnostic entities are still to be defined. The VUS remain a challenge and guidelines are needed to assist in the interpretation and disclosure of the results.

The discovery of novel mendelian genes and additional laboratory (long-read sequencing, RNA sequencing, and improvement of SV detection) and computational methods may further increase the diagnostic yield.

P03.033.A A novel mechanism for the origin of androgenetic/biparental chimeras with two biparental cell lines leading to placental mesenchymal dysplasia with Beckwith-Wiedemann syndrome

Mar Xunclà[1], *Natàlia Rey*[1], *Maria Ángeles Sánchez Duran*[2], *María Serrano*[1], *Lourdes Trobo*[1], *Pedro Antonio Martínez*[1], *Neus Castells*[1], *Alberto Plaja*[1], *Jessica Camacho Soriano*[3], *Maria Àngels Rigola*[4], *Elena García-Arumí*[1], *Eduardo Tizzano*[1]

[1]*Hospital Universitari Vall d'Hebron, Department of Clinical and Molecular Genetics, Barcelona, Spain;* [2]*Hospital Universitari Vall d'Hebron, Department of Prenatal Diagnostics, Barcelona, Spain;* [3]*Hospital Universitari Vall d'Hebron, Pathology Department, Barcelona, Spain;* [4]*Universitat Autònoma de Barcelona, Cellular Biology and Medical Genetics, Spain*

Background: Placental mesenchymal dysplasia (PMD) is often related to genome-wide paternal uniparental disomy and Beckwith-Wiedemann Syndrome (BWS), mostly due to the presence of androgenetic/biparental mosaics/chimeras.

Methods: G-band cytogenetic analysis, QF-PCR STR analysis (Devyser).

Results: An amniocentesis was performed on a 15w pregnant woman suspected of PMD, who underwent termination of pregnancy at 20w. PMD and BWS fetus were confirmed by fetal autopsy. Short tandem repeat (STR) analysis of amniotic fluid detected one maternal and two different paternal chromosomal endowments. Cytogenetic analysis found three different cell lines: 45,XX,der(15;22)(q10;q10)mat, 45,XY,der(15;22)(q10;q10)mat and 46,XY. Maternal contamination was ruled out. STR and chromosomal heteromorphisms analyses indicated that all three cell lines were of fetal origin. Cell lines with the Robertsonian translocation were biparental with the same maternal but different paternal haplotype; the 46,XY cell line was androgenetic showing uniparental paternal heterodisomy. Therefore, we conclude that the fertilization leading to this fetus involved one haploid ovum and two different haploid sperms. DPM with heterodisomic androgenetic cell line has been rarely described and the proposed mechanism is a concatenation of errors including nondisjunction events, resulting in androgenetic/biparental chimeras. To our knowledge, this is the first case of PMD with two different biparental and one androgenetic cell lines.

Conclusion: We propose a new, simpler mechanism in which a three pronuclei zygote through a heterogoneic division divides directly into three cells with different haplotype that will end up in the three different cell lines. We believe this mechanism could also explain other previously described cases of PMD.

Background/Objectives: Multiple congenital anomalies account for around 3% of live births and 20% of stillbirths. After standard genetic investigations, including karyotype, and/or chromosomal microarray analysis, greater than 60% of pregnancies do not have a genomic diagnosis.

Methods: In this French collaborative study, we performed trio-exome sequencing in deceased fetuses presenting structural anomalies of at least two systems documented by fetal autopsy, without chromosomal abnormality.

Results: We included 20 fetuses (16 termination of pregnancy, 3 intra-uterine fetal death and 1 neonatal death) aged between 11 to 39 weeks' gestation. We observed an overall diagnostic yield of 35% (7/20). Causative molecular variants were identified in 7 fetuses, involving *MYH7*, *NRAS*, *USP9X*, *KMT2D*, *DYRK1A*, *ACTN2* and *EPHB4 genes*. The variants were de novo in all but one case, in which we detected a biallelic dominant variant in *ACTN2*, each inherited from a healthy parent. Two variants (*ACTN2* and *EPHB4)* involved splicing sites and their pathogenicity was confirmed by functional studies (minigene, RNA sequencing). Two fetuses presented atypical features compared to the phenotype classically associated to the genes (*MYH7*, *NRAS*). In two fetuses (10%), variants of unknown significance involving *PKD1* were detected. For one fetus, *UBR5* was identified as a new candidate gene. Ten fetuses (50%) remained without diagnosis.

Conclusion: exome sequencing allowed to make a diagnosis in 35% of cases, contributing to guide future care and genetic counseling. Data obtained from fetal autopsy helped to conclude to the variants pathogenicity.

Grants: young researcher grants 2019 of HCL and CREGEMES.

P03.035.C Application of the ClinGen Framework for gene-disease relationship evaluation in prenatal genetic testing

Alejandra Reyes[1], *Mariana Ferreira*[1], *Emir Zonic*[1], *Catarina Pereira*[1], *Ligia Almeida*[1], *fatima torres*[1], *Joaquin Ferzuli*[1], *Douglas deFaria*[1], *Nayla Leon Carlos*[1], *Jorge Pinto Basto*[1], *Peter Bauer*[1], *Aida Bertoli-Avella*[1]

[1]*CENTOGENE GmbH, Rostock, Germany*

Background/Objectives: Prenatal testing involving genes with limited or unclear gene-disease relationships (GDR) necessitates careful evaluation. Here we describe the approach followed in our laboratory when prenatal testing is requested or considered after a potentially relevant variant is identified in a family. Our objective

was to assess the impact of applying the ClinGen framework for GDR evaluation in prenatal testing.

Methods: We evaluated targeted prenatal testing requests received at our laboratory from January to December 2023. Requests involving genes with limited or unclear GDR, as reported in databases (e.g., OMIM, ClinGen), were selected. Acceptance criteria for performing the genetic test were primarily based on GDR evaluation using the ClinGen framework, variant classification, and clinical information.

Results: We received 18 requests for targeted testing in genes with previously limited or unclear GDR. The associated phenotypes varied but could be grouped into neurological disorders and genetic syndromes. Following ClinGen framework evaluation, two genes were upgraded to strong, nine to moderate, and seven remained with limited association. Test requests involving genes with strong or moderate associations were accepted for prenatal testing. Only two requests (2/6) from the limited association group were accepted based on specific clinical overlap with described phenotypes, additional patients in our Biodatabank, and variant strength.

Conclusion: Seventy-two percent (13/18) of test requests were accepted based on supporting GDR evidence. This is very relevant for the families/couples with genetic disorders as it impacts the clinical management of ongoing pregnancies. The 'upgrade' of 11 genes broadens our knowledge of genetic diseases and benefits future genetic diagnoses.

P03.036.D DNA methylation episignatures in fetal DNA: Preliminary study on CHARGE syndrome

Nicolas Bourgon[1;2], *Amale Achaiaa*[3], *Badreddine Mohand Oumoussa*[4], *Hélène Madry*[4], *Karim Labreche*[4], *Lucile Boutaud*[2;3], *Antonio RAUSELL*[2;3], *Veronique Pingault*[2;3], *Tania Attie-Bitach*[2;3]

[1]*Necker Enfants Malades University Hospital, Obstetric and Fetal Medicine, Paris, France;* [2]*Imagine Institute, INSERM UMR1163, Paris, France;* [3]*Necker Enfants Malades University Hospital, Genomic Medicine for Rare Diseases, Paris, France;* [4]*Sorbonne University, P3S Platform - INSERM UMS 37 PASS, Paris, France*

Background/Objectives: Some Mendelian disorders have been associated with DNA methylation episignatures (DME), a specific pattern of DNA methylation. In a postnatal setting, DME performed on blood samples have been suggested as candidate biomarkers, essentially to reclassify VUS identified by genome-wide sequencing. However, their application in a prenatal setting may be challenged by DNA methylation variation across fetal development and tissues. Validation of DME in DNA extracted from fetal samples is mandatory for exploring their application in fetal disorders.

Methods: We conducted a preliminary study in a cohort of 36 individuals, including 15 patients with *CHD7* variant (7 children and 8 fetuses) and 21 controls (6 children and 15 fetuses). DNA was extracted from blood for children, and fetal DNA was extracted from lung and amniotic fluid (uncultured and cultured). DNA methylation was analysed using EPICv2 array. Raw data (iDAT) were analysed using EpigenCentral and a local pipeline. The predictive abilities of published DME were assessed for both children and fetuses.

Results: The mean detection rate of CpG dinucleotides was 99.93%. Sensitivity was 85.7%, specificity was 100% for postnatal cases, but dropped to 50.0% and 53.3%, respectively, for fetal samples. DNA methylation profiles varied significantly depending on the fetal tissue. Bioinformatics analysis are ongoing to potentially identify specific fetal DME and compare them with postnatal DME.

Conclusion: Our results confirm the validity of published episignature in a postnatal setting for *CHD7*-related disorders. However, the postnatal episignature is not applicable in a fetal setting. Further studies are needed to identify and validate specific fetal episignature.

P03.037.A New homozygous mutation c.32G>A in TMEM107 gene revealed in a fetus with a posterior fossa abnormality

Rada Staneva[1;2], **Ivelina Dimitrova**[2], *Kunka Kamenarova*[2], *Kalina Mihova*[3], *Ivanka Dimova*[3]

[1]*MBAL Nadezhda, Sofia, Bulgaria;* [2]*Medical University Sofia, Sofia, Bulgaria;* [3]*Medical University Sofia, Molecular Medicine Centre, Sofia, Bulgaria*

Background/objectives: The systematic evaluation of the brain anatomy of the fetus is an essential part of every ultrasound assessment during the pregnancy.

One of the most frequently detected congenital abnormalities of the brain are those of the posterior fossa with the incidence of 1:5000 livebirths. Furthermore, the presence of an abnormal posterior fossa of the fetus always requires to carry out an invasive testing to exclude aneuploidies or genetic syndromes.

We present the case of two consecutive pregnancies of a non-consanguineous couple, in which were detected similar abnormalities of the fetuses during the early ultrasound anatomy assessment (11 + 2 - 13 + 6 g.w.) - abnormal posterior fossa, shortening of the long bones with abnormal position of the wrists and feet, postaxial polydactyly in all four limbs.

Method: Whole exome sequencing of isolated fetal DNA was performed to detect possible genetic aberrations.

Resuts: A novel genetic variant - c.32G>A (p.Arg11His) in *TMEM107* gene in homozygous condition was detected in the fetus and classified as likely pathogenic based on the established relation to the phenotype and in silico predicted pathogenicity. The parents were found to be heterozygous carriers of the variant. Mutations in *TMEM107* gene are associated with Meckel-Gruber syndrome (MGS).

Conclusions: MGS is an autosomal-recessive condition and presents with occipital encephalocele or other CNS abnormalities, polydactily and polycystic kidneys and has a lethal outcome in utero or shortly after birth. We report a novel genetic variant detected in non-consanguineous parents. Meckel-Gruber syndrome should be suspected in the presence of posterior fossa abnormalities.

Conflict of Interest: None declared

P03.038.B Biallelic *ITGA9* variants related to chylothorax and nonimmune hydrops fetalis in three patients

Tugba Kalayci[1], *Michael E. March*[2], *Tugba Sarac-Sivrikoz*[3], *Zehra Oya Uyguner*[1], *Gulandam Bagirova*[1], *Hakon Hakonarson*[2], *Yoav Dori*[2], *Dong Li*[2]

[1]*Istanbul University, Istanbul Faculty of Medicine, Department of Medical Genetics, Istanbul, Türkyie;* [2]*The Children's Hospital of Philadelphia, Philadelphia, United States;* [3]*Istanbul University, Istanbul Faculty of Medicine, Division of Maternal-Fetal Medicine, Department of Obstetrics and Gynecology, Istanbul, Türkyie*

Background: The Integrin Alpha 9 (*ITGA9*), a member of the integrin family, plays a pivotal role in cell-cell adhesion and interactions between cells and the extracellular matrix. In murine models, biallelic null variants of Itga9 have been linked to fatal chylothorax. Morever, heterozygous missense variants reported in humans have been associated with central congenital lymphatic anomalies (CCLA). In this study, we present three patients exhibiting biallelic novel variants in the *ITGA9*, presenting varying degrees of CCLA.

Methods: Comprehensive prenatal and postmortem clinical examinations were conducted in all patients, with whole exome sequencing employed to identify disease-causing variants.

Results: The first patient, a female, exhibited prenatal-onset pleural effusion, postnatally diagnosed as chylothorax, along with labial and lower extremity lymphedema and umbilical hernia. She was found to have a splice site(c.1236+4A>G) and a missense[c.289T>G, p.(Cys97Gly)] variant in *ITGA9* inherited from each parent. In vitro assay demonstrated that the splicing variant led to exon skipping[c.1142_1236del, p.(Asp381Glufs*23)]. The other patients involved dizygotic twins with nonimmune hydrops fetalis detected prenatally, and medically terminated at 18 gestational weeks. Both fetuses had homozygous frameshift[c.818delG, p.(Gly273Alafs*17)] variants.

Conclusion: Our findings establish the first instances of biallelic *ITGA9* variants, confirming the association of *ITGA9* and CCLA. The null variants, as evidenced by the homozygous frameshift variant in our cohort, may contribute to a more severe phenotype. This study enhances our understanding of CCLA genetics and emphasizes the clinical relevance of *ITGA9*.

Grants: This study was funded by the Research Fund of Istanbul University (project no:TDK-2023-39690) to TK.

Conflict of Interest: None declared

P03.039.C Diagnostic efficiency of clinical exome sequencing in fetuses with congenital anomalies

Candy Kumps[1], *Machteld Baetens*[1], *Sofie Symoens*[1], *Ellen Roets*[2], *Noortje Van Oostrum*[2], *Olivier Vanakker*[1], *Bert Callewaert*[1], *Björn Menten*[1], *Sandra Janssens*[1]

[1]*Center for Medical Genetics, Molecular Medicine, Gent, Belgium;* [2]*Prenatal diagnostics, Gynaecology, Gent, Belgium*

Background/Objectives: Structural fetal abnormalities are detected by prenatal ultrasound in ~3% of pregnancies. Identifying a genetic cause in prenatal or fetal context is impactful, enabling prognosis for current as well as risk assessment and reproductive options for subsequent pregnancies. In addition to routine tests, i.e. NIPT and CNV sequencing with diagnostic uptake rates up to 15%, exome sequencing (ES) based analysis has become feasible in clinical practice. We assessed the diagnostic value of ES-based virtual gene panel analysis, in fetuses with congenital abnormalities.

Methods: This retrospective study (2020-2022) reports on (trio) ES-based analyses of 99 fetuses with ultrasound abnormalities, pregnancy terminations or mors in utero with neither a clear environmental etiology, nor explanatory NIPT or CNV sequencing result.

Results: ES-based analysis obtained a molecular diagnosis in 25.3% of cases, i.e. in 27.3% of cases with multiple organ (n = 55) and 22.7% of cases with single organ (n = 44) anomalies. In particular, skeletal dysplasia (50%), multiple congenital anomalies (26.2%), congenital heart disease (16.7%) and nephrology (10%) virtual gene panels, including 522, 4878, 471 and 343 genes, harbored the highest number of diagnoses, comprising 52% inherited and 48% de novo variants with a limited number of incidental findings (n = 1).

Conclusion: Generally, ~15% of fetuses with ultrasound abnormalities have an abnormal karyotype or submicroscopic CNV confirming diagnosis. ES-based virtual gene panel analyses offer a significant additional diagnostic value to routine analyses, increasing the overall diagnostic yield to an estimated 40% in our cohort. The approach limits incidental findings, while offering a systematic laboratory workflow.

P03.040.D *RMRP* and *RNU4ATAC* reportable variants in prenatal exome sequencing: the value of including non-coding genes in exome enrichments.

Louise McClelland[1], *Rebecca Keelagher*[1], *Harjeet Rai*[1], *Deirdre Cilliers*[2], *Samuel Clokie*[3], *Stephanie Allen*[1]

[1]*West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom;* [2]*Oxford Centre for Genomic Medicine, Oxford, United Kingdom;* [3]*Nonacus, Birmingham, United Kingdom*

Background/Objectives: Prenatal exome sequencing (pES) for fetuses with structural abnormalities has been offered within the NHS since October 2020. Most whole exome sequencing (WES) enrichments only capture protein-coding exons with limited coverage of UTRs or non-coding genes (PMID: 37082142). Here we summarise three years of pES service and demonstrate the utility of including clinically-relevant non-coding genes within WES capture.

Methods: We report results from trio pES using the Nonacus ExomeCG WES enrichment and filtered for a panel of genes associated with fetal anomalies. These results represent the first 3 years of service from October 2020 to November 2023.

Results: During this time period, 667 pregnancies were tested, with diagnoses made in 29% of cases (194/667). Diagnoses were in 117 different genes, with recurrence in 31 genes. Most common were *PTPN11* (n = 11; Noonan syndrome), *CHD7* (n = 7; CHARGE syndrome), *COL2A1* (n = 7), *FGFR3* (n = 6), *COL1A1* (n = 5), *PIEZO1* (n = 5), *COL1A2* (n = 4), *DHCR7* (n = 4), *DYNC2H1* (n = 4), *RAF1* (n = 4). Three confirmed diagnoses and one probable diagnosis were identified in non-coding genes, representing 2.1% of the positive diagnostic yield (*RMRP* n = 3; *RNU4ATAC* n = 1). These cases will be presented.

Conclusion: Use of a whole exome approach allows rapid reporting in a prenatal setting with a high diagnostic yield in fetuses with structural anomalies. Exome enrichments focus on protein-coding regions and therefore miss detection of variants in non-coding genes. Inclusion of clinically-relevant non-coding genes within exome enrichments enhances diagnostic yield and negates the need to proceed with further testing such as WGS in these cases.

P03.041.A Evaluation of the clinical utility of using SNP-array chromosomal analysis in prenatal diagnosis

Timothée Moyret[1], *Massymissa Braik*[1], *Lucie Guilbaud*[2], *Nicolas Rive Le Gouard*[1], *Sarah Grotto*[3], *Mikaël Tassin*[4], *Daphné Lehalle*[3], *Anne Gael Cordier*[4], *Solveig Heide*[5], *Sandra Chantot-Bastaraud*[1], *Marc Dommergues*[6], *Valentine Faure*[6], *Delphine Heron*[3;5], *Jean-Marie Jouannic*[2], *Laïla El Khattabi*[1;7]

[1]*Chromosomal Genomics, Department of medical genetics, Armand Trousseau hospital, AP-HP Sorbonne Université, Paris, France;* [2]*Fetal medicine, DMU ORIGYNE, Armand Trousseau hospital, AP-HP Sorbonne Université, Paris, France;* [3]*Clinical Genetics, Armand Trousseau hospital, AP-HP Sorbonne Université, Paris, France;* [4]*Obstetrics and Gynecology, Tenon hospital, AP-HP Sorbonne Université, Paris, France;* [5]*Clinical Genetics, Department of medical genetics, Pitié-Salpêtrière hospital, AP-HP Sorbonne Université, Paris, France;* [6]*Obstetrics and Gynecology, Pitié-Salpêtrière hospital, AP-HP Sorbonne Université, Paris, France;* [7]*Brain development team, ICM - Paris Brain Institute – Pitié-Salpêtrière, Paris, France*

Background/Objectives: DNA-microarray analysis has become widely used for prenatal diagnosis in high-risk pregnancies. Current recommendations suggest their use at least in cases of elevated nuchal translucency, severe intrauterine growth restriction (IUGR) or ultrasound (US) abnormalities. Comparative genomic hybridization is the most used approach although SNP-arrays offer an added-value of detecting uniparental disomy. This advantage has been evaluated only in few studies. We, retrospectively, evaluated the diagnosis rate, including uniparental disomy, when using SNP-arrays in our prenatal population over 3 years.

Methods: In this retrospective cohort study, we collected results from SNP-array analysis using the Affymetrix platform in a context of prenatal diagnosis in fetuses presenting mostly with US abnormalities. We calculated the diagnosis rate of copy number variations or uniparental disomy, according to the category of US aberrations. Trio analysis was preferentially performed. We compared our results to published data using CGH-microarray.

Results: Out of 745 pregnancies included, we identified 61 chromosomal anomalies (8.2%), among which 5 uniparental disomies (0.7%) (2 upd(15), 1 upd(16) and 2 upd(22)) all of which were associated with IUGR. Among the published cohorts, 27631 fetuses were investigated using SNP-arrays, 15 uniparental disomies were identified (0.05%), with high variability between the different studies.

Conclusion: The rate of uniparental disomy identified by SNP-arrays in prenatal diagnosis is low, but their identification can significantly impact the pregnancy management. This is particularly interesting in case of IUGR. This approach provides also additional information, compared to CGH, such as the identification of triploidies and maternal contamination.

Conflict of Interest: None declared

P03.042.B Enhancing non-invasive prenatal screening: a comprehensive analysis of Trisomy test performance, clinical implications, and future directions

Michaela Hyblova[1], *Andrej Gnip*[1], *Dominik Hadzega*[1], *Oliver Petrovic*[1], *Gabriel Minarik*[1]

[1]*Trisomy s.r.o., Nitra, Slovakia*

Background/Objectives: Since its launch in 2016, the Slovak Trisomy test has evolved significantly from detecting whole-chromosome aneuploidies to identifying subchromosomal aberrations and advancing towards nucleotide-level analysis. The test is noted for its highly competitive sensitivity and specificity across all chromosomal aberations, including those involving sex chromosomes. It differentiates between fetal and maternal aberrations, significantly enhancing screening quality and expanding the range of screening options

Methods: We analysed more than 30,000 plasma samples from pregnant women, utilizing low-coverage whole-genome sequencing for comprehensive screening. The methodology for circulating cell-free DNA isolation and DNA library preparation adheres to previously established protocols. We targeted 5 million reads for whole-chromosome aneuploidy detection, while copy number variants required 20 million reads.

Results: The positive predictive values (PPV) for trisomy 21, 18, 13, X0, XXY, XYY, XXX, rare autosomal trisomies (RAT), and copy number variations (CNV) are 99.09%, 97.96%, 86.21%, 38%, 67%, 70.9%, 57.5%, 15%, and 75%, respectively. The overall rate of non-informative results after the second collection, defined as a fetal fraction below 4%, is significantly below 1%.

Conclusion: Non-invasive prenatal testing has evolved significantly beyond its initial scope as a screening tool for assessing fetal health. With its high PPV, it is now considered not just a screening test but also a diagnostic tool for maternal genetic findings and markers that could impact both current pregnancy outcomes and future fetal health. The use of non-invasive testing as a liquid biopsy is continually advancing, promising to revolutionize genetic screening and care in unprecedented ways

P03.043.C Exome and genome sequencing as time effective methods for prenatal diagnosis: overview of 679 patients

Catarina Pereira[1], *Ligia Almeida*[1], *Alejandra Reyes*[1], *Omid Paknia*[1], *Aida Bertoli-Avella*[1], *Jorge Pinto Basto*[1], *Peter Bauer*[1]

[1]*CENTOGENE GmbH, Rostock, Germany*

Background/objectives: Prenatal exome (ES) and genome sequencing (GS) have the potential to enable a more comprehensive and time effective genetic diagnosis in fetuses with sonographic abnormalities for single-nucleotide variants and copy number variations (CNVs). We present our experience using prenatal ES/GS solo or trio.

Methods: The study cohort comprised referred cases within a two-year period (January 2022-January 2024). ES/GS was performed for 130 trio and 545 solo cases of ongoing or terminated pregnancies with fetal abnormalities or positive family history of severe early onset disorders.

Results: From 679 cases evaluated, a 30% (202 cases) diagnostic yield with a clear genetic diagnosis including SNV and CNVs was achieved. For 1.8% (12 cases), analysis could not be performed due to sample quality related issues. For the trio analysis, the simultaneous study of the parents allowed the identification and reporting of de novo variants in 8/27 positive cases. A 27% (54/202 cases) diagnostic rate with CNVs was achieved (from single exon deletions to whole chromosome aneuploidies). The analysis of these cases is performed in a seamless and straightforward workflow allowing a turnaround time (TAT) of less than 15 days.

Conclusion: Prenatal ES and GS contributed to the clinical management in a single step analysis with a diagnostic yield of 30% in fetuses mostly presenting with structural anomalies. The short TAT enables the identification of early onset and severe diseases which would have not been diagnosed by other technologies in the same timeframe. This data suggests an actionable impact for the clinical management and genetic counseling of families.

P03.045.A RhD variants: when serology reaches its limits - observation in the determination of the fetal rhesus factor from maternal blood

Sofia Isabell Rupp[1], *Thomas Hackenbeck*[1], *Gudrun Göhring*[1]

[1]*amedes genetics, Hannover*

Background/Objectives: The blood group including rhesus factor is determined by serologically at the latest during pregnancy. If the rhesus factor is negative, pregnant women are able to analyse fetal rhesus factor of their unborn child molecularly from maternal blood as a health insurance benefit (Germany) since 01.07.2021 in order to enable targeted anti-D prophylaxis.

Methods: A commercial kit was used to determine the fetal rhesus factor (ingenetix GmbH, Hüttenbrennerg 5, 1030 Wien). The Ct-values generated or not detected indicate whether the unborn child is positive or negative. The raw data were analysed in regard to the presence of a previously unkown RhD variant.

Results: The methodology used has revealed the presence of an unexpected high percentage of previously unknown RhD variants in analysed pregnant women. In 2022, 473 suspected RhD variants were detected (samples received: 24599). We were able to identify two main groups: RhD variants that occur in the mother herself and mask the analysis or RhD variants that were found in the unborn child.

Conclusion: The data collected could not yet be examined with further molecular analyses. However, the initial results indicate that there is an increase in RhD variants in Germany. If they remain undetected and no anti-D-prophylaxis is given, RhD variants could have serious consequences and, in the worst case, lead to haemolytic neonatal disease. The results demonstrate how important additional molecular analyses are for blood group and rhesus determination as there are many RhD variants that cannot be detected serologically.

P03.046.B Comparative analysis of dPCR and NGS-based NIPT methods for fetal aneuploidy detection

Veronika Korenika[1], *Samanta Strojeva*[1], *Sandra Martinsone*[1], *Ludmila Volozonoka*[2], *Mikus Gavars*[1]

[1]*E. Gulbis Laboratory, Riga;* [2]*Riga Stradinš University, Scientific Laboratory of Molecular Genetics, Rīga*

Background/Objectives: Non-invasive prenatal testing (NIPT) has become a widely adopted approach for screening fetal aneuploidies. While next-generation sequencing (NGS) is the predominant technology in NIPT, digital PCR (dPCR) has recently emerged as an alternative method for absolute target quantification.

Methods: A total of 100 samples, with an average gestational week of 14 (±4.3 SD), were assessed. Cell-free plasma DNA from pregnant women was subjected to NIPT using both NGS and dPCR methods. The evaluation included analysis for chromosome 13, 18, 21, and sex chromosomes.

Results: Comparative analysis revealed no difference in sex determination between the two methods. On average, dPCR-based NIPT exhibited reduced fetal fraction estimation by 3.5 percentage points or 29% ($p < 0.001$) for male and 3.5 percentage points or 34% ($p < 0.001$) for female fetuses. The specificity of dPCR NIPT for chromosome 21, 18, 13, and X was 97.9%, 93.9%, 100%, and 88.5%, respectively. An investigation was conducted on a case involving a confirmed vanishing twin, wherein the developing fetus was female. NGS-based NIPT indicated no aneuploidy and suggested a male fetus gender. In contrast, dPCR NIPT revealed a general fetal fraction of 6.2%, while the fetal fraction based on Y chromosome count was 1.8%.

Conclusion: dPCR-based NIPT stands out as a fast (~ 24h turnover from sample receipt to report) and economically efficient screening technology when compared to NGS-based NIPT. Its promising capabilities position dPCR NIPT as a tool capable of surmounting the challenges associated with NGS-based NIPT.

P03.047.C Hemoglobin screening and genetic counseling in prenatal diagnosis for the prevention of hemoglobinopathies in Albania

Suela Leli[1], *Merita Xhetani*[2], *Eliona Demaliaj*[3], *Irena Korita*[4]

[1]*University Hospital Obstetrics - Gynecologic "Mbreteresha Geraldine", Center for Molecular Diagnostics and Genetic Research, Tirane, Albania;* [2]*University of Tirana, Faculty of Natural Sciences, Department of Biology, Tirane, Albania;* [3]*University of Medicine, University Hospital Obstetrics Gynecologic, Department of Obstetrics gynecologic, Tirane, Albania;* [4]*University of Medicine and University Hospital "Mother Tereza", Department of Clinic laboratory, Tirana, Albania*

Consortium: NanoAlb

Background/Objectives: Screening for carriers of hemoglobinopathies has been included in the routine protocols of examinations for all pregnant women. Here we present data from pregnant women diagnosed with a combine screening and molecular diagnosis from our center within one year.

Methods: We analyzed 50 pregnant women hospitalized in the Department of Pregnancy Pathology at UHOG in the 1st trimester of pregnanc. Whole blood with K3 EDTA was used for HGB electrophoresis by the Mini Lite device; cell counter for blood parameters and for DNA extraction in samples with abnormalities in the percentage of Hb fractions. Molecular diagnosis was done by PCR Reverse dot blot using Strip Assay®.

Results: Of the 50 pregnant women analyzed, 10 (20%) showed abnormalities in the percentage of Hb fractions. Out of 10 women, 4 with sickle cell anemia and 6 carriers of thalassemia minor with these HbA fraction values were 58.1%; HbS 37.8%; HbA2 4.1%, HbA 62.2%; HbS 34.5%; HbA2 3.3%, HbA 55.6%; HbS 40.8%; HbA2 3.6%, HbA 57.2%; HbS 38.8%; HbA2 4%. Molecular diagnosis report heterozygous mutation in codon 6 [A>T] HbS in individuals suspect sickle cell anemia and IVS-I-110 (G->A), Codon 39 (C->T) and IVS-I-6 (T ->C) in heterozygous in β-thalassemia minor suspect individuals. Genetic counseling for the couples was done, and 2 prenatal diagnosis was performed.

Conclusion: Hereditary anemia is evident in a Mediterranean country like Albania (our result of 20% out of 50 shows this). The only way of prevention is informing the population, screening, genetic counseling and prenatal diagnosis if both parents are carriers.

Conflict of Interest: None declared

P03.048.D Enhancing Fetal Outcomes in GCK-MODY Pregnancies: A Precision Medicine Approach via Non-Invasive Prenatal GCK Mutation Detection

Valerie Schwitzgebel[1], *Jean-Louis Blouin*[2], *Barbara Dehos*[3], *Bettina Kohler-Ballan*[4], *Jardena Puder*[5], *Claudine Rieubland*[6], *Maria Triantafyllidou*[7], *Anne Zanchi*[8], *Marc Abramowicz*[2], **Thierry Nouspikel**[2]

[1]*Geneva University Hospitals, Pediatric Endocrine and Diabetes Unit, Genève;* [2]*Geneva University Hospitals, Genetic Medicine, Genève;* [3]*Spital Grabs, Division of Endocrinology and Diabetes, Grabs, Switzerland;* [4]*Geneva University Hospitals, Department of Infectious*

Diseases, Genève; [5]Lausanne University Hospital, Department Women-Mother-Child, Lausanne, Switzerland; [6]Hospital of the Valais, Department of Medical Genetics, Sion, Switzerland; [7]Luzerner Kantonsspital, Division of Endocrinology, Diabetes and Clinical Nutritio, Lucerne, Switzerland; [8]Lausanne University Hospital, Service of Endocrinology, Diabetes and Metabolism, Lausanne, Switzerland

Background/Objectives: Mutations in the *GCK* gene cause Maturity Onset Diabetes of the Young (MODY-GCK, MODY2) by impairing glucose-sensing in pancreatic beta cells. Diabetes management during pregnancy depends on fetal genotype: Fetuses carrying a *GCK* mutation can benefit from moderate maternal hyperglycemia, stimulating insulin secretion in fetal islets, whereas this may cause macrosomia in wild-type fetuses. Modulating maternal glycemia is thus a form of personalized prenatal therapy, highly beneficial but not justifying the risk of invasive testing. We therefore developed a monogenic non-invasive prenatal diagnostic (NIPD-M) test to detect the transmission of known maternal *GCK* mutations to the fetus.

Methods: Small amounts of fetal circulating cell-free DNA are present in maternal plasma but cannot be distinguished from maternal cell-free DNA. Determining transmission of a maternal mutation to the fetus thus implies sequencing adjacent polymorphisms to determine the balance of maternal haplotypes, the transmitted haplotype being over-represented.

Results: We present a series of such tests in which fetal genotype was successfully determined and show that it can be used to guide therapeutic decisions during pregnancy, improving the outcome for the offspring. We discuss the principal hurdles inherent to the haplotyping approach, and strategies to overcome these. We also introduce a metric to detect several potentially confounding situations, like placental mosaicism or vanishing twins.

Conclusion: Our NIPD-M test allows reliable determination of the presence of a maternal *GCK* mutation in the fetus, thereby enabling personalized in-utero therapy by modulating maternal glycemia, without incurring the risk of miscarriage inherent to invasive testing.

P03.049.A Whole Exome Sequencing- first tier test for fetuses with severe central nervous system anomalies

Natalia Salgueiro[1], *Lisandra Castro[1], Ariana Conceição[1], Elsa Garcia[1], Claudia Alves[1], Carolina Dias[2], Maria Lopes Almeida[3], Fabiana Ramos[4], Nuno Pereira[2], Lina Ramos[4], Margarida Reis-Lima[1]*

[1]SynlabHealth Genética Médica, Porto, Molecular Genetics Department, Porto, Portugal; [2]Viseu Hospital, Obstetrics Gynaecology, Fetal Medicine unit, Viseu, Portugal; [3]Guimarães Hospital, Medical Genetics Department, Guimaraes, Portugal; [4]Coimbra Pediatric Hospital, Medical Genetics Department, Coimbra, Portugal

Background/Objectives: Next–generation sequencing technology, such as targeted multigene panels or Whole Exome sequencing (WES) is sometimes used as a second–or third–option diagnostic test in selected cases of central nervous system (CNS) fetal anomalies. Recent studies have shown that WES provides an additional rate of 5–57% over that of chromosomal microarray analysis (CMA) in prenatal setting.

We retrospectively studied 21 cases referred to our center for genetic evaluation due to CNS anomalies. Five of these cases were evaluated after termination of pregnancies (TOP) and 19 were ongoing pregnancies.

Methods: WES analysis were performed in all cases. Bioinformatic analysis was focused on our 60 gene panel for congenital anomalies of nervous system and mainly on the targeted phenotype. In all cases the bioinformatic analysis included copy number variants (CNVs).

Results: In 28,7% (6/21) of the cases, our study identified a genetic aetiology for the fetus phenotype. Of these 6 diagnosed cases, 2 were "de novo" autosomal dominant (AD) condition, 3 were X linked diseases, and the last one was an inherited autosomal recessive (AR) condition.

Conclusion: In our study, WES provided a high diagnostic rate (around 30%) in fetuses with CNS anomalies. These results demonstrated that an accurate identification of the ultrasound detected anomalies is crucial for a successful diagnosis. These data suggest that WES may be considered a major tool for the prenatal diagnosis of fetal CNS anomalies. This is of particular importance given the time constraints of an ongoing pregnancy and the risk of recurrence in future pregnancies.

P03.050.B Size Selection impact on Fetal Fraction estimates by SeqFF for late Gestational Age in NIPS

seyedeh saideh daryabari[1], *Sylvie Giroux[1], andre caron[1], francois rousseau[1,2]*

[1]Université Laval, Centre de recherche du CHU de Québec-, Québec, Canada; [2]Université Laval, Department of Molecular Biology, Medical Biochemistry and Pathology, Faculty of Medicine, Quebec, Canada

Background/Objectives: Noninvasive prenatal screening (NIPS) uses cell-free DNA (cfDNA) from maternal plasma to detect fetal abnormalities. Fetal fraction estimation is influenced by factors like gestational age (GA), prompting a need for comprehensive assessment to optimize screening protocols. This study investigated GA's impact on fetal fraction and SeqFF precision in samples with advanced gestational ages.

Methods: Peripheral blood samples were collected from 24 pregnant women across two distinct gestational age groups (>25 weeks and <16 weeks). In-vitro and in-silico size selection techniques were applied to increase smaller cfDNA fragments abundance. FF estimation was conducted using SeqFF and RAPIDR algorithms after paired-end sequencing.

Results: Results revealed that size selection significantly increased fetal fraction, in samples <16 weeks, SeqFF results were consistent with RAPIDR results. However, SeqFF unexpectedly resulted in a decrease in FF in samples >25 weeks, which diverged from RAPIDR estimates. In silico size selection confirmed this trend, suggesting that SeqFF may lose crucial fragments in samples from late GA.

Conclusion: Smaller fragment selection improves FF, sensitivity, and specificity of NIPS, yet SeqFF is no longer working for samples over 25 weeks. This observation suggests that some genomic locations used by SeqFF to estimate FF might not be filled by fragments after size selection. Without size selection, fragments are preserved for both groups of GA. Further research is needed to explore cfDNA fragment size dynamics during pregnancy to advance our understanding of cfDNA biology.

P03.051.C Prenatal phenotype of Coffin-Siris Syndrome: Insights from a case series

Giulia Vitetta[1], *Vera Uliana[2], Enrico Ambrosini[2], Mina Grippa[3], Valeria Barili[2], Sofia Cesarini[2], Giulia Lanzoni[1], Giulia Severi[1], Antonio Percesepe[2]*

[1]IRCCS AOU Policlinico S. Orsola, Medical Genetics, Bologna, Italy; [2]University of Parma - Hospital, Medical Genetics, Parma, Italy; [3]AOU Policlinico di Modena, Medical Genetics, Modena, Italy

Background: Coffin-Siris syndrome (CSS) is an autosomal dominant disorder characterized by developmental delay, intellectual disability, dysmorphic features, and congenital anomalies. Its aetiology involves mutations in various genes, leading to a broad phenotypic spectrum.

Methods: We conducted a retrospective collection of prenatal CSS cases, employing detailed morphological ultrasound examinations and genetic testing, including exome sequencing and targeted gene panel analysis.

Results: Three out of six patients in our cohort exhibited a likely gene-disrupting variant in the ARID1B gene; each of them presented brain anomalies (colpocephaly, hydrocephalus, partial corpus callosum agenesis) associated with other minor malformations. In Case 4, a terminated pregnancy revealed hypoplasia of the cerebellar vermis, bilateral clubfoot, and a conotruncal heart defect upon morphological ultrasound. Exome sequencing identified a de novo truncating pathogenic variant (c.1991C>G,p.Ser664Ter) in the ARID1A gene. Case 5 involved an infant who passed away at six months of age due to a severe syndromic condition, displaying prenatal agenesis of the corpus callosum, colpocephaly, and polyhydramnios. Postnatal exome analysis detected a de novo pathogenic variant (c.1121G>A,p.Arg374Gln) in the SMARCB1 gene. Case 6 followed up on a prenatal diagnosis marked by IUGR, cystic hygroma and partial corpus callosum agenesis. Upon re-evaluation at six years of age, a panel of CSS genes revealed a de novo pathogenic variant, c.3641T>G (p.Ile1214Ser), in the SMARCA4 gene.

Conclusions: We present six unreported prenatal CSS cases outlining the distinct phenotypes and outcomes observed based on the identified genes, providing new insight into the spectrum of prenatal diagnostic signs linked to this condition.

P03.052.D Prenatal Genome-Wide Sequencing analysis in Central Nervous System Anomalies: systematic review and meta-analysis

Enrica Marchionni[1], *Daniele Guadagnolo*[1], *Gioia Mastromoro*[1], *Antonio Pizzuti*[1]

[1]*Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy*

Background: Prenatal Genome-Wide Sequencing analysis showed a significant incremental diagnostic yield over karyotype and chromosomal microarray analysis (CMA) in fetal structural anomalies.

Presently, Prenatal Exome Sequencing (pES) is the predominant sequencing approach in prenatal clinical practice, however prenatal genome sequencing (pGS) studies are emerging. The aim of this study was to assess the incremental diagnostic yield of Prenatal Genome-Wide Sequencing analysis (pES or pGS) in fetuses affected by apparently isolated and non-isolated Central Nervous System (CNS) anomalies.

Methods: A systematic review on antenatal diagnosed CNS anomalies was performed according to PRISMA guidelines, including $n = 12$ paper, accounting for 428 fetuses. Results were pooled in a meta–analysis fitting a logistic random mixed-effect model. The primary effect of interest was the incremental diagnostic rate of pES over karyotype/CMA in detecting likely pathogenic/pathogenic Single Nucleotide Variants (SNVs). A further meta-analysis adding the available pGS studies (including diagnostic coding SNVs only) and submeta-analysis on three CNS subcategories were also performed.

Results: The pooled incremental diagnostic yield estimate of pES studies was 38% (95% C.I.: [29%;47%]) and 36% (95% C.I.: [28%;45%]) when including diagnostic SNVs from pGS studies. The point estimate of the effect resulted 22% (95% C.I.: [15%;31%] in apparently isolated anomalies, 33% (95% C.I.: [22%;46%]) in CNS-only related anomalies (≥1) and 46% (95% C.I.: [38%;55%]) in non-isolated anomalies (either ≥ 2 anomalies in CNS, or CNS and extra-CNS).

Conclusion: Meta-analysis and sub meta-analysis showed a substantial diagnostic improvement in performing Prenatal Genome-Wide Sequencing analysis over karyotype and CMA in CNS anomalies.

P03.053.A Tortuous arteries : a new prenatal sign of Kabuki 2 ?

Alice BOURGES[1;2], *Françoise Boussion*[3], *Agnes Guichet*[1;2], *Florence Biquard*[3], *Mathilde Becmeur-Lefebvre*[4], *Clara Houdayer*[1;2], *Vincent Procaccio*[1;2], *Frederic Tran Mau Them*[5], *Antonio Vitobello*[5], *Estelle Colin*[1;2]

[1]*University Hospital of Angers, Genetics, Angers, France;* [2]*University of Angers, Mitovasc Unit, UMR CNRS 6015 INSERM 1083, Angers, France;* [3]*University Hospital of Angers, Gynecology and Obstetrics, Angers, France;* [4]*Hospital of Orléans, Genetics, Orleans, France;* [5]*University Hospital of Dijon, Genetics, Dijon, France*

Background/Objectives: Kabuki Syndrome (KS), a rare genetic disorder, is caused by pathogenic variations in *KMT2D* and *KDM6A*. There is a significant lack in the literature regarding the description of signs during the prenatal stage. Reports indicate the presence of organ malformations in KS during pregnancy, especially cardiac anomalies. These include aortic insufficiency and stenosis, hypoplastic left heart syndrome, valve-related problems, and coarctation of the aorta.

Methods: A woman was referred to our center at 22 weeks of gestation (WG) because of vascular abnormalities. These findings were subsequently confirmed at 25 WG + 2, revealing a tortuous aortic arch, a dolicho-aorta, sinuosity of the right common carotid artery and IUGR. The first hypothesis raised was the syndrome of tortuous arteries.

Results: The array performed on amniotic fluid was normal. Trio exome sequencing evidenced a heterozygous pathogenic variant in *KDM6A* inherited from her healthy mother, who carries it at a low mosaic level. No pathogenic variant has been identified in *SLC2A10*. The fetal pathology examination confirmed the morphological anomalies. Even though we know that *KDM6A* has an essential function in the differentiation of embryonic stem cells and the development of tissues, including cardiac tissues, no comparable phenotype had been described until now.

Conclusion: We report the first case of prenatal tortuous aortic arch in KS. Although this case is unusual, clinicians should be aware of the possibility of prenatal tortuous arteries in patients with KS.

P03.054.B NGS based analysis in fetuses with isolated brain anomalies

Susanne Leidescher[1], *Moneef Shoukier*[1], *Birgit Anwald*[1]

[1]*Eurofins Humangenetik und Pränatal-Medizin MVZ GmbH, München, Germany*

Background/Objectives: Identifying the genetic cause of fetal brain anomalies is a diagnostic challenge. We present the results of NGS based analysis of fetuses with isolated brain malformations analyzed from January 2018 until November 2023.

Methods: 344 prenatal cases with isolated brain anomalies were analyzed by targeted NGS of the coding regions of selected genes in a custom designed panel analysis. When necessary, pathogenicity assessment of variants was performed by familial co-segregation analysis. Variants were categorized into classes 1 to 5 (ACMG-AMP guidelines (2015)). Fetal karyotypes were normal.

Results: Likely pathogenic (class 4) and pathogenic (class 5) variants were identified in 62/344 (18%) cases (autosomal dominant: 29/62 (47%), autosomal recessive: 17/62 (27%), X-linked dominant: 1/62 (2%), X-linked recessive: 7/62 (11%). The mutations were found in 35 different genes. In eight cases copy number variations were detected (8/62 (13%)). Variants of uncertain significance (class 3) were detected in 31 cases (9%) (in 29 different genes). No class 3-5 variants were identified in 251/344 fetuses (73%). Furthermore, we specify phenotypical subgroups and assess diagnostic yield as well as causative mutations within these groups.

Conclusion: Genetic causes can often be detected in isolated fetal brain malformations. It is therefore advisable to carry out a genetic analysis for corresponding indications, particularly with regard to a possible risk of recurrence in the event of a further desire to have children. The expansion of genetic analyses including comprehensive exome sequencing in a trio setting is expected to increase the diagnostic yield in the future.

Conflict of Interest: Susanne Leidescher Eurofins Humangenetik und Pränatal-Medizin MVZ GmbH, Moneef Shoukier Eurofins Humangenetik und Pränatal-Medizin MVZ GmbH, Birgit Anwald Eurofins Humangenetik und Pränatal-Medizin MVZ GmbH

P03.055.C Beyond prenatal exome sequencing. Lessons learned from postnatal follow up of patients with inconclusive prenatal testing

Irene Valenzuela Palafoll[1], *Anna Abulí*[1], *Amaia Lasa-Aranzasti*[1], *Laura Trujillano*[1], *Eulàlia Rovira-Moreno*[1], *Marta Codina*[1], *Barbara Masotto*[1], *Núria Martínez-Gil*[1], *Patricia Muñoz-Cabello*[1], *Mar Costa-Roger*[1], *Alejandro Moles-Fernandez*[1], *Berta Campos*[1], *Paula Fernandez-Alvarez*[1], *Jordi Leno*[1], *Anna Maria Cueto-González*[1], *Elena García-Arumí*[1], *Eduardo Tizzano*[1]

[1]*Hospital vall d'hebron, Clinical and Molecular Genetics, Spain*

Prenatal exome sequencing (PES) increases genetic diagnoses in fetuses with ultrasound structural abnormalities and a normal microarray. Published diagnostic yields from PES differ between studies and may be influenced by sample size, case selection and fetal phenotype.

This study aims to assess the evolution of patients born with inconclusive prenatal exome results. Our cohort includes 35 children born between 2018-2023. Postnatal follow up in this cohort ranged from 6 months to 4 years.

Fifteen children showed adequate postnatal development in the last review. Most indications for PES in these children included minor anomalies of the central nervous system and intrauterine growth retardation. In the remaining 20 cases, suspicion of an unexplained genetic entity persisted. Postnatal exome re-analysis was conducted in 18, including new postnatal phenotypic manifestations. Molecular diagnosis was achieved in two (11%). One of the children corresponded to orofaciodigital syndrome (homozygous variant in a novel gene) and the other to a Rubinstein-Taybi with a likely pathogenic variant in *EP300*. In 1/20 (5%), an alternative study leads to the diagnosis (Beckwith-Wiedemann). In another child, postnatal diagnosis of prenatal Caffey disease was made (5%). Five children are pending of genome sequencing (25%) due to suspicion of an unexplained genetic entity.

Postnatal follow-up of children born after inconclusive PES is relevant not only to achieve unexplained diagnosis but also to better define guidelines to improve indications for PES. Re-analysis of exome should be recommended in case of new postnatal clinical findings, together with the consideration of other alternative studies.

P03.056.D Non-invasive prenatal screening (NIPS) for Trisomy 21, 18 and 13: empiric conclusions after 10,000 samples

Ana Rita Pereira[1], *Inês Moura Tavares*[1], *luena pitrez*[1], *Joaquim Sá*[1;2], *rita cerqueira*[1], **Alexandra Lopes**[1]

[1]*Unilabs, CGC Genetics, Portugal;* [2]*ULS Coimbra, Serviço de Genética, Portugal*

Background: Our private diagnostic laboratory in Porto has been offering NIPS screening from ten weeks gestation since 2015. Screening is strongly recommended for all pregnant women with singleton and twin pregnancies by international guidelines [PMID: 36524989] but the Portuguese national health system doesn't make this test available to the vast majority of women. In Portugal's public health system, the availability of screening is dependent on clinical information allowing the risk to be assessed as high for trisomies 21, 18 or 13.

Methods: Evaluation of the rates of inconclusive results and of each of these trisomies in the total number of samples processed; categorisation of clinical information when screening indicates trisomy 21.

Results: In 10,068 samples, *no call* occurred in 43 (0.4%), trisomy 21 in 107 (1.1%), trisomy 18 in 23 (0.2%), trisomy 13 in 15 (0.1%). In 64% (69/107) of the samples with trisomy 21 result the pregnancy was classified as high risk.

Conclusion: In our sample, around 1/3 of pregnant women with NIPS indicative of trisomy 21 would have their trisomy 21 diagnosis delegated to an amniocentesis to be carried out in the event that the ultrasound scan between 20-22 weeks identified anomalies. These empirical data corroborate the validity of current recommendations, revealing the importance of this screening in public health.

P03.057.A Diagnostic yield of SNP-array and NGS-based testing in fetal ultrasound anomalies: results from 220 cases

Hilal Pırıl Saraçoğlu[1], *Umut Altunoglu*[2;3], *Esra Börklü*[3], *Şahin Avcı*[3], *Serpil Eraslan*[3], *Mert Turğal*[4], *Ebru Çelik*[4], *Recep Has*[5], *Atıl Yüksel*[5], *Hülya Kayserili*[2;3]

[1]*Graduate School of Health Sciences, Koç University, İstanbul, Türkyie;* [2]*School of Medicine, Koç University, Medical Genetics Department, İstanbul, Türkyie;* [3]*Genetic Diseases Evaluation Center, Koç University Hospital, İstanbul, Türkyie;* [4]*Obstetrics and Gynecology Department, Koç University Hospital, İstanbul, Türkyie;* [5]*Division of Perinatology, Department of Obstetrics and Gynecology, İstanbul Faculty of Medicine, Istanbul University, İstanbul, Türkyie*

Background/Objectives: The aim of this retrospective study is to evaluate the diagnostic yield of SNP-array and next generation sequencing (NGS) analyses in fetal anomalies at a tertiary health center.

Methods: In an eight-year period (2016-2023), 220 fetuses were consulted at the Medical Genetics Department of Koç University School of Medicine due to positive ultrasound (USG) findings. All fetuses underwent SNP-array analysis, and 62 underwent NGS comprising clinical exome sequencing (CES) and prenatal exome

sequencing (pES). The diagnostic yield of SNP-array and NGS was analyzed, along with the impact of diagnosis on pregnancy management and outcome.

Results: SNP-array showed likely pathogenic/pathogenic (LP/P) variants in 13/220 (5.9%) of samples, while the general diagnostic yield for NGS was 12/62 (19.4%). Most common referrals were due to multisystem anomalies (n = 77), followed by gastrointestinal (n = 28) and cardiovascular (n = 24) anomalies. Diagnostic yield of SNP-array was 10.4% (8/77) for multiple ultrasound abnormalities, and diagnostic yield of NGS was 27.3% (6/22) for multiple fetal structural anomalies.

Conclusion: Our retrospective fetal anomaly cohort further supports the additional diagnostic yield of SNP-array and NGS-based testing in the prenatal setting, and contributes to existing literature on genetic variants in association with specific prenatal phenotypes.

P03.058.B Single-cell Analysis Reveals the Spatial-temporal Expression of Genes Associated with Esophageal Malformations

Antonia Eberts[1], *Carlo Maj*[1], *Johannes Schumacher*[1], *Pouria Dasmeh*[1]

[1]*Center for Human Genetics, Marburg University and Marburg University Hospital, Marburg, Germany*

Background/Objectives: Esophageal malformations (EM) are congenital diseases that arise due to the abnormal development of the esophagus. We know little about the molecular mechanisms of such congenital diseases as they primarily occur within specific developmental stages. This knowledge helps us identify disease-relevant genes for enhanced diagnosis and risk assessment as well as the development of potential therapeutic strategies.

Methods: Here, we analyzed the single-cell preferential expression of the genes known to be associated with EM from genetic studies including GWAS, genes implicated in foregut anomalies in animal models, and genes identified from exome analysis of patients. We then calculated single-cell disease-relevant risk scores to detect cells with a significant excess expression of EM-associated genes across large-scale single-cell atlases in mouse, and human embryos as well as single cells from 24 human organs (approximately 800,000 cells).

Results: EM-associated genes showed a significant preferential expression in mesodermal cell types and a significantly higher expression at early stages of development. The expression of *FOXF1*, *PTCH1* and *SOX2* contributed the most to the preferential expression of EM-associated genes. In the human adult cells, subpopulations of epithelial cells, and fibroblasts showed the most significant preferential expression of EM-associated genes.

Conclusion: Our observations demonstrate that genes associated with esophageal malformations show their highest cell-type specific expression in lateral plate mesoderm cells and at the developmental stage of E8.75-E9.0 days. Overall, our findings provide insights into the temporal and cellular contexts contributing to esophageal malformations.

Conflict of Interest: None declared

P03.059.C Exploring the fetal presentation of 3M syndrome: clinical, imaging, and molecular insights for prenatal recognition of a rare constitutional bone disease

Background/Objectives: 3M syndrome, a rare constitutional bone disorder, is characterized by severe pre- and postnatal growth retardation, distinctive facial features, and normal intelligence, with an average final height of around 125 cm. Pathogenic variants in *CUL7*, *OBSL1*, or *CCDC8* are predominantly identified postnatally, leaving limited clinical data for the prenatal period. This study seeks to unravel the fetal presentation of 3M syndrome, aiding clinicians in recognition and supporting biologists in interpreting variants from exome/genome sequencing.

Methods: collaboratively through ERN-ITHACA, a data collection initiative for prenatal and molecular data was launched for individuals molecularly diagnosed with 3M syndrome.

Results: our fetal cohort included 18 fetuses from 14 families with pathogenic variants in *CUL7* and *OBSL1*. Eight pregnancies were terminated, one resulted in intrauterine demise, and nine continued. Initial signs emerged between 17 and 28 weeks of gestation, revealing severe intrauterine growth restriction (IUGR), relative macrocephaly, thin long bones without fractures, and preserved fetal movements. Autopsies unveiled suggestive dysmorphia, prominent heels, short arms and thin long bones. Families exhibited *CUL7* and *OBSL1* variants, predominantly truncating variants yet unreported. Amid approximately 450 skeletal dysplasias, precise diagnosis in fetal medicine remains challenging. Severe IUGR without fractures or curvatures may suggest Silver-Russell syndrome, Dubowitz, Mulibrey, fetal alcohol syndromes, or 3M syndrome in cases of extreme IUGR.

Conclusion: this study unveils the inaugural fetal cohort of 3M syndrome, presenting crucial clinical, imaging, and molecular insights for its recognition. Emphasis is placed on slender long bones, beyond fetal akinesia context, guiding prenatal and fetal genetic diagnosis of 3M syndrome.

P03.060.D Outcome of 2 years of prenatal parent-fetus trio exome sequencing in 107 pregnancies with multiple fetal anomalies

Stefanie Beck-Wödl[1;2], *Andreas Dufke*[1;2], *Ulrike Mau-Holzmann*[1;2], *Stephanie Spranger*[3], *Marc Sturm*[1;2], *Tizia Matthäus*[1;2], *Miriam Bertrand*[1;2], *Luise Hackenbruch*[1;2], *Markus Hoopmann*[4], *Karl Oliver Kagan*[4], *Ute Grasshoff*[1;2], *Olaf Riess*[1;2], *Tobias Haack*[1;2]

[1]*University Hospital Tübingen, Institute of Medical Genetics and Applied Genomics, Tübingen, Germany;* [2]*Rare Disease Center, ZSE, Tübingen;* [3]*Limbach genetics, Bremen, Germany;* [4]*University Hospital Tübingen, Department for Women's Health, Tübingen, Germany*

Background/Objectives: Here we report on the results of 2 years of fast track trio exome-based diagnostics in a cohort of 107 pregnancies with fetal ultrasound abnormalities. The fetuses presented with fetal akinesia, increased nuchal translucency, ascites, hydrops fetalis, renal agenesis or multiple congenital

anomalies. Cytogenetic analyses performed prior to the trio exome analyses revealed a normal karyotype in all cases.

Methods: Trio exome sequencing was done on DNA from chorionic villi samples, amniocentesis and parental blood. We performed diagnostic sequencing on a NovaSeq6000 platform (Illumina) using the Twist Bioscience (Twist Custom Exome IMGAG V2) on 107 patient-parent trios. Prioritization of clinically relevant genomic variants was performed according to in-house standard procedures.

Results: Clinically relevant pathogenic sequence variants were identified in 44% of cases, including copy number variations in more than 10%. The causative variants detected occurred de novo in 38% of cases and were thus easily identified with the trio approach.

Conclusions: In summary, our trio exome-based approach in pregnancies with various fetal anomalies proved to be a fast and highly efficient diagnostic tool in detecting disease-causing single nucleotide and copy number variants. The current study confirms our previous published observations (PMID: 35574990) and highlights the clinical utility of trio-based prenatal exome diagnostics.

P03.061.A A novel likely pathogenic variant in the non-coding gene *RNU4ATAC* causing MOPD1

Valerie Krauth[1], *Matthias Vockel*[1], *Judit Horvath*[1], *Frank Tüttelmann*[1], *Mareike Moellers*[2], *Katja Masjosthusmann*[3], *Andreas Busche*[1]

[1]*Department of Medical Genetics, University Hospital Münster, Münster, Germany;* [2]*Department of Gynaecology and Obstetrics, University Hospital Münster, Münster, Germany;* [3]*Department of Paediatrics, University Hospital Münster, Münster, Germany*

Background/Objectives: Biallelic pathogenic variants in *RNU4ATAC* cause the rare autosomal recessive disorder Microcephalic Osteodysplastic Primordial Dwarfism, type I (MOPD1). This condition is characterised by small stature, microcephaly, immunodeficiency and cognitive impairment. *RNU4ATAC* is encoding the small nuclear RNA (snRNA) U4atac, which is a part of the minor spliceosome complex responsible for removing minor introns.

Methods: Prenatal trio-exome sequencing and analysis of genes potentially related to the prenatal phenotype led to a comprehensive review of rare variants in non-coding RNA genes in combination with the clinical phenotype.

Results: We present a 7-month-old girl whose mother was referred to us in the 27th week of gestation. Prenatal ultrasound showed intrauterine growth restriction as well as brain and facial anomalies. Exome sequencing on DNA extracted from amniotic fluid revealed compound-heterozygosity for two variants in *RNU4ATAC*. While the maternally inherited variant n.51G>A has been published as pathogenic before, the paternally inherited nucleotide substitution n.38A>T had not been described yet. This variant is affecting a highly conserved nucleotide in the 5′ Stem-Loop of the U4atac-snRNA and was classified as likely pathogenic according to ACMG guidelines (class 4: PM1, PM2, PM3, PP5). After birth, the girl showed typical symptoms of MOPD1, including skeletal dysplasia, dysgenesis of the corpus callosum and agammaglobulinaemia.

Conclusion: The description of the aforementioned novel nucleotide substitution is extending the spectrum of pathogenic variants in *RNU4ATAC*. Genetic and detailed clinical data of a patient with MOPD1 will further delineate the phenotypic and genotypic spectrum of this rare condition.

SENSORY DISORDERS (EYE, EAR, PAIN)

P04.001.B Functional characterization of *ABCA4* missense variants aids variant interpretation and phenotype prediction in patients with ABCA4-retinal dystrophies

Ingvild Aukrust[1;2], *Sigrid Aslaksen*[1;2], *Laurie Molday*[3], *Josephine Prener Holtan*[4], *Ragnhild Wivestad Jansson*[5], *Siren Berland*[1], *Eyvind Rødahl*[5;6], *Cecilie Bredrup*[5;6], *Ragnheiður Bragadóttir*[4;7], *Eirik Bratland*[1;2], *Robert S. Molday*[3;8], *Per Morten Knappskog*[1;2]

[1]*Haukeland University Hospital, Department of Medical Genetics, Bergen, Norway;* [2]*University of Bergen, Department of Clinical Science, Bergen, Norway;* [3]*University of British Columbia, Department of Biochemistry and Molecular Biology, Vancouver, Canada;* [4]*Oslo University Hospital, Department of Ophthalmology, Oslo, Norway;* [5]*Haukeland University Hospital, Department of Ophthalmology, Bergen, Norway;* [6]*University of Bergen, Department of Clinical Medicine, Bergen, Norway;* [7]*University of Oslo, Institute of Clinical Medicine, Oslo, Norway;* [8]*University of British Columbia, Department of Ophthalmology and Visual Sciences, Vancouver, Canada*

Background/Objectives: Biallelic pathogenic variants in the gene encoding the ATP-binding cassette transporter ABCA4 are the leading cause of irreversible vision loss in inherited retinal dystrophies. Interpretation of *ABCA4* variants is challenging, due to cis-modifying and hypomorphic variants. We have previously detected 10 missense variants of unknown significance (VUSs) in patients with suspected ABCA4-retinal dystrophies (ABCA4-RDs) in Norway. In this study, we functionally characterized the VUSs to aid interpretation of the variants and to determine if they are associated with the disease.

Methods: The *ABCA4* VUSs were expressed in HEK293T cells and the ABCA4 expression and ATPase activity were determined and correlated with the patients' phenotype. The functional data was further used for reclassification of the VUSs following the ACMG guidelines.

Results: Two variants, Cys205Phe and Asn415Thr, were categorized as functionally severe. The age at presentation in the two patients carrying these variants was divergent and seemed to be driven by the patients' second pathogenic variants. Three variants, Val643Gly, Pro799Leu and Val1433Ile, were categorized as functionally moderate, and were found in patients with intermediate/late age at presentation. The remaining five variants were categorized as functionally normal/mild. Based on our data, Cys205Phe, Asn415Thr and Pro799Leu, were reclassified to (likely) pathogenic, while four of the functionally normal/mild variants could be reclassified to likely benign.

Conclusion: Functional analyses of ABCA4 variants are a helpful tool in variant classification and enable us to better predict the disease severity in patients with ABCA4-RDs.

Grants: Norwegian RP Association and Norwegian Association of the Blind and Partially Sighted.

P04.002.C HiFi long-read genome sequencing uncovers a large novel *RD3* deletion representing a founder allele in Afghan patients with Leber congenital amaurosis

Monika Gawai[1], **Ariane Kröll-Hermi**[1], *Milan Hiersche*[1], *Christian Decker*[1], *Johannes Birtel*[2], *Anna Lentzsch*[3], *Christoph Friedburg*[4], *Markus Preising*[4], *Christian Betz*[1], *Hanno Bolz*[1;5]

[1]*Bioscientia Institute for Medical Diagnostics GmbH, Human Genetics, Ingelheim am Rhein, Germany;* [2]*University Medical Center*

Hamburg-Eppendorf, Ophthalmology, Hamburg, Germany; [3]University Hospital of Cologne, Ophthalmology, Köln, Germany; [4]Justus-Liebig-University Giessen, Ophthalmology, Gießen, Germany; [5]University Hospital of Cologne, Institute of Human Genetics, Köln, Germany

Background/Objectives: Leber congenital amaurosis (LCA) is an inherited congenital retinal dystrophy associated with severe visual impairment. More than 30 LCA genes are currently known. Loss-of-function (LoF) variants in the retinal degeneration 3 gene (*RD3)* cause LCA12. We carried out in-depth genetic analyses of three apparently unrelated LCA patients (P1-3) from Afghanistan.

Methods: Genomic DNA was extracted from peripheral blood leukocytes and analyzed by short-read whole-exome sequencing (SR-WES) and PacBio HiFi long-read whole-genome sequencing (LR-WGS). Variants were called with in-house CNV and SNV pipelines.

Results: We identified a novel deletion encompassing *RD3* exon 3, (c.296+641_*606del (p.(?)), in homozygous state in P1 and P2, while P3 carried the deletion and a novel nonsense *RD3* variant (c.394G>T, p.(Glu132*)), both in heterozygous state. SR-WES indicated the deletion, but not the exact breakpoints, and in P3, the nonsense variant was initially called as homozygous. LR-WGS accurately determined the deletion's breakpoints and size (2050 bp) and correctly annotated the nonsense variant as hemizygous. The three patients shared identical breakpoints and haplotypes, qualifying this *RD3* deletion as a novel founder mutation.

Conclusion: Particularly in heterozygous state, this founder deletion may escape detection in SR-WES and could represent an underrated cause of LCA in Central Asia. In contrast, HiFi LR-WGS precisely detects such structural variants. Because difficult regions (e.g. disease genes with pseudogene backgrounds or highly repetitive elements, such as *RPGR-ORF15*) become readable as well, the clinical application of this comprehensive technology will increase the diagnostic yield – for retinal dystrophies and beyond.

P04.003.D Streamlined CRISPR-Cas9-mediated gene knockout in zebrafish for swift assessment of auditory developmental and behavioral anomalies.

Daniel Bengl[1], *Julia Doll*[2], *Daniel Liedtke*[1], *Michaela AH Hofrichter*[1], *Thomas Haaf*[1]

[1]*Institute of Human Genetics at the University of Würzburg, Würzburg, Germany;* [2]*Universität Würzburg Institut für Pathologie, Würzburg, Germany*

Background/Objectives: Hearing loss (HL), a prevalent sensory disorder, affects up to two newborns per 1,000, with 50-80% of cases attributed to genetic factors. Advances in molecular methods enable the rapid identification of novel disease-causing candidate genes. Studying the pathophysiology of these genes is essential for understanding the complexity of auditory development. For this purpose, the zebrafish serves as an exemplary model organism due to the similarities of its auditory system to humans, the ease of manipulation, and the repertoire of modern molecular biological tools. This study aims to validate potential HL candidate genes and understand their impact on zebrafish auditory development by using a CRISPR Cas9-mediated knockout screen.

Methods: Injecting multiple guide RNAs per genetic target alongside the Cas9 protein into zebrafish embryos allows the reliable generation of a statistically significant number of knockout individuals. Headloop PCR is employed to quantify the knockout efficiency. Five days post-fertilization, larvae are examined for their innate acousto-vestibular response by using an imaging setup with a high-speed camera. Behavior analysis, extraction of kinetic data, and quantification of behavioral changes are performed using the open-source software ZebraZoom.

Results: We were able to validate the entire experimental pipeline by a proof-of-principle experiment involving the zebrafish ortholog of the known HL gene *MYO6*. Our experiments replicated published results for a myo6b mutant line and furthermore enables the differentiation of individual behavioral phenotypes.

Conclusion: We present a rapid and reliable screening pipeline to quantify changes in the zebrafish acousto-vestibular escape response after knockout of potentially disease-causing HL candidate genes.

P04.004.A Modeling genetic forms of hearing loss with Inner Ear Organoids

Giulia Pianigiani[1], *Anna Morgan*[1], *Mabel Troian*[1], *Giovanni Turchetto*[1], *Beatrice Spedicati*[1,2], *Marta Roccio*[3,4], *Giorgia Girotto*[1,2]

[1]*Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy;* [2]*University of Trieste, Department of Medicine, Surgery and Health Sciences, Trieste, Italy;* [3]*University Hospital Zurich (USZ), Zurich, Switzerland;* [4]*University of Zurich (UZH), Zurich, Switzerland*

Background/Objectives: iPSC-derived inner ear organoids (IEOs) have recently emerged as new tools to model inherited inner ear diseases. Here, we used IEOs to assess the expression and function of *MYO5C* as a candidate gene for HL. Indeed, a novel homozygous missense variant in *MYO5C* was identified in a Pendred syndrome-like patient, negative for mutations in the *SLC26A4* gene and presenting with a severe-to-profound HL and inner ear malformations.

Methods: MYO5C expression was analyzed in fetal human and early postnatal mouse inner ear tissues. MYO5C knockout (KO) and patient-identified variant (NM_018728.4, c.3592C>T, p.(Arg1198Cys)) knock-in (KI) iPSCs were generated with CRISPR/Cas9 technology.

Results: scRNA-seq and immunofluorescence analysis show that at day-30 of differentiation, MYO5C is expressed in otic progenitors and other epithelial cells. At day-60, when sensory epithelia appear in IEOs, MYO5C becomes visible at the developing hair bundle in hair cells. A similar expression is observed in vivo in the sensory epithelia of the utricle, saccule (week-10) and cochlea (week-12) primary tissues. Genome-edited iPSCs and the isogenic control line were induced to differentiate in IEOs following a stepwise induction protocol. We did not observe differentiation defects towards the otic lineage so far at the histological level. Ongoing work is focused on the analysis of IEOs derived from the engineered iPSCs by transcriptional profiling.

Conclusion: this study will not only allow to investigate MYO5C potential role in sensory organ development, but also provide the basis for a broader application of IEOs as a tool to probe disease-causing mutation.

P04.005.B An integrated approach to uncover the genetic architecture of inherited blindness in a consanguineous Iranian cohort

Lieselot Vincke[1], *Kristof Van Schil*[2], *Marieke De Bruyne*[1], *Quinten Mahieu*[1], *Marta del Pozo Valero*[1], *Mattias Van Heetvelde*[1], *Toon*

Rosseel[1], Ebrahim Al Hajj[3], Astrid Rombaut[1], Sarah Van Malderen[1], Reza Maroofian[4], Fatemeh Suri[5], Miriam Bauwens[1], Elfride De Baere[1]

[1]Center for Medical Genetics Ghent, Ghent University and Ghent University Hospital, Ghent, Belgium; [2]Center for Medical Genetics Antwerp, Antwerp University Hospital, Antwerp, Belgium; [3]Free University of Brussels, Brussels, Belgium; [4]Institute of Neurology, Department of Neuromuscular Diseases, University College London, London, United Kingdom; [5]Ophthalmic Research Center, Research Institute for Ophthalmology and Vision Science, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Objectives: This study aimed to elucidate the genetic architecture of inherited retinal disease (IRD) in 192 unrelated Iranian families using an integrated approach combining whole exome sequencing (WES) and autozygosity mapping.

Methods: WES was conducted on 192 Iranian IRD patients, predominantly originating from a consanguineous background (76%). Data-analysis was performed using the in-house Seqplorer tool. Copy number variants (CNVs) were assessed via ExomeDepth, while AutoMap identified runs of homozygosity (ROHs). Variants were validated and classified (ACMG/ACGS guidelines).

Results: Interrogating 290 IRD genes via WES yielded a molecular diagnosis for 73% of the cohort, revealing 208 variants in 77 IRD-associated genes. Of these variants, 82% were unique, and 53% were novel. Most variants were homozygous (69%) and 83% of variants found in consanguineous families were located in a ROH. In addition, the importance of structural variation (SV) in IRD was demonstrated, with CNVs identified in 6% of the cohort, including novel CNVs in *ABCA4, CDH3, CDHR1, CHM, CNGA1* and *RD3*. Locus heterogeneity was observed in two families, in which multiple genotypes segregated with IRD.

Conclusion: This integrated study, utilizing WES and comprehensive variant assessment, provided genetic diagnoses for 73% of IRD patients. The molecular spectrum of IRD in Iran was expanded with the identification of both known and novel variants, offering valuable insights for family counselling. The study contributes to understanding the genetic architecture of IRD in the understudied Iranian population and presents unsolved cases as a unique cohort for identifying novel candidate IRD genes.

P04.006.C Evaluation of the efficacy of multigene panel tests in the largest Bardet Biedl Syndrome cohort in Turkey

Şenol Demir[1], *esra arslan ateş[2], cekdar kapazan[1], AYBERK TURKYILMAZ[3], Hamza Polat[4], Bilgen Bilge Geçkinli[1]*

[1]Marmara University School of Medicine, Department of Medical Genetics, Istanbul, Türkyie; [2]Istanbul University-Cerrahpaşa Cerrahpaşa Faculty of Medicine, Department of Medical Genetics, Istanbul, Türkyie; [3]Karadeniz Technical University School of Medicine, Department of Medical Genetics, Trabzon, Türkyie; [4]Gazi Yasargil Training and Research Hospital, Department of Medical Genetics, Diyarbakır, Türkyie

Background/Objectives: Bardet-Biedl Syndrome (BBS) is a ciliopathy characterized by retinitis pigmentosa, polydactyly, obesity, renal malformation, cognitive impairment, and hypogonadism. The syndrome's prevalence is estimated to be 1 in 100,000 live births. BBS is a genetically heterogeneous syndrome which is associated with more than 20 genes. This study aims to determine the effectiveness of multigene panel testing in patients who have BBS clinical features and to reveal the genetic etiology of the BBS patients.

Methods: Thirty patients having specific examination findings related to BBS were included in this study. After evaluation of clinical and family histories, probands were screened using a custom-designed Bardet Biedl syndrome panel including 24 genes via next-generation sequencing (NGS). The family members of the probands carrying pathogenic variations were screened via Sanger Sequencing.

Results: Among 30 cases major clinical findings were polydactyly (n = 22)(73%), obesity (n = 16)(53%), and retinal dystrophy (n = 13)(43%). We detected in 21 (70%) patients biallelic pathogenic variations, of which 5 were novel, in BBS1(n = 4), BBS9(n = 4), BBS10(n = 4), BBS4(n = 3), MKKS(n = 3), BBS7(n = 2), ARL6(n = 1) genes.

Conclusion: The detection of 5 novel pathogenic variations has contributed to the expansion of the mutation spectrum. Also, the confirmation of clinical diagnosis in 70% of the patients with molecular genetic testing supports that the screening related genes via NGS panel is an effective diagnostic method for BBS. Defining the molecular etiology of BBS is important in terms of screening at-risk family members and providing appropriate genetic counseling for preimplantation genetic diagnosis opportunities.

P04.007.D Pacbio HiFi long-read genomes offer better exomes by unlocking retinal disease variants missed by short-read sequencing

Kadin Karakaya[1], *Ariane Kröll-Hermi[1], Milan Hiersche[2], Christian Decker[2], Sandra Liakopoulos[3;4], Markus Preising[5], Klaus Rohrschneider[6], Christian Betz[1], Hanno Bolz[1]*

[1]Bioscientia Institute for Medical Diagnostics GmbH, Bioscientia Human Genetics, Ingelheim, Germany; [2]Bioscientia Institute for Medical Diagnostics GmbH, Bioscientia Bioinformatics, Ingelheim, Germany; [3]Goethe University, Department of Ophthalmology, Frankfurt am Main, Germany; [4]Cologne Image Reading Center, University of Cologne, Department of Ophthalmology, Köln, Germany; [5]Justus-Liebig-University, Department of Ophthalmology, Gießen, Germany; [6]University of Heidelberg, Department of Ophthalmology, Heidelberg, Germany

Background/Objectives: Next-generation sequencing enables rapid, comprehensive and cost-effective analysis of disease-associated genes. Short-read (SR) technologies currently predominate, but face several limitations: For example, regions with high repeat content or pseudogene background may be inaccessible, and large structural variations may escape detection.

Methods: We investigated 3 patients with inherited retinal disease (IRD) who had remained unsolved after short-read whole-exome sequencing (SR-WES), and a patient with a known *RPGR-ORF15* mutation, with Pacbio HiFi long-read genome sequencing (LR-WGS).

Results: Patient 1 with a known monoallelic pathogenic variant in *USH2A*, c.14926G>A p.(Gly4976Ser), was found to carry a previously undetected *Alu* element insertion in exon 45 which, of note, had been missed despite high coverage in WES. In Patient 2, a WES-derived seemingly pathogenic *PDE6B* variant (c.169_239dup p.(Leu83Cysfs*91)) turned out homozygous in LRS. In Patient 3, LRS showed that *EYS* exon 33 was duplicated on both alleles instead of one and precisely identified the breakpoints. Patient 4 has a known variant in the highly repetitive *ORF15* of X-linked *RPGR*, a mutational hotspot that is only accessible via special adaptations of SR-WES and bioinformatics. LRS unlocks this formerly difficult-to-sequence major IRD locus.

Conclusion: Pacbio LR-WGS provided a clear genetic diagnosis in IRD patients whose causative exonic variants had not or only partially been detected by SR-WES. In addition to resolving difficult regions of the genome, LR-WGS provides detailed information on phasing and structural variations and should soon become a major diagnostic technology for the comprehensive analysis of human genetic disorders.

P04.008.A Identification of expression and splicing Quantitative Trait Loci in the retina and retinal pigment epithelium implicates novel regulatory regions and divergence in genetic regulation across diverse human populations

Jacob Sampson[1;2], *Steve Haynes*[1], *Siddharth Banka*[1;2], *Panagiotis Sergouniotis*[1;2], *Graeme Black*[1;2], *Jamie Ellingford*[1;2;3]

[1]*University of Manchester, Division of Evolution, Infection and Genomic Sciences, School of Biological Sciences, Faculty of Biology, Medicines and Health, Manchester, United Kingdom;* [2]*St Mary's Hospital, Manchester University NHS Foundation Trust, Manchester Centre for Genomic Medicine, Manchester, United Kingdom;* [3]*Genomics England, United Kingdom*

Background/Objectives: Interpreting the functional impact of non-coding variants is important for rare and common ophthalmic disorders. Molecular Quantitative Trait loci (molQTL) mapping detects genetic variation significantly associated with gene expression and/or splicing. We present a novel molQTL resource that advances our understanding of the regulatory landscape of the human adult retina and retinal pigment epithelium (RPE).

Methods: Whole genome sequencing (WGS) and bulk RNA-sequencing of retina and RPE was performed in 206 post-mortem eyes. Expression and splicing QTLs (eQTL/sQTL) in retina and RPE were detected using a linear regression model.

Results: We identified 1.4 million genetic variants (allele frequency >2.5%) significantly associated (FDR < 5%) with expression (n = 544,345), splicing (n = 412,571) or both expression and splicing (n = 422,005) of 12,076 genes in retina or RPE (including 333 known ophthalmic disease-associated genes). eQTL variants (eVariants) were enriched in previously annotated cis-regulatory elements (CREs) compared to non-eQTL variants (p-value < 2.2e-16). Moreover, the relative enrichment in retina-specific CREs was significantly stronger than in other tissue-specific CREs (p-value < 2.2e-16). Despite this, 84% of all eVariants and 77% of the top hits do not overlap with known CREs in any tissue (99% of eVariants when including only retina CREs). Further, we observe significant variability in the allelic frequency of molQTLs across diverse human populations.

Conclusion: This resource facilitates the discovery of novel retina-specific regulatory mechanisms and provides insight into non-coding variants that regulate ophthalmic disease-related genes. These findings have broad applications to the discovery and diagnosis of ophthalmic genomic disorders.

P04.009.B Using the pSPL3 exon trapping vector to unmask splicing effects of otoferlin coding variants

Friederike Jahnke[1;2], *Barbara Vona*[1;2], *Daniel Owrang*[1;2], *Zijin Zhang*[3]

[1]*University Medical Center Göttingen, Institute of Human Genetics, Göttingen, Germany;* [2]*University Medical Center Göttingen, Institute for Auditory Neuroscience and InnerEarLab, Göttingen, Germany;* [3]*University Medical Center Frankfurt, Pediatric and Experimental Hematology, Frankfurt, Germany*

Background/Objectives: Otoferlin (OTOF) is an essential protein with at least three distinct functions in the synaptic signaling of inner hair cells. Genetic variations in otoferlin contribute to a clinically recognizable autosomal recessive auditory synaptopathy known as DFNB9 or AUNB1. An overlooked yet significant consequence of missense and synonymous variants encompasses the potential profound influence on the contextual landscape of splice signals. These signals are crucial for coordinating proper splicing orchestrated by the spliceosome.

Methods: All documented missense variants were gathered from literature sources and clinical databases, and then subjected to comprehensive analysis using various splice prediction tools. Similarly, synonymous variants listed in the Deafness Variation Database underwent parallel scrutiny. A prioritized catalog, comprising 8 missense and 15 synonymous variants based on potential splice effects, was compiled for further investigation through minigene assays.

Results: Out of the 23 minigenes, only four exhibited normal splicing patterns, while the remaining ones displayed evidence of aberrant splicing. The most prevalent anomalies included frameshift effects and indications of incomplete or "leaky" splicing, resulting in multiple splice effects.

Conclusion: This study functionally characterizes the splicing effects of missense variants, often misclassified as pure non-synonymous substitutions, and synonymous variants, typically regarded as lacking deleterious effects. This is a crucial step in understanding the molecular mechanisms of coding variants in *OTOF*, which is vital for successful genotype-phenotype correlation studies and for identifying potential sources of variability in gene therapy clinical trials.

Grants: DFG funding: VO2138/7-1 #469177153 (B.V.)

P04.010.C The discovery of the second family with Clarin-2-related autosomal recessive hearing loss

Nele Christophersen[1;2], *Barbara Vona*[1;2], *Neda Mazaheri*[3], *Mina Zamani*[3], *Aboulfazl Rad*[4], *Reza Maroofian*[5], *Hamid Galehdari*[3]

[1]*University Medical Center Göttingen, Institute of Human Genetics, Göttingen, Germany;* [2]*University Medical Center Göttingen, Institute for Auditory Neuroscience and InnerEarLab, Göttingen, Germany;* [3]*Shahid Chamran University of Ahvaz, Department of Biology, Faculty of Science, Ahvaz, Iran;* [4]*Eberhard Karls University Tübingen, Department of Otolaryngology—Head and Neck Surgery, Tübingen Hearing Research Centre, Tübingen, Germany;* [5]*UCL Queen Square Institute of Neurology, University College London, Department of Neuromuscular Diseases, London, United Kingdom*

Background/Objectives: The recently discovered deafness-associated gene Clarin-2 (*CLRN2*, DFNB117) encodes a tetraspanin-like protein essential for maintaining auditory hair cell bundles. A homozygous c.494C>A, p.Thr165Lys (NM_001079827.2) variant in *CLRN2* has been previously linked to autosomal recessive non-syndromic hearing loss that manifests post-lingually and shows progression in a single family. Continued work led to the discovery of a second family whose autosomal recessive deafness is caused by the same variant in *CLRN2*, strengthening the association between *CLRN2* and hearing loss. In response to this discovery, we sought to aggregate audiometry and clinical reports from the only two identified *CLRN2* families to date.

Methods: DNA samples of a multi-ethnic patient cohort were exome sequenced. Exome data from the two *CLRN2* families were analysed including haplotype analysis and autozygosity mapping.

Sanger sequencing was used for validation and segregation analysis. Minigene studies explored aberrant splicing. Clinical information such as audiometry was compared in the two *CLRN2* families.

Results: Exome analysis and Sanger sequencing confirmed a homozygous *CLRN2* c.494C>A, p.Thr165Lys variant in a newly recruited family. The variant causes aberrant splicing through exonic splice enhancer activation. Individuals in both families describe hearing impairment onset range from 7-10 and 9-10 years of age, respectively. Audiometry of the new family shows a progression to moderate-to-severe sensorineural hearing loss.

Conclusion: The pathogenic c.494C>A variant in *CLRN2* is associated with autosomal recessive, non-syndromic, post-lingual, progressive hearing loss in humans.

Grant: Funding was provided by the German Research Foundation VO 2138/7 (BV).

P04.011.D A combined approach of innovative DNA- and RNA-technologies reveals hidden LINE-1/ERV insertion in *IQCB1* as causative variant for Senior Løken syndrome

Suzanne E. de Bruijn[1], *L. Ingeborgh van den Born*[2], *Ronny Derks*[1], *Luke O'Gorman*[1], *Ronald van Beek*[1], *Alexander Hoischen*[1,3], *Susanne Roosing*[1], *Kornelia Neveling*[1]

[1]*Radboud University Medical Center, Department of Human Genetics, Nijmegen, Netherlands;* [2]*The Rotterdam Eye Hospital, Rotterdam, Netherlands;* [3]*Radboud University Medical Center, Department of Internal Medicine and Radboud Center for Infectious Diseases (RCI), Nijmegen, Netherlands*

Background/Objectives: Senior Løken syndrome is a rare ciliopathy characterized by retinal degeneration and nephronophthisis (chronic kidney disease). The recessively inherited disease can be caused by pathogenic variants in several genes including *IQCB1*. Previously, short-read genome sequencing failed to identify a second causative allele in a Senior Løken patient harboring a monoallelic *IQCB1* defect. By combining innovative DNA- and RNA-technologies we aimed to find a genetic explanation for this patient.

Methods: Optical genome mapping was performed to identify structural variants potentially missed by short-read sequencing. Long-read sequencing (LRS) of DNA was performed to validate and determine the breakpoints of the candidate variant. Functional consequences of the variant were explored by targeted LRS using blood-derived RNA.

Results: Optical genome mapping revealed an intronic 6.2kb-insertion in *IQCB1*. LRS determined the variant constituted a LINE-1/ERV class-I element insertion. Targeted RNA-sequencing revealed that the insertion results in a complex splice-defect including exon 6 skipping and partial inclusion of the LINE-1 element as a pseudoexon. This splice defect leads to the introduction of a premature stop codon and the variant has been classified as pathogenic.

Conclusion: We identified a novel causative *IQCB1* variant by combining long-read DNA and RNA-approaches. This finding suggests that mobile element insertions still represent a underestimated variant class that are difficult to detect using short-read sequencing. Recent studies have shown that a combination of different mobile element insertion callers can help to resolve this problem, and therefore should be considered in standard diagnostic pipelines to increase diagnostic yields of Mendelian diseases.

P04.012.A Sequencing 105 macula disease-associated genes in an AMD cohort highlights the involvement of *PRPH2*, *BEST1* and *RP1* in AMD-mimicking diseases.

Rebekkah Hitti-Malin[1], *Anna Tracewska*[1], *Carel Hoyng*[2], *Caroline Klaver*[2], *Yara Lechanteur*[2], *Anneke den Hollander*[2], *Björn Bakker*[1], *Erica Boonen*[1], *Susanne Roosing*[1], *Frans P.M. Cremers*[1]

[1]*Radboud University Medical Center, Department of Human Genetics, Nijmegen, Netherlands;* [2]*Radboud University Medical Center, Department of Ophthalmology, Nijmegen, Netherlands*

Background/Objectives: Inherited macular dystrophies (iMDs) and age-related macular degeneration (AMD) often present with similar clinical features, complicating an accurate diagnosis. Genetic screening plays a crucial role in distinguishing between AMD and AMD-mimicking diseases, guiding appropriate treatment decisions.

Methods: We conducted targeted sequencing of 105 genes associated with iMD and AMD, intronic disease-associated loci, AMD-associated risk variants and the mitochondrial genome in 1,115 AMD cases and 841 controls from the Netherlands and Germany. Variants were analysed using the Franklin by Genoox platform, with a focus on ACMG-classified variants of uncertain significance (VUS), likely pathogenic, and pathogenic variants. Copy number variant analysis was performed using an in-house pipeline.

Results: Sequencing revealed potentially explanatory variants in 3.0% of AMD cases ($n = 34$) implicating iMD-associated genes. Notably, *PRPH2* variants were found in 27.3% of these cases ($n = 9$), including the previously reported variant of reduced penetrance c.424C>T; p.(Arg142Trp), which was absent in controls. Six probands (18.2%) harbour variants in *BEST1* and six probands (18.2%) carry *RP1* variants. Additionally, an intergenic SNV linked to North Carolina macula dystrophy was found in an AMD patient and a control.

Conclusion: These findings highlight the importance of genetic screening in refining an iMD or AMD diagnosis. Ophthalmologic reassessment of individuals will elucidate the clinical implications of these genetic findings. Genetic analysis can aid in distinguishing AMD-mimicking dystrophies from AMD to achieve the best outcome for patients that are eligible for treatment.

P04.013.B Correlation of CAD-related disorder (EIEE-50) with cortical visual impairment (CVI).

Sarah Thurman[1], *Callie Fischer*[2], *Julie Guerin*[3], *Michael Brodsky*[4], *Ralitza Gavrilova*[1]

[1]*Mayo Clinic, Clinical Genomics, Rochester, United States;* [2]*Mayo Clinic, Pediatrics, Rochester, United States;* [3]*Mayo Clinic, Diagnostic Radiology, Rochester, United States;* [4]*Mayo Clinic, Ophthalmology, Rochester, United States*

Background/Objectives: To document the association of *CAD*-related disorder (EIEE-50) with cortical visual impairment (CVI).

Methods: Carbamoyl phosphate synthetase/aspartate transcarbamylase/dihydroorotase *(CAD)* enzyme deficiency(OMIM #114010), first described in 2015, also referred to as Early Infantile Epileptic Encephalopathy (EIEE50, OMIM 3616457), is characterized by seizures, language delay, difficulty with fine motor skills, wide based gait, and anemia. Case reports indicate benefit of uridine supplementation that results in decreased seizure activity, improved development and resolution of anemia. Uridine supplementation bypasses the intrinsic pyrimidine synthetic pathway defect in CAD-related disorders, working through the salvage pathway to provide uridine that the body needs for DNA and RNA synthesis. We describe profound cortical visual impairment (CVI) impairment in an infant with *CAD*-related disorder.

Results: An 8 month old Caucasian male presented for work up and evaluation of seizures, microcephaly, hyperreflexia, hypotonia, anemia, and severe CVI. MRI brain noted thickened cortical gray matter along the right calcarine fissure as well as radiographic changes suggesting malformation of cortical development. Trio WGS testing confirmed two CAD variants in trans: one variant of uncertain significance CAD:c.4837T>C and another likely pathogenic variant (CAD:c.3016G>A). Empiric uridine therapy (100mg/kg/d) provided notable improvement in seizure activity and hypotonia with concomitant resolution of his anemia. EEG at 19 months notes no seizure activity.

Conclusion: *CAD*-related disorder is treatable and may affect visual cortical development causing severe secondary CVI, a newly described clinical manifestation.

P04.015.D A multi-omic approach to characterize the corneal epithelium in patients with post-refractive ectasia

Katarzyna Jaskiewicz[1], *Alicja Wysocka*[1], *Eliza Matuszewska*[2], *Magdalena Maleszka-Kurpiel*[3;4], *Jakub Wozniak*[5;6], *Rafał Płoski*[7], *Jan Matysiak*[2], *Malgorzata Rydzanicz*[7], *Marzena Gajecka*[1;5]

[1]*Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland;* [2]*Poznan University of Medical Sciences, Department of Inorganic and Analytical Chemistry, Poznan, Poland;* [3]*Poznan University of Medical Sciences, Chair of Ophthalmology and Optometry, Poznan, Poland;* [4]*Optegra Eye Health Care Clinic in Poznan, Poznan, Poland;* [5]*Poznan University of Medical Sciences, Chair and Department of Genetics and Pharmaceutical Microbiology, Poznan, Poland;* [6]*Poznan University of Life Sciences, Department of Genetics and Animal Breeding, Poznan, Poland;* [7]*Medical University of Warsaw, Department of Medical Genetics, Poznan, Poland*

Background/Objectives: Post-refractive ectasia (PRE) is a sight-threatening complication of 0.09-0.66% of corneal refractive surgeries. As the mechanism of the PRE as well as genetic predisposition/susceptibility remain unknown, we applied a multi-omic approach to characterize the corneal epithelium (CE) of PRE patients and screen for molecular biomarkers.

Methods: The 11 PRE patients (7 males/4 females) undergoing cross-linking procedure and 8 control-mild myopia patients (4 males/4 females) undergoing refractive error correction were ascertained. The RNA and proteins were extracted using RNA/DNA/Protein PurificationPlus MicroKit (Norgen Biotek) from the *central*, *middle*, and *peripheral* CE *topographic* regions of each CE sample (a total of 57 experimental samples). Next, NGS libraries were prepared using TruSeq Stranded TotalRNA LibraryPrep Gold (Illumina) and sequenced on Novaseq platform (60 mln read pairs/sample). MALDI-TOF/TOF Tandem Mass Spectrometry was performed after tryptic digestion, with an UltrafleXtreme mass spectrometer (Bruker Daltonics) in the mass-to-charge range of 700 to 3500. The obtained data were interpreted regarding our previous keratoconus data (https://doi.org/10.1167/iovs.64.2.22).

Results: In *central* and *peripheral* CE regions differentially expressed genes and proteins contributing to the JAK-STAT pathway via interferon-gamma and interleukin 12 signaling were identified. The main disrupted pathway, downregulated across the corneal surface, was keratinization (including downregulated expression of *KRT3*, *KRT7*, *KRT12*, and *KRT76*). The upregulated level of TBC1D4 protein was limited to the *central* region of CE.

Conclusion: These results, validated by future studies of ectasia-free fellow eyes, may contribute to the development of preoperative molecular tests to identify patients who may develop ectasia.

P04.016.A Demographic, genetic and phenotypic association of Fuchs endothelial corneal dystrophy in a large, multi-centre, molecularly and clinically characterised cohort

Siyin Liu[1;2], *Amanda Sadan*[1], *Anita Szabo*[1], *Nihar Bhattacharyya*[1], *Christina Zarouchlioti*[1], *Marcos AbreuCosta*[1], *Nathaniel Hafford-Tear*[1], *Lubica Dudakova*[3], *Marc Ciosi*[1], *Ismail Moghul*[1], *Pavlina Skalicka*[3;4], *Mark Wilkins*[2], *Bruce Allan*[2], *Alison Hardcastle*[1;2], *Nikolas Pontikos*[1;2], *Catey Bunce*[5], *Darren Monckton*[6], *Kirithika Muthusamy*[1;2], *Petra Liskova*[1;3], *Stephen Tuft*[1;2], *Alice Davidson*[1;2]

[1]*UCL, Institute of Ophthalmology, London, United Kingdom;* [2]*Moorfields Eye Hospital NHS Foundation Trust, London, United Kingdom;* [3]*Charles University, Department of Paediatrics and Inherited Metabolic Disorders, Czech Republic;* [4]*General University Hospital in Prague, Department of Ophthalmology, Czech Republic;* [5]*National Institute for Health and Care Research (NIHR) BRC at the Royal Marsden NHS Foundation Trust and the Institute of Cancer Research, National Institute for Health and Care Research (NIHR) BRC at the Royal Marsden NHS Foundation Trust and the Institute of Cancer Research, United Kingdom;* [6]*University of Glasgow, School of Molecular Biosciences, United Kingdom*

Background/Objectives: Fuchs endothelial corneal dystrophy (FECD) is commonly associated with an intronic CTG repeat expansion (CTG18.1) in *TCF4*. Rare pathogenic variants in other genes have also been reported. This large multi-centre study probes links between genotype, demographic factors, and age-at-first corneal transplant (a surrogate for severity) in a genetically characterized FECD cohort.

Methods: Blood DNA was collected from participants at Moorfields Eye Hospital, London($n = 569$) and the General University Hospital, Prague($n = 353$). Ethnicity was determined by Principal Component Analysis. CTG18.1 was genotyped by capillary electrophoresis of PCR amplicons. Cases with ≥1 expanded allele (≥50 CTG repeats) were classified as expansion-positive. Biallelic expansion-negative cases were analysed by exome/genome sequencing.

Results: A CTG18.1 expansion was detected in 672/836(80.4%) of European cases, conferring >77-fold increased odds for FECD($OR = 77.3$, CI:49.51-120.69, $P < 0.0001$). CTG18.1 expansions were significantly less common in non-European cases(23/65[35.38%], $P < 0.0001$). In the expansion-positive group, the CTG18.1 length was inversely correlated with age-at-first keratoplasty($r = -0.0859$, $P = 0.011$), but independent of sex and ethnicity. Females were enriched in the total cohort(58.25%), with

a more marked difference in the expansion-negative group(76.1%). Biallelic expansion-positive cases in European patients were enriched compared to ethnicity-matched controls(Chi-square = 218.62, P < 0.00001). Furthermore, biallelic expansion-positive cases had surgery at a younger mean age(66 vs 69 years, P = 0.02). Candidate pathogenic variants (MAF < 0.01; CADD >10) in FECD-associated genes were identified in 6.4% of expansion-negative cases.

Conclusion: Our results demonstrates that CTG18.1 length is a modifier of FECD severity, that female preponderance is mainly driven by CTG18.1 independent factors, and that allelic dosage increases both disease penetrance and severity.

P04.017.B Identification of genetic modifiers for *RIPOR2*-associated hearing loss type DFNA21

Janine Reurink[1], *Hedwig Velde*[1], *Suzanne E. de Bruijn*[2], *Jordi Corominas Galbany*[2], *Christian Gilissen*[2], *Ronald Pennings*[1], *Hannie Kremer*[1;2]

[1]*Radboud University Medical Center, Otorhinolaryngology, Nijmegen, Netherlands;* [2]*Radboud University Medical Center, Human Genetics, Nijmegen, Netherlands*

Background/Objectives: DFNA21 is a dominantly inherited, mainly adult-onset type of hearing impairment caused by a 12-nucleotide deletion in *RIPOR2*. A remarkable feature of DFNA21 is its high variability in (self-reported) age of onset. We hypothesize that genetic modifiers may underlie this high variability in age of onset.

Methods: Whole genome sequencing was performed for 16 cases with a relatively early onset (≤20 years of age) and 15 cases with a relatively late onset of hearing loss (≥40 years), derived from nine families. We assessed variants in and surrounding *RIPOR2*, genes encoding interaction partners of RIPOR2, 37 genes that encode stereocilia proteins and that are associated with hearing loss and 48 risk variants associated with age-related hearing impairment[1].

Results: Four haplotypes, located in or upstream of *RIPOR2*, were found to be associated with the onset of hearing loss. Genotyping of target SNPs of the haplotypes in 61 additional DFNA21 subjects from 10 families confirmed the association of one of these haplotypes with an earlier onset of disease (p = 0.0017). This haplotype locates on the wildtype allele and two of its 28 variants are in a cluster of predicted binding sites of the hair cell transcription factor POU4F3.

Conclusion: We identified a haplotype upstream of *RIPOR2* that is associated with an earlier onset of DFNA21. A potential effect of two variants on POU4F3-mediated gene regulation is being assessed.

P04.018.C A novel *RPE65*-related dominant retinopathy caused by founder variant c.1555G>A p.(Glu519Lys) enriched in Belgian patients with a recognizable pattern dystrophy spectrum

Eline Van Vooren[1;2], *Filip Van den Broeck*[3;4], *Eline Geens*[1;2], *Marieke De Bruyne*[2], *Stijn Van de Sompele*[2], *Quinten Mahieu*[1;2], *Sheetal Uppal*[5], *Eugenia Poliakov*[5], *Michael T. Redmond*[5], *Julie De Zaeytijd*[3;4], *Bart Leroy*[3;4;6], *Miriam Bauwens*[1;2], *Elfride De Baere*[1;2]

[1]*Biomolecular Medicine, Ghent University, Ghent, Belgium;* [2]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium;* [3]*Department of Head and Skin, Ghent University, Ghent, Belgium;* [4]*Department of Ophthalmology, Ghent University Hospital, Ghent, Belgium;* [5]*Laboratory of Retinal Cell and Molecular Biology, National Eye Institute, NIH, Bethesda, United States;* [6]*Division of Ophthalmology & Center for Cellular & Molecular Therapeutics, Children's Hospital of Philadelphia, Philadelphia, PA, United States*

Consortium: AD-RPE65

Background/Objectives: Recessive *RPE65*-retinopathy is a well-known target for gene therapy (Luxturna). Dominant *RPE65*-retinopathy however has been reported only once, caused by the 'Irish' variant c.1430A>G p.(Asp477Gly). Here, we discovered a novel dominant *RPE65*-retinopathy caused by variant c.1555G>A p.(Glu519Lys), enriched in Belgian patients with pattern dystrophy.

Methods: The c.1555G>A variant was identified in genome sequencing (GS) data (n = 3), RetNet filtered exome data (n = 27) and targeted NGS data of unsolved inherited retinal disease (IRD) cases (n = 40) with pattern dystrophy/maternally-inherited diabetes and deafness (MIDD)-like phenotypes. Haplotype phasing was done by long-read GS (n = 4), followed by broader SNV and microsatellite analysis. The variant was functionally assessed using an enzymatic RPE65 assay, Western blotting, co-immunoprecipitation, cellular thermal shift assay (CETSA), minigene assays and protein modelling (AlphaFold). Affected cases were clinically reassessed.

Results: We identified 70 index patients and family members with the rare and highly conserved c.1555G>A *RPE65* variant (gnomAD v4, 5x). Haplotyping revealed a shared region of 200 kb, supporting a founder effect. Segregation analysis showed complete penetrance with extensive variability, from subtle mottling to macular pattern dystrophy resembling the one found in MIDD. Enzymatic activity of Glu519Lys was lowered to ~56%, similar to the Irish Asp477Gly. Immunoblotting showed reduced mutant protein expression. Protein modelling and CETSA support a potential shift in protein stability and binding. Unlike Asp477Gly no splice-effect was observed.

Conclusion: We report a novel dominant *RPE65*-IRD in Belgian patients with a recognizable retinal phenotype, reducing the diagnostic gap in dominant IRD and opening new therapeutic perspectives.

P04.019.D Closing the gap: overcoming the challenges of *RPGR* ORF15 sequencing, a target for gene therapy of X-linked retinitis pigmentosa

Stijn Van de Sompele[1;2], *Marieke De Bruyne*[1;2], *Mattias Van Heetvelde*[1;2], *Toon Rosseel*[1;2], *Bart Leroy*[1;3;4], *Julie De Zaeytijd*[3], *Brecht Guillemyn*[1;2], *Kathleen Claes*[1;2], *Kim De Leeneer*[1;2], *Miriam Bauwens*[1;2], *Elfride De Baere*[1;2]

[1]*Ghent University, Department of Biomolecular Medicine, Ghent, Belgium;* [2]*Ghent University Hospital, Center for Medical Genetics Ghent, Ghent, Belgium;* [3]*Ghent University Hospital, Department of*

Ophthalmology, Ghent, Belgium; [4]The Children's Hospital of Philadelphia, Division of Ophthalmology & Center for Cellular & Molecular Therapeutics, Philadelphia, United States

Background/Objectives: Retinitis pigmentosa (RP) is a group of inherited retinal diseases (IRD) causing vision impairment in 2 million people worldwide. X-linked RP (XLRP), comprising 10% of cases, is the most severe, leading to earlier onset and rapid progression. *RPGR* is the major XLRP gene, harboring approximately 80% of pathogenic variants, primarily in ORF15, a retina-specific exon. Gene therapy trials aim to halt *RPGR*-IRD degeneration, requiring a precise molecular diagnosis. However, ORF15's repetitive and purine-rich nature presents technical challenges for genetic testing, including PCR artifacts, inadequate coverage, misalignments, and variant calling inaccuracies.

Methods: To overcome these challenges, the performance (coverage and variant calling) of different sequencing technologies were evaluated for ORF15. In particular, we compared targeted PCR- and probe-based approaches, whole exome sequencing (WES) using two types of probes, and short- and long-read whole genome sequencing (WGS).

Results: WES and short-read WGS provide a minimum coverage of <20X for ORF15, limiting their variant calling performance. Long-read WGS demonstrated drastic improvements in the coverage uniformity for ORF15, albeit at a significantly higher cost and suboptimal variant calling performance. Our custom KAPA HyperCap probes for the enrichment of 400kb clinically relevant regions, provides a minimum coverage of >120X for ORF15. Moreover, this low-cost technology allowed the accurate detection of variants in ORF15 and a broad selection of other IRD.

Conclusion: The targeted probe-based approach allows sufficient coverage and reliable variant calling in ORF15, which will accelerate molecular diagnoses of *RPGR*-IRD in a cost-effective way, thereby improving patients' eligibility for therapeutic interventions.

Consortium: the EyeConic Study Group

Objectives: The EyeConic study is a multicenter study, aiming at estimating the proportion of low-vision patients with preserved foveal cone photoreceptors. Previous studies have shown that in inherited retinal degenerations (IRDs) cones may lose their outer segments, involved in light sensing, while keeping their cell bodies intact. Thus, this dormant state creates an opportunity to re-sensitize cone cell bodies with optogenetic tools to restore vision in blind patients.

Methods: We enrolled 446 eyes from 291 low-vision patients with generalized IRDs (study patients) from 11 centers, in addition to eyes from 31 individuals with Stargardt disease (atrophy controls), and from 93 healthy controls. Machine-learning algorithm segmented Optical Coherence Tomography scans to calculate corrected rod-free volume (cRFV) in the central part of the macula, excluding hyperreflective material for accurate cone volume estimation. Genotype data was manually annotated and classified using ACMG classification and ClinVar. Linear mixed model analysis was performed to identify genetic association with foveal preservation.

Results: Mean (±s.d.) cRFV values were $8.7 \pm 4.4 \times 10^6$ μm^3, $4.2 \pm 1.7 \times 10^6$ μm^3, and $1.29 \pm 1.97 \times 10^7$ μm^3, for study patients, atrophy controls, and healthy controls, respectively. In total, 235 study patients had informative genotype-phenotype data, with causal mutations identified in 53 known IRDs genes. Only ABCA4 was found to have a significant effect on foveal preservation.

Conclusions: Mean foveal volumes in the EyeConic cohort are significantly higher than in the atrophy control group. Still, genotype was found only to have a limited effect on the presence of foveal preservation.

of Internal Medicine, Division of Endocrinology, Rotterdam, Netherlands; [13]Erasmus University Medical Center, Department of Ophthalmology, Rotterdam, Netherlands; [14]University of Tuebingen, Molecular Genetics Laboratory, Institute for Ophthalmic Research, Center for Ophthalmology, Tuebingen, Germany; [15]Eberhard Karls University, University Eye Hospital, Department for Ophthalmology, Tuebingen, Germany; [16]University of Tuebingen, Institute for Medical Genetics and Applied Genomics, Tuebingen, Germany

Background/Objectives: A homozygous loss-of-function (LoF) variant in *POC5* was previously described as a novel cause for retinitis pigmentosa.[1] This patient, however, was also reported to have short stature, microcephaly and recurrent glomerulonephritis. We studied a cohort of patients with bi-allelic *POC5* LoF variants.

Methods: We identified eight patients from seven families with homozygous LoF *POC5* variants and performed detailed phenotype analysis. POC5 localization studies were performed in three patient-derived fibroblast cell lines.

Results: In depth phenotyping of patients with *POC5* variant showed not only retinitis pigmentosa but also variable other organ involvement including lipodystrophy with diabetes and liver disease, kidney disease, and dysmorphic features.

The POC5 protein localizes to the centrioles and plays an essential role during the cell cycle and cilium formation. Ciliopathies are a clinically heterogeneous group of disorders that can affect almost any organ of the human body. The phenotypes of the eight patients in this study fit well in the ciliopathy phenotypic spectrum, except for lipodystrophy which is not common in ciliopathies.

Interestingly, POC5 localization studies in three patient-derived fibroblast cell lines show aberrant localization indicating a ciliary defect in these patients. This further supports the hypothesis that defective POC5 results in a ciliary disorder.

Conclusion: In conclusion, we describe a novel syndrome caused by autosomal recessive LoF variants in *POC5* that includes retinitis pigmentosa, lipodystrophy, and dysmorphic features and provide further evidence that this is a novel ciliopathy. Further studies are required to elucidate the role of POC5 in lipodystrophies.

Conflict of Interest: None declared

P04.022.C The establishment of a patient registry for Otoferlin-related hearing loss

Barbara Vona[1;2], Nicola Strenzke[2;3], Tobias Moser[2;4;5], **Bernd Wollnik**[1;4]

[1]University Medical Center Göttingen, Institute of Human Genetics, Göttingen, Germany; [2]University Medical Center Göttingen, Institute for Auditory Neuroscience and InnerEarLab, Göttingen, Germany; [3]University Medical Center Göttingen, Department of Otolaryngology, Göttingen; [4]University Medical Center Göttingen, Cluster of Excellence "Multiscale Bioimaging: from Molecular Machines to Networks of Excitable Cells" (MBExC), Göttingen; [5]Max Planck Institute for Multidisciplinary Sciences, Auditory Neuroscience and Synaptic Nanophysiology Group, Göttingen

Background/Objectives: Among the hundreds of genes responsible for isolated hearing impairment, otoferlin (*OTOF*, DFNB9, AUNB1) ranks among the prevalent forms. Biallelic otoferlin variants cause auditory synaptopathy, frequently appearing as congenital/early onset deafness with absent auditory brainstem responses but preserved otoacoustic emissions. In response to promising pre-clinical and early in-human trial results, we sought to develop the first global registry for otoferlin patients.

Methods: REDCap software guided database development. An interdisciplinary team was consulted to shape data fields and consent forms. Fields were created for entry of phenotype, genotype and inheritance patterns in pseudonymized form, following digital consent. A data security concept was devised and approved.

Results: The registry provides an overview of the frequency and manifestations of *OTOF* and of the success of various treatment strategies. It supports patient-driven clinical and translational research. The registry, available in English and German languages, was approved by the Ethics Committee of the University Medical Center Göttingen and is registered under the ClinicalTrials.org ID NCT05946057.

Further information and link to consent forms can be found via the Institute of Auditory Neuroscience: http://www.auditory-neuroscience.uni-goettingen.de/otoferlin_registry_en.html

Conclusion: We foresee this registry as essential infrastructure for conducting longitudinal natural history studies on a broad spectrum of patients, monitoring outcomes of future gene therapies, and prioritizing patient-driven research. We have since extended a collaborative invitation to the facebook "Otoferlin Gene Mutation" patient group. We invite patients and clinicians to participate.

Grants: DFG funding: VO2138/7-1 #469177153 (B.V.); Heisenberg program #406266759 (N.S.); Multiscale Bioimaging Cluster of Excellence EXC 2067/1-390729940 (T.M., B.W.).

P04.023.D Elucidation of the *OTOA* paralogous sequence in non-syndromic deafness

Tine Tesovnik[1;2], *Katarina Trebušak Podkrajšek[1;3], Robert Sket[1;2], Marusa Debeljak[1;4], Saba Battelino[5;6], Jernej Kovač[1;2], Barbara Jenko Bizjan[1;2]*

[1]University Medical Centre Ljubljana, Clinical Institute of Special Laboratory Diagnostics, Ljubljana, Slovenia; [2]Faculty of Medicine, University Ljubljana, Department of Paediatrics, Ljubljana, Slovenia; [3]Faculty of Medicine, University Ljubljana, Institute of Biochemistry, Ljubljana, Slovenia; [4]Faculty of Medicine, University Ljubljana, Institute of Cell Biology, Ljubljana, Slovenia; [5]University Medical Centre Ljubljana, Department of Otorhinolaryngology and Cervicofacial Surgery, Ljubljana, Slovenia; [6]Faculty of Medicine, University Ljubljana, Department of Otorhinolaringology, Ljubljana, Slovenia

Background/Objectives: Otoancorin is a protein that plays a crucial role in the development and function of the inner ear, specifically in auditory and vestibular function. *OTOA* genetic aberrations cause autosomal recessive deafness, which manifests as a severe to profound sensorineural non-syndromic hearing impairment affecting all frequencies, manifesting in the prelingual phase. The impact of *OTOA*-related hearing loss may be underestimated due to the limitations of NGS sequencing technology and the paralog-specific region.

Methods: Our study involved 328 individuals referred for genetic testing due to hearing impairment and without other syndromic features. All subjects underwent WES and WGS was performed in cases with significant discrepancies in the *OTOA* paralog-specific region. Long-range PCR with long-read sequencing was used to characterize all participants, and additional long-read sequencing of chromosome 16 was conducted to confirm *OTOA*-associated deafness.

Results: The WES analysis did not identify known pathogenic or likely pathogenic SNV or CNV. However, the CNV analysis revealed a significant variability representation of reads in the *OTOA* paralogous region, which could not be resolved by WGS. To clarify the NGS results, we performed long-range PCR and long-read

sequencing. This revealed *OTOA* paralogous sequence variants as the cause of hearing loss in over 1% of subjects.

Conclusion: Our study revealed *OTOA* paralogous deafness in a non-negligible proportion of subjects with non-syndromic deafness. These results emphasize the importance of integrating long-read sequencing into clinical diagnostics to enhance the understanding of complex, repetitive, and paralogous sequences in the human genome.

P04.024.A The diagnostic chameleon of Hereditary Hearing Loss (HHL): a genetic investigation on Non-syndromic Mimics (NSMs)

Beatrice Spedicati[1;2], *Anna Morgan*[2], *Stefania Lenarduzzi*[2], *Elisa Rubinato*[2], *Gabriele Zucca*[1], *Mabel Troian*[2], *Dario Marangoni*[3], *Giorgia Girotto*[1;2]

[1]*University of Trieste, Department of Medicine, Surgery and Health Sciences, Trieste, Italy;* [2]*Institute for Maternal and Child Health – I.R.C.C.S. "Burlo Garofolo", Trieste, Italy;* [3]*University of Trieste, Department of Medicine, Surgery and Health Sciences, Eye Clinic, Ophthalmology Clinic, Trieste, Italy*

Background: HHL is characterised by extensive clinical and genetic heterogeneity and its molecular diagnosis is further complicated by peculiar and understudied clinical conditions known as NSMs.

Methods: In the last 18 months, 73 apparently non-syndromic Italian HHL patients, negative to *GJB2* and *STRC* analyses, underwent Whole Exome Sequencing to identify NSMs.

Results: The genetic cause of HHL was identified in 36/73 patients (49.3%). Among them, 12 subjects were found to be affected by NSMs, which may be divided in two groups: 1) two patients with subtle additional signs that were missed during the initial clinical evaluation; 2) ten patients whose further clinical features are expected to develop later in life. In group 1, we identified pathogenic variants in *MITF* and *GATA3* genes, associated with Waardenburg and Barakat syndromes, respectively. In group 2, the identified genes were *CDH23* (one patient) *USH2A* and *ADGRV1* (six and three patients, respectively). These results highlight how 75% of all NSMs are represented by Usher syndrome type 2 and are in line with our previous findings, that confirmed the high prevalence of Usher syndrome type 2 carriers in the Italian population (1:70).

Conclusion: Group 1 NSMs provide crucial insight on very mild forms of syndromic deafness, thus helping clinicians to a critical re-evaluation of the diagnostic criteria of each condition. Conversely, group 2 NSM patients need to be assessed by a multidisciplinary team to provide a tailored management plan, with the final goal of identifying a personalized follow-up and specific preventive strategies.

P04.025.B Retrospective analysis over 20 years of DNA diagnostics in 7,017 index patients with inherited retinal dystrophies (IRDs)

Christina Kiel[1], *Heidi Stöhr*[1], *Kristin Geiger*[1], *Helmut Roth*[1], *Ulrike Friedrich*[1], *Fabiola Biasella*[1], *Bernhard Weber*[1;2]

[1]*University of Regensburg, Institute of Human Genetics, Regensburg, Germany;* [2]*University Hospital Regensburg, Institute of Clinical Human Genetics, Regensburg, Germany*

Background/Objectives: Inherited retinal dystrophies (IRDs) are a diverse group of rare retinopathies ultimately culminating in vision impairment of varying degrees. High clinical and genetic heterogeneity makes DNA diagnostics in IRDs a challenging task. Our retrospective study reports one of the largest IRD cohorts with over 7,000 index patients representing a wide spectrum of IRD phenotypes.

Methods: Genetic data of 7,017 index patients with clinically distinct IRD conditions collected over 20 years were considered retrospectively. Patients were analyzed by either targeted next-generation sequencing (NGS), DNA microarray or Sanger sequencing. The obtained data were standardized and a characterization of the entire cohort was performed.

Results: Overall, 47 % of patients (3,300 out of 7,017) obtained a fully informative DNA diagnosis, whereby the diagnostic yield strongly varied between disease entities. The majority of solved cases displayed autosomal-recessive (54.1 %), followed by autosomal-dominant (28.7 %), X-linked (15.7 %) and mitochondrial (1.5 %) inheritance. In total, 145 genes were found to be associated with disease in at least one patient. The most common disease-causing genes were *ABCA4* (26.1 %), *BEST1* (7.8 %), *PRPH2* (5.7 %), *RPGR* (5.5 %) and *RS1* (5.5 %). Out of 5,378 genetic variants identified, 61.9 % were not listed in HGMD, of which 28.6 % were classified as (likely) pathogenic.

Conclusion: The results of genetic testing in our large cohort provide important insight into the spectrum of mutated alleles in the IRDs, which is a crucial basis for future clinical trials and therapeutic options.

P04.026.C Functional analysis of *CNGA3* missense variants associated with autosomal recessive achromatopsia allows confirmation and reclassification of variants

Susanne Kohl[1], *Maria Solaki*[1], *Bernd Wissinger*[1], *Peggy Reuter*[1]

[1]*Institute for Ophthalmic Research, Centre for Ophthalmology, Tübingen, Germany*

Background/Objectives: Achromatopsia (ACHM) is a rare congenital retinal disorder due to impaired cone photoreceptor function. CNGA3, responsible for up to 40% of ACHM cases, encodes the A3 subunit of the cyclic nucleotide-gated (CNG) channel. Most missense variants in CNGA3 are functionally uncharacterized, often leading to uncertain significance (VUS) classification. To address this, we developed a medium-throughput aequorin-based calcium influx assay for assessing the functional impact of uncharacterized CNGA3 missense variants, aiding in clinical variant interpretation.

Methods: Wild-type or variant homomeric CNGA3 channels were expressed in HEK293 cells stably expressing aequorin. Activation of CNG channels was achieved through 8-Br-cGMP application. CNG channel-mediated Ca^{2+} influx was recorded via aequorin-mediated luminescence, correlating with channel functionality. Dot blot analysis of whole cell lysates confirmed CNGA3 protein expression.

Results: The bioassay validation included testing 9 benign and 15 extensively studied pathogenic CNGA3 missense variants. Thresholds for "functionally normal" and "functionally abnormal" were determined through ROC analysis. Out of 150 uncharacterized missense variants, 55 were previously classified as VUS. Among the variant channels, 80 showed no function, while 70 displayed luminescence signals. Of these, 45 indicated altered but residual channel function, and 25 exhibited wild-type-like

behavior. The functional assessment led to the re-classification of 33 VUS as (likely) pathogenic and 19 VUS as (likely) benign.

Conclusion: Our bioassay is a crucial instrument for assessing the influence of CNGA3 missense variants on the functionality of homomeric CNGA3 channels, ultimately contributing to the reclassification of 94.5% of VUS.

P04.027.D Expanding the Enhanced S cone Syndrome (ESCS) phenotype-genotype correlation the role of the developmental gene NRL

John Grigg[1;2], *Elisa Cornish*[1;2], *Stephanie Rozos*[1], *Vanessa Leung*[1], *Chris Ovens*[1], *Marium Raza*[1], *Benjamin Nash*[2;3], *Julie McGaughran*[4], *Robyn Jamieson*[1;2]

[1]*Save Sight Institute, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia;* [2]*Eye Genetics Research Unit, Children's Medical Research Institute, The Children's Hospital at Westmead, Westmead, Australia;* [3]*Sydney Genome Diagnostics, Western Sydney Genetics Program, Sydney Children's Hospitals Network, Westmead, Sydney, Australia;* [4]*Genetic Health Queensland, Royal Brisbane and Women's Hospital Metro North health Service District, Herston, Australia*

Background/Objectives: We describe the ocular phenotype in three patients from two families with novel mutations in Neural retina leucine zipper (NRL) resulting in an enhanced S-cone phenotype (ESCS). Visual electrophysiology recordings in ESCS have traditionally been identified as being specific for the gene NR2E3. Recently cases of autosomal recessive NRL mutations have been described resulting in an ESCS phenotype.

Methods: Investigations including full-field electroretinogram (ffERG), best corrected visual acuity (BCVA), optical coherence tomorgraphy (OCT) and ultra-wide field autofluorescence (UWAF) and colour imaging are reported.

Results: Family 1 I1 (Male) initially with symptoms from age 5 years. BCVA was 6/120 in both eyes with nystagmus, UWAF, OCT and ffERG were consistent with the classic features of ESCS. Genetic testing identified a novel homozygous likely pathogenic NRL variant c.256G>T; p.Glu86*

Family 2 II1 and II2 (Female aged 4.5 and Male 3 years) presented with nyctalopia. BCVA 3/6 Kay pictures both eyes. ffERG, retinal curvilinear yellow glistening stripes and hyperfluorescent dots throughout the fundus were recorded representing an atypical ESCS phenotype. NRL pathogenic variants c.223dup p.Leu75Profs* and c.16del p.Ser6Alfs*13 were identified.

Conclusion: Biallelic NRL genetic variants in these two families expand the geneotype association with the Enhanced S cone Syndrome phenotype.

NRL binds directly to the promoter of NR2E3 and thus acts upstream of this transcription factor to guide the developing photoreceptor into the rod lineage. It is this interaction that contributes to the clincal phenotype of ESCS for NRL in addition to NR2E3.

P04.028.A Virtual, national ocular genomic multidisciplinary team (OcularGen MDT) for variant reclassification, and functional genomic and therapy eligibility in inherited retinal disorders

Robyn Jamieson[1;2], *Benjamin Nash*[1;3], *Alan Ma*[1;2], *Emma Hackett*[3], *Elisa Cornish*[4], *John Grigg*[1;3], *Bruce Bennetts*[3]

[1]*University of Sydney, Children's Medical Research Institute & Save Sight Institute, Eye Genetics Research Unit, Sydney, Australia;* [2]*Sydney Children's Hospitals Network, Department of Clinical Genetics, Sydney, Australia;* [3]*Sydney Children's Hospitals Network, Sydney Genome Diagnostics;* [4]*University of Sydney, Save Sight Institute*

Background/Objectives: The growing number of emerging genetic therapies/clinical trials for patients with inherited retinal disorders (IRDs), leads to increased demand for accurate molecular diagnosis to fulfill eligibility criteria. Variants of uncertain significance (VUS) need resolution, which requires detailed review and assessment for functional genomic studies where indicated.

Methods: A virtual, ocular genomic multidisciplinary team (OcularGen-MDT) approach was implemented, with lead clinical genetic, ophthalmic, genetic counsellor, diagnostic scientist and IRD researcher contributions. Referring clinical teams presented history, pedigree and ophthalmic information. The OcularGen MDT diagnostic scientists independently evaluated variant curation using ACMG criteria. Cases were reviewed in context with ophthalmic and pedigree information.

Results: Over 120 cases with VUS or other pathogenicity queries were referred from across Australia between 2019-2023. Overall, 227 variants in 94 genes were reviewed. 42% (42/99 variants) of VUS were able to be resolved through a combination of detailed ophthalmic analysis, literature review, family segregation studies and review of ACMG criteria. Cases with *RPE65* variants were assessed to meet therapy eligibility. In almost all referred cases, clinically significant information was returned.

Conclusion: The OcularGen-MDT provides referring clinical teams an avenue for expert review of unresolved cases in a regular, virtual format. The combined expertise led to VUS resolution, or other recommendations for clinical management or functional genomic studies in almost all cases. The virtual format facilitated access for rural and regional cases. This study highlights the benefits of a cross-discipline structured MDT, especially in assessing suitability for emerging clinical trials and therapies.

Consortium: the DOOFNL consortium

Background/Objectives: Non-syndromic hereditary hearing loss (HL) is genetically highly heterogeneous, yet at least half of the cases remain unexplained in medical genetic testing. One of several reasons for this is that pathogenic variants are located in "unknown" deafness genes. With a variant prioritization approach, we aimed to identify novel (candidate) genes for HL.

Methods: Exome-wide sequencing data were collected for subjects with (presumed) genetic HL that remained unexplained in medical genetic testing (gene-panel analysis). Cases in group AD had presumed autosomal dominantly inherited HL (n = 124) and in group AR presumed autosomal recessive HL (n = 337). Variants in known or candidate deafness genes (e.g. preferential inner ear expression, mouse deafness genes) were prioritized based on allele frequencies and predicted effects (e.g. truncating). In silico tools were employed to predict effects on transcript splicing or deleteriousness of missense variants. Selected variants were tested for their co-segregation with HL.

Results: We associated *IKZF2* with dominantly inherited non-syndromic HL in three families. Missense variants specifically affected Cysteines or Histidines of C2H2 Zn-finger motifs 2 and 3 of the encoded protein Helios. Our findings indicate a complex genotype-phenotype correlation for defects in *IKZF2* since this gene was previously associated with ICHAD syndrome or non-syndromic dysfunction of the immune system. Only two cases were solved by variants in recently identified deafness genes.

Conclusion: Variants of *IKZF2* can underlie non-syndromic HL. The large number of candidate genes for HL stresses the importance of inclusion of family members (e.g. for trio analysis) for variant prioritization.

[1]Manchester Centre for Genomic Medicine, St Mary's Hospital, Manchester University NHS Foundation Trust, Health Innovation Manchester, Manchester, UK., Manchester, United Kingdom; [2]Division of Evolution, Infection and Genomics, School of Biological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, UK., Manchester, United Kingdom; [3]IOB - Institute of Molecular and Clinical Ophthalmology Basel, Basel, Switzerland; [4]Universität Basel, Basel, Switzerland; [5]Leipzig University, Leipzig, Germany; [6]Department of Genetics and Genome Biology, University of Leicester, Leicester, UK; [7]University of Crete Medical School, Department of Ophthalmology; [8]University of Crete, Medical School, Department of Neurology; [9]Semmelweis University Budapest, Dept. of Ophthalmology, Budapest, Hungary

Background/Objectives: ADIPOR1 is one of two receptors for Adiponectin, a well-known hormone produced by adipose tissue and implicated in metabolic dysfunction. ADIPOR1 is also essential for lipid homeostasis in photoreceptors. Thus far, two families with *ADIPOR1* variants and retinitis pigmentosa have been described. The extra-retinal consequences of *ADIPOR1* variants are poorly understood.

Methods: We genetically and clinically characterised individuals with biallelic *ADIPOR1* variants, performed RT-QPCR on patient samples, undertook haplotype analysis and examined tissue expression datasets.

Results: We identified 4 individuals from 2 families of Pakistani origin with an identical homozygous frameshift *ADIPOR1* variant and showed that the transcript undergoes nonsense-mediated decay. Haplotype analysis showed that the affected individuals from the two families likely shared an ancestor ~200 years ago. We identified 6 additional individuals from three families with rare biallelic predicted deleterious missense *ADIPOR1* variants. In total, 7/10 individuals displayed retinal pigmentary abnormalities. In two families, retinal changes were identified following reverse phenotyping, whilst in two families visual symptoms were the presenting feature and in one family retinal phenotyping was not possible. Importantly, 9/10 individuals also had significant developmental delay and intellectual disability. Analysis of gene expression in retinal tissue demonstrated high expression of *ADIPOR1* but negligible expression of its close paralog, *ADIPOR2*.

Conclusion: *ADIPOR1* variants cause a recessive syndrome of intellectual disability and retinitis pigmentosa. ADIPOR1 likely transduces both Adiponectin-dependent and Adiponectin-independent signalling that may result in the neurodevelopmental and retinal phenotypes, respectively.

P04.032.A A novel hypothesis on Choroideremia manifesting female carriers: could *CHM* in-frame variants exert a dominant negative effect? A case report

Niccolò Di Giosaffatte[1;2], *Michele Valiante[1], Stefano Tricarico[3], Giulia Parise[1;2], Anna Maria De Negri[4], Guido Ricciotti[5], Florean Lara[1], Alessandro Paiardini[6], Irene Bottillo[1;7], Paola Grammatico[1;2]*

[1]San Camillo Forlanini Hospital, Laboratory of Medical Genetics, Roma, Italy; [2]Sapienza University of Rome, Department of Experimental Medicine, Roma, Italy; [3]ASL Roma C, Roma, Italy; [4]San Camillo Forlanini Hospital, Neuro-Ophthalmology Clinic, Roma, Italy; [5]University of Parma - Hospital, Department of Ophthalmology, Parma, Italy; [6]Sapienza University of Rome, Department of Biochemical Sciences "A. Rossi Fanelli", Roma, Italy; [7]Sapienza University of Rome, Department of Molecular Medicine, Roma, Italy

Background/Objectives: Choroideremia is a X-linked recessive condition presenting in males with progressive retinal degeneration and visual loss. It is associated with variants in *CHM* gene that lead to loss of REP-1 expression/function which is required for Rab prenylation by Rab geranylgeranyl transferase (GGTA). Even though female carriers are predicted to be not affected by the disease, a wide phenotypic spectrum has been reported.

Methods: We describe a family with a novel CHM pathogenic splicing variant. The variant, initially found in a 63 female proband with impaired visual acuity and severe retinal degeneration, segregated in the 31 years old daughter and the 37 years old son, both presenting with fundus anomalies.

Results: mRNA studies revealed a shorter *CHM* isoform lacking exon 10 without alteration of the reading frame. Molecular modelling of the ternary REP-1/Rab/GGTA protein complex, predicted significant impairing of REP-1/Rab binding without alteration of REP-1/GGTA interaction.

Conclusion: While chromosome X inactivation (XCI) skewing has been proposed as putative mechanism for choroideremia manifestation in female carriers, some evidence suggest that *CHM* could variably escape from XCI. We hypothesize that, in the two females, the biallelic expression of *CHM* could have led to the production of both the mutant and wild type REP-1. The mutant isoform, sequestrating GGTA, could have reduced its availability for prenylation of Rab proteins, thus exerting a dominant-negative effect which contributed to disease manifestation. More studies regarding the escape of *CHM* from XCI are warranted as this could open new possibilities in understanding clinical heterogeneity in female carriers.

P04.033.B Functional evaluation of *CNGB3* variants associated with Achromatopsia for their potential to affect mRNA splicing

Peggy Reuter[1], *Katharina Rawnsley*[1], *Bernd Wissinger*[1], *Susanne Kohl*[1]

[1]*Institute for Ophthalmic Research, Molecular Genetics Laboratory, Tübingen, Germany*

Background/Objectives: Achromatopsia is a rare congenital retinal disorder caused by impaired cone photoreceptor function. *CNGB3* accounts for the majority of ACHM cases and encodes the modulatory B3 subunit of the cyclic nucleotide-gated channel. Several variants have been described that are located at or in proximity to exon-intron junctions but do not affect the canonical splice sites essential for mRNA splicing. Such variants are often of uncertain significance. To understand their impact on *CNGB3* splicing, in vitro minigene splice assays were conducted.

Methods: Preferentially multi- but also single-exon minigenes were created by amplifying wild-type *CNGB3* exons and flanking intronic regions, followed by cloning into the pSPL3 exon trapping vector. Mutant constructs were generated by in vitro mutagenesis. Wild-type or mutant minigenes were transfected into HEK293T cells. After RNA isolation and cDNA synthesis, PCR amplified splice products were analyzed by direct sequencing or sequencing of subcloned fragments.

Results: Of the 20 variants examined, 80% were initially classified as VUS. Minigene splice assays showed no effect on splicing for 3 variants. For the remaining 17 variants exon skipping, intron retention and/or the use of cryptic splice sites could be confirmed. Using these minigene data, 13 VUS were re-classified as (likely) pathogenic, and 2 were deemed likely benign. One variant was confirmed as pathogenic, while 3 variants initially classified as likely pathogenic were re-categorized as pathogenic.

Conclusion: Using the in vitro Minigene splice assay, 94% of the uncertain variants were successfully reclassified.

Grants: Deutsche Forschungsgemeinschaft (DFG) project number: KO 2176/3-2, 398539671.

Background: Consanguinity offers a unique opportunity to unveil novel gene-phenotype correlations, as children of consanguineous parents exhibit significantly higher genomic homozygosity, providing an ideal setting for identifying high-impact genomic variants associated with autosomal recessive disorders. Pakistan and Iran, characterized by high rates of consanguineous marriages (up to 70% and 38.6%, respectively), serve as valuable populations for such investigations.

Methods: This study encompasses the genetic analysis of 244 consanguineous families (913 individuals) from Pakistan and Iran, with two or more offspring with Retinal Disorders. Whole exome sequencing (WES) was conducted on affected individuals, followed by genotyping of potential candidate variants in all family members, including parents and siblings.

Results: Among the families with known Inherited Retinal Disorder (IRD) genes, the diagnostic yield was 71% (174 out of 244 families). In the 70 undiagnosed families, several novel candidate genes were identified including, *MOB1A* (NM_018221:c.503C>G:p.Ser168Cys), *CCDC180* (NM_020893:c.1969_1970del: p.Asn657ArgfsTer10), *PLA2G3* (NM_015715:c.601C>T:p.Arg201Ter), *ATP8A1* (NM_006095:c.3043C>T:p.Pro1015Ser), and *MPHOSPH6* (NM_005792:c.414T>G: p.Tyr138Ter). Notably, *PLA2G3* and *CCDC180* have been associated with ciliary dysfunction which has previously been linked to various ocular diseases. A $Ccdc180^{-/-}$ mouse model was shown to exhibit pronounced ocular phenotypes. MOB1A, a regulator of YAP1 activity, has implications in IRDs. Lastly, while *ATP8A1* and *MPHOSPH6* are expressed in the eye, their roles in visual function remain unclear.

Conclusions: This study underscores the effectiveness of WES in unraveling the genetic basis of IRDs in consanguineous families. The identification of novel candidate genes enhances our understanding of molecular pathways involved in these disorders, paving the way for future therapeutic interventions.

Genetics, University of Oxford, Oxford, United Kingdom; [3]NIHR Biomedical Research Centre, Oxford, United Kingdom; [4]University College London, Department of Cell and Developmental Biology, London, United Kingdom; [5]West Midlands Regional Clinical Genetics Service and Birmingham Health Partners, Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom

Consortium: Genomics England Research Consortium

Background/Objectives: Anophthalmia, microphthalmia and coloboma (AMC) form a spectrum of rare congenital eye anomalies; >50% of cases exhibit associated systemic features. AMC is genetically heterogenous: >130 genes are routinely tested for these disorders, including members of the Wnt signalling pathway. Essential to the secretion of all Wnt proteins is the transmembrane receptor Wntless (WLS), recently implicated in AMC in three out of seven families with Zaki syndrome.

Methods: To determine the role of *WLS* in AMC, we analysed whole exome/genome sequencing data of individuals with AMC from 174 UK families, the Deciphering Developmental Disorders (DDD) study (CAP69) and the 100,000 Genomes Project, and then generated a CRISPR-Cas9 zebrafish *wls* knockout model.

Results: We identified two individuals with rare biallelic *WLS* variants inherited from unaffected parents and predicted damaging. Individual 1 presented with bilateral microcornea, colobomas, microcephaly, ear and renal anomalies, and developmental delay. She carried a maternal stop-gain variant (c.G443A;p.W148X) and a paternal missense variant (c.G473A;p.R158Q). Individual 2 presented with bilateral microphthalmia, colobomas, cleft lip, preauricular tags, renal anomalies, cryptorchidism and developmental delay, and carried a homozygous missense variant (c.C1261T;p.R421W). Our zebrafish knockout models exhibited a truncated body axis, consistent with the short stature observed in patients with Zaki syndrome, but no AMC phenotypes. However, coloboma was observed in *wls* knockouts performed in AMC-sensitized genetic backgrounds.

Conclusion: Our new cases support AMC as part of the phenotypic spectrum associated with human *WLS* variants. Furthermore, the zebrafish data indicate important gene-gene interactions underlying developmental eye phenotypes.

P04.036.A IHH enhancer within neighboring *NHEJ1* intron acts in eye development and its variant causes microphthalmia, anophthalmia and coloboma

Ohad Wormser[1], *yonathan perez[1], Vadim Dolgin[1], Bahman Kamali[2], Jared Tangeman[3], Iiba gradstein[4;5], Yuval Yogev[1], Noam Hadar[1], ofek freund[1], Max Drabkin[1], Daniel Halperin[1], Inbar Irron[6], Erika Grajales-Esquivel[3], Katia Del Rio-Tsonis[3], Ramon Birnbaum[6], Gidon Akler[7;8], Ohad Shmuel Birk[1;9]*

[1]Ben Gurion University of the Negev, The Morris Kahn Laboratory of Human Genetics, National Institute for Biotechnology in the Negev and Faculty of Health Sciences, Be'er Sheva, Israel; [2]Shaare Shalom - Mashadi Jewish Center, Medical Advisory Committee, Great Neck, United States; [3]Miami University, Department of Biology and Center for Visual Sciences, Oxford, United States; [4]Soroka Medical Center, Department of Ophthalmology, Be'er Sheva, Israel; [5]Ben Gurion University of the Negev, Be'er Sheva, Israel; [6]Ben Gurion University of the Negev, Department of Life Sciences, Be'er Sheva, Israel; [7]Precision Medicine Insights, GREAT NCK PLZ, United States; [8]TOVANA Health, Houston, United States; [9]Soroka Medical Center, Genetics Institute, Be'er Sheva, Israel

Background/Objectives: Microphthalmia, anophthalmia and ocular coloboma (MAC) constitute a phenotypic continuum, resulting from incomplete choroid fissure fusion. We set out to unravel the molecular mechanism of autosomal recessive isolated MAC in inbred Iranian Jewish kindreds.

Methods: Homozygosity mapping, whole genome sequencing, segregation analysis and population screening, ATAC-seq library preparation and sequencing, mouse and chicken embryonic studies, enhancer reporter assays.

Results: Genetic studies identified a 0.5Mb disease-associated chromosome 2q35 locus (maximal LOD score 6.8) harboring a single-nucleotide intronic founder variant in *NHEJ1*, not predicted to affect NHEJ1. Notably, a nearby intronic deletion in the canine *NHEJ1* ortholog is related to a coloboma-like phenotype called "Collie eye anomaly". The human *NHEJ1* intronic variant lies in the core of PAX6's predicted binding site. Furthermore, it lies within a known limb-development enhancer in mice, affecting the neighboring gene, Indian hedgehog (Ihh). Extracellular signaling through Ihh was previously shown to be involved in eye development in mice, and haploinsufficiency of Ihh in chickens causes the "Creeper" phenotype with its microphthalmic and colobomatous eyes. Through extensive mouse and chicken molecular embryonic studies, we demonstrated that the *Ihh* enhancer drives gene expression in the developing eye, and that the variant identified affects this enhancer activity.

Conclusion: We delineate an Ihh enhancer active in mammalian eye development whose mutation causes human MAC. We highlight disease causation by an intronic mutation affecting the expression of a neighboring gene, unraveling novel molecular pathways of eye development.

P04.037.B Matching patients with ultra-rare inherited retinal diseases using deep retinal phenotype representations from Eye2Gene

Alexander Hustinx[1], *William Woof[2], Kristina Pfau[3;4], Larissa Mattern[5], Tibor Karl Lohmann[6], Miriam Elbracht[5], Frank G. Holz[3], Peter Krawitz[1], Nikolas Pontikos[2], Behnam Javanmardi[1]*

[1]University Hospital Bonn, Institute for Genomic Statistics and Bioinformatics, Bonn, Germany; [2]University College London, Institute of Ophthalmology, London, United Kingdom; [3]University Hospital Bonn, Department of Ophthalmology, Bonn, Germany; [4]University Hospital Basel, Department of Ophthalmology, Basel, Switzerland; [5]University Hospital RWTH Aachen, Institute for Human Genetics and Genomic Medicine, Aachen, Germany; [6]University Hospital RWTH Aachen, Department of Ophthalmology, Aachen, Germany

Background/Objectives: Inherited retinal diseases (IRDs) are a group of rare monogenic conditions affecting about 1 in 3000 people. Most IRDs exhibit distinctive retinal phenotypes observable through various imaging modalities. Utilizing artificial

intelligence, trained on large image datasets linking retinal phenotypes to the corresponding syndromes, ophthalmologists can be assisted in identifying these patterns. Eye2Gene's deep learning algorithm, trained on the largest available imaging dataset of IRD patients using three different imaging modalities (fundus autofluorescence, infrared reflectance, and spectral-domain optical coherence tomography), achieves expert-level accuracy in genetic diagnosis for the 36 most prevalent IRDs (Pontikos et al. 2022). However, this 'supervised' method requires including the to-diagnose IRD in the training set, which for ultra-rare conditions can be difficult.

Methods: To enable the identification of ultra-rare IRDs, we adopt a strategy similar to GestaltMatcher (Hsieh et al. 2022). We construct a high-dimensional feature space, referred to as the clinical retinal phenotype space (CRPS), using the penultimate layer of Eye2Gene's deep learning architecture. Different disorders occupy different regions in this 2048-dimensional CRPS.

Results: We show that the inter-case distances within CRPS establish syndromic similarity, providing a quantitative means for matching patients with identical molecular diagnoses. We also show that the distances in CRPS can be used to match cases even if their IRDs were absent from Eye2Gene's training set.

Conclusion: We present Eye2Gene's CRPS, the first high-dimensional phenotype space for IRDs. The CRPS not only accelerates clinical diagnosis for patients with ultra-rare IRDs but also facilitates the delineation of novel retinal phenotypes.

P04.038.C Non-canonical splicing variants as genetic cause of Nance-Horan syndrome

Carolina Ruiz-Sanchez[1], *Alejandra Damián*[1;2], *Alba Martín*[1], *Carmen Ayuso*[1;2], *María José Trujillo Tiebas*[1;2], *Berta Almoguera Castillo*[1;2], *Marta Corton*[1;2]

[1]*Health Research Institute - Fundación Jiménez Díaz (IIS-FJD), Genetics Department, Madrid, Spain;* [2]*Center for Biomedical Network Research on Rare Diseases (CIBERER), ISCIII, Madrid, Spain*

Background/Objectives: The X-linked *NHS* gene codes for an essential protein in embryonic lens development and is involved in the congenital cataract (CC) related Nance-Horan syndrome. In this work, we studied the implication of several non-canonical variants in *NHS* detected in male probands with syndromic CC.

Methods: Clinical exome sequencing and/or functional splicing assays were performed. RNA assays were carried out from blood and/or in vitro minigene constructs using RT-PCR and nanopore sequencing to validate the potential splicing deregulation of synonymous and non-canonical *NHS* variants.

Results: First, we identified the synonymous variant NM_198270.4: c.1008A>G in exon 4 of *NHS*, previously unreported, in a male proband referred with a clinical suspicion of Nance-Horan syndrome. This variant arose de novo in the asymptomatic heterozygous mother and showed. In silico analysis suggested that this variant could activate an exonic cryptic donor. Similar in silico effects were predicted for synonymous and non-canonical splicing variants initially reported as benign in ClinVar. Splicing assays showed the presence of an aberrant 37-nt skipping of *NHS* exon 4, confirming the potential pathogenicity of both synonymous variants.

Conclusion: This work helped us to reclassify 2 splicing synonymous variants altering the *NHS* splicing as pathogenic. Variant c.1008A>G showed an allele-specific expression in female carriers, possibly associated with skewed X chromosome inactivation. Abnormal skipping of this exon constitutes a new pathogenic mechanism associated with *NHS*, thus synonymous variants can be potentially pathogenic and should not be overlooked in routine genetic studies.

P04.039.D Metabolic biomarkers for earlier diagnosis of retinal disease Macular Telangiectasia Type 2 (MacTel)

Ajda Kunčič[1], *Elmar Zügner*[2], *Christoph Magnes*[2], *Eva Maria Prugger*[2], *Mojca Urbančič*[3], *Darja Dobovšek Divjak*[3], *Petra Hudler*[1], *Nataša Debeljak*[1]

[1]*University of Ljubljana, Faculty of Medicine, Institute of Biochemistry and Molecular Genetics, Ljubljana, Slovenia;* [2]*JOANNEUM RESEARCH HEALTH, Graz, Austria;* [3]*University Medical Center Ljubljana, Department of Ophthalmology, Ljubljana, Slovenia*

Background/Objectives: Macular telangiectasia type 2 (MacTel) is clinically and genetically intricate bilateral retinal condition. Loss of glial cells in the macular area and degeneration of photoreceptors lead to central vision loss. Although a genetic predisposition to MacTel is suspected based on relatives' studies, the exact cause of the disease remains elusive. There is a great need to improve the current multimodal imaging diagnostics to identify the disease at earlier stages. Our pilot study aimed to identify potential disease-associated biomarkers in the liquid biopsies of MacTel patients.

Methods: Plasma and tear fluid samples were collected from patients and healthy controls (age, gender, and BMI-matched) at the Department of Ophthalmology, UMC Ljubljana. Samples were extracted using 80% methanol (v/v) and analysed using UHPLC-HRMS. Metabolites were identified based on reference lists with accurate mass and retention time. Data was analysed using PCA and ANOVA with pairwise post hoc tests.

Results: A total of 375 known metabolites in plasma and 306 in tear fluid were detected. Notably, a trend of elevated free fatty acids and lipids was observed in plasma samples from MacTel patients. Furthermore, a significant alteration in plasma serine levels ($p = 0.0325$) was identified, and a similar reduction was found in tear fluid.

Conclusion: MacTel patients showed significant alternations in plasma and tear fluid metabolic profiles. Non-invasive collection of tear fluid makes it a potential source of diagnostic biomarkers. These preliminary findings lay the groundwork for developing a biomarker analysis protocol for earlier disease diagnosis.

Grants: ARIS grants P1-0390 and young researcher funding to the presenting author.

Necker-Enfants Malades, Centre de recherche en audiologie, Paris, France; [4]ern cranio

Background/Objectives: Vestibular and cochlear hair cells share the same embryologic origins and show physiological mechanism similarities.

The prevalence of vestibular impairment is high in children and adults with HL. For the vast majority of genetic forms for which VD is associated to HL in human, VD is also present in the animal models and responsible for motor and swimming abnormalities.

RIPOR2 was associated to both congenital profound recessive non syndromic sensorineural HL and late onset dominant HL.

Methods: Whole exome sequencing in 3 tunisian siblings suffering from congenital bilateral severe to profound hearing loss associated with vestibular dysfunction Using Crispr/Cas9 genome editing, we generated zebrafish models of the human variant.

Results: An homozygote pathogenic variation c.1561C>T (p.R521*) in RIPOR2 (RHO family interacting cell polarization regulator 2) has been identified by whole exome sequencing in the 3 siblings.

We have generated three independent zebrafish lines with mutations leading to a truncated Ripor2 protein in exon 14. Exon14 nonsense homozygous F2 larva did not exhibit a different hearing and balance behaviour from wild-type or heterozygous larva at 5dpf.

Conclusion: We describe a discrepancy between the presence of a severe VD in our patients presenting with a homozygous *RIPOR2* stop mutation and the absence of evidence for vestibular abnormality in animal models (*Ripor2* KO mouse and our Zebrafish model).

For success of future therapies, a deep phenotyping with complete vestibular tests in patients and animal models is mandatory to improve the knowledge regarding the physio-pathology and natural history of the vestibular impairments.

P04.041.B Success of Targeted Sequencing in the Search for Genetic Causes of Usher Syndrome Type 2

Dominika Ozieblo[1], *Janine Reurink*[2], *Natalia Baldyga*[1], *Henryk Skarzynski*[3], *Hannie Kremer*[2;4], *Monika Oldak*[1]

[1]*Institute of Physiology and Pathology of Hearing, Department of Genetics, Warsaw, Poland;* [2]*Radboud University Medical Center, Department of Human Genetics, Nijmagen, Netherlands;* [3]*Institute of Physiology and Pathology of Hearing, Oto-Rhino-Laryngology Surgery Clinic, Warsaw, Poland;* [4]*Radboud University Medical Center, Department of Otorhinolaryngology, Nijmagen, Netherlands*

Background/Objectives: Usher syndrome is one of the most common rare diseases in which both hearing impairment and retinitis pigmentosa coexist. Currently, four types of Usher syndrome are known and they are genetically and clinically heterogenous. The aim of the study was to characterize the genetic background of Usher syndrome type 2 (USH2) in a group of Polish patients.

Methods: A total of 55 patients with a clinical diagnosis of USH2 were recruited to the study. The DNA was isolated from blood and genetic testing was performed using three different methods: RT-PCR genotyping, targeted sequencing of the *USH2A* gene, and a multigene panel (237 genes). Segregation analysis was performed using Sanger sequencing and RT-qPCR.

Results: The cause of USH2 was identified in all patients. In 98% (54/55) of the individuals, causative variants were located in the *USH2A* gene. In one patient (2%; 1/55), a new homozygous terminating variant in the *ADGRV1* gene was identified. In *USH2A* gene, 42 different genetic variants were identified (28 known and 14 novel). A total of 74% (31/42) of the variants were deleterious. The most frequently identified genetic cause of USH2 was c.11864G>A (p.Trp3955Ter) (29 alleles). Deletions of exons 22-24 (17 alleles) and 10-11 (8 alleles) of the *USH2A* gene also contributed frequently to USH2 development.

Conclusion: Genetic testing of USH2 patients should be based on high-throughput tests that enable simultaneous identification of SNVs and CNVs. The gathered data can serve as a starting point for further genotype-phenotype association analyses.

Background/Objectives: Congenital hearing loss have a genetic origin in 80% of the cases and 10% of them are syndromic. Neonatal audiologic screening is done in many European countries and an early genetic consultation is recommended by the European societies in the standard care.

Methods: In France, patients presenting with early onset isolated or syndromic hearing loss have access to whole genome sequencing through the Plan France Medecine Genomique 2025 sequencing platforms. From 2020 to 2023, almost 500 families had whole genome sequencing for this indication on the SeqOIA platform only.

Results: Among patients assessed in our Reference Center for Genetic Deafness and presenting at the moment of the genetic consultation with isolated early onset hearing loss, whole genome sequencing identified pathogenic variations in a gene responsible for syndromic hearing loss in 4 patients: *PEX6*, *NARS2*, *BCAP31* and *GATA3*.

Conclusion: Diagnostic whole genome sequencing enables the diagnosis of rare or ultra-rare syndromic forms of genetic hearing loss before the onset of the additional clinical signs. For the patients, the diagnosis of a syndromic form allows for better care and for parents to have an accurate genetic counselling. However, "presymtomatic" diagnosis of a syndromic hearing loss with a variable prognosis can also be distressing, requiring appropriated conditions to deliver and follow those diagnoses.

Conflict of Interest: None declared

P04.043.D Genetic background of hearing loss in patients with inner ear malformations

Natalia Baldyga[1;2], *Dominika Ozieblo*[1], *Nina Gan*[1;2], *Mariusz Furmanek*[3], *Marcin Leja*[1], *Henryk Skarzynski*[4], *Monika Oldak*[1]

[1]*Institute of Physiology and Pathology of Hearing, Department of Genetics, Warsaw, Poland;* [2]*Medical Centre of Postgraduate*

Education, Doctoral School of Translational Medicine, Warsaw, Poland; [3]Institute of Physiology and Pathology of Hearing, Bioimaging Research Center, Warsaw, Poland; [4]Institute of Physiology and Pathology of Hearing, Oto-Rhino-Laryngology Surgery Clinic, Warsaw, Poland

Background/Objectives: Inner ear malformations (IEMs) can occur in an isolated manner or in genetically determined syndromes. Enlarged vestibular aqueduct (EVA) is the most frequently observed IEM often accompanied with incomplete partition type 2 (IP2) of the cochlea and a dilated vestibule. *SLC26A4* is the major IEMs gene with 25% of EVA/IP2 patients carrying two *SLC26A4* pathogenic variants. In 2017, CEVA haplotype was identified upstream of *SLC26A4* but its role remains unknown.

Methods: DNA was isolated from blood samples of 23 hearing loss (HL) patients with bilateral IEMs. Sequencing was performed using custom multigene panel (237 genes) and the TruSight One clinical exome. CEVA haplotype and segregation of variants were tested with Sanger sequencing. Minigene assay was used to evaluate the impact of novel synonymous variant on splicing.

Results: Genetic testing identified the cause of EVA/IP2 in 74% (17/23) of individuals. Two pathogenic variants in the *SLC26A4* gene were identified in 8 of them (35%). CEVA haplotype was identified in 86% (6/7) of *SLC26A4* monoallelic patients. In two individuals, cochlear hypoplasia resulted from *EYA1* mutations. In one patient, a novel *CHD7* variant was detected. Minigene assay revealed that *SLC26A4* transcripts containing synonymous c.162C>T variant produce shortened proteins.

Conclusion: Mutations in *SLC26A4* and the CEVA haplotype account for more than half of EVA/IP2 cases. Syndromic forms of HL should also be considered in patients with EVA/IP2. There is a need to look for pathogenic variants in noncoding regions of known HL genes or in novel genes.

P04.044.A New insights on the genetic basis underlying hereditary high myopia in a cohort of more than 100 Spanish families

Xènia Ferrer-Cortès[1], *Sheila Ruiz-Nogales[1], Yasmin Soares de Lima[1], Oscar Recasens[1], Pilar Mendez[1], Laura González[1], Esther Pomares[1]*

[1]IMO Grupo Miranza, Genetica, Barcelona, Spain

Background/Objectives: High myopia occurs when the spherical refractive error exceeds -6.00 diopters or the axial length of the eye is greater than 26mm. Genetic factors play a crucial role in its development, since it has an estimated heritability in more than 70% of cases, according to the literature. This study focuses on the identification of new mutations and novel genes associated with hereditary high myopia, in order to determine the most prevalent variants in the Spanish population.

Methods: DNA samples from 347 patients were analysed by Whole Exome Sequencing. In silico analyses were carried out prioritising a custom-designed panel of 549 genes related to myopia.

Results: Genetic analysis was performed in 102 families affected by high myopia. In more than 20% of them, a clear genetic cause was identified in genes already involved with high myopia. Additionally, potentially pathogenic variants in the myopia-related genes were identified in about 25% of the cases, and in 15% of the families, we identified likely pathogenic variants in candidate genes that have not yet been directly associated to myopia. These evidences lead us to estimate the genetic diagnosis in approximately 50% of the families. As we expected, most of the cases presented mutations in genes involved in the extracellular matrix's organisation (*COL9A3, COL11A1, COL11A2, COL12A1* and *FBN1*).

Conclusion: We were able to point out a possible genetic cause in about 50% of the families. Furthermore, we target new genes that could be involved in the molecular basis of hereditary high myopia, expanding the knowledge of this condition.

Conflict of Interest: None declared

P04.045.B Autosomal dominant macular dystrophy associated to *THRB* gene: identification of new families and variants

Lidia Fernández-Caballero[1;2], *Fiona Blanco-Kelly[1;2], Inmaculada Martin Merida[1;2], Pablo Mínguez[1;2;3], Saoud Tahsin-Swafiri[1;2], Ester Carreño Salas[4], María Pilar Martin Gutierrez[4], Blanca García Sandoval[4], Marta Corton[1;2], Carmen Ayuso[1;2]*

[1]Department of Genetics & Genomics, Instituto de Investigación Sanitaria-Fundación Jiménez Díaz University Hospital, Universidad Autónoma de Madrid (IIS-FJD, UAM), Madrid, Spain; [2]Center for Biomedical Network Research on Rare Diseases (CIBERER), Instituto de Salud Carlos III, Madrid, Spain; [3]Bioinformatics Unit, Instituto de Investigación Sanitaria-Fundación Jiménez Díaz University Hospital, Universidad Autónoma de Madrid (IIS-FJD, UAM), Madrid, Spain; [4]Department of Ophthalmology, Fundación Jiménez Díaz University Hospital, Madrid, Spain

Background/Objectives: Inherited retinal dystrophies (IRD) are a group of rare diseases that affects the photoreceptors and retinal pigment epithelium cells. *THRB* gene encodes thyroid hormone receptor β which produces two human isoforms (TRβ1 and TRβ2) by alternative splicing. Recently, the first *THRB* variant associated with autosomal dominant macular dystrophy, c.283+1G>A, has been described. This study aims to refine the ophthalmologic phenotype and describe a novel variant in the gene *THRB*.

Methods: *THRB* variants were identified by re-analysis of next-generation sequencing data from the FJD database (6,688 both IRD and pseudocontrols). Clinical data were collected from a self-reported ophthalmic history recorded from questionnaires and ophthalmic exam data.

Results: We identified 12 patients from 3 new families carrying variants in *THRB*. Two of them carry the variant c.283+1G>A. In a third family, we identified the novel variant c.283G>A (p.Gly95Arg), with a predicted similar splicing consequence. Patients were diagnosed with macular dystrophy or cone/cone-rod dystrophy. Most patients showed common fundus and OCT findings with disruption of subfoveal ellipsoid layers. However, onset of symptoms ranged from the first to the seventh decade, with visual acuity loss or dyschromatopsia.

Conclusion: Our results confirm a common autosomal dominant macular dystrophy phenotype associated with *THRB* with high intra-familial variability, which could be due to modifiers. Additionally, c.283+1G>A shows a likely founder effect in the Spanish population. This study confirms that *THRB* is an IRD-associate gene, therefore it should be considered in diagnostic NGS panels.

P04.046.C SMARCA4 Mutation Causes Human Otosclerosis in Humans and Mice

Matan M. Jean[1], *Max Drabkin[1], yael noy[2], Daniel Halperin[1], Yuval Yogev[1], Ohad Wormser[1], Regina Proskorovski-Ohayon[1], Vadim*

Dolgin[1], noam levaot[3], vlad brumfeld[4], shira ovadia[5], mor kishner[5], udi Kazenell[6], keren b avraham[2], Ilan Shelef[7], Ohad Shmuel Birk[1;8]

[1]Ben-Gurion University, The Morris Kahn Laboratory of Human Genetics, Faculty of Health Sciences, Beer Sheva, Israel; [2]Tel Aviv University, Department of Human Molecular Genetics and Biochemistry, Faculty of Medicine and Sagol School of Neuroscience, Tel Aviv, Israel; [3]Ben-Gurion University, Department of Physiology and Cell Biology, Beer-Sheva, Israel; [4]Weizmann Institute of Science, Rehovot, Department of Chemical Research Support, Rehovot, Israel; [5]Ben-Gurion University, Faculty of Health Sciences, beer sheva, Israel; [6]Kaplan Medical Center, Department of Otolaryngology, Rehovot, Israel; [7]Soroka Medical Center and Faculty of Health Sciences, Ben-Gurion University, Department of Radiology, Beer-Sheva, Israel; [8]Soroka University Medical Center, Genetics Institute, Beer-Sheva, Israel

Background/Objectives: Otosclerosis is a common cause of hearing loss in adults, with known familial predilection. The molecular pathogenesis of otosclerosis is mostly unknown.

Methods: Linkage analysis and whole-exome sequencing studies of an affected kindred, followed by bioinformatics data analysis and segregation studies using Sanger sequencing; Generation of CRISPR-Cas9 mutant mice harboring the human mutation in the mouse ortholog. The genetically modified mice underwent comprehensive auditory function assessments, including acoustic startle responses and auditory brainstem response tests, alongside micro-CT imaging to evaluate changes in bone structure within the otic capsule.

Results: Through combined linkage analysis and whole exome sequencing studies of seven individuals of a single kindred affected with apparently autosomal dominant heredity of otosclerosis, we identified a disease-causing variant in SMARCA4, encoding a key component of the PBAF chromatin remodeling complex. We generated CRISPR-Cas9 transgenic mice harboring the human mutation in the mouse SMARCA4 orthologue. Mutant Smarca4 + /E1548K mice demonstrated marked hearing impairment demonstrated through acoustic startle response and auditory brainstem response tests. Isolated ossicles of the auditory bullae of mutant mice exhibited a highly irregular structure of the incus bone. Their in situ micro-CT studies demonstrated anomalous structure of the incus bone, causing disruption in the ossicular chain.

Conclusion: Otosclerosis can be caused by a variant in SMARCA4, with a similar phenotype of hearing impairment and abnormal bone formation in the auditory bullae in transgenic mice carrying the human mutation in the mouse SMARCA4 orthologue.

Grants: The Morris Kahn Family Foundation.

P04.047.D Optimization of Capture Area coverage of spatial transcriptomics slide with cryosections of small specimen/ corneas

Alicja Wysocka[1], *Katarzyna Jaskiewicz[1], Małgorzata Rydzanicz[2], Rafał Płoski[2], Jakub Wozniak[3;4], Monika Udziela[5], Jacek Szaflik[5], Marzena Gajecka[1;3]*

[1]Institute of Human Genetics, Polish Academy of Sciences, Department of Cancer Genetics, Poznan, Poland; [2]Medical University of Warsaw, Department of Medical Genetics, Warsaw, Poland; [3]Poznan University of Medical Sciences, Chair and Department of Genetics and Pharmaceutical Microbiology, Poznan, Poland; [4]Poznan University of Life Sciences, Department of Genetics and Animal Breeding, Poznan, Poland; [5]Medical University of Warsaw, Department of Ophthalmology, Warsaw, Poland

Background/Objectives: Keratoconus (KTCN) is a progressive disorder of cornea characterized by its gradual thinning in the cone apex and histopathological changes noted in all five corneal layers. Due to the complexity of this tissue and the multilevel dimension of the KTCN-associated changes, a method combining and assessing both histology aspects and spatially performed whole transcriptome gene expression profiling should be implemented. Substantial technical challenges of using such protocols are sectioning and placement of the tissue on the slide.

Methods: The O.C.T.-embedded corneas, derived from KTCN patients qualified for the penetrating keratoplasty procedure, and unaffected corneas derived from deceased individuals as controls were evaluated. The microscopic H&E imaging assessment and Tissue Optimization step (Visium, 10xGenomics) were performed. Three corneal sections from each individual were placed within a single Capture Area of the Spatial Gene Expression Slide and proceeded to spatial gene expression analysis (Visium, 10xGenomics). The libraries prepared according to the manufacturer's protocol were subjected to next-generation sequencing (NovaSeq6000,Illumina).

Results: Cryosection thickness and tissue permeabilization time were successfully optimized. We managed to place three cryosections derived from one individual within a single Capture Area, measuring 6.5 × 6.5mm, from both affected and unaffected corneas. Thus, we increased the percentage of coverage and total sequencing depth threefold compared to one section per capture area, significantly improving the quality of results for low-input samples.

Conclusion: Preparation of experimental material – corneal samples according to our protocol, substantially increases the size of input data and the sequencing depth in spatial transcriptomics.

P04.048.A Diagnostic genome sequencing improves diagnostic yield in a single-center study of 100 patients with non-syndromic and syndromic hearing impairment

Nanna Dahl Rendtorff[1], *Lisbeth Tranebjærg[1;2], Mette Bertelsen[1]*

[1]The Kennedy Centre, Department of Clinical Genetics, Rigshospitalet, Copenhagen, Denmark; [2]Institute of Clinical Medicine, The Panum Institute, University of Copenhagen, Copenhagen, Denmark

Background: Hearing impairment (HI) is a common sensory disorder, which is genetically heterogeneous. Identification of causative variants underlying HI is challenging, since >100 genes for non-syndromic HI and >450 genes for syndromic HI have been reported.

Methods: 100 index patients with HI and variable additional clinical features underwent Whole Genome Sequencing (WGS) in clinical settings. The samples were analyzed using virtual gene-panels of 174 (76% of patients) or 500 genes, respectively, for patients suspected of having non-syndromic and syndromic HI. Nine patients had prior to WGS been prescreened for DFNB1, *SLC26A4*- and/or *STRC*-related HI and six using gene-panels for HI.

Results: A definite genetic diagnosis was made in 42/100 patients, distributed in 25 different genes. In total, 45 different likely pathogenic/pathogenic variants were detected, and 14 variants were novel. In addition, six patients had variants of uncertain significance (VUS) identified, where further work-up was recommended, which might change the classification to likely pathogenic. Finally, in an additional ten patients only one pathogenic variant was identified, so far. Variants in rare/recently identified genes causative of HI included *SLC12A2* and *ATOH1*.

Conclusion: WGS allowed detection of a definite or possible genetic diagnosis in ~48% of 100 cases (~53% excluding patients with unilateral HI and patients prescreened with previous NGS HI panel). Causative variants were found in >25 different genes, including both common and rare/recently identified HI genes, emphasizing the genetic heterogeneity of the condition. In non-solved selected families, the data will be re-analyzed with improved methods for detecting deep structural and intronic variants and with broader gene panels.

Conflict of Interest: None declared

P04.049.B Risk-adapted prevention and treatment in ophthalmogenetics based on a retrospective evaluation of a cohort of 455 patients

*Anica Leubner[1], Mareike Mertens[2;3], Saskia Biskup[4], Katrin Hoffmann[2], **Claudia Grünauer-Kloevekorn**[1;5], Pablo Villavicencio Lorini[2]*

[1]PraxisKlinik Augenärzte am Markt, Halle; [2]Martin-Luther-Universität Halle-Wittenberg, Institut für Humangenetik, Halle, Germany; [3]MVZ Universitätsklinikum Halle, Facharztzentrum für Pädiatrie & Humangenetik, Halle, Germany; [4]Zentrum für Humangenetik, Tübingen, Germany; [5]Martin-Luther-Universität Halle-Wittenberg, Medizinische Fakultät, Halle, Germany

Background/Objectives: We report on the ophthalmogenetic consultation and the results of molecular genetic testing and therapeutic options in 455 consecutive patients with suspected hereditary eye disease from our ophthalmogenetic consultation "rare eye diseases", which takes place since 2016.

Methods: An NGS-based in silico gene panel analysis based on exome enrichment was performed on a cohort of 455 patients during the period from 01/2019 to 01/2024 with a suspected hereditary ophthalmologic disease. Retrospectively, the diagnosis rate was determined depending on the clinical entity and the therapeutic options based on the molecular genetic results.

Results: The underlying molecular genetic cause was diagnosed in 266 patients (mean 58.5%, range 28.6% to 66.7% depending on the entity).

The highest diagnosis rate was found for hereditary retinal dystrophies (66.7 %) and diseases of the anterior segment (corneal dystrophies, 60.11 %). A lower rate was found for complex malformations (50 %) and hereditary optic atrophies (28.6 %). Therapeutic benefits were mainly seen in patients with corneal dystrophies (DMEK versus penetrating keratoplasty / limbokeratoplasty). Patients with retinal dystrophies benefited from rehabilitative measures and were assigned to study centers with gene therapy approaches.

Conclusion: Ophthalmogenetic consultation and diagnostics for suspected hereditary eye diseases are essential for prompt, personalized therapy and optical and social rehabilitation in affected families. Detailed medical history and diagnostics can optimize the detection rate and patient care can be provided quickly and adequately. Close interdisciplinary collaboration between human genetics and ophthalmology is crucial for the best possible treatment.

P04.050.C Insights into the FOXE3 Transcriptional Network from Exploration of the impact of a regulatory Variant in Complex Microphthalmia.

Lucas Fares Taie[1], *Julie Plaisancié[2], Clementine Angée[1], Elisa Erjavec[1], Isabelle Raymond Letron[3], Jean-Yves Douet[4], Mathilde Goetz[4], Catherine Vincent-Delorme[5], Ino Karemaker[6], Marijke Baltissen[6], Leonardo Valdivia[7], Yanad Abou Monsef[3], Patrick Calvas[8], Nicolas Chassaing[8], Jean-Michel Rozet[1]*

[1]Laboratoire de Génétique Ophtalmologique, INSERM U1163, Institut Imagine, Paris, France; [2]Laboratoire de Référence (LBMR) des anomalies malformatives de l'œil, Institut Fédératif de Biologie (IFB), CHU de Toulouse, Toulouse, France; [3]Ecole Nationale Vétérinaire de Toulouse (ENVT), Toulouse, France; [4]CHUVAC, Université de Toulouse, ENVT, Toulouse, France; [5]Service de Génétique Médicale, CHU de Lille, Lille, France; [6]Department of Molecular Biology, Faculty of Science, Radboud Institute for Molecular Life Sciences, Oncode Institute, Radboud University Nijmegen, Nijmegen, The Netherlands.; [7]Center for Integrative Biology, Facultad de Ciencias, Universidad Mayor, Santiago, Chile; [8]Centre de Référence des Affections Rares en Génétique Ophtalmologique (CARGO), site constitutif, CHU de Toulouse, Toulouse, France

Background/Objectives: *FOXE3* is a crucial transcription factor (TF) for lens and eye development, mutations of which cause microphthalmia associated with anterior segment dysgenesis (M-ASD). Previously, we reported a M-ASD case carrying p.Cys240* and an ultra-rare non coding regulatory variant (NCRV) in compound heterozygosity. In mice, homozygosity for the NCRV mildly affected eye development, whereas combined with a nonsense mutation it caused ASD. We aimed to understand the *FOXE3* transcriptional network in eye development by investigating how the NCRV influences *Foxe3* expression.

Methods: We conducted DNA pull-down assays and mass spectrometry, utilizing protein extracts from mouse ES, Rax-expressing ES or immortalized human epithelial lens cells, and wildtype (WT) or mutant (NCRV) oligonucleotides. TFs with differential binding were analyzed using RNAscope and siRNA-mediated silencing.

Results: 34 TFs displayed differential binding, with three being present in all three cell lines and co-localizing with *Foxe3* during ocular development. The binding of two of these three TFs was impeded by the NCRV, while there was a gain in binding for the remaining TF. Silencing these TFs in cultured lens cells from WT and homozygous NCRV mice demonstrated an impact on *Foxe3* expression.

Conclusion: We found three TFs binding to the WT or NCRV region of *FOXE3*. Two are linked to ocular malformations in mice, and one, a novel TF, binds to the WT sequence, suggesting a new role in lens development. This highlights the importance of studying unresolved cases in order to understand gene regulatory landscapes and to discover potential candidate genes for ocular malformations.

P04.051.D Processing eye samples from patients with high myopia towards DNA methylation and gene expression analyses

Joanna Swierkowska[1], *Anna Mikolajczyk-Lorkiewicz[2], Marcin Stopa[2], Malgorzata Mrugacz[3], Marzena Gajecka[1;4]*

[1]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland; [2]Department of Ophthalmology, Chair of Ophthalmology and Optometry, Poznan University of Medical Sciences, Poznan University Hospital, Poznan, Poland; [3]Department of Ophthalmology and Eye Rehabilitation, Medical University of Bialystok, Bialystok, Poland; [4]Chair and Department of Genetics and Pharmaceutical Microbiology, Poznan University of Medical Sciences, Poznan, Poland

Consortium: n/a

Background/Objectives: High myopia (HM), an eye disorder with a refractive error of ≤−6.0 diopters (D), has a multifactorial etiology with genetic and environmental factors involved. The relationship between changes in DNA methylation/gene expression and HM remains to be evaluated. The aim was to optimize protocols of processing biological material from eyes of patients with HM towards the investigation of DNA methylation and gene expression.

Methods: We have recruited 25 children with HM and 25 children without HM (<15 years old). Also, five adults with HM and five control individuals undergoing vitrectomy (a vitreo-retinal surgery) were ascertained. Patients' eyes were without inflammation, other diseases, and previous surgeries. Peripheral blood, serum, tear fluid, and conjunctival swabs as well as undiluted vitreous body and retinal samples from vitrectomy were collected.

Results: We optimized protocols for handling and storage of samples and chose commercial kits for nucleic acids isolations. We chose to place retinal samples in RNAlater and freeze vitreous body on dry ice for transport. Samples were processed for genome-wide DNA methylation analyses and RNA sequencing. Blood samples are designated for DNA/RNA isolations, serum and tear fluid for proteins and metabolites analyses, and conjunctival swabs for human and microbial DNA/RNA extractions. The influence of the type of biological material on the quality and quantity of extracted nucleic acids and obtained results will be presented.

Conclusion: Vitrectomy procedure is a good source of biological material from the eye that is normally impossible to obtain from living patients.

P05

INTERNAL ORGANS & ENDOCRINOLOGY (LUNG, KIDNEY, LIVER, GASTROINTESTINAL)

P05.001.A Phenotypic spectrum of individuals with SLC16A2 variants in MCT8 deficiency

Kirsty McWalter[1], Houda Elloumi[1], Richard Sidlow[2], Ben Willis[3], Andrew Bauer[4], **Marianne Berrens**[3]

[1]GeneDx, Gaithersburg, United States; [2]Valley Children's Hospital, Madera, United States; [3]Egetis Therapeutics; [4]Children's Hospital of Philadelphia, United States

Background/Objectives: Variants in SLC16A2 cause MCT8 deficiency, an X-linked condition associated with hypotonia, failure to thrive, neurodevelopmental impairment, and thyrotoxicosis. Pathogenic SLC16A2 variants are known in ~320 individuals, with genotype-phenotype correlations suggested. Here, we contribute a cohort with SLC16A2 variants to the phenotypic spectrum of MCT8 deficiency.

Methods: By approved IRB protocol, we queried genetic testing laboratory deidentified data for SLC16A2 variants, classified by ACMG criteria. Clinical abstraction of medical records was performed, including Human Phenotype Ontology (HPO) terms reflecting clinical features and symptoms. Descriptive statistics were generated to define cohort characteristics.

Results: We identified 57 cases with likely pathogenic/pathogenic variants in SLC16A2 and 47 individuals with variants of uncertain significance (VUS). At time of testing, 49 individuals were ≤3yrs old; 10 individuals were adults (≥20yrs). Most cases (101/104) were identified by exome sequencing (ES), the remaining by panels or single gene sequencing. In total, 506 different HPO terms were associated with 99 individuals (332/506 terms seen only once). Common HPO terms included: 'global developmental delay' (75/99); 'generalized hypotonia' (37/99); 'seizure' (30/99); 'delayed speech and language development' (30/99); 'failure to thrive' (28/99); 'intellectual disability' (27/99); 'gastroesophageal reflux' (25/99); 'feeding difficulties' (24/99); 'constipation' (23/99); and 'delayed gross motor development' (20/99). HPO terms related to thyroid function and/or hormone levels were seen in 9/99 individuals.

Conclusion: This study indicates ES can be beneficial in diagnosing MCT8 deficiency, characterizing genotype-phenotype correlations in individuals with SLC16A2 variants, and targeting education on the benefits of confirmatory thyroid function testing including TSH, free T4, and T3.

P05.002.B Deep phenotyping of patients with congenital anomalies of the kidney and urinary tract (CAKUT) and *PAX2* loss-of-function (LOF) variants

Leonie Greipel[1;2], *Helge Martens[1], Lina Werfel[1;2], Robert Geffers[3], Bernd Auber[1], Anna Bjerre[4], Nele Kanzelmeyer[2], Dieter Haffner[2], Ruthild G. Weber[1]*

[1]Hannover Medical School, Department of Human Genetics, Hannover, Germany; [2]Hannover Medical School, Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover, Germany; [3]Helmholtz Centre for Infection Research, Genome Analytics Research Group, Braunschweig; [4]Oslo University Hospital, Division of Pediatric and Adolescent Medicine, Oslo

Background/Objectives: Patients with renal coloboma syndrome, caused by *PAX2* variants, may develop end-stage kidney disease (ESKD). This study aimed to identify and characterize patients with *PAX2* LOF variants in a CAKUT cohort, and to compile kidney function data from previously reported CAKUT patients with *PAX2* LOF variants.

Methods: Whole-exome sequencing was performed on 258 pediatric CAKUT patients. Patients carrying *PAX2* LOF variants underwent deep phenotyping. Twelve pertinent studies from the literature were reviewed.

Results: Six of 258 (2.3%) CAKUT patients carried heterozygous pathogenic *PAX2* LOF variants. Mean age of onset of ESKD was 9.6 years in 56 patients with *PAX2* LOF variants and ESKD reported here and previously. In our cohort, albuminuria was significantly higher, on average in the nephrotic range, in three patients with *PAX2* LOF variants and ESKD versus 41 patients with wildtype *PAX2* and ESKD. Phenotypic variability was highlighted by (i) three patients carrying the same *PAX2* variant presenting either with early-onset ESKD and marked albuminuria or CKD stage 3 and no severe albuminuria, and (ii) two parents carrying *PAX2* variants presenting either with adult-onset ESKD due to focal segmental glomerulosclerosis or sonographically normal kidneys.

Conclusion: As CAKUT patients with *PAX2* LOF variants are prone to marked albuminuria and early-onset ESKD, close monitoring and, if necessary, antiproteinuric measures are recommended. Then again, kidneys of *PAX2* LOF variant carriers may appear normal in early adulthood. Therefore, evaluation of

related living donors of CAKUT patients with *PAX2* LOF variants should include screening for *PAX2* variants.

P05.003.C Screening for MUC1 mutations based on a customized HTS library offers a new, complete approach to diagnosing patients with ADTKD.

Jose María García-Aznar Navajas[1], *Lara Besada[1], Ricardo Pan[1], Emilia Maneiro[1]*

[1]Healthincode, Immunology & Nephrology, La Coruña, Spain

Background/Objectives: *MUC1* has traditionally been a challenge to screen for genetic mutations because of its VNTR region. This region consists of repeated modules of 60 repeats, showing high diversity between individuals from 20 up to 125 times. Due to the complex nature of the analysis, conventional WES uncovers this region, so other techniques like SNapShot have been used as standard methodology targeted to the most frequent cause of MUC1-ADTKD (c.428dupC). We propose an alternative approach to analyze the MUC1-VNTR.

Methods: We designed an enriched library by using *SureSelect* HS protocol (*Agilent Technologies*), to be sequenced, including 25 probes that covered the MUC1-VNTR region. An especial computational filtering was applied to examine the VNTR region. We used this procedure in 1005 patients with unaffiliated CKD.

Results: We found four relevant variants in 16 patients (1.6%). We identified 7 patients with the variant c.428dupC. One patient harbored a similar change in a different module (c.488dupC). Moreover, this approach allowed us to detect other previously undescribed variants, potentially deemed disease-causing mutations *(table 1*).

MUC1 variant	No. patients	Domain	ACMG classification
c.428dupC; p.Ala144Serfs*86	7	VNTR	P
c.488dupC; p.Ala164Serfs*106	1	VNTR	P
c.54_55insT; p.Thr19Tyrfs*7	1	Extracellular	LP
c.888G>A; p.Trp296*	1	Transmembrane	LP
c.548G>A; p.Val260Ile	6	SEA	VUS-hot

Conclusion: We highlight the importance to completely analyze the whole sequence of *MUC1* in the context of ADTKD and unaffiliated CKD. Other prevalent mutations in *MUC1* could have been underestimated. The use of this HTS-customized library with an accurate pipeline adapted to MUC1-VNTR synthetizes the genetic analysis, improving the cost-effectiveness of techniques and diagnosis.

Background/Objectives: Primary ciliary dyskinesia (PCD) is a rare airway disorder caused by defective motile cilia. Only male patients have been reported with pathogenic mutations in X-linked *DNAAF6*, which result in the absence of ciliary dynein arms, whereas their heterozygous mothers are supposedly healthy. Our objective was to assess the possible clinical and ciliary consequences of X-chromosome inactivation (XCI) in these mothers.

Methods: XCI patterns of 6 mothers of male patients with *DNAAF6*-related PCD were determined by DNA-methylation studies and compared to their clinical phenotype (6/6 mothers), as well as their ciliary phenotype (4/6 mothers), as assessed by immunofluorescence and high-speed videomicroscopy analyses. The mutated X chromosome was tracked to assess the percentage of cells with a normal inactivated *DNAAF6* allele.

Results: The mothers' phenotypes ranged from absence of symptoms to mild/moderate or severe airway phenotypes, closely reflecting their XCI pattern. Analyses of the symptomatic mothers' airway ciliated cells revealed the coexistence of normal cells and cells with immotile cilia lacking dynein arms, whose ratio closely mirrored their XCI pattern.

Conclusion: This study highlights the importance of searching for heterozygous pathogenic *DNAAF6* mutations in all female relatives of male PCD patients with a *DNAAF6* defect, as well as in females consulting for mild chronic respiratory symptoms. Our results also demonstrate that about 30% normal ciliated airway cells sufficed to avoid severe PCD, a result paving the way for gene therapy.

P05.005.C Three novel patients with lethal lung developmental disorders caused by variants in genes from the SHH-FOXF1 and TBX4-FGF10 signaling pathways

Katarzyna Bzdęga[1], *Gail Deutsch[2], Małgorzata Rydzanicz[3], Elżbieta Rafińska-ważny[4], Witold Błaż[5;6], Anna Terpin[7], Rafał Płoski[3], Tomasz Szczapa[8], Justyna Karolak[1]*

[1]Chair and Department of Genetics and Pharmaceutical Microbiology, Poznan University of Medical Sciences, Poznań, Poland;

[2]Department of Pathology, University of Washington School of Medicine, Seattle, United States; [3]Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland; [4]Department of Neonatology, Medical Center "Ujastek", Kraków, Poland; [5]Department of Neonatal and Intensive Care, Rzeszów Provincial Hospital No. 2, Rzeszów, Poland; [6]Faculty of Medicine, University of Rzeszów, Rzeszów, Poland; [7]Pro-Familia Hospital, Rzeszów, Poland; [8]II Department of Neonatology, Neonatal Biophysical Monitoring and Cardiopulmonary Therapies Research Unit, Chair of Neonatology, Poznan University of Medical Sciences, Poznań, Poland

Background/Objectives: Lethal lung developmental disorders (LLDDs), including alveolar capillary dysplasia with misalignment of the pulmonary veins (ACDMPV), acinar dysplasia (AcDys), congenital alveolar dysplasia (CAD), and primary pulmonary hypoplasias (PH) are rarely diagnosed lung anomalies in neonates, characterized by severe pulmonary arterial hypertension (PAH), refractory to treatment. In addition to histopathological evaluation, genetic testing plays a key role in accurate diagnosis of LLDD. In most newborns, LLDD is caused by abnormalities in genes from the SHH-FOXF1 (ACDMPV) and TBX4-FGF10 (AcDys, CAD, and PHs) signaling pathways. Here, we present molecular and histopathological findings in three Polish patients with LLDD.

Methods: Using whole-genome sequencing and histopathological lung evaluation, we analyzed three newborns who died due to respiratory failure within the neonatal period.

Results: Molecular analyses in Patient 1 revealed a heterozygous c.121G>T (p.Gly41Ter) variant in *TBX4* that was previously identified in two patients with PAH. In Patient 2, a novel heterozygous c.445C>T (p.Gln149Ter) variant in *FOXF1* was identified. A heterozygous recurrent ~2.2 Mb CNV deletion at 17q23.1q23.2 encompassing *TBX4* was detected in Patient 3. Histopathological assessment indicated LLDD in all three newborns, including PH (Patient 1), ACDMPV (Patient 2), and AcDys (Patient 3).

Conclusion: In neonatal cases of severe respiratory distress with PAH of an unknown etiology LLDD should be considered and confirmed by both genetic testing and histopathological evaluation. Our results further indicate that abnormalities in genes from the SHH-FOXF1 and TBX4-FGF10 signaling pathways, involved in human lung development, contribute to LLDD.

P05.006.B Kidney-Genetics – a reproducible and curated database of kidney-disease associated genes

Constantin Wolff[1], *Nina Rank*[1], *Jan Halbritter*[2], *Bernt Popp*[3]

[1]*Charité – Universitätsmedizin Berlin, Max Rubner Center for Cardiovascular Metabolic Renal Research, Berlin, Germany;* [2]*Charité – Universitätsmedizin Berlin, Department of Nephrology and Medical Intensive Care, Berlin, Germany;* [3]*Berlin Institute of Health, Center of Functional Genomics, Berlin, Germany*

Consortium: None.

Background/Objectives: Genomic insights are changing kidney disease (KD) diagnostics and treatment. Hundreds of monogenic KD genes have been identified to aid diagnosis, management, and monitoring. Lack of a unified and standardized KD gene database causes diagnostic blind spots and comparability issues in kidney genetics studies. To fill this gap, we created "Kidney-Genetics.org", a regularly updated, automated, and publicly accessible KD gene database.

Methods: KD-associated genes were obtained from (1) PanelApp, (2) a comprehensive literature review, (3) clinical diagnostic panels, (4) HPO-based searches in rare disease databases, and (5) automated PubTator-based search. Genes found in over two resources had high-evidence. Based on ClinGen recommendations, we created "Gene-Curator.org" for manual curation into entities and assignment of diagnostic genes to KD groups (e.g., syndromic vs. isolated; adult vs. pediatric; cystic, nephrotic).

Results: Kidney-Genetics.org contains annotations on gene expression, kidney phenotype, inheritance mode, disease onset, possible syndromic disease mode, and genetic variation for 3025 kidney-associated genes. The five analyzed sources yielded 534, 822, 956, 789, and 2158 genes. Of the 3025 genes, 598 (19.8%) are in two or more of the analyzed information sources, indicating high confidence and diagnostic potential. Of these high-evidence genes, 526 (88.0%) are in at least one and 56 (9.4%) in all 10 comprehensive diagnostic laboratory panels analyzed. We show that phenotypic groups correlate with functional gene clustering.

Conclusion: Kidney-Genetics.org helps clinicians, geneticists, and researchers analyze genomic data and understand diverse KDs. Our database tracks kidney research and diagnostics using a standardized pipeline and automated system.

P05.007.C Interpretation of risk factors and incidental findings in a patient with acute kidney injury requiring kidney replacement therapy

Nicole Meier[1], *Ulla T. Schultheiss*[1;2;3], *Eva Wohlleber*[1], *Juergen Kohlhase*[1]

[1]*Synlab MVZ Humangenetik Freiburg, Freiburg, Germany;* [2]*Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center-University of Freiburg, Freiburg, Freiburg, Germany;* [3]*Department of Medicine IV, Nephrology and Primary Care, Faculty of Medicine and Medical Center-University of Freiburg, Freiburg, Germany*

Background: We report a sudden-onset acute kidney injury (AKI) case with no prior symptoms, requiring kidney replacement therapy. The patient's kidney function rapidly declined, with a creatinine level of 7.3 mg/dL and a proteinuria of 0.8 g/g. Nephropathology revealed preglomerular vascular thrombotic microangiopathy, arteriosclerosis, glomerular ischemia, severe tubular atrophy, and interstitial fibrosis (40-50%). No evidence of immunologic or complement-related glomerulonephritis or amyloidosis was found. The nephrologist referred the patient for diagnostics to assess recurrence risk before kidney transplantation.

Methods: We performed whole-exome sequencing (WES). Enrichment of target regions by the Twist Enrichment Kit for the Twist-Core/RefSeq Exome (Twist Bioscience). DNA sequencing (Next-Generation Sequencing, NGS) on Illumina NovaSeq 6000. Reference genome: GRCh37 (hg19). Bioinformatic analysis and gene dosage analysis via VarVis (Limbus Medical Technologies GmbH).

Results: WES detected no monogenic etiology but several risk factors for atypic hemolytic uremic syndrome (aHUS): a heterozygous variant in *CFHR5:* c.1411G>C, p.(Gly471Arg), a heterozygous deletion of *CFHR1/3* (confirmed by MLPA) and the CFH-H3 risk-haplotype. Incidentally homozygous FV-Leiden was detected.

Results were discussed with an interdisciplinary team. In this gremium we elucidated, that none of the variants were causal for the patients phenotype, but F5 should be taken into account regarding the functionality of the transplant. Regarding the risk-factors the transplanting facility may keep a complement suppressing therapy at the ready for the transplant procedure.

Conclusions: Even if no monogenic cause for the patient's phenotype was detected we should take risk factors and incidental findings into account regarding further therapeutic steps.

P05.008.D Odyssey of the first female pioneer with an intragenic *TCF12* deletion in hypogonadotropic hypogonadism 26

Dilsu Dicle Erkan[1], *ABDULLAH SEZER*[2;3], *Prof Dr Semra Cetinkaya*[4], *Naz Guleray*[1]

[1]*Hacettepe University Faculty of Medicine, Medical Genetics, Ankara, Türkyie;* [2]*Health Science University Dr. Sami Ulus Obstetrics and Gynecology, Children Health and Disease Training and Research Hospital, Medical Genetics, Ankara, Türkyie;* [3]*Health Science University Ankara Etlik City Hospital, Medical Genetics, Ankara, Türkyie;* [4]*Health Science University Dr. Sami Ulus Obstetrics and Gynecology, Children Health and Disease Training and Research Hospital, Pediatric Endocrinology, Ankara, Türkyie*

Background/Objectives: The *TCF12* gene, part of the basic helix-loop-helix transcription factor family, is linked to craniosynostosis type-3 (MIM:615314) and ultra-rare hypogonadotropic hypogonadism 26 (HH26) (MIM:619718). Previously, isolated HH26 cases without craniosynostosis were limited to nine individuals, with no clinical information on women. Here we present the first thoroughly described female case with HH26.

Methods: Whole exome sequencing (WES;TwistExome-2.0) was complemented by CNV analysis (Muskat) and SNP-microarray (Illumina) for structural variant confirmation.

Results: A 15-year-old female, referred for delayed puberty and anosmia. The Tanner-stage I breast development and prepubertal pelvic ultrasonography results with low gonadotropin levels suggested Kallmann Syndrome. A year later estradiol was commenced to regulate menstruation. WES did not reveal any pathogenic SNVs but identified a novel intragenic deletion in *TCF12* spanning exons 6-8 through CNV analysis, which was further confirmed by microarray. This marks the first association of a structural variant with HH26. Intriguingly the individual also had multifocal papillary thyroid cancer, potentially related to *TCF12* impairment as previously *TCF12* somatic mutations associated with several malignancies.

Conclusion: The comprehensive detailing of this individual not only enrich the phenotypic spectrum in females but also expand the mutational landscape of this pleiotrophic disorder. Our findings reiterate the importance of integrating CNV analysis into next-generation sequencing workflows when clinical symptoms strongly suggest a genetic origin. Lastly, given the lack of genotype-phenotype correlation of *TCF12*-associated entities where identical mutations present as either isolated craniosynostosis or HH26, conducting a thorough systemic assessment, including radiological examination, and scrutinizing nuanced phenotypic features particular to females, will aid tailored phenotype-specific counseling.

P05.009.A Molecular-genetic analysis of Bulgarian patients with nephrotic disorders

Mila Sleptsova[1], *Slavena Atemin*[1], *Tihomir Todorov*[1], *Aleš Maver*[2], *Borut Peterlin*[2], *Albena Todorova*[1;3]

[1]*Genetic Medico-Diagnostic Laboratory "Genica", Molecular Genetics, Sofia, Bulgaria;* [2]*UMC Ljubljana, Clinical Institute of Medical Genetics, Ljubljana, Slovenia;* [3]*Medical University Sofia, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria*

Background/Objectives: In 2018 630 per million people in Bulgaria suffered from end stage renal disease. It is considered that the fifth most common cause of kidney failure are genetic renal disorders. Inheritable diseases can be avoided through genetic analysis, medico-genetic consultation, and family planning. We present 11 cases of nephrotic disease, where WES was used to determine the genetic etiology of the disease.

Methods: WES was performed in all 11 cases and kidney disease-related genes were analysed based on the phenotype observed. Sanger sequencing was used to confirm and segregate the variants of interest. A total of 43 samples were tested throughout the analysis.

Results: In total 9 cases were successfully concluded (or 82%) and of the reported genetic variants (presented below) 54% are novel. As a result of the high percentage genetically clarified cases, 2 prenatal samples and 3 relatives were additionally tested.

Case	Gene	Genetic Variant	Zygosity	Type of variant
1	*PKD1*	c.8354G>A	heterozygous	missense
2	*PKD1*	c.11494_11505del	heterozygous	in-frame deletion
3	*PKD1*	c.7937T>C	heterozygous	missense
	TSC2	c.3132-3T>C	heterozygous	intronic
4	*PKD1*	c.5615T>G	heterozygous	missense
	DSTYK	c.1558-4dup	heterozygous	intronic
5	*PKHD1*	c.6038del	heterozygous	frameshift deletion
		c.6866-2A>T	heterozygous	splice site
6	*MEFV*	c.2084A>G	heterozygous	missense
7	*NPHP4*	c.3292G>A	assumed homozygous	missense
8	*LAMA5*	c.8395C>G	heterozygous	missense
		c.4761C>A	heterozygous	synonymous
9	*COL4A5*	c.1339+1G>A	heterozygous	splice site

Conclusion: The diverse genetic variants in the presented cases enrich the spectrum of molecular-genetic diagnostics of nephrotic diseases in Bulgarian patients. Furthermore, the genetic analyses have been crucial in future family planning.

P05.010.B Associations of genetic factors with diabetes complications: an umbrella review

Xuan Zhou[1], *Nan Yang*[2], *Wei Xu*[1], *Xue Li*[2], *Athina Spiliopoulou*[1], *Evropi Theodoratou*[1]

[1]*Usher institute, Edinburgh, United Kingdom;* [2]*Zhejiang University, Hang Zhou Shi, China*

Background/Objectives: To comprehensively assess evidence from published systematic review and meta-analyses (SRMAs) on the genetics of diabetes complications.

Methods: A systematic literature search conducted in Medline and Embase identified 63 non-overlapping SRMAs. Meta-analyses were re-conducted to compare diabetes with and without complications using multiple genetic models. Associations were evaluated using Venice criteria and Bayesian false-discovery probability (BFDP); graded as highly credible, credible, and not credible. Highly credible and credible associations were contrasted to recent large genome-wide association studies (GWASs) of diabetes complications.

Results: Highly credible evidence was discovered for *MCP-1* (rs1024611) and *VEGF* (rs3025039) and type 2 diabetic retinopathy (DR); *ACACB* (rs2268388), *ACE* (Ins/Del), *MTHFR* (rs1801133), and *TCF7L2* (rs7903146) and type 2 diabetic kidney disease (DKD); and *SOD2* (rs4880) and type 1 diabetic peripheral neuropathy (DPN). When combining type 1 and 2 diabetes highly credible evidence was discovered for *ACE* (Ins/Del), *AKR1B1* (rs759853) and *ENPP1* (rs1044498) and DKD, and *EPO* (rs1617640) for the combined endpoint of DR and DKD. None of these associations were directly replicated in the latest GWASs for DR and DKD, however, another single nucleotide polymorphism (SNP), rs55853916 at *TCF7L2* had been detected as a GWAS hit for DKD.

Conclusion: This umbrella review rigorously assessed evidence on the genetics of diabetes complications, highlighting ten candidate genes not detected in recent GWASs. Mechanistic or bioinformatic studies are warranted to further assess the role of these genes in the pathology of diabetes complications and their potential as drug targets.

P05.011.C The assessment of CDX1, IHH, SHH, GATA4, FOXA2, FOXF1 in congenital intra-abdominal adhesions

Helēna Freijere Pope[1;2], *māra pilmane*[1], *anna junga*[1], *aigars pētersons*[1;3]

[1]*Riga Stradiņš University, Department of Morphology, Rīga, Latvia;* [2]*Children's Clinical University Hospital, Medical Genetics, Rīga, Latvia;* [3]*Children's Clinical University Hospital, Surgery, Rīga, Latvia*

Background/Objectives: Congenital intra-abdominal adhesions are a rare condition that can result in a small bowel obstruction more in pediatric populations. The cause remains unknown, and the importance of congenital bands is related to the difficulty of diagnosis and early death. This research examines the expression of Caudal Type Homeobox 1 (CDX1), Indian Hedgehog (IHH), Sonic Hedgehog (SHH), GATA Binding Protein 4 (GATA4), Forkhead Box A2 (FOXA2) and Forkhead Box F1 (FOXF1) genes in human abdominal congenital adhesion fibroblast and endothelium cells.

Methods: The study group consisted of 14 children diagnosed with congenital intra-abdominal adhesions detected in various locations. The control group consisted of 6 children, their samples of peritoneal tissues were obtained during inguinal hernia repair surgeries. To view candidate gene mRNA transcripts, chromogenic in situ hybridization (CISH) was chosen. Semi-quantitative analysis investigated putative genes' signals.

Results: Significant correlations were found between CDX1 ($p < .001$) and SHH ($p = 0.032$) gene expression in congenital intra-abdominal adhesion fibroblasts compared to control peritoneal tissue. Statistically significant very strong correlations were found between the CDX1 and IHH gene comparing endothelium and fibroblast cells in congenital abdominal adhesion bands. The expression patterns of the genes IHH, GATA4, FOXA2, FOXF2, and SHH did not differ significantly.

Conclusion: Increased CDX1 gene expression in control group fibroblasts and endothelium, compared to congenital intra-abdominal adhesion-afflicted tissue, suggests involvement in congenital band formation. The control group's fibroblasts had a statistically significant increase in SHH-containing cells compared to the affected tissue of people with congenital intra-abdominal adhesions, suggesting that SHH may be involved in their development.

P05.012.D Identification of the molecular mechanism underlying the involvement of mutations in the *MYO5B* gene and cholestasis

Cecilia Del Vecchio[1], *Mariateresa Di Stazio*[2], *Anna Monica Rosaria Bianco*[2], *Francesco Giambuzzi*[2], *Benedetta Blarasin*[3;4], *Cristina Bellarosa*[3], *Adamo Pio D'Adamo*[1;2]

[1]*University of Trieste, Department of Medicine, Surgery and Health Sciences, Trieste, Italy;* [2]*Institute for Maternal and Child Health – IRCCS, Burlo Garofolo, Trieste, Italy;* [3]*Italian Liver Foundation, Trieste, Italy;* [4]*University of Trieste, Department of Life Sciences, Trieste*

Background/Objectives: Progressive Familiar Intrahepatic Cholestasis (PFIC) represents an heterogenous group of rare diseases occurring in the first year of life, characterized by severe itching, hepatosplenomegaly, steatorrhea, and liver failure. MYO5B (NM_001080467) gene was recently described in PFIC patients but the molecular mechanism is still unknown. Some authors described that mutated MYO5B protein causes a wrong localization of canalicular proteins, which induces an alteration in bile salt secretion causing cholestasis.

Methods: In the last years, a retrospective and prospective study was done on 32 patients with intrahepatic cholestasis of unknown origin to identify causative variants by WES. To understand the pathogenetic mechanism we will evaluate the main canalicular transporters localization in patients-induced hepatocytes obtained from urine-derived induced Pluripotent Stem Cells (iPSC). When the sample is not available, iPSCs could be edited with the genetic variant of interest by CRISPR/Cas9 methodology.

Results: In 6 patients we identified causative mutations in MYO5B gene. We verified the canalicular protein localization on liver biopsies of two patients and, in both patients, the protein was normally expressed and located at the canalicular membrane.

Conclusion: Since immunostaining on our patients samples didn't clarify the pathogenetic mechanism and it's in contrast with previously published data, in which the missense mutation in MYO5B induces a protein mislocalization, there is an urgent need to perform functional studies of these genetic variants. In vitro-induced hepatocytes represent a promising model to verify the trafficking of canalicular proteins and to try to explain the cholestatic phenotype occurring in the presence of MYO5B mutations.

Background/Objectives: The development of metabolic-associated fatty liver disease (MAFLD) is closely linked to aberrant synthesis of endogenous fatty acids in the liver mediated by fatty acid synthase (FASN). FASN produces saturated fatty acids, which are linked to cell stress and inflammation. Fatty acid synthesis can be reduced by supplementation of polyunsaturated fatty acids (PUFAs). However, it is not well understood, which factors determine the amount of PUFAs used in the liver from the diet and thus, the variable clinical outcome of its supplementation.

Methods: We performed trio-exome sequencing of a 5-year-old patient with autism and macrocephaly and performed plasma lipidomics via liquid chromatography mass spectrometry to study functional consequences in vivo. Further, we examined the effect of FASN in a clinical trial of patients with biopsy-confirmed MAFLD with a human FASN inhibitor, and performed studies combining FASN inhibitor with PUFA supplementation in mice.

Results: We identified a putative pathogenic de novo missense variant in *FASN*, leading to reduced FASN activity and surprisingly, increased PUFAs. This phenotype could be resembled in patients with MAFLD receiving a FASN inhibitor and mice receiving a combined FASN inhibition and PUFA supplementation treatment.

Conclusion: In common metabolic disease, the effectiveness of PUFA supplementation seems to depend on the rate of endogenous fatty acid synthesis. The combination of PUFA supplementation and FASN inhibition could contribute to the success of MAFLD treatment.

P05.014.B Carriership revisited: phenotypic spectrum associated with heterozygyous variants in the IFT140 gene

Susanne Koning[1], *Dorien Lugtenberg[1], Marja Van der Meer[1], Anneke Vulto[1;2], Albertien M. van Eerde[3], Wendy Van Zelst-Stams[1;2], Ronald Roepman[1], Ernie Bongers[1], Marijn Stokman[1]*

[1]Radboud University Medical Center, Human Genetics, Nijmegen, Netherlands; [2]Maastricht University Medical Center, Human Genetics, Maastricht, Netherlands; [3]University Medical Center Utrecht, Genetics, Utrecht, Netherlands

Consortium: TheRaCil Consortium

Background/Objectives: Biallelic pathogenic variants in the IFT140 gene cause Mainzer-Saldino syndrome and isolated retinitis pigmentosa. Recently, heterozygous variants in IFT140 were reported in patients with polycystic kidney and liver disease. We investigated clinical manifestations of patients with heterozygous variants in IFT140 including carrier parents of children with recessive IFT140-related disease.

Methods: patients with mono- and biallelic variants in IFT140 were included. Clinical information was retrieved from medical records and additional phenotyping was performed for carrier parents including laboratory measurements and kidney ultrasound.

Results: Of 16 index patients, 11 had monoallelic and 5 had biallelic variants. The recurrent c.2399+1G>T splice variant was identified in 8 families. This variant was also detected in a patient with multiple kidney cysts who presented at age 15, and in compound heterozygosity with a variant of unknown significance in a patient with prenatally detected kidney cysts. These cases represent the earliest reported cysts in patients with heterozygous IFT140 variants. A minority of patients had chronic kidney disease, and no one reached end-stage kidney disease.

Conclusion: We expand the phenotypic spectrum associated with variants in the IFT140 gene and show an attenuated phenotype in carrier parents of patients with recessive IFT140-related disease. The heterozygous IFT140 phenotype is at the mild end of the ADPKD spectrum and shows reduced penetrance. We advise genetic testing in families with an IFT140 variant and surveillance according to ADPKD guidelines.

P05.016.D Functional characterization of *ATP7B* missense variants detected in patients with Wilson's disease

Amelie Stalke[1;2], *Annika Behrendt[3], Finja Hennig[1], Holger Gohlke[3;4], Nicole Buhl[1;2], Thea Reinkens[1], Ulrich Baumann[2], Brigitte Schlegelberger[1], Thomas Illig[5], Eva-Doreen Pfister[2], Britta Skawran[1]*

[1]Hannover Medical School, Department of Human Genetics, Hannover, Germany; [2]Hannover Medical School, Department of Pediatric Gastroenterology and Hepatology, Division of Kidney, Liver, and Metabolic Diseases, Hannover, Germany; [3]Heinrich Heine University Düsseldorf, Institute for Pharmaceutical and Medicinal Chemistry, Düsseldorf, Germany; [4]Forschungszentrum Jülich GmbH, John-von-Neumann-Institute for Computing, Jülich Supercomputing Center, Institute of Biological Information Processing (IBI-7: Structural Biochemistry), and Institute of Bio- and Geosciences (IBG-4: Bioinformatics), Gülich, Germany; [5]Hannover Medical School, Hannover Unified Bank, Hannover, Germany

Background/Objectives: Wilson's disease (WD) is an autosomal recessive disorder resulting in copper excess caused by biallelic variants in the *ATP7B* gene encoding a copper transporting P-type ATPase. *ATP7B* variants of unknown significance (VUS) are detected frequently, sometimes impeding a clear diagnosis. Functional analyses can help to classify these variants as benign or pathogenic. Additionally, variants already classified as (likely) pathogenic benefit from functional analyses to understand their pathomechanism, thus contributing to the development of future personalized treatment approaches.

Methods: We describe the clinical features of six WD patients, clinically confirmed by Leipzig score, and functionally characterized five *ATP7B* missense variants (two VUS, three yet uncharacterized likely pathogenic variants), detected in these patients. We determined ATP7B protein level, copper export capacity by a luciferase-based assay, and cellular localization using immunofluorescence staining in an in vitro model. Finally, we also analyzed the effects on protein stability using a 3D ATP7B protein model based on AlphaFold2.

Results: Protein levels and copper export capacity were decreased for all tested variants. Four variants resulted, at least partially, in ATP7B protein endoplasmic reticulum (ER)-retention. For all tested variants, except one ER-retained variant, our ATP7B protein model predicted ATP7B destabilization.

Conclusion: Our analyses allowed a reclassification of two VUS to 'likely pathogenic' and for two of the three 'likely pathogenic' variants to 'pathogenic'. For the ER-retained variants, especially the one with potentially preserved protein stability, therapies targeting ER-associated degradation (e.g. by pharmacological folding chaperones) may be promising.

Background/Objectives: Primary ciliary dyskinesia (PCD) is a genetically heterogeneous, autosomal recessive disorder defined by dysfunction of the motile cilia. Diagnostic tests of PCD include functional laboratory measurements and genetic testing.

Methods: Over four years exome sequencing (ES) using a gene panel consisting of 40 PCD genes, was performed for individuals (n = 209) with clinical symptoms of PCD.

To improve the diagnostic yield and as an extension for the exome sequencing, functional assays were established in 2022: a) determine the ciliary beat frequency (CBF) and b) immunofluorescence imaging (IF). Nasal brushes of so far 39 individuals were collected, and used for IF/ CBF.

Laboratory findings and clinical phenotypes are discussed in a multidisciplinary expert group consisting of relevant clinical and laboratory personnel to obtain a final diagnosis of PCD.

Results: In our cohort, 18 (8,6%) individuals received a direct molecular diagnosis, 106 (51%) individuals had at least one sequence variant (variant of unknown significance (VUS), likely pathogenic, pathogenic) in a PCD gene and in 84 (40%) individuals no relevant variant was identified.

Aberrant staining could be observed in 19% (7/36:) of individuals. The diagnosis PCD was supported in six individuals (two variants). One individual had no relevant variants (PCD unlikely). Abnormal CBF was measured in seven individuals (19%; 7/36: 3x two variants (PCD positive); 1 carrier (VUS) and 3 with no relevant variant: both PCD unlikely).

Conclusion: The combination of genome diagnostics and functional assays will enhance the diagnostic yield for PCD and support the assessment of the likelihood of PCD.

Conflict of Interest: None declared

P05.018.B ADPKD phenocopies and a novel frameshift variant in *COL4A1*: a case report

Fiorenza Mioli[1;2], *Francesca Arruga*[1], *Valeria Bracciamà*[1;2], *Diana Carli*[1;2], *Angelo Corso Faini*[1;2], *Giulia Margherita Brach del Prever*[1;2], *maria luca*[1;2], *carmelo maria romeo*[1;2], *Caterina Scolari*[1;2], *Claudia Saglia*[1;2], *Massimo Gai*[3], *Roberta Giraudi*[3], *Luigi Biancone*[2;3], *Tiziana Vaisitti*[1;2], *Silvia Deaglio*[1;2]

[1]*AOU Città della Salute e della Scienza of Turin, Immunogenetics and Transplant Biology, Turin, Italy;* [2]*University of Turin, Department of Medical Sciences, Turin, Italy;* [3]*AOU Città della Salute e della Scienza of Turin, Nephrology Dialysis and Transplantation, Turin, Italy*

Background/Objectives: Different inherited conditions can lead to kidney cysts, including the most common autosomal dominant polycystic kidney disease (ADPKD) caused by *PKD1* or *PKD2* pathogenetic variants. However, ADPKD has phenocopies, making molecular analysis crucial for accurate diagnosis. Here, we present the case of a 47-year-old man with end-stage renal disease and a clinical diagnosis of ADPKD referred to our center for molecular diagnosis. The patient was also being evaluated for kidney transplant.

Methods: Clinical Exome Sequencing (CES) was performed and analysis restricted to specific in-silico gene panels. Identified variants were segregated by Sanger sequencing in family members

Results: Upon analysis of PKD-associated genes, two variants of unknown significance in *PKD1* were identified, one reported as hypomorphic and the other present in one sister and in the father, both without evidence of cysts. Analysis was extended to a panel of renal cysts-associated genes with identification of the heterozygous likely pathogenic variant c.1944del p.(Gly649fs*153) (NM_001845.6) in *COL4A1* gene, not previously reported in literature. *COL4A1* gene is associated with several disorders, including HANAC syndrome, which may present with isolated kidney cysts. Segregation analyses excluded the presence of the variant in the proband's sisters and father, strongly suggesting that this variant is responsible for the phenotype and arguing in favor of maternal origin. Indeed, the deceased mother had history

of recurrent strokes and muscle cramps, potentially compatible with HANAC syndrome.

Conclusion: This case highlights the importance of considering all phenocopies associated with ADPKD for accurate diagnosis, treatment and family counselling.

P05.019.C Unveiling a novel *INPP5E* mutation: Bridging the gap between Joubert Syndrome and MORM Syndrome

Nesibe Bulut[1], *Seda Hanife Oğuz*[2], *Selcuk DAGDELEN*[2], *Naz Guleray*[1]

[1]*Hacettepe University Medical Faculty, Department of Medical Genetics, Ankara, Türkyie;* [2]*Hacettepe University Medical Faculty, Division of Endocrinology and Metabolism, Ankara, Türkyie*

Background/Objectives: INPP5E encodes an inositol polyphosphate 5-phosphatase critical for primary cilium development and stability. Pathogenic biallelic INPP5E variants lead to ultra-rare ciliopathy spectrum ranging from Joubert Syndrome (OMIM:213300) to MORM Syndrome (Mental retardation, truncal obesity, retinal dystrophy, micropenis; MORMS; OMIM:610156). To date, approximately 35 mutations were reported only 2 of them being associated with MORMS. Adult phenotypic expression of this spectrum remains unclear. Here, we report a novel INPP5E mutation in an affected individual presenting with overlapping clinical features of both Joubert Syndrome and MORMS.

Methods: Clinical exome sequencing was performed to unravel underlying etiology.

Results: The affected 51-year-old woman exhibited congenital nystagmus, progressive retinal dystrophy, cataracts, hepatic fibrosis, portal hypertension and cirrhosis. She also had early-onset truncal obesity, hypertension, dyslipidemia, and obstructive sleep apnea. No developmental delay or ataxia was observed. Brain MRI demonstrated molar tooth sign. Three relatives older than 35-years also presented with similar findings. A novel homozygous mutation (c.1204A>G; p.Lys402Glu) affecting phosphatase catalytic domain in INPP5E (NM_019892) was identified.

Conclusion: The clinical findings of this patient align more with MORMS even though missense mutations affecting the catalytic domain were predominantly reported with Joubert phenotype and only truncating mutations in C-terminal domain were associated with MORMS. Therefore, the term "INPP5E-associated ciliopathies" is more appropriate to encompass the phenotypic spectrum of these separate entities. This study, in which the clinical course of multiple affected members is known until advanced age, emphasizes the importance of long-term follow-up of INPP5E-associated ciliopathies in terms of the progressive retinal and hepatic findings, and metabolic syndrome.

P05.020.D Diagnostic utility of multi-faceted genetic screening in kidney failure of undetermined aetiology

Jeff Granhøj[1;2], *Katja Venborg Pedersen*[1], *Jesper Aagaard Graakjær*[1], *Dorte Lildballe*[3;4], *Bjarne Ørskov*[5], *Birgitte Godskesen Tougaard*[6], *Mads Jørgensen*[1], *Per Svenningsen*[7], *Henrik Birn*[4;6;8], *Maria Rasmussen*[1;2]

[1]*Lillebaelt Hospital - University Hospital of Southern Denmark, Department of Clinical Genetics, Vejle, Denmark;* [2]*University of Southern Denmark, Department of Regional Health Research, Odense, Denmark;* [3]*Aarhus University Hospital, Department of Molecular Medicine, Aarhus, Denmark;* [4]*Aarhus University, Department of Clinical Medicine, Aarhus, Denmark;* [5]*Zealand University Hospital, Department of Medicine, Roskilde, Denmark;* [6]*Aarhus University Hospital, Department of Renal Medicine, Aarhus, Denmark;* [7]*Institute of Molecular Medicine, University of Southern Denmark, Cardiovascular and Renal Research, Odense, Denmark;* [8]*Aarhus University, Department of Biomedicine, Aarhus, Denmark*

Background/objectives: The underdiagnosis of genetic kidney diseases calls for optimized screening strategies. We investigated the diagnostic yields of a three-part genetic screening in patients with kidney failure of undetermined aetiology (uKF).

Methods: We recruited 172 unrelated patients with suspected uKF for eligibility assessment through the review of medical records, excluding patients with specific causes of kidney disease. Inclusion criteria were: i) uKF ≤50 years or ii) undetermined kidney disease and family history of uKF ≤50 years. A total of 124 patients underwent initial screening, which included single-nucleotide-polymorphism (SNP)-array and SNaPshot *MUC1* analysis. Negative results prompted follow-up with short-read whole-genome sequencing (WGS) restricted to 542 genes. Only pathogenic or likely pathogenic variants in relevant genes were considered diagnostic.

Results: The median age of uKF was 37 years, and 91% of the cohort had adult-onset uKF. Diagnostic variants were identified in 33/124 patients (27%), with yields of 3/123 by SNP-array, 5/123 by *MUC1* analysis, and 25/116 by WGS. Diagnostic variants were most frequently identified in *COL4A3*/A4/A5, *NPHP1*, and *MUC1*, accounting for 58% of the genetic kidney diagnoses. A genetic diagnosis was obtained in 60% of the patients with a positive family history (15/25), of which 5/25 were detected by *MUC1* analysis. No significant difference in diagnostic yields was observed between childhood-onset versus adult-onset uKF.

Conclusion: Genetic screening revealed a monogenic cause in one-fourth of this uKF cohort. Notably, 20% of patients with positive family history had a *MUC1* variant undetectable by short-read sequencing.

Introduction: Hypercalciuria is the most common metabolic risk factor associated with nephrolithiasis. Although the majority of hypercalciuria is explained by complex genetic factors, a monogenic cause of isolated renal calcium loss has not previously been described. Here, we demonstrate the first autosomal recessive pedigree with pure renal-leak type hypercalciuria and provide evidence that a loss-of-function variant in *TRPV5*, encoding a renal calcium channel, underlies the disorder.

Methods: We employed SNP-microarray-based homozygosity mapping followed by whole exome sequencing to elucidate the molecular basis of hypercalciuria in three affected siblings. Furthermore, the mutant TRPV5 channel was functionally characterized in HEK293 cells.

Results: We identified a homozygous ultra-rare variant in *TRPV5* (NM_019841.7:c.1792G>A; p.(Val598Met)), which co-segregates with hypercalciuria. This variant disrupts glycosylation and enhances proteasomal degradation of the mutant channel, thereby reducing its cell surface expression and diminishing calcium uptake. Intriguingly, besides hypercalciuria, the 10-year-old proband also displayed severe skeletal deformities, bone fractures, and hyperparathyroidism that could not be attributed solely to the *TRPV5* variant. Further investigation showed that the skeletal involvement unique to the proband was the outcome of a blended phenotype caused by an additional well-known pathogenic somatic *GNAS* mutation (NM_000516.7:c.601C>T; p.(Arg201Cys)).

Conclusion: *TRPV5* has long been proposed as a candidate for hypercalciuria in humans. This study provides the first evidence that biallelic *TRPV5* variants cause a novel form of monogenic hypercalciuria, which we name "Renal Calcium-Wasting Hypercalciuria" (RCWH). Given its recessive nature, RCWH might be overlooked as a cause of hypercalciuria and should be screened, particularly in inbred populations.

Consortium: Program for Undiagnosed Diseases (UD-PrOZA)

Background/Objectives: Phospholipase A/acyltransferase 3 (PLAAT3) is a phospholipid-modifying enzyme predominantly expressed in neural and white adipose tissue (WAT). It is a potential drug target for metabolic syndrome, as Plaat3 deficiency in mice protects against diet-induced obesity. We identified seven patients from four unrelated consanguineous families, with homozygous loss-of-function variants in *PLAAT3*, who presented with a lipodystrophy syndrome with loss of fat varying from partial to generalized, muscular hypertrophy and chronic muscle pain, associated with metabolic complications, as well as variable neurological features including demyelinating neuropathy and intellectual disability. We aimed to clarify the pathogenic mechanism of PLAAT3-related lipodystrophy syndrome and to further address the role of PLAAT3 in human adipogenesis.

Methods: We performed multi-omics analyses of mouse Plaat3−/− and patient-derived WAT. We next performed CRISPR-Cas9-mediated PLAAT3 inactivation in human adipose

stem cells and assessed the adipocyte differentiation signaling using morphological and expression studies.

Results: Multi-omics analysis of mouse Plaat3−/− and patient-derived WAT showed enrichment of arachidonic acid-containing membrane phospholipids and a strong decrease in the signaling of peroxisome proliferator-activated receptor gamma (PPARγ), the master regulator of adipocyte differentiation. Accordingly, CRISPR-Cas9-mediated PLAAT3 inactivation in human adipose stem cells induced insulin resistance, altered adipocyte differentiation with decreased lipid droplet formation and reduced the expression of adipogenic and mature adipocyte markers, including PPARγ.

Conclusion: These findings establish PLAAT3 deficiency as a hereditary lipodystrophy syndrome with neurological manifestations, caused by a PPARγ-dependent defect in WAT differentiation and function. The role of PLAAT3 in patients' neurological phenotype remains to be established.

P05.023.C Out-of-frame translation restores the reading frame and rescues a homozygous loss-of-function variant in a novel *TBCE* phenotype

Peter Sparber[1], *Alexandra Filatova[1], Eugene Tatarskiy[1], Evgeniia Ulas[2], Grigory Perelman[1], Makretskaya Nina[3], Elena Nagaeva[4], Maria Kareva[4], Elena Frolova[5], Natalia Kalinchenko[4], Sergey Golyshev[6], Anton Burakov[6], Elena Nadezhdina[2], Vyacheslav Tabakov[7], Victoria Voinova[8], Anatoliy Tiulpakov[3], Mikhail Skoblov[1]*

[1]Research Centre for Medical Genetics, Laboratory of Functional Genomics, Moscow, Russian Federation; [2]Institute of Protein Research of Russian Academy of Science, Moscow, Russian Federation; [3]Research Centre for Medical Genetics, Genetics of Endocrine Diseases, Moscow, Russian Federation; [4]Institute of Pediatric Endocrinology, Endocrinology Research Centre, Moscow, Russian Federation; [5]National Medical Research Center for Children's Health Federal state autonomous institution of the Russian Federation Ministry of Health, Consulting and diagnostic, Moscow, Russian Federation; [6]A.N. Belozersky Institute of Physico-Chemical Biology, Lomonosov Moscow State University, Moscow, Russian Federation; [7]Research Centre for Medical Genetics, Moscow, Russian Federation; [8]Veltischev Research and Clinical Institute for Pediatrics Pirogov RNRMU, Moscow, Russian Federation

Background/Objectives: Pathogenic variants in the TBCE gene, which codes for a tubulin-specific chaperone are associated with three severe neurodevelopmental phenotypes. As complete absence of TBCE is lethal in all cases, at least residual activity of the TBCE protein was detected. Here we report a novel milder TBCE phenotype with unique molecular mechanism.

Methods: Splicing analysis was performed using deep NGS sequencing of RT-PCR products. Western-blot was used for TBCE detection. Translation efficiency was mmeasured using luciferase reporter assay. Overexpression experiments were performed in Hela cells with further tubulin staining. Golgi complex compactness was analyzed by immunofluorescence analysis. Microtubule repolymerization dynamics was analyzed after nocodazole treatment. Electron microscopy was used for ultrastructural studies.

Results: We assessed seven patients with a novel, distinct and clinically recognizable TBCE-associated phenotype featuring hypergonadotropic hypogonadism, amyotrophy and short stature. All patients were homozygous or compound-heterozygous for the c.100+1>A variant. RT-PCR confirmed splicing alteration leading to an early frameshift - p.Thr33delInsAla62fsTer24. Western-blot and luciferase reporter assay demonstrated translation of mutated TBCE protein from an alternative open reading frame compensation the frameshift starting from exon 4. The reduced translation of the mutant TBCE protein was attributed by both decreased stability of the altered N-terminus and competition for ribosome binding with the reference start codon. Overexpression experiments showed partial activity of the mutant protein. Reduced Golgi complex compactness was observed alongside normal microtubule repolymerization dynamics. Muscle sample electron microscopy displayed varying levels of acto-myosin complex degradation

Conclusion: Our findings unveil a novel TBCE phenotype with a unique molecular mechanism

P05.024.D Study of the utility of genetic analyses in congenital hypothyroidism neonatal TSH screening

Silje Hogner[1], *William Nicholas Tourniaire[1], Emma Sofia Lundman[1], Janne Maren Strand[1], Julie Hellem AAby[1], Linda Karlsen Sørgjerd[1], Mona Christine Berge[1], Mari Eknes Ytre-Arne[1], Siv Merete Løvoll[1], Ingjerd Sæves[1], Cassandra Nicole Trier[1], Alexander Dominic Rowe[1], Magnus Odin Dahlseng[1], Andreas Øberg[1], Trine Tangeraas[1], Olve Moldestad[1], Asbjørg Stray-Pedersen[1], Jens Veilemand Jørgensen[1]*

[1]Oslo University Hospital, Norwegian National Unit for Newborn Screening, Oslo, Norway

Congenital hypothyroidism (CH) was included in the Norwegian newborn screening (NBS) program in 1979. Thyroid Stimulating Hormone (TSH) immunoassay (GSP, Revvity) are performed on all NBS dried blood spot samples. The Norwegian NBS program is regulated by an exception from the Biotechnology Act allowing for mass genetic screening for specific disorders. Genetic analyses have since 2012 been used as confirmatory test for most screening disorders, but not yet for CH. As part of improving the laboratory service, 42 genes associated with inherited CH were tested in samples with elevated TSH using Illumina DNA prep and bioinformatically filtered whole-genome sequencing.

After ~220,000 analyzed samples (2018-2022), a total of 349 infants were reported with elevated TSH and were subject for genome sequencing. So far, 146 samples have been sequenced. Nine individuals have a confirmed molecular cause of CH and 24 are carriers of one pathogenic variant in a gene related to autosomal recessive CH, six in compound heterozygozity with a variant of uncertain significance (VUS). In additional six cases, two VUS in the same gene were found, while in 24 samples one VUS was detected. In the remaining 83 samples, no variants of interest were found.

The current status of the project will be presented with regard to identified variants in TSH positive samples and evaluation of whether NGS panel determining the molecular causes of congenital hypothyroidism is useful in a NBS setting.

The study was approved by the local IRB (2017/2879) and funded by the South-Eastern Norway Regional Health Authority (2018080).

Genetic Laboratory, University Hospital of Obstetrics and Gynecology "Maichin Dom", Obstetrics and Gynecology, Sofia, Bulgaria

Background/Objectives: Cystic fibrosis is an autosomal recessive condition caused by loss-of-function variants in the CFTR gene. Some people with CF carry complex alleles, with more than one CFTR variant on the same allele. Genetic variants located in cis can affect disease severity or treatment response.

Methods: At 24-weeks of gestation a couple was referred for CF testing because of ultrasound finding of hyperechogenic bowel suggesting fetal meconium ileus. Carrier screening was performed of the parents for the most common mutations in Bulgarian population.

Results: The mother was found to be carrier of complex L467F-F508del allele. The newborn examination after delivery found the maternal double variant L467-F508del and a novel pathogenic frameshift variant 2217delA subsequently confirmed to be carried by the father. Initially the paternal variant 2217delA was not detected likely because of allele dropout.

Conclusion: The existence of a complex allele does not always affect the responce to CFTR modulators. L467F-CFTR is reported to be damaging to protein maturation. The L467F-F508del complex allele is not responsive to Kaftrio treatment, so it should be considered an indication for prescription of mutation-specific therapies. Risk of allele dropout artifact on screening and diagnostic tests could lead to a wrong diagnosis, so it is important to detect and avoid it in clinical molecular diagnostics. Identification of the new pathogenic CFTR variants provides useful information for further observing the genotype-phenotype correlations and could open the door to integration of precision medicine into routine clinical practice in the near future.

Background/Objectives: Capillary malformation-arteriovenous malformation 2 (CM-AVM2), caused by EPHB4 pathogenic variants, is part of a spectrum of autosomal dominant inherited vascular malformation syndromes. This group includes RASA1-mutated CM-AVM1 and hereditary hemorrhagic telangiectasia (HHT). CM-AVM2 is distinguished by the presence of arteriovenous malformations (AVMs) both within and outside the cranium, alongside multiple capillary malformations (CMs) and telangiectasias. We describe a familial case with lung involvement, suggesting a possible phenotypic expansion of the disease.

Methods: A 2-year-old boy had several episodes of life-threatening diffuse alveolar hemorrhage with severe anemia – (Hb – 4g/dl), was referred to our pediatric genetic unit. Despite extensive investigations, including repeated bronchoscopies, nasal endoscopy, lung MRI, CT imaging, lung biopsy, several cardiac and pulmonary arteries catheterizations, bubble echo, and RBC scan, the source of bleeding from the lung remained unidentified. Familial investigations revealed maternal lip telangiectasias and a capillary malformation on her forearm. Whole-exome sequencing (WES) was conducted for the child and his parents.

Results: The analysis identified a maternally inherited heterozygous c.2420G>A p.Gly807Glu variant in the EPHB4 gene, classified as likely pathogenic. This variant is not present in the gnomAD database. Computational prediction tools suggest a deleterious impact on the gene. A different missense variant at the same position has been previously reported in a patient with an AVM in the ear.

Conclusion: This case represents the first reported case of massive pulmonary hemprrhage, potentially as the primary symptom of CM-AVM2.

P05.027.C Diagnostic challenges in very early onset polycystic kidney disease

Elena Luppi[1;2], *Carlotta Cristalli*[1], *Enrico Ambrosini*[3], *Amalia Conti*[1], *Claudio Graziano*[4], *Francesca Montanari*[1]

[1]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy;* [2]*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy;* [3]*Medical Genetics Unit, University Hospital of Parma, Parma, Italy;* [4]*Medical Genetics Unit, AUSL Romagna, Cesena, Italy*

Background/Objectives: Very early onset polycystic kidney disease (VEO-PKD) defines the antenatal finding up to 18 months of age of cystic/hyperechoic enlarged kidneys. Differential diagnosis is challenging and encompasses recessive inheritance in autosomal dominant PKD genes.

We aim to define the occurrence of *PKD1/PKD2* genes variants in a cohort of VEO-PKD and their diagnostic implications by illustrative pedigrees.

Methods: We retrospectively reviewed clinical and molecular data of probands referred to the Medical Genetics Unit of Bologna from 2018 to 2023 for the perinatal detection of cystic/hyperechoic kidneys. All samples were tested by targeted NGS panel of cystic genes and multiplex ligation-dependent probe amplification of *PKHD1, HNF1B, PKD1 and PKD2*.

Results: Out of 20 VEO-PKD unrelated probands, 12 harboured likely causative variants in *PKD1/PKD2*. In 7 of them a single *PKD1/PKD2* variant was identified, while 5 patients had biallelic *PKD1* variants, of which 2 were inherited from a parent with a positive ADPKD history and 8 likely hypomorphic variants from otherwise healthy parents. The disease spectrum, even in biallelic genotypes, show a high variability from a prenatal onset with perinatal death to pauci symptomatic renal cysts in childhood. Of note, in the antenatal case we recorded a new genotype combining "in trans" a novel truncating variant (c.24_27dup; p.Ala10Profs) with the hypomorphic variant c.5830G>A (p.Gly1944Arg) and defining a severe phenotype.

Conclusion: Our results widen the VEO-PKD phenotypic and genotypic spectrum and underline the need for a careful ultrasound follow-up in pregnancies of ADPKD families and carrier testing/ultrasound screening of their partners.

P05.029.A Decoding gastrointestinal puzzle: Unmasking Congenital enterokinase deficiency beyond the Cystic fibrosis in Bulgarian patient

Gabriela Kovacheva[1;2], *Tihomir Todorov*[2], *Slavena Atemin*[2], *Mila Sleptsova*[2], *Mila Baycheva*[3], *Vanyo Mitev*[1], *Albena Todorova*[1;2]

[1]*Medical University of Sofia, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria;* [2]*Independent Medical Diagnostic Laboratory Genome Center Bulgaria, Sofia, Bulgaria;* [3]*University Children's Hospital, Department of Paediatric Gastroenterology, Hepatology and Nutrition, Sofia, Bulgaria*

Background/Objectives: Congenital enterokinase deficiency is a rare autosomal-recessive genetic disorder characterized by the absence/dysfunction of enterokinase - a crucial enzyme in the digestive system, converting trypsinogen into its active form trypsin. The genetic basis of this gastrointestinal disorder involves different loss-of-function variants in the TMPRSS15 gene, which encodes the enterokinase enzyme. The clinical features of Congenital enterokinase deficiency can mimic those of Cystic fibrosis, a more prevalent genetic disorder. Both conditions may present in infants with failure to thrive, malabsorption, and chronic diarrhea, thus creating diagnostic challenges.

Methods: We report a case of a 3-month-old boy with pancreatic steatorrhea, hypoproteinemia and anemia. Genomic DNA from the proband was extracted from their peripheral blood and analyzed through whole exome sequencing (WES).

Results: The initial results of WES analysis revealed a heterozygous variant CFTR:c.2756G>A/p.Tyr919Cys, classified as a variant of uncertain significance (VUS). Subsequently, a multiplex ligation-dependent probe amplification (MLPA) analysis was performed. A normal result was yielded and excluded the diagnosis Cystic fibrosis. Further investigation uncovered a homozygous variant c.3004G>A/p.Gly1002Arg in the TMPRSS15 gene, confirmed through Sanger sequencing. Both of the proband's parents were found to be heterozygous carriers of this variant.

Conclusion: The clinical mimicry of Cystic fibrosis in patients with Congenital enterokinase deficiency poses a significant challenge in diagnosis and management, potentially impacting the well-being of those with enterokinase deficiency. Patients with enterokinase deficiency may be mistreated for Cystic fibrosis, leading to delays in addressing the specific enzymatic deficit.

P05.030.B Investigation of genetic etiology in familial CAKUT cases

Durmuş Durmaz[1], *Güven Toksoy*[1], *Zeynep Yürük Yıldırım*[2], *bağdagül aksu*[2], *Zuhal Bayramoğlu*[3], *Zehra Oya Uyguner*[1], *alev yılmaz*[2], *Bilge Ozsait Selcuk*[1], *Birsen Karaman*[1;4], *Ayça Dilruba aslanger*[1]

[1]*Istanbul Faculty of Medicine, Istanbul University, Department of Medical Genetics, Istanbul, Türkyie;* [2]*Istanbul Faculty of Medicine, Istanbul University, Department of Pediatric Nephrology, Istanbul, Türkyie;* [3]*Istanbul Faculty of Medicine, Istanbul University, Department of Radiology, Istanbul, Türkyie;* [4]*Istanbul University, Institute of Health Sciences, Istanbul, Türkyie*

Background/Objectives: Congenital anomalies of the kidneys and urinary tracts (CAKUT) comprise a group of disorders that involve various structural anomalies resulting from defects in the embryologic development of the urinary system. Our objective is to identify the molecular etiology in CAKUT families, aiming to comprehensively understand the associated clinical and genetic characteristics.

Methods: Exome sequencing with CNV analysis was conducted on two affected individuals from each of the eight families. Variant confirmation and family segregation were carried out through Sanger sequencing and array-CGH analysis.

Results: We identified variants associated with CAKUT in four of the eight families. Family-I had a 9q32 duplication, including cases with renal hypoplasia and multicystic dysplastic kidney (MCKD). Heterozygous/novel variants in *TFAP2A* and *TFAP2B* were identified in Family-II with MCKD and subtle dysmorphic findings. A heterozygous novel variant in *GREB1L* was found in Family-III with horseshoe kidneys and vesicoureteral reflux. A heterozygous splice-site variant in *NOTCH2* and a heterozygous/novel variant in *ROBO2* were both found in Family-IV with renal agenesis, ureteropelvic junction obstruction, mild dysmorphic/skeletal findings.

Conclusion: This study reports novel variants associated with CAKUT and supports the pathogenicity of 9q32 duplication, which was previously reported in only one case with CAKUT. Identification of novel variants in genes involved in renal development in patients with syndromic CAKUT suggests that multigenic inheritance may influence the phenotype. In cases of CAKUT where genetic diagnosis is challenging, a detailed clinical examination and family study contribute to the diagnosis.

Grants: This project is supported by the Scientific Research Projects Coordination Unit of Istanbul University (Project-ID: TTU-2023-39892).

Conflict of Interest: None declared

P05.031.C CFTR diagnostics: patient data from 2020 to 2023

Bettina Desery[1], **Dorit Borchert**[1], *Anne Christians*[1], *Anna Teubert*[1], *Sarah Knippenberg*[1], *Gudrun Göhring*[1;1]

[1]*amedes MVZ wagnerstibbe für Laboratoriumsmedizin, Hämostaseologie, Humangenetik und Mikrobiologie Hannover, Hannover, Germany*

Background/Objectives: Cystic fibrosis (CF) is one of the most common autosomal recessive diseases worldwide. In addition to classic cystic fibrosis with severe lung involvement, atypical milder forms are also found, such as pancreatitis, disseminated bronchiectasis and infertility in men (congenital bilateral aplasia of the vas deferens (CBAVD)).

Methods: A total of 929 patients were examined for the presence of the most common variants and 1600 patients for the presence of additional (pathogenic) variants in the *CFTR* gene by next generations sequencing or hybridization assays. Relevant variants include (probably) pathogenic variants, variants of unclear significance (VUS) and the 5T allele (a disease-associated polymorphism).

Results: For the indication of CFTR-associated infertility, two relevant variants (suspected to be compound-heterozygous) were detected in 2.16% of patients. In 13.35% of patients, only one relevant variant (including VUS and 5T allele) was found. A total of 4.15% were carriers of at least one (probably) pathogenic variant.

In cases of cystic fibrosis, the diagnosis was confirmed with high probability in 13.19% of patients by detection of two pathogenic variants. Here, the F508del variant accounted for 78.95% of all detected compound-heterozygous or homozygous pathogenic variants. In additional 4.86%, only one pathogenic variant lacking a second variant could be detected.

Conclusion: The different proportions of confirmed diagnoses (two detected variants) in the indications suspected CFTR-associated infertility (2.2%) and suspected CF (13.2%) shows the higher diagnostic yield at the molecular level for a clinically well-defined suspected diagnosis such as cystic fibrosis than for CFTR-associated infertility.

P05.032.D Involvement of p38 gamma/delta kinases in the development of alcoholic steatohepatitis

Daniel Salete Granado[1;2], *Beatriz Cicuéndez*[3], *Cintia Folgueira*[3], *Alfonso Mora*[3], *Marta León*[3], *María de los Ángeles Pérez Nieto*[2;4], *Antonio Javier Chamorro*[1;2;5], *Maura Rojas-Pirela*[1;2], *Ana-Belén Herrero*[1;2], *Guadalupe Sabio*[3], *Miguel Marcos*[1;2;5]

[1]*Institute of Biomedical Research of Salamanca-IBSAL, Salamanca, Spain;* [2]*University of Salamanca, Department of Medicine, Salamanca, Spain;* [3]*Spanish National Cancer Research Center, Madrid, Spain;* [4]*Instituto de Ciencias de la Salud de Castilla y León, Soria, Spain;* [5]*University Hospital of Salamanca, Department of Internal Medicine, Salamanca, Spain*

Background/Objectives: Alcoholic steatohepatitis (ASH) is a severe manifestation of alcoholic liver disease (ALD) characterized by steatosis and inflammation. The pivotal role of MAP kinases p38 γ/δ in liver steatosis and inflammation influences the progression of high-fat diet-induced non-alcoholic liver disease.

Methods: Male mice, both wild-type (WT) and p38 γ/δ knockout (KO), underwent a chronic and binge ethanol (EtOH) diet following the NIAAA model for liver damage induction. Histopathological analysis through oil red staining, qPCR, and western blot were employed to examine ethanol's molecular effects on the liver.

Results: Histopathology and gene expression revealed that EtOH-KO mice had reduced hepatic steatosis and lower inflammatory cytokine expression compared to EtOH-WT mice. Both EtOH-WT and EtOH-KO mice on the NIAAA diet experienced oxidative stress and mTOR pathway activation in the liver. EtOH-WT mice exhibited phosphorylation of p62 at Thr269 and Ser272, which was diminished in EtOH-KO mice.

Conclusion: The deletion of p38 γ/δ proves beneficial in mitigating ALD in mice by reducing inflammation and steatosis. An alcoholic diet increased oxidative stress and inhibited autophagic pathways, which was partially restored by p38 γ/δ knockout.

Grants: This study has been funded by Instituto de Salud Carlos III (ISCIII) co-funded by the European Union through the projects PI20/00743, PFIS (FI21/00189) (Salete- Granada D) and a Sara Borrell contract CD22/00054 (Rojas-Pirela M), and Junta de Castilla y León, Spain, through the project GRS 2648/A/22.

P05.033.A Molecular heterogeneity in idiopathic chronic and recurrent acute pancreatitis among highly consanguineous south Indian Tamils

Aruna Mannil[1], *Reena Gulati*[1], *Raja Kalayarasan*[2]

[1]*Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Pediatrics, Pondicherry, India;* [2]*Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Surgical Gastroenterology, Pondicherry, India*

Background/objective: Idiopathic chronic pancreatitis (ICP) is a debilitating disease characterized by irreversible damage to pancreas. ICP and recurrent acute pancreatitis (RAP) with early age onset are commonly associated with variants in multiple genes. We performed NGS to identify genetic variants in the highly consanguineous south Indian Tamil population.

Methods: We analyzed DNA extracted from peripheral blood of 27 patients with a diagnosis of ICP/RAP by NGS (Illumina).

Results: Clinically significant variants were identified in 25 of 27 patients (Table1).

Among them,11 (44%) have consanguineous parents (9 third degree and 2 second degree). Significant variants were identified in 7 genes associated with pancreatitis.

Conclusion: Percentage of consanguinity was more among patients compared to general Tamil population. The most common variant was c.101A>G in *SPINK1* gene. Two novel, two pathogenic and ten variants of unknown significance (VUS) predicted to be deleterious were identified. Proportion of CFTR variants identified were higher than in other populations.

Grants: Nil

Table 1: Variants identified

Age in year/ Gender	Variant	ACMG Classification	Gene
12/F	c.3205G>A	Likely pathogenic	*CFTR*
	c.1210-11T>G	VUS	
10/F	c.489+733C>A

P05.034.B Investigation of leukocyte telomere length and hTERT gene (MNS16A-VNTR) variant in obese adolescents

Aylin Yetim Şahin[1;2], *Yasemin Oyacı*[1;3], *Shahri Khudiyeva*[2], *Mustafa Pehlivan*[4], *Melike Tuğrul Aksakal*[2], *Sacide Pehlivan*[3]

[1]*Institute of Graduate Studies in Health Sciences, Istanbul University, Istanbul, Türkyie;* [2]*Istanbul Faculty of Medicine, Istanbul University, Department of pediatrics, Istanbul, Türkyie;* [3]*Istanbul Faculty of Medicine, Istanbul University, Department of Medical Biology, Istanbul, Türkyie;* [4]*Basaksehir Cam and Sakura City Hospital, Department of Hematology, Istanbul, Türkyie*

Background/Objectives: This study aims to investigate whether leukocyte telomere length (LTL) and human telomerase reverse transcriptase (*hTERT*) gene MNS16A-VNTR variant in obese adolescents differs from healthy, age/gender matched peers and if there is any association with clinical parameters.

Methods: The study included 151 participants, comprising 96 obese and 55 healthy adolescents. DNA isolated from peripheral blood of all individuals was used for LTL and *hTERT* gene analyses. Relative LTL was quantified by real-time PCR. LTL analysis was calculated as a fold change between patients and controls using the relative T/S ratio. The PCR method was used for the detection of *hTERT* gene VNTR variant.

Results: In the comparison of hTERT-MNS16A-VNTR between patients and healthy controls, statistically significant decrease was observed in the LL genotype ($p = 0.029$). In genotype comparisons of clinical parameters (LL/LS + SS genotypes), it was found that insulin, HOMA-IR and ALT levels significantly increased in LL genotyped patients (respectively, $p = 0.027$; $p = 0.033$; $p = 0.012$). Regarding LTL analysis, the T/S ratios of patients were marginally significantly decreased compared to controls ($p = 0.055$). In comparison of fold changes, 61% of patients had shorter telomeres than controls. Evaluation of T/S ratio median values with clinical parameters revealed no relationship between physical exercise, sleep, screen time, smoking exposure, breastfeeding duration.

Conclusion: In conclusion, it appears that LTL in obese Turkish adolescents is marginally shorter compared to healthy peers. The LL genotype of MNS16A-VNTR, acting as a regulator of hTERT promoter activity, suggests a potential association both in protecting against obesity with insulin resistance and hepatosteatosis.

P05.035.C Silver-Russell like phenotype caused by variants in IGF1R and the imprinted IGF2 investigated with long read sequencing

Trine Maxel Juul[1], *Katja Venborg Pedersen*[2], *Emilie Lester*[1], *Caroline Hey Bækgaard*[1], *Martin Larsen*[1], *Susanne E. Boonen*[1], *Maria Kibaek*[3], *Niels Illum*[3], *Malene Heidemann*[3], *Signe Koch*[4], *Christina Fagerberg*[1;2]

[1]*Odense University Hospital, Dept. of Clinical Genetics, Odense, Denmark;* [2]*Sygehus Lillebælt, Vejle Hospital, Dept. of Clinical Genetics, Vejle, Denmark;* [3]*Odense University Hospital, H. C. Andersen Children's Hospital, Odense, Denmark;* [4]*The Hospital of Southern Jutland, Aabenraa Hospital, Dept. of Pediatrics, Aabenraa, Denmark*

Background/Objectives: The insulin-like growth factor system involves the insulin-like growth factors IGF1 and IGF2 that binds to the IGF1 receptor. Disturbances in this system are related to classic growth disorders including Silver-Russell syndrome.

The aim was to characterize the phenotype of the Silver-Russell like phenotype associated with *IGF1R* and the imprinted *IGF2* variants and describe the use of long read sequencing regarding parental allele origin of variants in imprinted genes.

Methods: Description of two individuals with a de novo variant in *IGF2*, and one family with an inherited variant in *IGF1R*. Long read sequencing was used to determine the phasing of the de novo variants.

Results: The two individuals with de novo missense variants in *IGF2* both had intrauterine and postnatal growth restriction. One of these, an adult female, had dysmorphic facial features and neurodevelopmental delay. In both cases, the de novo variant was showed to be located on the paternal allele.

In the IGF1R family, a paternal inherited missense variant in *IGF1R* was detected in three sisters, age from 10 months to 15 years old. All three had intrauterine and postnatal growth restriction, microcephaly and poor appetite.

Conclusion: We describe a phenotype of intrauterine and postnatal growth restriction in individuals affected by variants in *IGF2* and *IGF1R*. Phasing of the de novo variants in the imprinted *IGF2* can clarify which parental allele the de novo variant is located on. This information is of great importance to determine the significance of de novo variants in imprinted genes.

P05.036.D PNPLA3-rs738409 and TM6SF2-rs58542926 missense variants are associated with laboratory parameters in obese adolescents

Shahri Khudiyeva[1], *Yasemin Oyacı*[2;3], *Aylin Yetim Şahin*[1;3], *firdevs baş*[1], *Sevde Sayın*[2;3], *İbrahim Kandemir*[4], *Edanur Karapınar*[5], *Sacide Pehlivan*[2]

[1]*Istanbul Faculty of Medicine, Istanbul University, Department of pediatrics, Istanbul, Türkyie;* [2]*Istanbul Faculty of Medicine, Istanbul University, Department of Medical Biology, Istanbul, Türkyie;* [3]*Institute of Graduate Studies in Health Sciences, Istanbul University;* [4]*Biruni University, Department of pediatrics, Istanbul, Türkyie;* [5]*Istanbul Faculty of Medicine, Istanbul University, Deparment of radiology, Istanbul, Türkyie*

Background/Objectives: This study aimed to examine the relationship between PNPLA3-rs738409 and TM6SF2-rs58542926 missense gene variants and NAFLD in obese adolescents.

Methods: We included 71 NAFLD(+), 30 NAFLD(-) obese and 58 healthy adolescents (HA) in this study. Hepatosteatosis status was examined by ultrasonography in obese adolescents. Genotyping analyzes of PNPLA3-rs738409 and TM6SF2-rs58542926 gene variants were performed using the PCR-RFLP method. The relationship between genotype and allele frequencies of gene variants between HA, obese NAFLD(-) and obese NAFLD(+) groups was examined. Bayesian Kendall's tau test was used for

independence hypotheses in the evaluation of laboratory findings and clinical variables.

Results: No statistically significant relationship was determined between the genotype and allele frequencies of PNPLA3-rs738409 and TM6SF2-rs58542926 gene variants among the three groups. In the NAFLD(-) group, AST levels of PNPLA3-rs738409 GC or GG genotype carriers were found to be 3.3 IU/L ($p = 0.046$) higher on average than CC genotype carriers. In the same group, BUN levels of TM6SF2-rs58542926 TC genotype carriers were found to be 2.9 mg/dL higher on average than CC genotype carriers ($p = 0.005$). In the NAFLD(+) group, the serum creatinine level of PNPLA3-rs738409 GC or GG genotype carriers was on average 1.3 mg/L lower than that of CC genotype carriers ($p = 0.021$).

Conclusion: A significant relationship was found between the genotype frequencies of PNPLA3 and TM6SF2 missense gene variants and laboratory parameters in adolescent obesity in the Turkish population.

Grants: This study was supported by the Scientific Research Project Coordination Unit of Istanbul University under Grant [number:TTU-2023-40010].

P05.037.A Rare autosomal-recessive missense variants in *C2CD3* as a novel cause of non-syndromic nephronophthisis

Zachary Sentell[1], *Lina Mougharbel*[2], *Zachary Nurcombe*[1], *Sima Babayeva*[3], *Marc Henein*[4], *Lee Lee Chu*[2], *Murielle Akpa*[2], *Jean-Baptiste Rivière*[2], *Paul Goodyer*[5], *Elena Torban*[3], *Thomas Kitzler*[6]

[1]*McGill University, Department of Human Genetics;* [2]*The Research Institute of the McGill University Health Centre;* [3]*McGill University Health Centre, Department of Medicine;* [4]*McGill University, School of Medicine;* [5]*McGill University Health Centre, Department of Pediatrics;* [6]*McGill University Health Centre, Division of Medical Genetics*

Background/Objectives: Ciliopathies are heterogeneous genetic disorders predominantly caused by autosomal-recessive genetic variants that disrupt primary cilium function. Clinically, they manifest as a syndromic phenotypic spectrum, often involving kidney. Biallelic pathogenic variants in *C2CD3* disrupt ciliogenesis and cause a syndromic ciliopathy (Orofaciodigital syndrome XIV, OMIM #615948). We present evidence for compound heterozygous missense variants in *C2CD3* that result in an isolated renal-specific phenotype in a patient with non-syndromic nephronophthisis.

Methods: Exome sequencing identified biallelic *C2CD3* missense variants (p.Pro168Leu; p.Thr2079Met). Patient-derived fibroblasts and urinary renal epithelial cells (URECs), as well as human RPE-1 *C2CD3* knockout cell-lines were used for in vitro studies.

Results: Patient fibroblasts produced shorter cilia compared to a healthy sibling (2.309 vs. 2.850 µm, $P < 0.0001$), while URECs showed significantly shortened cilia (2.068 vs. 2.807 µm, $P < 0.0001$) and significantly reduced ciliation when compared to a healthy control. The latter was not observed in fibroblasts, suggesting a kidney-specific effect. Sonic hedgehog signaling was impaired in patient cells as expression of GLI3 activator protein and *GLI1* mRNA was reduced. Protein colocalization analysis demonstrated reduced C2CD3 localization to the basal body in patient URECs. Finally, rescue experiments in RPE1-*C2CD3*-KO cells corroborated the findings in patient-derived cells by demonstrating significantly reduced ability to restore ciliogenesis for each variant compared to wild-type.

Conclusion: Biallelic hypomorphic missense variants in *C2CD3* result in a novel non-syndromic nephronophthisis phenotype, as demonstrated by impaired ciliogenesis.

P05.038.B Clinical features and genetic analysis of a case series of Primary Ciliary Dyskinesia: the importance of trio analysis.

Federico Rondot[1], *Amedeo Primerano*[2], *Giulia Vinci*[1], *Patrizia Dentelli*[1], *Barbara Pasini*[1;2]

[1]*University of Turin, Department of Medical Sciences, Turin, Italy;* [2]*AOU Città della Salute e della Scienza di Torino, Italy*

Background/Objectives: Primary ciliary dyskinesia (PCD) is a rare genetic disorder characterized by impaired ciliary function, leading to recurrent respiratory infections and various multi-organ manifestations. We present a case series of 8 subjects with a clinical diagnosis of PCD with variable clinical manifestations including situs viscerum inversus, perinatal respiratory distress and recurrent airways flogistic episodes. Subjects underwent high-speed video microscopy identifying abnormal ciliary motion patterns, that strengthed the clinical suspicion of PCD. To establish a definitive genetic diagnosis, trio exome sequencing was employed.

Methods: SureSelect-Agilent Custom-Constitutional-Panel-17Mb encompassing 5219 genes. Virtual panel "PCD" (41 genes).

Results: Definitive molecular diagnosis was achieved in 4 of 8 patients (DNAH5, RSPH9, CCDC40). Molecular diagnosis was not conclusive in 3 patients due to the presence of uncertain significance variants or heterozygous pathogenic variant (DNAH11, DNAH5, ODAD2, DNAI1, DNAH1). Finally, we report for the first time, at the best of our knowledge, a likely pathogenic ALU insertion predicted to disrupt the canonical donor site of DNAH5 exon 26.

Conclusion: This study highlights the significance of a trio approach in enhancing the diagnostic yield for PCD, providing valuable insights into the inheritance pattern, and facilitating genetic counseling for affected families. The case series enhances our understanding of PCD, emphasizing the need for integrated clinical and genetic approaches in diagnosis and management. Furthermore, the identification of an ALU insertion expands the genetic mechanisms of disease, serving as a crucial warning to carefully consider such mutations in ambiguous cases or those lacking molecular diagnoses.

P05.039.C The role of nonsense variants of RET in the mechanisms of pathogenicity of Hirschsprung's disease: the first Italian family carrying the c.208C>T p.(Gln70Ter) variant

Ludovica Fortuna[1;2], *Eugenia Tulli*[1;2], *Claudio Ricciardi Tenore*[1;2], *Maria Elisabetta Onori*[1;2], *Alessia Perrucci*[1;2], *Elisa De Paolis*[1;2], *Maria De Bonis*[1;2], *Daniela Mazzà*[3], *Anna Saramin*[4], *Angelo Minucci*[1;2], *Martina Rinelli*[1;2]

[1]*Fondazione Policlinico Universitario A. Gemelli IRCCS, Departmental Unit of Molecular and Genomic Diagnostics, Roma;* [2]*Genomics Research Core Facility, Gemelli Science and Technology Park (GSTeP), IRCCS Fondazione Policlinico Universitario Agostino Gemelli, Roma;* [3]*Institute for Maternal and Child Health, IRCCS Materno Infantile "Burlo Garofolo", Trieste;* [4]*University of Trieste, Department of Medicine, Surgery and Health Sciences, Triese*

Background. Hirschsprung's disease (HSCR) is a dominant condition, occurring in approximately 2-2.8 in 10.000 newborns. It is a classical model of enteric neuropathy characterized by bowel obstruction and absence of enteric ganglia in distal colon.

Pathogenic variants in *RET*, *NRG1*, and *L1CAM* genes have been found in most cases of HSCR. *RET* proto-oncogene encodes a receptor tyrosine kinase for members of glial cell line-derived neurotrophic factor (GDNF) family. *RET* activating point mutations are responsible for multiple endocrine neoplasia type 2A whereas, *RET*-inactivating point mutations or deletions, lead to development of HSCR. We report a family of isolated HSCR associated with a nonsense variant in the *RET* gene.

Materials and methods. A 30 years-old female subject and her son were both affected by isolated HSCR, which required the surgical partial colon resection.

Results. Clinical Exome analysis and Sanger sequencing performed in our two subjects allowed to identify a nonsense *RET* variant, *c.208C>T* p.(Gln70Ter), in both. The truncating variant occurs in exon 2 and causes the loss of the entire RET protein.

Conclusions. *RET* mutations have been found in up to 5% of sporadic HSCR and up to 50% of familial cases. Mutations in *RET* extracellular domain impair its cell surface expression, most likely due to misfolding of protein. Nonsense changes result in deleterious form of truncated proteins, depending on position of variants.

Our findings suggest a pathogenic effect of this nonsense variant according to others loss of function changes in *RET*. This mutation was previously reported only in just one other study about 601 Chinese patients.

Conflict of Interest: None declared

P05.040.D Novel biallelic missense variants in LSR supporting cause of pediatric cholestasis

Carolin Meier[1], *Maria Eugenia Rocha*[1], *Javier Martini*[1], *Maryam Najafi*[1], *Omar Bawazir*[1], *Mariana Ferreira*[1], *Emir Zonic*[1], *Uros Hladnik*[1], *paskal cullufi*[2], *Rabab al-Qaysi*[3], *Huma Cheema*[4], *Omid Paknia*[1], *Jorge Pinto Basto*[1], *Aida Bertoli-Avella*[1], *Kornelia Tripolszki*[1], *Peter Bauer*[1]

[1]*CENTOGENE GmbH, Rostock, Germany;* [2]*University Hospital Center "Mother Teresa", Tirana, Albania;* [3]*Children Welfare Teaching Hospital, Baghdad, Iraq;* [4]*University of Child Health Sciences, Lahore, Pakistan*

Background/Objectives: The role of the Lipolysis-stimulated lipoprotein receptor (LSR) gene in human disease has not yet been fully established. However, it has been associated with pediatric cholestasis caused by biallelic missense variants based on two patients. Familial intrahepatic cholestasis is an autosomal recessive heterogenous disorder characterized by disruption of bile formation leading to hepatocellular cholestasis with infantile onset. The LSR protein is presumed to be involved in clearing of triglyceride-rich lipoprotein from blood. Here, we report six unrelated patients presenting with early-onset cholestasis. Four of them were known to have parental consanguinity.

Methods: To identify causative variants, exome/genome sequencing was performed in two female and four male patients clinically presenting with childhood-onset cholestasis, jaundice and/or conjugated hyperbilirubinemia. Analysis of the data and our Biodatabank was performed. Gene-disease relationship was evaluated according to ClinGen guidelines.

Results: Our analysis revealed homozygous missense variants in the *LSR* gene in all six individuals. No patient had a positive finding in an alternative diagnostic gene explaining the cholestasis, therefore the variants in *LSR* remain the only explanation. In two patients the variant NM_205834.3:c.658G>A p.Val220Met was identified, whereas the other patients presented with the variants NM_205834.3:c.715C>T p.Leu239Phe, NM_205834.3:c.889T>C p.Cys297Arg, NM_205834.3:c.832G>C p.Gly278Arg and NM_205834.3:c.511C>T p.Arg171Cys. To our knowledge, all variants were novel and have not been reported in the literature to date.

Conclusion: Although gene-disease relationship for this gene remains limited, our findings further contribute to the association of *LSR* with a cholestasis phenotype and support *LSR* as potential diagnostic gene. Furthermore, it emphasizes the genetic heterogeneity of familial intrahepatic cholestasis.

P05.041.A The Clinical and Molecular Spectrum of Bardet-Biedl Syndrome: 18 Cases

Turkan Turkut Tan[1], *Yusuf Dogan*[1], *Enise AVCI DURMUŞALİOGLU*[1], *Durdugül Ayyıldız Emecen*[1], *Esra Isik*[1], *Ozgur Cogulu*[1], *Tahir Atik*[1]

[1]*Ege University Faculty of Medicine, Department of Pediatric Genetic Diseases, İzmir, Türkyie*

Background / Objective:

Bardet-Biedl syndrome (BBS) is a rare, multisystemic autosomal recessive disorder caused by primary cilia dysfunction. It is a clinically and genetically heterogeneous group of diseases and commonly seen in populations where consanguineous marriages are prevalent. This study aims to evaluate the clinical and molecular features of Bardet-Biedl syndrome.

Method:

Clinical and molecular findings of 18 Bardet-Biedl syndrome cases followed at the Department of Pediatric Genetic Diseases, Ege University, were retrospectively reviewed.

Results: Of the cases diagnosed with BBS, 8 are female and 10 are male. Obesity was observed in 17/18 cases, retinal dystrophy in 8/18, polydactyly/brachydactyly in 10/18, renal anomalies in 4/18, learning difficulties in 18/18, and hypogonadism in 6/18. In 15 patients, 10 different single nucleotide variants/small indels in 5 genes (*BBS1, BBS2, BBS4, BBS9, BBS10*) are detected using NGS. One of these variants (*BBS1*:c.508C>T) has not been previously reported in the literature. In remaining 3 patients, NGS-based CNV analysis revealed one has a homozygous deletion in exons 18-19 of the *BBS9* gene, one in exon 16 of the *BBS9* gene, and one in exons 3-4 of the *BBS4* gene. According to the ACMG 2015 criteria, all the variants are classified as pathogenic.

Conclusion: Clinical and genetic diversity of BBS significantly complicates the diagnosis process. The use of next-generation sequencing (NGS) methods, along with NGS-based CNV analysis, has increased the rate of diagnosis. Identifying the underlying genetic cause allows for effective genetic counseling and provides predictions about the prognosis of the disease.

P05.044.D A novel missense variant in the imprinted *IGF2* locus causes monogenic short stature in two German families

Malin Dewenter[1], *Annemarie Jonasson*[1], *Stephanie Schwarz*[2], *Barbara Oekl-Jaschkowitz*[2], *Tilman Rohrer*[3], *Dorna Hogeabri*[3], *Gerhard Binder*[4], *Hanno Bolz*[1]

[1]*Bioscientia Institute for Medical Diagnostics GmbH, Human Genetics, Ingelheim, Germany;* [2]*Bioscientia, Practice of Human Genetics, Homburg, Saar, Germany;* [3]*Saarland University Medical*

Center, University Children's Hospital, Homburg, Germany; [4]University Children's Hospital, Pediatric Endocrinology and Hormone Laboratory, Tübingen, Germany

Background/Objectives: The chromosome region 11p15 contains numerous imprinted genes, including *IGF2*. Paternally inherited heterozygous pathogenic variants in *IGF2* (MIM *147470) are associated with familial Silver-Russell syndrome (MIM #616489). Here, we report on two presumably unrelated families with multiple cases of smallness for gestational age (SGA), short stature and feeding difficulties. The index patients from both families were 5 years and 1 year old, respectively.

Methods: We performed whole-exome sequencing (WES), segregation and biochemical analyses.

Results: WES revealed the previously unreported, very rare heterozygous *IGF2* variant c.172C>T p.(Arg58Cys) in both patients and their fathers. Results from extensive segregation analysis were in line with an imprinted inheritance mode in both families. In family 1, two paternal half-brothers showed a comparable phenotype. In family 2, the index patient's father was similarly affected. All affected individuals carried the heterozygous *IGF2* variant on their paternal allele. In all available samples from unaffected carriers, the variant was present on the maternal allele. In Family 2, further investigations in the index patient showed reduced IGF2 levels and an IGF2/IGF1 ratio consistent with IGF2 deficiency.

Conclusion: Our extensive segregation and cross-family analysis together with biochemical data allowed for classification of the variant as pathogenic. Further analyses are planned to verify the assumed founder nature of the variant and to investigate the methylation pattern in this imprinted region.

Conflict of Interest: None declared

P05.045.A The importance of screening treatable congenital diseases in the context of three congenital sodium diarrhea cases

Ezgi Çevik[1], *Taha Bahsi*[1], *Zeynep Özdemir*[1], *İzzet Özgürlük*[2], *Haktan Bağış Erdem*[1]

[1]*Dr. Abdurrahman Yurtaslan Ankara Onkoloji Eğitim ve Araştırma Hastanesi, Medical Genetics, Ankara, Türkyie; [2]Ankara Bilkent Şehir Hastanesi, Obstetrics and Gynecology, Ankara, Türkyie*

Background/Objectives: Congenital sodium diarrhea (CSD) is a rare, genetically and clinically assorted enteropathy that comprises two forms. Recessive *SPINT2* mutations lead to the syndromic form, however, the non-syndromic form may occur due to dominant mutations in *GUCY2C* or biallelic mutations in *SLC9A3* which is liable for normal functioning of the Na + /H+ antiporter 3 of intestinal brush border. Common clinical symptoms are intractable watery diarrhea of intrauterine onset with high fecal sodium loss, dilation of bowel loops, growth retardation, and a history of polyhydramnios.

Methods: We present two consanguineous families with three affected children. Two of the children were sisters. All three patients had a history of polyhydramnios, watery diarrhea, and growth retardation. Apart from these, one of the sisters had neuropsychomotor developmental delay. Additionally, the other sister and the male patient had a history of surgery due to ileus. All three had abnormal intestinal histopathological findings. The male patient's growth is normal without supplementation although both of the sisters were deceased. WES analysis was performed on the male patient and the parents of the siblings.

Results: A novel homozygous mutation of c.1446+1G>C in *SLC9A3*(NM_004174.4) gene was identified as the likely cause of the diarrhea.

Conclusion: We identified three patients with a novel variant in the *SLC9A3* gene. Considering the variable expressivity of the disease, diagnostic process is challenging. Nevertheless, CSD is a treatable congenital disease, since good evolution is possible with immediate and adequate fluid-electrolyte supplementation. Therefore, we emphasize the importance of newborn genetic screening for treatable congenital diseases.

Conflict of Interest: None declared

P05.046.B Shorter telomeres in individuals with COPD exposed to biomass-burning smoke.

Angélica Domínguez-de-Barros[1], *Malena Gajate-Arenas*[1], *Gloria Pérez-Rubio*[2], *Ingrid Fricke-Galindo*[2], *Alejandra Ramírez Venegas*[3], *Rafael Hernández-Zenteno*[3], *Salvador García-Carmona*[2], *Robinson Robles-Hernández*[3], *Ramces Falfán Valencia*[2], *Elizabeth Córdoba-Lanús*[4]

[1]*Instituto Universitario de Enfermedades Tropicales y Salud Pública de Canarias (IUETSPC). Universidad de La Laguna, La Laguna, Tenerife, Spain., San Cristóbal de La Laguna, Spain; [2]Instituto Nacional de Enfermedades Respiratorias, Ismael Cosío Villegas (INER) - Ciudad de México (Mexico)., HLA Laboratory, Ciudad de México, Mexico; [3]Departamento de Investigación en Tabaquismo y EPOC, Instituto Nacional de Enfermedades Respiratorias Ismael Cosio Villegas, - Ciudad de México (Mexico)., Ciudad de México, Mexico; [4]Consorcio Centro de Investigación Biomédica en Red (CIBER) de Enfermedades Infecciosas CIBERINFEC, Instituto de Salud Carlos III, Madrid, Spain., Madrid, Spain*

Background/Objectives: Tobacco smoke is the leading cause of chronic obstructive pulmonary disease (COPD), but biomass-burning smoke (BBS) exposure is a significant risk factor, especially in low-income countries. COPD has been described as a disease of accelerated aging, induced cellular oxidative stress and inflammation, and telomere length as an aging marker. The clinical consequences of telomere shortening and cellular senescence in COPD caused by biomass exposure (BE) have not been explored.

Methods: 93 COPD cases secondary to BBS (BE-COPD) and 96 individuals exposed to BBS daily as controls were selected for the study. A subset of 41 individuals from each group were matched by age and hours/day of BBS exposure. Leucocyte relative telomere length (rTL) was determined by qPCR. Pulmonary function variables were registered.

Results: TL inversely correlated with age ($r = -0.182$, $p = 0.016$) and biomass exposure ($r = -0.301$, $p = 0.003$). The matched individuals' subsample showed BE-COPD cases to had shorter telomeres than controls (mean rTL 0.73 ± 0.43 vs. 1.38 ± 0.47; $p < 0.001$). This was confirmed in the whole cohort (OR = 0.134, CI 95% = 0.053-0.339; $p < 0.001$), adjusting by age and hours/day biomass exposure. A borderline association was found between shorter telomeres and impaired pulmonary function, as noted for FEV_1 and FVC% ($p < 0.05$ respectively) in matched BE-COPD subjects.

Conclusion: BE-COPD cases present shorter telomeres than controls, independently of age and biomass-burning smoke exposure. The preliminary association found between lung impairment (decreased FEV_1 and FVC%) and a shorter rTL in BE-COPD needs to be assessed in a large cohort to confirm these findings.

P05.047.C The importance of genetic testing in adult-onset kidney diseases – Genetic Nephrology clinic overview

Galit Lazer Derbeko[1], *Omri Weiss*[1], *gheona Altarescu*[1;2]

[1]*Shaare Zedek Medical Center, Jerusalem, Israel;* [2]*Faculty of Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel*

Background: Kidney disease has reached near pandemic proportions with as many as 1:7 affected in certain populations. Individuals with kidney-related genetic disorders are at a high risk of developing end-stage renal failure, raising the need for genetic clinics specializing in nephrology.

Methods:Summarizing diagnostic yields and demographic data of our adult Genetic Nephrology Clinic.

Results: In 12 months (12.2022-01.2024), a total of 62 patients visited our Genetic Nephrology clinic due to suspected genetic kidney diseases. 40 individuals (64%), from 32 families, underwent genetic testing. A gene panel was done for all 32 probands, with an average age of 42 years during testing. 8 (25%) Pathogenic, 13 (40.6%) variants of uncertain significance (VUS), and 11 (34.4%) negative results were obtained. We report an overall diagnostic yield of 25%, found at the low end of the previously reported findings range (20%-78%). We are also reporting a high ratio of VUS results (40.6%), highlighting an issue with gene panel reporting criteria. In addition, we have observed a high disparity in testing of females (22:66%) vs. male (10:34%), even though the acceptance rate at the clinic was 29 (54%) females vs 25 (46%) males.

Conclusion: A genetic diagnosis of adult genetic kidney diseases often involves treatments, follow-up monitoring, genetic counseling regarding reproductive opportunities, family member testing and in some cases, kidney transplantation. Early diagnosis and intervention are crucial for effectively managing these conditions and improving the quality of life for affected individuals. Our results show the importance of integration of genetic clinics in adult nephrology diagnosis.

P05.048.D Common endocrine disorders- does genetic work-up influence clinical decisions? A joint perspective of geneticists and endocrinologists

Noa Shefer Averbuch[1;2;3], *Michal Levy*[3;4], *lina basel-salmon*[1;3], *Naama Orenstein*[1;3]

[1]*Rabin Medical Center, Beilinson campus, Recanati Genetic Institute, Israel;* [2]*schneider children's medical center of israel, The Jesse Z and Sara Lea Shafer Institute for Endocrinology and Diabetes, National Center for Childhood Diabetes, Israel;* [3]*Tel Aviv University, The Faculty of Medicine, Israel;* [4]*Rabin Medical Center, Beilinson campus, Recanati Genetic Institute, Ramat Hasharon*

Objective: This study aims to evaluate the impact of genetic testing on clinical decision-making in prevalent endocrine disorders.

Methods: Impact of 500 genetic consultations for diverse endocrinopathies performed between January 2018 to January 2024 was assessed, with a focus on short stature and diabetes, the two most common disorders referred for evaluation. The impact of genetic results on clinical decisions was assessed through two criteria: alterations in pharmaceutical treatment and modifications to the follow-up protocol that would not have been initiated otherwise.

Results: Out of 94 diabetes patients, 65 (70%) underwent genetic work-up, resulting in a significant clinical impact for 34 patients (52%). Notably, 8 patients (24%) experienced changes in pharmaceutical treatment, and in 26 (76%) modifications were made in medical follow-up. In the short stature group (118 patients), 77 (65%) completed genetic work-up, leading to substantial clinical impact for 30 patients (40%). This included medical treatment changes for 21 patients (27%) and alterations in medical follow-up for 56 patients (76%).

Discussion: Attaining a definitive diagnosis holds significant importance, impacting numerous family members and family planning decisions. While it may not always directly influence treatment, particularly in monogenic disorders where genetic treatments are limited, comprehending the molecular basis of the disorder, especially in endocrine disorders, frequently plays a pivotal role in determining the optimal medical therapy, choice of medications, and follow-up protocols.

P05.049.A Unraveling the Genetic Tapestry of Obesity: Insights from a Diverse Patient Cohort

Ehud Banne[1], *tal Ben Ari*[1], *Marina Michelson*[1], *Dikla Pivko Levy*[1]

[1]*Wolfson Medical Center, Affiliated with the Tel Aviv University*

Background/Objectives: Obesity is a pervasive global health issue, especially prevalent among younger demographics and with multifaceted etiology. This study aimed to investigate the clinical and genetic factors associated with obesity in a diverse cohort of pediatric and adult patients.

Methods: Data from 10 patients aged 8-32 years were analyzed, focusing on variables such as BMI, hyperphagia presence, genetic variants, birth weight, and parental obesity association. Genetic analysis assessed variants in genes linked to obesity and other biological functions.

Results: Among pediatric patients, the mean BMI was 41.6 kg/m^2, surpassing the 99th percentile threshold, indicative of severe obesity. Hyperphagia was noted in 80% of patients, hinting at genetic predisposition. Genetic analysis revealed 0-4 variants per patient, with 50% harboring at least one obesity-related variant. Birth weight varied, mostly within appropriate gestational age, while parental obesity correlated significantly with pediatric obesity.

Conclusion: Identified variants spanned genes involved in diverse functions, including Bardet-Biedl syndrome and neurodevelopmental pathways. Most variants were classified as variants of uncertain significance (VUS), highlighting challenges in interpretation. The study underscores the need for discerning between pathogenic and benign variants, emphasizing personalized management approaches guided by genetic profiles. Integrating genetic testing into clinical practice may enable targeted interventions, while further exploration of genotype-phenotype correlations is vital for advancing our understanding and refining precision medicine strategies in obesity management.

This Study was aided by the RHYTHM company sponsored genetic testing. Genetic testing was conducted in CGC Genetics.

P05.050.B Identification of genetic etiology in 130 patients with congenital hypopituitarism

Zehra Yavaş Abalı[1;2;3], *Guven Toksoy*[3], *Firdevs Bas*[4], *Tulay Guran*[2], *Ayse Pinar Ozturk*[4], *Volkan Karaman*[3], *Ayça Dilruba Aslanger*[3], *Sukran Poyrazoglu*[4], *Serap Turan*[2], *Abdullah Bereket*[2], *Feyza Darendeliler*[4], *Zehra Oya Uyguner*[3]

[1]*Istanbul University Institute of Health Sciences, Department of Genetics, Istanbul, Türkyie;* [2]*Marmara University School of Medicine, Department of Pediatric Endocrinology and Diabetes, Istanbul, Türkyie;* [3]*Istanbul University Istanbul Faculty of Medicine, Department of Medical Genetics, Istanbul, Türkyie;* [4]*Istanbul University*

Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkyie

Background Congenital hypopituitarism (CH) results from gene variants causing a deficiency in pituitary hormones. Identifying the genetic etiology is essential in predicting the degree of pituitary dysfunction and extra-pituitary features. We aimed to uncover the genetic causes in a large CH group using diverse techniques and an algorithmic approach.

Methods A targeted gene panel was used in 130 individuals (47 female) with CH. Multiplex ligation-dependent probe amplification (MLPA) was used in 67 cases, and exome sequencing (ES) was conducted for 22 of them with 16 indexes (including 2 trios and 2 paired) evaluated. Segregation analyses were performed.

Results The median age during molecular studies was 19 years (2-35 years), with a 35.6% consanguinity rate. Pathogenic/likely pathogenic variants/deletions in CH-associated genes were found in 19.6% of the cohort [*PROP1* = 4, *WDR11* = 3, *GH1* = 3, *IGSF1* = 2, *HESX1* = 2, *LHX3* = 2, *POU1F1* = 2, *PROKR2* = 2, *GHRHR* = 3, *GHSR* = 1, and *HHIP* = 1)]. ES revealed pathogenic variants in the *GLI2* (n = 2), and *RNPC3* genes (n = 2). Variants of uncertain significance (VUS) were found in *SMO* (n = 1), *ROBO1*(n = 1), *MFHAS1*(n = 1), and *SMCHD1*(n = 1) genes associated with CH. The synonymous variant in the *MFHAS1* gene is predicted to impact splicing with ongoing functional analyses. Further investigations on candidate genes are underway in two cases.

Conclusion The definitive molecular etiology could be determined in 24% of cases through various molecular techniques in a large cohort of CH. This implies that unknown molecular pathways or factors such as epigenetic and environmental influences may contribute to the etiology of CH.

Grants: Scientific Research Projects Coordination Unit of Istanbul University (TDK-2022-38742).

P05.051.C Syndromic subtypes of monogenic diabetes account for a third of all cases diagnosed in a UK diagnostic laboratory

Kevin Colclough[1], *Kashyap Patel*[2]

[1]*Royal Devon and Exeter NHS Foundation Trust, Exeter Genomics Laboratory, Exeter, United Kingdom;* [2]*University of Exeter Medical School, Institute of Biomedical and Clinical Science, Exeter, United Kingdom*

Background/Objectives: The Exeter Genomics Laboratory provides a diagnostic service for monogenic diabetes using a targeted next generation sequencing (tNGS) assay that sequences both non-syndromic (MODY) and syndromic monogenic diabetes genes. We assessed the diagnostic utility of this non-selective sequencing approach.

Methods: We retrospectively collated data on 1811 children and young adults with a clinical suspicion of monogenic diabetes. All probands were tested using a tNGS assay of 9 MODY and 18 syndromic diabetes genes from January 2020 to November 2023. We determined the diagnostic yield of this assay and the proportion of patients diagnosed with a syndromic form of monogenic diabetes.

Results: A diagnosis of monogenic diabetes was made in 326/1811 individuals (18%). 103 individuals had a pathogenic variant in a syndromic diabetes gene, giving a diagnostic yield of 6% and accounting for 32% of all monogenic diabetes cases. A total of 13 different syndromic subtypes were diagnosed. The pathogenic variant *MT-TL1* m.3243A>G and pathogenic variants in *HNF1B* and *WFS1* accounted for 78% of all syndromic diabetes cases, with *MT-TL1* m.3243A>G being the 3rd most common cause of monogenic diabetes after *GCK* and *HNF1A*. Only 14% of individuals with a variant in a syndromic gene had a clinical suspicion of the disorder. Variable clinical penetrance, diabetes as the first presenting feature or lack of supporting information from the clinician accounted for these unexpected diagnoses.

Conclusion: Sequencing of both MODY and syndromic monogenic diabetes genes maximises diagnostic yield and overcomes the limitation of selective gene testing based on clinical features.

Conflict of Interest: None declared

P05.052.D Gene expression dynamics of immune cells and its genetic determinants in primary sclerosing cholangitis

Chiara Caime[1], *Pietro Demela*[2], *Rosanna Asselta*[3], *Pietro Invernizzi*[1], *Alessio Gerussi*[1], *Blagoje Soskic*[2]

[1]*University of Milano-Bicocca, Medicine and Surgery Department, Monza, Italy;* [2]*Human Technopole, Population and Medical Genomics Department, Milan, Italy;* [3]*Humanitas University, Biomedical Sciences Department, Pieve Emanuele (Milan), Italy*

Background/Objectives: Primary Sclerosing Cholangitis (PSC) is a rare autoimmune cholangiopathy with polygenic influences and unknown etiology, and the role of T cells in its pathogenesis remains unclear. Elucidating relevant T cell states in which disease-associated variants alter gene expression is critical for testing new drug targets and identifying biomarkers. Here, we aimed to systematically identify T cell states that are enriched for PSC-related susceptibility variants.

Methods: Single-cell (sc)RNA-seq data on intrahepatic T cells from 11 patients with PSC (cirrhotic = 9, non-cirrhotic = 2) were downloaded from the EBI ArrayExpress database (E-MAT-10143). To identify possible causative cell types shared across diseases, summary statistics (GWAS Catalog) were downloaded and integrated with scRNA-seq data using CELLECT-MAGMA. Metabolic-associated Steatotic Liver Disease (MASLD), primary biliary cholangitis (PBC), systemic lupus erythematosus (SLE), celiac disease (CD), multiple sclerosis (MS), rheumatoid arthritis and heart attack were used as control diseases.

Results: We quantified the association between cell-type expression specificity and heritability in PSC, revealing that Th1 cells and Tem/Trm cytotoxic cells are prioritized among all cell types (p-value = 0.007 and p-value = 0.002). In contrast, none of the subpopulations studied were implicated in the pathogenesis of MASLD and heart attack. The Th1 subpopulation is shared with PBC, SLE and CD (p-value = 0.048, p-value = 0.006, p-value = 0.011). The Tem/Trm subpopulation is shared with SLE, CD and MS (p-value = 8.56*10-6, p-value = 4.67*10-6, p-value = 0.001).

Conclusion: By analyzing T cell gene expression and genetic data in PSC, our study identifies Th1 and Tem/Trm cytotoxic cells as key players in its pathogenesis, linking PSC with broader autoimmune disease mechanisms.

P05.053.A Renal and extrarenal disease progress in individuals with Alport syndrome and the "hypomorphic" variant p.Gly624Asp in *COL4A5*

Anna Neuhaus[1], *Annika Jens*[2], *Bastian Malte Krüger*[3], *Korbinian M. Riedhammer*[1;4], *Jasmina Comic*[1], *Julia Hoefele*[1], *Jan Halbritter*[2]

[1]*Klinikum rechts der Isar, Technical University of Munich, TUM School of Medicine and Health, Institute of Human Genetics, Munich, Germany;* [2]*Charité Universitätsmedizin Berlin, Department of Nephrology and Medical Intensive Care, Berlin, Germany;* [3]*University of Leipzig Medical Center, Division of Nephrology, Leipzig, Germany;* [4]*Klinikum rechts der Isar, Technical University of Munich, TUM School of Medicine and Health, Department of Nephrology, Munich, Germany*

Background/Objectives: Alport syndrome (AS) is a hereditary nephropathy characterized by microscopic haematuria and proteinuria leading to kidney failure (KF). Around 1/3 of individuals exhibit extrarenal symptoms such as hearing impairment. AS is predominantly linked to X-linked inheritance (disease-causing variants in *COL4A5)*. The variant p.Gly624Asp in *COL4A5* is most frequent in Eastern and Central Europe and was shown to be associated with a milder renal phenotype. The aim of this study was to collect clinical data of individuals with this variant and investigate their disease progression and extrarenal manifestation.

Methods: The cohorts comprised individuals from university hospitals in Munich, Berlin, and Leipzig. Data were collected from medical reports, and through direct communication with the treating physician and/or the patients.

Results: The total cohort comprised 93 individuals, 53 women and 40 men (mean age: 39 years). The control cohort consisted of 88 age- and sex-matched individuals (51 women and 37 men) with non-p.Gly624Asp-glycine missense variants in *COL4A5* (mean age: 37 years). A significant difference concerning the age of onset resp. proteinuria and in the reduction of glomerular filtration rate throughout the lifespan was observed among patients. There were no significant differences in the initial appearance of haematuria, the age of onset and the development of extrarenal symptoms, and the average age at first manifestation.

Conclusion: Although *COL4A5*-p.Gly624Asp is known to be a "hypomorphic" variant, the present data shows that affected individuals still have a substantial risk for the development of KF and extrarenal manifestations.

P05.055.C Partial duplication of HNF4A related to MODY1: molecular characterization and genotype-phenotype correlation

Marina Viñas-Jornet[1], *Carmen Asensio Ortega*[2], *Josep Oriola*[3;4], *Laura Piñol*[5], *Alba Cebollero Agusti*[6]

[1]*CLILAB Diagnostics, Genetics Lab;* [2]*Complex Hospitalari Moisès Broggi - Consorci Sanitari Integral, Endocrinology and Nutrition Service;* [3]*CDB. Hospital Clínic. Barcelona, Biochemical and Molecular Genetics Service;* [4]*University of Barcelona, Department of Biomedicine. Faculty of Medicine;* [5]*CDB. Hospital Clínic. Barcelona, Biochemical and Molecular Genetics Service;* [6]*CLILAB Diagnostics*

Background/Objectives: Maturity-onset diabetes of the young (MODY) is a group of monogenic autosomal dominant forms of diabetes mellitus, characterized by early onset (usually <25 years of age) and no autoantibodies. At least, 14 genes have been described related to this condition. One of them is *HNF4A*, specifically its haploinsufficiency, which is associated with MODY1. We report the case of a 20-year-old patient and her mother, both with clinical suspicion of MODY.

Methods: The proband DNA sample was processed using a custom NGS panel, a commercial MLPA (MRC Holland P241) and PCR followed by Sanger sequencing. Parental samples were analysed with MLPA.

Results: No pathogenic nor likely pathogenic point variants were detected by NGS sequencing. ExomeDepth copy number variation (CNV) suggested the presence of a partial duplication in tandem of exons 6 and 7 in the *HNF4A* gene. MLPA confirmed this duplication. Sequencing of an amplicon obtained using a forward primer located at 3′ of intron 6 and a reverse primer at 5′ of intron 6 confirmed it was in tandem and predicted the creation of a premature stop codon p.(Asp276GlyfsTer32). The study of her mother by MLPA confirmed she was also a carrier of this duplication. Proband and her mother had been previously diagnosed with idiopathic diabetes mellitus at the ages of 13 and 15 respectively.

Conclusion: We have characterized a new partial in tandem duplication of the gene *HNF4A* predicting a frameshift change in the protein. This duplication correlates with the MODY1 phenotype in the proband and her mother.

P05.056.D Molecular Diagnosis of Intrahepatic Cholestasis of unknown origin in pediatric patients

Francesco Giambuzzi[1], *Anna Monica Rosaria Bianco*[1], *Ilaria Ziccardi*[2], *Mariateresa Di Stazio*[1], *Cecilia Del Vecchio*[2], *Adamo Pio D'Adamo*[1;2]

[1]*Laboratory of Medical Genetics, Institute for Maternal and Child Health - IRCCS "Burlo Garofolo", Trieste, Italy;* [2]*Department of Medical, Surgical and Health Sciences, University of Trieste, Trieste, Italy*

Background/Objectives: Progressive Familiar Intrahepatic Cholestasis (PFIC) represents an heterogenous group of recessive diseases caused by mutations in genes encoding for hepatocanalicular acid transporters and phospholipids. At least 45% of pediatric cholestasis disorders have a genetic cause and 20% of liver transplants are performed for monogenic forms in which genetic characterization has important implications. Most of the genes responsible for PFIC are still unknown. Genes identification in PFIC patients may contribute to define cholestatic phenotype.

Methods: 37 patients, with diagnosis of intrahepatic cholestasis of unknown origin, with the aim to identify causative variants by whole exome sequencing (WES), were enrolled. Based on the results obtained, identified variants have been studied by means of functional tests such as immunofluorescence in liver biopsy.

Results: We found mutations in PFIC genes as ATP8B1 and ABCB4 as well as in MYO5B, PLEC, CFTR, ATP7B, NEK8, PHKD1, ATP6AP1 never described before as PFIC genes. We found heterozygous mutations in genes encoding proteins of the hepatocellular transport system, as well as in the cytoskeleton and liver regulatory proteins such as PLEC, which can cause cholestatic diseases with great variability and usually a less severe phenotype.

In patient's liver with PLEC mutations the immunofluorescence assay showed an impaired BSEP targeting and aberrant plectin distribution.

Conclusion: We identified genotype-phenotype correlation among mutations in PFIC genes as well as in genes not still associated with PFIC, which underscore the prognostic value of early genetic diagnosis and disease course could be favorably with positive effects on treatment choice and genetic counseling.

Grants: RC 26/17 IRCCS "Burlo Garofolo"

P05.057.A Two rare cases of Cholestasis with novel heterozygous pathogenic *PLEC* variants.

Ilaria Ziccardi[1], *Anna Monica Rosaria Bianco*[2], *Mariateresa Di Stazio*[2], *Saveria Lory Croce*[1], *Adamo Pio D'Adamo*[1;2]

[1]*University of Trieste, Department of Medical, Surgical and Health Sciences, Trieste, Italy;* [2]*Institute for Maternal and Child Health - IRCCS "Burlo Garofolo", Trieste, Italy*

Background/Objectives: Progressive Familial Intrahepatic Cholestasis (PFIC) is a group of early onset cholestatic liver diseases. Recently, cytoskeleton linker plectin (*PLEC*) gene was found to protect liver from cholestatic injuries, and a pair of siblings with severe cholestasis with compound heterozygous PLEC mutations has been reported.

Methods: We report two female patients with severe cholestasis. The second is a case of intrahepatic cholestasis in a 66-year-old woman with jaundice, initially interpreted as drug-induced liver injury but that, despite the suspension of medications, has not improved. Suspecting PFIC we analyzed by Whole Exome Sequencing and identified variants have been studied by functional tests in liver biopsy.

Results: In the first patient we found compound heterozygous missense mutations in the *PLEC* gene (R1906W and P1146L). Immunofluorescence on liver biopsy showed a reduced PLEC and K8 colocalization; BSEP staining showed an aberrant canalicular pattern suggesting that PLEC mutations may affect BSEP targeting, causing cholestasis.

A liver biopsy of the 66-year-old woman revealed a morphological pattern of severe cholestatic liver disease with modest ductopenia and without significant hepatic inflammation. We found two in cis heterozygous missense mutations (S413R and R3485W) with conflicting interpretation of pathogenicity.

Conclusion: *PLEC* mutations in the first patient are associated with PFIC phenotype, while in the other patient the phenotype has clinically and spontaneously improved. So, *PLEC* heterozygous defects could be associated also with milder forms of cholestatic disease. Sequencing cholestasis genes in patients with adult-onset disease should be considered, with interpretation in collaboration with histopathologists and geneticists.

SKELETAL, CONNETIVE TISSUE, ECTODERMAL AND SKIN DISORDERS

P06.001.B Review of 400 genome analysis for patients with osteochondrodysplasia in the national french SeqOIA laboratory

Sophie Rondeau[1;2], *Audrey Briand-Suleau*[2;3], *Corinne Collet*[1;2], *Séverine Bacrot*[2;4], *Fabienne Escande*[2;5], *Perrine Brunelle*[2;5], *Tania Attie-Bitach*[1;2], *Laurence PACOT*[2;3], *Céline Gaucher*[2;3], *sophie monnot*[1;2], *Lucile Boutaud*[1;2], *Virginie Saillour*[2], *Marine Rajaoba*[1], *Barbara Girerd*[1], *Pauline Marzin*[1;6], *Caroline Michot*[1;6], *Genevieve Baujat*[1;6], *Valérie CORMIER-DAIRE*[1;6]

[1]*Hôpital Necker Enfants malades, Service de médecine génomique des maladies rares, Paris, France;* [2]*Laboratoire SeqOIA, Paris, France;* [3]*Hôpital Cochin, Service de Médecine Génomique des Maladies de Système et d'Organe, Paris, France;* [4]*CH A Mignot, Unité de génétique constitutionnelle, Service de Biologie, Versailles, France;* [5]*CHU Lille, Institut de Biochimie et Biologie Moléculaire, Lille, France;* [6]*Hôpital Necker Enfants malades, Centre de référence des Maladies Osseuses Constitutionnelles, Paris, France*

Background/Objectives: In 2018, a government-led genomic program was introduced in France, resulting in the creation of two national laboratories, namely SeqOIA and Auragen.

Methods: Since then, SeqOIA laboratory has provided genome sequencing for 400 osteochondrodysplasia patients with either a negative targeted panel sequencing or in first line for atypical phenotype. We present the results from this cohort.

Results: A diagnosis was reached in 124 patients (31%), 42 cases (10%) carried a variant of unknown significance, while 234 genomes were negative (59%).

Regarding the 124 positive genomes, 92 genes were involved, with a maximum of 5 patients carrying variants in the same gene (*COL2A1, FGFR3, RPL13*). 8 patients carried structural variants : 3 inversions, 3 large deletions, 1 large duplication and 1 translocation involving *NSD1* gene. We also identified 5 deep intronic variants and 3 uniparental disomies. 4 double diagnoses were also made. Those findings highlight the benefit of the WGS approach.

Variants of uncertain significance, located in 38 different genes, encompass intronic variants, variants in genes not yet involved in human pathology, and variants of unknown significance currently studied at the functional level

Conclusion: We conclude that Whole Genome sequencing has revolutionized the molecular diagnosis of osteochondrodysplasias, improving significantly the diagnostic yield. This advancement is particularly noteworthy as it enables diagnoses that were not accessible through panel or exome sequencing coupled with an array CGH.

P06.002.C Functional study of the *GLI1* gene in Gorlin Syndrome

María Zubieta-Laseca[1;2], *Carlos Gutiérrez-Cerrajero*[1;2], *Angel Santos-Briz Terrón*[1;3], *Diego Iglesias-Corral*[1;2], *Laura Molinero-Sicilia*[1;2], *Miguel Ángel Collado-Pérez*[1;2], *Ana-Belén Herrero*[1;2], *Rogelio González-Sarmiento*[1;2]

[1]*Biomedical Research Institute of Salamanca (IBSAL), Salamanca, Spain;* [2]*University of Salamanca, Faculty of Medicine, Molecular Medicine Unit, Salamanca, Spain;* [3]*University Hospital Virgen de de la Vega, Dermathology, Salamanca, Spain*

Background/Objectives: Gorlin Syndrome is a rare disease characterized by various developmental abnormalities and a high susceptibility to different types of cancer, especially basal cell carcinomas and medulloblastomas. The underlying cause of this syndrome is a constitutive gain of function in the Sonic Hedgehog pathway, commonly resulting from heterozygous loss-of-function mutations in the *PTCH1* and *SUFU* genes. However, about 5% of Gorlin Syndrome patients lack mutations in these genes, and the cause of their disease remains unknown. Previous work in our group identified a heterozygous missense *GLI1* mutation (c.1591C>T/p.R531C) in three different patients without mutations in *PTCH1* and *SUFU*. In this study, we aimed to determine the pathogenicity of this mutation.

Methods: We cloned the *GLI1* cDNA both WT and mutated into a lentiviral vector that was used to infect the keratinocyte cell line Ker-CT. This way, we created two novel cell lines: one that overexpressed *GLI1* WT and another one that overexpressed *GLI1* R531C. We studied the expression of the GLI1 target genes in these cell lines and generated epidermal equivalents from them.

Results: The keratinocyte cell line that carried the *GLI1* mutation showed a higher expression of GLI1 target genes, consistent with

the behavior of a gain-of-function mutation. The epidermal equivalents showed that the cell line carrying the *GLI1* mutation suffered an altered differentiation and displayed features characteristic of Gorlin Syndrome.

Conclusion: These findings may point to a novel relationship between *GLI1* and the development of Gorlin Syndrome.

Grants: This project was funded by Fundación Nemesio Díez.

Conflict of Interest: None declared

P06.003.D Novel biallelic *PISD* missense variants cause spondyloepimetaphyseal dysplasia with disproportionate short stature and fragmented mitochondrial morphology

Tess Holling[1], *Line Nolting*[2], *Gen Nishimura*[3], *Jakob Ek*[4], *Mads Bak*[4], *Merete Ljungberg1*[2], *Kerstin Kutsche*[1], *Hanne Hove*[2]

[1]*University Medical Center Hamburg-Eppendorf, Institute of Human Genetics, Hamburg, Germany;* [2]*Copenhagen University Hospital, Rigshospitalet, Center for Rare Diseases, Department of Pediatrics, København, Denmark;* [3]*Saitama Medical University Hospital, Center for Intractable Diseases, Saitama, Japan;* [4]*Copenhagen University Hospital, Rigshospitalet, Department of Clinical Genetics, København, Denmark*

Background/Objectives: Biallelic *PISD* variants cause a phenotypic spectrum ranging from short stature with spondyloepimetaphyseal dysplasia to a multisystem disorder affecting eye, ear, bone, and brain. *PISD* encodes the mitochondrial-localized enzyme phosphatidylserine decarboxylase. The PISD precursor is self-cleaved to generate a heteromeric mature enzyme that converts phosphatidylserine to the phospholipid phosphatidylethanolamine. We report a patient with novel biallelic *PISD* missense variants.

Methods: Clinical, genomic, and functional studies, including immunoblotting and immunofluorescence analyses, using patient and control fibroblasts.

Results: The 17-year-old male patient born to unrelated healthy parents presented with disproportionate short stature and spondyloepimetaphyseal dysplasia, including platyspondyly, prominent epiphyses, and metaphyseal dysplasia. Trio genome sequencing revealed compound heterozygous *PISD* variants NM_001326411.1:c.569C>T; p.(Ser190Leu) and c.799C>T; p.(His267Tyr). By using patient, parent, and control fibroblasts, we showed similar levels of the PISD precursor in all cell lines. However, patient cells had a significantly higher proportion of fragmented mitochondria compared to control cells cultured under basal condition and after treatment with 2-desoxyglucose that represses glycolysis and stimulates respiration. Data from the published structure of the *E. coli* PISD orthologue suggest that Ser190Leu and His267Tyr likely impair PISD's autoprocessing activity and/or phosphatidylethanolamine biosynthesis.

Conclusion: Our data demonstrate that the novel *PISD* p.(Ser190Leu) and p.(His267Tyr) variants act as hypomorphs and underlie the pure skeletal phenotype in the patient. Recent data showing targeting of PISD to the endoplasmic reticulum and lipid droplets and PISD's role in lipid droplet biogenesis and neutral lipid storage suggest that different functional consequences underlie the different phenotypes associated with biallelic *PISD* pathogenic variants.

Grants: Deutsche Forschungsgemeinschaft (KU 1240/16-1, K.K.).

Background/Objectives: Short anagen hair (SAH) is a rare, paediatric hair disorder characterised by the inability of the scalp hair to obtain length due to a shortened anagen phase. SAH has a strong negative psychological impact on the affected individuals. The genetic basis of SAH was so far unknown.

Methods: Exome sequencing was performed in 27 patients with SAH or with a complaint of short, non-growing hair. Data was screened to identify genes whose variants were enriched in this cohort. Sanger sequencing was used for validation, screening of 21 additional affected individuals and of relatives. Genetic association testing of SAH-related variants with male pattern hair loss (MPHL) was performed using UK Biobank data.

Results: The analyses revealed that 20 affected individuals (~40% of the SAH cohort) carried bi- or mono-allelic pathogenic variants in *WNT10A*. Most of these patients had light-coloured hair, and a regression of the fronto-parietal hairline. The most frequent variant in the cohort, c.682T>A;p.(Phe228Ile), was in linkage disequilibrium with four common *WNT10A* variants with a known association with MPHL. c.682T>A;p.(Phe228Ile), together with another rare SAH-associated variant, partially explained the known associations between *WNT10A* and MPHL.

Conclusion: Rare *WNT10A* variants are associated with a phenotypic spectrum ranging from no clinical signs to severe ectodermal dysplasia. Our results suggest that *WNT10A* is also associated with SAH and SAH has a genetic overlap with the common phenotype MPHL. The presumed shared biological effect of *WNT10A* variants in SAH and MPHL is the shortening of the anagen phase.

P06.005.B Bone age in achondroplasia - comparative study using visual and AI-based technologies

*Minu Fardipour[1], **Kyra Skaf**[1], Sebastian Rassmann[2], Christoph Beger[3], Primoz Kotnik[4], Tinatin Tkemaladze[5], Dr. Katja Palm[1], Peter Krawitz[2], Klaus Mohnike[1], Behnam Javanmardi[2]*

[1]Otto-von-Guericke-University Magdeburg, Medical Faculty, Magdeburg, Germany; [2]University of Bonn, Institute for Genomic Statistics and Bioinformatics, Bonn, Germany; [3]Leipzig University, Growth Network CrescNet, Medical Faculty, Leipzig, Germany; [4]University Medical Center Ljubljana, Department of Endocrinology, Diabetes and Metabolism, Ljubljana, Slovenia; [5]Tbilisi State Medical University, Department of Molecular and Medical Genetics, T'bilisi, Georgia

Background/Objectives: In achondroplasia, the Gly380Arg mutation of the Fibroblast Growth Factor Receptor 3 (FGFR3) gene, results in constitutive activation of chondrocyte proliferation and differentiation during bone growth. Consequently, FGFR3 activation results in characteristic radiological features, e.g. shortening of the tubular bones and impaired epiphyseal growth. These features are used to determine bone age to evaluate growth and puberty as well as timing for limb lengthening and epiphysiodesis procedures. A significant bone age delay was already described in 2010 by Pannier et al. using the Greulich and Pyle (GP) method. However visual determination of skeletal maturation in bone dysplasia suffers from high interrater variability.

Methods: To address the limitations of visual determination, this study aimed to evaluate the effectiveness of an open-source artificial intelligence (AI) tool, *Deeplasia* (Rassmann et al., 2024). The mean absolute difference (MAD) between the AI and the average of four visual determinations performed by four different human raters is used as a measure of the performance of *Deeplasia*.

Results: The preliminary analysis using left-hand radiographs from 25 achondroplastic children within the age range of 5 to 16 years (from University Hospital Magdeburg) resulted in a MAD of 6.5 months between the AI and the average of human raters, compared to the inter-rater error of 13.3 months. We are expanding our current cohort to more centres.

Conclusion: The open-source bone age assessment AI, *Deeplasia*, has a significantly smaller uncertainty in assessing the bone age of individuals with achondroplasia compared to the inter-rater error.

P06.006.C Deletion of the intracellular region of LRP4 leads to sclerosis via dysregulation of the Wnt and Smad pathways

*Caroline Caetano Da Silva[1], Genevieve Baujat[2], Anaik Previdi[2], Kelvin Valmorin[3], Adrien Bloch[3], Valérie CORMIER-DAIRE[2], **Corinne Collet**[2]*

[1]Leonard and Madlyn Abramson Pediatric Research Center, Philadelphia, United States; [2]INSERM UMR 1163, Imagine Institute, Genomic department, Necker-Enfants Malades Hospital, Paris, France; [3]Inserm 1132, Bioscar, Paris, France

Background/Objectives: Sclerosteosis type 1 and 2 are rare bone diseases characterized by high bone mass resulting from excessive osteoblast formation. These diseases are due respectively to pathogenic variants in *SOST* and *LRP4* genes, both involved in the canonical Wnt pathway. *LRP4* facilitates the inhibitory effect of sclerostin on the Wnt pathway by creating a complex with LRP4/SOST/LRP5/6. Pathogenic variants in sclerosteosis type 2 are mainly located in the binding site of sclerostin but other pathological mechanisms seem possible. Therefore, our aim was to better understand the role of *LRP4* during osteoblastic differentiation.

Methods: CRISPR-Cas9-mediated deletions of the intracellular and extracellular domains of LRP4 were generated in U2OS cell lines. To compare mutated and wt cells, differentiation and mineralization assays were performed, along with an estimation of canonical wnt pathway activation and a transcriptome.

Results: The generation of heterozygous variants led to decreased LRP4 protein expression at the plasma membrane, with an abnormal distribution of LRP4 in cells with extracellular deletion. The intracellular variant in LRP4 has an enhanced capacity for differentiation and mineralization; conversely, cells with extracellular deletion resulted in decreased differentiation and mineralization compared to control cells. The intracellular deletion of LRP4 revealed constitutional activation of the canonical wnt pathway. Transcriptome analysis showed dysregulation of various osteoblast-related pathways, in particular Smads.

Conclusion: The intracellular region of LRP4 is important for bone regulation not only through wnt pathways but also by interacting with other pathways such as smads.

P06.007.D Functional studies of mutations responsible for the hereditary human limb malformations.

Akshaya Ramanujam[1], *Ewa Hordyjewska-Kowalczyk[2], Tylzanowski Przemko[3]*

[1]Medical University of Lublin, Department of Biomedical Sciences,Laboratory of Molecular Genetics, Lublin, Poland; [2]KU Leuven, Department of Human Genetics,Laboratory for Skeletal Dysplasia Research, Leuven, Belgium; [3]KU Leuven, Department of Development and Regeneration, Skeletal Biology and Engineering Research Centre,Laboratory for Developmental and Stem Cell Biology, Leuven, Belgium

Background/objectives: Our research concentrates on studying the molecular basis of Clubfoot, a hereditary limb disorder. We have recently identified *TPM2* as a candidate gene associated with that condition and the objective of the study is to establish the genotype-phenotype correlation.

Methods: The *wt* or *mt* mRNA will be injected into a single cell stage zebrafish embryos and the larvae will be analyzed during the next 5 days of development. The morphological analysis will include morphometric analyses and *whole mount* in situ *hybridization*. Loss-of-function experiments will use site directed mutagenesis using CRISPR/*Cas9* strategy by introducing the human mutation into the zebrafish genome and carry out the phenotypic analysis as described above.

Results: We have identified an autosomal dominant mutation, linked to Clubfoot, in *TPM2* gene. The gain of function experiments indicate that the mutation has a severe effect on the zebrafish development including the skeletal structures. The specific phenotypes include a change in the morphology of the somites and ventral tail bending suggesting a disturbance along the dorsal ventral axis. Larvae had also anterior-posterior axis shortening, empty swim bladders, malformed mandible and a pericardial edema. These phenotypes suggest defective *BMP signaling*. For the loss of function experiments, we are in the process of producing relevant crispants.

Conclusion: Our project aims to elucidate the phenotypic-genotypic correlation between the mutation in *TPM2* and the clubfoot phenotype. The identification of distinct genetic markers associated with this malformation will enhance our understanding of the molecular mechanisms governing skeletal morphogenesis.

Grants: OPUS (2019/35/B/NZ5/02955)

P06.008.A Functional studies of hereditary human mutations leading to craniofacial malformations

Paulina Krzesinska[1], *Anna Jaruga*[1], *Krystian Kuźniarz*[2], *Tylzanowski Przemko*[1;3]

[1]*Medical University of Lublin, Department of Biomedical Sciences, Laboratory of molecular Genetics, Lublin;* [2]*Medical University of Lublin, Chair and Clinic of Maxillofacial Surgery, Lublin, Poland;* [3]*KU Leuven, Laboratory for Developmental and Stem Cell Biology, Department of Development and Regeneration, Skeletal Biology and Engineering Research Centre, Leuven, Belgium*

Background/Objectives: We have identified family with autosomal dominant, Non-Syndromic Cleft Lip and Palate (NCL/P) and linked it to mutations in *EHHAD* and *MASP1* genes respectively. In order to explore that link we chose the zebrafish gain and loss of function studies. The main objective of the presented work is to link the mutation to the phenotypic changes in the skeleton and explain the mechanism of action of these genes.

Methods: The *wt* or *mt* mRNA will be injected into a single cell stage zebrafish embryos and the larvae will be analyzed during the next 5 days of development. The morphological analysis will include morphometric analyses and *whole mount* in situ *hybridization*. Loss-of-function experiments will use site directed mutagenesis using CRISPR/Cas9 strategy by introducing the human mutation into the zebrafish genome and carry out the phenotypic analysis as described above.

Results: Injections of mRNAs encoding wt or mutant variants of both genes resulted in dose dependent phenotypes. The most striking defects were shortening of mandible and dorsal bending of the embryo. Additionally, mt mRNA had cyclopic eyes due to lack of forebrain and severe pericardial edema.

Conclusion: Our data suggests that the zebrafish is a viable model organism to study human skeletal malformations. We are currently in the process of finalizing the CRSPR driven genomic site directed mutagenesis. The identification of specific genetic markers associated with these malformations can contribute to a better understanding of the underlying molecular mechanisms and pathways involved in craniofacial development.

P06.009.B Fifth patient with Silver-Russell Syndrome type 4 caused by a deletion of the entire *PLAG1* gene

Bianca Greiten[1], *Andreas Dalski*[1], *Malte Spielmann*[1;2], *Irina Hüning*[1;3]

[1]*Institute of Human Genetics, University of Lübeck, Lübeck, Germany;* [2]*Institute of Human Genetics, University of Kiel, Kiel, Germany;* [3]*MVZ für Humangenetik und Molekularpathologie GmbH, Rostock, Germany*

Background/Objectives: Silver-Russell Syndrome (SRS) is a genetically heterogeneous disorder primarily characterized by pre- and postnatal growth restriction, relative macrocephaly and facial dysmorphism. Recently, sequence variants in and deletions of *PLAG1* have been identified as the cause of SRS type 4. Haploinsufficiency of *PLAG1* leads to a decrease in IGF2 expression.

Methods: We report on an 8-year-old girl with SRS type 4 caused by a *PLAG1* deletion. She had intrauterine growth restriction and was born with birth length, weight and head circumference below the first percentile. Postnatally, she had severe feeding difficulties and mild developmental delay in the first year of life. After that, she reached developmental milestones in time. At the age of 4 years, she developed a tic disorder with motor and vocal tics. Her cognitive abilities were normal. Her body measurements at the age of 8 years were consistently below the 3rd percentile. Most severely impacted was her head circumference (-5,0 SD). She had mild craniofacial dysmorphisms, very suggestive for SRS, including a prominent forehead and triangular face.

Results: Array CGH analysis revealed a 1,2 Mb de novo microdeletion in 8p12.1 including the *PLAG1* gene (arr[GRCh37] 8q12.1(56897469_58105507)x1). It contained the genes from *LYN* to *LINC00968*.

Conclusion: The deletion of the *PLAG1* gene was the most suggestive cause of the patient's phenotype. Her clinical features were consistent with SRS type 4 and overlap with the phenotype of the four patients in the literature thus marking the fifth case. Although unusual for SRS, microcephaly has been described in another patient with *PLAG1* deletion.

P06.010.C Microbiome alterations in icthyotic skin

Judit San Segundo-Lozano[1;2], *Carla Sánchez-Jiménez*[1;2], *Carlos Gutiérrez-Cerrajero*[1;2], *María Zubieta-Laseca*[1;2], *Ana-Belén Herrero*[1;2], *Rogelio González-Sarmiento*[1;2], *Ángela Hernández-Martín*[3]

[1]*Faculty of Medicine, University of Medicine, Department of Medicine, Salamanca, Spain;* [2]*Biomedical Research Institute of Salamanca (IBSAL), Salmanca, Spain;* [3]*Hospital Infantil Niño Jesús, Department of Dermatology, Madrid, Spain*

Background/Objectives: Ichthyoses are disorders of cornification characterized by dry, scaly skin and a disruption of skin barrier function. This disruption promotes bacterial colonization, leading to recurrent infections that severely impair quality of life, can cause auditory complications and, in some cases, can be life threatening. However, very few studies explore the differences in cutaneous bacterial population profiles in the context of this disease.

Methods: A cohort of 34 patients from Hospital Niño Jesús under 18 years of age was analyzed. Clinical data were recorded and healthy and affected skin swabs were taken from scapula and armpit. Bacterial DNA was extracted and 16S rRNA, 18S rRNA and ITS sequences were sequenced in an Illumina NovaSeq X plus. Relative abundances of 246 bacterial *genera* were profiled using QIIME2 and statistical analyses were performed using RStudio.

Results: We initially performed a correspondence analysis comparing the profiles for healthy and affected samples. *Staphylococcus* was most predominantly associated to affected armpit and scapula samples. Meanwhile *Corynebacterium* was most predominantly associated to healthy armpit samples and *Streptococcus* and *Finegoldia* to healthy scapula. We then divided samples according to disease type and performed descriptive statistics. The most common forms of ichthyosis were epidermolytic ichthyosis (EI) and autosomal recessive congenital ichthyosis (ARCI). Within these groups, the most common genus were *Corynebacterium* for EI and *Staphylococcus* for ARCI.

Conclusion: The present study highlights differences in the microbiome between ichthyotic and healthy skin as well as between ichthyosis subtypes.

Craniometaphyseal dysplasia (CMD) is a rare genetic disease marked by progressive thickening of craniofacial bones and abnormal modelling of long bones metaphysis, related to monoallelic pathogenic variations in the *ANKH* gene. Diffuse and progressive hyperostosis is responsible for distinctive dysmorphism with upper airway stenosis, foramen magnum stenosis and cranial nerve compression causing optic atrophy, cranial nerve palsy and deafness.

The *ANKH* gene encodes a transmembrane protein that controls pyrophosphate levels, supporting a role of Ank in regulation of bone mineralization. In a AnkKI/KI mouse model mimicking CMD phenotype, bone matrix hypomineraisation and decreased osteoclastogenesis have been demonstrated. Moreover, transplantation of hematopoietic stem cells (HSCT) from healthy mice allowed bone mass reduction.

We present here the results of HSCT in three patients, with a severe form of CMD. Diagnosis was made at 3(P1), 13(P2) and 22(P3) months. Complications were already present with optic atrophy (3/3), facial nerve palsy (2/3), deafness (2/3) and nasal obstruction (3/3) requiring surgery (2/3). Patients were transplanted at the age of 6(P1), 21(P2) and 36(P3) months. To date, i.e. 6 years (P3), 15 months (P1) and 12 months (P3) after HSCT, we observed a significant improvement of patient condition, with decreased hyperostosis, slowdown in cranial perimeter growth velocity, stabilization of neurosensory status, and even an improvement in facial paralysis for patient P1.

Treatment with GCSH partially restores bone remodeling homeostasis in CMD, and therefore leads to stabilization of the disease. This report stresses the importance of an early diagnosis to improve the prognosis of this severe disorder.

P06.012.A Transcriptome analysis reveals genetic compensation in a murine model of Ehlers-Danlos syndrome, classic type

Fransiska Malfait[1;2], *Zoë Malfait*[1;2], *Rachel Miller*[3], *Anne-Marie Malfait*[3], *Delfien Syx*[2;4]

[1]*Ghent University Hospital, Center for Medical Genetics, Gent, Belgium;* [2]*Ghent University, Department of Biomolecular Medicine, Gent, Belgium;* [3]*Rush Medical College, Department of Internal medicine, Chicago, United States;* [4]*Ghent University Hospital, Center for Medical Genetics, Ghent, Belgium*

Background/Objectives: The heritable connective tissue disorder classic Ehlers-Danlos syndrome (cEDS) is caused by heterozygous defects in the genes encoding type V collagen (*COL5A1* and *COL5A2*). A well-studied mouse model of cEDS, the *Col5a1* haploinsufficient (*Col5a1*$^{+/-}$) model (gift dr. David Birk, USF), recapitulates the most common molecular defect seen in human cEDS patients (i.e., *COL5A1* haploinsufficiency) and mimic the skin hyperextensibility and ultrastructural collagen abnormalities characteristic of human cEDS.

Methods: RNA sequencing was performed on lumbar L3-L5 bilaterally pooled dorsal root ganglia (DRG) of male and female wild-type and *Col5a1*$^{+/-}$ mice.

Results: Unexpectedly, a 2-fold upregulation of *Col5a1* expression was found in DRG of *Col5a1*$^{+/-}$ mice compared to wild-type littermates, but decreased protein levels for type V collagen were detected on immunohistochemistry. To further investigate this intriguing finding, RT-qPCR for *Col5a1* was performed on nine different tissues (e.g., DRG, brain, kidney, liver, colon, heart, lung, tail, skin) of both wild-type and *Col5a1*$^{+/-}$ mice. The expected 50% decrease in *Col5a1* expression was only observed in tails from female mice. *Col5a1* expression was higher in *Col5a1*$^{+/-}$ male versus female intestine and consistently upregulated in *Col5a1*$^{+/-}$ brain. No significant difference in *Col5a1* expression levels were observed in liver, DRG, kidney, skin and male tails.

Conclusion: These results indicate that *Col5a1* expression is not uniformly reduced by half in *Col5a1*$^{+/-}$ mice but highly variable, suggesting a tissue- and sex-specific genetic compensation response. This novel finding has never been associated with (c) EDS but can possibly explain part of the phenotypic features observed in cEDS.

Grants: FWO-G041519N

P06.013.B *EFEMP1*-related connective tissue disorder: distinct subtype of Ehlers-Danlos syndrome?

Merel Mol[1], *John Vlot*[2], *Johanna Escher*[3], *Tjakko Van Ham*[1], *Hennie Brüggenwirth*[4], *Natalja Bannink*[5], *Jeroen Renkens*[6], *Robert Verdijk*[4], *Johan Max Kros*[4], *Virginie Verhoeven*[1;7], *S. Demirdas*[1]

[1]*Erasmus MC University Medical Center, Department of Clinical Genetics, Rotterdam, Netherlands;* [2]*Erasmus MC University Medical Center, Department of Pediatric Surgery, Rotterdam, Netherlands;* [3]*Erasmus MC University Medical Center, Department of Pediatric Gastroenterology, Rotterdam, Netherlands;* [4]*Erasmus MC University Medical Center, Department of Pathology, Rotterdam, Netherlands;* [5]*Franciscus Gasthuis and Vlietland, Department of Pediatrics, Rotterdam, Netherlands;* [6]*Erasmus MC University Medical Center, Department of Orthopedics and Sportsmedicine, Rotterdam, Netherlands;* [7]*Erasmus MC University Medical Center, Department of Ophthalmology, Rotterdam, Netherlands*

Background/Objectives: Heritable connective tissue disorders (CTD) can be difficult to diagnose due to wide clinical and genetic heterogeneity. Biallelic variants in *EFEMP1*, encoding Fibulin-3, were reported as rare cause of CTD with recurrent herniations and joint hypermobility.

Methods: Three new CTD patients were clinically evaluated, followed by whole exome sequencing, targeted *EFEMP1* reanalysis including copy number variant analysis, and RNA-sequencing to investigate aberrant splicing and gene expression.

Results: Two male siblings (10/13yrs) presented with marfanoid habitus, recurrent inguinal/umbilical herniations, joint hypermobility, and scoliosis. Parents and halfsiblings reported joint

hypermobility and umbilical herniations. The eldest boy died (16yrs) from diaphragmatic herniation complicated by gastric perforation. Autopsy revealed widespread intestinal diverticula and pulmonary bullae. Both siblings harbored compound heterozygous pathogenic *EFEMP1*-variants (c.1320+2T>A,p.? and c.698G>A,p.Gly233Asp).

A non-related male patient (58yrs) had marfanoid features, myopia, recurrent diaphragmatic/inguinal herniations, and chronic gastrointestinal dilatation with severe malabsorption (brown-bowel-syndrome). Both his dizygotic twin-brother and mother had diaphragmatic/inguinal herniations and high myopia. The patient died (59yrs) of unclear cause; autopsy showed extensive diaphragmatic herniation, diverticula and pulmonary emphysema. A heterozygous *EFEMP1* splice-variant (c.81+1G>A,p.?) was identified, present in his mother and affected brother, absent in a healthy brother. The variant caused exon skipping leading to a start-loss. Targeted genome reanalysis nor RNA-sequencing revealed a second variant.

Conclusion: Biallelic pathogenic *EFEMP1*-variants cause severe CTD with recurrent herniations and diffuse gastrointestinal dilatation/diverticulosis, with increased risk for life-threatening rupture. Cardiovascular manifestations were not reported so far. Heterozygous carriers may present with a milder phenotype. We propose *EFEMP1*-related CTD as potential novel entity within the Ehlers-Danlos syndrome spectrum.

Conflict of Interest: None declared

P06.014.C Towards creation and characterization of *COL2A1*-SEDC and *BGN*-SEMD iPSC-derived chondrocyte models

Pauline De Kinderen[1], *Josephina (Jeannette) Meester*[1], *Silke Peeters*[1], *Geert Mortier*[2], *Bart Loeys*[1;3], *Aline Verstraeten*[1]

[1]*University of Antwerp and Antwerp University Hospital, Center of Medical Genetics, Antwerp, Belgium;* [2]*University of Leuven and Leuven University Hospital, Center of Human Genetics, Leuven, Belgium;* [3]*Radboud University Medical Center, Human Genetics, Nijmegen, Netherlands*

Background/Objectives: Endoplasmic reticulum (ER) stress attributed to aberrant protein folding is increasingly emerging as a converging chondrodysplasia mechanism. We aim to develop a human disease model to investigate whether ER stress also contributes to *COL2A1*-SEDC and *BGN*-SEMD. Induced pluripotent stem cell (iPSC)-derived chondrocytes exhibit known chondrodysplasia mechanisms and are thus highly suitable.

Methods and results: Somatic cells of two *COL2A1*-SEDC (p.Gly408Asp; p.Gly1107Arg) and two *BGN*-SEMD (p.Gly259Val) patients were reprogrammed into iPSCs using Sendai vectors delivering the four key reprogramming factors. Pluripotency was confirmed using immunocytochemistry for OCT4, SOX2, NANOG, TRA-1-60 and TRA-1-81 and by demonstrating the iPSCs' ability to differentiate into the three germ layers by means of directed differentiation and RT-qPCR. Genomic integrity was verified using the HumanCytoSNP-12 BeadChip. For each patient iPSC line, an isogenic control was made with CRISPR/Cas9. To assess performance of the iPSC-chondrocyte differentiation protocol, we next created control pellets with mesenchymal cell (MC)-like cells as an intermediate. >95% of the resulting MC-like cells were positive for the mesenchymal stem cell markers CD105, CD90, CD73 and CD44, while <2% expressed hematopoietic markers. The MC-like cells' ability to differentiate into osteoblasts and chondroblasts was demonstrated using Alizarin Red and Alcian Blue staining, respectively. Validation of growth plate cartilage-specific gene expression and collagen type II deposition in the iPSC-chondrocyte pellets was obtained by RT-qPCR and immunostaining.

Conclusion: We have established *COL2A1*-SEDC and *BGN*-SEMD iPSC lines and successfully implemented the iPSC-chondrocyte differentiation protocol in our lab as a first step in establishing chondrodysplasia disease models to study ER stress.

P06.015.D Expansion of the complex genotypic and phenotypic spectrum of *FGFR2*-associated neurocutaneous syndromes

Julia Schmidt[1], *Silke Kaulfuß*[1], *Hagen Ott*[2], *Marianne Gaubert*[1], *Nadine Reintjes*[3], *Felix Bremmer*[4], *Steffi Dreha-Kulaczewski*[5], *Philipp Ströbel*[4], *Gökhan Yigit*[1;6], *Bernd Wollnik*[1;6;7]

[1]*Institute of Human Genetics, University Medical Center Göttingen, Göttingen, Germany;* [2]*Children's Hospital Auf der Bult, Department of Pediatric Dermatology, Hannover;* [3]*Institute of Human Genetics, University Hospital Cologne, Cologne, Germany;* [4]*Institute of Pathology, University Medical Center Göttingen, Göttingen, Germany;* [5]*Department of Pediatrics and Adolescent Medicine, University Medical Center Göttingen, Göttingen, Germany;* [6]*DZHK (German Center for Cardiovascular Research), partner site Göttingen, Göttingen, Germany;* [7]*University of Göttingen, Cluster of Excellence "Multiscale Bioimaging: from Molecular Machines to Networks of Excitable Cells" (MBExC), Göttingen, Germany*

Background: The fibroblast growth factor receptors comprise a family of related but individually distinct tyrosine kinase receptors. Within this family, FGFR2 is a key regulator in many biological processes, e.g., cell proliferation, tumorigenesis, metastasis, and angiogenesis. Heterozygous activating non-mosaic germline variants in *FGFR2* have been linked to numerous autosomal dominantly inherited disorders including several craniosynostoses and skeletal dysplasia syndromes. So far, postzygotic somatic activating FGFR2 alterations were found in various cancer types.

Objectives: We aimed to identify the causal variant in an individual with cutaneous nevi, ocular malformations, macrocephaly, mild developmental delay, and the initial clinical diagnosis of Schimmelpenning-Feuerstein-Mims syndrome, a very rare mosaic RASopathies.

Methods: We performed exome sequencing as well as high-coverage disease-specific panel sequencing of different tissues, clinical phenotyping, structural mapping, and further functional characterization.

Results: We identified the mosaic variant c.1647=/T>G p.(Asn549=/Lys) in *FGFR2*. The variant is located in the tyrosine kinase domain of FGFR2 in a region that regulates the activity of the receptor. Further analysis to explore the functional consequences of the identified postzygotic *FGFR2* variant upstream of the RAS signaling pathway indicated a constitutive tyrosine kinase receptor activation.

Conclusion: Mosaic activating variants in *FGFR2* cause a new neurocutaneous condition characterized by cutaneous nevi, ocular malformations, macrocephaly, and mild developmental delay. Interestingly, there is a striking genotypic and phenotypic overlap with other mosaic RASopathies and *FGFR*-associated syndromes.

P06.016.A Genotypic and phenotypic features of tooth agenesis in Japanese population

Junichiro Machida[1;2], *Junya Adachi*[3], *Yoshihiko Aoki*[4], *Yasuto Sano*[2], *Michiyo Ando*[2], *Shunsuke Hyodo*[1], *Kosuke Saida*[1], *Mitsuo Goto*[2], *Yoshihito Tokita*[5]

[1]*Toyota Memorial Hospital, Oral and Maxillofacial Surgery, Toyota, Japan;* [2]*Aichi Gakuin University, School of Dentistry, Maxillofacial Surgery, Nagoya, Japan;* [3]*Toyohashi Municipal Hospital, Toyohashi, Japan;* [4]*Okazaki Municipal Hospital, Okazaki, Japan;* [5]*Aichi Devlopmental Disability Center Central Hospital, Kasugai, Japan*

Background/Objectives: Tooth agenesis is one of the most common congenital anomalies in humans, classified by the number of missing teeth: hypodontia is defined as five or fewer missing teeth, excluding the wisdom teeth, while oligodontia is defined as six or more missing teeth. The etiology of tooth agenesis remains unclear. The aim of this study is to analyze the phenotypes of nonsyndromic tooth agenesis linked to gene mutations in Japanese.

Methods: Fifty-nine unrelated subjects with apparent isolated tooth agenesis visited the Aichi-Gakuin University hospital from 2015 to 2023. The Classification, site, family history, and genetic factors (MSX1, PAX9, LRP6, and WNT10A) by mutation and/or exome analysis, were examined.

Results: Among the 32 Oligodontia, 9 had the WNT10A mutation, and 9 had the PAX9 mutation. There were 3 with LRP6 mutation, 2 with MSX1 mutation, and 9 were unknown. Among the 27 cases of hypodontia, 6 had WNT10A mutations, 2 had LRP6 mutations, and 19 were unknown. The incidence of oligodontia was statistically significantly higher in patients with genetic mutations in any of WNT10A, PAX9, LRP6, and MSX1 ($p = 0.0017$). In cases with MSX1 and PAX9 mutations, the first incisor teeth to molars are missing, but in cases with WNT10A and LRP mutations, missing sites are concentrated in teeth second incisor to premolar.

Conclusion: This suggests that hypodontia can lead to the development of multifactorial genetic diseases. In individuals with posterior tooth agenesis, molecular genetic testing of *MSX1* and/or *PAX9* may be considered first.

P06.017.B Retrospective analysis of virtual gene panel analysis for genodermatoses reveals a high diagnostic yield in daily practice

Aude Beyens[1], *Jozefien Weytens*[1], *Lore Pottie*[1], *Sofie De Meulemeester*[2], *Karolien Aelbrecht*[1], *Silke De Feyter*[2], *Sofie De Schepper*[2], *Eline Van Holm*[1], *Sofie Symoens*[1], *Bert Callewaert*[1]

[1]*Ghent University Hospital, Center for Medical Genetics Ghent, Ghent, Belgium;* [2]*Ghent University Hospital, Department of Dermatology, Ghent, Belgium*

Background/Objectives: The complexity and heterogeneity of heritable skin disorders evidently cause a diagnostic delay impeding efficient clinical decision making. Virtual gene panel analysis (VPA) has proven to be a cost-effective, first-tier, genetic test in different settings, but results from dermatological practice are lacking. This study assesses the diagnostic yield of VPA for inherited skin disorders in an actual clinical setting without limitations on inclusion of patients.

Methods: A monocentric retrospective observational study to investigate the clinical characteristics, diagnostic yield, and management implications in 207 subjects referred for genetic testing.

Results: Molecular analysis yielded a definitive diagnosis in 38% and reached a probable diagnosis in an additional 3% of individuals. Extending the analysis to other panels in selected patients further increased the diagnostic rate with 2.4%. In 10% of the patients with a molecularly confirmed diagnosis, the findings changed the clinical diagnosis. Molecular diagnostics delineated previously unreported sub-entities in SAM and CHIME syndrome. The presence of mosaicism, absence of recognizable dermatological phenotypes, and panel settings are the main reasons of (false) negative results.

Conclusion: VPA for heritable skin disorders has a high diagnostic yield with implications to patient management, therapy, and genetic counseling. Our results highlight the feasibility and importance of implementing molecular testing into daily dermatological practice.

Grants: B.C. is a senior clinical investigator of the Research Foundation Flanders.

P06.018.C Report of two new *KRT10* mutations associated to ichthyosis with confetti

Carlos Gutiérrez-Cerrajero[1;2], *Nerea Gestoso-Uzal*[1;2], *María Zubieta-Laseca*[1;2], *Nelmar Valentina Ortiz Cabrera*[3], *Ana-Belén Herrero*[1;2], *Irene Lara-Saez*[4], *Ángela Hernández-Martín*[3], *Rogelio González-Sarmiento*[1;2]

[1]*University of Salamanca, Faculty of Medicine, Department of Medicine, Salamanca, Spain;* [2]*Biomedical Research Institute of Salamanca (IBSAL), Salamanca, Spain;* [3]*Hospital Infantil Universitario Niño Jesús, Department of Dermatology, Madrid, Spain;* [4]*University College Dublin, Charles Institute of Dermatology, Dublin, Ireland*

Background/Objectives: Ichthyoses are disorders of cornification characterized by dry, scaly skin and a disruption of skin barrier function (1). A rare form is ichthyosis with confetti (IWC, ORPHA: 281190), characterized by generalized ichthyosiform erythroderma at birth, with the appearance of healthy focal spots later in life (2). IWC is caused by dominant mutations in the tail domain of *KRT10* and, rarely, *KRT1*, which alter its polarity from apolar to polar (2).

Methods: Two patients were referred to Hospital Infantil Niño Jesús in Madrid with generalized ichthyosiform erythroderma, mild ectropion, and palmoplantar, scalp, and nail involvement. Genomic DNA was extracted from peripheral blood by standard phenol/chloroform purification and mutations were found using whole exome sequencing (WES). The patients developed revertant spots after molecular diagnosis.

Results: Patient 1 was heterozygous for *KRT10* (NM_000421.3) c.1367_1368delAG and patient 2 was heterozygous for *KRT10* (NM_000421.3) c.1598_1603delinsC. Both mutations had not been previously reported and cause a frameshift in the last two exons of *KRT10*, which translate its tail domain. PepCalc was used to analyze the polarity of the aberrant tails and both were found to be positively charged, which is consistent with other IWC-causing mutations.

Conclusion: The present study reports two IWC patients with new *KRT10* frameshift mutations that alter tail polarity.

Grants: This project was funded by Fundación Nemesio Díez

P06.019.D Type II collagenopathies: Unveiling a broader spectrum of phenotypic manifestations

Merve Soğukpınar[1;1], *Tuğba Daşar*[1], *Hatice Mutlu*[2], *Elçin Yıldız*[3], *gizem ürel-demir*[1], *Gulen Eda Utine*[1], *Pelin Simsek-Kiper*[1]

[1]*Hacettepe University, Department of Pediatrics, Division of Pediatric Genetics, Ankara, Türkyie;* [2]*Ankara University, Department of Pediatrics, Division of Pediatric Genetics, Ankara, Türkyie;* [3]*Hacettepe University, Division of Musculoskeletal Radiology, Department of Radiology, Ankara, Türkyie*

Background/Objectives: Type II collagen disorders include a distinct group of clinical phenotypes characterized by skeletal findings, orofacial features, ocular abnormalities, and hearing impairment. The spectrum ranges from severe perinatal lethal disorders to milder conditions presenting in adulthood. Herein, we aim to describe the clinical, radiological, and molecular findings of a group of type II collagenopathy patients.

Methods: The study included ten unrelated patients from Turkey with COL2A1 pathogenic variants.Medical history, anthropometric measurements, three-generation pedigree, phenotypic features, radiological images, and molecular features were evaluated for each patient retrospectively.

Results: Out of the ten patients, seven had severe short stature, two had short stature, and one had normal stature when they applied us.Additionally, 4/10 patients (40%) have midface retrusion, 4/10 (40%) patients have myopia, 3/10 (30%) patients have hearing impairment, 2/10 patients (20%) have cleft palate, and one patient have lower extremity length difference.The evaluation of the radiographic findings revealed a wide range of abnormalities, such as metaphyseal irregularity (6/10 patients), platyspondyly (6/10 patients), epiphyseal irregularity (4/10 patients), osteoporosis/osteopenia (4/10 patients), scoliosis (3/10 patients), and odontoid hypoplasia (2/10 patients).All patients had likely pathogenic or pathogenic variants in *COL2A1*.Four of the patients were diagnosed with spondyloepimetaphyseal dysplasia Strudwick type, three with spondyloepiphyseal dysplasia congenita, and one with Kniest dysplasia; two of the cases could not be classified due to their atypical presentation.

Conclusion: Type II collagenopathies constitute a heterogeneous group of diseases, forming a spectrum in terms of clinical features with significant phenotypic overlap.Therefore, any finding suggestive of type II collagenopathies should be evaluated from this perspective.

P06.020.A Molecular aspects of hypohidrotic ectodermal dysplasias in Russia

Valeriia Kovalskaia[1], *Tatiana Cherevatova*[1], *Olga Shchagina*[1], *Aleksander Polyakov*[1], *Oksana Ryzhkova*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russian Federation*

Background/Objectives: Hypohidrotic Ectodermal Dysplasia (HED) comprises a group of rare genetic disorders affecting two or more ectodermal derivatives (hair, teeth, nails, certain glands). X-linked ectodermal dysplasia is considered the most common form of HED; however, the precise contribution of individual genes (*EDA, EDAR, EDARADD, WNT10A*) to the development of HED has never been evaluated in Russia. The objective is to determine the mutational spectrum in a cohort of 233 Russian patients affected by HED to establish the prevalence of genetic variants in the four most frequently associated genes.

Methods: Targeted gene panel (NGS), Sanger sequencing, Multiplex Ligation-dependent Probe Amplification (MLPA), as well as segregation analysis to refine the pathogenicity of variants of uncertain significance, were performed.

Results: A total of 148 *EDA* mutations (including 50 novel ones) accounted for 63.5% of cases in our series, with gross deletions/duplications affecting one or more exons of the *EDA* found in 18 patients (7.7%). It is worth mentioning that about 1/6 of all variants in the *EDA* gene are missense variants affecting amino acids Arg153, Arg155, and Arg156. Moreover, almost 11% of the detected *EDA* variants constitute deletions of more than 10 b.p. in the exon 4. Recurrent variants in the *WNT10A* gene were detected in 12 Russian patients (5.1%), and 4.7% of all detected mutations account for the *EDAR* changes.

Conclusion: Molecular studies of HED have not been conducted in Russia until now; thus, investigating the mutational spectrum of different HED genes is crucial for the elaboration of an effective diagnostic approach.

P06.021.B A serie of NPR2-related idiopathic short stature

Sena Cetin[1;2], *Hamdi Cihan Emeksiz*[3], *Mustafa Gunes*[1;2], *Filiz Ozen*[2], *Elif Yilmaz Gulec*[1;2]

[1]*Istanbul Medeniyet University Faculty of Medicine, Medical Genetics, İstanbul, Türkyie;* [2]*Istanbul Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Medical Genetics, İstanbul, Türkyie;* [3]*Istanbul Medeniyet University, Faculty of Medicine, Pediatric Endocrinology, İstanbul, Türkyie*

Background/Objectives: The *NPR2* (MIM*108961) gene encodes the B-type natriuretic peptide receptor (NPR-B), functioning as a guanylyl cyclase in chondrocytes. Consequently, the *NPR2* signaling cascade plays a vital role in promoting bone matrix synthesis and regulating the growth plate. Biallelic variants lead to severe skeletal dysplasia, termed 'Acromesomelic dysplasia type Maroteaux (MIM#602875)'. Conversely, heterozygous variants cause a milder form known as 'Short stature with nonspecific skeletal abnormalities (MIM#616255)', mainly classified as idiopathic short stature (ISS).

Methods: Seven patients from different families, comprising four females and three males, were referred to us with a diagnosis of short stature. The mean age for females was 12, and for males, it was 13.6. The mean height SDSs were -2.96 and -2.68, respectively. They exhibited no prominent features other than mild facial dysmorphism. A NGS-based multigene panel test was conducted for evaluation.

Results: We identified seven monoallelic *NPR2* variants, including five missense, one nonsense, and one frameshift variant. Missense variants were classified as variants of uncertain significance (VUS), while the remaining two were considered likely pathogenic according to ACMG criteria. Two missense variants segregated with short stature in related families, specifically of maternal origin. Additionally, four missense variants and one frameshift variant were identified as novel.

Conclusion: Heterozygous variants in the *NPR2* gene were reported in 2-6% of cases of ISS. Affected patients displayed mild and variable degrees of short stature without a distinct phenotype. Variants in this gene could be a significant cause of nonsyndromic short stature and should be considered for testing in affected individuals.

P06.022.C comprehensive examination of the genotypic and phenotypic characteristics of turkish marfan syndrome patients.

Ceren Alavanda[1], *Bilgen Bilge Geçkinli*[2], *Serdar Epçaçan*[3], *figen akalın*[4], *Ahmet Arman*[2]

[1]*Van Research and Training Hospital, Department of Medical Genetics, Van;* [2]*Marmara University, School of Medicine, Department of Medical Genetics, Istanbul;* [3]*Van Research and Training Hospital, Department of Pediatric Cardiology, Van;* [4]*Marmara University, School of Medicine, Department of Pediatric Cardiology, Istanbul*

Background/Objectives: Marfan syndrome (MFS) is an autosomal dominant pleiotropic disease. The phenotype is associated with ocular, cardiovascular, and skeletal anomalies. Pathogenic variants in the *FBN1* gene that encodes fibrillin-1 cause MFS. Although a diagnostic criteria (Ghent criteria: GC) has been developed for MFS, it is difficult to diagnose every patient based solely on these criteria due to variable phenotype. Therefore, molecular diagnosis is important.

Methods: A total of 47 patients (23 female, 24 male) from 41 families were included in the study. The patients were evaluated according to GC. Single nucleotide variants and copy number variations in the *FBN1* gene were analyzed using next-generation sequencing, and segregation studies were performed via Sanger sequencing.

Results: The GC scores of the patients ranged from 2 to 11. Eight patients had ectopia lentis, 7 patients had aortic root dilatation. Mitral valve prolapsus was the most common cardiac anomaly. In the *FBN1* gene, 36 different variants (15 novel, 41.6%; 21 recurrent, 58.3%) were detected. Twenty-five (69.4%) of the variants were non-truncating (missense), 11 (30.5%) were truncating (6 were nonsense, 4 were splice-site and one was frameshift). Fifteen variants (41.6%) were causing substititon of cysteine residues. Twenty-three (65.7%) variants were localized in the EGF-like domains.

Conclusion: This study indicates that not all MFS patients fully met the GC. The identified 15 novel variants contribute to the variant spectrum of the *FBN1* gene. This study also showed that the variants were unique for patients and the majority of the variants were affecting cysteine residues.

P06.023.D Cleidocranial dysplasia: A comprehensive case series from a single center

Ipek Gorusen[1], *Nursel Elcioglu*[1], *Funda kokali*[1], *Ali Mentes*[2]

[1]*Marmara University Faculty of Medicine, Department of Pediatric Genetics, İstanbul, Türkyie;* [2]*Marmara University Faculty of Dentistry, Department of Pediatric Dentistry, İstanbul, Türkyie*

Background/Objectives: Cleidocranial dysplasia(CCD) is a rare autosomal dominant skeletal dysplasia characterized by delayed fontanelle closure, clavicle aplasia/hypoplasia and dental anomalies.Heterozygous loss of function in the RUNX2 gene located on chromosome 6p21.1 causes the clinical phenotype.We aimed to present our cases to improve the knowledge of this disorder.Cleidocranial dysplasia should be considered in patients with wide fontanel, frontal and parietal bossing, dental anomalies, clavicle hypoplasia/aplasia, bone deformities and short stature.

Methods: In the case series, eleven patients who were followed up clinically with cleidocranial dysplasia will be presented.Genetic results were provided by DNA exome sequencing.

Results:A total of 11 patients (male, $n = 2$ and female, $n = 9$) were enrolled in this study.The most common clinical findings were delayed closure of the anterior fontanel (72%, 8/11), frontal bossing (81%, 9/11), clavicle hypoplasia/aplasia (90%, 10/11) and short stature (90%, 10/11).Skeletal deformities were noted in all of the patients.Hypermobile shoulders, metopic groove and dental anomalies as supernumerary teeth were frequent findings.When the family history of the patients were evaluated, it was evident that (81%, 9/11) most of them had family members with similar clinical features.Various heterozygous mutation in the RUNX2 gene was detected in four patients from three families and the genetic analysis results of remaining patients are awaited.

Conclusion: Although cleidocranial dysplasia is rare, it is important to raise awareness for early diagnosis, provide symptomatic pediatric and dental care with multidisciplinary follow-up and provide accurent genetic counselling for affected patients and their parents.

P06.024.A Clinical utility of diagnostic NGS for detection CNV variants in genes associated with skeletal dysplasia

Marija Mijovic[1], *Goran Cuturilo*[1;2], *Jelena Ruml Stojanovic*[1], *Aleksandra Miletic*[1], *Brankica Bosankic*[1], *Hristina Petrovic*[1]

[1]*University Children's Hospital, Department of Clinical Genetics, Belgrade, Serbia;* [2]*Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

Introduction: Copy Number Variants (CNVs) may be a mechanism of gene dysfunction. It is traditionally considered that routine diagnostic Next Generation Sequencing (NGS) technology is not suitable for detecting CNVs. The goal of the present study was to determine NGS-based CNV calling yielded in genes for skeletal dysplasia.

Materials and Methods: CNVs were extracted from results reports of clinical or whole exome sequencing of 168 consecutive patients with different skeletal dysplasia. Genome sequencing was applied in the second step, only for highly suspicious patients.

Results: Molecular diagnosis by determining the causative gene variant(s) was established for 102 out of 168 patients (60.71%). CNVs were detected in the following genes: *IFT140*: heterozygous tandem duplication of exons 27-30 confirmed by long range PCR combined with another point variant in the same gene; *DYM*: homozygous exon 14 deletion confirmed by long range PCR; *TCF12*: heterozygous deletion of exons 9-19 confirmed by MLPA. Additionally, in two patients with skeletal dysplasia large chromosomal aberration was detected (14q32.33 deletion ~2.08 Mb; 15q26.2-26.3 deletion ~5.6 Mb) and confirmed by arrayCGH. In one negative patient a small deletion of 4.2 Kb encompassing the 3'UTR region of the *RUNX2* gene was identified using whole genome sequencing.

Conclusion: Among all diagnosed patients, CNVs were found in five patients (4,90%). Our results confirm that NGS should be the test of first choice in patients with skeletal dysplasia due to the high detection rate, including the possibility of detecting CNVs.

P06.025.B Palmoplantar keratoderma related to FAM83G gene. Clinical and molecular characterization of a new case

Amaia Lasa-Aranzasti[1], *Lorraine Glennie*[2], *Marta Codina*[1], *Mar Xunclà*[1], *Gloria Aparicio Español*[3], *Elena García-Arumí*[1], *Eduardo Tizzano*[1], *Gopal Sapkota*[2]

[1]*Vall d'Hebron, Medicine Genetics Group, Vall d'Hebron Institut de Recerca (VHIR). Department of Clinical and Molecular Genetics, Barcelona, Spain;* [2]*School of Life Sciences, University of Dundee, MRC Protein Phosphorylation and Ubiquitylation Unit, School of Life Sciences, University of Dundee, Dundee, United Kingdom;* [3]*La Vall*

d'Hebron, Dermatology Service, Hospital Universitari Vall d'Hebron, Barcelona, Spain, Barcelona, Spain

Background/Objectives: Homozygous pathogenic variants in the *FAM83G* gene have been associated with palmoplantar keratoderma in dogs and humans. FAM83G activates WNT signalling through association with protein kinase CK1α. Here we report a novel case of palmoplantar keratoderma in humans due to a pathogenic variant in the *FAM83G* gene.

Methods: We report a woman with palmoplantar keratodermia and a homozygous variant in *FAM83G* identified by analysis of candidate variants in by whole-exome-sequencing (WES). A skin biopsy was obtained to perform functional studies in cultured fibroblasts. The ability of the pathogenic FAM83G mutant to bind to CK1α and activate WNT signalling was tested in various human cell lines, including cultured fibroblasts derived from the patient.

Results: A 60-year-old female with uneventful pregnancy and normal development first exhibited symptoms such as alterations in the hair and skin of both hands, and dystrophic nails at the age 3, and was diagnosed with palmoplantar keratoderma. Physical examination revealed features including thin, curly, and sparse hair, long upper eyelid eyelashes, poor dental enamel, and palmoplantar keratoderma. Family history included parental consanguinity and two unaffected siblings. WES identified a homozygous *FAM83G* gene variant (c.794G>C, p.Arg265Pro), which were heterozygous in unaffected siblings. Overexpression assays and skin fibroblasts analysis showed that theFAM83G^{R265P} showed less stability, inability to bind CK1α and attenuated WNT signalling response

Conclusions:

We report the second case of palmoplantar keratoderma in humans resulting from *FAM83G* mutations. Functionally, this novel variant implies impaired CK1α binding and the loss of WNT signalling leading to the pathogenesis of palmoplantar keratoderma.

Conflict of Interest: None declared

P06.026.C Urine-derived stem cells: A cutting-edge, non-invasive approach for investigating osteogenesis and chondrogenesis

Schulz Alexander[1], *Steffen Uebe*[1], *Arif B Ekici*[1], *Cornelia Kraus*[1], *Mandy Krumbiegel*[1], *André Reis*[1;2], *Christian Thiel*[1]

[1]*Universitätsklinikum Erlangen, Institute of Human Genetics, Erlangen;* [2]*Universitätsklinikum Erlangen, Center for Rare Diseases Erlangen (ZSEER), Erlangen*

Background/Objectives: Obtaining samples from relevant tissues for genetic analysis in affected individuals is often challenging, especially for tissues where biopsies cannot be readily obtained such as bone and cartilage. Therefore, it is necessary to establish cell culture models that can replicate pathophysiological processes in vitro. An easily accessible source of material is urine, containing epithelial cells, but also cells with stem cell properties, known as urine-derived stem cells (USC).

Methods: We successfully isolated cells with stem cell-like properties from urine of four healthy donors and differentiated two of them into osteogenic and chondrogenic lineages.

Results: Osteogenically induced cells exhibited positive calcific depositions and a significant upregulation of expression of the bone-specific *SPP1* gene. Conversely, chondrogenically induced cells, positive for glycosaminoglycans, showed overexpression of the specific chondrocyte marker *COL2A1*. To better mimic the in vivo environment, we established a 3D self-aggregating chondrogenic spheroid model of USC, confirmed by Immunofluorescence analysis demonstrating expression of the late chondrocyte marker aggrecan in the spheroid.

Conclusion: We confirmed the abundance of stem cells in human urine and highlights their potential to study developmental processes of the bone. Notably, we demonstrated the remarkable capability of USCs to form chondrogenic spheroids as a novel in vitro model for the study of chondrogenesis. Future research is dedicated to exploring protein alterations and their effect on chondrogenesis in individuals harbouring pathogenic variants linked to growth-related disorders. Our approach centers on the utilization of CRISPR Cas9 technology, strategically applied to three candidate genes *LAMA5, UBR4*, and *SMARCA5*.

P06.027.D A study of Polish family with scoliosis and limb contractures expands the *MYH3* disease spectrum

Agnieszka Pollak[1], *Justyna Frasunska*[2], *Pawel Turczyn*[3], *Anna Kutkowska-Kaźmierczak*[4], *Jakub Peplowski*[5], *Rafał Płoski*[1], *Beata Tarnacka*[2]

[1]*Warsaw Medical University, Department of Medical Genetics, Warsaw, Poland;* [2]*Warsaw Medical University, Department of Rehabilitation, Warsaw, Poland;* [3]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Clinic of Early Arthritis, Warsaw, Poland;* [4]*Institute of Mother and Child, Department of Medical Genetics, Warsaw, Poland;* [5]*Medical University of Warsaw, The Rare Diseases Laboratory, Laboratory of Genetics, University Center for Laboratory Medicine, Warsaw, Poland*

Background/Objectives: The causes underlying the congenital spine defects are heterogeneous and comprises variety of environmental and genetic factors. Furthermore, spine defects may be component of various diseases such as: hemivertebra, Klippel-Feil syndrome, Chiari malformation, tethered cord, spina bifida, diastematomyelia and many others. Some of these deformities are caused by genetic syndromes related to pathogenic variants in many genes i.e. fibrilin -1 gene (*FBN1*), fibriline – 2 gene (*FBN2*) or myosin heavy chain (*MYH3)* and share many similar defects such as scoliosis, joint limpness, joint contractures, arachnodactyly, muscle hypoplasia, often making the accurate diagnosis difficult. A disease associated with malfunction of the *MYH3* gene is characterized by scoliosis, contractures of the V fingers, knees and elbows, dysplasia of the calf muscles, feet deformity and limb lengths asymmetry. The aim of this study was to identify a cause of musculoskeletal deformities in a three-generation Polish family by exome sequencing.

Methods: Exome sequencing followed by family replication study and comprehensive phenotype analysis.

Results: Segregation of the newly described c.866A>C variant of the MYH3 gene in the family indicates an autosomal dominant model of inheritance. The detected MYH3 variant segregates with the disease within the family. Comprehensive phenotype analysis reveals features that have never been reported to date in MYH3-related disease.

Conclusion: The presented results expands the *MYH3* disease spectrum and emphasize the clinical diagnostic challenge in syndromes harbouring congenital spine defects and joint contractures.

P06.028.A Short stature in Klinefelter Syndrome: new cases and a review of literature

Ivo van Bostelen[1], *Jeroen Knijnenburg*[1], *Yvonne Hendriks*[1], *Sjoerd Joustra*[1;2], *Monique Losekoot*[1]

[1]*Leiden University Medical Center (LUMC), Leiden, Netherlands;* [2]*Erasmus MC, Rotterdam, Netherlands*

Klinefelter syndrome (KS; 47,XXY) occurs in ~150:100.000 males and is characterized by tall stature, gynecomastia, small testes, and azoospermia. KS patients have a distinct growth pattern, with normal birth length and early growth, acceleration of growth velocity between 5 and 8 years old, and high-normal adult height. In rare cases of KS short stature (SS) has been reported, a substantial number of which has growth hormone deficiency (GHD). GH-therapy has been an effective treatment to reach normal adult height in these patients. Other KS patients with normal-to-short stature might have a second genetic syndrome such as achondroplasia or Prader-Willi syndrome, or carry a rearrangement on one of the X-chromosomes that can explain the phenotype. In a third subgroup no clear cause of the SS has been defined.

GHD in KS patients may result from an underdeveloped pituitary, although normal brain MRIs are also reported in this group. Hence, the causes of SS in KS remain poorly understood. Here we present three cases of KS with SS. A complete genetic work-up of SNV and CNV analysis of a SS-associated gene panel revealed no additional abnormalities in two patients. The third patient carried the previously described 47.5 kb deletion in the 3'-regulatory region of the SHOX gene on one X-chromosome. A summary of clinical characteristics of these three cases is presented and compared with the published cases to provide an informative clinical overview of the rare association of SS in Klinefelter syndrome.

Conflict of Interest: None declared

P06.029.B Discovering the Laminins: A Groundbreaking Gene in Familial Hidradenitis Suppurativa

Elena Maria Nardacchione[1], *Ronald Rodrigues Moura*[2], *Gudrun Ratzinger*[3], *Barbara Böckle*[3], *Nina Frischhut*[3], *Wolfram Jaschke*[3], *Cecilia Del Vecchio*[2], *Cecilia Giacalone*[4], *Cecile Nait-Meddour*[5], *Adamo Pio D'Adamo*[2], *Niloofar Ghaffar*[6], *Esther von Stebut-Borschitz*[6], *Lucas André Cavalcanti Brandao*[7], *Michele Boniotto*[5;5], *Matthias Schmuth*[3], *Sergio Crovella*[8], *Paola Maura Tricarico*[2]

[1]*University of Trieste, Department of Medical Surgical and Health Sciences, Trieste, Italy;* [2]*Institute for Maternal and Child Health - IRCCS Burlo Garofolo, Department of Advanced Diagnostics, Trieste, Italy;* [3]*Medical University of Innsbruck, Department of Dermatology, Venereology and Allergy, Innsbruck, Austria;* [4]*University of Trieste, Department of Life Science, Trieste, Italy;* [5]*University Paris Est Créteil, INSERM, IMRB, Translational Neuropsychiatry, Créteil, France;* [6]*University of Cologne, Department of Dermatology, Köln, Germany;* [7]*Federal University of Pernambuco, Department of Pathology, Recife, Brazil;* [8]*Qatar University, Laboratory of Animal Research Center (LARC), Doha, Qatar*

Background and Objectives: Familial hidradenitis suppurativa (fHS) is a chronic autoinflammatory condition targeting the pilosebaceous unit, inherited in an autosomal dominant pattern. Despite its genetic component, only 10% of cases are linked to mutations in γ-secretase genes. Aiming to bridge this knowledge gap, our research, conducted under the auspices of the ERAPerMed European consortium, seeks to expand understanding of the genetic predisposition to fHS.

Methods: Our study included four families, encompassing 9 individuals with fHS and 3 without. We extracted DNA from saliva samples for Whole Exome Analysis (WES), utilizing the InterOMICsPro bioinformatics pipeline for analysis. We specifically looked for new or rare variants (GnomAD allele frequency<1%) with a significant predicted impact on protein function (CADD_Phred score>15), that were heterozygous and shared among affected family members but not present in unaffected.

Results: Our analysis revealed three distinct damaging non-synonymous single nucleotide variants (SNVs) in laminin genes: one shared SNV in the *LAMA3* gene across families 1-2, a different SNV in *LAMA3* in family-3, and a SNV in *LAMA5* in family-4.

Conclusion: Considering that laminins play a critical role in the structural and functional integrity of basement membranes in the skin; this investigation highlights the laminin gene family as a newly identified factor in the pathogenesis of fHS, enhancing our understanding of fHS. It opens avenues for targeted therapeutic strategies focusing on regulating laminin gene expression, offering new hope for managing this challenging condition.

Grants: BATMAN project funded by ERAPerMed (JTC_2018); StartingGrant (SG-2019-12369421) and RC16/2018 funded by IRCCS 'Burlo Garofolo/Italian Ministry of Health.

P06.030.C Is severe epilepsy part of the ANO5 phenotype?

Mathilde Vester[1], *Janni Majgaard Jensen*[1], *Lone Sunde*[2]

[1]*Aalborg University Hospital, Department of Clinical Genetics, Aalborg, Denmark;* [2]*Aalborg University Hospital, Department of Clinical Genetics, Aalborg*

Background: Gnathodiaphyseal dysplasia (GDD) is an autosomal dominant, skeletal disorder characterized by cemento-osseous lesions of jawbones, bone fragility, and diaphyseal cortical thickening and bowing of tubular bones.

Methods: Trio whole-exome sequencing (WES) was performed using DNA obtained after amniocentesis. Re-analysis of trio WES was performed according to a childhood epileptic encephalopathy (CHE) panel consisting of 110 genes. Whole-genome sequencing (WGS) was performed as a trio, including the patient's grandmother. Also, analysis of mitochondrial DNA (mtDNA) was performed.

Results: We present a girl who, at prenatal ultrasound at $30+4$ weeks showed multiple fractures. Trio WES revealed heterozygosity for a de novo pathogenic variant (C5) of *ANO5* (c.15.33_1535dupGAT) consistent with the fractures. However, recurrent episodes of treatment-refractory epilepsy started at day 10. Scrutinizing genes related to CHE did not reveal any pathogenic variants. Magnetic resonance imaging revealed bilateral high signal changes in the basal ganglia, brain stem and thalamus. Interestingly, the patient's grandmother and other relatives had similar changes of the brain. However, neither WGS including the patient's grandmother, nor analysis of mtDNA, provided an explanation. The girl died at age two.

Conclusion: Variants in *ANO5* have been related to GDD and myopathy with autosomal dominant and recessive inheritance, respectively. Consistently we found heterozygotity for variant in *ANO5*, in a patient with GDD. However, the patient also had severe epilepsy and characteristic cerebral findings, of which the latter were also seen in relatives, suggesting a digenic cause of the epilepsy. Alternatively, the phenotypic spectrum of *ANO5* variants may be broader than thought.

Background/Objectives: Spontaneous dissection of cervical arteries (sCeAD) constitutes one of main cause of stroke in young age. Currently, a hereditary component has been identified approximately in 1-5% of sCeAD patients, particularly associated with monogenic diseases such as connective tissue diseases. However, in most cases the molecular bases still need to be elucidated. This study aims to define the prevalence of clinically actionable variants in sCeAD patients.

Methods: Adults with sCeAD were consecutively enrolled if meeting at least one of the following criteria: 1) multiple vascular wall abnormalities; 2) family history of arterial dissections/cerebrovascular disease; 3) clinical/radiological/dysmorphic findings suggestive of genetic diseases. Exclusion criteria were: 1) recent trauma; 2) cardiovascular/rheumatological disease. All patients performed a total-body CT and genetic evaluation. For eligible patients, a Next Generation Sequencing (NGS) using the Clinical Exome Solution® kit was performed, followed by the design of a virtual panel of 41 genes associated with vascular fragility. Bioinformatics analysis was performed using the SOPHiA DDM platform.

Results: Among 24 patients referred, molecular analysis was performed in 12 (5 males, median age 41 years). Five variants were identified: 1 incidental finding, 2 classified as variant of unknown significance (VUS), 2 evaluated as clinically actionable in connective-tissue genes and *MYLK* related disorder.

Conclusion: Clinically actionable variants have been identified in 16% of patients. In accordance with previous literature our results suggest that heritability in sCeAD plays a relevant role, and that genetic analyses should be performed in patients with at least one suggestive criterion.

Grants: none.

P06.032.A Structural heart disease in patients with osteogenesis imperfecta

Eva Gonzalez-Roca[1;2], *Anastasia Mocritcaia[3], Chafik Alejandro Chacur[3], Marc Ramos Jovani[4], Ana Garcia[4], Helena Florez[3], Ana Monegal[3], Nuria Guañabens[3], Pilar Peris[3]*

[1]Hospital Clínic de Barcelona, Molecular Biology CORE Laboratory, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Hospital Clínic de Barcelona, Rheumatology, Barcelona, Spain; [4]Hospital Clínic de Barcelona, Cardiology, Barcelona, Spain

Background/Objectives: Osteogenesis imperfecta (OI) is a genetic disorder characterized by connective tissue abnormalities of type I collagen (COL1) that leads to bone fragility. Few is known on the effects of OI in other COL1 containing tissues, such as the heart. Thus, the presence of heart disease should be evaluated in OI Subjects. Aim of the study: to evaluate the prevalence of structural heart disease in a cohort of adult subjects with OI and its relationship with the severity of the disease and the COL1 genotype.

Methods: We conducted a retrospective study of 28 adult patients diagnosed with OI. Clinical data, including type and genetic variant, fracture history, presence of hearing loss, blue sclerae and/or dentinogenesis was obtained from medical records. Laboratory, densitometric, and echocardiographic findings were collected.

Results: 26 out of 28 patients had OI type I. Thirteen exhibited echocardiographic alterations and 10 valvulopathies (4 moderate/severe). The remaining presented asymptomatic mild valve involvement. All four subjects with moderate/severe valvulopathies had OI type I, 3 were males with several previous fractures (<12), all had blue sclerae, and none presented hearing loss nor dentinogenesis. Moreover, 2 subjects with severe valvulopathies presented a marked low BMD (T-score <-4) and > 10 previous fractures. The *COL1A1* gene analysis identified pathogenic variants affecting glycine aminoacids (p.(Gly200Asp), p.(Gly221Arg)).

Conclusions: Patients with OI may present cardiac involvement, especially heart valvular disease. Periodic screening with echocardiography seems essential to identify and manage potential severe heart complications in this disorder. Whether some mutations favor valvular disease needs further studies.

Conflict of Interest: None declared

P06.034.D BMPER pathogenic variant heterogeneity in clinical presentation and prognosis

Sarah Chamieh[1], *Bashair Magadmi[1], YLINE CAPRI[2], sophie monnot[1], Céline Dupont[2], Jonathan Levy[2], Genevieve Baujat[1], Valérie CORMIER-DAIRE[1]*

[1]Hôpital Necker, Service de Médecine Génomique, France; [2]Hôpital Robert Debré, Service de Médecine Génomique, France

Background/Objectives: BMPER is a crucial gene for bone formation. Pathogenic variants in BMPER are largely associated with diaphanospondylodysostosis (DSD), a rare and often lethal phenotype characterised by skeletal and renal abnormalities. Lesser-known BMPER variant phenotypes include ischio-vertebral dysplasia (IVD), which often overlaps with spondylocostal dysostoses (SCDO) thereby challenging both descriptions in literature. This study aims to describe the clinical presentation and prognosis of 4 cases of bi-allelic BMPER-variant IVD phenotypes from 3 families.

Methods: Molecular analysis of confirmed BMPER mutations in 3 patients and 1 foetus revealed 3 cases of homozygous inherited mutations and 1 case of compound heterozygous de novo mutation.

Results: At the prenatal stage, IVD clinically presented with 4th and 5th finger hypoplasia, impaired vertebral body ossification, sacral agenesis, thoracic kyphosis, and thoracic cage anomalies. Postnatal skeletal features included kyphoscoliosis, wide iliac wings, and impaired ossification. One patient presented 4th and 5th finger hypoplasia, a novel finding for IVD. Two patients presented spinal cord compression, one of which complicated with post-surgical paraplegia. Imaging showed ischio-spinal dysplasia with impaired cervicothoracic segmentation, wide iliac wings, and impaired ossification. Dysmorphic features included wide anterior fontanel, downslanting and eversion of palpebral fissures, and long philtrum in all 3 live cases.

Conclusion: This study deepens our clinical understanding of IVD in the context of BMPER variants. Clinical consequences are orthopaedic and respiratory but can include impaired renal function and pituitary ectopy. There is no cognitive impairment. Challenges for prognosis in IVD are determined by surgical intervention and long-term respiratory function and re-education follow-up.

Poïkiloderma is characterized by cutaneous atrophy, telangiectasia and macular pigmentation changes resulting in a patchy skin appearance. This cutaneous disorder may have an acquired or genetic basis. Few poïkiloderma syndromes have been described including Bloom and Rothmund-Thomson syndrome.

CRIPT is a short highly conserved 101 amino acid cysteine rich PDZ-binding protein, expressed in a wide range of tissues. In brain, it regulates interaction between the post synaptic density-95 protein through its PDZ binding domain, critical for CRIPT-induced dendrite growth. Outside the brain, a functional role for CRIPT is unknown.

Biallelic variants in *CRIPT* were initially reported in two individuals with primordial dwarfism and characteristic facies in 2014. A formal dermatological examination was not performed. Following a further publication of an individual with a similar clinical phenotype, an OMIM disease entity was recognized, defined as "short stature, microcephaly and distinctive facies (SSMCF", MIM #615789). Here, we report the comprehensive clinical phenotype and longitudinal follow-up of two additional individuals, each of whom were homozygous for the same frameshift mutation in the *CRIPT* gene. Both individuals manifested poikilodermia, microcephaly, growth restriction, skeletal anomalies, epilepsy and intellectual disability. In addition to these previously described features, we expand the phenotypic spectrum to include severe myopia and extremity anomalies. Our additional cases provide further evidence that bilallelic variants in CRIPT result in a recognizable clinical entity of syndromic poikiloderma. The two unrelated families are of Moroccan origin, suggestive of a founder effect in this geographic area.

We summarize the genotypic and phenotypic spectrum of CRIPT-related SSMFC, including two new individuals.

Conflict of Interest: None declared

P06.036.B Unveiling Cardiovascular Dimensions in Weyers Acrofacial Dysostosis: A Unique Case and Genetic Parallels with Ellis-van Creveld Syndrome

Gorjan Milanovski[1], *Meri Kirijas[1], Teodora Brnjarchevska Blazevska[1], Tamara Savevska[1], Aleksandar Petlichkovski[1]*

[1]*Ss. Cyril and Methodius University in Skopje, Faculty of Medicine-Skopje, Institute of Immunobiology and Human Genetics, Republic of North Macedonia*

Background/Objectives: *EVC* and *EVC2* encode transmembrane proteins of the single-pass type 1, forming a constitutive association near the ciliary transition zone. Pathogenic variants in these genes result in rare autosomal recessive and dominant skeletal dysplasias, exemplified by Ellis-van Creveld syndrome (EvCS) and Weyers acrofacial dysostosis (WAD), respectively. These conditions share clinical similarities, with WAD representing the milder form and notably lacking reported cardiovascular malformations thus far.

Methods and Results: We introduce a 33-year-old female patient displaying skeletal abnormalities, short stature, dysplastic nails and teeth, postaxial polydactyly, and congenital heart disease. Successful pediatric heart surgery addressed the single atrium defect. Gene panel sequencing via the Illumina NGS platform identified a heterozygous pathogenic frameshift *EVC* variant (c.1694del; p.Ala565Valfs*23), expected to yield an absent or disrupted protein product. This premature translational stop signal aligns with observations in EvCS cases, where *EVC* loss-of-function variants are recognized as pathogenic. The variant is exceptionally rare in the gnomAD database, with a frequency of 0.00005329. Comprehensive bioinformatic analysis did not uncover any additional trans pathogenic variants in the *EVC* gene.

Conclusion: This case potentially marks the first instance of WAD accompanied by cardiovascular defects, reinforcing the genetic and phenotypic parallels between WAD and EvCS. The observation prompts inquiry into whether heart defects are exclusive to EvCS or may extend to other related disorders. Future investigations should delve into larger datasets to validate and extend our comprehension of the cardiovascular spectrum in these rare skeletal dysplasias, advancing diagnostic precision and enhancing clinical management strategies.

P06.037.C A novel form of autosomal dominant lamellar ichthyosis due to a missense mutation in the *NKPD1* gene

Katalin Komlosi[1], *Cristina Glocker[1], Hao-Hsiang Hsu-Rehder[1], Svenja Alter[1], Julia Kopp[1], Alrun Hotz[1], Andreas Zimmer[1], Ingrid Hausser[2], Roger Sandhoff[3], Vinzenz Oji[4], Judith Fischer[1]*

[1]*Institute of Human Genetics, Medical Center - University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg;* [2]*Institute of Pathology, Heidelberg University Hospital, Heidelberg;* [3]*Lipid Pathobiochemistry Group, German Cancer Research Center, Heidelberg;* [4]*Department of Dermatology, University Hospital Münster, Münster*

Background: The identification of monogenic causes for cornification disorders has enhanced our understanding of epidermal differentiation. While a dozen genes have been identified for non-syndromic autosomal recessive congenital ichthyoses, only few are known to cause autosomal dominant forms. Autosomal dominant lamellar ichthyosis (ADLI) is a rare condition, and *ASPRV1* was the only gene linked to ADLI to date.

Patients: Seven patients from a large German pedigree presented from birth with generalized lamellar ichthyosis with

very dry skin, whitish scaling of the trunk and scalp and brownish scales on the neck, in the axillary and inguinal areas.

Methods and Results: By WES of three affected members we identified a heterozygous variant (ENST00000686631.1:c.1372G>T, p.(Val458Phe)) in the *NKPD1* gene. Co-segregation was confirmed in all affected individuals tested. *NKPD1* is a member of the KAP family of P-loop NTPases and predicted to be involved in e.g. sphingolipid metabolism. Its role in human physiology and in the cornification cycle is not yet known. Skin histology showed acanthosis and compact orthohyperkeratosis, and the ultrastructure differed clearly from that seen in *ASPRV1*-ADLI. No changes in the expression of differentiation markers in 3D skin models of patient keratinocytes were observed, however, *NKPD1* mRNA expression increased during differentiation. While stratum corneum ceramides exhibited no significant alterations, patients showed an elevated ratio of protein-bound ceramides to omega-esterified ceramides.

Conclusion: We expand the clinicogenetic spectrum of ADLI, highlighting *NKPD1*'s role in impacting ceramide metabolism and skin lipid barrier formation, thereby raising the possibility of a novel pathway leading to cornification disorders.

P06.038.D Genotype-phenotype correlations for missense variants in the *NF1* gene: the French experience for previously described associations and identification of a new correlation

Laurence PACOT[1;2], *Dominique Vidaud*[1;2], *Audrey Sabbagh*[3], *Ingrid Laurendeau*[2], *Audrey Briand-Suleau*[4], *Audrey Coustier*[1], *Theodora Maillard*[1], *Cecile Barbance*[1], *Salah Ferkal*[5;6], *Béatrice Parfait*[1;2], *Pierre Wolkenstein*[5;6], *Eric Pasmant*[1;2]

[1]*Fédération de Génétique et Médecine Génomique, DMU BioPhyGen, AP-HP.Centre-Université Paris Cité, Hôpital Cochin, PARIS, France;* [2]*Institut Cochin, Inserm U1016, CNRS UMR8104, Université Paris Cité, CARPEM, PARIS, France;* [3]*Université Paris Cité, IRD, UMR261, MERIT, PARIS, France;* [4]*Laboratoire de biologie médicale multisites SeqOIA, PARIS, France;* [5]*Hôpital Henri Mondor, Assistance Publique-Hôpitaux de Paris (AP-HP), Département de Dermatologie, CRETEIL, France;* [6]*INSERM, Centre d'Investigation Clinique 1430; Hôpital Henri-Mondor, Assistance Publique-Hôpitaux de Paris (AP-HP), Centre de référence des neurofibromatoses, CRETEIL, France*

Background/Objectives: Neurofibromatosis type 1 (NF1) is a clinically heterogeneous genetic disorder with an autosomal dominant inheritance resulting from loss-of-function variants in the *NF1* gene. Only a few genotype-phenotype correlations have been published for some missense variants in *NF1* in international cohorts. We describe our experience of these variants in the French cohort.

Methods: We compared the main clinical features of patients with those of a reference NF1 cohort.

Results: Clinical data were recorded from patients with missense variants modifying neurofibromin at the following codons: Met1149, Arg1809, Arg1276, Lys1423 and codons 844 to 848 (2, 21, 23, 31, and 25 patients respectively). None of the patients with missense variants at Met1149 or Arg1809 had neurofibromas. Cutaneous neurofibromas were less frequent in patients with missense variants at Arg1276 compared to the reference cohort, whereas spinal neurofibromas were more frequent. Patients with mutations at codons Arg1276, Lys1423 or 844 to 848 developed plexiform neurofibromas more frequently. Skeletal abnormalities were more frequently associated with mutations at Lys1423 and at codons 844-848. Cutaneous neurofibromas appeared less frequent and optic pathway gliomas more frequent in patients with missense variants at codons 844-848. We describe for the first time the association between a moderate form of NF1 and missense variants affecting neurofibromin at position Arg1204.

Conclusion: The description of the French cohort is in line with previously reported associations, except for missense variants affecting codons 844-848 of neurofibromin. We describe a new genotype-phenotype correlation, paving the way for future studies of NF1 pathogenic variants.

Conflict of Interest: None declared

P06.039.A Spondyloperipheral dysplasia caused by a non-coding 3-prime-UTR variant in *COL2A1* molecularly characterized using prime editing

Roberto Mendoza-Londono[1;2], *Ryan Marks*[2;3], *Lucie Dupuis*[1], *Gregory Costain*[1;2;3], *Megan Dickson*[1], *Shah Ahmed*[3], *Joseph Kozman*[3], *Evgueni Ivakine*[2;3;4]

[1]*Division of Clinical and Metabolic Genetics, Department of Paediatrics, The Hospital for Sick Children and University of Toronto, Toronto, Canada;* [2]*Department of Molecular Genetics, University of Toronto, Toronto, Canada;* [3]*Program in Genetics & Genome Biology, The Hospital for Sick Children, Toronto, Canada;* [4]*Department of Physiology, University of Toronto, Toronto, Canada*

Consortium: Care4Rare Canada Consortium

Background: Spondyloperipheral dysplasia is characterized by short stature, short extremities and brachydactyly caused by pathogenic variants in *COL2A1*. Structural perturbations that interrupt the assembly of the protein lead to COL2A1-related dominant negative effects. We describe an adult male who presented at birth with disproportionate short stature, narrow thorax, platyspondyly, short hands and feet, and scoliosis. Genome sequencing identified a de novo single variant in the 3' untranslated region (UTR) of *COL2A1* (NM_001844.5:c.*161A>G).

Methods: We hypothesized that the variant generates a cryptic splice site, leading to the generation of pathogenic alternative C-terminal isoforms. We utilized prime editing to model the variant in the HAP1MLH-/- human cell line and characterize splicing outcomes. Homozygous and heterozygous mutant cell lines were established, and RT-PCR was used to identify alternative COL2A1 isoforms involving exon 52 to the 3'UTR proximal to the variant described.

Results: Isolation and sequencing of alternative RT-PCR COL2A1 isoforms indicated the formation of novel isoforms with altered exon 52-54 splicing at moderate frequency. The predominant isoform generates a stop-loss variant, producing 40 de-novo amino acids at the conserved c-terminus and likely acts in a dominant negative manner to cause disease.

Conclusion: To date, only a limited number of 3' UTR changes associated with disease have been reported. We present a patient that remained molecularly undiagnosed until detailed analysis of the non-coding regions of the gene was completed. Moreover, we demonstrate how prime editing can be a rapid and efficient tool to model and characterize variants of unknown significance for meaningful interpretation.

Conflict of Interest: None declared

P06.040.B Partial deletion of TTN gene in two brothers affected by arthrogryposis multiplex congenita

Johanna Naab[1], *Steffi Döhnert*[1], *Birgit Eichhorn*[1], *Susanne Anders*[1], *Alexander Schulz*[2], *Mirjam Klaus*[1]

[1]*Mitteldeutscher Praxisverbund Humangenetik, Dresden, Germany;* [2]*Mitteldeutscher Praxisverbund Humangenetik, Erfurt, Germany*

Consortium: MVZ Mitteldeutscher Praxisverbund Humangenetik

Background: Titin, encoded by the gene *TTN* (OMIM *188840), is an important structural protein of the sarcomer and expressed in the cardiac and skeletal muscles. Pathogenic variants of *TTN* are associated with a variety of skeletal muscle diseases and cardiomyopathies with autosomal dominant or autosomal recessive inheritance. *TTN* is also discussed as candidate gene for distal arthrogryposis. We report on two brothers with arthrogryposis multiplex congenita and normal cognitive development.

Methods: A clinical exome diagnostic via sequencing by synthesis and an array-cgh analysis were conducted for both brothers on DNA from peripheral blood.

Results: We identified a heterozygous deletion in 2q31.2 for both patients. The deletion interval affects the *TTN* gene partially and includes exon 1 to 173 of 312 exons (NM_133378.4), thus likely resulting in haploinsufficiency. No other likely pathogenic or pathogenic variant was detected by the performed analyses, especially not in *TTN*. The deletion interval also partially involves the neighbouring gene *CCDC141* (OMIM *616031), for which no association to a disease is known so far.

Conclusion: Partial deletions affecting *TTN* are rarely described in literature. None of the already reported deletions encompasses the first coding exon of *TTN*. We propose the deletion as possibly causative for the phenotype of both patients, although an assured genotype-phenotype-correlation is hardly possible. Other affected and unaffected family members should be examined to further investigate the pathogenicity of the identified deletion.

Conflict of Interest: None declared

P06.041.C A homozygous synonymous *FAM111A* variant leading to FAM111A deficiency is associated with craniectodermal dysplasia and postnatal growth retardation

Loisa Dana Bonde[1], *Ibrahim Abdelrazek*[2], *Lara Seif*[1], *Malik Alawi*[3], *Khaled Matrawy*[4], *Karim Nabil*[5], *Ebtesam Abdalla*[2], *Kerstin Kutsche*[1], *Frederike L. Harms*[1]

[1]*University Medical Center Hamburg-Eppendorf, Institute of Human Genetics, Hamburg, Germany;* [2]*Alexandria University, Medical Research Institute, Department of Human Genetics, Alexandria, Egypt;* [3]*University Medical Center Hamburg-Eppendorf, Bioinformatics Core, Hamburg, Germany;* [4]*Alexandria University, Medical Research Institute, Diagnostic Radiology and Medical Imaging Department, Alexandria, Egypt;* [5]*Alexandria University, Faculty of Medicine, Department of Ophtamology, Alexandria, Egypt*

Background/Objectives: FAM111A (family with sequence similarity 111 member A) is a member of the family of trypsin-like serine proteases and removes covalent DNA-protein cross-links during DNA replication, which helps to prevent replication stress. De novo heterozygous *FAM111A* variants cause skeletal dysplasias, including the milder Kenny-Caffey syndrome (KCS) and the lethal osteocraniostenosis (OCS).

Methods: Clinical, genomic, and functional studies, including RNA analysis, immunoblotting, cell proliferation and viability assay, and cell cycle analysis by FACS, using subject- and control-derived fibroblasts were performed.

Results: We report two siblings born to consanguineous parents with craniofacial features, postnatal growth retardation, and ectodermal dysplasia. Whole-exome sequencing revealed a homozygous synonymous *FAM111A* variant NM_001312909.2: c.81G>A; p.Pro27= in both siblings that affects the last base of exon 4. We observed aberrantly spliced *FAM111A* transcripts and nearly absent FAM111A protein in patient-derived fibroblasts. Following the induction of covalent DNA-protein cross-links by the topoisomerase I inhibitor camptothecin, we identified a tendency towards a reduced proportion of metabolically active cells in patient compared to control fibroblasts. However, we could not detect a significant difference in cell cycle progression between patient and control cells.

Conclusion: Our data suggest that loss of FAM111A is associated with a novel autosomal recessive form of craniectodermal dysplasia with proportionate short stature that shows clinical overlap with autosomal dominant KCS. Similar to the proposed pathomechanism for KCS and OCS, a reduced ability to deal with replication stress induced by DNA-protein cross-links may underlie the autosomal recessive *FAM111A*-related disorder.

Grants: Deutsche Forschungsgemeinschaft (KU 1240/13-1 to K.K.)

P06.042.D A familial UBA2 variant presenting with isolated skeletal involvement

ABDULLAH SEZER[1;2], **Zeynep Özdemir**[2], *Erdem Özkan*[3], *Prof Dr Semra Cetinkaya*[4]

[1]*Dr. Sami Ulus Kadın Doğum, Çocuk Sağlığı ve Hastalıkları Eğitim ve Araştırma Hastanesi, Medical Genetics, Ankara, Türkyie;* [2]*Ankara Etlik Şehir Hastanesi, Medical Genetics, Ankara, Türkyie;* [3]*Ankara Etlik Şehir Hastanesi, Radiology, Ankara, Türkyie;* [4]*Dr. Sami Ulus Kadın Doğum, Çocuk Sağlığı ve Hastalıkları Eğitim ve Araştırma Hastanesi, Pediatric Endocrinology, Ankara, Türkyie*

Background/Objectives: When considered from a syndromic perspective, Developmental Dysplasia of the Hip (DDH) could be attributed to some syndromes, such as Aplasia Cutis Congenita with Ectrodactyly Skeletal Syndrome (ACCES, OMIM #619959), caused by haploinsufficiency of the *UBA2* gene. This syndrome is extremely rare and presents with growth retardation, dysmorphic facial features, neurodevelopmental delay, skeletal problems such as ectrodactyly and scoliosis, skin findings such as aplasia cutis, and some internal organ problems. We present here a unique presentation of ACCES syndrome exhibiting isolated spondyloepiphyseal involvement.

Methods: A 13-year-old female patient presenting with disproportionate short stature and bilateral DDH was neurodevelopmentally normal and had mild dysmorphic facial features, and her father had osteoarthritis in addition to these findings. The dominant inheritance pattern in the pedigree suggested the prediagnosis of spondyloepiphyseal dysplasia tarda. WES analysis was conducted for the daughter using genomic DNA extracted from peripheral blood lymphocytes. The familial segregation analysis of the variants was evaluated using Sanger sequencing.

Results: The WES analysis has identified a novel heterozygous variant, NM_005499.2:c.460-2A>G, in the *UBA2* gene. It is shown that the father carried the same variant of the *UBA2* gene.

Conclusion: The *UBA2* gene in the SUMOylation pathway, which is known to cause degenerative skeletal problems, may cause spondyloepiphyseal dysplasia tarda. This case report investigates the potential phenotypic spectrum of conditions associated with the *UBA2* gene by emphasizing the distinctive clinical features of our case and highlighting the importance of comprehensive differential diagnosis in the evaluation of patients with bilateral DDH, short stature, and spondyloepiphyseal problems.

Conflict of Interest: None declared

P06.045.C Cancer incidence in neurofibromatosis 1: searching for subgroups associated with increased risk

Roope Kallionpää[1], *Jussi Leppävirta*[2], *Elina Uusitalo*[1], *Heli Ylä-Outinen*[1;3], *Minna Pöyhönen*[4;5], *Sirkku Peltonen*[2;6;7;8;9;10], *Juha Peltonen*[1]

Background/Objectives: Neurofibromatosis 1 (NF1) is an autosomal dominant disease that is associated with a high risk for cancer, yet there are few means to predict the personal cancer risk of an individual with NF1. The present study aims to search for indicators of cancer incidence among individuals with NF1.

Methods: The Finnish NF1 cohort consists of 1811 individuals, whose NF1 diagnoses have been verified using medical records. The cancers of individuals with NF1 were obtained from the Finnish Cancer Registry and summarized using standardized incidence ratio (SIR).

Results: Individuals with NF1 and a history of a prior cancer displayed a SIR of 3.69 (95% CI 2.79-4.76) for second primary cancers, which did not differ from the SIR of 4.15 (95% CI 3.68-4.66) for the first cancers. In addition, there were no significant differences between those with a history of any specific prior cancer compared with those without history of cancer. Two cancers were identified during pregnancy or the year following the delivery among women with NF1 (SIR 6.44, 95% CI 1.07-19.89), and 15 cancers were detected within 1-10 years after pregnancy (SIR 7.54, 95% CI 4.15-12.41). These SIRs did not differ from that of women with NF1 aged 20-49 years, and without a known history of deliveries (SIR 8.63, 95% CI 6.08-11.81).

Conclusion: The history of a prior cancer or pregnancy are not predictors of cancer incidence in NF1.

Grants: Children's Tumor Foundation Young Investigator Award (Award ID: 2023-01-006; https://doi.org/10.48105/CTF.CTF-2023-01-006.pc.gr.172004), Cancer Foundation Finland, Turku University Hospital.

[1]*University of Parma, Department of Medicine and Surgery, Parma, Italy;* [2]*University Hospital of Parma, Medical Genetics, Parma, Italy;* [3]*University Hospital of Parma, Hematology and BMT Unit, Parma, Italy*

Background/Objectives: Darier's Disease(DD) is a rare, dominantly inherited genodermatosis with the loss of desmosomal adhesion and abnormal keratinization, caused by variants in *ATP2A2*. *ATP2A2* encodes for a SERCA2 protein, a ubiquitously expressed cellular pump responsible for calcium translocation from cytosol to endoplasmic reticulum. The molecular mechanism underneath *ATP2A2* alterations is not known. Intriguingly, in other disease models SERCA2 is a master regulator of NOTCH1 signaling and SERCA2 inhibition causes NOTCH1 pathway inactivation. The project aims to define a DD transcriptional profile and the genetic, biochemical and physiological impact of DD *ATP2A2* alterations on NOTCH1 signaling and/or on other new pathways.

Methods: We collected patients' skin biopsies: i)to perform transcriptomic RNA-sequencing analysis on affected and unaffected subjects; ii)to generate keratinocytes and fibroblasts primary cells for expression analysis and immunofluorescence assays of the NOTCH1-downstream effector targets (*HES1*, *HEY1*, *c-MYC*); iii)to investigate NOTCH1 signaling deregulations through immunohistochemistry on FFPE bioptic samples. Furthermore, we generated plasmids containing patients' specific *ATP2A2* variants to evaluate their impact on the NOTCH1 signaling and the proteins interaction by performing in vitro functional and biochemical assays.

Results: We define a DD transcriptomic gene signature, focused on metabolic, ribosomal and immunological deregulations. We pointed out a molecular dependency of NOTCH1 pathways and *ATP2A2* defects through the effects evaluation of patient-specific variant overexpression and by ex vivo assays based on patient-derived primary cell lines and tissue IHC.

Conclusion: By understanding the molecular network between SERCA2 and NOTCH1 in DD, novel and effective therapeutic approaches may be developed and tested in DD

P06.048.B Clinical and genomic profile of genodermatoses in an Indian cohort

Priyanka Patra[1], *Dhanya Lakshmi Narayanan*[1], *Gandham Sri Lakshmi Bhavani*[1], *Raghavendra Rao*[2], *Katta Girisha*[1;3], *Anju Shukla*[1], *Vivekananda Bhat*[1]

[1]*Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, Medical Genetics, Manipal, India;* [2]*Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, Department of Dermatology, Venereology and Leprosy, Manipal, India;* [3]*Sultan Qaboos University, Muscat, Oman*

Background: Genodermatoses are inherited disorders of skin with extensive genetic heterogeneity. Broad spectrum tests like exome sequencing have accelerated the rate of molecular diagnosis of genodermatoses. We describe clinical characteristics and genomic spectrum of genodermatoses from a tertiary care centre in India.

Methods: After clinical evaluation, affected individuals & their families were divided into broader subgroups and offered targeted gene testing or whole exome sequencing based on their clinical diagnosis.

Results: Over a period of 10 years, 155 individuals were clinically diagnosed as genodermatoses and offered genetic testing. Fifty-four individuals from 50 families opted for genetic testing. Consanguinity was recorded in 48% (24/50) families. Molecular diagnosis was achieved in a total of 45 out of 50 families (90%): five (11%) by targeted testing and in 40 (89%) by exome sequencing. Thirty-three monogenic disorders were identified in

50 families with predominance of autosomal recessive inheritance (25/33; 76%). The commonest group was disorders of cornification (9/33; 27%). Eighteen (36%) of 50 identified variants were novel. Forty-eight (48/50; 96%) variants were classified as disease causing according to ACMG/AMP guidelines. Copy number variant analysis of exome sequencing data was able to identify diagnosis in five families. Reproductive counselling was offered to 44% (22/50) of the families and prenatal testing was opted by 41% (9/22) of them.

Conclusion: Our study expands the genetic spectrum of genodermatoses in Indian population.

P06.049.C Geroderma osteodysplasticum: new data regarding the clinical evolution of a mild phenotype.

Isabelle Bacchi[1;2], *Stefano Giuseppe Caraffi*[2], *Roberta Zuntini*[2], *Allessandra Terracciano*[3], *Simona Viglio*[4], *Andrea Superti-Furga*[5;6], *Antonio Novelli*[3], *Livia Garavelli*[2]

[1]*Alma Mater Studiorum University of Bologna, Department of Medical and Surgical Science, Bologna, Italy;* [2]*Azienda USL-IRCCS di Reggio Emilia, Medical Genetics Unit, Reggio Emilia, Italy;* [3]*Bambino Gesù Children's Hospital, IRCCS, Laboratory of Medical Genetics, Translational Cytogenomics Research Unit, Rome, Italy;* [4]*University of Pavia, Biochemistry Unit, Department of Molecular Medicine, Pavia, Italy;* [5]*Lausanne University Hospital (CHUV) and University of Lausanne, Division of Genetic Medicine, Lausanne, Switzerland;* [6]*Genetica AG, Zurich and Lausanne, Switzerland*

Background/Objectives: Geroderma osteodyplasticum (GO) is a *GORAB*-related autosomal recessive disease: bone fragility, loose skin, hyperextensible joints and progeroid features are the main characteristics. This is a rare underdiagnosed condition with variable expressivity; there is limited amount of data regarding its natural history, especially concerning those who present mild phenotypes. Here we provide information on the good clinical evolution of a 20-year-old woman with GO.

Methods: Collagen production was evaluated on fibroblasts from a skin biopsy. Direct sequencing of selected genes and then Clinical Exome Sequencing (CES) were performed.

Results: At 8 months the proband was hospitalized for multiple spontaneous vertebral fractures. Persistent open bregmatic fontanelle, wormian bones, soft skin, joint hyperextensibility, malar hypoplasia were her main clinical features. She was treated with biphosphonate therapy for a year with success. The patient has consistently maintained a height at the upper limits of the normal range, in line with the family's genetic target. At 4 years, spine X-Ray findings showed great improvement. Beighton score is currently 0, bone density is normal. She has undergone dental interventions for dental overcrowding and prognathism. CES analysis identified two rare variants: c.14G>A and c.256delC in compound heterozygosity in the *GORAB* gene (NM_152281), respectively inherited from the mother and the father. They are predicted to lead to premature stop codon formation and likely transcript degradation, and truncating/loss-of-function variants are a known pathogenetic mechanism for *GORAB*.

Conclusions: This case provides new information about GO phenotype highlighting the presence of a novel variant not previously described in the literature.

Conflict of Interest: None declared

P06.050.D Enhancing molecular diagnosis of neurofibromatosis type 1: cultured melanocytes unveil somatic mosaicism in patients screened negative in blood samples

Annelies De Jaegher[1;2], *Suzanne Vanhauwaert*[1;2;3], *nathalie goderis*[1;2], *Hélène Verhaeghe*[1;2], *Aude Beyens*[1;2], *Kathleen Claes*[1;2;3]

[1]*Department of Biomolecular Medicine, Ghent University, Ghent, Belgium;* [2]*Center for Medical Genetics Ghent, Ghent University Hospital, Ghent, Belgium;* [3]*Cancer Research Institute Ghent (CRIG), Ghent University and Ghent University Hospital, Ghent, Belgium*

Objectives: Neurofibromatosis type 1, characterized by multiple cafe au lait macules (CALMs) and neurofibromas, affects 1 in 3500 individuals worldwide. While most diagnosed patients exhibit identifiable NF1 variants, detection rates are lower in sporadic cases, possibly due to mosaicism. This study aimed to uncover the underlying pathogenic NF1 variant within melanocytes from patients who previously tested negative in blood samples.

Methods: Melanocytes, harvested from skin biopsies taken from CALM were cultured from patients with (segmental) neurofibromatosis type 1, previously yielding negative blood screening results. We employed gDNA and cDNA sequencing of NF1, alongside MLPA analysis.

Results: Melanocytes from >1 CALM were available from 14 patients, identifying a common first hit in NF1 in 86% of the samples. Targeted deep sequencing failed to detect the variant in lymphocyte DNA (if available). The majority of identified first hits were nonsense variants (67%) and large deletions (25%). Second hits were not detected in 3/14 patients, but MLPA failed for 2 of them. Additionally, for 9 patients only melanocytes from 1 CALM were available, and in 78% of the samples, at least one pathogenic NF1 variant was found. For 5 additional patients, the analysis is ongoing.

Conclusion: The proposed workflow, addressing challenges such as correct biopsy collection and melanocyte growth, enhances the molecular diagnosis for mosaic NF1 cases and is implemented in clinical setting. Most patients are young adults seeking reproductive advice. Further investigations are warranted to assess transmission risks to offspring. Establishing an international database for somatic cases could serve as an invaluable resource for evaluating such risks.

P06.051.A Discovering Common and Distinct Pathogenic Mechanisms between Alopecia Areata, Vitiligo and Hashimoto's Thyroiditis: an Integrated Gene Expression Analysis

Hadis Abdolahzadeh[1], *Yasmina Gossmann*[1], *Regina C. Betz*[1], *F. Buket Basmanav*[1]

[1]*Institut für Humangenetik, Universitätsklinikum Bonn, Bonn, Germany*

Background/Objectives: Alopecia areata (AA) is a common hair loss disorder with an estimated lifetime risk of 2%. AA is a T-cell mediated autoimmune disease directed against the hair follicle and affected individuals are at increased risk of developing Hashimoto's thyroiditis (HT) and vitiligo. The aim of the current study is to identify common and distinctive gene expression signatures between AA, HT and vitiligo to gain pathobiological insights into their comorbid and non-comorbid presentations, respectively.

Methods: Microarray-based transcriptomic datasets from AA, HT and vitiligo patients and their respective controls were retrieved from public resources and analyzed to identify common and distinct gene signatures (i.e differentially expressed genes; DEGs) using GEO2R and the Venny 2.1.0 tool. Enrichment analyses were performed by the Enrichr tool.

Results: We identified 1,659, 3,390 and 257 DEGs in AA, HT and vitiligo, respectively. AA shared 288 common DEGs with HT and 33

with vitiligo. The DEGs common to AA and HT were significantly enriched for pathways related to immune response, such as interferon gamma signaling, TCR signaling, and the adaptive immune system. The DEGs common to AA and vitiligo were significantly enriched for biological processes including cellular response to epinephrine stimulus, SNARE complex assembly and negative regulation of exocytosis.

Conclusion: Our results suggest that AA and HT share a common pathobiology over several components of the immune response, while the dysregulation or disruption of the exocytosis-mediated melanosome-transfer from melanocytes to keratinocytes could be a possible mechanistic link between AA and vitiligo.

Background/Objectives: Ichthyosis, leukocyte vacuoles, alopecia, and sclerosing cholangitis (ILVASC), is a rare disease of autosomal recessive inheritance, resulting from loss of function of the tight junction protein claudin 1. Its clinical presentation is variable, and is characterized by liver and ectodermal involvement. Most ILVASC cases are attributed to homozygous truncating variants in *CLDN1*, but recently single missense variant CLDN1 p.Arg81His has been associated with isolated ichthyosis phenotype in a family of Moroccan Jewish descent. We aimed to delineate clinical features of ILVASC patients with p.Arg81His variant, to identify and determine carrier rate, and to examine for possible founder origin of this variant in Moroccan Jews.

Methods: For genotyping, whole exome sequencing, Sanger sequencing and restriction fragment length polymorphism analysis were used. Haplotyping was done using SNP arrays. Skin biopsies were assessed by light and electron microscopy.

Results: Seven patients with ILVASC from four families of North African Jewish ancestry, all harboring CLDN1 p.Arg81His variant, were found to have teeth, hair and liver/bile duct involvement, characteristic of ILVASC. Transmission electron microscopy of the affected skin revealed distorted tight junction architecture. Haplotype analysis in the vicinity of the *CLDN1* gene showed this variant to represent a founder variant in Moroccan Jews with an estimated carrier frequency of 1:220.

Conclusion: We emphasize the existence of diverse extra-cutaneous findings in individuals with ILVASC, bearing the CLDN1 p.Arg81His variant. Our data further support the pathogenicity of this variant and show it to represent a founder variant in Jews of Moroccan descent.

Molecular diagnosis of hereditary ichthyosis in pediatric patients

Background/Objectives: Congenital ichthyosis are a group of hereditary disorders of keratinization. Clinical findings are thickening of skin and desquamation, growth restriction, hearing and eye complications, infections, and thermodysregulation. A precise genetic diagnosis is crucial for proper genetic counselling and surveillance.

The aim of the study is to describe the phenotype and genotype of our sample

Methods: We show the data of cases studied at our department with clinical suspicion of from June 2018 to December 2023. Different techniques were used based on clinical suspicion. For suspected *STS* related ichthyosis, we used techniques oriented to copy number variation (CNV) detection. For suspected autosomal recessive congenital ichthyosis (ARCI) whole exome sequencing filtering by a virtual panel of 124 genes related to ichthyosis was used.

Clinical phenotype was described as mild, moderate, or severe.

Results: 25 patients were studied. A positive result was found in 88% of patients, non-conclusive results in 4% and negative results in 8%. The most common result was CNV involving *STS* in 30% (n = 7) of positive results, followed by ARCI related to *ABCA12* gene 13% (n = 3), *PNPLA1* and *TGM1* 9% (n = 2) each, and the rest of genes only were detected in one patient each.

Most of patients (55%) had a mild presentation, just 5% had a severe presentation.

Conclusion: We observed a high positivity rate among cases with clinical suspicion of ichthyosis referred for study in our laboratory. Clinical phenotype accurately oriented the genotyped encountered.

P06.055.A Genetic aspects of IP locus in Incontinentia Pigmenti patients with silent autoimmunity

Ezia Spinosa[1], *Stefania Picascia*[1], *Mattia Ritorti*[1], *Carmela Casale*[1], *Alete Colella*[1], *Alessandra Pescatore*[1], *Maria Brigida Lioi*[2], *Matilde Valeria Ursini*[1], *Francesca Fusco*[1]

[1]*Institute of Genetics and Biophysics "A. Buzzati-Traverso" CNR, Naples, Italy;* [2]*Università degli Studi della Basilicata, Dipartimento di Scienze, Potenza, Italy*

Background/Objective: Incontinentia Pigmenti (IP; OMIM#308300) is a rare genetic disorder due to IKBKG/NEMO mutations. Recently, we detected neutralizing interferon (IFN)-α2 and IFN-ω Auto-Abs in 25% of IP patients, pre-existing to SARS-CoV-2 infection [1]. Here, we molecularly characterize the cohort of IP patients, analyzed by neutralizing assays in collaboration with IMAGINE Institut.

Methods: Clinical data and biological samples (DNA and plasma/serum) from 21 italian IP family trios, were collected in the Incontinentia Pigmenti Genetic Biobank (IPGB (http://www.igb.cnr.it/ipgb) and stored at -80°C. Additionally, PBMC from 4 patients were isolated by Ficoll-Plaque gradient centrifugation. A long-range PCR, Sanger sequencing were performed to identify the IP locus alteration.

Results: All patients (mean age 30 yrs; range 1-60 yrs) exhibited conventional IP skin phenotype. The alteration in IP locus was identified in 81% (17/21). Particularly, NEMOΔ4-10 recurrent deletion was found in 14 patients and a point mutation in 3 patients (c.628_651delinsCG, c.646delG; c.976_978del).

Conclusion: These results suggested that hidden autoimmunity is a new clinical aspect of IP, and further genetic aspects should be investigated.

Grants: This research was supported by EU funding within the NextGenerationEU-MUR PNRR Extended Partnership initiative on Emerging Infectious Diseases (Project no. PE00000007, INF-ACT) to FF.

P06.056.B Inherited Epidermolysis Bullosa - lessons learned from the highly inbred Bedouin community.

Ahmad Bleydi[1], *Olga Shor*[2], *Danielle Landau*[2;3], *Ohad Shmuel Birk*[1;3;4], *Marina Eskin-Shwartz*[1;3;4]

[1]*The Morris Kahn Laboratory of Human Genetics, National Center for Rare Diseases, at the Faculty of Health Sciences, Ben-Gurion University, Beer-Sheva, Israel;* [2]*Saban Pediatric Medical Center for Israel, Soroka Medical Center, Beer Sheva, Israel;* [3]*Faculty of Health Sciences, Ben-Gurion University, Beer-Sheva, Israel.;* [4]*Genetics Institute at Soroka Medical Center, Beer-Sheva, Israel*

Background/Objectives: Hereditary Epidermolysis Bullosa (EB) is a group of monogenic blistering skin diseases, resulting from genetic defects leading to increased skin fragility. Depending on the EB subtype, dominant and/or recessive modes of inheritance have been reported. In its severe forms, EB is a debilitating disease, with shortened lifespan, necessitating meticulous daily skin care and multidisciplinary treatment.

The Negev Bedouin community exceeds 250,000 residents and is subdivided into more than 100 tribal units. The estimated prevalence of consanguineous marriages is 44%, with strict tribal endogamy. Extremely high carrier rates for a wide range of recessively inherited disorders have been reported for this community.

Methods: Retrospective analysis of clinical and genetic data on the EB cases of Bedouin descent referred to Soroka Medical Center during 1998-2019.

Results: We analyzed 40 EB cases from 21 families (including simplex, junctional and dystrophic subtypes). All cases were recessively inherited. The relative prevalence of EB Simplex, Junctional EB and Dystrophic EB was 62%, 19% and 19% respectively. Six different mutations in EB -related genes were found to underlie this disorder in this cohort, most probably representing founder variants in this population.

Conclusion: We show that recessively inherited EB is extremely prevalent in the Negev Bedouin population and reveal its genetic heterogeneity to be limited to a small number of genetic variants.

These data underscore the importance of deciphering the mutational landscape of EB and possibly other recessively inherited disorders in isolated inbred communities to achieve rapid genetic diagnosis and effective carrier screening and disease prevention.

Conflict of Interest: None declared

P06.058.D A novel case of split hand/foot malformation associated with 4q25 deletion encompassing *LEF1*

Katrin Bahlke[1], *Yvonne Stratis*[1], *Albrecht Röpke*[1], *Cornelie Müller-Hofstede*[1], *Judit Horvath*[1], *Frank Tüttelmann*[1], *Eva Klopocki*[2], *Andreas Busche*[1]

[1]*Department of Medical Genetics, University Hospital Münster, Münster, Germany;* [2]*Institute of Human Genetics, Julius Maximilians University Würzburg, Würzburg, Germany*

Background/Objectives: Split hand/foot malformation (SHFM) is a clinically and genetically heterogeneous congenital limb defect. To date, several genes as well as critical chromosomal loci have been identified in association with SHFM. Amongst others, mono- and biallelic sequence variants in *LEF1* have been shown to be associated with SHFM as well as mild ectodermal dysplasia (ED). In contrast, heterozygous deletions encompassing *LEF1* have been reported to cause severe ED, yet no limb defects. We report on a 5-year old boy with congenital SHFM and mild developmental delay but without any symptoms of ED. Family history was unremarkable with respect to limb malformations or ED.

Methods: Quantitative PCR, SNP-array, and exome analysis were performed. Segregation analysis was conducted in the father only since no maternal blood sample was available.

Results: Quantitative PCR did not reveal SHFM-typical micro-duplications in critical regions 10q24 and 17p13. Exome analysis remained without identifying the cause for SHFM. SNP-array revealed a heterozygous 212.6 kb-sized deletion in 4q25 encompassing exons 1-11 out of 12 *LEF1* exons. The deletion was not paternally inherited.

Conclusion: We describe the first patient carrying a deletion encompassing *LEF1* without showing any symptoms of ED but SHFM instead. The phenotype is more in line with the clinical presentation of sequence variants in *LEF1*. Our findings support the concept of *LEF1*-associated phenotypes as a syndromic spectrum with variable expressivity comprising symptoms of SHFM and/or ED. However, further studies are required to understand the exact molecular mechanisms underlying the inconsistent genotype-phenotype-correlation.

P06.059.A Ante- and peri-natal presentation of classical Ehlers-Danlos syndrome: experience of the French national reference center.

Théa Lanfranchini[1], *Malika Foy*[2], *Fabrice Gillas*[2], *Baptiste Vierne*[2], *Karelle Benistan*[2], **Caroline Michot**[3]

[1]*Versailles-Saint-Quentin-en-Yvelines University, Versailles, France;* [2]*Raymond Poincaré Hospital, GHU Paris Saclay, Reference Center for non-vascular Ehlers-Danlos syndromes, Garches, France;* [3]*Necker Enfants malades Hospital, Department of Genomic Medicine for Rare Diseases, Reference Center for non-vascular Ehlers-Danlos syndromes (pediatric site), Paris, France*

Background: classical Ehlers-Danlos syndrome (cEDS) is an autosomal dominant condition associating joint hyperlaxity, skin hyperelasticity, atrophic scars and tissue fragility. Premature rupture of membranes, breech presentation and hip/shoulder neonatal dislocation have been reported, but literature on obstetric and neonatal complications of cEDS is poor. Data are also often confusing, mixing complications observed in different

types of EDS. Our study aims at identifying early signs of the syndrome to offer adequate management.

Methods: we performed a retrospective case-control study. The records of cEDS patients followed at the French national reference center for non-vascular EDS were reviewed and compared to those of their healthy siblings.

Results: we included 109 individuals, consisting in 77 cases and 32 controls. Severe IUGR was observed in 82% cases versus 40% controls. Intensive cares were required in 17% cases, including 5% of full-term newborns, versus in 6% controls. Congenital hip dislocation was found in 10% cases, equinovarus feet in 10% cases and abdominal wall hernia in 13% cases, compared to respectively 3%, 3% and 0% controls. Hypotonia was seen only in cases (5%), 75% of whom were full-term newborns. Hyperlaxity, major skin signs of cEDS and ecchymoses in axillary and contact areas were noted in only 5% of cEDS cases.

Conclusion: Severe IUGR, intensive care unit admissions at term, limb malposition and abdominal hernia are red-flags directing to the diagnosis of cEDS. Nevertheless, major signs of cEDS are rarely recognized at birth, preventing from specific management in sporadic cases. In familial cases, we advise a close ultrasound monitoring as in higher risk pregnancies.

Conflict of Interest: None declared

P06.060.B The effect of Tuberous sclerosis complex 1 (TSC1) deficiency in adipose progenitor cells - case report and in vitro studies

Julika Friedrich[1], *Antje Garten*[1], *Sandy Richter*[1], *Julia Hentschel*[2], *Maria Arelin*[1], *Konrad Platzer*[2], *Andreas Merkenschlager*[1], *Steffi Mayer*[3], *Wieland Kiess*[1], *Rami Abou Jamra*[2], *Diana le Duc*[2], *Henriette Kiep*[1]

[1]*Center for Pediatric Research, University Hospital for Children and Adolescents, Leipzig, Germany;* [2]*Institute of Human Genetics, Leipzig University, Leipzig, Germany;* [3]*University Hospital for Pediatric Surgery, Leipzig, Germany*

Background/Objectives: Activation of mechanistic target of rapamycin (mTOR) as a regulator of adipogenesis and lipid accumulation is controlled by upstream regulators tuberous sclerosis complex (TSC) 1 and TSC2. The impact of TSC1 deficiency is not clearly defined in human adipose tissue. We identified a TSC1 variant in a boy with developmental delay and a lipoma. We aim to assess the effect on adipogenesis and proliferation of adipose precursors and to establish a cell model to test potential therapeutic options.

Methods: The boy presented with a lipoma within the gluteal muscle which is not typical for tuberous sclerosis. In the lipoma tissue we identified a loss of heterozygosity on chromosome 9 including TSC1. To establish an in vitro model we used siRNA TSC1 knockdown (KD) in the human adipocyte models SGBS and LipPD1 and compared to control cells. We examined proliferation and adipocyte differentiation using Hoechst, Nile Red and Oil Red O stain. Expression of adipogenesis markers was measured by qPCR, activation of mTOR downstream effectors was assessed via Western blotting. We investigate the effects of in vitro incubation with different pathway inhibitors.

Results: Preliminary analyses suggested a higher proliferation of TSC1 KD cells compared to control cells. There was no signigicant effect on adipocyte differentiation. We detected an increased phosphorylation of mTORC1 downstream targets in KD cells and in SVF cells derived from the patient's lipoma.

Conclusion: We conclude that the TSC1 variant is probably causative for lipoma formation and a therapy with mTOR inhibitors may be beneficial.

Grants: DFG, SFB 1052.

P06.061.C A second family with multiple epiphyseal dysplasia type 7 caused by the homozygous variant c.676G>A p.(Val226Met) in CANT1

André Travessa[1;2], *Silvia Modamio-Hoybjor*[3;4], *Luísa Brites*[5], *Miguel Beltrán*[6], *Karen E. Heath*[3;4], *Ana Berta Sousa*[1;2]

[1]*Department of Medical Genetics and ERN-BOND, ULS Santa Maria, Lisbon, Portugal, Portugal;* [2]*Faculty of Medicine, University of Lisbon, Lisbon, Portugal, Portugal;* [3]*Institute of Medical & Molecular Genetics (INGEMM), IdiPAZ, Hospital Universitario La Paz, Universidad Autonóma de Madrid (UAM), and CIBERER, ISCIII, Madrid, Spain, Spain;* [4]*Skeletal Dysplasia Multidisciplinary Unit (UMDE) and ERN-BOND, Hospital Universitario La Paz, UAM, Madrid, Spain, Spain;* [5]*Department of Rheumatology, ULS da Região de Leiria, Leiria, Portugal, Portugal;* [6]*Department of Orthopaedic Surgery, ULS Santa Maria, Lisbon, Portugal, Portugal*

Background: Variants in *CANT1* are responsible for Desbuquois dysplasia (DD) type 1, DD Kim type, and multiple epiphyseal dysplasia (MED) type 7, all with autosomal recessive inheritance. In 2017, *CANT1* variant c.676G>A p.(Val226Met), previously found in patients with DD Kim type, was shown to cause MED type 7 in one family. Here, we report an additional patient with the same homozygous variant and MED type 7.

Case report: 45-year-old woman, referred to our skeletal dysplasia multidisciplinary unit for clinical evaluation of severe osteoporosis. Her parents are distant cousins, and she has a brother with a similar phenotype. She has short stature (140cm, -7,11 SD), short trunk, kyphoscoliosis, left genu varum, right genu valgum, lumbar and knee pain, and astigmatism. She underwent multiple surgeries due to bilateral metatarsus varus, bilateral recurrent dislocation of the patella, disc herniation, left wrist fracture, and for evacuation arthrodesis of the right knee. Skeletal X-rays showed Swedish key appearance of the proximal femur, platyspondyly, and generalized epiphyseal dysplasia. Spine MRI revealed cervical-dorso-lumbar spondylosis, signs of L4 fracture, and multiple joint osteoarthritis. A NGS skeletal dysplasia panel revealed the presence of a homozygous pathogenic variant in *CANT1:* NM_001159773.2:c.676G>A p.(Val226Met).

Conclusions: In summary, *CANT1*-related MED is very rare, with only two families described so far. DD type 1, DD Kim variant, and MED type 7 are a continuum of severity, and their unification as *CANT1*-related dysplasias could be more appropriate. Description of further patients with p.(Val226Met) variant would contribute to understand their natural history.

Conflict of Interest: None declared

P06.062.D Enrichment of pathogenic copy number variants on 17q chromosome in patients with skeletal findings

Dijana Perovic[1], *Nela Maksimovic*[1], *Tatjana Damnjanovic*[1], *Biljana Jekic*[1], *Marija Dusanovic Pjevic*[1], *Milka Grk*[1], *Ana Djuranovic*[1], *Natasa Stojanovski*[1]

[1]*University of Belgrade - Faculty of Medicine, Institute of Human Genetics, Beograd, Serbia*

Background/Objectives: Human chromosome 17 (chr17) has the second highest gene density and is rich in segmental duplications. It is known for multiple microdeletion/microduplication syndromes, many of which include skeletal abnormalities. We aim to analyze the overall detection rate of pathogenic and likely

pathogenic copy number variations (pCNVs) in patients with complex phenotypes that include skeletal disorders, as well as the proportion and significance of CNVs of chr17 origin.

Methods: From the original sample of 1230 patients who underwent chromosomal microarray analysis (CMA) in our laboratory (2018-2023) by Agilent oligonucleotide $8 \times 60K$ or $4 \times 180K+SNP$ microarrays, those with skeletal abnormalities were selected. Detection rates of pCNVs were calculated for all chromosomes.

Results: 172/1230 (14,0%) patients had skeletal findings; 43 had pCNVs with a diagnostic yield of 25,0%, significantly higher than in the rest of the cohort (14,6%, $p < 0.001$). Chr17 was the most commonly affected in patients with skeletal findings (9/43). All but one pCNVs were on q arm, in region 17q12-q25.3. Of all detected pCNVs in our cohort (198/1230), those originating from chr17 were more frequently expressed in skeletal phenotype (9/17 for chr17 versus 34/198 for all other chromosomes; $p = 0.002$). One patient had a partial deletion of *the COL1A1* gene corresponding to osteogenesis imperfecta clinical diagnosis; all others had complex phenotypes and multiple genes involved, of which we distinguish *NOG* and *TBX4*.

Conclusion: Skeletal findings in phenotype could increase diagnostic yield of CMA. A high prevalence of CNVs in 17q12-q25.3 emphasizes the importance of genes in this region for skeletal development.

CARDIOVASCULAR DISORDERS

P07.001.A Genetic causes of different types of cardiomyopathies in Bulgarian patients

Valentina Peycheva[1], *Kunka Kamenarova*[1], *Kalina Mihova*[1], *Darina Kachakova-Yordanova*[1], *Martin Georgiev*[1], *Maria Sredkova-Ruskova*[2], *Irena Bradinova*[3], *Emil Simeonov*[4], *Ivanka Dimova*[1], *Radka Kaneva*[1]

[1]*Medical University of Sofia, Laboratory of Genomic Diagnostics, Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria;* [2]*Medical University of Sofia, University Pediatrics Hospital, Department of Clinical Genetics, Sofia, Bulgaria;* [3]*Medical University of Sofia, Department of Obstetrics and Gynecology, Sofia, Bulgaria; 2UHOG "Maichin dom", National Genetic Laboratory, Sofia, Bulgaria;* [4]*Medical University of Sofia, UMBAL "Alexandrovska" hospital, Sofia, Bulgaria*

Background/Objectives: Congenital cardiac abnormalities have strong genetic component and can be either isolated heart defects or to be a part of more complex syndromic phenotype like the RASopathies. The aim of the present study was to find the genetic diagnosis in a group of Bulgarian patients with cardiomyopathies.

Methods: Nine patients with either isolated congenital heart defect or cardiomyopathy in the context of syndromic condition were referred to the genome diagnostics lab. Both targeted next-generation sequencing (NGS) or whole exome sequencing (WES) were performed using MiSeq and Novaseq6000 platforms (Illumina) respectively. Direct sequencing was used for confirmation of the discovered variants.

Results: In 6 patients NGS detected an overall of 9 variants in 7 genes. Three pathogenic and one likely pathogenic novel variant were found in *MYH7*, *PTPN11*, *BRAF* and *ACTB* genes. Five variants of unknown significance but with potential role in the disease phenotype were found in *TCAP*, *ACTN2* and *TTN* genes. Thus, the suspected diagnosis was confirmed in two patients from our cohort. In other two patients with suspicion for Noonan-Costello syndrome the diagnosis was refined based on the genetic findings. *PTPN11* gene, which is involved in the pathogenesis of Noonan and LEOPARD syndromes, was found to cause isolated cardiomyopathy without additional syndromic features.

Conclusion: Identifying the molecular basis of cardiac abnormalities could help define the pathophysiology of the disease, which will help to improve the individual therapy and prophylactics in order to reduce the risk of sudden cardiac death and will elucidate the recurrent family risk.

Consortium: FinnGen

Background/Objectives: Cardiac arrhythmias pose a major public health burden, but diagnosis and prevention remain difficult. We recently described an *SCN5A* missense variant (rs45620037 [T220I], MAF = 5e-3 in Finland, MAF = 1.1e-3 in UK) with a protective effect from common cardiac arrhythmias in a heterozygous state.

Methods: Here, we investigate the variant's effects on ECG intervals, disease incidence and mortality and evaluate its interaction with polygenic background across lifetime in 3 cohorts totalling >1M individuals.

Results: We find significantly shorter QT intervals for heterozygous T220I carriers in the H2000 cohort (-7.84 ± 2.55 ms, $p = 2.1e-3$, $n = 6{,}048$), which we validate in the UK Biobank ($n = 81{,}195$), as hypothesized from the variant's experimentally determined small loss-of-function effect. Further, we find protective effects on multiple common arrhythmias in FinnGen ($n = 500{,}348$), including atrial fibrillation (AFib) (HR 0.60 [0.55, 0.66], $p = 3.13e-06$) which we replicate in the UK Biobank. The variant, however, increases the risk of sick sinus syndrome, especially in homozygotes (HR 12.65 [5.24, 30.53], $p = 1.68e-08$). Overall, the variant has a protective effect against mortality due to cardiac arrhythmia or heart failure (HR 0.74 (0.58, 0.95), $p = 1.93e-02$), while we do not observe significant differences in overall cardiovascular or all-cause mortality. In addition, we find a significant interaction ($p = 0.026$) between T220I carrier status and a polygenic score for AFib on lifetime risk of AFib.

Conclusion: We thus share results on a variant with effects on common arrhythmic diseases and associated endophenotypes with implications for disease prediction and drug development.

P07.004.D Characterization of a novel transgenic mouse model for arrhythmogenic cardiomyopathy: phenotype and heart transcriptome profile

Sara Vencato[1], Stefano Cagnin[1], Chiara Romanato[1], Karthik Murali[1], Sabina Ferron[1], Tommaso Becchi[1], Angelo Velle[1], Gabriele Sales[1], Chiara Romualdi[1], Agata Rakszewska[2], Christian Conrad[2], Paola Braghetta[3], Libero Vitiello[1], Alessandra Rampazzo[1], **Martina Calore**[1;4]

[1]Padova University, Biology, Padova, Italy; [2]Berlin Institute of Health, Center for Digital Health, Berlin; [3]Padova University, Department of Molecular Medicine, Padova; [4]Maastricht University, Cardiology-CARIM, Maastricht, Netherlands

Background:/Objectives Arrhythmogenic cardiomyopathy (ACM) is one of the most commonly inherited cardiomyopathies, characterized by the progressive substitution of the myocardium with fibrofatty tissue. Clinically, ACM is characterized by ventricular arrhythmias, syncope, and sudden cardiac death and shows wide phenotypic heterogeneity (1). Of the known disease genes, those encoding for plakophilin-2 (*PKP2*), desmoplakin (*DSP*), and desmoglein-2 (*DSG2*) are most commonly mutated. To study the pathogenic mechanisms of ACM, we generated a novel mouse model for the disease.

Methods: We generated transgenic mice overexpressing in cardiomyocytes human desmoglein-2 carrying the p.G100R mutation (TgG) found in an affected patient. To establish the transcriptomic ACM signature, we performed bulk and single nucleus-RNA seq on cardiac samples from 6 month-old TgG and control mice.

Results: TgG mice present several clinical features of ACM, such as fibrous replacement, increased inflammatory markers, and cardiac dysfunction. Accordingly, enrichment analysis and network construction performed on bulk RNA seq data identified upregulation of immune- and extracellular matrix-related processes. Ongoing data analysis from single nucleus-RNA seq revealed several (sub)clusters and differentially expressed genes in TgG hearts vs controls.

Conclusion: Collectively, these findings identified numerous processes and cell populations potentially altered in TgG mice that could pave the way for further studies focused on ACM pathogenic mechanisms.

P07.005.A Spectrum of *MYBPC3* variants in a cohort of hypertrophic cardiomyopathy patients

Giulia Margherita Brach del Prever[1;2], *Diana Carli[1;2], maria luca[1;2], Angelo Corso Faini[1;2], carmelo maria romeo[1;2], Fiorenza Mioli[1;2], Valeria Bracciamà[1;2], Francesca Arruga[1], claudia saglia[1;2], caterina scolari[1;2], tullia carradori[1;2], edoardo spagnolo[1;2], davide caldo[1;2], stefano pidello[3], claudia raineri[3], Gaetano Maria De Ferrari[2;3], marco cingolani[4], Walter Grosso Marra[4], matteo bianco[5], barbara mabritto[6], Tiziana Vaisitti[1;2], Silvia Deaglio[1;2]*

[1]Immunogenetics and Transplant Biology Service, Città della Salute e della Scienza University Hospital, Turin, Italy; [2]Department of Medical Sciences, University of Turin, Italy; [3]Division of Cardiology, Cardiovascular and Thoracic Department, Città della Salute e della Scienza University Hospital, Turin, Italy; [4]Division of Cardiology, Hospital of Ivrea, Italy; [5]Division of Cardiology, Coronary Intensive Care Unit, Clinical cardiology and cardiovascular imaging, A.O.U San Luigi Gonzaga, Orbassano, Italy; [6]Division of Cardiology, A.O. Ordine Mauriziano, Turin, Italy

Background/Objectives: a genetic etiology is identifiable in ~30% of cases of hypertrophic cardiomyopathy (HCM), being *MYBPC3* the most frequently involved gene, mutated in ~50% of cases with a confirmed genetic cause. Various mechanisms have been proposed as the *MYBPC3*-related HCM-pathogenesis, including haploinsufficiency. In this study, we aim to describe a cohort of molecularly characterized HCM patients, examine the *MYBPC3*-mutational spectrum and identify methods to assess variants pathogenicity.

Method: 396 HCM patients, recruited from 2018 to 2023, underwent next-generation sequencing analysis (NGS) of a panel of known HCM genes.

Results: 96 patients (24%) carried causative variants (pathogenic/likely pathogenic), 121 (31%) variants of uncertain significance (VUS) and 177 (45%) tested negative. Two patients, presenting both cardiac dilatation and hypertrophy, carried causative variants in DCM-associated genes (*LMNA* and *ABCC9*) suggesting a phenotypic overlap between HCM and DCM. 64 patients (16%) carried 71 *MYBPC3* variants, including 28 VUS (39%). Considering *MYBPC3* variants, 14 (20%) were truncating (frameshift, nonsense), 19 (27%) intronic splicing and 38 (53%) missense. 13 exonic variants (18%) were located near the exon-intron junction with potential impact on splicing.

Conclusion: NGS is a powerful tool to define molecular diagnosis of HCM. However, VUS represent a main clinical issue, limiting NGS usefulness in improving HCM clinical care and familial preventive measures. In our cohort, 32/71 (45%) *MYBPC3* variants, including many VUS, had a potential impact on splicing, thus complementary RNA studies may be of help for variants classification.

P07.006.B Two models, one mutation: functional characterisation of a Brugada syndrome associated CACNA1C variant in stem-cell-derived cardiomyocytes and zebrafish

Bert Vandendriessche[1], *Ewa Sieliwonczyk[1], Dogan Akdeniz[1], Hanne Boen[1], Merlijn Nemegeer[1], Charlotte Claes[1], Jolien schippers[1], Laura Rabaut[1], Bart Loeys[1], Dorien Schepers[1], Maaike Alaerts[1]*

[1]University of Antwerp and Antwerp University Hospital, Cardiogenomics, Center of Medical Genetics, Faculty of Medicine and Health Sciences, Edegem, Belgium

Background/Objectives: Brugada syndrome (BrS) is an inherited arrhythmic disorder which can lead to sudden cardiac death in the young (<40 years old). Only in circa 30% of BrS patients the underlying genetic cause can be identified with current cardiac arrhythmia gene panels. Moreover, numerous genetic "Variants of Uncertain Significance" (VUS) are being detected, but reliable functional models to prove their causality are lacking. Here I aim to model a VUS of the *CACNA1C* gene, detected in a BrS patient, both in human induced pluripotent stem-cell-derived cardiomyocytes (hiPSC-CM) and zebrafish to evaluate its pathogenicity. *CACNA1C* encodes the L-type calcium channel and the variant is hypothesised to induce a trafficking defect.

Methods and Results: First, the CRISPR gene-editing workflow was optimised to create the knock-in (KI) hiPSC and zebrafish lines. Using only Next Generation Sequencing (NGS) as an enrichment tool for the CRISPRed population, an average KI percentage of 2.99% (±5.09, N = 122) was achieved in zebrafish and even up to 64.2% (± 27.1%, N = 21) in hiPSCs. After downstream validation, we obtained homozygous and heterozygous lines of both study models. Fluorescence calcium imaging is a part of the functional

characterisation in both models and preliminary differences between calcium transient shapes could be noted in mutated versus wild type lines.

Conclusion: We showed that with our customised NGS workflow, we can successfully create KI lines irrespective of the study model. Preliminary characterisation of the models carrying the VUS hints at potential differences, but further in-depth analysis and more replicates are needed.

Background/Objectives: Congenital heart defects (CHDs) are the most common malformation amongst newborns, with *NOTCH1*-haploinsufficiency as a major monogenetic cause. Here, we investigated whether a *NOTCH1*-specific DNA-methylation signature can be established. Methylation analysis can aid variant classification, especially regarding variants of uncertain significance (VUS), thus improving counselling of patients.

Methods: The initial analysis of an exome-based cohort (3907 CHD cases, 5157 controls) identified *NOTCH1*-variants in 34 cases, comprising different variant types and pathogenicity levels. These 34 cases were further extended by additional samples with similar *NOTCH1*-variants. DNA of assembled samples were subjected to DNA methylation profiling using the Illumina Infinium MethylationEPIC array. Raw data was Quality Control (QC) processed and analyzed using the EpiSign™ Discovery Software in R. DNA methylation profiles of controls (EpiSign Knowledge Database) were age and sex matched. A linear model (limma) was applied to obtain differential methylated positions between patients and controls. An unsupervised model was applied to evaluate the robustness of the classifying probes. Subsequently, a support vector machine was used to construct the final DNAm signature.

Results: All included samples passed QC-criteria. A selective DNA methylation signature was established using patients harbouring pathogenic *NOTCH1*-variants and control samples. Moreover, the signature showed robust specificity concerning >50 other episignatures related to neurodevelopmental disorders. Analysis of included VUSes demonstrated overlap with the *NOTCH1*-signature in 3 cases.

Conclusion: While previous DNA-methylation signatures have been mainly established for neurodevelopmental disorders, we demonstrate that a *NOTCH1*-specific signature can be identified in non-syndromic CHD patients. Our data also illustrates that DNA-methylation analysis can improve *NOTCH1* variant classification.

P07.008.D A novel approach in functional genomics: identification of genetic variants associated with congenital heart disease in Down syndrome

NAZIMAH NIK-MAHMOOD[1;2], *Farook Ahmad*[3], *Thiloka Ratnaike*[2;4], *Timothy Hearn*[1]

[1]*University of Cambridge, Department of Medical Genetics, United Kingdom;* [2]*Colchester Hospital, ESNEFT, Children's Department, Colchester, United Kingdom;* [3]*Royal Papworth, Critical Care Unit, Cambridge, United Kingdom;* [4]*University of Cambridge, Department of Paediatrics, Cambridge, United Kingdom*

Background/Objectives: Congenital heart disease (CHD) is a major complication associated with Trisomy-21 and affects 40-50% of them. This study explores a novel hypothesis: the enrichment of critical genetic variants present in a triple-state on all three copies of chromosome 21 may influence the penetrance of the CHD phenotype in individuals with Down Syndrome (DS).

Methods: We obtained genomics data of DS patients through the Genomics England Research Environment (GEL RE) from the 100,000 genomes project and NHS Genomic Medicine Service patients and performed a focussed genetic analysis within a region known as the Down syndrome critical region (DSCR) for CHD. We used a bespoke variant allele count approach incorporating haplotype phasing to interrogate the variants. We analysed data from forty-four participants and compared variant enrichment in the DS with CHD (Cases, $n = 13$) with the DS without CHD (Controls) group.

Results: We found six significantly (p-value < 0.05, odd ratio (OR) = 5.8-7.3) enriched triple-state variants in the Cases group compared to the Controls group. These include the most enriched intron variant, rs7280353 (p-value = 0.18, OR = 7.27), located within the *DSCAM* gene, a gene that is associated with DS and CHD, and one enhancer variant, rs2837922 (p-value = 0.02, OR = 5.8), located within a regulatory region, close to the *DSCAM* gene.

Conclusion: The study proposes the potential 'sensitising' effect of common but critical variants in their triple state in altering the expression of cardiac candidate genes such as the *DSCAM*, leading to increased risk for CHD. This study introduces a novel approach to functional genomics when exploring the 'trisomy' environment.

P07.009.A Genetic analysis in sudden unexpected death in infancy and children

Rika Kosaki[1], *Yoshiko Uchida*[2], *Kumiko Yanagi*[3], *Tadashi Kaname*[3]

[1]*National Center for Child Health and Development, Division of Medical Genetics, Japan;* [2]*National Center for Child Health and Development, Division of Pediatric Emergency and Transport Services, Tokyo, Japan;* [3]*National Research Institute for Child Health and Development, Department of Genome Medicine, Tokyo, Japan*

Background: Approximately 2,000 pediatric out-of-hospital cardiac arrests occur annually in Japan, with infants accounting for 40%, and the prognosis is poor.

Determining the cause of death is important for preventable deaths in children and for the bereaved families to accept the child's death. Especially in genetic cardiac diseases, which allows for diagnosis and treatment of survivors.

Methods: Comprehensive genetic test was performed on deaths of unknown cause at our hospital since 2017-2023. Pediatric Sudden Cardiac Death Gene Analysis Panel (450 genes, including disease genes known to affect the ECG and disease genes based on anatomical abnormalities) and WES were done.

Results: Genetic analysis was performed on 25 cases for which consent was obtained from the family.

In 6cases, we concluded that the variants of the *KCNH2, SNTA1, SMC1A, AKAP9,PKP2 and COL3A1* genes. Some were strongly associated with the primary disease and cause of death. In addition, three of the patients was identified with a family history of the same variants and symptoms considered to be arrhythmias, leading to future follow-up. Genetic counseling including disclosure of the results to the bereaved families of the patients was provided.

Conclusion: The results suggest that comprehensive genetic analysis is useful in determining the cause of death in pediatric out-of-hospital cardiac arrest. However, our study has several limitations, the genetic information can lead to health management of the bereaved family members.

P07.010.B Biallelic NPR1 loss of function variants are responsible for neonatal systemic hypertension

YLINE CAPRI[1;2], *Theresa KWON*[3], *Olivia Boyer*[4], *Lucas Bourmance*[2], *Noe Testa*[2], *VERONIQUE Baudouin*[3], *Ronan BONNEFOY*[5], *Anne COUDERC*[4], *Laurence Heidet*[6], *Chakib Meziane*[7], *Elisabeth Tournier-Lasserve*[8], *Judith Melki*[2]

[1]*APHP Robert Debré, Genetics Department, Prais, France;* [2]*INSERM, UMR 1195, Le Kremlin Bicêtre, France;* [3]*APHP Robert Debré, Nephrology Department, Paris, France;* [4]*APHP Necker Enfants Malades, Nephrology, Paris, France;* [5]*APHP Robert Debré, Pediatric Cardiology Unit, Paris, France;* [6]*INSERM_Institut Imagine, UMR 1163, Paris, France;* [7]*Groupe Hospitalier Sud Ile de France, Neonatology Unit, Melun, France;* [8]*INSERM, UMR 1141, Paris, France*

Background: Early-onset isolated systemic hypertension is a rare condition of unknown genetic origin. Renovascular, renal parenchymal diseases or aortic coarctation are the most common causes of secondary systemic hypertension in younger children and neonates. We investigated the genetic bases of early- onset isolated systemic hypertension.

Methods: Whole- exome sequencing (WES) was followed by variant filtering and Sanger sequencing for validation and familial segregation of selected variants in a large consanguineous family. mRNA expression was performed to evaluate the impact of the predicted pathogenic variant on gene expression. WES or Sanger sequencing was performed in additional unrelated affected individuals.

Results: In one consanguineous family with four children presenting with isolated neonatal-onset systemic hypertension, we identified homozygous stop–gain variant in the NPR1 gene (NM_000906.4:c.1159C>T (p.Arg387Ter)) in the affected individuals. This variant leads to a dramatic reduction of NPR1 RNA levels. NPR1 gene analysis of additional families allowed the identification of another family with two affected children carrying homozygous frameshift variant in NPR1 (NM_000906.4:c.175del (p.Val59TrpfsTer8)).

Conclusion: We show for the first time that biallelic loss of function of NPR1 is responsible for isolated neonatal-onset systemic hypertension in humans, which represents a new autosomal recessive genetic cause of infantile systemic hypertension or cardiogenic shock. This is consistent with studies reporting early-onset systemic hypertension and sudden death in Npr1-deficient mice. NPR1 gene analysis should be therefore investigated in infants with early-onset systemic hypertension with or without cardiogenic shock of unknown origin.

P07.011.C The role of haemoglobin levels and coagulation deficiency in the genetic risk of SCAD: a genetic correlation and MR study

Josephine Henry[1], *Takiy Berrandou*[1;2], *Margaux-Alison Fustier*[1], *Eric Camerer*[1], *Nabila Bouatia-Naji*[1]

[1]*INSERM - Universite Paris Cite, Paris cardiovascular research center, Paris, France;* [2]*Aarhus University, Quantitative genetics and genomics, Aarhus, Denmark*

Background/Objectives: Spontaneous coronary artery dissection (SCAD) is an under-studied form of myocardial infraction, prevalent among women <60yrs. The ischemic event is due to a hematoma, resulting in arterial dissection. Whether it originates from the arterial wall or the lumen is unclear. Our recent GWAS identified one locus near the tissue factor gene (*F3*), involved in coagulation cascade activation following tissue damage. Reduced *F3* expression in arteries correlates with increased SCAD risk. This motivates the investigation of the role of haematological traits and coagulation proteins in SCAD.

Methods: We assessed genetic correlations using LDSC and summary statistics for SCAD, 29 haematological traits and 12 circulating coagulation proteins from population-based GWAS. Inverse variance weighted (IVW) Mendelian randomization (MR) implemented in TwoSampleMR was applied to explore associations between correlated traits ($P_{Bonf} < 3.1 \times 10^{-3}$) and SCAD.

Results: We report positive genetic correlation between SCAD and haemoglobin levels (Hb) ($r_g = 0.11$, $P = 1.8 \times 10^{-5}$). MR indicated significant association of genetically higher Hb with increased SCAD risk ($N_{SNPs} = 296$, $P_{IVW} = 3.3 \times 10^{-5}$). Genetically decreased Factor VIII levels, a protein regulated by thrombin that activates Factor X, associated with increased SCAD risk ($N_{SNPs} =$

12, $P_{IVW} = 2.9 \times 10^{-3}$). Platelet levels did not seem to impact SCAD genetic risk.

Conclusion: Our study provides novel insights into the mechanisms behind SCAD hematoma formation. We genetically confirmed the role of coagulation cascade deficiency through the association of lower levels of Factor VIII. Higher Hb role may reflect higher erythropoietin production, reported to promote arterial dissection in mice. Overall, our findings exclude circulating platelets in SCAD, supporting the hypothesis of intramural hematoma formation.

P07.012.D Variations in hypoxia-inducible factor-1α in cardiac infarction

Ivana Škrlec[1], *Snježana Džijan[1;2], Jasminka Talapko[1], Vera Cesar[1;3]*

[1]Faculty of Dental Medicine and Health, Josip Juraj Strossmayer University of Osijek, Department of Biophysics, Biology and Chemistry, Osijek, Croatia; [2]Genos Ltd., DNA Laboratory, Zagreb, Croatia; [3]Department of Biology, Josip Juraj Strossmayer University of Osijek, Osijek, Osijek, Croatia

Background/Objectives: The *HIF1α* gene regulates oxygen homeostasis in mammalian cells and is activated under hypoxic conditions. It is involved in many hypoxia-related diseases, including cardiovascular diseases, and is crucial for adapting to changes in oxygen availability during cardiac infarction. As genetic variability of *HIF1α* has been associated with cardiovascular diseases, it should be linked with cardiac infarction, the leading cause of myocardial hypoxia. It occurs when the heart's metabolic demands exceed the oxygen delivered to the myocardium. HIF1α provides cardioprotective effects for the oxygen-deprived myocardium. The present study aims to investigate a possible association between *HIF1α* polymorphisms and susceptibility to cardiac infarction.

Methods: This case-control study involved 188 Croatian patients (107 males, 81 females) who had experienced non-fatal cardiac infarction and 94 participants in the control group who had no prior history of cardiovascular disease. The study analyzed two SNPs in the HIF1α gene (rs11549465 and rs11549467).

Results: The rs11549465 polymorphism was found to be associated with cardiovascular risk factors such as hypertension ($p = 0.014$) in patients with cardiac infarction, while rs11549467 was associated with excessive daytime sleepiness ($p = 0.043$). A statistically significant difference in allelic ($p = 0.008$) and genotypic distribution ($p = 0.05$) was found between the patients and the control group at gene locus rs11549465 HIF1α.

Conclusion: The study suggests that polymorphisms in the *HIF1α* gene may be related to cardiac infarction, particularly genetic variations within the *HIF1α* gene, specifically rs11549465, which may modify susceptibility to cardiac infarction in the Croatian population.

P07.013.A Prioritizing causal genes and cell types in calcific aortic valve disease: Insights from integrating single-cell expression with GWAS

Shilin Jin[1], Shishi Wu[1], Feng Shen[2], Di Yang[3], Mengyao Yu[4]

[1]Human Phenome Institute, Zhangjiang Fudan International Innovation Center, Fudan University, Shanghai, China; [2]Department of Cardiovascular Surgery, Shanghai General Hospital, Shanghai Jiao Tong University of Medicine, Shanghai, China; [3]Human Phenome Institute, Shanghai Pudong Hospital, Zhangjiang Fudan International Innovation Center, Shanghai Key Laboratory of Bioactive Small Molecules, Fudan University, Shanghai, China; [4]Human Phenome Institute, Shanghai Pudong Hospital, Zhangjiang Fudan International Innovation Center, Fudan University, Shanghai, China

Background/Objectives: Calcific aortic valve disease (CAVD) is the second leading cause of adult heart diseases. The functions of genetic risks exhibit tissue specificity, as well as the cellular heterogeneity in CAVD. In this study, we aimed to uncover potential cell populations and genes that contribute to the development of CAVD and to explore the intricate mechanisms of CAVD.

Methods: Three independent scRNA-seq datasets (embryonic, healthy, and CAVD groups, N = 75,442 cells) from the GEO database were integrated by Harmony. Subsequently, scPagwas was utilized to identify the CAVD-relevant cellular populations and genes by integrating pathway activation transformation of scRNA-seq data and GWAS summary statistics (10 cohorts involving 13,765 cases and 640,102 controls). Additionally, a cell-cell communication network analysis was performed by CellChat.

Results: Unbiased cluster analysis of the three scRNA-seq data identified 18 clusters, in which 9 clusters significantly enriched in genetic association signals related to CAVD, particularly monocytes and valve-derived stromal cells (VDSCs). Increased cell-cell interactions, notably involving monocytes, were observed in CAVD patients. Furthermore, 20 high-risk pathogenic genes were identified that exhibited intriguing patterns throughout the lifecycle of CAVD (PCC < 0.25). For instance, inflammation-related genes such as *CXCL8* and *IL6* are activated during the disease, while the gene *RPS20*, encoding ribosomal proteins, is suppressed from embryo to adult but reactivated during the disease.

Conclusion: We identified monocytes as the CAVD-related cellular population and unveiled a set of prioritized genes linked to CAVD. Our research has innovatively expanded the genetic landscape of CAVD from the embryonic, healthy, and disease perspectives.

P07.014.B A pathogenic variant Gly148Arg of *ACTA2* gene causes left ventricular myocardial compaction: cardiac manifestations in a zebrafish model.

Wulan Apridita Sebastian[1], Masanori Inoue[1], Nobuyuki Shimizu[2], Ryosuke Sato[1], Saori Oguri[1], Tomoyo Itonaga[1], Shintaro Kishimoto[1], Hiroshi Shiraishi[2], Toshikatsu Hanada[2], Kenji Ihara[1]

[1]Oita University, Faculty of Medicine, Pediatrics, Yufu; [2]Oita University, Faculty of Medicine, Cell Biology, Yufu

Background/Objectives: The *ACTA2* gene encodes actin α2, a primary component of vascular smooth muscle cells. *ACTA2* missense variants are implicated in inherited thoracic aortic diseases, characterized by smooth muscle cell dysfunction in various organs including the lungs, brain vessels, intestines, pupils, bladder, and heart.

Methods: A heterozygous missense variant, Gly148Arg (G148R), was identified in a patient with thoracic aortic aneurysm,

dissection, and left ventricular non-compaction. To explore the potential functional and histopathological impacts of this variant, we employed zebrafish as a live model. We injected *ACTA2* mRNA (wild-type, G148R variant, and known pathogenic variant Arg179His [R179H]) into one-cell stage zebrafish embryos. These embryos were then observed up to 72 hours post-fertilization for cardiac analysis.

Results: We observed a significant reduction in heart shortening fractions in zebrafish with both pathogenic variants. Histopathologically, the myocardial walls in zebrafish with *ACTA2* pathogenic variants were thinner compared to the wild type, and a notable decrease in total myocardial cell count was evident. Additionally, the number of proliferating cells in endothelial and myocardial regions was significantly reduced in zebrafish with *ACTA2* variants, demonstrating the impact of G148R and R179H variants on left ventricular non-compaction and cardiac morphological abnormalities.

Conclusion: This study underscore the critical role of the *ACTA2* gene in various aspects of cardiovascular development, revealing previously unidentified implications of *ACTA2* variants in cardiac pathology.

Grants: This work was supported by JSPS Grant-in-Aid for Scientific Research (B) Grant Number JP22H03043.

P07.015.C A novel mosaic *RASA1* variant in a child with Parkes Weber syndrome

Robin A. Pilz[1], *Dariush Skowronek*[1], *Tamara Ehresmann*[2], *Ute Felbor*[1], *Matthias Rath*[1;3]

[1]*Department of Human Genetics, University Medicine Greifswald, and Interfaculty Institute of Genetics and Functional Genomics, University of Greifswald, Greifswald, Germany;* [2]*Limbach Genetics GmbH, MVZ Humangenetik, Frankfurt, Germany;* [3]*Institute for Molecular Medicine, MSH Medical School Hamburg, Hamburg, Germany*

Background/Objectives: Capillary malformation-arteriovenous malformation (CM-AVM) syndrome, with or without Parkes Weber syndrome (PWS), is a rare autosomal dominant disease that is caused by pathogenic *RASA1* or *EPHB4* variants and can lead to life-threatening complications. Approximately 70 to 80 % of CM-AVM cases are inherited from an affected parent. However, postzygotic de novo variants must also be considered in genetic testing for CM-AVM.

Methods: We performed NGS gene panel sequencing for a 4-year-old female PWS patient presenting with multiple capillary malformations, two capillary stains on the left leg, and associated overgrowth of the second toe. We also conducted a literature review on cases with mosaic *RASA1* and *EPHB4* variants.

Results: A postzygotic *RASA1* loss-of-function variant was detected with a variant allele frequency (VAF) of 20 % in blood and oral epithelial cells of the index patient. The literature review revealed no correlation between the severity of the clinical phenotype and the VAF. We also identified a germline nonsense variant in the patient's *TEK* gene, which is not expected to cause a vascular phenotype but confers an increased risk for primary congenital glaucoma with variable expressivity.

Conclusion: Our case report and literature review strengthen the importance of testing for genetic mosaicism in CM-AVM and illustrate that a good knowledge of the sequenced genes and associated disease mechanisms is essential for adequate genetic counseling.

P07.016.D A novel splice-site *FHOD3* founder variant is a common cause of hypertrophic cardiomyopathy in the population of the Balkans – a cohort study

Nina Vodnjov[1;2], *Janez Toplišek*[3], *Aleš Maver*[1;4], *GORAN CUTURILO*[5;6], *Helena Jaklič*[1], *Nataša Teran*[1], *Tanja Višnjar*[1], *Maruša Škrjanec Pušenjak*[1], *Alenka Hodžić*[1], *Olivera Miljanovic*[7], *Borut Peterlin*[1], *Karin Writzl*[1;4]

[1]*University Medical Centre Ljubljana, Clinical Institute of Genomic Medicine, Ljubljana, Slovenia;* [2]*University of Ljubljana, Biotechnical Faculty, Ljubljana;* [3]*University Medical Centre Ljubljana, Department of Cardiology, Ljubljana;* [4]*University of Ljubljana, Faculty of Medicine, Ljubljana;* [5]*University Children's Hospital, Department of Medical Genetics, Belgrade, Serbia;* [6]*University of Belgrade, Faculty of Medicine, Belgrade, Serbia;* [7]*Clinical Centre of Montenegro, Podgorica, Montenegro*

Background/Objectives: Hypertrophic cardiomyopathy (HCM) is often caused by variants in genes encoding sarcomeric proteins. The contribution of HCM-causing variants in non-sarcomeric genes, such as *FHOD3*, has been less well investigated. We report a novel *FHOD3*:c.1646+2T>C variant found to be a common cause of HCM in Balkan population.

Methods: An in-house database of exome sequencing results, collected during routine diagnostics, was searched for recurrent variants in 134 probands with HCM. The heterozygous *FHOD3*(NM_001281740.3):c.1646+2T>C was observed in five probands. Segregation study and variant screening of the probands who had previously undergone panel or clinical exome sequencing was performed by Sanger sequencing. Whole genome sequencing was performed for haplotype analysis in 11 individuals. Medical history was obtained from institutional medical records.

Results: In total, 8/134 (16%) probands and seven relatives were found to have the *FHOD3*:c.1646+2T>C. The variant was classified as likely pathogenic (PS4_STR, PP1_SUP, PP3, PM2). *FHOD3*:c.1646+2T>C shows incomplete penetrance (13/15 affected individuals; unaffected individuals were 22 and 42 years old) and highly variable age of disease onset (mean 32 ± 18, range 4-63 years). Individuals with *FHOD3*:c.1646+2T>C had no history of sudden cardiac death (SCD), aborted SCD or atrial fibrillation. Haplotype and pedigree analysis suggested that the variant arose in an ancestor living in the Balkans.

Conclusion: *FHOD3*:c.1646+2T>C is the second most common HCM-causing variant in studied cohort. Consistent inclusion of non-sarcomeric HCM-causing genes in HCM genetic testing is necessary to better assess the number of disease-causing variants in these genes and their contribution to HCM development worldwide.

P07.017.A Prenatal diagnosis of a PIK3R1- related overgrowth syndrome with cutaneous syndactyly and Peters anomaly

Eleonore Pairet[1;2], *Laurence Boon*[2;3], *Dana Dumitriu*[4], *Olivier Barbier*[5], *Pierre-Louis Docquier*[3;5], *Martina De Bortoli*[2], *Miikka Vikkula*[2], *Jean-Marc Biard*[6], *An Van Damme*[3], *Nicole Revencu*[1;3]

[1]*Cliniques universitaires Saint-Luc (UCLouvain), Human Genetics, Bruxelles, Belgium;* [2]*De Duve Institute UCLouvain, Human Genetics (GEHU), Woluwe-Saint-Lambert, Belgium;* [3]*Cliniques universitaires Saint-Luc (UCLouvain), Center for Vascular Anomalies, Bruxelles, Belgium;* [4]*Cliniques universitaires Saint-Luc (UCLouvain), Radiology, Bruxelles, Belgium;* [5]*Cliniques universitaires Saint-Luc (UCLouvain),*

Orthopedics, Bruxelles, Belgium; [6]Cliniques universitaires Saint-Luc (UCLouvain), Obstetrics, Bruxelles, Belgium

Background/Objectives: Somatic missense and indel variants in *PIK3R1* have recently been identified in a phenotypic spectrum that resembles *PIK3CA*-related overgrowth spectrum and in capillary malformation with dilated veins. The *PIK3R1*-associated phenotypic spectrum includes capillary malformations, venous ectasias/ engorgement, and mild soft tissue/bone overgrowth.

Results: We report a patient with a subcutaneous upper limb and thoracic mass identified at 25 weeks of gestation. An initial differential diagnosis included macrocystic lymphatic malformation and connective tissue tumour. Amniotic fluid analysis identified a *PIK3R1* variant (c.1735_1740del, p.(Gln579_Tyr580del)) with an allele fraction of 9.5%. The foetus developed anaemia at 31 weeks and had a transfusion. The child was born at term with an extensive capillary malformation of the 4 limbs and thorax, cutaneous syndactyly on 4 extremities, hypoplastic nails, and a left axillary mass with both lymphatic and venous components. A Peters anomaly was identified in his right eye. At day 9, a treatment by sirolimus was initiated because of disseminated intravascular coagulation. He is currently 2 years old and developing well and is under alpelisib treatment. Genetic testing performed postnatally showed the absence of the *PIK3R1* variant in the blood and its presence in a skin biopsy with an allele fraction of 16%.

Conclusion: This case represents the first prenatal diagnosis of the *PIK3R1*-associated phenotypic spectrum, confirming the risk of ocular phenotype and limb anomalies. Additionally, the evolution under sirolimus and subsequent alpelisib treatment will be discussed. This contribution enhances our understanding of the diverse manifestations and treatment strategies associated with this disease.

P07.018.B Identification of *BCAR1* as a novel candidate gene for hydrops fetalis and lower limb lymphedema

Charlotte Kemper[1], *Rene Hägerling*[1;2]

[1]Charité - Universitätsmedizin Berlin, Institute of Medical Genetics and Human Genetics, Berlin, Germany; [2]Berlin Institute of Health (BIH), BIH Center for Regenerative Therapies, Berlin

Background/Objectives: Primary congenital lymphedema is a genetic disease caused by altered lymph vessel development during embryogenesis. There are over 20 known disease-causing genes, however, many cases remain to be unsolved. To close this gap, we performed trio whole exome sequencing in patients with primary lymphedema.

Methods: Following trio exome analysis, potential gene candidates were further investigated including state-of-the-art imaging techniques of human, murine and zebrafish samples as well as in vitro experiments on human dermal lymphatic endothelial cells (HDLECs).

Results: We identified the homozygous variant c.1238C>T p.(P413L) in *BCAR1*, a gene encoding for an adaptor protein in cell motility, in a two-year-old patient with lower limb lymphedema and prenatal hydrops fetalis. BCAR1 was previously described to act downstream of VEGF-receptors and be involved in cardiovascular development. The identified p.(P413L) variant is located between phosphorylation sites in its functional domain. To further investigate this variant as causative, we analyzed BCAR1 protein expression in murine and human tissue samples. We could show high expression in lymphatic vessels during mouse development, in adult mice and human skin samples. Further in vitro experiments including siRNA knock-down in HDLECs, highlighted an essential role of BCAR1 in focal adhesions and proliferation of LECs. These results were confirmed in zebrafish using *BCAR1*-morpholinos.

Conclusion: We present *BCAR1* as a novel candidate gene for primary congenital lymphedema underlying an autosomal recessive inheritance mode. We could show that BCAR1 is essential for cell proliferation and adhesion in LECs through in vitro and in vivo analysis in mice, zebrafish, and human tissue samples.

P07.019.C Genetic background of inherited arrhythmia syndromes in a cohort of Czech patients

Jana Zídková[1], *Markéta Bébarová*[2], *Martin Král*[2], *Olga Švecová*[2], *Štefan Zelenák*[3], *Jiří Pacherník3*[3], *Tomáš Bárta*[4], *Iva Synková*[1], *Tereza Kramářová*[1], *Tomáš Novotný*[5], *Samuel Lietava*[5], *Lenka Fajkusova*[1]

[1]University Hospital Brno, Centre of Molecular Biology and Genetics, Brno, Czech Republic; [2]Faculty of Medicine, Masaryk University, Department of Physiology, Brno, Czech Republic; [3]Faculty of Science, Masaryk University, Department of Experimental Biology, Brno, Czech Republic; [4]Faculty of Medicine, Masaryk University, Department of Histology and Embryology, Brno, Czech Republic; [5]University Hospital Brno, Department of Internal Medicine and Cardiology, Brno, Czech Republic

Background/Objectives: Inherited arrhythmia syndromes are rare genetic disorders that can range in severity from no symptoms to sudden cardiac death, even within affected families. The interpretation of genetic findings can be challenging, particularly when it comes to identifying variants of uncertain significance (VUS). Our study presents an overview of the molecular characteristics of a group of Czech patients with a causative variant in a gene associated with arrhythmia syndromes, as well as functional analysis of a selected VUS variant.

Methods: We use custom capture panel sequencing for variant detection and CNV analysis. Functional analysis of the *RYR2* p.(Y4734C) variant was performed using a multielectrode array on patient-specific hiPSC-derived cardiomyocytes of the proband and an unrelated healthy control.

Results: Causative variants were most frequently identified in the potassium channel genes *KCNQ1* and *KCNH2*, followed by *RYR2*, *SCN5A*, and other genes (*CACNA1C*, *CASQ2*, *HCN4*, *KCND3*, *KCNE1*, *KCNJ2*). Regarding functional analysis, the pilot data showed: (i.) a shorter field potential duration, (ii.) a reduced reactivity on β-adrenergic stimulation, and (iii.) a higher short-term variability of CL during pro-arrhythmic conditions.

Conclusion: Our findings provide valuable insights into the genetic background of inherited arrhythmia syndromes in Czech patients. Detailed functional analysis is necessary to reveal a possible relationship between the genotype and phenotype and can contribute to improved diagnosis and family counselling.

Grants: Supported by the Ministry of Health of the Czech Republic– grant project NU22-02-00348 and by the Ministry of Education, Youth and Sports of the Czech Republic – grant project MUNI/A/1547/2023.

Molecular Genetics, Woluwe-Saint-Lambert, Belgium; [3]Sant Joan de Déu Barcelona Hospital, Department of Dermatology, Esplugues de Llobregat, Spain; [4]Cliniques universitaires Saint-Luc (UCLouvain), Pediatric Neurology Unit, Bruxelles, Belgium; [5]Sant Joan de Déu Barcelona Hospital, Laboratory of Molecular Oncology, Pediatric Cancer Center Barcelona, Esplugues de Llobregat, Spain; [6]Cliniques universitaires Saint-Luc (UCLouvain), Service d'anatomopathologie, Bruxelles, Belgium; [7]Cliniques universitaires Saint-Luc (UCLouvain), Rehabilitation Department, Bruxelles, Belgium; [8]Cliniques universitaires Saint-Luc (UCLouvain), Pediatric Radiology Unit, Bruxelles, Belgium; [9]Cliniques universitaires Saint-Luc (UCLouvain), Center for Vascular Anomalies, Division of Plastic Surgery, Bruxelles, Belgium

Background/Objectives: Capillary Malformations (CM) are the most common type of vascular anomalies, affecting around 0.3% of newborns. They are usually caused by somatic pathogenic variants in *GNAQ* or *GNA11*. *PIK3CA* and *PIK3R1*, part of the PI3K-AKT-mTOR pathway, are mutated in fainter CMs such as megalencephaly-capillary malformation (M-CM) and diffuse capillary malformation with overgrowth (DCMO).

Results: In this study, we present two young patients with a CM-like phenotype, associated with cerebral anomalies and severe epilepsy. Pathogenic variants in *PIK3CA* and *PIK3R1*, as well as *GNAQ* and *GNA11* were absent in affected cutaneous tissue biopsies. Instead, we identified two somatic pathogenic variants in the *AKT3* gene. Subsequent analysis of the DNA obtained from surgically resected brain tissue of one of the two patients confirmed the presence of the *AKT3* variant. Focal cortical dysplasia was also detected in this patient. Genetic analysis thus facilitated work-up to reach a precise diagnosis for these patients, associating the vascular anomaly with the neurological symptoms.

Conclusion: This study underscores the importance to search for additional signs and symptoms to guide the diagnostic workup, especially in cases with atypical vascular malformations. Additionally, it strongly emphasizes the significance of genotype-phenotype correlation studies in guiding clinicians' informed decision-making regarding patient care.

Conflict of Interest: None declared

P07.021.A Whole exome sequencing identifies novel genetic variants associated with syndromic Tetralogy of Fallot

Fanni Tóth-Szumutku[1], *Ilona Kun[1], Anna Lengyel[1], Eva Pinti[1], Krisztina Nemeth[1], Tunde Abonyi[1], Seung Woo Ryu[2], Yongjun Song[2], Eva Kis[3], Laszlo Ablonczy[3], Vera Goda[4], Gergely Krivan[4], Iren Haltrich[1], Árpád Ferenc Kovács[1]*

[1]Semmelweis University, Pediatric Center, Tűzoltó Street Department, Budapest, Hungary; [2]3billion Inc., Seoul, Korea, Rep. of South; [3]Gottsegen National Cardiovascular Center, Budapest, Hungary; [4]Central Hospital of Southern Pest National Institute of Hematology and Infectious Diseases, Budapest, Hungary

Background/Objectives: Tetralogy of Fallot (TOF) is one of the most common cyanotic congenital heart diseases. The pathogenesis of this condition needs further clarification. The aim of our study was to ascertain genetic variants among patients with syndromic Tetralogy of Fallot.

Methods: Patients were retrospectively collected between 2005 and 2023 from two Hungarian pediatric centers. Karyotype analysis and fluorescent in situ hybridization (FISH) or multiplex ligation-dependent probe amplification (MLPA) specific for 22q11.2 microdeletion syndrome were performed for all patients. Whole exome sequencing (WES) was completed for patients lacking 22q11.2 deletion. Validation of identified variants was run via Sanger sequencing and FISH.

Results: 26 unrelated patients with syndromic TOF underwent WES. We identified 13 variants, including four pathogenic, six likely pathogenic variants (38% diagnostic yield) and three variants of uncertain significance (VUS). Two patients carried *JAG1* and three patients *CHD7* variants. Four novel likely pathogenic variants were identified: a nonsense variant in Patient 1 [*JAG1*:c.1080dup (p.Glu361Ter)], and a nonsense variant in Patient 2 [*PHF8*:c.718C>T (p.Arg240Ter)]. Patient 3 carried a nonsense *CHD7*:c.3310_3311del (p.Ile1104Ter) variant and Patient 4 carried a nonsense *CHD7*:c.4505del (p.Ser1502Ter) variant.

Conclusion: This is the first study conducted on a Hungarian patient cohort with syndromic TOF. The WES approach is an effective diagnostic tool in syndromic TOF. Importantly, we identified four novel variants, thus our results extend the genotypic spectrum of syndromic TOF associated *JAG1* and *CHD7* genes. To our knowledge, this is the first report of *PHF8* potentially associated with syndromic TOF.

P07.022.B Clinical characteristics and cardiovascular disease outcomes of individuals with different familial hypercholesterolaemia gene-mutations in the UK Simon Broome Register

Nicole Omofoman[1], *Barbara Iyen[2], Steve Humphries[3], Nadeem Qureshi[2]*

[1]University of Leicester, Medical Genetics, School of Biological Sciences, Leicester, United Kingdom; [2]University of Nottingham, Centre for Academic Primary Care, Nottingham, United Kingdom; [3]University College London, Centre for Cardiovascular Genetics, London, United Kingdom

Background/Objectives: Familial hypercholesterolaemia (FH) is caused by a mutation in the *LDLR, APOB* or *PCSK9* genes. We investigated whether there are differences in cardiovascular disease (CVD). outcomes for the different FH genes, using the UK Simon Broome (SB) register linked with secondary care records in Hospital Episode Statistics (HES)

Methods: CVD incidence rates were determined (defined as a composite of coronary heart disease (CHD), myocardial infarction (MI), stable or unstable angina, stroke, TIA, peripheral vascular disease (PVD), heart failure or coronary revascularisation interventions). Conditional logistic regression determined hazards ratios for CVD associated with the different FH-genes.

Results: Of 2988 individuals in SB register with linked HES records, 399 (13.4%) had an identified FH-mutation (*LDLR* in 371(93%), *APOB* in 23(5.8%), and *PCSK9* in 5 (1.3%) individuals). At registration individuals with a *PCSK9* mutation had significantly higher mean pre-treatment total cholesterol (13.2mmol/l (SD1.6)), followed by individuals with *LDLR* and *APOB* gene mutations (10.3mmol/l (SD2.1) and 9.4mmol/l (SD1.3) respectively).

The composite CVD incidence rate (95%CI) (per 100,000 person-years) in individuals with an *LDLR* mutation was 23.8 (20.4-27.8), *APOB* was 17.2 (8.2-36.0), and *PCSK9* was 40.5 (13.5-125.5). Compared to clinical FH-individuals without an identified mutation, the highest CVD risk was observed in *PCSK9* mutation carriers (HR 1.9 [95%CI 0.6-6.1]), then *LDLR* (HR 1.06 [0.8-1.4]) and *APOB* (HR 0.5 [0.3-1.2]) carriers.

Conclusion: Individuals with *PCSK9* and *LDLR* gene mutations had more severe FH-phenotypes than those with *APOB* mutations, however there was no statistically significant difference in CVD risk between individuals with different FH gene mutations.

P07.023.C X-linked isolated dilated cardiomyopathy with myocardial emerin deficiency caused by missense variant in the EMD gene

Linda Bulmer[1;2], *Charlotta Ljungman*[2;3], *Johan Hallin*[1], *Pia Dahlberg*[2;3], *Carola Oldfors*[4], *Anders Oldfors*[4], *Anders Gummesson*[1;2]

[1]*Sahlgrenska University Hospital, Department of Clinical Genetics and Genomics, Gothenburg, Sweden;* [2]*Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Department of Molecular and Clinical Medicine, Gothenburg, Sweden;* [3]*Sahlgrenska University Hospital, Department of Cardiology, Gothenburg, Sweden;* [4]*Institute of Biomedicine, Sahlgrenska Academy, University of Gothenburg, Department of Laboratory Medicine, Gothenburg, Sweden*

Background/Objectives: The *EMD* gene, causative for Emery-Dreifuss muscular dystrophy type 1, has been suggested to associate with isolated dilated cardiomyopathy (DCM). However, evidence is currently insufficient to verify the gene-disease association. We investigated the causality for a missense variant, c.23C>G, p.(Ser8Trp), in *EMD* in a family with X-linked DCM without muscular dystrophy.

Methods: All family members confirmed to harbour the *EMD* variant underwent cardiac examination. Affected males were investigated for muscular dystrophy by physical examination, s-CK measurements and histopathological examination of skeletal muscle. Immunohistochemical analyses of emerin on myocardium and skeletal muscle were conducted. Segregation analysis was performed, and results quantified by estimation of LOD-score based on number of informative meioses and calculation of full-likelihood Bayes factor.

Results: Seven males and 19 females were included. Six hemizygous males were diagnosed with DCM at age 36-50 years. Conduction defects and ventricular arrythmias were prominent features, and three were heart transplanted due to heart failure. There was a family history of suspected sudden cardiac death in males. Muscular dystrophy was negated for all affected males and excluded by clinical examination in four. The *EMD* variant co-segregated with DCM (estimated LOD score 3.9, odds >2500:1 in favour of causality). Emerin immunostaining was profoundly reduced in myocardial specimens available from three affected males. Among the 17 heterozygous females, aged 20-87 years, one developed DCM at age 72.

Conclusion: We propose isolated DCM as a new *EMD*-phenotype, supported by the evidence implicating *EMD* in X-linked DCM without muscular dystrophy in this family.

Lurie Children's Hospital of Chicago, Chicago, United States*

Consortium: CHD Synergy Consortium

Introduction: Congenital Heart Disease (CHD) encompasses any structural abnormalities that are present in the cardiovascular system at birth. Individuals with CHD often have an added burden of co-morbidities, with approximately two thirds of patients affected by co-occurring medical conditions, which can significantly impact overall health and quality of life. The aim of this project was to assess the role of polygenic inheritance in the development of common co-morbidities.

Methods: Polygenic risk scores (PRS) for co-morbidities including hypertension, type 2 diabetes, obesity, and birth weight were calculated in two cohorts of CHD patients and their respective control groups. The first cohort consisted of 184 patients and 3,823 controls, while the validation cohort consisted of 486 patients and 503 controls.

Results: Several common CHD co-morbidities including hypertension, type 2 diabetes, and obesity had higher polygenic scores than comparable healthy controls, with significant associations for hypertension (9.8% higher mean) and type 2 diabetes (7.2% higher mean) in the first cohort. Results from the validation cohort supported this, with significant associations for hypertension (5.1% higher mean), type 2 diabetes (4.6% higher mean), and obesity (5.7% higher mean).

Conclusion: The data presented here suggests polygenic inheritance may contribute to the presence of some CHD co-morbidities, and therefore polygenic risk scores may provide a more comprehensive understanding of a patient's risk for development of co-morbidities.

Consortium: ClinGen - Clinical Genome Resource

Background/Objectives: Hypertrophic cardiomyopathy (HCM) is an inherited cardiac condition affecting ~1 in 500 and exhibits extensive genetic heterogeneity. In 2018, The ClinGen Hereditary Cardiovascular Disease Gene Curation Expert Panel (HCVD-GCEP) curated 57 genes associated with HCM. This study, represents a reappraisal of the clinical validity of genes linked to HCM.

Methods: The ClinGen gene curation approach was employed to re-assess the validity of gene-disease relationships in HCM and related syndromic entities involving left ventricular hypertrophy.

Results: Thirty-five genes were re-curated based on their previous classification and time since last curation, and an additional 5 genes recently associated with HCM were included. Among the re-curated genes, 17 (50%) genes changed classification: 1 limited (previously no evidence), 4 disputed (previously no evidence), 9 disputed (from limited), and 3 definitive (previously moderate). Notably, 3 (9%) genes had a clinically relevant upgrade, including *TNNC1*, a 9th sarcomere gene with definitive HCM association. Nine (26%) genes were downgraded to disputed, further discouraging clinical reporting of variants in these genes. Two genes were curated for multiple inheritance patterns (*TRIM63*, disputed for autosomal dominant [AD] but moderate for autosomal recessive [AR]; *ALPK3*, strong for AD but definitive for AR). Five genes recently associated with HCM were curated: two limited (*RPS6KB1* and *RMB20*), 2 moderate (*KLHL24* and *MT-TI*), and 1 definitive (*FHOD3*).

Conclusion: Important reclassifications of previously curated and assessment of recently implicated HCM genes informs reporting of genetic variants for patients worldwide. Our work highlights the need for periodic evidence-based re-appraisal of gene curations.

P07.026.B Genetic testing in a well-selected cohort of restrictive cardiomyopathy (RCM) detects variants in genes encoding sarcomeric proteins.

Markéta Adamová[1], *Alice Krebsová[1], Miloš Kubánek[1], Petra Peldová[2], Pavel Votýpka[2], Martin Kotrč[1], Lenka Piherová[3], Vojtěch Melenovský[1], josef Kautzner[1], Milan Macek[2]*

[1]Institute of Clinical and Experimental Medicine, Department of Cardiology, Prague, Czech Republic; [2]Charles University and Motol University Hospital, 2nd Faculty of Medicine, Department of Biology and Medical Genetics, Prague, Czech Republic; [3]Charles University in Prague and General University Hospital in Prague, First Faculty of Medicine, Department of Paediatric and Adolescent Medicine, Prague, Czech Republic

Background/Objectives: Restrictive cardiomyopathy (RCM) is the rarest form of cardiomyopathy. Its aetiology is rather complex ranging from infiltrative, inflammatory or hereditary causes, yet its genetic background is not entirely understood. Our goal was to analyse the genetic background in a selected cohort of Czech RCM cases.

Methods: RCM was defined according to the 2023 ESC Guidelines. A total of 12 probands (6 males, 6 females; mean age at diagnosis 43 ± 13 years) was included. Heart transplantation was necessary for terminal heart failure in 8/12 (67 %). All probands received clinical genetic consultation and molecular genetic analysis using next generation sequencing (targeted/exome sequencing; SOPHiA GENETICS, Switzerland). Family cascade screening was carried out in 38 relatives (3.2 per case).

Results: ACMG.net class 4 and 5 variants were disclosed in 10/12 (83 %) patients. Identified genes harbouring the pathogenic mutation encode sarcomeric proteins - *FLNC* (3/10), *DES* (2/10), *TNNT2* (2/10), *TNNI3* (2/10) and *MYBPC3* (1/10) genes. Among relatives, 10/38 persons were disclosed to be at risk of RCM or even already manifested cardiomyopathy (5/10), in its restrictive (2/10) or hypertrophic (3/10) forms.

Conclusion: The genetic yield in our selected cohort of familial RCM is high (83 %), mainly comprising variants in genes encoding sarcomeric and cytoskeletal proteins. The most frequently affected gene is *FLNC*. Even in a well-selected cohort with RCM, we found an apparent overlap with hypertrophic cardiomyopathy in relatives. Further studies are needed to elucidate the pathophysiological mechanisms leading to either restrictive or hypertrophic phenotype.

P07.027.C Genetic findings for cardiomyopathy and arrhythmia: a retrospective analysis of over 1,800 patients

Kirsi Alakurtti[1], *Julie Hathaway*[2], *Johanna Huusko*[1], *Marcos Cicerchia*[1], *Saija Ahonen*[1], *Johanna Tommiska*[1], *Kimberly Gall*[2], *Khalida Liaquat*[2], *Victoria Howell*[2], *Allison Sluyters*[2], *Janica Djupsjöbacka*[1], *Mikko Muona*[1], *Inka Saarinen*[1], *Eija H. Seppala*[1], *Tiia Kangas-Kontio*[1], *Lotta Koskinen*[1], *Pertteli Salmenperä*[1], *Samuel Myllykangas*[1], *Juha Koskenvuo*[1]

[1]*Blueprint Genetics, Espoo, Finland;* [2]*Blueprint Genetics Inc, Marlborough MA, United States*

Background/Objectives: Few cohort studies have examined the rate of informative test results in patients with inherited arrhythmias (IAs) and/or cardiomyopathies (CMs); but have not included the analysis of both the nuclear and mitochondrial (mtDNA) genes. We describe findings in an IA/CM cohort using a broad next-generation sequencing (NGS) panel that included both nuclear and mtDNA genes.

Methods: The NGS panel included 260 genes associated with IAs and/or CMs. 64.3% of patients had mtDNA genes included in their panel test. An informative test result was defined as the identification of pathogenic (P) or likely pathogenic (LP) variant(s) consistent with the patient's reported phenotype and known associated disease inheritance.

Results: 1,883 patients underwent testing, 81.1% were adults. 17.7% of patients received an informative test result. 1.2% had a LP/P deep-intronic variant and 4.5% had a LP/P copy number variant (CNV). 26.7% of these CNVs were single-exon deletions. 2.4% had a LP/P variant in a mtDNA gene. Children were more likely to receive an informative result (22.9%) than adults (16.6%). LP/P variants in *MYBPC3* were the most common finding in children (10%), followed by *RYR2* (8.8%). LP/P variants in *TTN* were the most common finding in adults (15.8%), followed by *MYBPC3* (7.9%).

Conclusion: 17.7% of patients received an informative result. Almost 5% were explained by a mtDNA variant, deep-intronic variant, or single-exon deletion. LP/P variants in *MYBPC3* were seen in 8% of patients. This study demonstrates that a NGS panel that includes the analysis of both nuclear and mtDNA genes has clinical utility for patients with IA and/or CM.

Thoracic aortic aneurysms (TAA) represent a critical medical condition characterized by abnormal dilation of the ascending aorta, posing significant risks due to vessel wall weakness. The congenital bicuspid aortic valve (BAV) is recognized as a risk factor for TAA development, particularly attributed to the disruptive influence of asymmetric blood flow on the aortic wall. Although NOTCH1 mutations have been linked to non-syndromic TAAs resulting from BAV, limited understanding exists regarding NOTCH1 haploinsufficiency and its association with connective tissue abnormalities.

Our study involved the analysis of 127 cases through whole exome sequencing (WES) or whole genome sequencing (WGS), revealing suggestive variants in 44% (56 cases). Notably, two cases presented clear evidence that NOTCH1 gene alterations can be causative factors for TAA even in the absence of BAV. Specifically, a 117 Kb deletion encompassing a significant portion of the NOTCH1 gene, without affecting other coding genes, suggests haploinsufficiency as a potential pathogenic mechanism associated with TAA.

Furthermore, our findings shed light on the complexity of aortic pathology, exemplified by two brothers carrying variants in both the NOTCH1 and MIB1 genes. This observation underscores the involvement of different genes within the Notch pathway in the manifestation of aortic abnormalities, contributing to a comprehensive understanding of the genetic landscape underlying TAA development

P07.029.A Identification of candidate genes for hypoplastic left heart syndrome using innovative exome sequencing data analysis and interpretation methods

Stella van Bergen[1], **Marrit M. Hitzert**[1], *Bart Charbon*[1], *Dennis Hendriksen*[1], *Jan Jongbloed*[1], *Cleo van Diemen*[1], *Wilhelmina S. Kerstjens-Frederikse*[1]

[1]*University Medical Center Groningen, Department of Genetics, Groningen, Netherlands*

Background/Objectives: Hypoplastic left heart syndrome (HLHS) is one of the most severe congenital heart diseases. Genetic causes are presumed to be heterogeneous. Although some causal genes have been identified, variants in these genes only explain a small subset of patients. We performed whole exome sequencing (WES) to identify novel candidate genes.

Methods: WES was performed on 42 index patients and their parents. Data was analysed with an in-house variant interpretation pipeline (VIP), using a deep learning-based trio variant caller and applying state of the art prediction algorithms. We filtered and interpreted candidate variants using dominant, recessive and complex inheritance models. Variant pathogenicity was determined using the ACMG guidelines and prioritisation of candidate genes was done by two clinical geneticists.

Results: In 26 of 42 patients, we identified at least one candidate variant. In total 37 variants were identified in 31 genes. In nineteen patients only one candidate gene was found while in seven patients multiple candidate genes (2-5) were identified.

Conclusion: This study revealed variants in various genes not previously associated with HLHS, results being in line with monogenic and multigenic aetiologies. Our findings need both replication in other patient cohorts as well as evaluation of gene function before a definitive causal role in HLHS pathogenesis can be established.

Grants: This research was funded by Dutch foundation for rare diseases (Stichting Zeldzame Ziekten Fonds)

Background/Objectives: Cardiovascular diseases (CVDs) are the most common non-communicable diseases, responsible for 17.9 million deaths each year. Hypertension a major risk factor for CVDs. GWAS studies have identified over 1,000 variants associated with hypertension. However, the functional impact of these variants is rarely known. Gene expression data generated by RNA-sequencing helps fill in the gaps by finding relevant genes affected by the identified variants.

Methods: RNA-sequencing was performed on 2,013 whole blood samples from a population cohort in Augsburg, Germany. This cohort is the first of its kind in the region. 10,685 genes passed QC and were used in dimensionality reduction analyses to find patterns in the data. Using these insights, differential gene expression analysis was done followed by pathway analysis. To investigate the connection between genetic variants and gene expression, genotyping array data was integrated to perform eQTL analysis.

Results: 132 genes in total were found significant after multiple testing correction, for systolic or Diastolic BP. The results of our analysis not only align with existing literature but also highlight new genes and pathways that could be further studied for hypertension. Some genes were reported for some cardiovascular phenotypes other than hypertension like LMNA and KCNJ2. Others, among many, were not reported for hypertension e.g TNFRSF10C, CEACAM3 and MIR23AHG. Our eQTL analysis also showed around 1,300 unique gene-snp pairs with some overlap with known hypertension GWAS loci, hence providing functional evidence.

Conclusion: RNA-sequencing data offers more information and unveils novel therapeutic avenues for managing hypertension.

P07.031.C Genetic investigation of inherited cardiac diseases in Cypriot patients by targeted Next-Generation Sequencing analysis

Constantina Koutsofti[1], *Marios Ioannides*[2], *christiana polydorou*[1], *Gregory Papagregoriou*[1], *Apostolos Malatras*[1], *George Michael*[1], *Irene Hadjiioannou*[1], *Grigoris Constantinou*[1], *Katerina Stefanou*[1], *Stylianos Pieri*[1], *Eleni Loizidou*[1], *Christos Eftychiou*[2], *Elias Papasavvas*[3], *Theodoros Christophides*[2], *Anna Alkelai*[4], *Manav Kapoor*[4], *Alan R Shuldiner*[4], *PANAYIOTIS AVRAAMIDES*[2], *Constantinos Deltas*[1;5]

[1]*biobank.cy Center of Excellence in Biobanking and Biomedical Research, University of Cyprus, Nicosia, Cyprus;* [2]*Nicosia General Hospital, Department of Cardiology, Nicosia, Cyprus;* [3]*Platonas Medical Center, Nicosia, Cyprus;* [4]*Regeneron Genetics Center, Tarrytown, New York, United States;* [5]*School of Medicine, University of Cyprus, Nicosia, Cyprus*

Background/Objectives: Inherited cardiac diseases represent a highly heterogeneous group of conditions. Pathogenic variants in genes expressed in the cardiomyocytes cause a diverse spectrum of phenotypes. We focused on genetic testing of Cypriots with a clinical phenotype of an inherited heart condition.

Methods: We applied massive parallel DNA sequencing using a 72-gene-panel for studying inherited cardiac diseases. The detected variants were analysed with a bioinformatics approach. All filtered variants were validated using Sanger analysis.

Results: We analysed the data of probands in 40 and 10 families with inherited cardiomyopathies and arrhythmias respectively. In the 40 families with cardiomyopathies, we identified 72 variants, 48 novel. The 72 variants were classified: 47 (65%) as variants of uncertain significance, 18 (25%) as likely-pathogenic, and seven (10%) as pathogenic. In the 10 families with arrhythmias, we identified 16 variants, 10 novel. We classified the 16 variants: 10 (62%) as variants of uncertain significance, three (19%) as likely-pathogenic, and three (19%) as pathogenic.

Conclusion: We characterized genetically families with a cardiac phenotype. In some cases, the genetic heterogeneity and the multiplicity of variants make the definite molecular diagnosis challenging, especially when there is suspicion for incomplete penetrance. This is the first systematic study attempted in Cyprus for inherited cardiac conditions, enabling us to develop a genetic baseline and contribute to precision cardiology.

Grants: Funded by the CY-Biobank, an EU-Horizon 2020 Research and Innovation Programme under GA no. 857122, the Republic of Cyprus, and the University of Cyprus. Supported by the Department of Cardiology, Nicosia General Hospital.

P07.033.A A young patient with an ajmaline induced type-I Brugada pattern in Cyprus and challenging genetic findings

Grigoris Constantinou[1], **Katerina Stefanou**[1], *Myria Zachariou*[1], *christiana polydorou*[1], *Gregory Papagregoriou*[1], *Pantelis Kourtellaris*[2], *Sofia Ourani*[3], *Elias Avraam*[4], *Emily Athanasiou*[3], *Constantinos Deltas*[1]

[1]*Molecular Medicine Research Center / Κέντρο Ερευνών Μοριακής Ιατρικής, biobank.cy, Center of Excellence in Biobanking and Biomedical Research, Nicosia, Cyprus;* [2]*American Medical Center, Cardiology, Strovolos, Cyprus;* [3]*Archbishop Makarios III Hospital, Clinical Genetics & Metabolic disorders clinic, Nicosia, Cyprus;* [4]*Archbishop Makarios III Hospital, Pediatric Nephrology Pediatric Rheumatology Pediatric Gastroenterology – Hepatology Pediatric Pulmonology Pediatrics Paediatric cardiology, Nicosia, Cyprus*

Background/Objectives: Brugada syndrome is associated with a high risk of cardiac arrhythmia and sudden cardiac death (SCD). Patients present with a structurally normal heart and a typical electrocardiographic (ECG) pattern, featuring right bundle branch block and persistent ST-segment elevation in right precordial

leads. The condition predominantly exhibits an autosomal dominant pattern of inheritance, while is mostly sporadic.

Methods: This study explores the case of an 11-year-old female admitted to the hospital in 2019 for an ajmaline provocation test, prompted by family history of Brugada Type-I as her father sustained an SCD at 37-yrs. Despite exhibiting normal heart structure and function, an ECG within normal limits and no arrhythmias, the patient displayed elevated blood pressure and a positive ajmaline test. Genetic testing was recommended and whole exome sequencing identified three variants of unknown significance as evaluated through the ACMG criteria.

Results: The patient bared a variant in KCND3:c.1348C>T (p.Leu450Phe), which was previously reported in patients with Brugada syndrome and independent electrophysiology studies in tissue culture systems further supported its pathogenicity. Interestingly, the same variant is carried by another 10 individuals out of a 1000 in the Cyprus general population Biobank (CYPROME).

Conclusion: Although not conclusive, data presented demonstrate that the KCND3 variant is pathogenic. However, the rather frequent carrier status general population (1:100) is now further addressed to investigate the true frequency of the disease in the Cypriot population.

Grants: This project is funded by a Horizon2020 grant [GA:857122/CY-BIOBANK] provided by the European Union, the Republic of Cyprus, and the University of Cyprus

Conflict of Interest: None declared

P07.034.B The mutational spectrum of Jervell and Lange-Nielsen syndrome: insights from highly consanguineous families

Aya Hataba[1], *Mona Allouba*[1], *Omnia Kamel*[1], *Alaa Afify*[1], *Mariam Fathy*[1], *Mohamed ElMaghawry*[1], *Besra Samy*[1], *Aliaa Mahfouz*[1], *Eslam Ahmed*[1], *Amany Ellithy*[1], *Magdi H. Yacoub*[1;2;3], *Yasmine Aguib*[1;2]

[1]*Aswan Heart Centre, Magdi Yacoub Heart Foundation, Aswan, Egypt;* [2]*National Heart and Lung Institute, London, United Kingdom;* [3]*Harefield Heart Science Centre, Harefield, United Kingdom*

Background/Objectives: Jervell and Lange-Nielsen syndrome (JLNS) is an autosomal recessive disease caused by mutations in *KCNQ1* or *KCNE1*. It is characterized by prolonged QT interval on electrocardiogram, deafness and an increased risk of sudden cardiac death (SCD) (25%). Given the high consanguinity rate (35%) in the Middle East and North Africa region (MENA), an enrichment of JLNS is expected, providing a powerful opportunity to identify ancestry-specific genetic determinants. We report genetic data from the largest MENA JLNS cohort analyzed to date.

Methods: Prospective Egyptian JLNS families and ancestry-matched controls were recruited to Aswan Heart Centre for clinical phenotyping and genetic testing for genes associated with inherited cardiac conditions (Illumina). Variants were classified according to the ACMG/AMP guidelines.

Results: We followed up 39 unrelated probands (20 males and 19 females; mean age at enrollment: 5.8 years) for 4 years. Consanguinity was reported in 85% of probands with complete family data. SCD was reported in 2 probands. Homozygous *KCNQ1* mutations were observed in 82.4% of sequenced probands (28/34). Among these variants, 89% were truncating. Heterozygous parents were confirmed to be healthy. A novel, recurring *KCNQ1* variant (p.W304X) was identified in Egyptian probands (17%), suggesting that it could be a North African-specific founder.

Conclusion: Variants discovered in this underrepresented population adds to the mutational spectrum of JLNS and provides ancestry-specific genetic determinants of disease. Expanding the cohort will provide important genetic and mechanistic insights into the global understanding of inherited arrhythmia syndromes.

P07.036.D To Copy or not to Copy? Copy Number Variant (CNV) analysis for diagnosing inherited cardiomyopathies

Camilla Calandrini[1], *Judith Verhagen*[1], *Wouter te Rijdt*[1], *roza ali amin*[1], *Robert van der Helm*[1], *joan kromosoeto*[1], *Marjolein Weerts*[1], *Ingrid MBH van de Laar*[1], *Marja Wessels*[1], *michelle michels*[2], *Rogier Oldenburg*[1], *Marjon van Slegtenhorst*[1]

[1]*Erasmus MC, Clinical Genetics, Rotterdam, Netherlands;* [2]*Erasmus MC, Cardiology, Rotterdam, Netherlands*

Background/Objectives: In the past, genetic testing for cardiomyopathies (e.g. hypertrophic (HCM) and dilated (DCM) cardiomyopathies) mainly focused on the detection of sequence variants with Sanger sequencing and Next Generation Sequencing, with a high diagnostic yield of ~40% for HCM. In this study, we performed Copy Number Variant (CNV) analysis on Whole Exome Sequencing (WES) data to investigate its added value in diagnosing inherited cardiomyopathies.

Methods: We collected CNV data from 1710 cardiomyopathy patients tested between January 2020 and December 2023. CNV analysis was performed by read-depth method using dynamic bins (BAM Multiscale Reference Method by BioDiscovery) in a cardiomyopathy gene panel of ~55 genes. Detected copy number alterations were confirmed by an independent method.

Results: A CNV was reported in 7/1710 cases (0.41%), including two deletions and five gains encompassing cardiomyopathy genes. A previously described pathogenic deletion in the *MYBPC3* gene (exons 23-26) was detected in a young HCM patient, while a novel deletion of unknown significance in the *JPH2* gene (exon 3-4) was found in a DCM patient. The detected gains ranged from 44 kb to 25 Mb, and the affected cardiomyopathy-related genes included *RYR2*, *TNNC1*, *ALPK3*, *TXNRD2* and *PLN*. Of the 7 identified CNVs, 1 constituted a definitive diagnosis, 2 were highly suspicious findings and 4 were of unknown clinical significance.

Conclusion: The diagnostic yield of CNV analysis for cardiomyopathies is estimated to be <0.5%, which is low in comparison with other tested panels in our department. Nevertheless, CNV analysis may contribute to unraveling new disease mechanisms of inherited cardiomyopathies.

Grants: not applicable

Conflict of Interest: None declared

P07.037.A In isolated hypertrophic cardiomyopathy patients, importance of LZTR1 gene which is specific for the Noonan syndrome

selman yıldırım[1], *hülya tarım*[1], *betül turan*[1], *rahime laçin*[1]

[1]*Necmettin Erbakan University, Medical Faculty, Medical Genetics*

Objectives: Hypertrophic cardiomyopathy(HCM), characterized by unexplained left ventricular hypertrophy and genetic heterogeneity, is most frequently associated with the MYBPC3 and MYH7 genes. Noonan Syndrome is a syndrome characterized by characteristic facial features, short stature, congenital heart defects and often associated with pathogenic variants in PTPN11, SOS1, and LZTR1 genes. We present two cases from different families to emphasize the significance of the LZTR1 gene in non-syndromic HCM.

Methods: In the pediatric cardiology clinic clinical exome sequence analysis was performed two patients with HCM diseases. Variants were classified according to the ACMG standards.

Results: Proband-1(13 years,male) and Proband-2 (14 years,female) were both referred due to interventricular septal hypertrophy. Both patients had normal growth parameters; in addition to HCM, ptosis and curly hair were observed in proband-1, while proband-2 had no additional findings. In Proband-1, a novel splice donor variant in heterozygous form was identified in the LZTR1 gene (ENST00000215739:c.1353+2T>C) and classified as "Likely Pathogenic". In Proband-2, two heterozygous missense variants were detected in the LZTR1 gene. Among these variants, ENST00000215739:c.1735G>T/V579L was classified as a "Variant of Unknown Significance", and ENST00000215739:c.1397G>A/R466Q was classified as "Pathogenic".

Conclusion: The main objective of the study is to emphasize the significance of the LZTR1 gene, which is specific to Noonan Syndrome in isolated HCM patients. Furthermore with the obtain finding the study intends to contribute to the literature.

Conflict of Interest: None declared

P07.038.B The impact of genetic diagnosis in elderly cardiomyopathy patients

Micaela Oliveira[1], *Rafael Graça*[1], *Diana Antunes*[1;2;3], *Catarina Silveira*[1], *Yuri Chiodo*[1], *Maria Carmo-Fonseca*[4]

[1]*GenoMed - Diagnósticos de Medicina Molecular, S.A, Genetic diseases and pharmacogenetics, Lisboa, Portugal;* [2]*Santa Marta Hospital, Medical Genetics, Lisboa, Portugal;* [3]*Dona Estefânia Hospital, Medical Genetics, Lisboa, Portugal;* [4]*Instituto de Medicina Molecular João Lobo Antunes, Lisboa, Portugal*

Background/Objectives: Cardiomyopathies lead to serious structural and functional alterations of the heart. The underestimated prevalence of hypertrophic (HCM) and dilated cardiomyopathy (DCM) represent a major concern, specially due to their late onset, which can delay diagnosis and treatment. Therefore, it is crucial to consider a genetic aetiology of cardiomyopathies in the elderly, with genetic testing playing an important role in the screening and prevention of disease-related complications.

Methods: Here, we present a retrospective observational analysis of genetic testing in patients over 65 years old with suspected cardiomyopathies, between 2020 and 2023. The mean age of the studied cohort was 72 years old and the study focused on identifying the genetic diagnostic success rate of these patients.

Results: From the 255 index cases under study, 45 (17.65%) obtained a positive result, with the identification of a pathogenic or likely pathogenic genetic variant that could explain the phenotype. Among them, 26 (57.78%) presented a HCM phenotype and 12 (26.67%) showed a DCM phenotype. Concordantly, the majority of the variants (58.70%) were found in the sarcomeric genes *MYBPC3*, *MYH7*, *MYL2*, *TNNT2* and *TPM1*, being known that alterations in these genes are frequently associated with HCM. The remaining variants, mainly detected in DCM patients, were located in other genes, such as *FLNC*, *LMNA*, *PKP2*, *RYR2*, *TTN* and *TTR*.

Conclusion: The obtained results reinforce the critical role of genetic testing in the management of cardiomyopathies in the elderly population, not only to allow a more appropriate treatment, but also to provide adequate genetic counselling to family members at risk.

Conflict of Interest: None declared

P07.039.C Exploring genetic factors in infarct-like patients with myocarditis

Patricia Muñoz-Cabello[1], *Paula Fernandez-Alvarez*[1], *Amaia Lasa-Aranzasti*[1], *Mercedes Tomeo-Fresno*[1], *Roger Esmel-Vilomara*[2], *paola dolader*[2], *ferran gran*[2], *Elena García-Arumí*[1], *Eduardo Tizzano*[1]

[1]*hospital Vall d'Hebron, Department of Clinical and Molecular Genetics., Barcelona, Spain;* [2]*hospital Vall d'Hebron, Pediatric Cardiology, Barcelona, Spain*

Background: Acute myocarditis (AM) exhibits a diverse clinical presentation, ranging from subclinical to fulminant presentations. Teenagers often present with an infarct-like syndrome, characterized by subepicardial involvement and edema on cardiac magnetic resonance imaging. While virus infections are suggested to be its primary cause, it is unclear why a small proportion of paediatric patients develop AM, suggesting a genetic predisposition. Previous series including complicated and uncomplicated myocarditis have shown a wide range of prevalence between 4-60% of pathogenic variants.

Objectives: To assess the prevalence of pathogenic/likely pathogenic variants in cardiomyopathy genes among children with AM presenting an infarct-like pattern.

Methods: Retrospective cohort study involving paediatric myocarditis with an infarct-like pattern at Vall d'Hebron University Hospital and other Catalonia hospitals between 2007-2024. A customized NGS panel targeting 62 cardiomyopathy genes was employed.

Results: 12 patients with an infarct-like pattern were included. 4 out of 12 (33%) had pathogenic or likely pathogenic variants in dilated (*TTN*, *ALPK3*), hypertrophic (*MYBPC3*) and arrhythmogenic right ventricular cardiomyopathy (*DSP*) genes.

Conclusion: Our findings reveal a 33% prevalence of pathogenic or likely pathogenic variants in cardiomyopathy genes within our cohort, indicating a potentially bad prognosis and familial implications. It remains unknown if environmental factors trigger the activation of an inflammatory/immune response resulting in myocardial dysfunction in genetically predisposed patients. Another alternative explanation could be that inflammation in cardiomyopathies is caused by the heart failure itself in patients who were misdiagnosed as myocarditis. Our results support the value of genetic testing in AM patients with an infarct-like pattern

P07.040.D Genetic basis of end-stage cardiomyopathies that require heart transplant

Benjamin Rodríguez-Santiago[1], *Carles Moliner*[2], *Ivon Cuscó*[1], *Lourdes Vega*[1], *Marta de Antonio*[2], *Marta Campreciós*[2], *Vicenç Brossa*[2], *Jose Guerra*[2], *Manel Baena*[1], *Núria Cilvillé*[1], *Eudald Tejero*[3], *Clara Serra-Juhé*[1], *Sònia Mirabet*[2]

[1]*Hopital de la Santa Creu i Sant Pau, Genetics Department;* [2]*Hopital de la Santa Creu i Sant Pau, Cardiology Department;* [3]*Institut de Recerca - Hospital Santa Creu i Sant Pau, Barcelona, Spain*

Background/Objectives: The underlying etiologies of advanced heart failure requiring a heart transplant (HT) in Spain are mainly ischemic cardiomyopathy (ICM) and dilated cardiomyopathy (DCM). Other cardiomyopathies (CM) such as hypertrophic (HCM), restrictive (RCM), and arrhythmogenic right ventricular (ARVCM) account for 28-32% of HTs. The diagnostic yield of genetic testing in CM has been well established in recent genotype-phenotype correlation studies. However, specific studies addressing the genetic basis of HT patients are scarce and limited to familial cases. We have studied a cohort of heart transplanted patients diagnosed with CM regardless of whether they were

familial or sporadic cases by using NGS to assess diagnostic yield rate and genetic basis of HT.

Methods: Clinical variables (family history, habits, comorbidities), electrocardiogram and cardiac imaging were recorded for all participants. DNA from 114 alive HT patients with a CM (DCM, HCM, RCM or ARCV, ischemic or other obvious causes excluded) not genetically tested before. NGS (cardio panel or clinical exome using cardio virtual panel).

Results: A pathogenic or likely pathogenic variant was identified in 49% of heart transplanted patients in 18 different genes. Most represented affected genes were TTN (9), MYH7 (7), LMNA (5), FLNC (5), MYBPC3 (4), TNNI3 (4), followed by other genes with less cases (DSG2, DSP, RBM20, BAG3, TPM1, LAMP2, DES, FKTN, TNNT2, TMP1, PKP2, MT-TL1).

Conclusion: Gene testing should be incorporated in heart transplanted patient's management, regardless of CM type or family history. Patient's relatives at/not at risk could be identified and subsequently managed accordingly.

Grants: CM is supported by Rio Hortega grant (MCIN, Spain)

P07.041.A Molecular basis of hereditary cardiovascular diseases (hCVDs) in a cohort of 486 Italian patients: a multi-step approach.

Giorgia Girotto[1;2], *Stefania Zampieri*[1], *Alessia Paldino*[3], *Beatrice Spedicati*[1;2], *Giovanni Turchetto*[1], *Daniela Mazzà*[1], *Matteo Dal Ferro*[3], *Gianfranco Sinagra*[2;3], *Stefania Lenarduzzi*[1]

[1]*IRCCS Burlo Garofolo, Trieste, Italy, SC Genetica Medica, Trieste;* [2]*University of Trieste, Trieste, Italy, Department of Medicine, Surgery and Health Sciences, Trieste, Italy;* [3]*Azienda Sanitaria Universitaria Giuliano-Isontina (ASUGI), University of Trieste, Center for Diagnosis and Treatment of Cardiomyopathies, Cardiovascular Department, trieste*

Background/Objectives: hCVDs are a leading cause of mortality globally, encompassing a broad range of heart conditions. This study provides a detailed genetic picture of hCVDs in a cohort of Italian patients.

Methods: 486 hCVD-patients recruited at the Medical Cardiological Unit of the Cattinara Hospital (Trieste, Italy) were analysed by Whole Exome Sequencing (WES). WES data allowed the identification of both single nucleotide and Copy number variants (CNVs), the latter further confirmed by MLPA or other high-throughput technology (i.e.,MinION).

Results: WES identified a molecular defect in 23% of patients, with a higher detection rate in familial cases than in sporadic ones (41% vs 16%). 108 causative variants in 22 genes were found. *TTN* was the most frequently mutated gene, followed by *MYH7, MYBPC3, FLNC*, *PKP2*, and *DSP*, characterizing 78% of resolved cases. Among them, two patients from the same geographic area carried the p.(Phe305Profs*27) *MYBPC3* variant, confirming a previously described founder effect. WES analysis also expanded the clinical spectrum of hCVDs with variants in *ACVRL1*, *GDF1*, *TMEM43*, *TRIM63*, and *TRPM4* genes, confirming the genetic heterogeneity of hCVDs.

Regarding CNVs analysis, the same deletion in *PKP2* was detected in three patients, while a novel large deletion, including *DSG2, DSC2*, and *TTR* genes, was identified in another proband. Both CNVs were confirmed by MLPA or MinION technology.

Conclusion: Our multi-step genetic diagnostic approach is a powerful tool to identify the molecular basis of hCVDs, highlighting their complex genetic background and providing crucial information for genetic counselling, clinical management and prognosis, and risk assessment.

P07.043.C First cases of somatic mosaicism in non-syndromic dilated cardiomyopathy

Jan Jongbloed[1], *Lisette Leeuwen*[1], *Debby Hellebrekers*[2], *Bianca J.C. van den Bosch*[2], *Imke Christiaans*[1], *Yvonne Hoedemaekers*[3]

[1]*University of Groningen, University Medical Centre Groningen, Genetics, Groningen, Netherlands;* [2]*Maastricht University Medical Centre, Clinical Genetics, Maastricht, Netherlands;* [3]*Radboud University Medical Centre, Clinical Genetics, Nijmegen, Netherlands*

Background/Objectives: Somatic mosaicism in non-syndromic cardiomyopathies is rare and has not been previously described. This study presents the first cases in two dilated cardiomyopathy (DCM) families with somatic mosaicism in known cardiomyopathy genes.

Methods: Genetic analysis of cardiomyopathy genes was performed in the index patients and clinical characteristics and family history were collected. Sanger sequencing was used for cascade screening and mosaicism detection in different tissues.

Results: The first patient is a 64-year old male with DCM with a left ventricular ejection fraction (LVEF) of 16%. Genetic analysis revealed pathogenic variant c.614G>A, p.(Arg205Gln) in *TNNT2*, present in 20% in blood, urine, hair and buccal mucosa. Family history was positive for sudden death on both sides of the family. However, the variant was not found in the parents.

The second patient is a 34-year old male who was successfully resuscitated after ventricular fibrillation. Cardiac-MRI showed DCM with an LVEF of 19%. Family history was negative for sudden death and cardiac diseases. Genetic analysis revealed likely pathogenic variant c.73C>A, p.(Arg25Ser) in *LMNA*. Subsequently, the *LMNA* variant was detected in the father in ~5% in blood, urine, hair and buccal mucosa. He had a normal echocardiogram.

Conclusion: Although germline mosaicism in cardiomyopathy patients, as well as somatic mosaicism for *LMNA* variants in Hutchinson-Gilford progeria has been described previously, this is the first report on somatic mosaicism identified in non-syndromic DCM. Identifying somatic mosaicism for DCM is important for determining the need for genetic cascade testing, cardiac evaluation in relatives, and reproductive choices.

P07.044.D A novel homozygous c.401C>T variant in CAP2 detected in an infant with dilated cardiomyopathy

Grażyna Kostrzewa[1], *Karolina Rutkowska*[1], *Małgorzata Rydzanicz*[1], *Piotr Gasperowicz*[1], *Agnieszka Pollak*[1], *Tomasz Książczyk*[1], *Bożena Werner*[1], *Rafał Płoski*[1]

[1]*Medical University of Warsaw, Department of Medical Genetics, Warszawa*

Background/Objectives: Heart disorders are common causes of human morbidity and mortality. Sudden cardiac failure is the most prevalent cause of death, accounting for 20% of cases with cardiomyopathy. Dilated cardiomyopathy (DCM), along with hypertrophic cardiomyopathy (HCM), is among the most common cardiomyopathies.

Methods: We performed exome sequencing (ES) on a 10-month-old female infant with DCM. To confirm the ES results, amplicon deep sequencing was performed on the proband's sample, as well as on samples from her parents and sister.

Results: In the proband's sample, using exome sequencing (ES), a homozygous missense c.401C>T variant in the CAP2 gene (hg38: 6:017507269-C>T) was identified. The population frequency for the c.401C>T variant was 0.00004275 in the gnomAD database v.4, with no homozygotes reported. Homozygotes were also absent in the in-house datasets, which comprised over 10,000 ES of Polish individuals. The studied variant in the CAP2 gene was observed in a heterozygous state in unaffected parents and was absent in the proband's sister. The observed c.401C>T variant has not been previously described in the literature. So far, only three publications have described CAP2 gene variants in association with DCM in an autosomal recessive mode of inheritance.

Conclusion: In the current study, we present a novel homozygous mutation in the CAP2 gene in a Polish patient with DCM. Further examination of additional cases is required to understand the impact of the c.401C>T variant on phenotype and to provide prognostic and treatment-related recommendations.

P07.045.A An in vitro system to study Desmoglein- 2 (*DSG2*) p.(N266S) related arrhythmogenic cardiomyopathy

Serena Pinci[1], *Rudy Celeghin*[1], *Maria Bueno Marinas*[1], *Marco Cason*[1], *Cristina Basso*[1], *Kalliopi Pilichou*[1]

[1]*University of Padua, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Italy*

Background: Desmoglein-2 (DSG2) p.(N266S) is a rare genetic variant previously identified in numerous families exhibiting arrhythmogenic cardiomyopathy (ACM) phenotypes (OMIM #107970; ORPHA247) while transgenic mice overexpressing the mouse equivalent variant recapitulated the pathognomonic features of the human disease. However, the molecular effect of this alteration remains an open question.

The purpose of this study is to use HL-1 (immortalized atrial mouse cardiomyocyte) cell line to define a stable in vitro model for investigating the pathogenesis of ACM related to the DSG2-N266S variant.

Methods: A plasmid carrying DSG2–N266S variant was synthesized through site directed mutagenesis and introduced into the HL-1 cells by using the 4-D Nucleofector System (Lonza). Since there was no specific protocol available for HL-1 transfection, a nucleofection protocol was optimized.

We investigated specific electrical and molecular properties in comparison to non-transfected HL-1 cells by performing Sanger sequencing, Real-time PCR, confocal microscopy, transmission electron microscopy (TEM), and Fluo-8 AM calcium imaging.

Results: Antibiotic selection, Real-Time PCR, and Sanger sequencing confirmed the ability of transfected HL-1 cells to express the plasmid carrying the DSG2–N266S variant. Confocal imaging confirmed the cardiac phenotype and revealed the insertion of the DSG2-N266S protein into desmosomes. TEM imaging showed the incapacity to form mature and well-defined desmosome in presence of DSG2-N266S protein compared to normal HL-1 cells. Finally, Fluo-8 AM calcium imaging revealed an alteration of calcium flux in transfected HL-1 cells.

Conclusion: Our study has provided a promising tool to investigate ACM pathogenic mechanisms, holding potential implication for future targeted therapeutic strategies.

P07.046.B A cardiac emerinopathy without atrial standstill, expanding the phenotype of non-syndromic emerinopathies

Paula Fernandez-Alvarez[1;2], *Patricia Muñoz-Cabello*[1;2], *javier limeres-freire*[3], *Alejandro Moles-Fernandez*[1;2], *Miriam Masas*[1;2], *Elena García-Arumí*[1;2], *Eduardo Tizzano*[1;2]

[1]*Vall d'Hebron Hospital Universitari, Department of Clinical and Molecular Genetics, Barcelona, Spain;* [2]*Vall d'Hebron Institut de Recerca (VHIR), Medicine Genetics Group, Barcelona, Spain;* [3]*Vall d'Hebron Hospital Universitari, Department of Cardiology, Barcelona, Spain*

Background/Objectives: Pathogenic variants in EMD are associated with Emery-Dreifuss muscular dystrophy (EDMD) characterized by the triad of early joint contractures, progressive myopathy and cardiac conduction defects and arrhythmias. EDMD follows an X-linked inheritance pattern with usually asymptomatic heterozygous females. Most variants cause loss of function resulting in absence of emerin expression and tend to have a more severe phenotype than missense variants. Only recently, 4 cases of non-syndromic cardiac emerinopathy have been described as a progressive atrial standstill associated with left ventricular non compaction

Methods: We present a 31-year-old man with bradycardia and auricular flutter, diagnosed with left ventricular dilatation, normal ejection fraction and without non-compaction criteria. NGS cardiac panel identified a hemizygous 20 nucleotide deletion in EMD: c.266-15_368del affecting the acceptor site of intron 3. In vitro splice predictions predicted the loss of the canonical acceptor and the gain of a new one at -67pb. To assess the outcome of the variant we performed RNA studies.

Results: RNA studies showed that the variant did not produce the wild type RNA but 3 aberrant transcripts all of them causing frameshift and the appearance of a premature stop codon. The isophorms were (from most to less predominant): 1) skipping of exon 4; 2) deletion of 41 nucleotides of exon 4; 3) retention of 86 nucleotides from intron 3.

Conclusion: Our case expands the phenotype of cardiac emerinopathies with left ventricular dilatation and without the described characteristic atrial standstill.

P07.048.D Direct RNA sequencing detects base modifications caused by chemokine-mediated oxidative stress in vascular smooth muscle cells

Tobias Reinberger[1], *Inken Wohlers*[2]

[1]*University of Lübeck, Institute of Cardiogenetics, Lübeck, Germany;* [2]*Research Center Borstel, Biomolecular Data Science in Pneumology, Borstel, Germany*

Background/Objectives: Vascular smooth muscle cells (VSMCs) reside in the medial layer of the arterial wall and are involved in the regulation of vascular tone and vascular remodeling. However, VSMCs possess phenotypic plasticity which plays a role in subclinical atherosclerosis. We investigated the transition from contractile SMCs to pro-inflammatory SMC phenotypes and the impact of disease-relevant stimuli on gene regulation.

Methods: Primary human SMCs were cultured on a collagen I hydrogel and stimulated with TGF-β1 and a mixture of IL1-β and PDGF-B. These pro-inflammatory SMCs were further stimulated with PDGF-B to induce oxidative stress, which was confirmed by CellRox™ assays. SMCs were characterized using immunofluorescence and Illumina RNA sequencing (RNA-seq). RNA modifications

were detected using direct RNA-seq using Oxford Nanopore Technologies.

Results: Comparison of transcriptome profiles of SMC phenotypes with single cell RNA-seq data from carotid atherosclerotic plaques revealed that TGF-β1 stimulated SMCs best reflect canonical ACTA2+ SMCs (Kendall's rank correlation of ~0.4). Whereas SMCs treated with PDGF-B de-differentiate and adopt a pro-inflammatory state; indicated by enhanced expression of cytokine genes (*e.g.*, CXCL8). Further stimulation with PDGF-B resulted in higher levels of reactive oxygen species and in a shutdown of genes involved in DNA repair and cell cycle progression. Moreover, pro-inflammatory SMC phenotypes showed more RNA modifications as compared to TGF-β1 stimulated SMCs.

Conclusion: We have identified pro-inflammatory SMC phenotypes that are susceptible to oxidative stress and RNA modifications, which could be harmful at the late stages of human atherosclerotic plaque development.

P07.050.B A novel therapeutic strategy for Hypertrophic Cardiomyopathy caused by MYBPC3 variants using antisense oligonucleotides

Serena Evelina Margaretha Munteanu[1], *Elisa Nicolas Rocamora*[2], *Carolina Martinez Perez*[2], *Angel Bernabe Garcia*[1], *Jesús Wagih Gómez*[1], *Francisco Jose Nicolas Villaescusa*[3], *Juan Ramon Gimeno Blanes*[4], *Virginia Arechavala Gomeza*[5;6], *Maria Sabater Molina*[1;7]

[1]*Imib Instituto Murciano De Investigación Biosanitaria, Cardiogenetics, El Palmar, Spain;* [2]*Universidad de Murcia, Murcia, Spain;* [3]*Virgen of Arrixaca University Clinical Hospital, Regeneration, Molecular Oncology and TGFß, El Palmar, Spain;* [4]*Virgen of Arrixaca University Clinical Hospital, Unidad de Cardiopatías Familiares, El Palmar, Spain;* [5]*IIS Biobizkaia, Nucleic Acid Therapies for Rare Diseases, Barakaldo, Spain;* [6]*Fundación Ikerbasque, Bilbao, Spain;* [7]*Universidad de Murcia, Departamento de Medicina Legal, Murcia, Spain*

Background/Objectives: Non-sense or frameshift mutations in the MYBPC3 gene encoding cardiac myosin-binding protein C (cMyBP-C)are a major cause for inherited forms of Hypertrophic Cardiomyopathy(HCM).Antisese oligonucleotide mediated exon skipping attempts to reframe mutated MYBPC3 transcripts, resulting in shortened but functional protein. We aim to design and evaluate antisense oligonucleotides (AONs)for efficient exon-skipping in targeted MYBPC3 exons.

Methods: We've designed two specific AONs to mask the MYBPC3 exon 26 and confirmed successfully mediated exon skipping without disrupting the MYBPC3 reading frame.Primary Human Cardiac Myocytes(PHCM)(Promocell)were transfected with the splice-site targeting AONs.

Results: In this study we designed two chemically modified AONs (AON1 and AON2) through the addition of a 2′-O-methyl RNA phosphorothioate backbone, targeting exonic splicing enhancers(ESEs)or splice sites (SSs) to induce skipping of MYBPC3 exon 26.We evaluated that AON1(i26-3SS) and AON2(ESE)treated Primary Human Cardiac Myocytes(PHCM) show skipping of exons 26-27 in comparison to control samples, as we detected through RT-PCR and confirmed by Sanger sequencing.Preservation of both nucleotide sequences of exons 25 and 28 was observed. We've identified that 24h post-transfection both AONs affect cell lenght and number. We've observed that cell number and percentage of cellular area showed no difference 7 days post-transfeccion using AON1, indicating cellular death.

Conclusion: These results demonstrate that disruption of the MYBPC3 reading frame due to a truncating HCM mutation can be restored by exon skipping in cardiomyocytes in vitro,expanding the framework of future advancements in the therapeutic potential of antisense-mediated exon skipping MYBPC3 based HCM.

Grants: Proyecto de Investigación Básica en Cardiología de los Socios Estratégicos de la SEC2017.

P07.051.C Rare genes in consanguineous families diagnosed as cardiomyopathy: A comprehensive review of autosomal recessive inheritance.

Farida Al Habib[1], *Reem M. Elshafie*[2], *Laila Bastaki*[2], *Ahmed Salem*[1], *Magdi Yacoub*[3]

[1]*Kuwait Foundation for Advancement of Science, Ministry of Health, Kuwait City, Kuwait;* [2]*Kuwait Medical Genetics Center, Ministry of Health, Kuwait City, Kuwait;* [3]*National Heart and Lung Institute, Imperial College London, United Kingdom*

Background/Objectives: Hereditary cardiomyopathy is a common cause of heart failure and sudden death. Molecular diagnosis is crucial in establishing the course of treatment, prognosis, and family screening. In contrast to more prevalent autosomal dominant forms, rare biallelic disease-causing variants linked to cardiomyopathies have been identified. These variants are frequently linked to an earlier clinical presentation and an increased risk of sudden cardiac death.

Methods: From a cohort of 145 patients in Kuwait diagnosed with cardiomyopathy, probands from consanguineous Middle Eastern families were selected. Whole exome sequencing was performed, and variants were classified according to the American College of Medical Genetics and Genomics guidelines.

Results: We identified homozygous missense variants in *ALPK3*, *MYL2*, *MYBPC3*, *OBSCN*, *FKTN*, and *TNNT2* linked to hypertrophic cardiomyopathy phenotype and *DSG2* linked to dilated cardiomyopathy. Segregation analysis in family members confirmed autosomal recessive inheritance presenting in childhood/early adulthood. Our results expand on the *OBSCN* gene's role as a culprit gene in recessive cardiomyopathies. We also provide evidence for novel recessive modes of inheritance of a well-established autosomal dominant *NEXN* gene, which might explain the clinical heterogeneity of cardiomyopathies.

Conclusion: This is the first comprehensive report of autosomal recessive cardiomyopathy cases in Kuwait. Gaining more knowledge about the genetic origins of recessive cardiomyopathies will have a significant impact on screening and diagnosis, especially in understudied Middle Eastern populations.

Grants: This work was supported by a research grant from the Kuwait Foundation for Advancement of Science (PII553MM 01) and the Ministry of Health, Kuwait.

Branch, Pavlodar, Kazakhstan; [3]Pavlodar City Clinic #1, Pavlodar, Kazakhstan; [4]Medical University Astana, Cardiology, Astana, Kazakhstan; [5]National Research Cardiac Surgery Center, Cardiology, Astana, Kazakhstan; [6]Nazarbayev University, School of Science and Humanities, Astana, Kazakhstan

Background/Objectives: Mutations of variety of genes contribute to dilated cardiomyopathy (DCM) development by altering cellular homeostasis of cardiomyocytes.

Methods: To identify the mutational spectrum in Kazakhstani cohort of DCM patients we performed targeted sequencing of 96 candidate genes for cardiomyopathies in 92 Kazakhstani patients with DCM ($n = 32$), coronary heart disease (CHD, $n = 23$), idiopathic VT (iVT, $n = 37$). 8 (25%) cases of DCM were familial and 24 (75%) were sporadic. ACMG/AMP guidelines were applied for variant interpretation of clinical significance.

Results: 307 unique variants in 74 genes totaling up in 456 variants for the overall study group were identified. Six (2.9% among all patient cohort) pathogenic genetic variants were observed in patients with DCM. Possible causative non-synonymous mutations (pathogenic and likely pathogenic) were identified in ~18.7% (6/32), VUS in 59.4% (19/32) patients, in 11% (4/32) no mutations were found in studied genes. We identified novel mutations in patients with DCM, not previously presented in HGMD. VUS in RBM20 gene G541A (G181R) was observed in patient with severe DCM (50 y.o. female) and missense variants - likely pathogenic variant C1898T (P633L) in 33 y.o. female with severe DCM. We identified 4 mutations in GAA gene, two of them were novel VUS C420A (N140K), C257G (P86R) in patients with DCM.

Conclusion: Novel mutations in DCM patients were revealed, and planned to be further assessed functionally using iPSC-derived cardiomyocites modeling.

P07.053.C Could telomere length serve as an early biomarker in hypertrophic cardiomyopathy?

Ángel Júdez Serrano[1], *Samira Louchachha Medhi*[1], *Serena Evelina Margaretha Munteanu*[1], *Elisa Nicolas Rocamora*[1], *Maria Sabater Molina*[1], *Juan Ramón Gimeno Blanes*[2]

[1]*Biomedical Research Institute of Murcia (IMIB-Arrixaca), Murcia, Spain;* [2]*Virgen de la Arrixaca University Clinical Hospital, Murcia, Spain*

Background/Objectives: Hypertrophic cardiomyopathy (HCM) is the leading cause of sudden death in people under 35 years of age. Its phenotype variability and incomplete penetrance have been an obstacle to a complete understanding of the disease. In recent years, there has been increasing interest in telomeric shortening and several authors have linked it to age-related diseases and HCM. Our aim was to study whether telomere length could affect the age at presentation and the severity of the HCM phenotype in genetic carriers.

Methods: Measurement of telomere length in circulating leukocytes (LTLc) was performed in 96 patients carrying a mutation in MYBPC3 causing HCM [58 affected (24 severely affected), 38 unaffected]. The variants included were c.2308+1G>A, p.Pro108Alafs*9, p.Arg891Alafs*160 and p.Glu258Lys, all considered founder mutations in our region.

Results: Our results show a lower LTLc in those affected patients with a more severe HCM phenotype compared to the affected and unaffected group ($p = 0.023$) independently of age and sex, which are two variables that affect LTLc. Similarly, a shorter telomere length was associated with greater severity of the phenotype, with patients presenting a larger left atrial size ($p = 0.032$), septal size ($p = 0.023$) and greater obstruction ($p = 0.044$). The presence of atrial fibrillation ($p = 0.039$) and sudden death ($p = 0.024$) was also higher in patients with shorter telomeres.

Conclusion: Telomere length is a variable that influences the expression of the phenotype in HCM patients carrying a MYBPC3 variant and it could have a prognostic role in the disease.

Grants: Research Project of the Spanish Society of Cardiology (SEC/FEC-INV-BAS21/021). Project Bristol Myers Squibb (CV027-063).

P07.054.A Structural gene mutations in Brugada syndrome support its reclassification as cardiomyopathy

Emanuele Micaglio[1;2], **Sara Benedetti**[1;2], *Giuseppe Ciconte*[1], *Marco Villa*[2], *Roberto Manuello*[1], *Flavio Mastrocinque*[1], *Gabriele Negro*[1], *Emanuela Locati*[1], *Sara D'Imperio*[1], *Paola Carrera*[3], *Carlo Pappone*[1;2]

[1]*IRCCS Policlinico San Donato, Arrhythmology Department, San Donato (MI), Italy;* [2]*IRCCS Policlinico San Donato, Institute for Molecular and Translational Cardiology, San Donato (MI), Italy;* [3]*IRCCS San Raffaele, Unit of Genomics for Human Disease Diagnosis, Milano, Italy*

Background/Objectives: Brugada syndrome (BrS) is an inherited cardiac disorder characterized by specific electrocardiographic alteration and predisposition to ventricular arrhythmias. BrS has been traditionally considered a purely electrical disorder, mainly associated with mutations in the *SCN5A* gene, encoding the cardiac sodium channel α subunit, however alteration of structural genes has been recently suggested. Our aim was to evaluate whether defects in genes encoding structural proteins contribute to BrS pathogenesis.

Methods: A panel of genes encoding cardiac ion channels and structural proteins was analysed in 325 BrS patients by next generation sequencing. Molecular results were correlated with clinical and electrophysiological data.

Results: We identified likely pathogenic and pathogenic (class 4-5) variants in nine genes encoding sarcomeric, cytoskeletal and desmosomal proteins (*DSC2, DSG2, FLNC, LMNA, MYBPC3, MYH7, TNNI3, TNNT2, TPM1*) in 24 BrS patients and 13 relatives. By comparing this cohort to 154 BrS patients (90 probands and 64 relatives) carrying class 4-5 mutations in *SCN5A*, we observed that *SCN5A* patients were more susceptible to induction of ventricular arrhythmias during electrophysiological study (68% vs 47%, $p = 0.023$), while structural probands more frequently displayed right bundle branch block (24% vs 11%, $p = 0.034$). No difference was observed in proportion of patients displaying BrS electrocardiogram, size of arrhythmogenic substrate or sudden death family history.

Conclusion: Our data support a role for structural defects in BrS pathogenesis and suggest that it should be not be considered a simply electrical disorder. Further studies will be needed to elucidate how these defects result in electro-mechanical dysfuction in BrS patients.

P07.055.B Chromosomal Microarray Analysis in Congenital Heart Disease: Meta-Analysis of Diagnostic Yield

Ana Peterlin[1;2], *Tea Mladenić*[3;4], *Sanja Dević Pavlić*[3;4], *Borut Peterlin*[1]

[1]*Clinical Institute of Genomic Medicine, University Medical Centre Ljubljana, Ljubljana, Slovenia;* [2]*Institute of histology and embryology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia;* [3]*Department of Medical Biology and Genetics, Faculty of Medicine, University of Rijeka, Rijeka, Croatia;* [4]*Center for genetic education, Faculty of Medicine, University of Rijeka, Rijeka, Croatia*

Background/Objectives: With a prevalence of approximately 1% in live births and even higher in foetuses, congenital heart disease (CHD) is the most common congenital abnormality. Pathogenic copy number variants are recognised as a prevalent and well-established genetic cause of CHD. Previous studies have highlighted the widespread adoption of chromosomal microarrays (CMA) as a first-tier genetic test for CHD. The primary outcome of this study was to determine the overall diagnostic yield of CMA, supplemented by subgroup analyses exploring patients with isolated CHD and those with both CHD and concomitant extra-cardiac congenital anomalies.

Methods: A systematic literature review was conducted in February 2024, using relevant keywords, within the PubMed database. Of the 531 identified studies, following the application of predefined inclusion and exclusion criteria, 36 were included in the proportional meta-analysis.

Results: In total, 9652 patients with CHD were included. The overall diagnostic yield of CMA was determined to be 10.6% (95% CI, 8.4%–13.2%), with a rate of 7.2% (95% CI, 5.1%–10.2%) observed among cases of isolated CHD and 17.4% (95% CI, 4.5%–48.4%) among patients presenting with both CHD and additional extra-cardiac congenital anomalies.

Conclusion: This meta-analysis provides evidence of the diagnostic efficacy of CMA in CHD and serves as a reference for expanding or replacing genetic testing with exome or genome sequencing.

Background/Objectives: Marfan syndrome (MFS) can lead to aortic aneurysms, dissections, and ruptures. Losartan, an angiotensin-II-receptor-type-1 inhibitor, has been shown to slow down aneurysm progression in mouse models and humans with MFS. However, it remains unclear whether losartan exerts its beneficial effect by the prevention of rises in blood pressure or by improving the biomechanical integrity of the aortic wall. We have recently established an objective approach to measure the rupture force of the murine aorta, enabling to assess the effect of drug treatments on the biomechanical integrity of the aorta at individual level, even in the absence of arterial events. Here, we applied our approach to losartan-treated mice modelling MFS.

Methods: 4-week-old homozygous (*Fbn1*$^{mgR/mgR}$) and wild-type mice were treated for 4 weeks with losartan and subsequently euthanized. Per mouse, three 1.5-mm rings of the thoracic aorta were prepared, mounted on a tissue puller, and uniaxially stretched until rupture.

Results: The mortality rate of losartan-treated *Fbn1*$^{mgR/mgR}$ mice was not significantly lower than that of untreated *Fbn1*$^{mgR/mgR}$ mice during the study interval. Losartan treatment reduced aneurysm formation, but had no impact on the aortic rupture force of *Fbn1*$^{mgR/mgR}$ mice. Aortic rupture force measurement revealed the weakened thoracic aorta prior to micro- and macroscopic changes.

Conclusion: In mice modelling MFS, the thoracic aorta treated with losartan remains susceptible to rupture despite the reduction in aortic diameter. Thus, aortic rupture force beyond aortic diameter may be useful for the investigation of drug therapies in mouse models of hereditary aortic diseases.

P07.058.A Reinterpretation of genetic testing for Cardiomyopathies: Less is more

MArtina Manzoni[1], *Elena Sommariva*[1], *Francesca Pizzamiglio*[1], *Saima Mushtaq*[1], *Stefania Farina*[1], *alessandra volpe*[1], *MAria Luisa Biondi*[1], **Valeria Novelli**[2]

[1]*Centro Cardiologico Monzino, IRCCS;* [2]*Centro Cardiologico Monzino, IRCCS, Milan, Italy*

Background/Objectives: In the last years, the concept of reinterpretation of genetic testing has been considered as part of the diagnostic workflow. However, this process requires time, expert curators and new evidences to evaluate.

Recently, the European Society of Cardiology (ESC) published the new guidelines for the management of cardiomyopathies including a precise list of genes associated with the different phenotypes, including their level of contribution, posing a real support in the reinterpretation of variants in genes not clearly correlated with the disease.

To evaluate the impact of the new ESC indications, we reconsidered all genetic testing results performed in our Clinic in patients with confirmed or suspicious Cardiomyopathy.

Methods: From 2017 to 2023 we analyzed 296 probands for Cardiomyopathy, in particular 105 patients tested for Arrhythmogenic Cardiomyopathy (ACM), 113 for Hypertrophic Cardiomyopathy (HCM) and 78 for Dilated Cardiomyopathy (DCM), using a custom sequencing panel including 44 genes (11 genes for ACM, 34 for DCM and 29 for HCM).

Results: Comparison analysis with the genes reported from the ESC guidelines, considering only the definitive, moderate and strong genes, showed that 24 genes are not more associated with the phenotype and then not clinically actionable. In this scenario, we reconsidered 12 variants (8%), previously classified as VUS, changing the referral status of 8 patients, from uncertain to negative.

Conclusions: These results highlight the importance of the variant reinterpretation as a fundamental step of the genetic testing, posing the importance in the selection of the genes to analyse in order to improve the management of the patients.

Consortium: Genomics England Research Consortium

Background/Objectives: Paediatric cardiomyopathies (PCM) are rare, serious diseases of the heart muscle with some of the worst outcomes in paediatric cardiology. The majority of children remain genetically unexplained. Trio analysis (comparing genomic data between a child and parents) is a powerful tool to detect rare causative variants when modelling for de novo dominant inheritance.

Methods: We studied protein coding de novo variants in 118 PCM trios and 448 rare disease adult controls in the 100,000 Genome Project, a UK large-scale genomics study. We used a previously reported de novo expectation model to assess and compare variant rates by variant class.

Results: We identify 141 protein-coding de novo variants in 118 PCM trios. Notably, there is a significant enrichment of protein truncating variants exome wide. In cardiac expressed genes, there is an excess of missense variants as well, findings absent in controls. We find 4 genes with de novo variants in >1 individual, significantly more than would be expected by chance. Two participants with dilated cardiomyopathy (DCM) harbour missense variants in *MAP3K7*, a gene we have recently identified as a novel candidate gene for DCM in adults. As part of this analysis, we uncover four new potential diagnoses in *MAP3K7*, *LZTR1*, *RYR2*, and *JAK1*.

Conclusion: This study, one of the largest investigations of paediatric cardiomyopathy trios to date, showcases the effectiveness of this approach even in the face of clinical and genetic heterogeneity. We identify new candidate disease genes and potential diagnoses for participants.

P07.061.D The risk of different cardiovascular disease outcomes in individuals with familial hypercholesterolaemia in the UK Simon Broome register

Barbara Iyen[1], *Joe Kai*[1], *Steve Humphries*[2], *Ralph Akyea*[1], *Nadeem Qureshi*[1]

[1]*University of Nottingham, Centre for Academic Primary Care, Nottingham, United Kingdom;* [2]*University College London, Centre for Cardiovascular Genetics, London*

Background/Objectives: Familial hypercholesterolaemia (FH) is a known cause of premature coronary heart disease but emerging evidence suggests that FH may increase the risk of other atherosclerotic cardiovascular disease outcomes such as stroke and peripheral vascular disease (PVD). We investigated cardiovascular disease (CVD) outcomes in individuals with FH in the UK Simon Broome (SB) register, linked with secondary care hospitalisation records. This was compared with CVD incidence observed in the general population.

Methods: Of a total of 3553 individuals in the SB register, 2,988 (84.1%) had linked secondary care admission records from 1997 to 2018. We determined incidence rates for composite CVD (defined as a composite of coronary heart disease (CHD), myocardial infarction (MI), stable or unstable angina, stroke, TIA, peripheral vascular disease (PVD), heart failure, coronary revascularisation interventions), as well as CVD subtypes.

Results: Individuals were aged 20-79 years at SB registration, 1,570 (52.5%) were women, and the median follow-up was 17.4 years. 399 patients (13.4%) carried an FH-causing genetic variant. Incidence rate of composite CVD (per 1000 person-years) was 25.5 (95%CI: 24.1-26.9). The incidence rate of CHD (21.9, 95%CI 20.6-23.2) was higher than observed incidence rates of stroke (4.7, 95% CI 4.2-5.3) and PVD (4.9, 95%CI 4.4-5.5).

Conclusion: Individuals with FH in the SB register are at higher risk of all major types of cardiovascular disease compared to the general population, with the greatest risk for CHD. This further emphasizes the cardiovascular disease burden of FH, and underscores the importance of early diagnosis and optimal management.

P07.062.A X-linked dilated cardiomyopathy: identification of de novo mutation of dystrofin gene: clinical characterization, genetic test and in silico analysis.

Alessandra Ranaldi[1], *Sara Cannito*[1], *Maria Francesca D'Ambrosio*[1], *Ilaria Ragnatela*[2], *Alessandra Margaglione*[2], *Rosa Santacroce*[1], *Giorgia Cordisco*[1], *Angelica Leccese*[1], *Giovanna D'Andrea*[1], *Francesco Santoro*[2], *Maurizio Margaglione*[1], *Maria d'Apolito*[1]

[1]*Medical Genetics, Department of Clinical and Experimental Medicine, Foggia, Italy;* [2]*Cardiology Unit, Foggia, Italy, University Polyclinic Hospital of Foggia, Foggia, Italy*

Background/Objectives: Dystrophin (DMD) gene mutations are associated with skeletal muscle disease as Duchenne and Becker Muscular Dystrophy (BMD) and X-linked dilated cardiomyopathy (XL-DCM)

Methods: We report the case of a 37 years old woman diagnosed with DCM at age of 33 that underwent genetic testing with whole-exome sequencing (WES) using the Illumina platform.

Results: A germline heterozygous A>G transversion at nucleotide 10103 in the DMD gene, leading to aspartic acid-glicine substitution at amino acid 3368 of the DMD protein (c.10103A>G p.Asp3368Gly) was identified and confirmed by Sanger's sequencing of the exon 70. In silico prediction suggests that this variant could have a deleterious impact on protein structure and function (CADD = 30). The genetic screening was extended to the first-degree relatives of the proband (his mother, father her sister) and due to absence of the variant in both parents, p.Asp3368Gly is considered de novo. The mutation has been searched in her 8-years-old son, the direct sequencing confirmed the hemizygosity. The young patient did not present signs and symptoms attributable to DCM, but reported asthenia, presented at clinical examination bilateral calf hypertrophy and at laboratory analysis,

there were increased levels of creatinine kinase (maximum value 19000 IU/L).

Conclusion: We report an early presentation of dilated cardiomyopathy in a 33 years old woman due to a de novo mutation of DMD gene (p.Asp3368Gly). Genetic identification of this mutation allowed an early diagnosis of skeletal muscle disease in her son.

P07.063.B Role of ADAMTSL6 in progressive TAA formation

Julia HUGUET HERRERO[1], *Zakaria Mougin*[1], *Angelique Bibimbou*[1], *Marie-Nathalie Lebel*[1], *Pauline Arnaud*[1;2], *Nadine Hanna*[1;2], *Jondeau Guillaume*[1;3], *Catherine Boileau*[1;2], *Carine Le Goff*[1]

[1]*Université Paris Cité and Université Sorbonne Paris Nord, INSERM U1148, Paris, France;* [2]*Département de Génétique, AP-HP, Bichat Hospital, Paris, France;* [3]*National Reference Centre for Marfan Syndrome and related disorders, AP-HP, Bichat Hospital, Paris, France*

Background/Objectives: Thoracic aortic aneurysm (TAA) is a permanent focal dilatation in the thoracic aorta. 20% of cases are genetic (HTAA). We identified pathogenic variants in *THSD4* related to a predisposition to HTAA. *THSD4* encodes the ADAMTSL6 protein, important in ECM by promoting the FBN1 matrix assembly. It was the first ADAMTS(L) associated with HTAA.The *Thsd4*$^{+/-}$ mice presented an aortic dilatation at 8 months old. Nevertheless, barely information is known about the exact role of ADAMTSL6 in HTAA. To elucidate this, we are studying at different ages 3, 6, 8 months old to understand the early steps of aneurysm formation/progression in this context.

Methods: To evaluate aneurysm formation, we studied TAA histological hallmarks: (i) the elastic fibre breaks; (ii) the unbalance in collagen content; (iii) the proteoglycans accumulation; (iv) the TGFβ signalling dysregulation.

Results: Preliminarily, we observed a pronounced TAA phenotype in heterozygous mice compared to the WT, which would confirm the role of ADAMTSL6 in TAA. Furthermore, there is a tendency of aneurysm formation age-depending, presenting the 8-month-old heterozygous mice significant TAA hallmarks. Interestingly, 3-month-old heterozygous mice present glycosaminoglycans accumulation, despite the premature age of the mice. It is tempting to think GAG could be a key factor for initiation of TAA formation in *Thsd4*$^{+/-}$ mice.

Conclusion: This study confirms the role of ADAMTSL6 in progressive TAA formation and suggests that the GAG is an initiator of the TAA formation. This will allow us to develop preventive approaches to stop the disease progression and prevent life-threatening outcomes.

P07.064.C Genotype-phenotype analysis of hypertrophic and dilated cardiomyopathy due to troponin complex mutations in Newfoundland and Labrador families

Ashley Baker[1], *Fiona Curtis*[2], *Emily Bonnell*[2], *Stephen Duffett*[3], *Lesley Turner*[2], *Anne Williams*[3], *Jenna Manuel*[4], *Peter Sutherland*[1], *Terry-Lynn Young*[1], *Kathy Hodgkinson*[4]

[1]*Memorial University of Newfoundland and Labrador, Faculty of Medicine, Department of Biomedical Sciences, St.John's, Canada;* [2]*Newfoundland and Labrador Health Services, Provincial Medical Genetics Program, St.John's, Canada;* [3]*Newfoundland and Labrador Health Services, Division of Cardiology, St.John's, Canada;* [4]*Memorial University of Newfoundland and Labrador, Faculty of Medicine, St.John's, Canada*

Background/Objectives: *TNNI3* p. R162Q and *TNNT2* p. K210del are two autosomal dominant pathogenic variants in the cardiac troponin complex, causing hypertrophic and dilated cardiomyopathy respectively. The natural history, penetrance, and range of symptoms for each variant is uncertain. *TNNI3* variants can increase calcium sensitivity: *TNNT2* variants can decrease sensitivity.

Methods: Six Newfoundland and Labrador families have one or both troponin variants. Extensive (up to seven generation) pedigrees are completed. Individuals born at an *apriori* 50% risk were defined as variant +ve, obligate carrier, severe cardiac event (sudden cardiac death (SCD), heart transplant, heart failure ≤50 years), variant -ve, or unknown (deceased, declined testing or not yet seen).

Results:

Variant	Sex	Variant positive		Variant negative	Obligate Carrier	Severe cardiac event
		Heterozygous	Homozygous			
TNNI3 p.R162Q	M	18	1	8	14	7
	F	25	2	19	12	7
TNNT2 p. K210del	M	1	0	1	1	1
	F	1	0	3	0	1

Three individuals have both *TNNI3* and *TNNT2* variants (2 F: 45y, 66y, and 1M deceased 84y). The females describe mild palpitations. The male never presented. Two individuals with the *TNNT2* variant have severe disease (onset < 20 yrs.). The diagnostic range for *TNNI3* heterozygotes is 16-67y. Thirty-six (5-77yrs) are variant +ve disease -ve. Five individuals had an SCD (range 32-57y). Homozygote *TNNI3* do not present differently.

Conclusion: *TNNT2* p.K210del is highly pathogenic. When paired with *TNNI3* p.R162Q, the pathogenicity is absent. The variant effect on calcium sensitivity likely has a cancelling effect. The *TNNI3* cohort is highly variable and homozygotes appear similar to heterozygotes.

P07.065.D The burden of cardiac genetic disease in Newfoundland and Labrador

Peter Sutherland[1], *Emily Bonnell*[2], *Fiona Curtis*[2], *Stephen Duffett*[3], *Sean Connors*[3], *Lesley Turner*[4], *Ashley Baker*[1], *Sajid Khayer*[5], *Kathy Hodgkinson*[6], *Ann Dorward*[7]

[1]*Memorial University of Newfoundland, Biomedical Sciences, St. John's, Canada;* [2]*Newfoundland and Labrador Health Services, Provinical Medical Genetics Program, St. John's, Canada;* [3]*Newfoundland and Labrador Health Services, Cardiology, St. John's, Canada;* [4]*Newfoundland and Labrador Health Services, Provincial Medical Genetics Program, St. John's, Canada;* [5]*Memorial University of Newfoundland, MUN Medicine, St. John's, Canada;* [6]*Memorial University of Newfoundland, Clinical Epidemiology, St. John's, Canada;* [7]*Memorial University of Newfoundland, Biomedical Sciences, St John's, Canada*

Background/Objectives: Catecholaminergic Polymorphic Ventricular Tachycardia (CPVT) is an autosomal dominant cardiac condition characterized by serious arrhythmia during exercise or stress. A Newfoundland and Labrador (NL) CPVT cohort was ascertained with a Ryanodine Receptor-2 (*RyR2* p.Y4962N) variant post a child's death. Classified likely pathogenic, it was downgraded to a variant of unknown significance (VUS). This study will determine the spectrum of CPVT phenotypes to aid classification in a family-based approach.

Methods: The extended family (n = 653, seven generations) was used to identify individuals with 50% a priori risk of inheriting the *RyR2* p.Y4962N variant. Clinical data is extracted from variant positive and negative individuals and placed in an SPSS.v28 dataset.

Results: Ninety family members at a priori 50% risk of inheriting the *RyR2* p.Y4962N variant are ascertained. Demographic data is available for 90: cardiac clinical data is currently available for 25.

Variant	Sex	Variant positive n = 29 (32.2%)		Variant negative n = 18 (20%)		Variant status unknown n = 43 (47.8%)	
		n	Age range(y)	N	Age range(y)	n	Age range(y)
RyR2-p.Y4962N	M	15	7-73	10	32-56	24	30-81
	F	14	15-92	8	7-91	19	29-83

Three cases of sudden death have occurred (range 7-29 years). Preliminary analysis reveals 4/25 with signs and symptoms of CPVT from mild (palpitations) to severe (syncope whilst driving).

Conclusion: Variant classification relies upon multiple lines of evidence. Segregation in large related cohorts with robust ascertainment is a powerful tool. For families experiencing severe clinical events, a VUS is psychologically traumatic. This study we hope will help solidify classification for this variant.

P07.066.A Cardiovascular disease outcomes in individuals with probable or definite FH diagnosis in the Simon Broome register

Barbara Iyen[1], Ralph Akyea[1], Steve Humphries[2], Joe Kai[1], **Nadeem Qureshi**[1]

[1]University of Nottingham, Centre for Academic Primary Care, Nottingham, United Kingdom; [2]University College London, Institute Cardiovascular Science, London, United Kingdom

Background/Objectives: The Simon Broome (SB) diagnostic criteria for definite or probable FH take into account combinations of laboratory tests, clinical criteria and family history. We assessed cardiovascular disease (CVD) risk in people with probable or definite FH by linking patient records in the UK SB register with secondary care records in Hospital Episode Statistics (HES).

Methods: Baseline characteristics and type of FH diagnosis (probable or definite) were assessed at time of SB registration. Using linked HES data, we determined incidence rates for CVD (a composite of coronary heart disease (CHD), myocardial infarction (MI), stable or unstable angina, stroke, TIA, peripheral vascular disease (PVD), heart failure, coronary revascularisation interventions). Cox proportional hazards regression models determined adjusted hazard ratios (aHR) for CVD in individuals with probable compared to definite FH.

Results: Of 2,988 individuals with linked SB register and HES data (median follow-up: 17.4 years), 1548 (51.8%) had definite FH while the remainder had probable FH diagnosis. Incidence rates (95%CI) of CVD (per 1000 person-years) were 25.1 (23.2-27.2) and 25.8 (24.0-27.7) with probable and definite-FH respectively. Compared to definite-FH individuals, those with probable FH had a lower risk of CHD (aHR 0.79, 95%CI 0.70-0.88), but no statistically different risk of stroke (aHR 0.89, 95%CI 0.71-1.13) and PVD (0.89, 95%CI 0.70-1.12).

Conclusion: Individuals with probable FH had a lower risk of CHD but a similar risk of stroke and PVD, compared to those with a definite FH. Improved risk-factor management in all patients with FH is still required to reduce risk of CVD.

METABOLIC AND MITOCHONDRIAL DISORDERS

P08.001.B Long-chain fatty acid oxidation disorders: a novel gene database for LC-FAOD genes *ACADVL, CPT1A, CPT2, HADHA, HADHB*, and *SLC25A20*

Heather Richbourg[1], Omid K. Japalaghi[1], Vanessa Rangel Miller[1], Sean Daugherty[1], Moeen Al-Sayed[2], Peter Baker II[3], Aneal Khan[4], Mark Kiel[5], Lawrence Korngut[6], Deborah Marsden[1], Stephanie Monteleone[5], Gerard Vockley[7], **Nicole Miller**[1]

[1]Ultragenyx Pharmaceutical Inc., Novato, United States; [2]Al Faisal University, College of Medicine, Riyadh, Saudi Arabia; [3]University of Colorado, Anschutz Medical Campus, Aurora, United States; [4]M.A.G.I.C. (Metabolics and Genetics in Canada) Clinic Ltd, Calgary, Canada; [5]Genomenon, Inc, Ann Arbor, United States; [6]University of Calgary, Department of Clinical Neurosciences, Calgary, Canada; [7]UPMC Children's Hospital of Pittsburgh, Division of Medical Genetics and The Center for Rare Disease Therapy, Pittsburgh

Background/Objectives: Long-chain fatty acid oxidation disorders (LC-FAOD) comprise six rare, life-threatening conditions detected through plasma acylcarnitine profile abnormalities, identified either through NBS or via clinical presentation. Genetic testing is critical as limited functional testing is available. Correlation of clinical and biochemical features with genotype is incomplete, and numerous variants of uncertain significance (VUS) have been reported.

Methods: This database of variants in LC-FAOD genes (*ACADVL*, *CPT1A*, *CPT2*, *HADHA*, *HADHB*, *SLC25A20*) integrates data from: a systematic literature review using Mastermind, a sponsored gene panel program dataset, NBS results, and patient phenotypes.

Results: As of APR 2023, the LC-FAOD database reported 5365 variants from 3217 individuals with ≥1 gene variants, representing 975 unique variants: 662 (68%) pathogenic (P) or likely pathogenic (LP) and 301 (31%) VUS. 1842/3217 (57%) patients had a positive molecular diagnosis/MDx (≥2 P/LP) and 230/3217 (7%) had a potential MDx (LP/VUS, P/VUS), combined by gene as follows: *ACADVL* 38%, *HADHA* 28%, *CPT2* 21%, *CPT1A* 5%, *SLC25A20* 4%, *HADHB* 4. Of 2,059 LC-FAOD genotypes, 932 (45%) were private variants.

Phenotypic data were reported for 939 positive/potential LC-FAOD patients. Common phenotypes reported: *ACADVL* – Elevated CK (27%); *CPT2* – myoglobinuria (33%); *HADHA* – liver abnormality (28%); *SLC25A20* – liver abnormality (26%); *HADHB* – peripheral neuropathy (22%); *CPT1A* – liver abnormality (39%). The most common phenotype for patients <1y vs >12y: hypoglycemia (151; 47%) and myoglobinuria (56; 52%), respectively.

Conclusion: Gene databases are important for rare diseases: clinical information associated with variants are scarce; VUS are frequent and insufficient to support MDx. Genotype-phenotype data are important diagnostic aids.

P08.002.C Analysis of lncrna expression in patients with metabolic syndrome: an investigation based on RNA-sequencing data

Yasemin Oyacı[1], *Naci Şenkal*[2], *Alpay Medetalibeyoğlu*[2], *Fatima Ceren Tunçel*[1], *Murat Köse*[2], *Tufan Tükek*[2], *Sacide Pehlivan*[3]

[1]*Institute of Graduate Studies in Health Sciences, Istanbul University, Medical Biology, Istanbul, Türkyie;* [2]*Istanbul Faculty of Medicine, Istanbul University, Department of Internal Medicine, Istanbul, Türkyie;* [3]*Istanbul Faculty of Medicine, Istanbul University, Medical Biology, Istanbul, Türkyie*

Background/Objectives: Long non-coding RNAs (lncRNAs) have been known to play a role in the pathogenesis of metabolic diseases. However, what we know about the regulatory role of lncRNAs in metabolic syndrome is limited. In our study we aimed to investigate the lncRNAs that are potentially involved in Metabolic Syndrome (MetS).

Methods: lncRNA profiles were analyzed in 12 MetS samples and 10 healthy control samples using Illumina Novaseq 6000 platform. Differentially expressed transcripts between two groups were identified, and Gene Ontology and Kyoto Encyclopedia of Genes and Genomes enrichment analyses were performed to identify the biological functions of lncRNAs.

Results: Out of a total of 15,771 lncRNA transcripts, 293 transcripts were significantly differentially expressed of which 144 were upregulated, 149 were downregulated and 180 novel lncRNAs. MIAT, associated with myocardial infarction, and LINC00299, associated with atherosclerosis, were identified as two of the lncRNAs that were highly upregulated in MetS patients.

PTPRN2-AS1, antisense of the PTPRN2 gene, which is associated with cardiometabolic diseases and ZFPM1-AS1, antisense of the ZFPM1 gene, which has a role in heart development have been identified as two of the lncRNAs that were significantly downregulated in Mets patients.

Conclusion: The study suggests that the functions of lncRNAs are important in MetS development and progression. Especially the change in the expression of MIAT, LINC00299, PTPRN2-AS1 and ZFPM1-AS1 lncRNAs in patients is a promising finding in terms of the increased CVD risk in MetS patients.

Grants: This study was supported by the Scientific Research Project Coordination Unit of Istanbul University under Grant [number: TOA-2022-39395].

P08.003.D Nuclear Mitochondrial DNA disruption in KLHL10 gene causes Spermatogenic Failure

Murtadha Ali[1], *Najim Ameziane*[1], *Aboulfazl Rad*[1], *Gabriela Oprea*[1], *Shivendra Kishore*[1]

[1]*Arcensus GmbH, Rostock*

Consortium: Arcensus GmbH, Rostock, Germany

Background/Objectives: Translocation of Mitochondrial DNA (mtDNA) fragments into the nuclear genome, results in Nuclear Mitochondrial DNA segments (NUMTs). Novel or de novo NUMTs may show detrimental effects, contributing to human diseases, carcinogenesis, and ageing. Here we report a rare NUMT occurrence which disrupts the kelch like family member 10 gene (KLHL10), that plays an important role in male infertility.

Methods: A 41-year-old male patient with oligospermia and no family history (isolated case) was analysed via whole genome sequencing (WGS) to yield an average coverage depth of 30x for the nuclear genome and at least 1000x for the mitochondrial genome. Previous analysis showed no Y chromosome microdeletion. Chromosomal analyses revealed the presence of Robertsonian translocation between the long arm of chromosome 13 at 13q10 and the long arm of chromosome 15 at 15q10. However, this event did not explain the patient's phenotype.

Results: The WGS analysis unveiled the presence of a heterozygous insertion of the mitochondrial genome into exon 3 of KLHL10 gene (NM_152467.5), with breakpoints at chr17:41845555 (17q21.2) -chrM:3595. Consequently, this insertion disrupted the KLHL10 gene. Mutations in this gene have been previously associated with autosomal dominant spermatogenic failure type 11, a rare genetic male infertility medical condition.

Conclusion: To the best of our knowledge, this is the first reported instance of NUMTs causing a rare form of male infertility. Since NUMTs may create artefacts resembling mixed populations of mtDNA (pseudo-heteroplasmy), WGS is a comprehensive approach to accurately detect potential disease causing NUMTs.

Conflict of Interest: None declared

P08.004.A Perrault syndrome-associated missense variants affect HARS2 protein homodimerization and functional activity

Huw Thomas[1;2], *Maria Obregon Comino*[2], *Rob Harkness*[1;2], *Thomas Smith*[1;2], *William Newman*[1;2], *Raymond O'Keefe*[1;2]

[1]*Manchester University NHS Foundation Trust, St Mary's Hospital, Manchester Centre for Genomic Medicine, Manchester, United Kingdom;* [2]*The University of Manchester, Division of Evolution, Infection and Genomics, School of Biological Sciences, Manchester, United Kingdom*

Background/Objectives: Perrault syndrome is a rare, genetically heterogenous, autosomal recessive disorder characterised by sensorineural hearing loss and primary ovarian insufficiency. Bialleleic variants in nine genes to date have been linked to Perrault syndrome, with all associated with altered peroxisomal or mitochondrial function. Of these genes, *HARS2* – a mitochondrial histidyl-tRNA synthetase – has had 14 Perrault syndrome-associated variants reported, located throughout its protein sequence. Of note, 5 missense variants lie within a dimer-interface region and are predicted to influence the correct assembly of HARS2 homodimers - a prerequisite of normal HARS2 function.

Methods: Here, we undertook a series of in vitro analyses to investigate the consequences of Perrault syndrome-associated

missense variants on HARS2 protein homodimerization and function. We complemented these analyses with in silico modelling to validate and further identify additional HARS2 protein regions and residues of importance.

Results: We demonstrated that 2 of 5 variants studied caused significant disruption to HARS2 dimerization and identified residues 138, 139 and 150 as key contact points between HARS2 monomers. We also showed that some variants can lead to a decrease in aminoacylation-activity and a change in protein thermal stability.

Conclusion: These findings further our understanding of how missense changes in *HARS2* contribute to mitochondrial dysfunction and help to reclassify variants of uncertain significance as likely pathogenic, providing clinical utility.

Grants: This study was supported by the Medical Research Council (MR/W019027/1); Royal National Institute for the Deaf and Masonic Charitable Foundation (S60_Newman); Action Medical Research (GN2494); NIHR Manchester Biomedical Research Centre (NIHR203308).

P08.005.B GLA p.Asp313Tyr variant in a large German cohort - genetic, biochemical, and clinical characterization

*Tobias Böttcher[1;2], Christian Beetz[1], Daniel Schulze[3], Deepa Saravanakumar[1], Emir Zonic[1], Sabine Schröder[1], Anett Kaune[1], Omid Paknia[1], **Jorge Pinto Basto**[1], Peter Bauer[1;4]*

[1]Centogene GmbH, Rostock, Germany; [2]Universitätsmedizin Greifswald, Neurology, Greifswald, Germany; [3]Charité-Universitätsmedizin Berlin Campus Charité Mitte, Institute of Biometry and Clinical Epidemiology, Berlin, Germany; [4]Universitätsmedizin Rostock, Rostock, Germany

Fabry disease (FD; OMIM #301500) is a lysosomal disorder, caused by pathogenic variants in the GLA gene, resulting in enzymatic deficiency of α-galactosidase A (AGLA). The pathogenicity of certain variants is controversially disputed, particularly the c.937G>T (p.Asp313Tyr) variant which causes an enzymatic pseudodeficiency in plasma [PMID 14680977]. According to the ACMG/AMP guidelines [PMID 25741868] most genetic laboratories had reclassified this variant to likely benign/benign over time. Nevertheless, there is ongoing discussion claiming p.Asp313Tyr a variant with FD-causing properties.

Genetic, biochemical, and clinical characteristics of GLA p.Asp313Tyr individuals were evaluated in patients from Germany screened in our laboratory for FD between 1st January 2015 and 31st December 2020.

From 18,290 male and 18,198 female samples examined, p.Asp313Tyr was detected in 204 and 309, respectively. The allele frequency was increased (males: 0.011, $p < 0.0001$, odds ratio 2.39, 95% CI 1.94-2.93; females: 0.008, $p < 0.0001$, odds ratio 1.98, 95% CI 1.68-2.35) compared to gnomAD data for European (non-Finish) population (0.0047 and 0.0043, resp.). Enzyme activity was not reduced to values accepted for provoking clinical symptoms of FD [PMID 30559317] and globotriaosylsphingosine levels were even normal in all cases. Furthermore, no significant associations with clinical symptoms were found in a multivariable analysis.

Applying ACMG/AMP criteria, the GLA variant p.Asp313Tyr must be classified as a benign variant and therefore does not cause FD. However, the fact of increased allele frequency in our screening cohort compared to general population reference data, demands further clarification of the role of this variant as a potential risk factor or modifier for a yet to be defined disorder.

P08.006.C Novel association of *COQ7* with frontal lobe leukodystrophy and isolated progressive spastic diplegia

*Clair Habib[1], Liana Semcesen[2], Jun Xiong Lee[1], Tegan Stait[3], Cas Simons[2], Eloise Uebergang1[3], John Christodoulou[2;3], Richard Leventer[1;2;3], David Thorburn[2;3], David Stroud[2], **Chloe Cunningham**[2;3]*

[1]Royal Children's Hospital, Parkville, Australia; [2]University of Melbourne, Department of Paediatrics, Parkville, Australia; [3]Murdoch Children's Research Institute, Parkville, Australia

Consortium: MitoMDT

Background/Objectives: *COQ7*-related CoQ_{10} deficiency 8 is a rare disorder that causes a spectrum of disease including spasticity, ranging from mildly progressive encephaloneuronephro-cardiopathy to fatal multisystemic disorder [MIM# 616733]. The phenotypic spectrum was recently expanded to include distal neuropathy with upper motor neuron signs. We present an individual with a novel phenotype of spastic diplegia and frontal lobe leukodystrophy with compound heterozygous *COQ7* variants and multi-omics functional analyses supporting causality.

Methods: Trio genome sequencing was undertaken in a study of unclassified leukodystrophies. Variants of uncertain significance in *COQ7* were investigated with functional studies of patient fibroblasts. Levels of COQ7 and associated proteins were assessed by proteomics and immunoblotting. CoQ_{10} levels were assessed by untargeted lipidomic analysis and complex II + III assays +/- CoQ_1 supplementation.

Results: The compound heterozygous variants in *COQ7* (c.319C>T;p.(Arg107Trp) and c.161G>A;p.(Arg54Gln)) had each been reported in a compound heterozygous state with different *COQ7* variants in unrelated individuals with limited evidence of pathogenicity. Immunoblotting demonstrated a marked deficiency of COQ7 protein, and proteomic data were consistent with previous studies of *COQ7* knockouts. Lipidomic analysis and complex II + III activity showed a deficiency of total CoQ_{10} and the CoQ_{10} pool accessible to respiratory chain enzymes.

Conclusion: This study provides strong evidence supporting the pathogenicity of the p.(Arg107Trp) and p.(Arg54Gln) variants in *COQ7*. We propose that the phenotypic spectrum associated with biallelic *COQ7* variants should be expanded to include leukodystrophy with isolated spastic diplegia and normal cognition.

P08.007.D Genetic diagnostic yield of obesity

Robert Künzel[1], *Helene Faust[1], Antje Garten[2], Matthias Blüher[3;4], Eric Göpel[2], Rami Abou Jamra[1], Mariami Jasaszwili[2], Anna Kirstein[2], Albrecht Kobelt[5], Antje Koerner[2;4], Johannes Lemke[1], Robert Stein[2;4], Diana le Duc[1;5]*

[1]University of Leipzig Medical Center, Institute of Human Genetics, Leipzig, Germany; [2]University Hospital for Children and Adolescents, Pediatric Research Center, Leipzig, Germany; [3]University of Leipzig Medical Center, Medical Department III—Endocrinology, Nephrology, Rheumatology, Leipzig, Germany; [4]Helmholtz Institute for Metabolic, Obesity and Vascular Research (HI-MAG) of the Helmholtz Zentrum

München at the University of Leipzig and University Hospital Leipzig, Leipzig, Germany; [5]Chemnitz Clinic, Diagnostic Center GmbH MVZ, Practice for Human Genetics, Chemnitz, Germany

Background/Objectives: Obesity poses a major public health concern. Although studies have shown that the heritability of BMI in individuals with obesity lies around 60-80%, the underlying genetics are still poorly understood. This study reports the genetic findings of a large cohort of patients with obesity, who underwent NGS-based diagnostic of exomes and large clinical panels. We aim to characterize the cohort in order to improve future diagnostic yield.

Methods: 560 patients with reported obesity underwent genetic diagnostics at the Institute of Human Genetics at Leipzig University between 2016 and 2023. The cohort includes 421 children and 139 adults, with 256 female and 304 male patients. 84.1% of patients (n = 471) received exome analyses, the rest underwent diagnostic based on large clinical panels.

Results: Initial results show that 4.8% of patients (27 of 560) received a genetic diagnosis explicitly explaining their obesity. Eight of these patients had *MC4R* variants. Syndromic obesity was diagnosed in 17 patients, four of whom had a 16p11.2 microdeletion. We reported a possible obesogenic variant in a further 7.7% of patients. Affected genes include *KSR2*, *SRRM2*, *PLIN1* and *NCOA1*. Definitive diagnostic yield was higher in children (5.5%) compared to adults (2.9%). Additionally, we reported a possible obesogenic variant in 7.4% of children and 8.6% of adults.

Conclusions: Only a small fraction of patients with obesity received a monogenetic diagnosis. Several identified variants may increase susceptibility to obesity. Further research is needed to reduce what appears to be a large diagnostic gap.

P08.008.A Comprehensive analysis of gut virome diversity in hypertriglyceridemia individuals

Shahbaz Raza[1], **Hanna Kim**[1;2]

[1]Sungkyunkwan University, Department of Clinical Research Design and Evaluation, Samsung Advanced Institute for Health Sciences and Technology, Seoul, Korea, Rep. of South; [2]Samsung Medical Center, Biomedical Statistics Center, Research Institute for Future Medicine, Seoul, Korea, Rep. of South

Background/Objectives: Hypertriglyceridemia is characterized by elevated triglyceride (TG) levels in the bloodstream and is a key component of metabolic syndrome. The prevalence of hypertriglyceridemia in Korea has increased from 10.2% in 1998 to 16.4% in 2017, with higher rates observed in men (25.2%) compared to women (8.0%). Recent studies have shown an association between gut virome and metabolic diseases. In this study, we investigated the gut virome in individuals with elevated TG levels (n = 402) compared to healthy individuals (n = 402).

Methods: We utilized gut metagenomic data from 1710 Korean individuals, calculating the relative abundance of the gut virome using the Kraken2 tool.

Results: We identified 1341 viral sequences, of which 17 were differentially abundant between the groups ($q < 0.05$). Among the 10 differentially abundant viral sequences in hypertriglyceridemia, 7 were phages. Notably, three *Escherichia* phage were significantly enriched in the hypertriglyceridemia group. While no significant differences in alpha diversity were observed, there were significant dissimilarities based on beta-diversity indices, including non-phylogenetic Bray-Curtis, Jaccard, and Canberra distances ($p < 0.05$). Correlation analysis revealed that Escherichia coli was associated with the majority of the significantly different viral species.

Conclusion: Our findings underscore the significance of viruses and phages in individuals with hypertriglyceridemia compared to healthy individuals. Further investigations are warranted to elucidate the role of these viral species in hypertriglyceridemia individuals.

Grants: This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean government (MSIT) (No. 2023R1A2C2006416).

P08.009.B Evaluation of newborn screening for X-linked adrenoleukodystrophy in Southern Spain

Maria Isabel Cabrera Gonzalez[1;2], Yolanda de Diego Otero[1], Rocio Calvo Medina[1], José Miguel Ramos Fernández[1], Javier Blasco-Alonso[1], María del Carmen Benito López[1], Marta García de Burgos[1;2], Sara Franco Freire[1], **RAQUEL YAHYAOUI MACIAS**[1]

[1]Malaga Regional University Hospital. IBIMA-Plataforma BIONAND; [2]

Background:

X-linked adrenoleukodystrophy (XALD) is the most common leukodystrophy and peroxisomal disease, with an estimated prevalence 1:10,000 live births. Early detection is essential to treat adrenal insufficiency, and in cases with cerebral XALD, hematopoietic stem cell transplantation may be curative if performed in early stages of the disease.

Methods: From July 2022 to December 2023, C26:0-LPC levels were measured by an inhouse LC-MS/MS method in 50,000 newborn screening (NBS) dried blood spot (DBS) samples. In newborns with a positive result, biochemical and genetic analysis were performed.

Results: Eight newborns had a positive result. Two patients displayed severe neonatal symptoms due to pathogenic variants in the *HSD17B4* and *PEX6* genes. The rest of newborns are asymptomatic. Four presented biochemical alterations, confirming the presence of a genetic variant in the *ABCD1* gene.

CASES	DBS C26:0-LPC (NV < 0,14 micromol/L)	Plasma C26:0 (NV < 0,72 micromol/L)	Plasma C26:0/C22:0 (NV < 0,016)	Genetic analysis
1 (female)	0,306	NA	NA	NA
2 (male)	1,512	18,07	0,904	***HSD17B4*** gene: c.1369A>T,p.Asn457Tyr (pathogenic) and c.1681G>C,p.Ala561-Pro (likely pathogenic)
3 (male)	0,229	0,58	0,030	NA
4 (male)	0,225	0,60	0,020	***ABCD1*** gene: c.1900G>A,(p.Ala634Thr) (VUS)
5 (male)	0,418	1,54	0,025	***ABCD1*** gene: c.1747G>A,p.(Val583Met) (VUS)
6 (male)	1,068	NA	NA	***PEX6*** gene: c.531delA,p.Pro179fs (pathogenic) and c.402delC,p.Gly135fs (likely pathogenic)
7 (male)	0,145	0,88	0,034	***ABCD1*** gene: c.2111C>T,(p.Ala704Val) (VUS)
8 (female)	0,687	2,58	0,059	***ABCD1*** gene: c.1415_1416delAG,p.Gln472fs (pathogenic)

Conclusion: Our study is the first universal XALD NBS program performed in Europe. Neonatal screening for XALD is an effective

tool for early detection of the disorder which allows early treatment, genetic counselling and carrier detection.

P08.010.C A noval congenital generalized lipodystrophy type 2 patient caused by *BSCL2* gene

Ayse Busra Akalin[1], *Fatih Demircioğlu*[2], *Ibrahim Akalin*[3]

[1]*Bahcesehir University Faculty of Medicine, Medicine, Istanbul, Türkyie;* [2]*Medistate Hospital, Pediatric Hematology, Istanbul, Türkyie;* [3]*Metagentech Center for Genetic Diseases, Istanbul, Türkyie*

Background/Objectives: Lipodystrophies are genetically heterogenous disorders. It causes a person to lose adipose tissue in some parts of the body while gaining it to others, such as liver. The muscle tissue can be seen clearly which can be mistaken for hypertrophy due to loss of hypodermic fat loss.

Methods: A 2,5-year-old female patient was born to third degree consanguinity referred with dysmorphic facial appearance and distinct subcutaneous adipose tissue loss and elevated triglyceride levels. Physical examination revealed hepatomegaly. Whole exome sequencing was performed for mutation analysis.

Results: Exome sequencing analysis revealed germ line c.650C>G (p.S217X) homozygous mutation in *BSCL2* gene responsible for "Congenital Generalized Lipodystrophy Type 2 Syndrome [MIM#269700]", suggesting autosomal recessive inheritance.

Conclusion: Clinical findings detected in the patient align with the symptoms of Congenital Generalized Lipodystrophy Type 2 Syndrome, thus supporting the molecular diagnosis of the disorder in the patient. Additionally, the frequency of the variant has not been found in gnomAD database but was reported in literature only once, up to date.

P08.011.D A novel quantification method using digital PCR for Preimplantation Genetic Testing of Mitochondrial DNA disorder.

Yuki Mizuguchi[1;2], *Kou Sueoka*[3], *Suguru Sato*[1;4], *Mamoru Tanaka*[1]

[1]*Keio University School of Medicine, Obstetrics and Gynecology, Japan;* [2]*Nasu Red Cross Hospital, Obstetrics and Gynecology, Ohtawara, Japan;* [3]*Shizuoka Graduate University of Public Health, Graduate School of Public Health, Shizuoka, Japan;* [4]*Ogikubo Hospital Niji Clinic, Tokyo, Japan*

Background/Objectives: PGT for mitochondrial DNA (mtDNA) disorder is identifying embryos with mtDNA mutation ratio (mutant load; ML) below the threshold level. We have developed and applied a method for analyzing ML using quantitative multiplex PCR. However, the need of calibration curves makes this method complicated and time consuming. We aimed to develop a new quantification method for analyzing ML using digital PCR.

Methods: Blood sample from carrier of the 8993T>G mutation of mtDNA, which has a ML of 45%, was used. Experiments were conducted to find out the optimal settings of digital PCR for the mtDNA ML analysis by checking three points: PCR cycle number, sample concentration, and comparison of ML by analysis methods.

Results: Forty cycles were enough to produce a sufficient yield. Digital PCR was not able to analyze high concentration samples (1ng/μl). Low concentration samples, on the other hand, could be analyzed as low as 1 pg/μl. 50 pg/μl seemed to be the optimal concentration, at which stable amplifications of wild-type and mutant mtDNA were obtained. ML analyzed with optimal setting was 36.1% which was almost the same as the ML analyzed by pyrosequencing assay (36.3%).

Conclusion: This is the first report of the use of digital PCR for PGT in mitochondrial disorder. The results indicate that analysis using digital PCR is possible from limited number of cells, making it an ideal method for PGT. On the other hand, the ML was lower than the known value of 45% at all methods, and further study is needed to determine the cause.

P08.012.A Molecular genetic analysis of familial hypercholesterolemia in a cohort of Czech patients

Radovan Bakalar[1], *Petra Slavikova*[1], *Veronika Todorovova*[1], *Renata Svacinova*[1], *Martin Reboun*[1], *Karolina Peskova*[1], *Pavel Jesina*[1], *Lenka Dvorakova*[1]

[1]*General University Hospital in Prague and 1st Faculty of Medicine, Charles University, Department of Pediatrics and Inherited Metabolic Disorders, Prague, Czech Republic*

Background/Objectives: Familial hypercholesterolemia (FH) is one of the most significant risk factors for atherosclerotic cardiovascular diseases (ASCVD). FH is predominantly caused by heterozygous variants in low density lipoprotein receptor (*LDLR*), apolipoprotein B (*APOB*) or proprotein convertase subtilisin/kexin type 9 (*PCSK9*) genes. Our aim was to monitor the frequency of variants, including CNVs, in individual genes in the Czech population.

Methods: Next-generation sequencing using a custom panel of 10 genes related to FH and FH-like phenotype was performed on Miseq platform (Illumina). An in-house pipeline including the ANNOVAR annotation tool and CNVkit was used for variant calling and CNV detection. Presence of CNVs was verified by SYBR Green qPCR and/or sequencing of the overlapping PCR products.

Results: In 53 out of 175 tested Czech suspected FH patients (30.3%), we detected various heterozygous causal variants in *LDLR* or *APOB*:c.10580G>A in 41 and 12 patients, respectively. Heterozygous variants of uncertain significance in *APOB* were identified in 6 patients. No causal variants were found in *PCSK9*. In *LDLR*, we identified a novel splicing variant c.2312-2A>C and 2 CNVs – a novel exon 2-14 duplication and a previously described exon 9-14 deletion. In other 10 patients, hypercholesterolemia could possibly be explained by variants in *LIPA*, *ABCG5*, *APOE*, *LDLRAP1 or LIPC*.

Conclusion: Pathogenic *LDLR* variants as the most common cause in our cohort are consistent with globally published data. Diagnostic genetic testing improves prognosis and personalized therapy for FH patients and helps to reduce the risk of ASCVD.

Grants: MZ ČR–RVO-VFN00064165

P08.013.B Urine organic acid and acylglycine testing as auxiliary diagnostic tools for diagnosing flavin adenine dinucleotide synthase deficiency: A retrospective investigation

Zinandre Stander[1], *Zineb Ammous*[2], *Joanne Werker*[2], *Kai Muru*[3;4], *Katrin Ounap*[3;4], *April Studinski*[1], *Matthew Schultz*[1], *Patricia Hall*[1], *Dietrich Matern*[1], *Devin Oglesbee*[1], *Silvia Tortorelli*[1], **Dimitar Gavrilov**[1]

[1]*Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, United States;* [2]*The Community Health Clinic, Topeka, United States;* [3]*University of Tartu, Department of Clinical Genetics,*

Tartu, Estonia; [4]University of Tartu, Institute of Clinical Medicine, Tartu, Estonia

Background: Flavin adenine dinucleotide synthase deficiency (FADSD) is a rare autosomal recessive disorder caused by pathogenic variants in *FLAD1*. Since FAD is a redox modulating cofactor of various acyl-CoA dehydrogenase reactions, FADSD patients generally present with neuromuscular symptoms and biochemical abnormalities resembling multiple acyl-CoA dehydrogenase deficiency (MADD). While investigations have characterized FADSD using plasma acylcarnitine profiles, literature regarding urinary signatures of these patients is lacking. Hence, this investigation aimed to provide insights into the urinary organic acid and acylglycine profiles of FADSD patients as auxiliary evidence for identification of the disorder prior to molecular analysis.

Methods: Retrospectively collected urine organic acid and acylglycine profiles of FADSD deficiency patients ($n = 4$) were qualitatively and quantitatively evaluated to: (1) establish a urinary signature for FADSD; and (2) determine whether these urinary signatures could be differentiated from MADD patients ($n = 21$).

Results: Collaborative Laboratory Integrated Reports (CLIR) based analysis of FADSD profiles revealed that ethylmalonic acid, methylsuccinic acid, and 12-associated ratios deviated notably from reference ranges (≤20% overlap). Although useful for the identification of FADSD, 5 ratios mainly related to the more prominent hexanoylglycine elevations in MADD cases, appear to be better suited for differentiation (0% overlap) of the two disorders.

Conclusion: Retrospective analysis of urinary FADSD profiles provided insights to a metabolic signature, that could be useful in the identification and differentiation of these patients from MADD cases prior to molecular testing. Hence further aiding in more timely diagnosis and/or treatment of FADSD patients.

Grants: PRG471 funding related to selected FADSD cases

P08.014.C Ubiquitination regulates the activity of GDP-mannose pyrophosphorylase B, which is associated with a congential disorder of glycosylation

Patricia Franzka[1], *Sonnhild Mittag[2], Obinna Umeh[3], Henriette Henze[4], Marie Juliane Jung[4], Véronique Blanchard[3;5], Julia von Maltzahn[4;6], Otmar Huber[2], Christian Hübner[1]*

[1]University Hospital Jena, Institute of Human Genetics, Jena, Germany; [2]University Hospital Jena, Department of Biochemistry II, Jena, Germany; [3]Charité-Universitätsmedizin Berlin, Institute of Diagnostic Laboratory Medicine, Clinical Chemistry and Pathobiochemistry, Berlin, Germany; [4]Leibniz-Institute on Aging-Fritz-Lipmann-Institute, AG von Maltzahn, Jena, Germany; [5]Medical School Berlin, Department of Human Medicine, Berlin, Germany; [6]Technische Universität Cottbus-Senftenberg, Stem Cell Biology of Aging, Cottbus, Germany

Background/Objectives: Glycosylation is the most common post-translational protein modification. Abnormal glycosylation can induce deleterious effects as observed in congenital disorders of glycosylation (CDGs) and often results in serious malfunctions of different organ systems such as brain and muscle. A typical example are mutations in the gene encoding for GDP-mannose-pyrophosphorylase-B (GMPPB). GMPPB generates GDP-mannose, a mannose donor for glycosylation. Its catalytically inactive paralogue GDP-mannose-pyrophosphorylase-A (GMPPA) serves as its feedback inhibitor and is associated with a CDG as well.

Methods: Co-immunoprecipitation followed by immunoblot analyses in HEK cells transfected with WT and variant GMPPB constructs together with ubiquitin and/or GMPPA constructs. GMPPB turnover was assessed in the presence of MG132 to inhibit proteasomal degradation or bafilomycin-A1 to inhibit lysosomal degradation. GMPPB activity was measured for GMPPB WT as well as different variant proteins. Myoblasts and N2a cells were used to study consequences of siRNA-mediated GMPPB knockdown on cell differentiation.

Results: We show that GMPPB is ubiquitously expressed and that its knockdown impairs myoblast and neuron-like differentiation. GMPPB is ubiquitinated and interacts with the E3 ubiquitin ligase TRIM67. Patient mutations localizing to the C-terminal part of GMPPB are associated with a diminished ubiquitination of GMPPB and display reduced enzymatic activity. Importantly, inhibition of GMPPB ubiquitination decreases its catalytic activity, while its turnover or interaction with GMPPA remains unaffected.

Conclusion: We here show a novel level of regulation of GMPPB activity by ubiquitination, which may serve as a potential target for future therapies.

Grants: DFG, IZKF.

Conflict of Interest: None declared

P08.015.D A challenging case of trichothiodystrophy: the patient's journey from clinical to genetic diagnosis

Albena Todorova[1;2], *Slavena Atemin[1], Mila Sleptsova[1], Tihomir Todorov[1], Dimitar Stamatov[3], Mila Baycheva[4;5]*

[1]Genetic Medico-Diagnostic Laboratory Genica and Genome Center Bulgaria, Sofia, Bulgaria; [2]Medical University of Sofia, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria; [3]University Children's Hospital, Sofia, Bulgaria, Department of Paediatric Neurology, Sofia, Bulgaria; [4]University Children's Hospital, Sofia, Bulgaria, Department of Paediatric Gastroenterology, Hepatology and Nutrition, Sofia, Bulgaria; [5]Medical University of Sofia, Department of Paediatrics, Sofia, Bulgaria

Background/Objectives: A 6-years old boy was referred for genetic testing after exhaustive clinical consultations and negative report from clinical exome sequencing. Born at term after pathological pregnancy with intrauterine growth retardation. The patient manifested with hypoproteinemia, hypoglycemia, physiological developmental delay (failure to thrive, severe hypotrophy, poor appetite, nasogastric feeding up to third year of age), neuro-psychological delay, microcephaly, dysmorphic features, brittle hair, trichorrhexis, EEG changes, no seizures, hepatomegaly, liver hemangiomas, hypothyroidism in treatment.

Methods: Genetic testing proceeded with whole exome sequencing – negative result. For the period of 2 years WES data were reanalyzed 6 times. Finally, two heterozygous missense variants were detected in the *CARS1* gene: c.1022G>A, p.Arg341His with maternal origin, and c.1108C>T, p.Arg370Trp with paternal origin.

Results: *CARS1* gene encodes cysteinyl-tRNA synthetase, mutations in which have been recently published in association with recessive multisystem disease that includes microcephaly, developmental delay, brittle hair and nails. Very few patients have been reported so far.

Conclusion: Trichothiodystrophy is a group of syndromes which affect mainly organs with neuroectodermal origin. The abnormalities, manifested at birth, always include brittle hair/nails, growth retardation and intellectual disability. *CARS1* gene has been recently included in the group of trichothiodystrophy-

causing genes. Here we present the first Bulgarian case of *CARS1*-related disorder. Genetic confirmation of the diagnosis is very important, because after treatment (special diet, rehabilitation, psychological and language help, ursodeoxycholic acid, levothyroxine, vitamins and minerals supplementation) and follow-up by gastroenterologist, endocrinologist and neurologist, the child's development has stabilized.

P08.016.A Rare forms of (non)syndromic monogenic diabetes in the Czech registry of patients susceptible for monogenic diabetes

Petra Dusatkova[1], *Klara Vesela*[1], *Katerina Kolarova*[1], *Jan Lebl*[1], *Zdenek Sumnik*[1], *Stepanka Pruhova*[1]

[1]*2nd Faculty of Medicine, Charles University and University Hospital Motol, Department of Paediatrics, Prague, Czech Republic*

Background/Objectives: Monogenic diabetes accounts for approximately 3.5% of patients manifesting diabetes till 30 years. Majority of these patients had subtypes of Maturity-Onset Diabetes of the Young (GCK/HNF1A/HNF4A-MODY). We aimed to describe rare forms of monogenic (non)syndromic diabetes in a Czech registry of patients susceptible for monogenic diabetes.

Methods: Probands with pathogenic variants in all pancreas-related but major MODY genes were selected. Data were obtained from the clinical questionnaires. The genetic testing was performed by Sanger sequencing, MLPA, followed by tNGS of 52 (63) genes since 2018.

Results: Out of 1903 probands with suspected monogenic diabetes, rare forms were detected in 52 families (87 persons). Median age at diabetes diagnosis was 17 (13-30) years. Median HbA1c reached 58 (45-69) mmol/mol (7.5%; 6.3-8.5%). Insulin was prevailing type of treatment (59.7%).

Gene	Persons/ families	Comorbidities
HNF1B	27/21	Renal cysts (n = 7), hypomagnesemia (n = 8), chronic renal insufficiency (n = 3), kidney transplantation (n = 1), kidney anomaly (n = 3), pancreas atrophy (n = 2)
INS	14/7	
WFS1	8/7	Optic hypoplasia (n = 3)
MT-TL1	14/6	Hearing impairment (n = 8), cardiomyopathy (n = 2), stroke (n = 2), heart transplantation (n = 1)
PDX1	8/4	
ABCC8	8/2	
INSR	2/2	
CEL	3/1	Pancreas atrophy and cysts (n = 2)
KCNJ11	1/1	
RFX6	2/1	

Diabetes alone displayed 19 persons with *HNF1B*, *MT-TL1* or *WFS1* anomaly.

Conclusion: Rare forms of monogenic diabetes caused by variants in 10 genes accounted for 7.1% of all families with monogenic diabetes. Genetic diagnosis not only clarify the diabetes aetiology but importantly allow to specifically investigate and treat in time additional comorbidities in probands with syndromic monogenic diabetes mimicking as "diabetes only" phenotype.

Conflict of Interest: None declared

P08.017.B Manifestations of ultra rare homozygous c.612C>G mutation in C1QBP gene in three members of one family

Background/Objectives: *C1QBP* gene encodes the complement component 1Q subcomponent-binding protein. It is crucial for preserving normal mitochondrial structure and preventing fragmentation. Patients with homozygous or compound heterozygous *C1QBP* mutations have a diverse spectrum of clinical manifestations with an onset at any age. We report the clinical manifestations of patients with homozygous c.612C>G mutation of *C1QBP*, considering its ultra rare occurrence.

Methods: The analysis of C1QBP gene was conducted using Next Generation Sequencing (NGS), followed by Sanger sequencing of the region of interest in the proband`s family members.

Results: A 28-year-old woman sought medical attention with complaints of drooping eyelids, accompanied by rapid fatigue, morning nausea, weakness in facial and skeletal muscles and rhinolalia. A subsequent medical examination identified bilateral ptosis and ophthalmoplegia. The electromyography results revealed signs of chronic diffuse changes of the myopathic type. Further genetic analysis using NGS uncovered a homozygous c.612C>G mutation in *C1QBP*, with conflicting classifications of pathogenicity (NM_001212.4). Both parents and two of the four siblings carried the heterozygous mutation and haven't presented any symptoms. The other two siblings were found to have the homozygous c.612C>G mutation. The 22-year-old male exhibited droopy eyelids, muscle weakness, and nausea/vomiting when fatigued. The 15-year-old female displayed morning nausea and generalized weakness, with no facial manifestations noted thus far.

Conclusion: It is suggested a milder and non-fatal course of the disease when the homozygous c.612C>G mutation of *C1QBP* gene is present. The allele frequency of this mutation is extremely low, which raises the possibility of a shared ancestry.

Consortium: mitoNET consortium

Background/Objectives: Mitochondrial disorders are a class of complex, heterogenous diseases, which show highly variable clinical and phenotypic differences. Many genetic diseases cause direct or indirect changes in lipid metabolism, such as in storage lipids, membrane lipids, metabolites or circulating lipid signaling molecules. As mitochondrial disorders are able to affect synthesis and degradation of lipids, these disorders reflect an interesting target for lipidomic biomarker analysis to evaluate signatures for distinct mitochondrial disorders, for phenotypic affection and for the prediction or progression of the diseases.

Methods: We conducted lipidomics of 299 human plasma samples of patients with confirmed genetic mitochondrial diseases via LC/MS-based lipidomics and correlated them to clinical chemistry parameters measured via the Roche Cobas system to measure affection of different internal organs by parameters, such as lipoproteins, liver transaminases, skeletal and heart muscle parameters, inflammation parameters and others.

Results: By conducting lipidomic analyses of 299 plasma samples with confirmed mitochondrial disorders, we could identify over 800 different lipid species, which included several potential biomarkers for distinct mitochondrial disorders, such as *OPA1*- or *ETFDH*-associated diseases. Further, we identified specific lipidomic signatures for organ affections distinctly describing cardiac involvement of mitochondrial disorders.

Conclusion: In sum, we show that plasma lipidomics are a powerful tool for investigation of lipid signatures for distinct mitochondrial diseases and its related organ manifestations.

Background/Objectives: Type 2 diabetes (T2D) and elevated blood pressure (BP, including systolic [*SBP*] and diastolic [*DBP*]) are complex frequently co-occurring conditions. Understanding shared genetic factors between them could bring insight into the underlying pathophysiological processes.

Methods: We dissected the effects of 563 T2D and 999 BP variants established using genome-wide association studies (GWAS), by constructing polygenic score (PGS) in a set of 457,386 European individuals from UK Biobank (UKB). We gathered Z-scores from GWAS on 49 endophenotypes and utilised them to cluster 1,542 genetic variants into distinct pathophysiological processes and investigated cluster-specific PGSs for comorbidity. We performed bi-directional two-sample Mendelian Randomization (MR) to explore causal relationships between T2D/BP. We used GTEx expression quantitative trait loci (eQTL) in 49 tissues to identify co-localisation of these variants.

Results: T2D overall PGS was associated with risk of elevated BP, and vice versa (P-values ≤ 0.0167). MR suggested that T2D has an heterogenous causal effect on BP. Partitioning genetic variants defined five clusters of different pathogenetic processes, whereby Cluster2 featured individuals with metabolic syndrome characteristics, *i.e.*, central obesity, insulin resistance and shorter stature. MR using Cluster2 variants revealed a circle of causality between DBP, T2D, and SBP, with each increasing risk of comorbidity ($OR_{IVW\ DBP\rightarrow PP\ through\ Cluster2}$ [95% CI] = 1.04[1.02–1.06]; $\beta_{IVW\ T2D\rightarrow SBP\ through\ Cluster2}$[SE]=1.987 [0.278], P-values ≤ 1.86×10^{-5}). Cluster2 co-localised genes had enriched co-expression in adipose subcutaneous, thyroid and artery tibial tissues (*PP.H4.abf* >0.8).

Conclusion: Clustering SNPs by pathogenetic process highlighted the importance of central obesity and insulin resistance into causal effect of T2D leading to altered BP.

[1]*Faculty of Medicine, Chulalongkorn University, Center of Excellence for Medical Genomics, Medical Genomics Cluster, Department of Pediatrics, Bangkok, Thailand;* [2]*King Chulalongkorn Memorial Hospital, the Thai Red Cross Society, Excellence Center for Genomics and Precision Medicine, Bangkok, Thailand*

Background/Objectives: Primary mitochondrial disorders (PMD) exhibit clinical and genotypical heterogeneity, posing challenges in diagnosis for patients. Utilizing a comprehensive genetic testing approach, such as exome or genome sequencing, has shown to enhance diagnostic yield.

Methods: We conducted a retrospective review of patients who were molecularly diagnosed and followed-up at King Chulalongkorn Memorial Hospital from January 2020 to December 2023. Data on clinical presentations, investigations, Mitochondrial Disease Criteria scores (MDC; Witters et al., 2017), and genotypes were systematically collected.

Results: We identified seven patients with PMD with five cases attributed to nuclear DNA (nDNA) mutations (*SURF1*, *SDHA*, *SERAC1*, *SLC19A2*, *PDHA1*) and two cases associated with mitochondrial DNA (mtDNA) mutations (*MT-ATP6* m.9176T>G; *MT-ND5* m.12706T>C). Five out of seven cases can be definitive diagnosed by comprehensive genetic tests only. Notably, both patients with mtDNA origin exhibited symptoms of ophthalmoplegia and symptom onset during childhood (age 125 and 14 months old) and MDC scores reaching 8 (definite). The *MT-ND5* patient initially tested positive for acetylcholine receptor antibodies and experienced a misdiagnosis one year before the progressing neurological symptoms (stroke-like episode). In the nDNA group, the majority, four out of five patients, manifested symptoms in the infantile period. MDC scores for the nDNA group ranged from probable (5-7) in three patients to definite in two patients.

Conclusion: PMD can mimic other disorders. Distinct features such as external ophthalmoplegia and the onset age may suggest the aetiologic genetic classes (nDNA versus mtDNA). Utilizing comprehensive genetic testing is crucial for achieving a definitive diagnosis.

Consortium: N/A

Background/Objectives: Glycogen is synthesized de novo in the nucleus, and nuclear glycogenolysis provides a carbon pool for histone acetylation. Abnormal nuclear glycogen catabolism results in epigenetic changes. We found hepatic nuclear glycogen storage in $Asl^{Neo/Neo}$ mice, a model of Argininosuccinic Aciduria (ASA), an inherited urea cycle disorder due to argininosuccinate lyase deficiency. In $Asl^{Neo/Neo}$ mice we investigated mechanisms of aberrant nuclear glycogen storage and its consequences on liver homeostasis.

Methods: Nuclear glycogen storage in hepatocytes was investigated by electron microscopy. Enzymes and acetylated histones were determined by Western Blot on nuclear purified fractions. Hepatic gene expression was performed by QuantSeq. Survival of $Asl^{Neo/Neo}$ mice was investigated following intravenous administrations of an adeno-associated virus (AAV) vector encoding glycogen phosphorylase (PYGL), the rate-limiting enzyme in glycogenolysis or after intraperitoneal injections of vorinostat, a pan-Histone Deacetylase (HDAC) inhibitor.

Results: In nuclei of $Asl^{Neo/Neo}$ mouse livers, quantification of glycogen metabolizing enzymes suggested increased glycogen synthesis and reduced glycogenolysis. These nuclei also showed reduced acetyl-CoA content, and decreased lysine acetylation of histones. Neither nuclear glycogen accumulation nor reduced histone acetylation were observed in murine models of defective glycogen metabolism (PYGL deficiency) or ureagenesis. Hepatic transcriptomic analysis revealed H3K9-dependent changes. Increased histone acetylation, by hepatocyte-specific PYGL overexpression or HDAC inhibition, improved $Asl^{Neo/Neo}$ mouse survival.

Conclusion: Defective hepatic nuclear glycogen mobilization and histone hypoacetylation result in global transcriptomic changes and reduced survival in ASA mice. These findings may have implications for development of improved therapies for liver disease in ASA and potentially, other liver disorders with aberrant nuclear glycogen storage.

P08.023.D A single-center genotype-phenotype correlation cohort study of Hyperphenylalaninemia patients: Genetic analysis as a deterministic tool for treatment consistency

Alp Peker[1], *sezin yakut uzunuer[2], Erdoğan Soyuçen[3], Özden Altıok Clark[1], Gülay Dal Demirelli[4], Belgin Akcan Paksoy[3], banu nur[5], ercan mihci[5]*

[1]Akdeniz University Medicine Faculty, Medical Genetics, Antalya, Türkyie; [2]Akdeniz University Medicine Faculty, Medical Biology, Antalya, Türkyie; [3]Akdeniz University Medicine Faculty, Pediatric Metabolic Diseases, Antalya, Türkyie; [4]Akdeniz University Medicine Faculty, Pediatric Metabolic Diseases, Antalya; [5]Akdeniz University Medicine Faculty, Pediatric Genetics, Antalya, Türkyie

Background/Objectives: Hyperphenylalaninemia (HPA, increased blood phenylalanine levels) refers to a disorder spectrum, with Phenylketonuria (PKU) being a widespread autosomal recessive form caused by *PAH* gene mutations. Phenotypical outcomes and symptom severity are significantly influenced by genetic variations in HPA. This study investigates the genotypical-phenotypical correlation in a cohort of HPA patients, aiming to evaluate treatment consistency concerning specific genotypes and demonstrate that genotyping can provide guidance for optimal treatment and prognosis.

Methods: Genomic DNA was obtained from 31 PKU, 2 Tetrahydrobiopterin (BH4) deficiency, and 1 Dihydropteridin Reductase deficiency patients for Next-Generation Sequencing of HPA-associated genes. Variants were analyzed using Sophia DDM program, dbSNP, ClinVar, Ensembl services, and ACMG 2015 criteria. Allelic phenotypic values consistent with enzyme functionality regarding literature data were assessed with patient anamnesis'.

Results: Carriers of two null variants (homozygous/compound heterozygous) were unresponsive to BH4 therapy, reflecting the literature. Notably, BH4 therapy was also inadequate for two PKU patients who were compound heterozygous carriers with one null variant, albeit other variants' assumed protein function (*PAH* [NM_000277.3] c.1289T>C, c.143T>C). However, *PAH* variants c.1169A>G, c.533A>G, c.1114A>T, c.898G>T demonstrated positive BH4 responses when compounding a null variant. Homozygous c.782G>A variant, linked to classical PKU, responded to BH4 therapy along with diet.

Conclusion: This study implies genetic testing is plausible in predicting pre-treatment BH4 testing outcomes, aiding in decision-making before patient evaluation as it also provides valuable guidance to metabolism specialists during treatment. With more HPA genotypes analyzed and clinical data published, genotyping will hold better deterministic position towards patient prognosis and therapeutic management.

P08.024.A A biallelic variant, c.1139T>G in *DAP3* is associated with encephalopathy, liver failure, lactic acidosis, and early infantile death

Mayuri Yeole[1], *Namanpreet Kaur[1], Vivekananda Bhat[1], Ramesh Bhat[2], Anju Shukla[1], Radhakrishnan Periyasamy[1]*

[1]Department of Medical Genetics, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, India; [2]Department of Pediatrics, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, India

Background/Objectives: Death-associated protein (DAP3), also known as mitochondrial ribosomal protein S29 (MRPS29), is a novel GTP binding protein, with dual function in apoptosis and mitochondrial protein translation.

Methods: We ascertained a six-month-old female, born to a consanguineously married couple. Singleton exome sequencing (ES) followed by Sanger validation and segregation was performed in the family. In silico protein modelling and analysis was done using HOPE and I-Mutant.

Results: Proband presented with recurrent episodes of vomiting and lethargy associated with fever and encephalopathy at five months. She developed hepatosplenomegaly, acute liver failure followed by multi-organ dysfunction, and later succumbed at six

months. Blood gas analysis indicated severe metabolic acidosis, mildly elevated liver enzymes, and deranged coagulation profile. Liquid chromatography with tandem mass spectrometry revealed malonyl-CoA decarboxylase and short-chain L-3-hydroxyacyl-CoA dehydrogenase deficiency. There is a history of deceased elder sibling with similar complaints at 11 months of age. On singleton ES, we identified a homozygous variant, c.1139T>G p.(Leu380Arg) in *DAP3* (NM_004632.4) in the proband. This variant is absent in population database gnomAD and in-house database of 3106 exomes. In silico prediction tools (REVEL, CADD, MutationTaster) are consistent in predicting the variant to be damaging to the DAP3 function. In silico mutagenesis predicted that the Arg380 mutant residue would affect the intramolecular interactions in the mutant protein, thus leading to conformational changes and affecting its interactions with other proteins.

Conclusion: With this report, we propose a novel disease-gene association in *DAP3* leading to multi-organ dysfunction with early infantile death.

P08.026.C Three Canavan disease patients with a single heterozygous pathogenic variant in ASPA gene – where is the missing part of the puzzle ?

Silvia Andonova[1;2], *Mariya Ivanova*[1], *Tihomir Todorov*[2], *Iliyana Pacheva*[3], *Dimitar Stamatov*[4], *Viktoriya Yordanova*[1], *Irena Bradinova*[1], *Alexey Savov*[1], *Albena Todorova*[2;5]

[1]*National Genetic Laboratory, UHOG "Maichin dom", Sofia, Bulgaria;* [2]*GMDL Genica, Sofia, Bulgaria;* [3]*Medical University-Plovdiv, Department of Pediatrics and Medical Genetics, Plovdiv, Bulgaria;* [4]*University Pediatrics Hospital, Department of Pediatric Neurology, Sofia, Bulgaria;* [5]*Medical University-Sofia, Department of Biochemistry, Sofia, Bulgaria*

Background/Objectives: Canavan disease is a rare condition due to an aspartoacylase deficiency that leads to a lethal infantile neurogenerative disease from the Leukodystrophies group. This autosomal recessive disorder is caused by pathogenic variants in *ASPA* gene, encoding the enzyme aspartoacylase. The disease is manifested in the early infancy with elevated levels of the substrate N-acetylaspartic acid (NAA) and neurologic findings including hypotonia, blindness, megalocephaly, etc. due to demyelination and spongy degeneration of the brain. Here we describe three infant patients from non-consanguineous families with clinical presentation and specific metabolic profile of Canavan disease.

Methods: Sanger sequencing of the *ASPA* gene and MLPA analysis were performed; the NAA levels were analyzed by GC/MS (gas-chromatography/mass-spectrometry).

Results: *ASPA* gene sequencing detected a different single heterozygous pathogenic variant in each patient - c.740T>C/p.Leu247Pro, c.863A>G/p.Tyr288Cys, and c.876_879del/p.Glu293-LeufsTer8, respectively. Segregation analysis revealed that all variants were inherited from a parent. Subsequently, MLPA analysis did not detect deletions or duplications in the targeted *ASPA* gene region.

Conclusion: Performing genetic analysis with advanced technologies (WES/WGS) would be beneficial for genetic profiling and revealing the precise molecular profile of Canavan disease in the presented Bulgarian patients. This could allow inclusion of these patients in clinical trials for a possible gene therapy with potential benefits.

Grants: The present study was financially supported by the Medical University Sofia (Grant D-175/2023).

Shupyka, Department of Medical and Laboratory Genetics, Kyiv*

Actuality: Galactosemia type I (GALAC1, OMIM#230400) is an autosomal recessive disorder caused by pathogenic variants of *GALT* with frequency of 1:16,000-100,000 in Europe. The neonatal screening contributes to early detection and dietary treatment, which could prevent the acute manifestation and reduce the lethality.

Aim: To assess the molecular features of positive cases of neonatal screening for GALAC1 in Ukraine during the first year of its implementation.

Methods: The GALT activity in DBS by fluorometric method, NGS and Sanger sequencing.

Results and discussion: Neonatal screening for GALAC1 started in Ukraine in October 2022. During the first year of expanded screening, 145,693 newborns were examined, in 19 patients (0.013%) decrease in the activity of the GALT was detected (cut off 1.7 U/dL). Molecular genetic analysis of the *GALT* in patients with positive neonatal screening revealed only one patient with GALAC1 (5% of all positive cases) (p.Q188R/p.H114P). The rest of the patients had galactosemia Duarte (n = 13, 68%) or were heterozygous carrier of one pathogenic variant in *GALT* (n = 5, 26%). In patients with Duarte galactosemia, the genotype p.Q188R/p.N314D was detected in 54% cases (7/13), and another patients had a combination of the p.N314D variant with such variants as p.M142K (n = 2), p.K285N (n = 1), p.Y209D (n = 1), p.N314D (n = 2).

Conclusion: The frequency of confirmed cases of GALAC1 is 1:145,693 newborns, which is significantly lower than the European. These are preliminary data, a larger number of examined newborns is needed. The high frequency of the Duarte variant among positive cases was revealed compared to Europe.

Conflict of Interest: None declared

P08.028.A Novel treatments for primary Coenzyme Q10 deficiency

Cristina Cerqua[1], *Giulia Toffanin*[2], *Valeria Balmaceda*[3], *Cristina Calderan*[1], *Raffaele Cerutti*[3], *Carlo Viscomi*[3;4], *Eva Trevisson*[1;2]

[1]*Istituto di Ricerca Pediatrica IRP Città della Speranza, Padova;* [2], *Department of Women's and Children's Health, University of Padova, Padova, Italy;* [3]*Venetian Institute of Molecular Medicine, Padova, Italy;* [4], *Department of Biomedical Sciences, University of Padova, Padova, Italy*

Background/Objectives: Coenzyme Q (CoQ) is a mitochondrial electron transporter and one of the main cellular antioxidants. Mutations in human *COQ* genes, involved in CoQ biosynthesis, cause primary CoQ deficiency, associated with variable clinical phenotypes. Since treatment with CoQ is not always efficient, we

aimed to test two novel therapeutic strategies using a model of CoQ deficiency, the *Pdss2*$^{kd/kd}$ mouse, which harbors a mutation in *Pdss2* and develops a renal phenotype similar to that of most *PDSS2* patients, recognizable by increased proteinuria, decreased survival and glomeruli destruction.

Methods: First, we aimed to test the effects of gene replacement, by injecting in *Pdss2*$^{kd/kd}$ mice an adeno-associated vector (AAV) containing murine *Pdss2*. Then we decided to supplement mice with CoQ ring analogues, that represented a valid alternative to CoQ treatment in some CoQ models.

Results: In our hands, the gene replacement was ineffective in the mouse strain CBA/H, in which the *Pdss2* mutation occurred for the first time. After injecting the same vector at the same dose in a different mouse strain, the C57BL/6, we could observe a significant transduction increase in all tissues tested, compared to the CBA/H strain, demonstrating that the mouse genetic background influences the viral transduction efficiency. For the supplementation protocol, we studied mice survival, proteinuria and kidney histology.

Conclusion: Treatment with 2,4-dihydroxybenzoic acid, a CoQ analog, significantly prolonged the mice survival, reduced the proteinuria and improved the glomerular appearance. These results will be fundamental to encourage the development of analogous therapies for other *COQ* gene defects.

Grants: Fondazione Cariparo – Bando Ricerca Pediatrica 2020-2024

Conflict of Interest: None declared

P08.029.B Fine mapping and functional investigation of the novel type 2 diabetes (T2D) susceptibility locus *ACAD11/NPHP3*.

Hatice Bahar Sahin[1], *Hannah Maude*[1], *Bethany Quinton*[2], *David Michael*[1], *winston lau*[2], *Inês Cebola*[1], *nikolas maniatis*[2], **Toby Andrew**[1]

[1]*Imperial College, Metabolism, Digestion and Reproduction, London, United Kingdom;* [2]*UCL, Genetics, Evolution & Environment, London, United Kingdom*

Background/Objectives: We previously reported a replicated association between the *ACAD11/NPHP3* locus and type 2 diabetes (T2D) using population-specific genetic maps in a genome-wide study. Precise genetic co-localisation with expression quantitative trait loci (eQTL) implicated several target genes including *ACAD11*, which encodes the mitochondrial acyl-CoA dehydrogenase enzyme participating in fatty acid beta-oxidation. Here, we test the hypothesis that T2D-risk variants confer risk of disease by dysregulating the expression levels of *ACAD11* and neighbouring *cis*-genes in T2D-relevant tissues using in silico and functional experiments.

Methods: Chromatin activity datasets were used to prioritise non-coding variants that might disrupt enhancer activity. These were further investigated by transcription factor motif disruption analysis. Targeted sequencing of independent T2D cases and controls was used to identify candidate functional variants. Evidence of enhancer disruption by a candidate variant (rs73000573) was validated using a dual-luciferase reporter assay. To assess potential target *cis*-genes, CRISPR-mediated activation of the enhancer hosting the rs73000573 variant was undertaken in Hep3B cells, followed by RT-qPCR analysis of predicted *cis*-genes.

Results: *ACAD11* shows evidence of rare coding-variant enrichment. rs73000573 (MAF> = 0.01) disrupts TF binding at a validated enhancer in *ACAD11* intron 1, which in turn regulates *ACAD11* expression in Hep3B cells. GTEx data indicates rs73000573 acts as an eQTL for *ACAD11* and *NPHP3*.

Conclusion: The *ACAD11/NPHP3* locus contains multiple T2D-associated variants of interest, with a rare haplotype containing at least one functional variant that alters *ACAD11* expression and splicing, implicating altered mitochondrial fatty acid oxidation in the aetiology of T2D.

P08.030.C Rare mtDNA variants in an Italian cohort of patients with suspected mitochondrial diseases.

Alberto Pietro Pasti[1], *Claudio Fiorini*[1], *Danara Ormanbekova*[1], *Eleonora Pizzi*[1], *Chiara La Morgia*[1;2], *Maria Lucia Valentina*[1;2], *Valerio Carelli*[1;2], *Leonardo Caporali*[1;2]

[1]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy;* [2]*Alma Mater Studiorum - Università di Bologna, Dipartimento di Scienze Biomediche e Neuromotorie (DIBINEM), Bologna, Italy*

Background/Objectives: Mitochondrial disorders comprise a group of heterogeneous rare pathologies, with a cumulative minimum prevalence of greater than 1 in 5000 in adults. For suspected mitochondrial primary diseases' molecular diagnosis, the analysis of mitochondrial DNA (mtDNA) is always suggested to identify both pathogenic SNVs and deletions.

Methods: As a reference center for the diagnosis of mitochondrial diseases in Northern Italy, the Institute of Neurological Sciences of Bologna between 2014 and 2023 has collected a cohort of 532 patients with suspected mitochondrial pathology which underwent mtDNA sequencing. We performed sequencing through a targeted NGS approach on DNA from blood and skeletal muscle tissues. The bioinformatic analysis followed the Mitoverse pipeline, with manual curation of predicted damaging variants.

Results: This cohort included cases of suspected optic neuropathy (n = 166, 31.2%), mitochondrial encephalomyopathy (n = 152, 28.6%), mitochondrial myopathy (n = 212, 39.9%), cardiomyopathy (n = 2, 0.3%). Although, the sampled cohort is depleted from the most common pathogenic variants (m.3243A>G, m.3460G>A, m.11778G>A, m.14484T>C), that are usually screened before the request of mtDNA testing, we solved 13.2% of the cases (n = 70). The most resolved category are optic neuropathies, with 16.2% of yield, while encephalomyopathies and myopathies resulted in 13.8% and 9.4% of solved cases, respectively. Notably, most of the pathogenic variants in myopathies involve the mitochondrial tRNA genes (60% of cases), and most of the variants causing optic atrophy are found in respiratory complex I subunits (81% of cases).

Conclusion: We expand the list of candidate pathogenic variants, to be confirmed through independent case reports or in vitro validation.

Grant: Italian Ministry of Health, Ricerca Corrente.

Conflict of Interest: None declared

P08.031.D Diagnosis of mtDNA disorders by exome and genome sequencing

Ana beatriz Hinojosa Amaya[1], *Ingrid Bader*[1], *Hans A. Mayr*[2], *Peter Freisinger*[3], *Stefanie Beck-Wödl*[1], *Marc Sturm*[1], *Susana Peralta*[1], *Tobias Haack*[1]

[1]*University of Tübingen, Institute of Medical Genetics and Applied Genomics, Tübingen, Germany;* [2]*Paracelsus Medical University,*

University Children's Hospital, Salzburger Landeskliniken (SALK), Salzburg, Austria; [3]Klinikum am Steinenberg, Children's Hospital Reutlingen, Reutlingen, Germany

Background/Objectives: Mitochondriopathies are clinically and genetically heterogenic disorders. Thanks to Next-Generation-Sequencing their diagnosis have been improved and accelerated. Nevertheless, in cases of mtDNA variations the diagnosis is still a challenge due to variable heteroplasmy level in different tissues. Our objective is to describe the cases diagnosed with pathogenic mtDNA variants in our institute by exome (ES) and genome sequencing (GS) and compare mtDNA depth coverage in both techniques.

Methods: We selected from our internal database cases with class 4 and 5 mtDNA variants in blood samples referred to our institute for a diagnostic ES or GS between 2016 and 2023. We calculated mean read depths and standard deviations (±SD) of mtDNA in exome (ES), short read (srGS) and long read genome sequencing (lrGS).

Results: We identified a total of 52 patients. In 35 cases (67%) variants were detected by ES and 17 (33%) by GS. The most frequent affected gene was *MT-ATP6* (62%). In only 35% a mitochondrial disorder had been suspected by the clinician. Most patients presented with neurological/neurodevelopmental phenotypes (61%). Mean read depth coverage values in mtDNA was as follows: ES: 98.41 ± 131.98, srGS: 1719.7 ± 751.38 and lrGS: 1806,36 ± 1189.

Conclusion: Our findings show the importance of including mtDNA analysis in patients with neurological symptoms. GS, particularly lrGS, showed a deeper and more uniform coverage across the mtDNA in comparison to ES. These findings together with the advantage of detecting copy number variants and also structural variants (particularly by lrGS) makes GS the preferred first-line diagnostic test for inherited mitochondrial disorders.

P08.032.A Study of the frequent hypomorphic variant c.3045G>A in the *ATP7B* gene

Mikhail Skoblov[1], *Igor Bychkov[2], Nikita Vorobyov[1], Daria Akimova[1], Vyacheslav Tabakov[3], Alexandra Filatova[1]*

[1]Research Centre for Medical Genetics, Laboratory of Functional Genomics, Russian Federation; [2]Research Centre for Medical Genetics, Laboratory of hereditary metabolic diseases, Russian Federation; [3]Research Centre for Medical Genetics, Head of the Center for Collective Use "Biobank", Russian Federation

Background: Wilson's disease is a hereditary disorder that involves anomalous copper metabolism. Gene panel sequencing is commonly used to diagnose Wilson's disease but has an efficacy of only around 70%. RNA analysis offers an alternative method, detecting changes in RNA structure and expression levels caused by intron variants influencing splicing and regulatory variants affecting expression levels.

Methods: Total RNA was extracted from activated lymphocytes and primary cultured fibroblasts of patients using Trizol. An RT-PCR system with 8 loci was developed to detect pathogenic variants in the ATP7B gene. PCR products were analyzed by NGS on an Ion Torrent S5. Minigene and MPRA analyses characterized the hylomorphic variant. Splicing correction was performed using U7 snRNA in HEK293T cells.

Results: We performed RNA analysis on Wilson's disease patients to find the second pathogenic variant. We observed the partial skipping of 13 exon caused by the hypomorphic variant c.3045G>A which was missed during the initial panel sequencing due to its high population frequency. To investigate the molecular basis of this hypomorphic effect, the minigene with 13 exon of ATP7B was created. Analysis of the c.3045G>A variant confirmed splicing abnormalities. MPRA analyses on enhancer splicing sites in the minigene revealed other variants also caused exon skipping. We designed several U7 snRNA to compensate effect of hypomorphic variant thereby promoting the correct splicing of exon 13.

Conclusion: The investigation of frequent hypomorphic variants remains underexplored. Understanding their mechanisms not only enhances our comprehension of their actions but also leads to development of future treatments.

P08.033.B Microbiome analysis of total blood RNAseq: Insights from a prediabetic population

Claudia Solari[1], *Nelba Perez[2], Maria Soledad Rodriguez Varela[1;2], Razan Hijazi[1], Alan Möbbs[1], Florencia De Lillo[1], Estefania Mancini[1], Ignacio Berdiñas[1], Patricio Rickert[1], Maria Olivera[1], Silvina Waldman[2], Rosana Poggio[1], Alejandro La Greca[1], Carlos Luzzani[1], Santiago Miriuka[1;2]*

[1]MultiplAI Health, Cambridge, United Kingdom; [2]FLENI, Buenos Aires, Argentina

Background/Objectives: Human microbiome has emerged as a key player in health and disease. Prediabetes represents a critical juncture where early intervention may mitigate progression to overt diabetes and its associated cardiovascular complications.

Our objective is to characterize the microbiome at the phylum and genus levels and assess their association with clinical features.

Methods: Blood samples from 336 subjects were collected at FLENI foundation, Buenos Aires, Argentina. Total RNA was isolated, purified, and deep sequenced (~100m reads). The RNAseq data was aligned with STAR. Unmapped reads were classified with Kraken2 software. Prediabetes was defined as glycemia of 110 to 125 mg/dl and/or glycated HbA1 between 6 and 6.4% without any diabetes treatment.

Results: The RNAseq data showed an extensive amount of microbiome reads (0.07%). In our cohort, the most represented phyla were Proteobacteria, Actinomycetota, Bacillota, Bacteroidota, and Cyanobacteria, and at a genus level, we found Cutibacterium, Moraxella, Acinetobacter, Staphylococcus, Streptococcus, among others. While no statistical differences emerged at the phylum level in the preDBT versus normal populations, genus-level analysis revealed elevated Staphylococcus reads in the preDBT group (p-value = 0.04257). Prediabetic individuals exhibited an inverse correlation between HbA1C levels and Bacillota phylum reads (R^2: 0.87) and Streptococcus genus reads (R^2: 0.73). No relationship was found with c-Reactive protein levels.

Conclusion: We observed an association between blood microbiome and metabolic parameters. These findings hint at a potential role in contributing to cardiometabolic risk, providing valuable insights that can inform the development of targeted preventive strategies.

Background/Objectives: Deoxyguanosine kinase (dGK) deficiency is an autosomal recessive disorder presenting with early-onset of liver failure with/without neurological involvement and a clinical course rapidly progressive to death. The lack of enzyme activity causes mitochondrial deoxynucleotides pool unbalance leading to quantitative and qualitative impairment of mtDNA synthesis and multiple OXPHOS defect. Here we present an international, multicentre retrospective natural history study.

Methods: Clinical, biochemical, metabolic and molecular genetics data for genetically confirmed patients with dGk deficiency were collected. A systematic literature review from January 2001 to June 2023 was also conducted.

Results: A cohort of 202 patients, 36 unreported, and 166 from the systematic literature review, were analyzed. Patients had a neonatal onset (≤ 1 month) in 55.7% of cases, infantile (>1 month and ≤ 1 year) in 32.3%, pediatric (>1 year and ≤18 years) in 2.5%, and adult (>18 years) in 9.5%. Kaplan-Meier analysis showed a statistically significant difference in the survival rate among the age-at-onset subgroups ($p < 0.0001$) with the highest mortality for the neonatal group.

We defined four different clinical subtypes: hepatocerebral (58.8%), isolated hepatopathy (21.9%), hepatomyoencephalopathy (9.6%), and isolated myopathy (9.6%). Muscle involvement was predominant in adult-onset cases whereas liver dysfunction causes morbidity and mortality in early-onset patients with a median survival of less than 1 year. Liver transplant (LTx) significantly modified the survival rate in 26 treated patients when compared with untreated.

Conclusion: In conclusion, dGk deficiency is a disease spectrum with a prevalent liver and brain tissue-specificity in neonatal and infantile-onset patients and muscle tissue-specificity in adult-onset cases.

Conflict of Interest: None declared

P08.035.D Epimutation in the MMACHC promoter due to PRDX1 variant causing epi-cblC methylmalonyl aciduria and homocystinuria

Martina Skopkova[1], *Pavlina Kabelikova[2], Andrea Andresova[1], Silvia Dallemule[3], Robert Petrovic[3], Katarina Brennerova[4], Daniela Gasperikova[1]*

[1]*Biomedical Research Center SAS, Institute of Experimental Endocrinology, Bratislava, Slovakia;* [2]*Biomedical Research Center SAS, Institute of Experimental Oncology, Bratislava, Slovakia;* [3]*Medical Faculty University Comenius and University Hospital, Institute of Medical Biology, Genetics, and Clinical Genetics, Bratislava, Slovakia;* [4]*Medical Faculty of Comenius University and National Institute of Children's Diseases, Department of Paediatrics, Bratislava, Slovakia*

Background/Objectives: Methylmalonic aciduria (MMA) is a group of autosomal recessive disorders resulting from impaired intracellular metabolism of cobalamin. Depending on the point in the metabolic pathway that is impaired, MMA can be accompanied by homocystinuria. That is also the case of mutations in the *MMACHC* gene causing combined MMA and homocystinuria type cblC. Besides the biallelic mutations in the *MMACHC* gene, CblC type MMA can occur due to specific mutations in the *PRDX1* gene located downstream from *MMACHC* in the opposite direction. The *PRDX1* mutations giving rise to an aberrant transcript overlapping the promoter region of the *MMACHC* gene cause its methylation and subsequent downregulation of expression (so-called epi-CblC).

Methods: The DNA of a patient with biochemically diagnosed MMA and homocystinuria was analysed by WES, methylation of the *MMACHC* promoter was assessed using methylation-specific PCR and pyrosequencing of the bisulphite-treated DNA.

Results: We identified a heterozygous known pathogenic variant c.271dup in the *MMACHC* gene in combination with a novel stop-to-stop variant c.599G>A in the *PRDX1* gene. Pathogenicity of this variant was supported by detection of increased methylation of the *MMACHC* promoter in the patient's blood and fibroblast DNA. We sequenced the aberrant *PRDX1* transcript reaching the *MMACHC* promoter and identified usage of a cryptic splice site in the last exon of the *PRDX1* gene.

Conclusion: We confirmed pathogenicity of a novel otherwise unsuspicious stop-to-stop variant in the *PRDX1* causing methylation of *MMACHC* gene promoter. The patient was thus diagnosed with epiCblC type of MMA.

Service, Valladolid, Spain; [3]University of Valladolid, Department of Medicine, Valladolid, Spain; [4]University of Valencia, Department of Statistics and Operation Research, Valencia, Spain; [5]CIBERDEM, ISCIII, Madrid, Spain

Background/Objectives: Oxidative stress (OS) and obesity are interconnected conditions that play pivotal roles in predisponding individuals to various diseases. Our objective was to investigate the relationship between metabolism-related genes and OS and how they might influence the onset of obesity in general Spanish population.

Methods: SNPLex methodology was used to analyse about 900 SNPs from 272 candidate genes related to OS in 1502 subjects from the Hortega study. GSSG/GSH ratio, MDA and 8-oxo-dG were used as OS biomarkers. Linear regression models were used to calculate the interaction between OS parameters and selected SNPs in relation to BMI.

Results: Significant interaction were found between 60 SNPs and OS levels in relation to BMI. Adjusted p-values between 10^{-122} and 10^{-4}) was present in rs2694847 (*SP1*), rs11574777 (*IL6ST*), rs12665231 (*NOX3*), rs12524299 (*NOX3*), rs6816673 (*SLC39A8*) and rs198358 (*NPPA*) for GSSG/GSH ratio, rs35411892 (*SLC39A8*), rs697221 (*DDIT3*) and rs1800629 (*LTA*) for 8-oxo-dG and rs697221 (*DDIT3*) for MDA. These genes are involved in biological processes such as inflammation, endoplasmic reticulum stress, blood pressure and OS levels.

Conclusion: We have found an important effect of OS levels on genetic backgroung resulting in modulation of BMI by specific alleles. These data support the relationship between OS levels and BMI.

P08.037.B Elucidating mechanisms of mitochondrial dysfunction associated with BTRR complex deficiency

Marianne Gaubert[1], *Ipek Ilgin Gönenc[1], Halima Alachram[1], Kimia Mirzakhani[1], Lukas Cyganek[2;3;4], Gökhan Yigit[1;3], Bernd Wollnik[1;2;3]*

[1]University Medical Center Göttingen, Institute for Human Genetics, Göttingen, Germany; [2]University of Göttingen, Cluster of Excellence "Multiscale Bioimaging: From Molecular Machines to Networks of Excitable Cells" (MBExC), Göttingen, Germany; [3]German Center for Cardiovascular Research (DZHK), Partner site Göttingen, Göttingen, Germany; [4]University Medical Center Göttingen, Stem Cell Unit, Clinic for Cardiology and Pneumology, Göttingen, Germany

Background/Objectives: Bloom syndrome (BS) is an autosomal recessive disorder clinically characterized by primary microcephaly, short stature, immunodeficiency, and cancer predisposition, caused by biallelic mutations in genes encoding the members of the BTRR complex, i. e. *BLM, TOP3A, RMI1, and RMI2*. The topoisomerase TOP3A is crucial for relieving DNA torsional strain, highlighting its importance in genome maintenance. A mitochondrial isoform of TOP3A also exists, involved in the decatenation of mitochondrial DNA (mtDNA) molecules. Intriguingly, a subset of *TOP3A*-associated patients presented unusual phenotypic traits including dilated cardiomyopathy and clinical features of mitochondrial dysfunction. In the current study, we explore the mechanisms of BTRR-complex-related mitochondrial dysfunction in cardiomyopathies.

Methods: We employed BTRR complex knockout (KO) induced pluripotent stem cells to generate cardiomyocytes (iPSC-CMs). We assessed mitochondrial function through live cell imaging and Seahorse-based bioenergetics analysis. Furthermore, we established a high-throughput mtDNA ultra-deep sequencing strategy (30.000 x coverage), to explore mtDNA mutational signatures and evaluate the role of BTRR complex members in mitochondrial genome maintenance and stability.

Results: Our results demonstrate decreased mitochondrial membrane potential and respiration rates in TOP3A-KO iPSC-CMs, but also in RMI1-KO iPSC-CMs, previously thought to be devoid of function in mitochondria. Our mtDNA sequencing approach provides exceptional depth of coverage, enabling precise detection of rare low-frequency mtDNA variants and accurate estimation of heteroplasmy levels.

Conclusion: This study unveils new gene candidates in mtDNA maintenance and mtDNA mutational signatures linked to inherited forms of cardiomyopathy and offers insights into the occurrence and distribution of mtDNA mutations

Grants: Cluster of Excellence MBExC, Göttingen, Germany

P08.038.C Is there a relationship between global 5-methylcytosine and 5-hydroxymethylcytosine levels and metabolic syndrome and its clinical findings?

Sacide Pehlivan[1], *Naci Şenkal[2;3], Yasemin Oyacı[1;3], Ebru Teberik[2], Mustafa Pehlivan[4], Tufan Tükek[2], Alpay Medetalibeyoğlu[2]*

[1]Istanbul Faculty of Medicine, Istanbul University, Department of Medical Biology, Istanbul, Türkyie; [2]Istanbul Faculty of Medicine, Istanbul University, Department of Internal Medicine, Istanbul, Türkyie; [3]Institute of Graduate Studies in Health Sciences, Istanbul University, Istanbul, Türkyie; [4]Basaksehir Cam and Sakura City Hospital, Department of Hematology, Istanbul, Türkyie

Background/Objectives: Metabolic syndrome (MetS) encompasses a set of metabolic features associated with an increased risk of cardiovascular disease and type 2 diabetes. One of the primary epigenetic processes controlling gene expression in eukaryotes is DNA methylation. In this study, we aimed to evaluate the relationship of 5-methylcytosine (5-mC) and 5-hydroxymethylcytosine (5-hmC) levels with MetS and its clinical findings.

Methods: A total of 303 people, 200 MetS patients, and 103 healthy controls were included in the study. The 5-mC and 5-hmC levels were measured quantitatively by the ELISA method using 100 ng of input genomic DNA sample. The relationship of participant characteristics and clinical variables with both 5-mC and 5-hmC levels were evaluated by performing median comparisons and correlation analyses.

Results: The 5-mC levels and 5-mC/5-hmC ratios were significantly increased in the patient group compared to the control group ($p = 0.001$). The 5-mC levels showed a negative correlation with HbA1c, creatinine, and Hb in the patients. Also, a negative correlation was detected in 5-hmC levels with triglyceride, fasting blood sugar, HbA1c, creatinine and a positive correlation was detected with HDL in the patient group.

Conclusion: Our results suggest that 5-mC levels and 5-mC/5-hmC ratios may play a role in the development of MetS. The fact that 5-mC and 5-hmC levels are associated with clinical findings shows that the global methylation profile is effective in the course of the disease. This could be a promising development for the treatment of MetS.

Grants: This study was supported by the Scientific Research Project Coordination Unit of Istanbul University under Grant [number:TOA-2022-39395].

P08.039.D A digenic mechanism for Leigh syndrome on the background of the primary m.11778G>A LHON variant

Beryll Blickhaeuser[1;2], Sarah Stenton[3;4], Lea Dewi Schlieben[1;5], Thomas Klopstock[2], **Holger Prokisch**[1;5]

[1]Institute of Neurogenomics, Computational Health Center, Helmholtz Zentrum München, Germany; [2]Friedrich-Baur-Institute, Department of Neurology, LMU University Hospital, Ludwig-Maximilians-Universität München, Germany; [3]Division of Genetics and Genomics, Boston Children's Hospital, Boston, MA, United States; [4]Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA, United States; [5]School of Medicine, Institute of Human Genetics, Klinikum rechts der Isar, Technical University of Munich, Germany

Consortium: GENOMIT

Background/Objectives: Leigh syndrome spectrum (LSS) is the most frequent clinical manifestation of pediatric mitochondrial disorders characterized by neurodegeneration and bilateral symmetrical lesions in the basal ganglia and/or brainstem. Defects in more than 100 genes spanning the nuclear and mitochondrial genome have been associated with LSS, most commonly related to mitochondrial complex I (CI) dysfunction. Rarely, LSS has been described in association with primary Leber hereditary optic neuropathy (LHON) variants of the mtDNA encoding CI subunits (m.3460G>A in MT-ND1, m.11778G>A in MT-ND4, and m.14484T>C in MT-ND6). The underlying mechanism of how these variants manifest as LSS, a severe neurodegenerative disease, instead of the LHON phenotype of isolated optic neuropathy, is unknown.

Methods: We performed exome sequencing in six patients with LSS carrying primary mtDNA LHON variants. Rare pathogenic nuclear variants were analysed for potential digenic interactions.

Results: In comparison to healthy controls, we found a significant enrichment of heterozygous pathogenic variants in CI subunits in (all) five LSS patients with the m.11778G>A variant, while none of the mtDNA LHON only patients carried a pathogenic variant in CI subunits.

Conclusions: The genetic findings support our hypothesis that the unusually severe clinical manifestation of LSS in patients harbouring the primary m.11778G>A (MT-ND4) LHON variant is caused by a synergistic digenic impairment of CI. This is the second example of digenic inheritance in which the combination of mutations in CI genes changed the phenotype from LHON to LSS.

Conflict of Interest: None declared

P08.040.A *PAH* genotype database: exploring population structure and personalized treatment recommendations for phenylketonuria patients

Polina Gundorova[1], *Mathias Woidy[1], Ania Carolina Muntau[2], Soeren Gersting[1]*

[1]University Medical Center Hamburg-Eppendorf, University Chidren's Research, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, University Children's Hospital, Hamburg, Germany

Background/Objectives: In autosomal-recessive disorders like phenylketonuria (PKU), understanding the combination of alleles within a patient's genotype is crucial for determining disease severity and potential treatment responses. This is especially relevant in PKU, where the genotype influences the efficacy of pharmacological analogues of tetrahydrobiopterin (BH_4), the natural cofactor and chaperone of phenylalanine hydroxylase (PAH).

Methods: An online database was developed to catalog *PAH* genotypes and their respective sequence variants, showcasing their distribution across populations. Additionally, PAH activity landscapes were performed through enzymatic activity assay in a 96-well format, utilizing gradients of L-phenylalanine and BH4 concentrations, with Tyrosine detection via high-performance liquid chromatography.

Results: The online application comprises data on over 10,000 country-specific *PAH* genotypes, offering search and analysis tools to facilitate population genetic research on PKU. Furthermore, the database provides access to functional data, including PAH activity landscapes for over 100 prevalent *PAH* genotypes, enabling personalized BH_4 testing and treatment recommendations for PKU patients.

Conclusion: The systematic organization of scientific publications on sequence variants and genotypes not only aids in population genetic studies but also enhances routine clinical patient care. By providing readily available functional studies, this database drives the advancement of personalized medicine, integrating the latest scientific findings to benefit patients.

P08.041.B Investigating the relationship between biochemical profiles and genotype in inborn errors of metabolism

Clarissa Berardo[1;2], *Alessandra Vasco[2], Simona Lucchi[2], Laura Cappelletti[2], Laura Assunta Saielli[2], Elisa Pratiffi[2], Salvatore Fazzone[2], Erika Benedetti[2], Andrea Meta[2], Alessia Mauri[1;2], Stephana Carelli[1;2], Francesca Furlan[3], Valentina Rovelli[4], Francesca Menni[3], Viola Crescitelli[5], Serena Gasperini[5], Luisella Alberti[2], Cristina Cereda[2]*

[1]University of Milan, Department of Biomedical and Clinical Science, Mil, Italy; [2]Buzzi Children's Hospital, Functional Genomic and Rare Diseases Unit, Department of Pediatrics, Milan, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Pediatric Intensive Care Unit, Milan, Italy; [4]ASST Santi Paolo Carlo Hospital, Clinical Department of Pediatrics, Mi, Italy; [5]Fondazione IRCCS San Gerardo dei Tintori, Pediatric Rare Diseases Unit, Monza, Italy

Background: Newborn screening is a public health program aimed at the rapid detection of treatable inborn errors of metabolism (IEMs), with a considerable rate of false positives. To reduce it, we aim to correlate biochemical markers to the genotype.

Methods: DBS were collected from newborns' heels at 48-72 hours after birth, in Lombardy region (Italy). FIA-MS/MS was performed to evaluate specific biochemical markers on DBS. If required, biochemical confirmation was performed on plasma and/or urine. Genetic confirmation was achieved by Sanger or NGS on newborns referred to clinical center.

Results: In Lombardy region, from 2016 to 2020, 102/386,431 (0.03%) newborns were affected by IEMs: 50% by FAO disorders, 32% by OA disorders, 17% by amino acidemias. We analyzed our data to unravel specific genotype-biochemistry correlation. As expected, the same mutation in homozygosity or heterozygosity in *ASS1* gene for citrullinemia type 1 showed different biochemical profiles. Only one newborn exhibited persisted high citrulline plasmatic levels, being negative to the citrullinemia panel genes. Two tweens with altered long-chain acylcarnitines and 50% of enzymatic activity of the VLCAD protein, resulted to be genetically negative. A newborn with one VUS in *ACADVL* gene showed the corresponding enzymatic activity of only 25%.

Conclusions: These observations show that it is not always possible to establish a correlation between the genotype and the biochemistry in IEMs. Hence, to properly diagnose IEMs, the search for biomarkers should be accompanied not only by clinic and genetic analysis, but also by whole exome sequencing, transcriptomic and long reads analysis.

Conflict of Interest: None declared

P08.042.C Novel discontinuous homozygous deletion in FUT8 leading to Congenital disorder of glycosylation with defective fucosylation 1

Nesligul Hasibe Gonen[1], nurcan ucuncu ergun[2], abdulkadir tekin[3], **sumeyra oguz**[4]

[1]Sanlıurfa Training and Research Hospital, Department of Medical Genetics, Sanlıurfa, Türkyie; [2]Sanlıurfa Training and Research Hospital, Department of Pediatric Nutrition and Metabolism Clinics, Sanlıurfa, Türkyie; [3]Sanlıurfa Training and Research Hospital, Department of Pediatrics, Sanlıurfa, Türkyie; [4]Zeynep Kamil Women and Children's Diseases Training and Research Hospital, Department of Medical Genetics, Istanbul, Türkyie

Background/Objectives: FUT8-Congenital disorder of glycosylation (FUT8-CDG, MIM #618005) is due to biallelic loss-of-function mutations of *FUT8*, encoding alpha 1,6 fucosyltransferase crucial for posttranslational modification that takes place in mammalian cells. FUT8-CDG is limited to nine individuals presenting with intrauterine growth retardation (IUGR), severe postnatal growth-developmental delays, recurrent respiratory infections, feeding problems, short limbs and neurological impairments.

Methods and results: The 8-month-old male proband, born to consanguineous parents via caesarean section due to IUGR and polyhydramnios, exhibited dysmorphic features, especially shortened lower extremities and severe growth-developmental delays. His affected sibling had polyhydramnios, IUGR, feeding problems and epilepsy and died at 1,5 months without a definitive diagnosis. The proband passed away at 10 months due to recurrent respiratory tract infections, feeding problems and refractory seizures. Targeted epilepsy gene panel analysis showed no disease-causing mutation. However, chromosomal microarray analysis revealed two discontinuous homozygous deletions at 14q23.3. Whilst, proximal deletion (~89 kb) (chr14:65,821,471-65,910,544; hg19) encompassed complete non-coding first exon, partial 5'UTR and first intron of *FUT8*, there was no coding gene in distal deletion (~229 kb) (chr14:66,214,378-66,444,344; hg19). Segregation studies are ongoing for these deletions.

Conclusion: Here, we present the tenth affected individual with FUT8-CDG in the literature. Although single nucleotide variations have been described in FUT8-CDG so far, our study shows that copy number variations can also be included in its molecular etiology. *FUT8* deletion in this study may have produced a loss-of-function effect by causing inhibition of transcription initiation through the deletion of the promoter region or impairment of post-transcriptional modification due to deletion of untranslated regions.

Background/Objectives: Thioredoxin interacting protein, encoded by *TXNIP*, has been described to regulate systemic glucose metabolism in mice, making it an attractive target for the treatment of type 2 diabetes mellitus. However, recent findings link biallelic variants in *TXNIP* to cause a mitochondrial disorder in humans. Our research therefore investigates the effects of *TXNIP* variants on human glucose and lipid metabolism and studies potential therapeutic interventions in preclinical models.

Methods: The clinical presentation of eight patients with biallelic *TXNIP* variants and available plasma, organ samples, and fibroblasts were investigated using gene and protein expression studies, lipidomics, proteomics, histology and electron microscopy. To explore potential therapies, we treated patient fibroblasts and TXNIP-KO mice with pharmacological and dietary interventions.

Results: The patients presented with a range of clinical symptoms with an overlap in lactic acidosis, whereas hypoglycemia, combined dyslipidemia and cardiac and skeletal myopathy were variably present. Patient organ biopsies revealed the presence of glycogen and lipid deposits. Gene expression analysis indicated increased de novo fatty acid synthesis, which was resembled in TXNIP-KO mice and reversible by feeding low-carb diet in mice.

Conclusion: We introduce TXNIP to influence glucose and lipid metabolism in humans. Biallelic variants in *TXNIP* are associated with hypoglycemia and dyslipidemia, as well as muscular and hepatic lipid accumulation resulting from increased de novo fatty acid synthesis. Using preclinical models, we present a low-carb diet as a possible dietary symptomatic treatment for pathologically elevated organ lipid synthesis.

Andersen Children's and Youth Hospital, Odense, Denmark;* [4]*Odense University Hospital, Departement of Ophthalmology, Odense;* [5]*Odense University Hospital, Departement of Clinical Genetics, Odense;* [6]*Rigshospitalet, Departement of Clinical Genetics, København Ø, Denmark;* [7]*Sygehus Lillebaelt, Departement of Clinical Genetics, Vejle, Denmark*

Background: Biallelic variants in the *FDXR* gene, encoding ferredoxin reductase, are associated with a rare autosomal recessive progressive neurologic disorder characterized by visual impairment neuropathy, and hearing loss. Ferredoxin reductase is vital for iron-sulfur cluster biogenesis, impacting essential cellular processes such as mitochondrial respiratory chain function and iron homeostasis. We present two unrelated children carrying biallelic *FDXR* variants, one of which includes a suspected splicing variant, detected in both children.

Methods/Results: Individual 1, a 6-year-old girl, exhibited progressive visual impairment due to retinopathy, developmental delay, an unsteady gait, and tactile discomfort. Trio WGS detected two compound heterozygous variants of uncertain significance (VUS) in the *FDXR* gene: c.1402C>T, p.(Arg468Trp), and c.271-14G>A.

Individual 2, a 2-year-old boy, developed progressive retinopathy, hypotonia, dystonia and ataxia following a viral infection at the age of 1. He also exhibited touch-related discomfort on his lower legs. Trio WGS detected two compound heterozygous VUS' in the *FDXR* gene: c.310C>T, p.(Arg104Cys), and interestingly he also carried the intronic variant similar to individual 1, c.271-14G>A.

The c.271-14G>A variant was predicted to introduce a new splice acceptor site 14bp downstream of exon 4, indicating af longer transcript. Ongoing RNA analysis aims to classify the variant.

Conclusion: We present two unrelated patients with progressive retinopathy, motor dysfunction, and signs of peripheral neuropathy. Trio WGS revealed compound heterozygosity for two variants of uncertain significance in *FDXR*. Interestingly, one variant, c.271-14A>G, was observed in both individuals, supporting the possibility that this variant might indeed be pathogenic, thus reinforcing the diagnosis of *FDXR*-associated disease.

P08.045.B New case of MEDNIK syndrome: feeding related non-motor seizures could be a new feature?

Adelaide Peruzzi[1;2], *Francesca Peluso*[2], *anna cavalli*[3], *daniele frattini*[3], *giovanni malmusi*[4], *Roberta Zuntini*[2], *gianluca contrò*[2], *Antonio Novelli*[5], *giancarlo gargano*[4], *Carlo Fusco*[3], *Livia Garavelli*[2]

[1]*Alma Mater Studiorum - Università di Bologna, Department of Medical and Surgical Science, Bologna, Italy;* [2]*Azienda USL - IRCCS di Reggio Emilia, Medical Genetics Unit, Reggio Emilia, Italy;* [3]*Azienda USL - IRCCS di Reggio Emilia, Child Neurology and Psychiatry Unit, Reggio Emilia;* [4]*Azienda USL - IRCCS di Reggio Emilia, Neonatal Intensive Care Unit, Department of Mother and Child, Reggio Emilia, Italy;* [5]*Bambino Gesù Children's Hospital, IRCCS, Laboratory of Medical Genetics, Translational Cytogenomics Research Unit, Roma, Italy*

Background/Objectives: MEDNIK Syndrome (MS) is a neurocutaneous disease associated with biallelic variants of the *AP1S1* gene. The involvement is multisystemic and includes ichthyosis, intellectual disability, deafness, peripheral neuropathy and a severe enteropathy often resulting in neonatal mortality. To date, only 14 cases have been reported in literature. We present the clinical course of a newborn girl with MS and a review of the literature.

Methods: SNP Array analysis revealed multiple regions of homozygosity. Subsequent clinical exome analysis identified the homozygous c.256C>T p.(Arg86Ter) variant in the *AP1S1* gene, resulting in a premature stop codon confirming the diagnosis.

Results: A girl, third child of consanguineous parents, born at term, presented since birth congenital non-infectious diarrhea. At 15 days of age, breastfeeding was ceased and total parenteral nutrition (TPN) was introduced. At 23 days of age, re-feeding was attempted but failed due to recrudescence of enteropathy and simultaneous onset of focal epileptic non-motor seizures, which resolved upon reinstating TPN. At 4 months of age, she was weaned of TPN and from 6 months onwards, she remained seizure free with anti-epileptic therapy and zinc-acetate supplementation. Additionally, she presented with ichthyosis, mild hearing loss and hyporigenerative anaemia. At 2 years of age she showed axial hypotonia, psychomotor delay and growth retardation.

Conclusion: Given the rarity of the condition, the high neonatal mortality and the limited therapeutic options available, we present this case along with a review of the literature, outlining the main clinical and molecular aspects of the disease including electrophysiological features never reported before.

P08.046.C Mucopolysaccharidosis plus syndrome within identical twins having *VPS33A* and *VPS11* mutations

Ibrahim Akalin[1], *Fatih Demircioğlu*[2], *Nursel Elcioglu*[3], *Ayse Busra Akalin*[4], *Betül Tavil*[2]

[1]*Metagentech Center for Genetic Diseases, Medical Genetics, Istanbul, Türkyie;* [2]*Medistate Hospital, Pediatric Hematology, Istanbul, Türkyie;* [3]*Marmara University Faculty of Medicine, Pediatric Genetics, Istanbul, Türkyie;* [4]*Bahçeşehir University Faculty of Medicine, Medicine, Istanbul, Türkyie*

Background/Objectives: Mucopolysaccharidosis-plus syndrome (MPSPS) is inherited autosomal recessively in VPS33A gene and is an inborn error of metabolism result from diminished class C core vacuole/endosome tethering (CORVET) and the homotypic fusion and protein sorting (HOPS) complexes. Both are heterohexamers and consist of 4 subunits consisting of VPS33A, VPS11, VPS16 and VPS18. It presents with typical symptoms of mucopolysaccharidosis, as well as respiratory difficulties, congenital heart defects, renal and hematopoietic system disorders and delayed psychomotor activity in infants and early childhood. Most of the patients die because of cardiorespiratory failure in the beginning of their lives.

Methods: Two identical twins aged 3 year-old referred for genetic testing for undiagnosed cases whom represent dismorphic face, immunodeficiency, hepatomegaly, lethargy, distended abdomen, difficulty for breathing. One of the patient passed away due to worsening general conditions. Whole exam sequencing was run.

Results: WES analyses revealed heterozygous VPS33A (c.599G>A (p.Arg200Gln)), homozygous VPS11(c.101_103delATCinsGTT) and homozygous PRKDC (c.496dupA (p.I166Nfs*11)) mutations including PRKDC exon 5 an 23 deletions.

Conclusion: Mutations found in our patient suggesting a defect in endo-lysosomal pathway bey diminishing CORVET/HOPS complex not only with VPS33A but also with VPS11 and resulting the severe MPSPS with neurological components. Moreover, PRKDC mutations might be accomplished to immunodeficiency symptoms.

P08.047.D Characterising MRPL44(L156R) transgenic mouse model: insights into mitochondrial disorder pathogenesis and sex-dependent responses

Hamin Lee[1], *Chris Carroll*[1], *Alan Pittman*[1], *Susanna Cooper*[2]

[1]*St. George's, University of London, London, United Kingdom;* [2]*Oxford University, Oxford, United Kingdom*

Background/Objectives: Phenotypic heterogeneity is a hallmark of primary mitochondrial diseases (PMD). However, little is known about why variants in the oxidative phosphorylation (OXPHOS) system can lead to such variable and often tissue-specific disorders. We investigated whether biological sex modulates disease manifestation in response to mitochondrial dysfunction in PMD. Therefore, we generated MRPL44(L156R) transgenic knockin mice as a model of combined OXPHOS deficiency 16 and evaluated sex-specific differences in the disease pathogenesis of affected tissues.

Methods: MRPL44^{L156R} mice were generated using CRISPR. Tissues were harvested from young and mature MRPL44^{L156R} homozygous and wildtype mice, processed for histopathology, and molecular analyses of mitochondrial structure, content, and function. Additionally, RNA sequencing investigated the effect of the mutation on gene expression.

Results: The L156R variant destabilized the MRPL44 protein, impacting mitoribosomal large subunit assembly, leading to mitochondrial translation defects presenting as Complex I + Complex IV OXPHOS deficiency. Despite the marked biochemical deficiency, only mild tissue pathology was observed, indicating compensatory pathways activation, in line with the evidence of increased mitochondrial biogenesis. Females exhibited more severe OXPHOS and mitoribosome deficiency, along with induction of cardiomyocyte hypertrophy and inflammation markers. Transcriptomics unveiled a diametrically opposite response in mitochondria-related genes, with induction in females and reduction in males.

Conclusion: Our findings establish the MRPL44^{L156R} mouse model as a promising tool for studying mitochondrial diseases, elucidating the significance of sex specificity in these disorders. Moreover, our study identified a novel sex-specific mitochondrial-nucleus retrograde signalling pathway critical in PMD manifestation and respsonses to therapies targeting mitochondrial biogenesis.

P08.048.A The landscape of autosomal-recessive pathogenic variants, consanguinity and homozygozity detected on newborn screening

Janne Maren Strand[1], *Trine Tangeraas*[1], *Emma Sofia Lundman*[1], *Silje Hogner*[1], *William Nicholas Tourniaire*[1], *Mari Eknes Ytre-Arne*[1], *Magnus Odin Dahlseng*[1], *Julie Hellem AAby*[1], *Andreas Øberg*[1], **Asbjørg Stray-Pedersen**[1]

[1]*Oslo universitetssykehus HF, Rikshospitalet, Norwegian National Unit for Newborn Screening, Oslo, Norway*

Consortium: NEWBORN SCREENING NORWAY

Background: In silico calculations predicts overrepresentation of positive newborn screening (NBS) among children with consanguineous parents. We present our numbers focusing on the screening disorders with an autosomal recessive (AR) trait. The Norwegian NBS program is regulated by an exception from the Biotechnology Act allowing for mass genetic screening for specific disorders. Genetic testing of DNA extracted from the blood-spots is used as confirmatory test prior to reporting a positive screening and clinical follow-up of the child.

Methods: The sequencing results from positive screening during the years 2019-2023 were selected, and variants in AR NBS disorders sorted into two groups: the compound heterozygous and homozygous. Information about ethnicity and parental consanguinity are part of the clinical evaluation at the follow-up consultations.

Results: Out of 267 563 newborns tested during 2019-2023, 227 were reported with an AR NBS disorder, 81 compound heterozygous, 46 homozygous. Out of the 46 with homozygous disease causing variants, 27 had parents without history of consanguinity, while 13 had consanguineous parents, and 12 of these couples were first cousins. In 6 of the newborns with homozygous disease causing variants, parental consanguinity was expected, but not confirmed. The ethnic origin of the confirmed consanguineous couples: Iraq, Syria, Afghan, Pakistan, Kurdistan, and Somalia.

Conclusion: Based on our numbers of reported newborns with abnormal results from the NBS and an AR NBS disorder, the true risk for unrelated couples in the general population to have a baby with a NBS disorder and the risk for consanguineous couples can be calculated.

Background/Objectives: Current research highlights nutrigenetic effects on quality of life. The present explores gene-diet interactions and quality of life in adult participants of the iMPROVE study presenting overweight or obesity, following a 3-month high-protein or high-carbohydrate hypocaloric diet.

Methods: We used data from 80 participants to measure associations between the observed changes in physical and mental health post-intervention and 10 BMI-associated, candidate variants. Quality of life was assessed using the 12-item Short Form Survey (SF-12) physical (SF-PCS-12) and mental (SF-MCS-12) components. The level of statistical significance was corrected based on the Bonferroni method. Associations were examined through linear regression models adjusted for age and sex, using the PLINK version 1.9.

Results: SF-PCS-12 and SF-MCS were not significantly improved post-Intervention. Increase in SF-PCS-12 post-intervention was significantly lower among carriers of the BMI-raising rs17817449-G allele ($\beta = -3.758$, $p = 0.009$) and nominally lower among rs9939609-A alllele carriers ($\beta = -3.202$, $p = 0.028$). Increased SF-MCS-12 levels post-intervention were positively, nominally associated with four examined variants (rs1421085-C, rs1121980-A, rs17817449-G and rs9939609-A, $p < 0.05$ for all).

Conclusion: Although increase in SF-PCS-12 levels was lower in carriers of BMI-raising alleles, specific variants were associated

with higher levels of SF-MCS-12 increase. This denotes a favorable effect of a weight loss intervention on mental characteristics, even in the presence of favorable genetic makeup for increased BMI.

Grants: The BETTER4U project has received funding from the European Union's Horizon Europe Research and Innovation programme under Grant Agreement n° 101080117.

P08.050.C A pathogenic deep intronic variant in the PCCB gene masked by a common benign intronic deletion

Alina Kurolap[1], *dalit barel*[1], *Nava Shaul Lotan*[2], *Isaiah Wexler*[3;4], *Hofit Gadot*[1], *Adi Mory*[1], *Ortal Barel Barel*[5], *shlomo almashano*[6], *Hagit Baris Feldman*[1;7]

[1]*Tel Aviv Sourasky Medical Center, The Genetics Institute and Genomics Center, Israel;* [2]*Hadassah Medical Organization, Department of Genetics, Israel;* [3]*Hadassah Medical Organization, Department of Pediatrics, Israel;* [4]*Hebrew University of Jerusalem, Faculty of Medicine, Israel;* [5]*Sheba Medical Center, Genomics Unit, the Center for Cancer Research, Israel;* [6]*Public Health Services, Ministry of Health, National Newborn Screening Program, Israel;* [7]*Tel Aviv University, Faculty of Medicine, Israel*

Background/Objectives: Propionic acidemia (PA) is a metabolic disorder caused by bi-allelic variants in either *PCCA* or *PCCB*, encoding the propionyl-CoA carboxylase (PCC) enzyme sub-units. PCC is required for catabolism of certain amino acids and odd-chain fatty acids. In its absence, toxic metabolites accumulate, leading to a variable presentation, including metabolic acidosis, neurologic symptoms, multi-organ dysfunction and possible death, with typical neonatal or early infantile onset.

Methods: Exome sequencing (ES) followed by genome sequencing (GS) were used to identify the genetic cause of PA in two unrelated children initially diagnosed by newborn screening and enzymatic studies. RNA analyses were performed to study variant outcomes.

Results: ES failed to identify a pathogenic variant. We proceeded with GS, demonstrating homozygosity for a deep intronic *PCCB* variant. RNA studies established that this variant creates an out-of-frame pseudoexon, leading to loss of wild type *PCCB* expression. Surprisingly, three of the variant-carrier parents also appeared homozygous due to a common benign intronic deletion on the second allele.

Conclusion: Reaching a precise diagnosis, whether biochemical or genetic, can be crucial in directing lifesaving care, concluding the diagnostic odyssey, and allowing future family planning. This study demonstrates the power of integrative genetic studies in reaching a diagnosis, utilizing GS and RNA analyses to overcome ES limitations and define variant pathogenicity. Importantly, the presumed parental homozygosity merits special attention, as it initially masked the causative variant. Intronic deletions should be taken into consideration when analyzing genomic data to avoid misinterpretation of pseudo-homozygosity and mislabeling pathogenic variants as benign.

Conflict of Interest: None declared

P08.051.D Estimation of prevalence of Leigh Syndrome caused by three major nuclear genes mutations (*SURF1*, *SCO2*, and *NDUFV1*) in the Russian Federation

Denis Chistol[1], *Polina Tsygankova*[1], *Andrey Nekrasov*[1], *Nikita Beskorovayny*[2], *Ekaterina Zakharova*[1]

[1]*Research Centre for Medical Genetics, Laboratory of Inherited Metabolic Diseases, Moscow, Russian Federation;* [2]*Research Centre for Medical Genetics, Moscow, Russian Federation*

Background/Objectives: Leigh syndrome (LS) is the most common mitochondrial disorder in children, characterized by progressive neurological manifestations. The prevalence of LS and Leigh-like syndrome is usually estimated at 1:40,000 newborns, but the exact prevalence of LS in the Russian Federation is unknown. Our study presents an estimate of the prevalence of LS caused by the mutations in three major nuclear genes (*SURF1*, *SCO2* and *NDUFV1*) in the Russian Federation. *SURF1*, *SCO2* assumed to have founder mutations in Slavonic population.

Methods: We used the Russian Massive Parallel Sequencing dataset to approximate the prevalence of LS (total allele number = 18,012). For variant classification, we used the Franklin resource, which also classifies variants based on ACMG-AMP recommendations. Additional manual classification was performed for some variants based on knowledge accumulated in the laboratory of inherited metabolic diseases.

Results: For each gene, only those variants from the RuExac and Ruseq databases that were predicted to be pathogenic or probably pathogenic were included. The disease rate for each gene was calculated using the gene carrier rate (GCR). For each GCR we calculated a 95% CI (Wilson method): for *SURF1* = 1:237,419 (95%CI 1:127,849-1:441,248), for *SCO2* = 1:213,531 (95% CI 1:110,872-1:411,636), and for *NDUFV1* = 1:4,135,588 (95%CI 1:1,147,133-1:14,921,927).

Conclusion: The cumulative incidence of nuclear genes-associated LS in the Russian Federation is ~ 1:45,000. Based on our LS registry mtDNA-associated LS accounts not less than 1/3 of all cases. So the final estimation will be not less than 1:30,000. Which is probably the highest prevalence in the world.

Conflict of Interest: None declared

P08.052.A UCHL1 missense and loss-of-function variants as an emerging cause of autosomal dominant optic atrophy (ADOA)

Claudio Fiorini[1], *Giada Capirossi*[1;2], **Eleonora Pizzi**[1], *Federico Sadun*[3], *Maria Lucia Cascavilla*[4], *Chiara La Morgia*[1;2], *Marco Battista*[4], *Piero Barboni*[4], *Danara Ormanbekova*[1], *Valentina Del Dotto*[2], *Flavia Palombo*[1], *Valerio Carelli*[1;2], *Alessandra Maresca*[1], *Leonardo Caporali*[1;2]

[1]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Programma di Neurogenetica, Bologna, Italy;* [2]*University of Bologna, Department of Biomedical and NeuroMotor Sciences (DIBINEM), Bologna, Italy;* [3]*Ospedale Oftalmico, Roma, Italy;* [4]*University Vita-Salute, IRCCS Ospedale San Raffaele, Department of Ophthalmology, Milano, Italy*

Background/Objectives: The ubiquitin carboxyl-terminal hydrolase isozyme L1 (*UCH-L1*) is a deubiquitinating enzyme highly expressed in neurons, where it solely accounts for 1-2% of total cytosolic proteins. Recently, several pedigrees were described with autosomal dominant hereditary spastic paraplegia (HSP) and optic atrophy due to heterozygous *UCHL1* loss-of-function variants.

Methods: We performed WES for a cohort of 249 hereditary optic neuropathies patients, adding phenotypic characterization experiments on fibroblasts derived from probands carrying novel likely pathogenic variants through RNA sequencing, immunoblotting and cellular respiration analysis.

Results: We identified two pedigrees harboring heterozygous variants in the *UCHL1* gene, segregating with a phenotype of isolated dominant optic atrophy (DOA). Family 1 members carry a splice-site variant (c.586-2A>C), while Family 2 members carry a missense variant with a predicted deleterious effect (c.284T>G, p.Leu95Arg). On Family 1 proband fibroblasts, we confirmed a marked reduction in UCH-L1 protein and a decrease in OXPHOS complexes subunits, especially significant for complex I and IV. No cellular respiration phenotype was evident, with only a higher glycolytic acidification profile in mutant cells. In addition, we

observed a significant reduction of pyruvate dehydrogenase E2 and E3 subunits and of citrate synthase levels. Moreover, by incubation with galactose medium for 48 h, both control and mutant cell lines showed an induced mitochondrial biogenesis with recovery of all protein levels.

Conclusion: In conclusion, we present heterozygous variants in *UCHL1* as a new cause of DOA, widening the phenotypic spectrum associated with *UCHL1* defect, possibly accompanied by metabolic rewiring and secondary mitochondrial dysfunction.

Grant: Italian Ministry of Health grant GR-2016-02361449.

Background/Objectives: Maple syrup urine disease (MSUD) is a rare inherited metabolic disorder characterized by deficient activity of the branched-chain alpha-ketoacid dehydrogenase (BCKD) complex, required to metabolize the amino acids leucine, isoleucine and valine. Despite its profound metabolic implications, the molecular alterations underlying this metabolic impairment had not yet been elucidated.

Methods: We performed a comprehensive multi-omics integration analysis, including genomic, epigenomic and transcriptomic data from fibroblasts derived from a cohort of MSUD patients and unaffected controls to genetically characterize a MSUD case and to unravel the MSUD pathophysiology.

Results: The integration of multi-omics layers facilitated the identification of a strong epigenetic repression in the *DBT* promoter in a patient wherein no BCKD pathogenic variants had been detected, thereby unveiling alternative modes of disease inheritance and confirming its diagnosis potential. Furthermore, MSUD patients exhibit a defined episignature that reshapes the global DNA methylation landscape, resulting in the stimulation of HOX cluster genes and the restriction of cell cycle gene-related signatures. Subsequent data integration revealed the impact of AP1-related and CEBPB transcription factors on the observed molecular reorganization, with MEIS1 emerging as a potential downstream candidate affected by robust epigenetic repression in MSUD patients.

Conclusion: Integration of multi-omics data unveiled underlying molecular networks rewired in MSUD patients and represents a powerful approach with diagnostic potential for rare genetic disorders with unknown genetic bases.

IMMUNOLOGY AND HEMATOPOIETIC SYSTEM

P09.001.C Score-Based Candidate Gene Identification in Inborn Errors of Immunity

Claire Dudler[1], *Amica Müller-Nedebock*[1], *Maria Fasshauer*[2;3], *Stephan Borte*[2;3], *Marie Gerisch*[2;3], *Rami Abou Jamra*[1], *Isabell Schumann*[1]

[1]*Institute of Human Genetics, University of Leipzig Medical Center, Leipzig, Germany;* [2]*St. Georg Hospital, IDCL (ImmunDefectCentrum Leipzig), Leipzig, Germany;* [3]*St. Georg Hospital, Center for Pediatric and Adolescent Medicine, Leipzig, Germany*

Background/Objectives: Inborn Errors of Immunity (IEI) exhibit considerable heterogeneity in clinical presentation, age of onset, impact of exogenous factors, penetrance as well as expressivity. Our in-house exome sequencing (ES) diagnostic yield for IEI individuals is currently only 18%. Thus, in this study, we aimed to reanalyse the ES data from unsolved IEI cases to identify new candidate genes. Furthermore, we set out to create a scoring tool incorporating gene- and variant-specific attributes to aid the identification of such IEI candidate genes.

Methods: The cohort consisted of 178 individuals with disorders of the immune system, who had undergone ES diagnostics but remained without genetic diagnosis. We searched for single nucleotide variants (SNVs) and applied filtering steps with regard to quality, in-silico predictions, impact and frequency. Subsequently we reviewed the selected variants and outlined a scoring tool incorporating these steps.

Results: We were able to identify several candidate genes (e.g. *PRKCB, PTK2B, GIT2, PDE7A, LGALS1, GCNT1, PPT2, GRWD1, FLOT1, CETP* and *MYO7B*) that are promising regarding the deleteriousness of the variant, tissue-specific expression, phenotypes of animal models, and predicted protein-protein interactions. We subsequently uploaded our findings to GeneMatcher to compare the potential phenotypic spectrum of the identified candidate genes.

Conclusion: With a focused approach to identifying candidate genes and efficiently estimating their relevance, we aim to increase the likelihood of detecting novel genes associated with IEI and improving future diagnostic yield.

Grants: None.

Conflict of Interest: None declared

P09.002.D Dissecting genetic susceptibility to Zika virus

Marie Bourdon[1;2;3], *Caroline Manet*[3], *Laurine Conquet*[3], *Corentin Ramaugé Parra*[3], *Etienne Kornobis*[4], *Eliette Bonnefoy*[5], *Xavier Montagutelli*[3]

[1]*LMU Klinikum, Comprehensive Childhood Research Center, München, Germany;* [2]*Helmholtz Munich, Neuherberg, Germany;* [3]*Institut Pasteur, Laboratoire de génétique de la souris, Paris, France;* [4]*Institut Pasteur, Biomics, Paris, France;* [5]*Institut Cochin, Inserm, Paris, France*

Background/Objectives: Zika virus (ZIKV) is a flavivirus transmitted by mosquitoes and responsible, for infections which consequences range from an absence of symptoms to severe complications. Using the Collaborative Cross, a collection of mouse inbred strains with large genetic diversity, we previously showed that host genetics affects the severity of symptoms and plasma viral load. CC071 was identified as the most susceptible

strain, characterized by high virus replication, severe clinical signs, and mortality. In vitro, CC071 mouse embryonic fibroblasts (MEFs) showed an increased viral titer and a delayed production of type I interferon.

Methods: The genetic factors associated with the susceptibility of CC071 was assessed using a backcross between CC071 and the resistant strain CC001. 51 unique MEF lines were derived and phenotyped after ZIKV infection. Embryos were genotyped using the MiniMUGA chip array.

Results: Phenotypic analysis of infected backcross MEFs suggested a monogenic inheritance of ZIKV susceptibility and QTL mapping analysis identified *Irf3* (one of the interferon transcription factors) as a strong candidate gene. RNA sequencing showed that the CC071 strain has a de novo mutation in *Irf3* which leads to abnormal splicing. However, after in vivo ZIKV infection, CC071 mice exhibited higher susceptibility than C57BL/6J *Irf3* KO mice, demonstrating the involvement of other susceptibility genes in the disease of CC071 mice.

Conclusion: Our results provide new insight into the in vitro and in vivo roles of *Irf3*, and into the genetic complexity of host responses to flaviviruses.

P09.003.A Comprehensive and Integrative Single Cell Multi-omics Analysis of the Immune System of Private Mission Astronauts

JANGKEUN KIM[1], *Christopher E. Mason*[1], *Eliah Overbey*[1], *Braden Tierney*[1], *Deena Najjar*[1], *Krista Ryon*[1], *Cem Meydan*[1], *Jaime Mateus*[2], *Marissa Rosenberg*[2]

[1]*Weill cornell medicine, New York, United States;* [2]*SpaceX, Hawthorne, United States*

Background/objectives: Changes in immune function related to spaceflight are a common phenotype in astronauts, yet it remains poorly understood. Recent civilian astronaut missions, Inspiration4, Polaris Dawn, and Axiom-2 missions enabled single-cell multi-omics analysis, which enabled a state-of-the-art, multi-omic, single-cell profiling to address the gaps in our knowledge of the cellular response to space.

Methods: To better understand the immune response in human spaceflight, we generated single-cell, multi-ome, cell-free RNA (cfRNA), biochemical, and hematology data for the civilian astronauts from Inspiration4, Polaris Dawn, and Axiom-2 across pre-, in- and post-flight timepoints. We also integrated single-cell PBMC data with the NASA Twins Study, a set of 817 NASA GeneLab mouse transcriptomics, and other omics data from Inspiration4 to compare the changes in different samples.

Results: We found cell proportion, gene expression, chromatin accessibility, and overrepresented DNA motifs in differentially accessible regions after spaceflight. Also, we found that those biological changes mostly revert back to normal within a few months after spaceflight. We then identified a spaceflight gene signature of astronauts, representatively OXPHOS, translation, and UV response. This spaceflight signature was also observed in the other astronaut and spaceflight data.

Conclusion: In conclusion, these convergent signatures of spaceflight begin to detail the core, consistent set of human cellular and molecular responses to spaceflight and can help narrow the targets for countermeasures and monitoring in future studies. Moreover, any potential long-term changes need to be monitored longitudinally to scan for any reversion or exacerbation of the phenotypes before pharmacological or biomedical interventions can be considered.

Grants: Not applicable

P09.005.C Meta-analysis of determinants of trans-acting regulatory variation in primary human monocytes across immune contexts

Isar Nassiri[1;2], *James Gilchrist*[3], *Julian C Knight*[4], *Benjamin Fairfax*[3]

[1]*University of Oxford, Department of Psychiatry, Oxford, United Kingdom;* [2]*Oxford-GSK Institute of Molecular and Computational Medicine (IMCM), Nuffield Department of Medicine, Oxford, United Kingdom;* [3]*University of Oxford, Department of Oncology, Oxford, United Kingdom;* [4]*University of Oxford, Centre for Human Genetics, Nuffield Department of Medicine, Oxford, United Kingdom*

Background: Characterizing the downstream regulatory impact of genetic variants on global gene expression changes remains a major challenge. Trans-acting expression quantitative trait locus (eQTL) provide agnostic insights into transcriptional pathways, and we have previously demonstrated that trans-eQTL in monocytes frequently involve master regulatory regions. To increase the statistical power, we carried out an eQTL meta-analysis in primary human monocyte samples and replicated the results.

Methods: We systematically explored the trans eQTL meta-analysis in post-exposure to lipopolysaccharide (LPS) or IFNγ monocytes. We performed an eQTL meta-analysis on 509 primary human monocyte samples and replicated the analysis using 100bp paired-end RNA-seq from a new cohort of 185 healthy Europeans.

Results: A total of 1635 trans-acting eQTL (FDR < 1^{-10}) were identified and replicated across treated conditions, with 19 of them being new master regulatory loci (those with > 5 trans associated genes). By using RNA-seq, we replicated 94% (14/15) of previously described master regulatory loci and confirmed their biological importance. To improve our understanding of trans-acting genetic variation, we incorporated associations with GWAS summary statistics for 84 complex traits. The enrichment of eSNPs in multiple sclerosis, celiac disease, and cancer traits was observed in treated monocyte cells. Finally, our allele-specific trans analysis revealed sparse gene networks where all genes exhibited similar expression patterns and were influenced by genetic variants.

Conclusions: The results provide insight into the downstream effects of genetic variants in induced monocytes linked to etiology of autoimmunity and cancer diseases.

[1]Institute for Human Genetics and Genomic Medicine, Medical Faculty, RWTH Aachen University, Aachen, Germany; [2]Center for Integrated Oncology Aachen Bonn Cologne Düsseldorf (CIO ABCD), Germany; [3]Department of Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, Medical Faculty, RWTH Aachen University, Aachen, Germany; [4]Institute for Human Genetics, University of Würzburg, Würzburg, Germany; [5]Institute for Human Genetics, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany; [6]Department of Internal Medicine III, University Hospital Regensburg, Regensburg, Germany

Background/Objectives: Telomere Biology Disorders (TBD) are characterized by accelerated loss of telomeres. Bone marrow transplantation (BMT) can be a treatment option for hematological complications of TBD e.g. bone marrow failure (BMF). Here we report on three patients with TBD, who received a BMT from an asymptomatic matched family donor (MFD) also carrying an until then unrecognized germline variant for TBD.

Methods: All patients were included in the Aachen Telomere Registry. After obtaining informed consent, genetic analyses were performed, and clinical data were collected and analyzed.

Results: Patient 1 (NM_198253.3(*TERT*):c.2266C>T,-p.(Arg756Cys), homozygous) received a BMT from his brother (*TERT*:c.2266C>T,p.(Arg756Cys), heterozygous) at the age of 7, Patient 2 (NR_001566.1*(TERC):n.50C>A*, heterozygous) from her father (NM_032957.5(*RTEL1*):c.3604C>T,p.(Gln1202*), heterozygous) at the age of 5 and patient 3 (NM_198253.3(*TERT*):c.2851C>T,p.(Arg951Trp), heterozygous) from his identical twin brother at the age of 40. Surprisingly, two patients had had sufficient hematopoiesis for over 20 years without signs of BMF. In patient 3, BMF occurred nine years after BMT concurrently with a BMF in his twin brother. Telomere length testing showed premature telomere shortening in all three patients.

Conclusion: Here we provide evidence from three families that genetic testing of index patients with an unexplained BMF followed by their putative family donors prior to BMT could minimize the risk of transplanted TBD. If alternative donors are not available, BMT from a MFD with a pathogenic germline variant may represent a therapeutic option for BMF resulting in an improved clinical situation.

P09.007.A Pilot study: Use of GestaltMatcher as a tool for the diagnosis of monogenetic Inborn Errors of Immunity

Annabelle Arlt[1], *Hannah Klinkhammer[1;2], Sandra von Hardenberg[3], Peter Krawitz[1], Tim Niehues[4]*

[1]Institute for Genomic Statistics and Bioinformatics, University Hospital Bonn, Bonn, Germany; [2]Institute for Medical Biometry, University Hospital Bonn, Bonn; [3]Department of Human Genetics, Hannover Medical School, Hannover; [4]HELIOS Childrens Hospital Krefeld, Krefeld

Background: GestaltMatcher is an artificial intelligence that has been developed to analyze phenotypic features in medical imaging data of patients with rare diseases and enables clinicians to match patients with facial similarity.

Inborn errors of immunity (IEI) encompass nearly 500 monogenic disorders characterized by susceptibility to infections, immunodysregulation and bone marrow failure. Due to their phenotypic variability, IEI are difficult to recognize. At the same time, a delay of diagnosis is associated with a significantly poorer outcome. We hypothesized that GestaltMatcher can be used to accelerate the clinical diagnosis of IEI patients associated with syndromic features.

Methods: An expert committee classified IEI into categories based upon the segment of the immune system that is affected. In the category of IEI with facial dysmorphisms, we applied GestaltMatcher for individuals diagnosed to have IEI. Here, we analyzed 19 images from patients with Nijmegen breakage syndrome, 100 images from patients with Kabuki syndrome and 16 images from patients with DiGeorge syndrome. These cohorts are compared to cohorts with different genetic disorders that were randomly sampled from the GestaltMatcher database (GMDB).

Results: Our statistical analysis showed that the Nijmegen breakage and Kabuki syndrome exhibit a recognizable facial gestalt, whereas the DiGeorge syndrome has less distinct features.

Conclusion: Our results indicate that facial dysmorphism in IEIs can be detected with GestaltMatcher and suggest that its application could accelerate the diagnosis of such disorders.

Background/Objectives: Fanconi anemia (FA) is a clinically variable and genetically heterogeneous cancer-predisposing disorder representing the most common bone marrow failure syndrome. It is caused by inactivating predominantly biallelic mutations in >20 genes with roles in the FA/BRCA DNA repair pathway. Molecular diagnosis of FA is challenging due to the wide mutational spectrum, requiring the assessment of chromosomal fragility with DNA cross-linking agents to definitively confirm diagnosis.

Methods: We assessed peripheral blood genome-wide DNA methylation (DNAm) profiles in 25 subjects with molecularly confirmed clinical diagnosis of FA (FANCA complementation group) by means of EPIC v.1 array to identify differentially methylated CpGs able to distinguish subjects with FA from healthy individuals and subjects with other genetic disorders. Then, a machine-learning model able to classify DNAm profiles in unsolved cases was applied.

Results: The DNAm signature was clinically validated using 49 samples belonging to 12 complementation groups and carrying biallelic pathogenic variants, which were collected from peripheral blood and/or bone marrow aspirates. The episignature properly classified FA individuals belonging to 10 complementation groups (A-C, D2, E, G, J, L, P, T), including 8 reverted cases. The signature was used to classify 22 molecularly and/or clinically unclassified patients.

Conclusion: The use of DNAm profiling for functional classification of VUS in *FANC* genes or classification of molecularly uncharacterized patients is an informative tool to validate or rule out a clinical suspicion for a wide range of complementation groups, even in presence of gene conversion events.

P09.009.C Mutational load of somatic variants in autoinflammatory diseases-associated genes

Jaume Reig[1], *Juan Ignacio Aróstegui*[2], *Ferran Casals*[1;3]

[1]*Facultat de Biologia, Genètica, Microbiologia i Estadística, Barcelona, Spain;* [2]*Hospital Clinic, Servei d'immunologia, Barcelona, Spain;* [3]*Institut de Biomedicina de la Universitat de Barcelona (IBUB), Barcelona, Spain*

Background/Objectives: Mosaicism results from post-zygotic DNA variants, which may occur during embryonic development or later in life, often restricted to specific cells or tissues. Increasing evidence support that somatic variants contribute to non-cancer diseases, mostly monogenic but also complex disorders. Notably, gene mosaicism plays a relevant role in the pathogenesis of inborn errors of immunity, especially in the group of autoinflammatory diseases (AIDs). Clinical manifestations in certain AIDs appear later in life, suggesting the expansion of preexisting mutant clones through clonal hematopoiesis. Herein we aim to characterize the mutational load of somatic variants at subclinical frequencies in two genes related to AIDs.

Methods: We have analyzed whole-genome sequences from >400,000 individuals aged 40-60 years in the UK Biobank repository. A bioinformatic pipeline to detect low-frequency variants was applied, combined with a set of filters based on sequencing and mapping quality, minimum reads supporting the alternative allele, strand bias and proximity to read ends and indels was applied to reduce the number of false positives.

Results: We have identified carriers of pathogenic variants in *UBA1* and *NLRP3*. This preliminary evidence may establish the characterization of the load of somatic variants with low allele frequencies in these genes, enabling to perform a comparative analysis about the spatial distribution between germline and somatic variants.

Conclusions: The genetic load of somatic variants in unaffected individuals is informative on the number of individuals at risk of developing an AID of postzygotic origin, which can be of relevance for physicians visiting patients with late-onset inflammatory disorders.

[11]Center for Rare Diseases Erlangen (ZSEER), University Hospital Erlangen, Erlangen, Germany

Background/Objectives: In immunologic disorders with suspected Mendelian inheritance, the yield of exome sequencing is around 20%, lower than for many other disorders. To increase the diagnostic yield, we extended analysis of exomes to VUS and candidate genes, when results were normal.

Methods: We investigated 112 cases, 46% singletons and 47% trios, mainly for autoinflammatory disorders (82%). In the first tier, a panel of up to 449 genes (Tangye et al. *J Clin Immunol* 2022) was analysed. Rare copy number variants (CNVs) were determined using ExomeDepth. In 90 patients with research consent, the analysis was extended to all genes.

Results: In 20% of patients, disease-associated variants (class IV-V) in seven established genes were detected; additional two individuals carried a VUS in 9-11% of reads. Among seven "hot VUS" in genes previously associated with immunodeficiencies, two were classified as likely pathogenic by either RT-PCR or flow-cytometry, one further as benign. Three others are under investigation. To identify further candidates, we assessed de novo and recessive variants and identified 36 candidate variants in 30 genes, two in the same gene. The encoded proteins of 26 genes were predicted to be deleterious by structural protein-modelling, and these genes were enriched for GO-term 'leukocyte activation'. In one gene, we found rare CNVs in two patients. CNVs affecting ≥1 exon were enriched for molecular function 'complement binding'.

Conclusion: Systematic analysis of exome variants in unsolved cases increases the diagnostic yield to currently 21% and identifies additional candidate genes requiring further investigation.

Grants: None.

Conflict of Interest: None declared

P09.011.A Clinical exome sequencing has a diagnostic yield of 36% in patients with suspected monogenic hematological and immunological defects

[1]Immunogenetics and Transplant Biology Service, Città della Salute e della Scienza University Hospital, Turin, Italy; [2]University of Turin, Department of Medical Sciences, Turin, Italy; [3]Pediatric and Neonatology Unit, Ordine Mauriziano Hospital, Turin, Italy; [4]Department of Medical Sciences, Allergy and Clinical Immunology Unit, University of Torino and Mauriziano Hospital, Turin, Italy; [5]Department of Clinical and Biological Sciences, Università di Torino, Turin, Italy; [6]Division of Haematology, Città della Salute e della Scienza, Turin, Italy; [7]Department of Molecular Biotechnology and Health Sciences, Division of Hematology, University of Torino, Turin, Italy; [8]Department of Public Health and Pediatrics, University of Turin, Pediatria Specialistica U, "Regina Margherita" Children Hospital, Turin, Italy; [9]Pediatric Oncology Department, Regina Margherita Children's Hospital, AOU Città della Salute e della Scienza di Torino, Turin, Italy

Background: Numerous blood and immune disorders exhibit monogenic etiology. We describe a cohort of molecularly characterized pediatric and adult patients with suspected monogenic immuno-hematologic conditions, reporting diagnostic rates based on specific diseases.

Methods: We recruited 70 patients that underwent clinical exome sequencing (CES) in 2023.

Results: mean age was 16.8 ± 19.3 years (range 0-83 years), 51/70 patients (73%) had <18 years and 40/70 (57%) were males. 44 patients (63%) had bone marrow failure (BMF) (including hyporegenerative anemia, congenital neutropenia, non-immune thrombocytopenia); 18 (26%) had immune dysregulation (including combined immunodeficiency, autoimmune lymphoproliferative syndrome, complement deficiency and autoinflammatory disease) and 8 (11%) had congenital hemolytic anemia (CHA). The overall detection rate (patients with pathogenic and likely pathogenic variants consistent with the phenotype) was 36%, varying according to the macrocategory: 4/8 (50%) for CHA, 16/44 (36%) for BMF and 5/18 (28%) for immune dysregulation. In 13/70 of cases (19%) variants of unknown significance (VUS) were identified. *SPTB* was the most frequently involved gene in CHA while in BMF 11 different genes were involved, being ribosomal genes *GATA2* and *ELANE* the most represented. One case presented a double diagnosis (*ALAS2* and *G6PD*). No significant difference in diagnostic rates was observed between pediatric and adult patients (18/51, 35% vs 6/19, 32%, $p = 0.8$); however, the adult population was enriched in young adults with a heightened suspicion of monogenic disease.

Conclusion: our data confirm that CES analysis has a high diagnostic rate in immuno-hematological disease and is useful to define diagnosis, guide treatment and determine recurrence risk.

P09.012.B A novel mutation in *MECOM* affects *MPL* regulation in vitro and results in thrombocytopenia and bone marrow failure

Daniele Ammeti[1], *Antonio Marzollo*[2], *Maria Gabelli*[2], *Melania Eva Zanchetta*[1], *Caterina Tretti-Parenzan*[2], *Roberta Bottega*[1], *Valeria Capaci*[1], *Alessandra Biffi*[2], *Anna Savoia*[3], *Silvia Bresolin*[2], *Michela Faleschini*[1]

[1]1Institute for Maternal and Child Health – IRCCS Burlo Garofolo, Trieste, Italy; [2]Padua University and Hospital, Paediatric Haematology, Oncology and Stem Cell Transplant Division, Women and Child Health Department, Padua, Italy; [3]University of Verona, Verona, Italy

Background/Objectives: MECOM-associated syndrome (MECOM-AS) is a rare genetic disease characterized by a continuous spectrum of clinical phenotypes ranging from isolated radioulnar synostosis to severe thrombocytopenia and bone marrow failure.

Of note, the haematological phenotype of MECOM-AS partially overlaps with other congenital amegakaryocytic thrombocytopenia (CAMT), caused by mutations in *MPL* or *THPO* genes.

MECOM-AS is caused by mutations in *MECOM* gene, which encodes the transcription factor EVI1. Although EVI1 plays an important role in haematopoiesis, the correlation between EVI1 dysfunction and thrombocytopenia remains largely unexplained.

Here we report the functional characterization of a novel variant of *MECOM* gene and suggest a possible role of *MPL* gene in the pathogenesis of MECOM-AS.

Methods: Mutational screening was performed through targeted NGS analysis. Luciferase reporter assays on the promoters of several target genes were conducted to determine the pathogenic role of the variant and to investigate the role of EVI1 on the transcriptional regulation of *MPL*.

Results: In a paediatric patient affected by a severe thrombocytopenia, we identified a novel de novo variant in *MECOM* gene (p.P634L). Functional studies showed that p.P634L impairs repressive activity of the transcription factor on several promoters. Moreover, we demonstrated that EVI1 plays a role in the transcriptional regulation of the *MPL* gene.

Conclusion: We demonstrated the pathogenicity of the variant, providing a certain molecular diagnosis to the patient. Furthermore, we suggest an involvement of *MPL* in the pathogenic mechanism underlying MECOM-AS, potentially explaining the overlap of the haematological defects observed in patients with *MECOM* or *MPL* mutations.

P09.013.C Functional correction of DNA Ligase 1 deficiency in a homozygous patient-derived cell line

*Di Liu[1], **Yu-zhen Xiao**[1], Longlong Liu[2], Kristine Bousset[1], Britta Wieland[1], Michael Eckrich[3], Philip Roehrs[4], Virginia Thurston[5], Laurie Demmer[6], Niraj Patel[7], Jeffrey Huo[4], Thilo Dörk[1]*

[1]Hannover Medical School, Gynaecology Research Unit, Hannover; [2]University Hospital Münster, Department of Medicine A, Hematology, Oncology and Pneumology, Münster; [3]Texas Transplant Institute, Pediatric Blood & Marrow Transplant, Charlotte, United States; [4]Levine Children's Hospital, Pediatric Blood & Marrow Transplant, Charlotte, United States; [5]Carolinas Pathology Group, Charlotte, United States; [6]Levine Children's Hospital, Pediatric Genetics, Charlotte, United States; [7]Levine Children's Hospital, Pediatric Infectious Diseases, Charlotte, United States

Background: Human DNA ligase 1 (LIG1) is known to play a role in joining Okazaki fragments and participating in some DNA repair processes. LIG1 deficiency is a very rare autosomal recessive disorder with only seven patients described so far.

Patient/Methods: We used whole exome sequencing and Sanger validation to identify the genetic basis of disease in a seven-year-old girl with immunodeficiency, MDS, dysmorphic features, and growth retardation. We investigated a skin fibroblast line derived from the patient using immunoblotting, flow cytometry and proliferation assays, and we performed ABE single-base editing to correct the mutational defect.

Results: We found homozygosity for a missense variant, p.R305Q (*LIG1*c.914G>A), in the *LIG1* gene of the index patient. The variant was associated with a strong reduction of LIG1 protein in fibroblasts derived from the patient. Reversion of the p.R305Q homozygosity to the wildtype genotype using an ABE single-base editing approach fully restored LIG1 protein levels in the patient fibroblast line and corrected its aberrant cell cycle profile and proliferation in flow cytometry, EdU and xCELLigence measurements.

Conclusion: Homozygosity for the pathogenic missense variant p.R305Q gives rise to human LIG1 deficiency. Our isogenic pair of LIG1-deficient and LIG1-proficient fibroblast lines may become a useful tool to further study the functions of DNA ligase 1.

Conflict of Interest: None declared

P09.015.A Polygenic risk emerges from exome sequencing of inherited thrombocytopenia

Federica Isidori[1], *Federica Melazzini[2;3], Giulia Erini[4], Valeria Bozzi[2], Tania Giangregorio[1], Alessandro Mattiaccio[4], Carlo Sidore[5], Marco seri[1], Alessandro Pecci[2;3], Caterina Marconi[1], Tommaso Pippucci[1]*

Background/Objectives: Inherited thrombocytopenia (IT) is a heterogeneous group of bleeding disorders characterized by low platelet count (PC). Exome Sequencing (ES) so far has focused on the identification of rare variants with large effect, discovering >50 genes and diagnosing <50% of patients. However, GWAS reported the presence of common variants with low or moderate effect that are overlooked in clinical analysis although their combined effect may have a large effect on PC. We sought to assess their contribution to IT risk.

Methods: ES was performed on a large cohort of IT patients (N = 219 from 152 families). Rare variants were searched across 52 IT-associated genes and 56 common SNPs among the 577 reported in a published PLT-GWAS. Polygenic risk scores (PRS) were calculated in the 152 IT family probands and in 1350 individuals ascertained for non-IT disorders (COVID-19, N = 603 and Epilepsy, N = 747).

Results: Identification and segregation of rare variants divided the probands in diagnosed (N = 45) and undiagnosed (N = 107). Median PRS distribution was significantly lower for IT patients versus non-IT individuals, and even lower in undiagnosed probands (Wilcoxon *p.adjust* = 0.001 and 0.00018, in the two non-IT cohorts, respectively). Interestingly, in 6 probands (4% of probands), a key contributor to this effect was identified in a common coding variant with large effect in an established Mendelian IT gene.

Conclusion: The genetic basis of IT is more complex than commonly thought, and PRS can be useful in clinical evaluation of IT patients.

Background/Objectives: VEXAS syndrome (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic; MIM#301054) is a recently

described rare, adult-onset autoinflammatory disorder in males caused by somatic *UBA1* variants. It is characterized by wide range of inflammatory and hematological manifestations. We now investigated a VEXAS cohort from Germany.

Methods: We obtained whole blood samples of eight individuals with suspicion of VEXAS syndrome – mainly based on clinical presentation, gender, and age – and performed exome sequencing to assess variants in a gene panel of periodic fever syndromes or in a targeted analysis of *UBA1*.

Results: In 7/8 males, we identified a pathogenic *UBA1* variant affecting amino-acid position 41 (3x p.(Met41Leu), 3x p.(Met41Thr), 1x p.(Met41Val)), somatic mosaicism ranged between 35-92%. A coding *UBA1* variant could not be identified in the eighth affected individual.

Mean age at genetic diagnosis was 70.3 years, average disease duration 2.5 years. Main manifestations were relapsing polychondritis, skin lesions, various autoinflammatory symptoms, and infections. Most individuals had macrocytic anemia and elevated inflammation parameters. We could not observe any correlation between degree of somatic mosaicism in PBMCs and disease severity.

Conclusion: This high detection rate indicates that VEXAS syndrome is more frequent than initially thought and highlights that molecular testing is indicated in all cases with suspected VEXAS syndrome. Testing should be expanded to individuals with less typical manifestations, especially since effective specific treatments were reported in individual patients, e.g. hypomethylating therapeutics leading to remission of clones with *UBA1* variant.

P09.017.C Pathogenic Roles of a Human Telomerase RNA (hTR) template mutation in Dyskeratosis Congentia

Nathaniel Deimler[1], *Laura Holthöfer*[2], *Alex Orioli*[1], *Nadine Bobon*[1], *Matthias Linke*[2], *Verena Engelhardt*[2], *Mareike Selig*[2], *Fabian Beier*[3], *Susann Schweiger*[2;4], *Peter Baumann*[1;4]

[1]*Johannes Gutenberg University Mainz, Department of Biology, Mainz, Germany;* [2]*University Medical Centre of the Johannes Gutenberg University Mainz, Institute of Human Genetics, Mainz, Germany;* [3]*Medical Faculty, RWTH Aachen University, Department of Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, Aachen, Germany;* [4]*Institute for Molecular Biology, Mainz, Germany*

Introduction: Dyskeratosis congenita (DKC), a telomere biology disorder resulting from mutations in telomere maintenance mechanisms, is characterized by a triad of dysplastic nails, reticular skin hyperpigmentation, and oral leukoplakia. DKC commonly leads to bone marrow failure, carcinomas, and pulmonary fibrosis. Telomerase, a ribonucleoprotein responsible for telomere elongation, is composed of a catalytic protein subunit (TERT), which reverse transcribes the non-coding RNA subunit (*TERC*). While many *TERC* mutations have been identified that affect the stability or folding of telomerase RNA, mutations in the template region are rare.

Methods: Clinical characterizations were coupled with RNA-Seq, WGS, and telomere length measurements by Flow-FISH and nanopore sequencing.

Results: The patient presented with a classic case of DKC carrying a heterozygous *TERC*-variant r.50C>A, inherited from his deceased mother and present in his deceased twin sister who died due to DKC-related complications at the ages of 58 and 21, respectively. r.50C>A hTR telomerase exhibits a decreased processivity compared to wild-type telomerase resulting in shortened telomeres, <10th percentile by Flow-FISH in all individuals carrying the mutation within this family. The maternal aunt, also carrying the *TERC*-mutation, showed no signs of DKC until age 58 with telomere lengths <10th percentile. The healthy aunt's daughter does not carry the *TERC* mutation and shows normal telomere lengths, despite inheriting mutant telomeric repeats from her mother.

Conclusion: While the effect of mutant repeat load in the absence of mutant telomerase is unknown, it is clear the mutant, non-processive telomerase results in severely shortened telomeres and the DKC phenotype observed in the index patient and his twin sister.

P09.018.D Autoinflammatory diseases and germline vs. somatic mosaic variations

Eman Assrawi[1], *Camille Louvrier*[1;2], *William Piterboth*[2], *Florence Dastot-Le Moal*[2], *Farah Diab*[1], *aphrodite daskalopoulou*[1], *Rahma mani*[1], *romain Levergeois*[2], *quentin brandao*[1], *Bruno Copin*[2], *Angela Arenas-Garcia*[1], *Marie Legendre*[2], *Sonia Karabina*[1], *Serge AMSELEM*[1;2], **Irina Giurgea**[1;2]

[1]*Sorbonne Université, Inserm, Childhood Genetic Diseases Laboratory, Hôpital Armand-Trousseau, 75012 Paris, France., Paris, France;* [2]*Département de Génétique Médicale, APHP Hôpital Armand-Trousseau, 75012 Paris, France., Paris, France*

Background/Objectives: The study primarily investigates somatic mosaic variations within systemic autoinflammatory diseases (SAID) genes and their correlation with disease phenotypes, specifically focusing on variations in *NLRP3* and *TNFRSF1A* leading to NLRP3-AIDs and TRAPS (Tumor necrosis factor-Receptor-Associated Periodic Syndrome) respectively.

Methods: From 2018 to 2023, deep-targeted NGS was used to analyze the leukocyte DNAs of 800 patients using a SAID gene panel. All mosaic variations in SAID genes from PubMed and Infevers databases were reviewed.

Results: In *NLRP3*, 9 mosaic variations were identified in 12 independent patients, along with 10 germline variations in 10 patients. The literature reports 34 mosaic and 88 germline *NLRP3* variations.

Phenotype: genotype correlations suggest that *NLRP3* variations found only somatically may be incompatible with life if present germinally, while variations found only in germinal state could be asymptomatic in mosaic state.

In *TNFRSF1A*, two mosaic variations were found in three patients. The literature reports only three other mosaic variations. No obvious difference in disease severity between germline and mosaic variations has been observed.

Very few mosaic variations have been reported in the literature in other SAID genes: *NLRC4* (n = 4), *STING1* (n = 2), *NOD2* (n = 2), and *JAK1* (n = 1), precluding any genotype: phenotype correlation studies.

Most of mosaic variations identified in SAID genes were found to be widely distributed across different tissues.

Conclusion: The study underscores the high frequency of mosaic variations in NLRP3-AIDs and emphasizes the symptomatic nature of mosaic variations, even at very low allele frequencies (below 5%), potentially leading to false-negative diagnostic tests without deep sequencing.

Background/Objectives: The MRE11-RAD50-NBN (MRN) complex plays a key role in cellular DNA double-strand break response. Pathogenic variants in NBN and MRE11 give rise to the autosomal-recessive Nijmegen breakage syndrome (NBS) and ataxia telangiectasia-like disorder (ATLD), respectively. The clinical consequences of pathogenic variants in RAD50 are less well defined. RAD50 deficiency resembles NBS, but the first two patients described showed no immunodeficiency.

Methods: We report on a girl with microcephaly, mental retardation, bird-like face, short stature, bone marrow failure and B-cell immunodeficiency. We searched for candidate genes by whole-exome sequencing and analyzed the cellular phenotype of patient-derived fibroblasts using immunoblotting and functional complementation experiments.

Results: Compound heterozygosity for two variants in the *RAD50* gene (p.Arg83His and p.Glu485Ter) was identified in this patient. Expression of RAD50 protein and the MRN complex were maintained in patient derived fibroblasts. However, DNA damage-induced ATM kinase activity was markedly decreased, which was restored by the expression of wild-type RAD50. The RAD50*p.R83H missense substitution did not rescue the mitotic defect of RAD50-deficient fibroblasts, whereas wild-type RAD50 did. The RAD50*-p.E485X nonsense variant was associated with in-frame skipping of exon 10 (p.Glu485_545del).

Conclusion: These findings provide evidence for an important role of RAD50 in human bone marrow and immune cells. RAD50 deficiency should be considered in patients with an inborn bone marrow failure and B-cell immunodeficiency, in addition to its known features of microcephaly and short stature.

P09.020.A Genome-wide association study of COVID-19 vaccine side effects in Eastern Europe

Alexander Rakitko[1], *Elena Kovalenko[1], Alexey Kamelin[1], Anna Kim[1], Nicolay Plotnikov[1]*

[1]Genotek, Moskva, Russian Federation

Background/Objectives: COVID-19 vaccination has proven to be an effective method to reduce the incidence of coronavirus infection and the severity of its course. Post-vaccination adverse events varied among individuals, indicating a potential genetic basis for the different responses to the vaccine.

Methods: We studied the COVID-19 vaccine adverse reaction in a multi-ethnic group of 24381 vaccine (Sputnik-V) recipients (15545 controls, 8836 cases). The surveys encompassed inquiries regarding a spectrum of 11 symptoms, in addition to assessing the overall intensity of the post-vaccination reaction and its subsequent influence on daily activities. All samples were genotyped using Illumina GSA v3 microarray.

Results: Our study has detected several genome-wide significant loci on chromosome 6. Specifically, some alleles which showed the most significant association with severe COVID-19 vaccine reaction were HLA-DRB1*03:01 (OR = 0.807, p-value = 2.57×10^{-13}), HLA-DQA1*05:01 (OR = 0.806, p-value = 4.50×10^{-14}), HLA-DQB1*02:01 (OR = 0.809, p-value = 1.02×10^{-13}). This combination of alleles, known as DR3-DQ2, is associated with conditions such as celiac disease and diabetes mellitus. Our analysis has also revealed HLA-DRB1*07:01 (OR = 1.199, p-value = 1.92×10^{-14}), HLA-DQA1*02:01 (OR = 1.185, p-value = 1.28×10^{-13}).

Conclusion: We conducted the largest genome-wide association study to date on adverse reactions to the COVID-19 vaccine in a cohort of Eastern European descent. Our study underscores the significant associations between HLA genes and vaccine-related side effects. These insights have the potential to be integrated into clinical practice to guide personalized vaccine selection.

P09.021.B Late onset of an autoinflammatory disease: identification and functional characterization of a mosaic variation of *NLRC4*

*Farah Diab[1], Camille Louvrier[1;2], Marc Fabre[3], aphrodite daskalopoulou[1], Eman Assrawi[1], **Rahma mani**[1], quentin brandao[1], romain Levergeois[2], Angela Arenas-Garcia[1], Florence Dastot-Le Moal[2], William Piterboth[2], frederic lezot[1], Sonia Karabina[1], Serge AMSELEM[1;2], Irina Giurgea[1;2]*

[1]Sorbonne Université, Inserm, Childhood Genetic Diseases Laboratory, Hôpital Armand-Trousseau, Paris, France; [2]Département de Génétique Médicale, Assistance Publique–Hôpitaux de Paris (APHP), Hôpital Armand-Trousseau, Paris, France; [3]Service de Médecine interne, Maladies infectieuses et Hématologie, Centre Hospitalier Pierre Oudot, Bourgoin-Jallieu, France

Background/Objectives: *NLRC4* gene encodes an essential component of the NLRC4 inflammasome, a multiprotein complex involved in activating inflammatory pathways. Germline *NLRC4* variations are associated with severe forms of autoinflammatory diseases (AID) in children, often involving enterocolitis and potentially leading to macrophage activation syndrome. Somatic mosaic variations in *NLRC4* have been reported in only two adult patients. This study aimed to identify the molecular basis of adult-onset AID without macrophage activation syndrome.

Methods: The study involved deep sequencing of the patient's leukocyte genomic DNA through a panel of AID genes and functional evaluation of the identified *NLRC4* variation in

HEK293T cells expressing different protein partners (ASC and Caspase1) enabling the detection of specks, a hallmark of NLRC4 inflammasome activation. NF-κB pathway activation was also studied by a reporter gene system.

Results: The patient, a 28-year-old man, had a history of unlabeled psychosis since the age of 19, and severe inflammatory episodes from the age of 21. Sequencing revealed the presence of a mosaic variation in *NLRC4*, c.398C>T p.(Thr133Ile), with the mutant allele represented at a ratio of 5%. Functional studies demonstrated that this variation has a gain-of-function pathogenic effect on inflammation, as evidenced by a significant increase in the percentage of specks in cells expressing mutant NLRC4 and the activation of the NF-κB pathway.

Conclusion: This study identified a novel mosaic variation of *NLRC4* associated with adult-onset autoinflammatory disease (AID) without macrophage activation syndrome, and demonstrated its gain-of-function pathogenic effect on inflammation.

Grants: H2020_European Union_779295.

P09.022.C MR-PheWAS of circulating neutrophil characteristics and 20,740 disease outcomes, proteins and metabolites identifies multiple novel causal associations

Katy Fleming[1], *Emma Vincent*[2], *Borko Amulic*[1], *Andrew Mumford*[1], *Kate Burley*[1]

[1]*University of Bristol, School of Cellular and Molecular Medicine;* [2]*University of Bristol, Bristol Medical School*

Background/Objectives: Neutrophils mediate innate immunity and also inflammatory pathologies such as atherosclerosis and autoimmunity. Neutrophil granules are the likely effectors of these activities, yet evidence for causal associations between granularity and common human disease is sparse. Here we apply Mendelian randomisation (MR)-PheWAS to explore associations with circulating neutrophil count (NC) and side scatter (NSSC), a surrogate for granularity also measured in the blood count test.

Methods: Genetic variants independently associated with NC ($n = 154$) and NSSC ($n = 72$) in a prior European-ancestry GWAS were used to proxy exposures. Phenome-wide associations against 20,740 traits were identified by MR.

Results: NC and NSSC had weak phenotypic ($r = 0.03$) and genetic correlation ($rg = -0.02$), indicating that they are distinct cellular traits. NC had a causal effect (FDR $p < 0.05$) on 121 outcomes, including abundance of gut microbiota (e.g. Lactobacillus, -0.12 SD/SD increase in NC; FDR $p = 4.6 \times 10^{-2}$), products of anaerobic metabolism (e.g. lactate, 0.15 SD; FDR $p = 1.6 \times 10^{-18}$) and multiple measures of adiposity (e.g. BMI, -0.07 SD; FDR $p = 4.5 \times 10^{-2}$). NC-associated variants were predictive of Alzheimer's disease (OR 5.1 per SD increase in NC; FDR $p = 5.1 \times 10^{-4}$), consistent with previous association studies. NSSC had a causal effect on 26 outcomes, >80% of which were not associated with NC. These included dental problems (OR 0.99; FDR $p = 3.9 \times 10^{-2}$), a penetrant phenotype in rare Mendelian neutrophil granulopathies.

Conclusion: We report the first large-scale analysis of phenotypes causally associated with neutrophil characteristics. The approach identifies associations with infection and inflammation phenotypes already associated with neutrophils, and multiple hitherto unknown associations which warrant further functional investigation.

P09.023.D Bi-allelic MCM10 variants cause NK-cell deficiency manifesting a severe skin disorder and childhood malignancy

Yael Hoffman[1;2], *Alina Kurolap*[1;2], *Adi Mory*[1;2], *Hagit Baris Feldman*[1;2], *Daphna Marom*[1;2], *David Hagin*[2;3]

[1]*Tel Aviv Sourasky Medical Center, The Genetics Institute and Genomics Center, tel-aviv, Israel;* [2]*Tel Aviv University, Faculty of Medicine, tel-aviv, Israel;* [3]*Tel Aviv Sourasky Medical Center, Allergy and Clinical Immunology Unit, Department of Medicine, tel-aviv, Israel*

Background/Objectives: Minichromosome maintenance (MCM) proteins are essential for DNA replication and genome stability. MCM2-7 function as the core of replicative helicase, and together with the GINS complex and CDC45, form the CDC45:MCM2-7:GINS (CMG) helicase complex, which is stabilized by MCM10. Defects in CMG proteins, including MCM4, GINS1 and GINS4, were shown to be associated with natural killer (NK) cell deficiency in a limited number of individuals. Similarly, bi-allelic variants in *MCM10* were recently described as causing lethal NK cell deficiency in one subject, and prenatal cardiomyopathy with hypoplastic thymus and spleen in three embryos with progressive fetal hydrops. We report the first case of a rare lethal malignancy in a child homozygous for a novel *MCM10* variant.

Methods: Clinical case report, exome sequencing, RNA studies and flow cytometry-based immune-phenotyping.

Results: A six-year-old male presented with extensive poikyloderma, photosensitivity, and suspected chronic oral candidiasis. Urgent exome sequencing detected a homozygous pathogenic splice-site variant in *MCM10* (NM_018518.5): c.930+2T>A. The patient later developed and succumbed to an aggressive, EBV-positive, squamous cell carcinoma of the tongue. RNA studies confirmed that the identified variant leads to deletion of 51 bp from the 3'-end of exon 7, resulting in an in-frame deletion of 17 amino acids within the protein's oligonucleotide/oligosaccharide-binding (OB)-fold domain, critical for *MCM10* function. Immunophenotyping showed near absent NK cells with significant increase in NK-T cells and in terminally differentiated CD8 T-cells.

Conclusion: *MCM10* is a new autosomal recessive pediatric cancer predisposing gene, linking NK-cell deficiency and cancer risk. MCM10-deficiency belongs to an emerging group of syndromes we term "minichromosomopathies".

P09.024.A Identification of a large novel inversion in the *F8* gene by long-read sequencing in two siblings with severe Haemophilia A

Gregor Gilfillan[1], *Marit Sletten*[1], *June Åsheim*[1], *Heidi Knudsen*[2], *Knut Erik Berge*[1], *Nina Iversen*[1]

[1]*Oslo University hospital Ullevål, Dept. Medical Genetics, Oslo, Norway;* [2]*Oslo University hospital, Dept. Rare Disorders, Oslo, Norway*

Background/Objectives: Two brothers diagnosed with severe Haemophilia A had FVIII levels <1% at birth, and were therefore suspected to harbour a mutation in the *F8* gene. The patients were first subjected to standard genetic testing: *F8* Intron 22 Inversion, Sanger sequencing (all 26 *F8* exons and exon–intron junctions), MLPA, whole genome sequencing (WGS) and mRNA analysis to detect splicing defects. No genomic defects were found, but *F8* mRNA could not be detected. We therefore tested for the presence of structural genomic variants using long-read sequencing with Pacific Biosciences technology.

Methods: High molecular weight DNA was extracted from blood and sequenced on a Pacific Biosystems Revio system. The genomic rearrangement detected by sequencing was confirmed using break-point PCR and Sanger sequencing.

Results: Long-read sequencing revealed a 143 kb inversion disrupting the *F8* gene. Interestingly, the inversion was not detected by the PacBio SV caller PBSV, but was obvious upon manual inspection of aligned reads. The inversion was confirmed by PCR spanning the breakpoints, and subsequent Sanger sequencing of the amplified products. Inversion breakpoints were in intronic segmental duplication sequences of ca. 1 kb, precluding diagnosis with standard-of-care methods. The rearrangement inverted the promoter and first exon of the *F8* gene, suggesting a full disruption of the gene. This conclusion is supported by the lack of detectable *F8* mRNA.

Conclusion: Long-read sequencing succeeded in diagnosing a case of FVIII insufficiency caused by a genomic inversion that was not possible to detect with standard diagnostic tools or RNA analysis.

P09.025.B Molecular challenges in the diagnosis of X-linked chronic granulomatous disease: CNVs, intronic variants, skewed X-chromosome inactivation, and gonosomal mosaicism

Laura Batlle-Masó[1;2;3], *Jacques Riviere*[1;2], *Clara Franco-Jarava*[4;5], *Andrea Martin-Nalda*[1;2], *Marina Garcia-Prat*[1;2], *Alba Parra-Martínez*[1;2], *Aina Aguilo-Cucurull*[4;5], *Neus Castells*[6;7], *Monica Martinez-Gallo*[4;5], *Pere Soler-Palacin*[1;2], *Roger Colobran*[4;5;7]

[1]*Vall d'Hebron Research Institute (VHIR), Infection and Immunity in pediatric patients, Barcelona, Spain;* [2]*Vall d'Hebron University Hospital (HUVH), Pediatric Infectious Diseases and Immunodeficiencies Unit, Barcelona, Spain;* [3]*Universitat Pompeu Fabra, Barcelona, Spain;* [4]*Vall d'Hebron Research Institute (VHIR), Translational Immunology, Barcelona, Spain;* [5]*Vall d'Hebron University Hospital (HUVH), Immunology Division, Barcelona, Spain;* [6]*Vall d'Hebron Research Institute (VHIR), Medicine genetics research group, Barcelona, Spain;* [7]*Vall d'Hebron University Hospital (HUVH), Clinical and Molecular genetics department, Barcelona, Spain*

Chronic granulomatous disease (CGD) is a prototypical inborn error of immunity affecting phagocytes, in which these cells are unable to produce reactive oxygen species. CGD is caused by defects in genes encoding subunits of the NADPH oxidase enzyme complex (CYBA, CYBB, CYBC1, NCF1, NCF2, NCF4); inflammatory responses are dysregulated, and patients are highly susceptible to recurrent severe bacterial and fungal infections. X-linked CGD (XL-CGD), caused by mutations in the CYBB gene, is the most common and severe form of CGD.

In this study, we describe the analytical processes undertaken in 3 families affected with XL-CGD to illustrate several molecular challenges in the genetic diagnosis of this condition: in family 1, a girl with a heterozygous deletion of CYBB exon 13 and skewed X-chromosome inactivation (XCI); in family 2, a boy with a hemizygous deletion of CYBB exon 7, defining its consequences at the mRNA level; and in family 3, 2 boys with the same novel intronic variant in CYBB (c.1151 + 6 T > A). The variant affected the splicing process, although a small fraction of wild-type mRNA was produced. Their mother was a heterozygous carrier, while their maternal grandmother was a carrier in form of gonosomal mosaicism.

In summary, using a variety of techniques, including an NGS-based targeted gene panel and deep amplicon sequencing, copy number variation calling strategies, microarray-based comparative genomic hybridization, and cDNA analysis to define splicing defects and skewed XCI, we show how to face and solve some uncommon genetic mechanisms in the diagnosis of XL-CGD.

P09.026.C A cohort of patients with cryopyrin-associated periodic syndromes caused by postzygotic NLRP3 pathogenic variants

Nuria Bonet[1], *Juan Ignacio Aróstegui*[2], *Ferran Casals*[3]

[1]*Universitat Pompeu Fabra, Genomics Core Facility, Barcelona, Spain;* [2]*Hospital Clínic, Immunology Department, Barcelona, Spain;* [3]*Universitat de Barcelona, Facultat de Biologia, Barcelona, Spain*

Background/Objectives: Cryopyrin-associated periodic syndrome (CAPS) is a rare autoinflammatory disorder (AID) caused by *gain-of-function NLRP3* variants. Although most CAPS patients are carriers of germline *NLRP3* pathogenic variants, several cases of post-zygotic variants have been reported.

We hypothesize that the clinical phenotype in those patients with mosaicism may be a direct consequence of its cellular distribution and/or the variant allele frequency (VAF). To test this hypothesis, we aim to deeply characterize the frequency and distribution of the somatic *NLRP3* variant in CAPS patients with mosaicism, and its evolution along time.

Methods: Amplicon-based deep sequencing (ADS) was used to assess the VAF at different time points, if possible, in peripheral blood, isolated leukocyte subpopulations and nail clippings.

Results: We identified 17 individuals carrying somatic (likely) pathogenic variants at *NLRP3*. At time of diagnosis, the mean VAF was 11.9%. All *NLRP3* variants were located at exon 4, with 5 of them being novel variants. VAF at different time points and mosaicism distribution were evaluated in 7 individuals, revealing either mosaicism stability along the time, and myeloid restriction in only one patient, respectively.

Conclusions: We herein genetically evaluated one of the largest cohort of patients with CAPS and *NLRP3* mosaicism. Collected evidences support for an early occurrence of the mutational event, as well as VAF stability along the time. Additional experiments are currently ongoing to evaluate the potential relationship of VAF with the patients' phenotype.

Grants: PID2021-125106OB-C32 (FC) PID2021-125106OB-C31 (JIA) by MCIN/ AEI and FEDER.

Background: We described the KINSSHIP syndrome, a disorder associated with intellectual disability (ID), caused by de novo variants in the AFF3 degron. Mouse knock-ins/zebrafish overexpression provided evidence for a dominant-negative (DN) mode-of-action, wherein an increased level of AFF3 resulted in pathological effects.

Methods: Evolutionary constraints suggest other modes-of-inheritance. We challenged this hypothesis by screening ID cohorts and assessing the identified variants' deleteriousness.

Results: We detected twenty-one individuals displaying a milder syndrome with either hetero-/homozygous loss-of-function (LoF) or biallelic missense variants in *AFF3*. Matching zebrafish knockdowns exhibit neurological defects that could be rescued by expressing human *AFF3* mRNA, confirming their association with *aff3* ablation. Conversely, some of the human *AFF3* mRNAs carrying missense variants identified did not complement. Overexpression of mutated *AFF3* mRNAs in zebrafish embryos produced a significant increase of abnormal larvae compared to wild-type overexpression further demonstrating deleteriousness.

To further assess the effect of *AFF3* variation, we profiled the transcriptome of fibroblasts from affected individuals and engineered isogenic cells harboring +/+, DN/DN, LoF/+, LoF/LoF or DN/LoF *AFF3* genotypes. The expression of more than a third of the AFF3 bound loci is modified in either the DN/DN or the LoF/LoF lines. While the same pathways are affected, only about one-third of the differentially expressed genes are common to these homozygote datasets, indicating that *AFF3* LoF and DN variants largely modulate transcriptomes differently, e.g. the DNA repair pathway displayed opposite modulation.

Conclusions: Our results and the high pleiotropy shown by variation at this locus suggest that minute changes in *AFF3* function are deleterious.

P10.002.A Further evidence that the neurodevelopmental gene *FBXW7* predisposes to Wilms tumor

*Fabienne Meier-Abt[1], **Dennis Kraemer**[1;1], Nils Christian Braun[1], Michael Reinehr[2], Eveline Stutz-Grunder[3], Katharina Steindl[1], Anita Rauch[1]*

[1]University of Zurich, Institute of Medical Genetics, Schlieren, Switzerland; [2]University Hospital Zurich, Department of Pathology and Molecular Pathology, Zurich, Switzerland; [3]Children's Hospital Zurich, Department of Oncology, Zurich, Switzerland

Background/Objectives: Somatic variants in the NOTCH pathway regulator *FBXW7* are frequently seen in a variety of malignancies. Heterozygous loss-of-function germline variants in *FBXW7* have recently been described as causative for a neurodevelopmental syndrome. Independently, *FBXW7* was also considered as a susceptibility gene for Wilms tumor due to a few observations of heterozygous germline variants in patients with Wilms tumor.

Whether the same *FBXW7* variants are implicated in both, neurodevelopmental delay and Wilms tumor formation, remained unclear.

Methods: Trio-exome sequencing was performed in the propositus initially focussing on genes related to intellectual disability. Subsequently, DNA from the patient's Wilms tumor was evaluated for *FBXW7* second hit variants using exome sequencing. To test for diminished protein expression, immunohistochemical staining for FBXW7 protein was performed in tumor tissue.

Results: By clinical testing, we now observed a patient with neurodevelopmental delay due to a de novo constitutional mosaic *FBXW7* splice site pathogenic variant who developed Wilms tumor. In the tumor, we identified a second hit frameshift variant in *FBXW7*. Immunohistochemical staining was consistent with mosaic loss of FBXW7 protein expression in the tumor. Our data support the role of constitutional *FBXW7* pathogenic variants in both, neurodevelopmental disorder and the etiology of Wilms tumor.

Conclusion: Therefore, Wilms tumor screening should be considered in individuals with constitutional or germline pathogenic variants in *FBXW7* and associated neurodevelopmental syndrome.

P10.003.B "DYRK1A-associated neurodevelopmental disorder" - two new individuals further delineating the phenotype

Regina Rita Roth[1], *Rami Abou Jamra*[2], *Dagmar Wieczorek*[1], *Nuria Bramswig*[1]

[1]*Institute of Human Genetics, University Hospital Düsseldorf, Düsseldorf;* [2]*Institute of Human Genetics, University Hospital Leipzig, Leipzig*

Background/Objectives: *DYRK1A*-syndrome (OMIM #614104) is characterized by typical dysmorphic features, intellectual disability including impaired language development, autism spectrum disorder, seizures and microcephaly. About 200 cases have been reportet previously.

Methods: We present two further individuals with *DYRK1A*-syndrome from our cohort of patients with neurodevelopmental disorder. Both were examined with regard to their facial gestalt, dysmorphism and clinical abnormalities. The family anamnesis was taken and a pedigree was drawn up. Molecular genetic diagnostics was carried out in both cases.

Results: The first individual is a three-year-old boy with dysmorphic features and microcephaly. Clinically, he shows neurodevelopmental delay, particularly in the field of language, autistic traits, although an autism spectrum disorder has been excluded by neuropaediatric examination. He is prone to infections and febrile convulsions. Exome analysis identified a heterozygous pathogenic de novo nonsense variant in the *DYRK1A* gene.

The second patient is a four-year-old girl who also exhibits typical dysmorphia, but no microcephaly with a head circumference of 49 cm (-0.93 SD). She presents a speech-accentuated neurodevelopmental delay, an austism spectrum disorder, epilepsy and severe myopia. Exome based multigenepanel analysis identified a heterozygous likely pathogenic de novo nonsense variant in the *DYRK1A* gene.

Conclusion: We describe two individuals with *DYRK1A*-syndrome. Both patients have similar abnormalities that are described as being associated with de novo likely pathogenic and pathogenic variants in the *DYRK1A* gene. At the same time, both children differ in specific features like head circumference and autism spectrum disorder and thus broaden the phenotypic spectrum of *DYRK1A*-syndrome.

P10.004.C An IPSC-Model for the SRCAP-related neurodevelopmental disorder "non-Floating-Harbor Syndrome"

Johannes Rhode[1], *Lisa Hagenau*[1], *Stephanie Edwards*[1], *Falk Büttner*[2], *Ana Tzvetkova*[1;3], *Lars Jensen*[1], *Andreas Kuß*[1]

[1]*University Medicine Greifswald, Department of Functional Genomics, Greifswald, Germany;* [2]*Hannover Medical School, Institute of Clinical Biochemistry, Hannover, Germany;* [3]*University Medicine Greifswald, Institute of Bioinformatics, Greifswald, Germany*

Background/Objectives: The recently described Non-Floating-Harbor Syndrome (Non-FLHS or "Developmental Delay, Hypotonia, Musculoskeletal Defects and Behavioral Abnormalities", DEHMBA, OMIM # 619595) is a poorly understood neurodevelopmental disease caused by mutations in SRCAP. The aim of this study was to generate a disease model by introducing a non-FHS-causing mutation in the 3' end of SRCAP.

Methods: The iPSC line MHHi001-A (RRID:CVCL_QX51) was modified by introducing a frameshift mutation in a region known for non-FLHS mutations with an RNP-based CRISPR/Cas9 System. Resulting cells were screened for mutations and off-target effects. Expression of pluripotency markers was tested with qPCR and immunofluorescence microscopy. iPSC were differentiated as embryoid bodies, tested for differentiation markers with qPCR and immunofluorescence microscopy. Low coverage whole genome sequencing was performed on a MinION Mk1B to exclude chromosomal abnormalities.

Results: We generated an iPSC line (MHHi001-A-14) containing a heterozygous mutation (ENSG00000080603:c.[9307del]) in a locus known for non-FLHS associated mutations. The mutation was verified by Sanger sequencing of the target region and was classified as "deleterious" by MutationTaster (https://doi.org/10.1038/nmeth.2890). MHHi001-A-14 expresses the pluripotency markers OCT4, SOX2, NANOG and TRA-1-60. Embryoid bodies from this cell line tested positive for markers specific for all three germ layers. The cell line showed no off-target effects and no chromosomal abnormalities.

Conclusion: MHHi001-A-14 is a fully characterised iPSC, capable of differentiation in all three germ layers, with a newly introduced heterozygous frameshift mutation that resembles known non-FLHS mutations.

P10.005.D Two hits in RAS/MAPK: a case report of dual molecular diagnoses of Neurofibromatosis type 1 and Noonan syndrome.

Sarah Josephi-Taylor[1;2], *Kristi Jones*[1;2]

[1]*The Children's Hospital at Westmead, Department of Clinical Genetics, Westmead, Australia;* [2]*University of Sydney, Discipline of Genomic Medicine, Sydney, Australia*

Background/Objectives: Neurofibromatosis type 1 (NF1) and Noonan Syndrome (NS), two distinct genetic conditions, are both caused by disruptions to proteins within the RAS/MAPK pathway. The RAS/MAPK cellular pathway regulates cell growth and differentiation. To the best of our knowledge, we present the first reported case of an individual with a confirmed dual molecular diagnosis of both NF1 and NS, surviving beyond infancy.

Methods: Clinical case report.

Results: Our patient, 9 years old, has a heterozygous nonsense pathogenic variant in exon 29 of the *NF1* gene (p.(Gln1841Ter)) and a recurrent pathogenic missense variant in the *PTPN11* gene (p.(Asn308Asp)). She presents with an amplified NF1 and NS phenotype. She has marked short stature (<1st centile, -4.7 SD), relative macrocephaly (50th-75th centile), bilateral ptosis, high myopia, hearing impairment, a complex asymmetric pectus deformity, thoracic scoliosis, bilaterally restricted elbow extension, mild pulmonary stenosis, a plexiform neurofibroma on her wrist, multiple café au lait macules, and mild to moderate intellectual disability. MRI brain shows mildly thickened optic nerves, a middle cerebellar peduncle lesion consistent with a low grade glioma and a borderline Chiari 1 malformation. Resolved issues include severe feeding difficulties necessitating gastrostomy feeds until age 6, and an atrial septal defect that closed spontaneously.

Conclusion: We hereby challenge previous conclusions in the medical literature that dual diagnoses within the RAS/MAPK pathway are neonatally lethal. The oncogenic potential of dual disruptions within this pathway remains a significant concern for our patient.

Background: The *MBD6* gene encodes the MBD6 protein (methyl-CpG-binding domain protein 6, OMIM #619458), which is an important regulator of the BAP1 complex. Operating as a multiprotein complex, BAP1 functions as a general transcriptional activator by deubiquitinating epigenetic and transcription factors. Depletion of the MBD6 protein results in a reduction of BAP1-dependent gene expression. We hypothesize that germline variants in the *MBD6* gene may lead to a neurodevelopmental phenotype similar to the clinical syndrome caused by germline *BAP1* gene variants.

Methods: We collected information on twelve cases with a neurodevelopmental phenotype and suspected deleterious changes in the *MBD6* gene through GeneMatcher. The variants were detected by exome and genome sequencing.

Results: We gathered clinical data on twelve patients with potentially deleterious heterozygous changes in *MBD6* gene and a neurodevelopmental phenotype. Ten truncating, one missense and one intronic variant were identified. Variants occurred de novo in six patients and were inherited in two (not determined in four). Within our cohort the predominant clinical characteristics included global developmental delay (6/12), abnormal behaviour (7/12), epilepsy (4/12), and dysmorphic features (9/12). Among the observed behavioural abnormalities, 6/12 patients were reported to exhibit features consistent with autism spectrum disorder. Dysmorphic facial features were variable and nonspecific.

Conclusion: The data collected support the hypothesis that the *MBD6* gene is a candidate gene for neurodevelopmental disorders. We are planning to include functional studies in order to determine the molecular effect of the *MBD6* gene variants in our cohort.

Grants: Estonian Research Council grants PRG471, PRG2040, PSG774.

P10.007.B Truncating *ADNP* variants as a recurrent monogenic cause of neurodevelopmental disorders

Mirjana Gusic[1], *Steffen Lott*[1], *Oliver Wachter*[1], *Julia Philippou-Massier*[1], *Konstanze Hörtnagel*[1]

[1]*Medicover Genetics, MVZ Martinsried GmbH, Martinsried, Germany*

Background/Objectives: Neurodevelopmental disorders (NDDs), impacting up to 17% of the population, currently include intellectual disabilities, communication disorders, autism spectrum disorder (ASD), ADHD, specific learning disorders (SLD), and movement disorders (Cainelli et al. 2022). Increased implementation of large-scale sequencing methods (especially the whole exome sequencing) in the last decade has revealed a significant enrichment of de novo variants in individuals with NDD and is becoming a standard tool in genetic diagnostics (Brunet et al. 2021).

Methods: Four individuals age 2–6 were referred to our diagnostic center for whole exome sequencing upon suspicion of a NDD. They shared a common phenotype of global developmental delay, delayed speech and language development and intellectual disability, as well as different types of facial dysmorphisms.

Results: Whole exome sequencing analysis revealed pathogenic variants in the *ADNP* gene, encoding for a transcription factor involved in the SWI/SNF remodeling complex, which were confirmed as de novo in three individuals, where trio-analysis was performed. All variants (three novel) were truncating, located in the fifth (last) exon of the gene and thus predicted to escape nonsense-mediated decay. Review of the literature revealed the *ADNP* gene as one of the most frequent causes of NDD (van Dijck et al. 2019; Gillentine et al. 2022).

Conclusion: This work expands the genetic spectrum and reviews the knowledge of *ADNP*-related disorder, highlighting its prevalence among patients with NDD as well as the clinical value of (trio) sequencing for the rapid discovery of pathogenic variants.

Conflict of Interest: None declared

P10.008.C Clinical and molecular characterisation of BAF complex-related syndromes in the Portuguese population

Daniela Oliveira[1;2;3], *Sara Pinho*[4], *Joana Catanho*[5], *Ana Rita Ferreira Pacheco Quental*[6], *Inês V. Carvalho*[7], *Inês Nunes Vicente*[8], *Carla Marques*[8], *Cristina Pereira*[9], *Margarida Venancio*[5], *Ana Berta Sousa*[4], *Jorge Saraiva*[1;3;10], *Sérgio B. Sousa*[1;2;3]

[1]*Medical Genetics Unit, Paediatric Hospital, Coimbra Hospital and University Centre, Coimbra, Portugal;* [2]*University Clinic of Genetics,*

Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [3]Clinical Academic Center of Coimbra, Coimbra, Portugal; [4]Medical Genetics Unit, North Lisbon University Hospital Centre, Lisboa, Portugal; [5]Medical Genetics Unit, Central Lisbon University Hospital Centre, Lisboa, Portugal; [6]Medical Genetics Unit, São João University Hospital Centre, Porto, Portugal; [7]Neurology Unit, Coimbra Hospital and University Centre, Coimbra, Portugal; [8]Child Development Centre, Paediatric Hospital, Coimbra Hospital and University Centre, Coimbra, Portugal; [9]Paediatric Neurology Unit, Paediatric Hospital, Coimbra Hospital and University Centre, Coimbra, Portugal; [10]University Clinic of Paediatrics, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: BAF complex-related syndromes are a growing group of conditions resulting from mutations in over 29 genes that disrupt its function. Coffin-Siris and Nicolaides-Baraitser syndromes were the first to be recognised but several other intellectual disability (ID) phenotypes are being delineated.

Methods: Retrospective clinical and molecular characterisation of cases with BAF complex-related syndromes from four Portuguese hospital centres.

Results: We describe 38 patients with BAF complex-related syndromes due to variants in *ARID1B* (n:19), *ADNP* (n:3), *ARID2* (n:3), *SMARCA2* (n:3), *SOX11* (n:3), *SMARCB1* (n:2), *SMARCC2* (n:2), *ARID1A* (n:1), *BCL11A* (n:1) and *SMARCA4* (n:1). In two cases, the variant was inherited. We report 18 females and 20 males aged 3-34-year-old. All assessed patients presented developmental delay/ID: 31% mild, 42% moderate, 23% severe and 4% profound. Many patients had hypotonia (72%), CNS abnormalities (67%) and seizures (26%). Other frequent medical issues were visual impairment (69%), cryptorquidism (65%) and feeding problems (56%). Most common dysmorphisms included wide mouth (65%), broad nasal tip (56%), thick lower lip vermillion (55%), coarse facial features (54%), wide nasal base (53%), prominent eyelashes (49%), hypertrichosis (47%). and hypoplastic 5th finger/toenail (41%).

Conclusion: This multicentre study is the first on BAF complex-related syndromes on a large Portuguese cohort. Classical associated features, such as ectodermal anomalies, coarse face and 5th digit hypoplasia, were also commonly found in our cohort. *ARID1B* was confirmed as the most frequent gene involved. Thorough description contributes to increase knowledge of the natural history, genotype-phenotype correlations, and to accurate counselling and personalised management of these patients.

Conflict of Interest: None declared

P10.009.D Mutations in LRRC7, which encodes Densin-180, are linked to intellectual disability, autism, hyperphagia, and aggressive behaviour in human patients.

Jana Willim[1], *Daniel Woike*[2], *Christian Schlein*[3], *Prof. Dr. rer. nat. Hans-Jürgen Kreienkamp*[3]

[1]Human Genetics, University Hospital Salzburg, Salzburg, Austria; [2], Germany; [3]Human Genetics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background/Objectives: Densin-180/LRRC7 is a postsynaptic protein that acts as a scaffold of the postsynaptic density of glutamatergic synapses by connecting actinin and catenin proteins with Shank proteins and αCaMKII.

Methods: Exome-sequencing was performed to identify putative disease-causing variants. Functional analyses in HEK293T-cells were performed to confirm their pathogenicity.

Results: We identified eight individuals with heterozygous missense variants in *LRRC7*, affected by a neurodevelopmental disorder comprising intellectual disability, often accompanied by autism, ADHD and aggression. Variants affect conserved residues in the LRR region (six variants) and the PDZ domain (one variant) of the encoded Densin-180 protein. We analyzed the influence of these variants on the molecular and cellular functions of Densin-180. First, it was tested whether these LRR-specific variants have an influence on known interactions of Densin-180. The binding to αCaMKII, Shank3, and δ-catenin remained unchanged by the LRR domain variants. In contrast, the PDZ-specific missense variant strongly interfered with the interaction with δ-catenin, which is a known partner of the PDZ domain of Densin-180. This results in impaired synaptic targeting of Densin-180 in primary cultured neurons. For the LRR domain, we identified serine/threonine protein phosphatase 1, Erbin and MACF1 as new interaction partners. Four of the LRR-specific variants interfere with binding to all tested partners, while one variant showed a weakened, but non-significant effect. Again, several variants impaired synaptic targeting of Densin-180 in primary cultured neurons.

Conclusion: Taken together, our data suggest that the missense variants disrupt the scaffolding function Densin-180 at postsynaptic sites.

Grants: DFG, Kr1321/9-1 (to Hans-Jürgen-Kreienkamp)

College of Medicine; [21]Genetics Clinics, University Hospital Sharjah, Sahrjah, United Arab Emirates

Background/Objectives: *PPP1R21* encodes for a conserved protein that is involved in endosomal maturation. Biallelic pathogenic variants in *PPP1R21* have been recently linked with a syndromic neurodevelopmental disorder. Here we present 12 additional individuals from ten unrelated families.

Methods: We recruited 12 individuals from 10 unrelated families from diverse ethnic backgrounds. The molecular diagnosis of *PPP1R21*-related NDD was made from clinical or research exome sequencing

Results: We identified nine different variants in *PPP1R21*, of which seven were novel. The main feature of the phenotype is neurodevelopmental delay and all subjects exhibited moderate to severe GDD and ID. Almost all of our subjects had hypotonia (11/12; 92%) while seizures were seen in only four subjects. Three subjects had optic atrophy, one had pale disc with poor tracking and one had nystagmus. Several key features overlapped with lysosomal storage disorders with coarse facial features observed in most individuals along with hypertrichosis in several of them. Two subjects have hepato-(splenomegaly) and one has left ventricular hypertrophy. Respiratory problems, in the form of apnea, recurrent respiratory infections and bronchitis, reported in five subjects. Common findings in brain imaging include delays in myelination, wavy outline of the bodies of the lateral ventricles, and slight prominence of the bodies of the lateral ventricles.

Conclusion:*PPP1R21*-related neurodevelopmental disorder is associated with a consistent phenotype and should be considered in highly consanguineous individuals presenting with developmental delay/intellectual disability along with coarse facial features. While we report the first three missense variants in *PPP1R21*, we did not observe any clear genotype-phenotype correlation.

Conflict of Interest: None declared

P10.011.B Neuronal phenotypes associated with *FBXO11*-deficiency can be alleviated by activation of the proteasome with small molecules

Anne Gregor[1;2], *Laila Distel*[3], *Arif B Ekici*[3], *Philipp Kirchner*[3;4], *Steffen Uebe*[3], *Mandy Krumbiegel*[3], *Soeren Turan*[5], *Beate Winner*[5;6], *Christiane Zweier*[1;2]

[1]*University of Bern, Department of Human Genetics, Inselspital Bern, Bern, Switzerland;* [2]*University of Bern, Department for Biomedical Research (DBMR), Bern, Switzerland;* [3]*Friedrich-Alexander-Universität Erlangen-Nürnberg, Institute of Human Genetics, Erlangen, Germany;* [4]*University of Bern, Institute of Tissue Medicine and Pathology, Bern, Switzerland;* [5]*Friedrich-Alexander-Universität Erlangen-Nürnberg, Department of Stem Cell Biology, Erlangen, Germany;* [6]*Friedrich-Alexander-Universität Erlangen-Nürnberg, Centre for Rare Diseases Erlangen (ZSEER), University Hospital Erlangen, Erlangen, Germany*

Background/Objectives: Haploinsufficiency of *FBXO11* is associated with a variable neurodevelopmental disorder. So far, neither the underlying pathomechanisms nor the function of FBXO11 in the nervous system are well understood. This study aims to shed light on pathways disturbed upon *FBXO11*-deficiency in neurons and to investigate potential therapeutic options of *FBXO11*-associated NDDs.

Methods: Using a combined approach, we induced *FBXO11*-deficiency in a human stem cell based neuronal model and a *Drosophila* model. We performed transcriptomic analyses on neuronal material as well as molecular phenotyping in both models. Additionally, we performed rescue experiments with two proteasome activating substances.

Results: We found that loss of FBXO11 is associated with a range of neuronal phenotypes, including defects in neuronal migration, dendritic arborization and abnormal proliferation/differentiation balance in *Drosophila* and human neurons. We could furthermore identify the stemness factor NANOG as a potential novel substrate of the ubiquitin ligase complex protein FBXO11 and therefore suggest a molecular link between disturbed neuronal function and proteasomal dysfunction in *FBXO11*-deficiency. Activating the proteasome with small molecules PD169316 and R-Verapamil could partially alleviate *FBXO11*-deficiency-associated phenotypes in the fly model.

Conclusion: Our study shows the importance of FBXO11 for neurodevelopment and highlights the reversibility of related phenotypes, which opens an avenue for potential development of therapeutic approaches.

P10.012.C MicroRNAs as potential biomarkers for childhood epilepsy

Sofia Domenech[1], *Amparo Andres-Borderia*[1], *Edna Ripolles*[1], *Nerea Gorria-Redondo*[2], *Francisco García-García*[3], *Sergio Aguilera Albesa*[2], **Carmen Espinós**[1]

[1]*Valencia Biomedical Research Foundation - Centro de Investigacion Principe Felipe (CIPF), Rare Neurodegenerative Diseases, Valencia, Spain;* [2]*Hospital Universitario de Navarra, Navarrabiomed, Paediatric Neurology Unit, Department of Paediatrics, Pamplona, Spain;* [3]*Valencia Biomedical Research Foundation, Centro de Investigacion Principe Felipe (CIPF), Computational Biomedicine Laboratory, Valencia, Spain*

Background/Objectives: Epilepsy is a prevalent chronic disease in childhood. It is estimated that one in 20 children may experience a seizure before the age of 5, and one in 150 will develop epilepsy. Additionally, one in three cases may be associated with behavioral problems or attention deficit hyperactivity disorder, and one in four may develop an intelligence quotient of less than 80, despite good seizure control. The objective of this study is to characterise biomarkers that help in predicting the disease progression and are useful in monitoring treatment.

Methods: We conducted a comparative study between patient cohorts and a sex- and age-matched control cohort. The patient cohort consisted of 200 patients (<14 years old) classified according to their epilepsy: focal idiopathic, generalized, structural and epileptic encephalopathy. We analysed the plasma presentation of 20 microRNAs previously associated with epilepsy. The analysis strategy included data processing and normalisation, differential expression analysis and assessment of the predictive performance of significant miRNAs from logistic regression models.

Results: A significant differential pattern was detected in the presentation of six microRNAs, namely miR-15a-5p, miR-128-3p, miR-139-5p, miR-155-5p, miR-181c-5p and miR-323a-5p, both intra- and inter-cohorts.

Conclusion: The analysis of the miRNA profile mentioned above allows differentiation between the four study groups, and combinations of them are specific signatures for each of the patient groups (focal idiopathic, generalized, structural and epileptic encephalopathy).

Grants: This study was supported by the Alicia Koplowitz Foundation and Generalitat Valenciana (CIAICO/2022/24).

P10.013.D Insight into inter-individual phenotypic differences in Korean patients with 16p11.2 deletion

Ji Yoon Han[1]

[1]Deajeon St. Mary's Hospital, Pediatric Neurology, Daejeon, Korea, Rep. of South

Background/Objectives: The 16p11.2 copy number variations (CNVs) is increasingly recognized as one of the most frequent genomic disorders and the 16p11.2 deletion exhibits broad phenotypic variability and a diverse clinical phenotype. We describe on the neurodevelopmental course and discordant clinical phenotypes observed within and between individuals with the identical 16p11.2 deletion

Methods: The analysis of the CytoScan Dx Assay was conducted on the GeneChip System 3000Dx and the signal for the sample was then compared to a reference set using the Chromosome Analysis Suite (ChAs Dx) software.

Results: Ten patients from six separate families were identified with 16p11.2 deletion. Nine breakpoint (BP) 4-5 and one BP 2-5 of the 16p11.2 deletion were identified. All patients with 16p11.2 deletion exhibited developmental delay and/or intellectual disability. 60% of the patients presented with neonatal hypotonia, but muscle weakness improved with age. Benign infantile epilepsy manifested between the ages of 7-10 months (median 8 months) in six patients (60%). Vertebral dysplasia was observed in two patients (20%), and mild scoliosis was noted in three patients. 60% of patients were overweight.

Conclusion: We present six unrelated Korean families wherein identical 16p11.2 deletions resulted in diverse developmental trajectories and discordant phenotypes. The clinical variability and incomplete penetrance observed in individuals with 16p11.2 deletions remain unclear, posing challenges in accurate clinical interpretation and diagnosis.

P10.014.A Comprehensive in silico functional analysis of CDKL5 involved in a genetic Intellectual Disability

Tetsuya Inazu[1;2], Atsushi Morii[2], Yuuki Fujino[1], Kyoka Takeuchi[1]

[1]Ritsumeikan University, Department of Pharmacy, College of Pharmaceutical Sciences, Kusatsu, Shiga, Japan; [2]Ritsumeikan University, Graduate School of Pharmaceutical Sciences, Kusatsu, Shiga, Japan

Background/Objectives: Cyclin-dependent kinase-like 5 (CDKL5) deficiency disorder (CDD) is involved in X-linked epilepsy and intellectual disability. CDKL5 is a serine/threonine protein kinase whose pathological mutations cause CDD. Most missense mutations are concentrated in the catalytic domain.

As the mutations for the disease are increasing revealed by next-generation sequencing, variants of uncertain significance are occasionally determined.

Therefore, anticipating whether mutations in this region affect CDKL5 function is informative for clinical diagnosis.

We aimed to determine the comprehensively predicted the pathogenicity of all missense substitutions in the catalytic domain of CDKL5 using in silico analysis.

Methods: The analysis range is from amino acids 1 to 300 in the catalytic domain of CDKL5.

Each authentic human amino acid was virtually changed to 19 different amino acids for a total of 5700 missense substitution.

We used in silico prediction tools such as PolyPhen-2 HumDiv mode/HumVar mode, PROVEAN, and SIFT were selected individually or in combination with one another to analyze them. We also evaluated their accuracy using previously reported mutations as a reference. Each missense substitution was finally evaluated as "pathogenic" or "benign".

Results: Substitutions predicted as pathogenic were over 82.6% using each of the three tools.

A comprehensive in silico functional analysis of CDKL5 showed that the combination of PolyPhen-2 HumDiv, PolyPhen-2 HumVar, and PROVEAN tools gave the best performance for predicting the severity of mutations.

Conclusion: These results provide information that could accurately predict the pathogenicity of the disease.

P10.015.B GenIDA, an international participatory database to better characterize comorbidities of genetic forms of intellectual disability: novel findings on KBG, SETD5 and DDX3X syndromes

Pauline Burger[1], Chloé soyer[2], Nicolas Chatron[2;3], Charlotte Ockeloen[4], Tjitske Kleefstra[4;5], Valentin Ruault[6], David Geneviève[6], Elana Forbes[7], Lottie Morison[7], Angela Morgan[7;8], Jean Louis Mandel[1;9]

[1]I.G.B.M.C. - Institut de génétique et de biologie moléculaire et cellulaire, Université de Strasbourg, Department of Neurogenetics and Translational Medicine, Illkirch-Graffenstaden, France; [2]Institut NeuroMyoGène - Université de Lyon, Laboratoire Physiopathologie et Génétique du Neurone et du Muscle, Lyon, France; [3]Hospices Civils de Lyon, Service de Génétique, Lyon, France; [4]Radboud University Medical Center, Dept. of Human Genetics, Nijmegen, Netherlands; [5]Erasmus MC, Dept. of Human Genetics, Rotterdam, Netherlands; [6]Université de Montpellier, Centre Hospitalier Universitaire Montpellier, Montpellier, France; [7]Murdoch Children's Research Institute, Speech & Language, Melbourne, Australia; [8]University of Melbourne, Department of Audiology and Speech Pathology, Parkville, Australia; [9]University of Strasbourg Institute for Advanced Studies, Strasbourg, France

Background/Objectives: GenIDA is an international participatory registry designed to better characterize the clinical manifestations and natural history of genetic forms of intellectual disability (ID).

Methods: Clinical information reported and updated by the patient's family using a structured questionnaire exploring physical parameters, cognitive and behavioural aspects, etc. is analysed to identify new medically relevant information for families and professionals concerned with a given condition. The questionnaire currently available in 8 languages has been completed for over 1900 patients.

Results: We have evaluated the benefit of caregivers' self-reported data on clinical characterization of 2 conditions that can hardly be distinguished: ANKRD11 variants, responsible for KBG syndrome, and SETD5 variants, responsible for a KBG-like phenotype. This approach enabled us to highlight quality of life issues, such as the consequences of epilepsy for KBG individuals ($n = 57$), or gastrointestinal problems for SETD5 individuals ($n = 37$).

The phenotypic description of DDX3X-related condition has been extended: our results, consistent with the literature regarding sleep disorders, and delays in developmental milestones in these individuals ($n = 62$), further indicate that behavioural problems seem more important than previously reported: besides ADHD, caregivers experience significant daily impulsivity, stereotypies and anxiety issues.

Conclusion: These results validate the interest of our participatory approach: through their direct involvement, families can

reveal previously underestimated aspects of the disorder and highlight their major concerns in their daily lives. More than a complement to medical reports, GenIDA can be used by specialists for "prospective phenotyping" to consolidate knowledge of ID syndromes and improve prognosis and patient management.

P10.016.C Missense variant in PDZ-domain of DLG3 causes syndromic X-linked intellectual developmental disorder.

Shiomi Otsuji[1], *Seiji Mizuno*[1], *Natsuki Nakamura*[1], *Tomoko Uehara*[1], *Mamiko Yamada*[2], *Hisato Suzuki*[2], *Toshiki Takenouchi*[3], *Mie Inaba*[1], *Kenjiro Kosaki*[2]

[1]*Aichi Developmental Disability Center Central Hospital, Department of Pediatric Internal Medicine and Clinical genetics, Kasugai, Japan;* [2]*Keio University School of Medicine, Center for Medical Genetics, Tokyo, Japan;* [3]*Keio University School of Medicine, Department of Pediatrics, Tokyo, Japan*

Background/Objectives: Truncating variants in *DLG3* were found to cause X-linked intellectual disability (XLID), however, clinical significance of the missense variants has been unknown. DLG3 gene is located at Xq13.1 and encodes synapse-associated protein 102 (SAP102), a member of the membrane-associated guanylate kinase protein family. Neuronal SAP102 is expressed during early brain development and is localized to the postsynaptic density of excitatory synapses. We identified a novel missense variant in *DLG3* in a male with severe intellectual disability and dysmorphic features.

Methods: We compared our patient with reported patients regarding clinical features and discussed pathogenicity of the variant.

Results: The patient was 22-year-old Japanese male, who was referred to our department for developmental delay when he was 9 months old. He had no family history of neurological disorders. He was born to unrelated, healthy Japanese parents. He showed overgrowth of +2SD in his childhood, while his final height was 173 cm (1.0SD). He showed some dysmorphic physical features similar to reported patients with truncating variants in the *DLG3*. Whole exome sequencing identified a hemizygous missense variant in the PDZ2-domain of *DLG3* (NM_021120.3:c.848A>C;p.Asn283Thr), which was evaluated as of uncertain significance according to the ACMG guideline. Multiple lines of computational evidence support a deleterious effect on the gene product.

Conclusion: The PDZ domains have been shown to interact with the NR2 subunits of the NMDA glutamate receptor. We speculate the N283T variant causes syndromic XLID via impaired interaction with the NMDA receptor. Functional studies are necessary to provide more conclusive evidence.

P10.017.D Determining the optimal quality and depth of phenotypic information to maximize diagnostic yield in neurodevelopmental disorders

Alexander Dingemans[1], *David Koolen*[1], *Nicole de Leeuw*[1], *Rolph Pfundt*[1], *Janneke Schuurs-Hoeijmakers*[1], *Bregje van Bon*[1], *Charlotte Ockeloen*[1], *Carlo Marcelis*[1], *Marjolein Willemsen*[1], *Anneke Vulto-van Silfhout*[1], *Bert de Vries*[1], *Lisenka Vissers*[1]

[1]*Radboud University Medical Center, Human Genetics, Nijmegen, Netherlands*

Background/Objectives: Although phenotypic data is crucial in diagnostics, it remains unclear at what 'quality and depth' such data is needed. We investigated the minimal level of phenotypic detail and depth needed to maximally impact diagnostic yield.

Methods: We deep-phenotyped 285 individuals with neurodevelopmental disorders (median 17 Human Phenotype Ontology (HPO) terms per individual) for whom a diagnosis was established using trio-exome sequencing. Using Exomiser as benchmark, we assessed the impact on diagnostic yields in different scenarios by comparative analyses of permuted input data using complete phenotypic profiles, different branches of the HPO tree, and varying information content of HPO terms.

Results: Using all phenotypic data achieved a top-1 sensitivity of 78%. The use of specific HPO branches like the nervous system maintained 75% sensitivity using only 1553 of 5173 terms (27%), while several others (such as the immune system) lowered accuracy to 67%, with no phenotypic data resulting in a sensitivity of 69%. A reduced set of HPO terms from strategically selected branches maintained a high sensitivity (77%), despite comprising only 40% of the HPO terms. Surprisingly, there was no correlation between the information content (Pearson's $r = 0.04$, $p = 0.45$) or number of HPO terms ($r = 0.02$, $p = 0.79$) and diagnostic yield. Phenotypic data was especially useful when interpreting missense variants (72% vs 46% without phenotypic data) and inframe deletions (57% vs 43%).

Conclusion: Our study establishes guidelines for phenotypic data collection, demonstrating that carefully selecting key HPO terms can maintain high diagnostic accuracy while reducing data volume by 60%, saving time and resources, without sacrificing diagnostic yield.

P10.018.A Two novel distinguishable entities within the Coffin-Siris syndrome spectrum caused by specific missense variants in ARID1A and ARID1B

Eline van der Sluijs[1], *Alfredo M. Valencia*[2;3;4], *Ajinka Patil*[2;3], *Alexander Dingemans*[5], *Bert de Vries*[5], *Bekim Sadikovic*[6], *Marielle Alders*[7], *Cigall Kadoch*[2;3;8], *Gijs Santen*[1]

[1]*Leiden University Medical Center, Clinical Genetics, Leiden, Netherlands;* [2]*Dana-Farber Cancer Institute, Department of Pediatric Oncology, Boston, United States;* [3]*Broad Institute of MIT and Harvard, Cambridge, United States;* [4]*Stanford University, Department of Psychiatry and Behavioral Sciences, Stanford, United States;* [5]*Radboud University Medical Center, Department of Human Genetics, Nijmegen, Netherlands;* [6]*London Health Sciences Centre, Verspeeten Clinical Genome Centre, London, Canada;* [7]*Amsterdam UMC, locatie AMC, Department of Clinical Genetics, Amsterdam, Netherlands;* [8]*Howard Hughes Medical Institute, Chevy Chase, United States*

Consortium: ARID1 consortium

Haploinsufficiency of *ARID1A* and *ARID1B* causes Coffin-Siris syndrome (CSS) or non-specific intellectual disability (ID). Non-truncating variants in *ARID1A* and *ARID1B* are increasingly being identified owing to routine sequencing, however variant classification remains challenging due to the variable phenotype. We used two complementary approaches to investigate non-truncating variants: Phenoscore analysis, an artificial intelligence-based phenomics framework, using detailed phenotype data, photos, and DNA methylation analysis.

We identified 139 patients (*ARID1A* $n = 81$, *ARID1B* $n = 58$) with 124 unique non-truncating variants in *ARID1A* ($n = 70$) or *ARID1B* ($n = 54$). Sixteen variants were recurrent and 3 patients had

multiple non-truncating variants. Clinical data was available of 97 patients. DNA methylation analysis was performed for 64 variants.

Seventy-six variants were considered pathogenic because of a CSS-consistent phenotype, variant recurrence and/or de novo inheritance ($n = 46$), a BAFopathy episignature ($n = 8$), or both ($n = 22$). Pathogenic variants were predominantly located in either the ARID- DNA-binding($n = 26$) or C-terminal Core binding region (CBR)/Arm repeat-domains ($n = 33$) of both genes. In 5 *ARID1A* and 1 *ARID1B* patients with 4 unique variants in the CBR-domain and a CSS-compatible phenotype who lacked this episignature, a novel alternative episignature was identified. All patients had ID, other frequent features were short stature (*ARID1A* 85%, *ARID1B* 77%), brain anomalies (*ARID1A* 83%, *ARID1B* 75%) and cardiovascular anomalies (*ARID1A* 51%, *ARID1B* 15%, $p = 0.05$). PhenoScore analyses identified differences between *ARID1A* patients with variants in the ARID-domain compared to CBR-domain patients($p < 0.01$). ARID-domain patients have less severe ID ($p = 0.02$) and less myopia (100% versus 33%, $p = 0.03$) compared to CBR-domain patients.

Here, we report two novel clinical and (epi)genetic entities within the CSS spectrum.

P10.019.B Effects of *WDFY3* loss-of-function in a human neuroblastoma model

Moritz Paha[1;2], *Sandy Richter*[2], *Max Holzer*[3], *Rami Abou Jamra*[1], *Johannes Lemke*[1], *Wieland Kiess*[2], *Antje Garten*[2], *Diana le Duc*[1;4]

[1]*Institute of Human Genetics, University of Leipzig Medical Center, Leipzig, Germany;* [2]*Center for Pediatric Research Leipzig, University Hospital for Children and Adolescents, Leipzig, Germany;* [3]*Paul Flechsig Institute for Brain Research, Department for Molecular and Cellular Mechanisms of Neurodegeneration, Leipzig, Germany;* [4]*Department for Clinical Genetics, Zentrum für Diagnostik GmbH am Klinikum Chemnitz, Chemnitz, Germany*

Neurodevelopmental disorders (NDD) are poorly understood and late diagnosis and interventions result in a high burden for the society and health system.

WD repeat and FYVE domain-containing protein 3 (WDFY3) acts as an adaptor and scaffolding protein in selective autophagy. Variants in *WDFY3* have been identified as a monogenic cause for NDD and are also associated with altered brain size. We (re-) analysed a large cohort of patients ($n = 26$) and present a comprehensive description of *WDFY3*-associated phenotypes. We found that brain size phenotypes are not related to specific protein domains.

To dissect effects of *WDFY3* loss-of-function we used the human neuroblastoma cell line SH-SY5Y to establish a *WDFY3* knockdown. Proliferation was increased as determined by cell counting, staining for Ki-67 and *PCNA* expression. Differentiation was decreased as shown by quantification of neurite tracing. We suggest that *WDFY3* plays a role in neuronal differentiation as *WDFY3* expression was increased in differentiated cells. These effects might be caused by downregulated wnt/β-catenin signalling since we observed lower levels of endogenous β-catenin protein. We also observed impaired clearance of aggregated Huntingtin protein and decreased protein levels of the ubiquitin-binding protein p62. We believe that this impairment of selective autophagy could be caused by incorrect interaction of WDFY3 and p62. Lastly, we found that treatment with the GSK-3β inhibitor lithium chloride was able to increase the expression of *WDFY3* and are currently investigating therapeutic implications.

This study is funded by the Else Kröner-Fresenius-Stiftung 2020_EKEA.42 to D.L.D. M.P. holds a stipend from the Roland Ernst Stiftung.

P10.020.C Exome capture RNA-Seq from short-term lymphocyte cultures: A promising alternative to fibroblasts for diagnosing neurodevelopmental disorders

Thomas Besnard[1;2], *Laura Do Souto Ferreira*[1], *Virginie Vignard*[2], *Fabrice Airaud*[1], *Patricia Talarmain*[1], *Gaelle Landeau-Trottier*[1], *Eva Trochu*[1], *Delphine Quinquis*[1], *Jerome Buscail*[1], *Wallid Deb*[1;2], *Frédéric Ebstein*[2], *Sebastien Küry*[1;2], *Annastasia Voisine*[1], *Solène Conrad*[1], *Sandra Mercier*[1;2], *Mathilde Nizon*[1;2], *Marie Vincent*[1;2], *Bertrand Isidor*[1;2], *stéphane bezieau*[1;2], **Benjamin Cogné**[1;2]

[1]*CHU de Nantes, Service de Génétique médicale, Nantes, France;* [2]*Nantes Université, CHU de Nantes, CNRS, INSERM, l'institut du thorax, Nantes, France*

Background/Objectives: In France, the national genomic plan (PFMG 2025) has significantly advanced genome analysis for diagnosing neurodevelopmental disorders (NDD). However, with a current diagnostic rate of approximately 35%, many families still face diagnostic odyssey. RNA-Seq is being increasingly considered as the best complementary technique. However, whole blood yielded poor results and fibroblasts are currently the best clinically accessible tissue. Our objective was to find a clinical alternative to fibroblasts suitable for RNA-Seq analysis.

Methods: We collected 60 blood samples from probands with NDD or relatives. PBMCs were isolated and lymphocytes were cultured for 2 to 4 days on karyotyping medium with or without a 4-hour puromycin treatment. Automated exome capture RNA-Seq libraries were generated with SureSelect XTHS1 on the MAGNIS platform (Agilent) and sequenced on the NextSeq550 (2x75bp). Fastq were aligned with STAR on GRCh38, then splicing and expression outliers were identified using FRASER and OUTRIDER, respectively.

Results: Principal component analysis showed that short-term lymphocyte cultures exhibited homogenous gene expression, comparable to fibroblasts. We achieved at least 20X coverage for 66% of NDD genes, surpassing poly-A RNA-Seq on fibroblasts (58%) at equivalent sequencing depth (30 million paired-reads). We confirmed the pathogenicity of splicing-altering variants identified by genomics, alongside the detection of aberrant splicing and expression events in undiagnosed patients. We will show the first results of the study on undiagnosed patients confirming the interest of this strategy even after a negative genome.

Conclusion: Exome capture RNA-Seq from short-term lymphocyte cultures holds the potential for widespread application in NDD diagnosis.

P10.021.D Optical genome mapping finally unveils the genetic cause of aniridia and intellectual disability in a 17-year-old after seven years of diagnostic odyssey

Wilena Telman[1], *Uwe Heinrich*[1], *Aysegül Klapperich*[2], *Jenny Schiller*[1], *Konstanze Hörtnagel*[1]

[1]*MVZ Martinsried GmbH, Planegg, Germany;* [2]*MVZ Humangenetik Köln GmbH, Köln, Germany*

Background/Objectives: We report on a 17-year-old female with aniridia, optic nerve hypoplasia, intellectual disability, and current overweight, raising suspicion of WAGR syndrome (Wilms tumor, aniridia, genitourinary anomalies, and impaired intellectual development syndrome). Microdeletions involving the *WT1* gene (*WT1* transcription factor) and the *PAX6* gene (paired box gene 6) cause WAGR syndrome. Previous chromosome analysis revealed a de novo reciprocal translocation t(11;22)(p13;q11.2).

Methods: Despite inconspicuous pre-diagnostics in 2015 (MLPA of *WT1* and *PAX6*, *PAX6* sequencing and microarray analysis), we were able to characterize the translocation breakpoints by using optical genome mapping (OGM, Bionano Genomics), uncovering the genetic cause for the patient's symptoms.

Results: The translocation was defined as seq(GRCh38) t(11;22)(p13;q12.1), pinpointing the breakpoints to a 5.5 kb region in intron 9 of the *ELP4* (elongation acetyltransferase complex, subunit 4) gene. This breakpoint lies approximately 103 kb downstream of the *PAX6* gene and causes the loss of the highly conserved regulatory element "SIMO" (ultra-conserved *PAX6* cis-regulatory element) within the *ELP4* gene, which is essential for *PAX6* gene expression. Causative variants in *PAX6* or its regulatory cis-elements can lead to aniridia, optic nerve hypoplasia and, rarely, autosomal dominant mental retardation.

Conclusion: This case underscores the diagnostic value of OGM, identifying the genetic basis for symptoms persisting over seven years of negative molecular pre-diagnostics.

P10.022.A Rubinstein-Taybi syndrome: Characterization of epigenetic profiles to study the molecular mechanisms of the disease

Julien Van Gils[1], *Slim Karkar*[2], *Aurélien Barré*[2], *Sophie Nothof*[3], *Stéphane Claverol*[4], *Caroline Tokarski*[4], *Jean-Philippe Trani*[3], *Natacha Broucqsault*[3], *Claire El Yazidi*[3], *Didier LACOMBE*[1], *Patricia Fergelot*[1], *Frédérique Magdinier*[3]

[1]*Inserm U1211, Bordeaux, France;* [2]*Bordeaux Bioinformatic Center, Bordeaux, France;* [3]*Inserm U1251, Marseille, France;* [4]*Bordeaux Proteomic Platform, Bordeaux, France*

Rubinstein-Taybi syndrome (RTS) is a rare and severe genetic developmental disorder characterized by multiple congenital anomalies and intellectual disability. *CREBBP* and *EP300*, the two genes that are causative of RTS, encode transcriptional coactivators that possess a catalytic lysine acetyl transferase domain. RTS is considered as a model of epigenetic neurodevelopmental disorders. In RTS patients, nothing is known on the functional link between histone acetylation and transcriptomic profiles during neuronal differentiation.

We derived induced pluripotent stem cells from RTS patients carrying a recurrent *CREBBP* mutation. We differentiated these cells into cortical and pyramidal neurons. We compared their acetylome by LS-MS/MS and transcriptome by RNA-seq to cells derived from healthy donors at three different timepoints during neuronal differentiation.

We identified 25 specific acetylated histone marks that are specifically altered in RTS. All four core histones are regulated by CBP but H2B and H3 acetylation levels are the most impacted. By transcriptomic analyses, we identified the transition between neural progenitors and immature neurons as a critical step of the differentiation process, with an impact on genes involved in neuronal differentiation and brain development. Secondly, comparison of transcriptome analysis on fibroblasts with those obtained on neurons enabled us to identify 8 potential biomarkers that could define a transcriptomic signature of RTS in fibroblasts.

Our data highlight specific histone acetylation changes and a crucial phase of differentiation as a hallmark of RTS neuronal development. Analysis on fibroblasts reflects the alterations observed at neuronal level, making it a tissue of choice for the identification and testing of biomarkers in routine care diagnostics.

Conflict of Interest: None declared

Background: The *HCFC1* gene encodes a transcriptional co-regulator. Pathogenic missense variants have been reported in males with a X-linked neurodevelopmental disorder ranging from severe intellectual disability (ID) with drug-resistant epilepsy and cobalamin metabolism disorder (CblX) to non-specific ID without CblX, and even isolated epilepsy. A genotype-phenotype correlation has been evoked, with CblX associated variants being localized into the K1 and K2 repeats. However, as for other X-linked genes, the interpretation of inherited missense variants in *HCFC1* is a huge challenge, especially in case of non-CblX ID, as illustrated by the numerous variants of uncertain significance (VUS) reported (n = 205 VUS versus 7 pathogenic/likely pathogenic variants in ClinVar).

Objectives: The identification of relevant clinical and molecular data (including carrier mothers' X chromosome inactivation (XCI)

status) is therefore necessary to improve variants interpretation and increase the diagnostic of the non-CblX form of ID associated to *HCFC1* variants.

Methods and results: We identified one missense variant p.(Arg320Cys), located out of the K2 repeats, in three patients with moderate ID without CblX, from two unrelated families. Asymptomatic mothers presented with extremely skewed XCI, as in the three previously reported families. We collected clinical and molecular data for a dozen additional missense VUS through a French collaboration call.

Conclusion: These first results help to better describe the phenotypical spectrum of *HCFC1* related disorders, in particular the non-CblX ID form, confirm the correlation between variants' location and the CblX versus non-CblX phenotypes, and suggest that studying XCI in carrier females is useful to interpret *HCFC1* VUS.

P10.024.C *EXOC1*: A novel candidate gene for syndromic intellectual disability with autosomal recessive inheritance

Lauren Badalato[1]

[1]*Queen's University, Pediatrics, Kingston, Canada*

Background/Objectives: *EXOC1* is a component of a multimeric complex involved in ciliogenesis, cell migration, and fusion of secretory vessels. While *EXOC1* has not yet been associated with a particular genetic condition in humans, other genes in the same exocyst complex, including *EXOC7* and *EXOC8*, have been associated with autosomal recessive neurodevelopmental disorders. One study reported that knockout of *Exoc1* was perinatal lethal in mice, suggesting a crucial biological importance of this gene.

Methods: Whole exome sequencing (WES) was performed in a clinical laboratory; the patient's records were reviewed and a clinical genetics exam was performed.

Results: The patient is currently 19 years of age and has a history of microcephaly, dysmorphism, and moderate intellectual disability.

WES identified biallelic frameshift variants in *EXOC1*: c.113dupT, p.Leu38PhefsX8 (pat), / c.31_32delGA, p.Asp11HisfsX6 (mat). Familial variant testing was also completed in the proband's unaffected sister, who was found to be heterozygous for the paternal variant.

Conclusion: We present *EXOC1* as a candidate gene for an autosomal recessive intellectual disability syndrome. While we are unable to draw definitive conclusions from single patient, the association of other exocyst subunit proteins with autosomal recessive neurodevelopmental disorders and microcephaly raises suspicion that complete loss of function of *EXOC1* may have similar effects. Studies are ongoing to better understand the functional impact of these variants.

Conflict of Interest: None declared

P10.025.D Novel UPF3B nonsense variant in two brothers with X-linked intellectual developmental disorder MRXS14

Maria Yusenko[1], *Silke Loeper*[2], *Kristina Doering*[1], *Krzysztof P Lubieniecki*[1], *Joanna Lubieniecka*[1], *Huu Phuc Nguyen*[1], *Sabine Hoffjan*[1]

[1]*Faculty of Medicine, Ruhr University Bochum, Department of Human Genetics, Bochum, Germany;* [2]*University Children's Hospital, Ruhr-University Bochum, Department of Neuropediatrics, Bochum, Germany*

Background/Objectives: MRXS14 is a rare X-linked intellectual developmental disorder (OMIM: 300676) with variable severity and type of clinical presentations. It is caused by *loss-of-function* variants in the *UPF3B* gene located on chromosome Xq24. As a member of the nonsense-mediated mRNA decay pathway, UPF3B is known to be important for normal development und function of the brain. So far only a limited number of patients and variants for this rare disorder have been reported.

Methods: In a family with two affected boys, we performed whole-exome-sequencing (WES) which revealed the novel nonsense variant c.240del; p.(Phe80Leufs*51) in *UPF3B* in both children in hemizygous state. The healthy mother is heterozygous carrier of this variant. We compare the clinical phenotype to that of other patients described in the literature.

Results: Both boys share some clinical features, including global developmental delay, hypertelorism, facial dysmorphism and muscle hypotonia. However, the overall clinical picture differs between the brothers, with the older boy additionally only showing macrocephaly, whereas his younger brother was born with severe congenital heart disease and frontal brain atrophy with hydrocephaly.

Conclusion: WES allowed to make the diagnosis in our patients. Our findings will help to further delineate the genotypic and phenotypic spectrum of MRXS14 disorder.

Conflict of Interest: None declared

P10.026.A YAF2: a novel candidate gene implicated in autosomal recessive non-syndromic intellectual disability

Ghazala Zafar[1], *Lubaba Bintee Khalid*[1], *Zafar Ali*[2], *Sohana Nadeem Hashami*[1], *Mathias Toft*[3;4], *Zafar Iqbal*[4], **Ambrin Fatima**[1]

[1]*Aga Khan University, Biological and Biomedical Sciences, Karachi, Pakistan;* [2]*University of Swat, Centre for Biotechnology and Microbiology, Swat, Pakistan;* [3]*University of Oslo, Institute of Clinical Medicine, Oslo, Norway;* [4]*Oslo University Hospital, Department of Neurology, Oslo, Norway*

Background/Objectives: Non-syndromic intellectual disability is a rare neurodevelopmental condition with significant limitation of cognitive functioning and adaptive behaviour as the primary disability. Extreme clinical and genetic heterogeneity has been witnessed for this condition.

Methods: We recruited a consanguineous Pakistani family manifesting severe non-syndromic intellectual disability. Two affected brothers were subjected to whole exome sequencing (WES) and shared variants were further prioritized based on population frequency, predicted pathogenicity and functional relevance.

Results: The WES data revealed a homozygous frameshift variant, c.470dup (NM_005748.6); (p.Asn157Lysfs*62) in the gene *YAF2*, which co-segregated with the disease. *YAF2* encodes a zinc finger containing protein that functions in transcription regulation and an interacting partner of a transcriptional repressor protein YY1, which has been implicated in developmental delay/intellectual disability (DD/ID). *YAF2* deletion in zebra fish and mouse embryonic stem cells (mESCs) causes developmental arrest and leads to impaired proliferation and abnormal differentiation. It primarily acts as a transcriptional repressor, notably affecting genes related to ectoderm cell fate.

Conclusion: Our findings indicate that *YAF2* is a novel candidate gene responsible for non-syndromic intellectual disability. Further, genetic recurrence and functional studies are warranted to consolidate the role of *YAF2* variants in disease manifestation.

Conflict of Interest: None declared

P10.027.B Phenotypic variability of patients with an identical *SHOC2* variant

Reena Buurman[1], *Karsten Thiel*[2], *Ulrich Baumann*[3], *Nataliya Di Donato*[1], *Sandra von Hardenberg*[1], *Bernd Auber*[1]

[1]*Institute of Human Genetics, Hannover Medical School, Hannover, Germany;* [2]*Clinic for Children and Adolescent Care, St. Clemens Hospital Geldern, Geldern, Germany;* [3]*Pediatric Pneumology, Allergology and Neonatology, Hannover Medical School, Hannover, Germany*

Background/Objectives: The SHOC2 protein is involved in the MAPK-signaling pathway. A specific variant in *SHOC2*:c.4A>C is known to cause Noonan-like syndrome with loose anagen hair (NS/LAH) (MIM 607721). NS/LAH is a RASopathy characterized by symptoms such as macrocephaly, growth retardation, mental retardation and cardiac defects. Here we present two NS/LAH patients with additional distinct symptoms which might add to the phenotypic spectrum of NS/LAH.

Methods: Whole genome sequencing was performed using the Illumina NovaSeq 6000 platform. Variant analysis was conducted using the Alamut (Interactive Biosoftware, Rouen, France) and GSvar Tübingen, Germany) programs. Variant classification followed the current ACMG Standards. *SHOC2* reference transcript: NM_001324336.2

Results: We identified a well-known pathogenic variant c.4A>C p.(Ser2Gly), that is typically associated with a consistent clinical phenotype of NS/LAH, in two individuals referred for genetic analysis because of additional symptoms, which were previously not described in the SHOC2 phenotype. Patient 1: A one-year-old boy, presented with unexplained hepatopathy and mental retardation. Initial testing for hepatopathy-associated genes was requested and showed no significant findings. However, an extended WGS analysis identified the recurrent *SHOC2* variant. Patient 2: An 18-year-old male with cardiac issues, sparse hair, short stature and therapy-refractory autoimmune diseases was initially tested for immunodeficiency-associated genes with inconclusive results. Subsequent WGS analysis revealed the *SHOC2* variant. Trio genome analysis revealed no additional variants that might be causative for immune phenotype.

Conclusion: We report two novel phenotypes associated with the recurrent pathogenic missense variant in *SHOC2*. This variant appears to have a broader phenotypic spectrum than previously recognized.

P10.028.C Confirming *NUSAP1* as a disease gene for a syndromic neurodevelopmental disorder: insights from the third case

Maureen Jacob[1], *Susann Badmann*[1], *Theresa Brunet*[1;2], *Juliane Winkelmann*[1;3;4], *Matias Wagner*[1;2;4]

[1]*Institute of Human Genetics, School of Medicine, Technical University of Munich, Munich, Germany;* [2]*Dr. v. Hauner Children's Hospital, Department of Pediatric Neurology and Developmental Medicine, LMU - University of Munich, Munich, Germany;* [3]*Munich Cluster for Systems Neurology (SyNergy), Munich, Germany;* [4]*Institute of Neurogenomics, Helmholtz Zentrum München, Munich, Germany*

Background: By maintaining spindle function during metaphase, *NUSAP1* plays an important role in mitosis. Mo et al. recently described an association between a heterozygous de novo nonsense variant in *NUSAP1* in the penultimate exon and a neurodevelopmental symptom complex including congenital microcephaly, seizures, and severe developmental delay based on two unrelated individuals. Here, we present a third case with an overlapping phenotype and a heterozygous de novo nonsense variant in the last exon of *NUSAP1*.

Methods: DNA, extracted from blood samples of the patient and parents, was used for trio exome sequencing (ES). The patient's phenotype was systematically analyzed using HPO-terms (i.e. severe microcephaly, global developmental delay, seizures).

Results: ES failed to identify a pathogenic variant in established disease genes listed in OMIM. Subsequent analysis of rare de novo variants identified a heterozygous nonsense variant in the candidate gene *NUSAP1* (NM_016359.5:c.1264C>T, p.Arg422Ter), located in the last exon and not previously reported in the literature.

Conclusion: To date, we present the third case of *NUSAP1*-associated microcephaly and a neurodevelopmental phenotype, thereby strengthening its role as a disease gene. Notably, with a pLI of 0, *NUSAP1* appears to be tolerant to Loss-of-function variants. Our findings not only contribute to the growing evidence that variants located towards the C-terminus of *NUSAP1* escape nonsense-mediated decay but also raise the hypothesis that these variants, particularly in the charged helical domain, may have dominant-negative or gain-of-function effects. We propose that such variants could induce an over-stabilization of the spindle assembly and thereby disrupt cell division processes.

Background/Objectives: Zinc RING finger 3 (ZNRF3) is a negative-feedback regulator of Wnt/β-catenin signaling, which plays an

important role in human brain development. Although somatic mutations are frequently observed in cancer, germline variants in ZNRF3 have not been established as causative for neurodevelopmental disorders (NDDs).

Methods: We identified 12 patients with ZNRF3 variants and various phenotypes via GeneMatcher and evaluated genotype-phenotype correlation. After structural modelling, representative deleterious and control variants were assessed using in vitro transcriptional reporter assays with and without Wnt-ligand Wnt3a and Wnt-potentiator R-spondin (RSPO).

Results: We collected eight patients harboring de novo missense variants, who all presented with NDD. In addition, we obtained four patients with truncating variants, who showed non-NDD features, including heart, adrenal, or nephrotic problems. We found missense variants associated with macrocephalic NDD to cluster in the RING ligase domain. By structural modeling we predicted disruption of the ubiquitin ligase function likely compromising the Wnt receptor turnover. Accordingly, the transcriptional reporter assays showed enhanced Wnt/β-catenin signaling for these variants in a dominant negative manner. Contrarily, a patient with microcephalic NDD harbored a missense variant in the RSPO binding domain predicted to disrupt binding affinity to RSPO and showed attenuated Wnt/β-catenin signaling in the transcriptional reporter assays. In contrast to NDD-associated missense variants, the truncating variant behaved as the empty vector, and benign variants as the wildtype.

Conclusion: We provide evidence for mirror brain size phenotypes caused by distinct pathomechanisms in Wnt/β-catenin signaling through protein domain-specific deleterious ZNRF3 germline missense variants.

P10.030.A The cell division cycle protein 20 (*CDC20*) gene as a candidate gene for autosomal recessive syndromic microcephaly

Daniel L. Polla[1], *Mukunth Sadagopan*[1], *Javier Martini*[1], *Inês C Fernandes*[1], *Adnan Javed*[1], *Emir Zonic*[1], *Lia Abbasi Moheb*[1], *Tawfig Bin Omran*[2], *Peter Bauer*[1], *Aida Bertoli-Avella*[1]

[1]*CENTOGENE GmbH, Rostock, Germany;* [2]*Sidra and Hamad Medical Corporation, Genetic and Genomic Medicine, Doha, Qatar*

Background/Objectives: Microcephaly, characterized by a small head circumference, is usually caused by abnormal brain growth and development due to genetic and environmental factors. *CDC20* encodes a protein that regulates cell division and chromosome segregation, which is essential for the proper functioning of the anaphase-promoting complex (APC/C). It is also involved in apoptosis, tumorigenesis, immune responses, and stemness processes. *CDC20* has been previously associated with autosomal recessive oocyte/zygote/embryo maturation arrest type 14 due to its role in mitosis and meiosis, with *Cdc20* hypomorphic mice experiments indicating that female infertility results from dosage dependent CDC20 reduction, while *Cdc20* knockout mice were embryonic lethal. But its involvement in microcephaly is still unclear.

Methods NGS data was analyzed by CENTOGENE's bioinformatics pipeline and comprehensive variant filtering. Family history and clinical information provided were used to evaluate identified variants for pathogenicity and disease causality.

Results: We report four patients with microcephaly, neurodevelopmental delay, and behavioral abnormalities, who are homozygotes for a *CDC20* variant (NM_001255.2:c.556+1G>T, spliceAI score = 0.99) predicted to affect gene splicing. This variant is not reported in literature or population databases.

Conclusion: Previous studies showed that *CDC20* and APC/C play important roles in brain development, influencing the proliferation and differentiation of neural cells and the formation and function of synapses in rodents and *C. elegans*, and interaction with STIL, a centriole duplication factor associated with autosomal recessive primary microcephaly (OMIM 612703). While the applied ClinGen gene-disease validity guidelines showed limited relationship with the microcephaly phenotype, further research is needed to identify the underlying molecular mechanisms of this condition.

Consortium: Brain Gene Registry Consortium

Background/Objectives: Clinically ascertained variants are under-utilized in intellectual and developmental disability (IDD) research; published reports are relied upon for the establishment of gene disease validity and understanding of disorder spectrum. We established the Brain Gene Registry (BGR) to co-register clinical variants with participant phenotypes. Here, we analyze the first 179 variants in the first 179 BGR registrants for novelty to ClinVar at the time of entry and presence in 6 other disease databases.

Methods: Participants with clinical variants (variant of uncertain significance [VUS] or above) in putative brain genes were enrolled from 12 IDD Research Centers, with co-registration of variant with standardized neurodevelopmental assessment and electronic health record. Individuals also enrolled into Genome Connect, the ClinGen patient registry. The first 179 variants were cross-referenced for previous presence in ClinVar and for presence in 6 other genetic databases.

Results: At present, there are 574 BGR registrants, representing 183 genes and 225 VUS classifications. Analysis of the first 179 variants showed that 76 (42.5%) were novel to ClinVar, and 62 (34.6%) were absent from all databases analyzed. Of the 103 variants present in ClinVar, 37 (35.9%) were uncertain (ClinVar aggregate classification of VUS or conflicting classifications).

Conclusion: A significant proportion of clinical variants that are novel or uncertain are siloed in healthcare systems, limiting the evidence base for new gene-disease relationships and full understanding of disorder spectrum. By co-registering variant and phenotype, the BGR serves as a unique resource for translational advances relating to rare IDDs.

Grants: IDDRC-CTSA BGR: 1U01T002764-01A. GenomeConnect: U24HG006834.

Background/Objectives: Schuurs-Hoeijmakers syndrome (SHMS, OMIM # 615009) is a Mendelian disorder caused by pathogenic heterozygous variants in *PACS1*. It primarily manifests with global developmental delay, facial dysmorphisms, and various other congenital anomalies, including hypotonia, heart and eye abnormalities, and digestion problems. Given the clinical phenotypic overlap between SHMS and other neurodevelopmental disorders, definitively diagnosing the syndrome poses significant challenges.

The objective of this study is to identify a robust episignature for SHMS that can be used as a reliable biomarker for diagnosis in a clinical setting.

Methods: The EpiSign™ discovery pipeline was utilized to conduct genome-wide DNA methylation analysis on DNA samples extracted from peripheral blood of individuals with SHMS, comparing them with samples from controls and other known episignature disorders within the EpiSign Knowledge Database (EKD). Methylation levels were assessed using Illumina Infinium MethylationEPIC microarrays, and machine learning and statistical models were applied to identify the SHMS episignature.

Results: A robust episignature was detected for SHMS. Notably, this identified episignature successfully classified a previously unresolved subject within the EKD. Subsequent investigation revealed that the individual harbored one of only two known pathogenic *PACS1* variants associated with the syndrome, providing additional evidence for the episignature's robustness and sensitivity.

Conclusion: This study establishes a highly sensitive and specific episignature for SHMS, highlighting the expanding utility of episignature analysis in patients with suspected rare diseases.

Grants: Funding was received from the government of Canada through Genome Canada and the Ontario Genomics Institute (OGI-188).

P10.033.D Causative single nucleotide variants in patients with mendelian disorders of the epigenetic machinery detected through whole exome sequencing in routine diagnostics

Judith Gottfreund[1], *Anna Munzig-Schmidt*[1], **Christian Albig**[1], *Julia Philippou-Massier*[1], *Konstanze Hörtnagel*[2]

[1]*MVZ Martinsried GmbH, Scientific Services, Planegg, Germany;* [2]*MVZ Martinsried GmbH, Medical Services, Planegg, Germany*

Background/Objectives: Conditions within the spectrum of mendelian disorders of the epigenetic machinery (MDEMs) comprise a group of multiple congenital disorders resulting from causative variants in genes encoding members of the epigenetic machinery. These mainly include epigenetic players responsible for defining DNA methylation, histone modifications and chromatin structure. Together with the transcription machinery, these components dynamically orchestrate gene expression and play an important role in mammalian development, environmental response and disease. MDEMs are phenotypically associated with neurodevelopmental disorder (ND), intellectual disability (ID) and abnormal growth. The recent improvement of NGS technologies and their use in genetic routine diagnostics has substantially refined the identification of MDEMs and provided enhanced opportunities for their diagnosis.

Methods: As part of our routine diagnostic procedures, most patients with sporadic ND undergo initial genetic testing by chromosomal analyses, array-CGH, and FMR1 repeat expansion analysis. In case of negative preliminary genetic tests, we perform WES as extended diagnostics, preferably as a trio analysis.

Results/Conclusion: Since 2019, we tested 1427 patients with unresolved ND, ID, and/or abnormal growth by WES analysis as part of our routine diagnostics. In 605 cases (42.4 %), we found at least one (likely) pathogenic variant or a variant of uncertain significance in genes associated with a ND. In 116 cases (19.2 % of positive cases), the reported variant was associated with MDEMs. Of these, 14 variants (12.0 %) can be assigned to the epigenetic regulation mechanism affecting DNA methylation, 53 variants (45.7 %) affecting histone modifications and 44 variants (37.9 %) affecting chromatin remodeling.

Conflict of Interest: None declared

P10.034.A Studies on X-linked ZC4H2 to better understand the molecular mechanisms and pathophysiology of ZC4H2-Associated Disorders

Jessica Gibbons[1], *Vanessa Suckow*[1], *Vera Kalscheuer*[1]

[1]*Max-Planck-Institute for Molecular Genetics, Development and Disease, Berlin*

Background/Objectives: Our group has long been involved in research into the genetic causes of rare neurodevelopmental disorders, with a focus on X-linked intellectual disability. One of the X-linked disease genes identified through our studies is *ZC4H2*, which encodes a zinc finger domain protein. We and others have associated ZC4H2 with variable clinical phenotypes of male and female patients presenting with a syndromic form of arthrogryposis multiplex congenital with central and peripheral nervous system involvement. Our understanding of the molecular functions and pathophysiology of ZC4H2-Associated Rare Disorders (ZARD) is currently limited.

Methods: CRISPR/Cas9, expression of ZC4H2 protein in bacterial cells and purification of stable protein, co-localization studies and biochemical assays.

Results: Since a complete knockout of *Zc4h2* in male mice is lethal, we have generated knockin mouse embryonic stem cells for two patient-specific missense variants. Furthermore, we have successfully purified ZC4H2 protein for antibody production, and validated that the microtubule tethering protein HOOK3 is a complex partner of ZC4H2. We are currently investigating the impact of mutant ZC4H2 protein on binding.

Conclusion: Establishing and characterizing knockin mice with patient-specific missense variants potentially serve as a valuable model for studying ZARD. Furthermore, successful purification of ZC4H2 protein is a crucial step for antibody establishment. Changes in protein interactions could disrupt normal cellular functions, contributing to the observed clinical phenotypes.

Grants: This work was supported by a research grant from the University of Pennsylvania Orphan Disease Center in collaboration with the ZCH42 Deficiency Research Foundation and the Max Planck Foundation.

Conflict of Interest: None declared

Background/Objectives: *ANK3* encodes ankyrin-G, a protein involved in neuronal development and signaling, and is associated with a neurodevelopmental disorder (NDD) characterized with non-specific syndromic intellectual disability. To date, only 14 individuals with mono- or biallelic *ANK3* variants are reported in separate studies. The primary objective of this study was therefore to investigate and define the phenotype and genotype spectrum of *ANK3*-related NDD and explore a potential genotype-phenotype correlation.

Methods: Through GeneMatcher collaboration, we have collected the clinical and genetic information of 17 new individuals with *ANK3* variants and have reviewed the data from the 14 previously described individuals.

Results: In total, we describe 31 mono- or biallelic individuals with 35 different *ANK3* variants. The observed clinical spectrum spans language delay (93%), behavioral and/or psychiatric disturbances (88%), intellectual disability (73%), autism spectrum disorder (65%), motor delay (62%), hypotonia (63%), sleep disturbances (45%), and epilepsy (37%). Seventeen individuals have monoallelic *ANK3* variants and the remaining 14 have biallelic variants. While majority of the monoallelic variants are predicted to result in a truncated protein, the individuals with biallelic variants, which almost exclusively are missense, present with a more severe phenotype. Moreover, mono- and biallelic variants appears to be distributed differently across the different ankyrin-G isoforms.

Conclusion: Our data give a better understanding of the clinical phenotype of *ANK3*-related NDD and suggest that biallelic variants in *ANK3* are associated with increased severity of symptoms as well as an ankyrin-G isoform-specific mutational constraint.

P10.036.C Mutation in mitochondrial chaperone TRAP1 results in male-specific autism

Malgorzata Rydzanicz[1], *Bożena Kuzniewska[2], Marta Magnowska[2], Tomasz Wójtowicz[3], Izabela Chojnicka[4], Ewelina Knapska[5], Andrzej Dziembowski[6;7], Rafał Płoski[8], Magdalena Dziembowska[2]*

[5]Nencki Institute of Experimental Biology, Laboratory of Emotions Neurobiology, Poland; [6]International Institute of Molecular and Cell Biology in Warsaw, Laboratory of RNA Biology, Poland; [7]University of Warsaw, Faculty of Biology; [8]Medical University of Warsaw, Department of Medical Genetics

Background: There is increasing evidence of mitochondrial dysfunction in autism spectrum disorders (ASD), but the causal relationships are unclear.

Methods: ASD-discordant monozygotic twins were analyzed using exome sequencing. Knock-in mice with *Trap1* p.Q641* mutation (equivalent of human p.Q641*) were generated using CRISPR/Cas9 and characterized by social interaction and neuroanatomical analysis.

Results: In ASD-affected twin, but not in his healthy brother, we identified a postzygotic mosaic p.Q639* mutation in the *TRAP1* gene encoding a mitochondrial chaperone of the HSP90 family. Additional screening of 176 unrelated ASD probands revealed an identical heterozygous *TRAP1* variant in a male patient who had inherited it from a healthy mother. Notably, newly generated knock-in *Trap1* p.Q641* mice display ASD-related behavioral abnormalities exclusively in males. Accordingly, *Trap1* p.Q641* mutation also resulted in sex-specific changes in synaptic plasticity and the number of presynaptic mitochondria.

Conclusion: The *TRAP1* p.Q639* mutation is the first example of a monogenic ASD caused by impaired mitochondrial protein homeostasis.

Grants: National Science Centre (NCN) Poland grant numbers 2014/13/B/NZ5/0028 and 2019/35/B/NZ4/043, TEAM TECH CORE FACILITY/2017-4/5, European Union's Horizon 2020 research and innovation programme under grant agreement no 810425.

P10.037.D Making sense of non-sense: Identification of an intronic deletion in ARID1A in Coffin-Siris syndrome

Sarah Schuhmann[1], *Georgia Vasileiou*[1;2], *Steffen Uebe*[1], *Andreas Fink*[1], *Antje Wiesener*[1], *André Reis*[1;2]

[1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Institute of Human Genetics, Erlangen, Germany; [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Centre for Rare Diseases Erlangen, Erlangen, Germany

Consortium: Bavarian Genomes Network

Background: Disruption of chromatin regulatory genes belonging to the BAF complex represents one of the most frequent genetic causes for neurodevelopmental disorders (NDD). Coffin-Siris syndrome (CSS) is a multiple congenital anomalies NDD caused by pathogenic variants in 11 different genes encoding BAF complex subunits. However, in a subset of cases with a suspected CSS diagnosis the genetic basis remains unsolved.

Methods: Within the research project *Bavarian Genomes Network* we identified a four year old female individual from healthy non-consanguineous parents with global neurodevelopmental delay, muscular hypotonia, hypoplasia of the corpus callosum, coarse facial features, sparse scalp hair, hypoplastic toe nails, laryngo-tracheomalazia and dysplastic aortic valve suggestive of CSS. As trio exome sequencing and CNV analysis did not identify a causative variant, we applied short-read genome sequencing (GS) and other genomic assays for further characterization.

Results: Trio GS revealed a de novo 24 kb deletion, not detectable in exome sequencing, located in intron 4 of the *ARID1A* gene, which is associated with CSS type 2. RNA sequencing showed a 165 bp intron retention in 21% of the reads, predicted to result in a stop codon after 9 amino acids. This represents a loss-of-function allele compatible with the clinical diagnosis of CSS. Methylome analyses are pending.

Conclusion: To our knowledge this case represents the first intronic deletion identified in a patient with CSS. Our case highlights the benefits of genome sequencing in the diagnosis of unsolved cases as well as the necessity of additional genomic techniques to interpret variants in non-coding regions.

P10.038.A *ARHGEF9*-associated developmental and epileptic encephalopathy: just an X-linked and not an X-linked recessive disease

Susann Badmann[1], *Maureen Jacob*[1], *Kristina Huß*[2], *Ingo Borggräfe*[2], *Saskia Biskup*[3], *Jerome Jüngling*[3], *Kathrine Bjørgo*[4], *Juliane Winkelmann*[1;5], *Matias Wagner*[1;5]

[1]Institute of Human Genetics, School of Medicine, Technical University of Munich, Munich, Germany; [2]Dr. v. Hauner Children's Hospital, Department of Pediatric Neurology and Developmental Medicine, LMU - University of Munich, Munich, Germany; [3]Center for Genomics and Transcriptomics (CeGaT), Tübingen, Germany; [4]Department of Medical Genetics, Oslo University Hospital, Oslo, Norway; [5]Institute of Neurogenomics, Helmholtz Zentrum München, Munich, Germany

Background: Variants in the X-chromosomal gene *ARHGEF9* cause a developmental and epileptic encephalopathy. Initially, the condition was considered as an X-linked recessive disorder, affecting males and females with a skewed X-inactivation pattern. A recent report of two affected females with loss-of-function (LoF) variants and random X-inactivation suggested an X-linked dominant inheritance for LoF and an X-linked recessive inheritance for missense variants (Ghesh et al., 2021).

Methods: Trio-exome sequencing was performed, and the X-inactivation pattern was assessed based on methylation analysis of *RP2* and *AR* from leukocyte DNA or RNA sequencing from leukocyte RNA.

Results: We report three affected females with heterozygous de novo variants in *ARHGEF9* (NM_001173479.2) and random X-inactivation pattern. In patient 1 a novel splice-donor variant c.222+1G>C was identified. Patient 2 has a novel microdeletion affecting exons 5-6 of *ARHGEF9*. Patient 3 carries a missense variant c.151C>T, p.(Arg51Trp). While patient 1 and 2 initially presented with developmental delay, learning difficulties/mild intellectual disability (ID) and developed epilepsy/hyperekplexia at 13 and 9 years respectively, patient 3 shows a developmental and epileptic encephalopathy with severe ID.

Conclusion: By presenting three affected females (in addition to two previously published) we provide further evidence that heterozygous LoF and missense variants in *ARHGEF9* can be disease causing also in females with random X-inactivation in blood DNA. Therefore, *ARHGEF9*-associated developmental and epileptic encephalopathy should be considered just as X-linked and not as X-linked recessive disorder. Based on this example we support the revision of the dichotomous model of X-chromosomal recessive and dominant inheritance.

P10.039.B Recurrent cases of somatic mosaicism in KANSL1 identified in standard diagnostics

Vincent Arriens[1], *Kirstin Hoff*[1], *Anna-Sophie Liegmann*[2], *Christina Post*[2], *Irina Hüning*[2], *Nadine Hornig*[1], *Britta Hanker*[2], *Inga Vater*[1], *Malte Spielmann*[1], *Inga Nagel*[1]

[1]University Hospital Schleswig-Holstein, Campus Kiel, Institute of Human Genetics, Kiel, Germany; [2]University Hospital Schleswig-

Holstein, Campus Lübeck, Institute of Human Genetics, Lübeck, Germany

Background/Objectives: *KANSL1* variants are linked to Koolen-de Vries Syndrome, characterized by variable degrees of intellectual disability, speech and motor delay, and neonatal/childhood hypotonia. Additionally, epilepsy, behavioral abnormalities and dysmorphic features commonly accompany the disorder. Two cases with somatic mosaicism in *KANSL1* were identified during our standard diagnostics.

Patients/Methods: Exome, trio genome and Sanger sequencing were performed on two male patients aged 5 and 18 years. Both presented with global developmental delay (especially speech delay), hypotonia, epilepsy, brain abnormalities and macrocephaly.

Results: Two mosaic variants in *KANSL1* were detected by exome and genome sequencing and subsequently validated by Sanger sequencing. One patient carried a pathogenic de novo variant, c.611dup p.(Met205Tyrfs*9), in *KANSL1*. All three techniques showed somatic mosaicism, with an allelic frequency of 35% based on genome sequencing (exome: 21%). Similarly, in the second case, a likely pathogenic de novo variant (c.1420C>G p.(Arg474Gly)) in *KANSL1* showed somatic mosaicism across all three techniques, with an allelic frequency of 30% according to genome sequencing (exome: 28%).

Conclusion: The repeated occurrence of mosaicism in *KANSL1* raises the question of whether it is an incidental observation or due to a biological mechanism. Mosaic occurrences have been documented in genes linked to neurodevelopmental disorders and epilepsy and *KANSL1* might be another candidate. However, regarding a specific underlying mechanism causing mosaics in *KANSL1*, we can only speculate and further analyses are necessary.

P10.040.C The additional clinical benefit of exome sequencing: the return of ACMG/AMP recommended incidental findings and data re-analysis

*Markéta Wayhelová[1], **Jan Smetana**[1], Vladimira Vallova[1], Petr Brož[1], Renata Gaillyova[2], Petr Kuglik[1]*

[1]Institute of Experimental Biology, Dept. of Molecular Genetics, Brno; [2]Institute of Medical Genetics and Genomics, Brno

Background/Objectives: Despite of the unquestionable clinical benefit of exome sequencing (ES) for the paediatric population with neurodevelopmental disorders (NDDs) and their families, the medical and clinical specialists have to face the increasing number of clinically actionable incidental findings and the need to reanalyze and reinterpret ES data, respectively.

Methods: We present our experience and yields for these incidental findings and data reanalysis based on the outlined ACMG/AMP general recommendation.

Results: In the paediatric population of 100 individuals with NDDs and their parents we returned the incidental findings. (*BRCA1, BRCA2, TGFBR1, RYR1, HFE, SDHB* genes) for 11 individuals from 7 families. Additionally, we revised the ES interpretation for two families, resulting in the elucidation of molecular diagnosis (the *CRAT* gene, 1 case) and the possible prevention of future medical complication due to the reclassification and report of the incidental finding (the *RYR1* gene, 1 case)

Conclusion: Our results declare and support the clinical benefit of returns of incidental findings and periodical data reanalysis. Future debates on the reporting of clinically actionable non-ACMG secondary findings for the carriers of causative variants for prevalent recessive congenital diseases and reinterpretation of the increasing number of novel variants may be required due to the widespread routine implementation of trio exome analyses in the clinical practice.

P10.041.D A homozygous stop variant in *DDIAS* is a plausible cause of a novel neurodevelopmental disorder

__Zafar Iqbal__[1], Bilal Ahmad Mian[2], lubaba khalid[2], Asmat Ali[2], Mohammad Raza[3], Mathias Toft[1;4], Ambrin Fatima[2], Grant S Stewart[5]

[1]Oslo University Hospital, Department of Neurology, Oslo, Norway; [2]The Aga Khan University, Department of Biological and Biomedical Sciences, Karachi, Pakistan; [3]The Aga Khan University, Department of Paediatrics and Child Health, Karachi, Pakistan; [4]University of Oslo, Institute of Clinical Medicine, Oslo, Norway; [5]University of Birmingham, Institute of Cancer and Genomic Sciences, Birmingham, United Kingdom

DNA damage-induced apoptosis suppressor protein is encoded by the gene *DDIAS* and has been implicated in activating the apoptotic signaling pathway in response to DNA damage. Unlike other DNA damage response genes, variants in *DDIAS* have never been implicated in human disease. However, recently we identified a five-year-old child from a consanguineous marriage, presenting with global developmental delay, intellectual disability, microcephaly, generalized clonic seizures, generalized spasticity, horizontal nystagmus, high arched palate, bilateral clinodactyly, and some hypopigmented macules on the neck. The patient is not able to sit, stand or hold his neck. Vision and hearing abilities of the patient are unaffected. Whole-exome sequencing of the affected child identified a homozygous stop variant in *DDIAS*: c.1631C>A (NM_145018.4); p.(Ser544*), which segregated with the phenotype. In keeping with a role for DDIAS in responding to DNA damage, skin fibroblasts from the affected child exhibited signs of increased genome instability and an inability to repair damaged DNA induced by mitomycin C but not aphidicolin or camptothecin. This suggests that DDIAS may work together with the Fanconi Anemia pathway to repair inter-strand DNA cross-links and/or DNA-protein cross-links. Further analysis is underway to identify

how defects in the DDIAS-dependent DNA damage response is responsible for causing disease.

P10.042.A Homozygous truncating variant in *OGFOD1* in a patient with neurodevelopmental disorder: is it a novel ribosomopathy?

Amita Moirangthem[1], *Rajesh Kumar Maurya*[1], *Ankit Dhakad*[1], *Ashwin Dalal*[2]

[1]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Medical Genetics, Lucknow, India;* [2]*Center for DNA Fingerprinting and Diagnostics, Diagnostics division, Hyderabad, India*

Background/Objectives: 2-oxoglutarate Fe(II)dependent oxygenase domain containing protein (OGFOD1) plays a role in translational regulation by hydroxylation of the Pro62 residue of the small ribosomal protein subunit RPS23. De novo pathogenic variations in RPS23 have been reported to cause a developmental disorder with dysmorphism and variable cognitive dysfunction. OGFOD1 knockdown in human cell lines and in drosophila have also shown accumulation of stress granules, translational arrest and impaired cell growth. OGFOD1 has not been reported to be causative of any monogenic disorder yet.

Methods: We ascertained a 9 years old boy, born of healthy non-consanguineous parents, with global developmental delay, behavioral issues and epilepsy. He had moderate intellectual disability, microcephaly, low anterior hairline, downslanted eyes, flat occiput and overhanging columella. He was evaluated for possible genetic causes using exome sequencing (ES) and 750K SNP array.

Results: ES prioritized a homozygous variant c.1180_1181insA-TAG in *OGFOD1* (NM_018233). Segregation analysis of the variant in the family conformed to Mendelian pattern. In silico analyses predict this variant to lead to shifting of the reading frame and premature truncation of protein.Copy number variation analysis from ES data and SNP array was negative. A 5.5MB region of homozygosity was detected which included *OGFOD1*.

Conclusion: Existing literature suggests a close functional interaction between OGFOD1 and RPS23 and our patient shares overlapping phenotypic features with the RPS23 deficient patients. Therefore, OGFOD1 deficiency may also cause a ribosomopathy and we plan to study the functional effects in the patient derived cell lines.

Background/Objectives: Post-zygotic, somatic mosaic, gain-of-function mutations in *PIK3CA* cause *PIK3CA*-related overgrowth syndrome (PROS). While germline gain-of-function variants affecting *PIK3CA* activity have also been described, we are not aware of published descriptions of patients with germline loss-of-function variants.

Methods: We performed whole exome sequencing and identified a putative germline loss-of-function *PIK3CA* variant in a proband with intellectual disability. We then used matchmaker exchange to identify and collect clinical and molecular data from additional patients for whom clinical sequencing identified a heterozygous putative loss-of-function variant.

Results: Three probands have predicted loss-of-function variants. Two mutations arose de novo and one was inherited from a mother who presents with learning difficulties. The 4 individuals exhibited a range of intellectual disability that tended to mild, two were microcephalic (<-2SD), and a third had a head circumference of -1.8 SD.

Conclusion: Our data suggest heterozygous loss-of-function *PIK3CA* variants are associated with neurodevelopmental disorders. The reduced head circumference observed in several of our patients is consistent with the observation that *PIK3CA* haploinsufficiency in mice also causes microcephaly. Also notable are that *PIK3CA* has a pLI of 1 in the gnomAD database and that putative loss-of-function alleles are associated with reduced brain grey matter volume in the Genebass database. A larger cohort of individuals with loss-of-function alleles is needed to better determine the spectrum of the haploinsufficiency phenotype.

Background/Objectives: Only recently, mostly de novo, truncating variants in *SCAF4* were identified in 18 individuals with variable neurodevelopmental phenotypes. However, knowledge on the molecular and clinical spectrum is still limited.

Methods: We assembled data on 37 novel cases with *SCAF4* variants and neurodevelopmental phenotypes, ascertained via GeneMatcher and personal communication. With detailed evaluation of clinical data, in silico predictions and structural modeling, we further characterized the molecular and clinical spectrum of the *SCAF4*-associated Fliedner-Zweier syndrome.

Results: The molecular spectrum in this cohort comprised 33 truncating (incl. splice-site) and four missense variants. While truncating variants were classified as (likely) pathogenic, significance of missense variants remained unclear. Two missense variants in the CID-domain of SCAF4 were predicted by structural modeling to destabilize the domain. Frequent clinical findings in affected individuals were mild developmental delay with prominent speech delay, seizures (37%), and variable skeletal abnormalities such as clubfoot, scoliosis or hip dysplasia. Cognitive abilities ranged from normal IQ to severe intellectual disability, with borderline to mild ID in the majority of individuals. Notably, there were more inherited *SCAF4* variants from similarly affected parents than de novo occurrences (15 vs 10).

Conclusion: Our study confirms the role of *SCAF4* variants in neurodevelopmental disorders and further delineates the associated clinical phenotype.

Conflict of Interest: None declared

P10.046.A *CTNNB1* variants: clinical and genetic observations from the UK's cohort

Taisiia Sazonova[1;2], *Sarah Richardson*[3], *Dianne Newbury*[4], *Usha Kini*[1;3]

[1]*University of Oxford, Nuffield Department of Clinical Laboratory Sciences, Oxford, United Kingdom;* [2]*University of Oxford, Radcliffe Department of Medicine, Oxford, United Kingdom;* [3]*Oxford University Hospitals NHS Foundation Trust, Oxford Centre for Genomic Medicine, Oxford, United Kingdom;* [4]*Oxford Brookes University, Department of Biological and Medical Sciences, Oxford, United Kingdom*

Background/Objectives: Catenin-beta 1 (*CTNNB1*) encodes a cadherin-associated protein and is crucial in embryonic development. It is linked to neurodevelopmental disorders and familial exudative vitreoretinopathy (FEVR). This study investigates genotype-phenotype correlations in the largest UK cohort of patients with reported *CTNNB1* variants, focusing on developmental, neurological, and ocular outcomes.

Methods: We studied clinical details and genotypes of 81 unreported patients: 45 from the Deciphering Developmental Disorders study, 23 from the 100,000 Genomes Project, and 13 via NHS. We ensured no double-counting of patients tested through multiple routes. Pathogenic variants were identified by exome or genome sequencing and classified via ACMG guidelines.

Results: All variants identified were loss-of-function variants, except for 1 missense variant. Recurrent variants (p.Arg535Ter, p.Arg474Ter, p.Tyr333Ter) did not show consistent phenotypes. Global developmental delay (87%), microcephaly (66%), and muscle tone abnormality (41%) were the most common findings. Spasticity was observed in 25% of patients, unrelated to any specific genotype. Motor milestones delay was observed: mean ages for sitting of 19 months and 34 months for walking independently. Progressive motor regression in 1 patient included transitioning from using a baby walker to knee walking and loss of independent standing ability. 41% had ocular symptoms, but FEVR was observed in 1 patient harbouring a p.Arg474Ter variant.

Conclusions: Our study is the largest UK cohort report on *CTNNB1* variants. The observed lack of genotype-phenotype correlations confirms that the genotype in this disorder cannot be used as a prognostic indicator. FEVR is rare complication but needs monitoring.

P10.047.B Experience using ExpansionHunter to identify diseases caused by STRs from exome sequencing data

Marta Codina[1;2], *Irene Valenzuela Palafoll*[1;2], *Jordi Leno*[1;2], *Héctor San Nicolás*[1;2], *Mar Costa-Roger*[1;2], *Paula Fernandez-Alvarez*[1;2], *Eulàlia Rovira-Moreno*[1;2], *Amaia Lasa-Aranzasti*[1;2], *Laura Trujillano*[1;2], *Barbara Masotto*[1;2], *Anna Maria Cueto Gonzalez*[1;2], *Desirée Martínez-Cruz*[1;2], *Anna Abuli*[1;2], *Elena García-Arumí*[1;2], *Eduardo Tizzano*[1;2]

[1]*Vall d'Hebron Institut de Recerca (VHIR), Medicine Genetics Group, Barcelona, Spain;* [2]*Vall d'Hebron Hospital Universitari, Department of Clinical and Molecular Genetics, Barcelona, Spain*

Background/Objectives: Expansion of short tandem repeats (STRs) cause more than 40 diseases, most affecting primarily the nervous system. Recently, bioinformatics tools such as ExpansionHunter (EH) have been developed to identify STRs from exome sequencing data (ES).

Methods: We applied EH to 1610 exomes from a cohort of rare disease patients to study 30 known loci. Expanded STRs in loci not related to the patient's clinical indication were discarded. The remaining were manually curated using REViewer to discard false positive results and validated with TP-PCR (Tripled repeat Primed-PCR).

Results: We identified 51 possible aberrant STR alleles in 49 patients (3% of the cohort). Correlation with the clinical indication

discarded 45/51 of the positive findings, resulting in a final number of six expanded STRs in six different patients (Myotonic dystrophy type I/DMPK: 4, Dentatorubral-pallidoluysian atrophy/ATN1: 1, SCA8/ATXN8OS; 1). Three expansions were already known, although unsuspected at the time of ES. All detected expanded STRs but one (ongoing) have been validated by TP-PCR. Of the four cases with an expansion in DMPK, three were full expansions in three patients diagnosed with Myotonic Dystrophy, whereas one was in the premutated range and considered an incidental finding.

Conclusion: Our work shows the utility of implementing STR analysis in clinical ES. Although ES is not the gold standard technic for STR analysis and has a high false positive rate, application of EH or other methods can pinpoint potential diagnosis. Our results show that STR evaluation could potentially increase diagnostic ES yield by approximately 0,4%.

Background/Objectives: Megalencephaly (MEG), i.e. excessive brain growth, is diagnosed in individuals with macrocephaly and a brain imaging ruling out other causes of exaggerated head growth. When MEG is assessed, the choice of etiological investigations depends on a series of criteria, including associated cerebral / extracerebral malformations, neurodevelopment, clinical signs. During the last years, genome-wide studies allowed the identification of numerous genes of MEG with a large range of clinical presentations. However, there is no series of patients taking all these etiologies into account.

Methods: To provide the landscape of the genetic etiologies of MEG, we performed a comprehensive review of its genetic etiologies in PubMed and OMIM. We then collected data from the medical files of patients with OFC > + 3 SD and a MEG confirmed by brain imaging examined in our genetics unit since 20 years

Results: More than 70 genes of MEG are known to date. We retrieved 232 patients with MEG, including 52% with intellectual disability (ID). Pangenomic sequencing (ES/GS) were conducted in 147 with a diagnostic yield of 50%, including in patients without ID, and involved 61 genes. One third of the diagnoses were made in only 5 genes (PTEN first). 26% of the variants were associated with a tumor risk, they were inherited in 38% of cases.

Conclusion: Etiological investigations of MEG have a high diagnostic yield, even in the absence of ID. The great heterogeneity of the genes involved argues in favor of genome-wide testing. Diagnosis has a major impact on patient medical follow-up.

Background: The WDR gene family, with 286 members including *WDR47*, plays an important role in physiology and development. WDR47's role in mouse brain development has been recently found, yet its link to human disorders remains unclear.

Methods: We generated mouse knock-out models for *Wdr47* and conducted detailed neuroanatomy studies across different developmental stages. These were then compared with human cases with WDR47 variants, collected through international data sharing. For human variants not indicative of loss of function, we examined knock-in models.

Results: Our study identified 11 unrelated families worldwide, with five showing bi-allelic and six mono-allelic missense variants in *WDR47*. All bi-allelic cases consistently displayed neuroanatomical phenotypes, including corpus callosum dysgenesis and microcephaly, along with intellectual disability and epilepsy. Bi-allelic cases with a clear loss-of-function mechanism were attributable to neuronal cell death due to disrupted cellular processes. By contrast, mono-allelic cases presented a broader range of symptoms, with some showing similar neuroanatomical

and neurological concerns. Our detailed study of the de novo missense variant p.Val660Ala in a mouse model revealed significant defects, confirming its pathogenicity and aiding in molecular diagnosis. The pathogenicity of the other monoallelic variants remains to be confirmed, and more patients are needed to fully understand the autosomal dominant phenotypes associated to WDR47-related neurodevelopmental disorders.

Conclusion: Our murine findings recapitulate the clinical features of the human diseases. Importantly, our study underscores the power of mouse models as starting point to find correspondence in humans especially for ultra-rare neurodevelopmental conditions like those related to *WDR47*.

P10.050.A Secondary rare variants in Rett syndrome: toward a morbid gene card for personalized care and cure

Kristina Zguro[1;2], Susanna Croci[1;2], Giulia Brunelli[1;3], Roberto Canitano[4], Sabrina Buoni[4], Valeria Scandurra[4], simone furini[5], Caterina Lo Rizzo[6], **Alessandra Renieri**[1;2;6]

[1]Med Biotech Hub and Competence Center, University of Siena, Department of Medical Biotechnologies, Siena, Italy; [2]Medical Genetics, University of Siena, Siena, Italy; [3]Institute of Informatics and Telematics, CNR, Pisa, Italy; [4]Neuropsychiatric Unit Azienda Ospedaliera Universitaria Senese, Siena, Italy; [5]Department of Electrical, Electronic and Information Engineering "Guglielmo Marconi", University of Bologna, Cesena, Italy; [6]Genetica Medica, Azienda Ospedaliero-Universitaria Senese, Siena, Italy

Background and Methods: To understand the clinical variability of Rett syndrome (RTT), ranging from an autistic-like disorder to a very severe disease without speech, we performed whole-exome sequencing (WES) and genotyping in 142 MECP2-mutated girls. Clinical severity score was used for both global and domain-specific clinical assessment.

Results: Our analysis showed that the MECP2 variant type influences both global and specific severity scores, while polygenic risk score does not contribute to explaining epilepsy or cognitive level severity. Notably, 30% (43 patients) harbored co-occurring pathogenic variants in other genes relevant to RTT management and treatment. The mutated genes are associated with intellectual disability and epilepsy (*CHD2, GRIN2B, NHLRC1*), central (*TARDBP*), and peripheral (*TTR*) neurodegenerative disorders or scoliosis (GDF3). These results highlight the importance of performing WES in all RTT patients who undergo clinical trials, to avoid biases in drug efficacy assessment. Secondary rare variants hold aldo significant potential for personalized patient care in various areas, including dietary (*G6PD, MHCMAC, PHA, LDLR*), lifestyle (*CFTR, SERPIN1, AIRE*), post-surgery (*VWF*), and even oncological surveillance (*BRCA1, MUTYH*).

Conclusion: this study addresses unmet clinical needs in managing patients with complex and pleiomorphic diseases such as RTT. Furthermore, our findings open an innovative view on the pathogenesis of the so-called, monogenic diseases, showing the benefits of an accurate analysis of rare variants in every gene. This comprehensive approach is particularly relevant for an improved patient care and a reduced risk of false negatives/false positives in clinical trial outcomes.

P10.051.B *IMMP2L* gene deletions detected by array-CGH – variants of uncertain clinicalsignificance or benign deletions?

Isabel Marques Carreira[1;2;3], *Susana Isabel Ferreira[3], Mariana Val[1], Alexandra Mascarenhas[1], Marta Pinto[1], Nuno Lavoura[1], Luís Miguel Pires[1], Ana Jardim[1], Joana Barbosa de Melo[1;2;3]*

[1]Laboratory of Cytogenetics and Genomics - Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [2]Center for Innovative Biomedicine and Biotechnology (CIBB), University of Coimbra, Coimbra, Portugal; [3]Institute for Clinical and Biomedical Research (iCBR) and Center of Investigation on Environment Genetics and Oncobiology (CIMAGO), Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background/Objectives: *IMMP2L* gene has been reported as a candidate gene for Tourette syndrome, autism spectrum disorder (ASD) and additional neurodevelopmental disorders such as attention-deficit hyperactivity, speech-language delay and various developmental delays. There is some controversy in the literature concerning this association.

Methods: We have performed Agilent 180K oligonucleotide array-CGH in more than 4000 blood samples from patients with ASD, intellectual disability, language delay or global developmental delay.

Results: We detected 34 patients, 24 males and 10 females, with *IMMP2L* gene partial deletions, most of them involving the first exons of the gene. Inheritance determination was only possible in 7 patients, being maternally inherited in 5 cases and paternal in 2.

Conclusion: *IMMP2L* gene encodes a protein involved in processing the signal peptide sequences used to direct mitochondrial proteins to the mitochondria. In mice heterozygous for an inactive *Immp2l* gene, increase of ischemic brain damage and apoptosis of cerebellar neurons have been detected, and this observation lead to the notion that *IMMP2L* alterations may predispose to cognitive/behavioral disturbances in humans. However, some studies found no evidence of association.

We struggle with the question if we should continue reporting aCGH detected *IMMP2L* gene deletions, since most of them are inherited from normal progenitors, and considering the controversial literature reports. We also question the value of this diagnosis for the clinical management and genetics counseling of the diagnosed patients, and how to deal with genetics counseling in subsequent pregnancies of a couple with an affected child and a carrier normal progenitor.

Background/Objectives: The Coffin-Lowry Syndrome (CLS) is a rare condition associated with the loss of function of the *RPS6KA3* gene (OMIM 300075), located on the X chromosome. Diagnosis is frequently clinically considered in boys, presenting with severe

intellectual disability (ID) and craniofacial peculiarities. In females, the presentation is of a different spectrum, often leading to delayed diagnosis in adulthood, typically after identification of the condition in a male family member. Lack of knowledge of female phenotype impedes management for syndrome-specific issues, as well as genetic counseling and information to families.

Methods: This study reports the clinical, morphological, and neurodevelopmental phenotype of 9 females, diagnosed molecularly with CLS, who sought consultation at the Clinical Genetics Department of La Pitié-Salpêtrière Hospital between 2016 and 2023, as well as 43 patients via collaboration calls (ERN-ITHACA, DéfiScience, AnDDI-Rares).

Results: The majority of the patients in the series experienced learning difficulties, and did benefit from adaptions or specialized schooling. All evaluated patients exhibited neurodevelopmental disorders (ID or complex neurodevelopmental disorder). Additionally, almost all adult patients were referred for psychiatric follow-up, and presented with overweight or obesity.

Conclusion: To date, few reported cohorts have presented CLS in females. Literature data suggest inconsistent ID, learning difficulties, and rare psychiatric disorders. This study presents the largest phenotypic series of females with CLS, to our knowledge. Our findings suggest that female CLS encompasses a distinct clinical entity, with a neurodevelopmental phenotype that is more prevalent, and a majority of females exhibiting severe learning difficulties or ID, psychiatric comorbidities and obesity in adulthood.

Background/Objectives: A significant proportion of people with rare diseases (RD) don't have a genetic diagnosis after genomic studies. Reanalysis of genomic data has proven to be a useful approach to increase diagnostic yield. We present the results of reanalysis of genomic data from patients selected in the region of Madrid to participate in the national IMPaCT-GENóMICA RD program whose network is configured by 10 hospitals.

Methods: Researchers from this network selected a total of 285 patients with presumptive diagnosis of rare, monogenic disease without genetic diagnosis to participate. All of them had a previous complete exome study with inconclusive result. Those with an exome study performed in 2020 or earlier were considered for reanalysis. Exome data from 215 patients were reanalyzed.

Results: A conclusive diagnosis was obtained in 12% (n = 27/215). The causes that did not allow a diagnosis to be reached in the initial study were the absence of gene-disease association at the time of the first study, or the application of virtual panels that did not include the causal gene (66.7%; n = 18/27), the loss of the causal variant in the primary or secondary analysis (18.5%; n = 5/27) and differences between the phenotype of the patient and that of the published cases (14.8%; n = 4/27). In 23% of cases, the variant was classified as a pathogenic or probably pathogenic variant in Clinvar/HGMD

Conclusion: The diagnostic process is dynamic, reanalysis of genomic data and continuous clinical evaluation allow for improved diagnostic performance.

P10.055.B The clinical phenotype of Bosch-Boonstra-Schaaf optic atrophy syndrome

Ilia Valentin[1], *Pilar Caro[1], Christine Fischer[1], Christian Schaaf[1]*

[1]*Institute of Human Genetics, University Heidelberg, Heidelberg, Germany*

Background/Objectives: (Likely) pathogenic variants in *NR2F1* are associated with Bosch-Boonstra-Schaaf optic atrophy syndrome (BBSOAS, OMIM 132890), a rare neurodevelopmental disorder. Patients present with a variety of symptoms including intellectual disability, developmental delay, visual impairment, hypotonia, seizures and/or autistic features. Since its initial description in 2014, the phenotype steadily expanded. However, there is limited information regarding the natural course of the disorder. Here we present data of 47 individuals who answered our questionnaire.

Methods: A questionnaire was created to assess the phenotype more comprehensively and to better understand the course of the symptoms. In addition, families sent medical documents and photos. To investigate genotype-phenotype correlation in our cohort, we compared the clinical features of two genotypic groups (variants in the DNA-binding domain (DBD, n = 17) vs. variants elsewhere in the gene (n = 30)).

Results: We observed a range of common symptoms, such as developmental delay, hypotonia, optic atrophy, nystagmus, strabismus, autistic features and thin corpus callosum on brain MRI. Overall, more improvements than worsenings were reported. Individuals with variants in the DBD showed higher prevalences of severe clinical features, such as infantile spasms (46.7% vs. 3.8%, $p = 0.002$) or being nonverbal (41.2% vs. 3.4%, $p = 0.002$).

Conclusion: Our study confirms characteristic clinical features of BBSOAS. Variants in the DBD are associated with a more severe clinical phenotype. We found no evidence that the disease is progressive; rather several symptoms are reported to improve over time. However, longitudinal studies are necessary to further investigate the course of the disease.

Background/objectives: (NM_005691:c.1320+1G>A) loss-of-function (LoF) mutation of *ABCC9* was recently associated with autosomal recessive *ABCC9*-related intellectual disability and myopathy syndrome (AIMS)[1] in six patients with mild intellectual disability, white matter hyperintensities, myopathy and cardiac dysfunction. *ABCC9* encodes the SUR2 subunit of ATP sensitive-potassium (K_{ATP}) channels widely expressed throughout the body.

Methods: Phenotypic description including neuroradiologic evaluation of nine additional subjects and genotypic description of their different homozygous ABCC9 variants by heterologous expression studies. Three additional patients were recently identified, and will be included. In vivo studies in zebrafish and treatment trials in mice.

Results: All individuals show psychomotor delay and intellectual disability of variable severity associated with microcephaly, seizures, spasticity, short stature, muscle fatigability, and weakness. Cerebral MRIs demonstrate white matter abnormalities resembling periventricular leukomalacia, and corpus callosum hypoplasia. The AIMS phenotype expands to severe intellectual impairment, cerebral palsy, epileptic seizures in more patients, additionally, rhabdomyolysis in one patient.

K_{ATP} channels for AIMS variants are shown to be non-functional, implying LoF by severe truncations or in-frame deletions within SUR2.

abcc9 LoF zebrafish react to pentylenetetrazole (pro-convulsive) with exacerbated motor response, consistent with increased seizure-susceptibility. In skeletal muscle dominant-negative mice, verapamil (calcium-blocker) was ineffective in improving excercise tolerance, and unexpectedly lethal in SUR2-STOP mice[2].

Conclusion: Our findings further define a distinct *ABCC9*-related recessive phenotype, expand the genotypic and phenotypic spectrum of AIMS, revealing novel human pathologies arising from K_{ATP} channel dysfunction.

Grants: Wellcome trust. UCL-team funding. NIH award.

P10.057.D CTNND2 variants are associated with developmental delay, mild intellectual disability, and behavioral problems

*Denisa Weis[1], Andrej Ficek[2], **Ricarda Reiter**[1], Katarína Kušíková[3], Andrea Soltysova[2;4]*

[1]Institute of Medical Genetics, Kepler University Hospital, Dpt. Medical Genetics, Linz; [2]Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, Department of Molecular Biology, Bratislava 4, Slovakia; [3]Faculty of Medicine, Comenius University Bratislava and National Institute of Children's Diseases, Bratislava, Slovakia, Department of Pediatric Neurology, Bratislava, Slovakia; [4]Institute for Clinical and Translational Research, Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovakia, Research Center, Bratislava, Slovakia

Consortium: CTNND2 Consortium

Background/Objectives: Heterozygous loss of CTNND2 has been linked to a broad spectrum of neurodevelopmental disorders such as autism, schizophrenia, mild intellectual disability, and neurocognitive abnormalities with developmental delay phenotype. Some authors report the association of CTNND2 variants with dysmorphic features, attention deficit, or myopia. Next-generation sequencing revealed many novel variants with low or no frequency in the European control database. While large deletions and translocation of the CTNND2 gene are reported as pathogenic, all missense variants are of uncertain significance in the ClinVar database.

Methods: In the present study, we evaluated 54 patients' clinical manifestations with whole exome sequencing, SNP array, and karyotyping methods. Patients with available facial photos were analyzed using Face2gene. Pathogenicity prediction, nonsense-mediated RNA decay, and sequence conservation regarding patients' phenotypes were tested in silico.

Results: The 54 patients carried 41 different CTNND2 variants. The main clinical presentation was intellectual disability (64.81%), developmental delay (61.11%), speech problems (50%), and apparent facial dysmorphism (50%). More than half of affected individuals presented abnormal behavior (51.85%), including impulse control difficulties (31.48%), emotional and social immaturity (24.07%), and aggressiveness (12.96%). Out of 27 cases with available family data, 40.7% of identified mutations were de novo, and disease phenotype was present in 25.9% of

parents with transmitting mutation. A broad spectrum of CTNND2 variants were identified; further studies of predominantly missense variants are needed to elucidate their role in the pathogenesis of the disease.

Conclusion: Our comprehensive monitored clinical data contribute to the knowledge of the CTNND2 variant's role in neurodevelopmental disorders.

P10.058.A MED13L is critical for OTX2 brain-specific regulatory element activation and neural cell fate commitment

jamal ghoumid[1], *Jerome Sige*[1], *Thomas Smol*[1], *Jade Fauqueux*[1], *Fiona Leduc*[1], *Caroline Thuillier*[2], *Marie Balerdi*[1], *Ryan Ziffra*[3;4], *Dianne Laboy Cintron*[3;4], *Florence Petit*[1], *Nadav Ahituv*[3;4]

[1]*Université de Lille - Pôle Recherche de la Faculté de Médecine, Lille, France;* [2]*Hospital Center University De Lille, Lille, France;* [3]*University of California San Francisco, San Francisco, Department of Bioengineering and Therapeutic Sciences, San Francisco, United States;* [4]*UCSF Institute for Human Genetics, San Francisco, United States*

Background: The Mediator Complex is a coordinator of cell lineage determination, forming and stabilizing enhancer-promoter loops. Mutations in MED13L, a subunit of the complex, lead to intellectual disability, suggesting MED13L has a neural developmental role. Despite this, its precise function remains unknown.

Methods: We performed MED13L ChIP-seq in human iPSC to identify MED13L-bound cis-regulatory elements (CREs). We generated homozygous *MED13L*-knockout iPSC and following 48 hours post neural induction carried out 4C-seq, to assess for chromatin interactions, using the *OTX2* promoter as the viewpoint, as this gene regulates cell fate decisions during neural patterning. We also generated cerebral organoids (CO) from these iPSCs and characterized them via single-cell (sc) RNA-seq and scATAC-seq.

Results: Single-cell transcriptome analysis showed that the *MED13L*-knockout COs had a neuroretinal-like phenotype compared to wild-type. scATAC-seq showed a loss of activation of *OTX2*-brain CREs and ectopic *OTX2*-retinal CRE activation in these COs. Analysis of chromatin interactions (4C-seq) at the *OTX2* locus showed loss of interaction between the *OTX2* promoter and brain-associated CREs that was replaced with *OTX2* retinal-associated CRE interactions.

Conclusion: In wild-type cells, brain CREs closely interact with the *OTX2* promoter, leading to a developmental program recapturing early brain development, as observed in our COs. In contrast, in the *MED13L*-knockout, the *OTX2* brain CREs show significant interactions with retinal-associated CREs, leading to a neuroretinal-like development in CO. These results suggest that MED13L is a major determinant of neural cell fate decisions and that MED13L-related intellectual disability could result from altered gene expression during this process.

Background/Objectives: DNA methylation (DNAm) patterns, or episignatures, are poweful diagnostic biomarkers for single-gene neurodevelopmental disorders (NDDs). This report illustrates the power of episignatures to resolve familial NDDs with irregular inheritance patterns.

Methods: Our cohort is a small subset of NDD cases derived from a larger study involving almost 600 families examined by EpiSign™ DNAm. We focused here on (i) three pairs of siblings with similar phenotypes but different genetic findings and (ii) three cases with suspected chromatinopathy but negative exome

Results: Family #1: one boy had a de novo TRIP12 (L1044Ffs*3) variant, confirmed by the TRIP12 episignature. His brother had a de novo variant in FBN (A1728V), as yet without a diagnostic episignature. Family #2: two brothers with Kleefstra-like syndrome, one had a de novo EHMT1:K462Vfs*7 variant, confirmed by the EHMT1 episignature. Family #3: a boy with a ZMYM3:R441Q variant was confirmed by the ZMYM3 episignature; his sister had an isodicentric 15q11.2-q13.1 chromosome. The second group consisted in NDD cases with variants inherited from unaffected parents. Case #1: we discovered a maternally inherited variant (SMARCA2:G1129D) from an unaffected mosaic mother. Case #2: in a Sotos-like case, we found a paternally inherited variant (NSD1:K1002Efs*8). Case #3: the proband was diagnosed clinically with Cornelia de Lange but instead showed the ANKRD11-associated episignature, revealing an ANKRD11:N725Kfs*23 variant inherited from the mildly affected father

Conclusion: Episignature analysis is a powerful tool for identifying the molecular culprit in cases that show irregular Mendelian segregation patterns.

Background/Objectives: Heterozygous de novo variants in *CNOT3* were first reported by Martin et al in 2018 in 16 patients with hypotonia, relative short stature, developmental delay, intellectual disability and behavioral disorders. Two years later, Meyer et al reported for the first time two families in which a variation of *CNOT3* segregated. A total of 31 affected individuals from 25 families have been reported in the literature to date.

Methods: Thanks to an international collaboration, we collected clinical and molecular data of 37 additional patients from 34 families. Together, with the addition of the data from litterature, this allowed us to build up a large cohort of 68 patients from 59 families.

Results: The study of this large cohort enabled us to highlight a homogenous clinical presentation between patients, including developmental delay, mild to moderate intellectual disability, autism spectrum disorder, behavioral disorders and morphological features. Some patients presented with epilepsy or deafness.

Conclusion: We have not identified any genotype-phenotype correlation for *CNOT3* variants, which could be explained by a loss-of-function effect of all of these variants. Our findings suggest that missense variants located in binding sites equally present with a loss-of-function effect.

The study of large cohorts is necessary to better characterize the phenotype of rare diseases, as well as to better understand their natural history and provide families with appropriate genetic counseling.

Background/Objectives: Common variants in the *CSMD1-3* paralogs were shown to be GWAS-associated with neurodevelopmental and psychiatric disorders. These CUB and Sushi domains-containing synaptic proteins play a role in neuron development.

Methods: We screened diseased cohorts for *CSMD2* variants and assessed the function of its zebrafish ortholog.

Results: GnomAD suggests that *CSMD2* is under constraint and that both haploinsufficiency and missense variation could be deleterious (pLI = 1; missense Z-score = 5.45). Consistent with this hypothesis, we identified sixteen individuals carrying biallelic missense mutations in *CSMD2* in developmental delay/intellectual disability cohorts. Patients present also with autism, attention deficit hyperactivity disorder, brain anomalies and epilepsy. While the identified mutations are spread along the gene, 3D in silico modelling of the encoded proteins shows that the mutated residues are structurally close. Their side chains cannot be incorporated without clashing into the backbone of the surrounding amino acids regardless of the rotamers.

Zebrafish ablated for the orthologous *csmd2* using crispr-cas presented with microcephaly (reduced size of optic tecta and increased distance between tecta), smaller cerebellum due to smaller Purkinje's cells, a decrease in the number of neural connections between optic tecta, a higher number of abnormal peripheral neuronal branches and a decreased swimming velocity further substantiating a possible role of this gene in neurogenesis and synapse formation. Both the 3D modelling and functional analyses in zebrafish of the variants identified in patients suggested that the encoded proteins were functionally impaired.

Conclusion: Our experiments demonstrate a link between missense mutations in *CSMD2* and an abnormal development of the central and peripheral nervous system.

P10.062.A Genetic architecture of neurodevelopmental disorders based on a series of 402 patients diagnosed with next generation sequencing.

Lucia Lopez-Lopez[1], *Laura Lapeña-Gil*[1], *María José Trujillo Tiebas*[1;2], *Almudena Avila Fernández*[1;2], *Inmaculada Martin Merida*[1;2], *Marta Corton*[1;2], *Pablo Mínguez*[1;2;3], *Fermina Lopez-Grondona*[1], *Ana Isabel Sánchez Barbero*[1], *Saoud Tahsin-Swafiri*[1;2], *Marta Rodriguez de Alba*[1;2], *Carmen Ayuso*[1;2], *Isabel Lorda*[1;2], *Fiona Blanco-Kelly*[1;2], **Berta Almoguera Castillo**[1;2]

[1]*Fundacion Jimenez Diaz University Hospital. IIS-FJD, Genetics and Genomics, Madrid, Spain;* [2]*CIBERER, Madrid, Spain;* [3]*Fundacion Jimenez Diaz University Hospital. IIS-FJD, Bioinformatics Unit, Spain*

Background/Objectives: The genetic architecture of neurodevelopmental disorders (NDDs) is complex with a great genetic heterogeneity and over 2,500 genes estimated to be involved. The aim of this work is to catalogue the main genetic causes of monogenic NDDs in a series of 402 patients diagnosed by next generation sequencing (NGS).

Methods: All patients with a definitive genetic diagnosis followed by NGS were included. Both Clinical Exome Sequencing using the Clinical Exome Solution v1-3 and the DDM platform (SOPHiA Genetics) and Whole Exome Sequencing were used. Variants were classified according to the ACMG guidelines. Segregation studies were performed using Sanger sequencing or array CGH.

Results: We identified 402 patients with a definitive genetic diagnosis, 16.7% of whom carried a pathogenic copy number (CNV) or structural variant detected with NGS. There were 175 different causative genes/*loci* with the most frequent diagnoses being a Bafopathy in 5.2% (N = 21), KBG syndrome in 4.2% (N = 17), Rett syndrome in 3.5% (N = 14), a Rasopathy in 2.2% (N = 9), and *CHD2* and *SCN1A*-related disorders in 2% of the patients each (N = 8). The rest of the genes/*loci* explained less than 2% of the diagnoses and included very rare forms of monogenic NDDs and three potential new gene-disease associations.

Conclusion: The spectrum of genetic causes seen in our sample of NDD patients reflects the high genetic heterogeneity associated with this condition and support the use of NGS as the first line approach.

Background/Objectives: Diagnosing intellectual disability (ID) requires defining a frontier of normal intelligence that may

become permeable to neurodevelopmental disorders of varying severity. The KDM5B gene codes for an H3K4 demethylase that regulates the expression of numerous genes, and whose cerebral activity peaks during fetal development. The first deleterious monoallelic mutations in this gene were linked to ID of varying severity. However, the frequency of these mutations in the general population has called into question their diagnostic significance, and the disorder associated with KDM5B is now firmly established only in recessive forms (OMIM 618109).

Methods: We describe here a cohort of 44 carriers of a truncating or de novo monoallelic KDM5B variant from 23021 genome-wide sequenced individuals and 5 individuals added from exome-wide sequencing.

Results: Eighteen of them have a neurodevelopmental disorder and were phenotyped in detail. Comparison with 17 monoallelic and 5 biallelic cases in the literature reaffirms the existence of a dominant form of KDM5B-associated syndrome, distinct from the recessive form. A search for a modifier allele was carried out on the genomic data to explain the incomplete penetrance of the disease, but was inconclusive.

Conclusion: The diagnostic value of these variants remains difficult to establish. Recent genotype-phenotype studies in the general population suggest the involvement of KDM5B loss-of-function variants in cognition, and the existence of a continuum going beyond ID. Further studies are needed to understand what modulates the expression of these variants.

Grants: University of Caen Normandie

Conflict of Interest: None declared

P10.064.C Recurrent homozygous variant in the *NDST1* gene. A clinically recognizable syndromic intellectual disability.

Vanesa López González[1], *Ana Teresa Serrano Antón*[1], *María José Sánchez Soler*[1], *Marta Domínguez Jiménez*[1], *María Juliana Ballesta Martínez*[1], *Carmen María Dolores*[1], *LLuís Armengol*[2], *Encarna Guillén-Navarro*[1]

[1]*Hospital Clínico Universitario Virgen de la Arrixaca, Sección de Genética Médica. Servicio de Pediatría, El Palmar, Murcia, Spain;* [2]*Quantitative Genomic Medicine Laboratories, S.L "qGenomics", Barcelona, Spain*

Background/Objectives: Variants in *NDST1* are causative for autosomal recessive intellectual disability (ID) type 46 (MRT46, OMIM#616116), characterized by ID with language impairment, ataxia, epilepsy, behavioral disorder and growth retardation. Our objective is the clinical characterization of a group of patients with a recurrent homozygous variant.

Methods: Descriptive, retrospective study, through review of medical records of patients diagnosed with MRT46.

Results: 9 cases (5 males) of Roma ethnicity. Average age: 10,4 years. Consanguinity 5/9. All with moderate-severe ID. 4/9 hypotonia and 3/9 epilepsy. 4/9 stereotypies (hand flapping). None with brain structural abnormalities. 2/9 hearing loss and myopia respectively. Physical exam with relative macrocephaly (7/8), sparse eyebrows (5/8), wide nasal bridge (8/8), macrostomia (6/8), thick lips (5/8), dental diastema (3/7), prominent and low-set ears (8/9). All with skeletal anomalies (short and wide hands and feet, brachydactyly, clinodactyly, deep palmar and plantar creases, and elbow contracture). The homozygous pathogenic variant c.1831G>A, p.G611S in *NDST1* was identified in all cases.

Conclusion: Since its identification as a causative gene in 2011, just a few patients have been reported, these new 9 constituting an important contribution to the better clinical characterization of this entity. The existence of a recurrent variant in patients of Roma origin points to a founder effect, making it important to screen carriers, and to become familiar with its phenotype, in order to diagnose it early and in a targeted manner. A recognizable phenotype stands out, not described as specific in previous publications, with a behavioral phenotype in the Angelman-like spectrum.

Grants: none.

Background/Objectives: *DDX3X*-related neurodevelopmental disorder is among the most common monogenetic causes of intellectual disability in females, with currently >1000 females diagnosed worldwide. However, reports on affected males with *DDX3X* variants are scarce. The limited knowledge on this X-linked disorder in males hinders the interpretation of hemizygous *DDX3X* variants in clinical practice.

Methods: In this study, we present a new cohort of 19 affected males with possibly disease-causing *DDX3X* variants, for whom we collected clinical and molecular data. Additionally, we reviewed the existing literature on hemizygous *DDX3X* variants.

Results: The vast majority of males have missense variants, mainly located in the helicase domains of the encoded protein. Two specific missense variants are recurrently present. No truncating variants have been reported, consistent with the presumed lethality of complete loss-of-function of *DDX3X* in males. In our cohort, four variants are de novo in the affected male and three variants are de novo in the carrier mother. The phenotype in males is diverse, including intellectual disability (mild-severe), speech delay, behavioral challenges and structural brain abnormalities. Interestingly, about half of the carrier mothers in our cohort have mild behavioral or learning difficulties.

Conclusion: This study presents the largest cohort to date of males with *DDX3X* variants, providing a comprehensive overview of the genetic and phenotypic spectrum. Our data show that specific missense variants in *DDX3X* cause an X-linked neurodevelopmental disorder in males, with unaffected or mildly affected carrier females. These insights will aid the interpretation of

hemizygous missense variants in *DDX3X* and can guide clinical management.

P10.066.A Syndromic Intellectual Disability in Cypriot patients: variant discovery through diagnostic exome sequencing

Athina Theodosiou[1], *LUDMILA KOUSOULIDOU*[1], *angelos alexandrou*[1], *ioannis papaevripidou*[1], *Constantia Aristidou*[2], *paola evangelidou*[1], *Sofia Ourani*[3], *Emily Athanasiou*[3], *George A. Tanteles*[2;4], *carolina sismani*[1]

[1]*The Cyprus Institute of Neurology and Genetics, Cytogenetics and Genomics, Nicosia, Cyprus;* [2]*The Cyprus Institute of Neurology and Genetics, Clinical Genetics and Genomics, Nicosia, Cyprus;* [3]*Hospital Archbishop Makarios III, Department of Paediatrics, Clinical Genetics clinic, Nicosia, Cyprus;* [4]*Acropoleos Medical Centre, Nicosia, Cyprus*

Background/Objectives: Intellectual disability (ID) is characterized by significant limitations in both intellectual functioning and adaptive behaviour that originates before the age of 22. It can be isolated (non-syndromic ID) or present with one or multiple clinical features or co-morbidities in addition to ID (syndromic ID, SID). This study presents the results obtained during years 2021-2023 of Whole exome sequencing (WES) or Clinical Exome Sequencing (CES) in patients with SID and no diagnosis after extensive genetic workup including chromosomal analysis, array-CGH and other targeted tests.

Methods: WES/CES was performed on Illumina NextSeq500 or 2000 platforms using Illumina exome sequencing kits. Analysis was performed with VarSome Clinical platform (hg19 genome reference) to detect single-nucleotide variants and small insertions/deletions. Findings were confirmed by Sanger sequencing.

Results: A total of 235 samples from 88 families with SID were sequenced and variants were reported in 24 patients, giving a 27% detection rate for this specific group of patients. Findings include 20 dominant variants (16 de novo), two X-linked and one complex compound heterozygous in genes: *CDC42BPB*, *PHIP*, *ZBTB18*, *CHD8*, *SATB2*, *ANKRD11*, *CREBBP*, *MECP2*, *KCND2*, *SCN2A*, *CSNK2B*, *BICRA*, *TLK2*, *PCDH19*, *PRKAR1B, PPP3CA*, *PTEN*. Ten variants (~43%) were novel.

Conclusion: We present known and novel disease-causing variants within genes related to SID expanding the pathogenic variant spectrum of these genes. We emphasize the importance of trio analyses for novel variant discovery and highlight that exome sequencing, despite existing challenges, remains a cost-effective diagnostic tool for the benefit of the patients and their families.

P10.067.B Deregulation of ion channels contributes to *RHOBTB2*-associated developmental and epileptic encephalopathy

Franziska Langhammer[1;2], *Anne Gregor*[1;2], *Niels R. Ntamati*[3], *Arif B Ekici*[4], *Beate Winner*[5;6], *Thomas Nevian*[3], *Christiane Zweier*[1;2]

[1]*Inselspital, Department of Human Genetics, Bern, Switzerland;* [2]*University of Bern, Department of Biomedical Research (DBMR), Bern, Switzerland;* [3]*University of Bern, Department of Physiology, Bern, Switzerland;* [4]*Friedrich-Alexander-University Erlangen-Nürnberg, Institute of Human Genetics, Erlangen, Germany;* [5]*Friedrich-Alexander-University Erlangen-Nürnberg, Department of Stem Cell Biology, Erlangen, Germany;* [6]*Friedrich-Alexander-University Erlangen-Nürnberg, Center of Rare Diseases Erlangen (ZSEER), Erlangen, Germany*

Background/Objectives: While de novo missense variants in the BTB domains of *RHOBTB2* cause a severe developmental and epileptic encephalopathy (DEE), de novo missense variants in the GTPase domain or bi-allelic truncating variants are associated with variable neurodevelopmental phenotypes, frequently with seizures. Apart from the observation of increased RHOBTB2 abundance resulting from BTB-domain variants and increased seizure susceptibility in *Drosophila* overexpressing *RhoBTB*, our knowledge on the *RHOBTB2*-related pathomechanisms is still limited.

Methods: Aiming to close this gap, we first performed RNA-Seq on fly heads overexpressing *RhoBTB*. Genetic interaction experiments were performed in flies with simultaneous overexpression of *RhoBTB* and dosage manipulation of either *paralytic, slowpoke* or *ir76a* and subsequent assessment of phenotypic modifications. Using CRISPR/Cas9, we established hiPSCs with either homozygous frameshifts or patient-specific heterozygous missense variants in the GTPase or the BTB domains. After differentiation into mature neurons, whole patch clamp recordings were performed.

Results: We found enrichment of genes encoding ion channels among the differentially expressed genes in transcriptomes from flies overexpressing *RhoBTB*. Subsequently, we confirmed a functional link between *RhoBTB* and *paralytic*, the orthologue of human sodium channels, including *SCN1A*, in vivo. In hiPSC-derived, mature neurons we observed altered neuronal activity and increased excitability resulting from heterozygous missense variants in the BTB domain region but not from variants in the GTPase domain or upon complete loss of RHOBTB2.

Conclusion: Our study indicates a role of deregulated ion channels in the pathogenesis of *RHOBTB2*-related DEE and points to different pathomechanisms underlying the observed genotype-phenotype correlations regarding variant zygosity, location and nature.

P10.068.C Transcriptional study of early neural development in iPSCs-derived from Williams-Beuren Syndrome patients

Esmee ten Berk de Boer[1;2;3], *Mansoureh Shahsavani*[1], *Jesper Eisfeldt*[1;2;3], *Ann Nordgren*[1;2], *Anna Lindstrand*[1;2]

[1]*Karolinska Institutet, Molecular Medicine and Surgery, Sweden;* [2]*Karolinska University Hospital, Department of Clinical Genetics, Sweden;* [3]*Science for Life Laboratory, Sweden*

Background/Objectives: Williams-Beuren syndrome (WBS) is caused by a recurrent deletion of 26-28 genes on 7q11.23. It is characterized by cardiac abnormalities, characteristic facial features, and cognitive and behavioural impairments. Despite the clear genomic cause of WBS, the genotype-phenotype link remains unknown. This study aims to address this gap through a transcriptomics study using an in vitro neural model.

Methods: We generated induced pluripotent stem cells (iPSCs) from 4 WBS patients and 4 controls, differentiating them into neuroepithelial stem cells (NESCs) and further maturing them into neurons. Transcriptomics was done at 3 timepoints; the NESC stage, after 4 weeks, and 8 weeks of neural maturation. Our study is unique in looking at 3 timepoints to study the transcriptomic landscape in WBS patients during early neural development.

Results: At all timepoints, the genes in the deleted region show reduced expression. Furthermore, we observed global gene expression changes. Specifically, we identified 596, 374, and 598 differentially expressed genes (DEGs) in NESCs, 4 weeks, and 8 weeks neurons. Surprisingly, there is little overlap among these DEGs, with only 37 DEGs shared across all timepoints.

Conclusion: We see that there is little overlap in the transcriptomic landscape of WBS patients at different stages of neural development. Many timepoints have unique DEGs, and unique disturbed pathways. Thus, we conclude that to understand the pathology of WBS, it is essential to study various timepoints during development, as different parts of the phenotype may arise at different times.

P10.069.D Determination of clinical significance and genotype-phenotype correlations in patients with copy number variations in the short arm of chromosome 16

Michal Pietrusinski[1], *Hanna Moczulska*[1], *Marcin Serafin*[2], *Edyta Budzyńska*[2], *Agnieszka Zmysłowska*[1]

[1]*Medical University of Lodz, Department of Clinical Genetics, Lodz, Poland;* [2]*Central Clinical Hospital, Outpatient Clinic for Clinical Genetics, Lodz, Poland*

Background/Objectives: Microdeletions or microduplications of chromosome 16p, including microdeletion syndromes 16p11.2, 16p12.2, 16p13.11 and microduplications have been found in patients with intellectual disabilities (ID), developmental delay (DD), autism spectrum disorders (ASD) and dysmorphic features, but the overall clinical significance of these chromosomal rearrangements remains controversial. There are several candidate genes associated with the neurological phenotype, but these loci have variable expression and incomplete penetrance. Our aim was to determine the genotype-phenotype correlation of these microaberrations in patients in order to improve genetic counseling and overall patient care.

Methods: The study included a total of 20 cases; 6 cases with 16p11.2 (3 microdeletions - 1 prenatal; 3 microduplications), 2 cases with 16p12.2 microdeletions (1 prenatal) and 12 cases with 16p13.11 (10 microduplications - 5 prenatal; 2 microdeletions - both prenatal) referred to the Outpatient Clinic for Clinical Genetics for ID, DD, ASD in postnatal diagnosis and high-risk microaberration syndrome in prenatal diagnosis. All cases underwent chromosome microarray analysis, in some cases confirmed by MLPA.

Results: Most of the patients were found to have ID, DD or ASD, and some had dysmorphic features, heart defects, diabetes in postnatal diagnosis, and fetal hypotrophy and heart defects in prenatal diagnosis.

Conclusion: It can be concluded that 16p microdeletions and microduplications are pathogenic/likely pathogenic when detected in the context of ID/DD/ASD and dysmorphic features at birth, as well as fetal hypotrophy, heart defects and abnormal ultrasound findings before birth. These results support the hypothesis that this region is dosage-sensitive, highlighting its clinical significance.

Background/Objectives: *UNC5C* encodes a netrin receptor involved in axon guidance during brain development. Axon guidance is a fundamental process ensuring that neurons send out axonal projections to their designated targets, a pivotal step in nervous system formation. While some polymorphisms in *UNC5C* gene are linked to Alzheimer's disease susceptibility, its possible relation to neurodevelopmental disorders remain unexplored.

Materials/Methods: Exome sequencing analysis was used to identify variants in *UNC5C*. The GeneMatcher platform was utilized to identify additional families. The CRISPR/Cas9 system was employed to create equivalent variants of patients in *Caenorhabditis elegans*, and subsequent morphological and behavioral analyses were conducted on these mutants.

Results: In the patient group, consisting of eight individuals from six unrelated families, each patient harbored one of six different homozygous variants, three of which were loss-of-function variants, two missense variants, and one splice region variant. All patients exhibited an early-onset neurodevelopmental disease phenotype, characterized by global developmental delay and walking problems. Additionally, more than half of the patients shared clinical features such as short stature, feeding difficulties, retrognathia, short neck, finger contractures, and foot deformities. We generated a corresponding variant of p.Cys362* in *unc-5* in *C. elegans*, leading to null-like phenotypes such as locomotion difficulties and a shortened body. The generation of other mutants and ongoing morphological and behavioral analyses are currently underway.

Conclusion: Herein, we report the first human disease caused by homozygous variants in *UNC5C* gene presenting a novel neurodevelopmental disorder.

P10.073.D tRNA 2'-O-methylation detection using mass spectrometry and nanopore sequencing in Ftsj1 deficient and WT mouse liver.

Lars Jensen[1], *Lisa Hagenau*[1], *Robert Hieronymus*[2], *Corinna Jensen*[1], *Johann Wurz*[2], *Sabine Müller*[2], *Andreas Kuß*[1]

[1]*University Medicine Greifswald, Department of Functional Genomics, Greifswald, Germany;* [2]*University of Greifswald, Bioorganic Chemistry, Greifswald*

Background/Objectives: Inherited forms of intellectual disability (ID) affect approximately 0.5% of the general population. A part of the mutations causing ID is found in genes involved in protein synthesis. These include certain ribosomal proteins, tRNA synthetases and tRNA modifying enzymes. Mutations in *FTSJ1* cause severe, non-syndromic ID. This gene encodes a 2'-O- methyltransferase involved in the modification of certain tRNAs and so far tRNA-methylation is the only known function of its gene

product. To show that mutations in *FTSJ1* reduce catalytic activity we established an assay for FTSJ1 deficiency in a murine model.

Methods: We used hybridization-based methods to purify tRNA phenylalanine ($tRNA^{Phe}$) from WT and $Ftsj1^{-/y}$ mouse liver. The purified tRNA was sequenced using nanopore sequencing or digested with RNase T1 and analyzed by mass spectrometry.

Results: The results show that both methods are applicable for detecting either absence or presence of methylation of $tRNA^{Phe}$ and thereby allows to determine whether Ftsj1 is functional or not in cells from which the tRNA was obtained.

Conclusion: Both methods are still time consuming as they rely on tRNA purification and relatively large amounts of purified $tRNA^{Phe}$ (>100 pmol) but analysis of unpurified tRNA may be feasible in the near future as mass spectrometry and nanopore sequencing data analysis improves.

P11
NEUROGENETIC AND PSYCHIATRIC DISORDERS

P11.001.A Investigating differences in genetic susceptibility to autism in preterm and term births

Yali Zhang[1;2], *Ashraf Yahia*[1;2], *Sven Sandin*[3;4], *Ulrika Ådén*[5], *Kristiina Tammimies*[1;2]

[1]*Karolinska Institute, Center of Neurodevelopmental Disorders (KIND), Centre for Psychiatry Research, Department of Women's and Children's Health, Stockholm, Sweden;* [2]*Karolinska University Hospital, Astrid Lindgren Children's Hospital, Solna, Sweden;* [3]*Karolinska Institute, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden;* [4]*Icahn School of Medicine at Mount Sinai, Department of Psychiatry, New York, United States;* [5]*Karolinska Institute, Department of Women's and Children's Health, Stockholm, Sweden*

Background/Objectives: Autism Spectrum Disorder (ASD) is an early-onset neurodevelopmental condition with heterogeneous presentation and strong genetic liability. However, some environmental stressors are implicated in increased liability for ASD, such as prematurity. We hypothesized that ASD-associated genetic susceptibility would be different in individuals born term and preterm.

Methods: We used phenotype and genetic data from two large ASD cohorts, Simons Foundation Powering Autism Research for Knowledge (SPARK) and Simons Simplex Collection (SSC), to investigate the differences across prematurity and ASD. Cohorts included 9,364 preterm and 66,549 term for phenotype and 465 and 4,472 for genomics, respectively. We analyzed differences in rare de novo and inherited variants rates and polygenic risk score (PRS) for ASD using generalized estimating equation models.

Results: ASD-preterm have a significantly higher frequency of additional diagnoses and more severe symptoms than ASD-term. Within ASD, no significant differences between the preterm and term for de novo variant event rate and PRS distribution were observed. Within preterm, those with ASD had more exonic de novo variants than non-ASD, but the difference was inconsistent. We observed a significant interaction between PRS and preterm birth for ASD diagnosis. Ongoing analyses are being added for the inherited variants and full genetic model.

Conclusion: We demonstrate that preterm ASD is associated with a higher burden of additional diagnosis but similar genetic liability to ASD. Further studies should investigate additional genetic variants contributing to preterm birth and the complex phenotype.

P11.002.B Disentangling the Genetic Architecture of Alzheimer's Disease from Aging and Dementia

César Cunha[1;2], *Tuomas Kilpeläinen*[1;2], *Ruth Loos*[1]

[1]*Novo Nordisk Foundation Center for Basic Metabolic Research, København, Denmark;* [2]*Novo Nordisk Foundation Center for Genomic Mechanisms of Disease at the Broad Institute of MIT and Harvard, Cambridge, Massachusetts, United States*

Consortium: EADB Consortium

Late-onset Alzheimer's Disease (LOAD) has a complex genetic architecture that has been challenging to differentiate from the general effects of aging and dementia. We aimed to identify genetic effects specific to LOAD by utilizing EADB GWAS results with and without LOAD-by-proxy cases (*i.e.* parental disease history) or non-age-matched control individuals. SNP-based heritability for LOAD increases from 1.3% to 5.6% after excluding proxies and non-age-matched controls, suggesting a more accurate estimate of the true SNP-based heritability. Out of 235 genome-wide significant loci in total, 85 are exclusive to LOAD, while 78 are linked to a broader dementia phenotype. LOAD-specific loci show higher effect sizes whereas dementia-specific loci show lower effect sizes in clinically-relevant against standard proxy-prevalent cohorts. We identify 21 age-specific loci of which we highlight rs58859091 as LOAD-exclusive and rs28577986 as dementia-exclusive. Among the 235 loci, gene prioritization by cS2G highlighted 155 genes, 71 of which have not been previously linked to LOAD. Gene expression enrichment analysis across brain cell types revealed two gene clusters: one specific to LOAD and another related to dementia. Pathway enrichment for LOAD-specific loci highlighted cholesterol, lipid, immune, and viral pathways, and revealed a connection to body weight regulation. Druggability analyses spotlighted compounds in cancer, cardiovascular, cardiometabolic, and calcium flux pathways. In conclusion, our LOAD-specific analyses elucidate some of missing heritability and unveil 18 variants specific to LOAD, distinct from variants associated with broad aging or dementia phenotypes. These findings uncover unprecedented biology, inform analysis strategies for LOAD, and may give clues for drug discovery.

P11.003.C Utility of Exome sequencing in the diagnosis of Hereditary spastic paraplegia: An Indian perspective.

Dr. Varun venkat Raghavan Mandikal Srinivasan[1], *Vykuntaraju K Gowda*[2], *himani pandey*[3]

[1]*SGPGIMS, Medical genetics, Lucknow, India;* [2]*Indira Gandhi institute of child health, Pediatric Neurology, Bangalore, India;* [3]*Redcliffe labs, Lab Head - Clinical Genomics, Noida, India*

Background: Hereditary spastic paraplegias (HSPs) are genetically heterogenous group of neurogenetic disorders affecting corticospinal tracts predominantly. The molecular diagnosis remains unknown in >30% cases.

Methods: To study the spectrum of gene mutations and the yield of whole exome sequencing in an Indian cohort of patients with HSP over a period of 2 years.

Results: A total of 44 families were included in the study with 22 cases being males. Consanguinity was seen in 19 families (43.2%) with similarly affected siblings in 5 families (11.2%). Thirty-three (75%) were categorized to have complicated HSP. Exome sequencing identified disease causing variants in 27/44 cases with a yield of 61.4%. 19 (43.2%) had recessive and 8 (18.2%) had dominant mutations. Novel variation was seen in 19 cases (43.2%). Most common disease-causing genes were *FA2H* in 5 (11.36%), *AP4M1 in* 3 (6.81%), *SPG7* in 2 (4.54%) cases. Recurrent variation in *FA2H* and *AP4M1* were observed in 2 unrelated families suggesting a probable founder effect. Three cases had presented with features of spastic paraparesis with no mutations in known HSP genes and had mutations In *ATAD3A, TNR* and *NDUFA11* genes. Dual diagnosis was seen in 2 cases with one case having pathogenic variants in *KIF1A, TANC2* and the other case having pathogenic variants in *SPG7, HEXA*. Only one case had an actionable finding in the *DSP* gene.

Conclusion: This study expands clinical spectrum, etiology and disease variability among Indian patients with HSP. The yield of WES in current study was on par with published literature.

P11.004.D SCA4: low-cost detection of normal and expanded GCC repeats in *ZFHX3* by conventional PCR and fragment analysis

Andreas Dalski[1], *Yorck Hellenbroich*[1], *Christine Zühlke*[1], *Jassemien Strohschehn*[1], *Malte Spielmann*[1]

[1]*Institute of Human Genetics, University Hospital Schleswig-Holstein, University of Lübeck, Lübeck, Germany*

Background/Objectives: The introduction of long read sequencing is shedding light into the inaccessible regions of the human genome from telomer to telomer. We recently identified an exonic GCC-repeat expansion in *ZFHX3* causing spinocerebellar ataxia type 4 (SCA4), a dominant form of ataxia with sensory neuropathy has been published (Figueroa et al. 2024; Wallenius et al. 2024). However, long read sequencing is still expensive and technically challenging making it impractical for the screening of lager cohorts. Here we set out to develop a low-cost GCC-repeat test for clinical SCA4 screening.

Methods: Adapted PCR with *ZFHX3* specific primers was performed on the basis of a commercial FMR1-Kit (Bio-Techne AmplideX®). Fragment lengths were determined by capillary and classic agarose gel electrophoresis followed by Sanger sequencing.

Results: We present the results of 50 related (two independent kindreds) and unrelated patients and controls. Within the families clear anticipation is observed. Expanded alleles with 44 to 68 repeats show a striking effect on the age of onset ranging from 12 to 55 years.

Conclusion: Our protocol enables geneticists to perform analysis for the causative SCA4 repeat expansion on genomic DNA with a robust turn-around time at low costs. Furthermore, the exact repeat length prediction via this method and the proven clear anticipation allows an estimation of a possible disease onset for allele carriers at least in a research context.

Consortium: Genomics England Research Consortium

Background/Objectives: Alpha-tubulin 4A encoding gene (*TUBA4A*) has been associated with familial amyotrophic lateral sclerosis (fALS) and fronto-temporal dementia (FTD), based on identification of likely pathogenic variants in patients from distinct ALS and FTD cohorts. Very recently, the p.Glu415Lys *TUBA4A* variant has been identified in a large Italian family with spastic cerebellar ataxia and in an unrelated sporadic patient with de novo occurrence.

Methods: We describe 12 patients from 11 unrelated families harbouring ultra-rare missense variants in *TUBA4A*. We carefully characterized the patients' phenotype by providing detailed clinical data and imaging, when available. A rare-variant gene-based burden case-control analysis was performed within the rare disease component of the UK 100,000 Genomes Project (100KGP). Functional studies on microtubules properties were performed on cultured fibroblasts from 3 patients.

Results: We report 12 patients presenting with spasticity and/or cerebellar ataxia and harboring a predicted pathogenic *TUBA4A* missense mutation, including 5 confirmed de novo cases and a mutation previously reported in a large family presenting with spastic ataxia. In addition, gene burden analyses in the UK 100K GP showed enrichment of *TUBA4A* rare variants in the inherited ataxia group compared to controls (OR: 14.3 [5.0 – 41.2]; $P < 10\text{-}4$). Cultured fibroblasts from 3 patients harboring distinct *TUBA4A* missense mutations showed significant alterations in microtubule organisation and dynamics, providing insights for *TUBA4A* variants pathogenicity.

Conclusion: Our data confirm the identification of a hereditary spastic ataxia disease gene with variable age of onset, expanding the clinical spectrum of *TUBA4A* associated phenotypes.

Conflict of Interest: None declared

P11.006.B The broad phenotypic spectrum of *AIMP1*-related disorders: unveiling a new case of hereditary spastic paraplegia

*Sara Morais[1;2;3;4], José Leal Loureiro[1;2;5], Eva Brandão[5], Jorge Sequeiros[1;2;3;4], Giovanni STEVANIN[6], **Mariana Santos**[1;2;3]*

[1]IBMC - Institute for Molecular and Cell Biology, Universidade do Porto, Porto, Portugal; [2]i3S - Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal; [3]ICBAS School of Medicine and Biomedical Sciences, Universidade do Porto, Porto, Portugal; [4]CGPP - Center for Predictive and Preventive Genetics, IBMC - Institute for Molecular and Cell Biology, Universidade do Porto, Porto, Portugal; [5]Serviço de Neurologia, Centro Hospitalar de Entre o Douro e Vouga, Santa Maria da Feira, Portugal; [6]Université de Bordeaux, CNRS - Centre National de la Recherche Scientifique, INCIA - Institut de Neurosciences Cognitives et Intégratives d'Aquitaine, Bordeaux, France

Background/Objectives: Hereditary spastic paraplegias (HSP) are a heterogeneous group of neurodegenerative disorders, characterized by progressive lower limb spasticity and weakness. The clinical and genetic basis of HSP is very complex, with more than 80 genes associated with the disease. The genetic cause, however, remains elusive in nearly one half of all HSP cases. To improve diagnostic yield, and to identify novel HSP genes, a large Portuguese family with complex HSP was selected for this study.

Methods: Linkage analysis and whole-exome sequencing (WES) were performed to identify the causal gene in this HSP family with autosomal recessive inheritance. A minigene construct was created to confirm a predicted splicing effect.

Results: WES analysis focused on the defined linkage regions (maximum LOD score of 4.3 in chromosome 4), and led to the identification of an *AIMP1* variant (c.295G>A) in homozygosity. The minigene assay showed that this apparent *AIMP1* missense variant causes the loss of exon 3 donor splice site, resulting in the introduction of a premature stop codon, through the usage of an alternative splice site within the intron.

Conclusions: *AIMP1* was identified as a causal gene for complex HSP with early age-at-onset, contributing to the growing list of HSP genes. *AIMP1* variants have been previously associated with a spectrum of disorders, ranging from intellectual disability to more complex neurodegenerative diseases. Additional studies are required to definitively establish genotype-phenotype correlations.

Background/Objectives: Late-onset cerebellar ataxia (LOCA) encompasses heterogeneous neurodegenerative disorders with symptom onset after 30 years of age. A genetic diagnosis is established in fewer than 30% of LOCA patients. Intronic tandem repeat expansions (TREs) in *RFC1* and *FGF14* have recently emerged as common causes of LOCA. This study screened Greek LOCA patients for the commonest causative TREs.

Methods: Over a 28-year period, 206 consecutive LOCA patients were referred for genetic testing. Based on clinical data and inheritance pattern, patients were screened for FRDA, SCA1,2,3,6,7 and FXTAS, followed by testing for CANVAS and SCA27B. PCR, RP-PCR, agarose gel electrophoresis and fragment analysis were performed, as appropriate, to detect the pathogenic TREs.

Results: A genetic diagnosis was reached in 60 of 206 cases (29.1%). Mean age was 60.1 ± 11.2 (35-87) years and mean age at onset 52.5 ± 11.4 (30-80) years. SCA27B accounted for 9.7% of LOCA cases (n = 20), CANVAS for 6.8% (n = 14) and FRDA for 4.4% (n = 9). The overall frequency of SCA1 (n = 5), SCA2 (n = 6) and SCA7 (n = 3) was estimated at 6.8%. No cases of SCA3 and SCA6 were identified. FXTAS (n = 3) contributed another 1.5% of cases.

Conclusion: Our study provides comprehensive data on the genetic basis of LOCA in the Greek population. SCA27B, followed by CANVAS, represent the commonest known genetic causes of LOCA. FRDA is also a relatively common cause of LOCA. SCA1,2,7 and FXTAS are rare, whereas SCA3 and SCA6 are virtually absent. We recommend prioritizing testing for *FGF14* and *RFC1* expansions in the diagnostic algorithm of LOCA.

Background: Charcot-Marie-Tooth disease (CMT) is the most common cause of hereditary neuropathy, exhibiting extensive genetic heterogeneity, which can be addressed using whole exome sequencing (WES). This study screened previously undiagnosed Greek patients with CMT, using WES.

Methods: Over a 6-year period, 441 consecutive patients were referred for CMT molecular diagnosis. Following targeted testing for CMT1A and in selected cases for CMTX, 173 index-cases remained undiagnosed, of which 65 with a strong suspicion of hereditary neuropathy. To date, 32 of these, including 13 cases with demyelinating and 19 cases with axonal neuropathy, have been screened by WES using Ion Torrent technology and confirmed by Sanger sequencing.

Results: Causative variants were detected in 19 of 32 patients (59.4%) across 14 genes known to cause CMT, of which 3 were novel (in *MPZ*, *SH3TC2* and *KIF1A*). In demyelinating forms the diagnostic yield was 76.9 % and in axonal forms 47.4%. Most causative variants were found in *SH3TC2* (5 cases) and *GJB1* (2 cases), all in demyelinating CMT. In patients with demyelinating CMT, single causative variants were found in *EGR2*, *MPZ* and *NDGR1*. In patients with axonal CMT, single causative variants were identified in *HINT1*, *NEFH*, *BSCL2*, *NEFL*, *MORC2*, *GDAP1*, *KIF1A*, *SORD1* and *MPV17*.

Conclusion: The overall diagnostic yield of WES was comparable to other CMT populations. Our results contribute to the further mapping of gene variants associated with hereditary neuropathy and highlight the importance of WES in the diagnostic algorithm of disorders with high genetic heterogeneity, in the context of precision medicine.

Conflict of Interest: None declared

P11.009.A The genetic landscape of sporadic adult-onset degenerative ataxia: a systematic multi-modal genetic study of 377 consecutive patients from the longitudinal multi-center SPORTAX cohort

Danique Beijer[1], *David Mengel*[1], *Demet Önder*[2], *Carlo Wilke*[1], *Andreas Traschütz*[1], *Jennifer Faber*[2], *Florian Harmuth*[3], *Claudia Dufke*[3], *Bernard Brais*[4], *Olaf Riess*[3], *Ludger Schoels*[5], *Tobias Haack*[3], *Stephan Züchner*[6], *david pellerin*[4], *Thomas Klockgether*[2], *Matthis Synofzik*[1]

[1]*Hertie-Institute for Clinical Brain Research, Division Translational Genomics of Neurodegenerative Diseases, Tuebingen, Germany;* [2]*University Clinic Bonn, Department of Neurology, Bonn, Germany;* [3]*University of Tuebingen, Institute of Medical Genetics and Applied Genomics, Tuebingen, Germany;* [4]*McGill University, Montreal Neurological Hospital and Institute, Montréal, Canada;* [5]*Hertie-Institute for Clinical Brain Research, Tuebingen, Germany;* [6]*University of Miami - Miller School of Medicine, Miami, United States*

Consortium: SPORTAX consortium

Background/Objectives: While most sporadic adult-onset neurodegenerative diseases have a relatively minor monogenic component, sporadic adult-onset ataxias might have a substantial monogenic component, due to several recently identified late-onset ataxia genes. Here, we systematically map the genetic landscape of sporadic adult-onset ataxia in a well-characterized and longitudinal cohort, combining multi-modal genetic screening techniques.

Methods: Systematic clinic-genetic analysis of a prospective longitudinal multi-center cohort of 377 sporadic adult-onset ataxia patients (SPORTAX cohort) - including clinically defined sporadic adult-onset ataxia of unknown etiology (SAOA) (n = 285) and multiple system atrophy of cerebellar type (MSA-C) (n = 92)-, combining GAA-*FGF14* and *RFC1* repeat expansion screening and next-generation sequencing (NGS).

Results: 86 out of 377 (22.8%) all patients carried a pathogenic or likely pathogenic variant, thereof 73/286 patients (= 25.5%) with clinical SAOA and 13/91 patients (= 14.3%) with clinical probable MSA-C. This included: 45 (11.9%) patients with GAA-*FGF14*>250 repeat expansions (5 with a clinically probable MSA), 17 (4.5%) patients with *RFC1* repeat expansions (3 with a clinically probable MSA); and 27 (7.2%) patients with SNVs identified by NGS (5 with a clinically probable MSA).

Conclusion: Leveraging a strictly consecutive cohort, we demonstrate that sporadic adult-onset ataxias – de-riched for genetic causes - have a substantial burden of monogenic variants, particularly GAA-*FGF14* and *RFC1* repeat expansions, and including a substantial share of patients with clinical probable MSA-C. These findings have important implications for genetic work-up and counselling of sporadic adult-onset ataxia patients both SAOA and MSA-C; and - with genetic targeted treatments now in reach -also for providing these patients with access to targeted gene-specific treatments.

P11.010.B Human iPSCs-derived neuronal models to study the pathogenic mechanisms behind TANGO2-disease

Silvia Carestiato[1], *sofia galli*[2], *Paolo Scudieri*[2;3], *Lisa Pavinato*[1], *simona Baldassari*[2;3], *Federico Zara*[2;3], *Giovanni Battista Ferrero*[4], *Aldamaria Puliti*[2;3], *Alfredo Brusco*[5;6]

[1]*University of Turin, Medical Sciences, Turin, Italy;* [2]*University of Genoa, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DiNOGMI), Genoa, Italy;* [3]*IRCCS Istituto Giannina Gaslini, U.O.C. Medical Genetics, Genova, Italy;* [4]*University of Turin, Department of Clinical and Biological Sciences, Orbassano, Italy;* [5]*University of Turin, Department of Neurosciences "Rita Levi Montalcini", Turin, Italy;* [6]*Città della Salute e della Scienza University Hospital, Medical Genetics Unit, Turin, Italy*

Background/Objectives: The TANGO2 protein plays a significant role in vesicular trafficking, mitochondrial oxidation, and maintaining cellular homeostasis. Biallelic loss-of-function variants are associated to an autosomal recessive disorder characterized by cardiac arrhythmia, metabolic crises, rhabdomyolysis, and kidney damage. Additionally, a neurological component is observed, including neurodegeneration, developmental delay, and cerebral atrophy. Here, we investigated the previously unexplored role of TANGO2 loss in neurons by using neural stem cells and cortical neurons, and provided new insights into the disease pathogenesis.

Methods: iPSCs were generated from two siblings, who exibited different clinical presentation - one with a classical form and the other with milder features. iPSCs were used to derive neural rosettes (NRs), neural progenitor cells (NPCs) and mature neurons.

Results: In the patient with severe TANGO2 disease, analysis of NRs showed a reduction in area (~45%) and impaired morphological organization. The wound healing assay demonstrated altered migration in NPCs, which supports the previously reported role of TANGO2 in migration. Moreover, an increase cell death was observed during corticogenesis. The Reactive Oxygen Species (ROS) assay showed an oxidative stress condition, further supporting the involvement of TANGO2 in mitochondrial functions and cellular homeostasis.

In contrast, no significant differences were found in NRs, NPCs, and mature neurons in the milder sibling vs. controls.

Conclusion: We provide evidence for a crucial role of TANGO2 in early-stage neurodevelopment, particularly in neural tube formation, cell migration, and neuron maturation. Moreover, we suggest protective gene modifiers influencing patient phenotypes, highlighting the need for further transcriptomic and proteomic analyses.

P11.011.C Investigating the role of rare missense variants in RAB11B in Autism Spectrum Disorder

Marta Viggiano[1], *Laura Sandoni*[1], *Fabiola Ceroni*[1;2], *Paola Visconti*[3], *Annio Posar*[3;4], *Maria Cristina Scaduto*[3], *Alessandro Vaisfeld*[5], *Elena Bacchelli*[1], *Elena Maestrini*[1]

[1]*University of Bologna, Department of Pharmacy and Biotechnology, Bologna, Italy;* [2]*Oxford Brookes University, Faculty of Health and Life Sciences, Oxford, United Kingdom;* [3]*IRCCS Istituto delle Scienze Neurologiche di Bologna, UOSI Disturbi dello Spettro Autistico, Bologna, Italy;* [4]*University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy;* [5]*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy*

Background/Objectives: Autism spectrum disorder (ASD) is a highly heritable neurodevelopmental disorder with a complex genetic architecture. The identification of rare de novo variants in ASD individuals have highlighted hundreds of high-confidence susceptibility genes, many of which are also associated with Intellectual Disability (ID) and/or other Neurodevelopmental Disorders (NDD). Recently, recurrent de novo missense variants in *RAB11B* have been associated with a NDD including ID and white matter anomalies. *RAB11B* encodes a small Rab GTPase involved in intracellular transport and endosomal trafficking, essential for numerous neurodevelopmental processes.

Methods: We performed whole exome and/or genome sequencing (WES/WGS) in a cohort of 116 ASD families, and a review of public databases and literature to identify deleterious variants in *RAB11B* in individuals with ASD/NDD. Then, immunofluorescence analysis was carried out to functionally characterize these variants.

Results: We identified a novel de novo missense variant in *RAB11B* (p.R33H) in our cohort, and two additional *RAB11B* uncharacterized missense variants in individuals with ASD/NDD from other studies. Co-localization experiments using ARPE-19 showed that after induction of the primary cilium assembly there was enriched localisation of the R33H mutant to the Golgi network, similar to inactive RAB11B.

Conclusion: Our study provides evidence that de novo missense variants close to *RAB11B* functional domains affect the protein sub-cellular localization during primary cilium assembly, suggesting a role for *RAB11B* in ASD aetiology.

P11.012.D Genetic study of Portuguese Cerebral Cavernous Malformation patients using targeted gene panel sequencing

Maria Rosário Almeida[1], *João Durães*[1;2;3], *Ricardo Pereira*[4], *Ana Santos*[1], *Isabel Santana*[1;2;3]

[1]*Center for Innovative Biomedicine and Biotechnology, University of Coimbra;* [2]*Faculty of Medicine, University of Coimbra;* [3]*Neurology Department, Centro Hospitalar e Universitário de Coimbra;* [4]*Neurosurgery Department, Centro Hospitalar e Universitário de Coimbra*

Background/Objectives: Cerebral cavernous malformations (CCMs) are common vascular malformations in the central nervous system, known for causing headaches, hemorrhage, seizures, and neurologic deficits. CCMs can occur sporadically or in a familial autosomal dominant pattern, primarily linked to mutations in *CCM1* (*KRIT1*), *CCM2* (*MGC4607*), and *CCM3* (*PDCD10*) genes. This study aimed to unveil the mutation spectrum in patients diagnosed with CCMs in Portugal's central region and explore the related phenotypes.

Methods: A total of 24 subjects (20 patients and 4 family members) were investigated for the presence of pathogenic variants in the three CCM-related genes using targeted NGS panel or Sanger sequencing.

Results: The genetic analysis revealed five different pathogenic/likely pathogenic variants in 13 subjects (54%), including 9 patients and 4 family members (3 asymptomatic and 1 symptomatic) in the *CCM1* and *CCM2* genes, while no mutations were found in the *CCM3* gene. Of these pathogenic variants, three were novel, one in *CCM1* (p.N496Rfs*12) and two in *CCM2* (p.Q72*; p.G78Dfs*3). Furthermore, three variants were classified as VUS, two in *CCM1* (p.A30G; p.P114Q) and one in *CCM2* (p.A141T).

Conclusion: With the identification of three novel variants, this study expands the mutation spectrum of CCM-related genes and the associated clinical and imaging phenotypes. All identified pathogenic/likely pathogenic variants lead to a premature stop codon, while the three remaining missense variants were VUS. Thus, identification of underlying pathogenic variants in patients with CCMs has been essential to provide accurate genetic counselling to both patients and family members, and also to improve their clinical management.

Conflict of Interest: None declared

P11.013.A *ATXN1* intermediate repeat expansion among the Hungarian *C9orf72* positive cases

Zsófia Nagy[1;2;3;3], *Lilla Buzai-Kiss*[1], *Barbara Trombitas*[1], *Margit Pál*[2;3], *Adrienn Géresi*[1;4], *András Salamon*[5], *Péter Klivényi*[5], *Marta Szell*[2;3], *Maria Judit Molnar*[1;4]

[1]*Insitute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary;* [2]*Department of Medical Genetics, University of Szeged, Szeged, Hungary;* [3]*ELKH-SZTE Functional Clinical Genetics Research Group, Szeged, Hungary;* [4]*ELKH-SE Multiomics Neurodegeneration Research Group, Budapest, Hungary;* [5]*Department of Neurology, University of Szeged, Szeged, Hungary*

Background/Objectives: The hexanucleotide repeat expansion in the *C9orf72* gene is the most common genetic cause of frontotemporal dementia (FTD) and amyotrophic lateral sclerosis (ALS). Recently, the mutation has been detected in other neurodegenerative diseases, such as Parkinson's disease and Huntington's like phenotype. Literature has shown that intermediate length *ATXN1* repeat expansion are more frequent among *C9orf72* positive ALS patients. However, no data is known about the involvement of *ATXN1* repeats in other *C9orf72* positive neurodegenerative conditions.

Methods: Patients positive for the *C9orf72* repeat expansion (N = 86) and 178 control patients diagnosed with oncohematological malignancies were screened for the *ATXN1* gene repeat length by fragment analysis. Intermediate repeat expansion was defined as 32-39 CAG units.

Results: Altogether 18 C9orf72 positive (C9 +) patients (20,93%) and 2 control patients (1,12%) carried an intermediate length repeat expansion of the *ATXN1* gene. Ten of the C9+ cases had ALS phenotype, one – one FTD and Alzheimer dementia respectively and four patients had Parkinsonian phenotype. The age at onset of the C9 + ALS patients carrying an intermediate

ATXN1 allele was lower and their survival was longer in irrespective of clinical presentation compared to the *C9orf72* positive cohort without an *ATXN1* intermediate allele.

Conclusion: Our results indicate the role of *ATXN1* as a phenotype modifier among *C9orf72* positive patients not only diagnosed with ALS but with neurodegenerative disorders. More research is being carried out to delineate the interplay of these genes and their role in disease mechanism.

Conflict of Interest: None declared

P11.014.B Heterozygous variants in *ESRRG* cause a neurodevelopmental disorder with ataxia

Brandon Bresack[1], *Alexandra Afenjar*[2], *Lydie Burglen*[2;3], *Rami Abou Jamra*[1]

[1]*Institute of Human Genetics, University of Leipzig Medical Center, Leipzig, Germany;* [2]*Centre de référence des malformations et maladies congénitales du cervelet Et Laboratoire de Neurogénétique Moléculaire Pédiatrique, Département de Génétique, AP-HP.Sorbonne Université - Hôpital d'Enfants Armand-Trousseau, Paris, France;* [3]*Developmental Brain Disorders Laboratory, Imagine Institute, Paris, France*

Background/Objectives: *ESRRG* is involved in regulation of mitochondrial genes and is expressed in the brain. Among its ESRR paralogues, *ESRRG* exhibits the highest mutational constraint but remains not associated with a disease trait. This study aims at proving if *ESRRG* is a novel neurodevelopmental disorder gene.

Methods: Exome or genome sequencing with standard filtering of variant in individuals with neurodevelopmental disorders. Systematic and standardized clinical documentation of symptoms. Molecular modelling of the identified variants. Literature and database search and bioinformatic tools regarding functional aspects of the variants and the gene.

Results: We report on 4 patients from 3 unrelated families carrying heterozygous missense variants in *ESRRG*; p.(Lys149Arg), p.(Arg184Cys), and p.(Leu449Arg). The latter variant was identified in an affected father and his affected child. All variants are absent in gnomAD (v4), are in silico pathogenic and are located in intolerant segments of the protein. All affected persons have developmental delay, ataxia and muscular hypotonia. Three individuals additionally feature eye movement disorders or ptosis. Other symptoms include dysarthria, myopia, glaucoma and optic nerve coloboma. Further patients with variants in *ESRRG* are still in clarification.

Conclusion: Taken the clinical overlap of neurodevelopmental delay, ataxia and muscular hypotonia, the function, size and constraints of the gene, the segregation and in silico predictions of the variants, we propose *ESRRG* as a novel gene for neurodevelopmental delay and ataxia.

P11.015.C Human models for White Sutton syndrome: *POGZ* mutations change the transcriptome and induce defects in neural progenitor cell biology

Azza Soliman[1], *Jessica Leismann*[2], *Dewi Hartwich*[3], *Susanne Gerber*[3], *Susann Schweiger*[1], *Joan Barau*[2], *Hristo Todorov*[3], *Jennifer Winter*[1]

[1]*Institute of Human Genetics, Mainz, Germany;* [2]*Institute of Molecular Biology gGmbH (IMB), Mainz, Germany;* [3]*Institute of Human Genetics, Clinical Genomics and Bioinformatics, Mainz, Germany*

Background/Objectives: Pogo transposable element with ZNF domain (*POGZ*) has been identified as a frequently mutated gene in patients with neurodevelopmental disorders (NDDs), including autism spectrum disorder (ASD), intellectual disability and White-Sutton syndrome. However, the underlying disease-causing cellular and molecular mechanisms are still unclear.

Methods: We generated induced pluripotent stem cell lines (iPSCs) with heterozygous *POGZ* mutations, either derived from patient fibroblasts or through CRISPR/Cas9 editing, differentiated them into neural progenitor cells (NPCs) in 2D and 3D culture.

Results: We demonstrate that frameshift mutations, either in the N-terminus or in the HP1-binding zinc finger-like (HPZ) domain, decrease POGZ protein expression without affecting its nuclear localization. By using 3D neurospheres, we show that *POGZ* deficiency impairs self-renewal activity and enhances NPC differentiation and neuronal migration.

POGZ binds to chromatin and functions as a transcriptional regulator. RNA sequencing of the NPCs with *POGZ* mutations revealed widespread transcriptome changes. The differentially expressed genes were significantly enriched for GO terms including mitotic chromatid segregation, DNA repair, nonsense mediated decay and alternative splicing, among others. Interestingly, *POGZ* mutations were associated with a transcriptomic signature that was characterized by higher expression of neuron-specific genes. This finding might indicate "accelerated differentiation" in mutant NPCs similar to the phenotype observed in the 3D neurospheres. To identify direct POGZ targets, we are carrying out CUT&Tag sequencing. These experiments, which will be presented at the ESHG, will shed additional light into the regulatory role of POGZ during neural differentiation.

Conclusion: NPCs with *POGZ* mutations show alterations in POGZ expression, proliferation, differentiation and transcriptome, that suggest accelerated differentiation.

Conflict of Interest: None declared

P11.016.D NR2F1 in neural crest cells: a novel approach to model Bosch-Boonstra-Schaaf Optic Atrophy Syndrome (BBSOAS)

Ayat Ahmed[1], *Susanne Theiss*[1], *feven berhanne*[1], *tatyana kan*[1], *Michael Eibl*[1], *Malte Spielmann*[2], *veronica patricia yumiceba corral*[2], *Wilfred F. van Ijcken*[3], *Kerstin Ludwig*[4], *Ronja Hollstein*[4], *Christian Schaaf*[1], *Magdalena Laugsch*[1]

[1]*Institute of Human Genetics, Heidelberg University, Heidelberg, Germany;* [2]*Institute of Human Genetics, University Hospital Schleswig-Holstein, Lübeck, Germany;* [3]*Erasmus University Medical Center, University of Rotterdam, Rotterdam, Netherlands;* [4]*Institute of Human Genetics, University of Bonn, Bonn, Germany*

Background/Objectives: Bosch-Boonstra-Schaaf Optic Atrophy Syndrome (BBSOAS) is a rare autosomal dominant neurodevelopmental disease caused by aberrant NR2F1, which is crucial for brain and craniofacial development. Hence, we are investigating tissue-specific cis-regulatory landscape of *NR2F1* and unraveling the regulatory network controlled by NR2F1 during brain and craniofacial development.

Methods: Utilizing CRISPR/Cas9, we engineered induced pluripotent stem cells (hiPSCs) with *NR2F1* deletion and its putative regulatory elements (enhancers and neighboring lncRNA). We differentiated hiPSC into cranial neural crest cells (hNCC) to mimic craniofacial development and into neural progenitor cells (hNPC) and cortical neurons (CN) to mimic brain development. We then comprehensively examine the interaction of *NR2F1* and its cis-regulatory elements by Hi-C, 4C-seq. To explore the regulatory network controlled by NR2F1, we will combine RNA-seq and ChIP-seq to search for novel genetic

variants linked not only to BBSOAS but also to other neurocristopathies.

Results: We revealed that *NR2F1* lies within a topologically associated domain (TAD) divided into several sub-TADs harboring potential *NR2F1* enhancers and the neighboring lncRNA (*lncNR2F1*). Our findings indicate that *lncNR2F1* regulates *NR2F1* expression only in hNPC suggesting its temporal and tissue-specific action.

Conclusion: Investigating the regulatory landscape of *NR2F1* in its locus will allow us a better understanding of the BBSOAS phenotype and expand the molecular diagnostic of the disease. Our data on the regulatory NR2F1 network will provide new possible therapeutic targets as well as an excellent foundation for further studies of the relationship between brain and craniofacial development.

Grants: Deutsche Forschungsgemeinschaft (DFG) # 450057775

P11.017.A Comparative analysis of patient-specific *NR2F1* variants in mouse

Johann Maaß[1], *Susanne Theiss*[1], *Dominik Kamionek*[1], *Claudia Pitzer*[2], *Henning Fröhlich*[1], *Christian Schaaf*[1]

[1]*Institute of Human Genetics, Heidelberg, Germany;* [2]*Heidelberg University, Heidelberg, Germany*

Background/Objectives: Pathogenic *NR2F1* variants cause a rare neurodevelopmental disorder (BBSOAS, OMIM#615722), characterized by neurological symptoms such as autism, motor dysfunction, and intellectual disability, as well as morphological brain anomalies. Patient data suggest a genotype-phenotype correlation depending on the type and locus of the variant. As the most severe phenotypes are observed in patients with genomic alterations in the highly conserved DNA- and ligand-binding domain of NR2F1, a dominant-negative effect is suspected.

We compare three mouse lines, two with heterozygous patient-specific point variants in the DNA- or ligand-binding domain, as well as a heterozygous deletion, to improve our understanding of the etiology behind mild and severe BBSOAS cases.

Methods: We conducted behavioral experiments assessing autism-like behavior, social interaction, exploratory behavior, anxiety, sleep, motor skills, learning, and memory. Brain morphology was assessed using histological sections and MRI.

Results: All three mouse lines show signs of autism-like behavior, motor dysfunction, and intellectual disability. Mice harboring a variant in the DNA-binding domain were most severely affected, followed by mice with a variant in the ligand-binding domain, and mice with an *Nr2f1* deletion, respectively.

The two mouse lines with variants in the DNA- and ligand-binding domain displayed enlarged lateral ventricles, septal abnormalities, and striatal aplasia. Mice with an *Nr2f1* deletion showed cortical thinning.

Conclusion: Behavioral and brain morphology analysis revealed a clear genotype-phenotype correlation, supporting the dominant-negative effect associated with variants in the DNA- and ligand-binding domain. Our study provides valuable insights into the spectrum of BBSOAS severity and contributes to understanding the pathology associated with different *NR2F1* variants.

Conflict of Interest: None declared

P11.018.B A novel homozygous in-frame deletion variant in *TPRKB* causing Galloway-Mowat syndrome 5

Namanpreet Kaur[1], *Khushbu Shirsat*[1], *Mayuri Yeole*[1], *Sheeba Farooqui*[1], *Vivekananda Bhat*[1], *Shahyan Siddiqui*[2], *Dhanya Lakshmi Narayanan*[1], *Anju Shukla*[1]

[1]*Department of Medical Genetics, Kasturba Medical College, Manipal, Manipal Academy of Higher Education, Manipal, India;* [2]*Department of Neurovascular Interventional Radiology, Yashoda Hospitals, Hitech city, Hyderabad, India*

Background/Objectives: Biallelic variants in *TPRKB* (TP53RK-binding protein) are known to cause Galloway–Mowat syndrome 5 (MIM#617731), characterized by early-onset nephrotic syndrome, facial dysmorphism, developmental delay and brain imaging abnormalities. TPRKB is part of a highly conserved kinase, endopeptidase and other proteins of small size (KEOPS) complex which plays important role in efficient translation and DNA damage response. To date, two families with missense pathogenic variants in *TPRKB* have been reported.

Methods: Singleton exome sequencing (ES) of proband followed by Sanger validation and segregation in the family was carried out. In silico mutagenesis of the protein was performed using Chimera v1.16.

Results: An 11-month-old male presented with global developmental delay, neuroregression, mild dysmorphism, atonic seizures, microcephaly (-4.09SD), hypertonia and repetitive hand movements with no signs of nephropathy at present. Brain magnetic resonance imaging showed mild cerebral atrophy, delayed myelination and hyperintensities along white matter tracts and globus pallidus in T2-weighted images. ES revealed a novel homozygous in-frame deletion, c.92_94del p.(Arg31del) in exon 2 of *TPRKB* gene (NM_016058.5). Segregation analysis revealed his parents to be carriers for this variant.

In silico analysis of TPRKB mutant protein showed alteration in the interactions with the neighbouring residues due to Arg31 deletion, thus leading to altered protein conformation as compared to wild-type protein. This could potentially disrupt the assembly of the KEOPS complex, leading to impaired complex functionality.

Conclusion: We report a novel in-frame deletion in *TPRKB* expanding the genotypic spectrum of Galloway-Mowat syndrome 5.

Grants: 1R01HD093570-01A1(NIH,USA)

Background: Multiple system atrophy (MSA) is a neurodegenerative disease, likely triggered by environmental and genetic factors, with similarities to Parkinson's disease, as they both involve aggregation of alpha-synuclein. We had previously shown somatic CNVs (gains) of the alpha-synuclein gene in MSA brains and selected two for WGS on a single-cell level. Other somatic

mosaicism (SNV, STR and SV) is difficult to assess, due to high diversity within tissues on single-cell level.

Methods: To assess these other types of mutations we utilized droplet multiple displacement amplification (dMDA) to generate single-cell amplificons >10kbp across samples of 2 MSA brains and control.

We used Nanopore sequencing with two library protocols, one digesting MDA side-chains with T7 endonuclease, and a PCR-based one, on 6 cells of each of the three brains. After filtering chimeric and low-quality signals, up to >50% of the human genome was analyzed using Sniffles2.

Results: Single cells showed ~80% accuracy for insertions when compared to bulk sequencing of the same brain regions. Furthermore, we identified hundreds of mosaic mutations private to single cell highlighting involvement of transposons. In addition, we found mutations within cellular signaling and metabolic genes, associated with MSA and other neurological diseases including GBAP1 and NOTCH2.

Conclusion: This all together demonstrates the power of single cell long read based DNA sequencing, uncovering previously unknown transposon mediated mutations in addition to potential diseases impacting mutations.

Grants: Aligning Science Across Parkinson's [564669] through the Michael J. Fox Foundation for Parkinson's Research.

Background/Objectives: Autism spectrum disorder (ASD) is a complex neurodevelopmental condition with a strong genetic component in which rare variants contribute significantly to risk.

Methods: We performed whole genome and/or exome sequencing (WGS and WES) and SNP-array analysis to identify both rare sequence and copy number variants (SNVs and CNVs) in 435 individuals from 116 ASD families.

Results: We identified 37 rare potentially damaging de novo SNVs (pdSNVs) from 144 ASD individuals. Interestingly, two of them (one stop-gain and one missense variant) occurred in the same gene, *BRSK2*. Moreover, the identification of 8 de novo pdSNVs in genes not previously implicated in ASD (*AGPAT3, IRX5, MGAT5B, RAB8B, RAP1A, RASAL2, SLC9A1, YME1L1*) highlighted novel candidates. Potentially damaging CNVs (pdCNVs) provided support to the involvement of inherited variants in *PHF3*, *NEGR1*, *TIAM1* and *HOMER1* in neurodevelopmental disorders (NDD), although mostly acting as susceptibility factors with incomplete penetrance. Interpretation of identified pdSNVs/pdCNVs according to the ACMG guidelines led to a molecular diagnosis in 19/144 cases, although this figure represents a lower limit and is expected to increase thanks to further clarification of the role of likely pathogenic variants in new ASD/NDD candidates.

Conclusion: Our study highlights novel ASD candidate genes and contributes to characterize the allelic diversity, mode of inheritance and phenotypic impact of de novo and inherited risk variants in ASD/NDD genes.

Background/Objectives: Focal cortical dysplasia (FCD) is a brain malformation due to a genetic disorder of neuronal migration (mTORpathy). It is characterised by cortical malformations in the cerebral cortex that can manifest with drug-refractory epilepsy. Here, a genetic analysis of 16 paediatric patients histologically diagnosed with FCD II after epilepsy surgery has been performed to try to find the molecular cause.

Methods: NGS sequencing using a gene panel specific for mTORpathies has been used to try to detect mosaic variants using paired peripheral blood and lesioned brain samples (applying a new bioinformatics programme capable of annotating variants with frequencies <5%). In parallel, a re-analysis of CES data was carried out to detect pathogenic variants in the germline using a larger panel of genes.

Results: The genetic cause has been elucidated in 4/16 patients (25% of diagnostic rate): three low frequency (<8%) mosaic variants have been identified in brain tissue, affecting the *MTOR* gene and not present in the germline. They have been previously described and explain the clinical manifestation of the patients. The fourth variant has been detected in the *DEPDC5* gene, in the germline in de novo heterozygosis, not reported and classified as probably pathogenic and disease-causing.

Conclusion: In view of the high diagnostic rate obtained, a workflow diagram has been designed for the molecular diagnosis of patients clinically diagnosed with FCD II. We hope this will improve diagnostic accuracy and contribute to build more robust and sustainable healthcare infrastructures that will have a positive impact on patients' lives.

Introduction: The French Medicine Genomics Plan (PFMG) 2025 has enabled access to genome sequencing in clinical settings throughout France.

Methods: Access to whole genome sequencing has been granted for patients with schizophrenia when additional criteria are met. These criteria include a normal CGH array as well as psychiatric and non-psychiatric clinical red flag features defining a "syndromic form of schizophrenia". To date, over 32 prescriptions have been made in the North of France. Some had previous genetic investigations such as karyotype, Fragile X, phenotypically oriented gene panels and even exome sequencing.

Results: We report here the yield of whole-genome sequencing for "syndromic schizophrenia" in a clinical setting: 8 genomes were conclusive (26%), 12 reported a variant of uncertain significance (39%) requiring further investigation, and 11 were inconclusive (35%). The diagnostic rate is similar to that previously published for similar clinical presentations. The positive genomes involved 8 genes: *AHDC1*, *ATP9A*, *CHD8*, *DLL1*, *FAAH2*, *KANSL1*, *MACF1 and TRIP12*. Variants of uncertain significance involved 15 different genes; eight of them were carried in a compound heterozygous, homozygous or hemizygous status. Of the remaining heterozygous variants, 4 arose de novo and the rest were inherited from an a priori asymptomatic parent. Most of the genes were not previously associated with schizophrenia, but with neurodevelopmental disorders.

Conclusion: Our data suggest that whole-genome sequencing may be useful and highly successful in the context of genetic work-up of patients with schizophrenia, and should be considered under appropriate conditions.

P11.024.D Motor neuron disease, clinically similar to amyotrophic lateral sclerosis, as another extreme phenotype of *RFC1* spectrum disorder

Annalisa Schaub[1;2], *Hannes Erdmann*[1;2], *Veronika Scholz*[1], *Manuela Timmer*[3], *Peter Reilich*[2], *Angela Abicht*[1;2], *Florian Schöberl*[2]

[1]*Medical Genetics Center (MGZ), Munich, Germany;* [2]*University Hospital, Ludwig-Maximilians-University (LMU), Department of Neurology with Friedrich-Baur-Institute, Munich;* [3]*Gemeinschaftspraxis für Humangenetik, Dresden, Germany*

Background/Objectives: Biallelic pathogenic repeat expansions in *RFC1* have been recently identified as molecular origin of CANVAS and as one of the most common causes of adult-onset ataxia. The phenotypic spectrum has expanded massively and now is indicated as *RFC1* spectrum disease. Since clinical and subclinical motor neuron affection was described in patients with biallelic pathogenic *RFC1* repeat expansions, we systematically studied a cohort of altogether 107 ALS patients to analyze whether pathogenic *RFC1* repeat expansions can be found more frequently in sporadic ALS patients.

Methods: Genomic DNA was obtained from 107 patients with a clinical diagnosis of ALS (Gold Coast criteria). Known ALS-related genes were analyzed by NGS via gene targeted enrichment or exome sequencing. To identify pathogenic repeat expansions in *C9orf72* and *RFC1*, long-read sequencing by Oxford Nanopore Technology was used.

Results: In a cohort of 107 sporadic ALS patients, ACMG class 4/5 variants in genes associated with ALS were identified altogether in 12 % of the patients (*C9orf72*: 7%, *SOD1*: 3%, *TARDP*: 1%, *NEK1*: 1%). Including the patient previously described as case report by us, three patients in our cohort exhibited a biallelic pathogenic *RFC1* repeat expansion (i.e. ~3%).

Conclusion: *RFC1* spectrum disease should be considered in patients with ALS/MND, especially when additional atypical symptoms are present. Therefore, this highlights the relevance of genetic testing in addition to a clinical diagnosis. The usage of long-read sequencing in combination with deciphering the pathomechanism of *RFC1* spectrum disorder will be key for a more detailed understanding of the pathology and phenotypical variance.

Background/Objectives: Tuberous sclerosis (TS) is an autosomal dominant disorder caused by mutations in *TSC1* or *TSC2* that negatively regulate the mechanistic Target of Rapamycin (mTOR), resulting in mis-regulation of cell growth and proliferation. TS is characterized by tumors in several organs, brain dysfunction that comprises epilepsy, and TSC-associated neuropsychiatric disorders (TAND) including autism spectrum disorders (ASD). The sequential appearance of these symptoms suggests a dynamic process of disease development. Since most studies have been conducted at single time points, the trajectory of symptom formation and underlying molecular changes have largely been neglected.

Methods: To model these, we used a conventional heterozygous *Tsc2* knockout mouse model. We longitudinally analyzed behavior at different time points and matched this with molecular changes throughout brain development by performing comparative proteome analysis of cortical homogenates and synaptosomes in early to late postnatal stages.

Results: We found that like in patients, TAND symptoms developed stepwise in a time-dependent manner, starting with aberrations in autism-like behavior at two months, followed by impairments in social behavior at three to four months. In addition, Tsc2 was reduced only at very early stages and fully compensated at later time points suggesting that the behavior phenotype develops independent of the primary defect. Furthermore, we found that the formation of behavioral aberrations correlates with a window of neuroligin and neurexin misexpression in cortical but not hippocampal tissue.

Conclusion: Taken together, our data suggests substantial homeostatic dynamics of gene expression underlying the TS phenotype and a correlation of ASD-like symptoms with cortical dysregulation of neuroligins and neurexin.

P11.026.B Spectrum of ultrarare neurogenetic disorders and gene variants in Bulgarian paediatric patients

Slavyana Yaneva Staykova[1], *Maya Atanasoska*[1;2], *Lubomir Balabanski*[1], *Spasimir Shishinyov*[1], *Veneta Bozhinova*[3], *Silvia Cherninkova*[4], *Ivaylo Tournev*[4], *Alexander Oscar*[4], *Elitsa Becheva-Kraichir*[5], *Rosen Kalpachki*[6], *Maria Gaydarova*[7], *Daniela Avdjieva-Tzavella*[7], *Irena Bradinova*[1;8], *Radoslava Vazharova*[1;9]

[1]*GMDL CellGenetics, Sofia, Bulgaria;* [2]*Sofia University "St. Kliment Ohridski", Faculty of Biology, Department of Genetics, Sofia, Bulgaria;* [3]*MHATNP St. Naum, Sofia, Bulgaria;* [4]*Aleksandrovska University Hospital, Sofia, Bulgaria;* [5]*Heart and Brain Center of Clinical Excellence, Pleven, Bulgaria;* [6]*St. Anna University Hospital, Sofia, Bulgaria;* [7]*SBAL Children's Hospital Prof. Dr. Ivan Mitev, Sofia, Bulgaria;* [8]*National Genetic Laboratory, Maichin Dom Hospital, Sofia, Bulgaria;* [9]*Sofia University "St. Kliment Ohridski", Faculty of Medicine, Department of Biology, Medical Genetics and Microbiology, Sofia, Bulgaria*

Background/Objectives: Rare diseases affect thousands of individuals in Bulgaria and contribute to morbidity and mortality. We present twelve cases of ultrarare neurogenetic disorders in the Bulgarian paediatric population.

Methods: Twenty-one patients aged 2 months to 17 years with suspected neurogenetic disorders were referred for genetic testing. Whole-genome sequencing with targeted bioinformatic analysis of genes associated with neurological conditions was performed.

Results: Fifteen patients received genetic diagnosis. In five individuals, potentially causative variants were identified. Twelve probands were carriers of homozygous, heterozygous or compound heterozygous pathogenic/likely pathogenic variants, associated with ultrarare genetic disorders:

Patient#	Gene variant/ variants	Genetic diagnosis	Prevalence (Orphanet)
1	*GABRB1*:c.898A>T (heterozygous)	Developmental and epileptic encephalopathy 45	-
2	*TAF6*:c.212T>C (homozygous)	Alazami-Yuan syndrome	-
3	*KIF1A*:c.760C>T (heterozygous)	NESCAV syndrome	-
4	*LARP7*:c.691_694del (homozygous)	Alazami syndrome	<1/1000000
5	*COL6A3*:c.6220G>T (heterozygous)	Bethlem myopathy	<1/1000000
6	*ALS2*:c.3703-2A>G (homozygous)	Infantile-onset ascending hereditary spastic paralysis	<1/1000000
7	*CSF1R*:c.2051del (heterozygous)	Hereditary diffuse leukoencephalopathy with spheroids 1	<1/1000000
8	*DDX3X*:c.865-2A>G (heterozygous)	Intellectual developmental disorder, X-linked syndromic, Snijders Blok type	<1/1000000
9	*VARS2*:c.502C>T, *VARS2*:c.1587G>T (compound heterozygous)	Combined oxidative phosphorylation deficiency 20	<1/1000000
10	*ASXL3*:c.3349C>T (heterozygous)	Bainbridge-Ropers syndrome	<1/1000000
11	*MTOR*:c.7141A>G (heterozygous)	Smith-Kingsmore syndrome	<1/1000000
12	*HINT1*:c.334C>A, *HINT1*:c.110G>C (compound heterozygous)	Neuromyotonia and axonal neuropathy, autosomal recessive	<1/1000000

Conclusion: The forementioned clinical cases contribute to the relatively narrow spectrum of documented ultrarare genetic disorders in the Bulgarian population. In addition, identifying the precise causative change in the genome in complex cases with neurological symptoms and overlapping phenotypic presentation can lead the way to novel treatments or therapies and improve outcomes.

Medical Sciences, Newcastle upon Tyne, United Kingdom; [5]University of Toronto, Department of Molecular Genetics and McLaughlin Centre, Toronto, Canada; [6]Wake Forest School of Medicine, Section on Nephrology, Winston- Salem, United States

Background/Objectives: The genetic correlates of extreme impulsive violence are poorly understood, and there have been few studies that have characterized a large group of affected individuals both clinically and genetically.

Methods: We performed WES in 290 males with the life-course-persistent, extremely impulsively violent form of antisocial personality disorder (APD) and analyzed the spectrum of rare protein-truncating variants (rPTVs). Comparisons were made with 314 male controls and publicly available genotype data.

Results: Participants were significantly more likely to harbor rPTVs in genes that are intolerant to loss-of-function variants (odds ratio (OR) 2.06; $p < 0.001$), specifically expressed in brain (OR 2.80; $p = 0.036$) and enriched for those involved in neurotransmitter transport and synaptic processes. In 60 individuals (20%), we identified rPTVs that we classified as clinically relevant these, 37 individuals harbored rPTVs in 23 genes that are associated with a monogenic neurological disorder, and 23 individuals harbored rPTVs in 20 genes reportedly intolerant to loss-of-function variants. Functional annotation tools were used for biological interpretation.

Conclusion: The analysis presents evidence in support of a model where presence of either one or several private, functionally relevant mutations contribute significantly to individual risk of life-course-persistent APD and reveals multiple individuals who could be affected by clinically unrecognized neuropsychiatric Mendelian disease. Thus, Mendelian diseases and increased rPTV burden may represent important factors for the development of extremely impulsive violent life-course-persistent forms of APD irrespective of their clinical presentation.

P11.028.D Strategies beyond WES in SpainUDP: Improvement of diagnostic rate by WES reanalysis, SR-WGS and RNASeq

Estrella Lopez-Martín[1], *Beatriz Martinez-Delgado[1;2], María J. Barrero[1], Lidia López[1], Lidia Mielu[1], Beatriz Baladron[1], Gema Gomez-Mariano[1], Sergio Casas-Tintó[1], Eva Bermejo-Sanchez[1]*

[1]Instituto de Investigación de Enfermedades Raras (IIER), Instituto de Salud Carlos III (ISCIII), Madrid, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), CIBERER group 758, Madrid, Spain

Consortium: Spanish Undiagnosed Rare Diseases Program (SpainUDP)

Background/Objectives: Currently, the underlying etiologies for many rare diseases remain undiscovered and knowledge gaps continue to exist regarding genotype-phenotype correlation. To address these issues, the Spanish Undiagnosed Rare Diseases Program (SpainUDP) was established in Spain at the end of 2015 by the IIER-ISCIII.

Methods: The first phase of the SpainUDP protocol consists of deep phenotyping and trio-based WES in blood samples. However, more than 50% of patients continued undiagnosed after WES, so additional diagnostic strategies are being implemented to improve diagnostic rates of unsolved cases. Here, improvement of diagnostic rate after reanalysis of WES, SR-WGS and RNASeq was evaluated.

Results: Since the official launch of SpainUDP, 89 patients (42.4%) with ultrarare diseases have been diagnosed. Reanalysis of previous WES results led to the diagnosis of 8 patients (9 % of solved cases) and the use of technologies beyond the exome, such as SR-WGS and RNASeq, allowed the resolution of 3 additional cases (3% of solved cases). On the other hand, 121 undiagnosed patients (57.6%) are under study by using patient-derived cultured cells, organoids and animal models for functional assays, which are expected to allow the characterization of molecular mechanisms of unknown rare diseases. In addition, structural genomic variants are being investigated through LR-WGS and OGM with promising preliminary results.

Conclusions: Our experience highlights the need for establishing an integrated approach consisting of the use of combined omics methods, periodic reanalyses of results, as well as functional assays to support the phenotype-genotype relationship of a putative variant.

Conflict of Interest: None declared

P11.029.A Genetic Research and Testing for Epilepsy in a Resource-Constrained Setting – the South African experience.

Alina Esterhuizen[1;2;3], *Gemma Louise Carvill[4], Jo Wilmshurst[2;5]*

[1]University of Cape Town, Pathology, Division of Human Genetics, Cape Town, South Africa; [2]Neuroscience Institute, University of Cape Town, Cape Town, South Africa; [3]Groote Schuur Hospital, Human Genetics, Cape Town, South Africa; [4]Northwestern University, Ken and Ruth Davee Department of Neurology, Evanston, United States; [5]Red Cross War Memorial Children's Hospital, Paediatric Neurology, Cape Town, South Africa

Background: Sub-Saharan Africa bears the highest burden of epilepsy worldwide. A presumed proportion is genetic, but this aetiology is buried under the burden of infections and perinatal insults, in a setting of limited awareness and few options for testing. Children with developmental and epileptic encephalopathies (DEEs), are most affected by this diagnostic gap, as the rate of actionable findings is highest in DEE-associated genes. Here, we report findings of genetic analyses in local children with DEE, its relevance to precision medicine in South Africa. We emphasise the imperatives careful clinical assessment and multidisciplinary consultation, and describe the experience of translating this research into the South African, resource-constrained healthcare setting.

Methods: We recruited 234 genetically naïve infants clinically diagnosed with DEE. Genetic testing included gene panels, chromosomal microarray and exome sequencing of patient/parent trios. Statistical comparison of electroclinical features in children with and without candidate variants was performed to identify characteristics most likely predictive of a positive genetic finding.

Results: Of 41/234 children with likely/pathogenic variants, 26/234 had variants supporting precision therapy. Multivariate regression modelling highlighted neonatal or infantile-onset seizures and movement abnormalities as predictive of a positive genetic finding. We used this, coupled with an emphasis on precision medicine outcomes, to propose the pragmatic "Think-Genetics" decision tree for recognition of a possible genetic aetiology, pragmatic testing and multidisciplinary consultation.

Conclusion: Our findings emphasise the importance of access to early genetic testing in DEEs. The "Think-Genetics" strategy may facilitate early recognition, appropriate interim management and genetic testing in resource-constrained settings.

P11.030.B Investigating the extent and impact of splicing noise in Alzheimer's disease using genome-wide short-read RNA-sequencing

Sonia García-Ruiz[1], *Emil Gustavsson*[1], *Melissa Grant-Peters*[1], *David Zhang*[1], *Aine Fairbrother-Browne*[1], *Zhongbo Chen*[2], *Leonardo Collado-Torres*[3], *Mina Ryten*[1;2]

[1]*UCL Great Ormond Street Institute of Child Health, United Kingdom;* [2]*UCL Queen Square Institute of Neurology, United Kingdom;* [3]*Lieber Institute for Brain Development, Baltimore, United States*

Background/Objectives: Alternative splicing (AS) is a feature of most multi-exonic human genes and its dysregulation contributes to ageing and neurodegeneration, including Alzheimer's disease (AD). However, the genome-wide accuracy of AS in AD samples has received little attention despite the fact that high-depth RNA-sequencing data of diseased samples commonly contains partially unannotated reads within individuals implying the existence of splicing inaccuracies.

Methods: In this project, we investigated the characteristics of mis-splicing as detected using split reads partially mapping to known transcripts in the reference annotation. Using short-read RNA-sequencing data derived from 48 unique human postmortem brain samples (control and AD), we built an intronic database cataloguing all splicing events detected across the samples. We evaluated the structural differences and abundance of inaccurately spliced introns in AD samples as compared to controls.

Results: This analysis revealed significant increases in the levels of mis-splicing activity across the transcriptome in brain samples from AD patients as demonstrated by the higher rates of sequencing reads indicating the use of novel donor or acceptor splice sites. We observed that mis-splicing events in AD samples occurred more frequently at positions not divisible by three, equating to the size of a codon, and indicating a higher frequency of frame-shifting splicing events in AD samples as compared to controls. Finally, we detected that the genes containing higher frequencies of splicing inaccuracies in AD samples were enriched for synaptic functions.

Conclusion: Overall, these results suggest the key importance of splicing integrity at synapses, and that its failure could be a driving process in AD.

Background/Objectives: Parkinson's disease (PD) genetic risk embraces genetic and non-genetic factors. It has been suggested a link between CAG repeat number in the HTT, ATXN1 and ATXN2 genes and neurodegenerative diseases. In addition, some PD genetic factors are indeed associated with cancer pathways. Several studies found a low prevalence of cancer in neurodegenerative diseases that can be associated with a low? CAG repeats' size in several genes. This study aimed to investigate the influence of CAG repeat sizes in ATXN1, ATXN2, and HTT genes on the risk for developing the disease and cancer in a large cohort of PD patients and healthy controls.

Methods: The study included 1156 PD patients and 1070 controls of European ancestry. CAG repeat sizes in HTT, ATXN1, and ATXN2 genes were analyzed. Dunn's Multiple Comparison Test for quantitative variables and logistic and linear regression were used.

Results: The long ATXN1 allele and CAG size, and both, the ATXN2 short and long alleles were predictors for the PD risk. The long CAG ATXN1 allele gene was associated with the risk of cancer.

Conclusion: These results reinforce the hypothesis that ***α***-synucleinopathies and polyQ-linked neurodegenerative diseases can share common pathways. HTT, ATXN1, and ATXN2 CAG alleles' size can modify the risk of cancer among PD patients.

Grants: This study has been funded by the "Instituto de Salud Carlos III (ISCIII)" through the project PI21/0467 and co-funded by the European Union to V.A and M.M-G.

P11.032.D A framework for performing de novo variant analyses of complex psychiatric disorders in genetically isolated populations

Kate Bornais[1;2], *Jay Ross*[1;2], *Zoe Schmilovich*[1;2], *Miranda Medeiros*[1;2], *Dan Spiegelman*[2;3], *Patrick Dion*[2;3], *Guy Rouleau*[1;2;3]

[1]*McGill University, Human Genetics, Montréal, Canada;* [2]*McGill University, Montreal Neurological Institute-Hospital, Montréal, Canada;* [3]*McGill University, Neurology and Neurosurgery, Montréal, Canada*

Background/Objectives: Obsessive-compulsive disorder (OCD) is a common psychiatric disorder characterized by recurrent obsessions and compulsions. Childhood-onset OCD has a genetic component, with heritability estimates being ~45-65%. However, not all genetic factors are inherited. De novo variants (DNVs) arise spontaneously in zygotes and contribute significantly to childhood-onset OCD risk. To date, no DNV analyses of childhood-onset OCD have been performed in a genetically isolated population. Here, we identified DNVs in French-Canadian childhood-onset OCD trios.

Methods: Whole-exome sequencing was performed on 50 trios ($n = 150$). Variants were filtered for heterozygous genotype in the proband and wildtype in both parents. Single-nucleotide protein-coding DNVs with population minor allele frequency <1% were retained and confirmed in IGV. DenovolyzeR assessed the genome-wide burden of DNVs for different variant classes. Genes harbouring DNVs were examined for overlap with genes previously associated to OCD and other psychiatric disorders. Our candidate gene list was combined with those in previous OCD DNV publications for functional enrichment meta-analyses.

Results: 33 DNVs in 33 genes were observed across 36 probands (0.92 DNVs/proband, average CADD score = 16.1). An enrichment of splice-site DNVs was detected ($p = 0.0173$). 4 genes were identified in previous OCD studies (Halvorsen 2021; IOCDF-GC 2018). All 33 genes overlapped with genes associated to related psychiatric disorders. Genes involved in clathrin-dependent endocytosis (GO:0072583) and phosphatidylinositol binding (GO:0035091) were overrepresented in the combined gene list ($p\text{-}adj < 0.05$).

Conclusion: This study presents a framework for conducting DNV analyses in isolated populations. Using this framework, we have provided the first comprehensive list of candidate childhood-onset OCD genes specific to the French-Canadian population.

Background/Objectives: Autophagy is an essential homeostatic process, driving the endolysosomal degradation of protein aggregates, organelles and pathogens. Dysfunctional autophagy is implicated in complex human disease yet reports of congenital autophagy disorders were considered exceedingly rare until the recent report of unrelated families with bi-allelic *ATG7* variants encoding a core autophagy effector. In contrast to *Atg7* deletion in mice, causing perinatal lethality, affected patients survive into adulthood despite loss of ATG7 and diminished autophagic flux. We aimed to delineate the phenotypic spectrum of pathogenic *ATG12* variants and characterise associated molecular defects.

Methods: Bi-allelic *ATG12* variants were identified in three individuals from two families with complex neurological phenotypes. We performed structural modelling and functional studies (using patient-derived fibroblasts and yeast modelling) to determine pathogenicity.

Results: Affected individuals share a consistent phenotype comprising developmental delay and seizures, with cerebellar vermis hypoplasia evident on cranial MRI; one affected child had a nephritic syndrome, leading to chronic kidney failure; dysmorphic features included a broad nasal bridge, long philtrum, and low set ears. Fibroblasts from affected individuals demonstrated decreased steady-state levels of ATG12 protein and/or altered flux following starvation; Transmission Electron Microscopy revealed an accumulation of autophagic structures. Structural studies implicated disruption of ATG12-ATG5-ATG16N-ATG3 complex formation, supported by modelling of missense variants in yeast.

Conclusion: Our data emphasise an important, emerging group of genetic disorders characterised by dysfunctional autophagy, expanding the understanding of adaptive homeostasis in human health and disease.

P11.034.B A previously unreported splice variant in *FLNA* causing periventricular nodular heterotopia 1 in a Danish family; explored by functional studies

Ellen Steffensen[1;2], *Jenny Blechingberg[1], Thomas van Overeem Hansen[3], Anneli Bolund[1], Stephen Robertson[4], Pernille Axél Gregersen[1], Ida Charlotte Bay Lund[1]*

[1]*Aarhus University Hospital, Department of Clinical Genetics, Aarhus, Denmark;* [2]*Aalborg University Hospital, Department of Clinical Genetics, Aalborg, Denmark;* [3]*Copenhagen University Hospital – Rigshospitalet, Department of Genetics, Copenhagen, Denmark;* [4]*Dunedin School of Medicine, University of Otago, Department of Women's and Children's Health, Dunedin, New Zealand*

Background/Objectives: Filamin A (FLNA)-related periventricular nodular heterotopia 1 (PVNH1) is an X-linked dominant disorder.

We report our experience with functional studies of a previously unreported splice variant in *FLNA*.

Methods: Whole genome sequencing targeted on a non-syndromic epilepsy gene panel. Additional functional studies and segregation analysis to assess the pathogenicity of a detected *FLNA* variant. The effect on mRNA splicing was studied though RT-PCR on RNA isolated from cultured fibroblasts and transformed lymphoblasts, respectively, under nonsense-mediated decay inhibition and subsequent semi-quantitative capillary electrophoresis and nanopore sequencing.

Results: The female proband presented with epilepsy and PVNH at age 17 years. Genetic testing revealed heterozygosity for a splice site variant, c.6503-1del (NM_001110556.2), in *FLNA*. Her sister suffered from migraines and was found to have PVNH. Co-segregation analysis revealed the variant in the sister, the sisters' mother, having asymptomatic PVNH and aortic valve insufficiency, but not in their unaffected maternal uncle.

Analysis of RNA from fibroblasts showed that in approx. 5% of transcripts, a cryptic splice acceptor site was used, resulting in a frameshift mutation and premature stop codon p.(Glu2160Alafs*5). In contrast, in transformed lymphoblasts, this alternative transcript constituted approx. 90% of all transcripts.

Based on the functional studies and co-segregation analysis, the variant in *FLNA* was reclassified from a "variant of uncertain significance" to a "pathogenic" variant.

Conclusion: This report highlights the value of functional studies in different cell types in females affected by *FLNA*-related PVNH1. Our findings may reflect skewed X-chromosome inactivation.

P11.035.C A study of the natural history of *RARB*-related disorders

Valerie Chu[1], *Andre Tremblay*[1], *Jacques Michaud*[1]

[1]*CHU Sainte-Justine Azrieli Research Centre, Montréal, Canada*

Background/Objectives: Dominant variants in the Retinoic Acid Receptor Beta (*RARB*) gene underlie a syndrome known as MCOPS12 that is characterized by developmental eye defects, other congenital anomalies, and global developmental delay with dystonia. Although most affected individuals display severe developmental delay and motor impairment, some show minimal neurodevelopmental involvement. We initiated a natural history study of MCOPS12 to better characterize its clinical course.

Methods and Results: Individuals worldwide carrying pathogenic or likely pathogenic variants in *RARB* are eligible to participate. In addition to the baseline phenotype of the participants, developmental milestones, behavioural profiles, and dystonia severity are documented annually using standardized tools and video protocols. Clinical brain MRI images are also collected. The study framework includes a physician-driven arm and a participant-powered arm. For both arms, data are collected via an online REDCap platform.

Our group has characterized the functional impact of 26 pathogenic variants using in vitro transcriptional assays. We have found that these variants induce either a gain-of-function or a dominant-negative effect. We will use these assays to functionally classify novel variants identified in the participants. The natural history study will be piloted by 10 MCOPS12 families before its launch to all affected individuals.

Conclusion: As therapeutic options for MCOPS12 are being actively investigated, it is imperative to document the natural history of individuals with this condition. Our study will lead to the establishment of a framework for the development of clinical trials against MCOPS12.

Objective: We investigated the contribution of genomic data reanalysis to the diagnostic yield of dystonia patients who remained undiagnosed after prior genome sequencing.

Methods: Probands with heterogeneous dystonia phenotypes who underwent initial genome sequencing (GS) analysis in 2019 were included in the reanalysis, which was performed through gene-specific discovery collaborations and systematic genomic data reanalysis.

Results: Initial GS analysis in 2019 ($n = 111$) identified a molecular diagnosis in 11.7% (13/111) of cases. Reanalysis between 2020 and 2023 increased the diagnostic yield by 7.2% (8/111); 3.6% (4/111) through focused gene-specific clinical correlation collaborative efforts [*VPS16* (two probands), *AOPEP* and *POLG*], and 3.6% (4/111) by systematic reanalysis completed in 2023 [*NUS1* (two probands) and *DDX3X* variants, and a microdeletion encompassing *VPS16*]. Seven of these patients had a high phenotype-based dystonia score ≥3. Notable unverified findings in four additional cases included suspicious variants of uncertain significance in *FBXL4* and *EIF2AK2*, and potential phenotypic expansion associated with *SLC2A1* and *TREX1* variants.

Conclusion: GS data reanalysis increased the diagnostic yield from 11.7% to 18.9%, with potential extension up to 22.5%. While

optimal timing for diagnostic reanalysis remains to be determined, this study demonstrates that periodic re-interrogation of dystonia GS datasets can provide additional genetic diagnoses, which may have significant implications for patients and their families.

Grants: This study was funded by the Paul Ainsworth Family Foundation.

Consortium: SPATAX network

Background/Objectives: Repeat expansions in 20 genes represent two thirds of the known variants causing inherited spinocerebellar degeneration. A targeted sizing of one locus after the other is generally used for diagnosis. However, high-throughput sequencing can also detect expansions with a specific calling. We report this approach to promote exome as a global screening test.

Methods: 813 individuals with from 663 families with spinocerebellar degeneration were included after exclusion of frequent repeat expansions in 50% of the cohort (SCA1,2,3,6,7,17). *Expansionhunter* was used to call repeat sizes from exomes (TWIST capture and Illumina short read sequencing paired-end at 150 cycles). A targeted fragment analysis was done to confirm the presence of the expansions.

Results: We identified 34 individuals from 27 families with pathogenic expansions (4.2%) in *ATXN2*, *ATXN3*, *HTT*, *NOP56*, *ATXN1*, *ATXN7*, *CACNA1A* and *TBP*. All coding repeats were highly covered as expected. These exomes covered also non-coding repeats (*NOP56*, *ZFHX3* and *FMR1*) but not all (*ATXN10*, *BEAN1*, *DAB1*, *FGF14*, *FXN* and *RFC1*). Interestingly, five out of seven *HTT* expansions were incidental findings unrelated to the causal gene.

Conclusion: Exome can be used as a first-tier test in spinocerebellar degenerations to detect both, single nucleotide variants and expansions. Adding the capture of the uncovered non-coding repeats could improve the diagnosis yield. Analysis of multiple genes must be interpreted closely with the clinical data to consider frequent incidental findings such as the *HTT* expansion.

P11.038.B Diagnostic findings and yield of investigations requested for children with developmental regression

Kirsten Furley[1;2], *Katrina Williams*[2;3], *Michael C. Fahey*[4], **Matthew Hunter**[5]

[1]*Monash University, Paediatrics, Melbourne;* [2]*Monash Children's Hospital, Developmental Paediatrics, Melbourne, Australia;* [3]*Monash University, Head of Paediatrics, Melbourne, Australia;* [4]*Monash Health, Head of Neurology, Melbourne, Australia;* [5]*Monash Health, Head of Genetics, Melbourne, Australia*

Background: Childhood conditions that feature developmental regression are diverse and poorly understood. Phenotype-genotype characterisation and diagnostic yield data are needed to advance understanding of causal processes and inform clinical decision making. The objective of this study is to report childhood conditions featuring developmental regression and assess diagnostic yields of investigations.

Methods: A retrospective chart review of ninety-nine children presenting with developmental regression to an Australian tertiary paediatric genetic clinic.

Results: Of 99 children, 31% of (N = 31) children had intellectual disability (ID), 19% (N = 19) were autistic, 39% (N = 39) were autistic with ID, and 9% (N = 9) children did not have an ID or autism diagnosis. Thirty-two percent (N = 32) of children received a new informative diagnosis, including potential phenotypic expansion of genes for developmental regression. Genomic testing provided the highest diagnostic yield (51.1%, N = 24) and was highest, 63.6% (N = 14) for children with an ID. Fifty percent (N = 3) of children without autism or ID, and fifty percent of autistic children with an ID (N = 6) received an informative genomic result.

Conclusion: We highlight the heterogeneity of conditions featuring developmental regression and report phenotypic expansion not previously reported. The high diagnostic yield of genomic testing offers opportunities to identify causes and associations with diagnoses not previously reported to include regression.

Grants: First author is a PhD student and receives a stipend scholarship from Monash University

P11.039.C Diagnostic yield of exome sequencing in treatment-resistant schizophrenia

Sam Bradbrook[1], *Tatiana Maroilley*[2;3], *Maja Tarailo-Graovac*[2;3], *Chad Bousman*[1;2;4;5], *PY Billie Au*[1;2], *Mark Colijn*[5]

[1]*Cumming School of Medicine, University of Calgary, Medical Genetics, Calgary, Canada;* [2]*Alberta Children's Hospital Research Institute, University of Calgary, Calgary, Canada;* [3]*University of Calgary, Biochemistry and Molecular Biology, Cumming School of Medicine, Calgary, Canada;* [4]*University of Calgary, Physiology and Pharmacology, and Community Health Sciences, Calgary, Canada;* [5]*Hotchkiss Brain Institute, Mathison Centre for Mental Health Research and Education, Psychiatry, Calgary, Canada*

Background/Objectives: Schizophrenia is highly heritable, but the majority of affected individuals do not have an identifiable monogenic cause. Treatment-resistant schizophrenia (TRS) is characterized by positive symptoms despite ≥2 antipsychotic trials, requiring treatment with clozapine. We hypothesize that exome sequencing (ES) may be diagnostically useful in these individuals.

Methods: We completed singleton research ES and clinical SNP microarray on 34 probands who were previously diagnosed with TRS in Southern Alberta. The ES data analysis prioritized: (1) variants with a variant allele frequency <1% in gNOMAD v.2 and TopMED BRAVO databases; (2) variants reported by ClinVar; and (3) variants predicted as damaging by in silico predictors. A curated panel of genes with a strong association with schizophrenia or psychosis and their interacting genes was created through a literature review. Rare variants in these genes that met filtration criteria were identified. Finally, targeted pharmacogenomic testing for recognized variants related to drug metabolism was completed.

Results: 1/34 probands had a diagnostic result on ES, while 26/34 carried rare variants in panel-related genes. Two unrelated probands had an identical variant detected in *TYRO3*. To our knowledge, this candidate gene has not been associated with a psychiatric phenotype in humans. Pharmacogenomic analysis for rapid/ultrarapid metabolizer status did not entirely account for any individual's treatment resistance. Lastly, there were four variants identified on microarray, which are not conclusively associated with psychotic symptoms.

Conclusion: Our exploratory study's findings suggest that ES may be indicated in TRS. Larger studies will need to be completed to clarify its diagnostic yield.

P11.040.D Phenotypic characterization of individuals with schizophrenia with expression and splicing outliers in whole transcriptomes

Laura Kilarski[1], *Isabelle Claus*[2], *Vicente Yépez*[3], *Franziska Degenhardt*[4], *Markus Wolfien*[5], *Kristina Adorjan*[6;7], *Monika Budde*[6], *Janos Kalman*[6;8], *Mojtaba Oraki Kohshour*[6], *Sergi Papiol*[6;8], *Fanny Senner*[6;8], *Andreas Forstner*[2], *Urs Heilbronner*[6], *Markus M. Nöthen*[2], *Peter Falkai*[8], *Thomas G. Schulze*[6;9], *Julien Gagneur*[10;11], *Eva C. Schulte*[1;2;6]

[1]*University of Bonn, Department of Psychiatry and Psychotherapy, Bonn, Germany;* [2]*University of Bonn, Institute of Human Genetics, Bonn, Germany;* [3]*Technical University Munich, Computational Molecular Medicine, Munich, Germany;* [4]*University of Essen, Department of Child and Adolescent Psychiatry, Essen, Germany;* [5]*University of Rostock, Department of Systems Biology & Bioinformatics, Rostock, Germany;* [6]*University of Munich, Institute of Psychiatric Phenomics and Genomics (IPPG), Munich, Germany;* [7]*University of Bern, University Hospital of Psychiatry and Psychotherapy, Bern, Switzerland;* [8]*University of Munich, Department of Psychiatry & Psychotherapy, Munich, Germany;* [9]*SUNY Upstate Medical University, Department of Psychiatry, Syracuse, NY, United States;* [10]*Technical University Munich, Computational Molecular Medicine, School of CIT, Munich, Germany;* [11]*Technical University Munich, Intitute of Human Genetics, School of Medicine and Health, Munich, Germany*

Background: Rare genetic variants with high effect sizes for schizophrenia (SCZ) have been identified, yet functional consequences and impact on individual phenotypes as well as their clinical relevance in unselected, naturalistic cohorts remain unclear.

Methods: Expression and splicing outliers were identified in whole blood transcriptomes of 538 individuals with DSM-IV SCZ-spectrum diagnoses from the PsyCourse Study[1] using OUTRIDER/FRASER[2] and filtered for known high-confidence candidate genes ($n = 417$) implicated in GWAS, rare variant association studies, and SCZ-linked copy number variants (CNVs). Comparisons were made between cases with and without outliers across >20 biometric and clinical characteristics.

Results: We found 41 expression or splicing outliers in candidate genes ($|z\text{-score}| > 5.0$, $FDR < 0.1$) across 5.2% of 538 individuals, half of which affected known CNVs. Splicing outliers in at least one gene were present in 10 individuals (1.9%), with three genes (*SRRM2, TMEM219, PDE4B*) showing the same pattern of aberrant splicing in more than one individual. We observed significantly lower clinical severity and higher verbal intelligence in cases carrying expression outliers. Outliers in genes overlapping a known CNV at 16p11.2 correlated with a younger age at onset.

Conclusion: Outlier analysis can identify individuals with severe changes in expression/splicing of genes implicated in SCZ, highlighting the role of rare, strong effect genetic factors in this common, genetically complex phenotype. Specific phenotypic profiles in individuals with outliers could be related to unrecognized subphenotypic groups. The identification of the genetic variants underlying the outliers is currently underway.

P11.041.B Analysis of targeted epilepsy gene panel sequencing suggests that variants previously classified as uncertain significance in QARS1 and SCN9A genes may play an important role in epilepsy

Yara Hussein[1], **Hila Weisblum Neuman**[2], *Bruria Ben-Zeev*[2;3], *Shani Stern*[1]

[1]*University of Haifa, Sagol Department of Neurobiology, Faculty of Natural Sciences, Haifa, Israel;* [2]*Sheba, Pediatric Neurology Unit, The Edmond and Lily Safra Children's Hospital, Ramat Gan, Israel;* [3]*Tel Aviv University, Faculty of Medicine, Tel Aviv-Yafo, Israel*

Background/Objectives: Epilepsy, a chronic neurological disorder marked by seizures or epileptic syndrome, encompasses various etiologies, and carries implications for neurological, cognitive, psychological, and social well-being. There are over 500 genes associated with epilepsy occurrence. Therefore, Next-Generation Sequencing (NGS) epilepsy gene panels are commonly employed for patients with epilepsy. However, a substantial proportion of results remains uncertain and is not considered directly causative.

Methods: Between 2018-2022, a commercial epilepsy gene panel testing was conducted on pediatric patients at a single tertiary health center. Utilizing NGS technology, the panel

analyzed 187 genes associated with epilepsy, categorizing variants according to ACMG guidelines. A retrospective analysis of 156 probands and 74 parents delved into prevalence, population comparisons, and protein network path analysis, enhancing genetic comprehension. Advanced tools were employed for identifying notable variant combinations and calculating genetic correlations.

Results: Targeted gene panel sequencing revealed 18% negative, 22% positive and 60% uncertain outcomes among probands. Frequent pathogenic gene detections included SCN1A, MECP2, and CDKL5. Notably, two distinct variants, c.2133G>C in the SCN9A gene and c.316G>A in the QARS1 gene, were identified as likely pathogenic in contrast to their formal interpretation as variants of uncertain significance.

Conclusion: Epilepsy gene panel enables targeted gene analysis, emphasizing its clinical significance. The study elucidates the intricate genetic landscape of infantile and childhood epilepsy, with approximately 60% uncertainty in test results. We suggest an interpretation of two clinically significant variants in the QARS1 and SCN9A genes.

Grants: The Zuckerman STEM Leadership Program and Israel Science Foundation grants 1994/21 and 352/21.

Safarik University, Kosice, Slovakia, Department of Dermatovenerology, Kosice, Slovakia; [8]Munich Cluster for Systems Neurology (SyNergy), Munich, Germany; [9]Institute for Advanced Study, Technical University of Munich, Garching, Germany

Background/Objectives: Repeat expansions (REs) represent one of the major understudied types of genetic variation in cohorts of patients with movement disorders. Furthermore, variants residing outside of the coding regions usually escape detection via standard diagnostic methods still focused on exonic sequences. Therefore, within a cohort of patients with predominantly dystonic movement abnormalities and previously unyielding whole exome sequencing analysis we performed whole genome sequencing (WGS) studies.

Methods: ExpansionHunter algorithm (1) was implemented on WGS data to examine REs at thirty well-characterized disease-associated loci. Simultaneously, bulk proteomic and transcriptomic data were processed according to described protocols (2) from the patient-driven fibroblasts to check for expression changes associated with candidate genomic alterations.

Results: Pathogenic biallelic dodecamer REs (repeat count 38 and 32) within the 5`UTR of the gene *CSTB* (cystatin B) were identified in a pedigree with two similarly affected siblings presenting with adolescence-onset progressive myoclonus syndrome, epilepsy, ataxia, and upper-limb dystonia. Unaffected parents had one expanded allele each. Confirming the genomic findings, affected siblings had significantly reduced *CSTB* gene expression on both mRNA (p-value: $1.3e^{-22}$ and $5.2e^{-20}$) and protein level (p-value: $1.4e^{-10}$ and $3.2e^{-7}$) compared to control participants who did not carry *CSTB* REs.

Conclusion: Comprehensive genome analysis enables the detection of the pathogenic genetic variation beyond small coding variants and can significantly shorten the diagnostic odyssey for individual families with rare movement disorders.

P11.043.B Pathophysiology of a neurodevelopmental disorder caused by biallelic SLC4A10 loss-of-function

Antje K. Huebner[1], Lutz Liebmann[1], James Fasham[2], Reham Khalaf-Nazzal[3], Reza Maroofian[4], Kai Kaila[5], Andrew Crosby[2], Emma Baple[2], **Christian Hübner**[1]

[1]Jena University Hospital, Institute of Human Genetics, Jena; [2]University of Exeter Medical School, RILD Wellcome Wolfson Centre, Exeter, United Kingdom; [3]Arab American University of Palestine, Jenin, Palestine; [4]Molecular and Clinical Sciences Institute, London, United Kingdom; [5]Helsinki Institute of Life Science, Helsinki, Finland

Background/Objectives: *SLC4A10* encodes a plasma-membrane HCO_3^- transporter, which utilizes the Na^+ gradient to mediate acid extrusion. In the brain, *SLC4A10* is broadly expressed in neurons and choroid plexus epithelial cells. We recently reported that biallelic *SLC4A10* loss-of-function variants cause a neurodevelopmental disorder with hypotonia, intellectual disability and behavioral abnormalities. Neuroradiological findings include microcephaly, abnormalities of the corpus callosum and collapsed brain ventricles.

Methods: We used constitutive *Slc4a10* deficient mice to study Slc4a10 loss of function in vitro and in vivo. Apart from behavioral experiments, we assessed the consequences for synaptic transmission and network excitability.

Results: *Slc4a10* deficient mice show mild behavioural abnormalities. As in some patients, the brain of *Slc4a10* deficient mice is smaller and the weight reduced compared to controls. While the analysis of the cortical structure does not show gross alterations, we note collapsed brain ventricles in Slc4a10 deficient mice resembling findings in patients. We further show that SLC4A10 is abundantly expressed at inhibitory presynapses. Suggesting that Slc4a10 is important for the regulation of the presynaptic pH, GABA release is compromised at inhibitory synapses. Importantly, modulating brain pH partially rescues GABA release.

Conclusion: As GABAergic inhibitory interneurons gate signal flow and contribute to the timing and synchronization of cortical oscillations, we propose that compromised synaptic inhibition due to SLC4A10 loss-of-function likely contributes to the pathophysiology of this disorder. We hypothesize that modulation of GABAergic transmission could be a possible therapeutic approach for ameliorating some of the neurological symptoms in patients.

P11.044.C Association between polygenic risk and imaging derived phenotypes for the elucidation of essential tremor neuroanatomical vulnerabilities

Miranda Medeiros[1], *Alexandre Pastor-Bernier*[2], *Houman Azizi*[2;3;4], *Zoe Schmilovich*[1], *Patrick Dion*[2;5], *Alain Dagher*[2;5], *Guy Rouleau*[1;2;5]

[1]*McGill University, Human Genetics;* [2]*Montreal Neurological Institute;* [3]*McGill University;* [4]*Douglas Mental Health Institute;* [5]*McGill University, Neurology and Neurosurgery*

Background/Objectives: Essential tremor (ET) is a complex neurological disorder characterized by involuntary upper limb shaking. ET associated common variants can be leveraged to generate polygenic risk scores (PRS) to capture individuals' ET specific genetic risk. Here, we aim to identify regions of the brain made vulnerable due to heightened genetic risk of ET in healthy subjects by investigating the association of white matter diffusion-weighted magnetic resonance imaging (DTI), grey matter DTI and morphometry with ET PRS in the UK Biobank (UKB) cohort.

Methods: We paired genetic and imaging data from the UKB to model the associations of ET PRS on brain structure changes. Polygenic risk scores from healthy UKB participants were calculated using ET GWAS summary statistics (Liao et al., 2022) through PRS-CS. DTI mean diffusion measures (DM) fractional anisotropy (FA), mean diffusivity (MD), and free-water (FW), were obtained across 73 anatomically curated tracts in the ORG fiber clustering white matter atlas (Zhang et al., 2018). We performed multiple regression analysis with glmnet (R) for variable selection and cross-validation and conducted a white matter to grey matter tract crossing and volume analysis.

Results: Significant associations between ET PRS and DTI cerebellar microstructure (e.g., cerebellar peduncles and intracerebellar Purkinje tracts) and associations between ET PRS and grey mater DTI microstructure, in particular the red nucleus, hypothalamus, caudate, putamen, and several regions of a functional thalamus were identified.

Conclusion: We have found that most regions associated with ET PRS are part of a known motor network involved in ET pathogenesis.

Background/Objectives: *RORA* encodes the retinoic acid receptor-related orphan receptor α (RORα), which plays a pivotal role in the cerebellar maturation and function. A recent study reported 16 individuals affected with *RORA*-associated neurodevelopmental disorder (*RORA*-NDD). Here, we report a larger series of patients with a special focus on the cerebellar pathology and the epilepsy spectrum.

Methods: 40 individuals carrying *RORA* pathogenic and likely pathogenic variants were recruited through an international collaboration. Clinical data were collected by a standardized survey. Brain MRI files were re-analysed when available.

Results: 33 *RORA* variants were identified, including 14 frameshift deletions, 4 frameshift insertions, 9 missense, and 6 nonsense variants. They occurred de novo in 18 individuals, were inherited

in 9, and not determined in 13. Three cardinal features identified in *RORA*-NDD were cognitive impairment, cerebellar hypoplasia or atrophy or both, and epilepsy. Four individuals presented progressive cerebellar symptoms. Three epilepsy phenotypic subgroups were identified: i) genetic generalized epilepsy (n = 10), falling within the eyelid myoclonia seizure spectrum in five cases and characterized by myoclonic absence epilepsy in two cases; ii) developmental and epileptic encephalopathy (n = 5, including one myoclonic); iii) unclassified myoclonic epilepsy (n = 3). Autism was diagnosed in 21% of individuals. Missense variants in the DNA-binding domain tended to induce a more severe phenotype than those in the ligand-binding domain.

Conclusion: This study provides a more comprehensive clinical and radiological analysis of *RORA*-NDD with deeper phenotyping of cerebellar manifestations and epilepsy (with a striking range of myoclonic seizures), each present in more than 50% of cases.

Consortium: BIONIC

Background/Objectives: Although broad phenotyping strategies have led to significant genetic discoveries for major depressive disorder (MDD), there is a call for uniform in-depth phenotyping that adheres to clinical criteria; both to replicate the findings thus far and to fine-tune the genetic signal in the search for clinically relevant findings.

Methods: In the Netherlands we have established the Biobanks Netherlands Internet Collaboration (BIONIC) among biobanks with genotype data assessed in their participants, with the aim of facilitating Genome-wide Association Studies (GWAS) in a relatively homogeneous population. We collected data on DSM-5 lifetime MDD diagnosis, sociodemographic traits, depressive symptom and episode characteristics and psychiatric history in 132,850 Dutch individuals with a standardized instrument that can be administered online; 66,684 individuals also have genome-wide SNP data available. To test for genetic associations between case-control status and imputed SNP data, the combined datasets were analyzed with fastGWA.

Results: Data from 16 cohorts were combined to create a dataset of N = 29,650 lifetime MDD cases (22%) meeting DSM-5 criteria and 94,300 screened controls. In the GWAS dataset of N = 66,684 Dutch individuals the prevalence of MDD was 25.3%. The heritability of the MDD phenotype - based on pedigree analyses - is 34%. The first GWAS of lifetime MDD in the Netherlands will be presented, with results obtained through mega- and meta-analysis approaches.

Conclusion: We initiated this project because the complex genetic basis of MDD requires large population-wide studies with uniform in-depth phenotyping, and show the feasibility of such an approach.

Background/Objectives: Psychotic disorders develop progressively during adolescence though multiple stages: ultra-high-risk (UHR) state, first episode of psychosis (FEP) and, ultimately, chronic presentation. Approximately 20% of UHR individuals transition to psychosis within a 2-year period (converters), while others maintain attenuated psychotic symptoms or recovered (non-converters). Additionally, FEP can be the first manifestation of schizophrenia or bipolar disorder. Accurate prediction of the outcome is crucial for targeted interventions. We hypothesized that genetic can help to develop prognostic biomarkers. Leveraging Next-Generation Sequencing (NGS) advancements, this study delves into the association between rare copy number variants (CNVs) and psychosis in UHR and FEP individuals, aiming to develop a predictive model.

Methods: A cohort of 396 individuals was sequenced using IlluminaSeq. Whole-genome sequencing data was analyzed with the Illumina Dragen pipeline. After calling, the CNVs were annotated with ClassifyCNV. Differences between FEP, converters, non-converters were tested for various CNV parameters (numbers, lengths, encompassed genes, etc.).

Results: This study found 5 known pathogenic and 3 likely pathogenic CNVs in the population. However, no significant differences were found between the clinical groups regarding the number of CNVs, their size, the presence of brain-expressed genes.

Conclusion: While confirming the presence of schizophrenia associated CNVs in this specific population of early phases of psychosis, the study highlights the current limitations in using CNV data for discrimination of individuals based on their clinical outcome. Consequently, future developments may consider incorporating other types of omics data besides clinical information to enhance the effectiveness of prediction strategies.

P11.048.C Personalised penetrance estimation in *C9orf72*-related amyotrophic lateral sclerosis and frontotemporal dementia

Andrew Douglas[1;2], *Alexander Thompson*[2], *Martin Turner*[2], *Kevin Talbot*[2]

[1]*Oxford University Hospitals NHS Foundation Trust, Oxford Centre for Genomic Medicine, Oxford, United Kingdom;* [2]*University of Oxford, Nuffield Department of Clinical Neurosciences, Oxford, United Kingdom*

Background/Objectives: *C9orf72* hexanucleotide repeat expansions are the most common genetic cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD) in European populations. Variation in disease penetrance between families presents a challenge for genetic counselling of at-risk relatives and reduces predictive utility of testing asymptomatic relatives. We have developed a model for estimating disease penetrance in individual families affected by *C9orf72* using available family history information, allowing calculation of personalised risk estimations for at-risk relatives.

Methods: Published aggregated age-of-onset data for *C9orf72*-related ALS/FTD were used to generate a cumulative relative risk curve for unaffected at-risk individuals within example pedigrees based on current ages. Age-related relative risks are combined with a priori chance of an individual carrying an expansion based on known pedigree information. Penetrance is calculated as number of affected individuals divided by sum of cumulative age-related risks of relatives being affected by 80 years.

Results: This model behaves as expected, with family history influencing penetrance estimation. Complete absence of family history information in an affected individual yields an assumed penetrance of 100%, while penetrance reduces as number and age of at-risk unaffected relatives increases. A sporadic case with a typical three-generation pedigree has an estimated penetrance similar to or even below that for *C9orf72* carriers in control populations.

Conclusion: Family history is currently the best indicator of penetrance in *C9orf72* carriers. Calculating family-specific penetrance would aid genetic counselling by allowing at-risk relatives a more accurate understanding of their individual risk.

Background/Objectives: Many genetic variants have been associated with neurological disorders, but far less is known about the influence of changes at the level of post-transcriptional regulation. We have previously shown that the RNA-binding protein Pumilio1 (PUM1) is important for neurological function; variants in *PUM1* can cause either early-onset or late-onset disease (SCA47). However, there have not yet been reports of patients with variants in PUM1's homolog, PUM2, which recognizes the same RNA binding motif. We therefore sought to identify patients and characterize the effects of *PUM2* variants.

Methods: We identified 12 individuals exhibiting a neurodevelopmental phenotype with *PUM2* variants, and additional cases are currently under investigation. Comprehensive clinical data from consulting clinicians for all individuals was collected using standardized forms.

Results: Among the 12 cases, eight had variants predicted to lead to loss of function (comprising three canonical splice site, two nonsense, and three frameshift truncation variants). The remaining four cases had missense variants in regions intolerant to variation (Metadome). De novo variants were observed in ten individuals; for one elderly individual the parents were unavailable for testing and for another individual the father was unavailable for testing. The predominant clinical features encompassed developmental delay (11/12), seizures (6/12), and behavioral abnormalities (5/12).

Conclusion: Considering PUM2's established roles in neural development and synaptic function, we propose that *PUM2* variants may cause developmental delay with or without seizures and behavioral problems. Functional studies are currently in progress to gain a better understanding of the underlying disease mechanism.

P11.051.B SCA27B is a common cause of late-onset chronic ataxia in the Czech Republic

Emílie Vyhnálková[1], *Martin Vyhnálek*[2], *Jaroslava Paulasová Schwabová*[2], *Alena Zumrová*[3], *Jaroslav Jeřábek*[3], *Simona Karamazovová*[2], *Kuzmiak Michaela*[2], *Zuzana Blichová*[2], *Lucie Šťovíčková*[3], *Markéta Havlovicová*[4], *Zuzana Musova*[4]

[1]University Hospital at Motol and Charles University, Second Faculty of Medicine, Center of Hereditary ataxias, Department of Biology and Medical Genetics, Praha 5; [2]University Hospital at Motol and Charles University, Second Faculty of Medicine, Center of Hereditary ataxias, Department of Neurology, Praha 5; [3]University Hospital at Motol and Charles University, Second Faculty of Medicine, Center of Hereditary ataxias, Department of Paediatric Neurology, Praha 5; [4]University Hospital at Motol and Charles University, Second Faculty of Medicine, Department of Biology and Medical Genetics, Praha 5

Consortium: ERN-RND

Background/Objectives: SCA27B is a newly discovered autosomal dominant late-onset ataxia caused by the expansion of GAA repeats in the first intron of the fibroblast growth factor-14 gene (*FGF14*). Excellent response to treatment with 4-aminopyridine has been reported in patients.

Methods: Twenty-eight patients with chronic adult-onset degenerative ataxia of unknown origin, followed at the Center of Hereditary Ataxia, University Hospital at Motol, were tested for the *FGF14* GAA repeat expansion.

Results: The expansion in the *FGF14* gene within the pathological range ($GAA_{\geq 300}$) was found in 11 (39%) patients, and three patients (11%) had a borderline repeat length ($GAA_{250-299}$) with presumed incomplete penetrance. Eight patients had a positive family history of ataxia in a parent or sibling, and 6 cases were sporadic. The mean age of onset was 52 years. All patients had progressive cerebellar syndrome. Four patients (37%) presented with a parkinsonian syndrome. Significant fluctuations of symptoms during the day were present in 9 patients. Treatment with 4-aminopyridine was initiated in 5 patients, with an excellent effect in 4.

Conclusion: SCA27B is a newly described frequent cause of hereditary late-onset ataxia in the Czech Republic. Based on the estimated high frequency, we have included targeted molecular genetic testing for SCA27B in the standard protocol in patients with adult-onset chronic ataxia. This step is essential for accurate diagnosis and the significant therapeutic benefit observed with 4-aminopyridine treatment in SCA27B cases.

Grants: Supported by project No. LX22NPO5107 (Ministry of Education and Science of the Czech Republic).

P11.052.C Novel bialleleic missense SVBP variant causes neurodevelopmental disorder with microcephaly.

Aboulfazl Rad[1], *Raman Kumar*[2], *Hafiz Muhammad Mustafa*[3], *Shivendra Kishore*[1], **Gabriela Oprea**[1]

[1]Arcensus GmbH, Rostock, Germany; [2]International Medical Center, National Stadium Road, Karachi, Pakistan; [3]Department of Biotechnology, University of Karachi, Karachi, Pakistan

Background/Objectives: Small vasohibin-binding protein (SVBP) functions as a chaperone and a co-factor for vasohibin 1 and 2 (VASH1 and 2). VASH1-SVBP and VASH2-SVBP complexes exhibit specific Tyr/Phe carboxypeptidase activity on microtubules. Recent literature has associated biallelic truncating variants in SVBP gene with neurodevelopmental disorders in five unrelated families. Here we report four patients from two unrelated families with similar neurodevelopmental disorders.

Methods: The SVBP variant was detected either by whole genome (WGS) or whole exome sequencing (WES). The family members were screened by Sanger sequencing.

Results: Both consanguineous Pakistani families had two affected siblings. The first family had two sibs aged 10 and 12 years with gait disturbance, global developmental delay, microcephaly, and motor delay. The second family had two sibs aged 1 and 4 years with delayed speech and language development, and with motor delay. Additionally, brain abnormalities were observed in the MRI scans of all analysed patients. Our analysis identified a novel homozygous missense variant (c.125T>C, p.Leu42Pro) located in exon 3 of SVBP gene (NM_199342.4) in all four patients. This rare variant segregated with disease in both families (parents and unaffected siblings).

Conclusion: Our findings expand the SVBP gene mutation spectrum, identified in patients with autosomal recessive neurodevelopmental disorder with ataxia, hypotonia, and microcephaly (NEDAHM). Further functional studies are necessary to elucidate the pathogenic mechanisms associated with missense variants in this gene.

Conflict of Interest: None declared

P11.053.D Spastic paraparesis as a relatively frequent manifestation of X-linked severe lethal adrenoleukodystrophy

Anna Uhrova Meszarosova[1], *Radim Mazanec*[2], *Jana Lastuvkova*[3], *Alena Santava*[4], *Lucie Osickova*[4], *Eva Vlckova*[5], *Petra Lassuthova*[1], *Dana Safka Brozkova*[1]

[1]Second Faculty of Medicine Charles University and University Hospital Motol, Prague, Neurogenetic Laboratory, Department of Paediatric Neurology, Czech Republic; [2]Second Faculty of Medicine Charles University and University Hospital Motol, Prague, Department of Neurology, Czech Republic; [3]Masaryk Hospital, Usti nad Labem, Department of Medical Genetics, Czech Republic; [4]Faculty Hospital Olomouc, Department of Medical Genetics, Czech Republic; [5]Faculty of Medicine Masaryk University and Faculty Hospital, Brno, Department of Neurology, Czech Republic

Background/objectives: Pathogenic variants in the *ABCD1* gene are cause of severe lethal X-linked adrenoleukodystrophy(X-ALD). X-ALD can manifest as rapidly progressive lethal adrenoleukodystrophy (ALD), milder adrenomyeloneuropathy (AMN), adrenal insufficiency (Addison's disease), or mild spastic paraparesis. Some female carriers can even remain asymptomatic. It makes the diagnosis confusing.

Methods: During nine years of routine diagnosis of hereditary spastic paraplegias (HSP) we performed targeted panel sequencing (the *ABCD1* gene was included) in approx. 350 patients suspected of having HSP.

Results: We detected six pathogenic variants in the *ABCD1* gene (two novel) in six index patients (four females, two men). The spastic paraparesis was in fact the clinical manifestation of the X-ALD with adult onset. The genetic result finally confirmed the proper diagnosis in the families even after many years which allowed retrospectively explain different clinical symptoms in families. Subsequently performed family segregation analysis revealed eight more heterozygous/hemizygous individuals.

Conclusion: The knowledge of the pathogenic variant in *ABCD1* gene is extremely important in families for preventive care particularly in male hemizygous still asymptomatic carriers. These men are in a high risk of fatal course of the disease due to X-linked inheritance.

The number of X-ALD families can be underdiagnosed, because the *ABCD1* pathogenic variant can be transferred via females in generations. X-linked inheritance, presence of spastic paraplegia, together with ALD, AMN or adrenal insufficiency (Addison's

disease/ crisis) in the family should be the good clue leading to *ABCD1* pathogenic variant.

Grants: The Ministry of Health of the Czech Republic NU22-04-00097.

P11.054.A Study of *RELN*-associated neurodevelopmental disorders using cerebral and cerebellar organoids

Philine Dinkel[1], *Ilka Reichardt*[2], *Mihail Sarov*[2], *Julia Sigl*[2], *Christina Eugster Oegema*[2], *Jula Peters*[2], *Evelin Schröck*[1;2], *William B. Dobyns*[3], *Michael Heide*[2;4], *Nataliya Di Donato*[1;5]

[1]*Institute for Clinical Genetics, University Hospital Carl Gustav Carus at TUD Dresden University of Technology and Faculty of Medicine of TUD Dresden University of Technology, Dresden, Germany;* [2]*Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany;* [3]*Department of Pediatrics, Division of Genetics and Metabolism, University of Minnesota, Minneapolis, United States;* [4]*German Primate Center, Leibniz Institute for Primate Research, Göttingen, Germany;* [5]*Department of Human Genetics, Hannover Medical School, Hannover, Germany*

Background/Objectives: Reelin is essential for correct lamination of the cortex and cerebellum. Its absence results in complete disorganization of neuronal layering in the mouse mutant reeler and patients with *RELN*-associated recessive lissencephaly. Reelin functions as a key signal for migrating neurons when secreted into the extracellular matrix. For several pathogenic *RELN* variants associated with autism or epilepsy, reduced Reelin secretion was demonstrated with transfected HEK293 cells, thereby suggesting a possible disease mechanism.

Methods: We use whole-brain and cerebellar organoids, which both harbor Reelin-expressing cells and allow to assess variant-specific effects on Reelin secretion in a 3D neuronal system for the first time. We first generated gene-edited induced pluripotent stem cells (iPSCs) with biallelic out-of-frame deletion and/or inversion of exon 8, representing a *RELN* knockout model. Secondly, we introduced a pathogenic splice site variant [NM_005045.3:c.4747+2T>G] seen in patients with *RELN*-associated lissencephaly.

Results: We realized that all potential knockout organoids express an unexpected alternative *RELN* transcript with in-frame skipping of exons 8-10 (130 amino acids) to rescue the reading frame. However, the alternative Reelin isoform is not secreted into the extracellular space, indicating a functional knockout in neuronal organoids. Currently, we characterize the impact of the alternative *RELN* transcript on morphology and cytoarchitecture of these organoids at different developmental stages.

Conclusion: Different *RELN* variants disrupt the secretion of Reelin, thereby presumably disabling its extracellular function on target neurons. Further investigations on how the secretion mechanism is arrested, and which intracellular function the alternative *RELN* transcript may pursue, will give new insights into pathomechanism of Reelinopathies.

Background: Highly conserved TRAPP complexes are crucial for subcellular trafficking, essential for nervous system development. Variants in TRAPP complex subunits lead to neurodevelopmental disorders with overlapping phenotypes.

Methods: We examined TRAPPC6B, detailing clinical, neuroradiologic assessments, and disease mechanisms in 29 patients from 18 families with biallelic TRAPPC6B variants.

Results: We identified seven homozygous nonsense (n = 12 patients) and eight canonical splice-site variants (n = 17 patients). In addition, we identified one patient with compound heterozygous splice-site/missense variants with a milder phenotype and one patient with homozygous missense variants. These patients showed non-progressive microcephaly, developmental delays, intellectual disability, epilepsy, absent expressive language, and movement disorders. Brain imaging revealed reductions in cortex, cerebellum, and corpus callosum size with frequent white matter hyperintensity. Volumetric measurements indicated globally diminished volume. Molecular studies showed weakened interaction between mutant TRAPPC6B and TRAPPC3, reduced TRAPPC6B levels in patient-derived fibroblasts, and elevated TRAPPC6A levels. Co-immunoprecipitation suggested TRAPPC6B primarily affects TRAPP II complex functions. Drosophila models supported TRAPPC6B's role in neuromotor function.

Conclusion: Our findings confirm the association of damaging biallelic TRAPPC6B variants with microcephaly, intellectual

disability, language impairments, and epilepsy. These features overlap with disorders arising from pathogenic variants in other TRAPP subunits, particularly components of the TRAPP II complex. These findings suggest that TRAPPC6B is essential for brain development and function, and TRAPP II complex activity may be particularly relevant for mediating this function.

Grants: Supported by the Cerebral Palsy Alliance Research Foundation and the US National Institute of Neurological Disorders and Stroke.

P11.056.C Novel compound heterozygous variants in *ALDH18A1* gene: expanding knowledge on autosomal recessive spastic paraplegia 9B

Silvia Cali[1;2], *Valeria Capra*[2], *Pasquale Striano*[3], *Maria Stella Vari*[4], *Francesca Madia*[5], *Edoardo Henzen*[6], *Francesca Faravelli*[2]

[1]*University of Catania, Biomedical and biotechnological sciences, Medical Genetics, Catania, Italy;* [2]*IRCCS Giannina Gaslini, Genomics and Clinical Genetics, Genova, Italy;* [3]*University of Genoa, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Genova;* [4]*IRCCS Giannina Gaslini, Pediatric Neurology and Muscular Diseases Unit, Genova;* [5]*IRCCS Giannina Gaslini, Medical Genetics Unit, Genova, Italy;* [6]*Italian Institute of Technology (IIT), Genomics Facility, Genova, Italy*

Background/Objectives: The ALDH18A1 gene, encoding pyrroline-5-carboxylate synthase (P5CS), is involved in the biosynthesis of proline, ornithine, and arginine. Mutations in ALDH18A1 cause hereditary spastic paraplegia (HSP), a neurodegenerative disorder characterized by progressive lower limb spasticity and weakness, known for its clinical and genetic heterogeneity. In particular, biallelic variants in ALDH18A1 lead to autosomal recessive spastic paraplegia-9B (SPG9B), an ultra-rare and complex neurological phenotype characterized by developmental delay, psychomotor regression, and facial dysmorphisms, which highlight its critical role in maintaining neurological integrity.

Methods: Here we present a 17-year-old patient exhibiting intellectual disability, paraplegia, and distinctive dysmorphic features. Whole exome sequencing (WES) revealed compound heterozygosity in ALDH18A1.

Results: Born to non-consanguineous parents, the patient experienced late intrauterine growth restriction. Recurrent regurgitation, vomiting, and psychomotor regression from 12 months onward were observed. Dysmorphic features included an elongated face, deep-set ears, long philtrum and pointed chin. Postnatal growth retardation, microcephaly and severe intellectual disability were also noted. Brain MRI disclosed abnormalities consistent with ALDH18A1-related HSP, showing altered morphology and signal intensity in supratentorial and subtentorial regions, along with a partially empty sella. Molecular analysis through WES identified compound heterozygosity for two novel *ALDH18A1* gene variants: c.1892_1902delinsC and c.1112G>A. Variants were classified likely pathogenic according to ACMG criteria.

Conclusion: SPG9B is an extremely rare condition, with only nine families described worldwide. To the best of our knowledge, this is the second familial instance reported in Italy. This case contributes to expand the knowledge about an ultra rare condition and confirm the heterogenous genetic landscape of ALDH18A1-related HSP.

Background/Objectives: Large chromosomal deletions or imprinting defects spanning 15q11-q13 cause Prader-Willi Syndrome (PWS), marked by the loss of expression of maternally imprinted genes, including the gene *MAGEL2*. The most prominent symptoms are neonatal hypotonia, neurodevelopmental delay, and hormonal abnormalities. Remarkably, mutations in *MAGEL2* alone result in a similar but more severe phenotype known as Schaaf-Yang Syndrome (SYS). Despite the shared features between these syndromes, SYS patients show a higher prevalence of intellectual disability, autism spectrum disorders, and neonatal death compared to those with PWS. However, the specific contribution of *MAGEL2* to SYS and PWS remains to be elucidated.

Methods: To determine cellular pathways affected by aberrant MAGEL2 in neurons, we first generated CRISPR/Cas9-engineered heterozygous and homozygous *MAGEL2* deletions in human induced pluripotent stem cells (hiPSCs). Following the differentiation along with isogenic PWS type I/II deletion and two SYS-associated *MAGEL2* mutation cell lines into cortical neurons, we conducted RNA-sequencing, whole proteome, and ubiquitome analyses. To determine the specific location of MAGEL2 in neurons and its interaction partners, we generated two additional hiPSC lines carrying either WT or SYS-mutated endogenously tagged MAGEL2 enabling the utilization of co-immunoprecipitation and immunofluorescence applications.

Results: Our preliminary multi-omics studies indicate various differentially affected pathways associated with synaptic transmission, transmembrane transport, and cytoskeleton organization which may provide new insights into the pathophysiology of MAGEL2 that are currently further investigated. Co-IP and localization studies are ongoing.

Conclusion: Our results will help us deepen our knowledge about the role of MAGEL2 in neurodevelopment and its contribution to PWS and SYS.

Neurological Institute and Hospital, McGill University, Department of Neurology and Neurosurgery, Montreal, Canada

Background/Objectives: Clinical identification of individuals in early stages of psychosis, like ultra-high risk (UHR) or first episode of psychosis (FEP) has opened the way to investigate prognostic biomarkers. While genetic factors, including polygenic risk scores, show promise in predicting outcomes, rare variants such as tandem repeats (TRs) have been overlooked. We aimed to investigate their characteristics and functional implications in early psychosis.

Methods: A cohort of 396 individuals (318 FEP and UHR who developed FEP vs. 78 UHR who did not develop FEP) was sequenced using IlluminaSeq and genome-wide TRs and outlier identification was done by ExpansionHunter Denovo. Only TRs with a z-score >3.29 were characterized. Potential functional implications were assessed through gene-set confrontation, pathway, and functional enrichment analyses.

Results: Of the 2785 identified TRs, a subset of 156 TRs located in exonic regions was chosen for subsequent analysis resulting in 120 genes. While all these genes have already been associated with neuropsychiatric disorders, the gene-set confrontation analysis found that 63 of them were previously linked to schizophrenia. These genes were significantly expressed in brain tissue and were found to be enriched via functional and pathway analysis in the metabolic processes of unsaturated fatty acid, arachidonic acid, and eicosanoids.

Conclusion: This study highlights a potential link between TRs, lipid metabolism, and early psychosis. As lipid metabolism has been suggested to play an important role in psychosis vulnerability and as Omega-3 supplementation has been proposed as a preventive strategy for psychosis, these findings support the role of TRs in the pathogenesis of psychosis.

P11.059.B Disrupted oxytocin system development in rats with truncating *Magel2* mutation

Tim Schubert[1], *Yongxi Lu*[1], *Annabel Kleinwächter*[1], *Moritz Wimmer*[1], *Yuval Hazor*[1], *Colleen Bocke*[2], *Beril Demiryontar*[1], *Quirin Krabichler*[3], *Gina Yosten*[2], *Valery Grinevich*[3], *Christian Schaaf*[1], *Ferdinand Althammer*[1]

[1]*Institute of Human Genetics, Heidelberg University Hospital, Heidelberg, Germany;* [2]*St. Louis University, St. Louis, United States;* [3]*Central Institute of Mental Health, Department of Neuropeptide Research in Psychiatry, Mannheim, Germany*

Background/Objectives: The maternally imprinted *MAGEL2* gene gives rise to the MAGEL2 protein, which is linked to secretory granule formation and neuropeptide processing. *MAGEL2* is part of the Prader-Willi syndrome (PWS) deletion and truncating variants lead to Schaaf-Yang syndrome (SYS). Both are neurodevelopmental disorders with gross hypothalamic dysfunction and, in the case of SYS, a 75-85% prevalence of Autism Spectrum Disorder (ASD). Inconsistent improvements in patients receiving oxytocin (OT) in clinical trials suggest a critical period during brain development where treatment is most effective. This study compares OT system development in health and disease.

Methods: We studied rats harbouring a truncating *Magel2* mutation and performed semi-automated quantification of OT neurons throughout the entire rat hypothalamus in newborns, adolescents, and adults. Additionally, we mapped projections to socially relevant brain regions modulated by OT and analyzed oxytocin receptor mRNA levels via RNAScope hybridization.

Results: Our analysis reveals sex- and age-specific alterations in OT systems between wildtype and mutant rats. We show that *Magel2* deficient males display a transient increase in oxytocinergic neurons that disappears in adults. In females, these changes persist into adulthood, accompanied by reduced projections to the nucleus accumbens - a region crucial for social motivation and reward.

Conclusion: This work offers unprecedented insights into OT system development in health and disease, laying the foundation for further investigations into the development of oxytocinergic circuitry, its association with ASD and optimal windows for effective OT treatment in PWS and SYS.

P11.060.C Confirming *KCNQ3* as a disease gene for autosomal-recessive developmental and epileptic encephalopathy

Ava Oberlack[1], *Maureen Jacob*[1], *Claudia Nussbaum*[2], *Juliane Winkelmann*[1;3], *Ingo Borggräfe*[4], *Matias Wagner*[1;3;4]

[1]*Klinikum rechts der Isar, Technical University of Munich, Institute of Human Genetics, Munich, Germany;* [2]*Dr. v. Hauner Children's Hospital, LMU - University of Munich, Department of Neonatology, Munich, Germany;* [3]*Helmholtz Zentrum München Deutsches Forschungszentrum für Umwelt und Gesundheit, Institute of Neurogenomics, Neuherberg, Germany;* [4]*Dr. v. Hauner Children's Hospital, LMU - University of Munich, Department of Pediatric Neurology, Munich, Germany*

Background: Heterozygous variants in *KCNQ3*, encoding a subunit of a voltage-gated potassium channel, are a well-known cause of autosomal-dominant self-limited (familial) neonatal epilepsy, self-limited (familial) infantile epilepsy and, rarely, neurodevelopmental disorder with or without autism and/or epilepsy. Recently, three families with *KCNQ3*-associated autosomal-recessive developmental and epileptic encephalopathy (DEE) showing neonatal-onset epilepsy and mild to severe intellectual disability have been described. Heterozygous parents and siblings had no history of seizures or developmental retardation.

Methods: Patient-parent trio exome sequencing was performed and analyzed using a systematic filtering approach.

Results: We present an additional case of a term-born child of consanguineous, asymptomatic parents, who showed migrating focal seizures from the second day of life. Trio exome sequencing identified a homozygous frameshift variant in exon 1 of *KCNQ3* (NM_004519.4:c.328_329del). The estimated prevalence of homozygous *KCNQ3*-associated disease based on the allele frequency of loss-of-function variants in gnomAD is around 1/6 million (> 20 new cases/year worldwide).

Conclusion: Our patient corroborates the significance of *KCNQ3* as a disease gene linked not only to autosomal-dominant, mainly self-limiting epilepsy syndromes, but also to autosomal-recessive DEE phenotypes. As the number of known patients is well below the estimated prevalence, the homozygous condition is probably underdiagnosed. Given the loss-of-function character of variants identified in recessive families, these should also be disease causing in a dominant context. However, heterozygous, healthy family members indicate a reduced penetrance below previous estimates. Retigabine, a modulator of potassium channels, could be a treatment option, but is currently not available in the EU.

Consortium: FLVCR1 International Collaborative Group

Background/Objectives: *FLVCR1* encodes a widely expressed transmembrane protein implicated in heme, choline, and ethanolamine transport. While *Flvcr1* knockout mice die in utero with skeletal malformations and defective erythropoiesis reminiscent of Diamond-Blackfan anemia, rare pathogenic *FLVCR1* variants are linked to autosomal recessive childhood or adult-onset neurodegeneration of the retina, spinal cord, and peripheral nervous system. Here we sought to better characterize the phenotypic spectrum of *FLVCR1*-related disease and the molecular consequences of pathogenic FLVCR1 variants.

Methods: We analyzed exome and genome sequencing data from >29,000 rare disease individuals to identify cases with biallelic *FLVCR1* variants. Additional cases were identified through GeneMatcher and international collaborations. The functional impact of *FLVCR1* variants were examined in an in vitro choline and ethanolamine transport assay as well as a mini-gene splicing assay.

Results: We identified 27 individuals from 21 unrelated families with biallelic ultra-rare missense and loss-of-function (LoF) *FLVCR1* variants. We characterize an expansive *FLVCR1*-related disease spectrum ranging from adult-onset retinitis pigmentosa to severe developmental disorders with profound developmental delay, microcephaly, reduced brain volume, epilepsy, spasticity, and premature death. The most severely affected individuals, including six individuals wih homozygous LoF variants, share traits with *Flvcr1* knockout mice and Diamond-Blackfan anemia including macrocytic anemia, skeletal malformations, and hydranencephaly. *FLVCR1* missense variants primarily fall within transmembrane domains and significantly reduce choline and ethanolamine transport; a subset also disrupt splicing.

Conclusion: This study expands our understanding of Mendelian disorders of choline and ethanolamine transporters and demonstrates the importance of choline and ethanolamine in hematopoietic, skeletal, and nervous system development and homeostasis.

Doublesex- and mab-3–related transcription factor a2 (*DMRTA2*), intricately balances cell cycle progression and neuronal differentiation by directly regulating the neurogenesis repressor Hes1. Here, we have studied a five-generation Pakistani consanguineous family having three affected individuals presenting with primary microcephaly with developmental disorder including intellectual

disability, seizures and developmental delay. The plausible candidate variant for the phenotype was identified by whole exome sequencing. We identified a rare homozygous missense variant, c.347G>C; p.Arg116Pro (NM_032110.3) in *DMRTA2*, which segregated with the phenotype. The variant p.Arg116Pro is predicted as "deleterious" by multiple insilico-prediction programs and classified as variant of uncertain significance, according to the ACMG classification criteria.The patient's MRI displayed a simplified gyral pattern along with agenesis of the corpus callosum and colpocephaly. The abnormal Electroencephalogram indicated mild encephalopathy. DMRTA2 safeguards neural progenitor cells (NPC) maintenance and its loss promotes neuronal differentiation and depletion of the NPC pool, resulting in microcephaly. So far a single variant c.1197delT in DMRTA2 has been reported in three siblings affected by a severe prenatal neurodevelopmental disorder characterised by fronto-parietal pachygyria, agenesis of the corpus callosum and progressive severe microcephaly. Moreover, we have initiated a set of functional experiments to unravel the pathogenicity of the novel variant identified in this study. Our findings add important details to the clinical and genetic spectrum of DMRTA2, and highlight p.Arg116Pro as a cause of colpocephaly with associated agenesis of corpus callosum and primary microcephaly.

P11.063.B *GRIN2A* null variants confer a high risk for early-onset schizophrenia and other mental disorders and potentially enable precision therapy

Johannes Lemke[1], *Andrea Eoli*[2], *Ilona Krey*[1], *Bernt Popp*[1], *Vincent Strehlow*[1], *Dirk Alexander Wittekind*[1], *Anna-Leena Vuorinen*[3], *Stephen F Traynelis*[4], *Tim Benke*[5], *Henrike Heyne*[2], *Steffen Syrbe*[6]

[1]*Universtity of Leipzig Medical Center, Leipzig, Germany;* [2]*Hasso Plattner Institute (HPI), Potsdam, Germany;* [3]*University of Helsinki, Helsinki, Finland;* [4]*Emory University, Atlanta, United States;* [5]*University of Colorado Hospital, Aurora, United States;* [6]*University Hospital Heidelberg, Heidelberg, Germany*

Consortium: GRIN2A study group

Background: Mental disorders are considered highly polygenic. This is despite the observation of rare protein-truncating null variants in multiple genes that are believed to contribute to its heritability, particularly with respect to schizophrenia. *GRIN2A*, encoding the GluN2A subunit of the N-methyl-D-aspartate receptor (NMDAR) is one of very few such genes that had been identified to confer a substantial risk for schizophrenia.

Methods: We prospectively enquired the presence of psychiatric diagnoses in 235 individuals with pathogenic variants in *GRIN2A* who had previously enrolled in our global GRIN registry.

Results: We identified null variants in *GRIN2A* (*GRIN2A*null) to be significantly associated with mental disorders in general, including schizophrenia compared to missense variants (*GRIN2A*missense). *GRIN2A*null-related phenotypes can manifest as isolated mental disorder, i.e. as schizophrenia or mood disorder without further *GRIN2A*-specific symptoms, such as intellectual disability and/or epilepsy. *GRIN2A*null-related mental disorders manifest in early childhood or adolescence, which is significantly earlier than the adult onset in the general population.

Conclusion: *GRIN2A*null appears to be the first monogenic cause of isolated and early-onset mental disorders, including early-onset schizophrenia, and genetic testing should be considered in the diagnostic work-up of affected individuals. As L-serine is known to mediate co-agonistic effects on the NMDAR, it had been applied to four individuals with *GRIN2A*null-related mental disorders, all of whom experienced improvements of the neuropsychiatric phenotype. Thus, increasing brain concentrations of NMDAR co-agonists appears to be a promising precision treatment approach successfully targeting deficient glutamatergic signaling in individuals with mental disorders, i.e. due to *GRIN2A*null.

Consortium: ILAE Consortium on Complex Epilepsies, EpiPGX Consortium, EuroEPINOMICS CoGIE Consortium, Epi25 Collaborative

Background/Objectives: In this study, we aimed to investigate the combined contribution of both common and ultra-rare genetic variants (URV) on the development of genetic generalized epilepsy (GGE) and subphenotypes.

Methods: We analyzed a large cohort of 669 GGE cases and 41,700 ethnically matched controls to identify individuals with URVs in specific gene-sets related to GGE, including GABA-A receptors, GGE-related genes, and focal epilepsy-related genes. We generated a novel polygenic risk score (PRS) for GGE and stratified individuals according to their PRS deciles and URV carrier status. Logistic regression models were applied while adjusting for the ethnicity, age and gender.

Results: Individuals with GGE had a significantly higher PRS than controls (P-value $= 2.22 \times 10^{-16}$). For URV carriers in the GABA gene-set, depending on PRS decile the ORs for non-carriers ranged between 0.33 (CI = 0.30-0.37) to 3.48 (CI = 3.43-3.53), whereas for the carriers it ranged from 0.75 (CI = 0.44-1.29) to 8.08 (CI = 5-12.63); Similar trend was observed for URV GGE-related gene carriers. However, there was no substantial difference in the ORs between URV carriers and non-carriers in the focal epilepsy-related genes. In the GGE-subphenotypes analysis, only juvenile myoclonic epilepsy (JME) cases showed differences in the ORs in the carriers vs non-carriers.

Conclusion: We suggest that considering the polygenic background alongside ultra rare variants is likely to increase the accuracy of risk assessment for individuals who inherit ultra rare variants associated with epilepsy.

Conflict of Interest: None declared

P11.065.D Identification of novel driver risk genes in CNV loci associated with neurodevelopmental disorders.

Sara Azidane[1], *Mario Caceres*[2;3], *laura perez-cano*[1], *xavier gallego*[1], *lynn durham*[4], *emre guney*[1]

[1]*STALICLA DDS, Barcelona, Spain;* [2]*Institute of Biotechnology and Biomedicine (IBB-UAB), Bellaterra (Barcelona), Spain;* [3]*Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain;* [4]*STALICLA DDU, Genève, Switzerland*

Background/Objectives: Large and rare copy number vairants (CNVs) are known to entail risk for various neurodevelopmental disorders (NDDs). Nevertheless, given that NDD-risk CNVs cover

broad regions of the genome, it is particularly challenging to pinpoint the critical gene(s) responsible for the manifestation of the phenotype. Our aim was to identify NDD-risk regions, as well as genes within these genomic regions responsible for triggering the phenotype.

Methods: To identify NDD-risk regions we performed a meta-analysis of CNV data from the SFARI database. Dosage-sensitive genes within these risk loci were evaluated for enrichment of known NDD-risk pathways. Additional analyses of these genes included construction of protein-protein interaction networks, assessment of its expression in brain across development, and evaluation of transmitted deletions within multiplex ASD families. We also performed a burden analysis using data from Decipher, 1000 Genomes and iHART cohorts to validate the association of dose-sensitive genes with NDD-risk.

Results: Our findings revealed enrichment of dosage-sensitve genes within NDD-risk CNV loci, convergence in protein-protein interaction networks, high expression in brain across development, and overtransmission of deletions in ASD offspring. Burden analysis validated association for 154 dose-sensitive genes with NDD-risk, including 22 novel NDD-risk genes.

Conclusions:

This study highlights the complexity of NDDs, emphasizing a polygenic model in which multiple genes within NDD-risk CNV loci contribute to these heterogenous phenotypes. The identification of new risk genes enriches our understanding of the genetic basis of NDDs and opens routes for future research and therapeutic interventions.

Background/Objectives: This study investigates the impact of de novo heterozygous variants in *SRSF3*, which is involved in constitutive and alternative splicing and mRNA export.

Methods: Clinical, genomic, and functional studies using subject-derived fibroblasts and heterologous cellular systems were performed.

Results: We studied six individuals with variable phenotypes who had heterozygous de novo *SRSF3* (NM_003017.5) variants, including one missense variant [c.181G>C; p.(Asp61His)] affecting a highly conserved residue in the RNA recognition motif, three frameshift variants [c.330_331del; p.(Pro111Serfs*20), c.402_403del; p.(Arg137Ilefs*16), and c.477dup; p.(Ser160Valfs*3)] and one nonsense variant [c.445C>T; p.(Arg149*)] identified in two unrelated patients. The c.330_331del variant was predicted to cause nonsense-mediated mRNA decay, which was confirmed by RT-PCR in patient-derived fibroblasts. However, *SRSF3* mRNA and protein levels were similar in patient and control cells. As we lacked patient cells, we overexpressed the SRSF3-Asp61His, -Arg137Ilefs*16, -Arg149*, and -Ser160Valfs*3 mutants in HEK293T and HeLa cells. Our data revealed that the C-terminally truncated mutants had lower protein stability compared to wild-type SRSF3, correlating with reduced C-terminal phosphorylation of these mutants. All SRSF3 mutants showed decreased binding to polyadenylated RNA and reduced nucleocytoplasmic shuttling. Complex formation with YTHDC1, which recognizes N6-methyladenosine-modified mRNAs, and nuclear export factor 1 (NXF1) was reduced for SRSF3-Arg137Ilefs*16 and -Arg149*.

Conclusion: Our data suggest that impaired mRNA binding and reduced mRNA export from the nucleus contribute to the pathophysiology underlying variable phenotypes associated with de novo missense and truncating *SRSF3* variants. Notably, compensatory mechanisms were observed in fibroblasts with a heterozygous *SRSF3* loss-of-function variant to maintain normal SRSF3 levels.

P11.067.B Genetic determinants of mitochondrial impairment in primary progressive multiple sclerosis

Melissa Sorosina[1], **Elisabetta Mascia**[1]*, Michela Crotti[2], Ferdinando Clarelli[1], Antonino Giordano[1;3], Laura Ferrè[1;3], Daniele De Ritis[2], Francesca Maltecca[2], Massimo Filippi[3;4;5;6], FEDERICA ESPOSITO[1;3]*

[1]*IRCCS San Raffaele Scientific Institute, Laboratory of human genetics of neurological disorders, Institute of Experimental Neurology, Division of Neuroscience, Milan, Italy;* [2]*IRCCS San Raffaele Scientific Institute, Mitochondrial Dysfunctions in Neurodegeneration Unit, Division of Neuroscience, Milan, Italy;* [3]*IRCCS San Raffaele Scientific Institute, Neurology and Neurorehabilitation Unit, Milan, Italy;* [4]*Vita-Salute San Raffaele University, Milan, Italy;* [5]*IRCCS San Raffaele Scientific Institute, Neurophysiology Service, Milan, Italy;* [6]*IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division of Neuroscience, Milan, Italy*

Background/Objectives: Multiple sclerosis (MS) is a chronic, progressive neurological disorder. About 15% of patients experiences a progressive course from the onset, the primary progressive (PP) MS. Several lines of evidence demonstrate that mitochondrial dysfunction could be one of the driving factors of disease progression in MS. The purpose of this project is to explore the genetic determinants of mitochondrial impairment occurring in PPMS.

Methods: We performed a candidate gene-set enrichment analyses with magma tool, comparing 532 PPMS and 436 benign-MS (patients with EDSS < 4 after ≥20 years), starting from imputed whole-genome genotyping data (8.5M SNPs). A total of 166 gene-sets and 1704 nuclear genes covering the main mitochondrial functions were selected. Further functional evaluations to confirm the involvement of associated pathways were performed on 20 PPMS and 20 RRMS patient collected PBMCs, differentiated and expanded in $CD4^+$ T lymphocytes. We performed cytofluometric analysis of Tetramethylrhodamine Methyl Ester to measure mitochondrial membrane potential (MMP) and of MitoTracker staining to assess mitochondrial mass.

Results: Analyses highlighted gene-sets related to fatty acid beta oxidation ($p = 0.002$), mitophagy ($p = 0.004$) and mitochondrial uncoupling ($p = 0.03$) as associated with PPMS. At baseline, no differences were observed in terms of MMP comparing CD4+ enriched T lymphocytes collected from PP and Relapsing-Remitting patients, while a slight increase in mitochondrial mass was observed in PPMS (Kolmogorov-Smirnov test $p < 0.0001$), coherent with the presumed impairment of mitophagy-related processes.

Conclusion: Results suggest the presence of genetic-driven mitochondrial impairment in specific processes in PPMS. Additional functional assessments are ongoing.

P11.068.C *FOXP2* alterations: A comprehensive look beyond speech and language

Caroline Utermann-Thuesing[1], *Almuth Caliebe*[1], *Yorck Hellenbroich*[2], *Malte Spielmann*[1;2], *Inga Nagel*[1]

[1]*University Hospital Schleswig-Holstein, Campus Kiel, Institute of Human Genetics, Kiel, Germany;* [2]*University Hospital Schleswig-Holstein, Campus Lübeck, Institute of Human Genetics, Lübeck, Germany*

Background/Objectives: Heterozygous disruptions in the *FOXP2* gene cause severe speech and language disorder (SLD). In addition to SLD, fine and gross motor dysfunction and facial dysmorphology can occur. Whether *FOXP2* variants cause autism spectrum disorder (ASD) is still on debate and other clinical findings such as global developmental delay and neurological movement disorders are currently not considered as part of *FOXP2*-associated disorders.

Methods: Exome and Sanger sequencing were performed in two unrelated families with speech and language developmental delay and additional clinical manifestations. In family A, the mother presented with a tremor-ataxia-dystonia syndrome. Her children (1 son, 1 daughter) displayed a similar phenotype (ataxia, tremor) along with hypotonia (both), suspected ASD (son) and global developmental delay (son). In family B, the only son of unaffected parents presented in addition to SLD with intellectual disability, hypotonia, behavioral abnormalities and dysmorphic facies such as low-set ears.

Results: Exome sequencing identified a missense variant of unclear significance in *FOXP2* (NM_014491.4:c.1661A>G; p.(His554Arg)) in all affected members of family A. In family B, the son carried a pathogenic *FOXP2*-loss of function variant (NM_014491.4:c.1540del; p.(Arg514Glyfs*12)). Notably, both *FOXP2* variants have not been described so far.

Conclusion: While previous case reports and the OMIM database emphasize SLD-related phenotypes, our findings, literature review and database research reveal potentially additional features for *FOXP2*-related diseases, including ASD and neurological movement disorders like ataxia and tremor. Furthermore, family A's clinical findings indicate phenotypic variability within the same family. This broader spectrum of manifestations suggests considering more variable clinical phenotypes in genetic counseling of individuals with *FOXP2* variants.

Background: Bipolar disorder (BD) is a genetically complex neuropsychiatric disorder with a lifetime prevalence of 1-2% and a twin-based heritability of 60-80%. Common SNPs account for ≈20% of the observed phenotypic variance. It is assumed that at least part of the unexplained phenotypic variance is explained by rare variants. Studies aiming at the identification of rare variants have mainly focused on short-read sequencing and single-nucleotide variants. In the present study, we aimed at exploring the contribution of rare structural variants (SVs) to BD by using long-read whole-genome sequencing (lrWGS).

Methods: We performed PacBio lrWGS in nine Spanish multi-generational families multiply affected with BD. From each family, we sequenced three affected individuals and filtered for rare SVs shared by all three individuals.

Results: We present preliminary results from two families, for which we had an initial callset of 68,217 and 31,956 SVs, respectively. After a rigid filtering process, we retained 14 SVs (family1) and 7 SVs (family2). Notably, 6/14 and 4/7 of these SVs segregate in genes previously implicated in BD: *AGAP1, CACNA1C, CAMTA1, FAM135B, NXN, TENM4* (family 1), and *DLGAP2, NOL4, PRKG1, PTPRD* (family 2).

Conclusions: Our study tentatively identified rare SV in novel and previously implicated BD genes segregating with BD. We are currently following-up these findings in additional affected individuals from the two families. To better understand pathophysiological aspects of the most promising variants, we are planning functional work in iPSCs.

P11.070.A Genetic contributions to epilepsy and febrile seizure: A study of narrow-sense and single-nucleotide polymorphism (SNP) heritability

Janne Auning Hansen[1;2], *Bjarni Jóhann Vilhjálmsson*[1;3;4], *Julie Werenberg Dreier*[1;5], *Betina Trabjerg*[1], *Bjarke Feenstra*[6], *Jakob Christensen*[2;7]

[1]*National Centre for Register-based Research, Aarhus University, Aarhus, Denmark;* [2]*Department of Neurology, Aarhus University Hospital, Aarhus, Denmark;* [3]*Bioinformatics Research Centre, Aarhus University, Aarhus, Denmark;* [4]*Novo Nordisk Foundation Center for Genomics Mechanisms of Disease, Broad Institute of MIT and Harvard, Cambridge, United States;* [5]*Centre for Integrated Register-based Research, Aarhus University, Aarhus, Denmark;* [6]*Statens Serum Institut, Copenhagen, Denmark;* [7]*Department of Clinical Medicine, Aarhus University, Aarhus, Denmark*

Background/Objectives: This study aims to elucidate the heritable aspect of epilepsy and febrile seizures by estimating the narrow-sense heritability of these disorders using data from the Danish population-based health registers and compare with the SNP-heritability estimated using genotype data from the Lundbeck Foundation Initiative for Integrative Psychiatric Research (iPSYCH) sample.

Methods: We utilized the Danish nationwide registers to create a twin cohort with which we estimated the narrow-sense heritability utilising a modified Falconer's formula [1]. Additionally, we conducted genome-wide association studies (GWAS) in the iPSYCH cohort, estimating the SNP-heritability using LDpred2-auto.

Results: We identified 40,205 twin pairs, born in Denmark from 1977 to 2018 including 1140 persons with epilepsy and 2940 persons with febrile seizures. The narrow-sense heritability was 57% (95% CI: 17-91%) for epilepsy and 42% (95% CI: 23-62%) for febrile seizures, while the SNP-heritability for epilepsy was 7.8% (95% CI: 7.7-7.9%) and 28.3% (95% CI: 27.9-28.6%) for febrile seizures.

Conclusion: We demonstrated significant narrow-sense heritabilities underscoring the substantial genetic component in these disorders. The SNP-heritability estimates indicate that common genetic variants play a notable role. However, they account for less than a quarter of the heritable variation in epilepsy, pointing towards the involvement of e.g. structural and rare variants in its pathogenesis.

Grants: The Central Denmark Region, the Novo Nordisk Foundation (NNF16OC0019126 and NNF22OC0075033), and the Danish Epilepsy Association.

Consortium: FOR2107

Background/Objectives: Depression is a common psychiatric disorder caused by both genetic and environmental risk factors. Dysregulation of microglia - the brain-resident immune cells - has been implicated, but human data in this context is scarce. Here, we use induced pluripotent stem cell (iPSC) derived microglia (iMG) from patients with major depressive disorder (MDD) and healthy controls (HC) selected from the extreme ends of the genetic risk spectrum.

Methods: iPSC-lines were generated for donors selected from the German FOR2107 cohort based on depression polygenic risk scores and family history for psychiatric disorders ($n = 3$ MDD high risk, $n = 3$ HC low risk). Cells were differentiated into iMG, stimulated with lipopolysaccharide (LPS) and NLRP3 inflammasome activators and analysed using immunocytochemistry, ELISA, immunoblotting and 3'mRNA-sequencing.

Results: In first experiments, all iPSC-lines were successfully differentiated into iMG without major differences in cellular development or transcriptome profiles between MDD and HC. There was no difference in cytokine release after stimulation with LPS alone, however, MDD-iMG showed increased interleukin-β processing and release after activation of NLRP3 by LPS+nigericin, but not LPS + ATP. We further identified several differentially expressed genes between stimulated MDD- vs. HC-iMG, some of which have previously been associated with depression or related traits.

Conclusion: If replicated in upcoming experiments, these findings would suggest that high genetic risk for depression leads to dysregulated microglial NLRP3 inflammasome activation. Overall, our new iPSC-lines provide a valuable tool to study genes and mechanisms involved in depression pathogenesis, analyse gene-environment interactions (e.g. "stress") in a defined cellular model and potentially identify pathways relevant for therapy.

Background: Neurodevelopmental disorders (NDDs) are a genetically and clinically heterogeneous group of conditions, affecting 1%–3% of children. NDDs comprise several disorders including intellectual disability, autism spectrum disorder, attention deficit hyperactivity disorder or developmental delay, among others.

Methods: In this study, we evaluated 400 individuals with neurodevelopmental delay and additional clinical features between 2018 and 2023. Most of our patients were previously tested and negative for molecular karyotyping and *FMR1* CGG expansion. We performed whole-exome sequencing to identify the underlying molecular pathology.

Results: 205 of 400 (51%) affected individuals carry 208 different variants in 156 NDD genes. According to the ACMG/AMP criteria we identified 61 variants as pathogenic, 81 as likely pathogenic and 66 as variants of unknown significance. 151 (73.7%) individuals display heterozygous variants in autosomal dominant genes, 37 (18%) carry biallelic variants in autosomal recessive genes, and 17 (8.3%) patients have hemizygous variants in X-chromosomal genes. Furthermore, we detected 8 CNVs, including single-exon or whole-gene deletions.

Conclusion: We performed a retrospective study to estimate the diagnostic yield of whole-exome sequencing in 400 patients with neurodevelopmental disorders. In 36% of our patients pathogenic or likely pathogenic variants were identified and thus, the patients received a genetic diagnosis. In the present study, we identified 145 novel variants in NDD genes and expand the genotypic spectrum of NDDs.

P11.073.D Copy number variant analysis identifies diagnostic events across diverse epilepsies

Tania Giangregorio[1], *Lorenzo Serra*[2], *Paola Dimartino*[3], *Federica Isidori*[1], *Pamela Magini*[1], *Raffaella Minardi*[4], *Laura Licchetta*[4;5], *Francesca BISULLI*[4;5], *Tommaso Pippucci*[1]

[1]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy;* [2]*University of Bologna, Department of Pharmacy and Biotechnology (FaBiT), Bologna, Italy;* [3]*University of Bologna, Department of Medical and Surgical Sciences (DIMEC), Bologna, Italy;* [4]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Reference Center for Rare and Complex Epilepsies-EpiCARE, Bologna, Italy;* [5]*University of Bologna, Department of Biomedical and NeuroMotor Sciences (DIBINEM), Bologna, Italy*

Background/Objectives: Different genetic architectures underlie the main types of epilepsy including genetic generalized epilepsies (GGE), focal epilepsies and developmental and epileptic encephalopathies (DEE). Copy number variants (CNVs) can cause or confer genetic risk for epilepsy. Recent studies show an increased burden of CNVs in epilepsy patients compared to controls and the strong association of CNV hotspots with specific epilepsy types. Our study investigate the landscape of CNVs and their role in the aetiology of epilepsy.

Methods: We extracted DNA from blood samples and collected detailed phenotyping data of 781 individuals with epilepsy. Genotyping data were generated on the Illumina Infinium Global Screening Array. To infer CNVs calls we designed a portable workflow using PennCNV algorithm. We filtered out all samples with a standard deviation of log Rratio > 0.3, Ballele frequency drift > 0.01, waviness factor > 0.05 and a CNV load > 100. CNVs calls were annotated using AnnotSV software.

Results: We identified rare CNV in seizure-associated loci in three patients. An individual with GGE carried a 1.3 MB deletions at 16p13.11 locus previously associated with generalized tonic-clonic seizures, while two patients with DEE carried a 1.6 Mb deletion at 3q29 and a 4.8 Mb deletion at 15q13.1-q11.2 respectively. Almost 1% of patients carry rare pathogenic CNVs spanning known epilepsy genes.

Conclusion: Our findings reflect the complexities of phenotype-genotype relationships in epilepsy and highlight the emerging significance of CNVs that raise risk for specific epilepsy type.

P11.075.B Looking beyond labels: genetics of psychiatric traits cluster with insulin-related measures

Barbara Šakić[1;2], *Izel Erdogan*[2;3], *Giuseppe Fanelli*[2;3;4], *Martina Arenella*[2;3;5], *Nina Roth Mota*[2;3], *Janita Bralten*[2;3]

[1]*Radboud University Medical Center, Human Genetics, Cognitive Neuroscience, Nijmegen, Netherlands;* [2]*Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands;* [3]*Radboud University Medical Center, Human Genetics, Nijmegen, Netherlands;* [4]*University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy;* [5]*King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom*

Background/Objectives: Psychiatric disorders, like attention-deficit/hyperactivity disorder (ADHD), obsessive-compulsive disorder (OCD) and autism spectrum disorder (ASD) and insulin-related diseases co-occur and are genetically correlated, but an understanding of the molecular genetic underpinnings of this overlap remains sparse. Here we aim to explore the existence of dimensional genetic clusters based on ADHD, OCD and ASD symptomatology as well as insulin-related continuous measures observed in the general population.

Methods: We applied multivariate genomic structural equation modeling (genomicSEM) to investigate latent genetic factors underlying publicly available summary statistics of the largest genome-wide association studies (GWASs) of ADHD symptoms (n = 17,666), OCD symptoms and cases (n = 17,992) and sociability linked to ASD (n = 342,461) with GWASs of insulin-related traits (n = 98,210-697,734). Subsequently, we performed multivariate genome-wide association analyses on the observed genetic clusters including both psychiatric and insulin-related traits and follow-up annotation with Functional Mapping and Annotation of Genome-wide association studies (FUMA).

Results: A three-factor model fitted our data the best (AIC = 57, CFI = 0.99, SRMR = 0.068), highlighting a latent genetic factor including ADHD symptom scores together with body mass index, fasting glucose and glycated hemoglobin and a latent genetic factor including OCD symptoms together with glycated hemoglobin. Significant genes (n = 58) and gene-sets (n = 17) associated to these factors indicate a potential role for glycemic regulation

and insulin-related processes as well as neurodevelopmental biological pathways.

Conclusion: Our findings show that latent genetic factors exist reflecting shared liabilities underlying psychiatric traits with insulin-related measures introducing the concept of potential biologically informed subgroups in psychiatry.

P11.076.C DNA damage repair genes as modifiers of clinical outcomes in Cuban patients with Spinocerebellar Ataxia type 2

Luis Almaguer-Mederos[1;2], *Dany Cuello-Almarales*[3], *Raúl Aguilera-Rodríguez*[1], *Dennis Almaguer-Gotay*[1], *Yanetza González-Zaldivar*[1], *Suzana Gispert-Sánchez*[2], *Georg W. J. Auburger*[2]

[1]*Center for the Investigation and Rehabilitation of Hereditary Ataxias, Molecular Neurobiology, Holguín, Cuba;* [2]*Goethe University Frankfurt, University Hospital, Clinic of Neurology, Exp. Neurology, Frankfurt am Main, Germany;* [3]*Center for the Investigation and Rehabilitation of Hereditary Ataxias, Clinical Medicine, Holguín, Cuba*

Background/Objectives: DNA damage repair mechanisms have been associated with outcomes of disease severity in Huntington's disease and spinocerebellar ataxias, and are involved in the pathogenesis of these polyglutamine disorders. Here, we assess the role of 10 single nucleotide variants (SNVs) as candidate modifiers of clinical severity in a large cohort of patients with Spinocerebellar ataxia type 2 (SCA2).

Methods: A study involving 307 Cuban SCA2 patients was conducted. The *ATXN2* CAG repeat length was determined by PCR followed by polyacrylamide gel electrophoresis. Most SNVs (*MLH1* rs1800734, *MSH3* rs26279, *ERCC2* rs13181, *ERCC3* rs4150407, *ERCC6* rs2228528, *LIG1* Exon 6 A→C, *XRCC1* rs25487, *XRCC3* rs861539, and *OGG1* rs1052133), were assessed by PCR/RFLP; *MLH3* rs175080 was assessed by 4P-ARMS-PCR. The age at disease onset, SARA, and INAS scores were used as clinical outcome variables.

Results: All examined genotypes were in Hardy-Weinberg equilibrium ($p<0.05$). Age at onset was significantly associated with *MLH1* rs1800734, *ERCC3* rs4150407, *LIG1* Exon 6 A→C, and *OGG1* rs1052133. Nominally significant associations were also obtained between the SARA score and *XRCC1* rs25487, *XRCC3* rs861539, and *OGG1* rs1052133. Besides, the INAS score showed nominal significant associations with *MSH3* rs26279 and *MLH3* rs175080. Contributions of SNVs to clinical outcomes varied between 1.1 and 3.3 percent.

Conclusion: Evidence for modifier effects of SNVs on clinical outcomes of patients with Spinocerebellar ataxia type 2 is provided, suggesting that DNA damage repair pathways might be relevant to SCA2 physiopathology. However, further studies in additional SCA2 cohorts are needed to account for potential effects of population structure.

P11.077.D 25 years of genetic studies in movement disorders: in-depth insights from a cohort of >9,000 patients

Ana Filipa Brandão[1;2], *Alexandra Lopes*[1;2], *Miguel Alves-Ferreira*[1;2;3], *Ana Lopes*[1;2], *Sara Morais*[1;2], *Patrícia Isabel Marques*[1;2], *Fátima Lopes*[1;2], *Joana Sá*[1;2], *Rita Bastos Ferreira*[1;2], *Diana Pinto*[1;2], *Liliana Rocha*[1;2], *Paulo Silva*[1;2], *Maria João Sá*[1;2], *Jorge Sequeiros*[1;2;3], *João Parente Freixo*[1;2], **Jorge Oliveira**[1;2]

[1]*CGPP – Centre for Predictive and Preventive Genetics, IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Porto, Portugal;* [2]*i3S – Instituto de Investigação e Inovação em Saúde, Univ. Porto, Porto, Portugal;* [3]*ICBAS – School of Medicine and Biomedical Sciences, Univ. Porto, Porto, Portugal*

Background/Objectives: Movement disorders (MD) encompass neurological diseases with abnormal voluntary or involuntary movements. The genetic etiology of MD has advanced with next-generation sequencing (NGS) and gene discovery in recent years. Our aim is to delineate the mutational spectrum in a substantial cohort of MD patients from 1998 to 2023.

Methods: We reviewed our database for MD genetic studies (NGS multigene panel or fragment analysis), targeting disease-causing variants or those of unknown clinical significance (VUS).

Results: For hereditary ataxias due to repeats' expansions ($n = 2,836$) the diagnostic yield was 26.9%($n = 764$) [522 SCAs patients (mostly Machado-Joseph Disease/SCA3), 143 with FRDA and 99 CANVAS] and for non-repeat expansions by NGS ($n = 593$) 9.8%($n = 58$) had a molecular diagnosis, 49.1%($n = 291$) had VUS, and 41.2%($n = 244$) were negative.

Regarding Huntington's disease ($n = 2,203$), 44.0%($n = 973$) had a molecular diagnosis, 54.0%($n = 1189$) were negative, and ~2% reduced-penetrance disease-causing alleles.

For Parkinson's disease ($n = 318$), 10.7%($n = 34$) had a molecular diagnosis, 41.8%($n = 133$) had VUS, and no reported variants in 47.5%($n = 151$).

Concerning spastic paraplegia ($n = 495$), 21.0%($n = 105$) had a molecular diagnosis, 38.0%($n = 186$) had VUS and in 41.0% ($n = 204$) no variants were reported.

For dystonia ($n = 292$) 9.0%($n = 25$) had a molecular diagnosis, 51.0%($n = 150$) had VUS, while in 40.0%($n = 117$) no variants were reported.

Reassessment is ongoing to include >4,400 cases studied by single-gene analysis (Sanger seq. and/or MLPA), which will expand our results.

Conclusion: The diagnostic yield of MD patients was ~34%, mostly attributable to repeats' expansions. Further 14% have uncertain outcomes requiring clinical revaluation and/or additional studies for a definitive diagnosis. Globally, this data is crucial for developing a comprehensive genetic test, leveraged by ongoing NGS improvements.

P11.078.A Variation profiling of protein-coding genes in Bulgarian paediatric patients with specific language impairment

Iglika Sotkova-Ivanova[1;2], *Hristo Ivanov*[1;3], *Aleksandar Linev*[1;3], *Ivan Ivanov*[2;3], *Iliyana Pacheva*[1;2], *Nikolay Popov*[4], *Tihomir Vachev*[5], *Radoslava Vazharova*[6], *Vili Stoyanova*[1;3]

[1]*Medical University Plovdiv, Department of Pediatrics and Medical Genetics, Plovdiv, Bulgaria;* [2]*University Hospital "St. George" Plovdiv, Department of Pediatrics, Plovdiv, Bulgaria;* [3]*University Hospital "St. George" Plovdiv, Department of Medical Genetics, Plovdiv, Bulgaria;* [4]*Child Center Spectar, Povdiv, Bulgaria;* [5]*Plovdiv University "Paisii Hilendarski", Department of Plant Phisyology and Molecular Biology, Plovdiv, Bulgaria;* [6]*SU "St. Kliment Ohridski", Faculty of Medicine, Sofia, Bulgaria*

Background/Objectives: Specific Language Impairment (SLI) affects 7-10% of children, causing delayed speech development. The language deficit in SLI children is not due to cognitive, motor, sensory, or socio-emotional factors. Our study aims to characterize the variation profile of protein coding genes in SLI patients.

Methods: We conducted whole exome sequencing on 40 children with proven SLI and performed enrichment analysis of biological pathways using KEGG and Reactome.

Results: Sequencing and enrichment analysis revealed diverse genetic variants and interactions between genes associated with sound sensory processing, neural network development, axon guidance, and synaptic formation. We identified variants in new candidate genes: MSTO1, BAP1, PMABP1, and PRODH. The CACNA gene family, regulating calcium channels, and the CDH gene family, involved in cell adhesion and neuronal connectivity, emerged as compelling candidates.

Conclusion: Many variants linked to language deficits in our patients are implicated in pathways related to sound sensory processing. These genetic variants may coexist with other benign variants, leading to minor alterations in sound perception that result in SLI. Variants in genes associated with neural network development, axon guidance, and synaptic formation may subtly interfere with normal neural network development and functioning, resulting in impaired language abilities. The specific nature of the mutation and its impact on the function of their products may also contribute to the severity of the resulting phenotype. Further functional studies are warranted to fully comprehend the relationship between these mutations and SLI. This hypothesis offers a valuable framework for exploring the underlying mechanisms of this complex disorder.

P11.079.B A novel pathogenic *PTRH2* variant indicates seizure association with protein-truncating variants in Infantile-Onset Multisystem Neurologic, Endocrine and Pancreatic Disease (IMNEPD)

Ömer Çağrı Akçin[1], *Okan Kurtçu*[2], *Neşe Dericioğlu*[3], *Sevim Erdem Özdamar*[3], *Can Ebru Bekircan-Kurt*[3], *Şule Altıner*[2], *arda çetinkaya*[1;4]

[1]*Hacettepe University, Faculty of Medicine, Department of Medical Genetics, Ankara, Türkyie;* [2]*Ankara University, Faculty of Medicine, Department of Medical Genetics, Ankara, Türkyie;* [3]*Hacettepe University, Faculty of Medicine, Department of Neurology, Ankara, Türkyie;* [4]*Hacettepe University, Center For Genomics and Rare Diseases, Ankara, Türkyie*

Background: Infantile-Onset Multisystem Neurologic, Endocrine and Pancreatic Disease (IMNEPD) is an ultra-rare disorder with variable expressivity, resulting from biallelic loss-of-function variants in *PTRH2*. *PTRH2* encodes for peptidyl-tRNA hydrolase, possibly involved in release of peptides from stalled mitochondrial ribosomes, which is also involved in apoptosis.

Methods: Whole exome sequencing (WES) and detection of homozygosity regions were utilized to explore the disease-causing variant.

Results: Here, we report a novel IMNEPD-associated pathogenic *PTRH2* variant in a 24-year-old male born to consanguineous parents. The proband exhibited mild intellectual disability, sensorineural hearing impairment, absence seizures, demyelinating peripheral neuropathy, distal muscle weakness, pes equinovarus, ataxic gait and exocrine pancreatic insufficiency. He lacked significant motor delay in childhood. Cerebellar atrophy, endocrine abnormalities and hepatomegaly were absent. WES revealed a single homozygous nonsense variant within a homozygosity region, which results in a truncated PTRH2 protein (NM_016077.5:c.100C>T, p.Arg34Ter) lacking the hydrolase domain and part of mitochondrial localization sequence.

Conclusion: In contrast to previous studies associating severe disease phenotype with loss-of-function variants (PMID: 37239392), the proband had a mildly progressing clinical phenotype with previously unreported absence seizures. Non-absence seizures and EEG anomalies have only been associated with 4 of the 6 reported nonsense/frameshift variants and none of the 3 missense variants. For other phenotypic features, phenotypic variability is extensive even within the same families. In conclusion, we suggest that seizures in IMNEPD are associated with *PTRH2* genotypes leading to a truncated protein. However, the variability in other phenotypic features still need to be addressed, which are possibly explainable by *PTRH2*-independent causes.

P11.080.C World-second report of a family with familial narcolepsy, cataplexy and novel *MOG* variant

Jakub Trizuljak[1;2;3], *Jakub Duben*[1], *Tomáš Gyönyör*[2], *Zuzana Vrzalová*[1;3], *Renáta Michalovská*[4], *Věra Hořínová*[2;5]

[1]*University Hospital Brno, Department of Internal Medicine - Hematology and Oncology, Brno-Bohunice, Czech Republic;* [2]*University Hospital Brno - Children's Hospital, Department of Medical Genetics and Genomics, Czech Republic;* [3]*CEITEC MU, Czech Republic;* [4]*GHC GENETICS, s.r.o., Czech Republic;* [5]*Reprofit International Brno, Czech Republic*

Background/Objectives: Narcolepsy is a neurological disorder that is marked by the recurrent, sudden, uncontrollable compulsion to sleep. Narcolepsy is often associated with cataplexy, sleep paralysis, hypnagogic hallucinations (pre-sleep dreams), and automatic behaviours. Familial narcolepsy accounts for less than 10% of all narcolepsy cases. However, documented families are very rare and causative mutation has been identified only in one case. We present a 4-generational pedigree with autosomal dominant cataplexy and sleep disorder, caused by a novel mutation of myelin-oligodendrocyte glycoprotein (*MOG*) gene.

Methods: We performed whole exome sequencing (WES) and segregation analysis of both affected and healthy family members.

Results: WES identified a novel, likely pathogenic variant c.284G>C, (p.Arg95Pro, rs752019554) in *MOG* gene, segregating with sleep disorder and cataplexy in the family, but absent in unaffected family members. The affected individuals also show elevated prolactin serum levels. To date, only one Spanish family with *MOG* causal variant has been reported (Hor et al., 2011).

Conclusion: We present a second report of a family with autosomal dominant narcolepsy and cataplexy, segregating with a *MOG* likely pathogenic variant. These findings support a role for myelin and oligodendrocytes in disease susceptibility to this neurobehavioral disorder.

Grants: Supported by MUNI/A/1558/2023; MUNI/11/SUP/22/2020; European Regional Development Fund Project "A-C-G-T" CZ.02.1.01/0.0/0.0/16_026/0008448, and National Institute for Cancer Research LX22NPO5102 - Funded by EU - Next Generation EU.

P11.081.D Application of HiFi long-read genome sequencing reveals large 125 CAG repeat expansion in *HTT* in a patient with infantile Huntington's disease

Juliane Martinez Sena[1], *Christina Pontes*[2], *Roland Achmann*[3], *Rainer Koenig*[1], *Ulrich Seidel*[4], *Zafer Yüksel*[1], *Christian Betz*[1], *Hanno Bolz*[1]

[1]*Bioscientia Institute for Medical Diagnostics GmbH, Bioscientia Human Genetics, Ingelheim, Germany;* [2]*Heidelberg University Hospital, Pediatric Neurology, Heidelberg, Germany;* [3]*Labor Lademannbogen MVZ GmbH, Human Genetics, Hamburg, Germany;* [4]*Klinikum Worms gGmbH, Pediatric Neurology, Worms, Germany*

Background/Objectives: Huntington's disease (HD) is an autosomal dominant disorder caused by a CAG trinucleotide repeat expansion in the huntingtin gene (*HTT*). Repeat expansion correlates inversely with age of onset. HD is characterized by progressive decline of motor and cognitive function, and psychiatric changes, with onset mostly at 35-45 years. Infantile HD is rare and often accompanied by non-specific symptoms delaying the diagnosis. We describe a male with infantile HD and a large *HTT* repeat expansion.

Methods: The patient had previously been tested for HD in a reference laboratory using an established approach, triplet repeat-primed PCR (TP-PCR). After PacBio HiFi long-read whole-genome sequencing (LR-WGS) based on DNA from peripheral blood, data were processed using the tandem repeat genotyper (TRGT, PacBio). Further, samples from patients with confirmed repeat diseases (n = 8, FraX/*FMR1*, SCA1/*ATXN1*, SCA17/*TBP*, HD/*HTT*, BSMA/*AR*) were analysed by LR-WGS, and results compared with the respective repeat ranges identified by conventional tests.

Results: While TP-PCR displayed ">100, approximately 118 CAG repeats", LR-WGS identified 125 CAG repeats and repeat interruptions on the mutant *HTT* allele. LR-WGS results for the 8 additional samples from other repeat disorders closely or exactly corresponded to values identified by conventional methods.

Conclusion: HiFi LR-WGS represents a comprehensive approach for diagnosing pediatric patients with a differential diagnosis of HD. Although more comparative analyses are needed for *HTT* and other repeat disorder-associated loci, LR-WGS appears to be suitable for quantifying the respective expansions and additionally provides information on repeat interruptions as potential modifiers.

Background: Drug resistant focal epilepsy (DRFE) accounts for a significant proportion of epilepsy burden worldwide. DRFE-associated mutations can be brain-only somatic events often limited to the epileptogenic zone. Given their relatively low variant allelic fraction (VAF), their detection is challenging.

Methods: DNA was extracted from matched Fresh Frozen (FF) or Formalin-Fixed, Paraffin-Embedded (FFPE) brain and blood samples of 94 DRFE patients. We designed separate panels for Focal Cortical Dysplasia (FCD, 14 genes) and brain tumors (BT, 10 genes) using single molecule Molecular Inversion Probes (smMIPs).

Results: smMIPs sequencing obtained an adequate read depth required for the detection of low VAF variants. We obtained 3000X mean coverage for uncollapsed reads and target regions were covered with >200 unique reads on average. In the 175 tested samples, we identified a pathogenic variant in SLC35A2 with VAF 2.49% in FF lesional tissue of a FCD type I patient and not present in the blood, somatic mutations in MTOR with VAFs ranging from 1.07% to 5.89%, germline variants in DEPDC5, TSC1 and NPRL3 genes in brain-blood matched samples from FCD type II patients. We also detected BRAF somatic mutations (VAFs from 2% to 35%) and TP53 and IDH1 mutations in BT patients. For FFPE FCD type II samples, we discovered somatic mutations in RHEB, in MTOR and TSC2 (from 1.10% to 3.86%) and a germline pathogenic mutation in TSC1 gene.

Conclusion: smMIPs showed accurate detection of low-VAF mosaicisms in both FF and FFPE brain samples.

Grant: Italian Ministry of Health RF-2019-12370564

P11.083.B Diagnostic yield of chromosomal microarray analysis in 1.398 patients with autism spectrum disorder: A single Hospital experience over 9 years.

Anna Brunet-Vega[1], *Neus Baena*[1], *Laura Capel*[1], *Eduardo Perez-Romero*[1], *Núria Capdevila*[1], *Juan Pablo Trujillo Quintero*[1], *Carmen Manso*[1], *Victor Martinez-Glez*[1]

[1]*Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí (I3PT-CERCA). Universitat Autònoma de Barcelona., Center for Genomic Medicine, Sabadell, Spain*

Background/Objectives: Autism spectrum disorder (ASD) comprises a group of neurodevelopmental disorders characterized by impairment in social interaction, communication and behavioural challenges. Genetic factors play a role, and chromosomal microarray analysis (CMA) is a rapid and effective method for detecting copy number variants (CNV).

This work aims to evaluate the efficiency of using CMA as a first-line test in patients with ASD and to determine relevant CNV.

Methods: We enrolled 1.398 patients with ASD who underwent CMA between 2014-2023. Cases were evaluated by a clinical geneticist or neuropediatrician and had a clinical diagnosis of ASD (HP:0000717, HP:0000729, HP:0000753). An 8 × 60K array-CGH was performed on 714 patients and 4X180K exon-level on 684 patients.

Results: We identified pathogenic and likely pathogenic CNVs in 83 patients (59 males and 24 females), reaching an overall diagnostic yield of 6%. Most frequent CNVs were recurrent: 1q21.1 duplication (4 patients), 15q11.2 deletion (7 patients), 15q13.3 duplication (7 patients), 16q11.2 deletion (5 patients), 16p13.11 duplication (4 patients), and 22q11.21 duplication (4 patients). Nine patients carried unique large pathogenic CNVs (4-18Mb), 5 gains (2q31q33, 3q25q26, 16q21 and Xp11) and 4 losses (1p34, 4q34q35, 10q11 and 22q13). We highlight that 17% of pathogenic CNVs were small deletions (7.4 to 222Kb) of only one or few exons on *IMMP2L* (3 patients), *DMD* (2 patients), *TMLHE* (2 patients), SLC9A9, *PRKN*, *CNTNAP2*, *RBFOX1*, *GRIN2A* and *SHANK3* genes with an important role in neurodevelopment.

Conclusion: This series reaffirms the diagnostic yield of CMA in ASD and highlights the utility of exon-focus array-CGH for diagnosis.

Conflict of Interest: None declared

P11.084.C Investigating the early phases of psychosis in the light of human evolutionary genetics

Veronica Sandroni[1], *Qin He*[1], *Ridha Joober*[2], *Marie-Odile Krebs*[1;3], *Sebastien Jacquemont*[4], *Guy Rouleau*[5], *Boris Chaumette*[1;2;3]

[1]*Université Paris Cité, Institute of Psychiatry and Neuroscience of Paris (IPNP) - INSERM U1266, Paris, France;* [2]*McGill Université, Department of Psychiatry, Montreal, Canada;* [3]*GHU-Paris Psychiatrie et Neurosciences, Paris, France;* [4]*Centre de Recherche du Centre Hospitalier Universitaire Sainte-Justine, Montreal, Canada;* [5]*Montreal Neurological Institute and Hospital - McGill University, Department of Neurology and Neurosurgery, Montreal, Canada*

Background/Objectives: Schizophrenia appears gradually during adolescence after a period called ultra-high risk (UHR). The reasons why some UHR individuals convert (UHR-C) to a first-episode of psychosis (FEP) while other do not (UHR-NC) is poorly understood. We aim at testing the Olduvai domain, to explain this differential outcome. This domain is the highest amplified coding sequence in the human genome and six subtypes have been described: conserved (CON1-3), and human-lineage specific (HLS1-3). The number of copies has been associated with increased neuronal proliferation, brain volume, better cognitive performance, and symptoms severity in schizophrenia.

Methods: From a cohort of 396 individuals with Whole-Genome sequencing data (IlluminaSeq), we tested the association between the CON1 and HLS1 copy numbers and the evolution toward the disease (UHR-C, UHR-NC, FEP).

Results: CON1 mean copy number was 80.91 (± 4), 80.85 (± 3.76), and 81.29 (± 4.49) for UHR-NC, UHR-C and FEP respectively and no statistical difference was found. HLS1 mean copy number was 132.73 (± 22.44), 131.41 (± 15.41), and 148.24 (± 34.33) for UHR-NC, UHR-C and FEP respectively. Statistical difference in HLS1 copy number was found for UHR-NC vs UHR-C + FEP (p-value = 0.0002), UHR-C vs FEP (p-value = 7.10^{-7}), UHR-C vs UHR-NC vs FEP (p-value = 5.10^{-5}). No difference was found between UHR-NC and UHR-C.

Conclusion: CON1 copy number did not differ between UHR-NC, UHR-C and FEP. HLS1 copy number differed between the three groups with higher values in UHR-C and FEP.

P11.085.D Voltage-gated ion channels and their role in epilepsy

Magdalena Soukup Vodickova[1;2], *Barbora Jeřábková*[2], *Kamila Reblová*[2;3], *Lenka Fajkusova*[1;2]

[1]*Faculty of Science Masaryk University, National Centre for Biomolecular Research, Brno, Czech Republic;* [2]*University Hospital Brno - Children's Hospital, Centre of Molecular Biology and Genetics, Brno, Czech Republic;* [3]*Faculty of Medicine Masaryk University, Institute of Medical Genetics and Genomic, Brno, Czech Republic*

Background:

Epilepsy and epileptic syndromes are a group of heterogeneous neurological diseases characterized by spontaneous recurrent seizures caused by an imbalance of neuron excitability. Next-generation sequencing (NGS) brought to light multiple genes responsible for monogenic epilepsies. Some of the most commonly diagnosed genes are those coding voltage-gated ion channels. However, epilepsy management remains challenging, and patients often suffer from seizures even after receiving a diagnosis.

Methods: Patients with epilepsy underwent NGS-based targeted panel sequencing followed by bioinformatics analysis for variant detection.

Results: We have identified 53 pathogenic and probably pathogenic variants in our cohort of patients in eight ion channel genes. The most commonly diagnosed gene was *SCN1A*, which encodes alpha-1 subunit of the voltage-gated sodium channel Nav1.1. We have found a variant in *SCN1A* in 22 affected patients. Variants in this gene can cause a wide spectrum of phenotypes, and the management of epilepsy can defer depending on whether the variant is gain or loss of function. The second most common gene in our cohort, with 10 diagnosed patients, was *KCNQ2*, a gene encoding potassium channel subunit Kv7.2. *KCNQ2* is associated with neonatal epilepsies that can result either in benign familial neonatal epilepsy or in severe developmental epileptic encephalopathy. The localization of the variant within a protein may help predict the development of epilepsy.

Conclusion: This highlights the importance of finding genetic and molecular evidence supporting the pathogenic role of variants in ion channel genes. Moreover, these findings might play a crucial role in therapeutic approaches of precision medicine.

Conflict of Interest: None declared

P11.086.A Novel autism risk genes inferred by comparative sociogenomics and molecular network analysis

Alice Chiodi[1], *Francesca Anna Cupaioli*[1], *Ettore Mosca*[1], **Alessandra Mezzelani**[1]

[1]*Institute for Biomedical Technologies (CNR-ITB), National Research Council, Segrate (MI), Italy*

Background/Objectives: Autism spectrum disorders (ASD) are a group of complex neurodevelopmental conditions characterized by difficulty with social interaction and communication. Although ASD etiology is still uncertain, genetics play a key role: heritability is estimated at around 80% and thousands of autism risk genes have been reported in the Simons Foundation Autism Research Initiative (SFARI) database. Since some of these genes are involved in social behavior of different animals, including humans, we hypothesized that the genetic underpinnings of sociability should be in common and stable across multiple species and may be implicated in autism.

Methods: Network diffusion analysis was applied to 659 genes linked to sociability in several animals, including humans. The resulting top network was further studied in terms of communities, pathways and enrichment of SFARI genes.

Results: The top network, composed by 240 genes, is significantly associated with SFARI (46 genes, p < 10^-15), with 194 possible novel autism risk genes. Among the latter, the analyses highlighted cadherin and catenin family genes (*CDH-2/6/8, CTNN-A2/D1 and ARVCF*), acting in cell adhesion and cell-cell communication and involved in neurodevelopment. Impairment of *CDH2* and *CTNNA2* is related to blood-brain barrier immune cell transmigration, while of *CDH6/8* to a syndromic deafness.

Conclusion: Comparative sociogenomics, coupled with advanced bioinformatic methods, allows the identification of conserved gene networks involved in sociability and ASD. This approach is also powerful in predicting novel autism risk genes that, if validated, could represent novel biomarkers of the condition, shedding light on its complex etiology.

P11.087.B Additional Evidence of *ERBB4* as a Haploinsufficient Gene Associated with Neurodevelopmental Disorders

Irene Mademont-Soler[1;2], *Maria Camós-Carreras*[2;3], *Aida Palacín*[2;4], *Dolors Casellas-Vidal*[2;3], *Gemma Hernández-Gallego*[2;3], *Carles Garrido*[5], *Xavier Queralt*[1], *Susanna Esteba-Castillo*[2;4], *María Obón*[1;2]

[1]*Hospital Universitari de Girona Dr. Josep Trueta, Àrea de Genètica Clínica i Consell Genètic, Salt;* [2]*Institut d'Investigació Biomèdica de Girona (IDIBGI-CERCA), Salt;* [3]*Hospital Universitari de Girona Dr. Josep Trueta, Servei de Neuropediatria, Girona;* [4]*Institut Assistència Sanitària, Salt;* [5]*Reference Laboratory, Barcelona, Spain*

Background/Objectives: The gene *ERBB4* plays a crucial role in numerous neurobiological processes in both the developing and adult brain. It has been suggested that its haploinsufficiency may be related to intellectual disability (ID) or epilepsy, but evidence is still limited.

Methods: Array CGH was performed on a 6 year-old boy diagnosed with autistic spectrum disorder (ASD), who did not exhibit intellectual disability (ID) or language difficulties. Genetic studies were also conducted on five family members. All of them underwent a comprehensive evaluation covering cognition, mental health and behaviour.

Results: The proband presented a 310 Kb deletion of 2q34, involving exons 3-16 of the *ERBB4* gene. Both his father and paternal grandmother also carried the deletion and were diagnosed with ASD (without ID), although their phenotypes were milder. Mental health examination of non-carriers did not reveal any psychiatric disorder.

Conclusion: The identified intragenic deletion of *ERBB4* adds further evidence regarding the involvement of this gene in neurodevelopmental disorders and provides the first evidence of its association with ASD. Notably, expressivity appears to be variable among carriers, which is an important consideration when providing genetic counselling.

Grants: No grants were secured for this project.

Background/Objectives: Neurodevelopmental disorders (NDD) represent the most prevalent chronic disorders encountered in pediatric setting. Comprehensive care for individuals with NDD includes a search for an underlying etiologic diagnosis, primarily through a genetic evaluation. Recently, pathogenic variants in guanine nucleotide-binding protein, beta 1 (*GNB1)* gene have been identified as a cause of developmental delay. *GNB1*-encephalopathy is inherited in an autosomal dominant manner and is typically caused by de novo pathogenic variants, most of them missense variants in exons 6 and 7. So far, only around 60 cases with *GNB1*-encephalopathy have been reported.

Methods: Genetic testing was performed by whole exome sequencing.

Results: Here we present three cases with *GNB1* pathogenic variants, detected by WES analyses. Two novel pathogenic variants: c.1009A>G; p.Lys337Glu in exon 11 and c.343G>A; p.Gly115Ser in exon 7, occurring as de novo events were identified in a 33-years moderately affected male and 28-years mildly affected female patients, respectively, both with developmental delay and dystonia. A well-known pathogenic variant c.239T>A, p.Ile80Asn in exon 6 was identified in a male newborn with severe hypotonia and dysmorphic features and was inherited from a mosaic unaffected father.

Conclusion: In conclusion, our study describes the first cases of *GNB1*-encepholopathy in N. Macedonia with various phenotypes and contributes to the spectrum and associated clinical presentations of *GNB1* pathogenic variants.

P11.089.D Detection of a de novo loss-of-function variant in *KDM5A*: expanding the mutational and phenotypic spectrum of *KDM5A*-associated autism spectrum disorder

Kirstin Hoff[1], *Monika Kautza-Lucht*[1], *Daniel Kaschta*[1], *Christina Post*[2], *Katharina Schau-Römer*[1], *Inga Vater*[1], *Malte Spielmann*[1;2], *Inga Nagel*[1]

[1]*University Hospital Schleswig-Holstein Campus Kiel, Institute of Human Genetics, Kiel, Germany;* [2]*University Hospital Schleswig-Holstein Campus Lübeck, Institute of Human Genetics, Lübeck, Germany*

Background/Objectives: Despite the wide genetic and clinical variability of neurodevelopmental disorders (NDDs), proteins involved in NDD belong to only a few common frequently affected processes, including chromatin remodeling. In an individual with NDD and autism spectrum disorder (ASD), we report a de novo truncating variant in *KDM5A*, a lysine-specific histone H3 demethylase contributing to chromatin architecture modification.

Methods: Genome sequencing was performed on a four-year-old male patient and his parents. The patient exhibited NDD, ASD, macrocephaly, tall stature, urethral malformation and dysmorphic facial features.

Results: We could identify a de novo likely pathogenic variant c.1726C>T p.(Gln576*) in *KDM5A*. This variant, absent in population databases, introduces a premature termination codon, presumably resulting in protein truncation or nonsense mediated decay. It has been reported as an inherited variant of unknown significance in one individual with *KDM5A*-associated NDD (ClinVar-ID 1701668).

Conclusion: Little is known about KDM5A-associated NDDs, with potentially disease-relevant variants reported in both monoallelic and biallelic contexts. In a study by El Hayek et al. (2020, eLife), reduced levels of KDM5A were observed in a patient with a de novo loss-of-function variant. Recent functional studies indicate that KDM5A is essential for establishing hippocampal cell identity during early development. Given the hippocampus's involvement in NDDs and ASD, truncating variants in *KDM5A* may play a disease-relevant role.

P11.090.A Impact of de novo variants on epilepsy in neurodevelopmental disorders

Andrea Eoli[1;2], *Henrike Heyne*[1;2]

[1]*Hasso Plattner Institute for Digital Engineering gGmbH, University of Potsdam, Potsdam, Germany;* [2]*Icahn School of Medicine at Mount Sinai, Mount Sinai School of Medicine, New York, United States*

Background/Objectives: Epilepsy is often a comorbidity in neurodevelopmental disorders (NDDs), a significant proportion of which can be attributed to rare de novo variants (DNVs). Although previous studies identified more than 360 disease-associated genes, many more remain undiscovered at increasing sample sizes, which prompts the exploration of larger datasets.

Methods: To increase statistical power, we recruited and meta-analyzed eight different cohorts of parent-offspring trios of individuals with NDDs. After extracting DNVs from coding regions and harmonizing them across the cohorts, we applied a mutational model (DeNovoWEST) to compare each gene's observed *versus* expected DNV rate and discover novel genetic associations contributing to these complex phenotypes. Eventually, we compared DNVs in NDDs with versus without epilepsy, performing gene set enrichment analyses and phenotype enrichment analyses (using HPO terms).

Results: We meta-analyzed DNVs across 16,538 individuals diagnosed with different NDDs, of which 6,964 (42%) also had epilepsy, to identify disease genes associated with and without epilepsy. We compared DNVs in NDDs with versus without epilepsy.

Conclusion: With our findings, we gain insights into the pathobiology of epilepsy.

Grants: German Research Foundation (516649954).

P11.091.B The pathophysiology underlying congenital hydrocephalus

Marlene Dallmayer[1], *Karina Violou*[1], *Heymut Omran*[1], **Julia Wallmeier**[1]

[1]*University clinic Münster, Department of General Pediatrics, Münster*

Consortium: Hydrocephalus-Study Group

Background/Objectives: One in 1.000 newborns suffers from accumulation of cerebrospinal fluid, referred to as hydrocephalus, which is frequently caused by intracranial hemorrhage, infections or tumors. In about 10% of cases there is no external cause of hydrocephalus. In this group genetic defects have been identified underlying hydrocephalus development. Whereas some genetic defects are associated with cortical malformations, or multi-systemic disorders such as ciliopathies, RASopathies or craniosynostosis others only cause enlarged ventricles.

Methods: We performed whole exome sequencing / whole genome sequencing analyses in 62 affected (27 hydrocephalus only / 35 hydrocephalus + brain malformation). We first applied a virtual panel including 190 genes previously associated with hydrocephalus. Next, we performed virtual panels (~500 genes) for ciliopathies, brain malformations, craniosynostosis, RASopathies as well as congenital disorders of glycosylation.

Results: Utilizing the „Hydrocephalus"-panel we identified variants in eight families in seven different genes (*CCDC40, KIAA1109, L1CAM, MPDZ, POMGNT1, POMGNT2*), which we considered likely disease causing. These were very rare (<0.001 (aut.-rez.), <0.0001 (dom.)) nonesense-mutations or considered likely disease causing in Varsome. Applying the combined virtual panel, we identified five additional variants in *SMARCA4, TUBB4B*, *SLC12A6, KRAS* and *CDH2*, which were very rare and either homozygous or inherited de novo.

Conclusion: Consistent with previous reports we were able to identify the underlying genetic defect in ~ 20% of patientents with idiopathic hydrocephalus. Our data point to specific pathophysiological entities causing congenital hydrocephalus in the heterogenous group of disorders with idiopathic hydrocephalus. However, there is still a large group of genetically and pathophysiolgically unsolved cases.

Background/Objectives: Bi-allelic pathogenic variants in the *DMXL2* gene(MIM# 612186) have recently been recognized as a cause of Ohtahara syndrome, a very severe form of early-infantile developmental and epileptic encephalopathy(EIDEE). *DMXL2* encodes a vesicular protein highly expressed in brain and involved in autophagy. To date, six patients with this condition have been reported.

Herein, we describe new cases of DMXL2-related EIDEE.

Methods: A series of six unrelated patients with EIDEE and harboring novel homozygous variants of *DMXL2* was assembled through an international collaboration using GeneMatcher and the European Reference Networks(ITHACA and EPiCARE).

Results: All affected individuals were born to consanguineous parents. Family history was notable for decreased affected siblings and for deafness in two distinct cases.

Clinical findings were consistent with neonatal onset and drug-resistant seizures, suppression-burst pattern on EEG recordings, profound developmental delay with severe hypertonia, quadriparesis, peripheral polyneuropathy and sensorineural hearing impairment.

Repeated brain MRI scans showed progressive grey and white matter abnormalities including hypomyelinisation and leukodystrophy.

Genetic testing was based on exome(n = 3) or genome sequencing(n = 3). Six novel biallelic *DMXL2* pathogenic variants were identified including two splice site variants, a missense substitution, a nonsense variant, a deletion and a duplication. These variants were predicted to be damaging by in silico tools. Family segregation analysis showed parents to be heterozygous carriers for the causative mutation

Conclusion: Our results support the presence of core features and contribute to widen the genotypic spectrum of *DMXL2*-retated EIDEE. We consider performing functional studies to broaden our knowledge of the pathomechanism of *DMXL2* variants.

P11.093.D Evaluation of the hTERT-MNS16A variant and leukocyte telomere length in patients with cannabinoid or synthetic cannabinoid use disorder

*Sacide Pehlivan[1], Ayşe Feyda Nursal[2], **Hasan Mervan Aytac**[3], Yasemin Oyacı[3], Eren Aytaç[4], Mustafa Pehlivan[5]*

[1]Istanbul Faculty of Medicine, Istanbul University, Department of Medical Biology, Istanbul, Türkyie; [2]Faculty of Medicine, Hitit University, Department of Medical Genetics, Çorum, Türkyie; [3]Institute of Graduate Studies in Health Sciences, Istanbul University, Istanbul, Turkey, Istanbul, Türkyie; [4]Konya Beyhekim Training and Research Hospital, Department of Psychiatry, Konya, Türkyie; [5]Basaksehir Cam and Sakura City Hospital, Department of Hematology, Istanbul, Türkyie

Background/Objectives: Recent studies have reported that cannabis use predicts epigenetic changes associated with accelerated aging. The variable number of tandem repeats (VNTR) MNS16A in the human telomerase reverse transcriptase (*hTERT*) gene organizes the extension of telomeres. Therefore, we aimed to evaluate the relationship of the *hTERT* MNS16A VNTR variant and leukocyte telomere length (LTL) with the risk of cannabinoid or synthetic cannabinoid use disorder (CUD/SCUD).

Methods: A total of 228 subjects, including 147 CUD/SCUD patients and 81 healthy controls participated in the study. The MNS16A VNTR was genotyped using polymerase chain reaction (PCR). Relative LTL was quantified by real-time PCR. For a single-copy gene (S), the T/S ratio (telomere, T) was determined; LTL was expressed as the relative T/S ratio, and the relative quantification of telomeric DNA, rather than its absolute length, was assessed.

Results: There was no significant difference between patients and controls in terms of MNS16A VNTR genotype distribution. There was no relationship found between MNS16A VNTR genotype distribution and clinical symptoms. The log-transformed T/S ratio showed that LTL shortening was greater in the patient group than in the controls ($p = 0.001$). Psychotic symptoms and violent behavior were more common in patients with LTL fold changes L˃1 ($p = 0.022$ and $p = 0.011$, respectively). Also, substance usage time was higher in patients with LTL fold changes L˃1 ($p = 0.033$).

Conclusion: Although our results showed that the MNS16A VNTR variant was not a risk factor for CUD/SCUD, we found that LTL shortening was present in patients.

Grants: This research received no specific grant.

P11.094.A Lessons learnt from a genotype-first analysis of voltage-gated ion channels

Nathan Routledge[1], *Reza Maroofian[1], Stephanie Efthymiou[1], Rauan Kaiyrzhanov[1], Henry Houlden[1]*

[1]UCL Queen Square Institute of Neurology, London, United Kingdom

Background/Objectives: Voltage-gated ion channels (VGCs), comprising over a hundred genes, regulate neuronal action potential and trigger multiple ion-dependent processes. While some VGCs are linked to channelopathies like epilepsy and developmental epileptic encephalopathy, many remain unassociated. The study of ion channels is a promising avenue for successful treatment development, as understanding their functional and malfunctioning processes can lead to novel corrective treatments. The highly conserved and analogous structure of ion channel alpha units across channels enhances the value of variant observations in one channel for understanding others.

Methods: Using a genotype-first strategy, we screened the Queen's Square Institute of Neurology genomic database, housing 30,000 exomes from diverse backgrounds, focusing on Sodium VGC genes. This approach aimed to assess the genetic epidemiology and prevalence of channelopathies, exploring the clinical and genetic spectrum within a substantial dataset.

Results: Analyzing 3,947 variants indicated a prevalence of higher-than-variant-of-uncertain-significance (VUS) classifications in voltage-gated and pore-forming domains across nine channels. *SCN8A* exhibited a unique pattern, with a concentration of higher-than-VUS variants in the C-terminal. Surprisingly, likely pathogenic variants were found in unexpected contexts, including healthy individuals. While novel homozygous cases were identified in *SCN1A* and *SCN3B*.

Conclusion: The study's outcomes highlight the voltage-sensor and pore-forming domains as hotspots in Sodium VGCs, validating existing knowledge while proposing a distinct hotspot in *SCN8A*. Adopting a genotype-first diagnostic approach may uncover new causal genes and inheritance patterns. However, the robustness of variant classifications warrants scrutiny. This analysis underscores the dynamic nature of channelopathies and emphasizes the need for ongoing evaluation in variant classification methodologies.

Background/Objectives: SLC4A10 encodes a plasma membrane-bound ion transport protein, which mediates Na + -dependent HCO3− import thus mediating net acid extrusion. Recently neurodevelopmental disorders have shown in Slc4a10 knockout (KO) mice including collapsed brain ventricles, an increased seizure threshold, also mild behavioral abnormalities, impaired vision, and deafness. It is not reported before that pathogenic variants in SLC4A10 have been associated with monogenic human disease traits.

Methods: In an extensive international data sharing, we performed exome/genome sequencing and identified 11 patients from 6 independent families with biallelic predicted-damaging variants in SLC4A10. A minigene assay, localization studies, intracellular pH recordings, and protein modelling were performed to study the possible functional consequences of the variant alleles. Clinical features, neuroimaging data, and facial images were reviewed by a group of clinical geneticists, neurologists.

Results: The cohort contains 8 rare/ultra-rare biallelic SLC4A10 variants, which segregate with the disease within the families. Patients' conditions are characterised by global developmental delay/intellectual disability and central hypotonia, microcephaly, cerebellar ataxia, epilepsy, and facial dysmorphism. Neuroimaging features range from some non-specific to distinct neuroradiological findings. 6/7 missense variants affect evolutionarily highly conserved residues and are predicted to be damaging according to various in silico analyses. Functional analyses supported the pathogenic effect for 4/7 missense variants.

Conclusion: We provide evidence that pathogenic biallelic SLC4A10 variants can lead to neurodevelopmental disorder. We also demonstrate the challenges of assessing sequence variants identified in patients and distinguishing pathogenic variants from other potentially functional variants.

Conflict of Interest: None declared

P11.096.C Biallelic loss-of-function variants in *IST1* are associated with a complex neurologic disorder

Annette Lischka[1], Katja Eggermann[1], Andrea Maier[2], Dimah Hasan[3], Lena Franken[1], Emilia Michalewicz[4], Rebekka Götzl[5], Tibor Karl Lohmann[4], Martin Häusler[6], Miriam Elbracht[1], Ingo Kurth[1], Florian Kraft[1], **Cordula Knopp**[1]

[1]Institute of Human Genetics and Genomic Medicine, RWTH Aachen University, Aachen, Germany; [2]Medical Treatment Center for Adults with Intellectual Disabilities and/or Severe Multiple Disabilities, RWTH Aachen University, Aachen, Germany; [3]Department of Diagnostic and Interventional Neuroradiology, RWTH Aachen University, Aachen, Germany; [4]Department of Ophthalmology, RWTH Aachen University, Aachen, Germany; [5]Department of Plastic Surgery, Hand and Burn Surgery, RWTH Aachen University, Aachen, Germany; [6]Division of Neuropediatrics and Social Pediatrics, Department of Pediatrics, RWTH Aachen University, Aachen, Germany

Background:

IST1 (increased sodium tolerance 1) is an atypical member of the endosomal sorting complexes required for transport-III (ESCRT-III). For several ESCRT-III proteins (CHMP1A, CHMP2A, CHMP3, VSP4) as well as other direct interaction partners of IST1 like SPART or SPAST, complex neurologic or neurodegenerative disorders have been reported. However, *IST1* has not been associated with a human phenotype.

Methods: Trio WES was performed in an index patient and his parents. *IST1* protein expression was studied in patient-derived fibroblasts using western blot (WB) analysis. We are currently conducting functional studies on fibroblasts to show possible effects on cytokinesis, autophagy and endosomal morphology.

Results: Compound heterozygous loss-of-function (LOF) variants in *IST1* (NM_001270975.2:c.151C>T, p.(Arg51*); c.792T>A, p.(Tyr264*)) were identified in the patient. Complete loss of IST1 protein in fibroblasts was demonstrated by WB. The 20-year-old patient showed intellectual disability, tetra spasticity, hypotension of the trunk, optic nerve hypoplasia, nystagmus, microcephaly, short stature, and underweight. cMRI at the age of 14 years showed bilateral diffuse hypomyelination of the supratentorial white matter with slight reduction in brain volume of cerebrum and brainstem.

Conclusion: The clinical features of our patient resemble neurological diseases that are caused by genes that are direct

interaction partners of *IST1*. This implicates that biallelic LOF variants in *IST1* are associated with a neurological disorder that is clinically characterized by features of complex hereditary spastic paraplegia and hypomyelinating leukodystrophy. Additional patients are needed to confirm the link between *IST1* and neurological disease.

Conflict of Interest: None declared

P11.097.D Clinico-genetic findings in a cohort of 2750 frontotemporal dementia patients

Guillaume Cogan[1;2], Isabelle Leber[2], Dario Saracino[1], Foudil Lamari[1], Khrouf Walid[1], Julie Bogoin[1], Isabelle David[1], Patricia Moreau[1], Anne-Laure Fauret[1], Lionel Arnaud[1], Marion Houot[2], Eric Le Guern[1;2], **Fabienne Clot**[1]

[1]Assitance Publique - Hopitaux de Paris, La Pitié-Salpêtrière, Medical genetics; [2]Paris Brain Institute

Background/Objectives: Frontotemporal dementia (FTD) is the third most frequent neurodegenerative dementia after Alzheimer and Lewy body disease. It encompasses different clinical sub-types including behavioral variant of FTD (bvFTD), non-fluent variant Primary Progressive Aphasia (nfvPPA) and semantic variant PPA (svPPA). It can be associated with Parkinsonism, apraxia and motor neuron disease (MND). Genetics play an important role since approximatively 40% of cases have a positive family history of neurologic disorders, predominantly with a dominant pattern. Global genetic diagnostic yield in FTD vary greatly from 10 to 38% depending on cohorts and studies design. However, the relative small size of cohort (less than 1000) limit the ability to draw a comprehensive view of the phenotype-genotype correlation in FTD.

Methods: Using a three-steps genetic screening strategy, we report the genetic architecture of a French diagnostic cohort including 2750 index cases with sporadic or familial FTD.

Results: Overall diagnostic yield is 11.5% (n = 316). *C9orf72, GRN* and *MAPT* altogether represent 91% of diagnoses. We further performed multiple statistical analyses to decipher the association between all possible clinical variables (gender / clinical sub-type / type of FTD-associated symptoms / age at onset / positivity and type of family history etc.) and the probability to identify a causal variant.

Conclusion: Those results enable to suggest new guidelines for the genetic diagnosis strategy of FTD. We hope this cohort – the largest to date - will help European genetics and neurology departments to provide accurate genetic tests for FTD patients.

P11.098.A Epilepsies of presumed genetic etiology show enrichment of rare variants that occur in the general population

Linnaeus Bundalian[1], Yin-Yuan Su[2], Siwei Chen[3], Akhil Velluva[1], Anna Kirstein[4], Antje Garten[4], Saskia Biskup[5], Florian Battke[5], dennis lal[3], Henrike Heyne[6;7], Konrad Platzer[1], Chen-Ching Lin[2], Johannes Lemke[1], **Diana le Duc**[1;8]

[1]Institute of Human Genetics, University Hospitals Leipzig; [2]Institute of Biomedical Informatics, National Yang Ming Chiao Tung University; [3]Analytic and Translational Genetics Unit, Broad Institute of MIT and Harvard; [4]Pediatric Research Center, University Hospitals Leipzig; [5]CeGaT GmbH; [6]Program in Medical and Population Genetics, Broad Institute of MIT and Harvard; [7]Hasso-Plattner-Institut for Digital Engineering, University of Postdam; [8]Clinical Genetics, Center for Diagnostics GmbH at Chemnitz Clinics

Consortium: Epi25 Collaborative

Background/Objectives: Previous studies suggested that severe epilepsies, e.g., developmental and epileptic encephalopathies (DEEs), are mainly caused by ultra-rare de novo genetic variants. For milder disease, rare genetic variants could contribute to the phenotype.

Methods: To determine the importance of rare variants for different epilepsy types, we analyzed a whole-exome sequencing cohort of 9,170 epilepsy-affected individuals and 8,436 control individuals. Here, we separately analyzed three different groups of epilepsies: severe DEEs, genetic generalized epilepsy (GGE), and non-acquired focal epilepsy (NAFE). We required qualifying rare variants (QRVs) to occur in control individuals with an allele count ≥ 1 and a minor allele frequency ≤ 1:1,000, to be predicted as deleterious (CADD ≥ 20), and to have an odds ratio in individuals with epilepsy ≥ 2.

Results: We identified genes enriched with QRVs primarily in NAFE (n = 72), followed by GGE (n = 32) and DEE (n = 21). This suggests that rare variants may play a more important role for causality of NAFE than for DEE. Moreover, we found that genes harboring QRVs, e.g., HSGP2, FLNA, or TNC, encode proteins that are involved in structuring the brain extracellular matrix.

Conclusion: The present study confirms an involvement of rare variants for NAFE that occur also in the general population, while in DEE and GGE, the contribution of such variants appears more limited.

Grants: EKFS 2020_EKEA.42 to D.L.D.

P11.099.B Preliminary investigation on the contribution of risk alleles and copy number variants in Indian schizophrenia patients.

K Naga Mohan[1], *Minali Singh[1]*

[1]Birla Institute of Technology & Science Pilani, Hyderabad Campus, Biological Sciences, Secunderabad, India

Background: Schizophrenia is a complex disorder with multiple etiologies of which genome-scale studies focusing on genetic risk identified multiple risk alleles and CNVs. However, most data are on Caucasian patients and negligible from Indians. We conducted a pilot study to test the presence of risk-conferring SNPs and CNVs in patients and controls from South India.

Methods: DNA samples from 168 controls and 168 patients were analyzed using PsychArrays, followed by GenomeStudio, PLINK1.9 and PennCNV. Further analysis involved publicly available data from SZDB2.0.

Results: Medium-sized deletions (100 kb – 1Mb) occurred at a significantly higher frequency in patients ($p = 4.5E-5$; FDR = 2.7E-5). Of the total 30 CNVs identified of interest, 13 were previously reported; 17 had candidate genes with either de novo mutations or methylation or expression abnormalities. 4q35.1-35.2 duplication containing *TLR3* with a reported intronic variant, expression and methylation abnormality in schizophrenia occurred at a significantly higher frequency in controls ($p = 0.02$).

GWAS yielded five variants in *NTM* (FDR adjusted $p = 1E04$) and an overall, 17 variants that showed significant differences between controls and patients ($p = 1E03$-$1E04$). Of these, 12 were reported by the Psychiatric Genomics Consortium (PGC).

Conclusions: This pilot indicated potential of replication of PGC-identified risk-conferring SNPs, reported as well as unreported CNVs containing candidate genes. This lays the foundation for replication studies on larger samples from India.

P11.100.C The analysis of NGS data revealed a high incidence of pathogenic tandem repeat expansions in Czech patients with rare neurological diseases

Alena Musilova[1], *Petra Lassuthova*[1], *Lucie Sedlackova*[1], *Zuzana Musova*[2], *Anna Uhrova Meszarosova*[1], *Barbora Straka*[1], *Dana Safka Brozkova*[1]

[1]*Second Faculty of Medicine, Charles University and University Hospital Motol, NGL Laboratory, Department of Pediatric Neurology, Prague, Czech Republic;* [2]*Second Faculty of Medicine, Charles University and University Hospital Motol, Department of Biology and Medical Genetics, Prague, Czech Republic*

Background/Objectives: Tandem repeats (TR) are DNA regions of tandemly repeated nucleotide motifs. They are highly polymorphic, with very high mutation rates. Pathogenic TR expansions represent causal genetic events for various diseases (mainly neurological).

Methods: TR expansions were analyzed in patients who underwent whole-exome (WES) or whole-genome sequencing (WGS) of blood-derived DNA for the diagnosis of a rare neurological disease. The analysis was performed by the bioinformatic tool ExpansionHunter on the known set of 65 TR sites associated with disease onset in published literature.

Results: In our cohort of 1123 patient samples (1070 WES, 53 WGS) we discovered 99 TR loci within the pathogenic range in 95 (8.46 %) patients (84 WES, 11 WGS). Causal pathogenic TR expansions for the patient primary neurological disease were found in 5 patients in the genes *AR*, *CNBP*, and *DMPK*. Twelve patients were disease carriers with a pathogenic TR expansion in the genes *DMD*, *FXN*, *PABPN1*, *PRDM12*, *VWA1*, and *ZIC3*. As secondary findings, we also detected pathogenic TR expansions in the genes *HOXD13*, *HTT*, *NIPA1*, *PHOX2B, RUNX2, TCF4*, and *ZIC3*. The majority (71) of these pathogenic TR expansions were located in the *TCF4* gene. *TCF4* expansions are known to cause Fuchs endothelial corneal dystrophy, which has a high incidence in the Caucasian population.

Conclusion: TR analysis of WES and WGS data is profitable in the diagnostics of patients with rare neurological diseases and for discovering disease carriers, which is important for the prevention of disease reoccurrence in the family.

P11.101.D A case of an Angelman syndrome caused by intragenic duplication of *UBE3A* uncovered by adaptive nanopore sequencing

Laura Holthöfer[1], *Stefan Diederich*[1], *Lioba Lehmann*[1], *Charlotte Hewel*[1], *Susann Schweiger*[1], *Susanne Gerber*[1], *Matthias Linke*[1]

[1]*Institute for Human Genetics, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, Germany*

Background/Objectives: Angelman syndrome patients are characterized by severe intellectual disability, speech impairment, ataxia, epilepsy and distinct behavioural profiles. It is caused by a loss of function of the maternal copy of *UBE3A* and other genes on chromosome 15q11–13. AS is a genomic imprinting disorder underlying four possible molecular mechanisms: (1) deletions of the imprinted region on 15q11.2q13 on the maternal allele, (2) maternally inherited *UBE3A* genomic point mutations, (3) imprinting defects causing aberrant DNA methylation within chromosome 15q11–q13 and (4) uniparental disomy (UPD) of the paternal chromosome 15q11–q13.

Methods: Barcoded Nanopore libraries were subject to adaptive sampling of medically relevant regions with parent-of-origin methylation or Epi-variants.

Results: Adaptive Nanopore sequencing as a diagnostic method for imprinting disorders and episignature analysis revealed an intragenic duplication of Exon 6 and 7 in *UBE3A* (NM_000462.5) in a patient with relatively mild Angelman-like syndrome. In an all-in-one nanopore sequencing analysis DNA hypomethylation of the *SNURF*:TSS-DMR, known contributing deletions on the maternal allele and point mutations in *UBE3A* were excluded. In contrast, breakpoints and orientation of the tandem duplication could clearly be defined. Segregation analysis in the family showed that the duplication derived de novo in the maternal grandfather.

Conclusion: To our knowledge, this is the first report on a family with an intragenic

tandem duplication of Exon 6 and 7 in *UBE3A* causing Angelman syndrome. Our study shows the benefits of an all-in-one nanopore sequencing approach for the diagnostics of Angelman syndrome and other imprinting disorders.

Background/Objectives: Alzheimer's disease (AD) is the most common form of dementia. Neurofibrillary tangles, β-amyloid plaques, and neuronal death in specific brain regions are the characteristics of the disease. Amyloid beta has ability to translocate to nucleus and induce gene transcription, thus it may function as a transcription factor. We identified Jun, Fos, and RELA transcription factors have direct interactions with Aβ by using FpClass prediction tool. These transcription factors regulate the expression of mitochondrial Phosphoenolpyruvate Carboxykinase 2 (PCK2) protein. PCK2 is known to be a key enzyme in the gluconeogenic pathway. In the brain, mitochondria are the main sources of ATP to supply the high energy demands of neurons so that PCK2 protein could have a significant effect on both neuronal activity and neurodegeneration. We hypothesized that PCK2 levels in cerebrospinal fluid (CSF) of AD patients may be linked to the disease's progress and could be used as a biomarker.

Methods: CSF levels of PCK2 were determined by ELISA in 48 Alzheimer's patients, 12 mild cognitive impairment (MCI) patients, and 14 age-matched cognitively healthy individuals. Graphpad Prism was used for the statistical analysis. $p < 0.05$ was considered statistically significant.

Results: The results indicated that PCK2 levels were lower in AD patients compared to control group. PCK2 levels were also lower in MCI patients but this was not statistically significant.

Conclusion: This is the first study investigating the possibility of PCK2 as a biomarker that may be monitored in CSF of Alzheimer's patients.

Grants: This project was supported by IUCBAP (project no:37292).

Background/Objectives: Cerebral palsy (CP) is a group of disorders that involves permanent, non-degenerative motor function deficits. Regardless of the presence of prenatal and perinatal risk factors, CP is linked to an underlying genetic cause, despite its unclear origins. This genetic landscape overlaps with neurodevelopmental disorders, including brain malformations, epilepsy, and autism.

Parental sequencing, or 'trio-WES,' is used to assess the many variations in the index patient using whole exome sequencing (WES). Our approach aims to enhance diagnostic precision by using trio-WES data and reanalyzing clinical and WES data from unresolved cases in the Turkish CP cohort.

Methods: In the Turkish cohort, unsolved cases with CP and CP-like symptoms were selected according to essential criteria for CP clinical diagnosis. Biological materials and omics data from consenting patients were integrated into the ACU-Biobank. Genome analysis was conducted with our custom-built genome analysis pipeline. When necessary, candidate variants were confirmed by Sanger sequencing following variant filtering and prioritizing.

Results: Exome analysis revealed that 41% (26/63) of patients carried pathogenic or likely pathogenic variants, including 8 novel variants, causing or increasing risk of CP. *SPAST, KIF1A, and COL6A1* each harbor two or more candidate variants. Also, VUS were detected in 33% (21/63) of cases within genes correlating to the observed phenotypes. Notably, Trio-WES revealed de novo mutations in *KIF1A* and *SYNGAP1* genes.

Conclusions: These preliminary findings highlight the intricate genetic landscape of CP. Further research will significantly contribute to identifying the genetic etiology of CP and improving precision in differential diagnosis.

P11.104.C Oligogenic inheritance in sporadic Parkinson disease: a retrospective study

Chiara Fallerini[1;2], *Elena Pasquinelli*[1;2], *Samantha Minetto*[1;2], **Giulia Casamassima**[1;2], *Anna Maria Pinto*[3], *Lucia Monti*[4], *Alessandra Renieri*[1;2;3]

[1]*Med Biotech Hub and Competence Center, University of Siena, Department of Medical Biotechnologies, Siena, Italy;* [2]*Medical Genetics, University of Siena, Siena, Italy;* [3]*Genetica Medica, Azienda Ospedaliero-Universitaria Senese, Siena, Italy;* [4]*Unit of Neuroimaging and Neurointervention, "Santa Maria alle Scotte" Medical Center, Siena, Italy*

Background/Objectives: About 15% of Parkinson disease (PD) cases are considered monogenic rare disorders due to one (dominant) or 2 (recessive) mutations in one gene, transmitted following Mendelian rules. However, some hints indicate that in the remaining cases, genetics is likewise relevant, but the number and the nature of genes involved is still unclear. Here we explore the hypothesis that combination of rare variants in a handful of genes is the major etiology and pathophysiology in sporadic PD.

Methods: We performed exome-sequencing in a cohort of 14 sporadic PD patients and 26 controls analysing a panel of 68 genes involved in either PD or Parkinsonism (PanelApp).

Results: Gene combination analysis reveals that each patient has at least one rare variant in one of the three areas of PD pathophysiology: endolysosomal/lysosomal function (*LRRK2, VPS35, ATP13A2, GBA, LYST, ATP1A3, ATP6AP2, VPS13A*), synaptic vesicle trafficking (*SYNJ1, RAB39B, SNCAIP, SLC6A3, TH*) and mitochondrial impairments (*PINK1, HTRA2, PANK2, PLA2G6, c12orf12, COASY*), often in addition with one gene related to calcium (*PDGFB*) or magnesium (*SLC30A10*) deposits, dopaminergic neuron transcription factor (*NR4A2*),neuroinflammation (*GNR*) or axonal transport (*TUBB4A, MAPT, or DICTN1*).

Conclusion: Rare variants in PD/Parkinsonism genes are the main genetic determinant in sporadic PD with a sensitivity of 0.75 and specificity of 0.86 for PD recognition. This is relevant for clinical policy (identification of patients at risk in the population), clinical practice (identification of specific gene card for personalized treatment, including gene editing) and future research (for better understanding pathophysiological mechanisms).

Background/Objectives: Congenital Central Hypoventilation Syndrome (CCHS) is a rare autosomal dominant genetic disorder, characterised by abnormal ventilatory response to hypoxia and

hypercapnia, associated with heterozygous PHOX2B mutations. More than 80% of the variants are expansions from +4Ala to +13Ala of the polyalanine stretch, thus leading to cytoplasmic protein retention and aggregation. Little is known about the pathogenesis of CCHS. We applied transcriptomics to identify the pathways deregulated by the severe +13Ala mutation and to evaluate how a pharmacological treatment can recover a correct cellular phenotype.

Methods: RNA-sequencing was performed in cells expressing PHOX2B-WT and PHOX2B+13Ala, treated or not with 17AAG, an analogue of the antibiotic Geldanamycin, followed by GSEA analysis. Among the pathways resulted differentially involved in PHOX2B+13Ala pathogenesis, the production of reactive oxygen species (ROS) and cell cycle progression were validated in vitro.

Results: Consistent with the in-silico analysis, a relevant oxidative status, i.e. increased ROS production and stress-induced hypoxic cells, was confirmed in the presence of expanded PHOX2B protein compared to WT. A delayed cell cycle was also revealed by RNA-sequencing analysis in PHOX2B+13Ala cells, along with reduced percentage of G2 cells in PHOX2B+13Ala compared to PHOX2B-WT, implying a cell block at the S-G2 checkpoint.

Conclusion: RNA-sequencing is a promising approach to study the pathogenesis of CCHS in vitro. A transcriptome study of mesenchymal cells from CCHS patients carrying different PHOX2B mutations is also underway.

Grants: This work was supported by both the 2016 CCHS-Pilot Grant Awarded by the CCHS Family Network and "Associazione Italiana per la Sindrome da Ipoventilazione centrale Congenita" (AISICC)

Background/Objectives: Tubulinopathies encompass a spectrum of rare central nervous system malformations, classically featuring variable combinations of microlissencephaly, lissencephaly, pachygyria, polymicrogyria, cortical dysplasia, and characteristic abnormalities in the basal ganglia, thalami, corpus callosum, cerebellum, and brainstem. Typically, patients exhibit varying degrees of neurodevelopmental disorders, along with epilepsy, hypotonia, and features associated with autism spectrum disorders (ASD).

Several genes encoding different alpha or beta tubulins are implicated in these pathologies. *TUBB2A* pathogenic variants were first described in 2014 in a patient with neurodevelopmental disorders and typical brain anomalies associated with tubulinopathies. Since then, twelve patients have been reported, some of them having more subtle abnormalities, or even normal brain MRI (one patient).

Methods and Results: Here, we report on a new series of patients carrying de novo missense variants in *TUBB2A*, to better understand the phenotype associated with this disorder. Some patients, notably, exhibit mild to severe neurodevelopmental disorders with epilepsy and autistic traits, along with mild and inconspicuous brain anomalies. As suggested by recent literature on this gene, we hypothesize that the phenotypic spectrum associated with variations in the *TUBB2A* gene may extend to patients with neurodevelopmental disorders but without the brain anomalies typically described in tubulinopathies.

We also present challenges in interpreting variations within the *TUBB2A* gene due to sequence homology with several homologous genes and pseudogenes. We propose a technological variant confirmation pipeline to overcome these challenges.

A collaboration is about to commence to study the impact on neuronal migration in a murine model with several identified variations in the cohort.

Conflict of Interest: None declared

P11.107.B Recurrent *PACS2* variant in two children with developmental and epileptic encephalopathy 66: expanding the phenotype with relative macrocephaly and migrating focal seizures in one of them

Background: The *PACS2*-related early developmental and epileptic encephalopathy (MIM 618067) is a rare condition with only 53 patients reported so far. The causality of a recurrent variant c.625G>A, p.(Glu209Lys) was first recognized in 2018.

Methods: We report on two unrelated children with early-infantile focal seizures, one with clonic clusters, the other with migrating focal seizures manifesting in asymmetrical tonic semiology. Both children showed developmental delay, hypotonia, speech delay and recognizable facial gestalt. They are able to walk independently and became seizure free under antiepileptic

treatment. The first child developed good verbal communication, the second was able to speak some simple words at 4 years of age and had relative macrocephaly. WES analyses using Illumina sequencing technology were performed in both individuals. Pathogenic variant was confirmed by Sanger sequencing.

Results: WES identified the identical pathogenic heterozygous variant c.625G>A, p.(Glu209Lys) in the *PACS2* gene in both individuals.

Conclusion: Pathogenic *PACS2* variants are associated with developmental epileptic encephalopathy type 66. The recurrent c.625G>A, p.(Glu209Lys) missense variant has been reported in all but one individual to date with nearly consistent phenotype including neonatal- or infantile-onset epilepsy, developmental delay, facial dysmorphism. Relative macrocephaly is infrequently reported in the medical literature while migrating focal seizures are first described here.

Conflict of Interest: None declared

P11.108.C Identification of mitochondrial DNA variants enriched in primary progressive multiple sclerosis patients

Kaalindi Misra[1], *Melissa Sorosina*[1], *Antonino Giordano*[1;2], *Elisabetta Mascia*[1], *Sara Scirè*[1], *Laura Ferrè*[1;2], *Ferdinando Clarelli*[1], *Chiara Zanetta*[2], *Massimo Filippi*[2;3;4;5], *FEDERICA ESPOSITO*[1;2]

[1]*IRCCS San Raffaele Scientific Institute, Laboratory of Human Genetics of Neurological disorders, Institute of Experimental Neurology, Milano, Italy;* [2]*IRCCS San Raffaele Scientific Institute, Neurology and Neurorehabilitation Unit, Milano, Italy;* [3]*IRCCS San Raffaele Scientific Institute, Neurophysiology Service, Milano, Italy;* [4]*Vita-Salute San Raffaele University, Milano, Italy;* [5]*IRCCS San Raffaele Scientific Institute, Neuroimaging Research Unit, Division of Neuroscience, Milano, Italy*

Background/Objectives: Multiple sclerosis (MS) is a disorder where the immune system attacks the central nervous system, leading to gradual loss of neurological function. Mitochondria (mt) are important organelles within cells that produce energy. Researchers have found evidence of damage to mitochondria in people with primary progressive multiple sclerosis (PPMS), which is a type of MS that progresses from the beginning. The project aims to identify alterations in mtDNA genes that are more common in PPMS patients.

Methods: A cohort of 279 MS patients, comprising 113 with benign relapsing-remitting multiple sclerosis and 166 with PPMS was investigated. DNA from each patient was extracted, and mtDNA was amplified through two PCR reactions, generating two amplicons per sample. Amplification, library preparation and sequencing were performed with the TaKaRa LA PCR Kit, Nextera XT Library preparation kit and Illumina MiSeq (paired-end, 250bp reads). Variant calling and annotation were performed with MutServe (v2.0) by implementing the in-house pipeline. Variants were tested for association using an allelic chi-squared test and gene burden analysis.

Results: mtDNA analysis found six shared variants between PPMS and benign MS, with different frequencies ($p < 0.05$) among groups, and ten unique variants in the PPMS group. Six of them were classified as pathogenic, affecting genes encoding complex I proteins ND3, ND4, ND5, ND6, and CO1.

Conclusions: Our results suggest the existence of potentially pathogenic mtDNA mutations enriched in PPMS. Analyses of a larger cohort of patients are underway to replicate these findings.

Grants: This study is funded by Italian Ministry of Health GR-2019-12368672

P11.109.D Rare variant enrichment analysis in pediatric European Moyamoya Angiopathy patients unveils novel candidate susceptibility genes.

Elena Cabello[1], *Katharina Steindl*[1], *Ivan Ivanovski*[1], *Paranchai Boonsawat*[1], *Paolo Zanoni*[1], *Michael Papik*[1], *Angela Bahr*[1], *Nadia Khan*[2], *Anita Rauch*[1;2]

[1]*Institute of Medical Genetics - UZH, Schlieren, Switzerland;* [2]*Universität Kinderspital Zürich, Moyamoya Center, Zürich, Switzerland*

Background/Objectives: Moyamoya angiopathy (MMA) is a rare condition characterized by stenosis of the intracranial internal carotid artery and its branches resulting in transient ischemic attacks and strokes in children. Previous studies, mainly focusing on adult patients and/or Asians, have suggested few susceptibility genes, with *RNF213* being the most prevalent gene with a recurrent susceptibility variant p.R4810K in Asian populations. In adult European MMA patients, diverse *RNF213* rare variants have been positively associated, but not p.R4810K.

Methods: Exome sequencing was performed from blood samples in a pediatric cohort of 105 MMA patients and 234 healthy control individuals. Rare-variant enrichment test was performed using the R package SKAT. To verify the independence of our results, we repeated the test against a different control cohort of 307 individuals. A third test was done including 78 cases and 204 controls predicted as 100% of European origin.

Results: In the three tests there is significant enrichment of rare variants in two genes previously associated with MMA (*RNF213*, *NF1*), which underlines the validity of our approach and, among others, *COL18A1* (endostatin), which is known for its association with brain anomalies. As RNF213, endostatin is involved in angiogenesis and endothelial cell proliferation, and was previously considered to predispose to MMA in Trisomy 21 patients.

Conclusion: We present a MMA case-control study focusing exclusively on pediatric patients, mostly of European origin, tested with two independent control cohorts. The results show novel candidate genes that could improve the understanding of MMA.

Conflict of Interest: None declared

Background/Objectives: Body weight is predominantly regulated by the leptin-melanocortin system. Mutations in leptin (*LEP*) are known to cause a dysregulated energy homeostasis and are associated with monogenic forms of obesity. Leptin is also relevant for anorexia nervosa (AN).

Methods: Thus, we have screened the coding region of *LEP* in 462 female patients with AN, and 445 healthy lean controls. Functional implications of detected variants were analysed utilizing in silico tools. Additionally, we investigated the prevalence of pathogenic *LEP* variants in the general population.

Results: We detected one non-synonymous leptin mutation (p.Val94Met, rs17151919) in a patient with AN (15.94 kg/m^2). In silico analyses revealed a protein destabilizing effect. We further identified two rare heterozygous synonymous variants in patients with AN (rs201523305 and novel SNP g.128154532C/T) and an additional synonymous variant in the lean group (rs13306517). Further, we analysed 75 non-synonymous and loss-of-functions variants in *LEP* extracted from gnomAD and predicted their pathogenicity with in silico tools. The prevalence for pathogenic variants was estimated based on the Hardy-Weinberg-Equilibrium. Across all populations, the prevalence of heterozygosity of a pathogenic variant was 1:2,100, while the prevalence for homozygosity was 1:17,830,000.

Conclusion: Consequently, given the unexpected identification of a *LEP* variant in patients with AN that was previously associated with obesity and the fact that *LEP* variants are typically rare in the general population, we can assume that *LEP* variants might have a relevance for AN.

Grants: This study was funded by the DFG (HI 865/2-1, DFG Research Unit FOR2488), the BMBF (01GS0820; PALGER 2017-33: 01DH19010) and the Stiftung Universitätsmedizin Essen.

P11.111.B LSM7 variants involving key amino-acids for LSM complex assembly cause a neurodevelopmental disorder with leukodystrophy and cerebellar atrophy.

Matis CRESPIN[1], *Pauline Marzin[1], Thomas Courtin[1;2], Karine Siquier-Pernet[2], christine bole[3], VALÉRIE MALAN[1;2], Patrick Nitschke[4], Charles-Joris Roux[5], Michel Lemoine[6], Marlene Rio[1], Nathalie Boddaert[5], Vincent Cantagrel[2]*

[1]Necker Hospital, Service de médecine génomique des maladies rares, Paris, France; [2]Institute Imagine, Developmental brain disorders, Paris, France; [3]Institute Imagine, Genomics Platform, Paris, France; [4]Institute Imagine, Bioninformatics Core Facility, Paris, France; [5]Necker Hospital, Département de radiologie pédiatrique, Paris, France; [6]Necker Hospital, Service de médecine physique et de réadaptation, Paris, France

Background/Objectives: Cerebellar atrophy and hypoplasia are usually identified on MRI performed on children presenting signs of cerebellar ataxias, including imbalance, poor coordination, developmental delay and intellectual disability. These signs can be observed in the context of metabolic defects associated with hypomyelinating or demyelinating leukodystrophies. Known genetic defects include mutations in genes encoding subunits of the RNA polymerase III complex and enzymes involved in aminoacyl-tRNA synthetase pathway. However, the molecular diagnosis for many patients remains unsolved. A recent study reported two cases, a first one diagnosed with leukodystrophy and cerebellar atrophy and a second one who died in utero, with each of them having a different homozygous variant in the LSM7 gene. This gene has never been described in human pathology before, it encodes for a subunit of the LSM complex that is involved in pre-RNA maturation and mRNA degradation and consequently it has been suggested as a candidate disease gene. Presently, we report a patient with neurodevelopmental defects, leukodystrophy and cerebellar atrophy.

Methods: We performed a cerebral MRI and whole genome sequencing.

Results : The patient harbours compound heterozygous variants in the LSM7 gene. One of these variants is the same as the one carried by the first case previously reported and the other one is at the same position as the variant of the second case.

Conclusion :

Based on comparable neuroimaging, clinical features and the involvement of the same amino-acids previously demonstrated as key for LSM complex assembly, we propose that LSM7 disruption causes a neurodevelopmental disorder with leukodystrophy and cerebellar atrophy.

P11.112.C NKX6-2- related leukodystrophy: natural history study and novel genetic therapeutic approaches

Kristina Zhelcheska[1], *Viorica Chelban[1], Henry Houlden[1]*

[1]UCL Queen Square Institute of Neurology, Neuromuscular Disorders, London, United Kingdom

Background/ Objectives: Hypomyelinating leukodystrophies are a heterogeneous group of genetic disorders characterized by impaired formation of the myelin sheath in the CNS, leading to a wide spectrum of phenotypes. Bi-allelic variants in the *NKX6-2* gene were identified to cause spastic ataxia 8 (SPAX8), autosomal recessive, with hypomyelinating leukodystrophy. There are currently no disease modifying treatments nor biomarkers available for *NKX6-2* patients, where only supportive and palliative care is available.

Methods: We conducted a natural history study involving affected individuals with *NKX6-2*-related leukodystrophy from unrelated families to assess the progression of the disease.

Immunocytochemical staining of NKX6-2 protein in *NKX6-2* patient-derived fibroblasts was conducted to evaluate the consequence of pathogenic variants on NKX6-2 expression compared to unaffected healthy controls.

Results: We have identified affected individuals from families worldwide harbouring pathogenic variants in *NKX6-2*. Our findings reveal there is variation in phenotypic severity, both according to differences in the onset of disease and the specific disease-causing variant.

Conclusion: *NKX6-2*- related leukodystrophy is an untreatable neurological disorder and there is clinical need to develop new treatment strategies for this disorder. Our natural history study will be also used to identify serial biomarkers in patients with *NKX6-2*-related leukodystrophy, helping to provide outcome measures for potential future trials. Furthermore, we aim to use in vitro models to develop novel genetic therapeutic approaches to replace and rescue NKX6-2 protein loss.

Grants: Ataxia UK

P11.113.D Kaya-Barakat-Masson syndrome: Delineation of the clinical phenotype of an autosomal recessive YIF1B-related neurodevelopmental disorder and examination of the underlying mechanisms using in vivo disease modelling with zebrafish

Eva Medico Salsench[1], **Leslie Sanderson**[1], *Stefan Barakat*[1]

[1]*Erasmus MC University Medical Center, Department of Clinical Genetics, Rotterdam, Netherlands*

Consortium: International YIF1B study group

Background/Objectives: Intracellular vesicular trafficking is crucial to human brain development and its dysfunction is implicated in many neurodevelopmental disorders. YIF1B is an essential protein involved in anterograde trafficking from the endoplasmic reticulum to the cell membrane and in the architecture of the Golgi apparatus. We recently described bi-allelic variants in *YIF1B* as the cause of a severe neurodevelopmental disorder (Kaya-Barakat-Masson syndrome, KABAMAS, OMIM #619125) in 25 affected individuals from 20 independent families to date. KABAMAS is characterized by progressive encephalopathy with varying degrees of movement disorders, severe global developmental delay, microcephaly, and epilepsy. Both pathogenic truncating and missense variants have been identified. Here, we compare the clinical phenotype between all currently known YIF1B cases and expound on the disease mechanism through in vivo modeling using zebrafish.

Methods: Using CRISPR/Cas9 we generated *yif1b* knock-out zebrafish and extensively phenotyped their development and cellular alterations using transgenic lines, in vivo imaging, and multi-omics technologies including proteomics.

Results: *Yif1b* depletion causes delayed development and altered touch-evoked response. Neuropathological analysis and in vivo imaging shows increased apoptotic signaling and a swollen microglial phenotype. Further, the *yif1b* genotype impacts microglial morphology and ER stress response following tunicamycin treatment. The capacity of human missense variants to rescue these phenotypes has been assessed.

Conclusion: Our findings provide insight into the role of YIF1B during neurodevelopment in zebrafish and human. In addition, we provide a model system to study this disorder in vivo and further examine the essentiality of intracellular trafficking during brain development.

P11.114.A Uniparental IsoDisomy: a new mechanism in Friedreich ataxia

Brian Sperelakis Beedham[1], *Maryse Magem*[1], *Jean-Madeleine de Sainte Agathe*[2], *Zahra Assouline*[2], *Cyril Gitiaux*[3], *Isabelle Desguerre*[3], *Julie Steffann*[1], *Giulia Barcia*[1]

[1]*Necker Enfants Malades Hospital, Médecine Génomique des Maladies Rare, Paris, France;* [2]*Pitié Salpétrière Hospital, Génétique, Paris, France;* [3]*Necker Enfants Malades Hospital, Neurologie Pédiatrique, Paris, France*

Background/Objectives: Friedreich's Ataxia (FRDA) is the most common hereditary ataxia. Most patients are homozygous for a (GAA)n expansion in the first intron of the *FXN* gene. The remaining patients carry *FXN* point mutations or intragenic deletions.

We describe the first FRDA patient with a chromosome 9 segmental Uniparental isoDisomy (UPiD) unmasking a homozygous expansion of the *FXN* gene that initially went unnoticed by TP-PCR due to a deletion in the target region of one primer.

Methods: Molecular screening for *FXN* typically centers on the analysis of (GAA)n expansions, commonly performed by triplet-repeat primed PCR (TP-PCR). This method was initially employed before undergoing further investigation through genome sequencing (GS) and modified TP-PCR.

Results: The child (5 year-old) presented with a progressive proprioceptive ataxia since the age of 4, associated with peripheral neuropathy and severe scoliosis. Cardiac ultrasound and ECG were normal.

At first, TP-PCR failed to amplify the *FXN* locus for the patient. However, GS subsequently identified an expansion of *FXN*, coupled with a maternal segmental Uniparental Isodisomy (UPiD) encompassing the *FXN* gene. This diagnosis was ultimately validated through modified TP-PCR.

Conclusion: To the best of our knowledge, this is the first case of FRDA associated to segmental UPiD. This case highlights the complexity of the molecular diagnosis of FRDA, and emphasises the importance of integrating results from various approaches before dismissing FRDA as a potential diagnosis, particularly in cases with compelling clinical evidence.

P11.115.B Chromosomal microarray analysis in a cohort of 200 pediatric patients with epilepsy

Maria Chiara Baroni[1;2], *Luca Bergonzini*[2;3], *Giulia Olivucci*[1;4], *Giulia Severi*[1], *Francesca Montanari*[1], *Valentina Marchiani*[3], *Valentina Gentile*[3], *Luca Soliani*[3], *Antonella Boni*[3], *Tullio Messana*[3], *Angelo Russo*[3], *Duccio Maria Cordelli*[2;3], *Pamela Magini*[1], *Caterina Garone*[2;3]

[1]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Medical Genetics Unit, Bologna, Italy;* [2]*Alma Mater Studiorum, University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy;* [3]*IRCCS Istituto delle Scienze Neurologiche di Bologna, UOC Neuropsichiatria dell'Età Pediatrica, Member of the ERN EpiCare, Bologna, Italy;* [4]*Università di Palermo, Dipartimento di Discipline Chirurgiche, Oncologiche e Stomatologiche, Palermo, Italy*

Background/Objectives: Copy number variants (CNVs) are established risk factors for neurodevelopmental disorders. Our aim was to evaluate the role of CNVs detectable with chromosomal microarray in a cohort of pediatric patients with epilepsy.

Methods: We reviewed 200 pediatric patients referred to our Genetic and Neuropsychiatric Units for epilepsy diagnosed according to ILAE Classification (2017), who underwent array-CGH between 2017 and 2023. Clinical (age at onset, seizures, neurodevelopment, dysmorphisms, comorbidities) and neuroradiological data were collected and analyzed. CNVs were classified according to the ACMG guidelines.

Results: 34/200 probands had (likely) pathogenic CNVs, resulting in a diagnostic yield of 17%; 19/34 had focal epilepsy, 15/34 generalized epilepsy; 25/34 (73,5%) had additional signs of developmental disorder. 23 patients were diagnosed with deletion/duplication syndromes and reciprocal CNVs at 22q11.21, 1p36.33, and 16p13.11 were described in the cohort. Six patients had CNVs including genes previously associated with epilepsy/neurodevelopmental disorder (*NPRL3, MBD5, CDKL5, MECP2, EHMT1, ANKRD11*). Four probands had a 2p16.3 deletion, involving *NRXN1*, one had an intragenic deletion of *ANKS1B*, recently associated with a neurodevelopmental phenotype. Parental testing revealed de novo CNVs in 42,8% (9/21) and inherited CNVs in 57,1% (12/21). 37 patients (18,5%) had CNVs of unknown significance, including a de novo deletion within the neuronal splicing regulator *RBFOX1*, which is undergoing further evaluation.

Conclusion: We confirmed that CNVs contribute significantly to epilepsy, particularly when associated with neurodevelopmental delay and dysmorphism. We also highlighted incomplete penetrance and provided detailed phenotypic descriptions of patients with positive results, which can guide genetic counseling and clinical management.

P11.116.C Somatic alterations in drug-resistant focal epilepsy

Joana Ribeiro[1;2;3], Luís Miguel Pires[4], Ilda Patrícia Ribeiro[1;2;3;5], Olinda Rebelo[6], Francisco José Sales Almeida Inácio[6], Antonio Freire[4], **Joana Barbosa de Melo**[1;2;3;5]

[1]Lab of Cytogenetics and Genomics, Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [2]CIBB- Centro de Inovação em Biomedicina e Biotecnologia, University of Coimbra, Coimbra, Portugal; [3]iCBR CIMAGO – Centro Investigação em Meio Ambiente Genética e Oncobiologia, Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [4]Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [5]Clinical Academic Center of Coimbra, CACC, Coimbra, Portugal; [6]Serviço de Neurologia, CHUC, Unidade de Saude Local Coimbra, Coimbra, Portugal

Background/Objectives: Epilepsy stands as one of the most severe neurological disorders, impacting nearly 50 million individuals globally. The main objective of this study was to perform a comprehensive molecular analysis of pathological brain samples from epilepsy surgery in order to identify the most prevalent (cyto)genomic alterations and aberrant DNA methylation patterns in key genes for disease development.

Methods: Patients with drug-resistant focal epilepsy, both children and adults, associated to histologically proven focal cortical dysplasia and long-term epilepsy associated tumor who underwent surgical treatment were included. Different high-throughput genomic and epigenetic techniques were applied.

Results: Eight patients with long-term epilepsy associated tumors (4 dysembryoplastic neuroepithelial tumors, 3 gangliogliomas, 1 pilocytic astrocytoma) and 2 patients with focal cortical dysplasia (types Ia and IIa) were included. Somatic variants (*WDR24* p.Trp259Gly; *MICAL1* p.Lys1036Arg; *KATNB1* p.Leu566Ile; *MATN4* p.Phe91Val; *ANKRD6* p.His386Gln) were identified in patients with focal cortical dysplasia. Chromosomal abnormalities were observed in long-term epilepsy associated tumors, namely monosomy 19, deletions of 1p, 4p, 12p, 22q and gains of 20p. The promotor region of the genes *MGMT* and *CD44* exhibited methylation in one ganglioglioma.

Conclusion: Relevant molecular alterations related to the main histopathological diagnoses of epilepsy surgery were detected, which may contribute to the identification of new diagnostic biomarkers and targeted treatments and to decipher the molecular and pathological landscape of focal epilepsy.

Conflict of Interest: None declared

P11.117.D *SCN1A* related channelopathies, one gene - multiple phenotypes

Danai Veltra[1;2], *VIRGINIA THEODOROU[3], marina katsalouli[3], Pelagia Vorgia[4], George Niotakis[5], FILIO TSAPROUNI[6], Roser Pons[7], Konstantina Kosma[1], Aphrodite Kampouraki[1], Eirini Tsoutsou[1], Periklis Makrythanasis[1;8;9], Kyriaki Kekou[1], Jan Traeger-Synodinos[1], Christalena Sofocleous[1]*

[1]Medical School, National and Kapodistrian University of Athens, Laboratory of Medical Genetics, Athens, Greece; [2]National and Kapodistrian University of Athens, Research University Institute for the Study and Prevention of Genetic and Malignant Disease of Childhood, Athens, Greece; [3]St. Sophia's Children's Hospital, Pediatric Neurology Department, Athens, Greece; [4]Hellenic Mediterranean University, Agrifood and Life Sciences Institute, Heraklion, Greece; [5]Venizelion Hospital, Pediatric Neurology Department, Heraklion, Greece; [6]Tzaneio Hospital, Pediatric Neurology Department, Piraeus, Greece; [7]Medical School, National and Kapodistrian University of Athens, First Department of Pediatrics, Athens, Greece; [8]Medical School, University of Geneva, Department of Genetic Medicine and Development, Geneva, Switzerland; [9]Biomedical Research Foundation of the Academy of Athens, Athens, Greece

Background/Objectives: Epileptogenesis is related to various mechanisms including channelopathies, synaptopathies, and interneuronopathies caused by alterations in many genes. Of those *SCN1A* is considered a key epilepsy gene, especially in infants experiencing febrile seizures (FS) within the first year of life. The study reports and comments on findings and genotype-phenotype correlations assessed following testing for *SCN1A* in hospitalized patients.

Methods: Sanger sequencing and/or MLPA was performed on DNA from 338 patients for whom medical and family histories, as well as informed consent, were available. Five additional patients, underwent Whole Exome Sequencing (WES) with xGen Exome Research v2 kit on Illumina NextSeq-500 system. Bioinformatic analysis used Franklin and VarSome Clinical platforms. All variants were classified according to ACMG and ClinGen recommendations.

Results: Amongst 23 patients (18 with Sanger and 5 after WES) a causative *SCN1A* variant (14 known, 9 novel) was detected, associated with a wide variety of seizures and accompanying phenotypes. Segregation analysis performed in 16/23 cases revealed the variant in 8 additional family members, while 10 cases were considered de novo. In four patients, the first seizure occurred following an infection (e.g Covid-19).

Conclusion: Although in three cases genetic diagnosis was achieved immediately after the first seizure, many families, despite family history, were referred for *SCN1A* testing only after hospitalization, whence single gene tests are compensated by the National Health System. The variant type and the correlated range of clinical presentations (FS to Developmental Epileptic Encephalopathy), as well as impact of infections (specifically Covid-19) will be discussed.

P11.118.A Whole Exome Sequencing in Microcephaly: Assessing Clinical and Genetic Heterogeneity

Saadet Nur Bozgeyik[1], Enise AVCI DURMUŞALİOGLU[2], Turkan Turkut Tan[2], Tahir Atik[2], Ozgur Cogulu[2], Ferda Ozkinay[2], **Esra Isik**[2]

[1]Ege University, Medical Faculty, Türkyie; [2]Ege University, Türkyie

Background/Objectives: Microcephaly is a clinical and genetic heterogeneous condition that typically manifests as a neurodevelopmental disorder. It may occur isolated or as an accompanying feature of a syndrome. The aim of this study to evaluate the usefulness of whole exome sequencing (WES) in a heterogeneous group of patients presented with microcephaly.

Methods: Thirty patients from 27 unrelated families presenting with microcephaly and analyzed using WES during their diagnostic work-up were included. Patients were classified into two groups (non-syndromic/syndromic) based on the presence of accompanying additional anomalies.

Results: Twelve patients were classified as non-syndromic while 18 as syndromic. In 16 of 27 families (59.2%) a pathogenic or likely pathogenic variant in genes already known to be responsible for microcephaly were identified. In one family including two affected cases, a homozygous variant (c.511C>T, p.Arg171Cys) was detected in *XAB2* gene (NM_020196.3) which could be a candidate novel gene related with microcephaly and neurodevelopmental disorder.

Conclusion: In this study, a high diagnostic rate has been achieved in syndromic and non-syndromic microcephaly cases via WES. WES has revealed a potential novel gene XAB2 encodes a multi-functional protein that plays critical role in processes including transcription-coupled DNA repair and mRNA splicing. WES might be considered as the first-tier test in diagnostic approach of microcephaly.

P11.120.C Rapid genome sequencing for infantile-onset epilepsy within a national healthcare setting

Hannah Robinson[1], *Karen Stals[1], Lucy Mallin[1], Hayley Lees[1], Nicholas Head[1], Lewis Pang[1], Ewa Goljan[1], Natasha Grumbt[1], Suzanne Hocking[1], Jessica Adams[1], Verity Woodhall[1], Matthew Wakeling[2], Sue Hill[3], Caroline Wright[2], Sian Ellard[3], Andrew Parrish[1], Emma Baple[1;2;4]*

[1]Exeter Genomics Laboratory, Exeter, United Kingdom; [2]University of Exeter, Exeter, United Kingdom; [3]NHS England, London, United Kingdom; [4]Peninsula Clinical Genetics Service, Exeter, United Kingdom

Background/Objectives: The Exeter NHS Genomics Laboratory provides the rapid genome (previously exome) sequencing service in England for acutely unwell children with a likely monogenic disorder. Children <1 year with unexplained probable monogenic epilepsy are eligible for testing, irrespective of previous admission to intensive care (ICU), due to the high actionability of a precise molecular diagnosis in this group.

Methods: We conducted a review of all children sequenced through the service since 2019 to investigate diagnostic yield and actionability in epilepsy. The exome/genome analysis strategy employed was family-trio gene-agnostic (95%) when possible, or otherwise virtual gene-panel analysis on duos (4%) or singletons (1%).

Results: 2365 children were tested (1745 exomes, 620 genomes), 28% displayed signs of epilepsy/seizures (n = 654). Excluding those whose seizures had a probable environmental cause or were accompanied by multiple congenital abnormalities, 53% were referred for rapid testing by age 1 year (n = 346), with 62% from ICU settings (n = 214) and 38% from non-ICU settings (n = 132). Diagnostic yield was 55% (n = 189), with a maximum yield of 61%, including possible variants of uncertain significance and partial diagnoses (n = 210). Diagnostic yield from non-ICU settings (55%, n = 72) was similar to ICU settings (55%, n = 117). Results were communicated to referring clinicians within a median of 9 days (range 4–27 days). *KCNQ2* and *SCN2A* were the most frequent diagnoses in both ICU and non-ICU settings.

Conclusion: We demonstrate the feasibility and utility of implementing diagnostic rapid genome sequencing as a much needed first-line test for infantile-onset epilepsy, at scale, within a national healthcare setting.

Conflict of Interest: None declared

P11.121.D The CHGB rs742710 variant and its association with early ALS onset: a cross-cohort analysis

Ivan Tourtourikov[1;2], *Kristiyan Dabchev[2], Tihomir Todorov[2], Teodor Angelov[3], Teodora Chamova[3], Ivaylo Tarnev[4;5], Vanyo Mitev[1], Albena Todorova[1;2]*

[1]Medical University of Sofia, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria; [2]Genetic Medico-Diagnostic Laboratory Genica and Genome Center Bulgaria, Sofia, Bulgaria, Sofia, Bulgaria; [3]Medical University of Sofia, Department of Neurology, Faculty of Medicine, Sofia, Bulgaria; [4]Medical University of Sofia, UMBAL Aleksandrovska, Department of Neurology, Clinic of Nervous Diseases, Sofia, Bulgaria; [5]New Bulgarian University, Department of Cognitive Science and Psychology, Sofia, Bulgaria

Background/Objectives: Amyotrophic lateral sclerosis (ALS) is a multifactorial neurodegenerative disease, with a wide spectrum of behavioral and motor symptoms. ALS pathogenic models based on chromogranin (CHGB)-mediated secretion of toxic mutant SOD1 molecules have been studied, leading to reports of a specific variant, P413L, being associated with an earlier age of onset in some, but not all populations. Our aim was to investigate the effect of this variant, and the replicability of the findings across patients from Bulgaria and the Answer ALS (AALS) program.

Methods: Genotyping was performed on 150 sporadic ALS patients from Bulgaria via Sanger sequencing for the CHGB variant rs742710. Clinical and genotyping data for 700 individuals with sporadic ALS were obtained from the Answer ALS Foundation Program, 'Answer ALS' (https://www.answerals.org). Statistical analysis was performed via IBM SPSS Statistics v26.

Results: Carriers of the G allele of rs742710 demonstrated a 2-year earlier onset for both patient cohorts. Sex was found to cause an earlier onset in both cohorts, with males having a 3-year ($p < 0.001$, for AALS) and 4-year ($p = 0.016$, for the Bulgarian cohort) age of onset. The G allele was strongly associated with ALS for both cohorts, with $p < 0.0001$ for AALS and $p < 0.00062$ for the Bulgarian population.

Conclusion: Our findings, consistent across both Bulgarian and AALS cohorts, highlight the importance of genetic factors in ALS heterogeneity and underscore the need for further research to explore the mechanisms through which CHGB influences ALS onset and progression.

Grants: This study was supported by the Medical University Sofia, Bulgaria, grant no. D-148/03.08.2023.

P11.122.A RBL2/Rbf loss-of-function disrupts neurodevelopment in humans and flies and reveals a key role for an Rb proteins in post-mitotic neurons

Gabriel Aughey[1], *Elisa Cali*[1], *Henry Houlden*[1], *Reza Maroofian*[1], *James Jepson*[1]

[1]*University College London*

Background/Objectives: RBL2 is a key regulator of cell division and propagates senescence by repressing repair genes and controlling DNA methylation and telomere lenght. It has been found to be an important regulator of neuronal differentiation and survival in post-mitotic neurons, and its dysfunction is associated to BRUWAG syndrome, a neurodevelopmental disorder characterized by severe developmental delay, dysrmorphic features, microcephaly and behavioural abnormalities. To date, clinical features have been described in only six individuals carrying biallelic loss of function (LOF) variants in *RBL2*. Futhermore, the cell-types in which RBL2 expression is required to promote robust neural development remains unclear.

Methods: The affected individuals were identified through extensive data sharing and collaboration. Rbf knockdown was induced in all cells and in specific cell types. Behavioural and neuronal phenotypes were assessed using the *Drosophila* Activity Monitor (DAM) system, larval locomotion and climbing assays.

Results: We identified 30 affected indviduals with a neurodevelopmental disorder characterized by severe GDD/ID, behavioural abnormalities, dysmorphic features, severe microcephaly, and variable presence of seizures. *Rbf* fly mutants displayed morphological phenotypes and presented behavioural and locomotor defects that were reminescent of the human phenotype. Pan-neuronal expression of *Rbf* in post-mitotic neurons fully rescued the phenotype in the *Rbf* hypomorph mutants.

Conclusion: Taken together, our study expands the phenotypic and genotypic specturm of *RBL2*-related disorder, illustrates parallels between human and fly RB protein function in the nervous system and suggests RBL2/Rbf is important in neural precursors and post-mitotic neurons to promote normal brain morphology and motor development.

Consortium: TUDP Study Group

Background: The nosological definition of Autism Spectrum Disorders (ASD)/intellectual disability (ID) continues to be confusing. Various monogenic conditions are categorized within ASD/ID spectrum along with primary ASD, which is often multigenic in nature. Similarly, several risk alleles are mentioned as single-gene mutation in ASD/ID.

Aim: To determine whether distinct diagnostic flowcharts can be established for syndromic/monofactorial and non-syndromic/oligo-multigenic forms of ASD/ID.

Methods: Analysis of 500 consecutive patients referred to us for pre-test clinical evaluation due to ID and/or ASD. Pregnancy factors, including in vitro fertilization, hypotonia, peculiar facial characteristics, motor delay, micro/macrocephaly, brain anomalies, epilepsy and non-Mendelian family history for behavioural and psychiatric disorders were also recorded.

Results: ASD occurred in comorbidity with ID in of the half cases. One-third of them exhibited a monofactorial condition, including both complex diseases (i.e. *TCF4, CHAMP1, ASXL3*) and apparently non-syndromic presentation. Monofactorial conditions mimicking primary ASD were primarily *FMR1, RAI1, MECP2, PTEN*, del22q13, *ANRKD11* in children, *PPP2R5D* and (UPD)(15)pat associated disorders. However, additional key features were recorded in each.

Conclusions: Novel distinctive guidelines for primary or syndromic ASD/ID are proposed for application at a diagnostic level. A scoring system for the most sensitive clinical manifestations leading to the hypothesis of non-syndromic or syndromic ASD/ID is discussed. Our goal is to achieve a precise diagnosis, proper recurrence risk assessment, and an adequate pipeline for genetic investigations. The importance of pre-test and post-test clinical evaluations by the same clinical geneticist is highlighted.
