Background/Objectives: *ELFN1* encodes a postsynaptic protein found throughout the nervous system. *Elfn1*$^{-/-}$ mice demonstrate an increased propensity for seizures and locomotion, with reduced thigmotaxis and limb strength. Biallelic loss-of-function (LOF) variants in *ELFN1* were initially identified in a single family affected by developmental and epileptic encephalopathy.

Methods: Eight individuals from five independent families, aged between 10 months to 21 years, including 3/5 families with consanguinity, underwent comprehensive clinical and genetic evaluations.

Results: All individuals carried homozygous LOF deletions in *ELFN1*. These included three families with frameshift deletions (c.1767del, p.(Val591CysfsTer93); c.128_137del, p.(Ile43ArgfsTer120); c.1522del, p.(Gln508SerfsTer176)), of which the third was associated with uniparental disomy of chromosome 7. One family had an in-frame deletion (c.475_477del, p.(Val159del)), resulting in loss of Elfn1's localization and binding function. One family had a 5'UTR deletion (g.1697729_1779918del) confirmed by RNA-seq as exhibiting loss of expression. All cases exhibited neurodevelopmental delay/intellectual disability, with varying severity, and experienced epilepsy. Seizure onset varied, ranging from the neonatal period to four years, encompassing generalized tonic-clonic seizures, tonic seizures, and intractable infantile spasms. Neuroimaging revealed corpus callosum thinning and white matter loss in one case, while others were reported as normal or with non-specific findings. Autism and ADHD were diagnosed in three and two cases, respectively. Clinical examinations showed various neurological abnormalities and dysmorphism. Hypotonia was the commonest feature (6/8), with less frequent features including muscle weakness, muscle atrophy, ataxia and nystagmus.

Conclusion: This study expands the phenotypic spectrum and reinforces the association between *ELFN1* deficiency and a neurodevelopmental disorder with epilepsy.

P11.125.D Postzygotic Point Mutations in Genetic Diagnostics and Counselling in Neurodevelopmental Disorders

Anna Walczak[1], *Małgorzata Rydzanicz*[1], *Agnieszka Pollak*[1], *Rafał Płoski*[1]

[1]*Medical University of Warsaw, Department of Medical Genetics, Warszawa, Poland*

Background: De novo mutations are spontaneous, non-inherited changes in the genome sequence. Postzygotic variants, arising spontaneously in an organism, lead to mosaicism – the presence of genetically different cell lines. Mosaicism types include somatic, gonosomal, and germinal, with implications ranging from asymptomatic states to severe diseases.

Methods: This study aimed to estimate the clinical significance threshold of variant allele frequency (VAF), the frequency of germinal or gonosomal mosaicism among parents

of affected children, and the highest VAF of a pathogenic variant not causing symptoms.

The WES test and ADS based on next-generation sequencing were employed.

Results: Among 55 tested families (proband and parents), we identified 25 postzygotic variants in 17 genes linked to mostly neurodevelopmental human diseases, manifest mainly by ASD, ID and DD. Among probands, 9 variants in 5 gene were detected, while asymptomatic parents showed 16 different variants in 14 genes (4 in mothers, 12 in fathers). Eight of the 12 paternal variants led to gonosomal mosaicism. Paternal germinal mosaicism had an estimated frequency of 13% (4/30 tested semen samples). VAF ranged from 3% (proband) to 35% (asymptomatic mother).

Conclusion: This research underscores the significance of scrutinizing both probands and parents for postzygotic variants within a VAF range of 1-35%. It is essential to recognize potential "de novo" variants by excluding their presence in additional tissues of parents during diagnostics and genetic counseling, crucial for pinpointing causative variants. The recurrence risk associated with a specific variant detected in a mosaic form in an asymptomatic parent cannot be overlooked.

Conflict of Interest: None declared

P11.126.A Multi-polygenic risk score approach to neurodevelopment-associated trait prediction in a high risk admixed cohort

Catarina S Gomes[1], *Veronica Euclydes*[1], *Caroline camilo*[1], *Gisele Gouveia*[1], *Helena Brentani*[1]

[1]*University of São Paulo, Institute of Psychiatry, São Paulo, Brazil*

Background/Objectives: The polygenic scores (PGS) aim to summarize the effect of SNPs on an individual's genetic susceptibility to a phenotype. The predictive performance of polygenic scores (PGS) is largely dependent on the target phenotype, the ancestry of the target and development population, and the number of samples available to train the PGS. In the context of psychiatry genetics, it is very well known the existence a high genetic correlation among psychiatry disorders and neurodevelopmental-associated phenotypes. Therefore, this study aims to utilize a multi-polygenic risk score approach to predict emotional and cognitive problems in a high-risk Brazilian cohort.

Methods: As target phenotypes, we seek to predict the Regional Project on Child Development Indicators (PRIDI) and the Strengths and Difficulties Questionnaire (SDQ) measured in 524 children in a situation of high social vulnerability in a large Brazilian metropolis. The children had their DNA collected from the saliva and were genotyped by using the Illumina Global Diversity Array. The genotyping data was processed using the *gtc2vcf* pipeline and the polygenic scoring models will be built using GWAS performed for ADHD, schizophrenia and ASD as a basis.

Results: So far, we have carried out the ancestry characterization of the sample and verified the expected miscegenation characteristic of the sample (average European ancestry below 65%). This proves to be a problem for the use of PRS constructed in European populations and to overcome this issue, we will use PRS calculation approaches based on genetic correlation of predictive characteristics.

Grants: Fundação de Amparo à Pesquisa do Estado de São Paulo (Grant #18/18560-6).

P11.128.D Dissecting the impact of noncoding variation in ASD etiology

Julieta Bonacina[1], *julia scotellaro*[2], *Lili Kelley*[2], *Soleha Patel*[2], *taehwan shin*[2], *Ashish Jain*[2], *Paulina Gonzalez Tovar*[2], *Ryan Doan*[1]

[1]*Boston Children's Hospital and Harvard Medical School, Pediatrics, Boston, United States;* [2]*Boston Children's Hospital, Pediatrics, Boston, United States*

Background/Objectives: Despite heritability, only approximately 25% of individuals with Autism Spectrum Disorder (ASD) have an identifiable causal variant impacting a protein coding gene. Recently, many efforts, including ours, have suggested that noncoding regulatory variation may account for a substantial proportion of missed genetic diagnoses. In this study, we analyze the functional impact of de novo and inherited recessive noncoding promoter variants in individuals with ASD.

Methods: We examined available whole genome sequencing data from ASD cohorts (SPARK, HMCA and SSC) for predicted damaging rare de novo and inherited recessive promoter variation using our custom classification pipeline. Then, variants found only in cases were experimentally profiled using a massively parallel reporter assay. Thus, for each variant, we calculated a $\log_2$ score representing the comparative transcriptional regulatory activity of the alternative allele in relation to the reference allele, averaged across strands and replicates.

Results: Surprisingly, 12.4% (200/1617) of candidate noncoding variants significantly altered transcriptional activity and had a strong effect (absolute score > 0.2, FDR < 5%), with 76.5% of them leading to a decreased expression. Genes impacted by these 200 variants were enriched for neuron projection morphogenesis ($p = 0.04$) and histone modification ($p = 0.05$) processes, and included 30 known ASD genes (SFARI Gene database). Interestingly, 3 out of 4 of the variants identified in a regulatory element near HTATSF1, and 3 out of 7 associated with KDM5C, had strong functional impact.

Conclusion: Our results provide a systematic functional dissection of risk de novo and inherited promoter variants for ASD.

Grants: SFARI Bridge to Independence Award.

Background/Objectives: Delta-like 1 (DLL1) is a Notch receptor ligand, forming an important pathway for brain morphogenesis. Heterozygous pathogenic *DLL1* variants cause neurodevelopmental disorder with nonspecific brain abnormalities and with or without seizures (NEDBAS; MIM 618709). So far, detailed clinical and molecular data of 15 individuals from 12 unrelated families have been published.

Methods: The cohort was identified using GeneMatcher and ClinVar. We designed a questionnaire systematically evaluating clinical symptoms only described in single individuals before. It was also applied to the case reports of the previously published cohort for joint analysis.

Results: We report the clinical and molecular features of 32 unpublished individuals from 28 unrelated families with 25 different heterozygous de novo or inherited (likely) pathogenic *DLL1* variants (frameshift, splice site, nonsense, missense, multiexon deletions). Common clinical features in all 47 individuals were developmental delay and/or intellectual disability (88%), brain abnormalities (62%), attention deficit and hyperactivity disorder (50%), autism spectrum disorder (44%) and seizures (36%). Newly uncovered comorbidities in the current cohort include aggressive and/or self-injurious behavior (53%), sleeping problems (31%), anxiety (23%) and affective disorders (19%). 81% of the affected individuals receive help with developmental issues, physical therapy, and/or psycho/-pharmacological therapy. Seizures were almost exclusively associated with brain malformations and/or micro-/macrocephaly.

Conclusion: This work accentuates the complexity of the predominantly neurologic and psychiatric *DLL1*-associated phenotype, indicating the importance of specialized care in these domains. Functional in vivo and in vitro studies are needed to fully investigate the *DLL1*-related pathomechanism.

Grants: Not applicable.

P11.130.B Parenti-Mignot neurodevelopmental syndrome (PMNDS): three novel patients with disease-causing variants in *CHD5*

Lara Hartmayer[1], *Antonia Paes*[2], *Sven Hethey*[2], *David Overberg*[3], *Jan-Ole Gehrmann*[3], *Corinna Doege*[3], *Gregor Dückers*[4], *Sandra von Hardenberg*[1], *Bernd Auber*[1], *Anke Katharina Bergmann*[1], *Tim Ripperger*[1]

[1]*Deparment of Human Genetics, Hannover Medical School, Hannover, Germany;* [2]*Department of Neuropediatric, Child and Youth Hospital AUF DER BULT, Hannover, Germany;* [3]*Eltern-Kind-Zentrum Prof. Hess, Department of Pediatric Intensive Care and Department of Pediatrics and Adolescent Medicine, Neuropediatrics, Klinikum Bremen Mitte, Bremen, Germany;* [4]*HELIOS Childrens Hospital, Krefeld, Germany*

Background/Objectives: CHD5 plays an important role in radial migration and terminal differentiation of neuronal cells. Disease-causing variants in *CHD5* are linked to PMNDS, a rare autosomal dominant neurodevelopmental disorder with less than twenty reported cases. Causal variants frequently occurred de novo, including mosaic patients. We present three novel patients with PMNDS expanding its clinical spectrum.

Methods: Whole genome sequencing (WGS).

Results: A 3-year-old boy with mild developmental delay, mild facial dysmorphism, and respiratory infection-associated onset of seizures at 2 years was referred with suspected GLUT1-deficiency due to abnormal liquor results. While GLUT1-deficiency was genetically not confirmed, the variant NM_015557.3(CHD5):c.2514del p.(Ile839Serfs*8) [heterozygous] was identified. Parents were not available for testing.

A critically-ill 11-month-old girl with pre-existing global developmental delay, hypotonia, and mild facial dysmorphism presented with a viral encephalitis-associated left hemispheric recurrent status epilepticus. By rapid trio-WGS, we identified the de novo variant NM_015557.3(CHD5):c.2662C>T p.(His888Tyr) [heterozygous].

A critically-ill 5-year-old Syrian boy with consanguine parents, recurrent severe infections, neutropenia, anemia, mild facial dysmorphism, global developmental delay, hypotonia, and dental anomalies was referred for rapid WGS. We identified two disease-causing variants: NM_006118.4(HAX1):c.130_131insA p.(Trp44*) [homozygous] and NM_015557.3(CHD5):c.3988C>T p.(Gln1330*) [heterozygous], confirming the co-occurrence of severe congenital neutropenia-3 and PMNDS. Parents have not been tested yet.

Conclusion: PMNDS is characterized by an unspecific and variable phenotype including developmental delay, hypotonia, behavioral disturbances, epilepsy, mild non-specific facial dysmorphism, and variable degrees of intellectual disability. Our report complements known clinical phenotypes and associates PMNDS with severe epilepsy adding it to the list of differential diagnosis in critically-ill children.

Background/Objectives: The relationship between brain molecular traits (i.e., gene and protein expression) and brain anatomical features in living individuals, each independently shown to be associated with disease, has yet to be defined. Here, we use neuroimaging-linked molecular data, generated from 320 biopsies from the prefrontal cortex from 202 older individuals undergoing the deep brain stimulation electrode implantation procedure to characterize this relationship.

Methods: Gene expression (single-nuclei [snRNAseq], N = 31 and bulk RNA-seq, N = 289) as well as protein expression (liquid chromatography-mass spectrometry, N = 155) data generated as part of the Living Brain Project, were processed, and integrated with structural MRI-derived anatomical features (N = 197, cortical thickness, area, and volume) measured in the same individuals. Associations of molecular traits to anatomical features were performed for each imaging feature using linear mixed models. Associations were replicated between -omics and annotated to specific cell type effects using snRNA-seq data.

Results: Molecular signatures of brain anatomical features in living individuals were identified, with multiple features associated with bulk gene expression (19 features with ≥1gene at FDR ≤ 0.05). These associations replicated in protein expression (median absolute Spearman rho = 0.13). SnRNAseq replicated gene and protein expression signatures, and annotated them to specific cell types, providing further characterization of these signatures and their pathways (e.g., for medial orbitofrontal thickness, snRNAseq signature in excitatory neurons is correlated to gene [rho = 0.22] and protein [rho = 0.24] expression).

Conclusion: By associating molecular traits with imaging anatomical features generated from the same individuals, we provide an in-depth characterization of the molecular foundation of brain anatomy in living individuals.

Background/Objectives: Heterozygous pathogenic variants in *SPAST* are known to cause Hereditary Spastic Paraplegia 4 (SPG4), the most common form of HSP, characterized by progressive bilateral lower limb spasticity with frequent sphincter disorders. However, there are very few descriptions in the literature of patients carrying biallelic variants in *SPAST*.

Methods: Targeted Sanger sequencing, panel sequencing and exome sequencing were used to identify the genetic causes in 8 patients from 5 unrelated families with symptoms of HSP or developmental and epileptic encephalopathy.

Results:

We describe 8 patients with pure HSP with variable age of onset, mostly in infancy, and 3 patients with severe early-onset developmental and epileptic encephalopathy with a progressively worsening tetrapyramidal syndrome. The patients' parents, heterozygous carriers of pathogenic *SPAST* variants, included both asymptomatic carriers and patients with a classic form of HSP4.

These different phenotypes are consistent with the very rare descriptions available in the literature: a patient carrying a homozygous variant in *SPAST* presenting with developmental encephalopathy and epilepsy had been reported, as well as 3 patients with pure spastic paraplegia, of infantile or late onset.

Conclusion: Biallelic variants of SPAST may explain cases of hereditary spastic paraplegia with autosomal recessive inheritance. Furthermore, these biallelic variants may also cause epileptic encephalopathy with a tetrapyramidal syndrome, a new phenotype associated with the *SPAST* gene.

P11.133.A Spatial transcriptomics reveals mechanisms of degeneration and regeneration in multiple sclerosis

Jia Hui Khoo[1], *A. M. R. Van Den Bosch*[2], *Zhigang Lu*[1], *Dennis Wever*[2], *Li Pu*[1], *Bart Eggen*[3], *Joost Smolders*[2;4], *Jörg Hamann*[2;5], *Zhouchun Shang*[1], *Jan Mulder*[6], *Inge Huitinga*[2;7]

[1]*BGI Research Foundation Latvia, Riga, Latvia;* [2]*Netherlands institute for Neuroscience, Neuroimmunology Research Group, Amsterdam, Netherlands;* [3]*University Medical Center Groningen, Department of Neuroscience, Section Medical Physiology, Groningen, Netherlands;* [4]*Erasmus Medical Center, MS Center ErasMS, Department of Neurology and Immunology, Rotterdam, Netherlands;* [5]*Amsterdam University Medical Center, Amsterdam Infection and Immunity Institute, Amsterdam, Netherlands;* [6]*Karolinska Institute, Department of Neuroscience, Stockholm, Sweden;* [7]*University of Amsterdam, Swammerdam Institute for Life Sciences, Amsterdam, Netherlands*

Background/Objectives: In multiple sclerosis (MS), various lesion types are found across the central nervous system, with varying potential for demyelination, remyelination and scar formation. Mixed active/inactive (mA/I) lesions with foamy microglia correlate with neuro-axonal damage while those with ramified microglia do not, suggesting biological differences. Investigating these differences may elucidate critical mechanisms driving MS lesion progression and repair.

Methods: Postmortem tissue of n = 8 MS donors and n = 3 control donors was provided by the Netherlands Brain Bank. We performed high-resolution spatial transcriptomics and immunohistochemistry analyses, focusing on the demyelinated center, demyelinating border and the peri-lesion border of mA/I lesions with ramified microglia to those with foamy microglia within the same donors.

Results: Stereo-seq and IHC results at the single-cell and bin50 level showed that lesion border and demyelinated center had significantly different cellular composition as compared to the peri-lesion region. Unsupervised clustering and cell-bin pseudo bulk analysis identified distinct gene expression patterns. Gene expression of mA/I lesions with foamy microglia indicated higher levels of ongoing tissue damage, demyelination, complement activation, iron metabolism, reactive astrocytes, and immunoglobulin production in the centre, border, and peri-lesion region. In contrast, mA/I with ramified microglia showed higher levels of neurite outgrowth, stability of myelin, and lipid export in the border and peri-lesion.

Conclusion: mA/I lesions with ramified microglia may be more prone to remyelination, while those with foamy microglia may be more prone to lesion expansion. This study sheds light on the molecular mechanisms driving MS lesion dynamics and identifies potential targets for therapeutic interventions.

Background/Objectives: While random X-chromosome inactivation in female cells of placental mammalians silences one allele of the majority of X-chromosomal genes, a considerable fraction is only incompletely and variably inactivated resulting in a tissue-specific pattern of mono- and biallelic expression.

Methods: Here we used clonal human female induced pluripotent stem cells (iPSCs) allowing us to trace the (in)activation status of the two X-chromosomes individually along neural differentiation trajectories.

Results: We discovered X-chromosome-wide locus- and lineage-specific dynamic usage of the two X-chromosomal alleles in female cells induced by differentiation. Leveraging iPSCs derived from patients with an X-linked neurodevelopmental disorder, we demonstrate that activation of alleles on the inactive X-chromosome can exert protective effects on the manifestation of disease phenotypes in female neural cells and tissue.

Conclusion: Taken together, our data demonstrate that alleles on the inactive X-chromosome can serve as a critical reservoir reactivated during differentiation, thereby enhancing the resilience of female neural tissue.

P11.135.C Terminal duplications of the 17p13.3 region: Further case evidence of a cause for polymicrogyria

Eleanor Ludington[1], *David Francis[1], Tiong Yang Tan[1;2;3;4], George McGillivray[1;5], Anand Vasudevan[5], Richard Leventer[2;3;6], Chloe Cunningham[1;2;3]*

[1]Victorian Clinical Genetics Services, Parkville, Australia; [2]Murdoch Children's Research Institute, Parkville, Australia; [3]The University of Melbourne, Department of Paediatrics, Parkville, Australia; [4]The Royal Children's Hospital Melbourne, Parkville, Australia; [5]The Royal Women's Hospital, Department of Clinical Genetics, Parkville, Australia; [6]The Royal Children's Hospital Melbourne, Department of Paediatric Neurology, Parkville, Australia

Background/Objectives: The chromosome 17p13.3 microduplication syndrome is recurrent, reported in only 40 individuals. This interstitial duplication involves the Miller-Dieker critical region and can be categorised into class I (*PAFAH1B1*-absent) and class II (*PAFAH1B1*-present). It produces a variable phenotype including developmental delay, behavioural disorders, facial dysmorphism, and structural brain abnormalities. Terminal duplications incorporating this region are very rare, usually complicated by other structural CNVs, and only one individual in the literature has been reported to have polymicrogyria. The aetiology of polymicrogyria is heterogeneous and poorly understood. Genetic causes include chromosomal or monogenic variants. We report 3 individuals with terminal 17p13.3 microduplications, two of whom have bilateral perisylvian polymicrogyria.

Methods: Three unrelated individuals were seen by clinical genetics at a tertiary paediatric hospital in Melbourne, Australia for assessment of polymicrogyria and/or developmental delay. Each had a standard SNP chromosomal microarray (Illumina Infinium GSA-24 v3.0).

Results: In all 3 individuals standard SNP chromosomal microarray identified overlapping 17p13.3 duplications ranging from 4Mb - 4.3Mb. One individual also had a 2.3Mb terminal deletion of 5q35.3. Each duplication included *PAFAH1B1*, *YWHAE* and *CRK* within the Miller-Dieker critical region. MRI brain of two of the individuals demonstrated polymicrogyria. The third individual had expressive language delay, hypotonia and oromotor dysfunction without indication for a brain MRI.

Conclusion: Our observation of two cases of 17p13.3 microduplication syndrome with polymicrogyria strengthens the association of duplication of the Miller-Dieker critical region with polymicrogyria and underscores the variable neurodevelopmental phenotype.

Consortium: DysTract consortium

Background/Objectives: Dystonia is a movement disorder characterized by excessive muscle contractions leading to involuntary movements and abnormal postures. Pathogenic variants in several genes (*GCH1*, *GNAL*, *KMT2B*, *PRKRA*, *SGCE*, *THAP1*, and *TOR1A*) have been linked to monogenic forms of dystonia. To further elucidate the phenotypic and genetic spectrum, we screened a large sample of patients with dystonia or Parkinson's disease (PD), where dystonic signs are not infrequent.

Methods: We employed a next-generation sequencing-based gene panel to screen 1,207 dystonia and 1,036 PD patients for variants in dystonia-causing genes. Pathogenicity was assessed using the ACMG and MDSGene (www.mdsgene.org/methods) scoring systems. The impact on DNA methylation of *KMT2B* variants was evaluated by analyzing the gene's characteristic episignature.

Results: We identified 171 carriers (109 with dystonia [9.0%]; 62 with PD [6.0%]) of 131 rare variants (minor allele frequency <0.005). Thereof, 52 patients (48 dystonia [4.0%]; four PD [0.4%, all with *GCH1* variants]) carried 33 different (likely) pathogenic variants, including 17 previously unreported changes. Episignature analysis of 48 *KMT2B* variants suggested only two variants as pathogenic.

Conclusion: This study validates pathogenic variants in several genes as relevant contributors to dystonia and expands the mutational spectrum. Notably, likely pathogenic variants only in *GCH1* were also found in PD patients. For DYT-KMT2B, the recently described episignature served as a reliable readout to determine the functional effect of newly identified variants. Subsequent exome and genome sequencing in unresolved patients will identify additional genetic causes of dystonia.

P11.138.B Genome sequencing results of a cohort of pediatric patients with autism and neurodevelopmental disorders

Mariia Parfenenko[1], *Ilya Dantsev*[1], *Olga Groznova*[2;3], *Victoria Voinova*[2]

[1]*Veltischev Research and Clinical Institute for Pediatrics and Pediatric Surgery of the Pirogov Russian National Research Medical University of the Ministry of Health of the Russian Federation, laboratory of clinical genomics and bioinformatics, Moscow, Russian Federation;* [2]*Veltischev Research and Clinical Institute for Pediatrics and Pediatric Surgery of the Pirogov Russian National Research Medical University of the Ministry of Health of the Russian Federation, clinical genetics, Moscow, Russian Federation;* [3]*2. Charity Fund for medical and social genetic aid projects «Life Genome», Moscow, Russian Federation*

Background/Objectives: Autism is a neurodevelopmental disorder (NDD) characterized by communication difficulties and stereotypic behavior, which frequently co-occurs with intellectual disability, developmental delay, epilepsy, and other conditions. SFARI (Simons Foundation Autism Research Initiative) Gene database categorizes autism-associated genes into four levels of evidence: 1 – high confidence, 2 – strong candidate, 3 – suggestive evidence, and an extra category "S" for genes linked to additional features.

Methods: 116 unrelated patients (table 1) (mean age: 7.4 y/o (3-20), female: 41 (35%), male: 75 (65%)) with NDDs underwent genome sequencing. We viewed pathogenic, likely pathogenic, and variants of unknown significance (VOUS) in autism-associated genes as likely causative.

Feature	Autism	Signs of autism	Developmental delay	Speech disorders	Intellectual disability	Epilepsy	Known normal karyotype	NDDs in relatives
Number of patients (N, %)	49, 42%	116, 100%	50, 43%	56, 48%	12, 10%	25, 22%	30, 26%	20, 17%

Results: 156 variants (table 2) in 113 genes included in SFARI Gene were likely causative, 66 genes – associated with syndromic forms, 47 – isolated autism; 63 belonged to category 1, 34 – category 2, 16 – to others. 88 patients had 1 involved gene, 23 had 2, the rest – 3 or 4. The most frequently involved genes: *CHD8* (6 cases) and *SCN2A* (4 cases).

Pathogenic	8 (5%)
Likely pathogenic	21 (13%)
VOUS	127 (82%)
Inherited from parent	12 (8%)

Conclusion: Genome sequencing of 116 patients with NDDs provided insight into likely genetic causes of autism and autism-like phenotypes in our population.

Background/Objectives: For many neurodegenerative diseases, comprehensive genotype-phenotype correlations are challenging. But it has been proposed that disease-causing variants may lead to cellular and molecular perturbations long before the onset of clinical symptoms. Here we set out to explore whether the late-onset autosomal dominant leukodystrophy (ADLD), has early detectable signatures.

Methods: We sampled the brains of mouse mutants replicating known ADLD-associated variants. Based on the differences detected in the 3D genome between the two mutants, we subjected brains of two embryonic stages (E11.5 and E18.5) and in youth (P30) to single cell RNA sequencing (sc-RNAseq). We applied sc-RNAseq to provide an unbiased characterization of different SVs that result in the same clinical phenotype. In the analysis we compared changes in cell composition, differential gene expression, and intercellular signaling in an objective and comprehensive manner.

Results: Interestingly, we detected several significant changes in the cell composition and gene expression already at early embryonic stages in multiple cell types, including neuronal cell trajectories, indicating a gap between molecular and clinical onset of disease. Further, although categorized as the same disease, there are differences between the two SVs in early development, indicating alternate disease mechanisms.

Conclusion: Analysis of the single cell dataset revealed changes in brain development in the mouse models of ADLD, for example in the cellular composition, gene expression and specific gene pathways detectable. Further extensive and unbiased characterization is underway to uncover more subtle changes in the brain architecture of the developing embryo.

P11.141.A Transcriptomic and epigenomic consequences of heterozygous loss of function mutations in AKAP11, the first large-effect shared risk gene for bipolar disorder and schizophrenia

Nargess Farhangdoost[1;2], *Yumin Liu*[2], *Patrick Dion*[2;3], *Boris Chaumette*[4], *Anouar Khayachi*[2], *Guy Rouleau*[2;3]

[1]*McGill University, Human Genetics, Montréal, Canada;* [2]*Montreal Neurological Institute-Hospital, Montréal, Canada;* [3]*McGill University, Montréal, Canada;* [4]*Institute National De La Santé Et De La Recherche Médicale, Paris, France*

Background/Objectives: Bipolar disorder (BD) is a complex psychiatric condition with psychotic symptoms similar to schizophrenia (SCZ). Despite extensive research, the roots of BD remain largely unknown. *AKAP11* is a loss-of-function (LoF) rare-variant shared risk gene between BD and SCZ with large effects. Here, the effect of heterozygous LoF mutations in *AKAP11* is being investigated at the transcriptomic and epigenetic level in induced pluripotent stem cell (iPSC)-derived neurons.

Methods: Using a human iPSC, we generated 3 *AKAP11*-Knockout (*AKAP11*-KO) isogenic neuronal clones, each carrying a different heterozygous frameshift mutation. Subsequently, we carried out RNA sequencing, whole-genome bisulfite sequencing, and chromatin immunoprecipitation followed by sequencing of histone H3 lysine 27 acetylation.

Results: We identified an overall downregulation in genes related to ribosome function and transcription factor activity, and an upregulation in signaling receptor interactions, cytokine activity, and cytoskeletal dynamics. We detected global DNA methylation changes, predominantly in intergenic and intronic regions. Intergenic enhancers with reduced activity were associated with downregulated genes also primarily involved in transcription factor activity. Conversely, intronic enhancers with increased activity were linked to upregulated genes involved in signaling receptor binding, cytokine receptor binding, and cytoskeleton-related functions.

Conclusion: Our exploration into the epigenomic and transcriptomic impacts of heterozygous LoF of AKAP11 has revealed insights into significant outcomes in the regulation of gene expression. This is particularly evident in genes that function as transcription factors and co-factors, regulators of actin and cytoskeleton, and cytokine receptors, primarily through the modulation of intergenic and intronic cis-regulatory elements.

Background/Objectives: Defects in SUMOylation, a regulatory post-translational modification process, are an emerging cause of neurodevelopmental disorders (NDDs). SUMOylation involves the conjugation of SUMO protein to specific Lys residues of target substrates by E1, E2, and E3 enzymes. We investigated *UBE2I*, encoding UBC9, the only E2 enzyme in the SUMO system, as a potential causative gene for NDD.

Methods: Using trio-ES on a comprehensive survey of more than 600 NDD families, we discovered a de novo missense change, NM_194260.3:p.(Asn124Ile), in the *UBE2I* in a pediatric patient displaying a syndromic phenotype. GeneMatcher platform allowed us to identify three additional *UBE2I* patients (p.Val25Met; p.Trp53Leu; p.Glu143Gly) and gather clinical data. We generated stable inducible cell lines using the Flp-In T-Rex system, to express the wild-type (WT) or the variant forms. Using western blot analysis, we examined the impact of these variants on UBC9 protein levels and sumoylation.

Results: We have identified four unrelated cases with deleterious missense variants in *UBE2I*, affecting highly evolutionarily conserved aminoacids. All patients displayed common features, including neurodevelopmental delay, thick eyebrows, hypertelorism/telecanthus, almond shaped eyes, nasal shape anomalies and hand anomalies. In our cellular model, the expression levels of the *UBE2I* variants were lower compared to the wildtype. However, we also noted an increase in sumoylation suggesting that these variants may disrupt the normal regulation of sumoylation processes.

Conclusion: We propose *UBE2I* as a potential candidate gene for a novel NDD. Confirming its involvement in NDDs will provide valuable insights into the significance of sumoylation in brain function and development.

P11.143.C Improving work up amongst patients with rare movement disorders according to diagnostic yield findings– Update from single center Neurogenetic Clinic

Dvir Penn[1], *Yam Amir*[1], *Gili Ben David*[1], *Tatyana Gurevich*[1], *Hagit Baris Feldman*[1], *roy alcalay*[1], *yuval yaron*[1], **Penina Ponger**[1]

[1]*Tel Aviv Sourasky Medical Center - Ichilov, Tel Aviv-Yafo, Israel*

Background/Objectives: The diagnostic yield of genetic testing for movement disorders is increasing as next-generation-sequencing (NGS) and advanced molecular testing are incorporated into routine work-up. We present the genetic testing diagnostic yield in a tertiary center Neurogenetic Clinic, focusing on rare movement disorders.

Methods: Retrospective analysis (2019-2023) of 190 patients aged 1-84 years diagnosed with cerebellar ataxia (CA, N = 92), spastic paraparesis (SPP, N = 50) and hyperkinetic movement disorders, including dystonia and dyskinesia (HMD,N = 48). Work-up included NGS and repeat expansion testing. Undiagnosed cases underwent exome-sequencing (ES) or genome-sequencing.

Results: Amongst 190 patients, 107 were newly referred undiagnosed patients. Amongst these a genetic diagnosis was reached in 46 cases (43%): 29 (63%) by NGS and 17 (37%) by repeat expansion analysis. Diagnostic rate reached 46% in CA, 31% in SPP and 32% in HMD. Diagnostic yield of NGS panels was 26% and of ES (singleton and trio) 33%. Diagnostic yield was higher among patients with younger onset of disease and isolated phenotypes. 29 patients had at least two brain MRI examinations

during their work-up and 24 patients completed non diagnostic CMA tests.

Conclusion: Our Neurogenetic clinic reports higher diagnostic yield compared with reported literature (20-30%), especially in patients with early-onset disease. ES increased diagnostic yield, compared with panel testing, especially amongst patients with complex phenotypes. Our findings indicate that performing a tailored genetic work-up fashion according to phenotype complexity and age of onset can reduce the need for auxiliary and molecular testing. Further cost-benefit analysis is required to decrease expenses and ensure timely diagnosis.

NEUROMUSCULAR DISORDERS

P12.001.D Whole-exome sequencing in the diagnostics of rare diseases - solving the mystery of a 12-year-old case

Natalie Friedova[1], *Jana Tajtlova*[1], *Renata Kejkulova*[1], *Robert Rusina*[2], *Martina Langova*[1]

[1]*Thomayer University Hospital, Department of Medical Genetics, Prague, Czech Republic;* [2]*Department of Neurology 3rd Faculty of Medicine Charles University and Thomayer University Hospital, Prague, Czech Republic*

Background/Objectives: The method of massively parallel sequencing at the level of whole-exome sequencing (WES) brings fundamental benefits in the diagnosis of the genetic cause of the disease in patients in whom previously used methods have failed and no clinically relevant result has been achieved.

We present a case of a 51-year-old man who was undergoing the diagnostic procedure since the age of 39 for ataxia and chorea with subsequent progression of cognitive impairment and movement disorder. MRI revealed progressive brain damage and cerebellar atrophy. Since 2011, our patient has been gradually investigated for suspected Huntington's disease, early-onset Alzheimer's disease, and related neurodegenerative disorders with negative test results.

Methods: Sequencing of whole-exome was performed as part of the SSELXT HS Human All Exon V8 + NCV (Agilent) sequencing on the NextSeq 550DX (Illumina) high-capacity sequencer. Bioinformatic analysis was performed by GENOVESA (Bioxys) by virtual panel (neurological diseases, 189 genes).

Results: By using a virtual panel of neurodegenerative diseases, a heterozygous pathogenic variant

the HGVS/HGVp: FIG4(NM_014845.6):c.447-2A>T p.?; dbSNP:rs866895236 (deep reads 104) was detected. Pathogenic variants in the *FIG4* gene (FIG4 Phosphoinositide 5-Phosphatase) are associated with amyotrophic lateral sclerosis 11 (OMIM 61257).

Conclusion: Whole-exome sequencing marked a breakthrough in the diagnostics of our patient. Whole exome sequencing has the potential to significantly shorten the diagnostic procedures, leading to the successful diagnosis of rare genetic conditions.

P12.002.A Genome-wide meta-analysis provides novel insights into the polygenic architecture of myasthenia gravis

Alice Braun[1], *Stephan Ripke*[1], *Frauke Stascheit*[1], *Andreas Meisel*[1]

[1]*Charité – Universitätsmedizin Berlin, Berlin, Germany*

Consortium: 23andMe Research Team

Background/Objectives: Myasthenia gravis (MG) is a rare autoantibody-mediated disease of the neuromuscular junction that is characterized by muscle weakness and fatigue. We present a comprehensive genetic analysis of MG utilizing data from 12 cohorts and a replication sample provided by 23andMe, Inc.

Methods: We conducted discovery and replication case-control genome-wide association study, association analyses of imputed human leukocyte antigen (HLA), polygenic risk scoring (PRS), and genetic correlation analyses through linkage disequilibrium score regression. The discovery GWAS meta-analysis included 5,708 patients with clinically diagnosed MG and 432,028 control subjects. The results were replicated and meta-analyzed with a sample of 3,989 self-reported MG cases and 226,643 controls.

Results: The GWAS identified 12 genome-wide significant ($P < 5e^{-8}$) loci. Association analyses of imputed HLA alleles highlighted inverse effect sizes for late- (aged ≥50) and early-onset (aged <50), suggesting a potential modulatory influence on the time of disease manifestation. This study is the first to assess the performance of PRS for MG, which significantly predicted disease status in an independent unstratified target cohort, explaining 4.21% of the phenotypic variation ($P = 5.12e^{-9}$). We identified five significant genetic correlations with MG, with the strongest observed for type 1 diabetes ($r_g = 0.523$, $P = 1.42e^{-6}$, SE = 0.109) and rheumatoid arthritis ($r_g = 0.508$, $P = 1.11e^{-6}$, SE = 0.104).

Conclusion: The discovery and replication meta-analyses identified six novel associations and validated six known loci, enhancing our understanding of the genetic architecture of MG. Furthermore, polygenic risk scores effectively predicted MG in an independent cohort, presenting a promising addition to existing diagnostic and prognostic procedures.

Background/Objectives: Duchenne and Becker Muscular Dystrophy (DMD/BMD) are genetic disorders characterized by progressive muscle weakness, primarily caused by mutations in the *DMD* gene. Despite advances in genetic diagnostics, approximately 2-7%, of DMD/BMD cases remain genetically unsolved. The *DMD* gene consists of 99% intronic sequences, which emphasizes the importance of exploring deep intronic regions for the identification of new variants.

Methods: In this study, four cases are presented in which the causative variant could not be identified by conventional genetic analysis. All four patients have muscle weakness, elevated CK values (>10,000 U/l) and altered dystrophin in the muscle biopsy.

Results: Using whole genome sequencing, we were able to identify the four different causative intronic variants in the mentioned cases: two known variants in intron 55 and 61, and two novel variants in intron 15 and 53, respectively. These deep intronic variants in the *DMD* gene were previously missed by conventional sequencing methods.

Conclusion: The identification of these variants not only resolves the genetic ambiguity in these cases, but also emphasizes the importance of going beyond exonic sequences to understand the genetic basis of DMD/BMD. Our findings help to close the gap in the genetic characterization of unsolved DMD/BMD cases, paving the way for more accurate diagnosis and potentially treatments. This study highlights the need for further exploration of deep intronic regions to improve diagnostic yield in genetically complex diseases such as DMD.

Grants: Funded by Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – 444748124.

Background/Objectives: Neuromuscular diseases (NMD) constitute a diverse spectrum of disorders with a collective global prevalence of 100-200 cases per 100,000 individuals. The integration of next-generation sequencing into clinical practice has revolutionized their genetic diagnosis and has taken the lead over neurophysiological and histopathological tests. However, a large percentage of patients remain undiagnosed (50%).

Methods: We have assessed the usefulness of combining a standardized high-quality phenotyping with trio genome sequencing, and RNASeq if muscle biopsy was available (13 samples), to elevate the diagnostic rate for 58 individuals with unsolved childhood-onset NMDs that had previously undergone inconclusive exome studies.

Results: A genetic diagnosis was established in 23 out of 58 index patients (40%) and in two additional families we identified candidate variants whose pathogenicity is still awaiting confirmation. SNVs or smalls indels were identified as causative in 22 of the 23 solved cases, while a complex structural variant in *PLEKHG5* explained the condition in the remaining case.

Interestingly, the trio analysis uncovered a monoallelic *RYR1* variant in an asymptomatic mother and her offspring affected by congenital myopathy, proven to be in mosaic in the mother. Furthermore, in another patient with a congenital myopathy, the combination of RNASeq and genome sequencing let us identify a pseudoexon in the *NEB* gene and the causative deep-intronic variant.

Conclusion: With these examples, we illustrate how our genetic analysis approach proved to be effective to end the diagnostic odyssey of 23 patients.

Consortium: The OPTIMISTIC Consortium, the ReCognitION consortium

Background: Myotonic Dystrophy type 1 (DM1), caused by CTG repeat expansions in *DMPK*, is a progressive multisystem disease with large heterogeneity in disease onset, severity and

progression. This study aims to identify proteomic biomarkers that can serve as surrogate endpoints in clinical trials.

Methods: We profiled 450 peripheral blood samples from adult DM1 patients participating in the clinically well-characterised OPTIMISTIC trial cohort, using bottom-up mass spectrometry-based proteomics. Blood samples of an external cohort of 57 DM1 patients were used to validate the negative associations of ITIH3 expression with clinical measures of physical activity.

Results: We observed 165 protein groups significantly associated with CTG-repeat length and 73 with physical activity, as reflected by the 6-minutes-walk-test (6MWT) score. Severity biomarkers were associated with hypogammaglobulinemia, whereas reduced physical activity was mostly associated with increased levels of complement factors and the complement-associated factor ITIH3 (Rho -0.3, $p < 0.01$). The association between ITIH3 and physical activity has been confirmed in an external cohort, where similar negative associations were observed with the 6MWT score (Rho -0.2, $p = 0.19$) and grip strength (Rho -0.43, $p < 0.01$). Multivariate Elastic-Net analysis resulted in the selection of 10 proteins that explain up to 31% of the variance in CTG-repeat length and 27% in 6MWT scores.

Conclusion: DM1 induces a broad disease fingerprint in the peripheral blood proteome. We suggest a panel of carefully selected proteins for monitoring disease severity that deserves validation in longitudinal studies spanning larger time frames than the OPTIMISTIC study.

Grants: This study was funded by e-RARE JTC2018 grant N°643578.

P12.006.A Genetic and epigenetic profiling for FSHD diagnosis by nanopore sequencing

Florentine Scharf[1], *Hannes Erdmann*[1;2], *Morghan Lucas*[1;3], *Stefanie Gehling*[1], *Ariane Hallermayr*[1;3], *Anna Benet-Pages*[1;4], *Sibylle Jakubiczka*[5], *Martin Zenker*[5], *Annika Saak*[2], *Jochen Schaefer*[6], *Udo Koehler*[1], *Teresa Neuhann*[1], *Elke Holinski-Feder*[1;3], *Maggie C. Walter*[2], *Benedikt Schoser*[2], *Angela Abicht*[1;2]

[1]*MGZ - Medical Genetics Center, München, Germany;* [2]*Friedrich Baur Institute at the Department of Neurology, LMU University Hospital, Ludwig-Maximilians-Universität, München, Germany;* [3]*Department of Medicine IV, LMU University Hospital, Ludwig-Maximilians-Universität, Munich, Germany;* [4]*Institute of Neurogenomics, Helmholtz Research Center, Neuherberg, Germany;* [5]*Institute of Human Genetics, University Hospital Magdeburg, Magdeburg, Germany;* [6]*Department of Neurology, University Hospital Carl Gustav Carus, Dresden, Germany*

Background/Objectives: The genetic diagnosis of facioscapulohumeral muscular dystrophy (FSHD) poses a significant clinical challenge. Conventional diagnostic strategies address the required presence of a permissive haplotype, a contraction of the D4Z4 repeat of chromosome 4q35 (FSHD1), or a pathogenic variant in an epigenetic suppressor gene (FSHD2). However, it was recently shown that methylation serves as a reliable marker of disease severity, given an exact assignment of haplotype, which to date remains challenging.

Methods: To circumvent the known limitations of conventional diagnostics we leverage Oxford Nanopore Technologies (ONT) targeted long-read sequencing to simultaneously characterize haplotypes, number of repeat units, methylation profiles, single nucleotide and structural variants, hybrid alleles and somatic mosaicism within a single sequencing run.

Results: As proof of concept, we were able to clarify the unexpected high average distal methylation in a paucisymptomatic patient homozyguous for 4qA, harboring a repeat contraction with two repeat units on one allele. The ONT data revealed the presence of the contraction as a mosaic, causing an increase in the average percent methylation. In another patient, resolving a complex hybrid allele revealed the presence of a hypermethylated rare 4qC166H haplotype, which makes FSHD unlikely as reason for the patient's symptoms.

Conclusion: ONTs ability to provide long reads and base modification data allows the characterization of genetic parameters involved in development of FSHD in its entirety. The methylation data can unambiguously be assigned to single alleles. This approach not only enables a more precise diagnostic but will help answer yet unresolved questions regarding the pathomechanism of this highly complex disease.

Background/Objectives: Limb-girdle muscular dystrophy recessive 1 (LGMDR1) is a rare neuromuscular disorder caused by biallelic pathogenic *CAPN3* variants. The prevalence of cancer in patients with LGMDR1 is uncertain. Here, we present the clinical findings of a 17-year-old patient with LGMDR1 who developed a Soft Tissue Sarcoma (STS). Additionally, we conducted a literature review on muscular dystrophies (MD) and cancer.

Methods: As part of the nationwide Genomic Medicine Sweden Childhood Cancer project, the patient was offered paired germline-tumor whole genome DNA sequencing and tumor RNA-sequencing. A PubMed literature review on cancer in MD was performed.

Results: In the patient, identification of two germline biallelic pathogenic *CAPN3* variants (NP_000061.1:p.(Arg448Cys) and NP_000061.1:p.(Thr184ArgfsTer36)), confirmed the LGMDR1 diagnosis. STS analyses led to the diagnosis of a desmoplastic small round cell tumor with near-triploid karyotype and multiple numerical/segmental chromosomal aberrations. RNA-sequencing showed a EWSR1::WT1 fusion transcript. No germline variants in childhood cancer predisposition genes were detected.

MD mice are susceptible to STS development. In our literature review including 66 patients with MD and cancer, we observed an overrepresentation of STS in Duchenne muscular dystrophy (DMD,

10/24 patients) and LGMD (2/8 patients) and an early age at cancer onset amongst reported MD cases (average 31.3 years).

Conclusion: We describe the first patient with LGMDR1 who developed a STS. Our literature review revealed an early age at cancer onset in reported patients with MD, with an over-representation of STS in DMD and LGMD. Further studies involving population-based cohorts addressing the association between LGMDR1 and cancer are warranted.

Grants: The Swedish Childhood cancer fund.

[1]*University of Tartu, Estonia;* [2]*Tartu University Hospital, Estonia;* [3]*West Tallinn Central Hospital, Estonia;* [4]*Folkhälsan Research Center, Helsinki, Finland;* [5]*University of Helsinki, Helsinki, Finland;* [6]*Tampere University Hospital, Finland*

Background/Objectives: Tibial muscular dystrophy (TMD; MIM#600334, ORPHA:609) is an adult onset distal myopathy that was first described by Udd et al in Finnish patients. An 11-bp insertion/deletion in the last exon (exon 364) of the *TTN* gene is the Finnish founder variant (FINmaj). In heterozygous state, FINmaj causes autosomal dominant (AD) TMD with slow progression affecting preferentially the tibialis anterior muscle. To date, FINmaj variant is not described outside the Finnish population. After identification of a first family, this study aimed to retrospectively find more TMD patients and to estimate the FINmaj frequency in the Estonian population.

Methods: We retrospectively analyzed all large gene panel and whole exome sequencing data from 2011-2021 to find FINmaj carriers in Genetics and Personalized Medicine Clinic (GPMC) cohort (n = 4632) and in the cohort of unsolved myopathy/neuropathy patients in West Tallinn Central Hospital cohort (n = 52). Magnetic resonance imaging (MRI) was performed on seven FINmaj patients.

Results: We found four families with 16 patients who carry the heterozygous FINmaj variant: two patients with autosomal recessive limb-girdle muscular dystrophy type LGMD R10 and 14 patients with AD TMD. All the TMD patients in the cohort carried the FINmaj variant and had clinical symptoms by the age of 50 years. MRI analysis showed TMD-specific findings in >50yo patients. FINmaj variant incidence in the Estonian GPMC cohort is 1/1500. Haplotype analysis is at work.

Conclusion: AD TMD is the most common hereditary muscle disease in Estonia and is still underdiagnosed.

P12.009.D Clinical characterization of a cohort of female carriers of X-linked myotubular myopathy (XL-MTM) in Germany – extending the phenotypic spectrum and knowledge about the impact of heterozygous variants in the *MTM1* gene

Frederik Braun[1;2], *Frank J. Kaiser*[2], *Ulrike Schara-Schmidt*[1]

[1]*Centre for Neuromuscular Disorders, Centre for Translational Neuro- and Behavioral Sciences, University Duisburg-Essen, Department of Pediatric Neurology, Essen, Germany;* [2]*Institute of Human Genetics, University Hospital Essen, University Duisburg-Essen, Essen, Germany*

Background/Objectives: The mode of inheritance of X-linked myotubular myopathy (XL-MTM) is still considered recessive, although female carriers are frequently symptomatic. We aimed to characterize the phenotypic spectrum and burden of disease in a carrier cohort.

Methods: We performed a cross-sectional study among XL-MTM carriers in Germany, recruiting predominantly through a patient association. We used a custom-made questionnaire on medical and family history, the Checklist Individual Strength (CIS20-R), Short Form 12 (SF-12) health survey, Pain Detect, Short-Form McGill Pain Questionnaire (SF-MPQ-D), Graded Chronic Pain Scale (GCPS), and Depression Anxiety Stress Scale (DASS21). All participants received a neurologic examination including manual muscle testing (MMT), a 6-minute walking test (6MWT), and timed up-and-go (TUG) test. Where possible, we performed ultrasound of the abdomen and vastus lateralis muscles, echocardiography, pulmonary function testing, blood count, and further laboratory testing. Carriers were classified as manifesting based on the degree of muscular weakness and ambulatory status.

Results: In our study population (n = 14), most carriers were classified as manifesting with a mild (n = 8; independent ambulation, with limb or axial weakness) or minimal phenotype (n = 3; only facial muscle weakness). We consider only the minority non-manifesting (n = 3). Frequent features include a high-arched palate, fatigue, muscle pain and stiffness, and pulmonary problems. Many carriers are caregivers of boys with XL-MTM (n = 11). Families are burdened with stillbirth and death in early childhood (n = 8).

Conclusion: The majority of female carriers of XL-MTM show neuromuscular and additional symptoms. This should be considered in diagnostics, clinical care, and future clinical trials.

Grants: DFG FU 356/12-2

P12.010.A Novel deep intronic variant in the CAPN3 gene in trans with pathogenic variant as a cause of calpainopathy

Tihomir Todorov[1], *Slavena Atemin*[1], *Mila Sleptsova*[1], *Stoyan Bichev*[2], *Alexey Savov*[2], *Albena Todorova*[1;3]

[1]*Genetic Medico-Diagnostic Laboratory "Genica", Sofia, Bulgaria;* [2]*University hospital of Obstetrics and Gynecology, National Genetics Laboratory, Sofia, Bulgaria;* [3]*Medical University of Sofia, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria*

Background/Objectives: Patient with muscular dystrophy was referred for molecular-genetic analysis in order to identify the genetic reason for the observed phenotype. Based on whole exome sequencing (WES) a heterozygous pathogenic variant c.598_612del in the *CAPN3* gene was detected. Segregation analysis in the family showed that the variant was inherited from the patient's healthy father. Therefore autosomal-dominant model of inheritance was excluded. Additional molecular-genetic analyses were performed to determine the genetic etiology.

Methods: WES was performed and a panel of genes related to muscular dystrophies was analyzed. Variants flagged through the analysis were confirmed and segregated in the patient's family via Sanger sequencing. MLPA analysis for deletions/duplications along the *CAPN3* gene was performed.

Results: MLPA analysis did not show aberrations along the *CAPN3* gene. The analysis of WES data did not result in finding a potentially pathogenic variant in any of the other analyzed genes. Further analysis of the WES data revealed a novel intronic variant c.1914+309C>T in the *CAPN3* gene. Segregation analysis

confirmed maternal inheritance of the detected variant and hence both *CAPN3* variants are localized in trans.

Conclusion: Based on the performed analysis two biallelic variants in the *CAPN3* gene were detected. This suggests autosomal-recessive mode of inheritance. Muscular biopsy revealed lack of 3 calpain isoforms which supports pathogenic nature of the detected *CAPN3* genetic variants and confirms the genetic diagnosis of calpainopathy in the patient.

P12.011.B Unexpected cause of spastic ataxia

Martina Langova[1;2], *Natalie Friedova*[1;3], *Jana Tajtlova*[1], *Renata Kejkulova*[1], *Magdalena Vitkova*[1], *Antonin Sipek Jr*[1;2;3]

[1]*Thomayer University Hospital, Department of Medical Genetics, Prague, Czech Republic;* [2]*Third Faculty of Medicine, Charles University in Prague, Department of Medical Genetics, Prague, Czech Republic;* [3]*Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic*

Background/Objectives: Whole-exome sequencing (WES) has in recent years significantly expanded the range of diagnostic possibilities. WES helped to reveal the cause of difficulties in patients with so far unresolved diagnoses.

A 43-year-old woman was consulted for slowly progressive mobility impairment with associated spasticity and ataxia with the early onset of symptoms. The initial symptoms (walking and coordination disability) had occurred in early childhood. The latest MRI showed mild brain atrophy, and EMG revealed severe demyelination polyneuropathy.

Methods: Sequencing of whole-exome was performed as part of the SSELXT HS Human All Exon V8 + NCV (Agilent) sequencing on the NextSeq 550DX (Illumina) high-capacity sequencer. Bioinformatic analysis was performed by GENOVESA (Bioxys) by virtual panel (hereditary spastic paresis).

Results: Using WES were detected one pathogenic and two likely pathogenic heterozygous variants in gene *SACS*.

SACS(NM_014363.6):c.12150_12156del p.Glu4051PhefsTer5); dbSNP: - (deep reads 39)

SACS(NM_014363.6):c.12158_12159del p.(Leu4053ProfsTer7); dbSNP: - (deep reads 44)

SACS(NM_014363.6):c.4020T>A p.(Tyr1340Ter) dbSNP: - (deep reads 44)

All of them were confirmed by Sanger sequencing.

Conclusion: Conclusion: Pathogenic variants in the *SACS* (Sacsin Molecular Chaperone) gene are associated with spastic ataxia Charlevoix-Saguenay type (ARSACS; OMIM: 270550) with autosomal recessive inheritance. The symptoms are starting in the age of 12-18 months. Our patient was referred to the specialized center for hereditary ataxia for further treatment. Thanks to WES, it was possible to achieve a diagnostic result in a patient with a long diagnostic odyssey.

P12.012.C 5q spinal muscular atrophy epidemiology in Russia: insights from a large-scale pilot project involving 202,908 newborns.

Irina Efimova[1], *Andrey Marakhonov*[1], *Natalya Balinova*[1], *Kristina Grishina*[1], *Olga Schagina*[1], *Alexander Polyakov*[1], *Sergey Voronin*[1], *Rena Zinchenko*[1], *Sergey Kutsev*[1]

[1]*Research Centre for Medical Genetics, Moscow, Russia;, Moscow, Russian Federation*

Background/Objectives: Spinal muscular atrophy (SMA) is the one the most common neurodegenerative disease in childhood. We report here the results of a pilot project of newborn screening (NBS) for SMA5q in 8 regions across Russia for 2022 year. The objective was to assess the viability, consistency, and utility of (NBS) for SMA5q across diverse populations.

Methods: A real-time PCR kit, the Eonis SCID-SMA, was used for NBS. Verification of the homozygous *SMN1* deletion was performed using MLPA.

Results: 26 patients with SMA were identified. Birth prevalence appeared to be 1:7804 newborns (95%CI:5263-12500). 38.46% (95%CI:20.23-59.43%) had two SMN2 copies, 42.31% (95%CI:23.35-63.08%) had three copies, 15.38% (95%CI:4.36-34.87%) had four copies, and 3.85% (95%CI:0.10-19.64%) had five copies of SMN2.

All infants possessing 2-3 copies of SMN2 underwent immediate treatment. Newborns with 4 and 5 copies followed a "watchful waiting" strategy and received treatment upon the emergence of clinical symptoms, with two manifesting symptoms at 3 months of age. Among those treated, the significant majority (82%, 18/22) underwent gene therapy. Subsequent short-term monitoring post-gene therapy demonstrated improvements in motor function.

Conclusion: The study underscores the necessity for a standardized algorithm facilitating early diagnosis and management through NBS, thereby providing substantial benefits to affected families. Future research should focus on long-term outcomes and evolving medical needs of NBS-diagnosed children. Overall, our pilot project experience let to expansion of our SMA5q NBS to the whole of Russia and reduce the time interval between a screening result and prompt SMA-specific treatment.

[1]*University of Minnesota, Genetic Counseling Program, Minneapolis, United States;* [2]*Mayo Clinic, Laboratory Medicine and Pathology, Rochester, United States;* [3]*Johns Hopkins University, Genetic Medicine, Baltimore, United States;* [4]*Ascension Medical Group, Neurology, Baltimore, United States;* [5]*M Health Fairview University of Minnesota Medical Center, Genetic Counseling, Minneapolis, United States;* [6]*Mayo Clinic, Neurology, Rochester, United States*

Background/Objectives: Friedreich ataxia (FA) is characterized by progressive spasticity, ataxia, dysarthria, and hypertrophic cardiomyopathy. FA typically presents in childhood but late-onset forms can complicate a diagnosis. Homozygous intron 1 GAA-repeat expansions in *FXN* occur in 98% of cases, reducing frataxin levels, and causing disease. A rapid diagnosis can expedite omaveloxolone treatment and slow disease progression. Our laboratory has offered frataxin levels for rapid FA screening and diagnosis.

Methods: From 2011 to 2023, 1,126 blood samples were sent for frataxin analysis. Quantitation used a published method (Oglesbee et al. Clin Chem. 2013). Final diagnostic outcomes were obtained from 2011-2023 by chart review or external clinician contact from 2018-2023.

Results: Frataxin levels (< 12 ng/mL) consistent with FA were observed in 15.6% patients, while 5.8% had results overlapping possible carrier status. The remaining cohort (78.6%) demonstrated normal frataxin levels (21-74 ng/mL). Among intermediate frataxin levels (12-21 ng/mL), molecular testing for 12/65 resulted in a diagnosis for seven patients, carrier status for three individuals, and two patients with negative molecular results. Five cases are highlighted including two siblings, 10 and 13-years-old, with low frataxin levels, but atypical GAA repeat results; a 30-year-old with late-onset FA and GAA repeats (418 and 418 repeats); a 44-year-old with a neurological presentation, but a single expansion allele (>900 repeats) and frataxin of 23 ng/mL; and a patient presenting in their mid-50's.

Conclusion: Early detection of FA is important to initiate treatment to slow disease progression and frataxin concentrations are useful for rapid FA screening.

P12.015.B Whole genome sequencing reveals compound heterozygous *RYR1* variants in a patient with severe congenital myopathy: case report and comparison with additional cases of recessive *RYR1*-related myopathy

Sören Janßen[1], Leoni Erbe[2], Moritz Kneifel[3], Matthias Vorgerd[3], Kristina Döring[2], Krzysztof P Lubieniecki[2], Joanna Lubieniecka[2], Wanda Gerding[2], Nicolas Casadei[4], Thomas Luecke[1], Huu Phuc Nguyen[2], Cornelia Köhler[1], **Sabine Hoffjan**[2]

[1]University Children`s Hospital Bochum, Department of Neuropediatrics, Bochum; [2]Ruhr-University Bochum, Department of Human Genetics, Bochum; [3]University Hospital Bergmannsheil, Department of Neurology, Heimer Institute for Muscle Research, Bochum; [4]University of Tübingen, Institute of Medical Genetics and Applied Genomics, Tübingen, Germany

Background/Objectives: *RYR1*-related myopathies comprise a wide spectrum of myopathic phenotypes, including malignant hyperthermia, central core or multiminicore myopathy and severe congenital myopathy. Inheritance can be autosomal dominant, more frequently in milder phenotypes, or autosomal recessive, mostly in severe congenital forms. However, due to the large gene and heterogeneous clinical presentation, genotype-phenotype correlations are challenging. Further, there is limited knowledge about intronic or structural variation not covered by exome analysis.

Methods: We present a 6-year-old patient from a non-consanguineous German family with severe congenital myopathy requiring a wheelchair and constant ventilation, who was known to carry a heterozygous pathogenic, presumably recessive *RYR1* variant transmitted from the healthy mother. No other pathogenic variant in *RYR1* or another myopathy gene was evident from exome analysis. In this patient we performed optical genome mapping (OGM) and whole genome sequencing (WGS) to clarify the genetic cause of his myopathy.

Results: OGM did not reveal structural variants affecting myopathy-related genes. However, WGS identified an additional heterozygous intronic variant (c.10441-48G>A) that has recently been described in compound heterozygous state in another patient with severe congenital myopathy and shown to affect splicing. Segregation analysis confirmed the two *RYR1* variants to be compound heterozygous.

Conclusion: WGS confirmed the diagnosis of a *RYR1*-related myopathy in our patient. We compare his clinical symptoms to the patient with the same intronic variant from the literature as well as other patients with compound heterozygous *RYR1* variants from our muscle center.

P12.016.C Molecular insights into Pompe Disease: a study of PPARgamma, COL13A1 and cellular glycogen metabolism

Sophie Uyttebroeck[1], *DT Laura Vo Ngoc[1], Randy Osei[1], Bart Dequeker[1], Sara Seneca[1], Frederik Hes[1], Alexander Gheldof[1]*

[1]Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Clinical Sciences, Research group Genetics, Reproduction and Development, Centre for Medical Genetics, Jette, Belgium

Background/Objectives: Pompe disease, caused by bi-allelic pathogenic variants in the *GAA* gene leading to acid-alpha glucosidase enzyme deficiency and subsequent lysosomal glycogen accumulation, manifests predominantly with hypotonia and cardiomyopathy. The correlation between cellular glycogen accumulation and clinical phenotype in Pompe disease remains unclear.

Methods: Transcriptomic analysis of Pompe patients' fibroblasts versus healthy controls revealed downregulated COL13A1 mRNA levels and upregulated PPARG expression in patient cells. Promotor analysis identified two PPARG binding sites in the *COL13A1* gene promotor. Inhibiting PPARG by an siRNA-mediated knockdown led to COL13A1 upregulation. Experiments showed cytosolic glycogen depletion upregulating PPARG and COL13A1 in patient samples.

Results: COL13A1 encodes an atypical collagen crucial for neuromuscular junction (NMJ) function by stabilizing the acetycholine receptor clustering. PPARG is a transcription factor regulating energy metabolism. Our findings show an enhanced PPARG expression linked to cellular energy deficits. Additionally, PPARG influences the transcriptional regulation of COL13A1 expression to a certain extent, thereby linking glycogen accumulation in Pompe cells with the NMJ functionality. Upregulation of PPARG and COL13A1 post-glycogen depletion shifts focus from lysosomal to cytosolic glycogen in Pompe disease pathogenesis.

Conclusion: We show that COL13A1, an important mediator of the NMJ, is downregulated in Pompe patients' fibroblasts and is regulated by the transcription factor PPARG. Moreover, both COL13A1 and PPARG expression are regulated by cytosolic, rather than lysosomal glycogen. These findings uncover a potential novel disease mechanism in Pompe disease.

P12.017.D A novel SGCE gene variant found in a Hungarian myoclonus-dystonia syndrome family

*Katalin Koczok[1], **Eszter Kovács**[1], László Madar[1], Gabriella Csorba[1], Judit Boczán[2], Istvan Balogh[2]*

[1]University of Debrecen, Faculty of Medicine, Division of Clinical Genetics, Debrecen, Hungary; [2]University of Debrecen, Faculty of Medicine, Department of Neurology, Debrecen, Hungary

Background/Objectives: Hereditary myoclonus was suspected in four siblings suffering from myoclonic jerks mainly affecting the neck and upper limbs. Pedigree analysis suggested autosomal dominant inheritance pattern with reduced penetrance on maternal transmission. After thorough neurologic examination they were referred to genetic counseling for further investigation.

Methods: Based on the clinical symptoms and inheritance pattern we performed single gene testing by Sanger sequencing of the coding region of the *SGCE* gene in one of the affected siblings (female proband). In the case of the three other affected (two females and one male) and seven unaffected family members (children of the three female patients) targeted mutational testing by Sanger sequencing was perfomed. Variant classification was based on the ACMG variant classification guideline.

Results: In the proband and all other affected siblings the c.874G>T, p.(Glu292*) nonsense variant was detected in heterozygous form in the *SGCE* gene. This novel genetic alteration was classified as pathogenic. The parents did not consent to testing, we assume paternal inheritance of the variant. Testing of the female patients' children revealed 4 mutation carriers and 3 non-carrier individuals. The male sibling has no offspring.

Conclusion: Genetic diagnosis of myoclonic dystonia-11 was established in the siblings by single gene testing, which still has a place in the era of next-generation sequencing if sound clinical examination and pedigree analysis suggests a specific condition. All of the carrier children (aged >7 years) were unaffected as expected since the maternally derived mutant allele generally (~95%) does not result in disease.

P12.018.A Clarifying the etiology of cerebral palsy in pediatric patients by whole exome sequencing

Kristina Stefanova[1], *Nevyana Ivanova[1], Kalina Mihova[1], Genoveva Tacheva[2], Teodora Paneva[2], Ivan Litvinenko[2], Maya Koleva[3], Veneta Bojinova-Tchamova[3], Albena Jordanova[4], Ivanka Dimova[5], Radka Kaneva[1]*

[1]Medical University - Sofia, Molecular Medicine Center, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria; [2]Medical University - Sofia/SBAL "Prof.Ivan Mitev", Sofia, Bulgaria; [3]University Hospital for Neurology and Psychiatry "Sveti Naum", Sofia, Bulgaria; [4]VIB - UAntwerp, Center for Molecular Neurology, Antwerpen, Belgium; [5]Medical University - Sofia, Laboratory of Genome Diagnostics, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria

Background/Objectives: Cerebral palsy is a complex neurological condition that appears in infancy or early childhood and affects motor and developmental skills. It is generally accepted that it is not a genetic disease and occurs as a result of brain damage before, during birth or in early childhood. In many cases, it is difficult to distinguish cerebral palsy from the neurologic disorders with genetic origin; however, it has implications on the recurrence risk, therapeutic approach and prognosis. In this study we used whole exome sequencing (WES) to clarify the etiology of the disease in two patients with cerebral palsy.

Methods: WES was performed to look for potentially pathogenic variants in two pediatric patients with initial diagnosis of unspecified cerebral palsy. Sanger sequencing was used to confirm the variants and for segregation analysis in the families.

Results: WES-data analysis revealed disease-causing variants in 5 genes, including *CPLANE, COL1A1, RERE, AP1G1* which are associated with comparable symptoms. A known likely pathogenic variant in *KIDINS220* was found in one of the patients. This gene is associated with a complex form of spastic paraplegia, which is the most common differential diagnosis of cerebral palsy.

Conclusion: Our result showed that two pediatric patients have been misdiagnosed with cerebral palsy and that WES could be used as a robust method for differential diagnosis of the disease. Making a precise genetic diagnosis in these cases is crucial for prognosis, treatment, risk of recurrence and for informed reproductive decisions.

P12.019.B X-chromosome inactivation in women with dystrophinopathies: key to symptom manifestation or coincidental occurrence

Ekaterina Vorontsova[1], *Elena Zinina[1], Aleksander Polyakov[1], Sergei A. Kurbatov[2], Dariya Guseva[1], Aysylu Murtazina[1], Olga Schagina[1]*

[1]Research Centre for Medical Genetics, Moscow, Russian Federation; [2]Research Institute of Experimental Biology and Medicine Voronezh State Medical University named after N.N. Burdenko, Voronezh, Russian Federation

Background/Objectives: Dystrophinopathies are a spectrum of X-linked muscular disorders caused by pathogenic/likely pathogenic variants in the dystrophin gene (*DMD*). Symptoms of the disease have also been observed in women, which is often attributed to skewed X-inactivation.

Methods: The study group included 12 women with symptoms of muscular dystrophy and a confirmed pathogenic genetic variant in the *DMD* gene and control group of 16 healthy women. All DNA samples were extracted from blood. Quantitative methylation-sensitive fluorescent PCR (QF-PCR) was used to assess X-chromosome inactivation levels.

Results: The female patients included in our study had the following symptoms: decreased muscle tone, fatigue, muscle cramps and increased blood CK level (more than 500 U/L). All patients had pathogenic *DMD* variants: full exon and small deletions/insertion, nonsence mutations and splicing variants. A family history of the disease was traced in 4 (33%) patients, the other 8 patients were the only affected family. Unbalanced X-inactivation was detected in 17% of female with symptoms and *DMD* mutations. In the healthy control group, it was in 31% female.

Conclusion: According to the study, only a small number of women with *DMD* symptoms have unbalanced inactivation. The proportion of women with skewed X-chromosome inactivation does not differ from the proportion observed among controls. Thus, unbalanced inactivation may be only one of the many mechanisms of dystrophinopathies penetration in heterozygotes.

Background/Objectives: Arthrogryposis is a condition with contractures in two or more joints associated with approximately 400 conditions. The study aims to elucidate the clinical and genomic profile of human fetuses with arthrogryposis

Methods: We performed perinatal evaluation of fetuses referred for autopsy following pregnancy loss and clinical evaluation in neonates after taking informed consent. Fetal tissues and blood samples were used to obtain genomic DNA. Chromosomal microarray (CMA), whole exome, and genome sequencing were performed as required. Spinal muscular atrophy (SMA) and common aneuploidies were ruled out whenever necessary.

Results: We have recruited 29 families (33 subjects; males -19 ; females- 14) with arthrogryposis in the study. Eleven consanguineous families (41%) were noted. Gestation ranged from 14-32 weeks and there were three neonatal losses (3-28 days). The study identified rare phenotypes associated with *ADGRG6*, *ANKS6*, *AGRN, CHRNA1*, *CEP55, GUSB*, *COASY, SYNE2, CEP290, PIGN and ASCC1*. Gene of uncertain significance, *KIF21A* and *UNC50* were identified. Biallelic loss of function variants in *KIF21A* caused severe arthrogryposis and brain anomalies in a family. A homozygous variant c.644-13_644-9delCTTTC in *UNC50 lead to* aberrant splicing with an insertion of 17 nucleotides following reverse trancriptase-polymerase chain reaction and identified as cause of recurrent fetal akinesia deformation sequence in a family.

Conclusion: We achieved a molecular diagnosis in fifteen families. Most of the families had autosomal recessive (10 families) inheritance and were lethal. Detailed perinatal evaluation with integration of genomic tests in fetuses with arthrogryposis improves diagnosis.

P12.021.D Genetic findings from multi-gene panel for inherited myopathies

Monica Segura Castell[1], *Kimberly Gall[2], Kirsi Alakurtti[1], Julie Hathaway[2], Åsa Hagström[1], Heli Kuisma[1], Janica Djupsjöbacka[1], Mikko Muona[1], Tuuli Pietilä[1], Pertteli Salmenperä[1], Inka Saarinen[1], Lotta Koskinen[1], Ray Veeraraghavan[2], Samuel Myllykangas[1], Juha Koskenvuo[1]*

[1]Blueprint Genetics, Espoo, Finland; [2]Blueprint Genetics Inc., Marlborough MA, United States

Background/Objectives: Positive genetic test in inherited myopathies (IMs) can provide information about prognosis, risk to family members, and enable participation in clinical trials or precision medicine therapies. Using next-generation sequencing (NGS), we investigated the yield of genetic testing in an IMs-suspected cohort determining the clinical utility of simultaneously testing nuclear and mitochondrial genes.

Methods: Patients included underwent Comprehensive Muscular Dystrophy/Myopathy Panel testing at Blueprint Genetics (CLIA-certified diagnostic laboratory). Testing included sequence and copy number variant (CNV) analyses of NGS data from a validated whole or clinical exome. Variant interpretation adhered to ACMG/AMP guidelines. A positive result was defined as a pathogenic (P) or likely pathogenic (LP) variant(s) consistent with the patient's reported phenotype and associated disease inheritance.

Results: We reviewed 489 patient reports, being 45.2% children (0-18 years) and 57.7% male. Positive results occurred in 24.3%, with 33.9% children and 16.4% adults. *DMD* was responsible for almost one-third of diagnoses (31.2%), while variants in ten genes accounted for over two-thirds (66.4%). CNVs contributed to 21% of the positive results, with 80% found in *DMD*. Three (12%) CNVs were smaller than 500 bps.

Conclusion: This study highlights the clinical utility of multi-gene panel testing, covering nuclear and mitochondrial genes, as almost 25% of patients with suspected IMs received a molecular diagnosis. *DMD* accounted for almost one-third of positive results, with notable implications given the recent FDA approval of gene therapy for IMs such as Duchenne muscular dystrophy. The importance of sensitive CNV detection capabilities is emphasized.

P12.022.A Methylation epi-signature help to determine the pathogenicity of VUS in two cases of *KMT2B*-related dystonia

Gleyson Carvalho[1], Cláudio Gusmão[2], Matheus Castro[2], Mayara Sakuma[2], Beatriz Wolff[1], Lucas Vieira[1], Mariana Costa[1], Rafaela Mendes[1], Maria Fernanda Chagas[1], Yanca Gasparini[1], **Leslie Kulikowski**[1]

[1]Faculdade de Medicina da Universidade de São Paulo, Pathology; [2]Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, Neurology

Background/Objectives: *KMT2B*-related dystonia (OMIM #617284), is an autosomal dominant progressive neurological condition characterized by early-onset of movement disorder. Variants of uncertain significance (VUS) accounts for a significant proportion of genomic variation in patients with dystonia. In this study, we describe the usage of a genome methylation epi-signature consisting of 113 CpG previously described by Mirza-

Schreiber et al. (2022) and how can it impact the diagnostic in patients with variants of uncertain significance.

Methods: Genome-wide methylation status was accessed using the EPIC methylation assay in peripheral blood samples from two subjects with dystonic posturing and gait imbalance with novel variants classified as VUS in *KMT2B* (p.Leu1720Phe and p.Tyr2515Cys). After QC and normalization steps, we compared the M-values for all 113 probes from two subjects and 6 controls using a support vector machine classification model.

Results: The subject with p.Tyr2515Cys variant shows a hypermethylation results comparable to the individuals with pathogenic and likely pathogenic variants in *KMT2B*. The observed hypermethylation in the subject with p.Tyr2515Cys variant allowed us to enhance the classification to probably pathogenic, while the individual with p.Leu1720Phe variant showed no significant difference in methylation status compared to controls without variants in *KMT2B*.

Conclusion: The study of methylation can be a powerful tool to accumulate evidence of the pathogenicity of variants and improve the diagnostic in patients with variants of uncertain significance.

Grants: National Council for Scientific and Technological Development (CNPQ- 402951/2021-2).

Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, United States;* [5]*University of Pavia, Department of Brain and Behavioral Sciences, Pavia, Italy;* [6]*Roy and Lucille Carver College of Medicine, University of Iowa, Iowa City, United States*

Background/Objectives: Despite the best efforts, over 50% of axonal CMT cases do not receive genetic confirmation. Notably, current short read technologies, including whole exome (WES) and whole genome sequencing (WGS), present major shortcomings in the study of structural variants and repeated regions, contributing to the missing heritability in CMT.

Methods: Here we leverage long read sequencing (LRS) and non-sequencing based optical genome mapping (OGM) to identify a large structural variant involving *SORD* and its pseudogene *SORD2P*, which disrupts *SORD* reading frame and causes SORD = CMT in multiple families.

Results: In three unrelated axonal CMT patients with high serum sorbitol and a heterozygous c.757delG *SORD* variant, LRS and OGM revealed a 200Kb inversion spanning two highly homologous *SORD/SORD2P* introns, undetectable by WES or WGS. Additionally, inverse PCR in 37 CMT cases with a heterozygous pathogenic *SORD* mutation identified this inversion in 4 (~10%) of them. This inversion occurred de novo in one family and was inherited from an asymptomatic parent in another. These cases resemble previously described SORD = CMT cases. Public data on 3D chromatin structure suggest *SORD* and *SORD2P*'s proximity in the nucleus could facilitate such recombination events.

Conclusion: In conclusion, *SORD/SORD2P* inversion is key in axonal CMT cases with a single *SORD* mutation, especially when serum sorbitol is high. This study demonstrates LRS and OGM's effectiveness in identifying genetic causes in unresolved CMT cases, revealing a new mechanism by which structural variants in gene/pseudogene pairs (~3000 in the human genome) can cause genetic disease, often undetected by short-read sequencing technologies.

P12.024.C Medaka fish *Oryzias latipes* a promising model to study titinopathies: the HMERF case study.

Viviana Cetrangolo[1], *Marco Linari*[2], *Elena Polishchuk*[1], *Marco Savarese*[3], *Jaakko Sarparanta*[3], *Ivan Conte*[4], *Bjarne Udd*[3], *Vincenzo Vincenzo Nigro*[1;5]

[1]*Telethon Institute of Medicine and Genetics-Tigem, Pozzuoli, Italy;* [2]*Università degli Studi di Firenze - Dipartimento di Biologia, Firenze, Italy;* [3]*Folkhälsan Research Centre, Biomedicum, Helsinki, Finland;* [4]*UNINA - Dipartimento di Biologia, Napoli, Italy;* [5]*Università degli Studi della Campania "Luigi Vanvitelli", Napoli, Italy*

Background/Objectives: Titinopathies are severe diseases, affecting skeletal and heart muscles. They are caused by variants in the titin gene, whose protein is crucial for sarcomere architecture. Titin A150/FN3-119 domain variants are associated with hereditary myopathy with early respiratory failure (HMERF), a life-threatening disorder manifesting respiratory failure and proximodistal muscle weakness. Mouse models for several titinopathies have been developed, but an HMERF model is missing. This work aims to generate and characterize the first HMERF fish model.

Methods: *Oryzias latipes* (medaka) is a teleost fish, used for genetic studies. Medaka has one copy of titin gene paralog, which protein sequence is evolutionarily conserved. This allows a straightforward genome-editing, through CRISPR/Cas9 strategy.

Results: We generated the first HMERF vertebrate model, harboring a missense variant found in patients (p.C31712R). The morphological characterization shows a perturbation of muscle fiber organization at the ultrastructure level and immunofluorescence analyses show a reduction of sarcomeric protein signals, especially in homozygous individuals. Moreover, locomotor analyses reveal a decrease in homozygous movement. These differences are supported by the force-velocity relationship analyses, which reveal that the shortening velocity (V), at any load (T), is lower in homozygotes. Consequently, in homozygotes, the power (VxT) at any load drops drastically.

Conclusions: The medaka larvae phenotype seems to recapitulate HMERF patients' pathological conditions. This work highlights the potential of medaka fish model for our understanding of the mechanism underlying HMERF disease.

Grant: This work was supported by the European Joint Program on Rare Diseases, Telethon Undiagnosed Disease Program (TUDP), the Research Council of Finland and AFM-Telethon.

P12.025.D Long-read whole-genome sequencing in peripheral neurodegeneration: challenges, insights, and paths forward

Ayse Candayan[1;2], **Luiza Lorena Pires Ramos**[1;2], *Els De vriendt*[1;2], *Albena Jordanova*[1;2;3]

[1]*VIB-UAntwerp Center for Molecular Neurology, Antwerpen, Belgium;* [2]*University of Antwerp, Department of Biomedical Sciences,*

Antwerpen, Belgium; [3]Medical University of Sofia, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria

Background/Objectives: Inherited peripheral neuropathies (IPN) are genetically heterogeneous disorders that still present a significant diagnostic challenge, suggesting the presence of novel causative genes or 'non-conventional' mutational mechanisms yet to be identified. Using long-read sequencing (LRS) to bridge this heritability gap seems promising, as it allows identification of variants that were intractable by other technologies.

Methods: We selected 15 families with IPN that had undergone extensive analyses using short-read sequencers but remained genetically undiagnosed. Nanopore whole-genome sequencing was performed on 32 individuals on a PromethION device. Downstream data analyses were conducted using an in-house pipeline.

Results: Challenges surfaced across multiple layers of the pipeline, including issues related to the high-quality sample requirements for LRS from "historical" cases and the quality control process. Selecting parameters for accurate base-calling proved critical, along with combining structural variants (SVs) shared among different individuals due to ambiguous breakpoints. Our experience also highlighted the need for comprehensive SV databases for downsizing the list of candidate variants. Verification of candidate variants also proved challenging, requiring tailoring of different techniques for each variant of interest.

Conclusion: LRS is poised to become the next paradigm-shifting tool in human genetics and will help us bridge the many heritability gaps in genetic diseases. As technologies rapidly evolve, researchers embarking on such studies face numerous challenges, thus sharing experiences among early-stage LRS users will greatly facilitate advancement in the field.

P12.026.A A novel deep intronic MFN2 mutation in a patient with autosomal recessive CMT2.

Roxane van Heurck[1], *Thomas RIO FRIO[1], Caterina Marconi[1], Anne Vannier[1], Jean-Louis Blouin[1], Iman Boukrid[2], Joel Fluss[3], Marc Abramowicz[1]*

[1]Hôpitaux Universitaires de Genève (HUG), Genetic Medicine and Development, Genève, Switzerland; [2]Hôpital de La Tour, Neurology, Meyrin, Switzerland; [3]Hôpitaux Universitaires de Genève (HUG), Pediatric Neurology, Genève, Switzerland

Background/Objectives: Charcot Marie Tooth disease type 2A (CMT2A) is a rare axonal neuropathy caused by dominant (90%) or recessive (10%) pathogenic variants in the mitofusin gene *MFN2*. To date, anomalies have only been reported in *MFN2* coding sequence.

Methods: We collected clinical data in a patient presenting with mild intellectual deficiency and clinical CMT2. Molecular investigations were performed with primary analysis of 1694 genes with Whole Exome Sequencing (WES), followed by Whole Genome Sequencing (WGS) and mRNA analyses.

Results: A 23-Year-old female patient born of non-consanguineous parents of French and Swiss origins, was first seen at ten years with foot drop, *pes cavus*, absent lower limbs tendon reflexes and partial sphincter dysfunction. Initial ENMG showed signs of a predominant sensory axonal neuropathy. Subsequent motor involvement was noted and the patient became wheelchair dependent at age 16, displayed optic atrophy at age 21 and complained of neuropathic pain.

WES identified a founder recessive single allelic intragenic deletion in *MFN2*. WGS and RNA analyses revealed the presence of a deep intronic single nucleotide substitution in trans, that caused the inclusion of a cryptic exon in 50% of allele-derived mRNA. The combination of this hypomorphic allele that showed drastically reduced expression of MFN2 mRNA, with the allele carrying the deletion is compatible with a recessive CMT2A.

Conclusion: This is the first report of a deep intronic mutation in *MFN2* that causes a recessive CMT2A. This study highlights the benefit from WGS combined with the functional analysis at the RNA level for non-coding variants.

Grants: HUG QS07-38

P12.027.B Accelerated Whole Genome Sequencing provides rapid diagnosis and treatment in a 4-months-old girl with Congenital Myasthenic Syndrome

Maria Isaksson[1], *Lone Laulund[2], Maria Grevit[3], Ulla Larsen[3], Bjørk Larsen[4], Pernille Torring[1]*

[1]Odense University Hospital, Department of Clinical Genetics, Odense C, Denmark; [2]Odense University Hospital, H. C. Andersens Children's Hospital, Odense C, Denmark; [3]Odense University Hospital, Department of Anaesthesiology and Intensive Care, Odense C, Denmark; [4]Odense University Hospital, Department og Clinical Genetics, Odense C, Denmark

Background/Objectives: Congenital Myasthenic Syndromes (CMS) are a heterogeneous group of genetic disorders, characterized by impaired neuromuscular transmission, resulting in weakness of the skeletal muscles. The course and severity of disease is variable, with onset typically in the first two years. Neonates may present with respiratory insufficiency, multiple joint contractures, and feeding difficulties and dysmorphic features. Some subtypes may respond well to treatment with acetylcholinesterase inhibitors. We present a case, where Whole Genome Sequencing (WGS) ensured rapid CMS-diagnosis in a four-months-old girl.

Methods: Trio-WGS was performed on DNA extracted from peripheral blood, with Next Generation Sequencing technology (Illumina NovaSeq 6000).

Results: A girl was admitted twice to the paediatric intensive care unit, at two and four months of age respectively. In both occasions, she presented with respiratory insufficiency, episodes of apnoea and required intubation. Clinical features included hypotonia with reduced head control, frog-legged posture, reduced coughing, excessive drooling, a high arched palate and feeding difficulties. Electroencephalogram, brain MRI and Creatinine Kinase level were normal. Accelerated trio-WGS detected that the patient was compound heterozygote of a pathogenic variant (c.264C>A) and a likely pathogenic variant (c.690G>T) in the RAPSN-gene, compatible with the diagnosis of CMS with autosomal recessive inheritance. She responded well to treatment with acetylcholinesterase inhibitor (pyridostigmine) and was extubated after 4 days. She is currently within age-appropriate development at nine-months-old.

Conclusion: This case illustrates that accelerated WGS can ensure a fast diagnosis, immediately providing initiation of relevant treatment, significantly altering the disease course and improving quality of life for the patient.

Conflict of Interest: None declared

P12.028.C Identification of a novel neurodevelopmental syndrome caused by variants in the gene *PRKAR2B*

Ella Whittle[1], *marc ruiz*[1], *Hamin Lee*[1], *hannah gulliford*[1], *ratna romy*[1], *Debby Hellebrekers*[2], *Melanie O'Leary*[3], *Lynn Pais*[3], *Grace E VanNoy*[3], *Jean-Madeleine de Sainte Agathe*[4], *Mohamad Abdelhamid*[5], *Paria Najarzadeh Torbati*[6], *erika ignatius*[7], *Yalda Jamshidi*[1], *Alan Pittman*[1], *Shamima Rahman*[8], *Henry Houlden*[9], *reza maroofian*[9], *Ehsan Ghayoor Karimiani*[1], *Chris Carroll*[1]

[1]*St George's University of London, United Kingdom;* [2]*Maastricht UMC+, Maastricht, Netherlands;* [3]*Broad Institute of MIT and Harvard, Cambridge, United States;* [4]*Faculty of Medicine Pierre et Marie Curie, Paris, France;* [5]*National Research Centre (NRC), Egypt;* [6]*Islamic Azad University of Mashhad, Mashhad, Iran;* [7]*University of Helsinki, Helsinki, Finland;* [8]*UCL Great Ormond Street Institute of Child Health, United Kingdom;* [9]*UCL Queen Square Institute of Neurology, United Kingdom*

Background/Objectives: Protein Kinase A (PKA) is a well-known cell signalling complex essential to cellular proliferation, homeostasis and growth. PKA consists of two catalytic subunits under the control of a regulatory subunit dimer encoded by the gene protein kinase cAMP-dependent type II regulatory subunit type II beta (*PRKAR2B*). Here, we report for the first time recessive pathogenic variants in *PRKAR2B* as a cause of a neurodevelopmental disorder.

Methods: Whole-exome sequencing was employed followed by a prioritisation strategy to identify rare variants (absent or MAF <0.001 in gnomAD) predicted to have a deleterious impact (CADD Phred scores >20) within individuals. Suspected variants were validated with Sanger sequencing and functionally investigated utilising in silico and in vitro techniques. We generated HEK293 *PRKAR2B* knockout cells to investigate the impact of PRKAR2B protein loss alongside patient fibroblasts collected.

Results: We present five *PRKAR2B* variants, three loss-of-function variants, one splice variant and one missense variant, in six unrelated families. Patients presented with an overlapping clinical phenotype characterised by dystonia, brain atrophy, spasticity, seizure, delayed speech and language development. Pathogenicity of variants has been supported through the measurement of endogenous PRKAR2B protein from patient cells and through a minigene exon-trapping assay. Results indicate that the loss of PRKAR2B protein reduces the phosphorylation activity of the PKA complex and causes aberrant DRP1 signalling, a checkpoint for mitochondrial fission, suggesting perturbed mitochondrial dynamics as a possible molecular mechanism of PRKAR2B-related disease.

Conclusion: We have identified variants in *PRKAR2B* as a cause of rare monogenic neurodevelopmental disease.

Grants: MRC MR/N013638/1

P12.029.D A rare muscle disease: 3 cases diagnosed with myotonia congenita

Ali DURU[1], *Mert Coşkun*[1], *Özden Altıok Clark*[1], *Gokcen Karamik*[2], *Nuray Ozturk*[2], *Öznur YILMAZ BAYER*[2], *nadide cemre randa*[3], *Aslı Toylu*[1], *banu nur*[2], *ercan mihci*[2]

[1]*Akdeniz Üniversitesi Hastanesi, Medical Genetic, Antalya, Türkyie;* [2]*Akdeniz Üniversitesi Hastanesi, Pediatric Genetics, Antalya, Türkyie;* [3]*Antalya Education and Research Hospital, Medical Genetic, Antalya, Türkyie*

Background/Objectives: Myotoni Congenita (MC) is a disease characterized primarily by myotonia during childhood, along with muscle hypertrophy and the presence of the warm-up phenomenon. Blood creatinine kinase (CK) increases in these patients. Spontaneous electrical activity can be seen in electromyography. This disease is caused by pathogenic variants in the *CLCN1* gene.

Methods: Genomic DNA from patients were examined for genes associated with Myotonic syndromes using Next-Generation Sequencing method. During the evaluation of variants, we applied the ACMG 2015 criteria.

Results: Patient 1 underwent genotyping following the observation of extensive contractions in the lower extremities, alongside the occurrence of warm-up phenomena and spontaneous electrical activity detected during electromyography. Analysis of the sequencing data revealed a homozygous variant of c.568_569delinsTC in *CLCN1* gene. This missense variant was classified as pathogenic in Clinvar.

Patient 2 and Patient 3, siblings of consanguineous parents, were applied to our clinic with involuntary contractions of arms. Serum CK elevation was detected in both cases. Electromyography was performed in one case and myotonic discharges were detected. In genetic analysis, c.2533G>A homozygous missense variant was detected in the *CLCN1* gene in both patients. Later, the parents were analyzed to be heterozygous carriers of the variant. This variant was reported as a variant of uncertain clinical significance in the Clinvar database.

Conclusion: Variant c.2533G>A is presumed a candidate variant associated with MC because of its predicted functonal effect and affirming segregation analysis. Functional analysis' are expected to better elucidate the clinical outcomes of the observed variant.

P12.030.A Neuromuscular junction deficits in PURA syndrome

Magdalena Mroczek[1], *Magdalena Chrościńska-Krawczyk*[2], *Dimitrios Zafeiriou*[3], *Anna Małges*[2], *Volkan Adak*[4], *Adela Della Marina*[5], *Michał Bielak*[2], *Christoph Handschin*[4], *Andreas Roos*[5], *Stanley Iyadurai*[6]

[1]*University Hospital of Basel, Department of Neurology, Basel, Switzerland;* [2]*University Children Hospital, Department of Child Neurology, Lublin, Poland;* [3]*Aristotle University of Thessaloniki, "Hippokration" General Hospital, Thessaloniki, 1st Paediatric Department, Developmental Centre "A. Fokas", Thessaloniki, Greece;* [4]*University of Basel, Biozentrum, Basel, Switzerland;* [5]*University Duisburg-Essen, Department of Pediatric Neurology, Centre for Neuromuscular Disorders, Centre for Translational Neuro- and Behavioral Sciences, Essen, Germany;* [6]*Johns Hopkins All Childrens Hospital, Division of Neurology, St. Petersburg, United States*

Background/Objectives: PURA syndrome is a rare genetic central nervous system disorder caused by heterozygous variants in the *PURA* gene. Several phenotypic features recently suggested a neuromuscular junction (NMJ) source of weakness. We investigated if treatment response to the pyridostigmine, an NMJ agent, is generalizable over centers and questioned if PURA protein is localized at the NMJ on the molecular level.

Methods: Observational study with patients from Poland and Greece. Pyridostigmine was administered at 3 to 7 mg/kg in divided doses 4 to 6 times. Proteomics was performed on one human muscle biopsy and fibroblasts. Murine data were collected from the snRNAseq and the LCMseq (soleus/ extensor digitorum longus).

Results: 7 patients underwent treatment and one is to be included. There was an improvement after pyridostigmine, including neurodevelopmental improvements and muscle strength increase when assessed in a systematic way. Neurophysiological studies performed on 5 patients suggested postsynaptic deficits in 4 patients and pre- and post-synaptic deficits in 1 patient. Proteomics from the muscle biopsy and fibroblasts

showed interaction of PURA with synaptic proteins. In the single nuclei studies Pura expression was noted in subsynaptic NMJ nuclei at higher levels compared to the remaining myonuclei.

Conclusion: PURA syndrome although deemed a CNS disorder, localizes to the NMJ and manifests with NMJ deficits, which effectively responds to NMJ modulation. Some central nervous system disorders may have a peripheral component that can be treated effectively.

P12.031.B Genetic characterization of *RYR1* variants: Insights into neuromuscular disorders and malignant hyperthermia in Czech patients

Tereza Kramářová[1;2], *Johana Kopčilová[1;3], Jana Zídková[1;2], Kamila Reblová[1;2], Lenka Fajkusova[1;2]*

[1]University Hospital Brno, Centre of Molecular Biology and Genetics, Brno-Bohunice, Czech Republic; [2]Faculty of Medicine Masaryk University, Institute of Medical Genetics and Genomics, Brno, Czech Republic; [3]Faculty of Science Masaryk University, National Centre for Biomolecular Research, Brno, Czech Republic

Background:

The *RYR1* gene encodes a ryanodine receptor, which works as a sarcoplasmic reticulum calcium release channel in the skeletal muscle. RYR1-related diseases represent a wide range of disorders that affect the neuromuscular system and can be inherited in a dominant or recessive manner or result from de novo variants. The European Malignant Hyperthermia Group reports a direct association between malignant hyperthermia (MH) and sixty-six diagnostic mutations in the *RYR1* gene and two diagnostic mutations in the *CACNA1S* gene.

Methods: Targeted sequencing of genes associated with neuromuscular disorders, bioinformatic analysis for detection of small-scale gene variants and copy number variants.

Results: We present *RYR1* genetic findings in Czech patients with myopathy and/or MH. Pathogenic/likely pathogenic variants were identified in 75 unrelated patients – 17 patients had dominantly inherited myopathy, 21 patients recessively inherited myopathy, and 37 patients had a diagnostic MH variant without a myopathy phenotype. Significant clinical heterogeneity was noted among patients with the same type of inheritance, which correlated to some extent with the localization of the variant in the structure of the RyR1 protein.

Conclusion: Analysis of *RYR1* variants is essential for understanding the pathogenesis of RYR1-related diseases. Characterisation of variants in patients with suspected or confirmed MH can contribute to the expansion of MH diagnostic mutations and risk prediction of this life-threatening disease.

Grants: The work was supported by the grant of AZV ČR – NU21-06-00363.

P12.032.C The WWOX gene variants detection in patient with cerebellar ataxia using optical genome mapping

Karolina Rutkowska[1], *Agnieszka Pollak[1], Magdalena Krygier[2], Marta Zawadzka[2], Maria Mazurkiewicz-Bełdzińska[2], Rafał Płoski[1]*

[1]Medical University of Warsaw, Department of Medical Genetics, Warsaw, Poland; [2]Medical University of Gdańsk, Department of Developmental Neurology, Gdańsk, Poland

Background/Objectives: Cerebellar ataxias (CAs) are a heterogeneous group of neurological disorders characterized by degeneration of the cerebellum and other parts of nervous system. Clinical features of CAs include loss of coordination of limb and eye movements, dysarthria. Diagnosis of CAs remains a challenge due to large phenotypic and genetic heterogeneity.

Methods: We used optical genome mapping (OGM) to study ultra-high molecular weight DNA of the 16 year old female patient with cerebellar ataxia. The patient was previously examined using exome sequencing, however no pathogenic variants associated with proband's phenotype were found.

Results: In the patient's sample two heterozygous structural variants (SVs) in the *WWOX* gene were found: insertion (hg38 16:78,393,619-78,396,002; 3,688 bp) and deletion (hg38 16:78,275,761-78,281,462; 5,700 bp). We also performed OGM in proband's mother sample and found that she was a carrier of the *WWOX* insertion. OGM data suggest that both variants in our patient with high probability are an in trans configuration. Extensive study showed association of *WWOX* gene with developmental and epileptic encephalopathy and esophageal squamous cell carcinoma. The *WWOX* gene was also related to autosomal recessive spinocerebellar ataxia characterized by onset of generalized seizures in infancy, delayed psychomotor development with mental retardation, and cerebellar ataxia. The variants found in OGM study may be related to the proband's phenotype.

Conclusion: OGM is a valuable a high-resolution technology that enables detection all types of SVs in the genome. OGM can be a potential supplement to the available clinical genetics diagnostics methods.

P12.033.D RNA sequencing as a complementary diagnostic tool in a cohort of undiagnosed patients with muscle disease

Alba Segarra-Casas[1], *maria josé rodriguez[2], cristina domínguez[3;4], aurelio hernández-laín[3], Solange Kapetanovic[5], Laura González-Mera[6], Velina Nedkova[6], Adolfo Lopez de Munain[7], Daniel Natera-de Benito[8], Carlos Ortez[8], Cecilia Jimenez-Mallebrera[4;8], Andrés Nascimento[4;8], Benjamin Rodríguez-Santiago[4;9], Eduard Gallardo[4;9], Montse Olivé[4;9], pia gallano[1;4], lidia gonzalez-quereda[1;4]*

[1]Institut de Recerca - Hospital Santa Creu i Sant Pau, Genetics Department, Barcelona, Spain; [2]Hospital de la Santa Creu i Sant Pau, Genetics Department, Barcelona, Spain; [3]imas12 Research Institute, Hospital Universitario 12 de Octubre, Neuropathology Unit, Madrid, Spain; [4]CIBERER, Instituto de Salud Carlos III, Madrid, Spain; [5]Hospital de Basurto, Neurology Department, Bilbo, Spain; [6]IDIBELL-Hospital Universitari de Bellvitge, Neuromuscular Diseases Unit, Neurology Department, L'Hospitalet de Llobregat, Spain; [7]Biodonostia-Osakidetza Basque Health Service, Biodonostia Neurosciences Area Group of Neuromuscular Diseases, San Sebastian, Spain; [8]Hospital Sant Joan de Déu, Neuromuscular Unit, Department of Neurology, Esplugues de Llobregat, Spain; [9]Institut de Recerca - Hospital Santa Creu i Sant Pau, Neuromuscular Diseases Unit, Neurology Department, Barcelona, Spain

Background/Objectives: It is estimated that 50% of patients with neuromuscular diseases remain undiagnosed after exome sequencing (ES) or gene panel sequencing. Here, we evaluate total RNA sequencing from muscle biopsy as a diagnostic tool in genetically unsolved patients following genomic DNA testing.

Methods: Total RNAseq was extracted from muscle biopsies of 29 undiagnosed patients after ES/gene panel sequencing, 3 positive controls with an identified RNA defect in the *DMD* gene and 5 healthy controls. We evaluated the presence of aberrant splicing (FRASER, LeafCutterMD, rMATS), outlier gene expression (OUTRIDER) and monoallelic expression in autosomal recessive genes. In addition, variant calling was performed from RNAseq data (GATK).

Results: In 7/29 patients (24%) we detected pathogenic alterations at the mRNA level including: two exon skipping events (*COL6A1*), one intronic retention (*TTN*), one alternative splicing event caused by a synonymous variant (*RYR1*) and two cases of monoallelic expression in autosomal recessive genes (*GNE*).

Conclusion: RNAseq analysis improves the diagnostic rate in patients with muscle diseases after inconclusive results from exome sequencing or gene panel sequencing by identifying molecular events that would not have been detected by other methods, and also by reclassifying VUS variants identified at the gDNA level. With this pilot study, we demonstrate the utility of RNAseq as a complementary diagnostic tool in muscle diseases, being particularly useful in patients with a clear clinical suspicion focused on a subset of genes.

P12.034.A Congenital myopathy in male twins with biallelic variants in *TTN*: a case report

lisa isabel olfe[1], *Alisa Förster*[1], *Uta Diebold*[2], *Tim Ripperger*[1], *Corinna Hendrich*[1], *Anke Katharina Bergmann*[1]

[1]*Hannover Medical School, Department of Human Genetics, Hannover, Germany;* [2]*Children- and Teenager Hospital Auf der Bult, Social-Pediatric Center, Hannover, Germany*

Background/Objectives: Autosomal recessive titin-related myopathies are a heterogeneous group of potentially severe congenital muscle disorders caused by disease-causing variants in titin (*TTN)*. With its 364 exons, *TTN* encodes the largest known human protein involved in sarcomere formation. Due to its size and manifold splice variants, classification of genetic variants in *TTN* is challenging.

Methods: Whole genome sequencing (WGS)

Results: We report on 14-year old male twins with congenital myopathy. The boys were born from non-consanguineous parents with a gestational age of 36 + 3 weeks. The more severly affected sibling presented as floppy infant. Their phenotype was characterized by muscle weakness, neonatal feeding difficulties, delay in motor development milestones, short stature, dystrophy and scoliosis. MRI showed fatty infiltration of pelvis and leg muscles. Muscle biopsy showed a myopathic tissue pattern. No cardiac involvement was observed. Their parents and one older brother are healthy.

Phenotype-based interpretation of quattro whole genome sequencing revealed compound heterozygous variants in *TTN* in both index patients: The likely pathogenic variant NM_001267550.1(TTN):c.19709_19710del p.(Val6570Glufs*18) transmitted from the mother, and the variant of uncertain significance (VUS) NM_001267550.1(TTN):c.106531+5G>A r.(spl?) p.? inherited from the father.

Conclusion: We suspect an autosomal recessive *TTN*-related myopathy in accordance with the symptoms of the two brothers and RNA analysis to confirm functional impact of the VUS is ongoing. This case highlights the need for further (functional) data to reclassify detected VUS in *TTN* in order to provide a diagnosis and adequate genetic counselling for the affected family.

P12.035.B Multiexon *TRAPPC11* gene deletions as a cause of muscular dystrophy and their estimated genesis

Johana Kopčilová[1;2], *Tereza Kramářová*[2;3], *Jana Zídková*[2;3], *Kamila Reblová*[2;3], *Lenka Fajkusova*[1;2]

[1]*Faculty of Science Masaryk University, National Centre for Biomolecular Research, Brno, Czech Republic;* [2]*University Hospital Brno, Centre of Molecular Biology and Genetics, Brno-Bohunice, Czech Republic;* [3]*Faculty of Medicine Masaryk University, Institute of Medical Genetics and Genomics, Brno, Czech Republic*

Background: Transport protein particle (TRAPP) is a multiprotein complex involved in the localization of proteins to the Golgi compartment. To this day, only small-scale variants in the gene encoding TRAPPC11 subunit have been identified as a cause of muscular dystrophy. We present clinical and molecular genetic findings in three patients, all compound heterozygotes for a missense variant and a structural variant in the *TRAPPC11* gene. We assessed the possible mechanisms of origin of the structural variants by analysing the breakpoint junctions.

Methods: Custom capture panel sequencing and/or whole genome sequencing; bioinformatics analysis detecting small-scale gene variants and large gene deletions/duplications; long-range PCR for the sequencing of breakpoint junctions.

Results: In P1, a known missense variant and a deletion of exons 6-9 were found. In P2 and P3, a novel missense variant and a deletion of exons 24-25 and 26-30 were identified, respectively. The presumed mechanisms of origin are nonhomologous end joining in P1 and P2 and nonallelic homologous recombination in P3.

Conclusion: We describe patients in whom copy number variants along with single nucleotide variants in the *trans* position are associated with disease manifestation. Sequencing of breakpoint junctions of identified gene deletions allowed us to elucidate the upstream mechanisms leading to genomic instability. This knowledge enables us to improve strategy for identifying disease causing mutations.

Grants: This work was supported by MH CR - RVO (FNBr, 65269705), AZV CZ NU21-06-00363, MH CR NU22-07-00474, and MH CZ - DRO - VFN64165.

P12.036.C Comparison of two different doses of vitamin D3 supplementation on bone health in ambulatory boys with DMD- a double blind randomized controlled trial

Reena Gulati[1], *pranay reddy sangala*[1]

[1]*Jawaharlal Institute of Postgraduate Medical Education and Research, Pediatrics, Puducherry, India*

Background/Objectives: Duchenne muscular dystrophy (DMD) is a progressive, disabling genetic condition with high risk of osteoporosis. Vitamin D deficiency, aggravated by glucocorticoid treatment leads to fractures in some cases. However, the optimal supplemental dose is still under investigation. We compared the effect of two different daily doses of cholecalciferol supplementation for 3 months on bone mineral density (BMD) and muscle functional parameters in boys with DMD.

Methods: Forty-four DMD patients aged 4-15 years were randomized into 2 blinded groups (22 patients each), who received either 2000 or 4000 IU/day of Cholecalciferol along with routine calcium supplementation for 3 months. BMD by Dual-energy X-ray absorptiometry (DXA) at lumbar spine and 'total body less head' assessments, serum 25-hydroxy vitamin D (25-OHD) and functional scales were evaluated at entry and after 3 months.

Results: Both groups exhibited significant improvement in BMD after 3-month cholecalciferol supplementation [p = 0.006 (4000 IU/day), and 0.008 (2000 IU/day) at lumbar spine and p = 0.006 (4000 IU/day), and 0.024 (2000 IU/day) at 'total body less head' respectively]. Serum 25-hydroxy vitamin D levels improved to 'sufficient' category in 80% patients compared to 27% before supplementation. Functionality tests did not show any significant change in either group. Improvement in BMD and serum 25-OH D levels was comparable between the two groups.

Conclusion: In 4-15-year-old boys with DMD, Vitamin D3 supplementation at 2000 or 4000 IU/day for 3 months significantly improved BMD and serum 25-hydroxy vitamin D levels to similar extent. Functional scores may need longer supplementation to show improvement.

Gemelli IRCCS, Department of Neuroscience, Sensory Organs and Chest, Rome, Italy;* [6]*Università del Salento, Department of Experimental Medicine, Lecce, Italy*

Background/Objectives: Amyotrophic lateral sclerosis (ALS) is a lethal neurodegenerative disease, mainly due to the progressive loss of motor neurons. The great clinical and genetic heterogeneity of ALS mirrors the different underlying pathogenic mechanisms, yet to be fully understood. A major hurdle in identifying the causes of ALS is the inaccessibility of the disease target tissue, i.e. patient motor neurons. Human induced pluripotent stem cells (iPSCs) derived from ALS patients and differentiated into target cells has been taking hold as a precious resource for both molecular mechanism analysis and drug development in ALS.

Methods/Results: We established 40 iPSC cultures from ALS patient-derived fibroblasts by Sendai virus reprogramming: 17 from familial cases and 23 from sporadic. Causative genetic variants had been previously identified in 29 patients, including: 5 *C9orf72* repeat expansions, 6 variants in *SOD1*, 10 in *TARDBP*, 3 in *FUS*, 3 in *TBK1*, 1 in *VCP* and 1 in *OPTN*. Furthermore, we obtained iPSCs from 2 pairs of twins discordant for the phenotype (with a *TARDBP* variant in one pair), and two unaffected relatives carrying pathogenic variants (in *TARDBP* and *FUS*). For result comparison, we likewise generated iPSCs from healthy controls.

Conclusion: We provide a detailed characterization of both patients' phenotypes and iPSC lines genetic and molecular features. We discuss about iPSC differentiation into motor neurons we are carrying on, aiming to be able to study the consequences of specific genetic variants on those cells. In conclusion, we believe that our iPSC lines constitute a valuable tool for ALS research.

P12.038.A A systematic investigation of the role of the oligogenic/digenic inheritance in Amyotrophic lateral sclerosis with machine learning tools on WGS data

Lucia Corrado[1], **Fjorilda Caushi**[1]*, alessio bottrighi[2], Nicola Pomella[1], Fabiola De Marchi[3], Susanna Zucca[4], Federica De Paoli[4], Beatrice Piola[1], Benedetta Bartilomo[1], Fatima Masoomi Sarvestani[1], Adriano Chio[5], Letizia Mazzini[3], Maurizio Grassano[5], Andrea Calvo[5], sandra d'alfonso[1]*

[1]*Università degli Studi del Piemonte Orientale, Health Sciences, novara, Italy;* [2]*Università degli Studi del Piemonte Orientale, Dipartimento di Scienze e Innovazione Tecnologica, Alessandria, Italy;* [3]*Università degli Studi del Piemonte Orientale, Dipartimento di Medicina Traslazionale, Università del Piemonte Orientale, Clinica Neurologica AOU Maggiore della Carità, novara, Italy;* [4]*Engenome, Engenome s.r.l., Pavia, Italy;* [5]*università degli Studi di Torino, ALS Centre, "Rita Levi Montalcini" Dipartimento di Neuroscienze, Università degli Studi di Torino, SC Neurologia 1U, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino, torino, Italy*

Background/Objectives: ALS is a neurodegenerative motor neuron disease. Its genetic cause is unknown in 85% of cases despite identifying over 40 ALS genes. Digenic Inheritance (DI) represents the simplest model for complex genetic diseases. Here, a Machine Learning (ML) approach was used to study the impact of DI on ALS using a pilot WGS dataset.

Methods: We used DIVAs, a ML tool, to analyze 60 WGS data. DIVAs identified and classified digenic variant combinations based on the patient's phenotype, variant pathogenicity, and gene-gene interaction. For each combination, DIVAs assigns a score (0-1) proportional to the evidence of causation. We selected combinations with a score higher than 0.7 and prioritized pairs with likely pathogenic, pathogenic, or uncertain significance (VUS) variants.

Results: We obtained 6 patients with digenic combinations that met our criteria. Among these, two presented interesting digenic combinations (all including VUS) suggesting a possible pathway interaction. Patient 22 showed a missense mutation in *DCTN1* ALS-associated susceptibility gene, combined with a missense in *SPG11* juvenile ALS-associated gene, both involved in cytoskeletal and axon-transport defect. Patient 60 showed a 5'UTR deletion in *ERBB4* ALS gene coupled with a missense in *TRPM7* ALS susceptibility gene, both involved in secondary ion channel defects as transmembrane receptors.

Conclusions: Our initial findings suggest that DIVAs ML tool can detect digenic couples related to patient's disease. We are comparing the results with other ML tools (*DE profile*, VarCoPP, *OligoPVP*, ORVAL, DiGePred) to complete a pipeline to test a larger ALS cohort.

P12.039.B A global analysis of the CMT1A locus: implications for the origin and susceptibility to Charcot- Marie-Tooth disease type 1A across populations

Alexandra Alitsiou[1;2;2;2]*, Pedro M Rodriguez Cruz[1;2;3;4], Jon Andoni Urtizberea[5], Anne-Sophie Lia[6], Karima Ghorab[7], Sergi Beltran[1;8], Oscar Lao[9]*

[1]*Centro Nacional de Análisis Genómico - CNAG, Barcelona, Spain;* [2]*Universitat de Barcelona, Barcelona, Spain;* [3]*Université Cheikh Anta Diop De Dakar, Dakar, Senegal;* [4]*UCL Institute of Neurology,*

Department of Neuromuscular Diseases, London, United Kingdom; [5]Institut de Myologie, Paris, France; [6]University of Limoges, Department of Biochemistry and Molecular Genetics, Limoges, France; [7]University of Limoges, Department of Neurology, Limoges, France; [8]Universitat de Barcelona, Faculty of Biology, Department of Genetics, Microbiology and Statistics, Barcelona, Spain; [9]Institut de Biologia Evolutiva (CSIC - UPF), Barcelona, Spain

Background/Objectives: Charcot-Marie-Tooth type 1A (CMT1A) is an inherited neuropathy with an estimated prevalence of 1/5000 in the general population. CMT1A results from abnormal dosage of the *PMP22* gene, arising from non-allelic homologous recombination (NAHR) events between paralogous sequences called CMT1A-REPs, flanking the gene. While extensively reported in Caucasian individuals, CMT1A remains undocumented in those of African genetic ancestry. We hypothesise this is due to differences in CMT1A-REP regions between individuals of African and non-African genetic background. Our objective is to study the variability of CMT1A-REPs between populations using available genetic data and in silico analyses.

Methods: Leveraging data from previous whole genome sequencing projects, we built a combined dataset, with a focus on capturing African genetic variation. Using this dataset, we explore haplotypes based on both common and rare SNPs, structural variants in CMT1A-REP regions, recombination-related elements, and their potential interactions, as well as their distribution across different populations.

Results: Individuals of African genetic ancestry harbour distinct CMT1A-REP haplotypes with lower recombination rates and reduced sequence similarity compared to other ethnicities. This suggests potential genetic variation protective against the NAHR-mediated events causing CMT1A. Additionally, recombination regulators like PRDM9 might differ between African and non-African ethnicities, hinting at distinct mechanisms at play.

Conclusion: Our study suggests genetic differences in CMT1A-REPs between African and non-African ancestries, potentially contributing to the lack of CMT1A reports in individuals of African genetic origin. However, further research is needed to fully understand the epidemiology of CMT1A in Africa and how CMT1A-REP variations influence disease risk.

P12.040.C Prenatal description of three cases of 5q SMA type 0 detected by exome sequencing

Anna Abuli[1], *Mar Costa-Roger*[1], *Marta Codina*[1], *Carlota Rodó*[2], *Laura Blasco-Pérez*[1], *Desirée Martínez-Cruz*[1], *Jordi Leno*[1], *Eduardo Tizzano*[2]

[1]Vall d'Hebron Barcelona Hospital, Department of Clinical and Molecular Genetics, Barcelona, Spain; [2]Vall d'Hebron Barcelona Hospital, Maternal-Fetal Medicine Unit, Department of Obstetrics, Barcelona, Spain

Background/Objective: Spinal muscular atrophy (SMA) is a recessive neuromuscular disorder characterized by progressive muscle atrophy with high phenotypic variability. Cases of the most severe type, SMA 0, are uncommon and prenatal manifestations, beyond loss of fetal movements, are barely described. This work reports the presentation of three fetuses with SMA type 0 within one family.

Methods: A couple was referred to our Hospital due to ultrasound findings at 31 weeks of gestation. A similar presentation was observed in the couple's two following pregnancies. All pregnancies were terminated. After negative arrayCGH results, exome sequencing (ES) was performed in all fetuses and parents, using ExomeDepth to evaluate CNVs. Results were validated by MLPA.

Results: Ultrasound findings included short corpus callosum, ventricular septal defect and foot edema in fetuses 1 and 3; and increased nuchal translucency and hydrops fetalis in fetus 2. Results from ES indicated a possible deletion in the *SMN* locus, which was corroborated by manual IGV revision and quantification of the paralogous sequence variant c.840C>T. MLPA confirmed 0 *SMN1* and 1 *SMN2* copy in all fetuses, allowing the molecular diagnosis of SMA type 0.

Conclusions: This work highlights the challenges of recognizing the fetal presentation of known genetic entities due to lack of knowledge of their prenatal signs. When congenital heart defects together with increased NT and fetal edema are present, SMA should be suspected. Although ES is not the gold-standard technique for SMA, targeted analysis of the SMN locus may guide the diagnosis in prenatal cases or atypical presentations.

P12.041.D Validation of a Machine Learning tool for rapidly identifying FSHD patients

Claudia Strafella[1], *Domenica Megalizzi*[1;2], **Giulia Trastulli**[1;2], *Luca Colantoni*[1], *Emma Proietti Piorgo*[1], *Carlo Caltagirone*[3], *Raffaella Cascella*[1;4], *Emiliano Giardina*[1;2]

[1]Santa Lucia Foundation IRCCS, Genomic Medicine Laboratory-UILDM, Rome, Italy; [2]Tor Vergata University, Department of Biomedicine and Prevention, Rome, Italy; [3]Santa Lucia Foundation IRCCS, Department of Clinical and Behavioral Neurology, Rome, Italy; [4]Catholic University Our Lady of Good Counsel, Department of Biomedical Sciences, Tirana, Albania

Background/Objectives: FacioScapuloHumeral Dystrophy (FSHD) is a myopathy characterized by the loss of repressive epigenetic features affecting the *D4Z4* locus (4q35). The study aimed at validating a Machine Learning (ML) pipeline for discriminating FSHD subjects according to the DNA methylation profile of *D4Z4*.

Methods: 251 subjects with clinical signs of FSHD sent to our center during 2022-2023 were analyzed. The recruited subjects were tested for the 4q subtelomeric variant by means of specific PCR. Subjects carrying at least a 4qA allele underwent methylation levels analysis of two *D4Z4* regions. The identification of methylation profiles compatible with FSHD was performed by running a ML algorithm based on methylation levels. The presence of a short *D4Z4* allele and/or of pathogenic variants in FSHD genes was simultaneously evaluated.

Results: Among the 251 subjects, the 4q variant type distribution was 41% 4qA/4qA, 51% 4qA/4qB and 8% 4qB/4qB. Of the 232 carriers of at least a 4qA allele, the ML model predicted 122 subjects as FSHD in line with the reduced methylation levels compatible with the disease. The remaining 110 subjects were predicted as non-FSHD and showed high methylation levels. By comparing the results of *D4Z4* allele sizing, for 122 hypomethylated subjects the FSHD prediction was fully concordant with the presence of FSHD genetic signatures. Among the 110 subjects classified as non-FSHD, 85 were concordant with the absence of FSHD genetic alterations and 25 subjects displayed borderline methylation levels.

Conclusion: The present method emerges as a powerful tool to be implemented into the FSHD diagnostic practice.

Background/Objectives: FSHD is a genetic neuromuscular disorder. D4Z4 macrosatellite repeat contractions on chromosome 4q35 constitute 95% of all cases as FSHD type 1. The remaining cases, FSHD type 2, the underlying genetic defect is pathogenic variants in associated genes such as *SMCHD1*, *DNMT3B*. Variants in these genes could potentially modulate the phenotype of FSHD1 patients with borderline D4Z4 contractions[1]. The diagnostic algorithm of FSHD involves the analysis of D4Z4 Repeat Units (RU) and the analysis of the FSHD associated genes to confirm/exclude diagnosis and distinguish cases that require differential diagnosis[2].

Methods: Molecular combing (MC) technology was utilized for the detection of D4Z4 RUs in 86 Turkish index patients. Whole exome sequencing (WES) was performed in 12 potential FSHD2 patients with no contractions or borderline RUs with their consent.

Results: MC revealed 71/86 patients with contracted 1-10 RUs. 5/71 patients had borderline 8-10 RUs and 14/86 patients had no contractions. Pathogenic mutations were observed in *SMCHD1* in 3 patients, one in non-contracted group and two in borderline group. *CAPN3* variants were identified in two patients, shifting the diagnosis to LGMD. In the remaining patients did not reveal any results.

Conclusion: Our findings largely coincide with literature and underscore the significance of additional testing. It is crucial to explore the impact of NGS to reveal related phenotypes and overlapping genetic factors that may contribute to the clinical heterogeneity of FSHD and its differential diagnosis.

Neuromuscular Disorders., Madrid, Spain;* [9]*"12 de Octubre" University Hospital, Clinical and Molecular Genetics, Madrid, Spain*

Background/Objectives: McArdle disease (GSDV) is an autosomal recessive disease resulting from mutations in the *PYGM* gene, which encodes the muscle glycogen phosphorylase. The spectrum of this disorder ranges from moderate exercise intolerance to recurrent rhabdomyolysis or muscle weakness. Most patients exhibit undetectable levels of PYGM protein and enzyme activity. This study aims comprehensively characterize the clinical, biochemical and molecular features of a patient expressing a mild phenotype, harboring a homozygous deep intronic variant in the *PYGM* gene.

Methods: Exercise testing was conducted using cycle-ergometry. Genetic testing was performed by whole exome sequencing. Enzyme histochemistry and activity (spectrophotometry), PYGM expression (cDNA analysis by real-time PCR), and protein levels [western blot-(WB)] were studied in muscle biopsy.

Results: We identified a homozygous *PYGM*:c.425-26A>G variant in a 66-year-old male presenting with acute hyperCKemia and mild myalgia. This variant, previously reported in compound heterozygosis in one patient, presented an atypical clinical profile. Exercise testing was not consistent with those typically observed in McArdle patients. Histochemistry displayed normal staining, yet enzyme activity was very low (nearly 3% of controls) but significantly higher than in other PYGM patients. cDNA studies revealed a splicing defect and lower *PYGM* expression compared to controls and other GSDV patients. WB demonstrated undetectable PYGM protein levels.

Conclusion: Our findings support previous data indicating that the c.425-26A>G variant retains residual PYGM enzyme activity, sufficient to modulate the clinical phenotype, despite causing a gene expression defect and undetectable protein levels; and emphasizes the need for detailed molecular characterization in atypical presentations of GSDV.

P12.045.D DMD indel variant in exon 75 causes intellectual disability and congenital cataract in a family of four affected male patients

Mathilde Faurholdt Lauridsen[1], *Martin Sokol*[1], *Maria Rasmussen*[1;2]

[1]*Lillebaelt Hospital, University Hospital of Southern Denmark, Clinical Genetics, Vejle, Denmark;* [2]*University of Southern Denmark, Institute of Regional Health Research, Odense, Denmark*

Background/Objectives: Pathogenic variants in the *DMD* gene are known to cause X-linked Dystrophinopathies. The muscular dystrophies are sometimes accompanied by intellectual disability especially if the pathogenic variant is located in the distal part of the gene affecting most isoforms. Some of these isoforms are expressed in neuronal cells and fiber cells of the crystalline lens like the Dp71 isoform. Only very few patients have been described with pathogenic *DMD* variants primarily causing intellectual disability without muscular symptoms and only very rarely *DMD* variants have been associated with congenital cataract.

Methods: Trio whole genome sequencing and segregation analysis were performed in a family with four male patients affected by intellectual disability and congenital cataract.

Results: Trio whole genome sequencing revealed the indel variant *DMD*[NM_004006.3]:c.10751_10764delAACAGCTGGAGTCA, p.(Lys3584Thrfs*54) in the proband and his mother. Subsequently, segregation analyses found that the affected brother and maternal uncle also had the variant, whereas it was not found in two unaffected male family members. The variant is located in exon 75 and affects most isoforms of the *DMD* gene including Dp71 expressed in the brain and fiber cells of the crystalline lens.

Conclusion: Pathogenic frame-shift variants affecting isoforms primarily expressed in the brain and crystalline lens of the *DMD* gene are rarely described in the literature and should be considered a rare cause of intellectual disability and congenital cataract.

P12.046.A Biallelic variants in the *PLPP7* gene (Net39) cause a new neuromuscular disease in humans.

Katarína Kušíková[1], *Rene G. Feichtinger*[2], *Hans A. Mayr*[2], *Miriam Kolníková*[1], *Ognian Kalev*[3], *Serge Weis*[3], *Denisa Weis*[4]

[1]*Department of Pediatric Neurology, Faculty of Medicine, Comenius University Bratislava and National Institute of Children's Diseases, Bratislava, Slovakia;* [2]*University Children's Hospital, Salzburger Landeskliniken (SALK), Paracelsus Medical University (PMU) Salzburg, Salzburg, Austria;* [3]*Division of Neuropathology, Department of Pathology and Molecular Pathology, Neuromed Campus, Kepler University Hospital, Johannes Kepler University, Linz, Austria;* [4]*Department of Medical Genetics, Kepler University Hospital Med Campus IV, Johannes Kepler University, Linz, Austria*

Background/Objectives: The *PLPP7* gene (OMIM: *618743) encodes the nuclear envelope transmembrane protein 39 (Net39), which is crucial in muscle chromatin organization, gene expression, and myoblast differentiation. Loss of Net39 explored in vivo in Net39 knockout mice has been shown to cause juvenile mice lethality and muscle abnormalities consistent with Emery-Dreifuss muscular dystrophy. However, the Net39 deficiency phenotype has never been described in humans.

Methods: We present the first documented case report of an eight-year-old boy of consanguineus parents originating from Turkey with delayed motor development due to muscle weakness, positive Gowers's sign, gait disturbance, progressive muscle atrophy, but normal creatine kinase in blood.

Results: Muscle biopsy from vastus lateralis muscle showed fibrosis, endo-, peri- and epimysial lipomatosis, and numerous atrophic and hypertrophic fibers, corresponding to clearly pronounced myopathic changes. Karyotyping, array CGH, and NGS panels focused on neuromuscular disorders (NMDs) revealed no causal variants. WES analysis revealed a homozygous variant c.199G>A (p.Glu67Lys) in the *PLPP7* gene. This variant affects a conserved amino acid in the interaction domain of the membrane protein. Functional studies on patient muscles are currently ongoing.

Conclusion: *PLPP7* deficiency, previously considered to be a potential cause of neuromuscular phenotype in humans, is now reality and could be the cause of NMDs phenotype in undiagnosed patients. Therefore, we recommend to include the *PLPP7* gene in routine NGS neuromuscular panels.

P12.047.B Role of the *GFAP* gene in Alexander disease: in-depth statistical analyses using a large database of clinical signs and genetic variants

Francesca Rosamilia[1], *alice grossi*[2], *Silvia Carestiato*[3], *Marta Rusmini*[1,2], *Chiara Africano*[4], *Giada Recchi*[5], *Ettore Salsano*[6], *Isabella Ceccherini*[2], *Tiziana Bachetti*[7]

[1]*IRCCS Istituto Giannina Gaslini, Clinical Bioinformatics Unit - Scientific Direction, Genova, Italy;* [2]*IRCCS Istituto Giannina Gaslini, UOSD Laboratory of Genetics and Genomics of Rare Diseases, Genova, Italy;* [3]*University of Turin, Department of Medical Sciences, Torino, Italy;* [4]*University of Genova, Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics and Maternal Child Sciences (DINOGMI), Genova, Italy;* [5]*IRCCS Giannina Gaslini Institute, UOC Rheumatology and Autoinflammatory Diseases, Genova, Italy;* [6]*Fondazione IRCCS Istituto Neurologico C. Besta, SC Malattie Neurologiche Rare, Milano, Italy;* [7]*IRCCS Ospedale Policlinico San Martino, Proteomics and Mass Spectrometry Unit, Genova, Italy*

Background/Objectives: Heterozygous mutations of the gene encoding glial fibrillary acidic protein (*GFAP*) are responsible for Alexander disease (AxD), a rare autosomal dominant astrogliopathy classified, based on age of onset (AOO), in infantile, juvenile and adult. Although some mutational hotspots along the *GFAP* gene appear to be preferentially associated with specific AOO, the final effect of most variants and the clinical course of their carriers is still unpredictable.

Methods: Starting from an extensive literature review, we created a database containing 550 AxD-associated *GFAP* mutations, including observations from in-house AxD molecular diagnosis. The characterization of these variants in terms of affected protein regions, amino acid change, heritability, CADD score, distance from splice site boundaries, and associated disease, including AOO and neuroradiological symptoms, were analyzed to draw a genotype-phenotype correlation.

Results: Numerous suggestive associations were observed, in particular almost half (49.6%) of variants involve an arginine codon, of which 45.8% occur in infantile cases, 34.4% of these latter being de-novo. Consistently, infantile cases have mutations with higher CADD values than adults. Considering the most frequent mutations (p.R239C, p.R79H, p.R88C, p.R79C, p.R416W, p.R239H), the associated clinical signs were used to identify mutation-specific enrichments. To confirm our results, we conducted several meta-analyses on specific variants across distinct patient categories.

Conclusion: The creation of a large database of *GFAP* variants offers a tool to investigate still neglected aspects of the variants role in the onset and progression of AxD, such as the genotype-phenotype correlation, the incomplete penetrance and variable expressivity of some variants, opening new perspectives in diagnosis and genetic counseling.

MULTIPLE MALFORMATION/ANOMALIES SYNDROMES

P13.001.C Alkuraya-Kučinskas syndrome *BLTP1* brain-conditional knock-out leads to severe disruption in neocortical lamination

Jacqueline Chrast[1], *Siwar Ben-Ayache*[2], *Stephan Collins*[2], *Catherine Roger*[1], *Hector Gallart Ayala*[3], *Séverine Lorrain*[4],

Manfredo Quadroni[4], Julijana Ivanisevic[3], Binnaz YALCIN[2], Alexandre Reymond[1]

[1]Université de Lausanne, Center for Integrative Genomics, Lausanne, Switzerland; [2]University of Burgundy, INSERM U1231 Center for Translational and Molecular medicine, Dijon, France; [3]Metabolomics Unit, Faculté de Biologie et de Médecine, Lausanne, Switzerland; [4]Université de Lausanne, Protein Analysis Facility, Lausanne, Switzerland

Background/Objectives: We previously described the Alkuraya-Kučinskas syndrome, a disorder associated with biallelic variants in *BLTP1* (bridge-like lipid transfer protein), a.k.a *KIAA1109*. Most probands die in utero or soon after birth, and surviving patients present with corpus callosum agenesis, ventriculomegaly and arthrogryposis. Homozygous ablation of mouse *Bltp1* resulted in similar preweaning lethality.

Methods: To bypass this lethality, we engineered *Emx1*-Cre-mediated conditional knockouts (cKO) in which *Bltp1* expression is only removed in cortical and hippocampal neurons.

Results: This restricted ablation of *Bltp1* recapitulated the preweaning lethality observed in the constitutional knockouts, suggesting that lack of expression of *BLTP1* in neurons is sufficient to cause death. We also observe a significant decrease of heterozygote pups' survival suggesting that hemizygous carrier fitness is impacted. Consistent with this hypothesis, *BLTP1* pLOEUF is 0.58. A single homozygous cKO survived to adulthood out of 21 expected. It presented reduced thickness of the cortical plate, complete agenesis of the corpus callosum, 5-fold size decrease of the anterior commissure, and a malformed hippocampus. Brain histology of 18.5-day cKO embryos similarly showed a thinning of the cortex, as well as a lack of defined structural layers with total absence of both *Pax6*- and *Tbr2*-expressing apical and intermediate progenitors, respectively.

Consistent, with the recent description of BLTP1 as a tube-forming lipid transport protein that allows rapid lipid transport between the endoplasmic reticulum and the plasma membrane, we found that it interacted with membrane-bound and vesicle proteins and a disruption of the lipidome in our cKO models.

Conclusion: We engineered a clinically-relevant model of Alkuraya-Kučinskas syndrome.

P13.002.D First Patient With Rasmussen Syndrome Caused By A Small Deletion Encompassing The TSHZ1 Gene

Britta Hanker[1], *Vincent Arriens[2], Malte Spielmann[1;2], Inga Nagel[2]*

[1]Institute of Human Genetics, University of Lübeck, Lübeck, Germany; [2]Institute of Human Genetics, University of Kiel, Kiel, Germany

Background/Objectives: To date, the genetic cause of Rasmussen syndrome has not yet been described. In 1979, Rasmussen reported a family with congenital bilateral vertical talus, bilateral atresia of the external auditory canal and increased interocular distance. Until now pathogenic variants in *TSHZ1* are only associated with atresia or stenosis of external auditory canal.

Methods: We report on a three-year-old girl with facial features including epicanthus, hypertelorism as well as a broad nasal root. She had hearing impairment and stenosis of the external auditory canal as well as rocker bottom feet. The mother presented with the same foot deformity and hearing impairment due to bilateral atresia of the auditory canal.

Results: Exome sequencing in the child revealed a heterozygous deletion of 210 kb encompassing *TSHZ1*. We identified the same deletion in the mother.

Conclusion: Systematic review of the literature showed that patients with mutations in *TSHZ1* show atresia of external auditory canal but vertical talus (rocker bottom feet) has not been described. Feenstra *et al*. reported in 2011 on families with deletions or mutations in *TSHZ1* of more than 2,5 Mb in 18q22.3 including *TSHZ1*, which showed vertical talus, too. The patient's phenotype overlaps with the clinical signs of a family with a heterozygous frameshift variant we presented in 2019. Therefore, our findings support the hypothesis that deletions encompassing *TSHZ1* or mutations in this gene cause Rasmussen syndrome with incomplete penetrance and variable clinical expressivity. Atresia or stenosis of external auditory canal and foot malformation and dysmorphic feature are a consistent sign in Rasmussen syndrome.

P13.003.A Novel mutation c.564C>A in SNAP25 gene, revealed in a baby with prenatal abnormalities and postnatal death

Ivanka Dimova[1], *petya chaveeva[2], Kunka Kamenarova[1], Kalina Mihova[1], Darina Kachakova[1], Gergana Stancheva[1], Radka Kaneva[1]*

[1]Medical University Sofia, Molecular Medicine Center, Sofia, Bulgaria; [2]SAGBAL "Dr Shterev", Sofia, Bulgaria

Background/objectives: Deviations from fetal screening for congenital anomalies always raise serious concerns about the future health of the child. Here we report a case of a pathologically progressed pregnancy with persistently increased nuchal fold, intrauterine growth retardation (IUGR), oligohydramnios and increased resistance index in the umbilical artery. A chorionic biopsy with array CGH analysis was performed, with no aberrations found. After birth, the baby was hospitalized for respiratory distress syndrome; dysmorphic facies, pterygium colli, oblique eye slits, micrognathia; decreased muscle tone, hand contractures. At 1 year - severe retardation in physical and neuropsychological development, hospitalized due to severe shock state and ended with exitus letalis.

Method: Whole exome sequencing (using NovaSeq 6000, Illumina) of the isolated child's DNA was performed searching for the possible genetic etiology of the condition.

Results: A novel genetic variant c.564C>A (p.Asn188Lys) in *SNAP25* gene was discovered and classified as likely pathogenic, based on the established association between the gene and the patient's phenotype, the absence of the variant in control populations, and in silico predicted pathogenicity. The parents were tested for the carriership and they didn't carry the variant. Mutations in *SNAP25* gene are associated with autosomal dominant congenital myasthenic syndrome 18 (CMS18).

Conclusion: CMS18 is a presynaptic neuromuscular disorder characterized by early-onset muscle weakness with delayed psychomotor development and ataxia. Here we report de novo occurrence of mutation for this syndrome with fatal outcome. Our case demonstrates non-specific, but markable prenatal presentation of the syndrome with IUGR, increased nuchal fold and oligohydramnios.

P13.004.B A Pfeiffer phenotype in association with the common Apert FGFR2 S252W mutation: A clinical report and likely molecular explanation

Ramy Saad[1], *Caitlin Barns-Jenkins*[1], *Claire Lawn*[1], *Gregory James*[2], *Noor ul Owase Jeelani*[2], *Andrew Wilkie*[3], *Louise Wilson*[1]

[1]*North East Thames Regional Genetics Service, Great Ormond Street Hospital for Children NHS Foundation Trust, London, UK;* [2]*UCL Great Ormond Street Institute of Child Health and Craniofacial Unit, Great Ormond Street Hospital for Children, London, UK;* [3]*MRC Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, UK; Oxford Centre for Genomic Medicine, Oxford University Hospitals NHS Foundation Trust, Oxford, UK*

Background/Objectives: Apert Syndrome (AS) and Pfeiffer Syndrome (PS) result from different heterozygous FGFR2 missense variants. While the craniofacial features overlap, AS is characterised by symmetrical cutaneous and bony 'mitten' syndactyly of all 4 limbs, with complete syndactyly of the 3 central rays and variable involvement of the first and fifth rays. PS is characterised by broadened deviated thumbs and halluces with variable minor skin syndactyly.

There have been occasional reported cases of a PS phenotype in association with a common AS variant, for which no molecular mechanism has been elucidated.

Methods: We investigated an 18-year-old patient with brachyturricephaly, right coronal craniosynostosis, hypertelorism, exorbitism, mid-face hypoplasia, mildly broadened deviated halluces, wide sandal gaps and right 2/3 cutaneous toe syndactyly. Her forearm movements and hands were normal. Her phenotype is consistent with PS. Genetic testing was performed on lymphocyte DNA by Next Generation Sequencing of a gene panel comprising *FGFR1, FGFR2, FGFR3, EFNB1, TCF12, ERF* and *TWIST1*.

Results: We identified a heterozygous *FGFR2* c.755C>G p.(Ser252Trp) pathogenic missense variant, which is the commonest cause of AS. A second novel missense variant (Gly261Arg) was identified *in cis*.

AlphaMissense modelling suggests that G261R is likely pathogenic for loss of function (LOF) (Score: 0.993). Substitution of the equivalent residue in FGFR1 is associated with LOF and Kallmann syndrome.

Conclusion: We provide evidence that the second variant ameliorates the gain of FGFR2 function associated with the AS substitution resulting in the milder phenotype. Our findings provide further insight into the mechanism of the severe syndactyly in AS.

Background/Objectives: The PPP1R12A gene, located at position 12q21.2-q21.31, encodes a protein also known as MYPT1 and serves as a subunit of myosin phosphatase. It regulates interactions between myosin and actin and plays a crucial role in controlling cell morphology and contractility of smooth muscle cells. Pathogenic variations in PPP1R12A have been associated with various congenital malformations of the urogenital system, the digestive system, brain malformations, and neurodevelopmental disorders. To our knowledge, only 18 patients have been described in the literature.

Methods: Following a European call for collaboration, we collected patients presenting pathogenic variation in PPP1R12A identified by CGH Array, WES and WGS.

Results: We have identified an additional 7 individuals, including sporadic and familial cases. The pathogenic variations found in our patients all resulted in loss of function, similar to those described in the literature. The previously mentioned digestive or urogenital malformations are also observed in most patients in our cohort. Among our 7 patients, only one exhibited brain malformations, consisting of mild cortical atrophy and nodular heterotopias, which did not lead to intellectual disability. Notably, in 4 of our patients, the variation was inherited from a seemingly pauci- or asymptomatic parent, who may only exhibit subtle facial morphological characteristics such as narrow palpebral fissures and a high forehead.

Conclusion: Our results highlight a significant variability in expression within this phenotypic spectrum. It would be important to be able to describe a larger number of individuals in order to refine our understanding of the phenotype and potentially clarify the genotype-phenotype relationship.

P13.006.D Biallelic variants in centrosome linker component LRRC45 cause a novel ciliopathy

Radhakrishnan Periyasamy[1], *Neha Quadri*[1], *Florian Erger*[2], *Iba Kordorkhyriem*[1], *Priyanka Upadhyai*[1], *Anju Shukla*[1]

[1]*Kasturba Medical College, Manipal, Department of Medical Genetics, Udupi, India;* [2]*Institute of Human Genetics and Center for Rare Diseases Cologne, University Hospital Cologne and University of Cologne, Germany*

Background: Recently, biallelic variants in *LRRC45* have been reported in individuals from two unrelated families. Developmental delay and intellectual disability occurred in one family, while rod-cone retinal dystrophy was described in the other.

Methods: A detailed clinical and radiological evaluation followed by genetic testing was performed in probands from families 1 (P1) and 2 (P2&P3). Functional characterization of the candidate variant in P1 was performed using patient-derived skin fibroblasts.

Results: P1 is a 3-year-old female who presented with developmental delay, seizures, visual impairment, and dysmorphism. Cranial MRI revealed polymicrogyria, malformed brainstem, periventricular heterotopia, thin corpus callosum, and cerebellar vermian hypoplasia. Exome sequencing identified the homozygous variant c.1402-2A>G in *LRRC45* (NM_144999.4). The variant c.1402-2A>G triggers aberrant splicing, the resultant LRRC45 transcript lacks exon 14. The mRNA and protein levels of LRRC45 were drastically reduced in fibroblast cells. The number of ciliated cells in P1 was significantly reduced.

P2 presented with respiratory insufficiency, hypotonia, swallowing difficulty, club feet, and ventricular septal defect. Cranial MRI

revealed pachygyria, ventriculomegaly, corpus callosum hypoplasia, cerebellar and vermian hypoplasia. A subsequent affected fetus (P3) from the same family had polyhydramnios and similar CNS malformations. Exome sequencing identified the homozygous variant c.1262G>C (p.Arg421Thr) in *LRRC45* in P2 and P3.

Conclusion: Leucine-Rich Repeat-Containing Protein 45 serves as a centrosome proteinaceous linker and plays a role in centrosome cohesion and ciliogenesis. We propose that pathogenic variants in *LRRC45* are associated with a novel spectrum of ciliopathy phenotypes.

Background/Objectives: Heterozygous pathogenic *KDM2B* variants are associated with a novel neurodevelopmental disorder. *KDM2B* encodes the epigenetic regulator lysine-demethylase 2B (KDM2B), which has histone-modifying activity through its JmjC domain and DNA-binding ability through its CxxC domain. Both loss-of-function and missense variants have been identified in individuals with neurodevelopmental delay, autism/ADHD, congenital organ anomalies and facial dysmorphism. Missense variants appeared to cluster in the CxxC domain. Our goal is to further characterize this *KDM2B*-related disorder, including its molecular mechanisms and genotype-phenotype correlations.

Methods: We expanded our patient cohort of individuals with heterozygous *KDM2B* variants through GeneMatcher and personal communication. To assess DNA binding ability of 8 CxxC variants, we performed electrophoretic mobility shift assays (EMSAs).

Results: We collected data from 34 individuals with *KDM2B*-associated syndrome, including 14 individuals with 11 CxxC variants. Individuals with CxxC variants have a higher frequency of de novo occurrence and congenital organ anomalies compared to those with other variants. Cardiovascular anomalies are observed in 11/14, most commonly atrial septal defect. Ophthalmological and urogenital anomalies are both present in 6/14.

EMSA analysis shows 7/8 CxxC variants have a significantly decreased DNA-binding ability compared to wildtype.

Conclusion: Our study highlights the CxxC domain as a mutational hotspot and the excess of organ anomalies associated with CxxC variants. Our results indicate a distinct mechanism of CxxC variants through a dominant-negative mechanism as opposed to a loss-of-function effect in other patients. To further investigate the role of the CxxC domain during early development, we have created a patient-derived iPSC model.

P13.009.C Wiedemann-Steiner syndrome: clinical and molecular characterization of six Brazilian patients

Ana Mondadori dos Santos[1], *Caio Graco Bruzaca*[2], *Luciana Cardoso Bonadia*[3], *Carmen Silvia Bertuzzo*[3], *The Rare Genomes Project Consortium*[4], **Carlos Eduardo Steiner**[3]

[1]*São Leopoldo Mandic, Campinas Unit, Campinas, Brazil;* [2]*Hospital Municipal Infantil Menino Jesus, Sao Paulo, Brazil;* [3]*UNICAMP Universidade Estadual de Campinas, Translational Medicine, Campinas, Brazil;* [4]*Albert Einstein Israelite Hospital, Laboratory Medicine, Sao Paulo, Brazil*

Consortium: The Rare Genomes Project Consortium

Background/Objectives: Wiedemann-Steiner syndrome (WDSTS, MIM #605130) is neurodevelopmental disorder also characterized by hypertrichosis, short stature, and facial dysmorphisms. It follows autosomal dominant inheritance due to heterozygous variants in the *KMT2A* gene. This study describes six patients with WDSTS confirmed by molecular tests and compares clinical and molecular findings, characterizing the individuals in typical or atypical phenotypes.

Methods: Patients were seen in a Reference Center for Rare Diseases. Molecular investigation by target gene sequencing or next-generation sequencing had been previously carried out. All patients were seen by the same clinical geneticist and were classified as typical (classic) or atypical (expanded) phenotypes based on the descriptors OMIM, Genereviews, and two primary international studies.

Results: Of the six patients (3M:3F), four have the typical phenotype, including the patient from the original description by Steiner and Marques (2000), and two were considered atypical due to the absence of either growth deficiency and/or the characteristic facies. Short stature and hypertrichosis were found in four patients, and developmental delay in five. Most variants were novel and caused by frameshift mutations, and recurrence of the same variant was identified only in a pair of monozygotic twins. Five variants were novel, and only one variant was previously described, showing no concordance of clinical presentation between both individuals.

Conclusion: In addition to contributing to the expanded phenotypic description of WDSTS, the present study comprised a local sample with typical and atypical phenotypes that represented the findings in the Brazilian population.

Hermann Hospital, Division of Medical Genetics, Department of Pediatrics, Houston, United States; [5]Amsterdam University Medical Center, University of Amsterdam, Amsterdam Reproduction and Development Research Institute, Department of Human Genetics, Amsterdam, Netherlands

Background: *KDM2B*, encoding the epigenetic regulator Lysine-demethylase 2B, is associated with a neurodevelopmental syndrome characterized by developmental delay and/or intellectual disability, behavioral challenges, and congenital organ anomalies. KDM2B acts as a histone demethylase through its JmjC domain as well as protects the DNA from hypermethylation through its DNA-binding CxxC domain. Recently, we have shown in a collaborative effort that affected individuals show a distinct episignature with a strong hypermethylated profile. Previously, an individual with a deletion of 12q24.31 including *KDM2B* was reported who had features of Beckwith – Wiedemann syndrome (BWS): high birth weight (p90-p95), macroglossia, and hyperinsulinism. We wanted to further explore an overlap between these syndromes and hypothesized that KDM2B influences methylation of the BWS 11p15 locus.

Methods: We searched our KDM2B cohort and the literature for additional cases. We tested 11p15 methylation in available patient samples of KDM2B patients with and without BWS features.

Results: We identified 34 individuals with KDM2B-associated syndrome of which 7 (21%) had BWS features, macroglossia was present in all seven individuals. Four of them fulfill the clinical criteria for classical BWS. Although both BWS and macroglossia are associated with an increased pediatric cancer risk, malignancies were not reported in this cohort. 11pq15 methylation was normal in all tested patient samples.

Conclusion: KDM2B-associated syndrome should be included in the differential diagnosis of individuals with BWS features, especially macroglossia, and normal 11p15 methylation. Further studies are needed to explore the underlying mechanisms, which possible involve somatic 11p15 methylation events or epigenetic disturbances of other loci.

P13.011.A MED13L syndrome: Contribution of the GenIDA database to patient phenotyping

Roseline caumes[1], *Thomas Smol*[2], *Pauline Burger*[3], *Jean Louis Mandel*[4], *Jamal Ghoumid*[1]

[1]CHU Lille, Clinique de Génétique, Lille, France; [2]CHU Lille, Institut de Génétique Médicale, Lille, France; [3]Université de Strasbourg, INSERM U1258, CNRS UMR7104, GenIDA, IGBMC, Illkirch, France; [4]Université de Strasbourg, Institute for Advanced Studies of the University of Strasbourg (USIAS), strasbourg, France

Background : MED13L pathogenic variations cause the so-called MED13L-syndrome. The condition is characterized by a developmental delay in both motor and language acquisition, leading to a mild to severe intellectual disability (ID). A majority of patients may also exhibit malformations, particularly in the cardiac or skeletal system. GenIDA international project aims to improve the knowledge and management of rare genetic diseases.

Methods : The present study uses standardized HPO terms to comprehensively phenotype individuals' descriptions extracted from the literature (100 patients) and to compare patient phenotypic data from the GenIDA database. Additionally, by comparing variant identified in patients reported in the literature, we aim to identify potential phenotype-genotype correlation.

Results : There was no significant difference in the phenotype description between individuals from the GenIDA cohort and individuals from the literature. Nevertheless, the results highlight that developmental delay, dysmorphic features, and cardiac defects are predominantly described in the cohort based on scientific reports, whereas sensory defects, walking difficulties, and limb malformations are more emphasized in reports from families.

Further analysis comparing patients with missense variants to those with loss-of-function variants revealed statistically significant differences in four criteria : absence of speech, lack of independent walking, epilepsy, and cardiopathy were more prevalent in individuals with missense variations.

Conclusion : GenIDA provided a reliable description of patients with MED13L syndrome, in

emphasizing items few described in the literature. Patients with missense variants presented statistically more pronounced neurological symptoms than those with loss-of-function variants.

Conflict of Interest: None declared

Background/Objectives: Myhre syndrome (MS, MIM 139210) is a rare multisystemic disorder caused by recurrent pathogenic missense variants in *SMAD4*. The clinical features have been mainly documented in childhood and comprise variable neurocognitive development, recognizable craniofacial features, short stature, hearing loss, thickened skin, joint limitations, diverse cardiovascular and airway manifestations, and increased fibrosis often following trauma or surgery. Guidance for the medical management of adults with MS is currently lacking.

Methods: We describe 24 adults with MS and review the literature on adults with MS.

Results: Overall, our cohort shows a milder phenotype as well as lower mortality rates compared to what has been published in literature. Individuals with a codon 500 variant in *SMAD4* present with a more pronounced phenotype for both altered neurodevelopment as well as systemic manifestations. However, in contrast to the literature, we observe cardiovascular abnormalities in individuals with the p.(Arg496Cys) variant. In addition, we describe scoliosis as a new manifestation and we report fertility in two additional males with the p.(Arg496Cys).

Conclusion: Our study contributes novel insights into the clinical variability of MS and underscores the importance of variant-specific considerations. We provide recommendations for the management of MS in adulthood.

Background/Objectives: Large-scale sequencing among 1.52 million healthy individuals allows exploring genetic of recessive lethality, for example, a significant underrepresentation of double transmission of a protein-altering *BRF2* splicing variant. *BRF2* encodes a subunit of the RNA-polymerase III complex whose subunits were associated with autosomal recessive disorders, such as Treacher-Collins syndrome.

Methods: We combined NGS with functional analyses to investigate the effects of *BRF2* variants.

Results: We identified three pairs of Icelandic parents from the early 20th century heterozygous for this *BRF2* splicing variant. Five of their seventeen offsprings died before 3 months of age, while all surviving siblings are heterozygous. Using data aggregation, we identified seven more individuals worldwide from three unrelated families carrying biallelic variants in *BRF2*. Affected individuals present a variable phenotype ranging from severe craniofacial anomalies with early death to intellectual disability with motor and speech development, depending on the combination of the variants, *i.e.* homozygous stop-gain, truncation paired with missense in the DNA-binding domain, homozygous missense in the zinc-finger domain that recruits the polymerase III subunit, respectively. In silico 3D modelling and functional analyses suggested functional impairment of the identified variants. Zebrafish knocked-down for the orthologous *brf2* presented with abnormal escape response, reduced swimming velocity and head malformations, which could be complemented by the human wild-type but not mutated BRF2 mRNA further demonstrating their deleteriousness.

Conclusion: Our results show that *BRF2* biallelic alterations are associated with early death. We provide a new link between brain anomalies and RNA polymerase III subunits and its targets.

P13.014.D *ELMO2*-related Intraosseous Vascular Malformation: Report of four new cases with novel pathogenic variants, clinical follow-up and therapeutic approaches

Mert Karakaya[1], *iman ragab*[2], *Vera Riehmer*[1], *Florian Erger*[1], *Nihal Hussien Aly*[2], *Seung Woo Ryu*[3], *Go Hun Seo*[3], *Anne Schultheis*[4], *Marc Hoemberg*[5], *Boris Decarolis*[5], *Christian Netzer*[1]

[1]*Institute of Human Genetics, Faculty of Medicine and University Hospital Cologne, Cologne, Germany;* [2]*Ain Shams University Cairo, Pediatric Hospital, Hematology Oncology Unit, Cairo, Egypt;* [3]*Division of Medical Genetics, 3billion, Inc., Seoul, Korea, Rep. of South;* [4]*Institute of Pathology, Faculty of Medicine and University Children's Hospital of Cologne, Cologne, Germany;* [5]*Department of Pediatric Oncology, Faculty of Medicine and University Children's Hospital of Cologne, Cologne, Germany*

Background/Objectives: Primary intraosseous vascular malformation (VMPI) is an ultra-rare disorder characterized by severe intraosseous vascular malformations with autosomal-recessive inheritance. It is caused by biallelic germline loss-of-function variants in *ELMO2*. Therapeutic options are limited, often involving interventions such as sclerotherapy and radical surgical procedures, with significant risks and complications.

Methods: We present four unreported patients with VMPI. Genetic analysis was performed using whole exome sequencing, revealing pathogenic variants in *ELMO2*. Additionally, an extensive histopathological analysis was conducted in one patient. Clinical follow-up from prenatal diagnosis onwards, along with novel pharmacotherapeutic approaches, was evaluated.

Results: Clinical presentations of the affected individuals were consistent with VMPI. Genetic analysis identified homozygous

variants in *ELMO2*, including a novel homozygous 25bp-duplication (c.579_603dup). Therapeutic approaches included coil embolization, sclerotherapy, as well as pharmacotherapeutic agents, such as propranolol, sirolimus, and bisphosphonates. Notably, the pharmacotherapeutic strategies reported in our study represent novel approaches in the management of VMPI. Coil embolization addressed acute bleeding episodes, while pharmacotherapies showed variable responses and associated adverse effects. One patient, who was prenatally diagnosed, showed milder symptoms without any therapy to date.

Conclusion: VMPI remains a challenging and life-threatening condition with limited therapeutic options. Early genetic diagnosis enables preventive measures, yet the optimal time for intervention remains uncertain. This report contributes insights into the clinical, genetic and histopathological spectrum, expanding our understanding of VMPI. We underscore the importance of close monitoring, novel therapeutic strategies, and comprehensive care approaches. *ELMO2's* role in VMPI pathogenesis remains elusive, which is crucial to reveal for developing targeted therapies.

P13.015.A Acytokinetic mitosis results in impaired neurogenesis and erythropoiesis in *Mcph1* knockout mice

Yoann Vial[1;2;3], *Jeannette Nardelli*[2], *Adeline Bonnard*[1;3], *Justine Rousselot*[1], *Michele Souyri*[3], *Pierre Gressens*[2], *Hélène Cavé*[1;3], *severine drunat*[1;2]

[1]*Robert Debré Hospital - APHP, Genetics, Paris, France;* [2]*Neurodiderot, Paris, France;* [3]*Research Institute Saint Louis Université De Paris, Paris, France*

Background/Objectives: Microcephaly is a common feature of inherited bone marrow failure syndromes observed in 27% and 9% of patients with Fanconi anemia and dyskeratosis congenita, respectively. However, whether there are common fundamental pathways that are critical for both neuronal and hematopoietic development remains to be explored.

Methods: Using a well-characterized *Mcph1* knockout mouse model specifically developed for microcephaly, we examined erythropoietic abnormalities at birth and during fetal development by flow cytometry. Dysregulated pathways were identified by RNA-seq analysis. To validate our findings at the protein level, we performed Western blot and immunofluorescence analyses. The same methods were used to study *Mcph1* knockout fetal brains.

Results: Our research revealed that *Mcph1*-knockout mice exhibited congenital macrocytic anemia due to impaired terminal erythroid differentiation during fetal development. Anemia's cause is a failure to complete cell division, evident from tetraploid erythroid progenitors with DNA content exceeding 4n. Gene expression profiling demonstrated activation of the p53 pathway in *Mcph1*-deficient erythroid precursors, leading to overexpression of *Cdkn1a/p21*, a major mediator of p53-dependent cell cycle arrest. Surprisingly, fetal brain analysis revealed hypertrophied binucleated neuroprogenitors overexpressing p21 in *Mcph1*-knockout mice, indicating a shared pathophysiological mechanism underlying both erythroid and neurological defects. However, inactivating p53 in *Mcph1*$^{-/-}$ mice failed to reverse anemia and microcephaly, suggesting that p53 activation in *Mcph1*-deficient cells resulted from their proliferation defect rather than causing it.

Conclusion: These findings shed new light on Mcph1's function in fetal hematopoietic development, emphasizing the impact of disrupted cell division on neurogenesis and erythropoiesis - a common limiting pathway.

P13.016.B Etiology of congenital thyroid dysfunction in Down syndrome

Peter Lauffer[1], *Nitash Zwaveling-Soonawala*[2], *Bernadette de Bakker*[3], *Maurice van den Hoff*[4], *Anita Boelen*[5], *Peter Henneman*[6], *Paul van Trotsenburg*[2]

[1]*Amsterdam UMC, Clinical Genetics, Amsterdam, Netherlands;* [2]*Amsterdam UMC, Pediatric Endocrinology, Amsterdam, Netherlands;* [3]*Amsterdam UMC, Obstetrics and Gynaecology, Amsterdam, Netherlands;* [4]*Amsterdam UMC, Medical Biology, Amsterdam, Netherlands;* [5]*Amsterdam UMC, Endocrine Laboratory, Amsterdam, Netherlands;* [6]*Amsterdam UMC, Human Genetics, Amsterdam, Netherlands*

Background/Objectives: Down syndrome (DS) is a chromosomal disorder characterized by trisomy of chromosome 21 and is associated with various health problems. Congenital thyroid dysfunction is a common endocrine abnormality in DS, but its exact cause remains unknown. This work aimed at studying the etiology of congenital thyroid dysfunction in DS.

Methods: Thyroid tissue of fetuses with DS ($n = 4$) and fetuses without a genetic/developmental abnormality ($n = 5$) were analyzed using histopathological evaluation, RNA sequencing (RNA-seq), and DNA methylation (DNAm) profiling.

Results: Histological examination showed abnormally developed DS thyroid tissue compared to non-DS/healthy tissue. RNA-seq analysis showed numerous differences in gene expression between DS and healthy thyroid tissue, including significant downregulation of thyroid genes *FOXE1*, *IYD* and *DIO2*. Gene set enrichment analysis showed disruption of vital cellular processes and functions in DS fetal thyroid tissue. Analysis of DNAm and expression quantitative trait methylation (eQTM) analysis identified functional and biologically relevant associations, that can be linked to plausible disrupted pathways in DS.

Conclusions: Based on these observations, we conclude that congenital non-autoimmune thyroid dysfunction in DS is probably a DS-specific form of thyroid dysfunction, characterized by abnormal thyroid development, altered expression of genes that regulate thyroid development and hormone production, and altered expression and DNAm of genes pertaining to numerous vital pathways leading to significant metabolic disturbances. The disturbances as investigated by multi-omics analyses (RNA-seq, DNAm and eQTM analyses) are widely spread over the genome, and presumably caused by the direct and downstream effects of overexpressed chromosome 21 genes (dosage effect), and (epi)genomic disturbances.

P13.017.C Reclassification of a novel synonymous *PGAP1* variant disrupting splicing

Giada Moresco[1], *Martina Miceli*[2], *Carola Conca Dioguardi*[2], *Ornella Rondinone*[1], *Gianluca Tolva*[2], *Roberta Villa*[2], *Maria Saponaro*[2], *Laura Guarnaccia*[3], *Tiziano Palazzotti*[1], *Federica Alberti*[1], *Laura Fontana*[1;2], *Monica Miozzo*[1;2]

[1]*Università degli Studi di Milano, Medical Genetics, Department of Health Sciences, Milan, Italy;* [2]*ASST Santi Paolo e Carlo Hospital, Medical Genetics Unit, Milan, Italy;* [3]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Laboratory of Experimental Neurosurgery and Cell Therapy, Neurosurgery Unit, Milan, Italy*

Background/Objectives: Variants of uncertain significance (VUS) represent a major challenge in clinical genetic testing and their impact is often underestimated. In particular, synonymous variants may affect splicing mechanisms causative of multiple monogenic

disorders. In-silico tools are not always effective in predicting the impact of these variant and their characterization remains challenging.

Methods: We performed trio whole-exome sequencing (WES) and targeted mRNA sequencing in a 14-years-old girl born to healthy consanguineous parents and affected by global neurodevelopmental delay, absent speech, flaccid tetraparesis, and brain atrophy.

Results: We identified in the proband the novel homozygous synonymous variant c.1272G>A (p.Lys424Lys) in the *PGAP1* gene, inherited from her heterozygous parents. This variant is classified as a VUS and predicted to alter the donor splice site of the *PGAP1* exon 12. Targeted mRNA sequencing confirmed the expression of a mutated isoform with skipping of exon 12 in the proband and the presence of both the wildtype and exon 12-skipped isoforms in her parents. Exon 12-skipping leads to a frameshift and the generation of a premature stop codon, further resulting in the synthesis of a truncated non-functional protein or in nonsense mediated mRNA decay. Biallelic *PGAP1* mutations are responsible for the autosomal recessive neurodevelopmental disorder with dysmorphic features, spasticity, and brain abnormalities (NEDDSBA; OMIM #615802), a syndrome strongly correlated with the proband's phenotype.

Conclusion: The characterization of this *PGAP1* synonymous variant allowed its reclassification as likely pathogenic, further supporting the importance of synonymous variant evaluation in cases with a strong gene-disease correlation.

Grants: None.

Conflict of Interest: None declared

P13.018.D Biallelic mutation of CWF19L2, encoding a core spliceosome subunit, causes a combined neurodevelopmental and immunodeficiency disorder.

James Poulter[1], *Fatima Nadat*[2], *Eleanor O'Callaghan*[1], *Dylan Lawless*[1], *Alaa Alghamdi*[1], *Ailish McCafferty*[1], *Alisa Rose*[1], *Clive McKimmie*[1], *Daniel Peckham*[1], *Jacquelyn Bond*[1], *Asif Iqbal*[3], *Clive Carter*[2], *Christopher Watson*[1], *Helen McGettrick*[3], *Gina Doody*[1], *Sinisa Savic*[1;2]

[1]*University of Leeds, Leeds Institute of Medical Research, Leeds, United Kingdom;* [2]*Leeds Teaching Hospitals Trust, Clinical Immunology, Leeds, United Kingdom;* [3]*University of Birmingham, Birmingham, United Kingdom*

Background: CWF19L2 plays a key role in the post-mRNA release spliceosome complex during pre-mRNA splicing. Here we present biallelic CWF19L2 mutations in a family with microcephaly, autism and immunodeficiency.

Methods: Immunological assessment included immunophenotyping, functional T and B cell assessment and neutrophil migration assays. Quad exome sequencing was used to identify pathogenic variants. Long-read transcriptomes were performed on a PromethION-P48. Mitotic and cell proliferation defects were studied using siRNA of *CWF19L2* in HEK293s.

Results: An affected sib-pair presented with early onset bronchiectasis, recurrent sinopulmonary infections and microcephaly. Immunoglobulin profiling showed reduced IgM, but normal IgG and IgA levels. Lymphocyte populations and T cell proliferation were normal except for a reduction in naïve T-cells. B cells could differentiate in vitro and secrete antibodies (IgM, IgA and IgG) following T dependent stimulation. Whilst neutrophil burst test was normal, their migration towards IL-8 or across inflamed endothelium was severely impaired. Exome sequencing identified compound heterozygous *CWF19L2* variants (c.2200C>T, p.Gln734Ter; c.2251T>C, p.Cys751Arg), encoding a core component of the spliceosome, as the only variants segregating with the disease. Long-read nanopore RNA sequencing confirmed altered splicing in the affected sibling as well as differential expression of genes associated with immune and inflammatory response, chemokine-mediated signalling and actin cytoskeleton. *CWF19L2* knockdown in HEK293s resulted in reduced cellular proliferation and signficant mitotic defects.

Conclusion: We show biallelic loss-of-function variants in *CWF19L2* cause a novel neurodevelopmental and immunodeficiency disorder characterised by defects in splicing, mitosis and neutrophil migration.

Background/Objectives: Non-coding RNAs (ncRNAs), a group of ribonucleic acids that do not encode for proteins, exert regulatory roles in crucial biological processes implicated in cancer and syndromic diseases.

Methods: We previously reported the case of a 6-year-old boy diagnosed with cartilage-hair-hypoplasia, harboring compound heterozygous variants in the RNA-coding *RMRP* gene. Here, we present another 6-year-old boy who presented with global developmental delay, microcephaly and short stature, accompanied by phenotypic abnormalities such as clinodactyly, hypoplasia of the penis and distinctive facial dysmorphic features.

Results: Whole Genome Sequencing (WGS) revealed two variants in the *RNU4ATAC* gene (NR_023343.1:n.13C>T and NR_023343.1:n.51G>A). Family-based segregation analysis confirmed compound heterozygosity. *RNU4ATAC* encodes the small nuclear RNA (snRNA) U4atac that does not result in a protein product. This snRNA is a constituent of the minor (U12-type) spliceosome, responsible for specific intron splicing in the human genome. Biallelic pathogenic variants in the *RNU4ATAC* gene have been intricately linked to a spectrum of diseases collectively known as RNU4atac-opathy, encompassing Taybi-Linder syndrome (TLS)/Microcephalic osteodysplastic primordial dwarfism, type I (MOPD1, OMIM #210710), Roifman syndrome (RFMN, OMIM #616651) and Lowry-Wood syndrome (LWS, OMIM #226960). Common clinical manifestations across these syndromes include growth retardation, skeletal dysplasia/short stature, microcephaly and developmental delay/intellectual disability. Both of the identified variants have already been described in trans with other pathogenic variants. Functional studies indicated reduced U12-dependent splicing activity compared to wildtype.

Conclusion: In this case, WGS bridges a diagnostic gap by revealing non-coding pathogenic variants associated with syndromic disease.

Background/Objectives: *POLA2* encodes the accessory subunit of DNA polymerase α (polα)/primase, which is crucial for telomere C-strand fill-in. Incomplete fill-in of the C-rich telomeric strand after DNA replication has been proposed as a mechanism for Coats plus syndrome, a phenotype within the broader spectrum of telomere biology disorders (TBD), so far associated with pathogenic variants in *POT1*, *CTC1*, and *STN1*. The objective of the study was to describe the detailed phenotype and decipher the molecular etiology of TBD in two families negative for pathogenic variants in the known TBD disease genes.

Methods: Whole genome sequencing, segregation analysis and telomere length analyses.

Results: We report the findings of biallelic deleterious rare variants in the *POLA2* gene in all five affected individuals. All patients harbored the variant p.(Ile96Thr) in a heterozygous compound state with either p.(Pro424Leu) or an intragenic structural variant (deletion-inversion-deletion, 7.8 kb in total). All of the affected individuals displayed abnormally short telomeres and a clinical phenotype compatible with a TBD disorder / Coats plus, including retinal and gastrointestinal (GI) telangiectasias.

Conclusion: Our results suggest *POLA2* as a novel autosomal recessive gene for a TBD with Coats plus features.

Grants: Region Stockholm (FoUI-985957) and the Swedish Society of Medicine (SLS-973171). Intramural research program of the Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD, USA.

Background/Objectives: Differences of sex development (DSDs) are a group of congenital conditions, either isolated or syndromic, characterized by a discrepancy between chromosomal, gonadal, and genital sex development of an individual. Despite significant advances, almost half of the patients remains undiagnosed to date. Previous reports of exome sequencing (WES) of large cohorts of patients presenting with various phenotypes that may include DSD (for example the DDD cohort) showed that this approach allowed the identification of new DSD-causing genes. Since most studies focus on postnatal patients, we thus aimed at studying a cohort of 10 fetuses presenting with syndromic DSD.

Methods: trio/quatuor WES on Illumina platform, after dismissing pathogenic chromosomal imbalances through karyotype and aCGH (with exception of 1 patient).

Results: We found pathogenic or likely pathogenic variants in 5 disease-causing genes and 1 candidate gene, leading to a diagnosis yield of 60%, in accordance with previously reported postnatal DSD cohorts. Of the 5 disease-causing genes, 3 were previously reported as causing DSD (*MYRF, PORCN, AMH*). For the last 2 genes (*MMP21* and *PPP2R1A*), DSD were not usually reported, linking DSD to primary cilia anomalies (*MMP21*) or abnormal chromatin remodeling (*PPP2R1A*). Finally, we found a homozygous variant in a candidate gene, *SLC25A26*, usually responsible for a combined mitochondrial oxidative phosphorylation deficiency without DSD reported to date.

Conclusion: Deciphering the mechanisms of sex development is challenging. Studying syndromic DSD patients through WES remains a fast and interesting tool to highlight new genes and pathways, when WGS is not routinely available.

Background/Objectives: Mowat-Wilson syndrome (MOWS) is a rare congenital disease caused by haploinsufficiency of *ZEB2*, encoding a key developmental transcription factor. Individuals with MOWS show a variable phenotype including intellectual disability, epilepsy, typical facial features, short stature, Hirschsprung disease, brain and heart defects. By performing genome-wide DNA methylation (DNAm) analysis in a cohort of affected individuals, we defined a MOWS-specific DNAm profile or "episignature" as a novel diagnostic biomarker. We propose to apply this episignature to study uncertain and atypical MOWS cases.

Methods: By analyzing the DNAm profiles of 29 individuals with clinical and molecular diagnosis of MOWS using EpiSign™ software relative to the EpiSign Knowledge database reference, we defined and validated a specific MOWS episignature. Through international calls for patients, we are collecting individuals with: i) suspected MOWS-like disorder and a *ZEB2* variant of uncertain significance (eg. missense/noncoding, C-terminal truncation), or ii) typical MOWS presentation but no *ZEB2* gene/locus alteration detected. Their DNAm profiles are then compared to the MOWS episignature.

Results: We identified a reproducible MOWS episignature, with the potential to reclassify variants of uncertain significance. We highlighted its consistency with ZEB2 main role as a transcriptional repressor and with *ZEB2* previously suggested autoregulation ability.

Conclusion: Clinically or molecularly uncertain MOWS cases may be caused by variants affecting specific ZEB2 domains/functions, or by altered *ZEB2* auto- or eteroregulation. Investingating their DNAm profile relative to MOWS episignature will help define their diagnosis, and elucidate the epigenetic correlations between typical and atypical forms.

P13.024.B Novel 14q32.2 microdeletion encompassing BCL11B: a case with complex phenotype including neurodevelopmental disorders, dysmorphisms, Parkinsonism/dystonia and T-cell Acute Lymphoblastic Leukemia

Daniele Guadagnolo[1], *Gioia Mastromoro[1], Nader Khaleghi Hashemian[1], Barbara Torres[2], Maria Cecilia D'Asdia[2], Alessandro De Luca[2], Laura Bernardini[2], Antonio Pizzuti[1]*

[1]Sapienza University of Rome, Department of Experimental Medicine, RM - ROMA; [2]Casa Sollievo della Sofferenza, Laboratory of Medical Genetics, San Giovanni Rotondo

Background/Objectives: In patients presenting multisystemic involvement, the attribution of all clinical characteristics to a single novel molecular finding is challenging. Integrating cytogenetics and sequencing genome-wide analyses can help define new clinical entities. We describe a novel 14q32.2 microdeletion in a patient with neurodevelopmental, neurological, and hematological features.

Methods: The proband was a 26-year-old male. He had plagiocephaly at 6 months. By age 3 he presented global developmental delay. At age 26, he developed T-cell Acute Lymphoblastic Leukemia (T-ALL). He presented wide eyes, beaked nose, receding chin as facial dysmorphisms. He had Parkinsonism/dystonia signs: amimic facies, dystonic head tremor, rigidity, abnormal posture. Brain imaging was normal. Chromosomal Microarray Analysis (CMA) and the Next Generation Sequencing (NGS) analysis of Parkinsonism/dystonia genes were performed on peripheral blood.

Results: CMA identified a 14q32.2 de novo Likely Pathogenic 3.2Mb microdeletion, [GRCh37]14q32.2(96961518_100129367). The germline origin was confirmed on buccal swab. The region included 3 OMIM Morbid genes: *VRK1* (*602168), *BCL11B* (*606558), *CCNK* (*603544). Of these, *BCL11B* and *CCNK* can be associated with dominant syndromic neurodevelopmental disorders. The deletion was not reported in the literature or in DECIPHER. NGS analysis did not identify Pathogenic/Likely Pathogenic variants.

Conclusion: The novel 14q32.2 microdeletion is the likely cause of the neurodevelopmental phenotype of the patient. The exclusion of known causes of Parkinsonism/dystonia suggests that movement disorders can be associated with the microdeletion. The occurrence of T-ALL in the proband, and the proven role of somatic *BCL11B* loss in sporadic T-ALL, support a possible association with hematological malignancy susceptibility.

P13.025.C Microduplication encompassing *CCL2* and segregating in a family with anencephaly and pilonidal cyst: a possible link between chemokine and neural tube defects?

Gioia Mastromoro[1;2], *Daria Darelli[3], Daniele Guadagnolo[2], Nader Khaleghi Hashemian[2], Marta Tocchi[1], Antonella Mennella[1], Gianandrea Traversi[1], Stefania Mariani[1], Serena Bucossi[1], Laura*

Bernardini[4], Antonio Pizzuti[2], Andrea Zumpano[1], Mauro Ciro Antonio Rongioletti[1]

[1]Ospedale Isola Tiberina - Gemelli Isola, Roma, Italy; [2]Sapienza University of Rome, Roma, Italy; [3]San Pietro Hospital, Roma, Italy; [4]Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy

Background/Objectives: Anencephaly is a multifactorial condition, with a recurrence risk of 2-5% following a single case. Neural tube defects are usually induced by environmental factors, such as hyperthermia or vitamin deficiency.

Methods: A pregnant woman was referred for history of fetal anencephaly in a prior pregnancy. Since no genetic investigations had previously been performed, prenatal karyotype and Chromosomal Microarray Analysis (CMA) were offered in the ongoing pregnancy.

Results: CMA revealed a paternally inherited 640Kb microduplication encompassing *CCL2* and *CCL11*. At clinical re-evaluation, the father reported a personal history of pilonidal cyst and disclosed a previous pregnancy with another partner terminated following ultrasound findings of anencephaly in that fetus as well.

CCL2 (C-C Motif Chemokine Ligand 2; MIM + 158105) encodes a cytokine that displays chemotactic activity for monocytes and basophils and has a role in the MIF Mediated Glucocorticoid Regulation and TGF-Beta Pathway. The *CCL2* -2518A>G promoter polymorphism is associated with an increased risk factor for spina bifida in pregnant women with this variant in homozygosity. Exposure to heat in the first trimester is associated with an increased risk for neural tube defects. Previous studies demonstrated that chemokine receptors, including CCR2 (receptor of CCL2), are expressed in the brain by neural progenitor cells, playing a role in chemokine-directed migration in the context of normal neurogenesis.

Conclusion: The present family suggests that the *CCL2* overexpression might disrupt the early embryonic microenvironment by hindering the closure of the anterior and posterior neuropore, configuring itself as a susceptibility factor for neural tube defects.

P13.026.D Antenatal presentation of Mitochondrial Inorganic Pyrophosphatase (PPA2) deficiency: a report on two cases.

Anne Guimier[1;2], *Paul Gueguen[3;4], Jeanne Médéric[3], Anna C.E. Hurst[5], Lucile Boutaud[1;2], Nicolas Derive[4], Stanislas Lyonnet[1;2], Hans A. Mayr[6], Kit Doudney[7], Chris Gordon[2], Jeanne Amiel[1;2]*

[1]Hôpital Necker-Enfants Malades, APHP, Service de Médecine Génomique des Maladies Rares, PARIS, France; [2]Institut Imagine, Université Paris Cité, Laboratory of Embryology and Genetics of Malformations, Inserm U1163, PARIS, France; [3]CHRU de Tours, Université de Tours, Service de Génétique et UMR1253, iBrain, Inserm, TOURS, France; [4]SEQOIA, Laboratoire de Biologie Médicale Multi-Sites, PARIS, France; [5]University of Alabama at Birminghan, Department of Genetics, Birmingham, United States; [6]Paracelsus Medical University Salzburg, Department of pediatrics, SALZBURG, Austria; [7]University of Otago, Centre for Postgraduate Nursing Studies and the Department of Pathology and Biomedical Science, CHRISTCHURCH, New Zealand

Background: PPA2 is a mitochondrial pyrophosphatase essential for cellular energy metabolism. PPA2 biallelic alterations were first described in families with recurrence of sudden cardiac death in early childhood or adolescence. Subsequent studies extended the clinical spectrum to include neurological signs in adults and, in one prenatal case, the association of cerebral malformations and cardiomyopathy that awaited confirmation with further cases.

Methods: Trio genome sequencing was performed in two patients with antenatal presentation.

Results: The previously described fetal case presented severe intrauterine growth retardation (IUGR), ventriculomegaly, agenesis of the corpus callosum (ACC), cerebellar hypoplasia and dilated cardiomyopathy. He was born prematurely and died at 2 days of life. Two variants were identified in trans in PPA2: a recurrent missense (c.514G>A p.Glu172Lys) and a truncating variant (c.938C>A p.Ser313*). Here we report a second prenatal case, unrelated to the first, yet harbouring the same two PPA2 variants, with the association of IUGR, microcephaly, ACC, cerebellar hypoplasia and abnormal gyration, leading to termination of pregnancy at 24 weeks of gestation. Cardiac examination was normal. These cases combine a truncating variant and a hypomorphic variant with low residual pyrophosphatase activity, leading to severe prenatal developmental anomalies.

Conclusion: We report the first two prenatal cases of PPA2 deficiency sharing the same genotype and severe IUGR and cerebral malformations. Similar prenatal presentations of ACC and cerebellar hypoplasia have been reported in other energy metabolism disorders such as pyruvate dehydrogenase deficiency. The consequences of complete deficiency of PPA2 on development remain to be described and may be embryonic lethal.

Conflict of Interest: None declared

P13.027.A 18p11 microdeletion involving PTPRM in monozygotic triplets concordant for increased STAT3 activation, Th17 cell preponderance, and juvenile onset autoimmunity

Morten Krogh Herlin[1], *Jens Magnus Bernth Jensen[2], Lotte Andreasen[1], Mikkel Steen Petersen[2], Jonas Lønskov[3], Mette Bendixen Thorup[4], Niels Holtum Birkebæk[5], Trine Hyrup Mogensen[3;6], Troels Herlin[5;7], Bent Deleuran[3;8]*

[1]Aarhus University Hospital, Department of Clinical Genetics, Aarhus N, Denmark; [2]Aarhus University Hospital, Department of Clinical Immunology, Aarhus N, Denmark; [3]Aarhus University, Department of Biomedicine, Aarhus, Denmark; [4]Aarhus University Hospital, Department of Radiology, Aarhus, Denmark; [5]Aarhus University Hospital, Department of Pediatrics and Adolescent Medicine, Aarhus N, Denmark; [6]Aarhus University Hospital, Department of Infectious Diseases, Aarhus, Denmark; [7]Aarhus University, Department of Clinical Medicine, Aarhus N, Denmark; [8]Aarhus University Hospital, Department of Rheumatology, Aarhus, Denmark

Background/Objectives: 18p deletion syndrome is a chromosomal disorder with an estimated prevalence of 1 in 50,000 characterized by intellectual disability, facial dysmorphology, and brain abnormalities. Some patients also present with autoimmune disease, including thyroiditis, although a cause for this association has not been established. Here, we investigated a unique case of monozygotic triplets concordant for developmental delay and juvenile-onset Graves' thyroiditis.

Methods: We performed chromosomal microarray analysis and subsequently whole-genome sequencing. We also performed various immunological assays investigating STAT3 phosphorylation, Th1/Th2/Th17 cell fractions, Treg cells, and overall immunophenotype.

Results: We identified a de novo interstitial 5.9 Mb deletion of chromosome 18p11.31p11.21 spanning 19 protein-coding genes, NC_000018.10: g.5420142_11286542del. Due to concordance for juvenile-onset autoimmunity in the triplets, we hypothesized the deletion as a possible cause hereof and therefore searched the literature on the genes involved. Based on recent experimental studies identifying protein tyrosine phosphatase receptor type mu (PTPRM) as a phosphatase of STAT3, we hypothesized PTPRM hemizygosity as a potential cause for autoimmune susceptibility in

the triplets. This was supported by increased cell fractions with phosphorylated STAT3 and higher Th17 cell fractions.

Conclusion: We identified monozygotic triplets concordant for developmental delay and juvenile-onset autoimmunity with an interstitial 18p deletion. Based on increased STAT3 phosphorylation and Th17 cell preponderance, we suggest PTPRM hemizygosity as a putative cause of autoimmune susceptibility in 18p deletion syndrome, which potentially could be targeted by IL-17 inhibition.

Grants: M.K. Herlin is supported by the Health Research Foundation of Central Denmark Region (A4204) and Lundbeck Foundation (R403-2022-1385).

P13.028.B *DNAJC17* biallelic variants cause cerebellar hypoplasia and microcephaly - a novel gene-disease relationship

Aida Bertoli-Avella[1], *Mariana Ferreira*[1], *Nadine Jalkh*[1], *Indrani Manjunath*[1], *Rocio Garcia*[1], *Susan Zielske*[1], *Ruxandra Aanicai*[1], *Javier Martini*[1], *Claudia Krüger*[1], *Dragana Markovic*[1], *Fuad Al Mutairi*[2;3;4], *Hülya Kayserili*[5], *Jorge Pinto Basto*[1], *Peter Bauer*[1;6]

[1]*CENTOGENE GmbH, Rostock, Germany;* [2]*King Abdullah Specialized Children's Hospital (KASCH), Genetic and Precision Medicine Department, Riyadh, Saudi Arabia;* [3]*King Abdullah International Medical Research Center (KAIMRC), Riyadh, Saudi Arabia;* [4]*Ministry of National Guard - Health Affairs, Riyadh, Saudi Arabia;* [5]*Koç University School of Medicine (KUSoM), Medical Genetics Department, Istambul, Türkyie;* [6]*University of Rostock, Department of Internal Medicine III - Hematology, Oncology, and Palliative Medicine, Rostock, Germany*

Background/Objectives: Recently, *DNAJC17* was reported as a candidate gene for retinal dystrophy (RD). Given the limited gene-disease relationship (GDR), we the role of *DNAJC17* in human disease.

Methods: We queried our Biodatabank containing information from over 800,000 individuals for biallelic, rare variants in *DNAJC17* (NM_018163.2), and related phenotypes. Human phenotypes are recorded as Human Phenotype Ontology (HPO) terms. GDR was evaluated according to the ClinGen recommendations.

Results: Four unrelated patients were identified with ages ranging from childhood to adulthood with nyctalopia, reduced visual acuity, RD, and immunodeficiency. Additionally, one patient had global developmental delay, and another had seizures. All patients were homozygous for the same previously reported synonymous variant affecting splicing (c.681G>A p.Ala227Ala). Interestingly, we observed a different phenotype in patients with other biallelic variants including nonsense (c.898delG p.Glu300fs and c.560delG p.Gly187fs) and one missense predicted to affect splicing (c.792G>T p.Lys264Asn). A total of 11 patients (nine families) were identified with cerebellar hypoplasia (CH), intrauterine growth retardation/failure to thrive, global developmental delay, ataxia, renal malformations, and nystagmus. Furthermore, a knockout mice model (Dnajc17) has been reported to cause embryonic lethality prior to implantation.

Conclusion: The validity of the GDR for this new neurodevelopmental phenotype reached moderate evidence, supporting a causal role of biallelic *DNAJC17* variants for a new syndrome with cerebellar hypoplasia and microcephaly. The evidence for ophthalmological phenotype remains limited. The current result suggests *DNAJC17* pleiotropism and/or variable expressivity. Our results indicate the value of careful GDR assessment and the utility of biodatabanks in medical genetics.

P13.029.C A unique missense mutation in the RING domain impairs MID1 E3 Ubiquitin ligase activity and localisation and is associated with uncommon Opitz Syndrome-like signs

Martina Mascaro[1], **Elisa Lazzari**[2], *Luigi D'Ambrosio*[3], *Berta Almoguera Castillo*[4], *Saoud Tahsin-Swafiri*[4], *Melania Eva Zanchetta*[2], *Germana Meroni*[3]

[1]*University of Udine, Udine, Italy;* [2]*IRCCS "Burlo Garofolo", Trieste, Italy;* [3]*University of Trieste, Trieste, Italy;* [4]*Fundación Jiménez Díaz University Hospital, Madrid, Spain*

Background/Objectives: Mutations in *MID1*, a RING-type E3 ubiquitin ligase, are associated with the rare genetic disease X-linked Opitz Syndrome (XLOS; OMIM: #300000), characterized by incorrect development of the embryonic midline.

Methods: Genetic studies including karyotyping, CGH array and clinical exome sequencing were performed on the proband. Furthermore, ubiquitin ligase activity and subcellular localization were analysed in cells overexpressing exogenous mutant MID1.

Results: We have identified a novel mutation in MID1 RING, a domain in which XLOS-associated mutations have never been reported, in a family with a history of midline developmental defects. The proband, hemizygous for the *MID1* mutation, presents with signs compatible with XLOS in the context of a broader spectrum of intellectual disability. Mechanistically, the novel mutation identified in MID1 impairs the E3 ubiquitin ligase activity consistent with potential disruption of the catalytic RING domain. Furthermore, altered subcellular localization of mutated MID1 was also observed together with its impact on the stability of the microtubular network, the latter observation in contrast to what previously reported for classical XLOS-mutants.

Conclusion: Our study demonstrates that a newly discovered aminoacidic substitution within the RING domain impairs MID1 E3 ubiquitin ligase activity and alters its microtubular localisation in a manner that is different from the XLOS-associated mutations reported to date, potentially explaining the additional neurological signs in the proband. Altogether these observations raise the question of the relationship between MID1 activity and its microtubular localisation, an issue worth further investigation to understand the function of MID1 and its role in the pathogenesis of midline developmental defects.

P13.030.D Functional validation of a novel *RPS6KA3* splice-affecting variant causing Coffin-Lowry Syndrome: a case report.

Emanuele Coccia[1;2], *Maria Chiara Baroni*[1;2], *Gabriele Massaccesi*[1], *Chiara Diquigiovanni*[1], *Flavia Palombo*[3], *Alessandro Vaisfeld*[1;2], *Giovanni Innella*[1;2], *Daniela Turchetti*[1;2], *Elena Bonora*[1]

[1]*Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy;* [2]*Medical Genetics Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy;* [3]*IRCCS Istituto di Scienze Neurologiche di Bologna, Programma di Neurogenetica, Bologna, Italy*

Background/Objectives: A two-year-old boy was evaluated for delayed neurodevelopment, restrictive cardiomyopathy, bilateral profound hearing loss, dysmorphic features. Whole-exome-sequencing analysis detected the hemizygous c.1354-12T>G

variant in *RPS6KA3*, inherited from the healthy mother, a novel variant classified as of uncertain significance but predicted to alter splicing. To clarify the clinical role of the variant and to provide the parents with proper recurrency risk for the new ongoing pregnancy, we concurrently performed transcript analysis and segregation study.

Methods: Total RNA was extracted from peripheral blood and then retrotranscripted into cDNA. RT–PCR was performed, and its products separated by electrophoresis. Bands were excised, purified, sequenced and electropherograms visualized. Amplification of exon 16 of *RPS6KA3* and intron-exon splicing sites was performed on DNA extracted from peripheral blood of the proband's maternal grandparents.

Results: RT-PCR and sequencing analysis revealed only a shorter amplified product in the proband, corresponding to the abnormally spliced form lacking exon 16, whereas the heterozygous mother presented the band corresponding to the wild-type allele and the same shorter isoform. This demonstrated that the variant causes the "skipping" of exon 16 of *RPS6KA3*, altering the downstream reading frame. The segregation study demonstrated the de novo origin of the variant in the mother.

Conclusion: These findings supported the pathogenicity of the variant, allowing to confirm the diagnosis of Coffin-Lowry Syndrome in the proband. Moreover, these insights made it possible to quickly provide the parents with accurate prenatal counseling for the ongoing and future pregnancies, also offering the possibility of carrying out a prenatal diagnosis.

P13.031.A Deletion of RAI1 non-coding exons 1-2 causes Smith-Magenis syndrome

Uri Hamiel[1;2], *Alina Kurolap*[1], *Hofit Gadot*[1], *Daphna Marom*[1;2], *Adi Mory*[1], *Anat Bar Shira*[1], *Hagit Baris Feldman*[1;2]

[1]*Tel Aviv Sourasky Medical Center, Genetics Institute and Genomics Center, Tel Aviv, Israel;* [2]*Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel*

Background:

Smith-Magenis syndrome (SMS) is a complex genetic disorder characterized by distinctive physical features, developmental delay, and a typical behavioral phenotype. Interstitial 17p11.2 deletions, which include the *RAI1* gene, are detected in >90% of patients, while exon 3 single nucleotide variants are detected in the rest. The primary transcript of the *RAI1* gene is transcribed from exons 3 onwards, while exons 1-2 are non-coding. It is unclear whether genetic variants preceding exon 3 cause SMS. We evaluated an 15-month-old infant for developmental delay and infantile spasms. An exome-based gene panel revealed a deletion encompassing exons 1-2 of *RAI*.

Methods: Chromosomal microarray (CMA) was done to confirm exome sequencing results and suspected de novo inheritance. Real time quantitative PCR (RT-qPCR) analysis was conducted to evaluate *RAI1* mRNA expression.

Results: CMA confirmed a de novo 738 Kbp deletion on 17p11.2, which includes exons 1-2 of *RAI1* but spares exons 3 onwards. RT-qPCR analysis on RNA extracted from the patient, father and three unrelated controls revealed that the patient has *RAI1* haploinsufficiency.

Conclusion: While deletions encompassing the *RAI1* coding region are well established in SMS pathogenesis, only one patient with an SMS phenotype and exons 1-2 deletion was previously reported. We show, for the first time, that a deletion of the *RAI* non-coding exons 1-2, which spares the gene's coding region, causes *RAI1* haploinsufficiency by eliminating regulatory elements, including the gene promoter, thus causing Smith-Magenis syndrome.

P13.032.B Modeling a novel ciliopathy in *C.elegans*

Elena Tacchetto[1;2], *valeria morbidoni*[2], *luca pannone*[3], *Simone Martinelli*[3], *Eva Trevisson*[1;2]

[1]*Università degli Studi di Padova, Salute della Donna e del Bambino, Padova, Italy;* [2]*Istituto di Ricerca Pediatrica, Città della Speranza, Padova, Italy;* [3]*Istituto superiore di Sanità, Roma, Italy*

Background/ Objectives: Two novel heterozygous variants in *KIF3B* were identified in a patient with severe ciliopathy, and inheritance compatible with an autosomal recessive condition. KIF3B is a molecular motor that exploit ATP hydrolysis for intraflagellar transport along microtubules. *KIF3B* mutations have been previously identified as a cause for an autosomal-dominant ciliopathy [1], mainly characterized by retinitis pigmentosa. We propose to generate and characterize a *C.elegans* model to investigate the molecular consequences KIF3B defects.

Methods: The worm genome was edited with CRISPR/Cas9 reproducing patient's mutations and cilia-dependent behaviors were analyzed (chemosensation, osmotic avoidance, dye filling uptake). Cilia length and integrity was assessed by confocal microscopy to check on possible defects. Finally, movement and lifespan were evaluated to investigate possible different KIF3B function.

Results: Chemotaxis assays using different attractants resulted in significant differences between wild-type and *klp-11* mutant worms. In the dye-filling assay, to check for morphological intactness of cilia and sensory neurons, a significant decrease in dye uptake was observed. Moreover, *klp-11* knock-out worms showed a reduction in cilia length. Finally, *KIF3B* orthologue mutant worms showed a significant motor impairment and a significant reduction in lifespan compared to control worms.

Conclusion: These results suggest that KIF3B is not only important for cilia-dependent behaviours, as chemotaxis and chemosensation, but also for cilia structure and integrity as demonstrated by decreased cilia length and impaired dye uptake in mutants. Interestingly, *KIF3B* seems also to have roles in cilia-unrelated pathways, such as movement and ageing.

P13.033.C New insights into the molecular mechanism and pathogenesis of the *FBRSL1*-associated syndrome

Gina Kastens[1], *Roser Ufartes*[1], *Miriam Franken*[1], *Michaela Mischak*[1], *Christof Lenz*[2;3], *Silke Pauli*[1]

[1]*University Medical Center Göttingen, Institute of Human Genetics, Göttingen, Germany;* [2]*University Medical Center Göttingen, Department of Clinical Chemistry, Göttingen, Germany;* [3]*Max Planck Institute for Multidisciplinary Sciences, Bioanalytical Mass Spectrometry Group, Göttingen, Germany*

Background/Objectives: Pathogenic variants in *Fibrosin Like 1* (*FBRSL1*) cause a recently described congenital malformation syndrome. The affected patients presented with respiratory insufficiency, postnatal growth restriction, microcephaly, global developmental delay, heart defects, skin creases and other

malformations. Initial studies showed the existence of different wild-type FBRSL1 isoforms. All affected patients carry a truncating variant in the N-terminal region of the gene. To gain molecular insights into the pathogenesis of the *FBRSL1*-associated syndrome, we analyzed the nuclear function of wild-type FBRSL1 by performing protein interaction and gene expression analysis.

Methods and Results: Using affinity purification mass spectrometry and co-immunoprecipitation, we demonstrated an association of different FBRSL1 isoforms with chromatin remodeling complexes, which play a key role in embryonic development. In addition, we showed by ChIP-Seq that wild-type FBRSL1 is involved in the regulation of gene expression. Downstream enrichment analysis of FBRSL1 targets revealed an enrichment of genes associated with fundamental biological processes and developmental defects.

Conclusion: In summary, we were able to elucidate the nuclear function of FBRLS1 that seems to be particularly important in embryonic development. These findings and further investigations on the effect of pathogenic variants in FBRSL1 will help us to understand the pathogenesis of the FBRSL1-associated syndrome.

P13.034.D Expanding the phenotypic sprectrum of intellectual developmental disorder with dysmorphic facies and ptosis (IDDDFP)

Oğuz Çilingir[1], *Elif Saraç*[1], *Ezgi Susam*[1], *Derya Hazal Özbakır*[1], *Ebru Erzurumluoglu Gokalp*[1], *Sinem Kocagil*[1]

[1]*Eskisehir Osmangazi University, Meselik Campus, Eskisehir*

Background/Objectives: Intellectual developmental disorder with dysmorphic facies and ptosis (IDDDFP) (MIM#617333) is an autosomal dominant disorder identified by delayed psychomotor development, intellectual disability, and distinctive facial features, notably ptosis/blepharophimosis. EEG abnormalities and epilepsy also occur. IDDDFP is associated with pathogenic variations in the Bromodomain and PHD Finger Containing Protein (BRPF1) gene which encodes a multivalent chromatin reader that engages with and stimulates histone acetyltransferases, contributing to its involvement in epigenetic regulation.

Methods: 5 year-old female patient with history of hypotonia, psychomotor developmental delay, autistic features, sleep disturbances, hyperventilation, and seizures was referred to our outpatient clinic for evaluation. On examination her weight was 12 kg (-2,7 SD), length was 98 cm (-2,3 SD), occipitofrontal circumference was 48 cm (-1,8 SD). She had short and upslanted palpebral fissures, red hair and fair skin.

Results: A de novo pathogenic *BRPF1* variant (NM_001003694.2:c.3298C>T, p.(Arg1100Ter)) were identified at WES (Twist Human Core Exome capture kit, MGI DNBSEQ-G40).

Conclusion: Initially described in 2017, IDDDFP has been reported in 48 patients to date. Here we present an additional case diagnosed with this rare entity. Our patient had a neurocognitive phenotype and dysmorphic features similar to cases reported in the literature but sleep disturbances and abnormal breathing pattern has not been previously described. We believe that these novel findings will contribute to expanding the clinical spectrum of IDDDFP and our understanding of this rare phenotype.

P13.035.A Molecular insights into a new syndrome caused by *KMT2D* missense variants in exon 38 and 39 distinct from classical Kabuki syndrome

Michaela Mischak[1], *Roser Ufartes*[1], *Gina Kastens*[2], *Christof Lenz*[2;3], *Silke Pauli*[1]

[1]*University Medical Center Göttingen, Institute of Human Genetics, Göttingen, Germany;* [2]*University Medical Center Göttingen, Department of Clinical Chemistry, Göttingen, Germany;* [3]*Max Planck Institute for Multidisciplinary Sciences, Bioanalytical Mass Spectrometry Group, Göttingen, Germany*

Background: Pathogenic variants in *KMT2D* cause Kabuki syndrome type 1, a rare autosomal dominant developmental disorder characterized by a typical facial gestalt, developmental delay, mental retardation, and a variable degree of congenital malformations. *KMT2D* encodes a histone methyl transferase, which acts as a significant epigenetic regulator. Kabuki syndrome can have a remarkable phenotypic overlap with CHARGE syndrome, another congenital malformation disorder. Recently, a syndrome caused by missense variants in exon 38 and 39 (Ex38/39) in *KMT2D* has been described, with a phenotype that overlaps with but is distinct from CHARGE and Kabuki syndromes. The most striking clinical features of the patients were choanal atresia, hypoplastic nipples, anomalies of the branchial apparatus, nuchal pits, anomalies of the lacrimal canal, hearing loss, external ear malformations, and thyroid abnormalities, while intellectual disability was largely absent.

Objectives: Identification of the pathogenic effect of Ex38/39 missense variants in *KMT2D* that leads to this particular phenotype of the newly identified syndrome.

Methods and Results: To determine whether the described missense variants cause a loss- or gain-of-function in KMT2D, we analyzed the interaction of a part of KMT2D containing the missense variants observed in patients with the recently described atypical Kabuki syndrome. Additionally, we searched for KMT2D interaction partners in this region and analyzed the effect of the variants on the interaction.

Conclusion: In summary, we elucidated the function of the Ex38/39 region of KMT2D, which will help us to understand this new syndrome and potentially provide further insights into the epigenetic role of KMT2D.

P13.036.B Three additional cases with biallelic *CRIPT* variants. Broadening the phenotype of this ultra-rare disorder.

Maria Garcia-de Paso[1], *Irene Lazaro-Rodriguez*[2], *Victor Asensio-Landa*[1], *Damian Heine*[1], *Laura Torres-Juan*[1], *Ana Martín-Santiago*[3], *María Angeles Muñoz Miguelsanz*[4], *Juan Francisco Quesada Espinosa*[5], *Lucía Garzón Lorenzo*[2], *Jaime Cruz*[2], *Iciar Martínez*[1], **Fernando Santos-Simarro**[1]

[1]*Hospital Universitari Son Espases, Molecular Diagnostics and Clinical Genetics Unit, Palma, Spain;* [2]*Hospital Universitario 12 de Octubre, Pediatric Endocrinology Department, Madrid, Spain;* [3]*Hospital Universitari Son Espases, Pediatric Dermatology, Palma;* [4]*Hospital Universitari Son Espases, Pediatric Surgery Department, Palma, Spain;* [5]*Hospital Universitario 12 de Octubre, Genetics, Madrid, Spain*

Background: Biallelic *CRIPT* variants (Cysteine-Rich PDZ Domain-BindingProtein) have only been described in six patients and the clinical phenotype has only recently been delineated to include growth retardation, neurodevelopmental delay and Rothmund-Thompson-like features.

Case presentation and methods: We present three additional cases with biallelic *CRIPT* variants. Two of the cases are sisters, aged two and five years, born to a healthy consanguineous couple of Moroccan origin. Their common manifestations include:

prenatal growth retardation, moderate psychomotor delay, microcephaly, dysmorphic features and ectodermal abnormalities. In addition, the eldest has a cervical aneurysmal vascular lesion and the younger has a congenital heart defect and unilateral microphthalmia. The third case, unrelated to the previous two, is a 12-year-old girl born to consanguineous Moroccan parents. Her clinical features include prenatal growth retardation, moderate psychomotor delay, microcephaly, dysmorphic features and ectodermal abnormalities in addition to epilepsy, myopia magna and skeletal abnormalities.

Results: Whole exome sequencing identified the homozygous *CRIPT* (NM_014171.6): c.132delA; (p.Ala45GlnfsTer86) variant in both sisters and the homozygous *CRIPT* (NM_014171.5): c.126delA (p.A45Qfs*85) variant in the third case. The parents were confirmed to be heterozygous carriers.

Conclusions: We present three additional cases with biallelic *CRIPT* variants and contribute to the delineation of the clinical phenotype of this ultra-rare disorder. The *CRIPT* (NM_014171.6): c.132delA seems to be a recurrent variant in the Moroccan population, described in all (four) identified cases from this population.

P13.037.C Validation of a hypomorphic variant in CDK13 as the cause of CHDFIDD with autosomal recessive inheritance through determination of an episignature

Jan Fischer[1], *Karl Hackmann*[1], *Marielle Alders*[2], *Marcel Mannens*[2], *David Geneviève*[3], *Bekim Sadikovic*[4], *Evelin Schröck*[1;5], *Joseph Porrmann*[1]

[1]*Institute for Clinical Genetics, University Hospital Carl Gustav Carus at TUD Dresden University of Technology, and Faculty of Medicine of TUD Dresden University of Technology, Dresden, Germany;* [2]*Amsterdam Reproduction and Development Research Institute, Amsterdam UMC, University of Amsterdam, Department of Human Genetics, Amsterdam, Netherlands;* [3]*Reference Center for Rare Disease, Montpellier University, Medical Genetic Department for Rare Disease and Personalize Medicine, Montpellier, France;* [4]*Verspeeten Clinical Genome Centre, London Health Sciences Centre, Department of Pathology and Laboratory Medicine, Western University, London, Canada;* [5]*Max-Planck-Institut of Molecular Cell Biology and Genetics, Dresden, Germany*

Background: Heterozygous pathogenic variants in *CDK13* have been associated with an autosomal dominant disorder characterized by congenital heart defects, dysmorphic facial features and intellectual developmental disorder (CHDFIDD) (OMIM:617360). Besides haploinsufficiency, missense variants with a dominant-negative effect are also considered disease causing (PMID:30702837). All previously described pathogenic missense variants are located in the kinase domain of CDK13 with the phenotype likely being associated to the degree of functional domain alteration. CDK13 has been shown to influence DNA methylation and individuals with the CHDFIDD have recently been found to exhibit a characteristic episignature (PMID:35063350).

Methods/Results: We now report on a 2.5-year-old boy with an atrial septal defect, a mild pulmonary valve stenosis, a horseshoe kidney, corpus callosum hypoplasia, cerebellar hypoplasia, bilateral clubfoot with syndactyly (toes 2 and 3), feeding difficulties (requiring a PEG tube), psychomotor developmental delay and facial dysmorphism. Notably, the consanguineous parents both had mild intellectual disability without further signs of CHDFIDD.

Exome-wide sequencing of the boy revealed a previously undescribed homozygous missense variant of unknown significance in the kinase domain of *CDK13* (NM_003718.5:c.2330C>G, p.(Ala777Gly)). Due to the phenotypic overlap but discrepant mode of inheritance with CHDFIDD, a genome-wide methylation screen (EpiSignTM DNA methylation analysis) was conducted for improved variant assessment. This revealed the presence of a CHDFIDD-typical episignature in the index patient and milder methylation abnormalities in the heterozygous mother.

Conclusion: This suggests that p.Ala777Gly is a hypomorphic variant, which uniquely results in autosomal recessive inheritance. The general approach further highlights the utility of episignatures for the assessment of variants of unknown significance.

Background/Objectives: This study presents a unique case of ATRIP-deficient Seckel syndrome (SS), wherein the patient also suffers from combined immunodeficiency (CID), a rarely observed condition in SS. The objective is to understand ATRIP's role in the DNA damage response and its connection to the immune system.

Methods: Expression of ATRIP and its partners was analysed at RNA and protein levels. Chromosomal sensitivity post DNA damage was confirmed using micronucleus assays. Flow cytometry (FCM) assessed cell cycle dynamics. Live-cell imaging and CRISPR-SELECT^{TIME} quantified fitness of ATRIP-deficient cells. Immunophenotyping utilized FCM, single-cell RNA sequencing (scRNAseq) and linear amplification-mediated high-throughput genome-wide sequencing (LAM-HTGS).

Results: The proband harboured a homozygous ATRIP splice variant (c.829+5G>T), inherited from healthy parents, leading to a complete loss-of-function. In contrast to current state-of-the-art, residual ATR kinase activity was observed, albeit impaired. Similar to the ATR-SS phenotype, patient's cells exhibit compromised DNA replication, cell cycle progression, and increased susceptibility to genotoxic agents. CRISPR-SELECT^{TIME} affirmed reduced cell fitness in presence of the ATRIP variant. Immunophenotyping unveiled diminished B, CD4 + T, and NK cells. Both B and T cell maturation and function were impaired upon analysis. Aberrations in immunoglobulin class switch frequency and distribution suggest a recombination deficiency. scRNAseq identified profound immune dysregulation.

Conclusion: This study broadens the clinical and molecular spectrum of SS, revealing a CID phenotype linked with ATRIP

deficiency. It delineates the molecular and functional impact of ATRIP deficiency on the ATR pathway and immune development.

P13.039.A Assessment of ageing in Cornelia de Lange Syndrome

Feliciano Ramos[1], *Cristina Lucia Campos*[2], *Ana Latorre-Pellicer*[2], *Enrique Váquez*[3], *Marta Gil-Salvador*[2], *Beatriz Puisac*[2], *María Arnedo*[2], *Ariadna Ayerza Casas*[4], *Ana Dopazo*[3], *Julia del Rincón*[1], *Juan Pie*[2]

[1]*Hospital Clínico Universitario 'Lozano Blesa', Facultad de Medicina, Universidad de Zaragoza, Pediatría, Zaragoza, Spain;* [2]*Universidad de Zaragoza, Facultad de Medicina, Fisiología. Laboratorio Genética Clínica y Genómica Funcional, Zaragoza, Spain;* [3]*CNIC, Cardiology, Madrid, Spain;* [4]*Hospital Infantil Universitario 'Miguel Servet', Cardiología, Zaragoza, Spain*

Background/Objectives: Cornelia de Lange syndrome is a rare, congenital disorder characterized by a widely variable clinical presentation. In addition to distinctive facial features, affected individuals present physical abnormalities, growth retardation and cognitive disabilities. Its genetic cause is related to variants in genes related to the cohesin complex, with variants in the *NIPBL* gene being the most frequent.

There is a lack of understanding of the evolution and implications of pathogenic variants at the systemic and cellular level in adult individuals. Therefore, our aim is to characterize six adult individuals at the clinical, cellular and molecular level.

Methods: Application of the CdLS clinical score. Characterization of primary fibroblasts by evaluation of growth curves. Study of the transcriptome by RNA sequencing and set enrichment analysis.

Results: All patients presented a classic phenotype and pathogenic de novo variants in the *NIPBL* gene. Growth charts showed significant differences with controls. RNA sequencing showed a deregulation of genes mainly involved in neurodevelopment and mRNA processing, with a downward trend. In addition, gene set enrichment analysis showed a significant enrichment of processes related to mRNA regulation and maintenance. Finally, study of genes deregulated during the ageing process showed a trend of deregulation in all patients.

Conclusion: Differences at the cellular level seem to indicate an accumulation of damage that impairs proper cell proliferation. In addition, deregulation trend of genes involved in ageing could suggest an acceleration in this process.

Grants: M.G-S is supported by a Predoctoral Fellowship from the DGA and C.L-C by a Predoctoral Fellowship from the Spanish Ministry of Health-ISCIII.

P13.040.B A novel NR2F2 gene variant in a child with atrioventricular septal defect, growth delay and additional syndromic features

Anna Lengyel[1], *Eva Pinti*[1], *Rita Bertalan*[1], *Gyorgy Fekete*[1], *Iren Haltrich*[1]

[1]*Semmelweis University, Pediatric Center, Hungary*

Background: Nuclear receptor subfamily 2 group F member 2 (*NR2F2*) encodes a member of the nuclear receptor superfamily of ligand-activated transcriptional factors. Heterozygous loss-of-function variants are associated with congenital heart defects and 46,XX disorder of sexual development.

Methods: A 5-year-old boy presented with short stature, decreased weight, atrioventricular septal defect and cryptorchidism. The patient's history was notable for single umbilical artery, increased nuchal fold (NIPT was performed and revealed a normal fetal 46,XY karyotype), meconium aspiration, feeding difficulties in infancy (requiring transient tube feeding), strabismus, hypermetropia, astigmatism and delayed motor development. Speech and language development were normal; currently the child has mild learning difficulties. Physical examination identified a long face, thin lip vermillions, low-set ears and abnormal pinna morphology. CNV analysis inclusive WES was performed from peripheral blood.

Results: A novel heterozygous frameshift variant was identified in *NR2F2* gene: c.423del, p.(Val142Trpfs*3). This truncating variant is absent in gnomAD. Associated disorders are inherited in an autosomal dominant manner. As mentioned above, variants in *NR2F2* are associated with congenital heart defects, and have recently been reported in relation to a more complex phenotype including developmental delays, intellectual disability, hypotonia, craniofacial minor anomalies, feeding difficulties, cryptorchidism, renal failure, hearing loss, strabismus, and, less frequently, asplenia and congenital diaphragmatic hernia.

Conclusions: We report a novel likely pathogenic *NR2F2* variant in a patient with syndromic features, expanding the genotypic spectrum linked to the recently expanded NR2F2-associated phenotype.

Grants: n/a

Conflict of Interest: None declared

P13.041.C Lissencephaly with dysgenesis of the corpus callosum and congenital cataract due to a novel de novo variant of the *DYNC1H1* gene

Mikulas Zich[1], *Pavel Seeman*[1;2], *Sarka Cerna*[1], *Petra Cibulkova*[3], *Valentyna Kaduchova*[3], *Jana Lastuvkova*[1]

[1]*Krajska zdravotni, a.s. - Masarykova nemocnice Usti nad Labem, o.z., Department of Medical Genetics, Usti nad Labem, Czech Republic;* [2]*2nd Faculty of Medicine, Charles University and Motol University Hospital, Department of Paediatric Neurology, Prague 5, Czech Republic;* [3]*University Hospital Ostrava, Department of Molecular and Clinical Pathology and Medical Genetics, Ostrava-Poruba, Czech Republic*

Background/Objectives: Lissencephaly is a set of congenital gyrification disorders resulting from abnormal neuronal migration that affects the development of the cerebral cortex. Pathogenic heterozygous variants of the *DYNC1H1* gene are the 4th most common cause of lissencephaly and account for approximately 3% of its genetic causes.

Methods: Next-generation sequencing (NGS), Magnetic resonance imaging (MRI), electroencephalography, neurological and ophthalmic examination

Results: We present a 27-month-old male patient born with right-sided talipes equinovarus. By 3 months of age, diagnosis of a severe central coordination disorder and delayed psychomotor development had been established. The patient was also diagnosed with bilateral perinuclear cataract. At 5 months, the patient suffered status epilepticus. Subsequent brain MRI revealed lissencephaly, dysgenesis of the corpus callosum and delayed myelination. Seizures became well-controlled with antiepileptic medication. NGS of a gene panel for lissencephaly revealed a novel, previously undescribed heterozygous missense variant of the *DYNC1H1* gene (NM_001376.5): c.10886T>C, p.Phe3629Ser. This variant has not been detected in either parent, so it has emerged de novo. A few other de novo variants of the *DYNC1H1* gene, e.g. c.10973G>A, have been described in patients with a

very similar phenotype, i.e. lissencephaly, cataract, bilateral talipes equinovarus, delayed psychomotor development and epilepsy.

Conclusion: Given the similarity of our patient's phenotypic features to those associated with other previously described de novo variants of the *DYNC1H1* gene, we consider the c.10886T>C variant of the *DYNC1H1* gene to be the cause of our patient's medical condition.

Conflict of Interest: None declared

P13.042.D Neurodevelopmental anomalies associated with the disruption of the plasminogen pathway

Kevin Uguen[1], Tanja Frey[2], Osama Muthaffar[3], Jean-Claude Décarie[4], Najim Ameziane[5], Sarah Boissel[1], Yalda Baradavan-Heravi[2], Anita Rauch[2], Gabriela Oprea[5], Aboulfazl Rad[5], Katharina Steindl[2], **Jacques Michaud**[1]

[1]CHU Sainte-Justine Azrieli Research Centre, Montréal, Canada; [2]Institute of Medical Genetics - UZH, Schlieren, Switzerland; [3]King Abdul Aziz University, Department of pediatrics, Jeddah, Saudi Arabia; [4]CHU Sainte-Justine, Department of medical imaging, Montréal, Canada; [5]Arcensus GmbH, Rostock, Germany

Background/Objectives: Congenital hydrocephalus (CH) is a condition characterized by an accumulation of cerebrospinal fluid within the brain, sometimes associated with other brain anomalies such as Dandy-Walker malformation (DWM). In order to gain insight into the molecular basis of these disorders, we performed genome-wide sequencing in consanguineous families with CH and DWM.

Methods: Exome or genome sequencing was performed in three families with CH and DWM.

Results: We identified homozygous truncating variants in the *PLAT* gene in the four affected family members from these families. All of them showed tetraventricular hydrocephalus. In two individuals, a membrane at the inferior aspect of the fourth ventricle was likely the cause of their hydrocephalus. Three cases exhibited DWM whereas the two oldest individuals displayed intellectual disability. *PLAT* encodes the tissue-type plasminogen activator (tPA), a serine protease whose main function is to cleave the proenzyme plasminogen to produce active plasmin, which is a potent serine protease with an extensive range of substrates, including fibrin, the chief constituent of thrombus. Interestingly, plasminogen deficiency has also been shown to cause CH and DWM, suggesting that loss of *PLAT* function causes these defects by disrupting plasmin production.

Conclusion: In summary, we describe a new recessive disorder characterized by obstructive CH, DWM and intellectual disability in individuals with loss-of-function variants in *PLAT*. This discovery further strengthens the involvement of the plasminogen pathway in the pathogenesis of these neuro-developmental disorders.

Grants: This work was supported by grants from the Canadian Institutes of Health Research (CRI 88413 and MOP-136913), Chaire Jean-Louis Lévesque and Chaire Jonathan-Bouchard (JLM).

Conflict of Interest: None declared

Consortium: Telethon Undiagnosed Diseases Program (TUDP) Study Group

Background: *CHAMP1* disease is a rare condition, described in 40 individual so far, typically caused by truncating gene variants. The underlying pathomechanism in these cases is a dominant negative effect. Although a homogeneous phenotype is described, characterized by moderate to severe intellectual disability, autism and distinctive facial characteristics, the phenotypic spectrum of the disease is poorly understood. In addition, different pathomechanisms, namely haploinsufficiency as a consequence of gene deletion, and gain-of-function as a consequence of missense variants, cause different phenotypes, as we recently inferred. These preliminary suggestions need confirmation. Importantly, the role of missense variants remains conflicting.

Methods: We collaborated with the *CHAMP1* foundation to refine phenotype-genotype correlations through direct clinical evaluations of nine subjects during the July 2023 convention in Verona and online interviews with 18 families (21 with truncating variants, 4 with missense variants and 2 with unbalanced translocations).

Results: New insights were achieved by comparative evaluation of a larger patients series. **Truncating variants:** the clinical phenotype undergoes great variability in individual patients; a subset of patients who received early and intensive habilitation interventions presented with a very mild neurodevelopmental impairment, suggesting a high responsiveness to the treatments; whether it reflects the individual genomic background is under investigation. **Unbalanced translocations/13q deletions:** no homogeneous correlations were observed, reflecting the heterogeneity of the chromosome rearrangements; however small and isolated 13q deletions are associated with a milder phenotype. **Missense variants**: preliminary data point at different clinical outcome of certain variants, likely depending on the impairment of different protein domains.

Conflict of Interest: None declared

P13.044.B Delineating the phenotype associated with the 15q25.2-15q25.3 microdeletion

Maja Todorovic[1], *Daryl Scott[2], Himanshu Goel[3;4], Mohnish Suri[5], Levinus Bok[6], Rolph Pfundt[7], Ornella Galesi[8], Jill A. Rosenfeld[9], Antonio Novelli[10], Enrico Grosso[11], Vincenzo Antona[12], Marco Fichera[8;13], Han Brunner[14], Giovanni Battista Ferrero[15], Alfredo Brusco[1;11]*

Background/Objectives: The 15q25 region contains various copy number variants (CNV), some of which have already been linked to neurodevelopmental (NDD) and neuropsychiatric disorders. Our aim is to gather data to further characterize distal 15q25.2 deletion that is associated with an NDD.

Methods: We conducted a thorough search across multiple databases, including PubMed, Decipher, ClinVar, Database of Human CNVs IRCCS Troina, and DGV, to identify cases with 15q25.2-15q25.3 deletions (approximate coordinates hg19: chr15:85089979-85728844). Furthermore, we contacted clinicians to gather pertinent genetic and clinical information related to these deletions.

Results: We identified a total of 33 cases with a recurrent distal deletion 15q25.2-15q25.3. The core phenotypic features observed in most cases include autism spectrum disorder, mild to moderate developmental delay or intellectual disability, speech and language delay, behavioral abnormality. Morphological features were reported in a subset of cases and included esophageal atresia, scoliosis with lumbar hyperlordosis, bifid uvula, pulmonary atresia with intact ventricular septum, congenital cardiac anomaly, café-au-lait spots and mild facial dysmorphism such as synophrys, upslanted palpebral fissure, flat mid face on profile, a short philtrum, posteriorly rotated ears, macrocephaly. In 12% of the cases the deletion occurred de novo, while in 38% it was inherited, suggesting incomplete penetrance or variable expressivity; for half of the cases the parents' information was not available. The microdeletion encompasses 17 genes, with only ZNF592 being suggested as haploinsufficient (pLI = 1, LOEUF = 0.21).

Conclusion: Our findings provide additional evidence of a recurrent 15q25.2-15q25.3 deletion that contributes to neurodevelopmental disorders.

P13.045.C *Fetal anomalies of Potter sequence, IUGR, renal tubular dysgenesis, and osteopenia associated with placenta disorder of massive perivillous deposition with/without chronic histiocytic intervillositis: a report on four new cases with a focus on prenatal presentation*

Stanley Neufeld[1], *Mary Ann Thomas*[1;2], *Elaine Chan*[3;4;5], *seemab haider*[6;7], *weiming yu*[3;4;5], *Julie Lauzon*[1;2]

[1]*Alberta Children's Hospital, Department of Medical Genetics;* [2]*University of Calgary, Alberta Children's Hospital Research Institute;* [3]*University of Calgary, Cumming School of Medicine, Pathology and Laboratory Medicine;* [4]*Alberta Precision Laboratories;* [5]*Alberta Children's Hospital;* [6]*University of Calgary, Department of Radiology;* [7]*Alberta Children's Hospital, Department of Radiology*

Background/Objectives: Investigation of fetal anomalies in pregnancy often focuses on molecular testing of the fetus itself. However, placental disorders are increasingly being recognized for their pathogenic role. Here we present four new fetal cases involving growth restriction, shortened long bones, and osteopenia, where a fetal disorder such as skeletal dysplasia was suspected, but where the likely cause is in fact a certain placental disorder.

Methods: Four fetal cases with similar placental and fetal anomalies were reviewed including the prenatal imaging, fetal autopsy, and placental examination.

Results: Oligo-/anhydramnios and growth restriction developed between 19 and 28 gestational weeks, variably coinciding with the detection of anomalies including increased cardio-thoracic ratio and shortened long bones. Spontaneous fetal demise occurred between 28 and 30 weeks of gestation in three cases; in the fourth case, the pregnancy was interrupted at 21 weeks' gestation. Autopsy showed pulmonary hypoplasia, flattened facies, and talipes, all in keeping with decreased amniotic fluid/Potter sequence. Histologic examination revealed renal tubular dysgenesis in some cases, and placental massive perivillous fibrin deposition (MPFD) in all cases. Genetic testing for trisomies 13, 18, and 21 was normal.

Conclusion: The mechanism for the fetal anomalies appears to be MPFD leading to reduced fetal kidney perfusion, causing renal tubular dysgenesis and subsequently oligo/anhydramnios. The placental and renal abnormalities also lead to osteopenia, possibly via altered vitamin D metabolism. These case studies highlight the association of a placental disorder with fetal anomalies, suggesting that the placenta may have a broader role in fetal development than is currently appreciated.

P13.047.A Ophthalmological evaluation in Brazilian patients with Cornelia de Lange Syndrome presenting variants in the *NIPBL* gene

Thainá Vilella[1;2], *Beatriz Carvalho Nunes*[1], *Giulia Del Valle*[2], *Chong Kim*[3], *Isabel Pinheiro*[3], *Juliana Sallum*[2], *Hiromi Aoi*[4], *Naomichi MATSUMOTO*[4], *Maria Isabel Melaragno*[1], *Priscila Cardoso Cristovam*[2]

[1]*Universidade Federal de São Paulo, Department of Morphology and Genetics, São Paulo, Brazil;* [2]*Universidade Federal de São Paulo, Department of Ophthalmology and Visual Sciences, São Paulo, Brazil;* [3]*Instituto da Criança da Universidade de São Paulo, Department of Genetics, São Paulo, Brazil;* [4]*Yokohama City University, Department of Human Genetics, Yokohama, Japan*

Background/Objectives: Cornelia de Lange Syndrome (CdLS) is a multisystemic genetic disease. Mutations in the NIPBL gene cause Cornelia de Lange syndrome 1 (CdLS1; OMIM #122470), which accounts for approximately 60% of CdLS cases. This study aims to evaluate the ophthalmological phenotype of CdLS1 and its correlation with NIPBL genetic variants.

Methods: Sixteen probands with confirmed *NIPBL* mutations by whole exome sequencing (WES) underwent a thorough ophthalmological examination. Assessments encompassed facial distance measurements, ectoscopy, visual acuity, pupillary reaction, ocular motility, slit lamp examination, tonometry, cycloplegic refraction, and dilated fundus examination, performed according to individual tolerance levels.

Results: Among the identified *NIPBL* gene mutations, 5 were splicing site mutations, 4 were missense mutations, and 7 were loss of function (LoF) mutations. Consistently observed ophthalmological features included synophrys (100%), arched and thick eyebrows (94%), long eyelashes (94%), and curled eyelashes (88%). Downslanted palpebral fissures and moderate ptosis were exclusively associated with LoF variants, whereas missense or splicing variants were associated with neutral or positively slanted

palpebral fissures and mild ptosis. Strabismus affected 37.5% of the patients, and myopia and high myopia were observed in 68.75% and 18.75% of subjects, respectively. Additional findings included thinning of the iris pupillary zone and optic disc peripapillary atrophy.

Conclusion: The study is the first ophthalmological study within the Brazilian population and contributed to a better understanding of ophthalmological changes in patients with CdLS1. Furthermore, it suggests a potential correlation between the type of genetic variant and distinct ophthalmological phenotypes.

P13.048.B Single-chromosome methylation sequencing and gene expression data unravel spreading of X-chromosome inactivation into gene-rich autosomal regions in an unbalanced t(X;13) translocation

Bianca Pereira Favilla[1], *Ahmed Al-Rikabi*[2], *Danielle C. F. Bruno*[3;4], *Paula Asprino*[5], *Vera Ayres Meloni*[1], *Pedro A. F. Galante*[5], *Iscia Lopes-Cendes*[3;4], *Fernanda Teixeira Bellucco*[1], *Thomas Liehr*[2], *Maria Isabel Melaragno*[1]

[1]*Genetics Division, Department of Morphology and Genetics, Universidade Federal de São Paulo, São Paulo, Brazil;* [2]*Institute of Human Genetics, Jena University Hospital - Friedrich Schiller University, Jena, Germany;* [3]*Department of Translational Medicine, School of Medical Sciences, University of Campinas, Campinas, Brazil;* [4]*Brazilian Institute of Neuroscience and Neurotechnology, Campinas, Brazil;* [5]*Molecular Oncology Center, Instituto de Ensino e Pesquisa (IEP) - Hospital Sírio-Libanês, São Paulo, Brazil*

Background/Objectives: Patients with unbalanced X-autosome translocations present skewed X-chromosome inactivation (XCI) and autosomal silencing due to variable spreading of XCI into the translocated autosomal regions. Investigating chromosome-specific autosomal silencing in these cases not only offers an improved genotype-phenotype characterization of patients but also provides unbiased insights into intrinsic DNA and chromatin features that may mediate the XCI spreading.

Methods: Here, we combined chromosome-specific methylation sequencing analysis using an innovative chromosome-microdissection-based approach, bulk RNA-seq, and allele-specific expression analysis from peripheral blood cells to unveil silencing across the autosomal portion of the derivative chromosome from a patient with a t(X;13) translocation.

Results: Our analyses revealed differentially hypomethylated sites at gene bodies, exclusively on the derivative chromosome, which overlap with the downregulated genes (FDR < 0.05) across chromosome 13. Allele-specific expression analysis showed that differentially downregulated genes present inactivation of the allele from the derivative chromosome with different effect sizes, and are mostly clustered together in gene-rich topologically associating domains (TADs) across chromosome 13, while genes within gene-poor TADs tend to resist the spreading of XCI in the autosomal context. Moreover, downregulated genes are related to phenotypic characteristics that the patient presented, such as abnormalities of the eyes, neurodevelopmental delay, and microcephaly.

Conclusion: Our results suggest clinically relevant alterations in gene expression that can be attributed to the spreading of XCI into autosomal sequences and propose a variable XCI spreading in this context, with gene-rich autosomal regions being more prone to silencing.

P13.049.C A metabolic signature for *NADSYN1*-dependent congenital NAD deficiency disorder

Justin Szot[1], *Hartmut Cuny*[1], *Ella Martin*[1], *Delicia Sheng*[1], *Kavitha Iyer*[1], *Dimuthu Alankarage*[1], *Gavin Chapman*[1], *Kayleigh Bozon*[1], **Sally Dunwoodie**[1]

[1]*Victor Chang Cardiac Research Institute, Sydney, Australia*

Background/Objectives: Nicotinamide Adenine Dinucleotide (NAD) is essential for embryonic development. Biallelic loss-of-function variants in *KYNU*, *HAAO or NADSYN1*, enzymes of the NAD de novo synthesis pathway cause Congenital NAD Deficiency Disorder (CNDD). Congenital malformation can be prevented in *Kynu* or *Haao* mouse models with vitamin B3 (NAD precursor). To further understand CNDD causes and possible prevention, we assess 13 additional individuals with *NADSYN1* variants, a mouse model, vitamin B3 supplementation in mice, and quantified the NAD metabolome in patients and mice.

Methods: Patient variants in *NADSYN1* were assessed for pathogenicity using enymatic activity assays. A mouse model of *NADSYN1*-dependent CNDD was generated using CRISPR-Cas9, embryo phenotyping assesed using micro-CT, and various maternal NAD precursor supplements (vitamin B3 vitamers) were assessed to prevent adverse pregnancy outcomes. Some patients were orally supplemented with vitamin B3 vitamers. NAD and related metabolites were quantified in patients or mice using UHPLC-MS/MS.

Results: NADSYN1 variant proteins were functionally impaired in a domain-specific manner.

Nadsyn1 loss-of-function mouse embryos recapitulated the multiple malformations present in human cases. The efficacy of vitamin B3 supplementation depends on which gene (*KYNU*, *HAAO or NADSYN1)* caused the NAD deficiency and the type (amidated or deamidated) of vitamin B3 used. The circulatory NAD metabolome in humans and mice pre- and post-supplementation revealed a consistent metabolic signature with utility for patient identification and treatment.

Conclusion: Our data collectively improves clinical diagnostics of CNDD, provides guidance for the therapeutic prevention of CNDD, and suggests an ongoing need to maintain NAD levels via amidated vitamin B3 supplementation post-birth.

P13.050.D Spectrum of 33 individuals with Sotos syndrome in a single facility

Tomoko Uehara[1], *Shiomi Otsuji*[1], *Natsuki Nakamura*[1], *Seiji Mizuno*[1], *Mie Inaba*[1]

[1], *Japan*

Background: Sotos syndrome is caused by microdeletion of chromosome 5q35 or loss-of-function valiants of NSD1 gene. It is known that there are differences in the clinical phenotypes between patients with microdeletions and valiant types.

Methods: We examined retrospectively the clinical characteristics of 33 patient with Sotos syndrome. All patients were genetically diagnosed by FISH analyses, microarray, NSD1 sequencing, or whole exome sequencing.

Results: 17 patients had 5q35 microdeletion, 15 patients had NSD1 valiants, and one patient had NSD1 intragenic (exon 22 and the last exon) deletion. 8 of 33 patients showed normal intelligence or mild intellectual disability (ID). 6 of the 8 patients had substitutional mutations in NSD1. Macrocephaly were shown

in 66.7% (14 of 21) of patients with moderate to severe ID and 100% (all 8 patients) of patients with mild ID or normal intelligence. Congenital heart diseases (CHD) or renal tract abnormalities were occurred in 10 patients (25%) with severe to moderate ID. Nine and eight of them had 5q35 microdeletions, respectively. Large extremities and accelerated tooth eruption were shown in 14 of 20 patients and 21 of 30 patients, respectively.

Conclusion: As having been previously reported, our results support that intellectual disability can be more severe in Sotos syndrome patients with chromosomal microdeletions than with genetic valiants. In addition, it is speculated that CHD or renal tract abnormalities may occur more often in Sotos syndrome due to NSD1 deletion. Macrocephaly, large extremities, and accelerated tooth eruption are distinctive phenotypes and critical for making diagnosis.

Consortium: Qatar Genome Program Consortium

Background/Objectives: Genome sequencing of large biobanks from under-represented ancestries provides a valuable resource for the interrogation of Mendelian disease burden at population level, complementing familial studies.

Methods: We examine a set of 2,648 Mendelian genes from 20 panels, annotating known and novel pathogenic variants, and assessing their penetrance/impact on the measured traits.

Results: We find 62.5% of participants are carriers of at least 1 known pathogenic variant relating to recessive conditions, with homozygosity observed in 1 in 150 subjects, for which Peninsular Arabs are enriched versus other ancestries. On average, 52.3 loss-of-function variants were found per genome, 6.5 of which affect a known Mendelian-disorder gene. Several variants annotated in Clinvar as pathogenic appeared at intermediate frequencies (1-3%), highlighting Arab founder effect, while others have high frequencies (>5%) prompting reconsideration as benign. Cumulative gene burden analysis revealed 56 genes having gene carrier frequency >1/50, including 5 ACMG Tier3 genes. Additionally, we systematically assess the impact of novel/rare variants on biobank phenotypes and discover 39 candidate large-effect variants associating with extreme quantitative traits. Further, through rare-variant burden testing we discover 5 genes with high mutational load and impact on traits relevant to disease conditions, including metabolic disorder and type 2 diabetes.

Conclusion: This study on the first-phase of the Qatar Genome Program cohort provides a comprehensive resource from a Middle Eastern population to understand the global mutational burden in Mendelian disease genes, and their impact on traits in seemingly healthy individuals in high consanguinity settings.

P13.052.B Self-reported health status in adults with Bardet-Biedl syndrome in Norway

Cecilie F. Rustad[1;2], *Kristian Tveten*[3], *Ragnheidur Bragadottir*[2;4], *Jeanette Ullmann Miller*[1], *Charlotte von der Lippe*[3], *Solrun Sigurdardottir*[1]

[1]*Oslo University Hospital, Centre for Rare Disorders, Oslo, Norway;* [2]*University of Oslo, Faculty of Medicine, Oslo, Norway;* [3]*Telemark Hospital Trust, Department of Medical Genetics, Skien, Norway;* [4]*Oslo University Hospital, Department of Ophthalmology, Oslo, Norway*

Background/Objectives: Bardet-Biedl syndrome (BBS) is a rare condition belonging to the ciliopathies. Retinal dystrophy, central obesity, postaxial polydactyly and renal disease are some of the clinical features. We examined health-related quality of life (HRQoL) in adults with BBS.

Methods: This study was designed in the context of outpatient hospital clinics between January 2022 and February 2023. Data included demographics, clinical characteristics, genetic analysis and measures of health status. Self-reported HRQoL was measured using the EQ-5D-5L (mobility, self-care, usual activities, pain/discomfort, anxiety/depression). The EQ-5D-5L scores were compared with Norwegian norms and patient populations with chronic eye diseases.

Results: Thirty adults with BBS (50% female, median age: 36 years, range 20-69) were included. Pathogenic or likely pathogenic variants in *BBS1* and *BBS10* were found in 69% of the samples. Greater proportions of adults with BBS reported problems with mobility (53%), self-care (23%) and usual activities (53%) compared to the general population ($p < 0.001$). Problems with pain/discomfort (63%) and anxiety/depression (43%) had similar proportions to those in the general population. The mean EQ-index scale score was 0.79 (SD 0.18) and was similar to the index score of adults with chronic eye diseases ($p = 0.08$).

Conclusion: Adults with BBS were more likely to report problems with mobility, usual activities and self-care as compared with the general population. Impaired vision might be a contributing factor associated with these health problems, but due to the complexity of clinical features of BBS other factors cannot be ruled out.

Grants: Raagholtstiftelsen in Norway.

P13.053.C A rare co-occurance of Mayer-Rokitansky-Küster-Hauser and Sotos syndromes in a patient with novel *NSD1* variant

guldeniz oner[1], *Gokcen Karamik*[1], *Nuray Ozturk*[1], *Öznur YILMAZ BAYER*[1], *banu nur*[1], *Mustafa Gökhan Ertosun*[2], *Mesut Parlak*[3], *ercan mihci*[1]

[1]*Akdeniz Üniversitesi Hastanesi, Pediatric Genetics, Antalya, Türkyie;* [2]*Akdeniz Üniversitesi Hastanesi, Medical Genetics, Antalya, Türkyie;* [3]*Akdeniz Üniversitesi Hastanesi, Pediatric Endocrinology, Antalya, Türkyie*

Background/Objectives: Sotos syndrome is an autosomal dominant neurodevelopmental disorder characterized by overgrowth and dysmorphic facial features. Pathogenic sequence and copy number variants in the *NSD1* gene cause this syndrome. Mayer-

Rokitansky-Küster-Hauser (MRKH) syndrome is characterized by agenesis or aplasia of the uterus and upper part of the vagina in females. Here, we present a patient with clinical manifestations of both syndromes. We aimed to confirm the patient's diagnosis by next generation sequencing analysis.

Methods: Genomic DNA was extracted from the patient's peripheral blood sample. Exons and exon-intron transition regions of the candidate genes were investigated by next generation sequencing using Sophia DDM program. Variant information servers dbSNP, ClinVar, Ensembl and ACMG 2015 criteria were used for evaluations.

Results: In the sixteenth exon of *NSD1* gene, c.5326_5336del (p.His1776Cysfs*6) frameshift variant was detected in heterozygous state. This variant was expected to cause functional effects due to premature ending of the protein translation. It was not reported in large population studies or disease-specific databases.

Conclusion: The detected novel frameshift variant in our study was evaluated as in relation with Sotos syndrome because of its predicted deleterious effects. Our patient is the third to be reported with both Sotos syndrome and MRKH syndrome. To better elucidate a possible association between these syndromes, variant segregation status in the patient's family and larger population data will be examined.

P13.054.D A novel homozygous variant in *DCHS1* in a Brazilian boy with clinical features of Van Maldergem syndrome

Gabriela Correia-Costa[1], Bruna Fagundes Rodrigues[1], Carlos Eduardo Steiner[1], Vera Lucia Gil-da-Silva-Lopes[1], **Társis Paiva Vieira**[1]

[1]*School of Medical Sciences - Universidade Estadual de Campinas - Unicamp, Medical Genetics and Genomic Medicine, Department of Translacional Medicine, Campinas, Brazil*

Background/Objectives: Van Maldergem syndrome (VMLDS) is an extremely rare autosomal recessive disorder and is caused by biallelic variants in the *DCHS1* or *FAT4* gene. Less than 20 patients have been described, and few have variants in *DCHS1*. Here, we report a Brazilian patient with clinical features of VMLDS and a novel variant in *DCHS1*.

Methods: Exome sequencing (ES) was performed on genomic DNA. Analysis and classification of variants were performed following the American College of Medical Genetics and Genomics (ACMG) recommendations.

Results: The patient, first evaluated at four months of age, had hypotonia, chronic feeding difficulties, and was fed through a nasogastric tube. Dysmorphological evaluation showed large fontanelle, almond shaped eyes, epicanthus inversus, micrognathia, camptodactyly in fingers and toes, bilateral single transverse palmar crease, clinodactyly of the 5th toes, and tibial bowing, suggesting VMLDS. In his last evaluation, at one year of age, he was still being fed through a tube, with a swallowing disorder, had motor delay, hydrocephalus, joint laxity, and could not speak yet. ES detected a novel nonsense and homozygous variant in *DCHS1* - Chr11(GRCh38):g.6622021 T>A; c.9655A>T; p.Lys3219*; NM_003737.4. Since this variant is in the last exon, is not predicted to undergo nonsense-mediated decay, and removes <10% of protein, it was classified as a variant of uncertain significance. **Conclusion:** Since the patients' phenotype matches VMLDS, we believe this variant may be pathogenic, and further functional analysis may support this finding.

P13.055.A Curious case of recurrence in Mowat Wilson Syndrome: report of two siblings

ahmet kablan[1], **Esma Ertürkmen Aru**[1]

[1]*Ankara Etlik Şehir Hastanesi, Medical Genetics, Ankara, Türkyie*

Background/Objectives: Mowat–Wilson syndrome (MWS) is a neurodevelopmental disorder marked by distinctive facial features and a range of congenital anomalies. It is characterized by de novo monoallelic mutations in *ZEB2* gene. To date, MWS has been reported in over 300 individuals, with only a rare familial recurrence in the literature. Specifically, the recurrence in siblings reported in four families, which nonsense and frameshift mutations were identified. Here, we present a sister and a brother who exhibit neurodevelopmental delay, EEG anomalies, characteristic dysmorphic facial features, constipation and self-mutilation behavior. Both are diagnosed with MWS, exhibiting a de novo *ZEB2* deletion spanning 6 exons. We aim to explore recurrence rates, investigate gonadal mosaicism likelihood, and report the first sibling recurrence case with a large exon deletion.

Methods: Due to strong phenotypic indications of MWS and normal karyotype results, one sibling underwent single nucleotide polymorphism (SNP) chromosomal microarray analysis for CNV, while the other had clinical exome sequencing.

Results: The CNV analysis conducted on the younger brother revealed a heterozygous deletion of approximately 35 kb in size, encompassing exons 3-9 of the *ZEB2* located in the 2q22.3 region. The CNV analysis of the sister's clinical exome sequencing data displayed an exon 3-9 deletion identical to brother. Karyotype and SNP microarray analyses of parents did not reveal any carrier status, although father has 46,XY,t(9;16)(q34;p11.2) rearrangement which evaluated as incidental.

Conclusion: Herein, we aim to present the first report of siblings recurrence in MWS with a large de novo deletion of 3-9 exons in *ZEB2*, to our knowledge.

P13.056.B International Long COVID Host Genetics Initiative tackling genetics of Long COVID

Vilma Lammi[1], *Tomoko Nakanishi[2;3], Samuel Jones[1], Hugo Zeberg[4;5], Hanna Ollila[1;6;7]*

[1]*University of Helsinki, Institute for Molecular Medicine (FIMM), Helsinki, Finland;* [2]*McGill University, Department of Human Genetics, Québec, Canada;* [3]*Kyoto University, Kyoto-McGill International Collaborative Program in Genomic Medicine, Graduate School of Medicine, Kyoto, Japan;* [4]*Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden;* [5]*Max Planck Institute for Evolutionary Anthropology, Department of Evolutionary Genetics, Leipzig, Germany;* [6]*Broad Institute of MIT and Harvard, Cambridge, MA, United States;* [7]*Massachusetts General Hospital and Harvard Medical School, Center for Genomic Medicine. Anesthesia, Critical Care, and Pain Medicine., Boston, MA, United States*

Consortium: Long COVID Host Genetics Initiative

Background/Objectives: Long COVID is characterized by symptoms including fatigue, dyspnea, and cognitive dysfunction. Long COVID Host Genetics Initiative aims to elucidate genetic factors contributing to the risk of prolonged symptoms after SARS-CoV-2.

Methods: 33 studies from 19 countries conducted genome-wide association studies (GWAS) comparing Long COVID

(N = 15,950) to subjects recovered from COVID-19 or population controls (N = 1,892,830).

Results: A multiancestry meta-analysis of Long COVID after test-verified SARS-CoV-2 (N = 3,018) and 994,582 population controls identified a haplotype associated with increased risk for Long COVID (rs9367106-C, P = 1.8 × 10-10, odds ratio = 1.63(1.40-1.89), risk allele frequency = 4.2%). The association replicated in an independent sample of nine studies with 9,500 Long COVID cases and 798,835 controls.

Long COVID risk variant associated with increased *FOXP4* expression in lung (P = 5.3 × 10-9) and hypothalamus (P = 2.6 × 10-6). *FOXP4* expression in blood associated with Long COVID (P = 0.0063).

FOXP4 locus has earlier been associated with lung cancer and severity of acute COVID-19. Mendelian Randomization supported the role of COVID-19 severity as a causal risk factor for Long COVID (P = 2.4 × 10-3), but Bayesian modelling comparing the effects of *FOXP4* variants and other severity variants suggested an independent *FOXP4* association with Long COVID.

Conclusion: The global Long COVID Host Genetics Initiative has identified the *FOXP4* locus as a genetic risk factor for prolonged sequelae of SARS-CoV-2, suggesting the regulation of lung functions and immune system involved in the pathophysiology of Long COVID.

Grants: We acknowledge the work of healthcare professionals, technicians, patients, researchers, and funders working hard together to tackle SARS-CoV-2 and its long-term consequences. Full list of authors contributing to the Long COVID HGI: http://tinyurl.com/AuthorsLongCOVIDHGI

P13.057.C The crucial role of exome sequencing in clinical care of an infant patient cohort

Vanessa Geiger[1], Manuel Lüdeke[2], Gabriel Miltenberger-Miltenyi[1], Birgit Zirn[3], **Cord-Christian Becker**[1]

[1]MVZ genetikum, München, Germany; [2]MVZ genetikum, Neu-Ulm, Germany; [3]MVZ genetikum, Stuttgart, Germany

Background/Objectives: Critically ill infants and infants with multisystem involvement profit from early and precise diagnosis. Gene panel testing as well as whole exome and genome sequencing have evolved as first-tier diagnostic options. These methods not only identify the diagnosis and support clinical decision making, but also avoid more invasive (and harmful) diagnostic techniques. Here, we studied clinical usability of next generation sequencing (NGS) in a pediatric patient cohort below the age of 1 year.

Methods: Retrospective analysis of all neonates and infants aged 0-12 months who had next generation sequencing in our laboratory between 2021 and 2023. Patients were stratified by age (group A ≤2 months, group B 2-6 months, and group C 6-12 months) and analyzed for outcome and diagnostic yield.

Results: 259 patients were included in the study. Pathogenic and likely pathogenic gene variants were identified in 45,3% (24/53) of patients in group A, 42,2% (35/83) in group B and 38,2% (47/123) in group C. Younger age was associated with a higher rate of genetic diagnoses (group A vs. group C; OR 1,34). Infants ≤12 months with complex syndromal phenotypes (defined as ≥2 organs involved) received a genetic diagnosis in 47,6% (39/82). The highest diagnostic yield was observed in group A patients with cardiovascular/respiratory disorders (75%, 3/4) and group B patients with eye/ear anomalies (66,7%, 6/9).

Conclusion: Our study confirms that NGS in critically ill infants is an effective tool and has a high diagnostic yield. Examples from our cohort elucidate that patients benefit from early implementation.

Background/Objectives: Developmental Delay with Gastrointestinal, Cardiovascular, Genitourinary, and Skeletal Abnormalities syndrome (DEGCAGS, OMIM #619488) is caused by biallelic, loss-of-function (LoF) *ZNF699* variants, and is characterized by variable neurodevelopmental disability, discordant organ anomalies among siblings of consanguineous families and infant mortality. *ZNF699* encodes for a KRAB-Zinc Finger Protein of unknown function. We aimed to investigate the geno-phenotypic spectrum of DEGCAGS and the possibility of a diagnostic episignature.

Methods: We collected data on 28 affected individuals (11 new). We analysed 53 facial photographs from five individuals using GestaltMatcher. We applied methylation arrays on peripheral blood DNA samples in nine affected individuals. The methylation levels were fitted in a multivariate linear regression model to identify the differentially methylated probes. We constructed a binary Support Vector Machine classification model to differentiate DEGCAGS from controls.

Results: We expand the ZNF699-related molecular spectrum. We show that loss of ZNF699 causes novel, age-dependent clinical

findings and a similar facial gestalt. We identify a robust and distinct episignature for biallelic, LoF samples.

Conclusion: We further delineate the epi-geno-phenotypic spectrum of DEGCAGS. We discovered a sensitive and specific episignature for DEGCAGS, a robust biomarker for screening and diagnosis. Analysis of differentially methylated regions suggests an effect on genes potentially involved with disease manifestations.

P13.059.A An immortalised lymphatic cell line for modelling EPHB4 variants causative of lymphatic anomalies using CRISPR-Cas9 protocols

Ruby Moy[1], *Kazim Ogmen*[1], *Silvia Martin Almedina*[1], *Alan Pittman*[1], *Pia Østergaard*[1], *jeroen hagendoorn*[2], *lotte van den bent*[2]

[1]*St George's University of London, United Kingdom;* [2]*UMC Utrecht, Utrecht, Netherlands*

Background/Objectives: Primary Lymphatic Anomalies (PLA) have been associated with pathogenic variants in *EPHB4*, a receptor tyrosine kinase that binds to its ligand EphrinB2 regulating the development of blood and lymphatic vessels. Further work is required to characterise these variants and assess the mechanisms of disease. This will provide valuable information about targetable molecular pathways necessary to delineate novel drug treatment strategies.

Methods: This project aims to develop new in vitro tools using CRISPR-Cas9 protocols to create patient-modelled cells for in-depth investigation of the EPHB4 signalling pathway and the impact of PLA variants.

For this purpose, we have further characterised an immortalised lymphatic endothelial cell (imLEC) line, created by Frenkel and colleagues (PMID:34185991), in terms of lymphatic identity using immunofluorescence and western blot. RNA- sequencing and the label-free imaging microscopy system Livecyte have been used to study the response to Vascular Endothelial Growth Factor-C (VEGFC), the main growth factor promoting lymphangiogenesis.

Results: Results show that imLECs express lymphatic markers even in long-term culture, and after VEGFC treatment gene set enrichment suggests they regulate similar downstream pathways as primary lymphatic endothelial cells. VEGFC-driven proliferation was also validated by live imaging.

Using imLECs we can generate EPHB4 knock-in cell lines with CRISPR-Cas9 protocols using ribonucleoprotein complexes and fluorescence-labelled guide RNAs to induce single nucleotide changes using homology-directed repair.

Conclusion: In conclusion, imLECs retain a lymphatic identity and respond to VEGFC even when cultured for long time, making them a valuable new in vitro model to use CRISPR-Cas9 methodologies and investigate EPHB4 disease mechanisms in PLA.

Grants: MRC(MR/P011543/1)&BHF(RG/17/7/33217);Rosetrees-Trust(RES20-21 003)&ComplexLymphaticAnomalies(MDBR-22-137-CLAYIA)

P13.061.C 3q29 deletion syndrome in a patient with intellectual disability, facial dysmorphism, bilateral breast cancer, and secondary myelofibrosis

Jakub Duben[1], *Jakub Trizuljak*[1;2;3], *Tomáš Gyönyör*[2], *Ivona Blahakova*[1;3], *Zuzana Vrzalová*[1;3], *Karla Plevová*[1;2;3], *Paulína Likavcová*[3], *Katerina Stano Kozubik*[2;3], *Sarka Pospisilova*[1;2;3], *Michael Doubek*[1;2;3]

[1]*University Hospital Brno, Department of Internal Medicine - Hematology and Oncology, Brno-Bohunice, Czech Republic;* [2]*University Hospital Brno - Children's Hospital, Department of Medical Genetics and Genomics, Czech Republic;* [3]*CEITEC MU, Czech Republic*

Background/Objectives: Recurrent 3q29 deletions are characterized by neurodevelopmental and psychiatric manifestations, including mild-to-moderate intellectual disability, autism spectrum disorder, anxiety disorders, attention-deficit/hyperactivity disorder, executive function deficits, graphomotor weakness and schizophrenia. Other common findings are nutrition deficiency, gastrointestinal disorders, ocular issues, dental anomalies and congenital heart defects. We present an unusual occurrence of this disorder: a 22-year-old female with facial dysmorphism, myopia, bilateral breast cancer and significant chemo-and radiotoxicity.

Methods: We performed whole exome sequencing (WES) for testing of cancer susceptibility genes followed by chromosomal microarray analysis (CMA).Additionally, we carried out comprehensive bone marrow testing for myeloid malignancies.

Results: WES identified no causal variant for bilateral breast cancer. CMA revealed heterozygous

1,2 Mb-sized 3q29 deletion, subsequently confirmed by CNV analysis from WES. The extent of deletion corresponds to autosomal dominant recurrent 3q29 microdeletion syndrome. Bone marrow histology showed diffuse reticulin fibrosis, probably secondary to breast cancer treatment.

Conclusion: We present the first report of a patient with 3q29 deletion and early-onset breast cancer. While WES testing did not provide a definitive answer for the genetic cause of bilateral breast cancer, the 3q29 deletion explains the facial dysmorphy and intellectual disability. What is more, the deletion involves *RNF168* gene, a potential tumor suppressor gene, which has been suggested to play a role in the development of sporadic malignancies.

Grants: Supported by MUNI/A/1558/2023; MUNI/11/SUP/22/2020; European Regional Development Fund Project "A-C-G-T" CZ.02.1.01/0.0/0.0/16_026/0008448, and National Institute for Cancer Research LX22NPO5102 - Funded by EU - Next Generation EU.

P13.062.D Longterm survival in a patient with triploidy

Maike Dittmar[1], *Eva Maria Murga Penas*[2], *Rebecca. Gembicki*[2], *Yorck Hellenbroich*[2], *Malte Spielmann*[1;2], *Ann Carolin Longardt*[3], *Martin Schrappe*[3], *Christel Eckmann-Scholz*[4], *Kristin Andresen*[4], *Almuth Caliebe*[1]

[1]*Institute of Human Genetics, Universitätsklinikum Schleswig-Holstein, University of Kiel, Kiel;* [2]*Institute of Human Genetics, Universitätsklinikum Schleswig-Holstein, University of Lübeck, Lübeck;* [3]*Department of Pediatrics and Adolescent medicine I, University Medical Center Schleswig-Holstein (UKSH), Campus Kiel, Kiel;* [4]*Department of Obstetrics and Gynecology, University Medical Center Schleswig-Holstein, Campus Kiel, Kiel*

Background/Objectives: Triploidy is diagnosed in approximately 10-20% of investigated miscarriages with intrauterine growth restriction. Affected children usually die perinatally or within a few days after birth. In the literature 13 patients with non-mosaic triploidy surviving for more than 30 days have been reported (PMID: 35131773).

Methods: Herein we report a new patient with triploidy. The patient was born at 34 weeks gestation with a weight of 900g (-3,2z). The pregnancy was complicated by growth retardation due to placental insufficiency. Non-invasive prenatal testing was unsuccessful due to insufficient free fetal DNA quantity.

Physical examination revealed dysmorphism (pointed nose, hypertelorism, low-set ears, a high arched palate, hands with clinodactyly (3rd-5th fingers) and short thumbs, single palmar crease). The feet were disproportionately long with significantly shortened and receding big toes and a prominent calcaneus.

Organ malformations included suspected partial agenesis of the corpus callosum, horseshoe kidney, cardiomegaly with persistent ductus arteriosus, respiratory insufficiency with apnea-bradycardia syndrome, pulmonary hypertension, and mild right pleural effusion. Additionally, there was suspected hearing impairment and various eye abnormalities.

Results: By chromosomal analysis on blood lymphocytes and fluorescent in situ-hybridization of lymphocytes and buccal mucosa cells non-mosaic triploidy was diagnosed.

Conclusion: If the additional chromosome set is of maternal origin (digynic triploidy), life expectancy can be several months. Prenatal signs of digynic triploidy include a small fibrotic placenta and severe intrauterine growth restriction. Given that our patient is now almost 8 months old, this also suggests a maternal origin.

Background/Objectives: Alpha-actinins are dimeric crosslinking proteins involved in bundling and anchoring of the actin cytoskeleton to the cell membrane, with at least six isoforms encoded by four genes (*ACTN1-4*) in mammals. Pathogenic variants in *ACTN1* are associated with autosomal dominant congenital macrothrombocytopenia [MIM: 615193].

Methods & Results: By exome sequencing and global matchmaking we identified four de novo and inherited monoallelic *ACTN1* variants in six individuals from four unrelated families (including a three-generation family) segregating a distinctive frontonasal dysplasia phenotype with craniosynostosis, hypertelorism, down-slanting palpebral fissures, low-set posteriorly rotated ears, wide anterior fontanelle, broad nasal tip, costovertebral and genitourinary anomalies. All probands are *EFNB1*-negative and none have macrothrombocytopenia. Three of the variants are missense substitutions and one is an in-frame deletion. Protein modelling suggests that craniofacial variants occur in residues less tolerant of variation and are predicted to be more damaging compared to macrothrombocytopenia-associated variants. Ectopic expression of GFP-tagged protein suggests that craniofacial variants perturb localisation in a manner distinct from macrothrombocytopenia-associated variants. Cultured fibroblasts have been obtained from two patients and an unaffected parental control to examine the effects of these variants in vitro. We generated a CRISPR-gene-edited mouse to investigate whether the cranioskeletal anomalies are recapitulated and thus validate a pathogenic role for these variants.

Conclusion: *ACTN1* variants may be overlooked in genomic analysis of craniofacial patients because of the prior association with a haematological disorder. Our clinical and functional characterisation provide evidence of an *ACTN1*-related craniofrontonasal phenotype allelic to congenital macrothrombocytopenia.

P13.064.B Functional variability in Wolf-Hirschhorn syndrome.

Julián Nevado[1;2;3], *Xana Da Silva-Mori*[1], *Raquel Blanco-Lago*[4], *Cristina Bel-Fenellós*[5], *Maria Angeles Mori-Alvarez*[1], *Elena Mansilla*[1;2], *Fe Amalia García Santiago*[1;2], *Isabel Vallcorba*[1;2], *Harry Pachajoa*[6], *Jair Tenorio*[1;2;3], *Pablo LAPUNZINA*[1;2;3]

[1]*La Paz University Hospital, INGEMM, Madrid, Spain;* [2]*CIBERER, Madrid, Spain;* [3]*ITHACA network, Madrid, Madrid, Spain;* [4]*Central University Hospital of Asturias, Neuropediatrics, Oviedo, Spain;* [5]*Universidad Complutense, Dpto. Investigación y Psicología en Educación, Madrid, Spain;* [6]*ICESI University, Cali, Colombia*

Background/Objectives: Wolf-Hirschhorn syndrome (WHS, OMIM #194190) is caused by the loss of genetic material at the distal region of the short arm of chromosome-4. It is a neurodevelopmental characterized by global developmental delay, microcephaly, delayed speech, dysmorphic features, and mostly epilepsy. Individuals affected by this syndrome may have shown a high heterogeneity and variability established by parents, caregivers, and different clinical specialists. The main aim of this work is to compare functionally individuals in a large series of patients with WHS.

Methods: 140 diagnosed WHS individuals (75 from Spain and 65 from Latino-America), who are deeply phenotyped at clinical and molecular level by SNP-arrays. We estimated and validated an individual functional severity score (Global Functional Assessment of the Patient; GFAP), using different features taken from two questionnaires and weighed them by HPO-term frequencies.

Results: We highlight a positive correlation-ship between GFAP and the size of deletion, and other variables associated with a worst prognosis. Thus, low values for GFAP correlated with a better prognosis. We found high GFAP values in males, and single 4p deletions, but no differences have been found between origin-subpopulations.

Conclusion: Using this score, we established that, the functional variability in WHS individuals is mainly associated with the gender, the size of the deletions, and eventually with additional genetic rearrangements. Altogether this data are supporting a role for GFAP mimicking the evolve-prognosis in WHS. Which is also associated directly with size of the deletions, according with the idea of the existence of genotype/phenotype correlationships.

P13.066.D De novo pathogenic OTX2 variant in a paediatric patient with hypopituitarism and congenital ocular anomalies: a case report and review of literature

Nelly Miteva-Marcheva[1], *Hristo Ivanov*[1], *Tsvetelina Tsvetanova*[1], *Mariya Georgieva*[2], *Vili Stoyanova*[1]

[1]*Medical University of Plovdiv, Paediatrics and Medical Genetics, Plovdiv, Bulgaria;* [2]*Outpatient Clinic for Specialized Pediatric Endocrinology, Metabolic Disorders, and Pediatrics, Pediatric Endocrinology and Metabolism, Stara Zagora, Bulgaria*

Background/Objectives: OTX2, a member of the bicoid subfamily of homeodomain-containing transcription factors, governs brain, craniofacial, and sensory organ development. Heterozygous gene variants correlate with syndromic microphthalmia, combined pituitary hormone deficiency, and early-onset retinal dystrophy, with or without pituitary dysfunction.

Methods: We present a case of a 7-year-old boy exhibiting congenital hypopituitarism due to specific anomalies: markedly hypoplastic infundibulum, poorly developed adenohypophysis, bilateral cryptorchidism, and ocular abnormalities including congenital glaucoma and leucoria. The child's clinical diagnosis was initially set at 5 years of age. Subsequently, at the age of 7, the child underwent genetic consultation and diagnosis. No familial precedent of a similar condition is reported, though the father has poliosis.

Results: Blueprint Genetics Whole Exome Family Plus analysis revealed a de novo heterozygous frameshift variant, OTX2 c.106dup, p.(Arg36Profs*52), not present in the patient's parents.

Conclusion: The pathogenic classification of OTX2 c.106dup, p.(Arg36Profs*52) is supported by its association with the patient's phenotype, rarity in control populations, presence in two individuals with a related phenotype, frameshift nature, and de novo occurrence. Absence in the patient's parents lowers the recurrence risk for future siblings, yet a slight risk persists due to potential parental germline mosaicism. Genetic counseling is advised.

Grants: Diaczok D, Romero C, Zunich J, Marshall I, Radovick S. A novel dominant negative mutation of OTX2 associated with combined pituitary hormone deficiency. J Clin Endocrinol Metab. 2008 Nov;93(11):4351-9. https://doi.org/10.1210/jc.2008-1189. Epub 2008 Aug 26. PMID: 18728160; PMCID: PMC2582563.

P13.067.A Step-by-Step Genetic Insight into a Case of Growth Retardation

Ayşe Tekin[1], *Güven Toksoy*[1], *büşra gizem kına*[1], *Ayça Dilruba Aslanger*[1], *Birsen Karaman*[1], *Bilge Ozsait Selcuk*[1], *Cagri Gulec*[1], *Zehra Oya Uyguner*[1], *Esma Nur Konur*[1], *Gozde Yesil Sayin*[1], *firdevs baş*[2], *tuğçe kandemir*[2], *Ayse Pinar Ozturk*[2]

[1]*Istanbul University, Medicinal genetic, İstanbul;* [2]*Istanbul University, Department of Pediatrics, İstanbul*

Background. Uniparental disomy (UPD) is an inheritance pattern where both copies of a chromosomal pair originate from a single parent, notably affecting chromosomes that carry genes subject to parental-origin-dependent imprinting. The frequency of UPD is reported as 1 in 2,000. Russell-Silver Syndrome (RSS) is characterized by hypomethylation of the imprinting control region on chromosome 11, maternal UPD7 or pathogenic variants in related gene regions with an estimated prevalence of 1 in 3.000.

Methods: A patient presenting with growth retardation underwent clinical assessment, pedigree analysis, and hormone profiling. Step-by analysis included Sanger sequencing for *CUL7* and *OBSL1*, exome sequencing (ES), arrayCGH, MLPA-ME030 and MLPA-ME032 testing.

Results: A 16-year-old male patient was primarily considered for RSS. The parents, without consanguineous marriage, were healthy, with no affected individuals in the family. Initial symptoms began at the age of two with growth retardation. He had distinctive facial features, mild intellectual disability, and prominent heels. Sanger sequencing, ES, and MLPA-ME030 yielded normal results. Array CGH detected loss of heterozygosity across chromosome 7. MLPA-ME032 demonstrated methylation at HHA1 cleavage sites targeting the *GRB10* and *MEST* genes.

Conclusion: While maternal UPD7 frequency in RSS ranges from 7-10%, genetic heterogeneity complicates the molecular and cytogenetic RSS diagnosis. Genetic testing to elucidate rare molecular pathologies can only be performed in the presence of a strong clinical diagnosis. Molecular diagnosis contributes to better clinical monitoring of the patient

Consortium: The Genomics England research consortium

Background/Objectives: Heterozygous pathogenic variants in BCL11B have been described as causative for two Mendelian phenotypes. Here we provide a systematic review of the literature, providing evidence to support the notion that BCL11B-related disease (BRD) should be regarded as a single phenotypic entity. Furthermore, we supply four new patient reports, three with sequence variants and one with a deletion encompassing BCL11B. All of them presented with craniosynostosis (CRS), thus refining the phenotype of BRD and highlighting CRS as an important diagnostic clue.

Methods: Two databases were searched (MEDLINE and Embase) and snowballing was conducted on all selected results (backward via reference lists). Newly reported patients were identified through data from the Genomics England 100,000 Genomes Project, international collaboration and the Craniofacial Unit in Oxford. Pathogenic variants in BCL11B were detected through next generation sequencing and validated by Sanger sequencing.

Results: We present an analysis of the largest cohort of patients with pathogenic sequence variants in BCL11B: fifty cases, including three newly reported patients. We have defined the phenotype of BRD as a neurodevelopmental disorder with three cardinal features: neurodevelopmental delay, facial dysmorphism and immunodeficiency.

Conclusion: Major points of interest are the delineation of the phenotype, the addition of CRS to the major features, and the discussion on the role of 14q32 microdeletions in the molecular pathogenesis of the syndrome. We hope that the facial photographs and reconstructions of the skull presented here will prove useful in further defining this phenotype.

P13.069.C Impact of deep phenotyping: High diagnostic yield in a diverse pediatric population of 172 patients through clinical whole-genome sequencing at a single center

*OZLEM AKGUN DOGAN[1;2;3], Ecenur Tuc Bengur[4;5], Beril Ay[5], **Gulsah Sebnem Ozkose**[2;3], Emre Kar[5], Fuat Baris Bengur[5], Aybike Bulut[2;3], Ayça Yiğit[2;3], Eylül Aydın[2;3], Fatma Nisa Esen[6], Özkan Özdemir[2;7], Ahmet Yeşilyurt[6], Yasemin Alanay[1;2;3]*

[1]Acibadem Mehmet Ali Aydinlar University, School of Medicine, Department of Pediatrics, Division of Genetics, Istanbul, Türkyie; [2]ACURARE-Rare and Undiagnosed Diseases Center; [3]Acibadem Mehmet Ali Aydinlar University, Health Sciences Institute, Department of Genome Studies, Istanbul, Türkyie; [4]Washington University in St. Louis, School of Medicine, Department of Pediatrics, Division of Genetics & Genomic Medicine, Missouri, United States; [5]Acibadem Mehmet Ali Aydinlar University, School of Medicine, Istanbul, Türkyie; [6]Acibadem Labgen Genetic Diagnosis Center, Istanbul, Türkyie; [7]Acibadem Mehmet Ali Aydinlar University, School of Medicine, Department of Basic Sciences, Division of Medical Biology, Istanbul, Türkyie

Background/Objectives: Pediatric patients with undiagnosed conditions, particularly those suspected of having Mendelian genetic disorders, pose a significant challenge in healthcare. This study investigates the diagnostic yield of whole genome sequencing (WGS) in a pediatric cohort with diverse phenotypes, particularly focusing on the role of clinical expertise in interpreting WGS results.

Methods: A retrospective cohort study was conducted at Acibadem University's Maslak Hospital in Istanbul, Turkey, involving pediatric patients (0-18 years) who underwent diagnostic WGS testing. Clinical assessments, family histories, and previous laboratory and imaging studies were analyzed. Variants were classified and interpreted in conjunction with clinical findings.

Results: The cohort comprised 172 pediatric patients, aged 0-5 years (62.8%). International patients (28.5%) were from 20 different countries. WGS was utilized as first-tier in 61.6% of patients. The diagnostic yield of WGS reached 61.0%, enhanced by the reclassification of variants of uncertain significance (VUS) through reverse phenotyping by an experienced clinical geneticist. Consanguinity was 18.6% of the overall cohort. Dual diagnoses were present in 8.5% of solved patients.

Discussion: Our study particularly advocates for the selection of WGS as a first-tier testing in infants and children with rare diseases under 5 years of age, thereby potentially shortening the duration of the diagnostic odyssey. The results also emphasize the critical role of a single clinical geneticist's expertise in deep phenotyping and reverse phenotyping, which contributed significantly to the high diagnostic yield.

P13.071.A Heterozygous deletions of BCL11B broaden the spectrum of severe combined intellectual developmental disorder with dysmorphic facies, speech delay and T-cell abnormalities (IDDSFTA)

Corinna Hendrich[1], *Jana Lentes[1], Eva Tolosa[2], Hendrik Langen[3], Davor Lessel[4], Nataliya Di Donato[1], Tim Ripperger[1], Oscar de la Calle-Martín[5], Anke Katharina Bergmann[1]*

[1]Hannover Medical School, Human Genetics, Hannover, Germany; [2]University Medical Center Hamburg-Eppendorf, Institut für Immunologie, Hamburg, Germany; [3]Children- and Teenager Hospital Auf der Bult, Sozialpädiatrisches Zentrum Hannover, Hannover, Germany; [4]Paracelsus Medical University, Universitätsinstitut für Humangenetik der PMU, Salzburg, Austria; [5]Hospital de Sant Pau, Immunology Dept. Universitat Autonoma de Barcelona., Barcelona, Spain

Background Heterozygous missense, frameshift, splice site and truncating variants as well as chromosomal rearrangements of the *BCL11B* gene coding for a transcription factor are associated with a developmental disorder syndrome with language and cognitive impairment as well as facial abnormalities and a characteristic reduction in ILC2 T cells (innate lymphoid cells) (IDDSFTA). In addition, somatic alterations of *BCL11B* are known to be a contributory cause of lymphoid neoplasia. Heterozygous deletions of the *BCL11B* gene have been described in isolated cases in the literature and have not yet been classified as disease-causing.

Methods Whole exome sequencing, array cGH and karyotyping were performed in two unrelated patients with an IDDSFTA-typical phenotype. Due to the rarity of the variant and the lack of functional analyses regarding *BCL11B* deletions, this deletion is currently classified as a variant of undetermined significance (VUS).

Results Both patients carry a heterozygous deletion including the *BCL11B* gene. Additionally, significant reduction of ILC2 T-cells were shown in both patients.

Conclusion We postulate that heterozygous deletions of *BCL11B* contribute to the IDDSFTA genotypic spectrum with possible clinical consequences for the further surveillance of these patients with regard to immunological or hematological secondary diseases

[5]Juntendo University, Department of Obstetrics and Gynecology, Tokyo, Japan

Background/Objectives: Cornelia de Lange Syndrome (CdLS), a rare multisystemic developmental disorder, results mainly from germline mutations. However, around 15%-20% of cases present mosaicism, often undetectable in peripheral blood, and the overlapping features of CdLS with other syndromes complicate accurate diagnosis. This study employs next-generation phenotyping to prioritize CdLS patients for further investigation based on facial gestalt, offering a potentially more efficient diagnostic approach.

Methods: Out of the 62 patients, 38 were diagnosed with CdLS, eight received negative results in Whole Exome Sequencing (WES), and 16 were diagnosed with other conditions despite initial suspicion of CdLS. Facial analysis was conducted by GestaltMatcher, and we reported the top-10 detected syndromes. Buccal cells WES was performed with paired-end libraries in Illumina NOVASeq.

Results: Among diagnosed CdLS patients, 87.2% had CdLS ranked as their top-1 syndrome, with all presenting it within their top-10 syndromes. Among patients with negative WES results, 75% had CdLS as their top-1 syndrome and all within their top-10. For patients diagnosed with other conditions, 60% had their respective diagnosis within the top-10 syndromes, 66.6% had CdLS within the top-10, and one patient had it in their top-1. This patient was submitted to further analysis of buccal cells WES which revealed a likely pathogenic mosaic variant on the SMC1A gene (NM_006306.4:c.256G>T [p.Glu*]). Therefore, GestaltMatcher can identify potential syndromes even in cases where WES yielded inconclusive results.

Conclusion: This study highlights the effectiveness of GestaltMatcher in guiding the selection of appropriate tests in cases where WES results are inconclusive.

P13.073.C Kabuki Syndrome: prenatal and neonatal diagnosis and improved phenotyping

paolo infantino[1], *Elena Gennaro*[2], *Maria Teresa Divizia*[1], *Giulia Rosti*[1], *Pierangela De Biasio*[3], *Maria Gnazzo*[4], *Silvia Buratti*[5], *Francesca Faravelli*[1]

[1]*Giannina Gaslini Institute, Genomics and Clinical Genetics, Italy;* [2]*Giannina Gaslini Institute, Human Genetic Laboratory, Italy;* [3]*Ospedale San Martino, Diagnosi prenatale e Medicina perinatale, Italy;* [4]*Ospedale Pediatrico Bambino Gesù, UO di Malattie Rare, Italy;* [5]*Giannina Gaslini Institute, Intensive Care Unit, Italy*

Background: Kabuki Syndrome (KS) represents an heterogeneous entity, caused by pathogenic variants (PV) in the KMT2D or KDM6A gene. The most frequently associated prenatal findings are: cardiac anomalies, polyhydramnios, genitourinary anomalies, single umbilical artery and hydrops /pleural effusion/ascites. Prenatal and neonatal diagnosis of KS diagnosis remains uncommon, but the advance of the sequencing technology is covering the gap, revealing a broader clinical spectrum.

Methods: Two KS cases were ascertained through WES trio analysis. Case 1: a fetus with augmented nuchal translucency and augmented right atrium volume, non-visualization of the gallbladder, single umbilical artery and pleural effusion; case 2: a newborn with hyperbilirubinemia, cardiac malformation, mild immunodeficiency, diaphragmatic hernia, skeletal and cerebral abnormalities. In both cases, prenatal a-CGH and RASopathies NGS panel didn't reveal any causative variant.

Results: KMT2D c.10740+1G>A, p.(?) and c.16438_16441del, p.(Asn5480Valfs*) PVs were respectively identified and confirmed to be de novo; the first located at a canonical splicing site and the second predicted to cause a frameshift. Based on ACMG classification the two variants were classified as pathogenic, and considered causative of the clinical findings.

Conclusion: We describe two cases which confirm the heterogeneity of KS phenotype, and its prenatal and early onset features. In both cases the condition was ascertained through WES trio testing, confirming the value of the technique in prenatal/neonatal complex cases, shortening the diagnostic odissey and providing important information to clinicians and families.

P13.074.D The presence of cardiological manifestations in SHANK3-mutated patients

Lucia Dougherty de Miguel[1], *Roger Esmel-Vilomara*[2], **Alícia Artigas Baleri**[3], *Asunción Díaz*[1], *Eulàlia Turón-Viñas*[1], *Lourdes Vega*[3], *Luisa Panades de Oliveira*[4;5;6], *Ivon Cuscó*[3;7], *Susana Boronat*[1]

[1]*Institut d'Investigació Biomèdica Sant Pau (IIB Sant Pau), Hospital de la Santa Creu i Sant Pau, Paediatric Neurology, Barcelona, Spain;* [2]*Institut d'Investigació Biomèdica Sant Pau (IIB Sant Pau), Hospital de la Santa Creu i Sant Pau, Paediatric Cardiology, Barcelona, Spain;* [3]*Institut d'Investigació Biomèdica Sant Pau (IIB Sant Pau), Hospital de la Santa Creu i Sant Pau, Genetics Department, Barcelona, Spain;* [4]*Hospital del Mar, Epilepsy Monitoring Unit, Department of Neurology, Barcelona, Spain;* [5]*Hospital del Mar Medical Research Institute (IMIM), Epilepsy Research Group, Barcelona, Spain;* [6]*Universitat Pompeu Fabra (UPF), Barcelona, Spain;* [7]*Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Barcelona, Spain*

Background/Objectives: *SHANK3* has been established as the causative gene of 22q13.3 microdeletion syndrome. Patients with *SHANK3* point mutations have also been identified with a wide range of clinical manifestations. No genotype-phenotype correlation has been described. Recent studies showed that *SHANK3* plays an important role in cardiac function and suggest that genetic alterations may be associated with cardiac abnormalities. To date, cardiac alterations have been poorly associated with the 22q13.3 deletion, but not with *SHANK3* point mutations. The aim of this study is to expand the clinical manifestations related to *SHANK3* mutations.

Methods: We carried out a retrospective study of patients with *SHANK3* (NM_001372044.2) mutations. Detailed clinical data were collected, including psychomotor development, neuropsychiatric manifestations and electroencephalographic patterns. An exhaustive cardiological examination was also performed.

Results: We included five patients with a *SHANK3* mutation: two frameshifts (c.3286del, c.3610_3611del), one nonsense (c.4090C>T), one splice mutation (c.2448+1G>A) and a complete deletion (secondary to unbalanced translocation). In accordance with previous studies, our 4 loss-of-function mutations were located between the PDZ and SAM domains. Cardiological examination was performed in 4 patients, all of them had cardiac abnormalities: postictal atrial fibrillation, mild-moderate left ventricular dysfunction, borderline left ventricular function and persistent ductus arteriosus.

Conclusion: In our series we have observed cardiac abnormalities in most patients. Although the relationship of these findings remains to be clarified, the results showed the importance of performing a complete cardiological screening in these patients, especially in those with refractory epilepsy, which could contribute to the increase in the risk of SUDEP.

P13.075.A Two novel IGF2 missense variants in four patients with Silver-Russel(-like) syndrome

Stephany Donze[1], *Hermine van Duyvenvoorde*[2], *Arie van Haeringen*[2], *yvonne hilhorst- hofstee*[2], *Carlo Marcelis*[3], *Petra van Setten*[4], *Monique Losekoot*[2], *Daniëlle van der Kaay*[5]

[1]*Erasmus University Medical Center, Clinical Genetics, Rotterdam, Netherlands;* [2]*Leiden University Medical Center (LUMC), Clinical Genetics, Leiden, Netherlands;* [3]*Radboud University Medical Center, Clinical Genetics, Nijmegen, Netherlands;* [4]*Radboud University Medical Center, Pediatrics, Nijmegen, Netherlands;* [5]*Erasmus University Medical Center, Pediatric Endocrinology, Rotterdam, Netherlands*

Background/Objectives: Silver-Russell syndrome (SRS) is a rare disorder characterized by being born small for gestational age, postnatal growth failure, relative macrocephaly, a prominent forehead, feeding difficulties, and body asymmetry. Most cases are due to loss of methylation of the imprinting control region 1 on chromosome 11p15. Recently, pathogenic paternal IGF2 variants have been associated with a SRS phenotype. The variants and clinical spectrum remain, however, limited.

Methods: Four patients with a SRS(-like) phenotype and a variant in IGF2, detected by whole exome sequencing (WES), were collected.

Results: Clinical characteristics are summarized in Table 1. In patients 1, 2 and 3, WES showed a missense variant in the IGF2 gene, NM_000612.4:c.100G>A p.(Gly34Ser). In patient 1 and 2 from family 1, the variant was paternally inherited. In patient 3 from family 2 the variant occurred de novo, and was located on the paternal allele. In patient 4 from family 3 WES showed a de novo missense variant in the IGF2 gene, NM_000612.6:c.148T>C; p.(Phe50Leu). Unfortunately, paternal origin could not be confirmed.

Conclusion: In this case series we report 2 novel IGF2 missense variants in 4 patients with a variable SRS-like phenotype. In contrast to previous reports, pre- and postnatal growth retardation and congenital anomalies were less pronounced and two patients with pre- and/or postnatal growth retardation showed spontaneous catch-up growth. Behavioural issues were prominent and could present a new feature of SRS patients with an IGF2 pathogenic variant. This case series expands the genotypic and phenotypic spectrum of SRS patients with an IGF2 pathogenic variant.

Grants: Not applicable.

Table 1. Characteristics of four patients with an IGF2 variant

Pregnancy and delivery	**Patient 1**	**Patient 2**	**Patient 3**	**Patient 4**

P13.076.B Prenatal characterization of an additional chromosome 9 derivative

Juliane Maria Beuschlein[1], Niklas Hirschberger[1], Moneef Shoukier[1], Florian Vogel[1], Eva Kahles[1], Daniela Bayer[1], Markus Stumm[2], Rainer Wimmer[2], Julia Flunkert[2], Cornelia Daumer-Haas[1]

[1]Eurofins Humangenetik und Pränatal-Medizin MVZ GmbH, Munich, Germany; [2]Medicover Humangenetik Berlin-Lichtenberg MVZ, Berlin, Germany

Background/Objectives: Tetrasomy 9p is characterized by an additional isochromosome consisting of two short arms of chromosome 9. It is associated with a high variability of symptoms. About 25 cases have been described prenatally with the following findings: Intrauterine growth restriction (IUGR), heart defects, ventriculomegaly, Dandy-Walker malformation, cleft lip/palate and facial dysmorphism. Two third of these cases were non-mosaics.

Methods: A 37-year-old woman presented with the following abnormal fetal sonographic findings at 18 + 6 weeks of gestation: IUGR, brachycephalus, Dandy-Walker malformation, left choroid plexus cyst, absent nasal bone, micrognathia, persistent left superior vena cava and white spot. Amniocentesis was performed at 19 + 3 weeks. Array comparative genomic hybridization (CGH) analysis of uncultured amniocytes, chromosome and fluorescence in situ hybridization (FISH) analyses of cultured amniocytes and optical genome mapping of fetal lymphocytes were performed.

Results: Array CGH analysis detected a signal increase indicating a tetrasomy of the chromosome region 9pter→p22.3 (16 Mb) and a trisomy of the region p22.3→p13.1 (24 Mb). Considering the results of the array CGH analysis, chromosome and FISH analyses revealed the following non-mosaic karyotype: 47,XY,+i(9)(pter→q11.1::p22.3→pter). In contrast, optical genome mapping suggested that the region 9q11.1→q21.1 might be present in the additional chromosome 9 derivative. The patient opted for termination of pregnancy.

Conclusion: There are difficulties in interpreting the results regarding the pericentromeric region, as there were discrepancies between array CGH analysis and optical genome mapping. Advantages and disadvantages of the different methods, as well as their limitations, need to be taken into account when evaluating the findings.

Grants: None declared.

P13.077.C A *NEDD4* homozygous frameshift variant in a boy with multiple congenital anomalies overlapping the *Nedd4* knock-out murine model

Giulia Severi[1], Federica Isidori[2], Alessandra Vancini[3], Maria Chiara Baroni[1], Emanuela Scarano[4], Marco seri[5], Tommaso Pippucci[2]

[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, UOC Genetica Medica, Italy; [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Computational Genomics, Italy; [3]Maggiore Hospital, Neonatal Intensive Care Unit, Bologna, Italy; [4]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Rare Disease Unit, Department of Pediatrics, Italy; [5]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Italy

Background/Objectives: *NEDD4* encodes a E3 ubiquitin ligase and to date it is not associated to disease in humans. In the murine model, functional studies demonstrate that *Nedd4* regulates the craniofacial development, promoting neural crest cells survival and maintaining their staminality. When *Nedd4* expression is abolished, neural crest cells migrating from the posterior forebrain, midbrain and rostral hindbrain may undergo aberrant apoptosis, resulting in an insufficient population of these cells for proper brain functioning. *Nedd4*$^{-/-}$ mice have severe cranio-facial defects with a prevalent maxillary and mandibular involvement, clef lip and palate, and deficiency of the trigeminal ganglia. They are also significantly smaller than the wild type littermates.

Methods: We performed whole exome sequencing (WES) in a boy, first child of consanguineous parents from Pakistan, who presented prenatally with left cleft lip and palate and right clubfoot. At birth he also showed post-axial right polydactyly, bilateral iris and optic nerve coloboma, patent foramen ovale and ductus arteriosus and dysmorphic features. He showed developmental delay: at 4 years he could walk only if assisted and he was still non-verbal. He had short stature (-3.3 SD) and microbrachycephaply (-4.1 SD; -3.3 SD related to his stature).

Results: WES revealed a homozygous c.1369_1375delATTTCATinsCG (p.Ile457AlafsTer15) mutation in *NEDD4*; his parents were both heterozygous. RNA-seq, transcriptome, ubiquitinome and other functional studies are ongoing on skin fibroblasts.

Conclusion: The phenotype of this patient shows consistency with phenotypic features in mice, but more patients are needed to prove that *NEDD4* is implicated in human disease.

Conflict of Interest: None declared

P13.078.D Results of rapid trio exome sequencing in routine care of 90 critically ill newborns and infants with an unclear symptom complex at the University Hospital Cologne, Germany

Clara Velmans[1], Mert Karakaya[1], Louisa Lepkes[1], Sarah Thull[1], Zempel Hans[1], Jutta Becker[1], Nico Fuhrmann[1], Sophie Kaspar[1], Nadine Reintjes[1], Vera Riehmer[1], Nora Winnerling[1], Bodo B. Beck[1], Florian Erger[1], Julia Schreml[1], Christian Netzer[1]

[1]Institute of Human Genetics, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany

Background: The majority of congenital syndromic disorders are genetically determined. By means of trio exome analysis a genetic cause can currently be confirmed in up to half of those affected.

Methods: Since the beginning of 2021 rapid trio exome sequencing was implemented in routine care of hospitalized newborns and infants with an unclear symptom complex (abnormalities in at least two organ systems with unclear etiology) at the University Hospital of Cologne, Germany. The genetic diagnostics were embedded in extensive pre- and post-test genetic counselling and required close cooperation between pediatricians and clinical geneticists.

Results: The diagnostic result was available after an average of two weeks. Of the 90 patients examined so far a genetic cause could be confirmed in 46 patients (diagnostic rate: 51 %). In almost half of these patients the genetic diagnosis resulted in a direct clinical relevance or therapeutic benefit. The diagnoses were very heterogeneous ranging from more common rare diseases with atypical presentation to very rare syndromes with less than 50 described patients in the literature so far. 52 % of the confirmed diagnoses were caused by a de novo genetic variant, 28 % were autosomal recessive disorders and surprisingly in 9

patients (20 %) the dominant genetic disease was inherited from an unaffected or mildly affected parent.

Conclusion: Rapid trio exome sequencing in routine care of critically ill newborns and infants with an unclear symptom complex represents a good diagnostic option with a high diagnostic yield and considerable clinical relevance.

Conflict of Interest: None declared

P13.079.A Atypical Prader-Willi Syndrome: Insights into a rare mechanism and its implications

Sarah Graine[1], *Laurence Cuisset*[1], *jean-luc alessandri*[2], *Fatma Maazoun*[1], *Berenice Herve*[1], *Martine Montagnon*[1], *Thierry Bienvenu*[1], *Jean-Michel Dupont*[1], *Aziza Lebbar*[1]

[1]*Cochin Hospital, APHP Centre-Universite Paris Cité, Service de Médecine Génomique des Maladies de Système et d'Organe, Fédération de Génétique et de Médecine Génomique, Paris, France;* [2]*Hospital Center Félix Guyon, Department of Medical Genetics, Saint-Denis, France*

Background/Aims: 70% of Prader-Willi syndrome (PWS) result from a microdeletion mediated by NAHR between segmental duplications BP1 or BP2 and BP3.

This report describes a rare deletion mechanism affecting the imprinted PWS/AS locus within the 15q11-q13 region, resulting from a unique 3:1 malsegregation of a reciprocal translocation t(11;15)(p15;q12).

This 4.14 Mb deletion, is smaller than usual cases, expanding from BP1 to the *GABRB3* gene while leaving *GABRA5*, *GABRG3*, *OCA2*, and *HERC2* intact. This may have implications for the reduction of neuropsychiatric consequences. The clinical description and potential impact on genetic counseling will be discussed.

Methods: The patient underwent clinical assessment and genetic testing, including DNA methylation analysis (methylation-specific PCR), FISH (*SNRPN* probe), aCGH, and karyotyping to identify the specific rare mechanism involved.

Results: The 4-month-old patient presented with global hypotonia, and orality disorders at the time of examination.

The diagnosis of PWS was confirmed by methylation analysis, which indicated a loss of the paternal allele. Additionally, cytogenetic analysis identified a derivative chromosome 15 from a translocation t(11;15)(p15;q12), leading to an atypical 4.14 Mb deletion of the 15q11.2-q12 region. However, since no imbalance related to chromosome 11 has been detected by aCGH, the phenotype will be entirely linked to the 15q deletion. Parental karyotyping will be performed, to check for an inherited translocation.

Conclusion: This case emphasises the relevance of detailed chromosomal analysis in PWS with Karyotype for accurate genetic counselling.

Reduce size of deletion may suggest a milder PWS phenotype, which will be confirmed as the child ages.

Grants: None.

Conflict of Interest: None declared

P13.080.B Usefulness of new generation sequence analysis in rare diseases of childhood: dual molecular diagnosis

Esra Isik[1], *Enise AVCI DURMUŞALİOGLU*[1], **Mehmet Mert Topaloğlu**[1], *Turkan Turkut Tan*[1], *Fayize Maden Bedel*[2], *Tayfun Cinleti*[3], *Tahir Atik*[1], *Ozgur Cogulu*[1]

[1]*Ege University, Pediatric Genetics;* [2]*Erzurum City Hospital, Pediatric Genetics;* [3]*İzmir City Hospital, Pediatric Genetics*

Background/Objectives: The term "dual molecular diagnosis" denotes the identification of two distinct molecular causes contributing to a patient's clinical symptoms or disease manifestations. This can be especially important in rare diseases. Most rare diseases manifest during childhood, the age of onset of clinical symptoms, individual variability, modifying factors, and coexisting conditions introduce complexities to the diagnostic process. NGS enables the rapid, simultaneous analysis of a multitude of genes, facilitating the detection of multiple genetic changes underlying the patient's clinical manifestations. This study aims to showcase patients with dual molecular diagnoses within the pediatric patient group, utilizing clinical exome sequencing (CES) and whole exome sequencing (WES) results. By doing so, the study underscores the clinical importance of NGS in unraveling the intricate genetic landscape of rare diseases and enhancing diagnostic precision.

Methods: Between November 2021 and May 2023, we retrospectively reviewed 288 CES and 324 WES results from children aged 0-18 with various indications at the Ege University Department of Pediatric Genetic Diseases.

Results: Dual molecular diagnoses occurred in 17 (2.77%) cases, with 14 patients exhibiting parental consanguinity. Patient ages ranged from 1 to 16 years. Thirty-five different variants in 33 genes were detected, with 33 being single nucleotide changes/indels and two being intragenic copy number variations. Eighteen of those variants were novel.

Conclusion: Identifying dual molecular diagnoses in pediatric rare diseases is crucial for tailored patient management and effective genetic counseling. NGS methods enable early and precise diagnoses in complex phenotypes, providing insights beyond traditional diagnostic approaches.

P13.081.C The era of candidate genes: biallelic frameshift variants in *FAT1* and a new malformation syndrome?

Sara Pinho[1], *Aida Bertoli-Avella*[2], *Ligia Almeida*[2], *Juliette Dupont*[1]

[1]*Unidade Local de Saúde Santa Maria, Serviço de Genética, Departamento de Pediatria, Lisbon, Portugal;* [2]*CENTOGENE GmbH, Rostock, Germany*

Background: The *FAT1* gene belongs to a cadherin family involved in epithelial cell adhesion, migration and polarity. In 2019, Lahrouchi et al. reported 10 cases with homozygous frameshift variants in *FAT1* and ocular abnormalities, nephropathy, syndactyly and facial dysmorphisms.

Methods: We present an 18-year-old female, first child of a healthy consanguineous couple with unremarkable family history, with bilateral congenital ptosis, toe syndactyly, learning difficulties and facial dysmorphisms, such as elongated face, high arched eyebrows, micrognathia, narrow palate and oligodontia. She underwent surgery for biliary atresia in the neonatal period. Due to secondary biliary cirrhosis, she is now waiting a liver transplant.

Results: No pathogenic/likely pathogenic copy number variant was found by arrayCGH. Subsequent exome sequencing identified the homozygous frameshift variant NM_005245.3: c.1068_1069del, p.(Pro358Thrfs*10), in *FAT1* gene, still not linked to an OMIM clinical entity. However, following ClinGen framework for clinical validity, this gene is rated with strong evidence for autosomal recessive colobomatous-microphthalmia, ptosis, nephropathy and syndactyly syndrome. Both parents are heterozygotes.

Conclusion: Our patient's phenotype is consistent with other cases described in the literature with biallellic frameshift variants

in *FAT1*. Most patients have ptosis, toe syndactyly and similar facial features. Other ocular abnormalities can occur. Intellectual disability and nephropathy only exist in some individuals. No other cases of biliary atresia have been reported.

Although loss of function appears to be a mechanism of disease in this gene, additional evidence is necessary. This case adds evidence to the role of *FAT1* in a new multi-system disorder and contributes to the characterization of its associated phenotype.

Conflict of Interest: None declared

P13.082.D The role of rapid whole exome sequencing in critically ill newborns with a preliminary diagnosis of genetic syndrome

Durdugul Ayyildiz Emecen[1], *esra isik*[1], *Enise AVCI DURMUŞALİOGLU*[1], *aysegul yildirim*[1], *demet terek*[1], *Ozge Altun Koroglu*[1], *mehmet yalaz*[1], *mete akisu*[1], *esra er*[2], *pelin teke kisa*[3], *ozlem sarac sandal*[2], *gulhan atakul*[2], *Ozgur Cogulu*[1], *Ferda Ozkinay*[1], *Tahir Atik*[1]

[1]*Ege University Faculty of Medicine, Türkyie;* [2]*S.B.Ü Dr. Behçet Uz Çocuk Hastalıkları Ve Cerrahisi Eğitim Ve Araştırma Hastanesi, Türkyie;* [3]*Dokuz Eylul University Faculty of Medicine, Türkyie*

Introduction: Whole-exome sequencing has become one of the first-line diagnostic tests for patients with multisystem abnormalities and congenital anomalies. Although it has started to be used quite frequently in clinics, it is not yet widely utilized in neonatal intensive care services. It is vital to make a quick and accurate diagnosis when approaching a critically ill patient. In our study, we aimed to evaluate the utility of rapid whole-exome sequencing in critically ill patients.

Method: Whole-exome sequencing was performed on 8 critically ill patients hospitalized in the intensive care unit who were younger than 3 months.

Results: Five of the patients were female. The mean age was 22 days. Five patients had a certain diagnosis with whole-exome sequencing (P-1, P-4, P-5, P-7, P-8). Two of the patients had heterozygous pathogenic variants in the PTPN11 gene (P-5, P-8). One patient (P-7) was diagnosed with Stickler syndrome with a novel homozygous variant c.1152del (p.Trp384*) in the FOXL3 gene. In one patient (P-4) with dilated cardiomyopathy, a de-novo heterozygous pathogenic variant was detected in the TPM1 gene. One patient (P-2) was diagnosed with Kabuki syndrome. Three patients (P-5, P-6, P-7) died before receiving whole-exome sequencing results.

Conclusion: With the help of rapid whole-exome sequencing, timely changes in treatment, initiation of palliative treatment, creation of a long-term treatment program, and quality genetic counseling can be provided for patients diagnosed in a short time.

Therefore, it is inevitable that rapid whole-exome sequencing will become the first-line test in diagnosing critically ill patients in the future.

P13.083.A Hickam's dictum: Keeping up with the Diagnoses

Susana Lemos Ferreira[1], *Joana Catanho*[1], *Mafalda Melo*[1], *Sofia Nunes*[1], *Rui Gonçalves*[1], *Marta Amorim*[2], *Diana Antunes*[1], *Márcia Rodrigues*[3], *Teresa Kay*[1], *Inês Carvalho*[1], *Margarida Venancio*[1]

[1]*Hospital Dona Estefânia, Unidade Local de Saúde São José, Centro Clínico Académico de Lisboa, Serviço de Genética Médica, Lisboa, Portugal;* [2]*Hospital dos Lusíadas, Consulta de Genética Médica, Lisboa, Portugal;* [3]*Unidade Local de Saúde Santa Maria, Serviço de Genética Médica, Lisboa, Portugal*

Background/Objectives: Hickam's dictum sustains that a patient with multiple symptoms is more likely to have a combination of diseases rather than only one. Dual genetic diagnoses (DGD) consist of distinct or blend diagnoses of more than one locus that segregates independently. Whole exome sequencing (WES) is associated with increased DGD. Literature estimates that 7% of cases have DGD.

Methods: Retrospective review of paediatric patients with DGD referred to our Genetics Department (2001-2023).

Results: 25 patients were identified with a confirmed or potentially DGD. In 20/25, DGD were confirmed, clinical consistent with the phenotype and genetic results were classified as likely pathogenic/pathogenic. In 5/25, one variant was classified as uncertain significance but considered to be of potential clinical relevance. The main indication for referral was multisystemic disease (22/25). 3/25 patients were referred with a previous genetic diagnosis that did not fully explain the phenotype. Of the cases without previous diagnosis (22/25), 12 presented atypical features, 2 had a blended phenotype, and 8 had a second diagnosis after clinical validation of incidental/secondary findings. In 15/25, the first-tier test provided DGD. Primary diagnoses were obtained by WES (13/25) and array (7/25), and secondary diagnoses by WES (14/25) and array (8/25).

Conclusion: DGD should be considered in patients with atypical features and a multisystemic phenotype. Clinical suspicion was the main drive to continue investigation. WES improved our diagnostic capacity by identifying diagnoses that might be difficult to assert. Diagnostic investigation is not necessarily complete after achieving one diagnosis, and pursuing a DGD have implications to the patients and families.

[14]University of Melbourne, Royal Children's Hospital, Department of Paediatrics, Parkville, Australia

Background/Objectives: MN1 is a transcriptional cofactor of poorly understood function. Two phenotype groups associated with heterozygous *MN1* variants have been described: i) mild neurodevelopmental delay, deafness and minor dysmorphisms ascribed to loss-of-function by nonsense-mediated mRNA decay (NMD) or large deletions; and ii) severe intellectual disability (ID), craniofacial and brain malformations ascribed to *MN1* C-terminal truncating (MCTT) variants escaping NMD, leading to gain-of-function (GoF) via increased protein half-life. Here, we present probands with phenotypes and *MN1* variants not fitting either of these categories and explore their molecular mechanisms.

Methods: *MN1* variants were identified in probands by exome sequencing. Plasmids encoding wild-type or mutant MN1 were transfected into HEK-293T cells, with or without a translation inhibitor, followed by immunofluorescence assays and Western blots to assess subcellular localization and protein stability.

Results: Six novel *MN1* variants were identified in seven probands: i) p.(Ala1318Asp) in the C-terminal tail; ii) a cluster of four truncating variants in a region (Tyr878-Ala887) predicted to undergo NMD but whose phenotypic consequences are more severe than that expected for haploinsufficiency; and iii) p.(Ser829Phe) in two unrelated probands with frontonasal dysplasia and ID. As demonstrated previously for C-terminally truncated *MN1*, all variants induced nuclear aggregates upon overexpression. Relative to wild-type MN1, protein stabilization was increased by p.(Ala1318Asp) and by the truncations but was unchanged by p.(Ser829Phe).

Conclusion: Our results suggest that p.(Ala1318Asp) and the four truncating variants result in a GoF mechanism similar to the MCTT variants, while p.(Ser829Phe) has a unique qualitative effect on MN1 activity.

[1]Institute of Mother and Child, Department of Medical Genetics, Warsaw, Poland; [2]Independent Laboratory of Genetic Diagnostics, Medical University of Lublin, Lublin, Poland; [3]Medical University of Gdańsk, Department of Paediatrics, Haematology and Onkology, Gdańsk, Poland

Background/Objectives: Rahman syndrome (RS), also called HIST1H1E syndrome, is a rare neurodevelopmental disorder characterized by distinctive phenotype with the following symptoms: **h**ypotonia, **i**ntellectual disability with behavioral problems, **s**keletal, **t**estes (cryptorchidism), **t**hyroid, **h**eart (ASD) and **e**ctodermal anomalies (sparse hair, thin nails and abnormal dentition), seizures, craniosynostosis and deafness. To date, all patients were reported to have a heterozygous pathogenic de novo variant in the *H1-4* gene. The objective of this work is thorough analysis of clinical picture of patients with Rahman syndrome.

Patients and methods: We present clinical evaluation of 5 patients with the pathogenic variant in *H1-4* gene identified in high-throughput sequencing analysis and clinical features of RS, aged from 10 to 19 years.

Results: All patients presented generalized hypotonia at infancy, macrocephaly and dysmorphic features with thin hair, all but one - intellectual disability from mild to moderate, delayed or absent speech, motor developmental delay, strabismus and/or astigmatism Congenital heart defects (ASD) were found in three individuals. Two patients presented short stature, hypothyroidism, ADHD and anxiety. One patient had deafness, one cryptorchidism, one scoliosis and one submucosal cleft palate with thin nails and severe dental caries. Molecular analysis revealed the presence of pathogenic or likely pathogenic variants: c.116dup (p.Val40GlyfsTer7), c.389dup (p.Pro131AlafsTer65), c.435dup (p.Thr146HisfsTer50), c.441dup (p.Lys148GlnfsTer48) and c.436_458del (p.Thr146AspfsTer42) in the *H1-4* gene.

Conclusions: Our patients present with typical clinical features of Rahman syndrome including macrocephaly with hypotonia, intellectual disability and dysmorphic features. We conclude that this disease should be considered in the differential diagnosis of macrocephaly.

Background/Objectives: Rasopathies are a group of systemic disorders that present with distinctive dysmorphic features, short stature, congenital heart defect, delayed psychomotor development and skin abnormalities. They are caused by the presence germline pathogenic variants in genes of the RAS/MAPK signalling pathway. The aim of our study was the assessment of the utility of NGS panel in case of RASopathy suspicion.

Methods: The gene panel was designed based on the literature review and included RASopathy genes, genes related to dysmorphic syndromes that clinical symptoms are similar to those observed in RASopathy patients. The study included 698 patients with RASopathy suspicion that were tested with targeted gene panel (KAPA SeqCap/HyperCap Workflow, Roche). The analysis has

been performed with in-house analysis pipeline based on bcbio and Variant Effect Predictor software.

Results: The analysis of variants in known RASopathy genes revealed the presence of pathogenic / likely pathogenic variant in 149 patients (21.3%) and variants of unknown significance in further 42 individuals (6.2%). The most commonly mutated genes were *PTPN11* (49 cases), *NF1* (28), *SOS1* (22) and *BRAF* (11). The analysis of other genes included in our panel revealed the presence of pathogenic / likely pathogenic variants in 59 (8.4%) individuals, including 10 patients with *ANKRD11* variant (supporting diagnosis of KBG syndrome).

Conclusion: Panel next generation sequencing is a powerful tool in the diagnosis of patients with RASopathy suspicion. The application of extended gene panel allowed to provide differential diagnosis in our patients.

Grants: The study was partially supported from EJP-RD/I/NSEuroNet/01/2021.

P13.088.B Unveiling a pathogenic hotspot in PUM1 gene associated with PADDASS

Catarina Macedo[1], *Teresa Moreno*[2], *Mariana Soeiro e Sá*[1]

[1]*Hospital de Santa Maria, Serviço de Genética Médica, Departamento de Pediatria, Lisboa, Portugal;* [2]*Hospital de Santa Maria, Unidade de Neuropediatria, Departamento de Pediatria, Lisboa, Portugal*

Background/Objectives: *PUM1* gene encodes an RNA-binding protein linked to the Pumilio protein family, responsible for translation regulation during embryogenesis and cell differentiation. Diseases linked to *PUM1* encompass Spinocerebellar Ataxia 47 and *PUM1*-Associated Developmental Disability-Ataxia-Seizure Syndrome (PADDASS). PADDASS manifests with developmental delay (DD), intellectual disability (ID), ataxia, seizures, and short stature. Notably, four out of nine reported cases harbour the c.3439C>T, p.(Arg1147Trp) variant, with refractory seizures, hypotonia, and DD/ID being present in most patients. Dysmorphic features have been described in some of these patients.

Methods: We present a case of a girl born to nonconsanguineous parents, displaying fetal growth restriction and short bones in the second-trimester ultrasound. At the initial genetic assessment, in her first month of life, she exhibited refractory seizures, hypotonia, and distinctive dysmorphic features overlapping with Schinzel-Giedion syndrome (hirsutism, enlarged anterior fontanelle; low-set ears; sparse eyebrows; hypertelorism; short, narrow and up-slanted palpebral fissures; broad nasal bridge; bulbous nose; anteverted nares; long philtrum; thin upper lip; wide-spaced nipples; fifth finger clinodactyly; single transverse palmar crease). She evolved with severe DD, divergent strabismus, and recurrent respiratory infections. ArrayCGH yielded normal results.

Results: The first trio Whole Exome Sequencing (WES) in 2018 showed no diagnostic variants, but WES reanalysis in 2023 identified the de novo c.3439C>T, p.(Arg1147Trp) variant in *PUM1* gene.

Conclusion: Our findings contribute to the recognition of the c.3439C>T, p.(Arg1147Trp) variant as a disease-causing hotspot in PADDASS. This case emphasizes the distinctive facial gestalt as a cardinal feature, together with early-onset refractory epilepsy, hypotonia, and DD/ID.

Background/Objectives: TRAF7 syndrome (MIM#618164) is an ultrarare multisystemic neurodevelopmental disorder with heterogeneous clinical presentations caused by germline heterozygous missense variants in the *TRAF7* gene.

Methods: We present a detailed description of eleven new TRAF7 syndrome cases, featuring eight distinct genetic variants, including a novel one. Phenotypic analysis and a comprehensive review of the 58 previously reported individuals outline consistent clinical findings, emphasizing dysmorphic features, developmental delay, adaptive and behavioural phenotype, endocrine manifestations, and congenital heart defects.

Results: In this large cohort, new findings include a wider range of cognitive dysfunction, with some individuals exhibiting normal intellectual abilities despite early psychomotor developmental delay. Communication difficulties, particularly in expressive language, are common and often require alternative communication methods. Autistic traits, notably lack of cognitive flexibility, are observed in our cohort. Additionally, hearing loss, sleep disturbances, and endocrine anomalies, including short stature are described. Cardiac defects, frequently severe, cause early-life complications. The novel missense variant p.(Arg653Leu) further underscores the complex relationship between germline *TRAF7* variants and somatic changes linked to meningiomas and sheds new light into the controversial oncologic issue.

Conclusion: Our comprehensive analysis and description expands the phenotypic spectrum, emphasizing the need for oncological evaluations and proposing an evidence-based

guideline for clinical management. This study contributes to a better understanding of TRAF7 syndrome, offering insights for improved diagnosis, intervention, and patient care.

Grants: APP has an FPU fellowship (MIU). ESG is supported through IMPaCT-GENóMICA (CIBERER-MISAN/European Union). MCP has a CdT fellowship (IRSJD). Additional funding includes grants PID2019-107188RB-C21, PID2022-141461OB-I00 (MCIN/AEI/10.13039/501100011033), and 2021SGR-01093 (AGAUR-Gencat).

P13.090.D Neurological and cognitive outcome in primary microcephaly and chorioretinopathy.

Mathilde Gras[1], *severine drunat*[2], *Anais Ernault*[2], *Alain Verloes*[2], *Sandrine Passemard*[1]

[1]*APHP, Hôpital Robert Debré, Child neurology department, PARIS, France;* [2]*APHP, Hôpital Robert Debré, Genetic Department, PARIS, France*

Background/Objectives: Primary Microcephalies (PMs) are characterized by a reduction in brain size, associated or not with short stature or sensorineural disorders, and mainly recessively inherited. Although more is known about the cognitive outcomes of the three most common forms of PM, with or without dwarfism (*ASPM, WDR62*, and *CDK5RAP2*), patients with PM and neurosensory disorders remained unexplored.

Methods: We studied i) frequency of each genotype, ii) growth parameters, iii) sensorineural features and iv) cognitive profile of patients with PM and retinopathy caused by mutations in *PLK4, TUBGCP6, TUBGCP4, KIF14, KIF11* and *RBBP8*. We compared our data with those of the literature.

Results: Among the 267 reported patients, 211 patients had mutations in *KIF11*. Developmental delay (DD)/ID was identified in 53/149 (35,5%), and learning disabilities were described in 38/149 (25%). However, only 1/149 patient was assessed (FSIQ 77)

Patients with mutations in *PLK4, TUBGCP6, TUBGCP4, KIF14, KIF11* and *RBBP8* were much less frequent. DD was described in 8/9 reported patients with mutations in *KIF14*, 14/14 in *PLK4*, 4/8 in *TUBGCP4*, 11/11 in *TUBGCP6* and 11/11 in *RBBP8* genes. None of these patients were cognitively assessed.

We provide molecular and cognitive data from 4 new patients [*KIF11* (1), *TUBGCP6* (2), *PLK4* (1)] with a FSIQ ranging from 43 to 82.

Conclusion: The cognitive profile of patients with PM and retinopathy encompass a wide phenotypic spectrum ranging from normal to severe ID, making genetic counselling difficult. Increasing our knowledge on the outcome of these affections through European networks are mandatory.

P13.091.A Targeted re-sequencing of Neural Tube Defects patients and families identifies rare variants in genes candidate from animal models

Ferruccio Romano[1], *Michele Iacomino*[2], *Marzia Ognibene*[2], *Marcello Scala*[2], *Irene Schiavetti*[3], *Marco Pavanello*[4], *Gianluca Piatelli*[4], *Marco Di Duca*[2], *Yeraldin Chiquinquira Castillo De Spelorzi*[5], *Francesca Faravelli*[1], *Federico Zara*[2], *Patrizia De Marco*[2], *Valeria Capra*[1]

[1]*Istituto Giannina Gaslini, Unità di Genomica e Genetica Clinica, Genova, Italy;* [2]*Istituto Giannina Gaslini, Unità di Genetica Medica, Genova, Italy;* [3]*Università di Genova, Dipartimento di Scienze della Salute, Genova, Italy;* [4]*Istituto Giannina Gaslini, Unità di Neurochirurgia, Genova, Italy;* [5]*Istituto Italiano di Tecnologia, Genomics Facility, Genova, Italy*

Consortium: ERN-ITHACA

Background/Objectives: Neural tube defects (NTD) are congenital malformations arising when the neural tube, precursor of the brain and spine, fails to properly close during neurulation. Etiology is multifactorial, with environmental and genetic factors variably contributing, on a case by case basis. Molecular genetic studies of orthologues of the mouse NTD genes have been precious in the identification of predisposing NTD genes in humans, highlighting the peculiar role of the planar cell polarity (PCP) pathway in a fraction of human NTD patients.

Methods: Seventy-eight NTD patients were selected. Next-generation targeted re-sequencing of 29 genes encoding for components of the PCP pathway or for family members of proteins (including SHROOM and GRHL) underlying NTDs in well-known animal models was carried-out. A gene-burden analysis was also performed to assess for potential enrichment of rare damaging variants in the NTD cohort compared to the *in house* control exome dataset.

Results: 38 individuals (50%) presented with at least one putatively damaging rare variant, most of which were missense (64/76, 84%). *GRHL1* and *WNT5A* and, among gene families *GRHL* and *SHROOM*, were significantly enriched in the patients' cohort, compared to controls.

Conclusion: This study highlights the involvement of human orthologues of mouse genes in human NTD phenotype. Further re-sequencing, or whole exome sequencing of large groups of cases might give the clues for a better clinical management of patients and their families.

Grants: This research was supported by the "5xmille" founding to IRCCS Istituto Giannina Gaslini, and by Italian Health Ministry-Ricerca Corrente 2023.

P13.092.B Simultaneous copy number and methylation analysis using methylation-specific digitalMLPA in congenital abnormalities and intellectual disability

Irene Zwarts[1], *Marrit Rinsma*[2], *Santiago Castanedo*[2], *Lisette Stolk*[2]

[1]*MRC Holland, IVD Development, Amsterdam, Netherlands;* [2]*MRC Holland, Cytogenetics, Amsterdam, Netherlands*

Background/Objectives: In the general population, the prevalence of intellectual disability (ID) is estimated at 1-3% and that of congenital abnormalities (CA) at 2-4%. CA and ID can be caused by many genetic defects, as well as imprinting changes. When no distinct syndromic features are displayed, finding the (epi)genetic cause often proves to be challenging. Testing a broad range of regions and imprinting-associated differentially methylated regions (iDMRs) would therefore be a useful contribution to elucidate the genetic causes of CA and ID.

Methods: SALSA® digitalMLPA™ Probemix DM025 Congenital Anomalies is being developed for simultaneous detection of copy number variation in more than 40 genes/regions across all chromosomes, and methylation status of 11 iDMRs. This assay was tested with 136 control samples and more than 15 positive samples, including 4 imprinting disorders, 5 microdeletion and 1 microduplication syndromes.

Results: In control samples, the expected copy number was found and imprinting regions showed a median methylation status of 44-67% per iDMR. The positive samples with previously identified deletions, duplications and methylation aberrations were analysed and were 100% in concordance with the known genotype and methylation status.

Conclusion: This data shows the ability of this methylation-specific digitalMLPA assay to correctly determine both copy

number and methylation status of targets that are frequently altered in individuals with CA and ID. This assay provides a quick and easy solution for the challenge of finding genetic defects causing CA and ID within one assay.

P13.093.C Functional Insights of Truncated MAGEL2 in Schaaf-Yang Syndrome

Mónica Centeno-Pla[1;2;3], *Estefanía Alcaide-Consuegra*[1;2], *Sophie Gibson*[1], *Jonas Setzke*[4], *Aina Prat-Planas*[1;2], *Daniel Tornero*[4], *Isaac Canals*[5], *Daniel Grinberg*[1;2], *Roser Urreizti*[2;3], *Raquel Rabionet*[1;2], *Susanna Balcells*[1;2]

[1]*University of Barcelona, Department of Genetics, Microbiology and Statistics, IBUB, IRSJD, Barcelona, Spain;* [2]*Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Madrid, Spain;* [3]*Hospital Sant Joan de Déu, Clinical Biochemistry Department, CIBERER, Esplugues de Llobregat, Spain;* [4]*Institute of Neuroscience, University of Barcelona, Department of Biomedical Sciences, Barcelona, Spain;* [5]*University Children's Hospital Zurich, University of Zurich, Division of Metabolism and Children's Research Center, Zurich, Switzerland*

Background/Objectives: Schaaf-Yang syndrome (SYS) is an ultra-rare neurodevelopmental disorder caused by truncating mutations in *MAGEL2*, a gene that contributes to the regulation of retrograde transport, circadian rhythm, and mRNA metabolism. Previous heterologous expression assays in HeLa cells revealed a shift from a cytoplasmic to a more nuclear localization of a truncated MAGEL2 protein compared to the WT. We now extend the analysis to six other SYS mutations. Additionally, we generate neurons (iNs) and astrocytes (iAs) from SYS iPSC lines to study MAGEL2 in more relevant cellular contexts.

Methods: ICC assays were conducted in transfected HeLa cells to quantitatively assess the nuclear localization of FLAG-tagged MAGEL2 using Mander's colocalization coefficient. SYS and control iPSCs were differentiated into iNs and iAs, and co cultured.

Results: Truncated MAGEL2 proteins consistently displayed a predominantly nuclear localization, irrespective of the position and chemistry of the tag. Variants associated with arthrogryposis multiplex congenita showed a more pronounced nuclear retention phenotype. iNS and iAs were successfully generated from both SYS and control iPSCs. Calcium imaging and proteomic analyses revealed functional traits of SYS physiopathology.

Conclusion: Results suggest a correlation between clinical severity and the degree of nuclear mis-localization. Assays in different cell models will unveil deeper insights into MAGEL2 functional implications, now pointing to a pathogenic neomorphic effect of the truncated protein.

Grants: Projects PID2019-107188RB-C21 and PID2022-141461OB-I00 from MICIN, ACCI19P2AC720-1 from ISCIII-CIBERER, and donations from AESYS. MC-P supported by a CdT fellowship from IRSJD, and AP-P and EA-C recipients of a FPU fellowship from MICIN.

Background/Objectives: Over the past decade, pathogenic variants in genes encoding subunits of the SWI-SNF complex were identified as causal for Coffin-Siris syndrome (*ARID1B, ARID1A, SMARCB1, SMARCA4, SMARCE1, ARID2, DPF2, SMARCC2, SOX11, SOX4, SMARCD1, BICRA*). However, a significant knowledge gap persists regarding the clinical manifestations of Coffin-Siris syndrome in adulthood. Long-term outcomes and associated risks remain unclear, contributing to considerable uncertainty among caregivers and clinicians.

Methods: Through collaborative efforts, including an ERN-ITHACA call for collaboration, social media engagement, partnerships with syndrome-specific foundations, and collaboration with colleagues, we successfully recruited a cohort of adult individuals with Coffin-Siris syndrome. A comprehensive questionnaire was utilized to assess their phenotypes.

Results: We included 35 adult individuals with Coffin-Siris syndrome, revealing a broad spectrum of phenotypes. This cohort particularly emphasizes the high percentage of overweight/obesity, visual impairment, and behavioral anomalies.

Conclusion: Initiating our study as a collaborative project, we aimed to investigate and document the adult phenotype of Coffin-Siris syndrome. We will present the phenotypic data from our adult cohort of affected individuals, delineating the evolving features of this syndrome. The collected data allows for a more accurate prediction of risks and is of great value to affected individuals and their caregivers in making preventive and therapeutic decisions.

Background/Objectives: Heterozygous inactivating variants in the ETS2 repressor factor (*ERF*) gene, encoding a transcriptional regulator negatively controlling RAS-MAPK signaling, have been associated with syndromic craniosynostosis involving various cranial sutures and Chitayat syndrome, an ultrarare condition with respiratory distress, skeletal anomalies, and facial dysmorphism. Recently, a single patient with craniosynostosis and a phenotype resembling Noonan syndrome (NS), the most common disorder among the RASopathies, was reported to carry a de novo loss-of-function variant in *ERF*.

Methods: Here, we clinically profile 20 individuals from 10 unrelated families carrying different germline heterozygous mutations in *ERF* and showing a phenotype reminiscent of NS.

Results: The majority of subjects presented with a variable degree of global developmental and/or language delay. Their shared facial features included absolute/relative macrocephaly, high forehead, hypertelorism, palpebral ptosis, wide nasal bridge, and low-set/posteriorly rotated ears. Stature was below the 3rd centile in two-third of the individuals, while no subject showed typical NS cardiac involvement.

Notably, craniosynostosis was documented only in two unrelated individuals, while a dolichocephalic aspect of the skull in absence of any other evidence supporting a premature closing of sutures was observed in other 9 subjects. Unilateral Wilms tumor was diagnosed in one individual. Variants were nonsense and frameshift changes, supporting *ERF* haploinsufficiency.

Conclusion: These findings provide evidence that loss-of-function variants in *ERF* cause a disorder resembling NS with or without craniosynostosis, and allow a first dissection of the molecular circuits contributing to MAPK signaling pleiotropy.

Grants: Italian_Ministry_of_Health (5 × 1000_2024 and PNRR-MR1-2022-12376811 and 5 × 1000_2023), Fondazione_AIRC (IG28768), and European_Joint_Programme_on_Rare_Diseases (NSEuroNet).

Consortium: The SOGRI Consortium

Background/Objectives: Imprinting disorders comprise a group of diseases which molecular basis is due to defects in the pattern of methylation in specific regions, which either inactivate or activate specific genes. To date, several syndromes associated

with defects in the methylation pattern have been identified, including Beckwith Wiedemann syndrome and Silver-Rusell syndrome. In some cases, multilocus imprinting disturbances (MLID) have been identified, in cases in which more than one methylation loci is altered.

Methods: A cohort of 54 patients with BWS (n = 99) and SRS (n = 13) who already have a methylation defect at the pathology-associated locus (11p15) was analyzed. Methylation analysis was performed by two techniques: (1)MS-MLPA using the commercial kit MRC-Holland ME034 (MRC Holland, Amsterdam, Netherlands, Netherlands). This kit allows the analysis of 11 different imprinting regions. (2) Methylation arrays. Also, available DNA from mothers of patients with MLID have been also analyzed.

Results: In, approximately, 20% of the total number of patient studied, a Multi-locus Imprinting Disturbance was found.

Conclusion: A significant percentage of patients with BWS and SRS syndromes have methylation alterations in more than one locus. These "additional" alterations may be associated with a much more heterogeneous clinical features of the patients, confirming the multilocus syndrome. There are maternal genes associated with multilocus syndromes in their offspring. A consensus should be established for the clinical and molecular testing and reporting of patients with multilocus imprinting disturbances.

P13.097.C Expanding the clinical and molecular spectrum of Kabuki syndrome cases

Yusuf Dogan[1], *Enise AVCI DURMUŞALİOGLU[1], Filiz Hazan[2], Turkan Turkut Tan[1], Tahir Atik[1], Esra Isik[1], Ozgur Cogulu[1]*

[1]Ege University, Department of Child Genetics; [2]Dr. Behçet Uz Children's Education and Research Hospital, Department of Medical Genetics

Background/Objectives: Kabuki syndrome is a rare disorder characterized by typical facial features, minor skeletal anomalies, fetal fingertip pads, intellectual disability, and growth retardation, caused by variants in the *KMT2D* (56–76%) or *KDM6A* (5–8%) genes. This study aims to expand the clinical and molecular spectrum of Kabuki syndrome.

Methods: This study included ten Kabuki syndrome cases followed at the Department of Pediatric Genetic Diseases. The clinical and molecular findings were evaluated retrospectively.

Results: Ten Kabuki syndrome cases, aged 9 months to 14 years, were referred to the Pediatric Genetic Diseases outpatient service due to developmental delay and dysmorphic features. Developmental delay, intellectual disability, and renal anomalies were present in the majority of the cases. Additionally, strabismus, coloboma, cleft palate, atrial and ventricular septal defects, horseshoe kidney, kidney atrophy, and anal stenosis were observed. Using next-generation sequencing (NGS), eight variants were identified in *KMT2D*; five of them were truncating, one was missense, and one was in-frame deletion. NGS-based copy number variation (CNV) analysis revealed a 1699 bp heterozygous deletion covering exons 5 and 9 of the *KMT2D* gene. All of the variants were classified as either likely pathogenic or pathogenic. Furthermore, the KDM6A gene also had two variants: the missense variant (c.871G>A), inherited from the unaffected mother, and the novel frameshift variant (c.1302del), which was likely pathogenic.

Conclusion: Clinical manifestations in Kabuki syndrome exhibit a wide spectrum. NGS aids in refining the diagnosis and providing appropriate genetic counseling. NGS-based CNV analysis serves as a helpful method for identifying deletions responsible for Kabuki syndrome.

Conflict of Interest: None declared

P13.098.D Branchio-oto-renal (BOR) syndrome caused by a deep intronic variant in EYA1 in a Danish family

Marie Lorans[1], *Pernille Axél Gregersen[1;2;3]*

[1]Department of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark, Denmark; [2]Centre for Rare Diseases, Pediatrics and Adolescent Medicine, Aarhus University Hospital, Aarhus, Denmark, Denmark; [3]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark, Denmark

Background/Objectives: Branchio-oto-renal (BOR) syndrome is a rare autosomal dominant condition characterised by: 1) branchial arch defects; 2) structural defects of the ear; and 3) renal malformations. We describe a deep intronic variant in the *EYA1* gene that segregates with BOR-syndrome in a Danish family.

Methods: DNA from the index patient was processed and sequenced using an Illumina NovaSeq 6000 instrument. The whole genome sequencing (WGS) data was analysed with VarSeq software 2.4.0 (Golden Helix). SpliceAI prediction was used to evaluate splice variants. Sanger Sequencing was used to test relatives. In-vitro exon-trapping assay was applied to test the functional effect of splice-variants.

Results: A previously unreported heterozygous deep intronic variant in *EYA1*; NM_000503.6(EYA1):c.556+2123C>T, (p.(?)) was identified in the proband and 3 affected relatives. According to SpliceAI, the C-to-T transition creates a cryptic splice donor site in intron 7, 2 bp upstream of the variant and a cryptic acceptor site 118 bp upstream of the variant. The exon-trapping assay produced altered splicing products for the variant-specific sequencing libraries when compared to wild-type sequencing libraries. A transcript with inclusion of a 117 bp long cryptic exon was exclusively observed in the variant-specific sequencing libraries. This abnormal transcript is expected to undergo nonsense mediated decay resulting in *EYA1* haploinsufficiency.

Conclusion: We identified a deep intronic variant in *EYA1* that segregates with BOR syndrome. To the best of our knowledge, this is the first report of a causative deep intron variant in BOR-syndrome. Our results demonstrate the clinical utility of WGS in cases with highly specific phenotypes.

Pozzuoli, Italy; [10]University of Genoa, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Genoa, Italy; [11]IRCCS Giannina Gaslini Institute, Pediatric Neurology and Muscular Disease Unit, Genoa, Italy

Background/Objectives: Bohring-Opitz Syndrome (BOS) is a rare neurodevelopmental disorder caused by germline variants in the *ASXL1* gene. Its clinical presentation is heterogeneous but is mainly characterized by feeding difficulties in the neonatal period, hypotonia, seizures, the BOS posture, myopia, and distinct craniofacial features. Here, we report four novel cases, all harboring mutations in *ASXL1*.

Methods: *ASXL1* variants were identified by whole exome sequencing (WES) or direct sequencing, segregation analysis was performed to determine whether the variants were de novo. Additionally, we conducted a comprehensive review of the clinical and molecular characteristics documented in the existing literature on BOS.

Results: Three different truncating variants in *ASXL1* were identified: c.1544_1545del [p.(Val515Glyfs13)], located in exon 12, was found in two patients; c.3637_3640del [p.(Leu1213Ilefs3)] and c.3424C>T (p.Gln1142*), both in exon 13. The first variant is expected to undergo nonsense-mediated mRNA decay (NMD), while the mutations located in exon 13 are expected to escape this process. Including the variants in this report, a total of 36 pathogenic variants have been identified so far, with one of them located in exon 11 and the rest clustered in exons 12 and 13. No clear genotype-phenotype correlations have been established.

Conclusion: This study presents a comprehensive analysis of four previously unreported cases of BOS, contributing to the expansion of the molecular and clinical understanding of the syndrome. The novel patients exhibit distinctive clinical features that align with the diverse spectrum characterizing this syndrome, our clinical data review further enriches the knowledge of the presentation and underlying genetic variations.

CYTOGENETICS, GENOME VARIATION AND ARCHITECTURE

P14.001.C Blindspots in short-read genome sequencing for classic chromosomal rearrangements

Lucas GAUTHIER[1], *Claire Caillot[1], Mathilde Pujalte[1], Marianne Till[1], Damien Sanlaville[1;2], Nicolas Chatron[1;2]*

[1]Genetics Department, Lyon University Hospital, Lyon, France; [2]Univ Lyon, Univ Lyon 1, CNRS, INSERM, Physiopathologie et Génétique du Neurone et du Muscle, UMR5261, U1315, Institut NeuroMyoGène, Lyon, France

Background/Objectives: Short-read Genome Sequencing (srGS) has emerged as a powerful tool in medical genetics, providing comprehensive insights into the genetic landscape of individuals. However, detecting structural variants may pose significant challenges, particularly those involving repeated sequences as satellites repeats, telomeric and centromeric repeats, transposons or low complexity regions.

Methods: We previously described the first case of insertion of an alpha satellite DNA outside centromeric and regions (Giannuzzi et al., 2021) and herein present two other cases where default structural variant calling failed at the characterization of a karyotype-visible event. The first case is the recurrent t(11;22)(q23;q11.2) translocation, a clinically relevant variant obscured by the presence of low complexity regions in the chromosome 22 region but where we could fetch out spanning reads through manual inspection of alignments. The second case entails an addition of 57Mb of 8q telomeric region on top of the short arm of a chromosome 4. Manual inspection of read alignments identified reads spanning the junction between the chromosome 8 added region and the TTAGGG hexamere repeat. Only the combination of genome sequencing and karyotype could fully resolve this post-telomere addition.

Results: These case reports have allowed us to suggest new layers to our structural variant calling pipeline to detect such variants reputed invisible to srGS but still present in the data.

Conclusion: These three observations affect large repeats that can also be challenging for long-read sequencing technologies. We emphasize the need to describe these limitations and work on technological improvements to deliver the full power of these technologies to patients.

P14.002.D Mind the reference gap

Kristine Bilgrav Saether[1], *Claudia Carvalho[2], Jakob Schuy[1], Adam Ameur[3], Ann Nordgren[1], Jesper Eisfeldt[3], Anna Lindstrand[1]*

[1]Karolinska Institutet, Molecular Medicine and Surgery; [2]Pacific Northwest Research Institute; [3]Science for Life Laboratory

Background/Objectives: Inversions are a class of structural variants that are especially challenging to detect due to their copy number neutral state as well as their association with repetitive regions. Reference genome builds such as GRCh37 and GRCh38 lack sequence across large regions of centromeric, telomeric and repetitive DNA. This makes detection of structural variants, such as inversions particularly challenging, due to their association with these regions. The recently published Telomere to Telomere (T2T) reference genome offers a continuous sequence spanning the previously missing regions, promising heightened structural variant detection and improved mapping.

Methods: We reanalyzed five cytogenetically visible inversions previously unresolved using GRCh37 or GRCh38, short read genome sequencing (srGS) and in certain cases also long read GS (lrGS). Next, by pairwise comparison between five human/primate reference genomes, GRCh37, GRCh38, T2T, the chimpanzee and bonobo, we characterize Differential Reference Regions (DRRs), genomic segments that were missing in at least one reference genome.

Results: Two inversions were resolved where the breakpoints were located in regions missing in reference genomes GRCh37 or GRCh38. We found 217 Mb of DRR sequence missing from GRCh38 and present in T2T. Finally, we characterize the presence of DRRs using srGS from 100 healthy Swedish individuals.

Conclusion: Our findings call attention to the importance of complete, high-quality reference genomes for accurate structural variant detection. This seems to be especially important for inversions that often elude detection in both clinical and research analysis of srGS data.

Grants: 2019-02078, FO2022-0256, Stockholm City Council, NIGMS R01 GM132589.

Background/Objectives: Facioscapulohumeral muscular dystrophy (FSHD), an hereditary myopathy, has prevalence of 1:20.000. FSHD1 is associated with the reduction of the number of D4Z4 tandem repeats (DRA) located at 4q35. FSHD2 classifies 5% of FSHD clinical cases with no DRA. In 80% of FSHD2 cases heterozygous mutations have been reported in the chromatin remodeling factor SMCHD1 which is required for normal DNA methylation and transcriptional repression. Pathogenic variants in SMCHD1 have been also associated with Bosma Syndrome and hypopituitarism. Considering this clinical heterogeneity, we investigated if D4Z4 methylation status serves as a readout of the biological effects of *SMCHD1* variants in relation with different phenotypes.

Methods: We collected aggregated sequencing data from six centers in Italy, France and Finland. Three centers provide diagnosis for muscle genetic diseases and three investigate genetic syndromes and monogenic diseases.

Results: We evaluated sequencing data from 22.370 samples and identified 44 *SMCHD1* variants of interest. DNA samples from 22 subjects carrying 18 variants underwent T2T-based methyl-seq analysis using a customized molecular and bioinformatic approach to test D4Z4 methylation status. Reduced D4Z4 methylation was observed in 9 subjects presenting pathogenic variants: 8 from the myopathic and 1 from the non-myopathic cohorts. These findings indicate that our D4Z4 methylation assay can be applied to functional investigation of *SMCHD1* variant biological effect.

Conclusion: Our results point out the importance of reusing genomic data from ample cohorts to extend and deepen the correlation between gene variants and the observed individual phenotypic variability for preventing biased interpretations.

Background/Objectives: Short tandem repeats (STRs) are DNA sequences composed of multiple copies of 1-6bp motifs. STRs are ubiquitous in the human genome, and some are prone to expansions that cause disease. Many pathogenic STR expansions have highly variable genomic sequences, both at the individual and population scale. Motif composition, sequence length and CpG methylation often dictate disease onset and severity. An ideal approach to identifying pathogenic STR expansions requires accurate assessments of all these properties in a single assay.

Methods: We describe a robust amplification-free protocol to generate long-read HiFi sequencing libraries containing a panel of loci associated with 20 pathogenic STR expansions. The protocol can be multiplexed to sequence up to 48 samples at 20 to 1000x coverage per locus in one PacBio sequencing run. We measured accuracy in 86 samples with validated pathogenic expansions at loci including *CNBP*, *DMPK*, *RFC1* and *C9orf72*. We tested 1720 sample-expansion combinations, including technical replicates, for expansions between 66bp and >10kb.

Results: Our assay correctly categorized all (86/86) expansions, including the detection of hypermethylation in the *FMR1* expansion and differentiating the pathogenic AAGGG motif in *RFC1*. We identified additional expansions in *FXN*, *RFC1* and *TCF4*, consistent with these loci having carrier frequencies between 1:50 and 1:20. Excluding these three genes, we found no unexpected expansions (0/1405) in any sample-loci combinations.

Conclusions: The protocol provides an accurate description of the tissue-level molecular landscape of various pathogenic STRs and is adaptable to other loci in the human genome.

P14.005.C Phenotypic variability in rare NF2 patients carrying 22q12 microdeletions: exploring genetic and epigenetic mechanisms

Viviana Tritto[1], *Micol Pozzi*[1], *Rosina Paterra*[2], *Arianna Borghi*[2], *Serena Redaelli*[3], *Marica Eoli*[2], *Paola Riva*[1]

[1]*University of Milan, Department of Medical Biotechnology and Translational Medicine, Segrate (Milan), Italy;* [2]*IRCCS Foundation Carlo Besta Neurological Institute, Unit of Molecular Neuro-Oncology, Milan, Italy;* [3]*University of Milano-Bicocca, School of Medicine and Surgery, Monza (MB), Italy*

Background/Objectives: Neurofibromatosis type 2 (NF2) is an autosomal dominant tumor-prone disorder, mainly due to point mutations or intragenic deletions of the *NF2* gene, encoding Merlin protein, that inhibits proliferation pathways. Rare NF2 patients carrying 22q12 microdeletions, characterized by a severe and variable phenotype, have also been described. We characterized three NF2 microdeletion patients with a complex phenotype to evaluate the incidence of 22q12 microdeletions and the role of specific genetic/epigenetic mechanisms.

Methods: We carried out aCGH, in silico analysis, gDNA qPCRs, Long-Range PCRs, and Sanger sequencing to ascertain the deletions' extent, gene content, and breakpoints. To study a possible position effect generated by the chromatin alteration, we performed in silico analysis of 22q12 TADs and regulatory elements, and gene expression analysis by qPCR on 12 genes flanking patients' deletions. The possible phenotypic contribution of variants identified by Whole Exome Sequencing was evaluated.

Results: Patients 690, 568, and 647 show deletions spanning 2.35, 3.08, and 4.64 Mb, respectively, involving 59-65 genes and 5-9 TADs. The position effect on some flanking genes was detected by qPCR. Genotype-phenotype correlation studies reveal a possible association between *AP1B1* gene haploinsufficiency and cognitive impairment in patients 568 and 647. Furthermore, patient 647 showed *MN1* gene deletion possibly related to Toriello-Carey syndrome, and *SHANK3* gene duplication, which could be linked to neurobehavioral disorders.

Conclusion: Our results pinpoint the need to identify the incidence of 22q12 microdeletions in NF2 patients, suggesting a novel prognostic significance of these genetic lesions, contributing to provide genotype-phenotype correlations.

P14.006.D Identifying the role of somatic copy number variations in Parkinson's disease using single-cell whole genome sequencing

zeliha gozde turan[1;2], *Ester Kalef-Ezra*[1;2], *Dominic Horner*[1;2], *Caoimhe Morley*[1], *Diego-Perez Rodriguez*[1], *Zane Jaunmuktane*[1;2;3], *Jonas Demeulemeester*[2;4;5;6], *Fritz Sedlazeck*[2;7], *Christos Proukakis*[1;2]

[1]*UCL Queen Square Institute of Neurology, London, United Kingdom;* [2]*Aligning Science Across Parkinson's (ASAP) Collaborative Research Network, United States;* [3]*UCL Queen Square Institute of Neurology, Queen Square Brain Bank for Neurological Disorders, London, United Kingdom;* [4]*The Francis Crick Institute, Cancer Genomics Laboratory, London, United Kingdom;* [5]*KU Leuven, Department of Oncology, Leuven, Belgium;* [6]*Center for Cancer Biology, Leuven, Belgium;* [7]*Baylor College of Medicine, Human Genome Sequencing Center, Houston, United States*

Background/Objectives: Parkinson's disease (PD) is the most common neurodegenerative movement disorder with partly unexplained etiology. The heritability of PD is ~30%, leading to further research into other potential contributors, such as somatic copy number variations (CNVs).

Methods: To determine the role of CNVs on PD pathology, we generated and analyzed low-coverage single-cell whole genome sequencing data. We focused on neuronal (NeuN-positive) and non-neuronal (NeuN-negative) cell types from the cortex of three PD patients, three age-matched controls, and one individual with incidental Lewy body disease (ILBD). Out of the 532 analyzed cells, 90% passed the quality control criteria. Additional brain samples, including those from the substantia nigra, are being processed.

Results: The percentage of cells with at least one CNV was highest in the ILBD case (43.8%), followed by controls (14.1%), and then PD patients (7.6%) ($p < 0.001$). Notably, in PD, the number of NeuN-negative cells with at least one CNV is 3.39 times greater than that of NeuN-positive cells ($p = 0.004$). In contrast, this ratio is 1.37 for the control group ($p = 0.37$). These findings suggest that neurons in PD might be more susceptible to the CNV load, potentially resulting in increased cell death. This could have significant effects on both the progression and severity of the disease.

Conclusion: This study contributes to a better understanding of complex PD pathology and opens new avenues for further research into the factors influencing PD.

Grants: This research was funded in whole by Aligning Science Across Parkinson's [564669] through Michael J. Fox Foundation for Parkinson's Research.

P14.007.A The distribution of single nucleotide polymorphisms across consecutive exons and introns of the human genome

Magdalena Fraszczak[1], *Jakub Liu*[1;2], *Magda Mielczarek*[1;2], *Paula Dobosz*[2;3], **Joanna Szyda**[1;2]

[1]*Wroclaw University of Environmental and Life Sciences, Biostatistic Group, Department of Genetics, Wroclaw, Poland;* [2]*Poznan University of Medical Science, University Cancer Diagnostic Center, Poznan, Poland;* [3]*University of Warsaw, Institute of Genetics and Biotechnology, Warsaw, Poland*

Background/Objectives: Single nucleotide polymorphisms (SNPs) are the most common type of genomic variation. We explored the number of SNPs in the human genome, focusing on differences in SNP counts among consecutive introns and exons.

Methods: The analysed cohort consisted of 41836187 SNPs identified in the genomes of 1222 individuals of Polish origin. HSA01 and HSA22 were selected for downstream analysis representing of two markedly different DNA molecules. Statistical analysis consisted of testing the variability of SNP counts between genes, among exons/introns, and the pairwise differences in SNP counts between exons/introns.

Results: Considering exons, the number of SNPs differed significantly between genes and between exons. Pairwise comparisons showed a significant excess of SNPs in the outer exons (1st and last) in HSA01 (all genes) and in HSA22 (all genes except genes with 6, 7, 8 exons). For introns, the number of SNPs

differed significantly between genes, while the variability among introns was significant in all genes except for genes with 4, 6, 7 introns on HSA22. Pairwise comparisons demonstrated significantly higher SNP counts in the first intron in HSA01, with a less clear pattern in HSA22.

Conclusion: The special role of the first intron as well as the first and terminal exon has been discussed in the literature, where it was demonstrated that these functional units are characterised by sequence features distinct from the internal exons/introns. This phenomenon was also demonstrated by our study that utilised SNPs identified in a well-defined population representing individuals of Polish origin, albeit yielding contradictory results.

Conflict of Interest: None declared

P14.008.B Spatial exploration of human germline mutational signatures

Rahul Sharma[1], *Marcin Karpinski*[1], *Slavé Petrovski*[1], *Keren Carss*[1], *Dominik Glodzik*[2], *Dimitrios Vitsios*[1], *Xueqing Zou*[1]

[1]*AstraZeneca, Centre for Genomics Research, Discovery Sciences, R&D, Cambridge, United Kingdom;* [2]*Harvard Medical School, Department of Biomedical Informatics, Boston, United States*

Background/Objectives: Mutational signature analysis has been proven instrumental in gaining insights into underlying DNA damage and repair processes, particularly in cancer genomics. In contrast, germline mutational processes have received negligible attention. This study explores human germline single nucleotide variations (SNVs) to comprehensively understand germline mutagenesis and its dependence on genomic features and location.

Methods: We created spatial mutational profiles by binning filtered SNVs for 44,589 samples with EUR ancestry from Genomic England (GE) 100K genomes project into 10,000 base-pairs non-overlapping windows. For unique and robust mutational signatures, we employed an advanced volume-regularized non-negative matrix factorization approach.

Results: We identified eight SNV germline mutational processes, three strand-dependent and five strand-independent. Strand-dependent processes were associated with endogenous processes that create mutation strand bias, including transcription-coupled repair on transcribed strand and higher replication errors on lagging strand. Specific signatures correlate with replication timings, distribution of CpG islands, gene bodies, or specific chromatin regions. Several signatures align with previous TopMed dataset findings underlining their robustness. Notably, four GE germline mutational signatures have >0.85 cosine similarity with four COSMIC cancer signatures.

Conclusion: We obtained statistically robust germline mutational signatures from ~45K GE samples, demonstrated their variation spatially across the genome and revealed their associations with different genomic features. Future study will extend the analysis to double nucleotide substitutions, indels, and structural variants to identify all possible germline mutational processes. Such studies will advance our understanding of how germline mutations cause diseases, potentially revealing new avenues for diagnosis and treatment.

P14.009.C De novo structural variation in the Lithuanian population from short-read WGS data

Ingrida Domarkienė[1], *Giorgi Sokhadze*[1], *Alina Urnikyte*[1], *Laura Pranckeniene*[1], *Svetlana Dauengauer-Kirlienė*[1], *Aušra Matulevičienė*[1], *Ingrida Pylipienė*[2], *Vaidutis Kučinskas*[1]

[1]*Department of Human and Medical Genetics, Institute of Biomedical Sciences, Faculty of Medicine, Vilnius University;* [2]*Clinic of Children`s Diseases, Institute of Clinical Medicine, Faculty of Medicine, Vilnius University*

Background/Objectives: Structural variants (SVs) can have profound consequences in evolution and human disease. There is an increasing recognition in the scientific community of the need to explore SVs across different populations. Identifying de novo SVs is crucial for exploring variation diversity, the origins of disorders and assessing their occurrence rates, which is key to understanding evolutionary milestones in population history.

Methods: Illumina short-read whole genome sequencing (WGS) data of 25 families (trios) of Lithuanian origin from the general population was generated (on Illumina instrument). Data was of good quality (Q30 value: >90%), average coverage ~38x. SVs were called with *DELLY* and *LUMPY* software. De novo SVs were filtered by using at least 70% overlap. Called SVs (>49 bp) were annotated by using *AnnotSV*.

Results: The algorithms identified various types of de novo SVs. DELLY detected deletions (3%) and translocations (82%), while LUMPY identified duplications (11%) and inversions (4%). Two individuals excluded as outliers due to a significantly higher number of SVs. Average number of de novo SVs per person was approximately 6 with a range from 0 to 19 SVs. About 70% of de novo SVs were classified as singletons. Nearly half of these SVs were found to encompassed genes suggesting potential functional implications.

Conclusion: It is the first attempt to characterise de novo SVs from the short-read WGS data in the Lithuanian population. Further detailed SV characterization and integrative analysis will provide useful information on local human population genomic variation and will add data to the databases.

Grants: ANELGEMIA (No.S-MIP-20-34) funded by the LMTLT.

Palacky University Olomouc, Institute of Molecular and Translational Medicine, Olomouc, Czech Republic

Consortium: CzechArray

Background/Objectives: CNVs are a common cause of various genetic disorders and occur at defined genomic regions that are particularly prone to recurrent deletions and duplications and often exhibit variable expressivity and incomplete penetrance. Classification of the variants diverges. In our study we focused on selected RecCNVs: del/dup -1q21.1(*GJA5, RBM8A*), 2p16.3(*NRXN1*), 2q13(*NPHP1*), 3p26.3(*CNTN4*), 9p24.3(*DOCK8*), 15q11.2 (*NIPA1,2*), 15q13.3(*CHRNA7, OTUD7A*), 16p13.11(*MYH11*), 16p11.2 (*SH2B1, TBX6*), 17q12 (*HNF1B*), 22q11.2 (*TBX1*), Xp22.33-31(*STS, SHOX*) to determine their prevalence, impact and inheritance pattern. This group we compared to the group of the rare well-known pathogenic variants (RareCNVs): del/dup - 1q36.3, 4p16.3 (WHS), 5p15 (cri-du-chat), 7q11.23 (WBS), 15q11.2-q13 (PW/AS), 17q11.2 (PTLS, SMS), 17p13.3 (MDS), 22q11.2(DGS) detected in our cohort.

Methods: A cohort of 2342 patients was tested with microarray (Agilent/Affymetrix) and/or MLPA (MRC Holland) (SALSA MLPA microdeletions 1 and 2, Subtelomeres, Autism, DiGeorge, PWS/AS).

Results: We assessed 11 deletions and 12 duplications in the RecCNVs group (mostly associated with neurodevelopmental disorders) and 8 deletions and 4 duplications (associated with multi-systems disorders) in the RareCNVs group. The overall prevalence of the variants in RecCNVs and RareCNVs was 4.52 % and 1.67 % resp. Healthy carriers (parents or siblings) were detected in 1.28 % vs 0.09 %. Variants were inherited in 1,4% and 0.17 % in RecCNV and RareCNV group resp.

Conclusion: RecCNVs are widely disseminated and frequently inherited in the population contrary to the RareCNVs. This should be considered in genetic counselling especially in prenatal diagnosis.

P14.011.A A high resolution SNP array increases the diagnostic yield in genomic testing of undiagnosed neurocognitive disorders(UDD) and rare disease

David Francis[1], *Paul Kalitsis*[1], *Vivian Wei*[1], *Vida Petrovic*[1], *Simon Sadedin*[1;2], *Meghan Wall*[1]

[1]*MCRI, VCGS, Parkville, Australia;* [2]*The University of Melbourne, Pediatrics, Parkville, Australia*

Background/Objectives: SNP Microarrays have been utilised as the gold standard for detecting recurrent and novel pathogenic CNVs in UDD. High resolution arrays have tested these patients sporadically for detection of intragenic CNVs with varying detection rates. In this study we utilised a SNP microarray platform designed for intragenic CNV detection, the illumina GDA-Cyto.

Methods: Validation of the GDA-Cyto platform against whole genome (WG) data showed sensitivity down to single exon detection (dependant on probe coverage). The platform was implemented for confirmation of ES and WG CNVs, detection of 2nd hit CNVs in AR genes and more recently for UDD and rare disease cases post normal standard array or ES/panel (431 cases).

Results: The 431 cases showed a high pathogenic detection rate overall of 9.5% over standard genomic testing rates, and for specific clinical referrals, intellectual disability (ID) (17%), Epilepsy and ID (9.3%), capillary malformation disorders (25%) and stature/skeletal (25%). Data analysis showed that most pathogenic findings were partial or intragenic deletions (75%), non-mosaic (98%), involved autosomal dominant genes (70%), loss of function (100%), were 32kb in size(median) and showed 3 exon (median) involvement. Cases which involved untranslated regions, mosaicism, the first or last coding exons and enhancer regions were likely to be missed by standard testing.

Conclusion: : Clinical referrals showed a normal GSA standard MA or ES result, high resolution microarray being the next affordable genomic test. This study informs diagnostic laboratories and clinicians of high resolution microarray utility in their genomic workflows.

P14.012.B Gene Expression Profiles Induced by RNA interference on NSD1 Δ5Δ7, and NSD1 Δ19–23 isoforms in Fibroblast Cells.

Giuseppina Conteduca[1], *Davide Cangelosi*[2], *Chiara Baldo*[3], *Alessia Arado*[3], *barbara testa*[3], *Michela Malacarne*[3], *gilberto filaci*[1], *Domenico Coviello*[3]

[1]*IRCCS San Martino, Biotherapy, Genova, Italy;* [2]*IRCCS Giannina Gaslini, Clinical bioinformatics unit, Genova, Italy;* [3]*IRCCS Giannina Gaslini, Human Genetics, Genova, Italy*

Background/Objectives: Germline variants in NSD1 gene are responsible of Sotos syndrome (SoS), while somatic variants promote neoplastic cell transformation. Molecular pathways affected by NSD1 variants are to date uncharacterized. Our previously studies, showed three alternative RNA isoforms of NSD1 present in fibroblast cells lines (FBs): the canonical full transcript and 2 alternative transcripts, indicated as AT2 (NSD1 Δ5Δ7) and AT3 (NSD1 Δ19–23 5'end).

Methods: In order to elucidate the role of NSD1 isoforms in different molecular pathways, NSD1 isoforms expression was suppressed by siRNA knockdown in FBs cultures. In this study, using microarray gene expression analysis, transcriptome data was explored.

Results: We demonstrate that all 3 isoforms are involved both in cell cycle regulation and in tumoral and neoplastic development. We showed that one NSD1 isoform AT2 target is ARP3 actin-related protein 3 homolog B (ACTR3B). It may act downstream of the stress fibers and bundle of actin filaments formation and it might mediate the cellular division mechanisms. In vitro findings showed that loss of both NSD1 canonical isoform and AT2 isoform, impaired the ability of fibroblasts to regulate the actin cytoskeleton and we observed that this caused selective loss of the stress fibers.

Conclusion: Our findings provide novel insights of NSD1 function and demonstrate an essential role of NSD1 in regulating actin cytoskeleton and stress fibers formation in fibroblasts.

Hauner Children's Hospital, Department of Pediatric Neurology and Developmental Medicine, LMU - University of Munich, Munich, Germany; [5]Laboratoire CERBA, Saint-Ouen l'Aumône, France; [6]Department of Clinical Genetics, Medical Research Center Oulu and PEDEGO Research Unit, Oulu University Hospital and University of Oulu, Oulu, Finland; [7]Northern Finland Laboratory Centre Nordlab, Oulu, Finland; [8]Institute of Neurogenomics, Helmholtz Zentrum München, Munich, Germany; [9]Lehrstuhl für Neurogenetik, Technische Universität München, Munich, Germany; [10]Munich Cluster for Systems Neurology (SyNergy), Munich, Germany; [11]Department of Internal Medicine; Radboud Expertise Center for Immunodeficiency and Autoinflammation and Radboud Center for Infectious Disease (RCI), Radboud University Medical Center, Nijmegen, Netherlands

Background/Objectives: Next-generation sequencing has unraveled the genetic cause for many rare disease patients, but a significant number remain undiagnosed using standard-of-care tests. Here, optical genome mapping (OGM) identified structural variants (SVs) that have remained undetected by extensive prior genetic testing including exome and/or genome sequencing.

Methods: We performed OGM for 58 patient-parent trios and prioritized SVs using a two-step approach. First, we systematically identified all de novo SVs and subsequently we studied all rare inherited SVs. Potential pathogenic SVs were confirmed using orthogonal methods.

Results: On average, we identified 6,295 SVs >500bp per proband, primarily insertions (69.8%) and deletions (27.0%). In total, we identified 11 de novo SVs, including 3 insertions, 3 deletions, 3 duplications, 1 translocation, and 1 inversion. These SVs potentially impacted multiple candidate disease-associated genes, such as *ACSL6*, *CAP2*, *FAM8A1*, *FGF9*, *KIF13A*, *MSI2*, *NSF*, and *NUP153*. Additionally, on average per sample, we identified 11 inherited SVs overlapping with (the regulatory region of) an established OMIM disease gene, including a homozygous deletion affecting *SCN9A* causing congenital indifference to pain and a ~115kb inter-chromosomal insertion in the CMTX locus at Xq27.1 causing Charcot-Marie-Tooth disease, both leading to a novel diagnosis. In total, we identified (likely) pathogenic SVs in two individuals and candidate disease-causing SVs in five other individuals.

Conclusion: OGM enables the accurate detection of challenging de novo SVs. We detected a de novo SV mutation rate per genome of 0.19. Overall, our results suggest a potential additional yield of 12%, demonstrating that OGM can unravel previously hidden SVs in extensively tested patients.

P14.014.D Prenatal suspicion of monosomy X (NIPT) - postnatal complex aberrant X-chromosome

Susanna Schubert[1], *Senta Schönnagel[1], Jana Knorr[1], Robin-Tobias Jauss[1], Anne-Christin Teichmann[1]*

[1]Institute of Human Genetics, University of Leipzig Medical Center, Leipzig

Background/Objectives: We present a 1.5-year-old female patient without clinical manifestations. Prenatally, the fetus was notable for borderline nuchal translucency only, and there was suspicion of monosomy X in the non-invasive prenatal testing (NIPT). Prenatal invasive diagnostic was not performed.

Methods: For initial postnatal testing only EDTA-blood was available, so we conducted a short tandem repeat (STR) analysis to validate the NIPT result. Following this, a series of diagnostic procedures, including MLPA, Exome sequencing, and cytogenetic analysis were performed to elucidate the complexity of the X chromosome. Finally, the methylation pattern was determined to check for X-inactivation.

Results: STR analysis identified three homozygous X chromosome markers, one showing a distinct peak height ratio. MLPA confirmed the presence of *SHOX*-gene but suggested a duplication Xp and deletion Xq, indicative of an Iso-Xp chromosome. Subsequent CNV (copy number variation) and cytogenetic analysis revealed X chromosome complexities, including duplication of the p-arm and centromere-near region, triplication of the interstitial q-arm, and a large deletion up to Xqter. Methylation pattern analysis identified abnormal CAG repeats, indicating a pathologically skewed X-inactivation in the patient.

Conclusion: Based on these findings, the patient exhibits a complex structurally abnormal karyotype characterized by a dicentric X chromosome. The 100% X-inactivation (non-random X-inactivation) of the aberrant paternal X chromosome suggests that the patient is likely to undergo normal development. However, potential issues such as puberty and menstrual abnormalities, along with a higher risk of primary ovarian insufficiency (as the deletion includes the POF1 region), are anticipated.

Background: *Arginine-glutamic acid dipeptide repeats*, encoded by the *RERE* gene at locus 1p36.23, is a nuclear receptor coregulator that positively regulates retinoic acid signaling. Monoallelic pathogenic variations of *RERE* have been associated with neurodevelopmental disorders with or without brain, eye, or heart abnormalities.

Methods: We performed a comprehensive structural analysis of an initially suspected de novo duplication of the *RERE* gene identified in a patient with non-syndromic intellectual disability, using Nanopore long-read sequencing, secondarily combined by optical mapping.

Results: Reanalysis of the profile of each CGH array probe revealed that the duplication partially involving the *RERE* gene could be consistent with a duplication-triplication-duplication rearrangement (DUP-TRP-DUP). Long-read sequencing confirmed the presence of the unbalanced DUP-TRP-DUP, but also provided two other major information. First, the rearrangement of the additional *RERE* locus was more complex than might appear, with an inversion of the last duplication of the *RERE* rearrangement: DUP-INV(TRP-DUP). Second, the complex structural variant, supported by optical mapping, was inserted into the locus 22q11.2, in a region with a pattern of repeated PATRR motifs at the breakpoint sites on chromosome 22, which appears to destabilize the region and increase the likelihood of insertions.

Conclusion: Long-read sequencing approaches have provided a comprehensive understanding of a highly complex structural variant involving the *RERE* gene while shedding light on its pathogenicity, which may act more as an environmental disorganization structural factor within the locus 22q11.2, rather than an abnormality of *RERE* itself.

P14.016.B Structural Characterization of Recurrent Duplications Involving *FGF12* by Long-Read Nanopore Sequencing

Jade Fauqueux[1], Jean-Pascal Meneboo[2], Caroline Thuillier[3], Celine Villenet[2], Roseline Caumes[4], Marion Gerard[5], nicolas gruchy[5], Martin Figeac[2], Jamal Ghoumid[1;4], **Thomas Smol**[1;3]

[1]Univ Lille, ULR7364 RADEME, Lille, France; [2]Univ Lille, CNRS, Inserm, CHU Lille, Institut Pasteur de Lille, US 41 - UAR 2014 - PLBS, Lille, France; [3]CHU Lille, Institut de Génétique Médicale, Lille, France; [4]CHU Lille, Clinique de Génétique, Lille, France; [5]CHU Caen, Service de Génétique, Caen, France

Background: Fibroblast growth factor 12, encoded by the *FGF12* gene, is a member of the fibroblast growth factor homologous factor family. FGF12 interacts with voltage-gated sodium channels and enhances their excitability by delaying rapid inactivation. Pathogenic variations within *FGF12*, characterized by de novo heterozygous point variants, have been associated with developmental and epileptic encephalopathies. Here, we investigate structural variations encompassing *FGF12* by long read approaches.

Methods: A structural analysis of de novo duplications involving the *FGF12* gene, in patients with epileptic encephalopathies, was performed. We realized a targeted long-read sequencing approach on the *FGF12* locus using adaptive sampling from Nanopore. The data were then confirmed by PCR and nested PCR, followed by Sanger sequencing of the respective amplicons.

Results: Targeted long-read sequencing, covering 1% of the genome with a focus on *FGF12*, achieved coverage of the region to a depth of approximately 16X, allowing observation of the targeted duplications. Analysis of the reads covering the duplication revealed the mechanism as a tandem direct duplication, which was confirmed by PCR and Sanger sequencing. Furthermore, the observation of repeated intragenic LINE sequences at the duplication not only underscored the involvement of the non-allelic homologous recombination mechanism but also contributed to the understanding of their recurrent nature.

Conclusion: Long-read approaches, through Nanopore sequencing, provide a means for the detection of tandem duplications within a segment of the *FGF12* gene and offer a comprehensive understanding of their recurrent nature within *FGF12*.

Grants: BPI 2022 CHU Lille

Consortium: InvFEST

Background/Objectives: Inversions are a special type of structural variants whose study has lagged behind due to their balanced nature and the presence of large inverted repeats (IR) at their breakpoints. New techniques are finally making possible to identify the full spectrum of human inversions. However, in most cases, just a limited number of individuals has been studied, which precludes the analysis of the effects of the detected variants. Here, we take advantage of long reads to generate and characterize an exhaustive catalogue of IR-mediated inversions.

Methods: We have developed a computational pipeline that uses Oxford Nanopore Technologies (ONT) long read data to genotype inversions. Using this method, we have interrogated 636 candidate inversions from different studies, ranging from 265 bp to 7.9 Mb and flanked by up to 190 kb long IRs, in a diverse set of 90 individuals.

Results: We detected both orientations in 218 inversions, validating 140 novel inversions, with frequencies ranging between 1-50%. We also show that ONT genotypes are highly accurate, matching perfectly previous experimental genotypes of 53 inversions. Importantly, additional structural variants were identified in 136 predictions, revealing the complexity of repeat-rich regions. Finally, some of these regions show discrepancies with the new Pangenome reference, suggesting that they might not be well resolved.

Conclusion: Long reads therefore have a great potential for the characterization of currently missed inversions and other complex genomic regions in multiple individuals, opening the door to determine their real functional impact.

P14.018.D Search for monogenic causes of Hashimoto's thyroiditis (HT) in a family with a history of early-onset HT

Vesna Boraska Perica[1], *Dean Kaličanin[1], Robert Belužić[2], Ana Barić[3;4], Marko Vuletić[3], Sanda Gračan[3], Vedrana Čikeš Čulić[5], Ante Punda[3], Veselin Škrabić[6], Maja Barbalić[7]*

[1]School of Medicine University of Split, Department of Medical Biology, Split, Croatia; [2]Rudjer Boskovic Institute, Division of Molecular Medicine, Laboratory for Metabolism and Aging, Zagreb, Croatia; [3]University Hospital of Split, Department of Nuclear Medicine, Split, Croatia; [4]School of Medicine University of Split, Department of Nuclear Medicine, Split, Croatia; [5]School of Medicine University of Split, Department of Chemistry and Biochemistry, Split, Croatia; [6]University Hospital of Split, Department of Pediatrics, Split, Croatia; [7]Faculty of Science University of Split, Department of Biology, Split, Croatia

Background/Objectives: Hashimoto's thyroiditis (HT) is a complex autoimmune disorder of thyroid gland. To date, only one monogenic form of HT has been identified. Our aim was to investigate monogenic causes of HT in a family with a history of early-onset HT.

Methods: Whole exome sequencing (WES) was performed in six family members with HT (four with early-onset HT diagnosed between 5-12 years of age) and three healthy family members in order to find candidate variants segregating with the disease. Following WES findings, ELISA for the substrate (5-hydroxytryptofan, 5-HTP) of the candidate gene (*TPH2*) was performed in all family members and 19 control individuals to assess the functional impact of the detected variant.

Results: Under an autosomal dominance model, we identified a rare missense variant (rs17110563, MAF (CEU) = 0.0017) in the *TPH2* (tryptophan hydroxylase 2) gene as the likely causative

variant. The *TPH2* gene encodes an enzyme responsible for converting L-tryptophan to 5-HTP, which is further converted into serotonin. The levels of 5-HTP were shown to be slightly lower in family members carrying the variant, compared to controls, however this difference was not statistically significant.

Conclusion: By exploring a large pedigree burdened with early-onset HT, we identified a candidate variant within *TPH2*, a gene involved in serotonin metabolism. While largely unexplored, recent studies indicate a potential association between decreased serotonin levels and hypothyroidism. In addition, *TPH2* is located in close proximity of another promising candidate, *TRHDE* gene, involved in thyroid-axis regulation, which warrants further research of this region in relation to HT.

P14.019.A Characterizing the genetic architecture of thousands of different outcomes using LDpred2-auto.

Ole Hansen[1], *Lucas Rasmussen*[1], *Clara Albiñana*[1], *Zhihong Zhu*[1], *Jakob Grove*[2;3;4], *Florian Privé*[1], *Bjarni Jóhann Vilhjálmsson*[1;2;5]

[1]*Aarhus University, NCRR, Aarhus, Denmark;* [2]*Bioinformatics Research Centre, Aarhus, Denmark;* [3]*Department of Biomedicine, Aarhus University, Aarhus, Denmark;* [4]*Aarhus University, Aarhus, Denmark;* [5]*Broad Institute of MIT and Harvard, Cambridge, United States*

Background: Understanding the genetic architecture of health outcomes is important when planning future genetic studies, as well as for developing personalized medicine strategies and public health interventions. Recently we presented an updated version of LDpred2-auto (Privé *et al*., AJHG 2023) that models the genetic architecture (e.g. polygenicity and selection coefficients) to improve the estimation of SNP-based heritability and the prediction of polygenic risk scores. This method only requires genome-wide association studies (GWAS) summary statistics.

Methods: Here we develop a LDpred2-auto pipeline and apply it to thousands of different human phenotypes using GWAS summary statistics that are made available in the GWAS Catalog (https://www.ebi.ac.uk/gwas/). This pipeline provides a comprehensive map of genetic architectures of those human traits. The output of this pipeline includes the estimates of polygenic score, heritability, polygenicity, and a selection coefficient. Additionally, we output a range of metrics and quality control measures making the user more informed.

Results: We estimate adjusted R2, polygenicity p, (SNP) h2, and selection coefficient α for many different disorders and phenotypes. We infer out-of-sample prediction accuracy of the scores, and when possible, observed out-of-sample prediction accuracy in the iPSYCH cohort.

Conclusions: Our research introduces a new systematic approach in large-scale genetic analysis, integrating biological and selection perspectives using LDpred2-auto. This will enhance our understanding of genetic architecture in general and for specific traits in particular.

P14.020.B *AGAP* duplicons underlie genomic instability at chromosome 10q11.22

Vincenza Simona Delvecchio[1], *Stefania Fornezza*[1], *William Harvey*[2], *Philip Dishuck*[2], *Evan Eichler*[2;3], **Giuliana Giannuzzi**[1]

[1]*University of Milan, Department of Biosciences, Milan, Italy;* [2]*University of Washington School of Medicine, Department of Genome Sciences, Seattle, United States;* [3]*Howard Hughes Medical Institute, Seattle, United States*

Background/Objectives: Chromosome 10q11.22 is a duplication-rich interval of our genome and among the latest to be fully assembled. It carries copy-number variable genes that have been associated with brain diseases and obesity. Here, we sought to characterize structural diversity at this locus and gain insights into mechanisms of genomic instability.

Methods: We performed a detailed analysis of the region in 94 haploid assemblies that were produced from a panel of 47 diverse samples by the Human Pangenome Reference Consortium. We validated the structures by Illumina-based copy-number genotyping and by distance between unique k-mers in Nanopore reads. We narrowed down the breakpoints to a few kbp intervals.

Results: We identified eleven alternative haplotypes differing in the copy number of two main and large (200 and 450 kbp) genomic segments and by a 700 kbp inversion polymorphism. The size disparity from the most common haplotype ranged from 20 kbp to 1.7 Mbp, with 2.4 Mbp difference between the shortest and the longest haplotypes. The boundaries between structurally variant intervals correspond to duplicons containing functional or pseudogenized *AGAP* copies that emerged in the last 25 million years of human evolution. Longer duplicons mediated the rearrangements and they were generally broken at different positions.

Conclusion: We discovered extensive structural diversity at the 10q11.22 locus that includes large duplications, deletions, and inversion toggling. Such genomic instability derives from non-allelic homologous recombination between high-identity duplicons associated with a Catarrhini-specific subgroup of the *AGAP* gene family. Our breakpoint analysis suggests general rules of the molecular mechanism of repeat-mediated rearrangements.

Background/Objectives: Chronic lymphocytic leukemia (CLL) is a disease with a very heterogeneous course and genetic background. Numerous somatic structural variants (SVs) have been linked to this malignancy, but underlying pathogenetic mechanisms are not yet fully understood. We employed Micro-C, a chromatin conformation capture method, on CLL patient samples with complex genomic rearrangements to investigate long-distance and SV-related interactions and their potential impact on disease behavior.

Methods: We selected 10 CLL cases with clonally expanded complex SVs as a suitable model to provide insights into disease biology. Chromatin crosslinking was carried out on B cells

separated from peripheral blood of the patients. Classical cytogenetics, chromosomal microarray and whole genome sequencing were available for them to evaluate the results comprehensively. EagleC and NeoLoopFinder tools were used to determine the CNV profile, perform CNV-aware contact matrix normalization, detect novel loops, topologically associating domains (TADs), and recreate a map of SVs and affected regions.

Results: Numerous SVs were detected, including insertions, deletions, and translocations, that were independently confirmed by other methods. We also identified novel loops and TADs caused by those aberrations, providing insights into the molecular consequences of detected SVs and mechanisms underlying the disease development.

Conclusion: We assume that chromatin conformation analysis has great potential for detecting genomic rearrangements and their molecular consequences, worth future studies on larger datasets.

P14.022.D Rearrangements of the *NUP98* gene in adult patients with de novo acute myeloid leukemia (AML)

Sarka Ransdorfova[1], *Jana Markova*[1], *Marie Valeriánová*[1], *Iveta Mendlikova*[1], *Kristina Rochlova*[1], *Zuzana Zemanova*[2], *Libuse Lizcova*[2], *Lenka Pavlistova*[2], *Anna Jonasova*[3], *jan valka*[1]

[1]*IHBT, Prague 2, Czech Republic;* [2]*Center of Oncocytogenomic, Institute of Medical Biochemistry and Laboratory Diagnostics, Prague 2, Czech Republic;* [3]*1st Medical Department, General University Hospital and First Faculty of Medicine, Prague 2, Czech Republic*

Background/Objectives: *NUP98* gene rearrangements (11p15.4) belong to cryptic recurrent genetic alterations in cytogenetically normal AML patients that are associated with poor prognosis. The most frequent *NUP98* fusion gene partner is *NSD1*. It occurs most frequently in children (16%) and young (2%) AML patients, and is rare in adults.

Methods: Since 2017, we examined the bone marrow cells of 470 newly diagnosed adult patients with AML using conventional karyotyping in combination with molecular techniques: FISH (Abbott, MetaSystems), mFISH/mBAND (MetaSystems). Fusion genes were detected by RT-PCR followed by direct sequencing.

Results: We identified *NUP98* gene rearrangements in nine cytogenetically normal patients (median age 53 years, three > 60 years). We confirmed t(5;11)(q35;p15.5) with *NUP98::NSD1* gene fusion in seven of these cases (7/470; 1.5%). Sequence analyses proved the NUP98-NSD1 transcript, arising from fusion of exon 12 of *NUP98* with exon 6 in the *NSD1* gene, in all of them. In two other patients, we proved t(11;12)(p15.4;p13.33) and t(7;11)(p15.4;p15.2) with a *NUP98::KDM5A* and *NUP98::HOXA9* gene fusion, respectively. *FLT3*/ITD was detected in all nine patients. Specific primers and probes have been designed to monitor minimal residual disease during therapeutic treatment of the patients. Four patients died (median OS 13 months). Five patients are alive, three after allogeneic bone marrow transplantation.

Conclusion: We demonstrated the occurrence of *NUP98* aberrations with *FLT3*/ITD in cytogenetically normal adult AML patients older than 60 years. Subsequent molecular analyzes of these rearrangements provided information important for precise monitoring of the course of therapy.

P14.023.A Evaluation of cytogenetic response in chronic myeloid leukemia with variant translocation

Marie Valeriánová[1], *Kristina Rochlova*[1], *Iveta Mendlikova*[1], *Hana Klamova*[2], *Adam Laznicka*[2], *Zuzana Zemanova*[3], *Sarka Ransdorfova*[1]

[1]*IHBT, Cytogenetics, Prague, Czech Republic;* [2]*IHBT, Prague, Czech Republic;* [3]*Institute of Medical Biochemistry and Laboratory Diagnostics, Center of Oncocytogenomics, Prague, Czech Republic*

Background/Objectives: Variant Philadelphia (Ph) translocations involving chromosomes 9 and 22 and one or more other chromosomes occur in 5-10% of newly diagnosed cases of chronic myeloid leukemia (CML). Some previous studies have suggested a suboptimal response to TKIs in variant translocations compared to classical CML. However, the prognostic impact of partner chromosome loci remains unclear due to insufficient data.

Methods: We analyzed variant Ph translocations using cytogenomic methods to determine their molecular mechanisms and evaluate the response to treatment.

Results: Of 307 CML patients examined between 2013 and 2023, we detected variant Ph translocation in 21 patients in chronic phase and two patients in blast crisis (i.e. 7.5%). FISH revealed a one-step mechanism of translocation in 13/23 cases and two-step or multi-step mechanism in 10/23 cases. Cytogenetic evaluation of treatment response was performed in 18 of 23 patients. In 14 patients, treatment resulted in complete cytogenetic remission. Three patients, who achieved partial cytogenetic remission, two of them had high-risk additional chromosomal abnormalities - ACAs, failed first-line TKIs treatment. One patient achieved no cytogenetic response, had high-risk ACAs and a mutation in the *BCR::ABL1* tyrosine kinase domain (TKD).

Conclusion: Partner chromosomes and translocation mechanisms are unlikely to influence the therapeutic response in CML with a variant Ph translocation. The failure of therapeutic response is due to other aberrations or TKD mutations rather than the type of variant Ph translocation. Reporting new cases of variant translocations is essential to further elucidate their prognostic significance.

P14.024.B A new case with multiple de novo copy number variant (MdnCNV) phenomenon

Deborah Bartholdi[1], *Nijas Aliu*[1], *Dominique Braun*[1], *Mandy Krumbiegel*[2], *Christiane Zweier*[1]

[1]*Department of Human Genetics, Bern University Hospital, University of Bern, Bern, Switzerland;* [2]*Institute of Human Genetics, University Hospital Erlangen, Friedrich-Alexander University, Erlangen-Nürnberg, Germany*

Background/Objectives: We report on a 10 year-old individual with developmental delay, microcephaly and mild skeletal and neuromuscular features (kyphosis, camptodactyly of fingers, contractures of knees). The clinical features were not indicative of a specific genetic disorder.

Methods: We performed trio exome sequencing including screening for copy number variants and subsequently chromosomal microarray analysis (CMA), karyotyping, and FISH.

Results: Trio exome did not reveal pathogenic or likely pathogenic SNVs but showed six de novo copy number gains, each encompassing between 3-4 Mb on chromosomes 3

(3q26.2q26.31), 4 (4q13.3q21.1), 5 (5p15.32p15.31 and 5q34), 6 (6p21.2p21.1) and 13 (13q13.3q14.11), respectively. Chromosomal analysis did not show a complex chromosomal rearrangement (karyotype 46,XY). The CNVs were confirmed by CMA and FISH. The latter showed that the duplications were located at the original chromosome bands. All of the six duplications were classified as VUS.

Conclusion: This case fulfils the criteria for the MdnCNV (multiple de novo CNV) phenomenon, which is characterized by the carrying of four or more constitutional de novo CNVs arising independently throughout the genome within one generation in individuals with developmental disorders. MdnCNV seems to favor copy number gains and was first described in 2017 (PMC5407901). It is estimated to occur in 1 per 12,000 individuals referred for CMA. It is hypothesized that the CNVs in MdnCNV arise by a microhomology-mediated, break-induced replication mechanism during the peri-zygotic period.

This case adds to this very rare genome instability syndrome, the impact of which on human disease is not yet fully understood.

Background/Objectives: Genome Sequencing has transformed our practice of rare disease diagnosis. For cytogeneticists, who first applied GS to characterize balanced structural variants (BSV), GS is now upfront as a first-tier test where karyotypes and microarrays once stood with the benefit of maximizing diagnostic yield combining SNV, CNV and BSV detection. While short-read GS performances for SNV and CNV calling are known, we sought to evaluate the positive predictive value of BSV reported in a diagnostic setting.

Methods: We identified 47 rare disease patients carriers of a BSV identified through short-read GS.

Results: Nineteen of these were inversions, 17 reciprocal translocations, 11 more complex events including one 18-breakpoint chromoanagenesis. 28 were deemed (likely) pathogenic due to either gene disruption (n = 25) or position effect (n = 3). While an orthogonal confirmation was not performed in 20 cases, 26 out of 27 investigated variants were confirmed: 18 through conventional cytogenetics techniques, 7 with junction fragment PCR, 2 through optical mapping. The sole unconfirmed case was a false positive t(1;11)(p31.1;p13) from the bioinformatics pipeline during its development phase. In 3 cases, short-read GS analysis was deemed incomplete and led to the recommendation of a more thorough characterization.

Conclusion: The robustness of BSVs reported here (PPV = 96%) suggests that orthogonal techniques might be relevant for further familial or prenatal testing but optional for confirmation when a clear BSV signal could be observed. This performance is the result of validated pipelines and human expertise combined for optimal diagnostics. Such expertise and retrospective validations will be critical for future technologies' implementation (e.g.: long-read sequencing).

P14.026.D Direct evidence of deletion and gene conversion as origin of SMA alleles revealed by long-read sequencing

Maria Zwartkruis[1;2], *Martin Elferink[2], Demi Gommers[1;2], Laura Blasco-Pérez[3;4], Mar Costa-Roger[3;4], Ilaria Signoria[1], Ivo Renkens[2;5;6], Amber den Ouden[7], Ronny Derks[7], Jared Green[1], Joris Kortooms[1], Carlo Vermeulen[5;8], Roy Straver[5;8], Hanneke van Deutekom[2], Marjan Weiss[7], Fay-Lynn Asselman[1], Eduardo Tizzano[3;4], Renske Wadman[1], WL Van Der Pol[1], Gijs van Haaften[2], Ewout Groen[1]*

[1]University Medical Center Utrecht, Department of Neurology and Neurosurgery, UMC Utrecht Brain Center, Utrecht, Netherlands; [2]University Medical Center Utrecht, Department of Genetics, Utrecht, Netherlands; [3]Vall d'Hebron Research Institute (VHIR), Medicine Genetics Group, Barcelona, Spain; [4]Hospital Vall d'Hebron, Department of Clinical and Molecular Genetics, Barcelona, Spain; [5]University Medical Center Utrecht, Center for Molecular Medicine, Utrecht, Netherlands; [6]University Medical Center Utrecht, Utrecht Sequencing Facility, Center for Molecular Medicine, Utrecht, Netherlands; [7]Radboud University Medical Center, Department of Human Genetics and Radboudumc Research Institute for Medical Innovation, Nijmegen, Netherlands; [8]University Medical Center Utrecht, Oncode Institute, Center for Molecular Medicine, Utrecht, Netherlands

Background/Objectives: Spinal muscular atrophy (SMA) is a debilitating neuromuscular disease, caused by homozygous defects in the *survival motor neuron 1 (SMN1)* gene. *SMN1* and SMA-modifying paralog gene *SMN2* are located in the highly complex *SMN* locus. We aimed to elucidate the still unresolved structure of the *SMN* locus in SMA patients to determine the origin of SMA alleles as a possible disease modifier.

Methods: We performed long-read Nanopore sequencing for 32 SMA patients and additional PacBio HiFi sequencing for five patients. Combining both methods, we performed de novo assembly of the *SMN* locus. For Nanopore data, directed mapping was performed, followed by polyploid haplotype phasing.

Results: De novo assembly revealed the structure of the *SMN* locus in SMA patients. Firstly, we found alleles showing absence of *SMN1* in its expected location, but partial presence of surrounding genes, indicating *SMN1* deletion. Secondly, we found *SMN2* at the expected location of *SMN1*, indicating gene conversion of *SMN1* to *SMN2*. By polyploid phasing of Nanopore reads, we determined 200 kilobase-long haplotypes of *SMN2* and surrounding genes, which were linked to specific locations on the *SMN* locus. Of the resolved *SMN2* haplotypes, 61% were located in an *SMN2* environment and 39% in an *SMN1* environment.

Conclusion: We provide direct evidence for deletion and gene conversion as origin of SMA alleles lacking *SMN1*. Varying environments of the *SMN2* gene could have direct implications for gene expression through regulatory sequences or epigenetic signatures, providing a possible explanation for genotype-phenotype discordances in SMA.

P14.027.A A rare case of mosaic Turner Syndrome with Duchenne Muscular Dystrophy and Biotinidase Deficiency

Mustafa Gunes[1;2], *Sena Cetin*[1;2], *Filiz Ozen*[2], *Elif Yilmaz Gulec*[1;2]

[1]*Istanbul Medeniyet University Medical School, Medical Genetics, İstanbul;* [2]*Istanbul Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Medical Genetics, İstanbul*

Background/Objectives: Turner Syndrome (TS) is a common sex chromosome aneuploidy characterized by short stature and ovarian insufficiency in females. Approximately, half of the patients with TS have mosaicism for 45,X with another karyotype. Duchenne muscular dystrophy (DMD, MIM #310200) is a severe X-linked recessive neuromuscular disease. Biotinidase Deficiency (BD, MIM #253260) is a rare autosomal recessive metabolic disorder with variable neurological and cutaneous findings. We present a little girl expressing the phenotypes of these three disorders.

Methods: A 2-year-old girl, who was diagnosed with mosaic TS and BD in early infancy, was referred to us due to high serum creatine kinase (CK) levels since infancy. Since her aunt's son died due to DMD, the patient underwent *DMD* gene deletion/duplication MLPA analysis and *DMD* gene next-generation sequencing (NGS) respectively.

Results: The girl had the feature of TS with short stature (-2.71 SDS). Her karyotype was 45,X [10]/47,XXX[20] revealing a TS mosaicism, she also had homozygous c.1336 C>G variant in *BTD gene*. While *DMD* MLPA analysis was normal, a known pathogenic nonsense variant c.1912C>T (p.Gln638*) in *DMD* gene was identified via NGS. The variant was confirmed by Sanger sequencing in the proband and her mother.

Conclusion: X-linked recessive disorders such as DMD rarely affect women. Although our case additionally had trisomy X karyotype, her high CK levels ranging between 7000-24.000 IU/L at this early age concluded the diagnosis with DMD. This irrelevance is probably due to the higher mosaicism percentage of 45,X karyotype on myocytes. This patient is unique with the coexistence of mosaic TS, DMD and BD.

P14.028.B Utility of methylation episignature analysis for CNVs: A systematic review and case series

Sunwoo Lee[1], *France Docquier*[1;2], *Fay Rodger*[1;2], *Rhiannon Evans*[1;2], *Stephanie Allen*[3], *Dominic McMullan*[3], *Soo-mi Park*[4], *Richard Sandford*[4], *Marc Tischkowitz*[4], *Jose-Ezequiel Martin Rodriguez*[1;2], *Ana Toribio*[1;2], *Eamonn Maher*[1;2]

[1]*University of Cambridge, Department of Medical Genetics, Cambridge, United Kingdom;* [2]*Stratified Medicine Core Laboratory NGS Hub, Cambridge, United Kingdom;* [3]*West Midlands Regional Genomics Laboratory, Central and South Genomic Laboratory Hub, Birmingham, United Kingdom;* [4]*Cambridge University Hospitals NHS Trust, Cambridge, United Kingdom*

Background/Objectives: Copy number variants are an important cause of neurodevelopmental disorders but variability in size and gene content can make interpretation of the causation of the phenotype challenging. Pathogenic variants in chromatin modifying genes (CMGs) are also an important cause of neurodevelopmental disorders and many are associated with specific DNA methylation (DNAm) episignatures that can facilitate interpretation of variant pathogenicity. It can be postulated that if CMGs are within or close to CNVs, then episignature analysis could inform the potential role of the CMG in the associated phenotype unless other genes within the CNV modified or mitigated the phenotype.

Methods: To investigate genotype-epigenotype-phenotype relationships for CMG-associated CNVs we undertook a systematic literature review and undertook methylation profiling in a series of patients.

Results: We identified 93 CMG-CNV cases that satisfied eligibility criteria (82 published and 11 unpublished); 84 deletions, 9 duplications). DNAm profiling was performed by methylation array ((n = 82) or NGS-based methods (n = 11). Examples of deletion CNVs containing a CMG which were associated with the relevant CMG episignature were identified and the relationships between CNV type, size and gene content and presence/absence of episignature patterns will be presented with illustrative case reports.

Conclusion: Episignature analysis would appear to have potential for providing pathogenetic and diagnostic insights into a range of recurrent CNVs though more extensive analysis is required to determine the sensitivity and limitations of episignature analysis for specific CNVs.

P14.029.C Optical genome mapping of a patient with ring chromosome 3 shows the importance of choosing the proper reference genome for the analysis

Bruna Burssed[1], *André Rodrigueiro Clavisio Pereira de Oliveira*[2], *Marco Antonio Ramos*[1], *Mei Ling Chong*[3], *Peining Li*[3], *Fernanda Teixeira Bellucco*[1], *Maria Isabel Melaragno*[1]

[1]*Universidade Federal de São Paulo, Department of Morphology and Genetics, São Paulo, Brazil;* [2]*Uniscience do Brasil, Uniscience Molecular Laboratory, São Paulo;* [3]*Yale University, Department of Genetics, New Haven, United States*

Background/Objectives: Ring chromosomes are rare chromosomal alterations formed by circular DNA molecules. The proposal of a mechanism of formation relies on the investigation of the breakpoints' location, which is done by comparing the altered genome with a reference genome, regardless of the used technique.

Methods: We studied a male patient with intellectual disability, short stature, dysmorphisms, and clinodactyly. Karyotype and chromosome microarray revealed a ring chromosome 3 – r(3) – with a 5.7 Mb deletion in 3p. Short-read whole genome sequencing (SR-WGS) and optical genome mapping (OGM) were performed to find the precise location of the ring's breakpoints.

Results: OGM, first analyzed using GRCh37 and GRCh38 as references, detected an unexpected translocation between 3p and chromosome 19 with no indication of a ring chromosome. Using the T2T (telomere-to-telomere) as reference, OGM revealed the r(3), displaying a junction point between 3p (chr3:6,012,432) and 3q (chr3:201,097,227). SR-WGS using the T2T as reference located the breakpoint in 3p (chr3:6,010,296), which appears to have joined with a tandem repeat in 3q.

Conclusion: To locate the breakpoints in this r(3), the lack of a deletion in 3q creates a challenge when using the GRCh37 and GRCh38 as reference genomes since they contain unsequenced gaps that include the telomeres. The T2T presents the complete genome sequence, allowing for the precise characterization of the 3q subtelomeric region. The karyotype, which proved the presence of a r(3), was particularly important since it showed inaccuracy in the first alignments of the OGM analysis.

Grants: São Paulo Research Foundation (FAPESP), Brazil.

P14.030.D Breaking The Boundaries: Deciphering Elusive Structural Variants Through Short Reads Mapping Interpretation

Tomer Poleg[1], *ilana aminov*[1], *Noam Hadar*[1], *Amit Safran*[1], *Vadim Dolgin*[1], *Matan M. Jean*[1], *ofek freund*[1], *Nadav Agam*[1], *Marina Eskin-Shwartz*[1;2], *Gali Heimer*[3], *Bruria Ben-Zeev*[3], *Ohad Shmuel Birk*[1;2]

[1]*The Morris Kahn Laboratory of Human Genetics, Faculty of Health Sciences, Beer sheva;* [2]*Genetics Institute, Soroka Medical Center, Beer Sheva;* [3]*Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Ramat Gan*

Background/Objectives: Structural variants (SVs) pose challenges for detection using short-read sequencing (SRS) techniques. SRS encounters difficulties in spanning the exact SV breakpoints and accurately mapping them, hindering detection of SVs, especially those found in non-coding regions or those characterized by combinations of structural changes, known as complex structural variants (cSVs). Solving cases with SV detection software is a complex task, as it reveals thousands of SVs per genome, with a significant number of false positives and inaccurate variant predictions.

Methods: Whole Genome Sequencing (WGS) was conducted. HomozygosityMapper (HM) was employed for linkage analysis. MANTA software facilitated identification of potential SV breakpoints, focusing on linkage areas or genes known to be associated with the observed phenotype. Integrative Genomic Viewer (IGV) was utilized to visualize read mapping, enabling interpretation and hypothesizing the SV types, and accurately determining their respective boundaries. Borders of identified SVs were verified by PCR and Sanger sequencing.

Results: We present an effective approach that allowed us to uncover novel disease-causing SVs, deciphering unresolved cases. Examples include two distinct de-novo SVs in MECP2 causing Rett Syndrome: a cSV with two different deletion sites (~5Kbp and ~60Kbp) combined with a ~105Kbp inversion, and a~200Kbp translocation; A cSV involving a ~12Kbps deletion and 10bp duplication within FRA10AC1 causing a recessive neurodevelopmental disorder; And a novel ~20Kbp tandem duplication within NSMCE2 causing recessive Primordial Dwarfism.

Conclusion: Deciphering both SVs and cSVs with SRS is attainable through visualization of abnormal split reads and interpretation of the unusual distances and orientations between paired-end reads.

P14.031.A HLA-DRB1 single nucleotide polymorphism variability in patients with inflammatory bowel disease

Patrik Krumpolec[1], *Klaudia Babišová*[1], *Andrej Gnip*[1], *Oliver Petrovic*[1], *Michaela Hyblova*[1]

[1]*Medirex Group Academy, Nitra, Slovakia*

Background/Objectives: Inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), are characterized by chronic, relapsing-remitting inflammation of the gastrointestinal tract. These conditions are recognized as having a multifactorial etiology, resulting from a dysregulated mucosal immune response to commensal gut flora in genetically predisposed individuals, compounded by environmental risk factors. A suggested link exists between specific HLA genes and IBD development, notably the HLA-DRB1 gene. However, the mechanisms by which HLA genes influence IBD remain to be fully elucidated.

Methods: Our study cohort comprised 35 IBD patients (12 CD and 23 UC). Whole-genome sequencing with 30X coverage was used for SNPs determination.

Results: A comparative analysis of HLA-DRB1 single nucleotide polymorphisms (SNPs) variability between CD and UC patients revealed a significantly higher frequency of SNPs for HLA-DRB108 ($p = 0.0006$), HLA-DRB109 ($p = 0.0167$), HLA-DRB110 ($p = 0.0002$), HLA-DRB112 ($p = 0.039$), and HLA-DRB114 ($p = 0.003$). Among UC patients, a higher frequency of SNPs for the HLA-DRB112 allele was observed in patients experiencing repeated relapses compared to those with long-term remission ($p = 0.0007$).

Conclusion: The observed differences in HLA-DRB1 SNP frequencies between CD and UC patients suggest a potential role in distinguishing between these IBD forms. Furthermore, the frequency of HLA-DRB1*12 SNPs may serve as a genetic predictor of relapse rate in UC patients.

P14.032.B "Towards characterizing inversions in 1000 Individuals across the human population using single-cell pooled and long-read data"

Vasiliki Tsapalou[1], *Wolfram Hoeps*[2], *Tobias Rausch*[1], *Thomas Weber*[1], *Eva Benito*[1], *Siegfried Schloissnig*[3], *Tobias Marschall*[4], *Jan Korbel*[1]

[1]*EMBL Heidelberg, Genome Biology Research Unit, Heidelberg, Germany;* [2]*Radboud University Medical Center, Department of Human Genetics, Nijmegen, Netherlands;* [3]*Vienna Biocenter, Research Institute of Molecular Pathology (IMP), Vienna, Austria;* [4]*Institute for Medical Biometry and Bioinformatics, Medical Faculty, Heinrich Heine University Düsseldorf, Düsseldorf, Germany*

Consortium: Human Genome Structural Variation Consortium (HGSVC)

Background/Objectives: Structural variants (SVs) are key contributors to human genomic diversity. Despite technological advances in SV detection, knowledge gaps remain, notably for inversions. These copy-number neutral variations, often flanked by identical repeat sequences, are notoriously challenging to detect. Using data from 1000 individuals in the 1000 Genomes Project, we aim to comprehensively identify inversions, understand their formation mechanisms, and explore their phenotypic impacts.

Methods: Employing single-cell sequencing (Strand-Seq) and Oxford Nanopore Technologies (ONT) data from the 1000 Genomes IMP/MARVL study, we aim to identify a broad spectrum of previously undetected inversions. Strand-Seq's ability to reveal read directionality is crucial for detecting large inversions, particularly near complex regions. In this regard, we pursued an innovative single-cell data generation method, by coupling cell line pooling with strand-specific sequencing. This approach enables efficient sequencing of diverse human samples, optimizing cell numbers for precise inversion identification and genotyping. Concurrently, we leverage ONT data to capture smaller to mid-sized genomic rearrangements. A particular focus was to refine existing computational methods for detecting small inversions up to 1kb.

Results: Our research has identified several novel polymorphic inversions, establishing the most comprehensive inversion dataset to date. We will discuss these findings, emphasizing their biological significance and population distribution.

Conclusion: This endeavor is poised to advance large-scale population-genetics studies, providing a unique opportunity to decipher naturally occurring and disease-causing structural variations within various human population groups, and their role in adaptation and genome evolution.

Grants: Research funded by the Human Genome Structural Variation Consortium (HGSVC).

P14.033.C SNP array in 19 original cases of paternal genome wide uniparental disomy: from diagnosis to mechanistic

Uriel Bensabath[1], *Laïla El Khattabi*[1;2], *Irène NETCHINE*[3;4], *Sandra Chantot-Bastaraud*[1], *Frederic Brioude*[3;4]

[1]*AP-HP Sorbonne Université - Hôpital Armand Trousseau, UF de Génomique Chromosomique, Département de Génétique médicale, Paris, France;* [2]*Institut du Cerveau, ICM - Pitié Salpêtrière, Equipe Développement du Cerveau, Paris, France;* [3]*INSERM, Sorbonne Université, Centre de Recherche Saint-Antoine, Paris, France;* [4]*Sorbonne Université - Hôpital Armand Trousseau, Endocrinologie moléculaire et pathologies d'empreinte, Paris, France*

Background/Objectives: Genome-wide paternal uniparental disomy (GW-pUPD) is a rare disorder with common and variable clinical features depending on the percentage and tissue distribution of the disomic lineage. Phenotypic features may include those of any pUPD syndrome, with the Beckwith-Wiedemann syndrome (BWS) being the most represented, which is characterized by lateralized overgrowth, macroglossia, abdominal defects, hyperinsulinism, and predisposition to embryonal tumors.

About 35 GW-pUPD live-borns have been reported, with multiple possible mechanisms.

Methods: We present 19 GW-pUPD cases (12 live-borns, 7 fetuses), including 17 females and 2 males. We collected clinical data and molecular analysis results using single nucleotide polymorphism (SNP) microarray (Illumina Human OmniExpress-24v1-3). We analyzed the B Allele frequency profile in terms of numbers of clusters and allelic frequency, in autosome as well as in sex chromosomes.

Results: SNP microarray analysis suggested:

Single spermatozoon fertilization, followed by irregular reduplication of the male pronucleus, in 16 cases, leading to XX biparental and XX isodisomic paternal cell populations.
Multi-fertilization by two spermatozoa, resulting in a biparental (XX or XY) cell population and XX isodisomic paternal cell population, in two cases.
The remaining case, exhibited a XY heterodisomic paternal cell population and a XY biparental cell population. This unique case, with heterodisomic cell population, offers valuable insights into fertilization mechanisms.

Conclusion: Our study highlights utility of SNP-array in GW-UPD to understand the underlying mechanisms. We also suggest an abacus and a systematic methodology for interpretation. Additionally, we delineate the phenotype of 19 new GW-pUPD cases.

P14.034.D Intragenic Deletions in NRXN1: Insights from aCGH Analysis in Neurodevelopmental Disorders

Sofia Dória[1], *Joel Pinto*[1], *Carolina Almeida*[1], *Maria João Pinho*[1], *Maria Helena Santos*[2], *Ana Grangeia*[1;3]

[1]*Faculty of Medicine - Genetics, Pathology, Porto, Portugal;* [2]*Centro Hospitalar Vila Nova de Gaia/Espinho – CHVNG/E, Child and Adolescent Neuroscience Unit, Vila Nova de Gaia, Portugal;* [3]*Centro hospitalar Universitário de São João, Medical Genetics, Porto, Portugal*

Background/Objectives: Neurexins, pivotal pre-synaptic cell adhesion molecules, play a crucial role in facilitating and sustaining synaptic connections within diverse brain structures. The *NRXN1* gene encodes neurexin and is essential for efficient neurotransmission, contributing to the formation of synaptic contacts. Heterozygous intragenic deletions of *NRXN1* have been implicated in autism spectrum disorder, schizophrenia, attention deficit hyperactivity disorder, and intellectual disability. Our objective was to assess the prevalence of *NRXN1* intragenic deletions using array comparative genomic hybridization (aCGH) and establish genotype-phenotype correlations.

Methods: Patients with intragenic *NRXN1* deletions were selected from a cohort of 2608 individuals with neurodevelopmental disorders who underwent aCGH (Agilent 4 × 180K platform) at the Genetics Unit of the Faculty of Medicine, University of Porto.

Results: Nine patients (0.35%) with intragenic *NRXN1* deletions were identified, ranging in size from 17Kb to 314Kb. Three deletions involved exons, while the others six occurred within introns. The deletions were classified using the ACMG criteria and Franklin variant assessment platform. Two exonic deletions were classified as Likely Pathogenic, one as Pathogenic, and all intronic deletions as Variants of Uncertain Significance (VUS), with five involving intron 6. Phenotypic variability included epilepsy, autism, and cognitive impairment with severity ranging from mild to severe global developmental disorders.

Conclusion: Despite some intronic *NRXN1* deletions being considered polymorphisms, others were deemed pathogenic, emphasizing the need for a comprehensive understanding of their significance. Our findings revealed significant clinical heterogeneity in *NRXN1* deletions, indicating variable expressiveness and incomplete penetrance, complicating genotype-phenotype correlations and presenting challenges for genetic counselling.

P14.036.B Timing of de novo mutations in neurodevelopmental disorders: exploring low-level parental mosaicism in blood and sperm via integrated genomic approaches

François Lecoquierre[1], Kevin Cassinari[1], Olivier Quenez[1], Steeve Fourneaux[1], Sophie Coutant[1], Myriam Vezain[1], anne rovelet-lecrux[1], marion rolain[1], Fanny Jumeau[2], Angèle May[1], nathalie drouot[1], Charbonnier Françoise[1], celine derambure[1], Anne Boland[3], Robert Olaso[3], Vincent Meyer[3], Jean-François Deleuze[3], Pascale Saugier-Veber[1], Alice Goldenberg[1], Anne-Marie Guerrot[1], Charbonnier Camille[1], **Gaël Nicolas**[1]

[1]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, CHU Rouen, Department of genetics, Rouen, France;* [2]*Rouen University Hospital, Reproductive Biology, Rouen, France;* [3]*Cnrgh G2, Évry-Courcouronnes, France*

Background/Objectives: De novo variations (DNVs), typically assumed to occur in the zygote, actually happen mostly pre-zygotically, at various pre- or postnatal stages. Identifying the cell undergoing the mutation is crucial for genetic counseling. Our aim was to trace hundreds of DNVs by quantifying parental mosaicism.

Methods: We analyzed the proportions and rates of parental mosaicism in two distinct datasets. The first set consisted in 189 disease-associated DNVs from patients with neurodevelopmental disorders. Parental blood mosaicism was assessed through high-depth sequencing (smMIPs, median depth 7000x). The second dataset was based on 5 children in whom all DNVs (49 to 111 per individual) were identified and phased using trio-based short and long-read genome sequencing. Parental mosaicism was identified by deep sequencing in parental blood and paternal sperm samples.

Results: In both datasets, a similar proportion of 4% of variants were detectable in the blood of one of the parents, with allele fractions ranging from 0.02% to 31.5%, indicating parental embryonic mosaicism. Among the 5 trios deeply analyzed, 90% of variants could be phased on a parental haplotype, with paternal bias and paternal age effect consistent with prior studies. Variants on the maternal haplotype were 3x more likely to be mosaic in blood, and 3% of DNVs showed sperm mosaicism without being detectable in the father's blood.

Conclusion: We suggest that phasing DNVs and studying sperm offers accurate recurrence risk quantification of DNV on paternal haplotypes, suggesting that no further prenatal testing is required for future pregnancies in case of absent sperm mosaic.

P14.037.C DNA Extraction Methodologies for Ultra Long Nanopore Sequencing to Determine Chromosome Specific Rodent Telomere Lengths

Elliot Kidd[1], *Ravi Mooruth[1], Eirini Meimaridou[1], Andrew Walley[2], Una Fairbrother[1]*

[1]*London Metropolitan University, School of Human Science, London, United Kingdom;* [2]*St George's University of London, Centre for Biomedical Education, London, United Kingdom*

Background: Telomeres are involved in gene expression through Telomere Position Effect Over Long Distance (TPE-OLD) and indirectly through telomeric repeat containing RNA (TERRA). It is important to fully elucidate relationships between TL and disease, by observing TL, not only on average, per tissue or per cell, but of specific chromosome ends. Ultra long sequencing has been attempted with Human TL (5-15Kb) with some success. However, animal model TL, such as rat and mouse, are longer (20-100kb, and 30-150kb, respectively) and more problematic.

Method: Previous work in our lab shows that phenol/chloroform extraction damages DNA less than spin columns and magnetic beads and that extraction methods are crucial for accurate TL determination. We have generated long reads using low impact DNA extraction methods and nanopore sequencing with a Mk1C. Rat DNA was isolated using isotachophoresis (Purigen) and a mouse DNA sample isolated using phenol/chloroform. We designed a system of tagging telomere ends with a custom probe that hybridises to the 3' overhang present at the end of telomeric DNA, to ensure we are capturing the entire telomere.

Results: We generated sequence of similar ultra long reads of 120-170kb for both mouse and rat samples extracted with isotachophoresis and phenol/chloroform methodologies respectively. We have generated putative telomeric/subtelomeric reads of < 455Kb using an adaptive sampling approach, focussing on mouse chromosome 1.

Conclusion: Direct sequencing of highly repetitive stretches of DNA is difficult, using specific DNA extraction techniques and adaptive sampling and tagging approaches for targeted enrichment has generated chromosome specific ultralong reads in rodents.

P14.038.D Delving into the variation of human meiotic recombination

Philip Zahariev[1], *winston lau[1], Sioban Sen Gupta[2], nikolas maniatis[1]*

[1]*University College London, GEE, London, United Kingdom;* [2]*University College London, Institute for Women's Health, London, United Kingdom*

Background/Objectives: Meiotic recombination is the most important mechanism behind genetic variation and a fundamental process to evolution and gene mapping for human diseases. The study of recombination utilises genetic maps based on different methods and data. The low coverage of informative meiosis is a major limitation when estimating current recombination events with family-based linkage maps in centiMorgans (cM). Sperm genotyping increase resolution, but can only be done in small regions. Maps from WGS data of unrelated individuals evade such limitations but rely on linkage disequilibrium (LD), which can be influenced by factors other than recombination.

Methods: We conduct an in-depth investigation of the differences between family-based and population-based genetic maps across different populations. We use the NF1 gene-region as

a case study to investigate their relationship with recombination-estimates from embryo data of families undergoing IVF and 32 previously-studied regions using sperm genotyping data.

Results: Analysis of the embryo data shows clear evidence of recombination within NF1, which is only captured by population-based genetic maps in LD units (LDU). This overlap co-locates with a cluster of the well-established sequence motif CCNCCNTNNCCNC which is associated with recombination hot-spots. Analysis of the 32 hotspots using sperm genotyping also demonstrates better correlation between sperm-specific cM and LDU distances compared to family-based sex-average cM and population-based cM.

Conclusion: There is clear variation between different genetic maps when compared to gamete data. We show LDU maps offer the highest accuracy and resolution, and alongside their population-specificity, make them valuable in trans-ancestry genome-wide association studies

P14.039.A Genotype-phenotype correlation of deletions and duplications on chromosome 15q in a cohort of 2370 clinical cases using an oligonucleotide array CGH platform

Vlasta Cejnova[1], *Lenka Vancová*[1], *Lucie Liskova*[1], *Vjaceslav Harmas*[1], *Dana Safka Brozkova*[2], *Jan Jencik*[2], *Renata Chladova*[3], *Lilly Dejová*[1], *Monika Stará*[1], *Anna Pecková*[1], *Jana Lastuvkova*[1]

[1]*Department of Medical Genetics, Masaryk Hospital in Usti nad Labem, Regional Health Corporation, Usti nad Labem, Czech Republic;* [2]*Neurogenetic laboratory, Department of Paediatric Neurology, 2nd Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic;* [3]*GENvia Genetic Laboratory, Prague, Czech Republic*

Background/Objectives: The chromosome 15q locus is an enormously complex region of the human genome. Low-copy repeats in this region predispose genes to dosage changes mediated by non-allelic homologous recombination events, leading to chromosomal deletions and duplications.

Methods: Array CGH (Agilent SurePrint G3 8x60K), MLPA, karyotyping and FISH.

Results: We found genomic imbalances on chromosome 15q in 161 cases in a cohort of 2370 samples. We detected Prader-Willi syndrome in two newborns with hypotonia and failure to thrive. The 15q13.3 microdeletion syndrome was identified in eleven patients, in five cases the ~1.6 Mb 15q13.3 microdeletion was maternally inherited and in one case was de novo. Array CGH also revealed a 110 kb maternal heterozygous intragenic deletion of *IGF1R* gene at 15q26.3, Dup15q syndrome, a 15q26.3 terminal duplication as a part of an unbalanced translocation, a de novo terminal deletion of 15q26.2q26.3 leading to the formation of a ring chromosome, a 15q13.2q13.3 BP4-BP5 interstitial duplication, and a homozygous/heterozygous deletion of the *STRC* and *CATSPER2* genes at 15q13.3 as the cause or transmission of Deafness-infertility syndrome. The 15q11.2 BP1-BP2 ~500 kb microdeletion/microduplication, a susceptibility region for neurological dysfunction including developmental and speech delay, was present in thirty-six cases. Twenty individuals had deletion/duplication of 15q13.3 encompassing only the *CHRNA7* gene.

Conclusion: The chromosome 15q is associated with several devastating neurodevelopmental syndromes, autism spectrum disorders, and other genetic conditions. Array CGH is a suitable and reliable method for rapid and effective detection of deletions/duplications on chromosome 15q.

Background/Objectives: Prader-Willi syndrome (PWS) is a neurodevelopmental disorder resulting from the disruption of paternally expressed genes (PEGs) in the 15q11-q13 imprinted region, commonly caused by a paternal deletion or maternal uniparental disomy. The remaining cases have imprinting defects, or rarely, balanced translocations involving 15q11-q13. This study aimed to explain the PWS phenotypes in a female carrying a novel apparently balanced translocation 46,XX,t(3;15)(q21;q11.2)dn.

Methods: Detailed breakpoint delineation and identification of the translocation's parental origin was performed using Whole-Genome Mate-Pair Sequencing and Transposase Enzyme Linked Long-read Sequencing. The methylation status of PEGs was assessed with MS-MLPA and bisulfite sequencing; gene expression profiles were obtained by RT-PCR using RNA from lymphoblastoid cell lines.

Results: Initial data indicated that the translocation is truly balanced and of paternal origin. The der(15) breakpoint mapped ~5kb upstream *NDN*, maintaining the integrity of the SNURF-SNRPN locus and separating PEGs located centromeric to the breakpoint from the PWS imprinting center (PWS-IC). Normal biparental methylation was observed for PEGs on either side of the breakpoint, while gene expression levels were indistinguishable from those in controls except from an apparent over-expression of *NDN* and *MAGEL2*, both mapping upstream the breakpoint.

Conclusion: This is the first PWS case with a unique translocation mapping upstream the PWS-IC that maintains gene-promoter integrity of all 15q11-q13 critical genes. Positioning of a chr3 enhancer upstream *NDN* and *MAGEL2* could explain the differential expression observed. Further studies are required to support genotype-phenotype correlations in our patient and potentially provide novel insights into the pathogenic mechanisms for PWS.

Conflict of Interest: None declared

P14.041.C Beyond the coding DNA: deep-intronic splicing variants are a frequent cause of missing heritability in Joubert syndrome.

Fulvio D'Abrusco[1], *Elisa Giorgio*[1], *Monica Boggioni*[1], *Luca Cattaneo*[1], *Chiara Di Fini*[1], *Valentina Serpieri*[1], *Roebrta Scalise*[2], *Roberta Battini*[2;3], *Enza Maria Valente*[1;4]

Background/Objectives: Despite the NGS revolution, the diagnostic yield of many inherited disorders remains unsatisfactory. One example is Joubert syndrome (JS), a recessive ciliopathy. After WES, up to 30-35% patients fail to receive a definite diagnosis. By focusing on a cohort of JS patients in whom WES only disclosed single heterozygous coding pathogenic variants in a known JS gene, we already showed that a proportion of these cases are caused by CNVs or intronic variants detectable through WES reanalysis. However, some patients still remained negative, suggesting the existence of deep intronic variants not sequenced by WES.

Methods: Three JS patients carrying single heterozygous coding variants in a JS gene underwent WGS combined with RNAseq. We searched for deep intronic variants in the gene of interest, and the impact of candidate variants was validated on patients' cDNA.

Results: In each of the three patients tested, we identified a distinct heterozygous deep intronic variant, in trans with the exonic pathogenic variant. Notably, all three variants were shown to induce the insertion a pseudo-exon, resulting in the insertion of a premature stop codon.

Conclusion: The combined analysis of WGS and RNAseq allowed detecting deep-intronic "second hits" in all patients tested. Along with our previous data on cryptic intronic variants detectable on WES data, we provide proof of principle that cryptic variants are highly frequent mutational events in JS, and their search results in a significant increase of the diagnostic yield.

[1]*Tartu University Hospital, Genetics and Personalized Medicine Clinic, Tartu, Estonia;* [2]*University of Tartu, Institute of Clinical Medicine, Tartu, Estonia;* [3]*Tartu University Hospital, Pathology Department, Tartu, Estonia;* [4]*Broad Institute of MIT and Harvard, Program in Medical and Population Genetics, Cambridge, United States*

Background/Objectives: Diagnosing rare inherited disorders has improved significantly in recent years with the emergence of new technologies. Whole exome sequencing (WES) enables the detection of the molecular cause in ~50% of syndromic neurodevelopmental disorders (NDDs) and 25-30% of isolated NDDs. Different omics methods have been shown to improve the diagnostic yield. We aimed to implement RNA expression outlier detection in a cohort of unsolved cases at Tartu University Hospital.

Methods: Skin fibroblasts were collected from patients who had signed an informed consent form after a non-diagnostic WES. The patients belong to three general categories: strict NDD cohort (group 1), expanded NDD cohort (group 2), and patients with muscular or mitochondrial disorders (group 3). RNA was sequenced at GenomeScan or Broad Institute and analyzed using the OUTRIDER algorithm for detecting expression outliers.

Results: Overall, RNA sequencing was performed in 167 patients. Group 1 consisted of 54 patients (median age 8.6 years), group 2 of 85 patients (median age 9.6 years), and group 3 of 28 patients (median age 34.9 years). All cohorts included slightly more male participants (~60%). In group 1, RNA sequencing aided in finding the molecular cause of four patients (~7%) and revealed good candidate genes in two other cases. In groups 2 and 3, results are still pending.

Conclusion: RNA sequencing is a complementary analysis in undiagnosed patients and in patients with NDDs expression outlier detection can improve the diagnostic yield by up to 10%.

P15.002.B Benefits and risks of gnomAD v4 in a diagnostic setting

Stephan Drukewitz[1], *Amica Müller-Nedebock*[1], *Maximilian Radtke*[1], *Konrad Platzer*[1], *Rami Abou Jamra*[1]

[1]*Institute of Human Genetics, University of Leipzig Medical Center, Leipzig*

Background: The Genome Aggregation Database (gnomAD) is the largest database for human genetic variations and an essential reference for variant interpretation.

With the release of gnomAD version 4.0.0, the number of individuals included was raised to 807,162. However, collecting more samples from various sources adds additional challenges in quality control and increases the risk of including individuals with an undiagnosed genetic disorder.

Methods: We included all clearly pathogenic ClinVar variants and determined their respective allele frequencies in gnomAD v.2.1.1 versus v.4.0.0. In addition, we assessed the potential effect on our routine diagnostic work by focusing on ~1700 pathogenic and ~1600 likely pathogenic variants, reported in patients from our facility.

Results: Looking at developmental delay alone, we identified 252 pathogenic variants in 58 of 129 genes associated with this phenotype, 120 of those variants are exclusively present in gnomAD v.4.0.0. For 15 of those genes, no pathogenic ClinVar variants were identified in gnomAD v.2.1.1. Analyzing our in-house variant dataset, we identified 116 pathogenic or likely-pathogenic variants, present exclusively in v.4.0.0 and thus potentially impacting variant classification and necessitating an adaptation of our in-house filtering steps.

Discussion: The rapid growth of gnomAD will undoubtedly help to increase the quality of genetic diagnostics, especially for currently underrepresented ethnicities. However, the nearly five-fold increase in contributing individuals compared to previous releases requires adaptation in the way we work with this data to interpret clinically relevant variants. Here we present a first insight into the challenges and benefits of incorporating gnomAD v.4.0.0 in a contemporary NGS-based diagnostic setting.

Variants in intron 6 of SMN1 causing misdiagnosis in genetic detecting of SMA

1588

Yujin Qu[1], Jinli Bai[1], hui jiao[2], hong qi[3], xiaoyin peng[2], yuwei jin[1], hong wang[1], Fang Song[1]

[1]Capital Institute of Pediatrics, Medical Genetics, BEIJING, China; [2]Children's Hospital Affiliated to Capital Institute of Pediatrics, Department of Neurology, BEIJING, China; [3]Prenatal Diagnosis Center, Beijing Haidian District Maternal and Child Health Care Hospital, BEIJING, China

Consortium: no

Abstract

Background : An updated consensus on the approach to the diagnosis and management of SMA was published in 2018. However, clinicians should remain alert to some pitfalls of genetic testing that can occur when following a routine diagnosis.

Methods: Three unrelated individuals, misdiagnosed as homozygous deletion of *SMN1*, were enrolled. MLPA (P060 and P021) and qPCR were used to detect copy number of *SMN* gene. *SMN1* variants were identified by *SMN1* Clone Sequencing and next-generation sequencing. Transcription of *SMN1* variants were detected using qRT-PCR and ex vivo splicing analysis.

Results: Three individuals were eventually identified as a SMA patient carrying a heterozygous deletion and pathogenic variant (c.835-17_835-14delCTTT) of *SMN1*, a carrier only carrying one *SMN1* gene with healthy phenotype, and a patient with nemaline myopathy 2 with heterozygous deletion of *SMN1* exon 7, respectively. We found that the misdiagnosis can be attributed to the presence of the c.835-17_835-14delCTTT or c.835-17C>G variants in intron 6 of the *SMN1* gene, which generate a false signal for the SMN1 exon 7 due to their influence on the amplification of *SMN1* exon 7 during the MLPA-P060 kit assay and the qPCR kit testing.

Conclusion: Accurate genetic diagnosis is the primary basis for guiding treatment of spinal muscular atrophy (SMA). We recommend that additional detecting methods are considered in cases where the *SMN1* copy number is ambiguous to minimize the misdiagnosis of SMA.

P15.004.D Optimization and quality control of library preparation in bulk and single-cell ATAC-sequencing

Patrick Schindele[1], Woo-Jin Kim[2]

[1]Agilent Technologies, Waldbronn, Germany; [2]Seoul National University School of Dentistry, Seoul, Korea, Rep. of South

Background/Objectives: The assay for transposase-accessible chromatin with sequencing (ATAC-Seq) is currently the most widely used technique for determining chromatin accessibility and relies on the activity of the hyperactive DNA transposase Tn5. ATAC-Seq libraries aim to have a nucleosomal fragmentation pattern that is crucial to achieving reliable outcomes. Here, we investigated and optimized various conditions for both bulk ATAC-Seq and single-cell ATAC-Seq for improving ATAC-Seq library preparations.

Methods: Bulk ATAC-Seq library preparation was performed according to the original publication[1]. Single-cell ATAC-Seq library preparation was performed using the Chromium Next GEM Single Cell Multiome ATAC kit (10x Genomics). Library quality control (QC) was performed using the Agilent 4150 TapeStation System with the High Sensitivity D5000 ScreenTape.

Results: For bulk ATAC-Seq, a custom protocol was established by optimizing total cell number, lysis conditions and Tn5 concentration that shows equal to superior nucleosomal patterning of the library than comparable commercially available kits. For single-cell ATAC-Seq, methods were tested to assess optimal lysis conditions for efficient isolation of individual nuclei. Determining the amount of nuclei RNA turned out to be a reliable indicator to confirm optimal lysis conditions and high quality libraries.

Conclusion: The findings from this study offer insights into improving and how to assess the efficiency and quality of ATAC-Seq library preparations for both bulk ATAC-Seq and single-cell ATAC-Seq.

P15.005.A Targeted Oxford nanopore long-read sequencing of the *LDLR* gene with CRISPR/Cas9-mediated selection

Dariush Skowronek[1], Robin A. Pilz[1], Agnieszka Gach[2], Tadeusz Kałużewski[2], Loisa Bonde[1], Ute Felbor[1], Matthias Rath[1;3]

[1]Department of Human Genetics, University Medicine Greifswald, and Interfaculty Institute of Genetics and Functional Genomics, University of Greifswald, Greifswald, Germany; [2]Department of Genetics, Polish Mother's Memorial Hospital Research Institute, Lodz, Poland; [3]Institute for Molecular Medicine, MSH Medical School Hamburg, Hamburg, Germany

Background/Objectives: Familial hypercholesterolemia (FH) affects around 1 in 250 people. Most FH cases are caused by pathogenic variants in the *LDLR* gene, with copy number variations (CNVs) accounting for about 10 %. However, short-read sequencing is limited in the specification of CNV breakpoints and the identification of complex structural variants (SVs).

Methods: High-molecular weight DNA was extracted from blood of two FH patients with a known deletion of the first two exons of *LDLR* or a multi-exon *LDLR* duplication, respectively. Four crRNAs were used for CRISPR/Cas9-mediated target selection of the *LDLR* gene in a dual-cut excision approach. Long-read sequencing was performed on an Oxford Nanopore MinION device.

Results: Complete coverage of the *LDLR* gene was achieved with a mean read length of 22.9 kb and 21.05 kb, respectively. Long-read sequencing allowed us to specify CNV breakpoints and showed that the *LDLR* deletion is 19.2 kb in size and encompasses the first two exons as well as the 5'-untranslated and promotor regions of *LDLR*. Breakpoints were located in *Alu* repeat elements. Furthermore, long-read sequencing verified an *in tandem* localization of a large *LDLR* duplication covering exons 4-8. Both CNVs could be clearly classified as loss-of-function.

Conclusion: Accurate characterization of CNVs with CRISPR/Cas9-mediated target selection and Oxford Nanopore long-read sequencing facilitates variant interpretation and enables cost-effective PCR-based variant confirmation in subsequent familial analyses. Screening for more complex SVs with this amplification-free approach may also help to elucidate the missing heritability in mutation-negative FH patients.

Grants: No specific grants were received.

Conflict of Interest: None declared

P15.006.B Virtual panels have a superior diagnostic yield for inherited rare diseases relative to static panels

Massomeh Sheikh Hassani[1], *Ahmad Abou Tayoun*[1]

[1]*Al Jalila Childrens Hospital, Dubai, United Arab Emirates*

Background/Objectives: Exome-base panels – also known as slices or virtual panels – are now a popular, cost-effective and efficient method of analyzing a capture backbone using a phenotype guided set of genes, especially in heterogenous disorders, performed in clinical laboratories optimizing genetic testing diagnosis. Given the advantages of potential interrogation of all the known human genes in exome slices, this strategy allows analysis flexibility by enabling frequent gene updates based on disease association and specific order requests.

Methods: Here we perform exome slice testing on 949 mostly pediatric patients (50.7% females; age rage 3 months–82 years old) referred from multiple pediatric /clinics within a single Center in the Middle East specialties (82.8% Arabs; 17.2% non-Arabs).

Results: The overall diagnostic yield was 27% out of the total exome slices reported. Interestingly, 13.2% of the positive cases were due to pathogenic variants identified in genes outside the "panel" gene list at the time of testing, and could have been missed in "static" panels as result of novel gene-disease associations and phenotype spectrum broadening.

Conclusion: We highlight specific cases where this practice has resulted in better clinical management of patient upon the extracurricular findings; suggesting regular and guided disease-centric updates and modifications to gene lists composed and maintained by clinical laboratories for best practices and high-quality analysis of exome slices.

Conflict of Interest: None declared

P15.007.C Initial analysis of long-read whole genome sequencing data generated using an Oxford Nanopore Technologies PromethION.

Christopher Watson[1;2], *Laura Crinnion*[1;2], *Sarah Dixon*[2], *Florentina Sava*[3], *Harry Daisley*[1], *Anne-Cecile Hogg*[3], *Rodney Nyanhete*[3], *Verity Hartill*[4], *Emma Hobson*[4], *Rosalyn Jewell*[4], *James Poulter*[1]

[1]*University of Leeds, Leeds Institute of Medical Research, Leeds, United Kingdom;* [2]*North East and Yorkshire Genomic Laboratory Hub, Central Lab, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom;* [3]*North East and Yorkshire Genomic Laboratory Hub, Sheffield Diagnostic Genetics Service, Sheffield, United Kingdom;* [4]*Yorkshire Regional Genetics Service, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background/Objectives: The widespread availability of short-read next generation sequencing data has transformed the speed and cost of molecular diagnostic testing. Nevertheless, there are a proportion of patients whose diagnosis remains incomplete.

Methods: Here we present two exemplar scenarios where long-read "third generation" whole genome sequencing has been used as a follow-up to routine genetic testing.

Results: The first patient presented with congenital diarrhoea, trichorrhexis nodosa and cleft palate. Targeted mutation analysis of coding exons and immediate splice site sequences of a 47 gene panel identified a heterozygous pathogenic mutation c.2808G>A p.(Trp936*) in the autosomal recessive disease gene TTC37. To identify a second plausibly pathogenic variant long-read sequencing was performed. This revealed a single heterozygous candidate variant, c.2634+679A>G, in intron 25 which was observed to be in trans. In silico predictions supported the creation a novel splice donor site (SpliceAI score of 0.98). A globin-depleted whole transcriptome library, in combination with short-read sequencing, validated the predicted novel splice junction and confirmed a molecular diagnosis of trichohepatoenteric syndrome. In a further pair of unrelated families, we investigated the recurrent de novo duplication, c.136_138dup p.(Leu46dup), identified in GNAS exon 1. Analysis of bulk genomic DNA (which removes the need for PCR amplification) enabled characterisation of methylation status at this imprinted locus. By identifying single nucleotide variants that tag the parental haplotypes we could determine the parent-of-origin of the mutations and assess future disease severity.

Conclusion: Adoption of single molecule nanopore sequencing, by diagnostic laboratories, promises to aid the analysis and interpretation of incompletely resolved molecular investigations.

Consortium: German Human Genome-Phenome Archive consortium

Background: The National Center for Tumor Diseases (NCT) Heidelberg and the German Cancer Research Center (DKFZ) have developed, maintained, and used somatic variant calling pipelines for high-throughput data analysis. These pipelines have played a significant role in large consortia, including the International Cancer Genome Consortium (ICGC). The workflows encompass diverse software components for calling somatic single nucleotide variations (SNVs), short insertions and deletions (indels), structural variants (SVs), and allele-specific somatic copy number aberrations (sCNAs).

Methods: With the ultimate aim of providing adequate resources for data sharing and harmonizing the processing of data, as a part of the federated European Genome-Phenome Archive (EGA), The German Human Genome-Phenome Archive (GHGA) is committed to the utilization of FAIR-compliant bioinformatic workflows which requires efforts on secure portability of data and workflows, flexibility, scalability and automation

of the processes. Nextflow, a prevalent workflow management language, has emerged as a solution for such reproducible workflows aligning with the goals of GHGA. In a fruitful collaboration with nf-core, a community effort supporting nextflow, GHGA is ensuring standardized and non-repetitive work in this respect. The translation of DKFZ somatic variant calling workflows to nextflow enables us to create a framework for the standardization of workflow processes.

Results: The initial releases of standardized nf-platypusindelcalling, nf-snvcalling, and nf-aceseq workflows are readily available under the GHGA GitHub repository.

Conclusion: GHGA collaborates with the nf-core community to provide FAIR-optimized versions of the DKFZ/NCT Somatic Variant calling pipelines.

P15.009.A Genome sequencing clearly outperforms exome in identifying small deletions: two case reports

Luise Kulosik[1], *Arne Herting*[2], *Rami Abou Jamra*[1]

[1]*Institute of Human Genetics, University of Leipzig Hospitals and Clinics, Leipzig;* [2]*Department of Epileptology, Mara Hospital, University of Bielefeld Hospitals and Clinics, Bielefeld*

Background/Objectives: Neurodevelopmental disorders and epilepsy often remain unsolved in exome sequencing (ES). We propose that genome sequencing (GS) offers distinct advantages and could increase the diagnostic yield in such cases. In this study, we highlight the impact on identifying copy number variants.

Methods: In the context of a medical thesis, we performed GS for 43 individuals with neurodevelopmental delay and/or epilepsy who remained negative after ES. We performed standard wet-lab methods. We used Emedgene for the bioinformatics analysis and variant filtering. Our filtering steps included single nucleotide variants as well as structural variants, repeat expansions and mitochondrial variants.

Results: In two cases, we identified deletions that could not be detected in WES. We identified and confirmed a pathogenic de novo 50% mosaic deletion in *CDKL5* (seg[GRCh38] Xp22.13p22.13(18493442-18556487)) in a male patient with epileptic encephalopathy, severe combined developmental delay, microcephaly, and short stature. Furthermore, we identified a de novo deletion of uncertain significance in *GRIN2B* (seg[GRCh38] 12p13.1p13.1(13959860-14015156)x1) in a female patient with moderate global developmental delay, absence epilepsy, autistic features and falls.

Conclusion: Due to consistent coverage, also of the GC rich 5` exons, and the precise mapping of the intronic breakpoints, GS offers enhanced capabilities for the CNV analysis, presenting a notable advantage over ES.

P15.010.B Accelerating reanalysis in 100,000 Genomes Project participants with a cohort wide bioinformatics approach

Cassandra Smith[1], *Liam Abrahams*[1], *Nadezda Volkova*[1], *Ken Hanscombe*[1], *Alex Stuckey*[1], *Chris Odhams*[1], *Zandra Deans*[2], *Rachael Mein*[2], *Sue Hill*[2], *Ellen Thomas*[1], *Augusto Rendon*[1], *Susan Walker*[1]

[1]*Genomics England, London, United Kingdom;* [2]*Genomics Unit, NHS England & NHS Improvement, United Kingdom*

Background/Objectives: The overall diagnostic yield following primary analysis for the families in the 100,000 Genomes Project was 20%. Reanalysis of genomic data increases diagnostic yield, but is challenging to perform efficiently and at scale, especially because a lower number of high-confidence candidate variants and a larger contribution of diagnostic variants which are challenging to identify or interpret are anticipated, compared with the primary analysis.

Methods: We have developed a large-scale research-based bioinformatics workflow for cohort-wide reanalysis of whole genome sequencing data, and applied it to >70,000 genomes, including 39,400 affected individuals, in the 100,000 Genomes Project.

Results: The workflow identifies and annotates rare small variants, copy number variants, inversions, insertions and breakends in targeted genes or regions. Variants can be prioritised according to the mode of inheritance and associated mechanism for diagnostic variants in a gene of interest. Combinations of small variants and other variant types identified in the same participant are flagged, supporting identification of compound heterozygous variants. Parameter flexibility allows tailored analysis for complex genes or regions. To date, over 2,500 genes and regions known to be associated with rare disorders have been analysed for >39,000 affected individuals from the 100,000 Genomes Project.

Conclusion: Our cohort-wide approach for reanalysis improves efficiency by focusing analyst time on variants with a high potential to be relevant to patient phenotypes. It helps mitigate limitations of family-based analysis and supports interpretation through shared variants. The candidate diagnostic variants identified are being returned to NHS laboratories through the Diagnostic Discovery pathway.

P15.011.C Utility of Mosdepth Coverage Analysis Tool to Identify Copy Number Variations in Exome Sequencing Data

Ashwin Dalal[1], *pragna lakshmi t*[1], *aparna roy*[1]

[1]*CENTRE FOR DNA FINGERPRINTING AND DIAGNOSTICS, DIAGNOSTICS DIVISION, HYDERABAD, India*

Background/Objectives: Copy number variations (CNVs) are important causes of genetic disorders. Existing CNV pipelines have limited capability for detection of homozygous and partial exonic CNVs. Mosdepth, a coverage analysis tool, can be adopted to identify these abnormalities.

Methods: Mosdepth calculates the sequencing coverage from BAM or CRAM files using a "start-stop" method to count coverage at each base position without double-counting overlaps. It offers 2x faster per base depth calculation than the bedtools. Here, we show two case studies of utilization of Mosdepth to identify the disease causing variant from exome data.

Results: Exome sequencing in two families with proband suspected to be a case of Bardet-Biedl syndrome and Microcephalic Osteodysplastic Primordial Dwarfism, type II (MOPD II) respectively, did not reveal any significant variant in any of the genes related to phenotype. Coverage analysis by Mosdepth for the respective genes associated with the clinical phenotype revealed absence of reads for four consecutive exons which is very likely to be due to homozygous deletion of exon 20 – 23 in *BBS9* gene (Likely Pathogenic, with the criteria 2A-2E, 3A) in case 1 and a homozygous 393bp deletion encompassing part of exon 19 and subsequent intron of *PCNT* gene (Pathogenic with PVS1 and PM2 criteria) in case 2.

Conclusion: The two cases exemplify the utility of MosDepth as a tool for detection of homozygous whole exon or partial exon deletions which may be missed by common SNV/CNV pipelines.

Grants: Department of Biotechnology, Government of India (Project Id BTI/AAQ/01/CDFD-Flagship/2019)

P15.012.D Ancestry-related differences in clinical prioritisation of genetic variants in the 100,000 Genomes Project Cancer Programme

Thuy Nguyen[1], *Samuel Tallman*[1], *Yoonsu Cho*[1;2;3], *John Ambrose*[1], *Alona Sosinsky*[1], *Maxine Mackintosh*[1;4], *Loukas Moutsianas*[1], *Matt Silver*[1], *Karoline Kuchenbaecker*[1;5]

[1]*Genomics England, United Kingdom;* [2]*University of Bristol, Medical Research Council Integrative Epidemiology Unit, United Kingdom;* [3]*University of Bristol, Population Health Sciences, Bristol Medical School, United Kingdom;* [4]*Alan Turing Institute, London, United Kingdom;* [5]*University College London, Division of Psychiatry, London, United Kingdom*

Background/Objectives: The 100,000 Genomes Project Cancer Programme (100KGPC) served as a precursor for the NHS (National Health Service) Genomic Medicine Service in England, the first national healthcare programme to offer routine whole-genome sequencing. We examined how representative the 100KGPC was of demographics in England's cancer registry and assessed the effect of genetically-inferred ancestry on genetic variants prioritised for clinical review.

Methods: We analysed ancestry-related differences in detection rates for germline pathogenic variants (GPVs) and actionable somatic mutations by regression modelling using data from 14,775 cancer patients.

Results: Ratios of age-adjusted cancer incidence rates between self-reported ethnicities were not significantly different from those in England. Exceptions included breast, bladder, and prostate cancers where minority ethnicities were included in higher proportions (>1.4x, $p < 0.05$).

Non-European ancestries were more likely to have one or more high priority GPVs than European ancestry (>1.9x, $p < 0.05$). Non-European ancestries also had more lower priority GPVs (>1.5x, $p < 1e\text{-}3$). At least 20% of the lower priority GPVs in patients of African ancestry were putative benign variants that could have been excluded through application of ancestry-stratified allele frequency filtering.

In contrast, fewer actionable somatic mutations were identified in South Asian ancestry than in European ancestry (0.83x, $p < 0.05$). Ancestry-related differences diminished after accounting for age and tumour mutation burden.

Conclusion: Our analysis demonstrates the need for better variant classification across diverse ancestries and showcases opportunities for improvement, which will be crucial to ensure equitable implementation of genomics in cancer care.

Grants: Data supplied by the National Genomic Research Library.

P15.013.A Incorporating Nanopore Sequencing into a Diverse Diagnostic Toolkit for Incontinentia Pigmenti

Simone Ahting[1], *Denny Popp*[1], *Henry Oppermann*[1], *Vincent Strehlow*[1], *Maria Fasshauer*[2;3], *Bernt Popp*[1;4], *Maike Karnstedt*[1], *Isabell Schumann*[1]

[1]*Institute of Human Genetics, University of Leipzig Medical Center, Leipzig;* [2]*Center for Pediatric and Adolescent Medicine, St. Georg Hospital Leipzig, Leipzig;* [3]*IDCL (ImmunDefectCentrum Leipzig), St. Georg Hospital Leipzig, Leipzig;* [4]*Berlin Institute of Health at Charité, Center of Functional Genomics, Berlin, Berlin, Germany*

Background/Objectives: Incontinentia pigmenti (IP) is a rare hereditary multisystemic disorder predominantly affecting females. Conventional short-read sequencing is complicated by a highly homologous pseudogene, which usually makes alternative approaches such as long-range PCR or analysis of skewed X-chromosome-inactivation (XCI) necessary. This study proposes incorporating Nanopore Sequencing into the diagnostic framework for IP. It enables determination of both, the precise localization of the variant in the gene or pseudogene, as well as its prevalence on the active or inactive X-chromosome.

Methods: We employed a comprehensive multi-method approach, incorporating whole-exome sequencing (WES), long-range PCR, RT-PCR and XCI analysis to identify a small heterozygous deletion in the *IKBKG* gene in a family affected with IP. Furthermore, we used Nanopore Sequencing to analyze haplotype-specific methylation at the *IKBKG* promoters.

Results: After variant detection through WES, XCI analysis and long-range PCR both indicated the variant to be located in *IKBKG*. It was undetectable at the RNA level, potentially due to nonsense-mediated mRNA decay or an insufficiently low allelic fraction. Nanopore Sequencing however, not only confirmed the variant to be located in *IKBKG*, but also allowed us to confirm the skewed XCI, with the variant-carrying allele found to be predominantly inactivated.

Conclusion: This study underlines the importance of thorough investigation, exceeding the mere variant detection, especially in genes with homologous pseudogenes. It also demonstrates for the first time, the potential of Nanopore Sequencing as a tool for precise variant mapping in the context of differentially methylated promoter regions due to skewed XCI.

Conflict of Interest: None declared

P15.014.B Implementation of routine diagnostic genome sequencing: understanding the diagnostic performance

Joohyun Park[1], *Marc Sturm*[1], *Olga Kelemen*[1], *Stephan Ossowski*[1;2], *Tobias Haack*[1;2]

[1]*Institute of Medical Genetics and Applied Genomics, Tübingen, Germany;* [2]*Center for Rare Diseases, Tübingen*

Background/Objectives: Short-read genome sequencing (GS) is now adopted as first-tier diagnostic testing method for rare genetic disorders in our center. Here, we share our experience we have gained while establishing GS as a reliable diagnostic tool, covering aspects from validation of sequencing pipelines to the practical implementation in clinical routine.

Methods: The small variant calling performance of our pipeline was evaluated by benchmarking against the GiaB reference NA12878. After thorough quality control, all datasets were analyzed based on our in-house standard filtering scheme. Diagnostic ES ($n = 1{,}016$) and GS ($n = 1{,}977$) datasets from 2022 were compared in terms of coverage, the number of detected rare variants and identified causal findings.

Results: Our standard benchmarks for ES yielded an F1 score of 0.9875 (SNVs) and 0.9427 (InDels). GS outperformed with F1 scores of 0.9955 (SNVs) and 0.9858 (InDels). Regarding coverage, ES had insufficient coverage (<20x) in 2.80% of OMIM regions whereas GS had low coverage in only 0.23%. In total, GS detected $24{,}809 \pm 5{,}655$ rare (MAF < 0.1%) and $5{,}533 \pm 1{,}746$ private ($MAF = 0$) small variants, and ES detected 302 ± 86 and 73 ± 28, respectively. Finally, almost 9% of solved diagnostic cases by GS

had either a non-coding variant, small deletions (<3 exons) or structural genomic variations as causal variant.

Conclusion: Our benchmarks and coverage statistics indicate that GS outperforms ES in both variant detection and achieving uniform coverage. Furthermore, GS can identify causal genomic variants that are undetectable by ES. Despite various challenges, the successful implementation of GS in our diagnostic center demonstrates its feasibility.

P15.015.C The effect of cryopreservation on DNA methylation signals

*Ning Yuan Lee[1], Melissa Hum[1], Guek Peng Tan[2], Ai Choo Seah[3], Patricia Kin[3], Ngiap Chuan Tan[3;4], Hai Yang Law[2], **Ann Lee**[1;5;6]*

[1]National Cancer Centre Singapore, Division of Cellular and Molecular Research, Singapore, Singapore; [2]KK Women's and Children's Hospital, DNA Diagnostic and Research Laboratory, Singapore, Singapore; [3]SingHealth Polyclinics, Singapore, Singapore; [4]Duke-NUS Medical School, SingHealth Duke-NUS Family Medicine Academic Clinical Programme, Singapore, Singapore; [5]Duke-NUS Medical School, SingHealth Duke-NUS Oncology Academic Clinical Programme, Singapore, Singapore; [6]National University of Singapore, Department of Physiology, Singapore, Singapore

Background/Objectives: Genetic or epigenetic studies often use cryopreserved DNA samples. However, long-term cryopreservation may introduce biases and changes in DNA methylation. The objective of this study was to determine the effect of cryopreservation on DNA methylation profiles.

Methods: DNA methylation profiling was performed using the Infinium MethylationEPIC bead chip on DNA samples extracted from peripheral blood samples. Two cohorts were profiled: a discovery ($n = 126$) and a validation ($n = 136$) cohort.

Results: DNA methylation profiling revealed no significant change in mean global methylation across increasing storage durations of up to four years. For individual CpG methylation levels, both cohorts had a higher number of hypomethylated CpGs than hypermethylated CpGs at q-value < 0.05 (4,049 hypomethylated and only 50 hypermethylated CpGs in discovery; 63 hypomethylated and only 6 hypermethylated CpGs in validation). No difference was found when controlling for age, estimated cell type composition and storage duration as buffy coat prior to DNA extraction. In addition, it was observed that CpGs are more likely to be hypomethylated the closer they are to CpG islands.

Conclusion: This study has quantified the effects of cryopreservation on DNA methylation profiles and shown a detectable bias towards hypomethylation at the level of individual CpG methylation. Future studies using cryopreserved DNA samples should be mindful of this bias, and further efforts can be made to develop more stable methods for DNA storage.

Grants: National Medical Research Council of Singapore (MOH-OFIRG19nov-0019) awarded to Ann Lee.

P15.016.D CF screening challenges in Georgia

*Nino Vardosanidze[1], Nana Kavlashvili[1;2], Lali Margvelashvili[3], **Saba Iordanishvili**[4], Oleg Kvlividze[5;6], Dodo Agladze[3;4]*

[1]Tbilisi State Medical University, Tbilisi, Georgia; [2]M. Iashvili Children's Central Hospital, Tbilisi, Georgia; [3]Medical Genetics and laboratory diagnostic center, Tbilisi, Georgia; [4]Petre Shotadze Tbilisi Medical Academy, Tbilisi, Georgia; [5]New Vision University, Internal Medicine, Tbilisi; [6]Georgian Foundation for Genetic and Rare Diseases (GeRaD)

Background/Objectives: Cystic fibrosis is an autosomal-recessive multisystem disorder caused by mutations of the *CFTR* gene. It is typically characterized by recurrent respiratory tract infections, pancreatic insufficiency leading to malnutrition and growth impairment. In Georgian national guideline for CF diagnostics, sweat chloride test is used as a gold standard

Methods: The results of 40,420 patients born in 2022 were statistically analyzed. Patients with elevated IRT were identified. Data was analyzed to determine the efficiency of the protocol for newborn screening in Georgia.

Results: 40,420 newborns were screened in 2022. 768 newborns with elevated IRT levels (1,9%) were detected. From 768, only 460(59,9%) were followed up. 308(40.1%) patients did not undergo further evaluation. 460 tested newborns, 62(13,5%) showed elevated chloride levels(>29mmol/l). When retested, only 6(9,7%) patients showed increased levels. In 2022, 8 new CF patients were registered, 6 of them via national screening program and 2 of them late diagnosis.

Conclusion: Data analyzes of 2022 screening in Georgia, emphasizes prevalence and diagnostic challenges of CF. Individuals retested with ST were diagnosed, but only 59,9% of cases were tested. Only 18,7% of patients with elevated IRT underwent the recommended second checkup. 1:5053 individuals born in 2022 was diagnosed with CF. 308 individuals with elevated IRT were not retested. Mandatory retest implementation can be a solution, involving collaboration with the Ministry of Health, the social agencies and the national screening center. It is also important to raise awareness among health care professionals.

P15.017.A Genome sequencing in clinical diagnostics in a heterogeneous patient cohort

Chen Du[1], *Sandra von Hardenberg[1], Reena Buurman[1], Alisa Förster[1], Anja Schöner-Heinisch[1], Brigitte Pabst[1], Michaela Losch[1], Bernd Haermeyer[1], Benedikt Schnur[1], Winfried Hofmann[1], Florian Kaisen[1], Nataliya Di Donato[1], Gunnar Schmidt[1], Bernd Auber[1]*

[1]Medical School Hannover, Hanover, Germany

Background/Objectives: We implemented short-read genome sequencing for genetic analysis of rare hereditary disorders because of the superior quality of genome sequencing over exome sequencing, including detection of non-coding variants and structural variations. We report the results of two years of genome sequencing in clinical diagnostics.

Methods: (1) library preparation with an IDT DNA Library Prep Kit, (2) 160 bp paired-end genome sequencing with an insert size of 350-400 bp on an Illumina NovaSeq 6000 or X Plus instrument, (3) inhouse data analysis using megSAP, (4) variant interpretation according to standard guidelines, (5) clinical reporting.

Results: We analyzed >1700 independent consecutive index cases (58% pediatric). 91% of samples were analyzed as singleton, 9% as trio or other. Median turnaround time was 35 days. The overall diagnostic rate was 18% with substantial variation across disease groups (40% for metabolic vs. <10% for immunodeficiencies and liver disorders). In 19% of cases a variant of unknown significance was reported. 2% of cases generated candidate variants in genes of unknown significance. Variants in positive reports were 48% truncating, 38% missense, 3% small in-frame deletions, 2% single exon deletions/inversion, 4% large deletions,

2% recurrent microdeletion/duplication syndromes and 3% intronic or regulatory. Trio genome sequencing following unremarkable singleton genome analysis was performed in 35 cases and unmasked the diagnosis in 20% of cases.

Conclusion: Genome sequencing is a feasible tool in diagnostic routine to detect various classes of variation and diagnostic yield is enhanced by trio analysis. A major limitation is the lack of annotation of non-coding variants.

Background/Objectives: DNA analysis using next-generation sequencing (NGS) techniques has become routine in the diagnosis of genetically-based diseases in most hospitals world wide due to reductions in sequencing costs and simplification of technique methods. The study of exomes and even whole genomes has increased the complexity of data analysis and interpretation. In order to improve genetic healthcare is increasingly recognized the need to eliminate data and knowledge "silos". Hence, a network of seven hospitals has been established to query genetic variants using standard and secure tools compliant with GDPR regulations.

Methods: Approximately 70 variables are to be shared encompassing both phenotypic and genotypic information. To ensure clarity and consistency, a common vocabulary has been established for each field using specific dictionaries or internationally accepted ontologies.

Results: Data has been stored in an aggregated manner and integrated by each institution into a local database following a common structure defined by the Beacon_v2 reference implementation from the Global Alliance for Genomics and Health (GA4GH). More than 15.000 genomic tests will be accessible within the network to be interrogated (increasing 4000/year approximately).

Conclusion: To our knowledge, this is the first federated hospital centered network to query genomic data. The exchange of genomic and associated data between centers can help interpret and classify variants, leading to multiple benefits: 1) consolidating information to interpret a variant as a cause of the disease or not, 2) identifying interpretation conflicts, reducing the possibilities of a less robust interpretation, 3) improving the quality and effectiveness of diagnosis.

Background/Objectives: Patients with rare and intractable diseases face difficulties finding diagnoses and treatments for their conditions, including diagnostic odysseys, multiple incorrect diagnoses, and unreached treatments. The Japan Agency for Medical Research and Development (AMED) launched a nationwide study called the Initiative on Rare and Undiagnosed Diseases (IRUD) in 2015. IRUD plays an important role in the national medical support network for rare and intractable diseases together with university hospitals as well as children's hospitals. Many patients with rare and intractable diseases in Osaka and neighboring prefectures visit Osaka Women's and Children's Hospital (OWCH). OWCH is consisted with a perinatal center, children's hospital, and research institute. The mission of the Department of Medical Genetics in OWCH is to pursue basic and clinical research for the diagnosis and treatment of genetic diseases.

Methods: Whole-exome sequencing and whole-genome sequencing have been used for the genetic diagnoses of patients who remain otherwise undiagnosed. Furthermore, IRUD constitutes an international data-sharing framework.

Results: We have registered nearly 800 pedigrees with undiagnosed diseases since 2015. Genetic analyses revealed their diagnoses with a high diagnostic rate of approximately 54%. We have identified novel causative genes and new disease entities, including Takenouchi-Kosaki syndrome, *CDK8*-associated disorder, *CDK19*-related disorder, and abnormalities in *DHX9* and *STARD9*. Model organism approaches play important roles in the resolution of these issues.

Conclusion: We are investigating a number of novel genes. The promotion of IRUD is essential for elucidating the causes of and, ultimately, providing cures for rare and undiagnosed diseases. We report our 9-year experience in OWCH.

Grants: AMED

P15.020.A Evaluating the UTRannotator tool in a clinical diagnostic environment

Shilu Amin[1;2], *Sam Nalty*[1], *Michael Spiller*[1]

[1]*Sheffield Children's NHS Foundation Trust, Sheffield Diagnostic Genetics Service, Sheffield, United Kingdom;* [2]*The University of Manchester, Manchester, United Kingdom*

Background/Objectives: Over 98% of the human genome consists of non-protein-coding regions including a wide range of regulatory regions. Whole genome sequencing (WGS) within the NHS Genomic Medicine Service (GMS) can now explore these regions. However, software tools to annotate potentially pathogenic non-coding variants are still limited. To expand WGS analysis, focusing on untranslated regions (UTRs) of transcripts is highly relevant; variants within 5'UTRs have been shown to lead to rare/developmental disorders.

The recently developed UTRannotator tool identifies 5'UTR variants with functional consequences, and outputs detailed annotations for predicting the likely impact on protein translation. The aim of this study is to test UTRannotator in a clinical diagnostic environment for patients with developmental disorders.

Methods: Variant call format files from reported local GMS WGS cases on the R27 panel (congenital malformation and dysmorphism syndromes) were filtered and annotated using the UTRannotator Ensembl Variant Effect Predictor plug-in. After filtering for R27 green genes, 5'UTR consequence and absence in gnomAD, 5'UTR variants in autosomal dominant (AD)/X-linked (XL) genes were prioritised. The UTRannotator outputs were used for downstream analysis following non-coding variant interpretation guidelines.

Results: From a total of 254 local R27 cases, the UTRannotator provided annotations for 31 5'UTR variants (in 27 cases; 3 had >1 variant); 20 variants in AD/XL genes were prioritised for further analysis. Final results will be presented at the conference.

Conclusion: UTRannotator is a promising tool to aid in the interpretation of 5'UTR variants. However, classification and interpretation of these variants remain difficult.

P15.021.B Determining the impacts of a critical genotyping error identified by External Quality Assessment (EQA); are laboratories considering the implications for patients?

India Roderick[1], *Victoria Williams*[1], *Nicola Wolstenholme*[1]

[1]*EMQN CIC, Manchester, United Kingdom*

Background/Objectives: In line with our educational objectives, EMQN CIC provides a form to guide the root causes analyses (RCA) for critical errors in EQA (errors with potential to cause patient harm). Here, we present the data from a single year's submissions, identifying the most common causes of genotyping error, good practice in RCA and suggesting improvements to the investigation process.

Methods: 255 Participating laboratories made critical genotyping errors in the 2022 scheme year. RCA Forms received from 95 laboratories were analysed by RCA category, reflection on consequences and risks for similar errors in their usual practice, and corrective and preventative actions performed.

Results: The most common error was a false negative result, accounting for over 75% of all critical genotyping errors. The most common root causes were issues with the test method (30.5%), and transcription errors (21.1%). 95% of forms submitted had considered corrective and preventative actions, whereas only 76% had fully considered the consequences and risks for other patients tested.

Conclusion: Good practice was observed for corrective and preventative measures, but 24% submissions did not fully consider the extent and impact of the error, leaving residual risk in existing tests and potential consequences for patient care. It is vital to review if the cause of an error could have affected other patients. Participating in EQA can help laboratories improve the quality of testing for patients by identifying errors proactively so the root cause can be resolved, and services improved.

P15.022.C Identification of a novel deep intronic *DDC* variant in patients with aromatic l-amino acid decarboxylase deficiency

Naomichi MATSUMOTO[1]

[1]*Yokohama City University Graduate School of Medicine, Department of Human Genetics, Yokohama, Japan*

Background: Aromatic l-amino acid decarboxylase (AADC) deficiency is an autosomal recessive neurotransmitter disorder prevalent in Southeast Asia. AADC deficiency caused by biallelic pathogenic variants in the *DDC* gene. We previously reported Japanese sibling cases with AADC deficiency, their diagnosis was confirmed by the lack of DDC activity but only with a heterozygous known variant in the *DDC* (c.329C>A, p.Ala110Glu) as one-hit.

Methods: To detect a missing pathological variant, we performed the targeted long-read sequencing with Nanopore sequencer for both siblings using adaptive sampling. Entire region of the *DDC* was successfully captured with a coverage depth of brother and sister were 40 and 30, respectively. After the haplotypes phasing and variant calling, we searched for candidate variants (as second-hit) in an allele harboring no c.329C>A.

Results: We identified a novel deep intronic variant (c.714+255C>A). This variant is common in siblings and was predicted by SpliceAI to potentially activate the noncanonical splicing acceptor site. We performed a minigene assay to determine the impact of the variant on splicing. Three transcripts, including the canonical transcript, were detected with the wild-type, but only the noncanonical cryptic exon was produced with the c.714+255C>A.

Conclusion: This noncanonical cryptic exon introduced a premature stop codon, which could lead to nonsense-mediated decay, supporting c.714+255C>A is pathogenic (second-hit).

Acknowledgments: Drs. Eriko Koshimizu, Satoko Miyatake, Mitsuhiro Kato are highly appreciated for their contribution to this study. This study is supported by AMED under Grant Number, JP23ek0109674, JP23ek0109549, JP23ek0109617, JP23ek0109648, and Takeda Science Foundation.

P15.023.D Bioinformatics fieldnorm for Genetic medical laboratories.

Tobias Beers[1], Roxane Boyer[2], Robert Ernst[3], Geert Geeven[4], Bart de Koning[5], Thomas Leenders[6], Rick Medemblik[2], Pieter Neerincx[7], Ruben Vorderman[8], **Hanneke van Deutekom**[3]

[1]The Netherlands Cancer Institute (NKI), Department of Pathology, Amsterdam, Netherlands; [2]Amsterdam University Medical Center, Department of Human Genetics, Amsterdam, Netherlands; [3]UMC Utrecht, Department of Genetics, Utrecht, Netherlands; [4]Erasmus MC, Department of Clinical Genetics, Rotterdam, Netherlands; [5]Maastricht UMC+, Department of Clinical Genetics, Maastricht, Netherlands; [6]Radboud University Medical Center, Department of Human Genetics, Nijmegen, Netherlands; [7]University Medical Center Groningen, Department of Genetics, Groningen, Netherlands; [8]Leiden University Medical Center (LUMC), Department of Biomedical Data Sciences, Leiden, Netherlands

Background/Objectives: In the past years bioinformatics has become a crucial part in several medical laboratories, such as Genetics, Pathology and Medical Microbiology. Hence, the work of bioinformaticians within these laboratories needs to comply to both the ISO-15189 and the IVDR. Where the IVDR contains requirements for software development, "software shall be developed and manufactured in accordance with the state-of-the-art taking into account the principles of development life cycle, risk management, … ", the ISO-15189 does not include requirements for bioinformatics or software development processes. These processes are described in the IEC-62304, a harmonized standard for "Medical Device Software – Software life cycle processes". The use of this standard is voluntary and gives good guidance to demonstrate compliance with legal requirements.

Methods: Bioinformaticians from all the genetic medical laboratories in the Netherlands gathered to discuss the processes used to develop bioinformatic workflows, i.e. software development. The processes within the different centers and the IEC-62304 were used as a guidance to create a fieldnorm for bioinformatics.

Results: The first version of the fieldnorm is available within GitHub. The main goal of this document is to give guidance to what should be documented and registered to comply to the ISO-15189 and the IVDR. The document could also serve as a guidance for (internal) auditors.

P15.024.A Comprehensive blood group genomic profiling: a leap forward with Adaptive Sampling

Morgan Gueuning[1], Gian Andri Thun[1], Maja P. Mattle-Greminger[1], **Stefan Meyer**[2]

[1]Blood Transfusion Service Zurich SRC, Research and Development, Schlieren, Switzerland; [2]Blood Transfusion Service Zurich SRC, Molecular Diagnostics and Cytometry, Schlieren, Switzerland

Background/Objectives: In transfusion medicine, genetic characterization of blood groups is of great importance, especially for patients regularly transfused like those with thalassemia or sickle cell disease. While SNV-based genotyping is generally effective for characterizing most of 45 known blood group systems, some systems involve paralogous genes prone to complex variation, which is challenging to resolve. Oxford Nanopore Technologies (ONT) has recently introduced a long-read sequencing enrichment method called 'adaptive sampling', which computationally eliminates off-target reads during real-time sequencing. As this approach does not pose restrictions on DNA fragment length, it is highly suitable to detect structural variants.

Methods: Our study aimed to evaluate adaptive sampling's effectiveness in the characterization of the entire blood group genome, particularly in cases where the genetic underpinnings for observed blood group phenotypes were unclear. We targeted ~8.6 Mb of the human genome, covering 51 blood group genes, along with 2 hematopoietic transcription factors and 7 human platelet antigen genes.

Results: Latest PromethION flow cells provided high mean read coverage across target regions (>45x), enabling accurate variant calling. Validation against genotype data for 17 blood group systems revealed 100% concordance with up to 73 pre-typed variants, including complex systems like RH and MNS. Notably, the sequencing data uncovered novel structural variants, such as a ~8.6-kb deletion in *RHCE*, providing explanations for previously unresolved blood group phenotypes.

Conclusion: In summary, adaptive sampling proved promising for complementing current tools in transfusion medicine, offering an accurate, user-friendly, and comprehensive approach to unravel the entire individual blood group genome.

P15.025.B Detection of BRCA1/2 ctDNA using a custom AmpliSeq™ panel in patients with metastatic castration-resistant prostate cancer (mCRPC)

Claudio Antonio Coppola[1], *Brunella Pilato[1], Giuseppina Matera[1], Rosanna Lacalamita[1], Antonia Lasorella[1], Graziana Gramegna[1], Simona De Summa[1], Debora Traversa[1], Vito Di Lorenzo[1], Alessandro Caniglia[1], Fulvia Colonna[1], Stefania Tommasi[1]*

[1]Giovanni Paolo II / I.R.C.C.S. Cancer Institute, Bari, Italy

Background/Objectives: To date, the Italian Association of Medical Oncology (AIOM) recommends the evaluation of *BRCA1* and *BRCA2* gene alterations in plasma of mCRPC patients when tissue is not available for therapeutic setting. However, only a limited number of tools are available to detect these alterations in depth and at an affordable cost.

The aim is to establish and validate a custom panel to identify *BRCA1/2* mutations in ctDNA of mCRPC patients suitable for therapeutic use.

Methods: Plasma from 10 mCRPC patients and 3 synthetic plasma from the EMQN EQA scheme were collected and ctDNA was automatically extracted (KingFisher Duo Prime). The custom panel was designed using Ion AmpliSeq Designer software. Libraries were prepared using the Ion AmpliSeq™ HD Library Kit and sequenced using the Ion GeneStudio™ S5 System (Thermo Fisher). Data were analysed using Torrent Suite and Ion Reporter software. The entire procedure was performed according to the manufacturer's protocols.

Results: The results of *BRCA1/2* analysis were completely concordant between tissue and plasma of the 10 patients. Five of them presented pathogenic alterations also at the germline level. *BRCA1/2* alterations found in synthetic plasma samples were confirmed by CQ assessment.

Conclusion: The data obtained demonstrate the utility of developing a customised panel for *BRCA1/2* alterations in ctDNA for use in the therapeutic setting. However, the study still has major limitations due to the sensitivity of the analysis, which needs to be optimised. This could be overcome with a larger cohort and the inclusion of patients carrying only somatic mutations.

P15.026.C A novel DNA extraction column to improve the sensitivity of circulating cell free DNA (cfDNA) detection in liquid biopsies

Juliette Goulay[1], Corentin Germain[1], Ludivine Beaussire[2], Frederic DiFiore[2;3], Florian Clatot[2;3], Florine Hallez[1], Michel Arotçarena[1], Kaynoush Naraghi[1], Sami Bayoudh[1], **Nasrin Sarafan-Vasseur**[2]

[1]AFFINISEP SAS, Le Houlme, France; [2]Université de Rouen Normandie, Inserm U1245, IRON Group, Rouen, France; [3]Centre Henri Becquerel, Department of Medical Oncology, Rouen, France

Background/Objectives: Cell free DNA (cfDNA) has been implicated as an important biomarker in cancer management. The natural characteristics of cfDNA make it a challenging analyte to extract because in various liquid biopsies, it is poorly concentrated and highly fragmented (~180bp). Moreover, interfering genomic DNA can make it difficult to accurately detect rare cancer mutant targets. Thus, precision liquid biopsy requires precision cfDNA extraction.

The extraction of DNA from biological matrices is usually performed using an extraction column in the presence of a chaotropic agent. A new thin and uniform membrane was designed for DNA extraction. Thanks to its dense and uniform particles distribution, this membrane shows high capacity for extraction and purification of molecules. It can also be used for miniaturization in µspin columns or Spin Tips format, to reduce loading and elution volumes. Moreover, the miniaturized formats are perfectly compatible with automated liquid handlers and can be used for high throughput analysis (HTS).

Methods: For our proof of concept, we used control plasmas and urines spiked with fragmented DNA harboring HPV-18 sequences, to mimic samples from cervical cancer patients.

The new extraction support was compared, in the form of a complete kit with all the required reagents (new buffer solutions), to other kits.

Results: The results showed an efficient and a highly quantitative extraction, with recovery yields up to 100%.

Conclusion: This innovative kit improves the efficiency of short fragment isolation by removing genomic DNA compared other methods and could be used for both plasma and urine matrices.

P15.027.D The clinical utility of DNA methylation episignatures in neurodevelopmental disorders: a single center experience

Daphne Smits[1], *Alice Brooks[1], Arjan Bouman[1], Virginie Verhoeven[1], Laura Donker Kaat[1], Sarina Kant[1], Stefan Barakat[1]*

[1]Erasmus Medical Center Rotterdam, Department of clinical genetics, Netherlands

Background/Objectives: Disease causing variants in genes encoding chromatin regulators are the cause of numerous neurodevelopmental disorders. Episignatures, disorder-specific DNA-methylation patterns, have been developed for many disorders and have emerged as a diagnostic tool to provide insights into disease pathophysiology or classification of variants identified with other DNA diagnostics. Here, we evaluated the diagnostic utility of episignatures in a routine clinical setting.

Methods: We analyzed the reports of 293 cases seen at Erasmus MC that underwent commercial EpiSign™ testing between June 2019 and June 2023. The cohort included 70 targeted analyses, in subjects with a previously identified genetic finding, and 223 complete analyses when previous diagnostics testing has not resulted in a diagnosis.

Results: Of the cases that underwent targeted analyses, a positive episignature was observed in 22% (11/50) for variants of unknown significance (VUS), 81.8% (9/11) for likely pathogenic variants, and 100% (9/9) for pathogenic variants. For the 223 cases in which a complete episignature was requested, a positive episignature was observed in 9.4%. Among 61.8% of these, the suggested profile matched the phenotypic features and provided valuable insights into the diagnosis. In about half of them, a causative variant was found retrospectively. For the other 38.2% of positive episignatures, the observed profile did not explain the clinical features for which the test was requested.

Conclusion: This study supports the clinical utility of comprehensive episignature analysis in cases without previous genetic findings, even beyond extensive exome sequencing, as well as during the interpretation and classification of VUS.

P15.028.A Unveiling the Diagnostic Potential: Comprehensive Analysis of 61 Repeat Expansion Loci in 20,000 Exomes

Helene Faust[1], *Theresa Sujatta[1], Stephan Drukewitz[1], Björn Schulte[2], Jerome Jüngling[2], Florian Battke[2], Martin Schulze[2], Christine Zühlke[3], Malte Spielmann[3], Ina Schanze[4], Bernt Popp[5], Rami Abou Jamra[1], Julia Hentschel[1], Denny Popp[1]*

[1]Institute of Human Genetics, University of Leipzig Medical Center, Leipzig, Germany; [2]Center for Genomics and Transcriptomics (CeGaT), Tübingen, Germany; [3]Institute of Human Genetics, University Hospital Schleswig-Holstein, Lübeck, Germany; [4]Institute of Human Genetics, University Hospital Magdeburg, Magdeburg, Germany; [5]Center of Functional Genomics, Berlin Institute of Health at Charité, Berlin, Germany

Background/Objectives: Although the bioinformatic tool ExpansionHunter was developed for short-read genomes, several studies showed the tool's good performance detecting repeat expansions in exome data. However, these studies analyzed only a small number of the disease-associated repeat expansion loci and focused on movement disorders. In the gnomAD data set v3.1.2 are currently 59 disease-associated repeat expansion loci available. We wondered whether these could be detected in exome data.

Methods: In this study, we applied ExpansionHunter v5.0 for 61 repeat expansion loci in 20,000 exomes from two institutes. We filtered for pathogenic repeat expansions in the loci with sufficient coverage to detect clinically relevant repeat expansions. In addition, we investigated different setups for repeat expansion detection with ExpansionHunter and compared the influence of the different wet lab conditions at the two institutes.

Results: Sufficient coverage was detected for 50 loci. Of these, we found repeat expansions in the pathogenic range in 38 loci. For 17 loci, repeat expansions were confirmed in patients with a disease-overlapping phenotype, including movement disorders, neurodegenerative and muscular diseases as well as malformation syndromes. We observed atypical disease manifestations in many patients. Furthermore, optimizing the pre- and post-processing of each locus enhances reliable repeat expansion detection.

Conclusion: We showed the benefit of repeat expansion detection in exome sequencing, also beyond movement disorders. With this study, we developed a guide for implementing repeat expansion detection with ExpansionHunter for exome data and, in perspective, for short-read genome data in a diagnostic setting.

P15.029.B Reclassification of variants of uncertain clinical significance in mendelian cardiomyopathies and arrythmias using targeted blood RNA analysis

Thomas RIO FRIO[1], *Anne Vannier*[1], *Caterina Marconi*[1], *Marc Abramowicz*[1;2], *Jean-Louis Blouin*[1;2], *Siv Fokstuen*[1;2]

[1]*University Hospitals of Geneva, Division of Genetic Medicine, Geneva, Switzerland;* [2]*University of Geneva-School of Medicine, Department of Genetic Medicine and Development, Geneva*

Background/Objectives: Molecular diagnosis of mendelian cardiomyopathies and arrythmias is performed through screening of associated genes by NGS. Some rare non-coding or missense variants may be classified as of uncertain clinical significance (VUS) although predicted altering RNA splicing in silico.

Methods: Using mRNA from blood, we investigated 4 patients with hypertrophic cardiomyopathy and one with long-QT syndrome who carried a VUS in *MYBPC3*, *TPM1* or *KCNH2* identified outside canonical ±1,2 splice-site positions and predicted to alter/create splice sites.

Results: An intronic deletion c.2737+4_2737+7delAGTG in *MYBPC3* was shown to lead to 3 transcripts with different abnormal splicing patterns. Deep intronic variant c.1927+337G>T in *MYBPC3* caused inclusion of a cryptic exon. Missense variant p.Gly148Arg in *MYBPC3* created a splice acceptor site partially used to produce a transcript with a partial exonic deletion. An intronic variant c.1945+3G>C in *KCNH2* was shown to abolish the canonical splice donor site. Finally, a missense variant in *TPM1* (p.Asp84Glu) was shown not to alter splicing.

Conclusion: Of the 5 VUS with supporting in silico predictions, we could reclassify the 3 intronic variants as pathogenic. Although an incomplete or absent effect on splicing was shown for the 2 missense variants, we could not downgrade them, as uncertainty remains regarding the effect of the amino acid substitution on the protein function. This targeted variant-specific RNA approach is a cost-effective functional test applicable in blood, which allowed to solve 60 % of VUS predicted to alter splicing. Such complementary approach is expected to increase significantly diagnostic sensitivity of NGS-based gene tests.

P15.030.C The *TANGO2* Lesson

Siren Berland[1], *Lene Hjertnes*[1], *Anna Owczarz*[2], *Espen Lien*[3], *Julie Paulsen*[4], *Henrikke Nilsen Hovland*[1], *Lars Utne Haukland*[5], *Marianne Jortveit*[6], *Cathrin Lytomt Salvador*[7], *Trine Tangeraas*[8]

[1]*Haukeland University Hospital, Department of Medical Genetics, Bergen, Norway;* [2]*Ski Barneklinikk, Ski, Norway;* [3]*Trondheim University Hospital, Department of Pediatrics, Trondheim, Norway;* [4]*Trondheim University Hospital, Department of Medical Genetics, Trondheim, Norway;* [5]*Nordland Hospital Trust, Department of Paediatrics, Bodø, Norway;* [6]*Sørlandet Hospital, Department of Paediatrics, Kristiandsand, Norway;* [7]*Oslo University Hospital, Department of Medical Biochemistry, Oslo, Norway;* [8]*Oslo University Hospital, Norwegian National Unit for Newborn Screening, Division of Paediatric and Adolescent Medicine, Oslo, Norway*

Background: TANGO2 deficiency, described in 2016, is a recessive disorder of cellular trafficking characterised by developmental delay, seizure, spasticity, and hypothyroidism. Sudden "TANGO2-spells" with hypotonia, dysarthria, ataxia, and head tilt can last for hours without symptoms in between. Acute metabolic decompensation can occur, with life-threatening cardiac arrhythmia, rhabdomyolysis, and hypoglycaemia. Treatment with B-vitamin complex might prevent decompensation and thus be lifesaving. The most common allele is a deletion of exons 3-9 (60%). We aimed to search for missed diagnoses among patients analysed with chromosomal microarray.

Methods: We reanalysed all 2013-2023 Cytoscan HD SNP arrays for intragenic *TANGO2* deletions. *TANGO2* is included in the 22q11.2 microdeletion (DiGeorge), but these were not reanalysed.

Results: Among 13000 arrays, we identified one homozygous and nine heterozygous deletions. One carrier had a suspicious phenotype on the 2014-referral form, and WES disclosed *TANGO2* VUS+ (NM_152906.7) c.473C>T p.(Ala158Val) in trans. Clinical follow-up showed a typical phenotype in both patients; one was wrongly assigned with alternating hemiplegia and treated with a calcium blocker. The deletion was ~ 34kb and included ~ 28 array probes, below our cut-off of 30. The homozygous patient already had a normal WES, but our WES pipeline does not call CNVs.

Conclusion: A manual search for *TANGO2* deletions resulted in two patients reaching a correct diagnosis and treatment that might prevent early death. The carrier frequency of the deletion in Western Norway is ~ 1/1000. We implemented interventions to detect homozygous *TANGO2* deletions on WES.

Conflict of Interest: None declared

P15.031.D Genes with limited proof of disease causality - to report or not to report

Adela Chirita-Emandi[1;2], *Maria Puiu*[1;2]

[1]*Clinical Emergency Hospital for Children Louis Trucanu, Regional Center for Medical Genetics Timis, Timisoara, Romania;* [2]*Univeristy of Medicine and Pharmacy Victor Babes, Genetics, Timisoara, Romania*

Background/Objectives: Significant efforts were made to establish whether particular DNA variants identified, are (likely) pathogenic or not. The interpretation criteria designed by ACMG, have become standard for variant interpretation in clinical practice. Yet, other guidelines are available, such as the ABC System that also take into account the disease. There is less consensus regarding which are genes are indeed associated with well-described phenotypic features in humans. For many, well-described conditions, gene–disease relationships(GDR) are usually clear, however much less for very rare or heterogeneous conditions(e.g. cardiomyopathies, intellectual disability). There are curated databases such as OMIM(omim.org) or ClinGen(clinicalgenome.org) that focus on establishing GDR. Yet, there is no guideline to advise on criteria regarding GDR. Consequently, the reporting of genes with limited proof of disease causality(GLPDC) varies between laboratories.

Methods:A retrospective analysis regarding GLPDC on NGS reports from the Regional Center of Medical Genetics Timis, Romania, evaluated panels(1494), exomes(105) and genomes(55) in people with various rare diseases.

Results:Depending on disease there could be 50% or more negative results for panel, exome and genome sequencing. Reporting variants in GLPDC depended on the NGS test, as the panel versus exome and genome sequencing had less chance to identify variants in GLPDC. Trio analysis increased the chance for GLPDC. Less than 5% of results had reported variants in GLPDC.

Conclusion: Reporting variants in GLPDC could be valuable as they could represent indeed monogenic causes of disease or could represent disease modifiers. However, reporting variants in GLPDC may also cause distress to the families. Guideline for GDR reporting are needed.

P15.032.A Variant-Curator: An open platform for the development and use of variant interpretation guidelines

Max Xiaohang Zhao[1;2], *Felix Boschann*[1;2;3], *Bernt Popp*[4]

[1]*Charité - Universitätsmedizin Berlin, Institute of Medical Genetics and Human Genetics, Berlin, Germany;* [2]*Berlin Institute of Health at Charité, Universitätsmedizin Berlin, Berlin, Germany;* [3]*Berlin Institute of Health at Charité, Universitätsmedizin Berlin, BIH Biomedical Innovation Academy, Clinician Scientist Program, Berlin, Germany;* [4]*Berlin Institute of Health at Charité, Universitätsmedizin Berlin, Center of Functional Genomics, Berlin, Germany*

Background/Objectives: Since the ACMG's 2015 sequence variant interpretation recommendation, variant interpretation systems have formalized, diversified, and become more complicated. The guidelines lack accompanying tools that allow easy utilization. Also, no standardized formats exist for exchanging interpretation information. We propose an open solution for creating, validating, and utilizing diverse variant interpretation frameworks that is capable of fully implementing currently published best practices for variant interpretation.

Methods: Our interpretation framework solution is web-based and built using modern web-development methodologies, including TypeScript and vue.js for the front-end interface. Our tool does not require a central server and can be used in a decentralized manner. We also suggest an interchange format for variant interpretation schemas that includes a self-contained format with evidence and variant information.

Results: We present an early version of our framework, which includes a functional web service for assessing variants using flexible schemas and full support for ClinGen criteria specification (CSpec) interpretation guidelines. We provide a schema editor tool for editing and creating schemas. We provide a draft of the proposed schema data structure and tools for reproducible variant interpretation and structured inclusion of evidence data points. This will allow for automation of individual criteria. Our tools make variant assessments sharable and reproducible. The system is easy to install locally and integrate into existing pipelines.

Conclusion: Our variant interpretation platform enables reproducibility in variant interpretation while remaining open to future developments in the interpretation frameworks used. Our tools and code are open, free to use by anyone and can be tested at variant-curator.arsbrevis.de.

Consortium: UKSH Genom Konsortium

Background/Objectives: Genome sequencing (GS) promises to be a one-test-for-all strategy, but prospective studies on the benefits of GS for patients in a real-world setting are still limited. We performed a prospective real-world study, by directly comparing single GS (SGS) and trio GS (TGS) in rare diseases patients with the established tiered standard of care (SC) approach. We analyzed 1148 genomes of individuals affected by developmental disorders, congenital anomalies, or monogenic neurological conditions. Our study aimed to assess diagnostic yield and turnaround time in a head-to-head comparison.

Methods: Between January 2022 and April 2023 345 trios and 85 singletons underwent the SC workflow (cytogenetics, Array-CGH, index exome sequencing) and in parallel short-read SGS and TGS. Three independent scientific teams performed: 1. SC workflow 2. SGS and 3. TGS analysis. Results were compared afterwards.

Results: A Molecular diagnosis with clinical assertion was reported via cytogenetics in 1,8%, Array-CGH in 4,3%, and exome sequencing in 43% reaching a total of 49,1% for SC compared to 50,7% for SGS and 51,3% for TGS. Discrepancies were caused by deep intronic variants and small copy number variants. Turnaround times averaged at 18 weeks for SC, 10 weeks for SGS, and 6 weeks for TGS. TGS significantly reduced time for segregation analysis and improved evaluation of variants.

Conclusion: We demonstrate that SGS and TGS outperform SC approaches, significantly reduce turnaround times, and can serve as a one-test-for-all strategy in rare disease. We anticipate that diagnostic yields for TGS will increase with deeper knowledge about the noncoding variants.

P15.034.C Somatic TP53 mutations (sTP53m) in cell-free circulating DNA (cfDNA) in high-grade serous ovarian cancer (HGSOC)

Catherine Ramsden[1], *John McDermott*[1;2;3], *Andrew Clamp*[4;5], *Jurjees Hasan*[4], *Claire Mitchell*[4], *Zena Salih*[4], *Emma Woodward*[1;2;3], *Gareth Evans*[1;2;3], *Stephen Taylor*[5], *Gordon Jayson*[4;5], *Helene Schlecht*[1;2], *George Burghel*[1;2;3], *Robert Morgan*[4;5]

[1]*Manchester Centre for Genomic Medicine, North West Genomic Laboratory Hub, Manchester, United Kingdom;* [2]*Department of Clinical Genetics, Manchester University NHS Foundation Trust, Manchester, United Kingdom;* [3]*Division of Evolution, Infection and Genomics, School of Biological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom;* [4]*Department of Medical Oncology, The Christie NHS Foundation Trust, Manchester, United Kingdom;* [5]*Division of Cancer Sciences, School of Medical Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom*

Background/Objectives: The commonest type of ovarian cancer, HGSOC, is characterised by near ubiquitous s*TP53*m. Percutaneous diagnostic biopsies of abdominopelvic tumours are invasive and risk complications; therefore, we developed a non-invasive liquid biopsy to detect s*TP53*m in cfDNA (cf*TP53*m) for HGSOC.

Methods: Whole blood was centrifuged twice to extract plasma, and cfDNA was isolated using the cobas® cfDNA Sample Preparation Kit. gDNA was isolated from FFPE tissue using the cobas® DNA Sample Preparation Kit. Single-primed PCR enrichment used a QIAseq Targeted DNA Custom Panel, including UMIs, and next-generation sequencing was performed on an Illumina platform. An in-house bioinformatic pipeline reported variants with an allele frequency (VAF)≥5% and sequencing data was manually inspected for variants with lower VAFs.

Results: 33 women (median age = 53, range = 39-78) with HGSOC donated tumour/plasma. Plasma was donated at 61 timepoints (TPs; 14 women donated plasma at ≥2TPs) including pre-chemotherapy (n = 28), mid-chemotherapy (n = 4) and during surveillance (n = 29). s*TP53*m were detected in tumour DNA in 26/29 (90%; VAF 5-81%; n = 4 had no solid tumour available). cf*TP53*m were detected in 26/61 (43%; VAF 1-50%) plasma samples (21/33 women). cf*TP53*m were most often detected in pre-chemotherapy plasma (19/28, 68%). In 17 women with s*TP53*m detected in tumour and cfDNA, the concordance was 100%. 2/4 women with no solid tumour had a detectable cf*TP53*m. 2/3 women with no s*TP53*m in tumour DNA had a detectable cf*TP53*m.

Conclusion: We report a proof-of-concept liquid biopsy to detect cf*TP53*m in HGSOC. Further optimisation is required to enrich for cf*TP53*m in post-chemotherapy plasma.

P15.035.D Single-molecule real-time sequencing of an amplicon containing two highly identical homologous genes may lead to sequence errors.

Jeroen Knijnenburg[1], *Youp Zegers*[2], *Rebecca Van Esveldt*[1], *Leon Hailiang Mei*[2], *Susan Kloet*[3], *Sahila Balkassmi*[1], *Tamara Koopmann*[1], *Cornelis Harteveld*[1]

[1]*Leiden University Medical Center, Clinical genetics, Leiden, Netherlands;* [2]*Leiden University Medical Center, Sequence analysis support core, Leiden, Netherlands;* [3]*Leiden University Medical Center, Human genetics, Leiden, Netherlands*

Background/Objectives: The human alpha globin A (HBA) gene cluster region is involved in recessive alpha-thalassemia disease, which can be defined by reduced synthesis of alpha-globin chain and consequently a mild to severe (hemolytic) anemia. A series of founder mutations are well known, ranging from single nucleotide variants to larger deletions, duplications and gene conversions. Correct diagnostics of variants is hampered by the fact that the region is built up out of seven homologous genes and pseudogenes, of which the coding genes HBA1 and HBA2 are embedded in a duplicated homologous area. They differ slightly over the introns and the 5′ untranslated region, but more over the 3′ untranslated regions. Multiple techniques - usually deletion PCR, Sanger sequencing of several fragments and MLPA - are needed for a correct molecular diagnosis.

Methods: Single-molecule real-time (SMRT) sequencing of a 6,2 kb long-range PCR fragment including the HBA1 and HBA2 genes was set up to detect the most common variants in the HBA gene cluster. A pilot set with known variants was tested. Electrophoresis of the long-range PCR fragments showed the expected fragment length. SMRT sequencing was expected to generate reads of the same length.

Results: The majority of generated reads were shorter than expected, showing a hybrid 2,5 kb sequence fragment with an in vitro gene conversion, fusing HBA1 to HBA2 and splicing out the region in between during the sequencing process.

Conclusion: This technical artefact may hamper a correct identification of variants in amplicons covering homologous regions.

Background/Objectives: Congenital anomalies, affecting around 2-3% of births, predominantly stem from genetic disorders. The nascent implementation of trio-based exome sequencing for prenatal genetic diagnosis varies significantly among hospitals, yielding highly variable diagnostic rates.

This study aimed to assess the efficacy of prenatal genetic diagnosis through trio-based exome analysis.

Methods: Over the period 2019-2023, the Genetics Unit conducted 173 prenatal studies on pregnancies with ultrasound anomalies following genetic counselling and informed consent. Exome sequencing was performed on fetal DNA samples and parental DNA. Variants were classified according to ACMG criteria in genes directly linked to ultrasound abnormalities, categorized as pathogenic or non-informative.

Results: Of the 173 studies, 30% (n = 52) yielded pathogenic outcomes, while the remainder were non-informative. Pathogenic results comprised variants classified as pathogenic or probably pathogenic, with 60% being of de novo origin and 29% autosomal recessive.

Ultrasound abnormalities demonstrated varying detection rates, with skeletal anomalies leading at 40% (16/40). Central nervous system anomalies and intrauterine growth retardation/hydrops fetalis both exhibited a pathogenic report in 34% (10/29 and 14/41, respectively). Cardiovascular anomalies had the lowest detection rate at 21% (6/29).

Conclusion: Exome trio sequencing proves valuable for prenatal diagnosis, though its application necessitates specific guidelines and the establishment of comprehensive gene databases linked to prenatal ultrasound phenotypes. This study sheds light on the potential of this approach while emphasizing the need for standardized protocols and genetic databases to enhance its clinical utility.

P15.037.B Implementation of an automated diagnostic WES workflow for multiple sample types

Tom Hofste[1], *Fallon Berkhout*[1], *Jordi Corominas Albany*[1], *Michiel Oorsprong*[1], *Hilde Swinkels*[1], *Manon Oud*[1], *Sanne Smeekens*[1], *Remco van Cruchten*[2], *Marjan Weiss*[1], *Christian Gilissen*[1], *Marcel Nelen*[1], *Helger Yntema*[1]

[1]*Radboudumc, Human Genetics, Nijmegen, Netherlands;* [2]*Radboudumc, Pathology, Nijmegen, Netherlands*

Background/Objectives: The Genome Diagnostics laboratory of the Human Genetics department at Radboud University Medical Center provides rapid whole exome sequencing since 2017, with a maximum turnaround time of 15 days (from sample to report). With the continuously increasing number of requests, the manual workflow was no longer sufficient. Automated workflows are needed more than ever to meet the increasing demand in sample throughput and sequencing capacity, whilst minimizing the risk of human errors. A major goal was to enlarge the sample volume in the clinical rapid WES service while retaining the turnaround time.

Methods:

Results: We implemented an automated WES workflow based on Twist Bioscience protocol on a Hamilton Microlab® STAR Liquid Handling platform. This workflow has enabled high-quality exome data with less hands-on time and a decrease in human error potential with end-to-end sample tracking. However, being a core facility, our laboratory receives patient DNA samples from a large number of national and international laboratories, often varying in concentration, volume, and buffer composition. We noticed that these variables have a significant impact on enzymatic fragmentation showing more vulnerability to failures. In order to eliminate these concerns around sample quality, we integrated mechanical shearing using the Covaris R230 Focused-ultrasonicator on-deck, enabling standardized and robust shearing, regardless of sample input.

Conclusion: Using this automated library preparation workflow, we have been able to expand our clinical rapid WES service, through increased sample throughput for multiple sample types, such as blood, saliva, amnion, chorion, cell line and FFPE, whilst maintaining the turnaround time to patient report.

Conflict of Interest: Tom Hofste Radboudumc, Fallon Berkhout RadboudUMC, Jordi Corominas Albany Radboudumc, Michiel Oorsprong Radboudumc, Hilde Swinkels Radboudumc, Manon Oud Radboudumc, Sanne Smeekens Radboudumc, Remco van Cruchten Radboudumc, Marjan Weiss Radboudumc, Christian Gilissen Radboudumc, Marcel Nelen Radboudumc, Helger Yntema Radboudumc

P15.038.C Closing diagnostic gaps by long-read sequencing: from phasing to repeat expansion detection

Helene Faust[1], *Patricia Duffek*[1], *Henry Oppermann*[1], **Denny Popp**[1]

[1]*University of Leipzig Medical Center, Insitute of Human Genetics, Leipzig, Germany*

Background/Objectives: In routine diagnostics, the analysis of short fragments by short-read NGS and state-of-art molecular genetic methods, e.g. Sanger sequencing and qPCR, is often a limiting factor for phasing variants, discriminating genes from the respective pseudogenes, analyzing structural variants, methylation and repeat expansions. In contrast, long-read sequencing can overcome these limitations due to technically unlimited read lengths and methylation data. Here, we provide examples for a variety of long-read sequencing applications.

Methods: Nanopore sequencing was applied for clinical cases when a pathogenic variant could not be found or pinpointed by state-of-art molecular genetic methods. Either genomic DNA or long-range PCR amplicons were subjected to Nanopore sequencing optionally using adaptive sampling. Data was analyzed mainly by Integrative Genomics Viewer (IGV).

Results: Long-range amplicons were used to phase a de novo and an inherited variant in *AFG3L2* proving them as compound heterozygous and to locate a rare splicing variant in the gene *NBEA* excluding it in its pseudogenes. A 3.4 Mb inversion affecting *SLC19A2* was validated and segregated via differential annealing-mediated racket PCR and long-read sequencing. In another case, allele-specific methylation information was exploited to locate a pathogenic variant in *IKBKG* on the preferentially inactivated X-chromosome. A repeat expansion of the pathogenic motif ATTTC was identified in *DAB1* establishing the diagnosis of spinocerebellar ataxia 37.

Conclusion: Long-read sequencing is a valuable addition to the toolbox of routine genetic diagnostic methods as long read and methylation information can be used to close current diagnostic gaps and address manifold diagnostic questions.

P15.039.D Effects of rare protein-coding variants in reported monogenic obesity genes in a general population study

Raina Jia[1], *felix day*[1], *katherine kentistou*[1], *john perry*[1;2], *ken ong*[1]

[1]*University of Cambridge, MRC Epideimology Unit, Cambridge, United Kingdom;* [2]*University of Cambridge, MRC Metabolic Diseases Unit, Wellcome-MRC Institute of Metabolic Science, Cambridge, United Kingdom*

Background/Objectives: Previous clinical studies have identified variants in genes associated with monogenic obesity, but their penetrance in the general population remains largely unknown. This study uses exome sequencing data from the UK Biobank (UKBB) to evaluate the effect of heterozygous variants in these genes on adult BMI and recalled childhood body size.

Methods: This study assessed the impact of rare (MAF < 0.1%) deleterious protein-coding variants in nine monogenic obesity genes in 419,581 UKBB participants of white European ancestry. We examined loss-of-function variants predicted by in silico tools, and by literature extracted in vitro evidence. Moreover, we examined the interaction effects of rare variants with a polygenic risk score for adult BMI.

Results: Carriers of predicted loss-of-function heterozygous variants in *MC4R*, *PCSK1*, and *POMC* had a higher risk of increasing adult BMI and increasing childhood body size (all p <0.003, Bonferroni corrected). *KSR2* also had a significant effect on childhood body size. No significant interaction was found between rare variant carrier status in any gene and a common variant score ($p < 0.006$, Bonferroni corrected). Among heterozygous carriers of reported experimentally characterised loss-of-function variants, obesity penetrance ranged from 8% to 29% (median = 23%) for six genes with at least 10 carriers in the UKBB.

Conclusion: In this population study, rare variants in *MC4R*, *PCSK1*, and *POMC* contribute to childhood and adult obesity risk. The incomplete obesity penetrance observed for reported experimentally characterised loss-of-function variants highlights the ongoing challenges in interpreting the pathogenicity of variants in monogenic disease.

P15.040.A Detection of germline copy number variations in Inborn Errors of Immunity using Ion AmpliSeq™ custom panel in genetic diagnostic clinic

Mohammad Sina[1], *Seyedeh Zahra Mousavi*[2], *Rosalba Monica Ferraro*[1], *Elena Laura Mazzoldi*[1], *Keivan Majidzade-A*[3], *Shiva Zarinfam*[2;3], *Silvia Clara Giliani*[1]

[1]*A. Nocivelli Institute for Molecular Medicine, Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy;* [2]*Department of Molecular Genetics, Faculty of Biological Sciences, Tarbiat Modares University, Tehran, Iran;* [3]*Motamed Cancer Institute, Breast Cancer Research Center, ACECR, Genetics Department, Tehran, Iran*

Background/Objectives: Inborn Errors of Immunity (IEIs) are rare monogenic disorders that impair human immune system functions. More than 450 genes are analyzed by next generation sequencing (NGS), and analysis of copy number variations (CNVs) could enhance the diagnostic performance by approximately 12%. Identifying CNVs remained a persistent challenge, especially with the Ion Torrent PGM sequencing platforms

Methods: A cohort of 189 patients with IEIs, negative for small variants using AmpliSeq™ PGM NGS platform, underwent CNV analysis using the HMZDelFinder and GATK-gCNV. A search was conducted to identify a specific 23-base pair Alu insertions within the panel gene.

Results: HMZdefinder found 54 homozygous deletions, six oft hem were selected for wet lab validation; none were confirmed. Mappability analysis disclosed 80 targets (1.2%) of 6478 were not unique, primarily in the *PMS2* gene. There was no correlation between false-positive detection of homozygous deletion and mappability. GATK-gCNV identified 500 copy number variations across 181 samples, 106 occurrences were unique, including 88 heterozygous and six homozygous deletions, and 12 with an increase in copy number. Depth of coverage analysis by IGV and and Samtools was applied on these areas and regions with low consistency were excluded. A total of Seven regions were selected for real-time PCR analysis, and the mutation in the *CLBP* gene was confirmed. A tool to visually represent exons in consecutive sequences alongside their respective peers was developed.

Conclusion: Validating predicted variations through alternative methods is crucial, given the false-positive rate that exceeds 90%.

Background/Objectives: Large-scale CNVs analysis in exomes remains challenging.

Methods: A novel pipeline for homozygous CNV analysis from exomes was developed. Relevant calls were validated. Clinical and functional studies were performed for novel disorders.

Results: From a phenotypically heterogeneous cohort of 2,021 exomes enriched for consanguinity we called 42,386 homozygous losses and filtered 1,224 calls, which we prioritised to identify 20 diagnoses resulting from homozygous chromosome deletions involving known recessive disease-genes.

We also identified 9 possibly novel recessive ultra-rare single gene disorders and detected further patients with variants in 4 of these genes in additional datasets to confirm: *VPS36*-related neurodevelopmental disorder; *FAM177A1*-related motor disorder; *TFCP2L1*-related renal tubulopathy; and *FILIP1*-related arthrogryposis with microcephaly. RT-PCR from patient fibroblasts showed that the *VPS36* deletion results in a truncated transcript at a lower abundance than in controls. RNAi-mediated *vps36* knockdown in developing *drosophila* larvae caused developmental delay, early lethality, and locomotion defects. Further work with mutant transgenic lines and crispant zebrafish models of other selected genes is ongoing.

We also identified 2 potentially unique recessive contiguous gene deletion disorders: 14q32.33 *IGHV* genes cluster knockout in an individual with palmoplantar keratoderma; and 6p22.2 knockout including a histone genes cluster in a patient with microcephaly, seizures, and white matter abnormalities.

Conclusion: Our pipeline significantly reduces analytical burden, improves diagnosis, shows that disorders of ~2% probands in our cohort are attributable to homozygous chromosome deletions, and leads to discovery of novel ultra-rare and unique recessive diseases.

P15.042.C Development of external quality assessment for trio exome sequencing

Dave Cregeen[1], *Julia Baptista*[2], *Karen Stals*[3], *Hannah Robinson*[3], *Zandra Deans*[1]

[1]*GenQA, NINE, Edinburgh BioQuarter, Edinburgh, United Kingdom;* [2]*Synnovis, King's College Hospital, London, United Kingdom;* [3]*Exeter Genomics Laboratory, Royal Devon and Exeter University Healthcare Foundation Trust, Exeter, United Kingdom*

Background/Objectives: Trio exome sequencing analysis is performed routinely by diagnostic genomics laboratories for rare monogenic disorders which can be phenotypically and genetically heterogeneous. Genomics Quality Assessment (GenQA) has provided external quality assessment (EQA) for exome sequencing since 2021 to assess the quality of analysis, interpretation, and reporting. In 2021 the EQA comprised data analysis of single nucleotide variants (SNVs), in 2022 this was expanded to include data analysis of copy number variants (CNVs), and in 2023 DNA samples were included.

Methods: Exome sequencing results (or DNA samples) and clinical information were provided to participants who were required to analyse and report clinically relevant variants using their routine format. Variants reported (including classification), clinical interpretation and clerical accuracy was assessed by a panel against peer-reviewed marking criteria.

Results: Participation has increased to 64 laboratories in 2023 with the majority able to analyse both SNVs and CNVs. Variant classification and the evidence utilised varied considerably although clinically relevant variants are reported in most cases. Most participants included all results in a single report however many provided three separate reports. Clinical interpretation for the index case was generally good, however the implications for future offspring and the wider family were often omitted.

Conclusion: EQA for trio exome sequencing has been developed and run successfully for 3 years. Most participants can interpret both SNV and CNV results however variant classification can be inconsistent. This EQA will promote improvements to reporting in the clinical setting and will be provided as a DNA-based scheme going forwards.

Background/Objectives: The past decade has brought about significant changes to hereditary breast and ovarian cancer (HBOC) diagnostic testing therefore we sought to update the previous EMQN testing guidelines published in 2007.

Methods: To achieve broad expert consensus, laboratory representatives from centres across the UK, EU and Canada met via teleconferences to generate a first guideline draft. These were further consolidated with a final draft circulated to the broad EMQN community for feedback. The comments were considered and the final guidelines approved in November 2023.

Results: The guidelines summarise cancer risk data from recent studies for the most commonly tested high and moderate risk HBOC genes for laboratories to refer to as a guide. Furthermore, 50 recommendations are provided for somatic and germline testing services with regards to clinical referral, laboratory analyses, variant interpretation, and reporting. The guidelines present recommendations where '**must**' is assigned to advocate that the recommendation is essential; and '**should**' is assigned to advocate that the recommendation is highly advised but may not be universally applicable. Finally, for the purposes of encouraging standardisation and aiding implementation of recommendations, example report wording covering the essential points to be included is provided for the most common HBOC referral and reporting scenarios.

Conclusion: These guidelines are aimed primarily at genomic scientists working in diagnostic testing laboratories. In addition to the summarising cancer risk data from recent studies, the 50 recommendations alongside the example report wording encourages international HBOC test standardization.

P15.044.A Inter laboratory variability in DNA extraction from fresh tissue – A 2023 EQA review

Fiona Moon[1], *Zandra Deans*[1]

[1]*GenQA, Edinburgh, United Kingdom*

Background/Objectives: With advances in cancer genomic testing technologies, the requirement to optimise extraction methods to produce DNA of high quality is increasingly crucial. However, many laboratories are unable to benchmark their extraction protocols due to the variability of tissue routinely received within diagnostic laboratories.

Methods: To allow laboratories to evaluate the quality and quantity of DNA they can extract from fresh tissue, and benchmark their performance, GenQA provides a DNA extraction from fresh tissue EQA. Participating laboratories are provided with standardised fresh tissue samples and asked to extract DNA using their routine extraction protocol. Prior to extractions, laboratories could either snap freeze, or extract the tissue fresh.

Results: Laboratories returned the extracted DNA to GenQA, which was then assessed using droplet digital PCR (ddPCR) and weight to determine the quantity of DNA extracted. The quality of DNA extracted was determined by assessing the DNA integrity numbers (DIN) using TapeStation.

Nine different extraction methods were used by the 23 participating laboratories. There was no correlation between the weight of tissue supplied and the resulting mass of DNA extracted. The yield of DNA was variable across laboratories, ranging from 1.6 to 220µg. The DIN was consistently high, with an average DIN of 7.8 out of 10, which supports the evidence that fresh tissue is a good source of high molecular weight DNA.

Conclusion: The variability in mass extracted reaffirms the importance of EQA in supporting laboratories to highlight where improvements should be made to get the most from their samples.

Conflict of Interest: None declared

P15.045.B The association between Whole Exome Sequencing and Sanger sequencing in the discovery and (re)classification of gene variants in patients suggestive of cytogenomic alteration and normal results

Giovana Toccoli[1], *Henrique Garcia Silveira*[1], *Beatriz Carvalho Nunes*[1], *Priscila Soares Rodrigues*[1], *Maria Isabel Melaragno*[1]

[1]*Universidade Federal de São Paulo, Department of Morphology and Genetics, São Paulo, Brazil*

Background/Objectives: The investigation of genetic alterations using different methodologies allows the identification of the etiology of the disease with greater resolution. In this project, patients with a phenotype suggestive of cytogenomic rearrangement presenting normal karyotype and chromosome microarray results were referred for investigation of the diagnosis using Whole Exome Sequencing (WES). Thus, the determination of the variant' pathogenic mechanisms and relationship with the phenotype can benefit the patient, the genetic counseling of the family, and also the scientific knowledge.

Methods: A sample of 30 patients with a phenotype suggestive of cytogenomic rearrangement who have normal cytogenomic tests were studied by WES. The detected gene variants were classified following the recommendations of the American College of Medical Genetics (ACMG), with subsequent genotype-phenotype correlation.

Results: WES results showed pathogenic or likely pathogenic variants in 11 patients and a variant of uncertain significance in one patient. A variant classified as likely pathogenic was reclassified as pathogenic due to a de novo presentation, revealed by parental segregation analysis using Sanger sequencing. This variant was correlated with the phenotype of the patient, confirming the Xia-Gibbs syndrome, which is a rare syndrome with around 300 cases reported worldwide. Sanger sequencing for other cases will help in the reevaluation of the variant pathogenicity.

Conclusion: WES can assist in the diagnosis of patients with an altered phenotype and normal cytogenomic tests. The paternal segregation of the variants determined by Sanger sequencing allows their reclassification, thus completing the diagnostic investigation.

Grants: CNPq, CAPES and FAPESP.

P15.046.C Whole exome sequencing revealed variants in the *KMT2A* gene responsible for Wiedemann-Steiner Syndrome in three individuals with initial suspicion of 22q11.2 deletion syndrome

Henrique Garcia Silveira[1], *Carlos Eduardo Steiner*[2], *Giovana Toccoli*[1], *Luise Longo Angeloni*[2], *Júlia Lôndero Heleno*[2], *Samira Spineli-Silva*[2], *Ana Mondadori dos Santos*[2,3], *Társis Paiva Vieira*[2], *Maria Isabel Melaragno*[1], *Vera Lucia Gil-da-Silva-Lopes*[2]

[1]*Universidade Federal de São Paulo, Departament of Morphology and Genetics, São Paulo;* [2]*Universidade Estadual de Campinas, Genética Médica e Medicina Genômica, Departamento de Medicina Translacional, Campinas;* [3]*Faculdade São Leopoldo Mandic, Campinas*

Background/Objectives: 22q11.2 deletion syndrome (22q11.2DS) presents high phenotypic variability with no exclusive clinical features, resulting in phenotypic overlap with other conditions. *KMT2A* variants are associated with Wiedemann-Steiner syndrome (WDSTS) and result in variable phenotypes. Here we describe three patients with initial clinical suspicion of 22q11.2DS and later identification of variants in the *KMT2A*. For the first time in literature, it was possible to compare differences and similarities between both disorders.

Methods: The patients were evaluated by a checklist for 22q11.2DS. Karyotype, MLPA, FISH, and chromosomal microarray analysis were used to investigate the 22q11.2 locus. Whole exome sequencing (WES) was performed to identify sequence variants. Sanger sequencing was performed on one patient's parents to verify the segregation of the variant. The interpretation of the variants was conducted according to recommendations of the ACMG, followed by genotype-phenotype correlation.

Results: All patients showed clinical features compatible with 22q11.2DS. All cytogenomic tests were normal. WES revealed three different heterozygous pathogenic variants in *KMT2A*. One patient had a de novo variant confirmed by Sanger sequencing of the parents. The comparison of two large cohorts of both syndromes from the literature indicated a phenotypic overlap concerning neuropsychiatric disorders and some facial features. However, hypertrichosis and thick eyebrows were described in WDSTS, while congenital heart diseases and velopharyngeal

insufficiency were described in 22q11.2DS. The three patients have a combination of phenotypes from both syndromes.

Conclusion: We suggest that WDSTS and 22q11.2DS should be included in each other's differential diagnoses.

Grants: FAPESP, CNPq, and CAPES

P15.047.D Developing and scaling BeginNGS, an artificial intelligence-enabled genome sequencing system for newborn screening, diagnosis, and precision medicine for 412 childhood genetic diseases.

Katarzyna Ellsworth[1;2], *Meredith Wright*[1;2], *Lauren Olsen*[1;2], *Mei Baker*[3;4], *Sara Caylor*[1;2], *Thomas Defay*[5], *Annette Feigenbaum*[1;2;6], *Lucia Guidugli*[1;2], *Soofia Khan*[1;2], *Yong Kwon*[1;2], *Alisa Lam*[1;2], *Jennie Le*[1;2], *Jerica Lenberg*[1;2], *Yupu Liang*[5], *Lakshminarasimha Madhavrao*[1;2], *Rebecca Mardach*[1;2;6], *Bill Mowrey*[5], *Daeheon Oh*[1;2], *Liana Protopsaltis*[1;2], *Muhammed Saad*[1], *Erica Sanford*[1], *Gunter Scharer*[1], *Jennifer Schleit*[1;2], *Brandan Schultz*[1;2], *Laurie Smith*[1], *Mari Tokita*[1;2], *Lucitia Van Der Kraan*[1], *Kristen Wigby*[1;2;6], *Mary Willis*[1], *Mark Yandell*[7], *Charlotte Hobbs*[1;2;6], *Stephen Kingsmore*[1;2]

[1]*Rady Children's Institute for Genomic Medicine, San Diego, United States;* [2]*Rady Children's Hospital - San Diego, San Diego, United States;* [3]*State Hygiene Laboratory, Madison, United States;* [4]*University of Wisconsin School of Medicine and Public Health, Madison, United States;* [5]*Alexion Pharmaceuticals, Inc., Boston, United States;* [6]*University of California San Diego, Department of Pediatrics, La Jolla, United States;* [7]*Fabric Genomics, Oakland, United States*

Background: Newborn genome sequencing (GS) can build upon the success of existing newborn screening (NBS) in severe, childhood disorders by identification and treatment at/before symptom onset. BeginNGS is a precision medicine delivery platform for treatable/preventable genetic childhood diseases, based on rapid GS, artificial intelligence, and a precision medicine guidance system. We developed and tested version 2 of BeginNGS in preparation for a large, adaptive clinical trial.

Methods:54,168 pathogenic (P) and likely pathogenic (LP) variants from ClinVar and Mastermind (Genomenon) associated with 412 disorders and 341 genes were selected for this phase. These disorders were associated with 1,722 effective therapeutic interventions. The sensitivity and specificity of the platform were tested in diverse populations: ~450,000 UK Biobank, ~140,000 Mexico City Prospective Study subjects, and 7,575 individuals who had received diagnostic rGS.

Results: In 3,118 children with suspected genetic disorders diagnostic rGS had reported 187 variants in 152 BeginNGS disorders. BeginNGS identified 78.6% of these variants and 81.5% of these disorders. With the addition of Transformer (Fabric), BeginNGS identified 98.4% of diagnostic rGS-reported variants and 98.7% of rGS-positive probands. Among 3,519 family members of probands who received diagnostic rGS, BeginNGS identified 3.6% actionable findings. In archived newborn DBS from 705 infant deaths, BeginNGS identified 57 positive subjects, with 18% of these having effective therapies.

Conclusion: These studies suggest a generalizable approach to validation of pathogenicity assertions associated with rare/ultra-rare genetic disorders. BeginNGS has sufficient analytic performance to proceed to a large, adaptive clinical trial of BeginNGS as a supplement to standard NBS.

Background/Objectives: Just over half of 9,000+ rare genetic disorders have a known cause and clinical exome sequencing only diagnoses 35-40% of patients tested. To address these issues we created the University of Wisconsin Undiagnosed Disease Program (UW UDP), whose goals are to: 1) provide patients with actionable diagnoses; 2) discover new disease genes and mechanisms; and 3) evaluate emerging technologies.

Methods: Our standard workflow begins with clinical WES reanalysis, followed by trio genome sequencing, supplemented by long-read WGS, optical mapping, and/or RNA-Seq.

Results: To date, the UW UDP has enrolled 113 probands and 172 relatives. >85% of probands had prior clinical WES. We identified candidate causal variants for 9 of our first 22 probands, including detecting a deletion and an instance of chromoanasynthesis missed by clinical testing, identifying new candidate disease genes, using RNA-Seq to rule out a clinical diagnosis of Aicardi Goutieres syndrome as well as determining that a patient's novel phenotype is the likely result of synergy between two rare disorders. We recently switched to Nanopore long-read genome sequencing as our first-tier test and are investigating the diagnostic utility of routine methylome analysis.

Conclusion: Our initial results suggest that an undiagnosed disease program can be an important component of a comprehensive center for rare diseases, as augmenting clinical testing with comprehensive research evaluations and access to emerging technologies can yield overall diagnostic rates exceeding 55% while advancing our understanding of rare genetic disorders.

Grants: Funding provided by the UW Center for Human Genomics and Precision Medicine

P15.049.B Clinician access to genomic data improves diagnostic rate by 10%: experience of pitfalls of variant prioritization

Adrienne Elbert[1], *Indhu Rajan Babu*[2], *Nan Zhang*[3], *Cuong Bui*[3], *Karar Al-Mamaar*[1], *SHELIN ADAM*[2], *Stephanie Huynh*[1], *Shila Padhi*[3], *Hyun Lee*[1], *Jan Friedman*[2], *Cornelius Boerkoel*[1], *Laura Li*[3]

[1]*Provincial Medical Genetics Program, Medical Genetics, Vancouver, Canada;* [2]*The University of British Columbia, Medical Genetics, Vancouver, Canada;* [3]*Breakthrough Genomics, Irvine, United States*

Consortium: CAUSES

Background/Objectives: Clinical genomic and exome sequencing are often conducted through proprietary, variant prioritization tools and analytic pipelines that are not transparent for biases

and weakness. We hypothesized that re-analysis through alternate variant prioritization tools could improve diagnostic rates where clinical genomic testing was uninformative. We question the analytic, clinical and cognitive factors leading to missed molecular diagnoses.

Methods: We use an artificial intelligence platform Virtual Geneticist, as well as Exomiser and LIRICAL, in a cohort of solved research exome cases (positive control). Then we utilized these tools to perform a re-analysis within the clinic in two cohorts (n = 163 undiagnosed research cases and n = 71 undiagnosed clinical cases) ascertained for suspected genetic disease. We quantify the number of new diagnoses that result from factors internal to the process of variant prioritization, with reflection on the contributing factors for each solved case.

Results: AI-based variant prioritization in positive controls ranks the diagnostic variant among the top 10 in 99% of solved cases. Further clinical work-up and collaboration between the clinicians, laboratory and research resulted in new diagnoses in 10% of the cases. We identify increased phenotype complexity (dual genetic diagnoses and phenotype expansion) in the newly solved cases. Conflicting interpretation of disease mechanism, in particular for genes with multiple gene-phenotype dyads, and variant mechanism data (amorph, hypomorph, antimorph), are a major factor contributing to non-reported variants.

Conclusion: Clinician access to non-diagnostic exome data for the purpose of variant re-prioritization through alternate analytic pipelines improves diagnostic rates in suspicious cases by 10%.

Grants: N/A

P15.050.C Using episignatures for reclassifying variants of uncertain significance: A real world systematic analysis and guidelines development

Christopher Campbell[1], *Siddharth Banka*[1,2], *Bekim Sadikovic*[3], *Marielle Alders*[4], *Matthew Tedder*[5]

[1]*Manchester University NHS Foundation Trust, Manchester Centre for Genomic Medicine, Manchester, United Kingdom;* [2]*University of Manchester, Division of Evolution, Infection and Genomics, Manchester, United Kingdom;* [3]*London Health Sciences Centre, Verspeeten Clinical genome Centre, Ontario, Canada;* [4]*Amsterdam Reproduction and Development Research Institute, Department of Clinical Human Genetics, Amsterdam, Netherlands;* [5]*Greenwood Genetic Center, Greenwood, United States*

Consortium: Manchester Centre for Genomic Medicine

Background/Objectives: Episignatures are being increasingly used to assess variant pathogenicity. However, guidelines for application of episignatures to reclassify VUS are required.

Methods/Results: From England's national diagnostic episignature service database, we identified 89/309 individuals who underwent testing for VUS interpretation. To ensure uniformity, we classified all variants using the ACMG guidelines.

EpiSign™ episignature analysis was positive in 45/89 (51%) cases. The prior Bayesian pathogenicity probabilities of 38/45 of these variants were ≥0.675 (warm VUS) (range 0.325-0.812). Adding a moderate (PP4/PS3_Mod) or strong (PP4/PS3_Strong) weighted pathogenic evidence criterion enabled reclassification of 38 or 45 variants respectively to Likely Pathogenic.

An episignature was not present in 44/89 (49%) cases. The prior Bayesian probabilities of 27/41 of these variants were ≤0.5 (tepid VUS) (0.1-0.812). Adding a moderate (BS3_Mod) or strong (BS3_Strong) weighted benign evidence criterion enabled reclassification of 2 or 4 variants respectively to Likely Benign. The remainder remained classified as a VUS, but with reduced posterior probability of pathogenicity.

These results were used to develop internal laboratory guidelines for VUS reclassification using episignatures. In brief, we recommend adding PP4/PS3_Strong to VUSs with positive episignatures; and BS3 to VUSs with negative episignatures with a prior probability of ≤0.5, and where the variant attributes fit the properties of the variants included in the episignature.

Conclusion: Episignature results correlate with prior Bayesian pathogenicity probabilities and are effective in reclassification of VUSs. These guidelines are being validated through the international Episign™ Clinical Testing Network (ECTN) expert group to help consolidate clinical reporting of episignature results in VUS reclassification across ECTN.

Conflict of Interest: None declared

P15.051.D Trio-genome analysis followed by subsequent targeted deep sequencing as diagnostic strategy for very low-grade mosaic detection

Maj-Britt Salewski[1], *Inga Nagel*[1], *Kirstin Hoff*[1], *Caroline Utermann-Thuesing*[1], *Daniel Kaschta*[1], *Franziska Gaass*[2], *Yorck Hellenbroich*[2], *Malte Spielmann*[1,2], *Inga Vater*[1]

[1]*University Hospital Schleswig-Holstein, Campus Kiel, Institute of Human Genetics, Kiel;* [2]*University Hospital Schleswig-Holstein, Campus Lübeck, Institute of Human Genetics, Lübeck*

Background/Objectives: Trio genome sequencing (GS) is increasingly supplanting diagnostic standard care strategies in human genetics. The advantages of this technique are not only the streamlined workflow of elucidating the segregation patterns of potentially disease causing variants, it also enables the identification of germline mosaics with low frequencies. The detection of such mosaics plays a pivotal role in assessing the likelihood of variant recurrence in offspring and thus has a significant impact on genetic counseling practices.

Methods: Short-read GS was performed in a patient with non-syndromic intellectual disability and gait disturbances and his unaffected parents. PCR amplification of the affected *ZNF711* sequence was required for subsequent in-depth sequencing.

Results: A hemizygous variant, NM_001330574.2:c.2299C>T p.(Arg767*), in *ZNF711* was identified, which likely caused the patient's symptoms. Trio GS revealed only one single read in the maternal dataset (Total depth: 37), that matched the variant of the index. Targeted deep sequencing confirmed a low-grade mosaic with an allele frequency of 2.1% (Total depth > 400,000).

Conclusion: The detection of low-frequency mosaic variants represents a challenge, but is crucial for the diagnosis and genetic counseling of affected families. Conventional Sanger sequencing lacks the sensitivity required for reliable mosaic detection and moreover is limited to a specific short sequence. With particular attention to evaluation, trio GS enables the detection of low-frequency mosaics on a genome-wide basis. Followed by in-depth sequencing this promises to be a highly suitable method for uncovering very low-frequency germline mosaics in health care.

P15.052.A Preparing for paediatric screening: Targeted next-generation sequencing of saliva DNA from patients with Familial Hypercholesterolemia

Mosekunola Oladapo[1], *Niloofar Shirvanizadeh*[1], *Kristina Duvefelt*[1], *Peter Benedek*[1]

[1]*Karolinska University Hospital, Translational Analysis in Molecular Medicine, Cancergenomics and Proteomics, Pathology and Cancer-diagnostics, Medical Diagnostics Karolinska, Stockholm, Sweden*

Background/Objectives: Familial hypercholesterolemia (FH) is the most common autosomal dominant inherited disease, with a prevalence of 1/300. The disease causes highly elevated LDL cholesterol levels and left untreated it is strongly associated with premature atherosclerotic cardiovascular disease and premature death. FH is predominantly caused by heterozygous mutations in one of three genes: *LDLR*, *APOB*, or *PCSK-9*. DNA extracted from saliva is easy to obtain, non-invasive and stable at room temperature, and therefore suitable for paediatric genetic testing.

The aim of this study was to evaluate the suitability of using DNA prepared from saliva for DNA sequencing utilizing the Devyser FH NGS V2 kit to facilitate future paediatric screening.

Methods: Paired blood and saliva samples were obtained from twenty patients with suspected FH. DNA from blood was extracted with the QiAsymphony automated method, saliva DNA was collected and prepared using Oragene OG-610 kits. The total DNA concentration of all samples was measured using Picogreen. The DNA content of the saliva samples was analyzed using qPCR.

Sequencing was performed with Devyser FH-v2 kit according to their protocol on a MiSeq instrument.

Results: All QC parameters for the sequencing were within specifications from the vendor. The SNV data concordance was 100% between the paired blood and saliva samples, this applied both to common SNVs and FH mutations. The results were 100% concordant between replicates. A study concerning CNV detection is ongoing.

Conclusion: Saliva samples can be used for detection of FH mutations using the Devyser FH-v2 kit, and could facilitate testing through easier, non-invasive sampling.

P15.053.B Integration of updated ACMG/AMP criteria for solving VOUS: a comprehensive review of past results in diagnostic tests

Thaís Córdova[1], *gui rosa*[1], *isa salgado*[1], *cintia ventura*[1], *joaquim sá*[1;2], **marisa teixeira**[1], *rita cerqueira*[1]

[1]*CGC Genetics, Unilabs, Porto, Portugal;* [2]*ULS de Coimbra, Coimbra, Portugal*

Background: In 2015, the American College of Medical Genetics and Genomics/Association for Molecular Pathology (ACMG/AMP) published their first guidelines for variant interpretation. However, Variants of Unknown Clinical Significance (VOUS), as defined by this system, pose a significant challenge in clinical settings. As such, a series of subsequent updates have been produced to improve criteria accuracy. Here, we revisited VOUS reported by our laboratory to assess whether the three latest updates (PP3/BP4, PVS1, PP1/PP4/BS4) could help solve their clinical significance.

Methods: Non-CNV VOUS reported in WES-based panels and single gene analysis for Alport Syndrome, CADASIL, Paraganglioma/Pheochromocytoma, Tuberous Sclerosis, Hereditary Hemorrhagic Telangiectasia and Noonan Syndrome, performed between 2020-2023, were filtered from our in-house data. Variants were reassessed leveraging the above-mentioned updated ACMG/AMP criteria. We also updated allele frequencies and constraint metrics according to GnomAD version 4.

Results: 131 VOUS were filtered, of which three (2.3%) were solved to Pathogenic, and twenty (15.3%) to Likely Pathogenic. No reported variant was reclassified to Likely Benign, but six (4.6%) gained benignity and/or lost pathogenicity criteria. The diagnostic yield virtually increased 17.6%, but the rate of solved VOUS was uneven between the chosen disorders.

Conclusion: We performed a comprehensive analysis of VOUS reported by our laboratory in the past four years for six different disorders. Integrating the most recent variant interpretation guidelines into our workflow improved VOUS resolution. Lack of curated disease-specific information and insufficient clinical information were the most important causes of an uneven diagnostic yield between the chosen disorders.

Conflict of Interest: None declared

P15.054.C A highly specific molecular diagnostic pipeline designed to sequence PKD1, a GC-rich gene partially existing in multiple copies, using a single round amplicon-based next-generation sequencing workflow

Maria Pozova[1], *Grigoris Constantinou*[1], *George Michael*[1], *Avgousta Petrou*[1], *Margarita Kazdagli*[1], *Apostolos Malatras*[1], *Alkis Pierides*[1], *Christoforos Stavrou*[2], *christiana polydorou*[1], *Constantinos Deltas*[1;3], *Gregory Papagregoriou*[1]

[1]*University of Cyprus, biobank.cy Center of Excellence in Biobanking and Biomedical Research, Nicosia, Cyprus;* [2]*Evangelismos Private Hospital, Nephrology Department, Paphos, Cyprus;* [3]*University of Cyprus, Medical School, Nicosia, Cyprus*

Background/Objectives: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease and is primarily caused due to mutations in genes *PKD1* and *PKD2*. Existing in multiple copies, *PKD1* remains a technical challenge for standard and next-generation sequencing (NGS) approaches. Hence, a cost-effective and robust pipeline was developed and optimized to sequence *PKD1*.

Methods: Sequence selection for *PKD1* was achieved by highly specific long-range PCR amplification of the gene in five sections, followed by amplicon-based NGS on the S5 GeneStudio system. To validate this method, 48 patients with previously described cystic kidney disease were screened for *PKD1* pathogenic variants. A complementary amplicon-based panel was used to sequence 23 additional genes, including *PKD2, PAX2*, *DNAJB11*, *GLIS2*, *JAG1*, *TSC1*, *TSC2*, *SEC63*, *GANAB*, *ALG5*, *ALG8*, *MUC1*, *UMOD*, *REN*, *HNF1B* and *SEC61A1*. Variants were called and annotated using the IonReporter V5.12 platform and validated by orthogonal methods.

Results: Quality checks of NGS runs confirmed the validity and high performance of the pipeline. Moreover, patient analysis revealed 40 pathogenic variants in *PKD1* and 4 in *PKD2* (13 missense, 23 nonsense/frameshift, 3 splicing, 3 large indels, 2 in-frame deletions), and 10 in other genes tested.

Conclusion: We have developed a first-in-line diagnostic tool for fast, confident, and specific clinical screening of *PKD1* by NGS, paired with a comprehensive analysis of additional genes explaining chronic renal failure due to cystic kidneys or tubular defects.

Grants:
This project is funded by a Horizon2020 grant [GA:857122/CY-BIOBANK] provided by the European Union, the Republic of Cyprus, and the University of Cyprus

P15.055.D Beat the clock: Exome reanalysis based on the new genes described during the ESHG 2023 conference.

Núria Martínez-Gil[1;2], *Amaia Lasa-Aranzasti*[1;2], *Jordi Leno*[1;2], *Irene Valenzuela Palafoll*[1;2], *Laura Trujillano*[1;2], *Anna Maria Cueto-González*[1;2], *Barbara Masotto*[1;2], *Eulàlia Rovira-Moreno*[1;2], *Anna Abulí*[1;2], *Patricia Muñoz-Cabello*[1;2], *Miriam Masas*[1], *anna tenes*[1], *Elena García-Arumí*[1;2], *Eduardo Tizzano*[1;2], *Marta Codina*[1;2]

[1]*Vall d'Hebron University Hospital, Department of Clinical and Molecular Genetics, Barcelona, Spain;* [2]*Vall d'Hebron Research Institute, Medical Genetics Group, Barcelona, Spain*

Background/Objectives: Whole Exome Sequencing (WES) is used for the diagnosis of genetic disorders, with a diagnostic yield of approximately 20-50%. Data reanalysis increase the diagnosed cases by 15-20%, thanks to new clinical information and novel causative genes. Every year a plethora of new articles are published describing new gene-disease associations. Although the information is eventually included in databases such as OMIM or HPO, the time lag between the publication and inclusion of information eventually result in a diagnostic delay.

Methods: To overcome this drawback we investigated a quicker diagnosis method, taking advantage of the knowledge shared between researchers at the ESHG 2023 conference. In particular, we have collected all novel genes described in oral and poster sessions and the phenotypes coded in HPO terms. With this data, we retrospectively searched through an in-house pipeline for potential pathogenic variants among more than 1300 exomes of rare disease patients followed at the Vall d'Hebron university hospital.

Results: Overall, we have compiled 83 new gene-disease associations, 46 with a recessive inheritance and 37 with a dominant inheritance. After variant prioritization, we identified in our series 102 candidate variants in 30 genes. Comparing the phenotype of our patients with the newly described entity, we found 12 variants in 10 different genes that could lead to the patient's diagnosis.

Conclusion: This approach may be applied to routine clinics as it helps to accelerate the diagnosis process and provides new information in the description of a novel gene, reducing the genetic diagnostic odyssey of undiagnosed cases.

Grants: FJC2021-046715-I

P15.056.A CYP21A2 variant detection for molecular diagnosis of Congenital Adrenal Hyperplasia from Whole Genome Sequencing

Kevin Savage[1], *Louise McClelland*[2], *Gavin Ryan*[2], *Piers Fulton*[2], *Vitor Onuchic*[3], *Eric Roller*[3], *Susan Walker*[1], *Katrina Stone*[1], *David Bick*[1], *Matt Brown*[1], *Ellen Thomas*[1], *Richard Scott*[1], *Sue Hill*[2], *Dalia Kasperaviciute*[1]

[1]*Genomics England, London, United Kingdom;* [2]*NHS England, London, United Kingdom;* [3]*Illumina, San Diego, United States*

Background/Objectives: Congenital Adrenal Hyperplasia (CAH), prevalence 1:15,000, can be caused by CYP21A2 variants. High homology with paralog CYP21A1P complicates analysis using short-read sequencing.

Methods: We investigated performance of Dragen v4's CYP21A2 caller for clinical diagnosis of CAH, using WGS (150bp paired-end) across four cohorts:

Controls (n = 4644): no expected CAH.
CAH cases (n = 6): explicit CAH phenotype.
Potential CAH cases (n = 2080): compatible phenotype including ambiguous genetalia and salt wasting.
PCR genotyped (n = 9): with additional PCR test results. 6/9 had no pathogenic variants.

The caller only reports variants from known variants included in software configuration. We compared configuration against diagnostic variants reported by current standard of care testing in England (527 alleles covering 43 variants).

Results: In controls 2% (101/4644, CI 0.17-0.26%) had combined CYP21A2/CYP21A1P copy number = 2 (reference = 4), indicating common paralog deletion. 0.2% (10/4644, CI 0.1%-0.3%) had two pathogenic variants. Only 0.08% (4/4644, CI 0.02%-0.2%) had two predicted severe variants.

4/6 CAH cases had two pathogenic variants detected, showing strong enrichment. No enrichment of variants was seen among potential CAH cases (4/2080, 0.2%, CI 0.05%-0.4%).

From the PCR cohort, we detected 2/3 positive cases with no false positives. The variant in the remaining positive case was absent from caller configuration. 92% (488/527) of diagnostic alleles reported by current PCR testing were in caller configuration.

Conclusion: The CYP21A2 caller accurately detects known variants, improving clinical WGS for CAH. However, novel variant detection remains challenging.

P15.057.B Diagnostic efficacy of WGS data reanalysis in a clinical setting

Majbritt Busk Madsen[1], *Andreas Ørslev Rasmussen*[1], *Magnus Gislason*[1], *Luca Robinson*[1], *Frederik Otzen Bagger*[1], *Maria Rossing*[1]

[1]*Copenhagen University Hospital, Rigshospitalet, Department of Genomic Medicine, Copenhagen, Denmark*

Background/Objectives: The use of whole genome sequencing (WGS) in clinical diagnostics has increased rapidly, and one of the advantages of WGS is that it allows for revisiting data when new knowledge occur. Thus, initially, we determined the diagnostic success rate in a patient cohort analyzed with WGS as part of their diagnostic work-up. Subsequently, we aim to reprocess and reanalyze the WGS data applying the latest knowledge of the genetic background of their respective diseases, hopefully increasing the diagnostic yield.

Methods: All clinical WGS samples sequenced at the Department of Genomic Medicine, Copenhagen University Hospital, from Dec 2017 to Nov 2022 were included in the study (n = 2990). The original diagnostic reports were curated, and reporting of a likely

pathogenic or pathogenic variant in a disease-relevant gene was regarded as a solved case (n = 405). The cohort consist of 2318 patients with various diseases, assessed either as single probands (n = 2141) or as part of a pedigree (n = 177). Samples were reprocessed with the latest version of the Danish national bioinformatic pipeline, including analysis of large structural variants, and reinterpreted with updated gene-lists and knowledge of respective disease mechanisms.

Results: Based on the curation of the clinical reports, preliminary results show a positive diagnostic yield of 17.5%, thus 1913 samples were eligible for WGS data reprocessing and reinterpretation. Sixty percent (1386/2318) had not previously been analyzed for large genomic rearrangements.

Conclusion: These preliminary results of a large-scale reevaluation project show great promise for increasing the diagnostic yield in a clinical diagnostic setting.

Background/Objectives: The crucial impact of re-assessment of the genetic data by medical geneticist in the era of artificial intelligence and automated variant filtering and interpretation is underestimated but remains essential in difficult cases. Demonstrating the clinical utility of craft genetics, we report on four clinical scenarios from our outpatient clinic in which manual reevaluation together with joint clinical and genetic data interpretation were essential to make the diagnosis. We highlight aspects being important to consider in clinically highly suspicious cases with negative routine test results.

Methods: We report four families with a strong suspicion of a rare monogenic disease. Array-CGH, short-read exome or genome sequencing were performed. Automated routine diagnostic workflows were applied and reevaluated.

Results: Routine diagnostic workflows failed to identify causative variants in all scenarios. However, various cases-specific reassessment approaches, such as re-annotation of non-coding DNA regions or data complementation from a second tissue, led to firm diagnoses. By reevaluation, we identified (likely) pathogenic variants and established the diagnoses of Wieacker-Wolff syndrome (*ZC4H2*), mosaic Cornelia de Lange syndrome (*NIPBL*), alveolar capillary dysplasia with misalignment of pulmonary veins (*FOXF1*), and distal hereditary motor neuronopathy type 8 (*SORD*).The automated workflows were unsuccessful in finding a causative variant on account of the existence of multiple transcripts, low allele fraction, deletion in an enhancer region and a novel disease association absent from databases, respectively.

Conclusion: In modern genetic diagnostics, craft genetics stays invaluable and can significantly increase the diagnostic yield. The inclusion of novel assessment strategies is a prerequisite to develop more intelligent analysis tools.

P15.059.D A *COL4A4* novel founder mutation causes autosomal recessive Alport syndrome in the Cypriot population

christiana polydorou[1], *Gregory Papagregoriou*[1], *Despina Hadjipanagi*[1], *George Michael*[1], *lakis yioukkas*[2], *maria kkolou*[3], *androulla pastelli*[4], *panayiota loukaidou*[4], *Chrysoula Pipili*[5], *kypros constantinou*[6], *toumasi elpida*[6], *isavella savva*[6], *andreas soloukides*[7], *Constantinos Deltas*[1;8]

[1]*University of Cyprus, biobank.cy Center of Excellence in Biobanking and Biomedical Research, Nicosia, Cyprus;* [2]*Paphos General Hospital, Nephrology Department, Paphos, Cyprus;* [3]*Nephrology Department, Larnaca General Hospital, Larnaca, Cyprus;* [4]*Larnaca General Hospital, Nephrology Department, Larnaca, Cyprus;* [5]*Famagusta General Hospital, Nephrology Department, Paralimni, Cyprus;* [6]*Nicosia General Hospital, Transplant Center, Nicosia, Cyprus;* [7]*Nicosia General Hospital, Transplantation Center, Nicosia, Cyprus;* [8]*University of Cyprus, University of Cyprus Medical school, Nicosia, Cyprus*

Background/Objectives: Alport syndrome (AS) is a rare genetically heterogeneous inherited glomerulopathy, which is characterized by persistent microscopic hematuria (MH) since childhood, progressing to proteinuria and chronic kidney function decline, leading to kidney failure.

Methods: In this study we studied seven patients from four Cypriot families with collagen IV nephropathy, using next generation sequencing (NGS) analysis.

Results: Patients in all four families, which originate from geographically different parts of the island, inherited a founder novel pathogenic variant in the *COL4A4* gene, substituting arginine for glycine at amino acid residue 1248 (COL4A4:p.-Gly1248Arg). This variant was never reported in genomic or exomic databases or the Human Gene Mutation Database (HGMD), while it has high scores of pathogenicity in prediction algorithms. The variant has not been detected in 1000 exomes of the Cypriot general population (CYPROME) and according to ACMG-AMP criteria, it is classified as a variant of uncertain significance leaning to likely pathogenic (VUS-Franklin by Genoox). A homozygous patient for COL4A4:c.3742G>C, (p.Gly1248Arg) variant, reached end-stage renal disease (ESRD) and was transplanted at the age of 46-yrs, whereas another heterozygous relative in the same family reached ESRD at 58-yrs. All other heterozygous patients presented a spectrum of clinical symptoms, always including MH.

Conclusion: This is strong evidence that the variant should be classified as pathogenic/likely pathogenic, establishing a clinical diagnosis, and enabling correct counseling and treatment.

Grants: This project is funded by a Horizon2020 grant [GA:857122/CY-BIOBANK] provided by the European Union, the Republic of Cyprus, and the University of Cyprus

Genetics, Rotterdam, Netherlands; [4]Hospital Center University De Montpellier, Montpellier, France; [5]Bioscientia Labor Ingelheim, Ingelheim am Rhein, Germany

Background/Objectives: Inherited retinal disorders (IRDs) represent an important cause of blindness. Pathogenic variants in >250 genes have been identified as causal. The clinical utility of a precise genetic diagnosis is well documented. Gene augmentation therapy for patients with IRD due to biallelic variants in *RPE65* is now available, and several clinical trials for gene-specific therapies are underway. Thus, diagnostic proficiency is vital for improved patient outcomes. The aim of this work was to implement an external quality assessment (EQA) scheme for IRDs, to ensure laboratories correctly identify patients eligible for therapeutic intervention.

Methods: Thirty laboratories from 17 countries were selected to participate in a pilot EQA scheme. Four DNA samples and corresponding mock clinical case scenarios were supplied for testing. Three samples were provided for analysis of genes associated with approved/in trial therapies (e.g.- *RPE65*, *RPGR*, *RPGR ORF15*) and one for gene panel analysis. Clinical reports were assessed for genotyping, interpretation, and accuracy by an independent team of experts.

Results: Twenty-six laboratories returned clinical reports. Preliminary data indicates on average, 83% of laboratories received full marks for genotyping, 27% received full marks for interpretation and 65% received full marks for clerical accuracy. Laboratories performed least well in the case involving RPGR ORF15 testing.

Conclusion: EQA for IRDs has enabled a thorough assessment of laboratory performance, including the reporting of variants associated with crucial clinical interventions. We anticipate that continued provision of this scheme will serve to raise and maintain testing standards and facilitate standardisation of clinical reporting.

P15.061.B Family study of the distribution pattern of whole-genome-based polygenic risk scores in families with ulcerative colitis

Ingrid Lojova[1;2;3], Jaroslav Minárik[1;3], Zuzana Pös[1;2], Mario Hlavacka[4], Adam Hurtuk[5], Oliver Kubicka[5], Natalia Forgacova[1;2;3], Silvia Bokorová[2], Lýdia Lukyová[2], Zuzana Holesova[6], Andrea Zatkova[1], Tatiana Sedlackova[2], Juraj Gazdarica[2;7], Jaroslav Budiš[2;7], Tomas Szemes[2;3], **Jan Radvanszky**[1;2;3]

[1]Institute of Clinical and Translational Research, Biomedical Research Center of the Slovak Academy of Sciences, Department of Human Genetics, Bratislava; [2]Comenius University Science Park, Bratislava; [3]Department of Molecular Biology, Faculty of Natural Sciences, Bratislava; [4]Faculty of Mathematics, Physics and Informatics, Comenius University, Department of Applied Informatics, Bratislava; [5]Institute of Informatics, Information Systems and Software Engineering, Faculty of Informatics and Information Technologies of Slovak University of Technology, Bratislava; [6]Geneton Ltd., Bratislava; [7]Slovak Center of Scientific and Technical Information, Bratislava*

Background/Objectives: Genomic predispositions for inflammatory bowel disease (IBD), including ulcerative colitis (UC), may have complex patterns, including both monogenic, oligogenic and highly polygenic forms. We present our findings on: 1) the effect of four different selection strategies for choosing potentially relevant genomic positions for polygenic risk score (PRS) calculations; 2) the patterns of PRS distributions among UC affected and unaffected family members; and 3) the results of screening for potential monogenic pathogenic variants.

Methods: WGS data were generated for 62 individuals, including 7 UC patients, 7 family members (three families) and 48 controls. Risk positions were extracted from GWAS Catalog. PRSs were calculated using the linear weighted sum of risk alleles. Monogenic causes were screened using a commercial annotation tool.

Results: We proved the potential of PRSs in identifying at-risk individuals, but also in selecting patients for screening of monogenic/oligogenic UC. Considering the different variant sets tested, those obtaining the widest range of genomic positions (i.e. positions associated with traits IBD) were found to have the largest discriminatory power between patients and controls. Family members have not always increased PRSs. We also identified a novel variant/gene-phenotype association, possibly causing mono-/oligogenic UC. The significance of the identified *ZBP1* variant (NM_030776.3:c.3G>A) will require further studies.

Conclusion: PRSs promise breakthroughs in prevention, diagnostics and therapy of complex diseases, especially when combined with screening for monogenic genetic causes.

P15.062.C STRavinsky STR database and PGTailor PGT tool, demonstrating superiority of CHM13-T2T over hg38 and hg19 for STR-based applications

Noam Hadar[1], **Amit Safran**[1]*, ginat narkis[1;2], Shirly Amar[2], Marina Varnavsky[2], Glenda Calniquer Palti[2], Ohad Shmuel Birk[1;2]*

[1]Morris Kahn Laboratory of Human Genetics, NIBN and Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel; [2]Genetics Institute, Soroka Medical Center, Beer Sheva, Israel

Background/Objectives: The possible involvement of Short-Tandem-Repeats (STRs) in various biological processes has been a subject of extensive research. STRs are significant in diverse fields, including forensics, evolutionary biology, and pre-implantation-genetic-testing (PGT). Commonly used reference genomes such as GRCh37/hg19 and GRCh38/hg38, primarily constructed through short-read sequencing, have been limited in STR mapping. However, advancements in long-read sequencing and the creation of the CHM13-T2T reference genome have now allowed for an accurate and comprehensive integration of STRs into the human genome framework.

Methods: We developed *STRavinsky*, a detailed and extensive STR database, compatible with hg19, hg38, and T2T genomes, using high performance computing. Using *STRavinsky*, we developed *PGTailor*, an interactive web-application designed for PGT assay creation.

Results: Our analysis reveals that the T2T genome outperforms its predecessors, hg19 and hg38, by identifying a significantly higher number of STRs. Notably, we observed a pronounced frequency of TGGAA repeat sequences in the short arms of acrocentric chromosomes, supporting earlier hypotheses about their role in the genesis of Robertsonian translocations. Intriguingly, we pinpointed a unique concentration of these repeats in specific regions, such as 16q11.2 and 9q12, hinting at their potential involvement in prevalent cytogenetic abnormalities. Finally, leveraging the enhanced capabilities of T2T and *STRavinsky*, we introduced *PGTailor* - an innovative freely-available

online tool designed to streamline and simplify the creation of STR-focused PGT assays in mere minutes: https://fohs.bgu.ac.il/birklab/PGTailor.

Conclusion: *STRavinsky* leverages the comprehensive nature of the T2T genome to offer a complete STR mapping database, essential for both research and clinical purposes, enabling novel insights to aberrations in human genetics.

Conflict of Interest: None declared

P15.063.D Trio whole exome sequencing in pediatric intensive care unit patients: Illuminating the clinical utility

Hannah Wallaschek[1], *Nadia Meyer*[1], *Joelle Ronez*[1], *Manuela Richter*[2], *Jost W. Richter*[3], *Alexander von Gise*[2;4], *Gunnar Schmidt*[1], *Nataliya Di Donato*[1], *Bernd Auber*[1], *Sandra von Hardenberg*[1]

[1]*Hannover Medical School, Department of Human Genetics, Hannover, Germany;* [2]*Children's Hospital Auf der Bult, Department of Neonatology, Hannover, Germany;* [3]*Klinikum Braunschweig, Department of Neonatology, Braunschweig, Germany;* [4]*Hannover Medical School, Department of Pediatric Cardiology and Intensive Medicine, Hannover, Germany*

Background/Objectives: Rare genetic disorders often present as severe multisystemic conditions and are a significant cause of pediatric hospitalization in intensive care units (ICU). Diagnosis can be challenging and often includes a variety of invasive procedures. Whole exome sequencing (WES) including parent sequencing (trio-WES) is a potent tool to detect the genetic causes of rare diseases. Here we report on the utility of trio-WES from the clinicians' perspective and the position of trio-WES in the diagnostic pathway.

Methods: The diagnostic yield and clinical utility was evaluated via the C-GUIDE™ questionnaire in 45 pediatric ICU patients in which trio-WES had been performed. Furthermore, operations and procedures (OPS) during the ICU stay were analyzed.

Results: The 45 patients received 331 OPS before initiating trio-WES, another 109 OPS were performed while waiting for the genetic results. The average turnaround time (TAT) for genetic results was 25 days. Genetic diagnosis was provided for 37.8% of the children. Clinical utility was considered generally high with a mean score of 7.34 in the C-GUIDE, and even higher when a genetic diagnosis was confirmed (14.07 vs 3.42).

Conclusion: Trio-WES is an effective diagnostic tool. The high C-Guide score underline its clinical utility. Our results should encourage clinicians to consider genetic testing during ICU stays as a first-tier diagnostic to avoid invasive OPS. Duration of WES is still time-consuming. Numerous additional tests were performed during TAT, and some children passed away in the meantime. In the future, rapid sequencing can address this issue.

P15.064.A COL4A5 p.(Gly743Ala) missense substitution identified in a large Italian family. Is this variant truly likely pathogenic, or could it be considered a likely predisposing allele?

Sergio Daga[1;2], *Lorenzo Loberti*[1;2;3], *Riccardo Pracella*[4], *Anna Carrer*[1;2;3], *Pietro Ilardi*[1;2;3], *Giulia Rollo*[1;2], *Kristina Zguro*[1;2], *Andrea Guarnieri*[5], *Guido Garosi*[5], *Alessia Giorli*[6], *Marco Mandalà*[6], *Francesca Ariani*[1;2;3], *Rossella Tita*[3], *Marco Castori*[4], *Alessandra Renieri*[1;2;3], *Maria Antonietta Mencarelli*[3]

[1]*Medical Genetics, University of Siena, Siena, Italy;* [2]*Med Biotech Hub and Competence Center, Department of Medical Biotechnologies, University of Siena, Siena, Italy;* [3]*Genetica Medica, Azienda Ospedaliero-Universitaria Senese, Siena, Italy;* [4]*Division of Medical Genetics, Poliambulatorio "Giovanni Paolo II", Fondazione IRCCS-Casa Sollievo della Sofferenza, Viale Padre Pio 7, 71013, San Giovanni Rotondo, Italy;* [5]*Department of Medical Sciences, Nephrology, Dialysis and Transplantation Unit, University Hospital of Siena, Siena, Italy;* [6]*Department of Otolaryngology Unit, University of Siena, Azienda Ospedaliero Universitaria Senese, Siena, Italy*

Background/Objectives: *COL4A5* gene variants cause X-Linked Alport Syndrome (AS) with males exhibiting severe renal impairment while females present only microhaematuria. Most of the deleterious substitutions, affecting Glycines in the collagenous domain, significantly alter the protein, impact the folding capacity of the heterotrimer, and often lead to end-stage kidney disease. Nevertheless, is it possible that some *COL4A5* variants are not associated with typical AS?

Methods: Employing Clinical Exome Sequencing (CES) we identified a p.(Gly743Ala) *COL4A5* variant, classified as likely pathogenic according to ACMG guidelines, as an incidental finding in a 6-years-old boy without microhaematuria/proteinuria.

Results: We ascertained the germinal origin, identifying it in 12 out of 15 family members screened (80%), unusually without AS signs except for two which reported eGFR decrease and transplantation *COL4A5*-unrelated. No variants in modifier genes allowing to mitigate or reduce the pathogenic impact of p.(Gly743Ala), have been identified. The in-silico comparison on the prediction of mutant stability suggests destabilizing impact and disfunctionalization, however these data are in contrast with the genotype/phenotype correlation so much so this variant seems to not cause renal-extrarenal manifestations.

Conclusion: The ever-increasing use of CES opens up new chapters in the diagnostic field, in particular in late-onset or chronic diseases that are not devoid of difficulties in interpretation in the clinical context. A crucial role is taken on by variants such as the p.(Gly743Ala) that can be classified as a "likely predisposing allele" assuming a new role in follow-up, therapeutic interventions and psychological management of patients and families.

P15.065.B Flexible and rapid validation of structural variation using nanopore adaptive sequencing

Aida Paivandy[1], *Felix Lenner*[1], *Tord Jonson*[2], *Hans Ehrencrona*[2], *Anna Lindstrand*[3], *Jennifer Howe*[4], *Stephen Scherer*[4], **Lars Feuk**[1]

[1]*Uppsala University, Immunology, Genetics and Pathology, Uppsala, Sweden;* [2]*Lund University, Department of Laboratory Medicine, Lund, Sweden;* [3]*Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden;* [4]*The Hospital for Sick Children, The Centre for Applied Genomics, Toronto, Sweden*

Background/Objectives: Identification of genomic rearrangement by microarrays or shortread sequencing often lacks information about the exact architecture and breakpoints of variants due to technical limitations. In addition, validation of complex structural variants (SVs) is often performed using custom assays, complicating confirmation of relevant findings. In this study we evaluate nanopore adaptive sequencing for flexible and rapid validation and characterization of complex genomic rearrangements.

Methods: Adaptive sequencing is an in silico target enrichment, where continued sequencing or ejection of a fragment is based on whether it matches a defined reference sequence. Using adaptive sequencing, we targeted 10 regions of different SV types, including deletions, translocations and complex rearrangements. Each sample was analyzed on a MinION flow-cell, and to evaluate multiplexing, four samples were run together on flow-cell on the P2 device.

Results: MinION sequencing resulted in between 13.5-17.8 Gb of data per flow cell, with mean on-target coverage of 18-34X and an off-target read depth average of 4.6X. We were able to validate all targeted SVs, and identify breakpoints at nucleotide resolution with one exception. We also show that background reads can be used to detect SVs in non-targeted regions of the genome.

Conclusions: Our results show that adaptive sequencing represents a robust, flexible and rapid strategy for validation of clinically relevant complex genomic rearrangements in patient samples. By providing sequence information, read depth and methylation data, nanopore adaptive sequencing has advantages over other validation assays used in diagnostic labs today.

P15.066.C Comprehensive evaluation of AlphaMissense predictions by evidence quantification for variants of uncertain significance

Amina Kozaric[1;2], *Lejla Delalic*[1], *Belma Mutapcic*[1;2], *Lejla Comor*[1], *Eric Siciliano*[1], *Mark Kiel*[1]

[1]*Genomenon, Inc, Ann Arbor, United States;* [2]*International Burch University, Ilidža, Bosnia and Herzegovina*

Background: Accurate variant classification is critical for genetic diagnosis. Variants without clear classification, known as variants of uncertain significance (VUS), pose a significant diagnostic challenge. The AI-based AlphaMissense algorithm, correlating with known variants, has not been evaluated for VUS. This study examines AlphaMissense performance in variant classification, specifically for VUS.

Methods: A systematic comparison between AlphaMissense predictions and ACMG/AMP classification was conducted for 5845 missense variants in 59 genes associated with representative Mendelian disorders. A framework for quantifying and modeling VUS pathogenicity was used to facilitate comparison. Sensitivity, specificity, density distribution, heatmaps, Sankey plot, and statistical analyses were performed using R studio.

Results: Manual review classified 5845 variants as 4085 VUS, 1576 pathogenic/likely_pathogenic, and 184 benign/likely_benign. AlphaMissense prediction and ACMG classification were concordant for 1887 variants (1352 pathogenic, 132 benign, and 403 VUS/ambiguous). The sensitivity and specificity of AlphaMissense predictions for pathogenicity were 92% and 78%. Quantitation of VUS evidence and heatmaps weakly correlated with AlphaMissense score. For VUS without computational evidence, AlphaMissense incorporation changed VUS quantification for 878 variants, while 56 were reclassified to likely pathogenic. When AlphaMissense replaced existing computational evidence for all VUS, 1709 variants changed quantified criteria, while 63 were reclassified to likely pathogenic.

Conclusion: AlphaMissense, while promising for predicting known pathogenicity, currently lacks reliability suitable for predicting classification of clinically encountered VUS. Our research suggests augmenting AlphaMissense with empirical evidence may improve performance through incorporation of a quantitative framework aiding in VUS classification.

Grants: This study was funded by NHGRI R44HG010446.

Consortium: International Precision Child Health Partnership (IPCHiP)

Background/Objectives: GeneSTEPS is a multi-centre study examining the diagnostic yield and clinical utility of rapid trio whole genome sequencing (WGS) in epilepsy patients <12 months old. Current analysis strategies show a 48% diagnostic yield. However, bioinformatic filtering strategies face several limitations, such as variants in non-coding regions, calling of mosaic variants and detection and filtering of structural and mitochondrial variants. Here, we describe initial results of deeper interpretation strategies which have increased diagnostic yield.

Methods: Four strategies have been applied 1) gene agnostic analysis was used to look for potential novel genes, 2) all known pathogenic variants in the ClinVar database were called, 3) de novo non-coding variants within epilepsy genes were investigated, 4) non-coding variants were investigated in cases with a single hit in an autosomal recessive gene.

Results: Two novel genes have been identified as potential candidate genes; work is being undertaken to investigate these further. A novel *DNM1* de novo deep intronic variant near other variants with proven effect on splicing was detected in one patient and a previously published likely pathogenic variant in the *UFM1* promoter region was identified that had not been called by the pipeline due to being non-coding.

Conclusion: Deeper interpretation approaches improve diagnostic yield from short-read WGS. Other approaches we are applying include improving the detection and filtering of structural and mitochondrial variants, detection of mosaic variants and repeat expansions and further analysis of non-coding regions.

Grants: GeneSTEPS grant & NIHR Biomedical Research Centre at Great Ormond Street Hospital, London, UK.

Consortium: the IRUD-NCCHD-GM consortium

Background/Objectives: Comprehensive genome analysis for diagnosis and cause identification of undiagnosed diseases is useful and national projects are underway in many countries. We have been participating in a major project in Japan, 'The Initiative on Rare and Undiagnosed Diseases', since its launch in summer 2015, and are performing a comprehensive genome analysis. Here we report on the statistical results of 1560 undiagnosed cases in which whole exome analysis was performed on patients and/or their families in a single department.

Methods: Undiagnosed cases were enrolled at IRUD-NCCHD-GM consortium hospitals where no diagnosis had been made after prior direct sequencing or panel analysis of candidate genes for the suspected disease. All patients, or their family members, were subjected to whole exome analysis after written informed consent was obtained. We performed in-house CNV analysis in addition to the usual variant calling and filtering.

Results: The yield of reaching a conclusive diagnosis, including re-analysis, in these 1560 cases (2015-2021) was 45.9%. Re-analysis in 2022 of 1560 cases from 2015 to 2021, when all exome analyses were conducted, led to the identification of a cause and diagnosis in 100 new cases (6.4%). In addition to the diagnosis of ultra-rare diseases, novel diseases such as MAPK8IP3-related disease and STAT6-gain-of-function disorder were found.

Conclusion: Whole exome analysis is currently cost-effective and is the first choice for cause identification of undiagnosed diseases. Re-analysis should also be performed on a regular basis, as it is certain to increase the rate of identification of the cause of undiagnosed cases.

P15.069.B Evaluation of quality of WGS and WES results using validated protocols

Katerina Kvapilova[1;2], *Pavol Misenko*[3], *Ján Radvánszky*[3], *ondrej brzon*[1], *Jaroslav Budiš*[3], *Juraj Gazdarica*[3], *Ondrej Pos*[3], *Marie Korabecna*[4], *Martin Kasny*[1], *Tomas Szemes*[3], *Petr Kvapil*[1], *Jan Pačes*[5], *Zbynek Kozmik*[6]

[1]Institute of Applied Biotechnologies a.s., Praha 10; [2]Charles University, Faculty of Science, Prague, Czech Republic; [3]Geneton s.r.o., Bratislava, Slovakia; [4]Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic; [5]Institute of Molecular Genetics of the Czech Academy of Sciences, Laboratory of Genomics and Bioiformatics, Prague, Czech Republic; [6]Institute of Molecular Genetics of the Czech Academy of Sciences, Laboratory of Transcriptional Regulation, Prague, Czech Republic

Background/Objectives: Whole exome sequencing (WES) and whole genome sequencing (WGS) are standards in human clinical diagnostics and population genomics. We evaluated the quality and genotype concordance of single nucleotide variants (SNVs) and small insertions/deletions (indels) in paired blood and saliva genomic DNA (gDNA) isolates for WES and WGS protocols using reference-validated protocols.

Methods: The NIST standard Coriell NA12878 was repeatedly sequenced to validate WGS and WES protocols. NA12878 data calls were compared to the truth dataset published by the Genome in a Bottle Consortium. A paired comparison of blood-derived gDNA and saliva-derived gDNA was performed for SNVs and indels for both, WES and WGS. The level of genotype concordance was studied using ACMG SF v 3.2. gene set in two settings: exonic regions only/complete genes.

Results: The F1 score of ten paired blood-saliva samples range between 0.8030-0.9998 for SNVs and between 0.8883-0.9991 for indels in the WGS, and between 0.8643-0.999 for SNVs and between 0.7781-1.000 for indels in WES. The quality pattern of called variants obtained from genomic-reference-based technical replicates correlates with data calls of paired blood–saliva-derived samples in all levels of tested examinations.

Conclusion: The resulting data shows a clear advantage of the WGS approach over WES; especially for indels analysis while confirming no significant differences between blood and saliva samples.

Consortium: The SpadaHC Consortium

Background/Objectives: The accurate classification of genetic variants is crucial for clinical decision-making in hereditary cancer. In Spain, genetic diagnostic laboratories have traditionally approached this task independently due to the lack of a dedicated resource. Here we present SpadaHC, a web-based database for sharing variants in hereditary cancer genes in the Spanish population.

Methods: SpadaHC is implemented using a three-tier architecture consisting of relational database, web tool and bioinformatics pipeline. Spanish genetic diagnostic laboratories can share variant classifications and variants from individuals in VCF format.

Results: The platform supports open-restricted access, flexible dataset submissions, automatic pseudo-anonymization, VCF quality control, variant normalization, and liftover between genome builds. Users can explore and search data flexibly, receive automatic discrepancy notifications, and access SpadaHC population frequencies based on many criteria. Current version of SpadaHC (v1.58.0, February 2024) includes 17 laboratory members, storing 1.17 million variants (20908 unique) from 4306 patients and 14834 laboratory classifications. We analyzed classification discrepancies from SpadaHC v1.21.0 (July 2023), where a total of 2469 unique variants were classified by at least two laboratories, and 84 of these had clinically relevant discrepancies, between class 1-2-3 and class 4-5. We addressed these diescrepancies through a 3-phase resolution strategy, which resolved 80 of them.

Conclusion: This work highlights the importance of data sharing to allow discussion and promote consistency in variant classifications among laboratories, so patients and family members can benefit from more accurate clinical management.

P15.072.A Development of an RNA-sequencing service within an NHS Diagnostic Laboratory

Claire Kyle[1], *Sam Kidman*[1], *Ciaron McAnulty*[1], *Brian Wilson*[2]

[1]*Newcastle Genetics Laboratory, Newcastle Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom;* [2]*Northern Genetics Service, Newcastle Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*

Background/Objectives: The growing volume and complexity of DNA-based genetic testing has increased detection of variants of uncertain significance (VUS). Determining the splicing impact of VUSs is predicted to increase diagnostic yield by >35%. At present, RNA-sequencing is almost exclusively used in a research setting, and guidance on how this data should be analysed and reported in a diagnostic setting is not well developed. Our aim is to develop diagnostic-standard RNA-sequencing for both identified VUSs and as an independent test. Here we describe our experience with a sub-cohort of 75 individuals harbouring a potentially spliceogenic VUS, underpinning our approach to diagnostic RNA-sequencing.

Methods: RNA was extracted from blood or fibroblast cultures from participants, as part of a broader RNA-sequencing project. Short read RNA-sequencing and multiple bioinformatics analyses were undertaken and compared.

Discussion: Challenges to the diagnostic evaluation of RNA-sequencing data include thresholds for sequencing depth and quality, appropriateness of the tissue tested (e.g. similarity of splicing/expression profiles), evaluation of 'leaky' splicing or intron retention, and the potential impact of nonsense-mediated decay for incomplete mRNAs. We describe development of a novel bioinformatics analysis pathway to accurately detect and quantify all types of splicing variant (exon skipping, cryptic splicing and intron retention) with appropriate quality thresholds, and creation of a variant assessment pathway, illustrated by key cases.

Conclusion: RNA-sequencing can be an effective tool to increase diagnostic yield. We propose an RNA-sequencing analysis and reporting pathway to support reclassification of known DNA variants in a diagnostic laboratory setting.

This work was funded by NHS England as a Transformation Project.

P15.073.B Targeted NGS sequencing of RT-PCR products: a powerful diagnostic tool for hereditary diseases

Alexandra Filatova[1], *Daria Akimova*[1], *Ksenia Davydenko*[1], *Evgeniya Osipova*[1], *Iuliia Viakhireva*[1], *Peter Sparber*[1], *Mikhail Skoblov*[1]

[1]*Research Centre for Medical Genetics, Moscow*

Background/Objective: An increasing number of studies emphasize the importance of RNA-analysis in the diagnosis of inherited diseases. In this study, we used targeted NGS of RT-PCR products to conduct a comprehensive RNA-analysis.

Methods: Total RNA was isolated from patients' clinically available tissue samples (predominantly fibroblasts and PBMC, occasionally other tissue types: muscle biopsy, intestinal organoids, etc.). RNA underwent DNaseI treatment, followed by reverse transcription and PCR of targeting loci. PCR-products were sequenced using various NGS platforms and processed via an in-house pipeline.

Results: We analyzed over 200 patient samples using targeted NGS of RT-PCR products and investigated dozens of genes associated with various hereditary diseases. This approach provided mean coverage of the loci of interest ranging from 5'000x to 300'000x (with an average of ~100'000x), enabling the detection of minor splicing events (subject to NMD degradation or residual expression of the reference isoform) and quantification of allele expression imbalances. Unlike gel electrophoresis and Sanger sequencing, targeted NGS allows for the analysis of multiple isoforms and their proportions. Sequencing of different gene loci in a single run made our approach cost-effective for

routine use. As a result, our comprehensive RNA-analysis identified mRNA structure/expression changes and associated nucleotide variants in many patients where pathogenic variants were previously unidentified. For many VUS variants, we confirmed their effect on splicing and mRNA structure. In some cases, our analysis clarified the clinical features of the disease.

Conclusion: The use of targeted NGS during RNA-analysis is a very effective approach for diagnosing patients with hereditary diseases.

P15.074.C Improvement of histopathological & genetic diagnostics of vascular anomalies using non-destructive 3Dhistopathology

Rene Hägerling[1;2]

[1]*Charité - Universitätsmedizin Berlin, Institute of Medical and Human Genetics, Berlin, Germany;* [2]*Berlin Institute of Health, BIH Center for Regenerative Therapies, Berlin, Germany*

Background/Objectives: For histopathological analysis and subsequent diagnosis of diseased tissues a rapid, accurate histopathological and genetic analysis of biopsied tissues are essential. However, the 2-dimensional slide-based histopathological analysis does not represent tissue structures and molecular targets sufficiently, which aggravates an accurate and spatial analysis of tissue.

Methods: To overcome these limitations, we have established a 3D-histopathology approach based on non-destructive volumetric lightsheet-microscopy, which bears the potential to revolutionize the way pathological analysis are done. In comparison to conventional 2D-pathology, non-destructive 3D-histopathology allows rapid slide-free histological imaging of a whole tissue sample, volumetric analysis of diagnostic relevant structures such as immune cells, vessels and an improved spatial analysis of cell distribution relevant to study e.g. the microenvironment.

Results: To achieve this, we have successfully established a fluorescence-based analogue of the histological gold-standard (hematoxylin&eosin), suitable for lightsheet-microcopy. In combination with codon-reassignment-technology and nanobody-based staining protocols detecting relevant markers such as immune cells, vessels or proliferation state, this approach offers cutting-edge diagnostic phenotyping of the specimen. Due to non-destructive nature of the optical-sectioning methodology, the sample is available for downstream applications such as molecular diagnostics of the previously imaged specimen. Using this approach we were able to identify genetic alterations in combination with new vascular phenotypes, which will set the basis for future improved histological & genetic classification.

Conclusion: In summary, this innovative approach for 3D-histopathology allows more detailed diagnosis of tissue samples from patients with vascular anomalies and has the potential to become translated to tumor tissue as well.

P15.075.D The clinical genome: validation data beyond clinical exome

Kornelia Tripolszki[1], *Melina Bilinski*[1], *Matthias Bieg*[1], *Anett Marais*[1], *Catarina Pereira*[1], *Javier Martini*[1], *Vasiliki Karageorgou*[1], *Mukunth Sadagopan*[1], *Divine Lawir Fondzenyuy*[1], *Swathi Chinnappa*[1], *Stephanie Weissgraeber*[1], *Malgorzata Bochinska*[1], *Thomas Hackenberg*[1], *Katja Bruesehafer*[1], *Chris Junghans*[1], *Johannes Numrich*[1], *Krishnakumar Kandaswamy*[1], *Jorge Pinto Basto*[1], *Peter Bauer*[1], *Omid Paknia*[1]

[1]*CENTOGENE GmbH, Rostock, Germany*

Background/Objectives: Difficult-to-sequence regions are usually neglected by exome sequencing. Here, we report the establishment of a PCR-free genome sequencing (GS) based assay, that systematically screens hard-to-sequence regions such as repeat expansion (RE), SMN1/SMN2, GBA1, and in addition detects structural rearrangements.

Methods: For the PCR-free GS library preparation gDNA extracted from blood was used. After genome sequencing, the reads were aligned to the hg19 reference genome. A bioinformatics pipeline that integrates the DRAGEN pipeline (Illumina) and in-house algorithms was used. Throughout the validation, 52 positive control cases were utilized (thirty-five RE, six SMN1/SMN2, six GBA1/GBAP1 conversion and five cases with structural variants (SV)). In 2269 samples, we performed post-launch monitoring and inspected the performance of the bioinformatic pipeline. The identified variants were confirmed through orthogonal methods.

Results: All 52 positive control samples were successfully detected by our combined assay. In the subset of 2269 post-launch monitoring patients, four individuals were detected to have 0 copies of SMN1, one patient was detected to carry a recombinant variant in GBA1, and a total of 24 patients had positive RE findings that were considered to be clinically relevant. Regarding the complex SV results, seven different variants were detected by SV calling in eight patients.

Conclusions:

In our study, we present a validated GS assay, that leverages the benefits of the PCR-free GS technology and seamlessly integrates the secondary DRAGEN pipeline and our in-house pipeline. This comprehensive workflow not only increases the diagnostic yield, advances genomic research, but also substantiates our understanding of genetic variation in rare disease patients.

P15.076.A Catalogue of alternative splicing events of the NBN gene

Vita Setrajcic Dragos[1], *Srdjan Novaković*[2]

[1]*Institute of Oncology Ljubljana, Ljubljana, Slovenia;* [2]*Institute of Oncology Ljubljana, Department of Molecular Diagnostics, Ljubljana, Slovenia*

Background/Objectives: Nearly all human multi-exon genes are involved in alternative splicing. RNA splicing defects are a common molecular mechanism of disease, and RNA sequencing (RNAseq) considerably improves diagnostics yield. Understanding the naturally occurring alternative splicing isoforms of clinically relevant genes is of great importance for correct interpretation of

RNA splicing assays and also for determining the strength level of ACMG/AMP PVS1 evidence.

Methods: Control samples harboring only undoubtedly benign variants in the coding region and 25 nt of intronic sequence of *NBN* gene were selected for alternative splicing isoform discovery. Blood samples were sequenced using an in-house developed RNAseq protocol.

Results: We have identified all 10 previously described alternative splicing events as well as 49 previously undescribed alternative splicing events. The highest expressed alternative splicing event was cryptic exon 2 inclusion. No exon skipping event was observed at high percentage, suggesting all exons are crucial for normal protein function.

Conclusion: While alternative transcripts expressed in blood for the *NBN* gene had only been evaluated in the literature using RT-PCR and Sanger sequencing, we were the first to determine alternative transcripts for this gene using the NGS method. We have gathered all known and newly discovered alternative transcripts in an annotated catalog of alternative transcripts of the *NBN* gene.

P15.077.B Adaptive sampling long-read sequencing to improve repeat expansion and methylation detection in neurological disease genetic diagnostics

Eddy de Boer[1;2], Arjen Scheper[1;2], Dennis Hendriksen[1;2], Bart Charbon[1;2], Laura Bosscher[1;2], Danielle Schoonhoven[1;2], Joukje Kloosterman[1;2], Lennart Johansson[1;2], Henny Lemmink[1;2], Jan Jongbloed[1;2], B. Sikkema-Raddatz[1;2], **Cleo van Diemen**[1;2]

[1]*University Medical Center Groningen, Genetics;* [2]*University of Groningen, Groningen*

Background/Objectives: Though short-read sequencing is increasingly becoming the standard method in genome diagnostic workflows, numerous other methods are still required. The detection of repeats, pseudogenes, complex genomic rearrangements and also important phasing, orientation and methylation information are difficult, or even impossible, to acquire using just short-read sequencing. This makes diagnostics time-consuming, expensive, difficult to maintain, and limited. To overcome this, we aim to introduce ONT to streamline and improve our diagnostic workflow.

Methods: We have designed a neurological disease gene panel for ONT adaptive sampling to simultaneously analyze genes carrying repeat regions, genomic regions where methylation status affects pathogenicity (e.g. *FRM1*) and genes with pseudogenes (e.g. *PMS2*). We optimized the laboratory process by altering various technical variables, such as short-read elimination, shearing methodologies and flowcell loading conditions. We used an in-house developed variant interpretation pipeline (https://github.com/molgenis/vip/). For validation we retrospectively sequenced twenty patients with a known variant in one of the included genes of the ONT adaptive sampling gene panel and determined the coverage needed for accurate variant calling.

Results: Our optimized technical workflow reaches an output of approximately 15 Gb (13-18 Gb) with a mean read-length of 10 Kb, resulting in 95% 30x coverage of 455/471 genes of our gene panel.

Currently, the validation is still ongoing, but first results show that repeat length determination and methylation status are fully concordant with diagnostic test results.

Conclusion: ONT seems a relevant technique in a diagnostic workflow and the possibilities of adaptive sampling are promising.

P15.078.C Involvement of *GSPT2* variants in a new X-linked inherited syndrome with developmental delay and epileptic encephalopathy

Helga Westers[1], *Jelkje de Boer-Bergsma[1], Elles Wierenga[1], Jasmine Kiers[1], Gea Beunders[1;2], Cleo van Diemen[1]*

[1]*University of Groningen, University Medical Centre Groningen;* [2]*Amsterdam UMC*

Background/Objectives: Here we describe a family with X-linked inheritance with one affected index boy and two presumably affected uncles with partly overlapping phenotypes, including central and obstructive apneas, severe epilepsy, profound developmental delay, a secondary microcephaly, mild nonspecific dysmorphic features and edema. We identified a VUS in the GTPase domain of *GSPT2*. *GSPT2* encodes eRF3b, which forms a complex with eRF3a (encoded by *GSPT1*). This complex is involved in translation termination. Here we describe the clinical and functional follow-up to prove causality.

Methods: New index patients were searched for via GeneMatcher. Wildtype and mutant eRF3b proteins were generated via an in vitro transcription translation kit followed by GTPase activity assays. Changes in translation termination efficiency were investigated via read-through assays in cell lines.

Results: A GeneMatcher query led us to five patients with similar phenotypes with variants in *GSPT2*. Using our newly developed cell-free assay we were able to generate wildtype and mutant eRF3b proteins. Preliminary data suggest impaired GTPase activity of at least one of the variant proteins. The read-through assay did not provide evidence that termination efficiency is impaired by this particular variant.

Conclusion: eRF3b missense variants are implicated in severe X-linked epileptic encephalopathy. We hypothesize that these variants disrupt GTPase activity of the eRF1/eRF3 complex which might affect polypeptide release from the ribosome. Ongoing functional studies aim to confirm this hypothesis. Furthermore, our cell-free GTPase activity assay has the potential to be broadly used for functional assessment of VUS located in GTPase domains of any protein.

Conflict of Interest: None declared

P15.079.D Benefits of the analysis of a complex chromosomal rearrangement in the implementation of long read approaches

Mathilde Quibeuf[1], Kevin Cassinari[1], Oriane Mercati[1], Anne-Marie Guerrot[1], Claude Houdayer[1], Geraldine Joly-Helas[1], **Pascal Chambon**[1]

[1]*Rouen Normandie Univ, Inserm U1245, CHU Rouen, Department of Genetics and reference Center for Developmental Disorders, Rouen, France*

Background/Objectives: The detection of structure variants by long-read approaches is one of the keys to the management of patients in diagnostic deadlocks. This work will show how the analysis of a highly complex chromosome rearrangement, such as a chromoanagenesis, helps to acquire new benchmarks and new interpretation logics specific to the different types of alterations that are now detectable by these techniques, especially by Optical Genome Mapping (OGM).

Method:

Results: A chromoanagenesis was identified in a 3-month-old girl presenting with mild dysmorphic elements, minor

malformations and a significant motor delay. This diagnosis was based on (i) the results of array-CGH showing a 8,3Mb 6q15q16.3 deletion, associated with seven smaller deletions and restricted to a limited number of chromosomes and (ii) the analysis of the karyotype showing an additional complex reciprocal translocation between chromosomes 5, 6 and 12. Long read analysis was performed by OGM for further characterization of the anomaly. Interestingly, OGM data helped new users to apprehend the different algorithms and tools. New users were guided to retrieve (i) all the CNVs detected by array CGH, (ii). the translocation identified by karyotyping, and also (iii) additional balanced structural variants. Both the graphical interface and the raw text result files were needed to fully characterize the chromoanagenesis.

Conclusion: This work illustrates the interest of analyzing a complex chromosomal anomaly in order to quickly apprehend the whole spectrum of anomalies identifiable by long read approaches. Sharing such data on complex rearrangements could help the community to improve the understanding and the use of long-read approaches.

P15.080.A Highly sensitive variant detection in VNTR is possible with boosted exome sequencing: the example of MUC1-related nephropathy

Hassan Saei[1], *Vincent Moriniere*[2], *Laurence Heidet*[3], *Bertrand Knebelmann*[4], *Patrick Nischke*[5], *Corinne ANTIGNAC*[3], *Guillaume Dorval*[3]

[1]*Imagine Institute, Labortory of Hereditary Kidney Diseases, INSERM U1163, Paris, France;* [2]*Necker Children Hospital, Genetic Diagnosis Department, Paris, France;* [3]*Imagine Institute, Labortory of Hereditary Kidney Diseases, INSERM U1163, paris, France;* [4]*Necker Children Hospital, Nephrology Department, Paris, France;* [5]*Imagine Institute, Bioinformatics Department, Paris, France*

Background/Objectives: Tandem repeats in the human genome can be associated with significant and yet underdiagnosed genetic disorders. Frameshift variations in the *MUC1* coding-VNTR cause autosomal dominant tubulointerstitial kidney disease (ADTKD-*MUC1*). Short-read sequencing (SRS) is hindered by poor read mappability and motif complexity for discovering these variations. We developed a computational pipeline for precise variant discovery in the *MUC1* VNTR region from SRS data. We aimed to improve *MUC1* VNTR coverage in exomes since regular exome sequencing proved ineffective in this context.

Methods: Our pipeline utilizes k-mer frequency-based genotyping method and proven to be effieicnt in diagnosing 44 overlooked patients in a cohort of 3735 patients. We improved *MUC1* gene VNTR capture in exome sequencing by incorporating spike-in probes, which include probes with 4x tiling of the VNTR region, using the Twist custom panel protocol. We compared regular (six samples) and boosted exome data (16 samples) from known *MUC1*-positive and negative controls.

Results: The enhanced exome achieves a coverage of 144x for *MUC1* VNTR, compared to 72.1x in the regular exome. As expected, our genotyping tool missed pathogenic variations in 2 out of 3 true positives in the standard exome. However, we successfully detected all 13 true positives using the enhanced exome. Our pipeline identifies coverage below 100 as insufficient for VNTR genotyping in panel data, even with a mean coverage of 700x achieved after downsampling trials.

Conclusion: Adequate coverage is crucial for accurate VNTR genotyping. This approach could improve the diagnostic yield of the VNTR-associated diseases.

Grants: This work was supported by state funding (ANR-10-IAHU-01).

P15.081.B Dual molecular diagnoses of Cutis Laxa and Noonan Syndrome in Rwandan Individuals: A differential analysis of the facial dysmorphism with GestaltMatcher

Alexej Knaus[1], *Tzung-Chien Hsieh*[1], *Meghna Ahuja Bhasin*[1], *Nobert Dukuze*[2], *Olivier Hakizimana*[2], *Shahida Moosa*[3;4], *Uwe Kornak*[5], *Peter Krawitz*[1], *Annette Uwineza*[6]

[1]*University Hospital Bonn, Institute for Genomic Statistics and Bioinformatics, Bonn, Germany;* [2]*University of Rwanda, College of Medicine and Health Sciences, Kigali, Rwanda;* [3]*Stellenbosch University, Division of Molecular Biology and Human Genetics, Stellenbosch, South Africa;* [4]*Tygerberg Hospital, Medical Genetics, Stellenbosch, South Africa;* [5]*University Medical Center Göttingen, Institute for Human Genetics, Göttingen, Germany;* [6]*University Teaching Hospital of Kigali, Department of Clinical Biology, Kagali, Rwanda*

Background/Objectives: The detection of multiple Mendelian disorders in a single individual is complicated by the overlap or interference of gene-specific phenotypes. Here, we use next-generation phenotyping (NGP) to dissect the dual diagnosis of Cutis Laxa and Noonan Syndrome. Further we assessed the prediction of the disease-causing genes in published cases with various dual molecular diagnoses.

Methods: Exome sequencing was performed on a cohort of individuals with facial dysmorphisms from Rwanda, and data was prioritized with PEDIA (Prioritization of Exome-Data by Image Analysis). Additionally, multiple cases with diverse dual diagnoses, identified through a literature review, were subjected for facial analysis with GestaltMatcher.

Results: In two siblings from Rwanda, presenting with large fontanelles, developmental delay, and cardiac anomalies, pathogenic multilocus variations (PMVs) in *ATP6V0A2* (c.1935+1G>C and c.688dup) and in *PTPN11* (c.145G>A) were prioritized on the top ranks, confirming dual diagnosis with autosomal-recessive Cutis Laxa type IIa and Noonan syndrome 1.

Exemplarily, facial analysis of published cases revealed that coexistence of characteristic phenotypes with high similarities to both disorders is rare, but signals can be detected in the lower ranks of the GestalMatcher analysis. However, in some instances, PMVs seem to result in novel facial dysmorphism with little similarity to known disease patterns.

Conclusion: NGP is a promising technology for differential analysis of the facial gestalt complementing comparisons that are based on clinical features. GestaltMatcher may potentially identify novel genetic interactions. A practical implication is particularly significant for guiding the correct diagnosis and prediction of genes associated with rare diseases, especially in low-resource settings.

Background/Objectives: Short-read DNA sequencing is the main technical approach used in clinical diagnostics. However, for some challenging genes, additional non-NGS methods are required, such as PCR/CE, qPCR, MLPA or Sanger sequencing. To simplify user workflow, eleven traditionally hard-to-decipher genes (*CFTR, FMR1, HBA1/2, HBB, SMN1/2, F8, GBA, CYP21A2* and *TNXB)* have been pooled in a new prototype Asuragen kit. In this beta program, we evaluated the workflow on clinical samples and reviewed genotype agreement between the new assay and classical methods.

Methods: We evaluated the prototype Asuragen AmplideX Nanopore Carrier Plus kit, combining the PCR enrichment technology with Nanopore DNA sequencing (Oxford Nanopore Technologies; ONT). Target genes were amplified by LR-PCR from positive clinical samples. Libraries were prepared, pooled, and loaded on a MinION R10.4.1 flow cell. Automated analysis and reporting was performed using the prototype Asuragen AmplideX Reporter software.

Results: The eleven candidate genes were sequenced and multiple variant types were assessed, including STR, SNV, Indel, CNV or SV. Variant allele phasing was determined for multiple genes including *CFTR, HBA1/2, HBB, SMN1/2, GBA, CYP21A2* and *TNXB*. Variant zygosity, sequencing accuracy, and average error rate of ONT sequencing were evaluated.

Conclusion: We have been satisfied by the usability and performance of this assay, including the purpose-built software to enable accurate genotyping and reporting of challenging targets. We anticipate this assay will streamline testing conducted for screening as well as for diagnostic purposes.

Grant: Asuragen (PCR reagents, analysis software and laptop, library prep reagents) ONT (Mk1B, Flow cells, library prep reagents)

P15.083.D Pilot project: Neonatal screening using genomic methods

Kristína Valovičová[1;2], *Iveta Valášková*[1;3;4]

[1]*Sophgena a.s., Praha 3, Czech Republic;* [2]*Masaryk University, Faculty of Science, Department of Experimental Biology, Section of Genetics and Molecular Biology, Brno, Czech Republic;* [3]*University Hospital Brno, Center of Molecular Biology and Genetics, Internal Hematology and Oncology Clinic, Brno, Czech Republic;* [4]*Masaryk University, Faculty of Medicine, Institute of Medical Genetics and Genomics, Brno, Czech Republic*

Background/Objectives: Rare illnesses are the primary contributors to infant death and lifelong disability. Genomic sequencing has revolutionized the diagnostic approach, offering many individuals a swift, precise, and economically viable genetic diagnosis. The use of genomic sequencing for neonatal screening has the ambition to improve and expand the early detection of treatable rare diseases, while the genomic data stored can potentially contribute to improved health care across the lifespan and support further research.

Methods: DNA was isolated from a dried blood drop and a buccal swab from newborns. KAPA HyperPETE Newborn Screening Panel commercial kit (Roche) was used for library preparation. Samples were also subjected to WES and subsequently analysed using the enhanced virtual panel of genes associated with rare diseases. Illumina DNA Prep with Enrichment and Twist Alliance VCGS were used. Libraries were sequenced using NovaSeq X Plus (Illumina).

Results: Using both approaches, we were able to capture pathogenic variants in control samples (CF, SMA, immunodeficiencies, CAH, PHE). These pathogenic variants in control samples were previously detected using NGS, Sanger sequencing, MLPA or allele specific PCR and qPCR assays and were interpreted based on relevant information in integrated databases of genomic variants and relevant scientific literature.

Conclusion: We tested DNA samples from newborns using a commercially available panel kit and WES to detect rare diseases. Both approaches seem to be suitable method for neonatal screening for rare diseases, but further studies are needed to compare the benefits and challenges (scientific, ethical and social aspects) of these two approaches.

P15.084.A Genome sequencing outperforms karyotyping, chromosomal microarray and exome sequencing for structural variants detection in prospective head-to-head comparison

Franziska Gaass[1], *Christina Post*[1], *Daniel Kaschta*[1], *Bianca Greiten*[1], *Anna-Sophie Liegmann*[1], *Rebecca. Gembicki*[1], *Jelena Pozojevic*[1], *Katharina Schau-Römer*[1], *Maj-Britt Salewski*[1], *Franka Rust*[1], *Christine Zühlke*[1], *Eva Maria Murga Penas*[1], *Nadine Hornig*[1], *Kirstin Hoff*[1], *Juliane Köhler*[1], *Vincent Arriens*[1], *Caroline Utermann-Thuesing*[1], *Varun Sreenivasan*[1], *Kristian Händler*[1], *Valerie Katharina Berge*[1], *Saranya Balachandran*[1], *Neseebullah Kakar*[1], *Maike Dittmar*[1], *Britta Hanker*[1], *Yorck Hellenbroich*[1], *Irina Hüning*[1], *Monika Kautza-Lucht*[1], *Almuth Caliebe*[1], *Inga Vater*[1], *Inga Nagel*[1], *Malte Spielmann*[1]

[1]*Institute of Human Genetics, University Hospital Schleswig-Holstein, University of Lübeck and Kiel University, Lübeck, Germany, Lübeck, Germany*

Consortium: UKSH Genom Konsortium

Background/Objectives: Genome Sequencing (GS) represents a powerful tool to detect all genetic variants in a single test including structural variants (SVs). However, karyotyping, chromosomal microarray (CMA) and exome sequencing (ES) are still part of standard diagnostic care in many European countries. Here we set out to conduct a prospective study to compare karyotyping, chromosomal CMA and ES for SVs detection with single GS and trio GS.

Methods: We prospectively recruited 345 individuals affected with developmental disorders and/or congenital anomalies and performed karyotyping, CMA and ES and in parallel short read single GS and trio GS. Three independent scientific teams then performed SVs analysis and compared results.

Results: We identified 34 diseases associated SVs (10,83%: 24 deletions, 7 duplications, 2 translocations, 1 mosaic-trisomy). All 34 variants were detected by single GS and trio GS, whereas 3 were missed by karyotyping, CMA and ES (3 deletions). The diagnostic gap was caused by single exon deletions with deep intronic breakends.

Conclusion: In our prospective head-to-head comparison GS outperformed karyotyping, CMA and ES for SVs detection. Based on our results, GS could replace karyotyping and CMA for SVs detection and improve care for rare diseases.

P15.085.B Integration of ExpansionHunter into the clinical variant interpretation platform EVAdb

Erik Tilch[1;2], *Martin Pavlov*[1;2], *Mohsen Shakibafar*[2], *Ivana Dzinovic*[1;2], *Michael Zech*[1;2], *Juliane Winkelmann*[1;2], *Christian Mertes*[1;2], *Riccardo Berutti*[1;2;3]

[1]*Institute of Neurogenomics, Computational Health Center, Helmholtz Munich, Neuherberg, Germany;* [2]*Institute of Human Genetics, Klinikum rechts der Isar, Technical University of Munich, Munich, Germany;* [3]*NGS Bioinformatics, Center for Advanced Studies, Research and Development in Sardinia, Pula, Italy*

Background/Objectives: More than 50 short tandem repeats (STR) expansion loci have been associated to monogenic disorders and most of them are detectable with ExpansionHunter on whole genome sequencing data. We implemented ExpansionHunter and a tool for clinical interpretation into the open source EVAdb Project. EVAdb is the raw data processing pipeline, variant call database, and diagnostic expert system in use at the Institute of Human Genetics of the University Hospital Klinikum rechts der Isar in Munich, Germany.

Methods: We examined the available literature, original and reviews, and OMIM to collect reliable information on pathogenic ranges of the STR expansions detectable with ExpansionHunter. We aggregated this information in an annotation table. Finally, we run our analysis on a cohort of more than 2500 genomes.

Results: We created an easily maintainable and expandable, literature-based annotation database that collapses distinct repeat count effect ranges from diverse sources into a single range, which can account for different phenotypes for the same locus and discrepancies between locus definition in ExpansionHunter and the literature. Additionally, we provided the system with a resource of clinical repeat count distributions, which increases with each sample analyzed. Z-scores for a patient's repeat counts are generated on the fly by the EVAdb, facilitating the detection of outliers e.g. based on the disease prevalence.

Conclusion: We introduced ExpansionHunter in EVAdb and created an expandable literature annotation resource and a resource of clinical distributions of repeat expansions for more than 2500 samples. These resources are available for clinicians and collaborators using EVAdb.

Conflict of Interest: None declared

P15.086.C Gene-Curator.org: A user-centric tool for managing gene disease associations

*Constantin Wolff[1], Nina Rank[1], Jan Halbritter[1], **Bernt Popp**[2]*

[1]Charité – Universitätsmedizin Berlin, Department of Nephrology and Internal Intensive Care Medicine, Berlin, Germany; [2]Berlin Institute of Health, Center of Functional Genomics, Berlin, Germany

Background/Objectives: ClinGen and other large expert groups are curating gene-disease entities, but still few genes have reliable gene-disease associations. We created "Gene-Curator.org" to simplify gene disease curation for genetic researchers by providing a user-friendly interface and a comprehensive database.

Methods: Utilizing a web-based platform developed with Vue, JavaScript, and Firebase as a backend, Gene-Curator provides functionalities for uploading gene lists and performing gene-disease curation. It is fully customizable, displays important genetic information for curation, and allows manual and automated annotations with a JSON configuration file-based workflow. The platform emphasizes user-friendly and automated interfaces to improve curation efficiency and accuracy. Freely available code makes the tool easy to install standalone.

Results: We used ClinGen recommendations to simplify the curation workflow for kidney disease (KD) diagnostic genes. The workflow includes pre-curation, curation, and a curated entity repository. Lumping and splitting create gene-disease entities during pre-curation. In the curation section, entities are assigned to KD groups (e.g., syndromic vs. isolated; adult vs. pediatric) and given a point-score which results in four confidence levels. Tracking of curation workflow versions, users involved in the curation, and a second look system enable reproducibility and quality control. The design makes curation easy, fast, intuitive, reproducible, and shareable.

Conclusion: Gene-Curator is a versatile tool that significantly aids researchers in gene data analysis and curation, thanks to a strong and intuitive software design that prioritizes user engagement and data accuracy. Future developments include a versioned curation workflow repository, data sharing with PanelApp, and federated instance communication.

P15.087.D High prevalence of GAA-*FGF14*-related late-onset spinocerebellar ataxia in a Dutch cohort

Ana Ignjatijevic[1;2], *Elles Wierenga[1;2], Femke Boorsma[1;2], Fleur Vansenne[1;2], Corien Verschuuren[1;2], Dineke Verbeek[1;2], Helga Westers[1;2], Cleo van Diemen[1;2]*

[1]University Medical Centre Groningen, Genetics, Groningen; [2]University of Groningen, Groningen, Netherlands

Background/Objectives: A pathogenic GAA repeat expansion in the first intron of the fibroblast growth factor 14 gene (*FGF14*) has been recently identified as a highly prevalent cause of spinocerebellar ataxia 27B (SCA27B) in various populations. We screened 262 Dutch cases with late-onset spinocerebellar ataxia for *FGF14* repeat expansions using a combination of long-range PCR (LR-PCR) and repeat-primed PCRs.

Methods: Genomic DNA samples were first tested by LR-PCR spanning the GAA-expansion to determine the presence of expanded alleles. Next, the presence of the correct repeat motif was verified by repeat-primed PCR of the GAA and another prevalent GAAGGA repeat. Several samples were validated by Oxford Nanopore Technologies long read sequencing.

Results: Overall, 48/262 patients had an expanded *FGF14* repeat based on LR-PCR. Of these, 34 were identified to have a likely pathogenic expanded allele of $(GAA)_{>250}$, resulting in a total diagnostic yield of 13%. Long read sequencing confirmed the sizes and sequence of the repeats.

Conclusion: We conclude that *FGF14* GAA repeat expansions are the most common known genetic cause of late-onset spinocerebellar ataxia in the Dutch population, which is comparable to studies in other populations.

Conflict of Interest: None declared

P15.088.A lonGER - German National initiative for clinical long-read sequencing

Nadja Ehmke[1], *Florian Kraft[2], Gunnar Schmidt[3], Elena Buena-Atienza[4], Nicolas Casadei[4], Casper Groß[4], Sebastian Giesselmann[2], Thomas Eggermann[2], Benedikt Schnur[3], Manuel Holtgrewe[5], Ingo Kurth[2], Janine Altmüller[6], Stephan Ossowski[4], Tobias Haack[4], Bernd Auber[3]*

[1]Charité - Universitätsmedizin Berlin, Institute of Medical and Human Genetics; [2]RWTH Aachen University Hospital, Institute for Human Genetics and Genomic Medicine; [3]Hannover Medical School, Department of Human Genetics; [4]University of Tübingen, Institute of Medical Genetics and Applied Genomics; [5]Berlin Institute of Health, Core Unit Bioinformatics; [6]Berlin Institute of Health, Core Unit Genomics

Background/Objectives: With over 50% of rare disease patients unresolved after short-read genome sequencing (SR-GS), 'solving the unsolved' genetic diseases is arguably the largest unmet need in clinical genetics. Streamlined diagnostic-grade implementation of long-read (LR) GS is expected to improve accurate variant detection and interpretation. We founded the lonGER consortium to evaluate the clinical utility of LR-GS and provide a scalable framework with harmonized data background and statistical methodology for data interpretation.

Methods: To demonstrate increased diagnostic sensitivity of LR-GS, we are sequencing a multi-center cohort of unsolved patients with neurological, neurodevelopmental, and imprinting disorders that is expectedly enriched for complex genomic variation. We will implement, for the first time, LR-GS in the diagnostic work-up of a prospective cohort of patients (250 trios and 250 singletons) with a broad range of clinical indications including rare diseases and cancer predisposition. Sequencing is performed on PromethION instruments at 4 sequencing centers: Aachen, Berlin, Hannover, and Tübingen. A pilot study was conducted to demonstrate their ability to generate high quality datasets and apply appropriate bioinformatics pipelines.

Results: 80 reference and patient samples were sequenced with LR- and SR-GS and prospective inclusion of patient samples is ongoing. Our benchmarking studies support the increased sensitivity of LR-GS to detect different types of (epi-)genetic variation.

Conclusion: The lonGER pilot study has demonstrated the advantages of LR-GS in routine clinical diagnostics. Over the next two years, lonGER will provide a unique data set for the evaluation of LR-GS in clinical diagnostics through LR-GS of 1000 deeply phenotyped individuals.

Conflict of Interest: None declared

P15.089.B Genetic mosaicism: an important element to take under consideration for accurate genetic counselling

Sofia Ourani[1;2;2], *Katherine Anagnostopoulou*[3], *Nikolaos Marinakis*[4], *Emily Athanasiou*[1], *christiana polydorou*[2;2;5], *Avraam Elia*[6], *Jan Traeger-Synodinos*[4], *Constantinos Deltas*[2;5], *Athina Ververi*[7;8;8]

[1]*Hospital Archibishop Makarios III, Clinical Genetics, Nicosia, Cyprus;* [2]*University of Cyprus, School of Medicine, Nicosia, Cyprus;* [3]*Neoscreen Laboratory, Athens, Greece;* [4]*St. Sophia's Children's Hospital, National and Kapodistrian University of Athens, Laboratory of Medical Genetics, Medical School, Athens, Greece;* [5]*University of Cyprus, 4. biobank.cy, Center of Excellence in Biobanking and Biomedical Research, Nicosia, Cyprus;* [6]*Hospital Archibishop Makarios III, Paediatric Department, Nicosia, Cyprus;* [7]*Papageorgiou Hospital, Genetic Unit, Thessaloniki, Greece;* [8]*Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, Greece*

Background/Objectives: Somatic mosaicism refers to the presence of two or more populations of genetically distinct cells within an individual. Current literature estimates the percentage of parental mosaicism ranging from 0.33 to 25.9%.

Methods: We describe three unrelated patients in whom parental mosaicism was proved through detailed investigation.

Results: The first patient is a boy diagnosed with a pathogenic variant in *GRID2* gene due to motor delay and ataxic gait, which was considered to be of de novo origin at first hand. The couple had a second pregnancy and through the prenatal testing which showed the same mutation in the fetus, low level of mosaicism for the causative variant in the father's sample of DNA extracted from peripheral blood was identified. The second child is a boy studied for epilepsy and neurodevelopmental disorder. Trio Whole exome sequence revealed a pathogenic variant in *YWHAG* gene, which was also identified in DNA of leukocytes of the mother in a mosaic state (~18%). Our third case is an adult patient who was studied after his brother died of complications of vascular Ehlers Danlos syndrome due to a pathogenic variant in *COL3A1* gene. Mosaicism was shown in the maternal sample.

Conclusions: Recent data support the hypothesis that somatic and/or germinal mosaicism should be considered in the pathogenicity of inherited human diseases. New advanced diagnostic tools give us the opportunity to detect mosaicism more easily and accurately than before, thus facilitating precise genetic counseling, prenatal diagnosis as well as creating appropriate plans for pregnancy and delivery.

Conflict of Interest: None declared

P15.090.C 1 Sequencing per life

Filip Zembol[1], *Martina Bittoova*[1], *Monika Koudová*[1], *Petr Klempt*[1], *Simona Suhajova*[1], *Hana Dvorackova*[1], *Barbora Honysová*[1]

[1]*GNT Labs by GENNET, Bioinformatics*

Background/Objectives: The 1 sequencing per life project is designed to improve genetic care for patients and also reduce the costs associated with sequencing and the need to resample the patient. The goal is to create a sufficiently robust sequencing panel and workflow to get all important genetic information about patients.

Methods: The first phase was the creation of a robust LIMS (GLIS) to automatically pass samples from the requisition to the laboratory. The next phase was the creation of a robust bioinformatics analysis from sample prioritization and selection, through registration and evaluation environment to report generation. The last phase is the automation and proper interfacing of the sub-pipelines backed by CEIVD software.

Results: Creating a robust LIMS with the right database structure ensured an automated system for receiving requests into the lab and prioritizing them for deployment for sequencing. Automation and integration of multiple bioinformatics approaches ensured correctness of outputs. The next phase was sub-panelisation and panel-specific bioinformatics analyses. The automatically linked reporting system generated panel-specific reports after manual validation.

Conclusion: This project has simplified the process of passing the sample from Doctor to patient, with faster and more accurate genetic outputs. Automation has also prevented human error with such a large volume of samples. Furthermore, the large database of exome variants used for population studies is a great advantage.

Grants: No grants.

P15.091.D A multimodal approach to molecular diagnosis in NF1 highlights the need for bespoke analysis in undiagnosed patients

Ellie McAleese-Park[1], *Emily Whittle*[2], *Laura Weir*[2], *Claire Kyle*[2], *Giles Holt*[3], *Brian Wilson*[2;3]

[1]*Newcastle University, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom;* [2]*Northern Genetics Service, Newcastle-upon-Tyne, United Kingdom;* [3]*Newcastle University, Biosciences Institute, Newcastle upon Tyne, United Kingdom*

Background/Objectives: Neurofibromatosis type 1 (NF1) is a complex autosomal dominant disorder, characterised by a susceptibility to developing nerve sheath tumours and a range of potential multisystemic complications. Genetic confirmation of the diagnosis can provide prognostic information, and enable reproductive decision making and definitive cascade testing in relatives. Diagnostic testing in NHS England involves DNA/RNA analysis and copy number evaluation of the *NF1* gene. The molecular diagnostic rate among clinically affected individuals is ~90% with DNA analysis, and ~95% with RNA analysis. As NF1 is a monogenic disorder with a highly specific phenotype, this suggests that some causative variants are missed using standard diagnostic approaches. We aimed to explore the use of non-standard techniques to achieve a molecular diagnosis in this scenario.

Methods: We adopted a multimodal approach to further investigation in a patient with classical NF1, using techniques not available in standard NHSE workflows, including Bionano optical genome mapping, long-range PCR and Nanopore Flongle sequencing

Results: Bionano analysis identified a 6kbp insertion into intron 1 of the *NF1* gene. Long-range PCR was used to generate a 12kb fragment for Nanopore Flongle sequencing, allowing us to identify the breakpoints.

Conclusion: We achieved a molecular diagnosis of NF1 using a multimodal approach to investigation in this patient, allowing definitive testing of at risk relatives. This highlights the need for diagnostic laboratories to have a spectrum of technologies at their disposal to further investigate those with a firm clinical, but not molecular, diagnosis.

Grants: This work was supported by the Newcastle Hospitals Charity.

Conflict of Interest: None declared

P15.092.A EVAdb: a comprehensive clinical variant interpretation platform incorporating automated scalable analysis workflows

Martin Pavlov[1;2], *Erik Tilch*[1;2], *Mohsen Shakibafar*[1], *Matias Wagner*[1;2], *Michael Zech*[1;2], *Elisabeth Graf*[1], *Thomas Meitinger*[1],

Thomas Wieland[2], Thomas Schwarzmayr[2], Holger Prokisch[1;2], Juliane Winkelmann[1;2], Christian Mertes[1;2], Tim Strom[1], Riccardo Berutti[1;2;3]

[1]Klinikum rechts der Isar, Institute of Human Genetics, München, Germany; [2]Helmholtz Munich, Institute of Neurogenomics, Oberschleißheim, Germany; [3]Center for Advanced Studies, Research and Development in Sardinia, NGS Bioinformatics, Pula, Italy

Background/Objectives: Next-Generation Sequencing (NGS) has catalysed a paradigm shift in genomics, advancing clinical and research frontiers. The vast data volumes generated by NGS platforms demand advanced data management solutions, intricate analysis pipelines, and a meaningful interpretation platform to bridge genomic findings with clinical utility. The EVAdb framework is developed to address these challenges, offering a unified platform that streamlines NGS data processing, ensures analytical and statistical rigour, and translates complex genomic datasets into actionable insights for diagnostics and research.

Methods: EVAdb employs a modular implementation approach, integrating a lab inventory and sample management system, NGS processing and analysis pipelines, a variant interpretation and evaluation platform, as well as visualisation and quality assessment utilities. The platform supports a growing range of analyses, such as exome, genome, RNA-, ChIP-, and ATAC-sequencing. It is designed for accredited diagnostic purposes and is expanding with additional analysis workflows and cloud-ready capabilities (open-source, GitHub). EVAdb accommodates sample submission, library preparation, sequencing monitoring, and downstream analysis, all through a specialised web interface.

Results: To date EVAdb has processed 40,312 exomic, 5,909 genomic, and 31,810 RNA sequences of diverse backgrounds, aiding the molecular diagnosis of 3,409 rare genetic disorder patients and the identification of over 100 novel disease genes. Hence, it has been selected as the basis for various large-scale collaborative local and international efforts.

Conclusion: Established as a comprehensive framework for NGS analysis, EVAdb significantly enhances molecular diagnostics and the study of rare genetic disorders, making a case for its wider adoption in the genomic community.

Grants: Bavarian Genomes, GENOMIT, DigiMed, mitoNET.

Conflict of Interest: None declared

P15.094.C Diagnosis journey and main determinants of diagnosis delays of people living with a rare disease in Europe: a Rare Barometer retrospective patient survey

Jessie Dubief[1], *Fatoumata Faye[1]*

[1]EURORDIS-Rare Diseases Europe, Rare Barometer, Paris, France

Background/Objectives: Identifying the main steps of the diagnosis journey and the main determinants of the time to diagnosis for people living with a rare disease in Europe.

Methods: Retrospective survey of 6,507 (family members of) people diagnosed with 1,675 different rare diseases.

Results: Descriptive analysis of the number of years between symptom onset and each step of the diagnosis journey:

	Mean	Lower quartile	Median	Upper quartile	Maximum	N
First medical contact	0.4	0.0	0.0	0.3	45.0	5,762
First symptomatic treatment	3.4	0.0	0.5	3.3	60.6	5,535
Initial diagnosis	3.4	0.0	0.3	3.3	70.0	6,232
First referral to a Centre of Expertise	3.6	0.0	0.3	3.0	70.0	3,420
Confirmed diagnosis	4.7	0.1	0.8	5.0	71.2	6,507

Main determinants of diagnosis delays (ordinal logistical regression):

	OR (95% CI)
Number of healthcare professionals consulted	5.15 (4.1–6.4)
Symptom onset at adolescence (10-19 years old)	4.79 (3.7–6.2)
Symptom onset during childhood (2-9 years old)	3.11 (2.4-4.0)
Misdiagnosis	2.48 (2.1–2.9)
Living in Northern Europe	2.15 (1.8–2.6)
Patient is a woman	1.22 (1.1–1.4)
Living in Western Europe	1.96 (1.6–2.3)
Family history of the rare disease	1.36 (1.1–1.6)
Needs for psychological support unmet	1.34 (1.2–1.5)
Genetic disease	1.33 (1.1–1.5)
Referral to a Centre of Expertise	1.17 (1.0-1.3)
Needs for financial support unmet	1.16 (1.0-1.3)

Conclusion: These results can inform policies and actions to improve access to diagnosis for all people living with a rare disease.

Grants: Operating Grants 2022 and 2023 from the European Union's Health Programme (EU4Health, 2021-2027).

Conflict of Interest: None declared

P15.095.D Evaluating global metabolomics profiling as a diagnostic tool for rare diseases

Adam Kennedy[1], *Karen DeBalsi[1], Kaisa Teele Oja[2], Karit Reinson[2], Mihkel Ilisson[2], Katrin Ounap[2], Laura Sommerville[1], Matt Mitchell[3], Anne Evans[4]*

Background/Objectives: Here, we evaluated global metabolomics profiling as a diagnostic tool for rare diseases.

Methods: We analyzed the plasma metabolomic profiles of 133 persons suspected of having a rare disease but without a conclusive diagnosis. Metabolite raw peak intensities were normalized, log-transformed, and Z-scored. Metabolite concentrations higher than the 97.5th percentile or lower than the 2.5th percentile of the normal range were flagged as potential diagnostic markers.

Results: We detected 1237 compounds in the cohort, covering 9 super pathways and 120 sub-pathways. Every patient demonstrated metabolic perturbations, the majority of which could be linked to disease. For example, one patient demonstrated

significantly elevated carnitines and long-chain fatty acids, which are characteristic of very-long-chain acyl-CoA dehydrogenase deficiency. Another patient showed significant decreases in carnitine and acylcarnitines, suggesting systemic primary carnitine deficiency. In a third example, a set of twins both demonstrated a significant increase in arginine and citrulline, a decrease in ornithine, and the presence of argininosuccinate, which altogether, suggest dysfunctional urea cycle metabolism. In cases where validated metabolic signatures of disease were not observed, perturbations aligned with patients' symptomologies, suggesting that global metabolomics profiling can elucidate novel disease signatures and inform on the patient's clinical phenotype.

Conclusion: While further studies are needed to confirm the suspected diagnoses and characterize novel disease signatures, this study supports the hypothesis that global metabolomics can narrow the focus of diagnostic testing for rare diseases to ultimately reduce the time-to-diagnosis and improve patient outcomes.

Consortium:

Abstract text

Background/Objectives: Autosomal dominant Kabuki syndrome (KS) is a rare neurodevelopmental disorder caused by heterozygous inactivating variants of the lysine-specific methyltransferase 2D (*KMT2D*) gene. Despite the distinctive gestalt, the disorder is clinically variable, and a phenotypic scoring system has been introduced to help clinicians reach a clinical diagnosis. The phenotype, however, can be less pronounced in some patients, including those carrying postzygotic mutations. The full spectrum of pathogenic variation in *KMT2D* has not been fully characterized, which may hamper the clinical classification of a portion of these variants.

DNA methylation (DNAm) profiling has previously been used as a tool to classify variants in genes associated with several neurodevelopmental disorders, including KS.

Methods: We applied a KS-specific DNAm signature, optimized by a machine learning based classifier, in a cohort of 30 individuals with *KMT2D* variants and clinical features of KS.

Results: We succeeded in correctly classifying all the tested individuals. Three *KMT2D* variants were upgraded to disease-causing, while for 10 variants, a pathogenic role in the context of KS was rejected.

By testing five individuals with postzygotic pathogenic *KMT2D* variants, we also provided evidence that DNAm profiling has power to recognize pathogenic variants at different levels of mosaicism, identifying 15% as the minimum threshold.

Conclusion: The use of DNAm profiling applied for functional classification of *KMT2D* variants and postzygotic mosaicism in the context of KS demonstrates that it is a robust and reliable tool to rapidly rule out or confirm a clinical suspicion of this disorder.

P15.097.B Assessing the clinical utility of a breakpoint analysis method in identification of structural variants in targeted sequencing genetic tests

Lotta Koskinen[1], *Margarita Andreevskaya*[1], **Antti Väisänen**[1], *Mikko Muona*[1], *Tuuli Pietilä*[1], *Janica Djupsjöbacka*[1], *Ville Kytölä*[1], *Kati Kämpjärvi*[1], *Samuel Myllykangas*[1], *Pertteli Salmenperä*[1], *Juha Koskenvuo*[1], *Miko Valori*[1]

[1]*Blueprint Genetics, Espoo, Finland*

Background/Objectives: Structural variants (SVs) are a diverse group of genetic alterations impacting gene copy number, structure, and regulation. Despite their clinical relevance certain SV types are typically not detected by standard short-read variant calling pipelines. We assessed the frequency and types of clinically relevant SVs in targeted NGS genetic testing using a breakpoint analysis method.

Methods: Samples referred to clinical genetic testing were sequenced using whole or clinical exome assay and a short-read Illumina platform at Blueprint Genetics laboratory. SV calling was done using an in-house developed read breakpoint method that combines read-pair (RP) orientation-based and split-read(SR)/clipped-read based approaches to detect deletions, tandem duplications, inversions, novel insertions and retrotransposon (RTE) insertions such as Alu-insertions. Only variants undetected by standard variant calling methods and those classified as pathogenic, likely pathogenic, or of uncertain significance were considered.

Results: In the analysis of ~80,000 samples, we detected 162 clinically relevant SVs from which 79% were diagnostic and 21% were considered a carriership in a recessive disorder. RTE insertions, specifically Alu-insertions, were the most common type of SV. The second most identified type was deletions.

Conclusion: SV detection based on read breakpoints enables the detection of clinically relevant SVs that are not recognized by standard NGS variant callers, increasing diagnostic yield even in targeted sequencing. Besides detecting additional SVs, breakpoint analysis results can be used to assist design of orthogonal confirmation of copy-number variants and can decrease the need for confirmation tests.

P15.099.D Diagnostic genome sequencing improves genetic testing workup in imprinting disorder phenotypes: a retrospective study

Luise Kessler[1], Jeremias Krause[1], Florian Kraft[1], Asmaa Kenawy[2], Gyorgy Fekete[3], Anna Lengyel[3], Cordula Knopp[1], Ingo Kurth[1], Miriam Elbracht[1], **Thomas Eggermann**[1]

[1]RWTH Aachen, Human Genetics and Genomic Medicine, Aachen; [2]Alexandria University, Human Genetics; [3]Semmelweis University, Budapest, 2nd department of pediatrics

Background: The molecular confirmation of imprinting disorders (ImpDis) is challenging due to their clinical and molecular heterogeneity and overlap to monogenic differential diagnoses (DD). Therefore, many patients do not receive a diagnosis with the current stepwise and targeted diagnostic procedure. To circumvent the limitations, we assessed the suitability of whole genome sequencing (WGS) as diagnostic step after methylation testing and exclusion of ImpDis-specific alterations.

Methods: WGS was conducted in 46 clinically diagnosed patients with Silver-Russell- (SRS n = 35) and Beckwith-Wiedemann syndrome (BWS n = 11). Parental samples were available in 27 cases for trio-analysis. Data processing was based on an integrated AI pipeline (emedgene/ILMN). Targeted variant types included SNVs, CNVs, uniparental disomy, and repeats.

Results: 14 pathogenic variants and 4 VUS could be identified. The detection rate differed markedly between the ImpDis. Whereas 37% referred as SRS were diagnosed with SRS-specific monogenic alterations or DD, no pathogenic variants were detected in the clinically suspected BWS-cohort.

Conclusions: WGS significantly improves the diagnostic yield in patients with phenotypically suspected SRS, broadens the spectrum of overlapping disorders and allows further insights into the etiology of this heterogeneous disorder. A precise molecular diagnosis provides the basis for personalized clinical management. The negative results in the BWS-cohort might be explained by the lower threshold of clinical criteria, and the mosaic occurrence of overgrowth-causing alterations. However, WGS should be implemented as the second-tier diagnostic tool, as it addresses all currently known variant types in differential diagnoses of ImpDis and shortens the diagnostic odyssey.

Grant: In-kind reagents provided by Illumina.

P15.101.B Advantages of genome sequencing in a large cohort of exome-negative cases

Konrad Platzer[1], Eva Berger[1], Brandon Bresack[1], Luise Kulosik[1], Christian Stockhaus[1], Monica Wojcik[2;3], Dagmar Wieczorek[4], Steffen Syrbe[5], Vincent Strehlow[1], Heidi Rehm[3], Maximilian Radtke[1], Denny Popp[1], Tilman Polster[6], Henry Oppermann[1], Johannes Lemke[1], Gabrielle Lemire[3], Anne O'Donnell-Luria[3], Andreas Merkenschlager[7], Julia Hentschel[1], Janina Gburek-Augustat[7], Tobias Bartolomaeus[1], **Rami Abou Jamra**[1]

[1]University of Leipzig Hospitals, Institute of Human Genetics, Germany; [2]Divisions of Newborn Medicine and Genetics and Genomics, Boston Children's Hospital, United States; [3]Broad Center for Mendelian Genomics, Broad Institute of MIT and Harvard, United States; [4]University of Duesseldorf Hospitals and Clinics, Institute of Human Genetics, Germany; [5]Department of Pediatrics, University of Heidelberg Hospitals and Clinics, Germany; [6]University of Bielefeld Hospitals, Department of Pediatrics, Mara Hospital, Germany; [7]University of Leipzig Hospitals, Department of Pediatrics, Germany

Background/Objectives: Half of rare disorder remain elusive after exome sequencing (ES). However, the benefit of genome sequencing (GS) is still poorly defined.

Methods: We performed GS (trio in 90%) using standard wet-lab techniques for 220 individuals (n = 350 in June), who remained undiagnosed after ES. We used the software Emedgene, Varvis, and ExpansionHunter to analyze single nucleotide, small indel, repeat expansion, mitochondrial and copy number variants.

Results: We successfully solved 9% of the cases. We partially or possibly solved further 9%. Careful evaluation showed that a third of the above-mentioned solved cases clearly required GS and that ES is not sufficient to identify the relevant variant. Identified variants were small copy number variants, repeat expansions and (relatively few) non-coding variants. In the other two thirds, GS solved the cases due to trio design or as it uncovered human errors in the initial ES analysis. Further reasons were progress in public databases and a better software. We observe that GS depends more on having differential diagnoses. Two major, but solvable inconveniences are the difficulty of evaluating non-coding variants, and structural variants without gain or loss of DNA. We joined forces with Wojcik, O'Donnell-Luria, et al., medRxiv, who obtained similar results of 744 GS cases.

Conclusion: GS clearly outperforms ES in identifying copy number variants and repeat expansions. Further benefits with room for improvements are non-coding variants and structural variants. GS is the better first line analysis as it has a higher yield and it avoids time-consuming step-by-step diagnostics.

BIOINFORMATICS, MACHINE LEARNING AND STATISTICAL METHODS

P16.002.A Integrative multi-omics analysis leverage molecularly-defined subgroup identification: A novel subgroup of UCHL1-related cancers is associated with genomic instability and sensitivity to DNA-damaging treatment

Sebastian Burkart[1;2], *Christopher Weusthof[2], Karam Khorani[2], Sonja Steen[2], Jochen Heß[2;3]*

[1]Institute of Human Genetics, University Heidelberg, Heidelberg; [2]Section Experimental and Translational Head and Neck Oncology, Heidelberg University; Departement of Otolaryngology, Heidelberg; [3]Research Group Molecular Mechanisms of Head and Neck Tumors, German Cancer Research Cencer, Heidelberg

Background/Objectives: Identification of molecularly-defined cancer subgroups and targeting tumor-specific vulnerabilities have the potential to improve treatment response and patient outcomes, but remain an unmet challenge of high clinical relevance.

The establishment of a comprehensive multi-omics analysis approach allows versatile molecular subgroup characterization in head and neck squamous cell carcinoma (HNSC), which is easily adaptable to multiple clinical questions.

Methods: We established an UCHL1-related gene-set to identify and molecularly characterize an UCHL1-related subgroup by

integrative analysis of multi-omics data. A xgbTree-model was trained with TCGA-HNSC based on GSVA scores for gene-sets of MSigDB to robustly predict UCHL1-related cancers. Potential vulnerabilities of UCHL1-related cancer cells were elucidated by an in-silico drug screening approach.

Results: This study describes a versatile integrative multi-omics workflow for identification of molecularly-defined subgroups in cancer.

UCHL1-related HNSC were characterized by higher frequencies of genomic alterations, which was also evident for UCHL1-related cancers of other solid tumors predicted by the classification model. These data indicated an impaired maintenance of genomic integrity and vulnerability for DNA-damaging treatment, which was supported by a favorable prognosis of UCHL1-related tumors after radiotherapy, and a higher sensitivity to irradiation or DNA-damaging compounds (e.g. Oxaliplatin).

Conclusion: Our study established UCHL1-related cancers as a novel subgroup across most solid tumor entities with a unique molecular phenotype and DNA-damaging treatment as a specific vulnerability.

The described workflow of integrative multi-omics analysis is a versatile tool for molecularly-defined subgroup identification and elaboration of treatment targets. It might be transferable to different clinical questions to leverage translational research in the field of multi-omics.

Background/Objectives: Rare genetic variants can strongly predispose to disease, yet accounting for rare variants is statistically challenging. Meta-analysis methods over different test types and annotations have demonstrated the added value of incorporating a broad spectrum of annotations. However, methods integrating variant annotations in a data-driven manner are lacking.

Methods: Here, we propose DeepRVAT (Deep Rare Variant Association Testing), a deep set model that learns gene impairment scores from rare variants, annotations, and phenotypes. DeepRVAT infers the relevance of different annotations and their combination directly from data, eliminating ad hoc modeling choices that characterize existing methods. DeepRVAT yields a single, trait-agnostic gene impairment score, enabling both risk prediction and gene discovery in a unified framework and seamless integration into established association testing frameworks.

Results: We apply DeepRVAT on 34 quantitative and 26 binary traits across 167,245 UK Biobank (UKBB) whole-exome-sequenced (WES) individuals. We integrate state-of-the-art annotations, including AlphaMissense, PrimateAI, AbSplice, DeepRipe, and DeepSEA, and find a substantial increase in gene discoveries and improved replication rates on held-out individuals over previous methods. Furthermore, we significantly improve detection of individuals at high genetic risk by combining common variant polygenic risk scores with DeepRVAT. We demonstrate the applicability of pre-trained DeepRVAT models to new traits, facilitating the study of disease cohorts with limited training data, and finally apply DeepRVAT to the latest 500k UKBB WES release.

Conclusion: DeepRVAT combines a flexible deep neural network with a rigorous statistical testing framework, thereby contributing to the understanding of human trait biology and boosting the identification of genetically predisposed individuals.

P16.004.C REEV - Novel platform for variant evaluation

Dzmitry Hramyka[1], Henrike Sczakiel[2;3;4], Felix Boschann[2;4], Mikko Petteri Nieminen[1], Max Xiaohang Zhao[1;4], Lara Einicke[4], Stefan Mundlos[3;4], Dominik Seelow[1], Nadja Ehmke[4], Dieter Beule[1], Manuel Holtgrewe[1]

[1]Berlin Institute of Health, Core Unit Bioinformatics, Berlin, Germany; [2]Berlin Institute of Health at Charité - Universitätsmedizin Berlin, BIH Biomedical Innovation Academy, Clinician Scientist Program, Berlin, Germany; [3]Max Planck Institute for Medical Genetics, RG Development & Disease, Berlin, Germany; [4]Charité - Universitätsmedizin Berlin, Freie Universität Berlin and Humboldt-Universität zu Berlin, Institute of Medical Genetics and Human Genetics, Berlin, Germany

Background/Objectives: The rapid advancement in broad genetic testing, especially through exome sequencing (ES) and genome sequencing (GS), has resulted in a significant surge in the detection and analysis of genetic variations. This advancement brings the significant challenge of distinguishing the causal variant(s) among numerous non-pathogenic variants. Here, we introduce REEV (Review, Evaluate, and Explain Variants), a novel web-based platform aiming to streamline the variant evaluation process, focusing on sequence and structural variants in the context of rare diseases.

Methods: We implemented REEV as a web server that provides integrated data from various free and public domain sources, providing comprehensive genetic information analysis. The platform integrates external tools such as InterVar and AutoCNV to

allow semi-automatic assessment of variants using ACMG criteria. REEV is implemented in the TypeScript and Python programming languages.

Results: REEV facilitates both casual and registered users in generating and sharing public permanent links for specific variants and allows for the submission of these variants to ClinVar. Additionally, the platform offers functionality to bookmark particular variants and store their associated ACMG assessments, thereby enhancing collaborative research and facilitating more efficient data exchange.

Conclusion: REEV supports genetic diagnostics with a user-friendly platform that uniquely integrates diverse data sources and adheres to ACMG criteria, becoming essential for rare disease research.

Grants: H.L.S. is a participant in the BIH Charité Clinician Scientist Program founded by the late Prof. Duska Dragun and funded by the Charité — Universitätsmedizin Berlin and the Berlin Institute of Health.

P16.005.D EAGLE-MUT: Predicting and evaluating per-nucleotide somatic mutation susceptibility

Mario Aguilar[1;2], *Yana Vassileva*[1], *Melissa Sanabria*[1], *Anna Poetsch*[1;2]

[1]*TU Dresden, Dresden, Germany;* [2]*National Center for Tumor Diseases, Partner site Dresden (NCT), Dresden, Germany*

Background/Objectives: Mutagenesis distributes heterogeneously over the genome and depends on different mutational processes. Distribution is dependent on the direct sequence context and larger range influences, such as the epigenome and genome functionality. As a consequence, each nucleotide in the genome has a distinct context-dependent probability to mutate. We estimate somatic mutation probabilities genome wide. By interrogating specific loci, such as cancer genes, we can investigate the mutation probability alone, as opposed to mutation rates that depend on selective processes.

Methods: We developed EAGLE-MUT (Efficient Analysis with a Genome-wide LSTM to Evaluate per-nucleotide MUTation susceptibility), a Long Short-Term Memory (LSTM) recurrent neural network model, that infers the susceptibility to somatic mutagenesis genome-wide in nucleotide resolution. It uses 500 nt windows, the human reference sequence and single-base-substitutions in esophageal adenocarcinoma ($n = 423$).

Results: EAGLE-MUT achieves a 12-fold increase in correct predictions compared to a random model and learns DNA trinucleotide content (cosine similarity $= 0.99$), but utilizes a broader context that reveals motifs of > 100 nt in size. Applying EAGLE-MUT to individual patients underscore individual differences in somatic mutation probabilities. We highlight divergent susceptibilities for the same driver genes throughout the cohort (e.g., TP53, SMAD5, ARID1A).

Conclusion: EAGLE-MUT captures the specificity of mutagenesis in WGS data and derives per-nucleotide probabilities of mutagenesis through a bigger sequence context. EAGLE-MUT can be applied for individual patients to personalize the assessment of mutagenesis and can support the investigation of evolutionary trajectories in individual tumor samples.

P16.006.A Face Mesh Detection and Annotation for Genetic Disorders with Facial Phenotypes

Fabio Hellmann[1], *Marc Lorenz*[1], *Leonhard Okrusch*[1], *Dominik Schiller*[1], *Tobias Baur*[1], *Silvan Mertes*[1], *Daniela Angelova-Toshkina*[2], *Michaela Kuhlen*[2], *Elisabeth André*[1]

[1]*University of Augsburg, Chair for Human-Centered Artificial Intelligence, Augsburg, Germany;* [2]*University of Augsburg, Pediatrics and Adolescent Medicine, Augsburg, Germany*

Background/Objectives: Facial dysmorphism does often manifest in syndromic conditions that are genetically related. These dysmorphisms exemplify facial feature abnormalities, which are difficult or impossible to represent by today's facial landmark algorithms due to their sometimes complexity in detail. Adapting the facial landmark algorithms to faces affected by syndromic conditions is challenging as, to date, no dataset with those faces and their corresponding landmarks is available. Therefore, we propose a workflow to semi-automatically annotate faces with dysmorphism and fine-tune a facial landmark detection model during the annotation process. Furthermore, we will provide the manually annotated landmarks.

Methods: We propose a workflow to enhance the adaptability and robustness of the state-of-the-art face landmarks detection model introduced by Kartynnik et al. [1]. To fine-tune the model on faces with genetic syndromes, we incorporated the cooperative machine learning paradigm into our workflow to annotate the facial landmarks semi-automatically.

Results: Preliminary results of our method indicate that the fine-tuned model on the manually annotated landmarks based on the syndromic faces increases the automatic detection.

Conclusion: This research aims to improve the accuracy of facial landmark detection for faces affected by genetic syndromes. Our method uses the landmark detection model by Kartynnik et al. [1] as a basis and fine-tuned it on semi-automatedly annotated syndromic images with facial dysmorphism.

Grants: None.

P16.007.B A regional nonsense constraint score offering clinical and biological insights into genetic disorders.

Alexander Blakes[1;2], *Nicola Whiffin*[3;4;5], *Colin Johnson*[6], *Jamie Ellingford*[1;2], *Siddharth Banka*[1;2]

[1]*Manchester Centre for Genomic Medicine, Division of Evolution and Genomic Sciences, School of Biological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom;* [2]*Manchester Centre for Genomic Medicine, Manchester University NHS Foundation Trust, Health Innovation Manchester, Manchester, United Kingdom;* [3]*Big Data Institute, University of Oxford, Oxford, United Kingdom;* [4]*Wellcome Centre for Human Genetics, University of Oxford, Oxford, United Kingdom;* [5]*Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, United States;* [6]*Leeds Institute of Medical Research, Faculty of Medicine and Health, University of Leeds, Leeds, United Kingdom*

Background: Nonsense-mediated decay (NMD) critically influences the molecular and clinical impact of protein-truncating variants (PTVs). PTVs in some regions may escape NMD. The accurate interpretation of these variants is a major challenge in clinical genomics. However, existing constraint scores do not comprehensively account for NMD escape.

Methods: Canonical protein-coding transcripts were partitioned into regions likely to trigger or escape NMD, and exome sequencing data from 730,947 individuals in gnomAD v4 was used to calculate regional nonsense constraints therein. These data were compared with distributions of de novo PTVs (*dn*PTVs) in 44,966 rare disease trios.

Results: 1,947/19,694 transcripts (10%) have significant regional nonsense constraint. Of these, 625 transcripts (32%) have weak pLI and LOEUF annotations, suggesting that our regional score may prioritise disease-relevant genes missed by transcript-level metrics.

Bases in constrained regions are more highly conserved (phyloP) and have higher AlphaMissense scores than unconstrained regions ($p < 10^{-8}$).

In 44,966 rare disease trios, *dn*PTVs are 4- to 7-fold enriched in constrained regions versus unconstrained regions. In 13,921 trios with clinical outcome data, *dn*PTVs in a constrained region are more likely to be diagnostic than those in unconstrained regions (OR 4.6-6.5, $p < 0.01$).

Finally, we identified 31 genes with at least three unique *dn*PTVs in a constrained region and no disease association in OMIM, highlighting the potential of our metric for prioritising novel disease-gene associations. Work to identify new diagnoses and validate our metric against variants in ClinVar is ongoing.

Conclusions: Our results will improve diagnosis, gene discovery, and mechanistic insights in genetic disorders.

Consortium: Landes Initiative Rheinland-Pfalz and the Resilience, Adaptation, and Longevity (ReALity) initiative of the Johannes Gutenberg University of Mainz, Deutsche Forschungsgemeinschaft (DFG)

Background/Objectives: Oxford Nanopore Technologies' (ONT) sequencing platform offers an excellent opportunity to perform real-time analysis during sequencing. This feature allows for early insights into experimental data and accelerates a potential decision-making process for further analysis, which can be particularly relevant in the clinical context. Here, we present NanopoReaTA (Nanopore-seq real time transcriptional analysis), an innovative real-time transcriptional analysis toolbox designed for the Oxford Nanopore Technologies (ONT) sequencing platform.

Methods: Functioning directly on the data output from MinKnow, the tool integrates a Nextflow pipeline, allowing comprehensive analyses for both genome wide and gene-specific expression patterns. Additionally, an Rshiny based GUI offers an interactive experience, guiding users through configuration settings and allowing them to extract valuable information from sequencing runs in progress.

Results: By having access to real-time insights into both transcriptome-wide and gene-specific data, users can enhance decision-making in scientific experiments and diagnostic investigations, potentially leading to significant time and resource savings.

Conclusion: With NanopoReaTA, differential expression analysis for ONT based RNA sequencing experiments can be performed in real-time. The interactive graphical user interface allows to visualize results on demand with the opportunity to gain genome-wide and gene-specific insights on gene and transcript expression patterns.

Grants: Landes Initiative Rheinland-Pfalz and the Resilience, Adaptation, and Longevity (ReALity) initiative of the Johannes Gutenberg University of Mainz, SFB 1551 Project No. 464588647 Deutsche Forschungsgemeinschaft (DFG)

P16.009.D Contributing to genetic diagnostic effectiveness with heterogeneous graph neural networks

Jose L. Mellina-Andreu[1], *Luis Bernal*[1], *Antonio Gómez-Skarmeta*[1], *Mina Ryten*[2], *Sara ALVAREZ*[3], **Alejandro Cisterna García**[1], *Juan Botia*[1,4]

[1]*Faculty of Informatics, Universidad de Murcia, Department of Information and Communications Engineering, Murcia, Spain;* [2]*UK DRI Centre at Cambridge;* [3]*NIM Genetics, Genómica y Medicina S.L., Spain;* [4]*University College London, Department of Neurodegenerative Diseases, London, United Kingdom*

Contributing to genetic diagnostic effectiveness with heterogeneous graph neural networks

Background/Objectives: We are concerned with predicting novel causal associations between genes and phenotypes to increase the yield of genetic diagnosis. A comprehensive gene-phenotype associations catalogue is paramount for effective diagnosis. Yet unknown phenotype-gene associations may contribute to a significant percentage of undiagnosed patients.

Methods: We redefined the prediction of novel gene-phenotype associations as a link prediction task between nodes on a heterogeneous graph. We modelled the graph with machine learning starting from a graph of phenotypes and genes based on HPO. Phenotypes were encoded using BERT, a transformer-based deep learning network. Genes were characterized using information from various sources (Gnomad, GTEx, STRING amongst others). With this we then created a deep heterogeneous graph neural network called PhenoLinker.

Results: PhenoLinker outperforms cutting edge methods (HPODNets, GeneMANIA and 6 other) in AUCPR (0.503 vs 0.357) and F1 (0.643 vs 0.433). When trained on an HPO version and tested on associations added in later versions, the average AUCPR is of 0.73. When tested on the Gene2Phenotype associations not in HPO, PhenoLinker predicted that 58% should be added to HPO, 14 fold over random associations. Moreover, PhenoLinker improved a genetic diagnostic software. After reanalysing a battery of undiagnosed cases using the software empowered with PhenoLinker predictions, 13 new variants helped nominally diagnosing subjects through new gene-phenotype associations like ARHGEF10 and peripheral neuropathy (HP:0009830) and OPA1 and Microcephaly (HP:0000252).

Conclusion: PhenoLinker can help increasing diagnostic yield of genetic diseases. Predictions and their corresponding in-silico explanations are available at https://huggingface.co/spaces/Melland/PhenoLinker.

P16.010.A Decoding the intercellular communication of immune cells in neuromyelitis optica and multiple sclerosis

Maria Jose Cardenas Espinosa[1;2], *Anika Witten*[1], *Catharina Groß*[2], *Lisa Lohmann*[2], *Eva Dawin*[2], *Heinz Wiendl*[2], *Monika Stoll*[1], *Luisa Klotz*[2]

[1]*University of Münster, Institute of Human Genetics, Münster, Germany;* [2]*University of Münster, Department of Neurology, Münster, Germany*

Background/Objectives: Neuromyelitis optica (NMO) and multiple sclerosis (MS) are neuroinflammatory and neurodegenerative diseases characterized by infiltration of immune cells in the central nervous system (CNS). Despite of inherent similarities, the identification of antibodies targeting water channel aquaporin-4 (APQ4) and myelin oligodendrocyte glycoprotein (MOG) in NMO has differentiated them as two distinct diseases. The specific molecular mechanisms involving autoreactive immune cells in both disorders remain to be fully elucidated.

Methods: Bulk RNA- sequencing was performed on sorted PBMCs (B cells, $CD4^+$T cells and monocytes) from 22 NMO patients (AQP4/MOG), 11 MS patients and 11 healthy donors (HD). Sample were processed using HISAT2 and Stringtie pipeline. Subsequently, differential gene expression analysis was performed using DESeq2, and cell-cell communication analysis via CellChat.

Results: In monocytes, differential gene expression analysis comparing NMO and HD (criteria: padj < 0.05 and $\log_2$FC >1) showed a higher number of upregulated genes (IL1A, TGIF1, CSF1) associated with pro-inflammatory responses than B cells and CD4 T^+ cells. Moreover, TGF-β and MAPK signaling pathways were among the top enriched pathways, suggesting a prominent inflammatory role of monocytes in the pathology of NMO.

Further analysis of ligand-receptor interactions identified dysregulated-signaling pathways including CCL, CXCL, MHC-II in NMO and IL-16, CXCL and NRXN in MS, particularly in interactions between monocytes and CD4 T^+ cells.

Conclusion: Further analysis of ligand-receptor interactions identified dysregulated-signaling pathways including CCL, CXCL, MHC-II in NMO and IL-16, CXCL and NRXN in MS, particularly in interactions between monocytes and CD4 T^+ cells.

P16.011.B A novel life-time risk model to estimate the age-dependent penetrance of rare and common variants in complex diseases and application to Alzheimer disease

Catherine Schramm[1], *Emmanuelle Génin*[2], *Olivier Quenez*[3], *Gaël Nicolas*[3], *Camille Charbonnier*[4]

[1]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, F-76000, Rouen, France;* [2]*Inserm UMR1078, Brest, France;* [3]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, CHU Rouen, Department of genetics, F-76000, Rouen, France;* [4]*Univ Rouen Normandie, Inserm U1245, Normandie Univ, CHU Rouen, Department of biostatistics, F-76000, Rouen, France*

Consortium: ADES consortium

Background/Objectives: Recent association studies on exome sequencing datasets unveiled rare genetic risk factors with stronger levels of association with complex diseases than most of their common counterparts. Although each of them are rare or ultra-rare, together they affect a non-negligeable part of the population. It is thus essential to accurately estimate their absolute penetrance before putative use in a clinical setting.

Methods: We developped a model combining information from prospective cohorts and case/control sequencing data into a Kaplan-meier-like estimator to assess age-dependent penetrance of different rare variant categories, stratified for major common risk factors and/or genetic risk score (GRS) strata. When cumulative frequencies allowed for it, we tested for epistasy between common and rare variants via bootstrap. After validation through extensive simulation studies, we applied our model to Alzheimer disease, integrating the ADES-ADSP case-control sequencing dataset with large published prospective data.

Results: We derived Alzheimer disease penetrance curves for rare but recurrent *TREM2*-p.R47H, *TREM2*-p.R62H, *ATP8B4*-p.G395S and *ABCA7* truncating variants, stratified for the common APOEe4 allele and GRS tertiles. Cumulated effects of *TREM2*-p.R47H and APOEe4/e4 led to almost complete penetrance by age 85, although *TREM2*-p.R47H alone and APOEe4/e4 alone confered less than 30% and 50% risk by age 85, respectively.

Conclusion: Our model offers a perspective to estimate the penetrance of combinations of risk factors integrating prospective and case/control data. Results on Alzheimer disease data show the importance of accounting for digenic dimensions, at least, and that the background effect of GRS appears negligeable, in comparison.

P16.012.C Mind the ancestry gap: Improving the genetic prediction of psychiatric disorders

Jette Steinbach[1;2], *Emil Michael Pedersen*[1;2], *Florian Privé*[1;2], *Andrew Schork*[3;4;5], *Bjarni Jóhann Vilhjálmsson*[1;2;6;7]

[1]*The National Centre for Register-based Research, The National Centre for Register-based Research, Aathus BSS, Aarhus University, Denmark, Aarhus V, Denmark;* [2]*Lundbeck Foundation Initiative for Integrative Psychiatric Research, Aarhus V, Denmark;* [3]*Institute of Biological Psychiatry, Mental Health Center Sct Hans, Roskilde, Denmark;* [4]*The Translational Genomics Research Institute (TGEN), Neurogenomics Division, Phoenix, AZ, United States;* [5]*GLOBE Institute, Faculty of Health and Medical Sciences, Copenhagen University, Section for Geogenetics, Copenhagen, Denmark;* [6]*The Broad Institute of MIT and Harvard, Novo Nordisk Foundation Center for Genomic Mechanisms of Disease, Cambridge, MA, United States;* [7]*Bioinformatics Research Centre (BiRC), Bioinformatics Research Centre (BiRC), Aarhus University, Aarhus, Denmark*

Background/Objectives: Existing polygenic scores (PGS) are not transferable between genetic ancestries. A decrease in PGS prediction accuracy by up to 78% in individuals of African genetic ancestry relative to individuals of European genetic ancestry can introduce bias and increase health disparities in clinical practice. Even though this problem is well known for PGS, we lack information about the transferability of alternative measures capturing genetic (or environmental) information. This study will evaluate and compare the impact of genetic heterogeneity on the prediction accuracy of PGS, family history (FH) and electronic health records (EHR) for psychiatric disorders.

Methods: I will predict risk in > 650.00 individuals using data from the iPSYCH2015 case-cohort study, Danish registers and the UK Biobank. The outcome will be the partial correlation between the observed and predicted case-control status as stratified by genetic ancestry.

Results: Our preliminary results, obtained in the iPSYCH2015 sample, show that FH is more robust than PGS for

predicting the case-control status in individuals of non-European genetic ancestry. We expect to replicate our findings in data from the UK Biobank. We also hypothesize that the accuracy of EHR-based prediction models may differ significantly between Denmark and the UK.

Conclusion: By evaluating the prediction accuracy of three commonly used measures capturing genetic and environmental information, this study provides valuable insight into the development of unbiased and transferable prediction models. Our results will help decrease health disparities and social injustice present in current clinical prediction models.

Background/Objectives: Copy-number variants (CNVs) play a substantial role in the molecular pathogenesis of many hereditary diseases, in cancer, as well as in normal human interindividual variation. Yet, they are still rather difficult to identify in mainstream sequencing projects, especially involving Whole-Exome Sequencing (WES), because they tend to occur in DNA regions that are not routinely chosen for sequence analysis.

Methods: We discovered that DNA reads from uncaptured sequences, present as contaminants in WES procedures, could be used to identify elusive pathogenic CNVs, especially when 'off-target' reads can be mapped back to the noncoding regions of the genome. We therefore developed OFF-PEAK, a user-friendly tool that harnesses the enormous, although neglected power of such reads.

Results: We tested OFF-PEAK on sequencing data from 96 cancer samples, as well as 130 exomes of individuals with Mendelian diseases. For both sets of data, OFF-PEAK identified an unexpectedly large number of novel and bona-fide pathogenic CNVs, which were then validated experimentally by standard molecular biology techniques,. Specifically, our tool demonstrated a very high performance (97% sensitivity and 87% specificity), when compared to values obtained experimentally in the wet lab.

Conclusion: In conclusion, our data show that CNVs represent an underestimated element of pathogenicity in both Mendelian conditions and in cancer, and that such events can be easily identified by the analysis of off-target reads from NGS procedures.

Grants: This work was supported by the Swiss National Science Foundation (grant #176097 to C.R.) and by the Swiss RetinAward (to M.Q.).

P16.014.A Exploration of the mutational landscape in Clinvar & Gnomad for the functional effect in (over-) lapping short open reading frames (sORFs)

Jeremias Krause[1], *Martin Danner*[1;2], *Lars Perchalla*[2], *Florian Kraft*[1], *Matthias Begemann*[1], *Miriam Elbracht*[1], *Ingo Kurth*[1]

[1]*University hospital Aachen, Institute for Human Genetics and Genomic Medicine, Aachen, Germany;* [2]*scieneers GmbH, Karlsruhe, Germany*

Background/Objectives: Short open reading frames (sORFs) are a class of genomic elements which recently gained attention because sORFs may encode functionally relevant micropeptides. These sORFs are dispersed across the whole genome and may overlap with canonical coding regions. Such overlapping sORFs are usually neglected in genetic analysis because it is difficult to distinguish their effect from effects on the respective canonical transcript.

Methods: Using the custom annotations feature of the ensembl variant effect predictor (VEP) and the genome analysis toolkit (GATK) we implemented a pipeline, which enabled us to annotate a potential impact on sORFs versus the main coding region of an overlapping gene, in which the sORF is embedded. We utilized this pipeline to visualize the landscape of variants present in ClinVar and gnomAD for a consensus set of sORFs, previously published by gencode. Using ESMFold we subsequently generated 3D Structures of the observed variants and their corresponding wild type micropeptides to train a deep learning model to predict potentially deleterious variants.

Results: A noticeable proportion of variants present in ClinVar affect sORFs, most of which are currently classified as variants of uncertain significance (VUS). Most variants in ClinVar that fall into sORFs and that are predicted to have a functional impact on the sORF are missense variants.

Conclusion: sORF affecting variants might depict an overlooked disease mechanism. To prove this hypothesis, future functional evidence beyond bioinformatic predictions is required.

Grants: This research project was funded by the START-Program of the Faculty of Medicine, Uniklinik RWTH Aachen.

P16.015.B Establishing the impact of genome and transcriptome reference on gene co-expression

Ariela Buxbaum Grice[1], *Noam Beckmann*[1], *Anina Lund*[1], *Ryan Thompson*[1]

[1]*Icahn School of Medicine at Mount Sinai, Genetics and Genomics/ Neuroscience, New York, United States*

Background/Objectives: Since 2003, six genome assemblies (NCBI34, NCBI35, NCBI36, GRCh37/hg19, GRCh38/hg38, T2T-CHM13) and a myriad of transcriptome assemblies (GENCODE v1 to v45) have been released, each filling in gaps or correcting errors in its predecessors. Due to time and resource constraints, research is often performed using non-up-to-date references, with an implicit assumption that reference choice has a negligible impact on findings. Here, using five references spanning multiple genome and transcriptome assemblies, we characterized the effect of reference usage on gene-gene correlations.

Methods: Raw reads from 2 large Alzheimer's disease gene expression datasets of the human prefrontal cortex (ROSMAP, n = 633; MSBB, n = 246) were mapped and quantified using 5 references (NCBI36, GRCh37/hg19, GRCh38.12[v30], GRCh38.13[v43], T2T-CHM13). Counts were processed independently for each reference using the same procedure: removal of low count genes, raw counts normalization (*voomWithDreamWeights*), and residualization using previously defined covariates. For every pair of genes, Pearson correlations were compared for each pair of references. Additionally, WGCNA coexpression network module memberships were compared across assemblies.

Results: Although gene-gene correlations and module membership were generally consistent between assembly pairs, they were never identical (e.g., range of differences between correlations: -1.72-1.46). Consecutive references were most similar, with GRCh38 (v30, v43) and T2T-CHM13 closest. Interestingly, gene-gene correlation differences altered coexpression module memberships significantly (mean Jaccard index = 74.7%).

Conclusion: While gene-gene correlations and coexpression network structure are generally replicated between references, reference usage plays an important role for a non-trivial number of genes, thereby impacting coexpression structure.

P16.016.C Efficient and local pleiotropy-robust omic-wide mendelian randomization with LaScaMolMR.jl

Samuel Mathieu[1], *Louis-Hippolyte Minvielle-Moncla*[1], *Mewen Briend*[1], *Valentine Duclos*[1], *Anne Rufiange*[1], *Patrick Mathieu*[1,2]

[1]*Institut Universitaire de Cardiologie et de Pneumologie de Québec, Québec, Canada;* [2]*Laval University, Medecine Faculty, Surgery Department, Québec, Canada*

Background: The recent rise of large genetic cohorts led to an increase in scale of molecular Quantitative Trait Loci studies, leading to more extensive Mendelian randomization (MR) investigations aiming to identify causal relationships between molecular traits and diseases. This increase led to the identification of multiple causal candidates and potential drug targets over time. However, the increase in scale of such studies and more complex study designs come with computational challenges.

Methods and Results: We present "LArge SCAle MOLecular Mendelian Randomization with Julia" (LaScaMolMR.jl), an integrated all-Julia package optimized for Omic-wide Mendelian Randomization (OWMR) Studies. This versatile package eliminates the two-language problem and implements fast algorithms for instrumental variables selection approaches with both cis and trans instruments and perform the most popular regression estimators for MR studies with molecular exposures. It reduces the compute time via metaprogramming allowing easy deployment of multi-threaded approach and the internalization of linkage disequilibrium (LD) investigation of potential instrumental variables. Via its integrated approach and high-computational performance, LaScaMolMR.jl allows users who have minimal programming experience to perform large scale OWMR studies. We developed the "No Local Pleiotropy" (NoLoP) approach that allows the user to further investigate potential pleiotropic effects local to the exposure dataset. We further show the NoLoP approach can identify causal genes when there are multiple potential targets in the same locus compounded by the LD structure in case studies.

Conclusion: LaScaMolMR.jl is an easy to implement and computationally performant package that allows control of local pleiotropy in OWMR.

P16.017.D An explainable, ontology-based genetic algorithm for diagnosis and outcome prediction using patient phenotypic data

Elena Casiraghi[1], *Nariman Ammar*[2], *Bryan Laraway*[3], *Corneliu Antonescu*[4], *Julius Jacobsen*[5], *Yasemin Bridges*[5], *Harry Caufield*[6], *Harshad Hegde*[6], *Carlo Kroll*[5], *Kevin Schaper*[3], *Madan Krishnamurthy*[3], *Melissa Haendel*[3], *Christopher Mungall*[6], *Peter Robinson*[7], **Justin Reese**[6]

[1]*University of Milan, AnacletoLab, Computer Science Department, Milano, Italy;* [2]*Illinois State University, Information Technology, Normal, United States;* [3]*University of Colorado Anschutz Medical Campus, Aurora, United States;* [4]*Banner Health, Colorado Medical Center, Greeley, United States;* [5]*William Harvey Research Institute, Queen Mary University of London, Barts and the London School of Medicine and Dentistry, London, United Kingdom;* [6]*Lawrence Berkeley National Laboratory, Division of Environmental Genomics and Systems Biology, Berkeley, United States;* [7]*Berlin Institute of Health, Charité Universitätsmedizin, Berlin, Germany*

Background/Objectives: Rich phenotypic data from electronic health records and clinical case reports can be used for computational phenotyping of rare disease and to predict clinical outcomes. For these use cases, explainability and accuracy of predictions are particularly important.

Methods: We describe a genetic algorithm to learn a set of phenotypic features (an "HPO profile") that can diagnose patients, characterize important phenotypic features, and predict clinical outcomes. While traditional genetic algorithms use mutation operations (adding, removing, and crossing over of "genes") on chromosome representations of features, we have adapted this strategy to use mutation operations on the HPO graph. In addition, we developed a fitness function that uses semantic similarity of the HPO profile to a patient to determine the fitness of each profile.

Results: We applied this algorithm to learn HPO profiles to predict the correct diagnosis for 8,171 synthetic disease cases and 3,305 case reports from literature. Performance as measured by test AUPRC was excellent in predicting the presence of Marfan Syndrome (1.0 and 0.802 on synthetic and real cases, respectively). We next applied this strategy to identify phenotypic features that predict important sequelae after acute COVID-19 infection. The genetic algorithm predicted myocardial infarction and kidney disease with a test AUPRC of (0.215 and 0.208, respectively, vs. an expected value of 0.09 for a random classifier).

Conclusion: Our genetic algorithm provides a method to directly learn explainable phenotypic features with diagnostic and prognostic value.

P16.018.A A three level modeling for identifying important predictor variables in genome-wide association studies suffering from p >> n.

Jakub Liu[1;2], *Joanna Szyda*[1;3], *Paula Dobosz*[3;4]

[1]*Wroclaw University of Environmental and Life Sciences, Department of Genetics, Wrocław, Poland;* [2]*Freie Universitaet Berlin, Berlin, Germany;* [3]*Poznan University of Medical Science, University Cancer Diagnostic Center, Poznań, Poland;* [4]*University of Warsaw, Institute of Genetics and Biotechnology, Warsaw, Poland*

Background/Objectives: Many genomic datasets are characterized by a much greater number of explanatory variables (p) than the number of observations (n). As a consequence, it is not possible to fit all the variables into a single statistical model.

Methods: A three-level approach was applied to the association analysis of COVID-19 susceptibility with SNPs identified in whole genome sequences of 1222 individuals. The first stage consisted of fitting k logistic regression models with subsets of SNPs that guarantees $p < n$. Each SNP was present in at least one of the k models. In the second stage, goodness-of-fit of each model was used as a dependent variable in a single Elastic Net Regression model that incorporated effects of all explanatory variables estimated in the first stage. In the third step, the effects of the p explanatory variables were clustered using the k-means clustering algorithm to identify SNPs that are important predictors of the susceptibility to COVID-19.

Results: For the original set of ~42 million SNPs, two groups representing SNPs important and irrelevant to being resistant or susceptible to COVID-19 infection were identified.

Conclusions: This approach enables the selection of explanatory variables for the situation of $p < n$, for which fitting all variables in the same model would enforce shrinkage while fitting a multitude of single SNP models poses problems with multiple testing. Even though the method is computationally intensive, it is well suited for parallelization and, hence, computationally feasible.

P16.019.B Evaluation of structural variants calling performances using short and long reads sequencing

Valentina Andrioletti[1], *Federica De Paoli*[1], *Ivan Limongelli*[1], *Susanna Zucca*[1], *Ettore Rizzo*[1]

[1]*enGenome srl, Pavia, Italy*

Background/Objectives: In recent years, the scientific community has shown a growing interest in structural variants, genetic alterations involving more than 50 bp, as they are involved in the mechanisms of many genetic diseases. Illumina-based NGS technologies face challenges in identifying such complex events, due to the nature of their short reads, even if variant callers are becoming more and more sensitive. Third-generation platforms promise to overcome this issue by sequencing long DNA fragments up to 20 Kbps, spanning the break ends of these structural variants. To assess the real potential of both approaches, we benchmarked the "best in class" solutions, Illumina-Dragen and PacBio on the well characterized Coriell samples.

Methods: We evaluated the structural variants calling performances of Illumina and PacBio sequencing platforms on HG002 and HG001 WGS Coriell samples, comprising more than 14K deletions and 2K duplications. To be as comprehensive as possible, the variants have been stratified by length and type, and compared using both "truvari" and "witty.er", tools able to determine the overlap of complex structural events.

Results: Long-read technology outperforms short-reads in terms of sensitivity (average improvement: 20%, maximum for PacBio: 98.5%, maximum for Illumina: 69.2%), with deletions being the most detectable type of variant, but precision decreases on average by 10%, affecting mostly duplications.

Conclusion: Our analysis confirms the increase in detection power of long-read sequencing which comes at the cost of precision, suggesting that this technology requires even more stringent filtering and prioritization steps.

P16.020.C Extracting phenotypes from clinical descriptions using large language models: a comparison between automated and manual approach.

Silvia Berardelli[1;2], *Andrea Gazzo*[3], *Federica De Paoli*[1], *Ivan Limongelli*[1], *Ettore Rizzo*[1], *Paolo Magni*[2], *Susanna Zucca*[1]

[1]*enGenome srl, Pavia, Italy;* [2]*University of Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy;* [3]*Memorial Sloan Kettering Cancer Center, Department of Pathology and Laboratory Medicine, New York, United States*

Background: Standardized phenotypic descriptions are essential in healthcare. Clinicians struggle to manually extract and convert them from literature or medical records. The advent of large language models has the potential to streamline the extraction of clinical descriptions into standardized Human Phenotype Ontology (HPO) terms.

Methods: We evaluated GPT-4 (openai.com) and PhenoBERT (PMID:35471885) for their ability to extract and convert clinical descriptions into HPO terms. GPT-4 excels in extracting and analyzing phenotypic descriptions in text but produces hallucinations when converting to HPO terms. Conversely, PhenoBERT is effective in conversion but often misses phenotypic descriptions in the raw text. To optimize the process, we adopted a two-steps method. Initially, GPT-4 analyzes textual, tabular or image-based input to generate a phenotypic description. Subsequently, PhenoBERT converts it into the corresponding HPO terms. This approach was tested on a benchmark of patients carrying oligogenic variants (PMID:35411390) described in the literature and lacking HPO terms. Its accuracy was evaluated by comparison with expert-driven manual curation of phenotyping.

Results: On 488 digenic and oligogenic combinations, an average of 4 phenotypes per case (median = 3, max = 47, min = 1) were extracted, with execution times ranging from 5 to 10 minutes. Compared to manual curation, we obtained complete concordance in 92% of cases. Unrecorded phenotypes were observed in 5% of cases, while extra unnecessaries phenotypes in 3%.

Conclusions: In conclusion, our LLM-based approach enables the automated extraction of phenotypes. Applied to the genomic context, it can contribute to speed up the diagnostic process.

P16.021.D In-depth variant interpretation: AI-powered tools for advancing genomic understanding

Federica De Paoli[1], *Silvia Berardelli*[1;2], *Giovanna Nicora*[1;2], *Ettore Rizzo*[1], *Ivan Limongelli*[1], *Susanna Zucca*[1]

[1]*enGenome srl, Pavia, Italy;* [2]*University of Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy*

Background/Objectives: Identifying causative variants is a major challenge in genomics and there's an urgent need to uplift the diagnostic yield of Rare Diseases. Envisioning a solution, we developed a suite of AI-driven tools to support the genomic community.

Methods: We developed the "Suggested Diagnosis" AI system, using pathogenicity, phenotypes, and familial inheritance to prioritize causative variants. A layer of Explainable-AI elucidates the rationale behind results and identifies potential Incidental Findings.

Beyond monogenic analysis, we developed diVas, an AI-model to identify digenic/oligogenic variants, leveraging gene-gene interaction evidence.

Finally, riding the wave of generative AI, we released VarChat (varchat.engenome.com, 10.20944/preprints202311.1130.v1), to synthesize scientific literature into clinically relevant summaries.

Results: The "Suggested Diagnosis", awarded as "Best performing Genome Interpretation" model within the CAGI6 challenge (https://doi.org/10.1101/2023.08.02.23293212), was benchmarked on 220 real samples from 6 different cohorts (SNV/INDELs and CNVs). Causatives were ranked in the top 20 in 90% of cases. This model is integrated in the eVai platform (evai.engenome.com). IF identification reduces the list of candidate variants by 80%.

DiVas was benchmarked on 600 manually curated combinations (sensitivity: 81%) and 11 real samples (sensitivity 73%). Digenic predictions are available at oliver.engenome.com (https://doi.org/10.1101/2023.10.02.560464).

VarChat validation is ongoing through manual curation by an expert.

Conclusion: We benchmarked our AI models on heterogeneous cohorts, and we made our predictions explainable, thus promoting human trust in AI predictions. We released two new open tools for the genomic community, to further boost the diagnostic yield of rare diseases.

Grants: EIC Accelerator 190164416

P16.022.A A novel VEP plugin to annotate Short Tandem Repeats with HGVS nomenclature

Giovanni Cerchia[1], *Federica De Paoli*[1], *Valentina Andrioletti*[1], *Susanna Zucca*[1], **Ettore Rizzo**[1], *Ivan Limongelli*[1]

[1]*enGenome srl, Pavia, Italy*

Background/Objectives: Short Tandem Repeats (STR) play a pivotal role in unraveling the genetic underpinnings of some genetic conditions. As their significance grows, it becomes increasingly essential to establish a standardized HGVS notation for STR. The "STRike" plugin supports the annotation process directly with the Variant Effect Predictor (VEP) tool, enabling a correct application of HGVS rules.

Methods: Following the standard guidelines outlined by the HGVS consortium, the plugin generates STR HGVS notation at both genomic and coding level, directly leveraging VEP annotations. It was developed using the Perl API offered by VEP.

The plugin was tested on a dataset of variants obtained by considering STR events submitted in ClinVar (release 2023-09) overlapping a manually curated catalog of clinically relevant STR, for a total of 331 expansions and 90 contractions. The concordance between the newly generated notation and the one reported in this database was evaluated.

Results: During the testing phase, VEP release 97.4 was run in offline mode within a dedicated containerized environment. Tested on the 421 STR events submitted in ClinVar, the plugin reaches a 98.81% concordance in HGVS notation generation. Among the tests performed, only 5 mismatches were found and manually investigated, highlighting an error during the submission process to the database.

Conclusion: The "STRike" plugin is publicly available and its use can be a step forward for standardizing STR annotation. This could support the analysis of these events and their proper disclosure in the literature.

Background/Objectives: Medulloblastoma (MB) is an aggressive brain tumor accounting for 30% of all malignant central nervous system cancers in childhood. As the molecular subtype classification (WNT, SHH, Gr3 and Gr4) does not account for all existing heterogeneity, we aimed to stablish the role of long non-coding RNAs (lncRNAs), which may play a pivotal role in brain tumors, in the classification of MB, especially of Gr3/Gr4 subtypes.

Methods: Fifty-five pediatric patients and 5 controls from 25 hospitals classified upon their clinical immunochemical (IHC) and methylation status (MS-MIMIC profiling) were studied. LncRNA expression profile was performed by total RNA paired-end sequencing, aligning with STAR v2.5.3a, using FeatureCounts for quantification (lncKB hg38), and performing non-supervised clustering and batch effect correction.

Results: The IHC and methylation-based classification and lncRNA expression-based clustering showed subtype coincidence of 78% of patients. The lncRNAs profiling showed Gr3, Gr4 and previously non-classified (n/c) patients on a unique cluster, suggesting a relevant expression continuum of those subtypes. A specific hierarchical clustering of that group revealed 5 clusters: one for Gr3 (7 patients) and 4 for Gr4/n/c patients (26 Gr4 and 12 n/c patients). One of the Gr4 clusters showed the highest median age at diagnosis, *SNCAIP* overexpression and chromosome 8p loss, common genetic features of the subgroup 4β. All n/c patients located on a specific Gr4 subgroup.

Conclusion: LncRNAs may be key biomarkers for MB classification, unveiling the molecular landscape of Gr4 subtype.

P16.025.D A user-centric approach in the development of a decision support system for whole-genome-sequenced (WGS) cancer cases

Clare Kennedy[1], *Syrus Nourbakhsh[1], Alona Sosinsky[1], Liz Edwards[1], Kristof Goossens[1], Laura Valis[1], Jamie Trotman[2;3], Patrick Tarpey[2;3], Dorte Wren[2;4], Laura Ions[2;5], Alistair Reid[2;6], Christopher Wragg[2;7], Gareth Gerrard[2;8], Azim Mohamedali[2;8], Steven Best[2;8], Helen Warren[2;5], Eleanor Baker[2;6], Jonathan Williams[2;9], Natasha Vafadar[2;9], Noha Eltawil[2], Mikel Valganon[2;10], Carryl Dryden[2;4], Angharad Goodman[2;5], Kate Moloney[2;9], Katharine Jones[2;4], Polly Talley[2], Angela Hamblin[2], Sandra Hing[2], Joo Wook Ahn[2;3]*

[1]*Genomics England, London, United Kingdom;* [2]*NHS England, United Kingdom;* [3]*Cambridge University Hospital NHS Foundation Trust, East Genomic Laboratory Hub, Cambridge, United Kingdom;* [4]*Great Ormond Street Hospital for Children NHS Foundation Trust, North Thames Genomic Laboratory Hub, London;* [5]*Newcastle upon Tyne Hospitals NHS Foundation Trust, North East and Yorkshire Genomic Laboratory Hub, Newcastle, United Kingdom;* [6]*Manchester University NHS Foundation Trust, North West Genomic Laboratory Hub, Manchester, United Kingdom;* [7]*North Bristol NHS Trust, South West Genomic Laboratory Hub, Bristol, United Kingdom;* [8]*Guy's and St Thomas' NHS Foundation Trust, South East Genomic Laboratory Hub, London, United Kingdom;* [9]*Birmingham Women's and Children NHS Foundation Trust, Central and South Genomic Laboratory Hub, Birmingham, United Kingdom;* [10]*The Royal Marsden NHS Foundation Trust, North Thames Genomic Laboratory Hub, London, United Kingdom*

Background/Objectives: While landmark studies have demonstrated the potential therapeutic and prognostic utility of WGS for cancer, case analysis represents a bottleneck threatening such benefits to the patient. Highly skilled Clinical Scientists undertake the challenging and intricate task of variant interpretation. Reducing the time resource required at the analysis stage could significantly improve case turnaround times, enabling faster patient care and actionability of findings. Here, we present a decision support system (DSS) to fulfil an unmet need for solutions to streamline WGS case analysis and thus maximise the clinical utility of WGS to cancer patients.

Methods: A user-centric approach supported the identification of functional and non-functional requirements. Platform architecture and infrastructure was developed by a collaborative team of expert data architects, software engineers and bioinformaticians utilising engineering and software best practices and harnessing the power of cloud computing.

Results: In close collaboration with NHS England (NHSE), Genomics England (GEL) have custom-built a DSS for the analysis of NHS cancer referrals. WGS referral data is automatically loaded into the DSS, and to date, Clinical Scientists have access to >1,700 cases and can visualise genome-wide changes, prioritise variants with advanced filtering, access database annotations and record variant interpretations.

Conclusion: Embedding the DSS into analysis workflows will eventually contribute to reducing turnaround times and through ongoing collaboration with NHSE, GEL will continue to implement new DSS features. Focusing our attention to aligning with newly emerging UK Somatic Variant Interpretation Guidelines will further support Clinical Scientists and maximise the clinical utility of WGS in the patient pathway.

P16.026.A Indiscriminate usage of surrogate variables leads to overfitting in differential gene expression analyses

Dung Hoang[1], *Anina Lund[1], Ryan Thompson[2], Noam Beckmann[2]*

[1]*Icahn School of Medicine at Mount Sinai, Neuroscience, New York, United States;* [2]*Icahn School of Medicine at Mount Sinai, Medicine, New York, United States*

Background/Objectives: Surrogate variable analysis (SVA) aims to reduce heterogeneity in high-throughput experiments by identifying and accounting for latent confounders (surrogate variables, SVs). This approach, essential for certain analyses (e.g., eQTL), is becoming increasingly used for differential expression analyses (DEA). This study evaluates the impact of SVA on DEA, using simulated and published datasets.

Methods: Expensive simulations (20,000 genes for 1,000 samples) with varying signal (known and unknown) to noise (2.9×10^6 parameters) were performed to characterize the impact of SVA on DEA where the true differentially expressed genes (DEGs) are known. Five DEA approaches were employed: oracle (all parameters are known), no SV adjustment, SV adjustments for: known number of SVs and number of SVs estimated by SVA "BE" and "leek" algorithms. Effect of SVA was assessed in real data by evaluating the reproducibility of DEA results (performed with limma) with and without SVA in two large Alzheimer's disease (ROSMAP, MSBB) and schizophrenia (MSSM-Penn-Pitt, NIMH-HBCC) gene expression datasets.

Results: Overall, accounting for SVs in DEA led to overfitting in simulation analyses, with a high false positive rate of DEG identification (mean = 0.22, standard deviation = 0.26). When SVA was applied to real data, the reproducibility of DEG signatures dropped substantially for Alzheimer's disease (Spearman's correlations pre-SVA rho = 0.479 and post-SVA rho = 0.127) and for schizophrenia (pre-SVA rho = 0.383 and post-SVA rho = 0.126).

Conclusion: The use of SVA in DEA requires careful consideration to avoid overfitting, cautioning against its indiscriminate usage.

P16.027.B Comprehensive network modeling approaches unravel dynamic enhancer-promoter interactions across neural differentiation

Anat Kreimer[1]

[1]*Rutgers University, Piscataway,NJ, United States*

Background/Objectives: Increasing evidence suggests that a substantial portion of disease-associated mutations occur in enhancers, cis-regulatory regions essential to gene regulation. Understanding the structure and mechanism of regulatory programs this variation affects can shed light on disease mechanisms.

Methods: Here, we collected epigenetic and gene expression datasets from seven time points during neural differentiation. Focusing on this model system, we constructed intricate networks of enhancer-promoter interactions at individual stages of neural induction. These networks functioned as the base of a rich series of analyses, through which we demonstrated the network's temporal dynamics and enrichment for various disease-associated variants. We applied the Grivan-Newman bi-clustering algorithm to these networks to reveal biologically relevant sub-structures of gene regulation. We also validated our predicted enhancer-promoter interactions using transcription factor overexpression datasets and massively parallel reporter assays.

Results: Our results suggest a general framework for exploring gene regulation programs and their dynamics across developmental processes and a comprehensive approach to exploring the effects of disease-associated variants on transcriptional networks. The techniques applied to our networks have been published alongside our findings as a computational tool, E-P-INAnalyzer. Our approach is general and can be applied across different cellular contexts and disorders.

Conclusion: Analysis of enhancer promoter intecation networks can shed light on mechanisms of gene regulation underlying most biological processes and can suggest how genetic variants disrupt gene transcription networks.

P16.028.C SMapper: Visualising spatial prevalence data while accounting for data sparseness and incompleteness

Lynn Khellaf[1], arwin ralf[2], Khanh Toan Nguyen[1], Manfred Kayser[2], **Michael Nothnagel[1]**

[1]University of Cologne, Cologne Cener for Genomics, Cologne, Germany; [2]Erasmus University Medical Center, Department of Genetic Identification, Rotterdam, Netherlands

Background/Objectives: Available spatial prevalence data are often limited by sparse geographic coverage and insufficient sample size. Not accounting for sparseness and incompleteness in the data visualization, as done by most previously developed bioinformatic tools, carries the risk of severe misinterpretation e.g., concluding an apparently restricted occurrence of a feature of interest, such as disease prevalence, allele or Y-haplogroup frequency, while the true occurrence region maybe much larger.

Methods: To overcome these limitations, we developed the SMapper bioinformatic tool to visualize spatial prevalence data including those that are sparse and incomplete. In its spatial visualization at the worldwide level, SMapper clearly separates geographic regions where the feature of interest was observed at some frequency, from those regions not covered by the data, and those where, although covered, the feature was not observed (zero frequency). Moreover, the uncertainty of a zero-frequency observation is visualized by taking the respective sample size into account.

Results: This way, SMapper overcomes interpretational issues known for existing tools that are caused by data limitations. Here, we introduce SMapper and present data and applications in fields such as epidemiology, anthropology and forensic genetics.

Conclusion: For widespread applications, we made SMapper publicly available as a web service as well as a native Linux installation and a singularity container at https://rhodos.ccg.uni-koeln.de/smapper/.

Grants: This work was supported from the European Union's Horizon 2020 Research and Innovation programme under grant agreement No 740580 within the framework of the Visible Attributes through Genomics (VISAGE) Project and Consortium.

(German Center for Cardiovascular Research), Partner Site Hamburg/Kiel/Lübeck, Germany; [10]Department of Congenital Heart Disease and Pediatric Cardiology, University Hospital of Schleswig-Holstein, Kiel, Germany

Background/Objectives: Clinical exome and genome sequencing transformed disease genetics, but many genes lack functional annotation and characterization, hindering interpretation of genetic variants underlying human genetic disorders. However, tissue-specific gene expression information can be used to identify candidate genes for rare congenital diseases.

Methods: Here, we introduce Single cell TIssue-specific Gene prioritization using MAchine Learning (STIGMA), an approach that leverages single-cell RNA-seq (scRNA-seq) data. While existing scoring methods fail to capture expression heterogeneity within tissues, STIGMA prioritizes genes by learning the temporal expression dynamics across cell types during healthy organogenesis. By supervised machine learning, it predicts the probability of pathogenicity for all genes from scRNA-seq expression and intrinsic gene properties.

Results: STIGMA's performance, was evaluated using mouse limb and human fetal heart scRNA-seq datasets. In individuals with congenital limb malformations, STIGMA prioritized 469 variants in 345 genes, with *UBA2* as a notable example. For congenital heart defects, we detected 34 genes harboring nonsynonymous de novo variants in two or more individuals from a set of 7,958 individuals, including *Prdm1*, which is associated with hypoplastic left ventricle and hypoplastic aortic arch.

Conclusion: We demonstrate that STIGMA effectively prioritizes tissue-specific candidate genes from scRNA-seq. The ability to capture the heterogeneity of gene expression across cell populations makes STIGMA a powerful tool for the discovery of disease-associated genes and facilitates the identification of causal variants.

P16.031.B Integrating single-cell with bulk transcriptomics combined with machine learning identifies metabolic pathway epithelial-enriched gene signature predictive of 5-year survival in breast cancer patients

Chengyi Wang[1], Samuel Chong[2], **Caroline Lee**[1;3;4]

[1]Duke-NUS Medical School, Singapore; [2]National University of Singapore, Pediatrics, Singapore, Singapore; [3]National University of Singapore, Biochemistry, Singapore; [4]National Cancer Centre, Singapore, Singapore

Background/Objectives: Breast cancer's (BC) cellular heterogeneity complicates prognosis. Single-cell transcriptomics (SCT) can assess specific cell-types' roles in prognosis, but their clinical implications in BC are not fully understood. This study integrates single-cell with bulk transcriptomics to analyze the clinical relevance of cell-type enriched genes (CEGs) identified from SCT, developing a machine-learning (ML) based prognosis predictive model.

Methods: CEGs, identified from SCT data of 81 BC patients, were defined as those expressed in significantly greater proportions (percentage difference > 0.3) and at higher levels (fold change > 1.5) in specific cell types (e.g., epithelia, immune, stroma). These genes were trained on The Cancer Genome Atlas (TCGA) dataset (701 patients) using about 100 ML algorithms and validated on TCGA test datasets (300 patients) and the METABRIC dataset (over 2000 patients).

Results: Epithelial-enriched CEGs predicted lower 5-year survival in BC. ML models achieved an AUC of 0.75 in TCGA training and 0.71 in METABRIC validation. TCGA testing confirmed the models' robustness (AUC 0.63). Gene analysis showed significant metabolic pathway enrichment in these genes, especially glycolysis and the Pentose Phosphate Pathway.

Conclusion: This study underscores the prognostic value of epithelia-enriched gene signatures in BC. The ML models demonstrated strong predictive capabilities, linking specific metabolic pathways to prognostic outcomes. These findings enhance understanding of BC cellular heterogeneity and support precision treatment strategies. By integrating SCT with advanced ML techniques, our approach refines prognostic stratification and enhances clinical decision-making in BC management.

P16.032.C HerediClassify: Automated variant classification on a hereditary breast and ovarian cancer variant database

Anna-Lena Katzke[1], *Marvin Döbel[2], Jan Hauke[3], Marc Sturm[2], Gunnar Schmidt[1]*

[1]Hannover Medical School, Department of Human Genetics, Hannover, Germany; [2]University Hosptial Tübningen, Institute of Medical Genetics and Applied Genomics, Tübingen, Germany; [3]University Hosptial Cologne, Center for Familial Breast and Ovarian Cancer, Center for Integrated Oncology (CIO), Cologne, Germany

Background/Objectives: The progressively more detailed guidelines for variant interpretation in combination with the increase in samples and the introduction of whole genome sequencing pose a challenge to manual variant classification. Variant interpretation has become a bottleneck in genetic diagnostics.

Especially challenging is the occurrence of variants of uncertain significance (VUS). The German Consortium of Hereditary Breast and Ovarian Cancer alone encounters an estimated 1,600 VUS every year. In order to aid in the classification and reclassification of these variants, we are developing a tool for automated variant classification.

Methods: To develop HerediClassify, we implemented (1) ACMG/AMP guidelines along with the most recent SVI recommendations and (2) gene specific guidelines for ATM, BRCA1, BRCA2, CDH1, PALB2, PTEN and TP53. 20/28 ACMG rules were implemented. Data availability limits application of ACMG rules that rely on functional or segregation data.

Results: We present an open-source variant classification algorithm designed for modularity and extensibility. This does not only allow for easy switching between, for instance, prediction tools but also provides the option to choose between different rule specifications. Additionally, the clear separation between annotation and rule assessment allows for the easy implementation of new rules, rule specifications and classification frameworks.

Conclusion: Whilst HerediClassify is not yet at a stage where all variants can be classified, it already can be used for the prioritization of variants for classification or reclassification

Grants: German Cancer Aid grand no. 70114178

P16.033.D *comorbidPRS*: an R package assessing shared predisposition between correlated traits using polygenic scores

Vincent Pascat[1;2;3], Liudmila Zudina[1;3], Anna Ulrich[1;3], Jared Maina[2], Marika Kaakinen[1;3;4], Igor Pupko[1], Amélie Bonnefond[2;3], Ayse Demirkan[1;4], Zhanna Balkhiyarova[1;3;4], Philippe Froguel[2;3], **Inga Prokopenko**[1;2;4]

[1]University Of Surrey, Department of Clinical and Experimental Medicine, United Kingdom; [2]European Genomic Institute for Diabetes, INSERM UMR1283, CNRS UMR 8199, Lille, France; [3]Imperial College London, Department of Metabolism, Digestion and Reproduction, United Kingdom; [4]University Of Surrey, People-Centred Artificial Intelligence Institute, United Kingdom

Background/Objectives: Polygenic (Risk) Score (PRS) is a useful approach in evaluation of the estimated genetic liability to a given outcome or genetic variability contributing to a quantitative trait level. While PRSs for complex diseases and traits are very popular, there a limited implementation of PRSs to uncover the shared genetic predisposition between phenotypes, i.e. when genetic variants influence more than one phenotype. We developed an *R* package, *comorbidPRS*, enabling a systematic evaluation of shared genetic effects between (cor)related phenotypes through the use of PRSs.

Methods: As input, *comorbidPRS* uses a set of SNPs with their effects on original phenotype (P_o) as P_o-PRS. *comorbidPRS* outputs

a summary of associations between P_o-PRS and target phenotype (P_t) with customisable graphical features. We applied *comorbidPRS* to dissect the shared genetic predisposition between elevated blood pressure (systolic, diastolic, pulse pressure [SBP/DBP/PP = SBP − DBP]) and several cancers (Kidney Cancer, Prostate Cancer, Colorectal Cancer [KidC/PrC/CrC]) using the UK Biobank and GWAS summary statistics.

Results: We confirmed a nominal higher risk of KidC for individuals with genetic predispositions to elevated DBP ($OR_{PRS-DBPtoKidC} = 1.04\,[1.00 - 1.08]$, $P - value_{PRS-DBPtoKidC} = 4.34 \times 10^{-2}$). We report an association between elevated DBP and the genetic risk of PrC ($OR_{PRS-PrCtoDBP} = 1.06\,[1.03 - 1.10]$, $P - value_{PRS-PrCtoDBP} = 9.64 \times 10^{-5}$), as well as associations between CrC PRS and decreased SBP ($OR_{PRS-CrCtoSBP} = 1.06\,[1.03 - 1.10]$, $P - value_{PRS-CrCtoSBP} = 9.64 \times 10^{-5}$), DBP($OR_{PRS-CrCtoDBP} = 1.06\,[1.03 - 1.10]$, $P - value_{PRS-CrCtoDBP} = 9.64 \times 10^{-5}$), and PP ($OR_{PRS-CrCtoPP} = 1.06\,[1.03 - 1.10]$, $P - value_{PRS-CrCtoPP} = 9.64 \times 10^{-5}$).

Conclusion: Using *comorbidPRS*, we highlight mechanistic relationships between regulation blood pressure traits and susceptibility to three comorbid malignancies. *comorbidPRS* provides the evaluation of shared genetic susceptibility between (cor)related phenotypes through PRS.

P16.034.A A new forensic DNA phenotyping tool that improves intermediate eye colour prediction in Brazilians

Thassia Mayra Telles Carratto[1], *Chris Phillips*[2], *Maria Angeles Casares de Cal*[3], *Antonio Gomez Tato*[3], *Ana Freire-Aradas*[2], *Aguinaldo Simões*[4], *Heather Norton*[5], *Esteban Parra*[6], *Denise Syndercombe Court*[7], *Celso Teixeira Mendes-Junior*[8]

[1]*University of São Paulo, Department of Chemistry, Faculty of Philosophy, Sciences and Letters at Ribeirão Preto, Ribeirão Preto, Brazil;* [2]*University of Santiago de Compostela, Forensic Genetics Unit, Institute of Forensic Sciences, Santiago de Compostela, Spain;* [3]*University of Santiago de Compostela, Faculty of Mathematics, Santiago de Compostela, Spain;* [4]*University of São Paulo, Ribeirão Preto Medical School, Ribeirão Preto, Brazil;* [5]*University of Cincinnati, Department of Anthropology, Cincinnati, United States;* [6]*University of Toronto at Mississauga, Department of Anthropology, Mississauga, Canada;* [7]*King's College London, King's Forensics, Department of Analytical, Environmental and Forensic Sciences, Faculty of Life Sciences and Medicine, London, United Kingdom;* [8]*University of São Paulo, Faculty of Philosophy, Sciences and Letters at Ribeirão Preto, Ribeirão Preto, Brazil*

Background/Objectives: In forensic DNA phenotyping, accurately predicting intermediate eye colour remains a challenge. While IrisPlex falls short in this regard, the Snipper system, although capable, exhibits lower accuracy compared to blue and brown eyes. Given the prevalence of intermediate eye colour in Brazil, this project aims to develop a more accurate predictive tool tailored for Brazilians and suitable for forensics.

Methods: DNA extracted from 501 individuals from Ribeirão Preto, Brazil, was subjected to next-generation sequencing and microarray assays. SNP genotypes from 504 genes were obtained, with missing markers imputed. Divergence values were calculated for each marker, and the top 21 were selected for further evaluation. Using the Naive-Bayes algorithm, we incrementally added markers, selecting the model with the best accuracy across three eye colour categories. IrisPlex and Snipper were also employed for comparison.

Results: The optimal model, consisting of 14 markers, achieved a sensitivity of 72.82% for intermediate eye colour, surpassing IrisPlex (0.00%) and Snipper (36.89%). For blue and brown categories, the 14-marker model demonstrated sensitivities of 93.18% and 81.64%, respectively, with an overall accuracy of 80.84%. Notably, only one SNP (rs1129038) from the 14 used had been employed by other tools for eye colour prediction.

Conclusion: The preliminary results indicate the potential for enhancing intermediate eye colour prediction. However, evaluating the model's performance in independent samples is crucial to ensure its forensic applicability.

P16.035.B Performance of deep-learning based approaches to improve polygenic scores

Martin Kelemen[1], *Yu Xu*[1;2], *Michael Inouye*[1;2]

[1]*British Heart Foundation Cardiovascular Epidemiology Unit, University of Cambridge, Department of Public Health and Primary Care, Cambridge, United Kingdom;* [2]*Cambridge Baker Systems Genomics Initiative, University of Cambridge, Department of Public Health and Primary Care, Cambridge, United Kingdom*

Background/Objectives: Polygenic risk scores (PRS) have the potential to become part of genomic healthcare initiatives across the developed world over the coming decade. To maximise their clinical relevance, PRS models will need to incorporate environmental risk factors and also leverage the latest methodological improvements. Neural-network (NN) based deep learning has emerged as the premier method to model complex, non-linear phenomena, which may be used to exploit gene-gene (G*x*G) and gene-environment (G*x*E) interactions to improve the accuracy of phenotype prediction.

Methods: We present a framework for using NNs to infer the amount of non-linearity present in a phenotype, which also controls for the confounding effect of LD. We fit NN models to both simulated and 28 real disease and anthropometric traits in the UK Biobank.

Results: Simulation results confirmed that our framework could adequately control for LD and may be used to infer non-linear effects, when such effects genuinely exist. Using this approach on real data, we found evidence for small amounts of non-linearity due to G*x*G and G*x*E at ~7% and ~4% difference in r^2, respectively. Despite this evidence for non-linear effects, the NN models were outperformed by linear regression models for both genetic-only and gene+environmental input scenarios by ~7% and ~5% difference in r^2, respectively.

Conclusion: Despite NNs being the state-of-the-art method for modelling DNA sequence features, our results indicate that similar success in predicting phenotypic variance should not be expected. Therefore, the usefulness of NNs for genomic medicine through PRS generation may be limited.

P16.038.B Enhancing genomic data sharing with blockchain-enabled dynamic consent in Beacon v2

Leman Binokay[1;2], *Hamit Mervan Çelik*[3], *Gültekin Gürdal*[3;4], *Tolga Ayav*[3;5], *Tugkan Tuglular*[3;5], *Yavuz Oktay*[6;7;8], *Gokhan Karakulah*[1;2;8]

[1]Izmir International Biomedicine and Genome Institute, Molecular Biology and Genetics, Izmir, Türkyie; [2]Izmir International Biomedicine and Genome Center, Bioinformatics Platform, Izmir, Türkyie; [3]Research Ecosystems Araştırma Geliştirme Yazılım Sanayi ve Ticaret A.Ş., Izmir, Türkyie; [4]Izmir Institute of Technology, Library, Izmir, Türkyie; [5]Izmir Institute of Technology, Computer Engineering, Izmir, Türkyie; [6]Dokuz Eylül University School of Medicine, Medical Biology, Izmir, Türkyie; [7]Izmir International Biomedicine and Genome Center, Neurogenomics, Izmir, Türkyie; [8]Solaris Genomics Arge ve Sağlık Teknolojileri A.Ş., Izmir, Türkyie

Background/Objectives: Genomic data sharing faces the significant challenge of aligning individual consent preferences with data accessibility. This study aims to integrate dynamic consent within the Beacon v2 framework, enhanced with blockchain technology, to address these challenges and improve the ethical management of genomic data.

Methods: We developed a federated search and analytics platform, incorporating blockchain technology to secure and streamline consent management processes. The platform follows FAIR (Findable, Accessible, Interoperable, Reusable) data principles, ensuring efficient utilization of genomic and associated clinical data. The integration of blockchain technology with dynamic consent mechanisms was meticulously designed to complement Beacon v2's existing structure.

Results: The implementation of blockchain-enabled dynamic consent in Beacon v2 provided a more secure and transparent framework for genomic data sharing. This approach enhanced participants' ability to manage their consent preferences dynamically, aligning with ethical and legal standards. The initiative, primarily focused on rare diseases, demonstrated increased data utility and participant trust in the data sharing process.

Conclusion: The incorporation of blockchain technology with dynamic consent in Beacon v2 signifies a substantial step forward in genomic data sharing. This approach balances individual privacy and preferences with the need for scientific advancement, potentially serving as a model for future research practices in genomics. The broader implications of this study extend to enhancing data security and ethical management in various areas of genomic research and patient care.

Grants: This study was supported by the TÜBİTAK TEYDEB 1507 Program, under project number 7220189.

Conflict of Interest: None declared

P16.039.C Distinctive genotype-driven approach to panel analysis and reporting

Dina Yagel[1;2], *Rotem Greenberg*[1;2;3], *Michal Naftali*[1], *naama elefant*[1], *Ofer Isakov*[1;2;4], *Shay Ben-Shachar*[1;2;3;4]

[1]Clalit Health Services, Genomic Center, Petach Tikva, Israel; [2]Clalit Health Services, Berkowitz Family Precision Medicine Clinic, Clalit Research Institute, Ramat Gan, Israel; [3]Clalit Health Services, Clalit Research Institute, Ramat Gan, Israel; [4]Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel

Background: Target gene panels (GPs) are used to focus a genetic analysis around the primary phenotype presented by the patient. Accurate extraction of additional phenotypic details from clinical summaries is challenging and time intensive. Therefore, a phenotype-driven analysis may result in exclusion of causative variants.

Consequently, a standardized genotype-driven approach is essential to alleviate the workload for Variant Scientist (VS) and ensure consistent, reliable reporting.

Methods: GPs' genes are divided into "core" or "extended" lists based on the strength of phenotypic association. Variants within these genes are reported solely based on their likelihood of being deleterious (according to ACMG-guidelines), without additional assessment of the observed phenotype. Standardized reporting thresholds are determined by the variant's posterior probability of pathogenicity, which is more stringent for the "extended" set compared to the "core".

Results: A comprehensive Standard Operating Procedure (SOP) was drafted and followed by all VS. The SOP encompasses analysis filter-sets, variant classification rules, and reporting policies. The VS maintain a dedicated emphasis on variant classification and remain undistracted by phenotypic matching, resulting in a reduced turnaround time. Consistency was achieved through the examination of the same case by three VSs.

Conclusion: This approach is designed to ensure consistent and unified reporting of variants, leaving the responsibility for clinical decisions to the treating physicians. Although, this method might sometimes report more variants to physicians, it also ensures that variants are reported consistently and can help with diagnoses that might otherwise be missed by referring physicians.

P16.040.D Identifying regulatory variation in the human brain through single-cell multiomics and whole genome sequencing

Alexandra Pančíková[1;2;3], *Olga Sigalova*[2;3], *Koen Theunis*[2;3], *Gert Hulselmans*[2;3], *Julie De Man*[2;3], *Florian De Rop*[2], *Sara Salama*[4], *Katy Vandereyken*[4], *Shinjini Mukherjee*[4], *Thierry Voet*[4;5], *Jonas Demeulemeester*[1], *Stein Aerts*[2;3]

[1]VIB-KU Leuven Center for Cancer Genomics, Laboratory of Integrative Cancer Biology, Leuven, Belgium; [2]VIB-KU Leuven Center for Brain & Disease Research, Laboratory of Computational Biology, Leuven, Belgium; [3]VIB.AI, Leuven, Belgium; [4]KU Leuven Institute for Single Cell Omics (LISCO), Leuven, Belgium; [5]KU Leuven, Laboratory of Reproductive Genomics, Center for Human Genetics, Leuven, Belgium

Background/Objectives: The genetic causes of sporadic Parkinson's disease remain poorly understood. This is primarily due to the fact that the majority of SNPs identified in genome wide association studies implicate non-coding parts of the genome. Non-coding variation may lead to cell-type specific changes in gene expression that contribute to disease development, but this remains challenging to study.

Methods: To comprehensively identify all types of genetic variation and their impact on gene regulation in the brain, we are generating a large single nuclei multiomic atlas and matched long-read bulk whole-genome sequencing data from 190 donors (both patients and controls). We developed in-house pipelines to analyse these data and obtain comprehensive variant calls, epigenetic states (endogenous DNA methylation and exogenously labelled open-chromatin; Fiber-seq) and personalised diploid genome for each donor. We are now combining these personal genomes with donor-matched multiome data to identify allele-specific signals and reveal regulatory variation.

Results: Our genomes have average coverage of 28X, and we detect 32,991 structural variants 4,504,259 SNPs, and 295,560 and 338,821 small insertions and deletions per genome on average. Our atlas currently consists of over 1.2M RNA and 1.5M ATAC high quality nuclei from substantia nigra and cingulate gyrus. We can

identify expected cell types and assign pooled nuclei to corresponding donors.

Conclusion: Uniquely combining population-scale matched long read genomes and single-cell multiome atlassing is revealing the extent of regulatory variation in human brains and will implicate currently cryptic causal variation underpinning Parkinson's Disease.

P16.041.A Interpreting artificial neural networks for detecting genome-wide association signals for complex diseases

Burak Yelmen[1], *Maris Alver*[1], *Silva Kasela*[1], *Lili Milani*[1]

[1]*University of Tartu, Institute of Genomics, Tartu, Estonia*

Background/Objectives: Investigating the genetic architecture of complex diseases is challenging due to the highly polygenic and interactive landscape of genetic and environmental factors. Although genome-wide association studies have identified thousands of variants for multiple complex phenotypes, conventional statistical approaches can be limited by simplified assumptions such as linearity and lack of epistasis models.

Methods: In this work, we trained artificial neural networks for predicting complex diseases using both simulated and real genotypes from the Estonian Biobank. We assessed the weights and features learned by these models and extracted feature importance scores to identify potential genomic loci associated with the target phenotype. We used simulated data under various scenarios to test the capacity of our approach to detect causal loci.

Results: Simulation results demonstrated that causal loci can be detected with good precision using strict selection criteria but downstream analyses are required for fine-mapping the exact variants due to linkage disequilibrium. By applying our approach to the schizophrenia cohort in Estonian Biobank (1664 cases), we were able to detect multiple novel loci related to this highly polygenic and heritable disorder. We also performed enrichment analyses with detected loci in genic regions, which predominantly identified terms associated with neurological processes.

Conclusion: With further improvements in model optimization and confidence measures, nonparametric artificial neural network models can be utilised for identifying genomic loci associated with complex diseases, serving as initial screening tools for subsequent functional studies.

Grants: This work received funding from the European Union's Horizon 2020 programme under grant agreements No. 847776 (CoMorMent) and 964874 (Realment).

P16.042.B Novel genetic insights into human facial variation: integrating AI-enhanced phenotyping with C-GWAS

Xianjing Liu[1;2], *Ziyi Xiong*[3;4], *Fan Liu*[3], *Eppo Wolvius*[2], *Manfred Kayser*[3], *Gennady Roshchupkin*[1;4]

[1]*Erasmus MC, Department of Radiology and Nuclear Medicine, ROTTERDAM, Netherlands;* [2]*Erasmus MC, Department of Oral & Maxillofacial Surgery, ROTTERDAM, Netherlands;* [3]*Erasmus MC, Department of Genetic Identification, ROTTERDAM, Netherlands;* [4]*Erasmus MC, Department of Epidemiology, ROTTERDAM, Netherlands*

Background/Objectives: Genome-wide association studies (GWAS) are powerful tools for identifying genetic links to phenotypic traits, but they face significant computational hurdles when analyzing complex traits derived from medical imaging. To tackle this challenge, we have developed a sophisticated algorithmic pipeline: First utilizes AI-based techniques to derive phenotypes, in a federated learning (FL) setting, maintaining data privacy, thus eliminating the need to share raw data, particularly 3D facial images; Second, applies combined-GWAS (C-GWAS) to enrich genetic signal due to the similarity between imaging traits.

Methods: The study utilized two cohorts: 3,314 children from the Generation R Study and 3,995 elderlies from the Rotterdam Study. Facial morphology was encoded into a low-dimensional representation using a 3D mesh autoencoder, an advanced AI model, and trained via NVIDIA Flare, a federated learning open-source library, yielding 200 AI-based facial traits. Subsequent analyses included EasyQC, single-trait GWAS, standard meta-analysis, and C-GWAS.

Results: C-GWAS identified 43 genomic loci, including 12 novel ones. Facial heatmaps visualized the AI-based facial traits linked to these loci, such as rs4648379 (*PRDM16*), rs3122635 (*CRB1*), and rs752172 (*PAX3*), affecting nose shape, chin dimples, and nasal bridge structure, respectively. These loci also showed associations with various health conditions, including asthma, insomnia, snoring, dental development, brain morphology, and total ventricular volume.

Conclusion: Our study's findings of known and novel genetic loci linked to facial variation underscore the efficacy of our proposed methodological pipeline in studying image-based complex traits within the GWAS framework. This approach is promising for broader applications in large-scale consortia facilitating advanced research while maintaining data privacy

P16.043.C Modelling genetic effects on gene expression dynamics in B cells

Daniela Zanotti[1;2], *Alessandro Raveane*[1], *Matiss Ozols*[3], *Marc Jan Bonder*[4], *Francesca Ieva*[2;5], *Nicole Soranzo*[1;3;6], *Nicola Pirastu*[1], *Blagoje Soskic*[1]

[1]*Human Technopole, Genomics Research Centre, Milano, Italy;* [2]*Politecnico di Milano, MOX - Laboratory for Modeling and Scientific Computing, Department of Mathematics, Milano, Italy;* [3]*Wellcome Sanger Institute, Human Genetics Department, Hinxton, United Kingdom;* [4]*University of Groningen, University Medical Center Groningen, Department of Genetics, Groningen, Netherlands;* [5]*Human Technopole, Health Data Science Centre, Milano, Italy;* [6]*University of Cambridge, British Heart Foundation Centre of Research Excellence, Cambridge, United Kingdom*

Background/Objectives: During activation and differentiation B cells go through large changes in gene expression. Previous studies have shown that expression quantitative trait loci (eQTLs) can have dynamic effects in B cells undergoing differentiation. Some of these studies cluster cells along pseudotime trajectories and are dependent upon the binning choice, while other cluster-free methods are too computationally intensive to be applied to large-scale settings. We aimed to address both these limitations by modelling gene expression as a continuous function of pseudotime, and investigating allelic effects in differentiating B cells.

Methods: Using B cells from the OneK1K cohort, we estimated pseudotime trajectories and then modelled the gene expression of 8,324 genes along them using splines. Finally, we applied Functional Principal Component Analysis (FPCA) to the generated

curves and their derivatives and used the scores for cis-eQTL analysis.

Results: We detected 2,022 and 236 genes with significant dynamic cis-eQTLs using the FPCA scores of the original curves and the derivatives, respectively. In the first case, many functions showed differences in height between genotypes, while the derivatives capture effective differences in the functions' shape. The identified genes were enriched for specific immune cell signatures such as response to vaccination.

Conclusion: Our approach demonstrated high efficacy in detecting genetic loci which regulate dynamic gene expression in B cells. Moreover, we were able to detect both dynamic and static eQTLs, without relying on prior assumptions such as clustering while retaining low computational costs. This suggests that our method could be efficiently used in large-scale single-cell cohorts.

P16.044.D GestaltGAN: Artificially synthesizing photorealistic portraits of rare genetic disorders that preserve characteristic clinical features

Aron Kirchhoff[1], *Alexander Hustinx*[1], *Behnam Javanmardi*[1], *Tzung-Chien Hsieh*[1], *Fabian Brand*[1], *Peter Krawitz*[1]

[1]*Institute for Genomic Statistics and Bioinformatics, Bonn, Germany*

Background/Objectives: Medical images are often sparsely available due to privacy reasons or limited number of cases, but they are needed for research and teaching. Especially training deep learning models requires large amounts of training images, one example is GestaltMatcher which predicts the most likely syndrome for a given dysmorphic patient portrait.

Methods: Generative AI is increasingly used in many different fields, one example is medicine where it can be used to generate artificial medical images. We applied Generative Adversarial Networks (GAN) to dysmorphic portraits. The StyleGAN network was trained on images from the GMDB. We used ESRGAN to increase the resolution of portraits from the training data with low quality. Then the training data was aligned&cropped to achieve a uniform format. The 20 most frequent syndromes from the GMDB were included in the training of our conditional StyleGAN model. To give the model access to more features of human faces an unaffected class was added to the training data. The unaffected faces from the FFHQ dataset share many features like hair and skin with the dysmorphic faces and facilitate the learning effort of the deep learning model.

Results: We show that the model is capable of producing high-quality dysmorphic portraits that contain the characteristic features of the disorders. At the same time, we show that the persons in the synthesized images look distinct from the patients in the training data.

Conclusion: The images synthesized by our method can be used for publications, data sharing, and training of deep learning models while highly preserving patients' privacy.

P16.045.A Development of a polygenic risk score for metabolic dysfunction-associated steatotic liver disease prediction in UK Biobank

ioanna gavra[1], *Panagiota Giardoglou*[1], *Athina Amanatidou*[1], *Ioanna-Panagiota Kalafati*[1;2], *Maria Kafyra*[1], *Evangelia Mentsiou-Nikolaou*[1], *Despoina Brekou*[1], *panagiotis moulos*[3], **George Dedoussis**[1]

[1]*Harokopio University, Kallithea, Greece;* [2]*University of Thessaly, Department of Nutrition & Dietetics;* [3]*B.S.R.C. Alexander Fleming, Fundamental Biomedical Research (IFBR), Vari, Greece*

Background/Objectives: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the leading cause of liver-related morbidity and mortality. Although, the invasive liver biopsy remains the golden standard for MASLD diagnosis, MRI-derived Proton Density Fat Fraction (MRI-PDFF) is an accurate, non-invasive method for the assessment of treatment response. This study aimed at developing a Polygenic Risk Score (PRS) to improve MRI-PDFF prediction using UK Biobank data to assess an individual's genetic liability to MASLD.

Methods: We iteratively sequestered 10% of MRI-PDFF samples as a validation set and split the rest of each dataset into base and target partitions, containing GWAS summary statistics and raw genotype data, respectively. PRSice2 was deployed to derive PRS candidates. Based on the frequency of SNP appearances along the PRS candidates, we generated different SNP sets according to variable frequency cutoffs. By applying the PRSs to the validation set, we identified the optimal SNP set, which was then applied to a Greek Nonalcoholic fatty liver disease (NAFLD) study.

Results: Data from 3,553 UK Biobank participants yielded 49 different SNP sets. After calculating the PRS on the validation set for every SNP set, an optimal PRS with 75 SNPs was selected (incremental $R^2 = 0.025$, p-value $= 0.00145$). Interestingly, 43 SNPs were successfully mapped to MASLD-related known genes. The selected PRS could predict traits, like LDL cholesterol and diastolic blood pressure in the UK Biobank, as also disease outcome in the Greek NAFLD study.

Conclusion: Our findings provide strong evidence that PRS is a powerful prediction model for MASLD, while it can also be applied on populations of different ethnicity.

P16.046.B PANGEN: an online platform for the comparison and creation of diagnostic gene panels

Ofer Isakov[1;2;3;4], *Dina Yagel*[2], *Rotem Greenberg*[2], *Michal Naftali*[2], *Shay Ben-Shachar*[2;3;4]

[1]*Rabin medical center, Raphael Recanati Genetic Institute, Petah Tikva, Israel;* [2]*Clailt Research Institute, Ramat Gan, Israel;* [3]*Harvard, The Ivan and Francesca Berkowitz Family Living Laboratory Collaboration, United States;* [4]*Tel Aviv University, Faculty of medicine, Tel Aviv, Israel*

Background/Objectives: Targeted gene panel sequencing is used to limit the search for causative genetic variants solely to genes with established phenotypic association. Gene panel design is challenging due to the lack of consensus regarding phenotypic associations for some genes, which increases variation in gene composition for the same panel offered by different laboratories. We developed PANGEN, a platform that provides a centralized resource for gene panel information, with the ability to compare and generate new intelligent diagnostic panels.

Methods: Gene-phenotype associations were collected from 12 public and commercial sources (Blueprint, Cegat, Centogene, ClinGen, Fulgent, GeneDx, Health in Code, Human Phenotype Ontology (HPO), Invitae, PanelApp, Prevention genetics and Pronto diagnostics). Associations were stratified by levels of confidence. Pairwise similarity was calculated for every panel combination. Difficult to map regions in the panel were collected

from the Genome in a bottle (GIAB) stratifications dataset and the UCSC database.

Results: Overall, 1,533 panels, 9,759 phenotypes and 6,979 genes were collected. The platform provides an interface to (i) explore and compare collected panels, (ii) find similar panels, (iii) identify genes with high GC content or duplication levels, (iv) generate gene panels by combining various sources and (v) stratify a generated panel into genes with a strong phenotype association ("core") and those with a weaker association ("extended").

Conclusion: The presented platform represents a unique resource for gene panel exploration and comparison that facilitates the generation of tailored diagnostic panels through a public online web server (https://clalit-gc.shinyapps.io/gene_panel_generator_app/)

P16.047.C Gen-toolbox prompts potential oligogenic patterns in a clinical neuromuscular disease cohort

Villem Pata[1;2], *Markus Marandi*[3], *Katrin Ounap*[1;4], *Sander Pajusalu*[1;4]

[1]*University of Tartu, Department of Clinical Genetics, Institute of Clinical Medicine, Tartu, Estonia;* [2]*Tartu University Hospital, Anesthesiology and Intensive Care Clinic, Tartu, Estonia;* [3]*University of Tartu, Institute of Computer Science, Tartu, Estonia;* [4]*Tartu University Hospital, Genetics and Personalized Medicine Clinic, Tartu, Estonia*

Background/Objectives: We propose a framework to investigate oligogenic patterns in clinical sequencing cohorts, aiming to explore whether some phenotypes in undiagnosed cohorts result from the combined effect of multiple variants across biologically relevant genes.

Methods: Gen-toolbox, a novel Hail-based toolkit, categorizes high-quality filtered variants by Ensembl VEP-predicted variant impact and allele frequency, assessing variant burden in subgroups. Summary variant statistics are calculated in each subgroup (N = 12) for corresponding genes. Monte-Carlo simulations compare sums of variant burdens of gene sets (N = 5) between phenotype positive and negative cohorts with an arbitrarily large number of random (N = 6e6) combinations. This large number of simulations causes most ratios to approach 1 after data normalization. We hypothesize non-Gaussian distribution and gene grouping above the 99th percentile to correlate to potential oligogenic patterns. Highlighted genes are further studied with gene ontology enrichment analysis using g:Profiler. Gen-toolbox works with different generation (g)VCF files, including Dragen NovaSeq X Plus output.

Results: Analyzing 4462 samples sequenced in Tartu University Hospital between 2015-2022 sent for various conditions (285 with neuromuscular disorders, 4177 otherwise afflicted), non-Gaussian distribution was noted in the modifier, AF < 0.05 subgroups. In other subgroups with normal distribution, high-burden gene enrichment analysis included the terms "signal receptor binding", "collagen-containing extracellular matrix", "tissue development" with 2.5e-14 < p-value <5e-6.

Conclusion: Gen-toolbox may detect potential oligogenic patterns for neuromuscular disorders in clinical cohorts. Further ontological and expression analyses are warranted to validate associations.

Grants: Estonian Research Council grants PSG774, PRG471 and PRG2040.

P16.048.D In silico design of a recombinant multi-epitope vaccine against non-small cell lung cancer (NSCLC) via advanced immunoinformatics and reverse vaccinology approaches

Ali Alishavandi[1], *Tara Shekari*[2], *Mohammad Hossein Yazdi*[3]

[1]*Student Research Committee, Iranshahr University of Medical Sciences, Iranshahr, Iran;* [2]*Faculty of Pharmacy, Tehran University of Medical Sciences, Tehran, Iran, Department of Pharmacutics, Tehran, Iran;* [3]*Biotechnology Research Center, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran*

Background/Objectives: Non-small cell lung cancer (NSCLC) is the most common form of lung cancer. Nowadays, cancer vaccines offer promising prospects in treatment of malignancies. This study aims to develop a chimeric vaccine against NSCLC via immunoinformatics and reverse vaccinology methods.

Methods: Mutated amino acid sequences of KRAS, EGFR, and MUC1 were retrieved from the UniProt database. Epitope prediction for binding to the MHCI/II, B cells, and T cells was cunducted by IEDB and CTLpred servers. The semi-final vaccine construct was assembled, and its antigenicity, immunogenicity, allergenicity, and physicochemical properties were examined by respective tools.Thereafter, the secondary and tertiary structures of the vaccine were visualized by PSIPRED and RaptorX web servers, respectively. Docking of the vaccine/TLR-4 complex was performed using ClusPro2.0, followed by molecular dynamic (MD) simulation through normal mood analysis (NMA) using iMODS server.

Results: After multiple screenings, 18 T cell and 7 continuos/discontinuos B cell epitopes were identified. The final cunstruct consisted of 477 residues, and the docked vaccine/TLR-4 showed robust interactions. Also, Ramachandran plot demonstrated that over 96% of the residues were located in the favorable and permitted regions. MD simulation and physycochemical assessments, including B-factor, covariance matrix reported promising results with a neutral PH. C-ImmSim server immune simulation confirmed secreation of IFN-γ, IL-12, and IgG with a tendency toward Th1. Finally, IEDB estimated the vaccine's population coverage over 90% worldwide.

Conclusion: Our proposed chimeric vaccine showed favorable physicochemical properties and produced robust immune responses as well. Future research should assess the efficacy of this vaccine in animal experiments.

Grants: Recombinant vaccines research center

P16.049.A Computing constraint metrics in gnomAD v4

Kristen M. Laricchia[1;2], *Julia Goodrich*[1;2], *Michael Wilson*[1;2], *Avery Wang*[1], *Katherine Chao*[1;2], *Grace Tiao*[1;2], *F. Kyle Satterstrom*[1;2], *Mark Daly*[1;2;3], *Heidi Rehm*[1;2], *Kaitlin Samocha*[1;2], *Konrad Karczewski*[1;2]

[1]*Broad Institute of MIT and Harvard, Cambridge, United States;* [2]*Massachusetts General Hospital, Boston, United States;* [3]*Institute for Molecular Medicine Finland, Helsinki, Finland*

Consortium: gnomAD Consortium

Background/Objectives: The Genome Aggregation Database (gnomAD) provides many metrics that aid with variant classification, including gene constraint, which measures how tolerant a gene is to different classes of variation. Less tolerant genes are often implicated in rare disease, so constraint metrics can help clinicians with gene and variant prioritization. Here, we utilized the increased scale and diversity of gnomAD v4 to recompute constraint metrics previously calculated on gnomAD v2.

Methods: We restructured the v2 constraint pipeline and rebuilt the mutational models utilizing over 800,000 individuals (76,215 genomes and 730,947 exomes) in v4. We calculated updated counts of observed and expected synonymous, missense, and predicted loss-of-function (pLoF) variants, and used these counts to refine the LOEUF (loss-of-function observed/expected upper bound fraction) scores.

Results: We generated constraint metrics using gnomAD v4 for 16,862 MANE Select transcripts, of which ~86% are well powered for detecting constraint against pLoF variants (expected pLoF ≥ 10). The larger sample size in v4 increased the AUC for distinguishing haploinsufficient genes from 0.87 in v2 to 0.89, continuing to outperform RVIS, and an analysis comparing 31,058 development disorder cases to 5,492 controls revealed a stronger enrichment of de novo pLoFs in cases in the most constrained LOEUF deciles in v4 than in v2.

Conclusion: The addition of updated constraint metrics in gnomAD v4 provides a resource that can aid in gene and variant analyses and help identify novel gene candidates for rare disease, as well as inform variant pathogenicity.

P16.051.C GenoMed4All,a federated learning platform for clinical and omics data

Davide Piscia[1;2], Patricia A. Apellániz[3], Borja Arroyo[4], Santiago Barrio[4], Francisco Moreno[4], Juan Parras[3], Silvia Uribe[5], Federico Alvarez[4], **Sergi Beltran**[1;2;6]

[1]Centro Nacional de Análisis Genómico - CNAG, Barcelona, Spain; [2]Universitat de Barcelona, Barcelona, Spain; [3]Information Processing and Telecommunications Center, Universidad Politécnica de Madrid, Madrid, Spain; [4]GATV, Escuela Técnica Superior de Ingenieros de Telecomunicación, Universidad Politécnica de Madrid, Madrid, Spain; [5]Escuela Técnica Superior de Ingeniería de Sistemas Informáticos, Universidad Politécnica de Madrid, Madrid, Spain; [6]Facultat de Biologia - Universitat de Barcelona, Departament de Genètica, Microbiologia I Estadística, Barcelona, Spain

Consortium: GenoMed4All consortium

Background/Objectives: Machine learning (ML) models have the potential to assist healthcare professionals in tasks such as diagnostics and predictive analysis. However clinical and genomics data are often siloed and difficult to access due to legal, ethical and technical reasons.

The emerging paradigm of data federation enables the use of data at different levels across resources. To take advantage of federated datasets it is necessary to develop adequate federated infrastructures enabling the training of ML models and conducting federated analyses.

Methods: Within the EU funded project Genomed4All we developed a platform enabling its users to run ML training on federated data. The platform is built on open source technologies such as Mlflow, Keycloak and Flower. The platform was developed to support Haematological diseases (Myelodysplastic syndromes, Multiple Myeloma and Sickle Cell), but can be adapted for other diseases.

The platform is composed of a central node and of a worker node module which has to be deployed in the different hospitals. The data includes clinical and omics data (genomics, transcriptomics and radiomics data) and FHIR is used as data model schema.

Results: Preliminary results with synthetic data show that the platform is able to support federated learning on distributed clinical and genomics datasets. In the next phase of the project several hospitals will connect to the central node.

Conclusion: The platform developed through Genomed4All paves the way to use federated learning as a solution to exploit data in settings where data is siloed and data privacy is of paramount importance.

P16.052.D Accelerating variant interpretation with the Ensembl Variant Effect Predictor

Sarah Hunt[1], Ola Austine Orimoloye[1], S. Nakib Hossain[1], Diana Lemos[1], Nuno Saraiva-Agostinho[1], Likhitha Surapaneni[1], **Jamie Allen**[1]*, Andrew Yates[1]*

[1]European Molecular Biology Laboratory, European Bioinformatics Institute, Wellcome Genome Campus, Hinxton, Cambridge, United Kingdom

Background/Objectives: Genome sequencing to identify likely disease-associated variants is common in clinical research and diagnostic settings. Robust tools are needed to annotate the large number of variants found and identify a priority subset for further investigation. The Ensembl Variant Effect Predictor (VEP) is a powerful toolset for variant annotation and prioritisation.

Methods: Ensembl VEP's core algorithms predict variant molecular consequence and it integrates a wide range of tools and reference data, including ClinVar pathogenicity assertions and gnomAD population frequencies. We have recently extended the available functionality by the integration of new data and analysis methods.

Results: MaveDB scores, which report the cellular phenotypes observed via multiplexed assays of variant effect, are now available through Ensembl VEP. Ribosome profiling has revealed thousands of open reading frames within long non-coding RNAs and the UTRs of protein coding genes, some of which may be functional and of clinical importance. Ensembl VEP can now predict when variants impact such ORFs. Predictions of variant deleteriousness have recently been integrated from tools including: AlphaMissense and VARITY for missense variant tolerance, Enformer for impact on gene expression and SpliceVault for impact on splicing. Other improvements to reporting include flagging de novo genotypes when trios are analysed.

Conclusion: Ensembl VEP provides an extensive range of analysis options, choice of interfaces and a flexible filtering tool which together enable detailed annotation and accelerate variant interpretation.

Grants: Majority funding from Wellcome Trust [WT222155/Z/20/Z, WT226083/Z/22/Z], additional funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No825575 (EJP RD) and EMBL.

P16.053.A Genomic and metabolomic biomarkers for episodic memory

Anni Malmberg[1], *Matti Pirinen*[2;3;4], *Johannes Kettunen*[5], *Katri Räikkönen*[6], *Johan Eriksson*[7;8;9], *jari lahti*[6]

[1]*University of Helsinki, Department of Psychology and Logopedics, Finland;* [2]*University of Helsinki, Department of Mathematics and Statistics, Helsinki, Finland;* [3]*Institute for Molecular Medicine Finland, Helsinki Institute of Life Science, University of Helsinki, Helsinki, Finland;* [4]*University of Helsinki, Department of Public Health, Helsinki, Finland;* [5]*University of Oulu, Oulu, Finland;* [6]*University of Helsinki, Department of Psychology and Logopedics, Helsinki, Finland;* [7]*University of Helsinki, Helsinki, Finland;* [8]*Folkhälsan Research Center, Helsinki, Finland;* [9]*National University of Singapore, Singapore, Singapore*

Background/Objectives: Episodic memory (EM) is an endophenotype for dementia. We studied to what extent metabolomic and genomic biomarkers predict EM over and above traditional epidemiological markers in late adulthood and if the same markers predict EM in children.

Methods: With LASSO we selected 39 SNPs from 13M genomic variants and 14 metabolites from 137 NMR-derived metabolites associated with EM in the Helsinki Birth Cohort Study (HBCS) comprising ~61-year-old Finns (N = 711). We constructed a Cardiovascular Risk Factors, Aging, and Dementia (CAIDE) score from traditional risk factors for dementia: age, sex, education, systolic blood pressure, total cholesterol, BMI and physical inactivity. Finally, we used linear regression to test if CAIDE-score and biomarkers associated with EM in an independent HBCS-derived test sample (N = 101) and if the genome score predicted EM in the Glaku sample of 354 ~12-year-old children.

Results: In the HBCS test sample, the CAIDE-score, genome and metabolome scores explained 0.002% (p-value = 0.27), 4.6% (p-value = 0.017), and 0.012% (p-value = 0.14) of the variance in EM, respectively. After accounting for the CAIDE-score, the genome and metabolome scores explained 4.3% (p-value = 0.04), and 1.2% (p-value = 0.23) of the variance, respectively. The three scores together explained 5.4% (p-value = 0.039) of the variance. In the Glaku sample, the genome score showed no association with EM (p-value = 0.91).

Conclusion: Model predictability improved when accounting for genome score in addition to the CAIDE-score. However, the CAIDE-score and metabolome scores performed poorly in the independent HBCS test sample, and results for the genome score were not generalizable to children.

P16.055.C Identification of cell type specific transcript isoforms by integration of bulk short-read, long-read and single cell RNA-seq

Ryo Yamamoto[1], *Noah Zaitlen*[1], *Xinshu Xiao*[1]

[1]*University of California, Los Angeles, Los Angeles, United States*

Background/Objectives: Alternative splicing profoundly influences the functional diversity of cell types, impacting up to 95% of multi-exon genes in humans. While bulk RNA-seq has advanced our understanding in diverse functions of transcript isoforms, it is imperative to scrutinize isoform abundances at a finer granularity than bulk tissues. However, accurately estimating isoform expression at a cell level remains challenging due to sparsity and 3′ bias inherent in single cell RNA-seq data. Moreover, few attempts have been made to study cell type specific isoforms at a population level.

Methods: We introduce Besciege, a Bayesian inference method that integrates scRNA-seq with bulk long-read and short-read RNA-seq to estimate isoform abundance across different cell types. Given single-cell and bulk RNA-seq in the same tissue, we first estimate sample level cell fractions and isoform abundance which are then used to estimate the population mean of isoform abundance for each cell type using non-negative least squares. Finally, we employ the hierarchical Bayesian model to estimate sample level cell type isoform abundance, which accounts for co-variability between isoforms within the same gene.

Results: Rigorous simulations demonstrate that Besciege performs accurate estimation of isoform abundance at a population level (mean Pearson's correlation = 0.92). Applied to the GTEx dataset, Besciege identifies more than 5,000 genes that exhibit isoform switching across cell types in 7 tissues, providing evidence for prevalent differential isoform usage at a cellular level.

Conclusion: Besciege is a powerful tool to quantify isoform abundance in cell types, enabling studies to characterize diverse functions of cell type specific isoforms.

P16.056.D Privacy-preserving evaluation of polygenic risk scores using fully homomorphic encryption

Jiaqi Li[1], *Elizabeth Knight*[1], *Matthew Jensen*[1], *israel Yolou*[1], *Mark Gerstein*[1]

[1]*Yale University, New Haven, United States*

Background/Objectives: Polygenic risk scores (PRS), which are statistical models that utilize genetic variants to predict an individual's risk of having a particular trait or condition, can be valuable in various clinical applications. However, their calculation involves both patients' genomic data and PRS models, posing privacy concerns. Here we apply fully homomorphic encryption (FHE) to PRS calculation. FHE permits PRS calculations directly on both encrypted genomes and models, and allows only the genomic data owner with the secret key to decrypt the results.

Methods: We apply the CKKS FHE scheme implemented within the Lattigo library to perform encrypted PRS calculations. We demonstrate the effectiveness of our method using both models derived from synthetic datasets and a real PRS model for schizophrenia risk.

Results: The application of our FHE-based protocol to a 110k-SNP PRS model for schizophrenia demonstrates high accuracy and negligible statistical difference from non-encrypted methods. We demonstrate that a decrease in mean square error between results from our encrypted method and the optimal LDPred2 model correlates with an increased polynomial modulus degree, showing how enhanced encryption parameters reduce computational error. Running our program with 1000 genotypes on the 110k-SNP model can take less than 5 minutes on a personal laptop, underscoring the scalability and efficiency of our method.

Conclusion: Our work successfully applies FHE to PRS calculation without compromising data security, accuracy, or computational integrity, showcasing a promising tool for clinical genomic settings where data privacy is paramount.

P16.057.A Assess individual risk scores for rare variants in stratifying epilepsy cases

Maryam Erfanian Omidvar[1;2], *Emadeldin Hassanin*[2;3], *Dheeraj Bobbili*[2], *Holger Lerche*[1], *Patrick May*[2]

[1]*Department of Neurology and Epileptology, Hertie Institute for Clinical Brain Research, University of Tübingen, Tübingen, Germany;*

[2]LCSB - Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Esch-sur-Alzette, Luxembourg; [3]Institute for Genomic Statistics and Bioinformatics, University of Bonn, Bonn, Germany

Consortium: Epi25 Collaborative

Background/Objectives: The study investigates the potential of using individual rare genetic variant profiles to improve the classification and stratification of patients with epilepsy. Previous research has shown that rare genetic variants in specific genes are associated with different types of epilepsy, and this study aims to explore the cumulative contribution of these variants to create an individual risk score (IRS) that can better identify and stratify patients with epilepsy.

Methods: The study analyzed whole-exome sequencing data from 7,589 individuals with epilepsy (from the Epi25 dataset) and 3,962 ancestry-matched controls. We employed different allele frequency cutoffs and functional genomic annotations to evaluate the impact of the IRS on epilepsy stratification within genes associated with specific phenotypes.

Results: The findings revealed that all functional variants combined with AF ≤ 0.00001 exhibit the highest efficacy in distinguishing individuals with genetic generalized epilepsy (GGE) (OR: 1.4, $P = 5.73 \times 10^{-14}$) and developmental and epileptic encephalopathies (DEE) (OR: 1.3, $P = 5.91 \times 10^{-5}$) from controls. While for non-acquired focal epilepsy (NAFE), missense and splicing variants with AF ≤ 0.00001 showed strong discriminatory power (OR:1.4, $P = 2.86 \times 10^{-14}$), suggesting the insignificant role of LoF variants in improving the power to distinguish patients in this subphenotypes. Loss of function-based score could only distinguish DEEs (OR: 1.2, $P = 4.74 \times 10^{-2}$).

Conclusion: Overall, the study suggests that rare variant-individual risk scores could be a useful tool for improving the classification and stratification of patients with epilepsy.

P16.058.B ExHap: visualising shared homozygosity haplotypes in distant individuals from exome variants

Shahryar Alavi[1;2], *Reza Maroofian*[2]

[1]Palindrome, Isfahan, Iran; [2]UCL Queen Square Institute of Neurology, Department of Neuromuscular Diseases, London, United Kingdom

Objectives: Understanding the prevalence and distribution of homozygous pathogenic variants in recessive disease-causing genes is essential. We aimed to develop a tool, ExHap, to identify the founder/recurrent status of shared homozygous variants in patients' exome data, shedding light on the extent of variant spread within populations.

Methods: Genomic VCF files (GVCFs) were utilized to jointly call exome variants in patients and controls. ExHap, developed using R, organised individuals' homozygosity haplotypes based on the length of runs of homozygosity (ROH) surrounding the variant. A colour plot visualised WT/heterozygous/homozygous variant positions, facilitating the inspection of flanking haplotypes.

Results: ExHap successfully generated homozygosity haplotype maps for shared pathogenic variants in DPM3, TOR1A, MED27, HPCA, WBP4, and TMEM67. Measuring shared ROH lengths between distantly related patients allowed us to calculate the most recent common ancestor (MRCA) age. Notably, a rare pathogenic MED27 variant in two unrelated Pakistani families was identified as an ancient founder mutation.

Conclusion: Analysing homozygosity haplotypes of pathogenic variants in recessive disorders enhances our understanding of their distribution in populations. Calculating MRCA age enables the anticipation of founder variant frequency, improving genetic counselling. This approach has the potential to minimise the risk of genetic disorders in offspring from distantly related couples. For recurrent variants, assessing the burden of mutational hotspots proves informative in understanding variant dynamics.

P16.059.C Guideline for assessing phenotypic evidence (PM7) by computational facial analysis in ACMG/AMP variant classification framework for variant of unknown significance

Tzung-Chien Hsieh[1], *Hannah Klinkhammer*[1], *Simona Capponi*[2;3], *Elaine Marchi*[4], *Gholson Lyon*[4], *Peter Krawitz*[1]

[1]Institute for Genomic Statistics and Bioinformatics, University Hospital Bonn, Bonn; [2]German Cancer Consortium (DKTK), partner site Freiburg, German Cancer Research Center (DKFZ), Germany; [3]Department of Urology, Medical Faculty-University of Freiburg, Germany; [4]Department of Human Genetics, NYS Institute for Basic Research in Developmental Disabilities, United States

Background/Objectives: Streamlining the classification for variants of unknown significance (VUS) is vital for patients with undiagnosed conditions. While next-generation phenotyping techniques like GestaltMatcher have significantly contributed to diagnosing rare disorders, the lack of computational facial analysis support in current ACMG/AMP guidelines has prompted this study to propose its inclusion. This study introduced new criteria, PM7 for the moderate level of pathogenicity, alongside existing PP4, integrating GestaltMatcher within a Bayesian framework and aims to aid the reclassification of VUS.

Methods: In the Bayesian framework of ACMG/AMP guidelines, we used GestaltMatcher scores to evaluate phenotypic match strength across syndromes, calculating associated likelihood ratios (LR). GestaltMatcher was trained on 8,547 images representing 244 disorders. We validated it on 1,499 images of 321 syndromes not in the training set. For each image, gestalt scores were computed across all disorders. Five-fold cross-validation was performed to establish thresholds aligning with Bayesian framework. Ultimately, we tested the thresholds on 32 patients with mutations in *TAF1*.

Results: We determined thresholds of 0.56 and 0.47, resulting in LR of 18.6 and 4.29, respectively. These values correspond to PM7 for moderate evidence and PP4 for supporting evidence when the gestalt score for a disorder exceeds these thresholds. When testing *TAF1* patients, nine satisfied PM7 and 16 fulfilled PP4 criteria, and calculating LR against randomly selected patients yielded 18.2 and 4.28, aligning with ACMG/AMP Bayesian framework. Additionally, facial analysis reclassified three out of eight VUS patients as likely pathogenic.

Conclusion: We demonstrated that incorporating GestaltMatcher into PP4 and PM7 criteria in ACMG/AMP guidelines enhances VUS classification.

P16.060.D A robust liability scale coefficient of determination

Emil Pedersen[1], *Jette Steinbach*[1], *andrew schork*[2], *Morten Krebs*[2], *Esben Agerbo*[1], *Florian Privé*[1], *Bjarni Jóhann Vilhjálmsson*[1;3;4]

[1], national centre for register-based research, Aarhus, Denmark; [2]institute of Biological Psychiatry, Mental Health services, Sct. Hans, Roskilde, Denmark; [3]Bioinformatics Research centre, Aarhus university, Aarhus, Denmark; [4]Broad Institite of MIT and Harvard, Novo

Nordisk foundation Center for Genomics, Mechanisms of Diseases, Cambridge, United States

Background/Objectives: The liability-scale coefficient of determination (R-squared) is a popular measure for assessing the accuracy of prediction models, allowing for comparison between studies. Lee et al. (Gen Epi, 2012) provided the standard transformation of the observed-scale R-squared to liability-scale that accounts for case ascertainment. However, Krebs et al. (medRxiv, 2023) recently showed that the standard transformation is unsuitable for some types of sample ascertainment and predictors.

Methods: We compare the standard liability-scale transformation to a R-squared based on a weighted probit regression. Using simulation, we compare R-squared measures to the true liability-scale R-squared. Finally, we will assess the differences between R-squared measures in the UK biobank and iPSYCH cohort. We compare three predictors; polygenic scores (PGS), binary family history indicator, and LT-FH + +.

Results: Preliminary simulations have been performed. Without ascertainment, we find the standard transformation is biased for family-based measures and unbiased for PGS. The weighted probit model is within 5% of the true R-squared for all predictors. With ascertainment, the standard transformation underestimates the true R-squared by 20%, while the weighted probit R-squared underestimates the true R-squared by 9 % on average across all predictors.

Conclusion: Traditional liability-scale transformations of the coefficient of determination are significantly impacted by case ascertainment and deviations in distribution assumptions. The weighted probit regression is less biased. Hence, existing evaluations of prediction models may be biased and comparisons may be unreliable.

P16.061.A Validation of Twist CNV backbone panels at different probe densities for large pathological CNV detection

Ivan Limongelli[1], *Valentina Andrioletti*[1], *Tina Han*[2], *Ettore Rizzo*[1], *Alonzo Lee*[2], *Alessandro Davassi*[2], *Tanya Tannous*[2], *Susanna Zucca*[1]

[1]*enGenome srl, Pavia, Italy;* [2]*Twist Bioscience, South San Francisco, United States*

Background/Objectives: Accurate identification and annotation of pathogenic copy number variants (CNVs) is essential for providing proper diagnosis and treatment. Although array-based tests have been the gold-standard for detecting large CNV events, with the widespread use of NGS, a streamlined workflow with whole exome sequencing is becoming more appealing for many laboratories. Here we present a validation of an optimized method to detect large CNVs with ad-hoc designed Twist panels.

Methods: Twist CNV backbone panel was mixed with Twist Exome 2.0 plus Comprehensive Exome Spike-in and tested on 43 Coriell samples that had CNV previously confirmed by array. Three different probe densities were tested: 25kb, 50kb and 100kb. The 43 test and 12 additional reference samples were sequenced on Illumina NovaSeq 6000 and CNVs were called using the enGenome-eVai-Secondary Workflow, employing a read-depth approach to identify events. To benchmark our NGS results, a positive set of 52 CNVs was selected and the performance of each probe design was evaluated.

Results: All the samples except one had a great correlation with the baseline (>0.97). On average 345 filtered CNV variants could be identified per sample, with the 25kb design having the highest number of variants called (358). For all three designs, the sensitivity was 98.08%, with only one variant missed. We also determined a false positive rate (FPR) of <1% in all three designs.

Conclusion: Altogether these results support the use of these CNV backbone panels with exome to identify large CNVs with a sensitivity comparable to array based methods, without compromising SNV/INDEL calling.

P16.062.B Exploring the miRNA-Mediated Regulation of ERO1L as a Potential Prognostic Biomarker in Cervical Cancer

Havva Ozgen Eyupoglu[1;2], *erol eyupoglu*[2], *Şükrü Tüzmen*[1;3]

[1]*Eastern Mediterranean University, Faculty of Dentistry, via Mersin 10, Türkyie;* [2]*Marmara University, Medical Biology and Genetics, Istanbul, Türkyie;* [3]*GenBiomics R&D, Techno Park, Eastern Mediterranean University, via Mersin 10, Türkyie*

Background/Objectives: Cervical cancer is one of the most common malignancies among women. While screening programs are available, molecular biomarkers for disease prognosis are needed. Endoplasmic Reticulum Oxidoreductase 1 Alpha (ERO1L/ERO1A) has recently been studied as a potential biomarker in distinct malignancies. However, detailed molecular/cellular analyses for cervical carcinoma remain to be elucidated. To illustrate ERO1L's prognostic potential in cervical cancer, comprehensive in silico analyses have been performed.

Methods: The mRNA expression profile of cervical cancer patients and control samples from the TCGA databank was examined using the GEPIA2 platform. Gene alteration profiles were assessed by cBioPortal.Protein expression was determined by the Human Protein Atlas. Survival graphs were depicted by GEPIA2 and Kaplan-Meier(KM) Plotter. miRNA analyses were performed by the Cancer MIRNome platform.

Results: Gene expression analyses revealed that ERO1L was significantly upregulated in TCGA cervical carcinoma patients.These patients also had ERO1A gene amplification compared to healthy donors. High expression at the mRNA level was also consistent with the protein expression data both from patients and cervical cell lines. Notably, higher expression of ERO1L was correlated with worse survival in cervical cancer patients. Target analyses showed that ERO1L is a potential target of miR-218-5p.As expected, miR-218-5p was downregulated in cervical carcinoma patients and diminished miR-218-5p expression is correlated with worse survival.

Conclusion: To our knowledge, this study is the first to reveal the regulation of ERO1L, an important gene in cervical cancer prognosis, through miR-218-5p.We further aim to examine ERO1L;the work is in progress involving population-based mutation screening from patient biopsies.

P16.063.C The German Human Genome-Phenome Archive (GHGA) – Enabling secondary use of omics data in Germany by building a national secure infrastructure

Anna Benet-Pages[1;2], *Christian Mertes*[3], *Jan Eufinger*[4], *Ulrike Traeger*[4], *Julien Gagneur*[5], *Juliane Winkelmann*[6;7;8;9]

[1]*Helmholtz Research Center Munich, Institute of Neurogenomics, Neuherberg, Germany;* [2]*Medical Genetics Center Munich, Bioinformatics, Munich, Germany;* [3]*Technical University of Munich, Department of Informatics, Garching, Germany;* [4]*German Cancer Research Center (DKFZ), Computational Genomics and Systems Genetics, Heidelberg, Germany;* [5]*Technical University of Munich, Computational Genomics and Systems Genetics, Garching, Germany;* [6]*Helmholtz Research Center Munich, Institute of Neurogenomics, Neuherbergg, Germany;* [7]*Technical University of Munich, Institute of Human Genetics, München, Germany;* [8]*Munich Cluster for Systems Neurology, Munich, Germany;* [9]*Deutsches Zentrum für Psychische Gesundheit, Munich, Germany*

Consortium: The GHGA Consortium

Background/Objectives: The German Human Genome-Phenome Archive (GHGA) is building a secure national omics data infrastructure, as part of the National Research Data Infrastructure (NFDI) Initiative and as member of the federated European Genome-Phenome Archive (FEGA). This secure infrastructure will allow German institutions to share genetic data under controlled access, enabling GHGA's main goal: the facilitation of secondary use of human omics data for research purposes.

Methods: We are currently testing the core business logic and functionalities of the first public version of the GHGA Archive which include submission of research and metadata, handling of data access requests, and granting requesters access to data. The already publicly available GHGA Metadata Catalog collects and displays archived human omics data sets since 2022. It allows the search for non-personal information as defined in the GHGA Metadata Model using established ontologies and vocabularies describing the submitted data sets.

Results: We showcase GHGA's approach in development, deployment, and operation of a sustainable and secure infrastructure for data access embedded in an ethico-legal framework to handle omics data in a data-protection-compliant manner (open and FAIR).

Conclusion: GHGA is going to host a standardized and harmonized collection of human omics data in Germany with an ethico-legal framework for data sharing that helps to overcome challenges around consent and GDPR-compliance. Further integration into international collaborative efforts are ensured through interoperability with the German "Modellvorhaben" and with the participating countries of the European Genomic Data Infrastructure (GDI) project.

P16.064.D Variant effect predictors: a systematic review and practical guide

Cristian Riccio[1;2], *Max L. Jansen*[1;2], *Linlin Guo*[3;4], *Andreas Ziegler*[1;2;3;4;5]

[1]*Cardio-CARE, Medicine Campus Davos, Davos, Switzerland;* [2]*Swiss Institute of Bioinformatics, Lausanne, Switzerland;* [3]*University Center of Cardiovascular Science & Department of Cardiology, University Heart and Vascular Center Hamburg, University Medical Center Hamburg-Eppendorf, Hamburg, Germany;* [4]*Center for Population Health Innovation (POINT), University Heart and Vascular Center Hamburg, University Medical Center Hamburg-Eppendorf, Hamburg, Germany;* [5]*School of Mathematics, Statistics and Computer Science, University of KwaZulu-Natal, Pietermaritzburg, South Africa*

Background/Objectives: Large-scale association analyses using whole-genome sequence data have become feasible, but understanding the functional impacts of these associations remains challenging. Although many tools are available to predict the functional impacts of genetic variants, it is unclear which tool should be used in practice. This work provides a practical guide to assist in selecting appropriate tools for variant annotation.

Methods: We conducted a MEDLINE search up to November 10, 2023, and included tools applicable to a broad range of phenotypes that can be used locally and have been recently updated. Tools were categorized based on the types of variants they accept and the functional impacts they predict. Sequence Ontology terms were used for standardization.

Results: We identified 118 databases and software packages, encompassing 36 variant types and 161 functional impacts. Combining only three tools, namely SnpEff, FAVOR, and SparkINFERNO, allows for the prediction of 99 (61%) distinct functional impacts. Thirty-seven tools predict 89 functional impacts that are not supported by any other tool, while 75 tools predict pathogenicity and can be used within the ACMG/AMP guidelines. We launched a website allowing researchers to select tools based on desired variants and impacts.

Conclusion: More than 100 tools are already available to predict approximately 160 functional impacts. About 60% of the functional impacts can be predicted by the combination of three tools. Unexpectedly, recent tools do not predict more impacts than older ones. Future research should allow predicting the functionality of unsupported variant types, such as gene fusions.

P16.065.A The STOP g.APP: visualising the impact of stop-loss variants to aid variant interpretation

Alexandra Geary[1], *Elston N. D'Souza*[1], *Nicola Whiffin*[1]

[1]*Nuffield Department of Medicine (NDM), University of Oxford, United Kingdom*

Background/Objectives: Variants intersecting stop codons are linked to a broad range of both rare, and common human genetic conditions, including cardiomyopathies, and diabetes. However, interpreting their impact is not straightforward as (1) the effect of addition of amino acids to the C-terminus on protein function is difficult to predict, and (2) if there is no alternative stop codon upstream of the polyadenylation signal the transcript may be degraded by non-stop decay. Differentiating likely deleterious variants from those that are likely tolerated often requires specialist analysis and skills and, at present, no tools are available to assist in the interpretation of variants of this kind.

Methods: To address this issue, we have developed 'the STOP g.APP', an R/RShiny web app that allows users to visualise potential effects of stop disrupting variants in Ensembl v110 transcripts, providing information on downstream alternative stops, extension statistics, and whether non-stop decay is predicted. Importantly, the tool accounts for a change in frame when predicting the effect of insertion and deletion variants.

Results: As a validation of our approach, we show that variants predicted to cause non-stop decay are under significantly higher levels of constraint and cross-species conservation than variants predicted to result in small additions to the protein C-terminus.

Conclusion: The STOP g.APP is a freely available open-source resource that can be used by both research and clinical communities to

aid in the interpretation of stop-intersecting variants in human genes, and supplement interpretation using the ACMG-AMP guidelines.

P16.067.C Solve-RD experience in structural variant calling and clinical interpretation in 12,500 unsolved rare disease exomes

german demidov[1], *Steven Laurie*[2], *Stephan Ossowski*[3]

[1]*Institute of Medical Genetics and Applied Genomics, University of Tübingen, Tübingen, Germany, Germany;* [2]*Centre Nacional d'Anàlisi Genòmica (CNAG), Baldiri Reixac 4, 08028 Barcelona, Spain; Universitat de Barcelona (UB), Barcelona, Spain, Spain;* [3]*Institute of Medical Genetics and Applied Genomics, University of Tübingen, Tübingen, Germany, Germany*

Consortium: the Solve-RD Consortium

Background: Structural variants (SVs) including large deletions and duplications (CNVs), inversions, translocations, and complex SVs have the potential to disrupt gene function resulting in rare disease. Nevertheless, current pipelines and clinical decision support systems for exome sequencing (ES) tend to focus primarily on SNVs and short insertions and deletions. Solve-RD aims to identify disease-causing variants in previously undiagnosed rare disease (RD) families. We reanalysed exomes from 12,014 families and 12,520 affected individuals to detect overlooked causal copy-number and structural variants.

Methods: A comprehensive pipeline of three read-depth based tools, ClinCNV, Conifer, ExomeDepth, together with Manta for identification of paired-end and split-read signatures, was used to detect CNV/SVs across all 12,500 ES datasets in Solve-RD.

Results: Analysis of the first ~6,000 families resulted in a new molecular diagnosis as a result of CNV identification for 51 families (1). We also identified pathogenic CNVs that are partially explanatory of the proband's phenotype in a further 34 individuals. In addition, 8 structural variants detected solely by Mantat were considered causal (2). Here we present the findings of the analysis of the complete cohort with ~6,000 additional families.

Conclusions: CNV and SV reanalysis in exomes can be performed at large scale and provide diagnosis to patients which were considered unsolved for many years. Improved pipelines for CNV and SV detection as well as comprehensive visualization of variants can reduce the time required for the genetic data interpreters to reach the diagnosis.

P16.068.D Implementation of RNA-seq analysis in patients with rare diseases

Lucía Peña-Pérez[1;2;3], *Anders Jemt*[2;4], *Håkan Thonberg*[3], *Jesper Eisfeldt*[2;3;4], *Henrik Stranneheim*[1;2;4], *Anna Wedell*[1], *Anna Lindstrand*[3], *Valtteri Wirta*[2;4;5]

[1]*Karolinska University Hospital, Centre for Inherited Metabolic Diseases, Stockholm, Sweden;* [2]*SciLifeLab, Department of Microbiology, Tumour and Cell Biology, Stockholm, Sweden;* [3]*Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden;* [4]*Karolinska University Hospital, Genomics Medicine Center Karolinska, Stockholm, Sweden;* [5]*SciLifeLab, School of Engineering Sciences in Chemistry, Biotechnology and Health, Stockholm, Sweden*

Background/Objectives: Whole genome sequencing (WGS) is one of the most comprehensive techniques for rare disease diagnosis. However, many patients remain undiagnosed even after having had their genome analyzed. One of the main reasons is the bottleneck in variant interpretation, often caused by the inability to predict the effects of non-coding/deep intronic variants on protein. Performing RNA-seq can allow us to see the effects directly on the transcripts, potentially increasing the diagnostic yield. Herein we present our findings and experiences from analyzing a cohort of 126 RNA-seq samples through a newly developed bioinformatic pipeline called tomte.

Methods: Blood samples from 126 rare disease patients were collected in PAXgene tubes and RNA was isolated, sequenced, and processed through tomte (https://github.com/genomic-medicine-sweden/tomte). Tomte is a pipeline written in Nextflow that processes FASTQ files, performs alignment, transcript quantification, allele-specific variant calling, and variant annotation. Furthermore, it detects mono-allelic expression, aberrant expression, and aberrant splicing to aid in rare disease diagnostics.

Results: In our cohort of 126 samples, we could identify 18 aberrant splicing and 38 aberrant expression events, which we could correlate to potentially causative genetic variants previously identified with WGS.

Conclusion: RNA-seq has the potential of increasing the diagnostic yield for rare disease patients by directly showing the effects of variants on transcripts.

P16.069.A Novel discoveries and enhanced genomic prediction from modelling genetic risk of cancer age-at-onset

Ekaterina Maksimova[1], *Sven Erik Ojavee*[2;3], *Marie Sadler*[2;3;4], *Reedik Mägi*[5], *Zoltan Kutalik*[2;3;4], *Matthew Robinson*[1]

[1]*Institute of Science and Technology Austria (ISTA), Klosterneuburg, Austria;* [2]*UNIL - Université de Lausanne, Department of Computational Biology, Lausanne, Switzerland;* [3]*SIB Swiss Institute of Bioinformatics, Lausanne, Switzerland;* [4]*University of Lausanne, University Center for Primary Care and Public Health, Lausanne, Switzerland;* [5]*Institute of Genomics, University of Tartu, Tartu, Estonia*

Background/Objectives: Inference in case-control genome-wide association studies on late-onset diseases suffers from the uncertainty that control group subjects might be diagnosed later in life. Time-to-event analysis treats controls as right-censored, without additional assumptions about future disease occurrence, representing a more sound inference alternative.

Methods: We extensively compared the discovery and genomic prediction performance of the time-to-event model GMRM-BayesW to GMRM-BayesRR-RC and other state-of-the-art methods on simulated data and data on 11 cancers from the UK and Estonian Biobanks.

Results: In simulation analyses, we demonstrate that modern association testing methods are generally unable to recover the genetic basis of later-life infrequently occurring phenotypes within biobank data. Nevertheless, we show that GMRM-BayesW yields a better understanding of the polygenicity and genetic architecture

of the 11 cancers recorded in the UK Biobank and highlights that heritable genetic risk is attributable to many thousands of genomic regions. We replicate previous findings from large-scale case-control studies and find 25 previously unreported genomic regions, out of which 5 replicated in independent data. Finally, we show that Bayesian modelling utilizing time-to-event data increases prediction accuracy by on average 20% compared to the recent summary statistic approach LDpred-funct.

Conclusion: We provide empirical evidence that discovery, genomic prediction, and understanding of genetic architecture of traits are greatly improved by analyzing age-at-diagnosis. Thus, as sample sizes increase, incorporating time-to-event data should be commonplace, improving case-control studies by using richer information about the disease process.

P16.070.B CCUT - a versatile deep learning toolbox to enhance chromatin capture contact maps

Stanislav Sys[1], *Susanne Gerber*[1], *Karin Everschor-Sitte*[2]

[1]*University medicine at the Johannes Gutenberg University in Mainz, Human Genetics, Mainz, Germany;* [2]*University of Duisburg-Essen, Faculty of Physics, Duisburg, Germany*

Consortium: Mainz Institute of Multiscale Modeling (M3ODEL)

Background/Objectives: Chromatin Capture Experiments as Hi-C and Micro-C have become a popular method for genome architecture exploration. Nevertheless, these techniques come with the drawback of high sequencing cost and problems in mapping low coverage libraries to high resolution genomic structures. While there have been impressive breakthroughs in the field of pairwise contact matrix reconstruction, major challenges remain due to the high computational demands as well as the complexity and specificity of modern deep learning methods. Here we present the Chromatin Capture Upsampling Toolbox (CCUT) designed as a framework for deploying state-of-the-art pre-built and custom deep learning methods for matrix reconstruction. CCUT is a versatile toolbox not only capable of matrix reconstruction, but also offering a standardized way to transform, manipulate and visualize chromatin data.

Methods: CCUT consists of prebuilt models which can be directly used to enhance the quality of low-resolution matrices. All prebuilt models, which also include state-of-the-art models from other publications such as ESR-GAN, SWIN-Transformer and HiCARN by Hicks et al, were evaluated based on standardized metrics. Pre-built models were trained on the highest standard open datasets available (HiC & Micro-C @ 4DN).

Results: Our Toolkit provides excellent reconstruction results and offers the versatility needed to tackle noisy genomic data, while offering computationally efficient and best performance models at the same time.

Conclusion: CCUT offers a novel and user-friendly approach to designing and deploying deep learning models for chromatin matrix reconstruction, while allowing standardized and easy model evaluation.

P16.071.C Automatic identification of pathogenic rearrangements in the CFH region using long-read Nanopore sequencing

Marie Mille[1], **Denis Bertrand**[1], *Carine el Sissy*[2], *Nadhir Yousfi*[3], *Paula Vieira-Martins*[2], *Abderaouf Hamza*[4], *Sophie Vandermeersch*[3], *Sacha Beaumeunier*[1], *Michael Blum*[5], *Nicolas Philippe*[5], *Véronique fremeaux-bacchi*[2], *Laurent MESNARD*[3;6;7]

[1]*SeqOne, Bioinformatics, Montpellier, France;* [2]*APHP, Immunologie biologique, Paris, France;* [3]*INSERM-Sorbonne Université, UMRS 1155, Paris, France;* [4]*Institut Curie, Service de génétique, Paris, France;* [5]*SeqOne, R&D, Montpellier, France;* [6]*APHP, CNR-MAT, Paris, France;* [7]*APHP, Service de Soins Intensifs Néphrologique et Rein Aigu, Paris, France*

Background/Objectives: Genomics has the potential to reshape the management of Thrombotic microangiopathy (TMA) which encompasses various genetically-driven diseases. Complement-mediated thrombotic microangiopathy (cTMA) can be associated with complex structural variants (SV) rearrangement operating at the CFH-CFHRs locus. Gene fusions in the CFH-CFHR region is a specific molecular diagnostic bottleneck associated with 5% of c-TMA cases.

Methods: The highly repetitive character of sequences in this region makes it difficult to detect structural variants even with long-read sequencing. These events are occuring in two 30kb regions crossing partially CFH and CFHR1 genes that differ only by 500 single nucleotide variations (SNV).

To overcome this issue, we designed a bioinformatic pipeline that can detect gene fusions in the CFH-CFHR1 region. Our method uses SNV differences between the 2 regions to detect chimeric reads and breakpoint areas. Read mapping to these regions are extracted and mapped back to the CFH region to identify chimeric reads. According to the breakpoint location and the change of region identified in the chimeric reads we infer the structural variation in the CFH-CFHR1 region.

Results: We tested our approach on twenty patients for the detection of CFH-CFHR1 classic hybrids, CFHR1-CFH reverse, and homozygous deletions of CFHR1-CFHR3. In four samples, Multiplex Ligation Probe Amplification confirmed that the hybrids were detected correctly.

Conclusion: This novel SV detection method is able to call variations on highly homologous regions for long-read sequencing. This opens the way to molecular characterization of complex rearrangement structures including pathogenic structural variations associated with microangiopathy.

P16.072.D Ratio-based alternative splicing for assessing and enhancing the quality of transcriptomic data using Quartet RNA reference materials

Ying Yu[1], *Qingwang Chen*[1], *Leming Shi*[1;2], *Yuanting Zheng*[1]

[1]*Fudan University, State Key Laboratory of Genetic Engineering, Human Phenome Institute, School of Life Sciences, and Shanghai Cancer Center, Shanghai, China;* [2]*The International Human Phenome Institutes, Shanghai, China*

Background/Objectives: Certified RNA reference materials play a crucial role in evaluating the reliability of RNA sequencing (RNA-seq) for detecting subtle biological differences in clinical settings, such as molecular subtyping of diseases. In our previous work, we established Quartet RNA reference materials and created gene-level ratio-based transcriptomics-wide reference datasets (Yu Y et al., Nature Biotechnology, 2023). However, another analysis type in transcriptomics data is alternative splicing (AS), which holds significant potential for disease research. Unfortunately, objective assessment at the AS level is currently lacking.

Methods: To address this gap, we quantified AS of Quartet RNA reference materials using 21 batches of multi-laboratory RNA-seq datasets generated with diverse protocols. We then processed the data using three bioinformatics pipelines. Based on these multi-batch and multi-analysis datasets, we constructed ratio-based reference datasets at the AS level, serving as the "ground truth" for benchmarking. Subsequently, we employed the signal-to-noise ratio (SNR) metric and consistency with reference datasets (RC) to evaluate the RNA-seq quality of AS quantification across batches.

Results: Our findings revealed substantial variation in RNA-seq quality for AS quantification across different batches and analysis pipelines, as assessed by SNR and RC measurements. Additionally, combining multi-batch and multi-analysis data introduced batch effects that obscured the differentiation of biologically distinct groups. Notably, the ratio-based approach, *i.e.* scaling study samples' absolute values relative to concurrently profiled reference material(s), yielded reproducible and comparable data.

Conclusion: Our study provided a valuable resource for assessing and enhancing the quality of transcriptomic data at AS level.

Background/Objectives: Kleefstra syndrome 2 (KLEFS2) is a rare neurodevelopmental disorder characterized by a spectrum of features ranging from mild to severe intellectual disability, delayed psychomotor development, and distinctive facial dysmorphisms. This study aimed to identify a specific episignature associated with KLEFS2 arising from variants in *KMT2C*, elucidating its diagnostic potential and molecular distinctions from related syndromes.

Methods: DNA samples were extracted from peripheral blood of 22 individuals with genetic variants in *KMT2C* and clinical features consistent with KLEFS2. DNA methylation analysis was performed using the Illumina Infinium Methylation EPIC Bead Chip microarrays. Controls were randomly selected from EpiSign Knowledge Database (EKD) at the London Health Sciences Centre (LHSC). The methylation levels were fitted in a multivariate linear regression model to identify differentially methylated probes (DMPs). A support vector machine (SVM) classifier was constructed to train the model.

Results: In total, 225 DMPs were selected to construct the model. DNA methylation analyses indicated a clear and robust separation between patients carrying truncating variants and controls. The SVM classifier demonstrated robustness and specificity in distinguishing KLEFS2 from controls and other neurodevelopmental disorders, particularly KLEFS1, Rubinstein-Taybi and Kabuki syndromes. Additionally, identification of differentially methylated regions (DMRs) revealed several genes potentially associated to neurological functions observed in KLEFS2.

Conclusion: This study presents a distinct epigenetic signature specific to KLEFS2, providing a foundation for early diagnosis and understanding its molecular underpinnings, crucial for advancing clinical genetic practices and potential therapeutic interventions.

Grants: This study was supported by the Government of Canada through Genome Canada and the Ontario Genomics Institute (OGI-188).

P16.075.C Leveraging ATAC-seq with transformers for context-sensitive cis-regulatory modeling

Panos N. Firbas[1], *Carolina Gonçalves*[1], *Gonzalo de Polavieja*[1]

[1]*Champalimaud Foundation, Lisboa, Portugal*

Background/Objectives: Transformers are emerging as a promising tool in cis-regulation and chromatin modeling, but the typical design of relying solely on genomic sequences as input severely limits their applicability in biological research.

Methods: We introduce a transformer model that integrates genomic sequences with ATAC-seq signal to model individual cis-regulatory elements (CREs). ATAC-seq allows the identification of CREs to use as samples, but also facilitates the modeling of Transcription Factor binding sites (TFbs) through the 'shadows' created by DNA-bound proteins. Our approach allows the model to make context-dependent predictions, unlocking its potential for real-world applications.

Results: The model, which consists of a convolutional tokenizer, followed by a transformer-encoder body and the task heads, was trained with a masking task and fine-tuned with a nucleotide classification task for CTCF, H3k27ac, and H3k4me3. A small version of the model achieves F1 scores of over 0.9 at the center of CTCF targets and over 0.83,0.87 per nucleotide for the other two classes. Analysis of its attention mechanism reveals its ability to pinpoint CTCF binding sites with nucleotide-level precision. We present evidence that the predictions are protein-DNA binding events, even when those have not been captured by the ChIPseq assay.

Conclusion: We introduce a novel approach in modeling cis-regulatory elements and TFbs with transformers and provide an implementation that yields high-quality context-sensitive predictions. Researchers can use a single molecular assay to identify CREs and classify them for H3k27ac and H3k4me3, but also to locate CTCF and other TFbs with nucleotide resolution.

P16.076.D A fine-mapping knockoff filter approach revealed association between multiple sclerosis and SNPs in 3'UTR of MYO1D and intronic region of ASIC2 (17q11.2-q12) in a study involving trios from Sardinian population.

GIULIA NICOLE BALDRIGHI[1], *Claus Thorn Ekstrøm*[2], *andrea nova*[1], *teresa fazia*[1], *valeria saddi*[3], *maria luisa piras*[3], *luisa bernardinelli*[1]

[1]*University of Pavia, Brain and Behavioural Sciences;* [2]*University of Copenhagen, Public Health;* [3]*Presidio Ospedaliero S. Francesco, ASL*

Background/Objectives. Multiple sclerosis (MS) is a progressive autoimmune disease affecting the central nervous system, leading to diverse physical and cognitive impairments. Although its aetiology remains undefined, factors such as genetics and familial predisposition play pivotal roles. Here, a fine-mapping approach was applied to the region where ASIC2 gene, known for its association to MS, is located (17q11.2-q12). Moreover, the genetically isolated Sardinian population was employed because MS prevalence in this population is higher compared to the national mean, 330 per 100,000 inhabitants, 95%CI: [321, 338].

Methods. A multi-step analysis was used to find MS-associated genetic variants in a sample of 157 trios. Firstly, genotypes were imputed, through haplotype reconstruction and 2537 single nucleotide polymorphisms (SNPs) were obtained after post-imputation quality controls. Secondly, genotype matrix was augmented with knockoff variants and family-based association test was performed to study conditional associations of genetic segments at multiple resolutions. Eventually, consistencies between knockoff filter results and original non-imputed variants were evaluated.

Results/Conclusion. The alternative allele of variant rs756787 (involving CDK5R1 and the 3'UTR of MYO1D) consistently showed statistical significance in increased MS risk. This SNP was revealed to be associated with autoimmune traits and smoking initiation. Conversely, two intronic regions of ASIC2, marked by rs56175840 and rs12936220, reported significance in reduced MS risk. They were found to be associated with BMI and cerebellum cortex volume from literature. Since for these two SNPs the recessive homozygotes occur less frequently in Sardinian MS cases than in controls, this might suggest their involvement in pathways conferring a protection against MS.

P16.077.A Accurate identification of pathogenic structural variants guided by multi-platform comparison

Nico Alavi[1], **M-Hossein Moeinzadeh**[1], *Jakob Hertzberg*[1], *Uira Melo*[2], *Maryam Ghareghani*[1], *Lion Ward Al Raei*[1], *Eldar Abdullaev*[1], *Malte Spielmann*[3], *Stefan Mundlos*[2], *Martin Vingron*[1]

[1]*Max Planck Institute for Molecular Genetics, Department of Computational Molecular Biology, Berlin, Germany;* [2]*Max Planck Institute for Molecular Genetics, Research Group Development and Disease, Berlin, Germany;* [3]*University of Lübeck, Institute of Human Genetics, Lübeck, Germany*

Background/Objectives: Structural variants (SVs) are a common cause of human diseases and contribute to inter-individual variability. However, their detection remains a challenge, especially when relying on short-read sequencing. To investigate and overcome these challenges, we analyzed a cohort of 9 individuals genotyped by combining short-read, long-read, and linked-read sequencing as well as optical mapping.

Methods: Our dataset combined with novel tools for scalable manual variant inspection allowed us to create a comprehensive benchmark. Utilizing this benchmark, we evaluated how each technology and their corresponding SV callers perform across various settings. Guided by our comparison, we designed a short-read-based machine learning method to identify true-positive SVs using genomic annotations and alignment features. We demonstrate the method's applicability in a clinical scenario on a cohort of limb malformation patients.

Results: Our curated benchmark contains 79,645 deletions, 68,900 insertions, 16,506 duplications, and 331 inversions. Long-read-based SV detection outperforms all other surveyed methods, especially in detecting small to medium-sized deletions and insertions. To mitigate that, we demonstrate that our machine-learning method identifies 10% more true-positive deletions than state-of-the-art short-read-based methods while maintaining an accuracy above 84%. We further show the potential of our method in a clinical context, identifying 40% more manually confirmed candidates than a consensus approach.

Conclusion: While long-read-sequencing exhibits superior SV detection performance, short-read-sequencing remains more accessible, scalable, and less costly. We demonstrate that machine learning can push the boundaries of current short-read-based methods and drastically reduces the need for time-consuming manual inspection of variants in the context of clinical diagnostics.

P16.078.B Exploring the Impact of GLP1R Coding Variants on Type 2 Diabetes and Depression through a Multi-phenotype approach.

Zhanna Balkhiyarova[1;2;3], *Giuseppe Deganutti*[4], *Christopher Reynolds*[4], *Ben Jones*[3], *Inga Prokopenko*[1;2]

[1]*University of Surrey, 1 Department of Clinical and Experimental Medicine, School of Biosciences and Medicine, Guilford, United Kingdom;* [2]*University of Surrey, People-Centred Artificial Intelligence Institute, Guilford, United Kingdom;* [3]*Imperial College London, Section of Metabolism, Digestion and Reproduction, Department of Medicine;* [4]*Coventry University, Centre for Health and Life Sciences, United Kingdom*

Background/Objectives: In this study we investigate multi-phenotype association between type 2 diabetes (T2D) and depression, two conditions imposing a considerable burden on global healthcare systems. The bidirectional link between T2D and depression, contributing to adverse microvascular and macrovascular outcomes, is a focal point.

Methods: Leveraging phenotypic data from the UK Biobank, including whole exome sequencing for 467,836 individuals, we concentrated on the GLP1R gene and its 200kb flanking region. Analysing six key phenotypes in 70,001 individuals, including random glucose, HbA1c, BMI, T2D, major depressive disorder, and depressive symptoms, we employed plink for single-phenotype association analysis and SCOPA software, using a reverse regression approach for multi-phenotype analysis.

Results: Our meticulous approach, adjusting for demographic variables, revealed significance in multi-phenotype analysis for 19

variants. Notably, a rare GLP1R gene variant (6:39073639:G:A) exhibited significant associations with both glucose metabolism and depression ($p = 4.28 \times 10^{-9}$). Furthermore, a previously reported rare variant linked to random glucose, rs146868158, demonstrated significance in the model with metabolic phenotypes ($p = 0.026$).

Conclusion: These findings illuminate shared mechanisms in the development of type 2 diabetes and depression, providing insights for targeted interventions and personalized treatment strategies.

P16.079.C Copy number variations mapping in a cohort of 1860 asymptomatic individuals improving interpretation

Virginie Bernard[1], *Quentin Charret*[1], *Clément Lionnet*[1], *Maëlle Martinet Gerphagnon*[1], *Valentin Klein*[1], *Laura Fancello*[1], *Anthony Ferrari*[2], *Anne Sophie Sertier*[2], *Elise Dugas*[2], *Groupêment de Coopération Sanitaire Auragen*[3], *Jean François Scariot*[4], *Alain Viari*[4], *Julien Thevenon*[1]

[1]*Centre Hospitalier Universitaire de Grenoble, La Tronche, France;* [2]*Léon Bérard Center, Lyon, France;* [3]*Edouard Herriot Hospital, Lyon, France;* [4]*Inria Centre at the University Grenoble Alpes, Montbonnot-Saint-Martin, France*

Background/Objectives: Genome sequencing enables the fine detection of copy number variations (CNVs) and individual structural variations (SVs). This approach allows for the discovery of a wide variety and complexity of variations not accessible through previous techniques. CNV and SV detection limitation on short-read sequencing data are known. Clear variation visualization is crucial for confident interpretation and robust identification of differentiating predictive factors between true and false positives.

Methods: To improve CNV interpretation, a cohort of 1860 genome sequencings from asymptomatic individuals representing 2025 France Genomic Medicine Initiative sequencing AURAGEN routine is usefull. Cohort CNVs and SVs mapping, coupled with international dbVAR data are accessible. For each patient, a dynamic pan-genomic representation of CNV and LoH through a dynamic interface comparing to dbVar population frequency and local cohort are available.

Results: The regions observed in more than 1% of this population include 1,637 Mb. Additionally, we add 377 Mb losses and 380 Mb gains specific to the AURAGEN routine, for 178 Mb intervals dbVar absent. Those are intervals poorly covered at 40X depth or with high variability. This helps interpretation. Among mappable autosomal regions, it identifies 943 Mb of non-variable regions possibly under selection pressure. The 1,103 Mb of regions without loss concentrates 9339 genes for which no sequence in the coding sequence is deleted. Among them, 1576 genes have a pLI > 0.9, and 1510 genes have no loss in the cohort.

Conclusion: This mapping of CNV and LoH helps genome interpretation for diagnostic and research.

P16.080.D Differences in cell type composition in the liver by the linear mixed model in the deconvolution method under thermal stress conditions

Krzysztof Kotlarz[1;2], *Bartłomiej Hofman*[1], *Magda Mielczarek*[1;2], *Yachun Wang*[3], *Joanna Szyda*[1;2]

[1]*Wrocław University of Environmental and Life Sciences, Wrocław, Poland;* [2]*Poznan University of Medical Sciences, Poznań, Poland;* [3]*China Agricultural University, Beijing, China*

Background/Objectives: In recent years, the impact of environmental stressors on cellular composition has become a key point in biological research. Therefore, in our study, we were interested in checking whether thermal stress impacts the proportions of particular cell types in a given tissue. For this purpose, we used a custom-written program implementing a novel approach based on Linear Mixed Model (LMM).

Methods: Bulk tissue expression from the liver was measured under two environmental conditions where available for 10 individuals. Additionally, the control cell-type specific gene expression profiles from the liver were utilised as a reference. In this study, we suggested the LMM with expression cell type profile modelled as a random effect to estimate the proportion of particular cell types expressed under two conditions. Two LMMs were considered: (i) model assuming no-covariance between cell-types specific expressions, (ii) model including covariance between cell-types specific expressions quantified by Jaccard similarity coefficient. Different environmental conditions were expressed by thermal stress and rats were chosen as the experimental organisms by their physiological similarities to humans.

Results: Significant differences were estimated in most cell populations except B cells. Endothelial cells, immune cells, hepatocytes, cholangiocytes, and plasmocytes exhibited altered proportion levels under thermal stress conditions.

Conclusion: These findings highlight a systemic impact of thermal stress on cellular dynamics, suggesting potential implications for immune responses, inflammatory cascades, and hepatic function.

Grants: Calculations were carried out at the Wroclaw Centre for Networking and Supercomputing.

P16.081.A An end-to-end workflow to diagnose patients with rare diseases using only open-source components in a clinical setting.

Ramprasad Neethiraj[1], *Anders Jemt*[1], *Henrik Stranneheim*[1], *Daniel Nilsson*[1], *Måns Magnusson*[1;2], *Chiara Rasi*[1], *Valtteri Wirta*[1]

[1]*SciLifeLab, Clinical Genomics, Stockholm, Sweden;* [2]*Klarna, Stockholm, Sweden*

Background/Objectives: A rare disease diagnostic pipeline consists of four important steps: alignment, variant calling, annotation, and variant prioritization. While there are open-source tools available for the first two steps, the annotation and variant prioritization stages are more complex and require financial and personnel investment to develop and establish the necessary infrastructure. As a result, rare disease diagnosis typically relies on expensive commercial solutions for variant annotation and prioritization. Hence, there is a need to develop open-source alternatives that are easy to set up and customize according to local needs and, at the same time, do not compromise on the diagnostic yield.

Methods: We utilize tools like CADD, Variant Effect Predictor (VEP), and Vcfanno to combine annotations from several publicly available databases, like ClinVar and ClinGen, and in-house allele frequency databases like Loqusdb (https://github.com/Clinical-Genomics/loqusdb). For variant prioritization, we utilize Genmod,

which uses a customizable weighted sum rank model to score individual variants based on their annotations, disease models and inheritance patterns (https://github.com/Clinical-Genomics/genmod).

Results: Our system is currently in use to diagnose patients with rare diseases in the Stockholm healthcare region, and has a diagnostic yield of around 40%. Additionally, our results are fully compatible with Scout, an open-source web-based decision support tool that can be used in the clinic to visualize, share, and solve cases in a collaborative manner (https://github.com/Clinical-Genomics/scout).

Conclusion: Our approach provides an entirely open-source solution that is easy to set up and customize according to local needs. Importantly, it does not compromise on the diagnostic yield.

P16.082.B Optimised variant filtering specificity improves the efficiency of diagnostic genomic testing in rare disease

Rebecca Locke[1;2], Christopher Pyatt[1;2], Jethro Rainford[1;2], Gavin Fuller[1;2], Isabelle Delon[1;2], Kirsty Bradshaw[2;3], Elizabeth Johnston[2;3], Kate Downes[1;2], Joo Wook Ahn[1;2], Matthew Garner[1;2]

[1]Cambridge Genomics Laboratory, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [2]NHS East Genomic Laboratory Hub, East Genomics, United Kingdom; [3]Genomics and Molecular Medicine Service, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Background/Objectives: Variant classification presents a major bottleneck for diagnostic genomic testing in rare disease. Stringent variant filtering can reduce the classification workload but must be balanced with the requirement for sensitivity to maintain diagnostic yield. Increasing the number of cases where no variants require interpretation also facilitates automated reporting of these cases, enhancing service delivery efficiency. We assessed current filtering approaches and identified opportunities for improvement, which will enable scalability as testing demand increases.

Methods: Our new approach annotates a virtual gene panel-filtered VCF with mode of inheritance (MOI) information. This maps gene-level MOI to all rare diseases from PanelApp which allows gene-disease specific MOI thresholds to be applied. These thresholds were incorporated into our filtering rules along with other improvements, and their effectiveness was assessed against a set of 3184 previously reported cases.

Results: 17% of cases receive a positive report ($n = 527$) and 83% ($n = 2657$) receive no molecular diagnosis (NMD), of which 9% ($n = 234$) have no variants presented for review or classification with the current approach. Improved filtering has increased this to 53% ($n = 1403$) which has a significant impact on the workload required to review and exclude these variants to reach the same NMD conclusion. The optimised approach reduced the total number of variants requiring analysis by 61% compared to the current approach. Importantly, no pathogenic variants were filtered out.

Conclusion: We have optimised our genomic variant filtering which improves diagnostic specificity without impacting sensitivity. We expect this will reduce turnaround times for patients.

P16.083.C Advancing Therapeutic Insights in Cancer Biology through Integration of cBioPortal and Open Targets

Mirella Kalafati[1], Anika Bongaarts[1], Jessica Singh[1], Laura Varela[1], Zeynep Karagöz[1]

[1]The Hyve, Utrecht, Netherlands

Objectives: The growth of curated public data within cBioPortal presents an opportunity to unravel the intricate associations between genetic variants and cancer types. Open Targets (OT) stands out as a tool by integrating various datasources, including genomic data, to assess target-disease associations and the validity of therapeutic targets. While cBioPortal manages processed genomics data at the patient level, OT focuses on target-disease relations derived from these data without dealing with individual patient details. This project aims to develop an automated pipeline for generating OT-compatible summary/meta-data from cBioPortal and seamlessly integrating it into OT.

Methods: A scalable pipeline, written in Scala and Python, was developed at The Hyve to handle the generated evidence from the large amount of genomic data in cBioPortal, to be uploaded in OT. This pipeline includes an algorithm to transform the evidence derived from cBioPortal data into a score between 0 and 1, where each type of cBioPortal evidence will be weighted for its significance and relevance for the gene-disease association.

Results: The automated pipeline successfully extracts relevant data from cBioPortal, transforms and standardizes it to align with OT format, computes scores, and integrates evidence into OT. A dedicated section within OT for cBioPortal evidence is also developed, with an intuitive user interface.

Conclusions: The integrated platform allows users to easily rank drug targets for cancer based on advanced cancer genomics data. This automated integration significantly benefits the genomics and molecular data field of cancer biology, creating a more interconnected ecosystem for researchers and clinicians alike.

Conflict of Interest: None declared

P16.084.D Integrating high-throughput assays and deep learning for characterization of human *cis*-regulatory elements

Mohan Dash[1], Chengyu Deng[2;3], Jay Shendure[4;5], Nadav Ahituv[2;3], Martin Kircher[1;6], Max Schubach[1]

[1]Berlin Institute of Health at Charité – Universitätsmedizin, Berlin, Berlin, Germany; [2]University of California San Francisco, Department of Bioengineering and Therapeutic Sciences, San Francisco, United States; [3]University of California San Francisco, Institute for Human Genetics, San Francisco, United States; [4]University of Washington, Department of Genome Sciences, Seattle, United States; [5]Howard Hughes Medical Institute, Seattle, United States; [6]University Medical Center Schleswig-Holstein, University of Lübeck, Institute of Human Genetics, Lübeck, Germany

Consortium: Impact of Genomic Variation on Function (IGVF)

Background:

Nucleotide variants in *cis*-regulatory elements (CREs) are major drivers of phenotypic differences and human disease. However, their regulatory code remains allusive, thus requiring the development of deep-learning approaches that can predict CRE-activity only by their DNA sequence. These approaches have been either focused on biochemical features of a single cell-type (i.e., small-scale with underlying sampling bias) or predict thousands of features in parallel, thereby raising issues in terms of multi-collinearity and interpretability.

Methods: To better benchmark and improve these methods, we characterize >60,000 proximal regulatory CREs in diverse human cell-types with massively parallel reporter assays (MPRAs). We designed our MPRA library using a convolutional neural

network (CNN) architecture trained on sequences of accessible and closed chromatin in multiple cell-types. The library was tested in human hepatocytes and kidney epithelial cells, and data processed to compute MPRA-activity. Furthermore, we trained regression models to identify key features for MPRA-activity.

Results: MPRA experiments resulted in good replicate Pearson correlations of ~70% in both cell-types and our initial CNN model predicted chromatin-accessibility with a Pearson correlation of 35%. From the regression analysis of MPRA data, chromatin-accessibility (DNase-seq), boundary-element (CTCF), histone-modifications (H3K27ac), variant-density, and conservation (PhyloP) were found to be key features, with a Pearson correlation to 44%.

Conclusion: We identified features in addition to DNA sequence that led to better prediction of MPRA activity and more specific motif enrichment. We believe that the models and datasets generated here will increase our genome-wide interpretation of functional CREs and variation within them.

P16.085.A OncoClassify: Somatic Mutation Classification in Cancer Genomics

Claire Morgan[1;2], *Leslie Matalonga*[1;2], *Joel Dieguez*[1;2], *Raul Tonda*[1;2], *Genis Parra*[1;2], *Ivo Gut*[1;2], *Sergi Beltran*[1;3]

[1]*Centre Nacional d'Anàlisi Genòmica (CNAG), Barcelona, Spain;* [2]*Universitat de Barcelona (UB), Barcelona, Spain;* [3]*Universitat de Barcelona (UB), Departament de Genètica, Microbiologia I Estadística, Facultat, de Biologia, Barcelona, Spain*

Background/Objectives: Accurate classification of somatic mutations and subsequent assignment of actionability is crucial for data-driven cancer treatment. While joint recommendations have been proposed for the classification of oncogenic mutations by the cancer genomics community (ClinGen, CGC and VICC), there remains a gap in implementing these proposals within a next-generation sequencing context.

Methods: We introduce OncoClassify, a command-line tool designed to rapidly classify somatic mutations as benign or oncogenic in accordance with joint recommendations. OncoClassify leverages information from cancer mutation and biomarker databases and can be easily updated and harmonized. Notably, OncoClassify can be customized to utilize specific data sources based on the analysis objectives and the licenses of the data sources. Actionability is assigned at multiple levels including exact amino acid match, amino acid positional match, exonic region, and gene level for SNVs, indels, CNVs, and gene fusion events.

Results: OncoClassify generates an oncogenicity score for each mutation, which determines its classification. The tool also provides the underlying source data that contributes to the score. Benchmarking demonstrates that OncoClassify either outperforms existing tools or performs comparably. It efficiently processes annotated whole-genome sequencing (WGS)-derived VCF files in seconds. Furthermore, OncoClassify is containerized and can be deployable on local or high-performance computing (HPC) machines to be integrated in existing analysis workflows.

Conclusion: OncoClassify provides a robust and efficient solution for the classification of somatic mutations, thereby facilitating personalized cancer treatment strategies. The application will be improved and updated to ensure adherence to the latest guidelines by the cancer genetics community.

P16.087.C Unveiling Methylation Patterns: a novel workflow to identify and visualize differentiallymethylated regions and individual cytosines

Celeste Moya-Valera[1], *Francisco Lara-Hernández*[1], *Elena Quiroz*[1], *Veronica Lendinez*[1], *Sergio Valdes*[2;3], *Ana Lago-Sampedro*[2;3], *Pablo Marin-Garcia*[4], *Vicente Arnau*[5;6;7], *Gemma Rojo*[2;8], *Javier Chaves*[1;9], *Ana Barbara Garcia-Garcia*[1;9]

[1]*INCLIVA Biomedical Research Institute, Genomics and Diabetes Unit, Valencia, Spain;* [2]*Biomedical Research Institute of Malaga (IBIMA), Malaga, Spain;* [3]*Regional University Hospital of Malaga, Endocrinology and Nutrition Department, Malaga, Spain;* [4]*Mgviz.org;* [5]*University of Valencia, Valencia, Spain;* [6]*Spanish Research Council (CSIC), Spain;* [7]*Institute of Integrative Systems Biology (I2Sysbio), Valencia, Spain;* [8]*Regional University Hospital of Malaga, Malaga, Spain;* [9]*CIBERDEM, ISCIII, Madrid, Spain*

Background/Objectives: DNA methylation (mDNA) plays a crucial role in genome regulation and gene expression. The main method to study mDNA is bisulfite-treated DNA sequencing, focused on CpG sites in regulatory regions. Several bioinformatic methods are available for analysing and visualising differentially methylated regions (DMRs), but the complete study and representation of results remain complex and unresolved. We have developed a complete workflow for DMRs and methylated cytosines detection and visualization.

Methods: The workflow is divided into four modules that can be run individually, enabling a customised analysis. These modules include: read trimming and quality control; processed read alignment; cytosine clustering and DMR annotation; and DMR and cytosine visualization. The workflow was tested on 24 bisulphite-treated exome DNA samples selected from the Egabro-Pizarra study (general Spanish population from Andalucia), focused on Type 2 Diabetes Mellitus (T2D) development.

Results: Our workflow can identify altered exome mDNA with a high sensitivity and robustness. Furthermore, it has detected mDNA alterations in some genes (*AKT1*, *GNAS*, *DVL1*, *TCF7*, *IRS2*, and *SOCS2*) that could be involved in T2D development.

Conclusion: This workflow enables exploration of the epigenetic landscape, revealing patterns and trends in mDNA that may indicate regulatory processes or disease associations.

Grants: PI14/00874, PI17/00544, PI21/00506 (Instituto de Salud Carlos III, Ministerio de Ciencia e Innovación and co-funded by the European Union), CIBER -Consorcio Centro de Investigación Biomédica en Red-CB-07/08/0018, Instituto de Salud Carlos III, Ministerio de Ciencia e Innovación, co-funded by the European Union).

P16.088.D Rigorous screening for splice-altering mutations improves the identification of potential disease-causing variants in whole genome sequencing data.

Christian W Remmele[1;2;3], *Michaela AH Hofrichter*[1], *Daniel Bengl*[1], *Wahyu Prastyo*[1], *Asuman Koparir*[1], *Shoko Komatsuzaki*[1], *Thomas Haaf*[1], *Tobias Müller*[4], *Marcus Dittrich*[1;4]

[1]*Institute of Human Genetics, Julius-Maximilians-University, Würzburg, Germany;* [2]*Center for Rare Diseases, University Hospital Würzburg, Würzburg, Germany;* [3]*Bavarian Genomes Network for Rare Diseases, Germany;* [4]*Department of Bioinformatics, Julius-Maximilians-University, Würzburg*

Consortium: Bavarian Genomes Network for Rare Diseases

Background/Objectives: In whole genome sequencing (WGS) analyses, intronic regions of genes yield many times more rare single nucleotide variants (SNVs) and short insertions/deletions (INDELs) than exonic regions. Although variants in exons exhibit more pronounced deleterious effects on average, intron variants have also been demonstrated to be disease causing, particularly when they affect splice mechanisms. These intronic variants, constituting the majority of rare variants in genes, are often disregarded, difficult to classify, and underreported.

Methods: WGS datasets consisting of an inhouse cohort and public datasets were analyzed with an inhouse pipeline. Potential splice effects were predicted utilizing SpliceAI with optimized parameters for all identified SNVs and INDELs in the gene body (5′ to 3′ transcript borders) as well as for SNVs and INDELs in ClinVar.

Results: High splice prediction scores (>= 0.5, n = 125) for intronic variants in ClinVar were strongly overrepresented for known (likely) pathogenic (71/115) compared to known (likely) benign variants (26/6,865). Read mapping and variant calling of the WGS datasets yielded 3.9/0.9 million SNVs/INDELs per sample, of which 72.6/21.0 thousand rare variants were located in the gene body. A median of 12 intronic variants with high scores for splice-altering effects were predicted. Even though deep intronic variants exhibited on average lower splice prediction scores than canonical splice sites, we were able to validate the effect on splicing for a deep intronic variant experimentally and demonstrate its pathogenicity.

Conclusion: This study illustrates the advantage of screening intronic variants by predicting their potential splice-altering effects, thereby aiding in the classification of patients' mutations for pathogenicity.

P16.089.A Preliminary studies of human Pseudogene and Homology Database (hPHD)

Bilge Nihan Satkın[1;2], *Ayhan Kütükçü*[1], *Ece ÇİÇEK*[1], *Guzin Tunca Alparslan*[1]

[1]*Trakya University, Faculty of Engineering, Department of Genetics and Bioengineering, Edirne, Türkyie;* [2]*Trakya University, Faculty of Medicine, Department of Medical Genetics, Edirne, Türkyie*

Background/Objectives: The human genome harbors an estimated 20,000 pseudogenes, serving as archival records offering insights into evolutionary trajectory. Pseudogenes, arising from retrotransposition or duplication events, lack protein-coding capacity due to pathogenic variants. Variant calling in molecular diagnostics faces challenges due to high homology of pseudogenes with functional genes. Proper primer usage is crucial for accurate variant detection.

Methods: We aim to develop a publicly available repository of PCR primers tailored for disease-related genes with homology to pseudogenes or other genomic sequences. This repository will include validated primer sets from in-house data and literature. Users can search using NCBI gene symbols, accessing primer pairs with exon numbers and literature references. Future plans involve implementing a curation system for user-submitted primers.

A customized pipeline, derived from the Psi-Phi program suite, has been integrated for identifying pseudogenes. This pipeline utilizes tblastn analysis within clusters of closely related genomes. It accepts complete or draft genome files in *.fasta or *.fas formats. The pipeline identifies sequence homology and positions of homolog regions, highlighting differences.

Results: Access to this open source will be available with a domain address based on Trakya University's server for users.

Conclusions: The developed repository of PCR primers addresses challenges in variant calling due to pseudogene homology. Integration of the Psi-Phi program suite pipeline enhances identification and understanding of pseudogenes and high-grade homology. This comprehensive resource will facilitate accurate variant detection in molecular diagnostics and support evaluating homolog regions in the human genome.

P16.090.B Benchmarking deep learning-based retinal biomarkers against tangible features reveals their distinct potentials for systemic disease prediction

Michael Beyeler[1], *Sofia Ortin Vela*[1], *Sven Bergmann*[2]

[1]*UNIL - Université de Lausanne, Lausanne, Switzerland;* [2]*UNIL, Lausanne, Switzerland*

Background/Objectives: Colour fundus images (CFIs) allow for non-invasive assessment of retinal features providing important information on health. This study benchmarks 17 tangible vascular traits (TVTs) against "deep" retinal features (DRFs) from self-supervised deep learning models, aiming to enhance systemic disease prediction, interpret deep learning models, understand genetic disease mechanisms, and ease manual annotation workload.

Methods: Analysing retinal images from a cross-sectional dataset of 22k UK Biobank participants, we compared TVTs extracted and characterised using our in-house annotation pipeline (https://doi.org/10.1101/2023.07.07.23292368) with 1024 DRFs corresponding to the latent space embeddings from the recently published RETFound model trained on 1.6 million images in the Moorfields AlzEye study. We performed GWAS on these DRFs, as well as their 17 leading principal components. To compare TVTs and DRFs, we used simple Pearson correlation analysis and LD score regression to quantify phenotypic and genotypic correlations, and Cox models to explore disease associations.

Results: TVTs outperformed RETFound in predicting cardiovascular outcomes like myocardial infarction (HR = 1.20). Further, they exclusively predicted age at death (HR = 1.17). In contrast, DRFs more accurately predicted diabetes (HR = 1.27) and cataracts (HR = 1.32). Lastly, a DRF emerged as the most heritable feature across methods and as an analogue to vessel tortuosity (h2 = 0.26, genetic correlation = 0.9).

Conclusion: We conclude that TVTs and DRFs provide complementary characterisations of CFIs calling for more integrative methods to maximise their potential for early disease diagnosis and advancing our understanding of disease mechanisms through genetics. RETFound demonstrates the ability to learn classic features in a self-supervised manner, suggesting an avenue for reducing manual analysis in retinal imaging.

P16.091.C Reducing re-identification risk of genomic data using k-mer approach

Remy Costa[1;2;3], *William Ritchie*[2], *Alban Mancheron*[1;3]

[1]*Université de Montpellier, Montpellier, France;* [2]*Institute of Human Genetics, Montpellier, France;* [3]*LIRMM - Laboratoire d'informatique, de robotique et de microélectronique de Montpellier, Montpellier, France*

Background/Objectives: Advancements in genomics have greatly increased the volume of available genomic data, offering significant potential for disease understanding and personalized medicine. However, this also raises privacy risks due to the sensitive nature of genomic information. Addressing this challenge, our study explores innovative methods to minimize privacy vulnerabilities in genomic data sharing.

Methods: We propose an approach based on k-mers to estimate re-identification risks. K-mers, short DNA sequences, inherently reduce privacy risks by minimizing direct associations with identifiable genomic features such as Short Tandem Repeats or transposons. By analyzing Single Nucleotide Polymorphisms (SNPs) within these k-mers against public databases like dbSNP, we identify potential privacy vulnerabilities. The novelty lies in developing a risk score based on the SNP analysis within k-mers, aiming to assess re-identification risks. We aim to develop a risk score indicating the likelihood of re-identification from shared k-mer sets, offering a novel approach to mitigate privacy concerns.

Results: We expect to produce a risk score that enables precise evaluation of re-identification risks in genomic data sharing. This tool will facilitate the selective sharing of genomic data by filtering out sensitive k-mers, reducing privacy risks and supporting the safe advancement of genomics research.

Conclusion: By balancing genomic research benefits with privacy protection, our study contributes to safer data sharing practices. The development of a re-identification risk metric and data filtering tool represents a significant step towards secure, open science and research reproducibility.

P16.092.D SvirlPool. Long, lifted, pooled: Reliable structural variant detection

Vinzenz May[1], *Manuel Holtgrewe*[1], *Dieter Beule*[1]

[1]*Berlin Institute of Health, Core Unit Bioinforamtics, Berlin, Germany*

Background/Objectives: Reliable structural variant (SV) detection is integral to rare disease diagnostics and cancer genomics, as well as genome variation in populations. Existing methods of structural variant detection with long reads usually use read-to-reference alignments to detect SVs on abstractions of SV signals. Typical challenges are the detection of very large or complex SVs as well as SVs within difficult regions, such as repeats or low complexity regions.

Methods: We present a novel method to combine alignment- and assembly-based methods. We identify candidate regions in read to reference alignments and then assemble clusters of relevant parts of aligned reads. The resulting assembled fragments are then aligned to a reference sequence of choice and used for SV-calling. The pooling of sequencing samples in our workflow allows us to very exactly match SVs that are shared between several samples.

Results: On standard benchmark datasets for long-read whole genome sequencing, we achieve results that are at least as competitive as existing methods. A strong advantage of our approach is the reliable detection of SVs across samples, e.g., as needed for pedigree and matched tumor-normal analysis.

Conclusion: Our method will allow very precise structural variant calling with long reads well suited for rare disease research and diagnostics use case, as well as in cancer genomics research. Furthermore, our new method can take full advantage of the rapid advancements of new reference genomes.

P16.093.A Structure analysis of missense variants in MYBPC3

Ana Gomes[1], *luis enrique gomez*[1;2], *agustín izquirdo*[1;3;4], *héctor martin cifuenes*[1], *sofia de la fuente*[1], *Marisol Delea*[1], *Carlos David Bruque*[1;5]

[1]*Hospital de Alta Complejidad El Calafate - SAMIC, Unidad de Conocimiento Traslacional Hospitalaria Patagónica, El Calafate, Argentina;* [2]*Hospital General de Agudos Dr. Juan A. Fernández., Division de cardiologia., Buenos Aires, Argentina;* [3]*Centro de Investigaciones Endocrinológicas "Dr. César Bergadá" (CEDIE) CONICET – FEI, División de Endocrinología., Buenos Aires, Argentina;* [4]*Hospital de Niños Ricardo Gutiérrez, Unidad de Medicina Traslacional. Servicio de Inmunología, Buenos Aires, Argentina;* [5]*Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Buenos Aires, Argentina*

Background/Objectives: *MYBPC3*, encoding cardiac myosin binding protein C (MyBP-C), emerges as the second candidate gene to study genetic cases of hypertrophic cardiomyopathy (HCM). We thoroughly analyzed a dataset comprising pathogenic *MYBPC3* variants from the literature between 1995 and 2017, focusing on missense variants and their possible stability effect.

Methods: We generated a database of pathogenic variants from the literature and only missense variants (40%, 246 of 603) were considered in this study. Regarding the protein structure, we selected the structure defined by AlphaFold2. Stability was evaluated using the FoldX Program. Protein stability was calculated using FoldX's stability command and ΔΔG values were estimated as the difference between the energy of the wild-type protein and the average of five replicates for each missense variant. A threshold of 1,6 kcal/mol was considered, and values above this threshold significantly destabilize a protein.

Results: A subset of missense variants in the database was systematically classified and grouped based on the protein position, residue type, interactions with other proteins, correlation with protein domains, and stability. We found a significant stability concern in 39% (97 of 246) of missense variants across the protein domains/regions. In some cases, the analysis set revealed a possible effect on the pathogenicity of the missense variants.

Conclusion: Our results provide insights into the impact of *MYBPC3* missense variants on energy stability and structural characterization of the MyBP-C protein, contributing to a better understanding of the disease mechanisms in HCM.

P16.094.B Enhancing Detection of Low-Frequency SNPs in SARS-CoV-2 through Integrated Sequencing and umiVar Variant Calling

Victoria Cepeda Espinoza[1], *Bryant Gilot*[2], *Casper Groß*[1], *Leon Schütz*[1], *Stephan Ossowski*[1]

[1]*Institute for Medical Genetics and Applied Genomics, Medicine, Tübingen, Germany;* [2]*Wilhelm Schickard Institute for Computer Science, Computer Science, Tübingen, Germany*

Background/Objectives: The rapid emergence of new variants in SARS-CoV-2 highlights the importance of capturing intra-host diversity. Challenges in detecting low-frequency single nucleotide variants (SNVs) arise from errors introduced during reverse transcription, amplification, and sequencing. To overcome these challenges, we utilize an integrated framework that combines (i) Twist BioScience probes with magnetic bead capture for targeted enrichment of SARS-CoV-2, (ii) unique molecular identifiers (UMIs)

for precise PCR and sequencing error correction, (iii) ultra-deep short-read sequencing for high sensitivity, and (iv) our newly developed UMI-aware variant caller, umiVar.

Methods: We simulated clinical samples using binary mixtures of controls synthesized by Twist BioScience, spiked with ultra-high resolution (UHR) material. The experimental process involved active target capture/enrichment, reverse transcription, ligation of UMIs, and Illumina short-read sequencing. The computational process involved error correction using PCR duplicates, a nucleotide-exchange specific error model, and variant calling. UmiVar distinguishes PCR copies of the same DNA molecule based on barcodes and mapping positions, with 3-4 copies needed for good error correction.

Results: Compared to existing variant calling methods, umiVar demonstrates superior performance in identifying SNVs at extremely low allele frequencies. Its UMI correction mechanism significantly enhances mapping coverage and accuracy, enabling the detection of newly emerging mutations in the viral intra-host population.

Conclusion: By integrating an advanced sequencing approach with the innovative variant caller umiVar, we have significantly improved the accuracy of low-frequency SNV detection in SARS-CoV-2 compared to existing methods, which promises to advance our understanding of viral evolution and potentially improve public health responses.

P16.096.D Epigenetics in Multiple Sclerosis: a multi-level analysis combining DNA methylation pattern, age acceleration, epigenetic drift using public datasets

rebecca cavagnola[1], *GIULIA NICOLE BALDRIGHI*[1], *davide sacco*[1], *Davide Gentilini*[1;2]

[1]*Università di Pavia, Department of Brain and Behavioral Sciences, Pavia, Italy;* [2]*IRCSS, istituto Auxologico Italiano, Bioinformatics and Statistical Genomics Unit, Milano*

Background: Multiple Sclerosis (MS) is a complex trait disease, causing chronic inflammation of the central nervous system (CNS). Although its etiology remains unknown, it is widely proven that innate and adaptive immune processes contribute to its pathogenesis, interacting with genetic, environmental, and epigenetic factors. Epigenetic alterations might impact on the regulation of gene expression, interfering with biological pathways for brain and immunological development.

In this work, the role of epigenetics in the molecular mechanism underlined by MS was investigated by combining results obtained from public datasets.

Methods: Methylation profiles obtained through Illumina HumanMethylation450K chips and EPIC 850K were downloaded by GEO database, for a total of 439 subjects. For each dataset, genome-wide analysis was performed to identify DNA methylation differences, age acceleration between MS cases and controls. Subsequently, results were combined in a meta-analytical approach. Eventually, stochastic epigenetic mutations were evaluated as an indicator of epigenetic drift and regions characterized by enrichment of methylation defects were prioritized and studied.

Results/Conclusion: Results from differential methylation analyses were meta-analyzed to increase the power of the study. Although no significant genome-wide findings emerged from the aggregation, methylation patterns aligned with specific genes previously associated with MS were observed. Analysis of rare epivariation reveled interesting insights to understand plausible pathogenesis factors and therapeutic targets. This research might help in understanding the mechanism under the regulation of the transcription in such complex trait diseases.

P16.097.A TandemTwister, a rapid and universal tool for genotyping tandem repeats across all long-read sequencing technologies.

Lion Ward Al Raei[1;1], *Maryam Ghareghani*[1], *M-Hossein Moeinzadeh*[1], *Nico Alavi*[1], *Martin Vingron*[1], *Jakob Hertzberg*[1]

[1]*Max Planck institute for molecular genetics, computational molecular biology, Berlin, Germany*

Background: Tandem repeats (TRs) are parts of the genome sequence consisting of consecutively repeated units with polymorphic copy numbers and mutations in repeat units. They have been used in DNA fingerprinting for their hyper variability in the population. They have also been associated with complex traits and various genetic disorders, including neurodegenerative disease and developmental disorders. Having a fast and scalable tool for accurately genotyping these variants is indeed essential for understanding their functional impacts, phenotype and disease-association studies.

Methods: We developed TandemTwister, a novel algorithm written in c++, as a highly scalable and parallelized tool for the genotyping of copy numbers in tandem repeats.

Results: We evaluated the performance of TandemTwister on different sequencing technologies in the Ashkenazim trio on a set of ~900k GIAB's tandem repeat region annotations. For each Hifi sample, TandemTwister ran in ~5 minutes on 32 cpu cores, with 99,5% recall and 93.1% mendelian consistency and 99.1% considering an off-by-one error. In addition, we genotyped tandem repeat profiles of the HGSVC2 cohort of 35 assembled genomes from different populations and analysed inheritance patterns and haplotype blocks of tandem repeats in the three trio sets. Furthermore, we validated the ability of TamdemTwister to detect pathogenic repeat expansions in a cohort of 31 samples with neurodegenerative and developmental disorders.

Conclusion: TandemTwister is an accurate scalable tool for genotyping tandem repeats. It is the fastest genotyping tool up to date suited for all long-read sequencing technologies as well as assembled genomes.

Conflict of Interest: None declared

P16.098.B Removing array-specific batch effects in GWAS mega-analyses by applying a two-step imputation workflow

Mohammed Nasr[1;2], *Alexander Teumer*[1;2], *Eva König*[3], *Christian Fuchsberger*[3], *Sahar Ghasemi*[4], *Grabe Hans*[1;5], *Henry Völzke*[5;6], *Uwe Völker*[2;7]

[1]*University Medicine Greifswald, Department of Psychiatry and Psychotherapy, Greifswald, Germany;* [2]*Deutsches Zentrum für Herz-Kreislauf-Forschung (DZHK) e.V., Berlin, Germany;* [3]*Institute for Biomedicine, Eurac Research, Bolzano, Italy;* [4]*Institute of Genetic Epidemiology, Medical Center – University of Freiburg;* [5]*German Center for Neurodegenerative Diseases (DZNE), Greifswald, Germany;* [6]*Institute for Community Medicine, University Medicine Greifswald, Greifswald;* [7]*Interfaculty Institute for Genetics and Functional Genomics, University Medicine Greifswald, Greifswald*

Background/Objectives: Combining individual-level data in genetic association studies (mega-analyses) increases statistical power for identifying genetic effects underlying diseases. Batch effects occurring when combining imputed genotypes of different

array-type are a major limitation. Here, we developed a two-step imputation workflow, to overcome the array-type bias.

Methods: We included 8189 individuals genotyped altogether on three different array types (Illumina Omni 2.5, Illumina GSA, and Affymetrix SNP 6.0). In the two-step imputation, array-specific reference panels were designed for the first imputation step and subsequently imputed against the 1000GenomesPhase3 reference panel. We compared the results of the combined standard array-specific imputation (reference) against a one-step imputation using the intersection of variants of the included array and our two-step imputation. Batch effects were assessed using the first 20 genetic principal components of the combined sample after the final imputation. The performance of the different approaches was evaluated by comparing the imputation quality R2 value and the deviation of minor allele frequency (MAF).

Results: The one-step approach included 58,091 genotyped variants for imputation. In the two-step design, the intermediate imputation resulted in 2,128,598 autosomal variants used as input for the 1000Genomes imputation. Unlike the standard imputation, no batch patterns occurred in both the one-step and the two-step imputation workflow. Our two-step imputation outperformed the one-step approach by an 18% higher median R2 and a lower median MAF deviation.

Conclusion: Our new workflow removing batch effects will foster mega-analysis of different arrays for analysing genome-wide data and genetic scores using common and low-frequency variants.

P16.099.C Assessing the relative power of constraint metrics in variant prioritisation for rare-variant association testing

Barney Hill[1], *Nikolas Baya*[1], *Frederik Lassen*[1], *Duncan Palmer*[1], *Cecilia Lindgren*[1]

[1]*University of Oxford, Big Data Institute*

Background/Objectives: Recent rare-variant association studies have unveiled numerous gene-phenotype associations within the human exome. These associations are enabled by set-based testing applied to prioritised collections of variants with evidence of pathogenicity. As such, our power to detect significant associations is limited by our ability to accurately predict such damaging variations.

Methods: We aim to map missense variants in the UK Biobank onto their canonical protein sequences to then apply protein variant effect predictors such as EVE and Tranception to classify damaging missense variants. First, we evaluated the performance of these classifiers by comparing the number of significant burden tests across selected phenotypes in the UK Biobank 450K exome sequence dataset. Second, we compared the overlapping annotation sets with the existing ClinVar pathogenic labeled missense variants.

Results: EVE and Tranception successfully replicated almost all existing associations and increased the total number of associations across a wide range of phenotypes. The precision of both EVE and Tranception, when compared against ClinVar, was 68% and 57% respectively, significantly outperforming the 47% precision achieved by using PP3 moderate and/or SpliceAI > 0.2.

Conclusion: Our findings demonstrate that the use of protein fitness scores can significantly improve the prediction accuracy of damaging missense variants, enabling more powerful gene association tests. We anticipate that the continued development of methods integrating protein structural prediction into variant classification will further enhance accuracy and boost our ability to detect gene-phenotype associations.

P16.100.D Metadata-guided Feature Disentanglement for Training Robust Functional Genomics Models

Remo Monti[1;2], *Alexander Rakowski*[1], *Viktoriia Huryn*[2], **Marta Lemanczyk**[1], *Uwe Ohler*[2;3], *Christoph Lippert*[1;4]

[1]*Hasso Plattner Institute, University of Potsdam, Digital Engineering Faculty, Potsdam, Germany;* [2]*Max-Delbrück-Center for Molecular Medicine in the Helmholtz Association, Berlin Institute for Medical Systems Biology, Berlin, Germany;* [3]*Humboldt University, Departments of Biology and Computer Science, Berlin, Germany;* [4]*Hasso Plattner Institute for Digital Health, Icahn School of Medicine at Mount Sinai, New York, United States*

Background/Objectives: With high-throughput technologies, genomics datasets grow rapidly in size, including functional genomics datasets. This allows training large Deep Learning (DL) models to predict epigenetic readouts, such as protein bindings or histone modifications, from genome sequences. Large datasets come at a price of data consistency, aggregating results from studies with varying experimental conditions. While this can be beneficial, as it allows studying the effects of different biological conditions, it can also introduce unwanted biases from confounding experimental factors.

Methods: We propose Metadata-guided Feature Disentanglement (MFD) - a DL approach to disentangle biologically relevant features from potential technical biases. MFD incorporates target metadata into model training by conditioning weights of the model output layer on different experimental factors. It then separates the factors into disjoint groups and enforces independence of the corresponding feature subspaces with an adversarially learned penalty. We train MFD on human genome data to predict peak calls from ENCODE experimental tracks, and we demonstrate its impact on model interpretability and downstream task performance on independent data.

Results: Disentangling biological from technical MFD features improves classification of enhancer sequences on FANTOM5 and Vista data, achieving comparable performance to a non-interpretable baseline. Furthermore, MFD features lead to higher enrichment of rare and eQTL variants in gnomAD and GTEx datasets than the baseline.

Conclusion: The metadata-driven approach combined with disentanglement of feature subspaces allows for better model introspection, by connecting latent features to experimental factors, without compromising, or even improving performance in downstream tasks.

P16.101.A COMET: A comprehensive Python module for community detection in biological networks

Nicolas Ruffini[1], *Susanne Gerber*[2]

[1]*Leibniz-Institut für Resilienzforschung, Mainz, Germany;* [2]*Institute of Human Genetics, University Medical Center Mainz, Mainz, Germany*

Background:

Complex biological systems are characterized by intricate networks of protein-protein interactions (PPIs) that underlie

various physiological and pathological processes. Understanding the organization and function of these networks requires advanced computational tools that can dissect these interactions into manageable subcommunities.

Methods: COMET, a comprehensive Python module, has been developed to meet this need. It incorporates the Louvain and Leiden algorithms for efficient subcommunity detection within biological networks across different organisms. The module utilizes the STRING database to access extensive gene network connections, offering researchers the flexibility to analyze PPIs based on physical interactions, textual evidence, or user-defined thresholds.

Results: COMET enables a nuanced exploration of multi-omics data, providing insights into the intricate organization of biological networks. Through its advanced algorithms and the integration of the STRING database, it allows for the detailed analysis of PPIs. The addition of plotting functions significantly aids in the interpretation of data, offering clear, visual representations of the detected subcommunities and their interactions. This feature not only simplifies the complexity inherent in biological data but also aids in the dissemination of findings to a broader audience.

Conclusion: The COMET module represents a powerful tool for the analysis of biological networks, facilitating the detection of subcommunities and enhancing the interpretability of complex biological data through comprehensive plotting capabilities. By offering a user-friendly approach to dissecting multi-omics data, COMET aids researchers in uncovering specific molecular pathways and mechanisms, advancing our understanding of complex biological systems.

Consortium: The German Human Genome-Phenome Archive

Background: As human omics data expands, the requirement for data management is to facilitate secondary use. Therefore the German Human Genome-Phenome Archive (GHGA), within the federated European Genome-Phenome Archive (FEGA), is developing a scalable and secure IT infrastructure for Germany, an ethico-legal framework to handle omics data in a data-protection-compliant but open and FAIR manner, a harmonized metadata schema, and standardized workflows to process all incoming omics data.

Methods: We are building upon the nf-core and nextflow community to build NGS analysis workflows for all incoming data modalities such as nf-core/SAREK. GHGA enables the creation of harmonized and standardized NGS resources across datasets and projects by maintaining and developing workflows, creating runtime configurations for each data modality with stable identifies, and continuously evaluating the performance.

Results: In collaboration with the nf-core community and beyond, GHGA is maintaining and co-developing six workflows. To evaluate the performance of the workflows GHGA together with the German NGS Competence-Network developed a continuous benchmarking framework: NCBench. GHGA is creating a runtime configuration to uniformly process NGS data while guaranteeing the highest standards and quality of the workflows.

Conclusion: By maintaining scalable, reproducible, and continuously benchmarked workflows, GHGA will create a harmonized and standardized NGS data resource ready to be used by the German research community. Such a harmonized resource will enable cross-analysis of projects and population-scale studies, promote new collaborations and research projects, and establish the foundation for developing a German-based variant frequency database.

Consortium: Bioinformatics Working Group of the German Consortium for Hereditary Breast & Ovarian Cancer

Background/Objectives: The influence of numerous genetic loci on cancer risk can be represented as a polygenic risk score (PRS). The breast cancer (BC) PRS is included in the individual BC risk prediction via the CanRisk interface. Reproducibility of expected allele frequencies (AFs) at the respective loci is essential to calculate a legitimate PRS. Next-generation sequencing (NGS) is often used for genotyping, which revealed several challenges to be considered.

Methods: Five centers of the German Consortium on Hereditary Breast and Ovarian Cancer (GC-HBOC) provided NGS data of 324 unique BC PRS loci (PRS sets BCAC 313, BRIDGES 306). PRS loci were analyzed with different variant callers and settings, and the AFs per GC-HBOC center were determined. We compared expected AFs of the BC PRS sets against GC-HBOC center-observed and population database-derived AFs. Potential work-arounds such as alternative alleles in linkage disequilibrium were evaluated.

Results: In gnomAD v3, 4 of 324 BC PRS loci were missing, AFs of further 24 loci deviated from the PRS-expected AF, and for 39 loci, technical artifacts were reported. Data from GC-HBOC centers showed remarkably deviating AFs for 16 to 22 loci, thereby affecting final BC risk prediction. Both sequencing approach and variant caller, including mode of calling, influenced the results.

Conclusion: Prior to diagnostic use, sequencing quality of PRS loci and associated AFs need to be evaluated and optimized. Further, PRS sets developed based on SNP array data have to be re-evaluated in regards to the PRS loci and reproducibility of expected AFs.

P16.104.D Integrating Nanopore Sequencing: Unveiling High-Dimensional Chromatin Dynamics through Epigenetic Assays

Alejandro Ceron Noriega[1], *Anne Julia Sarah Kerber[1], Stanislav Sys[1], Nicolò Alagna[1], Tamer Butto[1], Susanne Gerber[1]*

[1]JGU- University Medicine, Institute of Human Genetics, Mainz

Consortium: SFB1551

Background/Objectives: Our research delves into the regulation of gene function within chromatin structures by integrating epigenetic assays and Nanopore sequencing, overcoming limitations associated with short-read technologies. Nanopore's unique ability to conduct three experiments simultaneously in a single flow cell contributes to comprehending high-dimensional chromatin folding in genomics and epigenetics. Despite the growing momentum in epigenetic sequencing assays, the integration of Nanopore sequencing remains unestablished. Our goal is to bridge this gap, merging epigenetic assays with Nanopore sequencing, a crucial step for understanding chromatin dynamics in a high-dimensional context.

Methods: We propose an integrated approach that combines library preparation with Nanopore sequencing for ATAC-seq, CUT&tag, and Pore-C assays. Leveraging our expertise, we focus on developing a workflow that integrates this information. Our methodology involves coupling neural differentiation cell populations with Pore-C, ATAC-seq and CUT&tag assays, combined with machine learning approaches that address challenges such as upsampling low-quality matrices and cell type identification. Integrating data from three trials significantly contributes to understanding high-dimensional chromatin folding.

Results: Successful implementation of the initial trials of ATAC-seq, CUT&tag, and Pore-C has been achieved. Ongoing work involves fine-tuning the pipeline for real-time data analysis of selected epigenetic assays.

Conclusion: Our approach demonstrates the feasibility of long-read epigenetic sequencing assays, advancing our understanding of chromatin dynamics in a high-dimensional genomic and epigenetic context.

Consortium: PEDIGREE

Background: Multiple Sclerosis (MS) is a multifactorial disease. Only 5% of MS patients develop the disease before 18 years (Pediatric MS). PedMS offers a unique opportunity to gain clinical, biological, environmental information in proximity to the actual disease onset. Our study aimed to identify genetic and environmental components associated to PedMS by performing multi omics data integration.

Methods: After recruiting an Italian multicentric cohort, we performed GWAS (Illumina GSA and HRC imputation), metagenomic (16S sequencing) and methylation (Illumina Epic Array v2) analyses on PedMS (up to 460) and matched healthy controls (HC,

up to 1693). We integrated data following either an early strategy with MOFA (omics matrices are concatenated in a single one containing features from all omics for co-occurrent samples) and a late one (each omics is analysed independently, and the most significant results are merged in the end).

Results: Late integration of the most significantly associated data from GWAS (1916 SNPs with $p < 1 \times 10^{-5}$) and 1382 differentially methylated regions from epigenetic analyses identified an overlap between 14 SNPs and 4 significant DMRs. We also investigated the co-localization of those SNPs and DMRs with 200 MS associated loci known from literature, identifying 2 significant overlaps for each omics.

Conclusion: We have analysed several omics individually underlining differences between PedMS and HC. We have already performed a preliminary late integration analysis and we are combining genetic, epigenetic and metagenomic data by an early integration strategy to identify latent factors that could explain PedMS pathogenesis.

P16.106.B Enhancing variant prioritisation pipeline - Integrating PEDIA with VarFish via plugin-driven approach

Meghna Ahuja Bhasin[1], *Pietro Incardona*[1;2], *Alexej Knaus*[1], *Alex Schmid*[1], *Peter Krawitz*[1], *Tzung-Chien Hsieh*[1], *Manuel Holtgrewe*[3], *Miriam Elbracht*[4]

[1]*Institute for Genomic Statistics and Bioinformatics, Bonn, Germany;* [2]*Core Unit for Bioinformatics Data Analysis, Bonn, Germany;* [3]*CUBI – Core Unit Bioinformatics, Berlin Institute of Health, Berlin, Germany;* [4]*Institute for Human Genetics and Genomic Medicine, RWTH Aachen*

Background: Variant prioritisation is a critical step in genomic analysis, crucial for identifying disease-associated genetic variations. Case Annotation and Disorder Annotation (CADA) and GestaltMatcher algorithms quantify phenotypic similarity throughout clinical features (HPO) and portrait photo analysis providing the user with applicable scores. PEDIA combines these scores with molecular information into a gene-based score that can be used for variant prioritisation. Here, we integrate PEDIA into VarFish using a plugin-based approach and improve the PEDIA score to be variant-based rather than gene-based. Performance was assessed in a multi-center study of TNAMSE.

Methods: Whole exome sequencing data from 163 patients with rare diseases were imported into VarFish and filtered by frequency, impact, and quality. Molecular pathogenicity was weighted using CADD scoring, while GestaltMatcher provided facial scores. Phenotypic scoring was performed with the latest CADA version with improved performance. Various score combinations were evaluated. The integration was made extensible using Django CMS plugin-based methodology. Further benchmarking was done with tools like LIRICAL, Amely, and Exomizer.

Results: PEDIA achieved a top-10 accuracy of 83%, significantly higher than CADD and CADA scores alone. Integrating GestaltMatcher and PEDIA into VarFish demonstrated the platform's capability to analyse medical images alongside variants. Extensive benchmarking showed superior performance of PEDIA over other freely available tools like LIRICAL, Amely and Exomiser.

Conclusion: The integration of PEDIA into VarFish offers a potent synergy for comprehensive variant prioritisation, with variant-based scores improving usability and efficiency for clinicians.

Grants: No external grants or funding were received for this study.

P16.107.C Multi-omics integration reveals (patho)physiological gene regulation in human neural crest cell differentiation

Michael Eibl[1], *Susanne Theiss*[1], *Ayat Ahmed*[1], *Hjorleifur Einarsson*[2], *Robin Andersson*[2], *Magdalena Laugsch*[1]

[1]*Institute of Human Genetics, Transcriptional Regulation in Developmental Disorders, Heidelberg, Germany;* [2]*Copenhagen Biocenter, Department of Biology, University of Copenhagen, Computational and RNA biology, København, Denmark*

Background/Objectives: Several neurodevelopmental disorders are associated with dysregulation of both the central nervous system and neural crest cells (NCC). This also applies to Bosch-Boonstra-Schaaf Optic Atrophy Syndrome (BBSOAS), caused by mutations in the transcription factor NR2F1, which is a driver of neurodevelopment and NCC differentiation. We aim to elucidate the global transcriptional landscape governed by NR2F1 within the overall regulatory circuitry of NCC by multi-omics integration and network analysis to help us understand pathomechanisms and advance molecular diagnosis.

Methods: We modelled neural crest development by differentiating human induced pluripotent stem cells (hiPSC) into NCC. We then performed Cap Analysis of Gene Expression (CAGE)-, Assay for Transposase-Accessible Chromatin (ATAC)-sequencing and NR2F1 chromatin immunoprecipitation followed by DNA-sequencing (ChIP-seq) at four time points of the differentiation. Subsequently, regulatory networks were inferred from paired expression and chromatin accessibility data (PECA2).

Results: We reproduced known and revealed novel transcription factor (TF)-target gene (TG) relationships underlying NCC differentiation. Predicted NR2F1 target genes were validated with corresponding NR2F1 ChIP-seq data. In addition, we identified active enhancers among the predicted regulatory elements (REs) through enhancer RNA (eRNA) expression analysis. Several SNPs associated with diseases such as orofacial clefting could be mapped to these REs.

Conclusion: Our multi-omics integration approach allows prediction of high-confidence gene regulatory relationships in the course of human NCC differentiation. We demonstrated the power of this approach by validating these networks with ChIP-seq data for the key driver of the neurodevelopmental disorder BBSOAS and showing that several disease variants can be mapped to the network.

P16.108.D Bringing together next-generation association studies and fine-mapping by leveraging genetic variant pleiotropy to improve our understanding of human complex traits

Martin Tournaire[1], *Yves Rozenholc*[1], *Marie Verbanck*[1]

[1]*Université Paris Cité, UR 7537 BioSTM, Biostatistique, Traitement et Modélisation des données biologiques, Paris, France*

Background/Objectives: Using molecular phenotypes (*e.g.* expression quantitative trait loci) to fine-map the associations between genetic variants and complex traits from genome-wide association studies (GWAS) seems highly limited because of their very small overlap. Taking the opposite view to current methods, we propose to leverage pleiotropy, occurring when a genetic

variant affects at least two traits, which is thought to play a central role in the genetic architecture of complex traits.

Methods: By conceptualizing 5 distinct biological mechanisms leading to observed pleiotropy (direct, polygenicity-mediated, confounding-mediated, trait-mediated, linkage disequilibrium), we have developed PleioVar, an algorithm to detect both direct and pleiotropic effects of genome-wide variants. PleioVar derives variant effects from an integrative Mendelian Randomization method (*i.e.* LHC-MR) modeling pleiotropy and allows to disentangle the variant-level effects using Gaussian mixture models. To assess the performances of PleioVar, we built a comprehensive network GWAS simulation framework encompassing multiple complex scenarios. Then, using GWAS summary statistics from UK Biobank, we used PleioVar to disentangle the variant effects on a set of heritable traits and diseases.

Results: On simulations, PleioVar successfully predicted variant effects with high accuracy, and simulated genetic variants were correctly clustered as displaying the proper type of pleiotropy. Using GWAS summary statistics from the UK Biobank, genetic variant effects were identified by PleioVar, leading to a genome-wide map of variant-trait association with promising results.

Conclusion: This method, designed to map genetic variants to traits by leveraging pleiotropy, could help better understand the human genetic architecture of complex traits and diseases.

P16.109.A GROVER: Building a language model of the human genome

Melissa Sanabria[1;1], *Jonas Hirsch*[1], *Anna Poetsch*[1]

[1]*Technische Universität Dresden, Dresden, Germany*

Background/Objectives: Large Language Models trained without explicit supervision, have enabled the generation of coherent and syntactically accurate text in natural language. While DNA is very analogous to language through sequence structure that resembles grammar, syntax, and semantics, a key distinction lies in the absence of a conventional concept of words.

Methods: We have built GROVER (Genome Rules Obtained Via Extracted Representations), a foundation DNA language model with an optimized vocabulary for the human genome, trained with no additional information besides sequence.

Results: Analyzing GROVER's learned representations, we observed that at the word level it primarily learns information related to their frequency, GC content, AG content, AC content, and length. Some tokens are almost exclusively localized in repeats, while the vast majority are distributed over different genome elements. The model also learns context and lexical ambiguity. Annotation of repeats and chromatin colors shows the ability to extract functional annotations from the genome such as orientation of LINEs and ALUs, satellites, and promoters. We also show possible applications on a selection of different tasks, including prediction of DNA-protein binding ($F1 = 0.75$ identifying CTCF binding sites across different cell types).

Conclusion: DNA language models like GROVER can be used to investigate individual predisposition to disease and treatment responses, which to a large extent is encoded in the patients' general and somatic genome. It has the potential to push progress in personalized medicine and its transparent design allows insight into sequence dependent molecular biological mechanisms.

P16.110.B Identifying non-coding somatic cancer driver mutations using sequence-based models

Carlos Urzua-Traslaviña[1;2], *Tijs van Lieshout*[1;2], *Lucía Barbadilla-Martínez*[2;3], *Noud Klaassen*[2;4], *Vinícius Franceschini-Santos*[2;4], *Jeroen de Ridder*[2;3], *Bas van Steensel*[2;4], *Lude Franke*[1;2]

[1]*University Medical Center Groningen, Groningen, Netherlands;* [2]*Oncode Institute, Utrecht, Netherlands;* [3]*UMC Utrecht, Utrecht, Netherlands;* [4]*The Netherlands Cancer Institute (NKI), Amsterdam, Netherlands*

Background/Objectives: With pending availability of large quantities of whole genome sequencing data, there is an urgent need to identify functional non-coding somatic variants in cancer. The indistinguishability of passenger variants pushes existing methods to require large sample-sizes to identify regions enriched for somatic mutations. Recently, several sequence-based models have become available that can make inferences on the functional consequences of non-coding single nucleotide variants (SNVs). We hypothesize the promoter regions of potential driver genes could be enriched for such 'functional' somatic variants in tumor genomes.

Methods: We collected publicly available somatic SNV calls from ICGC located around the transcription start sites of protein coding genes. Using two-tailed Wilcoxon rank test, we then compared the predictions of observed mutations against two background models: 1) alternative alleles at the same base pair positions and 2) nearby mutations (15bp) in the same region. We evaluated regions with the following strategy: We first used a new fast sequence-based model, trained on promoter activity assay data of K562 cells to generate a discovery set of regions which we then replicated with state-of-the-art model Borzoi.

Results: The well-known TERT promoter showed the strongest 'functional' non-coding somatic mutation enrichment with both models. We also identified several promotor regions of other genes that showed strong mutation enrichment. We are currently following up on these findings.

Conclusion: By applying sequence-based models to WGS data it is possible to identify regions enriched for non-coding somatic mutations.

Grants: L.F. is supported by NWO (ZonMW-VICI 09150182010019), the Oncode Institute, and Saxum Volutum.

P16.111.C More accurate and faster expression and splicing methods improve DROP, the Detection of RNA Outliers Pipeline

Felix Brechtmann[1], *Andrew Behrens*[1], *Ines Scheller*[1], *Cristian Sandu*[1], *Nicholas Smith*[1], *Vicente Yépez*[1], *Julien Gagneur*[1;2], *Christian Mertes*[1;2]

[1]*TUM School of Computation, Information and Technology (CIT), Department Informatik und Mathematik, Garching bei München, Germany;* [2]*Klinikum rechts der Isar der Technischen Universität München, München, Germany*

Consortium: German Human Genome-Phenome Archive (GHGA)

Background/Objectives: RNA-seq is a powerful approach to prioritise candidate genes for individuals affected with a rare genetic disorder and increases diagnostic yield by approximately 15%. DROP is a widely used workflow for RNA-seq-based diagnostics with a growing user base worldwide. Learning from

its application in many large-scale projects, such as Solve-RD, we updated DROP and integrated recently developed approaches, accelerating the detection of aberrant events in RNA-seq data.

Methods: We benchmarked the optimal hard thresholding procedure to determine the optimal latent space dimension, introduced by Gavish and Donoho, on several RNA-seq datasets and implemented it in OUTRIDER. We further integrated FRASER 2.0 for splicing analyses and extended QC measures, including a sex verification step. In addition, we are porting DROP to the workflow framework, Nextflow, adhering to the nf-core standards ensuring portability, reproducibility, and GA4GH compliance.

Results: DROP accelerates the adoption of RNA-seq in human genetic centres and has demonstrated success in expediting rare disease diagnoses. OUTRIDER's updates reduce the compute time for the expression outlier analysis by 15-fold. FRASER 2.0 uses the new intron Jaccard index that reduces the false positives by 8-fold while maintaining high sensitivity and simplifying the splicing analysis overall. By porting DROP to nf-core/Nextflow, we co-develop with the German Human Genome-Phenome Archive (GHGA) a containerized, scaleable, and cloud-ready workflow.

Conclusion: These improvements to DROP, and its integration as a Nextflow pipeline into GHGA's workflows, enable healthcare professionals and researchers to fully utilise RNA sequencing in rare disease diagnostics.

Grants: German Research Foundation (DFG) 441914366 (NFDI 1/1).

P16.112.D Integrating multigenerational sequencing data to enhance de novo variant detection

Laurens Hannes[1;2], *Kato Milis*[2], *Jeroen Breckpot*[1;2], *Alejandro Sifrim*[2]

[1]*UZ Leuven, Center for Human Genetics, Leuven, Belgium;* [2]*KU Leuven, Department of Human Genetics, Leuven, Belgium*

Background/Objectives: Adoption of genome sequencing in clinical practice has steadily increased, bringing forth a 60-fold increase in detected variant numbers compared to exome sequencing. As a result, there is a proportional increase in false variant calls, complicating the seemingly straightforward detection of de novo variants.

Methods: We present SeptoDeNovo, an adapted version of the TrioDeNovo model, integrating grandparental sequencing data to re-evaluate de novo variant calls and detect parental mosaicism. We benchmarked our model using simulated genome sequencing data at 30X coverage for 12 pedigrees with each 4 grandparents, 4 parents and an index, adding a known set of de novo variants to each index. To evaluate the robustness of the technique we also downsampled grandparental data to 15X coverage. We also compared the performance of SeptDeNovo to other tools, such as TrioDeNovo, DeNovoGear and DeNovoCNN, estimating the true and false positive rates of each approach.

Results: SeptoDeNovo outperformed TrioDeNovo and other widely used de novo callers, DeNovoGear and DeNovoCNN in recalling true variants while producing less false positive calls. This increased performance was also observed in scenarios of lower coverage of grand parental data, as well as in cases where less than 4 grandparents were available.

Conclusion: As a higher proportion of the general population will have their genome sequenced over their lifetime, we envision the usage of models like SeptoDenovo to fully leverage the available information and as such improve diagnostic performance.

Grants: KU Leuven internal fund (C24M/19/075)

P16.113.A Novel multi-omics deconfounding variational autoencoders can obtain meaningful disease subtyping

Zuqi Li[1], *Sonja Katz*[2;3], *Vitor Martins Dos Santos*[3;4], *David Fardo*[5], *Peter Claes*[1;6;7], *Edoardo Saccenti*[3], *Kristel Van Steen*[1;8], *Gennady Roshchupkin*[2;9]

[1]*KU Leuven, Human Genetics, Leuven, Belgium;* [2]*Erasmus MC, Radiology and Nuclear Medicine, Rotterdam, Netherlands;* [3]*Wageningen University & Research, Wageningen, Netherlands;* [4]*LifeGlimmer GmbH, Berlin, Germany;* [5]*University of Kentucky, Lexington, United States;* [6]*UZ Leuven, Medical Imaging Research Center, Leuven, Belgium;* [7]*KU Leuven, Electrical Engineering, Leuven, Belgium;* [8]*University of Liège, GIGA-R Medical Genomics, Liège, Belgium;* [9]*Erasmus MC, Epidemiology, Rotterdam, Netherlands*

Consortium: TranSYS

Background/Objectives: Unsupervised learning, particularly clustering, is crucial for disease subtyping and patient stratification. With the availability of large-scale multi-omics data, clustering algorithms can be empowered by deep learning models, e.g. variational autoencoder (VAE), to exploit the between-individual heterogeneity. However, the impact of confounders—external factors unrelated to the condition, e.g. batch effect and age—on clustering is often overlooked, introducing bias and spurious biological conclusions.

Methods: We proposed four VAE-based deconfounding approaches utilizing multi-omics data: including i) removal of latent features correlated with confounders (XVAE + FS), ii) a conditional variational autoencoder (cXVAE), iii) adversarial training (adv-XVAE), and iv) adding a regularisation term to the loss function (cr-XVAE). Based on real-life multi-omics data from The Cancer Genome Atlas, we simulated various confounding effects (linear, non-linear, categorical, combination) and evaluated each model's performance across 50 repetitions based on reconstruction error, clustering stability, and deconfounding effectiveness ($ARI_{cancerType}$).

Results: We demonstrate a substantial impact of the artificially introduced confounder effect on patient clustering ($ARI_{cancerType} = 0.33$), yet various proposed models effectively mitigated this effect, with cXVAE clearly outperforming other frameworks ($ARI_{cancerType} = 0.66$). cXVAE not only accurately recovers true patient labels but also reveals meaningful pathological associations among cancer types, reinforcing deconfounded representation validity.

Conclusion: The multi-omics deconfounding conditional autoencoder presented in this study has big potential in delivering accurate patient subgrouping in the presence of confounders.

Grants: This study received support from European Union's Horizon 2020 Marie Skłodowska-Curie grant agreement (860895). Gennady V. Roshchupkin supported by the ZonMw Veni grant (Veni 1936320).

P16.115.C Context-Adjusted Proportion of Singletons (CAPS): A robust metric for assessing negative selection and benchmarking variant pathogenicity predictors

Mikhail Gudkov[1], *Loic Thibaut*[2], *Steven Monger*[1], *Debjani Das*[1], *David Winlaw*[3], *Sally Dunwoodie*[1], **Eleni Giannoulatou**[1]

[1]*Victor Chang Cardiac Research Institute, Darlinghurst, Australia;* [2]*Institute for Molecular Bioscience, Saint Lucia, Australia;* [3]*Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, United States*

Consortium: Congenital Heart Disease Synergy Study group

Background/Objectives: Interpreting genetic variants remains challenging, especially for understudied variant classes. Population genetics methods, like the Mutability-Adjusted Proportion of Singletons (MAPS) metric, assess variant effects through population distributions. However, MAPS' sensitivity to the singletons-by-mutability model calibration may lead to biased estimates for specific variant sets. This study introduces Context-Adjusted Proportion of Singletons (CAPS), a novel metric refining MAPS methodology by eliminating the mutability layer, enhancing robustness in assessing negative selection in the human genome. Here, CAPS was employed to benchmark pathogenicity predictors without relying on known pathogenic variant sets.

Methods: CAPs derives the expected level of rare variation on a per-context basis from synonymous variants. For missing contexts, expected proportions of singletons were approximated from intronic variants using probit regression. Leveraging gnomAD genomic data, we benchmarked pathogenicity predictors using CAPS and compared our estimates to ClinVar variant classifications.

Results: CAPS outperforms MAPS, yielding more accurate negative selection estimates. Using CAPS, poorly calibrated predictors were identified, highlighting CADD and REVEL as the best-performing methods, with REVEL exhibiting better calibration. Our findings underscore the importance of cautious predictor integration into variant interpretation pipelines and emphasise biases associated with variant classification.

Conclusion: CAPS emerges as a promising metric for studying negative selection, serving as a valuable benchmarking tool for pathogenicity predictors. This study underscores the need for careful predictor integration and recognition of biases in variant classification, contributing to advancements in genetic variant assessment and interpretation.

Background/Objectives: Analysing the human blood proteome grants us an in-depth look into the health of an individual and opens horizons for the development of novel diagnostic and therapeutic methods. However, affinity-based techniques such as ELISA, which are used for single-protein quantifications, are being replaced by mass spectrometry (MS)-based methods that provide comprehensive results in even small sample volumes. Despite the attractiveness of MS-based workflows, there are prominent issues that need to be addressed, most notably, the abundance of missingness in MS datasets and the lack of cell-type resolution in bulk tissue MS. Therefore, our goal is to develop a pipeline that can impute these missing values and perform cell-type deconvolution from MS blood proteomics data.

Methods: Based on pre-existing MS proteomics datasets and comparative studies on the effectiveness of various mathematical imputation and deconvolution methods, we developed an R-based pipeline built on existing methods, capable of imputing missing protein expression values and with the help of a signature matrix, calculate the proportions of specific cell-types within a given sample.

Results: The pipeline is modular, allowing for customization and sample-specific optimization. Various normalization and data preparation workflows are included. Accuracy can be assessed by comparing with flow cytometry data of the same samples.

Conclusion: Implementing multiple imputation and deconvolution methods, our pipeline can serve as a valuable tool for blood MS proteomics. This enables the characterization of protein abundance in immune cells without needing to isolate them or in samples where sample volume is a limiting factor.

P16.118.B In silico study on the mutation induced conformational changes of vasopressin receptor 2 from a clinical nephrogenic diabetes insipidus case

Chun-Chun Chang[1], *Ting-Yu Hu*[2], *Hao-Jen Hsu*[2]

[1]*Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Department of Laboratory Medicine, Hualien, Taiwan;* [2]*Tzu Chi University, Department of Biomedical Sciences and Engineering, Hualien, Taiwan*

Background/Objectives: Congenital nephrogenic diabetes insipidus (CNDI) is a genetic disorder caused by mutations in arginine vasopressin receptor 2 (AVPR2), rendering collecting duct cells insensitive to the peptide hormone arginine vasopressin stimulation for water reabsorption. The CNDI condition of an 8-month-old male patient was identified with a Valine 279 deletion–mutation in the *AVPR2* gene according to symptoms, family history, and DNA sequence analysis. Mutation in AVPR2 can lead to kidney-related diseases. However, the signaling differences and conformational changes induced by these mutations in AVPR2 remain unclear.

Methods: We utilized molecular dynamics simulations to construct distinct mutant AVPR2 systems, both with and without AVP bound. This approach allowed us to explore how these mutations affect structural dynamics, molecular switches, and internal signal transmission.

Results: Our investigation revealed that mutated systems exhibit dynamic activity that is fundamentally distinct from the wild type. These differences included conformational changes in the transmembrane region and alterations in the molecular switch mechanism. The analysis of signal transduction pathways reveals that the presence or absence of AVP binding introduces variations in signal transmission. The amino acids identified may play a pivotal role in the functional deficits observed in mutations of AVPR2. Our results are also consistent with previous experiments that Tolvaptan may correct the M272R mutation.

Conclusion: Our findings provide a preliminary insight into the activation and inactivation mechanisms of AVPR2 under various mutations, which are valuable insights for future drug development targeting AVPR2.

Grants: This research was funded by the Tzu Chi Foundation (Grant Number: TCIRP109003).

P16.119.C Detection of tissue-border-specific marker genes using spatially resolved transcriptomics

Vincent Hammer[1], *Stephan Ossowski*[1]

[1]*Universitätsklinikum Tübingen – Institut für Medizinische Genetik und angewandte Genomik, Tübingen, Germany*

Background/Objectives: Direct cell-to-cell contact can trigger import developmental processes during organogenesis. Some of the short distance signalling pathways triggered by cell-to-cell contact mediate cell differentiation, proliferation, and structure of whole tissues. A better understanding of the gene expression patterns in these edge regions could improve our understanding of organogenesis and pathogenesis. Using untargeted spatially resolved transcriptomics data, we introduce a pipeline for identifying marker genes for tissue-to-tissue contact, and visualizing the gene expression changes across different timepoints.

Methods: Stereo-seq data of mouse embryos was obtained through the public CNGB sequence archive. Preprocessing was performed using the SAW pipeline. Binning, quality control, clustering, and annotation were performed with Stereopy.

The pipeline first filters the annotated regions by size to reduce noise. Then, spots with different types of tissue in direct contact are detected. These spots are expanded and linked to form edges. The resulting edges are filtered by their length and annotation robustness. Next, the average expression of a gene as a function of distance from these edges are calculated. These expression profiles are then filtered for correlation across replicates. Finally, these expression profiles are visualized and sorted by pattern.

Results: We identified genes with increased transcriptional activity at tissue edges. Sets of genes specific to individual tissue types could be defined. Additionally, changes in the expression patterns of these genes across different timepoints of organogenesis could be traced.

Conclusion: This pipeline offers new insights into the gene activity at tissue borders, and helps understand the transcriptional activity in these regions across distance and time.

P16.120.D Deep Generative Models to improve Polygenic Risk Scores' accuracy and portability across ancestries and admixtures

Andrea Lampis[1;2], *Michela Carlotta Massi*[1], *Andrea Mario Vergani*[1;2], *Matteo Matteucci*[2], *Francesca Ieva*[1;2], *Emanuele Di Angelantonio*[1;3]

[1]*Human Technopole, Italy;* [2]*Politecnico di Milano, Milano, Italy;* [3]*University of Cambridge, United Kingdom*

Background/Objectives: Polygenic Risk Scores (PRSs) hold potential for precision medicine but face limitations, especially in non-Europeans due to historical biases towards European genetic studies. Addressing the challenge of PRS transferability, this study leverages Deep Learning-based generative models to enhance PRS accuracy across diverse populations. We propose a novel approach employing Latent Diffusion Models (LDMs) for generating realistic genetic data across ethnicities, aiming to improve PRS calculation for underrepresented groups and admixed individuals, and offer new insights into disease etiology by analyzing the obtained latent space.

Methods: We trained a LDM with a Variational AutoEncoder (VAE) and a UNet-based denoising model, conditioned on disease presence. Utilizing Coronary Artery Disease (CAD) GWAS summary statistics to select SNPs of interest across populations, we developed population-specific models and a combined model for multiple ethnicities. We assessed model performance by comparing PRS accuracy using generated and actual genetic data, versus state-of-the-art approaches that only combine summary statistics from different cohorts. Additionally, we applied Machine Learning explainability and latent space arithmetic to investigate population-specific disease etiologies.

Results: Analyzing data from 449,557 controls and 37,541 CAD subjects from UKBiobank, our models achieved high reconstruction quality, with an average error rate of 20/2048 SNPs. Traditional PRSs calculated with our method showed improved performance over baseline methods, especially in non-European and admixed populations, while enriching results with insights from latent space analyses.

Conclusions: Our approach improves PRS transferability and accuracy across ethnicities, addressing privacy concerns and enhancing genetic research inclusivity, laying groundwork for disease genetic exploration in diverse groups.

P16.121.A GWAS of longitudinal changes in bodysize and their relationships with childhood and adulthood adiposity in UK Biobank

Yelyzaveta Poliakova[1;2], *Vincent Pascat*[3], *Yevheniya Sharhorodska*[4;5], *Zhanna Balkhiyarova*[4;6;7], *Marika Kaakinen*[2], *Marjo-Riitta Järvelin*[2;8], *Inga Prokopenko*[4;6]

[1]*Lviv State Regional Clinical Perinatal Center, Department of Newborn Screening, Lviv, Ukraine;* [2]*Imperial College London, School of Public Health, London, United Kingdom;* [3]*University of Lille, EGID, Lille, France;* [4]*University of Surrey, Department of Clinical & Experimental Medicine, Guildford, United Kingdom;* [5]*Imperial College London, Vascular Science of the National Heart and Lung Institute, London;* [6]*University of Surrey, People-Centred Artificial Intelligence Institute, Guildford, United Kingdom;* [7]*Imperial College London, Department of Metabolism, Digestion and Reproduction, London;* [8]*University of Oulu, Oulu, Finland*

Background. Genome-wide association studies (GWAS) identified hundreds of DNA variants contributing to higher child-/adulthood overall body adiposity, body-mass index (BMI) and central obesity, waist-to-hip ratio (WHR) in adults. Such cross-sectional estimates overlook regulation of longitudinal bodysize changes (LBC) through the lifecourse.

Methods. We performed GWAS of LBC from childhood (10y.) to adulthood BMI, grouped into thin, average, and plump/obese. We implemented linear mixed-models (BOLT-LMMv2.3) in 400,429 UK Biobank Europeans with both non-missing measures. Hierarchical clustering was employed to group the associated loci in relation to respective cross-sectional adiposity measures and WHR, using GWAS meta-analyses (GIANT consortium).

Results. We identified 111 independent significant LBC signals (P-value$\leq 5 \times 10^{-8}$). Of those, 66 LBC signals overlapped with established adulthood BMI loci, including *FTO, SEC16B, ADCY3, TMEM18, MC4R, GPRC5B, GPR139, RPL31P12, MAP2K5*. Additional 24 LBC signals were shared with childhood bodysize only, while further 18 LBC loci affected all three phenotypes. All three novel loci, at *RFPL4AP3, PCLO*, and *RASA4*, and six shared with BMI were established for educational attainment, bipolar or major depressive disorder, and T2D. Clustering highlighted that most LBC loci had "set-point" body size effect, where higher overall adiposity was related to lower central adiposity, while only 14 related to change from "thinner" childhood to "plumper/obese" adulthood.

Conclusion. Our investigation transcends traditional analyses of cross-sectional BMI and offers new insights into LBC trajectories genetics. We report that genetic predisposition to LBC from

childhood to adulthood does not fully overlap with respective cross-sectional measures. LBC processes highlight enrichment with mental health.

P16.122.B Unraveling complex chromosomal rearrangements: a clinical perspective on efficient enumeration in karyotype graphs

Barbara Poszewiecka[1], *Krzysztof Gogolewski*[1], *Anna Gambin*[1]

[1]*Faculty of Mathematics, Informatics, and Mechanics, University of Warsaw, Institute of Informatics, Warszawa, Poland*

Background/Objectives: With the evolution of sequencing technologies, the need to decipher genome plasticity resulting from various chromosomal rearrangements, particularly those involving multiple breakpoints, has become increasingly important. The main objective is to address the challenge of efficiently enumerating the rearrangements scenarios of Karyotype Graphs (PMID: 31842730), crucial for understanding complex chromosomal rearrangements observed in genomes.

Methods: To handle complex chromosomal rearrangements, we have developed an algorithm leveraging the Karyotype Graph model. This multigraph provides an efficient representation of sets of breakpoints and genomic segments. In scenarios lacking telomere-free connected components, the decomposition yields exclusively linear chromosomes. Our method ensures a structured enumeration of diverse chromosomal rearrangements offering a concise yet comprehensive understanding of potential scenarios with minimal cardinality.

Results: Our approach, utilizing connectivity and witness certificates representing the current state of the recursion, efficiently handles edge multiplicity decrements, avoiding undesirable graph disconnections. With a polynomial time complexity, it facilitates the exploration of diverse rearrangement scenarios, as illustrated by a case study involving a proband with congenital chromoanasynthesis in a patient harboring such alterations from Nazaryan-Petersen et al. (2018) study (PMID: 30419018). Notably, our algorithm identifies additional rearrangement scenarios beyond those initially presented, underscoring its effectiveness in handling complex genomic data.

Conclusion: Our algorithm offers a promising path for further development and clinical application, including enhancements for circular derivative chromosomes and integration of optical genome mapping data. It contributes to understanding genomic rearrangements and their clinical implications in various pathological conditions, particularly in complex cancer genomes.

P16.123.C A machine learning tool to predict gene-phenotype associations

Ana Santos-Pereira[1;2], *Joana Vilela*[1;2], *Ana Rita Marques*[1;2], *João Xavier Santos*[1;2], *Célia Rasga*[1;2], *Astrid Vicente*[1;2], **Hugo Martiniano**[1;2]

[1]*Instituto Nacional de Saúde Doutor Ricardo Jorge, Departamento de Promoção da Saúde e Prevenção de Doenças não Transmissíveis, Lisboa, Portugal;* [2]*Instituto de Biosistemas & Ciências Integrativas, Faculdade de Ciências da Universidade de Lisboa, LIsboa, Portugal*

Background/Objectives: Driven by rapid advancements in DNA sequencing techniques, both speed and cost have plummeted, propelling a significant shift in clinical diagnosis from targeted gene panels to whole-exome and whole-genome sequencing (WES/WGS). However, a major hurdle persists: effectively interpreting the vast pool of variants generated by WES/WGS, which presents a multitude of potential diagnostic candidates. While recent approaches using gene-phenotype association algorithms offer promise, they often struggle with limited data, hindering their effectiveness. To address these limitations, we developed a novel machine learning-based method to determine gene-phenotype associations leveraging data from large-scale, publicly available databases.

Methods: Our methodology consists on a data-driven approach, based on the use of graph machine learning methods. Graph Machine learning techniques were be used to predict ranked gene-disease associations for all combinations of genes and Human Phenotype Ontology (HPO) terms. These rankings form the basis for assessing the putative association of genetic variants to the disease or phenotype of interest.

Results: We show that our method improves the identification of pathogenic variants in the ClinVar database, when compared to recent tools, such as Exomiser, GADO, Phen2gene and Phenolyzer.

Conclusion: We developed a machine learning based method to determine gene-phenotype associations using data from publicly available databases. This allows us to prioritize candidate variants with greater accuracy and interpretability, potentially leading to faster and more precise diagnosis.

P16.124.D Integrating proteomic networks for comprehensive health assessment: a novel approach using the UK Biobank cohort

Alessia Mapelli[1;2], *Francesca Ieva*[1;2], *Emanuele Di Angelantonio*[1]

[1]*Human Technopole, Milan, Italy;* [2]*Politecnico di Milano, Milan, Italy*

Background/Objectives: The progression of diseases induces changes in both molecular and observable traits within the human body. Proteins, acting as crucial mediators of gene functions, influence trait determination, providing valuable insights for data-driven approaches to diagnosis, prevention, and monitoring. Understanding the functional interdependencies among molecular components becomes essential, as health conditions frequently arise from disturbances in the complex intracellular network rather than isolated gene abnormalities. Existing methods in network medicine often rely on either general biological graph databases or exclusively on data-driven approaches. However, protein-protein interaction databases tend to favor well-studied proteins, impacting the thoroughness of the analysis, and confounding factors may influence co-expression networks, leading to biased associations.

Methods: In this study, a novel representation method utilizes networks to integrate biological knowledge from databases into an estimation-based approach, minimizing noise in co-expression network construction and addressing the impact of confounding factors.

Results: The method was applied to the UK Biobank cohort, comprising 54,219 participants recruited in the United Kingdom, and 2,923 unique proteins were measured using antibody-based Olink technology. The data's high dimensionality in proteins and

samples contributes to the comprehensive description of the proteomes. This unique representation allows the capture of individualized imprints of current health status and can simultaneously represent behavioral traits such as smoking and the potential risk of diseases like diabetes.

Conclusion: This work aims to represent proteomes reliably within a network framework. This serves as a quantitative health assessment tool for simultaneously evaluating multiple health conditions - an emerging concept.

Background: Whole genome sequencing (WGS) is currently the most comprehensive genetic analysis as it enables the identification of different types of variations (SNPs, indels, copy-number variants, structural variation) through application of different specialised bioinformatic algorithms.

Methods: Whole genome sequencing was performed in collaboration with BGI Genomics on a large cohort of over 230 patients from Bulgaria with different rare diseases or partner pairs for carrier screening. Variant calling was performed applying the GATK toolkit for SNP/indel detection, algorithm *CNVnator* for copy-number variation and *BreakDancer* for structural variation. An in-house strategy based on genomic architecture and single-read analysis was developed to filter out the large number of false-positive findings for each patient and to map the potential breakpoints down to single-base-pair resolution.

Results: We detected in total 7 pathogenic/likely pathogenic structural variants of different types summarised in the table below (five causative variants, one incidental finding and one carrier status):

Variant	Type	Zygosity	Diagnosis
FANCA:c.190-256_283+1690delinsC	deletion-insertion	homozygous	Fanconi anaemia
CACNA1A:c.4250+814_*3032del	deletion	heterozygous	Episodic ataxia
EDA:c.654_742-382delinsCCA	deletion-insertion	hemizygous	Ectodermal dysplasia
SMN1:c.[343_367dup;407_421del; 450_461del;474 + 19_474+23del]	complex rearrangement	heterozygous	Spinal muscular atrophy
PSEN1:c.-51425_-136+5312inv	inversion	heterozygous	Alzheimer's disease
ABCC6:c.2996-1724_4209-479del	deletion	heterozygous	/Carrier screen/
FARS2:c.613-6799_904+27484del	deletion	heterozygous	/Incidental finding/

Comparing bioinformatic algorithm sensitivity and specificity, we concluded that *CNVnator* has an advantage at detecting CNVs based on coverage fluctuations, while *BreakDancer* performs better at detecting breakpoint-evident SVs with unmapped read fragments.

Conclusion: Applying a combination of different bioinformatic algorithms for SNV/CNV/SV detection on whole-genome sequencing data provides the highest diagnostic yield combining several methodologies in a single test.

Background/Objectives: Currently >50 monogenic human disorders are associated with short tandem repeat (STR) expansions. STRs are somatically unstable elements that can contract/expand in age and tissue specific manners. Somatic instability, repeat length variation, methylation status and sequence structure can modify disease severity and onset. Here we describe a workflow developed to investigate disease-associated STRs across the human genome. The workflow utilises a repeat expansion associated with an age-related eye disease, Fuchs Endothelial Corneal Dystrophy (OMIM # 613267; termed CTG18.1), as an exemplar locus to showcase the broad utility and outputs of the pipeline developed.

Methods: The workflow first genotypes a given tandem repeat and phases reads spanning it in a specified set of PacBio HiFi samples using the tandem repeat genotyping tool (TRGT). It then generates and visualizes the distribution of allele lengths and sequence composition across all samples. Then it performs an automated repeat interruption analysis and visualizes sequencing data containing repeats with abnormal lengths, sequence composition, or repeat interruptions.

Results: Using HiFi data generated from genomic DNA, we developed a workflow to interrogate and visualise the allelic structure, repeat length, instability and repeat interruption profiles. This workflow has been documented as a Jupyter Notebook to enable researchers to apply and analyse their repeat loci of interest.

Conclusion: Here we describe a computational workflow to enable researchers to interrogate their STR of interest using HiFi data. The generated outputs offer broad utility to the STR biology community.

P16.127.C Advancing precision medicine: A ML-based recommender system for accelerated diagnostics in rare hereditary diseases using next-generation sequencing data

Matthias Bieg[1], Vivi Lieu Mertes[1], Jorge Pinto Basto[1], Omid Paknia[1], Peter Bauer[1], **Krishnakumar Kandaswamy**[1]

[1]*CENTOGENE GmbH, R&D Bioinformatics, Rostock, Germany*

Background/Objectives: Diagnosing rare hereditary diseases through the molecular analysis of next-generation sequencing (NGS) data, encompassing both Whole Exome Sequencing (WES) and Whole Genome Sequencing (WGS) cases, involves collaboration across disciplines from NGS wet lab scientists to clinical and medical experts. Despite advancements of variant annotation and prioritization, the interpretation remains labor-intensive, requiring a substantial team of clinical specialists. To improve efficiency, we implemented a recommender system that calculates the likelihood of identifying a causal variant for a given patient. This system enables strategic case assignments to clinical specialists based on their experience and expertise, significantly expediting the diagnostic process.

Methods: We utilize our Centogene Biodatabank, incorporating clinically diagnosed in-house patients from WES/WGS data—11,829 without a causal variant and 17,066 with a confirmed clinically relevant DNA variant. Employing a gradient boosting model, we train the system using features like HPO terms, ethnicity, and family medical history, enhancing our binary classification for identifying the presence or absence of causal variants with high recall.

Results: The model was benchmarked against 3,211 previously diagnosed in-house patients. It achieves a recall of 82%, at a precision of 69%, while the AUC of the ROC curve is at 74%.

Conclusion: The AI model accurately determines the probability of identifying a causal variant based on specific patient details, including HPO terms, ethnicity, and family medical history. This information serves as a valuable recommendation tool for clinical specialists, qualifying the a-priori probability of a positive diagnostic finding and thereby contributing to a substantial acceleration of the diagnostic process.

Conflict of Interest: Matthias Bieg employed at CENTOGENE GmbH, Vivi Lieu Mertes employed at CENTOGENE GmbH, Jorge Pinto Basto employed at CENTOGENE GmbH, Omid Paknia employed at CENTOGENE GmbH, Peter Bauer employed at CENTOGENE GmbH, Krishnakumar Kandaswamy employed at CENTOGENE GmbH

P16.128.D Bridging the performance gap for underrepresented populations: Anchor regression for polygenic risk scores

Hannah Klinkhammer[1;2], Carlo Maj[3], **Peter Krawitz**[2]*, Christian Staerk[1], Andreas Mayr[1]*

[1]*Institute for Medical Biometry, Informatics and Epidemiology, Medical Faculty, University of Bonn, Bonn, Germany;* [2]*Institute for Genomic Statistics and Bioinformatics, Medical Faculty, University of Bonn, Bonn, Germany;* [3]*Center for Human Genetics, University of Marburg, Marburg, Germany*

Background/Objectives: Polygenic risk scores (PRS) lack performance in populations that are under-represented in the training data. To account for population structure, genetic principal components (PCs) are included in the derivation of PRS and in the subsequent analysis. In this study we propose a new approach to make use of the PCs aiming for more robust PRS performance across populations.

Methods: We implemented anchor regression in the statistical boosting framework snpboost. Anchor regression is a technique that transfers ideas from causality into predictive modelling and interpolates between two stage least squares regression, ordinary least squares regression and residual regression via its tuning parameter γ. Here, as a proxy for ancestry, we consider the first 10 PCs as anchors, comparable to instrumental variables that influence the genetic variants. Models for BMI and LDL were trained on data from the UK Biobank and evaluated on independent test sets from different populations (EUR, AFR, SAS, EAS).

Results: Depending on a suitable choice of its tuning parameter γ anchor regression could improve the predictive performance in terms of R^2 compared to the classical approach of including the PCs and PRS in a multiple regression. The largest potential gain in R^2 was found in individuals of EAS ancestry (from 3.3% to 5.6%). Noteworthy, the optimal performance was reached for different tuning parameters in the different populations.

Conclusion: Preliminary results suggest that using PCs as anchors in the anchor regression framework can help to bridge the transferability gap. Further research is warranted, e.g. regarding the choice of the tuning parameter.

P16.129.A AlphaMissense is better correlated with functional assays of missense impact than earlier prediction algorithms

Alicia Ljungdahl[1;2]*, Sayeh Kohani[1], Nicholas Page[1;2], Eloise Wells[1], Emilie Wigdor[1], Shan Dong[1;2], Stephan Sanders[1;2]*

[1]*University of Oxford, Paediatrics, Oxford, United Kingdom;* [2]*University of California, San Francisco (UCSF), Psychiatry, San Francisco, United States*

Background/Objectives: Missense variant interpretation remains a major challenge in functional genomics and medicine. Numerous different in silico approaches have been developed to predict missense impact. We performed an independent assessment, including AlphaMissense, using functional data generated from previously published multiplexed assays of variant effect (MAVE) of 17,696 missense variants in five genes.

Methods: For each gene, all possible missense variants from single nucleotide substitutions were predicted from the Matched Annotation from NCBI and EMBL-EBI (MANE) isoform. Functional data were downloaded from the published manuscripts and annotated against 36 prediction algorithms using ANNOVAR (dbnsfp42a). Missense severity scores were added from EVE, PrimateAI-3D, and AlphaMissense, along with pathogenicity, as defined by ClinVar. Correlation between functional scores and each predictor was assessed using absolute Spearman correlation.

Results: AlphaMissense was the highest correlated algorithm to the functional data for *PTEN* and *BRCA1*, 2nd for *MSH2*, 3rd for *DDX3X*, and 5th for *KCNQ4*. PrimateAI-3D ranked in the top five for four and ranked first for two genes (*MSH2, KCNQ4*). In four of the five genes, AlphaMissense scores show a modestly higher correlation than REVEL (an algorithm widely used for clinical predictions).

Conclusion: AlphaMissense represents the current best-in-class predictor by this metric; however, the improvement over other algorithms is modest. Across missense predictors, many variants are predicted to impact function despite minimal consequences observed with MAVE assays. ClinVar classification of these discordant variants is variable, agreeing with AlphaMissense in *DDX3X* and MAVE data in *MSH2*; training data quality is likely the limiting factor.

Background/Objectives: Several works have highlighted the role of germline mutations in the MMR genes for hereditary pancreatic cancer [1]. However, the recent implementation of NGS technologies into genetic diagnosis have resulted in a high rate (40%) of detection of variants of unknown significance (VUS). In this work, we present an AI tool for classification of germline VUSs, which we validate using known pathogenic germline variants from ACMG guidelines. The tool is then tested in a dataset of germline variants found in pancreatic cancer patients from Japan.

Methods: A graph-based deep learning model (GDLM) has been used to classify the pathogenicity of germline variants [2]. The model was validated by comparing the variant classification in ClinVar 2020 and the capacity of GDLM to reclassify variants with this information, with that of ClinVar 2023, considered as the ground truth for the comparison. Once validated, we tested GDLM in a clinical dataset of pancreatic patients from Japan and evaluated the potential to reclassify clinical VUSs [3].

Results: The obtained results show that GDLM classifies, in average, 98% of the variants classified as benign in ClinVar 2023 and 100% of the pathogenic variants correctly in the validation set.

For the pancreatic cancer dataset, GDLM reclassifies as pathogenic 3 of the 5 (60%) VUSs found in patients with pancreatic cancer. The other two are classified as benign variants.

Conclusion: These results support the use of GDML as a helpful tool for interpretation of VUSs in MMR genes.

P16.131.C Unveiling Common Genes in Alpha-Synucleinopathies Through Weighted Gene Co-expression Network Analysis

Omer Faruk Duzenli[1], *Medinenur Yozlu*[1], *Duygu Gezen-Ak*[2], *Emrah Yucesan*[1]

[1]*Istanbul University-Cerrahapasa Institute of Neurological Sciences, Department of Neurogenetics, Istanbul, Türkyie;* [2]*Istanbul University-Cerrahapasa Institute of Neurological Sciences, Department of Neuroscience, Istanbul, Türkyie*

Background/Objectives: Parkinson's disease (PD), Dementia with Lewy bodies (DLB) and Multiple system atrophy (MSA) are classified as alpha-synucleinopathies accompanied by Lewy bodies (LB) or glial cytoplasmic inclusions (GCI). Although these diseases show alpha-synuclein (α-syn) pathology, they affect different brain regions and cells and present with various clinical symptoms. The main focus of this study is to identify the common genes and pathways functioning in the mentioned diseases. Our goal is to enable a more rational evaluation of the diagnosis and treatment of the disease based on our findings.

Methods: For this purpose, three data set were utilized using the NCBI-GEO database, GSE134472 for MSA, GSE193438 for DLB, and GSE205450 for PD respectively obtained from post-mortem brain tissues. The analysis of Differentially Expressed Genes in these data sets was performed using the Weighted Gene Co-expression Network Analysis (WGCNA) tool in the R Studio program. The Metascape interface was employed for functional enrichment analysis.

Results: A total of 148 associated genes ($p < 0.001$) were identified as common in the diseases. Enrichment analysis revealed that these genes are associated with various pathways, e.g. regulation of cytoskeletal organization, membrane trafficking. The *ACTR2*, *CLTC*, *COPA* and *TUBB4A* are common hub genes related to three diseases.

Conclusion: Our findings have demonstrated the association between the failure of intracellular transport and neurodegenerative diseases, consistent with the literature. Consequently, research focusing on the diagnostic and therapeutic aspects of the intracellular transport system may contribute to the early detection and the exploration of potential therapeutic strategies for the presented diseases.

Grants: There is no grant received.

P16.132.D Evaluation of graph-based explainable AI in pathogenicity estimation using clinically relevant variants.

Laura Martinez Gomez[1], *Raul Valin*[1], *Serban Georgescu*[2], *Nooshin Bayat*[1], *Fuji Masaru*[3], *Shuya Abe*[3], *Shinichirou Tago*[3], *Ana Fernandez-Montes*[4], *Ceres Fernandez-Rozadilla*[5], *Jesus Garcia-Mata*[4], *Salvador Capella-Gutierrez*[6], *José María Fernández González*[6], *Anna Redondo Guitarte*[6], *Miguel Vazquez*[6]

[1]*Fujitsu Research of Europe, Computing Research Group, Madrid, Spain;* [2]*Fujitsu Research of Europe, Computing Research Group, Slough, United Kingdom;* [3]*Fujitsu Research, Fujitsu Ltd., Japan;* [4]*Complejo Hospitalario Universitario de Ourense – CHUO, Department of Medical Oncology, Ourense, Spain;* [5]*Instituto de Investigacion Sanitaria de Santiago, Cancer Predisposition and Biomarkers, Santiago de Compostela, Spain;* [6]*Barcelona Supercomputing Center (BSC), Life Sciences Department, Barcelona, Spain*

Background: Advancements in low-cost, high-throughput DNA sequencing and computing technologies have rapidly expanded the scope of genetic testing, leading to a substantial increase in the number of identified DNA variants per test. This inevitably culminates in the detection of variants that remain undefined and unclassified, referred to as variants of unknown significance, that comprise approximately 40% of all identified variants. We

developed a graph-based deep learning model that classifies the pathogenicity of germline variants using explainable artificial intelligence (XAI) which combines various pathogenicity prediction algorithms with data from multiple databases considering neighbouring variants and their potential clinical implications to identify potentially significant domains. Here we validate its performance using a set of clinically validated variants.

Methods: A clinically representative dataset of variants (n = 1757), including those identified from families in the Deciphering Developmental Disorders (DDD) study, that have been through multiple rounds of variant filtering and clinical evaluation was used to evaluate the performance of our algorithm. Integrating the dataset as a benchmarking event within the 'AMetaPred' community of ELIXIR's platform OpenEBench, we compared the performance of our tool with that of other available metapredictors, including REVEL, AlphaMissense and MetaRNN.

Results: The results show that the graph-based explainable AI consistently ranks within the top 5 across a comprehensive set of performance metrics, including precision, recall, accuracy and other additional relevant parameters.

Conclusions: The robust performance shown in this dataset underscores its efficacy and establishes it as a reliable choice in comparison to other algorithms relevant in the field.

P16.133.A MaLiPre - machine-learning-based estimation of lymphocyte infiltration in tumor tissues

Dennis Witt[1], *Axel Gschwind*[1], *Vincent Hammer*[1], *Andrea Forschner*[2], *Michael Bitzer*[3], *Irina Bonzheim*[4], *Janina Beha*[5], *Cristiana Roggia*[1], *Olaf Riess*[1], *Christopher Schroeder*[1], *Christian Müller-Kett*[6], *Stephan Ossowski*[1]

[1]*Universitätsklinikum Tübingen – Institut für Medizinische Genetik und angewandte Genomik, Tübingen, Germany;* [2]*Universitäts-Hautklinik Tübingen, Tübingen, Germany;* [3]*Innere Medizin I Tübingen - Gastroenterologie, Hepatologie, Infektionskrankheiten, Tübingen, Germany;* [4]*Universitätsklinikum Tübingen Institut für Pathologie, Tübingen, Germany;* [5]*Universitätsklinikum Tübingen - Zentrum für personalisierte Medizin, Tübingen, Germany;* [6]*IU International University of Applied Sciences - Campus Bad Honnef, Bad Honnef, Germany*

Background/Objectives: Next-generation sequencing forms the foundation of personalized cancer treatment decisions, as comprehensive genetic information allows for a better understanding of tumor processes. However, interpreting these OMICS data is complex, and the number of accessible samples is often too small to apply machine learning (ML) techniques successfully.

Methods: This explorative study used tumor RNA-seq data to assess if lymphocyte fractions in tumor samples could be efficiently predicted using gene expression data. Thousands of representative virtual tissues were generated from openly accessible single cell data, and several machine learning models were trained. Results were validated with pairs of histological slices and RNA-seq data taken from publicly available GDC-data and an unpublished in-house cohort of 130 Melanoma/CCC tumor samples. The ML prototypes were evaluated for their predictive accuracy in both regressive and classification contexts.

Results: Twenty-four prototypes were developed. Significant advantages were made in training by virtual tissues, achieving AUC of up ato 0.96 in classification contexts (low vs. high lymphocyte infiltration; deep learning model). In regression, the mean absolute error was as low as 0.02 (MSE: 0.002, RMSE: 0.045) with a corresponding R^2 of up to 0.449 for a generalized linear model.

Conclusion: The study demonstrates the potential of using ML methods to predict real-world lymphocyte fractions in several tumor entities from RNA-expression data. With a high AUC of up to 0.96 for significant lymphocyte infiltration, this approach can reliably differentiate patients susceptible to immunotherapy

P16.134.B ExonViz – A web application to generate and visualize transcripts including variants

Redmar R. van den Berg[1], **Marlen C. Lauffer**[1], *Jeroen Laros*[1;2]

[1]*Leiden University Medical Center (LUMC), Department of Human Genetics, Leiden, Netherlands;* [2]*National Institute of Public Health and the Environment (RIVM), Department of Bioinformatics and Computational Services, Bilthoven, Netherlands*

Background/Objectives: Visualization of transcripts, including features like coding regions and mutational landscape, is crucial within the field of human genetics. Apart from diagnostics, these illustrations can also be used to assess potential genetic treatment options, in teaching settings, and for genetic counseling. For certain types of genetic treatments, like canonical exon-skipping, these illustrations should also include information about the reading frames of exons.

To date, no application is available that visualizes transcripts including reading frame information, so clinicians and researchers must resort to manually drawing transcripts with tools like Illustrator, Photoshop, BioRender, PowerPoint, etc.

Results: Here, we present ExonViz, a simple application to draw transcripts that include coding and non-coding regions. All exons are to scale and the reading frames of the exons are visible. Single or multiple variants can be illustrated along the transcript and are shown in the correct location. Further, we allow the user to generate their own transcripts to incorporate features like poison or cryptic exons. ExonViz can be accessed as a web application via https://exonviz.rnatherapy.nl or as a Python package from https://pypi.org/project/exonviz/.

Conclusion: ExonViz is the first publicly accessible application that allows the user to draw transcripts including additional features such as coding regions, exon reading frames, and the mutational landscape along the transcript. ExonViz can be used for illustrations within publications, assessment of treatment options, teaching purposes, or genetic counseling.

P16.135.C Extraction of symptoms and HPO codes from Spanish health records generated by GPT

Nooshin Bayat[1], *Nuria García-Santa*[1], *Ander Martinez*[1], *Raul Valin*[1], *Laura Martinez Gomez*[1], *Serban Georgescu*[2], *Ceres Fernandez-Rozadilla*[3], *Ana Fernandez-Montes*[4], *Jesus Garcia-Mata*[4]

[1]Fujitsu Research of Europe, Computing Research Group, Pozuelo De Alarcon (Madrid), Spain; [2]Fujitsu Research of Europe Ltd, Computing Research Group, Slough, United Kingdom; [3]Foundation Health Research Institute of Santiago de Compostela (IDIS), Cancer Predisposition and Biomarkers lab, Santiago de Compostela, Spain; [4]Complexo Hospitalario Universitario de Ourense - CHUO, Medical Oncology Department, Ourense, Spain

Background/Objectives: The human phenotype ontology (HPO) [1] is being widely used to unify the terms related to patient phenotypes and symptoms which can be further used for diagnosis, decision support, or variant interpretation, amongst others. So far, there have been some studies related to HPO coding of natural language texts in English. In this study we describe a machine learning method that recognizes the symptoms from Spanish clinical records and extracts the related HPO code.

Methods: GPT-3.5 Turbo 16k was used to simulate clinical records related to colon cancer in Spanish. The Named Entity Recognition (NER) method was used to automatically label the symptoms from texts [2]. This was followed by the Entity Linking (EL), using knowledge graph [3], to extract the relevant HPO term for each symptom. Manual annotation of each step was used to evaluate the results.

Results: The NER system used in this study recognized 256 (94%) symptoms from a total of 273 manually labelled terms. Of these, 168 (66%) were correctly linked to their HPO code, while 88 (34%) were incorrect or missing.

Conclusion: As far as we know, this is the first report of a machine learning-based automatic extraction of both symptoms and HPO codes from Spanish clinical records. The patient-described symptoms were recognized with high accuracy (94%). However, further improvements are needed to reach the higher accuracy for HPO linking (higher than 66%).

P16.136.D Aberrant expression prediction across human tissues

Florian Hölzlwimmer[1], *Jonas Lindner*[1], *Nils Wagner*[1;2], *Francesco Paolo Casale*[3;4;5], *Julien Gagneur*[1;6;7]

[1]Computational Molecular Medicine, School of Computation, Information and Technology, Technical University Munich, Garching, Germany; [2]Munich School for Data Science (MUDS), Helmholtz Association, Oberschleißheim, Germany; [3]Institute of AI for Health, Helmholtz Munich, Neuherberg, Germany, Oberschleißheim, Germany; [4]Helmholtz Pioneer Campus, Helmholtz Munich, Oberschleißheim, Germany; [5]School of Computation, Information and Technology, Technical University Munich, Garching, Germany; [6]Institute of Computational Biology, Helmholtz Munich, Oberschleißheim, Germany; [7]Institute of Human Genetics, School of Medicine, Technical University of Munich, München, Germany

Background/Objectives: Despite the frequent implication of aberrant gene expression in diseases, algorithms predicting aberrantly expressed genes of an individual are lacking.

Methods: To address this need, we compiled an aberrant expression prediction benchmark covering 8.2 million rare variants from 633 individuals across 48 tissues. Using this benchmark, we developed AbExp, a specialized predictor combining in a tissue-specific fashion expression variability with variant effects on isoforms and on aberrant splicing.

Results: While not geared toward aberrant expression, the deleteriousness score CADD and the loss-of-function predictor LOFTEE showed mild predictive ability (1-1.5% average precision). Leveraging these and further variant annotations, AbExp yielded 10% average precision, significantly outperforming both CADD and LOFTEE. Integrating AbExp with expression measurements from clinically accessible tissues led to another two-fold improvement. Furthermore, we show on UK Biobank blood traits that performing rare variant association testing using the continuous and tissue-specific AbExp variant scores instead of LOFTEE variant burden increases gene discovery sensitivity and enables improved phenotype predictions.

Conclusion: The development of a DNA-sequence-based method for predicting aberrant gene expression in multiple tissues, which can also generalize to unseen variants, represents a significant advancement in the ability to identify and understand the genetic underpinnings of human traits and diseases.

P16.137.A Pathway Analysis in Cognitive Decline using Longitudinal Data with Respect to Common Variants

Elaheh Vojgani[1;2], *Kumar Parijat Tripathi*[3], *Luca Kleineidam*[4], *Alfredo Ramirez Zuniga*[3], *Michael Nothnagel*[1;2]

[1]University of Cologne, Cologne Center for Genomics (CCG), Köln, Germany; [2]Cologne University Hospital, Köln, Germany; [3]University of Cologne, Department of Psychiatry, Medical Faculty, Köln, Germany; [4]University Hospital Bonn, 3 Department of Neurodegenerative Diseases and Geriatric Psychiatry, Bonn, Germany

Background/Objectives: Biological pathways intricately govern cellular processes, and understanding their role in neurological disorders' cognitive decline is paramount. Alzheimer's disease (AD) is a multifaceted neurological disorder characterized by cognitive decline, often manifesting early in life. Investigating the underlying biological mechanisms triggering cognitive impairment before dementia onset is crucial.

Methods: In this study, we employ a pathway-driven statistical approach, considering common genetic variants across pathways, to generate pathway scores. These scores aim to assess their interaction with time in driving cognitive decline, utilizing longitudinal data with temporal cognitive scores. Our approach involves two key components: first, developing a pipeline for pathway score generation with simulation studies involving various degrees of variant effect sizes within a pathway as well as different proportions of protective variants within a pathway to evaluate its efficacy, and second, applying the scores in a linear mixed model to examine their association with cognitive decline using real data from available cohorts.

Results: Preliminary results indicate that with large proportions of deleterious variants in a pathway and a strong correlation between genetic effect size and CADD score of a variant, the linear

model is very well able to predict the phenotype, with coefficients of determination consistently exceeding 0.5.

Conclusion: The proposed model captures phenotypic variation in simulated data effectively through pathway scores. This approach promises to enhance the understanding of biological processes driving the neurological disorders. In future, we will implement an R-package pipeline to enable users to obtain CADD-based pathway scores.

Background/Objectives: Inborn errors of immunity (IEI) comprise a diverse group of severe disorders affecting the immune system. While the genetic foundations of IEI have been under study for decades, a significant percentage of patients remain undiagnosed following conventional genetic testing. In this project, we employed a combination of genome and transcriptome sequencing in 26 IEI patients with previous nonconclusive genetic testing and their families with the aim of establishing a molecular diagnosis.

Methods: Initially, we analyzed WGS data prioritizing variants with potentially high impact on the phenotype, this step included WGS for available relatives (26 patients plus 49 relatives). Next, RNA-seq data from peripheral blood was analyzed using the DROP pipeline (Yépez V. et al 2021) (27 patients plus 48 age and gender matched controls), yielding results for aberrant expression, aberrant splicing, and mono-allelic expression.

Results: The combination of both datasets led to the identification of 55 genes with aberrant expression, 516 genes with aberrant splicing, and 613 variants with mono-allelic expression. Among these, two particularly promising candidates are currently undergoing validation: a substantial reduction in CD40L expression in a young adult and a splicing alteration in STAT2 caused by two intronic variants.

Conclusion: We demonstrated that the integration of genomic and transcriptomic profiling has the potential to increase the diagnostic yield in complex cases of IEIs.

P16.139.C cfCNV: an optimized pipeline for detecting copy number variations for cell free DNA data

Fahimeh Palizban[1], *Sina Majidian*[1]

[1]University of Lausanne, Department of Computational Biology, Lausanne, Switzerland

Background/Objectives: Cell-free DNA (cfDNA) analysis has emerged as a promising approach for non-invasive detection of genomic alterations, particularly copy number variations (CNVs). CNVs are involved in many diseases, including cancer, developmental, and genetic disorders and identified utilizing short and long-read sequencing. However, no CNV caller has been developed for cfDNA data specifically, and the reliability and accuracy of existing CNV callers for cfDNA data is unknown. This study presents a benchmarking approach to evaluate the performance of different CNV callers on cfDNA short and long reads.

Methods: Benchmarking process assesses sensitivity, specificity, precision, and computational efficiency metrics. We evaluated the pipelines' robustness to varying sequencing depths, fragment sizes, and allelic imbalances, reflecting real-world challenges encountered in cfDNA analysis.

Results: Here, by reviewing around 30 tools we have selected five of the most related tools considering the low concentration of cfDNA data. Real and simulated cfDNA data were used to investigate the ability of different tools to identify CNVs in a diverse range of scenarios and the minimum coverage at which these tools can function was measured at approximately 5x depth of sequencing. In addition, the optimal window size for each read-depth-based method at different read coverages was obtained as 100Kb-1Mb showing more accurate results for short read sequencing.

Conclusion: This newly developed pipeline facilitates the broad applications of cfDNA CNV caller for clinical and research contexts, ultimately advancing the precision and reliability of cfDNA-based genomic analysis for potential diagnosis and monitoring of diseases. Availability: https://github.com/FPalizban/cfCNV.

P16.140.D Consistency of the facial phenotype in Koolen-de Vries and Jansen-de Vries syndrome

Jolijn Verseput[1], *Nina Claessens*[2], *Michiel Vanneste*[2;3], *Guido de Jong*[4], *Leonie de Vries*[1], *Sanne de Vries*[1], *Thomas Maal*[4], *Peter Claes*[2;3], *Bert de Vries*[1]

[1]Radboud University Medical Center, Human Genetics Department, Nijmegen, Netherlands; [2]UZ Leuven, Medical Imaging Research Center, Leuven, Belgium; [3]KU Leuven, Human Genetics Department, Leuven, Belgium; [4]Radboud University Medical Center, 3D Lab Radboudumc, Nijmegen, Netherlands

Background/Objectives: Facial shape modelling techniques can assist clinicians in determining the presence of a facial gestalt for a specific neurodevelopmental syndrome, and which facial features are most distinguishable. We used three-dimensional facial shape analysis to evaluate consistency in facial features for two neurodevelopmental disorders, namely Koolen-de Vries syndrome

(Koolen, 2012; Zollino, 2012; OMIM #610443) and Jansen- de Vries syndrome (Jansen, 2017; OMIM #617450).

Methods: 3D scans were made from 16 individuals with KDVS and 9 individuals with JDVS. These images were compared to 3D scans of the face of age and sex matched healthy controls based on craniofacial growth curves (Matthews, 2021). First, facial variation compared to the controls was displayed in terms of direction and severity for each individual (Matthews, 2023). These new age- and sex-normalized features were used in a subsequent analysis to determine phenotypic consistency in terms of variation in the direction of these features. Results were compared to a database of twenty well-known syndromes.

Results: The first analysis showed limited phenotypic consistency in the full face for both syndromes. The experiment was repeated for eight separate facial regions which revealed more consistency in specific features compared to others, fitting with the existing knowledge on the gestalt.

Conclusion: We show that 3D dense surface scans allow for improved facial characterization of both Koolen-de Vries and Jansen-de Vries syndrome when divided into separate facial regions contributing to the existing knowledge of the facial gestalt.

Grants: This work was supported by the Koolen-De Vries and Jansen-de Vries syndrome foundations, and the FWO (G0D1923N)

P16.141.A Extending DeepTrio for sensitive detection of complex de novo mutation patterns.

Fabian Brand[1], *Jannis Guski*[1], *Peter Krawitz*[1]

[1]*University Hospital Bonn, Institute for Genomics Statistics and Bioinformatics, Bonn, Germany*

Background/Objectives: De novo mutations (DNMs), and among them clustered DNMs within 20 base pairs of each other (cDNMs) are known to be a potential cause of genetic disorders. However, identifying DNM in whole genome sequencing (WGS) data is a process that often suffers from low specificity. We propose a deep learning framework for DNM and cDNM detection in WGS data based on Google's DeepTrio software for variant calling, which considers regions of 110bp up- and downstream from possible variants to take information from the surrounding region into account

Methods: We trained a model each for the DNM and cDNM detection tasks and tested it on data generated on the HiSeq and NovaSeq platforms. In total, the model was trained on 82 WGS trios generated on the NovaSeq and 16 on the HiSeq.

Results: For the DNM detection task, our model achieves a sensitivity of 95.7% and a precision of 89.6%. The extended model adds confidence information for cDNMs, in addition to standard variant classes and DNMs. While this causes a slight drop in DNM sensitivity (91.96%) and precision (90.5%), on HG002 cDNMs can be isolated from other variant classes in all cases (5 out of 5) with a precision of 76.9%.

Conclusion: Since the model emits confidence probabilities for each variant class, it is possible to fine-tune cutoff thresholds to allow users to select a desired trade-off between sensitivity and specificity. These results show that DeepTrio can be retrained to identify complex mutational signatures with only little modification effort.

Conflict of Interest: None declared

P16.142.B GenoPhenoCorr: Simplifying the characterization of genotype-phenotype correlations

Lauren Rekerle[1], *Daniel Danis*[1], *Peter N. Robinson*[1;2]

[1]*The Jackson Laboratory For Genomic Medicine, Farmington, United States;* [2]*Berlin Institute of Health, Berlin, Germany*

Background/Objectives: Understanding the intricate relationship between genotypes and phenotypes is a fundamental pursuit in genetics. Although many other areas of genetics research have been optimized through new computational technologies, genotype-phenotype correlations have remained tedious and time consuming for researchers. We present GenoPhenoCorr, a Python package that is designed to expedite the identification of genotype-phenotype correlations.

Methods: GenoPhenoCorr takes Global Alliance for Genomics and Health (GA4GH) phenopacket data as input. A typical use case investigates a cohort of individuals with pathogenic variants in a given gene and compares different classes of variants, different locations, or different variants. Each phenopacket represents a single patient with a list of recorded phenotypes and at least one variant. The software organizes the data into a table, showcasing all the recorded phenotypes, variants, affected transcripts, and the corresponding proteins along with the frequency of each within the cohort. Users can then run different comparisons based on the information in the table. Genotype phenotype correlations are then calculated by analyzing the counts of individuals with vs. without annotations to Human Phenotype Ontology (HPO) terms.

Results: We evaluated GenoPhenoCorr on ten cohorts of individuals with diseases including KBG Syndrome and Isolated Sulfite Oxidase Deficiency. We could replicate results of some published genotype phenotype correlation studies and will present new results on other cohorts.

Conclusion: GenoPhenoCorr enables interactive exploration of results, provides a library of functions for investigating correlations, and can be easily extended. By integrating novel algorithms, comprehensive data management, and interactive visualization, GenoPhenoCorr simplifies the identification of genotype phenotype correlations.

P16.143.C A novel and highly customisable pipeline for genome-wide detection of SNP-by-methylation interaction effects

Ellisif Nygaard[1], *Julia Romanowska*[1;2], *Astanand Jugessur*[1;2], *Miriam Gjerdevik*[2;3], *Øystein A. Haaland*[1]

[1]*University of Bergen, Department of Global Public Health and Primary Care, Bergen, Norway;* [2]*Norwegian Institute of Public Health, Centre for Fertility and Health, Oslo, Norway;* [3]*Western Norway University of Applied Sciences, Department of Computer Science, Electrical Engineering and Mathematical Sciences, Bergen, Norway*

Background/Objectives: Although many cohorts have both genotype and DNA methylation (DNAm) data, few tools are designed for genome-wide integrative analysis of such datasets. We aim to develop a robust and user-friendly pipeline to perform genome-wide scans for SNP-by-DNAm interaction effects.

Methods: We constructed a pipeline by substantially extending and refining our previously published candidate-SNP framework1 for integration of SNP and DNAm data. Our development process included devising and optimising the placement of omic-specific and cross-omics quality-control steps, and creating an updated approach for combining SNPs with aggregated DNAm data.

Results: Our pipeline transforms vast numbers of SNPs and DNAm probes into a manageable, analysis-ready structure. We define each contiguous genomic interval annotated with a specific

full-stack ChromHMM chromatin state as a 'state locus' (SL). DNAm probes are assigned to the SL they are located within, effectively grouping them into biologically meaningful categories. Each SL is then paired with SNPs according to genomic proximity, and based on within-SL aggregated DNAm levels, the individuals are divided into SL-specific strata. Finally, association analyses are performed for each SNP-SL pairing, testing for interaction effects across strata. The pipeline supports alternative quality-control preferences and user-supplied annotations.

Conclusion: Our pipeline introduces a novel genome-wide integration protocol for pairing SNPs with biologically meaningful groupings of DNAm probes, facilitating a genome-wide screening for SNP-by-DNAm interaction effects. This comprehensive toolkit is highly customisable in terms of user needs, research questions, and data characteristics.

P16.144.D Adapting fine-mapping for GWAS meta-analyses with missing information

Joonas Kartau[1;2], *Matti Pirinen*[1;2;3]

[1]*University of Helsinki, Department of Mathematics and Statistics, Helsinki, Finland;* [2]*University of Helsinki, Institute for Molecular Medicine Finland, Institute of Life Science, Helsinki, Finland;* [3]*University of Helsinki, Department of Public Health, Helsinki, Finland*

Background/Objectives: Fine-mapping is a statistical approach to identify causal variants from the summary data of a Genome-Wide Association Study (GWAS). To improve statistical power, data from multiple cohorts are routinely combined in a meta-analysis before fine-mapping, often leading to sample size mismatches due to variant exclusions in certain studies. Current methods like FINEMAP use computational approximations that ignore missing information, producing unreliable results. We have developed FINEMAP-MISS, an extension to the FINEMAP model that incorporates missing information.

A potential alternative to FINEMAP-MISS is GWAS summary statistics imputation (SSI). While SSI works well in some scenarios, we show that under realistic conditions SSI can lead to unreliable fine-mapping results.

Methods: We compare the performance of SSI with FINEMAP-MISS in different scenarios. Using dosage data from the UK Biobank we repeatedly generated two sets of GWAS summary statistics with one causal variant and set 50% of variants missing in one set. We vary causal variant effect size, sample size, or the selection of missing variants (systematic or random) and measure fine-mapping quality.

Results: We show that FINEMAP-MISS is well calibrated, but SSI results in an increase in posterior inclusion probabilities (PIPs) for non-causal variants. For example, with a sample size of 20,000 both methods perform similarly, but when increasing sample size to 200,000 SSI assigned at least one non-causal variant a PIP > 0.9 in 23% of simulations, while FINEMAP-MISS assigned none.

Conclusion: We recommend using FINEMAP-MISS when performing fine-mapping on meta-analysis data to enable fine-mapping on datasets of greater scale and power.

P16.145.A VarFish annotation capabilities extended for large-scale whole genome sequencing

Lara Einicke[1;2], *Max Xiaohang Zhao*[1;2], *Oliver Stolpe*[3], *Angela Abad Perez*[1], *Ronja Adam*[1;2], *Felix Boschann*[1;2;4], *Magdalena Danyel*[1;4], *Nadja Ehmke*[1;2], *Martin Atta Mensah*[1;4], *Sarina Schwartzmann*[1], *Henrike Sczakiel*[2;4;5], *Dieter Beule*[3], *Manuel Holtgrewe*[3]

[1]*Charité – Universitätsmedizin Berlin, Institute of Medical Genetics and Human Genetics, Berlin, Germany;* [2]*Berlin Institute of Health at Charité – Universitätsmedizin Berlin, Berlin, Germany;* [3]*Berlin Institute of Health at Charité – Universitätsmedizin Berlin, Core Unit Bioinformatics – CUBI, Berlin, Germany;* [4]*Berlin Institute of Health at Charité - Universitätsmedizin Berlin, BIH Biomedical Innovation Academy, Clinician Scientist Program, Berlin, Germany;* [5]*Max Planck Institute for Molecular Genetics, FG Development & Disease, Berlin, Germany*

Background/Objective: The interpretation of genetic variants from whole genome sequencing (WGS) requires the integration of many data sources. This includes population frequencies, variant pathogenicity predictions and per-gene intolerance scores, literature reference, and functional assay data. Fast and user-friendly presentation of this information is essential for enabling effective analysis of WGS variant data.

Methods: We have integrated many new and updated data sources into our existing web-based variant interpretation platform VarFish. Based on the key-value store RocksDB and a microservice-based architecture, the software supports users in the analysis of sequence and structural variants from short- and long-read sequencing data.

Results: We present an updated, user-friendly interface for VarFish. A large number of additional data sources and prediction scores have been integrated, including Genotype-Tissue Expression project (GTEx), dbNSFP and AlphaMissense. Additionally, support for multiple genome assemblies have been implemented. We also present a long-term approach to tracking and validating usability changes.

Conclusion: Through major architectural changes and the use of modern database software, we have been able to greatly enhance the annotation capabilities in VarFish.

P17
LARGE SCALE ASSOCIATION STUDIES (GWAS)

P17.001.B A functional schizophrenia-associated genetic variant near the *TSNARE1* and *ADGRB1* genes.

Rachel Boyd[1], *Marah Wahbeh*[1], *Christian Yovo*[1], *Bailey Rike*[1], *Andrew McCallion*[1], *Dimitrios Avramopoulos*[1]

[1]*The Johns Hopkins University School of Medicine, Genetic Medicine, Baltimore, United States*

Background/Objectives: Large-scale genome wide association studies (GWAS) have identified >200 independent loci contributing to schizophrenia risk. Overlap with epigenetic marks suggest that most GWAS-implicated variants are regulatory; however, there is no direct evidence that individual variants are functional or regulate genes involved in disease-relevant pathways. Based on the strength of association with schizophrenia and the presence of regulatory epigenetic marks, we chose a strongly associated variant (rs4129585) near *TSNARE1*, tested its functional potential, and assayed differences that may drive risk allele pathogenicity.

Methods: To test rs4129585 and the surrounding sequence for regulatory function, we utilized a transgenic zebrafish reporter assay. Next, we introduced the risk and non-risk alleles into human-derived iPSCs, differentiated isogenic clones into neural precursor cells (NPCs), and performed RNA-sequencing.

Results: We observed that rs4129585 and the surrounding sequence drives reporter expression in schizophrenia-relevant neuronal populations in zebrafish, including regions involved in auditory processing, anxiety/fear, and aggression. In NPCs, the two alleles generated significant transcriptional differences in the expression of 109 genes at FDR <0.05 and 259 genes at FDR <0.1. We show that these genes are highly interconnected in pathways enriched for synaptic proteins, axon guidance, and regulation of synapse assembly.

Conclusion: These results suggest that rs4129585 does not regulate *TSNARE1* transcripts in NPCs, as previously thought, but may regulate the neighbouring *ADGRB1*, a regulator of synaptogenesis. Our results suggest that rs4129585 is a functional, common variant that functions in specific pathways involved in schizophrenia risk.

P17.002.C Genome-wide association study reveals autoimmune basis of idiopathic achalasia

Sandeep Grover[1], *Carlo Maj*[1], *Pouria Dasmeh*[1], *Johannes Schumacher*[1]

[1]*Center for Human Genetics, Universitatsklinikum Giessen und Marburg - Standort Marburg, Marburg, Germany*

Consortium: Achalasia Risk Consortium (ARC)

Background/Objectives: Achalasia is a rare disorder of the digestive tract characterized by the failure of the lower esophageal sphincter to relax resulting in massive dilation and irreversible impairment of the esophagus. It results from the degeneration of neurons in the myenteric plexus; however, the exact cause of this degeneration is unknown. Previous targeted gene association studies have implicated several *HLA* alleles, suggesting an autoimmune etiology.

Methods: We undertook a comprehensive meta-analysis of genome-wide association studies across eight datasets spanning ten countries, encompassing a cohort of 4,602 cases and 10,766 controls of European ancestry.

Results: Analyzing approximately 11 million SNPs, we identified 28 independent genome-wide significant risk SNPs (lead SNPs) across six genomic loci, five of which were previously unidentified (*PTPN22*, *UGT1A8*, *TNFSF8*, *ZNF365*, *CASC20*). Notably a heritability estimate of 12.1% (SE = 3.6%) was observed. The most significant risk factor identified was the previously reported eight-amino-acid residue insertion within the HLA-DQβ1, encoded by the rs28688207 C allele (OR = 2.54, 95% CI = 2.36-2.86, p = 2.33E-55). Pleiotropic analysis highlighted the involvement of *TNFSF8* in the proliferation of CD4 + T-cells and *PTPN22* in predisposition to various autoimmune diseases. Furthermore, we identified 72 potential causal genes in non-HLA regions, notably enriched in the immune system-related genes, particularly those implicated in autoimmunity. Phenome-wide correlation analysis showed the strongest correlation of achalasia with Crohn's disease, an autoimmune disorder (rg = 0.309 (SE = 0.093), p = 9.85E-04).

Conclusion: These results strongly suggest that achalasia has an autoimmune origin, providing clear directions for further scientific experiments to understand its mechanisms.

Background/Objectives: Breastfeeding and human milk have many health benefits in infants. Earlier work by our team identified that maternal genomics and human milk components such as fatty acids (HMFAs) were associated with human milk microbiota (HMM). In this study, we determined if interactions between maternal genomics and HMFAs impact HMM and risk of childhood atopy among human milk-fed children.

Methods: HMM and HMFAs were analyzed using 16S rRNA-sequencing and gas-liquid chromatography, respectively, in breastmilk of 726 mothers from the CHILD Cohort Study. Maternal and infant genomics were obtained using the Illumina HumanCoreExome BeadChip. Linear regression analysis determined main and interaction effects of HMM and infant polygenic risk scores (PRSs) on childhood atopy (assessed by skin prick tests at ages 3-5 years). We also identified HMFAs that interact with maternal genomics to modulate HMM.

Results: Among infants with high PRSs, those exposed to elevated *Acinetobacter* in human milk had lower atopy prevalence ($P_{Bonferroni} = 0.05$). *Acinetobacter* abundance, in turn, were associated with interactions between maternal polymorphisms on chromosome X (e.g., rs3747309, P = 2.1e-8) and docosapentaenoic acid concentrations. Moreover, increased alpha-diversity in human milk was associated with reduced atopy prevalence as well as interactions between maternal loci on chromosome 18 and increased hexadecenoic acid (e.g., rs57924617, P = 6.81e-11).

Conclusion: Our findings suggest that interactions between maternal genomics and HMFAs may influence the microbial community in human milk, which may modulate risk of atopy. Understanding gene-by-exposure interaction may guide early-life prevention strategies for childhood atopy.

P17.004.A Landscape of effects of gene expression on immune-mediated diseases.

Sodbo Sharapov[1], *Arianna Landini*[1], *Nicole Soranzo*[1;2;3], *Nicola Pirastu*[1]

[1]*Human Technopole, Milan, Italy;* [2]*Wellcome Sanger Institute, Human Genetics Department, Hinxton, United Kingdom;* [3]*University*

of Cambridge, British Heart Foundation Centre of Research Excellence, Cambridge, United Kingdom

Background/Objectives: Most genome-wide association signals are suggested to act through gene expression. However, despite the extensive expression catalogs it has been difficult to attribute disease loci to these eQTLs. Here we aimed at exploring the contribution of eQTLs to disease in terms of number, primary vs secondary hit, and effect size distribution.

Methods: To test for pleiotropy between eQTLGen cis-eQTLs and immune-mediated disease's loci, we used leave-one-out conditional analysis coupled with Bayesian colocalization. We applied Mendelian randomisation to estimate the effect of gene expression on disease.

Results: Of the 139 significant disease loci overlapping with at least one eQTL we were able to colocalise 51 (36,7%). We compared if the colocalization could be attributed to the top hit or to secondary conditionally independent ones, the latter were 3.61x more likely to be responsible. Despite eQTLs of large effect have been described, when colocalized with a disease, the effect was generally below 0.4 standard deviations of gene expression, suggesting that they may be constrained due to their effect on health. Finally, we have identified several loci where eQTLs for multiple genes simultaneously colocalised with the disease locus, suggesting a common local regulation of their expression.

Conclusion: We show that disease loci are most likely driven by secondary association signals which can be detected when properly accounted for. The distribution of eQTLs puts an upper boundary to the disease relevant effect sizes that will be useful to plan future, larger eQTL studies.

P17.005.B A loci in *LINC01708* is associated with left ventricular outflow tract obstruction

Martin Broberg[1;2], *FinnGen Consortium*[3], *Emmi Helle*[1]

[1]*University of Helsinki, Stem Cells and Metabolism Research Program, Helsinki, Finland;* [2]*FIMM, FIMM, Helsinki, Finland;* [3]*FinnGen, FinnGen, Helsinki, Finland*

Consortium: FinnGen

Background/Objectives: Left ventricular outflow tract obstruction (LVOTO) are structural congenital heart defects (CHD) affecting the left side of the heart and the aorta. LVOTO defects are associated with aortic insufficiency (AI) and aortic stenosis (AS). However, AS and AI are also found in older individuals (>50 years of age) without CHDs. Our aim was to elucidate whether there are similar genetic determinants for congenital LVOTO defects and late onset AS/AI.

Methods: We performed a genome wide association study (GWAS) in FinnGen release 12 for broad LVOTO, including individuals diagnosed with congenital LVOTO defects (ICD-10 codes Q23-25) and early onset AS/AI (ICD-10 codes I35 in patients <50 years of age) cases = 2656. A separate GWASs were done for patients with congenital LVOTO defects (cases = 1734), early onset AS/AI (cases = 922), and late onset AS/AI (those diagnosed with an I35 code at >50 years of age, cases = 18,106). The number of controls was 475,604.

Results: We discovered a genome-wide significant loci associated with broad LVOTO group in rs35046143 (Chr1, *LINC01708*, beta = 0.21, stderr = 0.027, $p = 2.1 \times 10^{-14}$). This signal persisted in the congenital LVOTO cohort (beta = 0.21, stderr = 0.034, $p = 4.4 \times 10^{-10}$). A nearby signal in rs11166276 (Chr1, *LINC01708*, beta = 0.26, stderr = 0.025, $p = 7.6 \times 10^{-25}$) was significant in the late onset AS/AI cohort.

Conclusion: Our results suggest that congenital LVOTO defects share partially similar genetic risk loci with late onset aortic valve disease (AS/AI) not associated with CHD.

Consortium: The Ovarian Cancer Association Consortium (OCAC), Arbeitsgemeinschaft Gynäkologische Onkologie (AGO) Study Group

Background/Objectives: Survival from ovarian cancer strongly depends on the resection status after primary surgery. We aimed to identify genomic factors that may influence resection status.

Methods: We performed case-only GWAS analyses in the Ovarian Cancer Association Consortium to identify genetic variants associated with residual disease (complete resection RD = 0 cm versus any residual disease RD>0 cm). Logistic regression analyses were performed for overall (n = 7705) or restricted to invasive (n = 7099) or high-grade serous (n = 4954) ovarian carcinomas, and also with adjustment for FIGO stage (n = 7111, 6540, 4564, respectively). The most strongly associated variants were subsequently tested for their effect on methylation and mRNA expression in an independent set of 378 ovarian tumours from the German AGO-OVAR 11 study.

Results: A genome-wide significant association with resection status was observed for rs72845444, a variant upstream of *MGMT*, in HGSOC (MAF = 0.02; OR = 0.75, 95%CI = 0.57-0.97, $p = 3.9 \times 10$-8). In gene-based analyses, *PPP2R5C* was the most strongly associated gene in HGSOC after stage adjustment ($p = 4.8 \times 10$-6). *MGMT* encodes a DNA repair enzyme, and *PPP2R5C* encodes the B56γ subunit of the PP2A tumour suppressor. In ovarian tumours from the AGO-OVAR 11 study, variants near *MGMT* and *PPP2R5C* correlated with methylation and transcript levels, and *PPP2R5C* mRNA levels predicted progression-free survival in patients with residual disease.

Conclusion: Our results suggest that heritable variation at the *MGMT* and *PPP2R5C* loci impact resection status and progression-free survival in high-grade serous ovarian cancer.

Consortium: The VA Million Veteran Program

Background/Objectives: Differences in sleep duration, quality, and timing are associated with variation in health outcomes. Genetic studies may help explain the underlying mechanisms of sleep and its relationships to other conditions.

Methods: Using data from the UK Biobank and the Million Veteran Program we have conducted a cross-population genome wide association study of sleep duration (0-23hrs). We investigate the genetic correlation between sleep duration other traits, and use genomic structural equation modelling to consider causal relationships.

Results: We identify 363 (260 novel) independent loci for sleep duration. Genetic correlation analysis shows sleep duration is largely distinct from other measures of sleep or sleep disorders. We see several examples of negative corelation between a given trait and sleep duration, but positive associations to long (>9hrs) and short sleep (<6hrs) (e.g., depression, ADHD, cannabis use disorder, smoking). This supports clinical observations of a non-linear relationship between sleep duration and various other traits.

A sensitivity analysis of sleep duration restricted to 6-9hrs is >97% genetically correlated to the full sleep duration measure, demonstrating that a GWAS on sleep duration largely captures variation within the healthy range. This has implications for future work investigating sleep genetics.

Conclusion: This is the largest available GWAS of sleep duration, and the first to extend analyses outside of European ancestry populations. We identify novel loci for sleep duration and provide insight to the shared and unique genetic architecture across multiple sleep and neuropsychiatric traits.

P17.008.A Genetic architecture of fat and lean mass across body compartments in men and women

Alice Williamson[1;2], *Laura Wittemans*[2;3;4]

[1]*Precision Healthcare University Research Institute (PHURI), Queen Mary University of London, London, United Kingdom;* [2]*MRC Epidemiology Unit, Institute of Metabolic Science, University of Cambridge, Cambridge, United Kingdom;* [3]*Big Data Institute at the Li Ka Shing Centre for Health Information and Discovery, University of Oxford, Oxford, United Kingdom;* [4]*Nuffield Department of Women's and Reproductive Health, Medical Sciences Division, University of Oxford, Oxford, United Kingdom*

Consortium: The Body Composition Genomics Consortium

Background: Genetic analyses of overall adiposity and fat distribution have primarily focused on simple measures of body size (e.g., body mass index; BMI) or fat distribution (e.g., BMI-adjusted waist-hip ratio; WHR), important contributors to cardiometabolic disease risk. However, these simple measures do not explain the full spectrum of fat distribution across all body compartments nor consider lean mass. Dual X-ray absorptiometry scans (DEXA) provide greater insight into regional body composition.

Methods: We conducted fixed-effect genome-wide association study (GWAS) meta-analysis for 31 DEXA-derived regional fat and lean mass traits, including 74,554 individuals of European ancestry across 7 studies. Sex-stratified GWAS analyses allowed identification of sex-dimorphic loci. Cross-ancestry comparison included an additional 4,701 individuals of Qatari ancestry.

Results: We identified 679 independent signals ($P < 5 \times 10^{-8}$) after cross-trait fine mapping. Of these, 384 were specific to fat mass compartments, with limited overlap with signals for commonly used measures such as BMI (8%) or BMI adjusted WHR (48%), despite their much larger sample sizes. In Qatari-only analyses, 372 of these loci also had a significant signal ($P < 5 \times 10^{-5}$). We identified substantial differences in genetic effects between sexes on large body compartments, specifically peripheral fat distribution in the legs. Deep molecular and clinical phenotyping identified subsets of loci with distinct metabolic effects on human health.

Conclusion: This is the first large-scale study to identify the complex genetic architecture and sex differences of both fat and lean mass. This study demonstrates the value in going beyond simple indices to investigate the mechanisms influencing body composition.

P17.009.B Genome-wide aggregated *trans*-effects analysis on the risk of polymyalgia rheumatica and giant cell arteritis in UK Biobank

Amarachukwu Nwagbata[1], *Andrii Iakovliev*[1;2], *ann w morgan*[3], *Paul McKeigue*[1], *Athina Spiliopoulou*[1;2]

[1]*Usher institute, University of Edinburgh, Edinburgh, United Kingdom;* [2]*Institute for Genetics and Cancer, University of Edinburgh, Edinburgh, United Kingdom;* [3]*Leeds Institute of Cardiovascular and Metabolic Medicine and NIHR Leeds Biomedical Research Centre, University of Leeds, Leeds, United Kingdom*

Background/Objectives: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are frequently overlapping age-associated

systemic inflammatory diseases. We investigated the genetic architecture of PMR/GCA by integrating genotype, gene expression and proteins to identify "core" disease genes.

Methods: Using summary statistics for eQTLs (eQTLGen) and pQTLs (deCODE, UKB-PPP), we performed genome-wide aggregation of *trans*-effects (GATE) to compute genotypic scores for *trans*-regulated gene expression or protein level in 5673 PMR/GCA cases and 458530 controls in UK-Biobank. Core genes were identified by testing association between PMR/GCA and GATE scores, with subsequent validation using measured protein levels in 668 PMR/GCA cases and 50626 controls in UK-Biobank.

Results: We detected seven putative core genes at $P < 10^{-05}$: *ANKRD55* and *LEF1* from the eQTL-GATE analysis, and *CXCL9*, *PLG*, *IL13RA1*, *NRSN1*, *ASCC1* from the pQTL-GATE analysis. *ANKRD55* and *PLG* are GWAS hits for PMR/GCA. *ANKRD55* was additionally validated by a *cis*-score association. Protein-level measurement was available for *CXCL9*, *IL13RA1* and *PLG*. All three proteins were associated with PMR/GCA at $P < 10^{-03}$.

Conclusion: Using GATE analysis, we detected core genes for PMR/GCA pointing to relevant pathways: four genes are involved in cytokine/chemokine signalling pathways (*CXCL9, ANKRD55, ASCC1, IL13RA1*), and one (*PLG*) in blood coagulation. The *CXCL9-CXCR3* chemokine axis has been previously associated with recruitment and organisation of B-cells in the vessel wall in GCA. *PLG* encodes for plasminogen, which when activated degrades many blood plasma proteins, including fibrin-containing blood clots. The detected core genes present opportunities as drug targets or for drug repurposing once clinically validated.

Consortium: the EAGLE Eczema Consortium

Background/Objectives: Atopic dermatitis (AD) is a common inflammatory disorder. Filaggrin (*FLG*) loss-of-function mutations are the strongest genetic risk factor for AD, and are involved in skin barrier dysfunction. However, there is evidence for residual genetic modifier effects on AD risk. We explored gene-gene interactions with *FLG* on a genome-wide scale.

Methods: A genome-wide association (GWAS) meta-analysis was performed for 395,508 European individuals across 16 cohorts. For each cohort, GWAS was performed after stratifying individuals according to their *FLG* genotype (determined by the presence of any one of the most prevalent null mutations: R501X, 2282del4, R2447X, S3247X). Fixed effects meta-analysis was performed in individuals with *FLG* null mutations: 3,360 cases; 33,366 controls, the '*FLG* positive stratum', and those without *FLG* null mutations: 19,759 cases; 339,023 controls, the '*FLG* negative stratum'. An interaction Z-test was used to investigate differences in SNP associations between each stratum.

Results: The strongest signal for differential association was found for rs74445319 mapping close to *UBE2E3* ($P = 9.01 \times 10^{-7}$), which was more strongly associated with AD in the *FLG* positive stratum ($P = 3.42 \times$ 10-6; OR(95% CI) = 0.72(0.63-0.83)) compared to the negative stratum ($P = 0.09$; OR(95% CI) = 1.06(0.99-1.14)). Among 91 variants previously reported for AD risk, none showed strong evidence of interacting with *FLG* after correcting for multiple testing ($P < 5.49 \times 10^{-4}$).

Conclusion: We found limited evidence of *FLG*UBE2E3* interactions explaining AD risk. However stronger signals may be uncovered with the addition of larger sample sizes.

P17.011.D Genetic Determinants and Polygenic Score Assessment of Insulin Resistance

Usama Aliyu[1], *Umm-Kulthum Ismail Umlai*[1], *Salman Toor*[1], *Asma Anwar Fathi Elashi*[1], *Yasser Al-Sarraj*[2], *Abdul-Badi Abou-Samra*[3], *Karsten Suhre*[4,5], *Omar Albagha*[1]

[1]Hamad Bin Khalifa University (HBKU), Doha, Qatar; [2]Qatar Genome Program (QGP), Doha, Qatar; [3]Hamad Medical Corporation, Doha, Qatar; [4]Weill Cornell Medicine, New York, United States; [5]Weill Cornell Medicine - Qatar, Doha, Qatar

Background: Insulin resistance (IR) and beta cell dysfunction (BCF) are the major drivers of type 2 diabetes (T2D). Various common and rare genetic variants have been associated with IR and T2D in European populations. However, the genetic architecture of IR in Middle Eastern (ME) populations remains unexplored.

Methods: We conducted a comprehensive Genome Wide Association Study (GWAS) on the indices of IR (HOMA2-IR) and BCF (HOMA2-%B) in 6,217 non-diabetic individuals from the Qatar Biobank (QBB; Discovery cohort; n = 2170, Replication cohort; n = 4047) with and without body mass index (BMI) adjustment. We also developed polygenic scores (PGS) for HOMA2-IR and compared their predictive performance with European-derived PGS (PGS000877).

Results: We replicated 11 HOMA-IR-associated and 24 HOMA-%B-associated loci at nominal statistical significance. We also identified a novel locus associated with BCF near the *VEGFC* gene, tagged by rs61552983 ($P = 4.38 \times 10^{-8}$). Our top PGS performed similar to PGS000877 in predicting HOMA2-IR (adjusted R^2; $AdjR^2 = 0.229 \pm 0.014$; $P = 5.4 \times 10^{-4}$ versus $AdjR^2 = 0.231 \pm 0.014$; $P = 5.0 \times 10^{-7}$) and IR (area under the reciever operating characteristic curve; AUC = 0.552 versus AUC = 0.553).

Conclusion: This is the first GWAS on HOMA2 and the first GWAS focusing on IR and BCF in the ME. We reported a novel locus in *VEGFC* implicated in IR and BCF, highlighting the importance of population genetics on deciphering the genetics of complex humain traits.

P17.012.A Exploring the genetic landscape of pregnancy-related phenotypes and complications through low-pass whole genome sequencing in over 100,000 Chinese pregnancies

Huanhuan Zhu[1], *linxuan li*[1], **Xinyi Zhang**[1], *Xin Jin*[1]

[1]BGI Research, Shenzhen, China

Background: Over the last decade, significant advancements in Genome-wide Association Studies (GWAS) have been made. A primary challenge is the underrepresentation of non-European populations and limited availability of pregnancy phenotypic studies. Non-Invasive Prenatal Testing (NIPT) for fetal trisomies, utilizing maternal plasma cell-free DNA sequencing, has emerged as a globally adopted molecular test with over 10 million participants. Our previous research demonstrated the potential of NIPT data for human genetic studies.

Methods: We broadened this approach to encompass a range of maternal and neonatal phenotypes and common pregnancy complications. We conducted a genetic analysis of 104 pregnancy-related phenotypes from over 100,000 Chinese women, marking this as the largest such genetic study in the Asian population.

Results: Our GWAS revealed 410 genome-wide trait-locus associations, with 71.71% previously reported. Among the 116 novel hits, 83 were reproduced from independent replication studies. We discovered a significant association of ESR1 with fasting glucose, hemoglobin, hematocrit, and leukocyte counts. Considering the dramatic fluctuations in estrogen levels during pregnancy, we propose these ESR1- associations may be pregnancy-specific and merit further exploration. We investigated the genetic background of Gestational Diabetes Mellitus (GDM) and Intrahepatic Cholestasis of Pregnancy (ICP). For GDM, we replicated two known genes, CDKAL1 and MTNR1B. For ICP, we discovered a novel association SLC39A9. We established a website for offering all the GWAS results.

Conclusion: Our findings underscore the power of leveraging NIPT data to gain genetic insights into pregnancy-related phenotypes, accelerating future mechanistic studies into complex pregnancy traits and diseases.

P17.013.B Short tandem repeats and breast cancer risk

Joe Dennis[1], *Kyriaki Michailidou*[2], *Georgia Chenevix-Trench*[3], *Thilo Dörk*[4], *Douglas F. Easton*[1]

[1]Cambridge University, Centre for Cancer Genetic Epidemiology, Cambridge, United Kingdom; [2]The Cyprus Institute of Neurology & Genetics, Biostatistics Unit, Nicosia, Cyprus; [3]QIMR Berghofer Medical Research Institute, Herston, Australia; [4]Hannover Medical School, Gynaecology Research Unit, Hannover, Germany

Background/Objectives: Common genetic variants in approximately 150 regions are associated with breast cancer risk. These were identified through genotyping and imputation to reference panels of SNPs and indels but not short tandem repeats (STRs). We imputed STR genotypes from a panel phased onto SNP haplotypes for 133,000 breast cancer cases and 108,000 controls of European ancestry from the Breast Cancer Association Consortium (BCAC).

Methods: STRs at 446,000 loci were imputed using Beagle v5.4. We tested for associations using logistic regression, considering STRs in the model as: (a) a continuous covariate based on allele length, (b) each allele against all other alleles, (c) all alleles in a single model. We adjusted for country and ten principal components and ran conditional analyses adjusting for previously identified lead SNPs/indels.

Results: In the analysis by STR length, we identified significant associations ($P < 5 \times 10E\text{-}8$) at 1,164 STR loci. 1,083 of these were located in 106 of the previously established regions. Following conditional analyses, 122 STRs in 27 regions were associated at $P < 0.001$. 51 of the 161 strong SNP/Indel signals tested were no longer significant after conditional analysis, indicating that STRs may be driving these signals. Outside the known regions, novel associations driven by rare STR alleles were observed at seven loci.

Conclusion: A large proportion of established breast cancer associated variants are correlated with STRs, some of which may be causally associated with risk. Novel associations were observed for a small number of STR loci outside the previously known regions.

Chan School of Public Health, MA, USA; [5]National Heart & Lung Institute, Imperial College London – London (United Kingdom); [6]Translational Science and Experimental Medicine, Research and Early Development, Respiratory & Immunology, R&D BioPharmaceuticals, AstraZeneca - Cambridge (United Kingdom)

Background/Objectives: Approximately 10% of asthma patients remain uncontrolled despite maximal treatment and represent an unmet clinical need. We performed a genome-wide association study (GWAS) with moderate-severe asthma population to identify genetic risk factors.

Methods: UK Biobank participants with asthma were identified based on questionnaire data and electronic health records. Cases were further defined as having either: primary care prescriptions within stages 4-5 of British Thoracic Society guidelines, hospitalisation, or asthma-associated deaths. Controls were sex-matched, free from asthma, asthma-relevant prescriptions, and lung diseases. A GWAS was performed with ~9.8 million high-quality common variants, followed by a sensitivity analysis excluding allergic conditions. A meta-analysis of three independent studies was carried out for replication. Validated sentinel variants and their genomic loci (+/-1Mb) were fine-mapped to generate 95% credible sets, and linked to genes using variant/gene-annotation and colocalisation with molecular quantitative trait loci.

Results: We identified 7,681 cases (mean age of 57 years and 64% female) and 38,405 controls of European ancestry-like. The GWAS revealed 67 signals (p-value <= $5 \times 10\text{-}6$). Sensitivity analysis showed comparable results and replication in similarly defined subjects (11,862 cases and 30,377 controls) validated 21 signals all previously described. Fine-mapping revealed 615 putative causal variants in 16 different genomic loci. Variant-to-gene mapping analysis highlighted 90+ genes, including eight genes with at least three evidences of association (*BACH2*, *D2HGDH*, *IL4R*, *IL1RL1*, *NSMCE1*, *RORA*, *RPS26*, *SMAD3*).

Conclusion: Our GWAS identified 21 reproducible genetic signals associated with moderate-severe asthma. We generated hypotheses about which variants and genes are involved as a basis for future functional work.

P17.015.D Impact of control selection strategies on GWAS study of Schizophrenia and Bipolar disorder in UK Biobank

Jingzhan Lu[1], *Johan Thygesen*[2], *HARRY GREEN*[1]

[1]*University of Exeter, Medical School, Clinical and Biomedical Sciences, Exeter, United Kingdom;* [2]*University College London, Institute of Health Informatics, London, United Kingdom*

Background/Objectives: An essential part of a GWAS study is determining which control samples to use. Control selection is further complicated in extensive population datasets with longitudinal health records, as some choices must be made as to who classifies as healthy controls. The impact of these choices remains largely unexplored. This investigation provides insights into control selection strategies for GWAS.

Methods: We assessed the impact of three control selection strategies on GWAS in schizophrenia(SCZ) and bipolar disorder(BD) considering covariates: age, gender and deprivation. These were S1:random selection without covariates, S2:case/control matched analysis with covariates and S3:random selection with covariates. The study included 1,988 SCZ and BD cases of European ancestry from the UK Biobank, with a 1:4 case-to-control ratio. Individual GWAS were conducted under each strategy using regenie. Results were compared with the Psychiatric Genomics Consortium(PGC 2022), the largest GWAS meta-analysis(PGC: mean β/p-value difference −0.002/0.434) to date, which was considered the gold standard.

Results: The GWAS results showed that S2(matched) had smaller deviation from the PGC results(mean β/p-value difference −0.003/0.386) than S1(mean β/p-value difference 0.001/0.383) and S3(mean β/p-value difference −0.010/0.378). These results show that while including covariates improved concordance with the gold standard GWAS, case-control matching on covariates yielded optimal performance.

Conclusion: The strongest matching strategy ensures a more balanced control group selection in GWAS studies, as it maintains a close similarity in covariate levels between case and control groups. To ensure generalisability of these results, future studies will test the effectiveness of these three strategies on alternative cohorts and phenotypes.

P17.016.A Genome-wide association study of hemoglobin regulation and anemia during pregnancy in 96,558 Chinese pregnant women

Xinxin Guo[1], *Siyang Liu*[1]

[1]*Sun Yat-sen University, School of Public Health (Shenzhen)*

Background/Objectives: Gestational anemia is a global concern affecting about one-third of pregnant women, linked to various adverse birth outcomes. Despite its significance, our understanding of the genetic basis underlying gestational anemia remains limited. Our objective is to identify key genetic factors associated with gestational anemia and investigate whether there is a causal relationship between gestational anemia and adverse birth outcomes, as well as long-term health status.

Methods: We utilized data from 96,558 Chinese pregnant women and conducted separate Genome-Wide Association Studies (GWAS) in two distinct hospital cohorts and subsequently a fixed-effect meta-analysis encompassing five biomarkers (total hemoglobin (N = 96,558), hemoglobin A1 (N = 42,118), hemoglobin A2 (N = 42,128), fetal hemoglobin (N = 42,118), and ferritin(N = 53,000)) and two types of anemia (anemia (N = 96,546) and iron deficiency anemia (N = 32,578)). Pleiotropy and pathway enrichment analysis were conducted to interpret the genetic variants. Finally, two-sample Mendelian randomization studies between gestational anemia traits and 7 adverse birth outcomes, as well as 183 long-term health outcomes were conducted.

Results: We identified 175 signals at 89 loci, including 60 novel loci. We demonstrated that ESR1 may be a crucial regulator of hemoglobin during pregnancy by influencing the hypoxic response process mediated by EPAS1. Finally, we suggested the negative effect of gestational anemia on stillbirth and ovarian cancer.

Conclusion: This study deepens our understanding of the genetic basis of gestational anemia, offering insights into potential treatment strategies.

P17.017.B Identification of novel variants associated with LDL-C levels and evaluation of polygenic scores: a multi-ancestry Genome Wide Association Study

Umm-Kulthum Ismail Umlai[1], Salman Toor[1], Yasser Al-Sarraj[2], Shaban Mohammed[3], Moza Al-Hail[3], Ayman El-Menyar[3], Mohammed Gomaa[3], Amin Jayyousi[3], Nadeem Qureshi[4], Jassim AlSuwaidi[3], **Omar Albagha**[1]

[1]Hamad Bin Khalifa University (HBKU), Ar Rayyan, Qatar; [2]Qatar Foundation, Ar-Rayyan, Qatar; [3]Hamad Medical Corporation, Doha, Qatar; [4]University of Nottingham, United Kingdom

Background/Objectives: The genetic determinants of low-density lipoprotein cholesterol (LDL-C) levels in blood have been predominantly explored in European populations and remain poorly understood in Middle Eastern populations. We investigated the genetic architecture of LDL-C variation in Qatar.

Methods: Whole genome sequencing data of 13,701 individuals (discovery; n = 5,939, replication; n = 7,762) from the population-based Qatar Biobank (QBB) cohort was used to conduct a genome-wide association study (GWAS) on serum LDL-C levels. We also performed a multi-ancestry meta-analysis with the largest LDL-C GWAS conducted by the Global Lipids Genetics Consortium (GLGC). Lastly, we developed Qatari-specific polygenic score (PGS) panels and tested their performance against PGS derived from other ancestries.

Results: We replicated 165 previously reported loci that showed high correlation in allele frequency ($R^2 = 0.77$) and effect size ($R^2 = 0.53$) with the GLGC study (Graham *et. al*., Nature 2021). The multi-ancestry meta-analysis identified 2 novel LDL-C-associated loci; rs10939663 (*SLC2A9;* $P = 1.05 \times 10^{-8}$) and rs12783213 (*INPP5A;* $P = 3.17 \times 10^{-9}$). Moreover, the multi-ancestry derived PGS (PGS000889) performed best at predicting LDL-C levels, while the Qatari-derived PGS panels also showed comparable performance.

Conclusion: We report novel genetic variants associated with LDL-C levels, which may be explored further to decipher their potential roles in the etiopathogenesis of cardiovascular diseases. Moreover, our findings also highlight the importance of including underrepresented populations in GWAS to improve genetic insights into various traits/diseases.

Grants: This study was supported by a grant from the Qatar National Research Fund (QNRF; Grant No. PPM 03-0324-190038).

P17.018.C Variants across the allelic spectrum make important contributions to cystic kidney disease

Omid Sadeghi-Alavijeh[1], *Melanie Chan[1], Gabriel Doctor[1], Catalin Voinescu[1], Alex Stuckey[2], Alexander Ho[2], Horia Stanescu[1], Detlef Bockenhauer[1], Adam Levine[1], Daniel Gale[1]*

[1]University College London, Renal Medicine, United Kingdom; [2]Genomics England, United Kingdom

Consortium: Genomics England Research Consortium

Background/Objectives: Cystic kidney disease (CyKD) gene discovery has been led by family/candidate gene studies, limiting the ascertainment of additional genome-wide variants involved. Using whole genome sequencing data from the 100,000 Genomes Project (100KGP), we sought to systematically characterize CyKD across allele types and frequency.

Methods: We performed a genome-wide association analysis involving 1,209 unrelated CyKD patients and 26,096 ancestry-matched unaffected controls. We examined all types of variants across the allelic frequency, both genome-wide and per gene, using a generalized linear mixed model. Heritability and meta-analysis were conducted, including cohorts in the Finnish, UK, and Japanese biobanks.

Results: 995/1209 (82.30%) cases had an explaining monogenic variant. Gene-based analysis of rare damaging variants revealed *PKD1* ($P = 1.13 \times 10^{-309}$), *PKD2* ($P = 1.96 \times 10^{-150}$), *DNAJB11* ($P = 3.52 \times 10^{-7}$), *COL4A3* ($P = 1.26 \times 10^{-6}$) and truncating mono-allelic *PKHD1* ($P = 2.98 \times 10^{-8}$) variants to be significantly associated with CyKD. Removing "solved" cases revealed an association at *IFT140* ($P = 3.46 \times 10^{-17}$) and strengthened the *COL4A3* ($P = 9.27 \times 10^{-7}$) signal.

Genome-wide structural variant associations included deletions in *PKD1* ($P = 2.17 \times 10^{-22}$), *PKD2* ($P = 7.48 \times 10^{-12}$) and the 17q12 locus containing *HNF1–* ($P = 4.12 \times 10^{-8}$).

Meta-analysis of 2,923 cases and 900,824 controls across 6,641,351 common variants did not reveal significant associations. CyKD common variant heritability was 3-9% across three European cohorts.

Conclusion: This represents the first whole genome examination of a national CyKD cohort using robust statistical methodology. We confirm the recently described *IFT140* association, highlight CyKD as a presenting feature of collagen IV-related nephropathy and expand the spectrum of abnormalities associated with *PKHD1*. Common/structural variants play an under-recognized and important role in CyKD heritability. Further work is needed to understand the underlying biological mechanisms.

P17.019.D genome-wide association studies of thyroid-related hormones, dysfunction, and autoimmunity among 85,421 Chinese pregnancies

Yuandan Wei[1], *yuqin Gu[1], Yanhong Liu[1], Xinxin Guo[1], Siyang Liu[1]*

[1]Sun Yat-Sen University

Background/Objectives: To identify the missing genetic components related to thyroid function traits and thyroid autoimmunity, and to gain a deeper understanding of the genetic architecture of thyroid function in pregnant women and its impact on birth outcomes.

Methods: Utilizing hospital electronic medical records and non-invasive prenatal testing data from 85,421 Chinese pregnancies, we conducted the most comprehensive GWAS studies of thyroid traits during pregnancy. The comprehensive thyroid-related traits include thyroid-stimulating hormone (TSH)/ free thyroxine (FT4) levels, 4 thyroid dysfunctions, and 2 thyroid autoimmunity phenotypes related to thyroperoxidase antibodies. We explored the associations between 8 maternal thyroid traits and 6 fetal birth outcomes (birth gestational days, preterm birth, birth weight, birth length, low birth weight, and Macrosomia) through a combination of observational analysis of cohort data and Mendelian randomization (MR).

Results: We identified 141 genome-wide loci, of these 98 genome-wide associations that have not been previously reported for the 8 thyroid-related traits. 13 loci that contained more than one independent signal suggests allelic heterogeneity at the thyroid-associated loci. In MR analysis, we discovered a significant potential causal effect of elevated TSH levels during pregnancy on greater birth gestational days after Bonferroni correction (β95% CI = 0.07[0.05-0.09], P = 5.54E-4).

Conclusion: This study greatly improved our understanding of the genetic basis of thyroid traits during pregnancy. And MR studies offer evidence that maternal TSH levels during pregnancy may be a potential causal factor for gestational duration.

Grants: The study was supported by the Shenzhen Basic Research Foundation (20220818100717002), and the National Natural Science Foundation of China (31900487).

P17.020.A Determining the genetic correlation of glioma and five primary extracranial cancers which metastatise to the central nervous system

Zak Thornton[1], *jamie robinson*[1], *kathreena kurian*[1], *Lavinia Paternoster*[1]

[1]*University of Bristol, MRC Integrative Epidemiology Unit, Bristol, United Kingdom*

Background/Objectives: There are five extra-cranial cancers which are commonly metastasise to the central nervous system (CNS); breast, colorectal, kidney, lung, and skin melanoma. The aim of this study is to investigate whether there is an increased genetic correlation between these cancer types and glioma, compared to other cancers that don't typically metastasise to the CNS.

Methods: We used IEU OpenGWAS, NHGRI-EBI GWAS catalogue and dbGaP to retrieve GWAS summary statistics from 20 different cancer types. We used Bivariate linkage disequilibrium score regression (LDSC) to estimate global cross-trait genetic correlation (r_g) between various cancer types and glioma to determine if CNS metastasising cancers are more highly correlated with glioma compared to other cancer types. Additionally, we will use Local Analysis of Variant Annotation (LAVA) to estimate genetic correlation within smaller genomic loci, to highlight genomic regions of shared genetic aetiology between traits.

Results: Using LDSC, we found that five cancer types; breast, lung, non-small cell lung cancer (NSCLC), skin melanoma and squamous cell carcinoma had some evidence for global genetic correlation with glioma ($p < 0.05$). Skin melanoma had the highest genetic correlation with glioma ($r_g = 0.3175$, $p = 0.0013$). We found that NSCLC was significantly correlated in the non-glioblastoma caseload ($p = 0.0233$) but not in the glioblastoma caseload. We will also show results from our regional correlation analysis.

Conclusion: We have found three of the five CNS metastasising cancers of interest had positive global genetic correlation with glioma. These analyses shed light on the shared genetic aetiology between some cancers, which may help to identify common causes and drug repurposing opportunities.

P17.021.B Evaluating sex differences in the ultra-rare variant contribution to autism and their effects on liability.

Mahmoud Koko[1], *Varun Warrier*[2], *Hilary Martin*[1]

[1]*Wellcome Sanger Institute, Human Genetics, Hinxton, United Kingdom;* [2]*Autism Research Centre, University of Cambridge, Department of Psychiatry, Cambridge, United Kingdom*

Consortium: APEX Consortium

Background/Objectives: We examined the burden of de novo mutations (DNM) and ultra-rare inherited variants in 26,908 autistic children from the SPARK study, asking whether they contribute to the sex bias in autism prevalence.

Methods: DNM rates were compared between autistic children (10,482 males and 2,991 females) and their sex-matched siblings (3,305 males and 3,458 females). Over-transmission from 40,356 parents to 20,893 autistic males and 6,015 females was measured using the Transmitted/Untransmitted allele ratio. Rate differences were converted to the liability scale.

Results: Deleterious protein truncating and missense variants increased autism liability without significant sex differences, both when inherited (Z ~ 0.01 - 0.08) or occurring de novo (Z ~ 0.25 - 0.5). DNM variant liability in individuals with cognitive or motor impairment was two-fold higher than in individuals with autism only. The liability conferred by deleterious variants in established autism genes did not reveal significant sex differences in either phenotypic group. Genes that are more highly expressed in male than female fetal brain tissues were enriched for deleterious variants in the motor/cognitive impairment group, also without a significant sex bias. A Bayesian TADA meta-analysis of SPARK trios and published summary statistics (27,092 autistic individuals) identified 84 genes associated with autism (FDR < 0.1%) - an increase from 72 published, which increased further when SPARK was stratified to individuals with/out motor/cognitive impairment.

Conclusion: While they confer higher liability to comorbid motor and cognitive impairment, damaging rare variants are unlikely to mediate sex-differential risk.

P17.023.D Genetic risk for psychiatric disorders is associated with measurable differences in brain volume and cerebrospinal fluid volume at birth

Harriet Cullen[1;2], *Konstantina Dimitrakopoulou*[3], *Hamel Patel*[4], *Charles Curtis*[4], *Joseph Hajnal*[1], *A David Edwards*[1]

[1]*King's College London, Perinatal Imaging & Health Department, London, United Kingdom;* [2]*King's College London, Department of Medical and Molecular Genetics, London, United Kingdom;* [3]*Guy's and St Thomas' NHS Foundation Trust and King's College London, Translational Bioinformatics Platform, NIHR Biomedical Research Centre, London, United Kingdom;* [4]*King's College London, NIHR Maudsley Biomedical Research Centre, London, United Kingdom*

Background/Objectives: Case-control studies, predominantly in adults and adolescents, have consistently identified differences in brain morphology in individuals affected with psychiatric disorders. The genetic architecture of psychiatric disorders is polygenic and many of the genes identified through genome-wide association studies show elevated expression during foetal and early neonatal life. Here we focus on this early timepoint and

ask if polygenic risk for psychiatric disorders is associated with measurable differences in the infant brain at birth.

Methods: Our term-born European subsample comprises 267 infants with MRI volumetric and genetic data. Genotype data were used to compute polygenic risk scores (PRS) for five psychiatric disorders (ADHD, ASD, Major Depressive Disorder, Bipolar Disorder and Schizophrenia) and a Cross-Disorder risk (eight psychiatric disorders combined). Estimates of the total brain volume (TBV), cerebrospinal fluid (CSF) volume, white and grey matter volumes, ventricular volume, and volumes of five subcortical structures were extracted from T2-weighted MRI images at term-equivalent age. The relationship between infant brain volume and psychiatric PRS was explored using linear regression models with appropriate covariates.

Results: Greater genetic risk for ADHD ($p = 1.12 \times 10^{-3}$, $\beta = 0.13 \pm 0.04$) and Cross-disorder ($p = 1.44 \times 10^{-3}$, $\beta = 0.13 \pm 0.04$) were associated with larger CSF volume. Greater genetic risk for Cross-disorder was also associated with smaller white matter volume ($p = 1.06 \times 10^{-3}$, $\beta = -0.07 \pm 0.02$) and smaller total brain volume ($p = 3.22 \times 10^{-3}$, $\beta = -0.11 \pm 0.04$).

Conclusion: This work identified several statistically significant associations between genetic susceptibility for psychiatric disorders and both brain and CSF volumes at birth. It adds to the literature addressing the largely unexplored role of common genetic variation in shaping the developing brain.

P17.024.A Beyond Volume: Unraveling the Genetics of Human Brain Geometry

Sabrina Primus[1;2], *Felix Hoffstaedter*[3;4], *Federico Raimondo*[3;4], *Simon Eickhoff*[3;4], *Juliane Winkelmann*[2;5;6], *Konrad Oexle*[1;2;5], *Kaustubh Patil*[3;4]

[1]*Neurogenetic Systems Analysis Group, Institute of Neurogenomics, Neuherberg, Germany;* [2]*Institute of Neurogenomics, Helmholtz Munich, Neuherberg, Germany;* [3]*Institute of Neuroscience and Medicine, Brain and Behaviour (INM-7), Research Centre Jülich, Jülich, Germany;* [4]*Institute of Systems Neuroscience, Medical Faculty, Heinrich Heine University, Düsseldorf, Germany;* [5]*Institute of Human Genetics, School of Medicine, Technical University Munich, München, Germany;* [6]*Munich Cluster for Systems Neurology (SyNergy), München, Germany*

Background/Objectives: Laplace-Beltrami (LB) eigenmodes of brain structures allow for reconstructing brain activity, indicating a close relation between brain geometry and function[1]. Further, the spectrum (set of eigenvalues) of the associated LB operator can be regarded as an encoding of form ("Shape-DNA")[2]. The LB spectra of subcortical brain structures have been shown to have considerable heritability[3].

1.Pang, J. C. *et al*. Geometric constraints on human brain function. *Nature* **618**, 566–574 (2023).

2.Reuter, M., Wolter, F.-E. & Peinecke, N. Laplace–Beltrami spectra as 'Shape-DNA' of surfaces and solids. *Computer-Aided Design* **38**, 342–366 (2006).

3.Ge, T. *et al*. Multidimensional heritability analysis of neuroanatomical shape. *Nat Commun* **7**, 13291 (2016).

Methods: We examined the genetics of subcortical brain structure shapes in 19,862 healthy White-British UK Biobank participants by multivariate GWAS (MOSTest) on their LB spectra while controlling for global form descriptors. Moreover, a Canonical Correlation Analysis (CCA) was conducted to investigate the relationship between shape and polygenic risk scores of brain-related diseases and traits.

Results: We identified several independent variants being associated with the shapes of one or various brain structures at a genome-wide significance level. The CCA revealed significant correlations between brain structure shapes and polygenic risk scores of several traits.

Conclusion: We delineate the genetics of brain structure shapes beyond global attributes.

Background/Objectives: Environmental exposures such as diet and antibiotics are known to influence the gut microbiota. In comparison, less is known about the role of host genomics on gut microbial composition, especially during early-life. In this study we integrate host genomics with exposures to investigate their main and interaction effects on the gut microbiota during the first year of life, and identify microbes associated with risk of childhood atopy.

Methods: We leveraged microbiome data from the CHILD Cohort Study generated from 16S rRNA sequencing of stool samples collected at 3 months ($N = 747$) and 1 year ($N = 766$), genomic profiles from the Illumina HumanCoreExome Bead Chip, and questionnaire data on environmental exposures. Genome-wide gene-environment interactions were assessed using linear regression models.

Results: *Megasphaera micronuciformis* abundance at 1 year was associated with variants on chromosome 6 (e.g., rs7771791) among breastfed children exposed to low concentrations of the human milk oligosaccharide disialyl-lacto-N-hexaose ($P = 6.4 \times 10^{-9}$). Moreover, *Clostridium sensu stricto sp. 4* abundance at 3 months was associated with loci on chromosome 1 (e.g., rs6696969) in males born during the winter months ($P = 1.4 \times 10^{-9}$). These microbial abundances were correlated with allergic sensitizations ($P_{Benjamini\text{-}Hochberg} = 3.7 \times 10^{-2}$) and atopic dermatitis ($P_{Benjamini\text{-}}$

$_{Hochberg} = 8.8 \times 10^{-3}$) in children between ages 3-5 years, respectively.

Conclusion: Our findings suggest that interactions between host genomics and environmental exposures influence the early-life gut microbiota of children, which may impact their susceptibility to atopic diseases. Improved understanding of factors influencing gut dysbiosis and childhood diseases will inform early-life biomarkers and interventions.

P17.026.C Changes in the genetic architecture of SARS-CoV-2 infection observed for the Omicron variant

Frank Geller[1], *xiaoping wu*[1], *Vilma Lammi*[2], *Erik Abner*[3], *Ole Pedersen*[4], *Erik Sørensen*[5], *Lampros Spiliopoulos*[1], *Peter Bager*[1], *Anders Hviid*[1], *Hanna Ollila*[2], *Sisse Rye Ostrowski*[5], *Bjarke Feenstra*[1]

[1]*Statens Serum Institut, Copenhagen, Denmark;* [2]*Institute for Molecular Medicine, Helsinki, Finland;* [3]*Estonian Genome Centre, Tartu, Estonia;* [4]*Zealand University Hospital, Køge, Denmark;* [5]*Copenhagen University Hospital, Copenhagen, Denmark*

Background/Objectives: The genetics of SARS-CoV-2 infection has been investigated by the Host Genetics Initiative (HGI) in about 220,000 cases diagnosed before the predominance of the Omicron variant in late 2021. We performed a genome-wide association study in 22,041 cases infected with the Omicron variant and 24,841 controls with no known SARS-CoV-2 infection to investigate potential differences between associated SNPs for Omicron compared to previously reported SNPs identified by the HGI for earlier SARS-CoV-2 variants.

Methods: Cases of SARS-CoV-2 infection with Omicron and controls were identified through the Danish EFTER-COVID project and linked to genetic data from the Danish Blood Donor Study and Copenhagen Hospital Biobank.

Results: The SNPs identified in our GWAS only partly overlapped with SNPs previously identified by the HGI. The most remarkable findings were (1) a locus on chromosome 3q27.3 (a known QTL for BMI-adjusted adiponectin), and (2) drastic changes in associations at the AB0 locus, where a protective effect was no longer seen for the SNP associated with blood group 0 and where the SNP with the strongest association suggests a protective effect of blood group B against Omicron infection. We decided to extend our study to a meta-analysis with more than 150,000 cases from international cohorts, and preliminary results confirm our findings and show additional new associations.

Conclusion: The Omicron variant has a large number of mutations compared to the original Wuhan strain, which is probably a main reason for the observed changes in the genetics of SARS-CoV-2 infection.

P17.027.D Whole-exome sequencing association study for the identification of genetic modifying factors of lung and liver disease in Alpha-1 Antitripsin Deficiency

Nerea Matamala[1], *Sara Gil-Martin*[1;2], *Guillermo Pita*[3], *Anna Gonzalez-Neira*[3], *Myriam Calle-Rubio*[4], *Juan Luis Rodriguez-Hermosa*[4], *otto hagen*[1], *Gema Gomez-Mariano*[1], *Francisco Javier Alonso*[1;2], *Beatriz Martinez-Delgado*[1]

[1]*Institute of Health Carlos III (ISCIII), Rare Disease Research Institute (IIER), Majadahonda;* [2]*Institute of Health Carlos III (ISCIII), Biomedical Research on Rare Diseases Network Centre (CIBERER), Majadahonda;* [3]*Spanish National Cancer Research Centre (CNIO), Human Genotyping-CEGEN Unit, Madrid, Spain;* [4]*Hospital Clínico San Carlos (HCSC), Madrid, Spain*

Background/Objectives: Alpha-1 antitrypsin deficiency (AATD) is a genetic condition that can cause lung and/or liver damage. Although environmental factors are known to influence on clinical phenotype, not all the phenotypic variation in AATD can be explained by them, suggesting the contribution of genetic factors. The aim of this study was to identify genetic modifying factors of lung and liver disease in patients with AATD and PiZZ genotype.

Methods: We have performed a genetic association study with whole exome sequencing data from 72 patients with PiZZ genotype, 13 of them had liver damage (ZZ-HIG) while 59 developed lung disease (ZZ-PUL). Variants significantly associated with ZZ-HIG or ZZ-PUL cases were functionally annotated.

Results: We have identified 537 genes with variants significantly associated with one of the groups, 664 variants in 412 genes presented a higher frequency in ZZ-HIG cases and 270 variants in 125 genes appeared more frequently in ZZ-PUL cases. Fourteen percent (14%) of the significant variants are coding, while 86% are intronic variants that could have an effect on gene regulation. The functions of the genes associated with liver disease (ZZ-HIG) reveal involvement in transport pathways and lipid metabolism mainly. In the case of variants associated with lung disease (ZZ-PUL), they are related to specific functions such as neutrophil recruitment, surfactant production and lung function.

Conclusion: Although further validation is needed, the results suggest that these variants could be useful biomarkers for the stratification of patients with AATD, providing information about the risk of developing lung or liver disease.

P17.028.A Genome-Wide Polygenic Models for 2,922 Plasma Protein Levels from Over 50,000 UK Biobank Participants

Pouria Dasmeh[1], *Hannah Klinkhammer*[2;3], *Gabriel Schweizer*[1], *Peter Krawitz*[3], *Johannes Schumacher*[1], *Christian Staerk*[2], *Andreas Mayr*[2], **Carlo Maj**[1]

[1]*Philipps-University Marburg, Center for Human Genetics, Marburg, Germany;* [2]*Institut für Medizinische Biometrie, Informatik und Epidemiologie (IMBIE), Bonn, Germany;* [3]*Institute for Genomic Statistics and Bioinformatics, Bonn, Germany*

Background/Objectives: Protein expression is significantly influenced by genetics, with regulatory variants typically located within or close to their encoding genes (cis-pQTLs). The study of distant trans-pQTLs has been limited due to smaller effect sizes and also power and computational issues in analyzing genome-wide variant-gene pairs.

Methods: Using snpboost framework we derived genome-wide sparse polygenic models for 2,922 plasma proteins from 52,682 UK Biobank samples (60% training, 20% validation, 20% testing). Model performances were assessed by considering the incremental-R^2 with respect to covariates-only models (i.e., sex, age, and 10 PC). Cis-models were derived by filtering for variants within 500 kb of gene flanking regions.

Results: Polygenic models showed strong (mean incremental R^2 of 0.103) but heterogeneous performances (500 proteins with incremental-$R^2 < 0.01$, 68 proteins showing a predominant genetic component with incremental-$R^2 > 0.5$) and genetic architectures (from 1 to 3,211 variants, mean 405). On average cis-pQTL effect-sizes are 4.64 times stronger than trans-pQTL and represent only 5.78% of the PRS models but the corresponding cis-models reach on average 55.63% of the genome-wide models' performances. Noteworthy, predicted proteins among 14 pairs of genomic-

coordinates overlapping genes showed lower Pearson correlations in the genome-wide models than in the cis-models (average 0.126 vs 0.242).

Conclusion: Snpboost genome-wide polygenic models for plasma protein levels corroborated the presence of stronger oligogenic cis-regulatory effects but also revealed substantial distant-regulatory polygenic components which can also be less influenced by co-regulation or coincidental associations among overlapping genes. The models are available at https://proteinprs.com/.

P17.029.B New findings in the genetics of eating behaviour (EB): Genome-Wide Association Studies (GWAS) on taste perception (TP) and food liking (FL) in Italian cohorts

Maria Pina Concas[1], Sara Spinelli[2], Silvia Camarda[3], Erminio Monteleone[2], Alessandro Pecori[1], Caterina Dinnella[2], **Paolo Gasparini**[1;3]

[1]Institute for Maternal and Child Health IRCCS "Burlo Garofolo", Trieste, Italy; [2]University of Florence, Department of Agriculture, Food, Environment and Forestry (DAGRI), Florence, Italy; [3]University of Trieste, Department of Medicine, Surgery and Health Sciences, Trieste, Italy

Background/Objectives: Both TP and FL play a fundamental role in EB and, consequently, in health status. Despite moderate/high heritability, little is known about genes involved. Therefore, this study aimed to investigate the molecular bases of 1) TP and 2) FL in Italian cohorts.

Methods: The following individuals were enrolled in the study: 1354 individuals from the Italian Taste Project (ITP), 729 from Friuli-Venezia Giulia (FVG), and 701 from Val Borbera (VB).

1)GWAS on TP were conducted on the perceived intensity of eight different substances, in ITP subjects and replicated in FVG and VB.

2)GWAS on FL were performed testing 100 foods in FVG and replicated in VB.

Results: 1)A unique clear signal ($p < 5 \times 10^{-8}$) was detected in correspondence to the *TAS2R38* gene for bitterness, and for the first time, saltiness, sourness, and astringency. In addition, we identified suggestive loci ($p < 10^{-6}$) for sweetness, umami and pungency in regulator of G-proteins and potassium channel genes.

2)GWAS on FL led to an interesting signal for milk chocolate. The best SNP ($p = 1.02 \times 10^{-9}$) is an eQTL for the *LARP1* gene in Nucleus Accumbens (NAc), a central driver of reward response controlling food gratification and regulating behaviour. Subjects carrying the minor allele showed a reduced liking for sweet foods, and a reduced impulsivity ($p < 0.05$).

Conclusion: This study provided new findings in the genetics of EB that highlight both the role of *TAS2R38* not only in bitter perception, and that of NAc in regulating FL and impulsive behaviour. Further studies are needed to better elucidate these results.

P17.030.C Phenotypic and genome-wide association studies on dicarbonyls

Philip Harrer[1;2], *Julica Inderhees[3;4;5], Chen Zhao[1;6], Barbara Schormair[1;2], Erik Tilch[1;6], Christian Gieger[7;8], Annette Peters[7;9;10], Olaf Jöhren[3;4], Thomas Fleming[11], Peter P. Nawroth[11], Klaus Berger[12], Marco Hermesdorf[12], Juliane Winkelmann[1;2;13;14], Markus Schwaninger[3;5], Konrad Oexle[1;2;6]*

[1]Helmholtz Munich, Institute of Neurogenomics, Oberschleißheim, Germany; [2]Technical University of Munich, Institute of Human Genetics, München, Germany; [3]University of Lübeck, Institute for Experimental and Clinical Pharmacology and Toxicology, Lübeck, Germany; [4]University of Lübeck, Bioanalytic Core Facility, Lübeck, Germany; [5]German Centre for Cardiovascular Research, Hamburg-Lübeck-Kiel, Germany; [6]Helmholtz Munich, Neurogenetic Systems Analysis Group, Oberschleißheim, Germany; [7]Helmholtz Munich, Institute of Epidemiology, Oberschleißheim, Germany; [8]Helmholtz Munich, Research Unit of Molecular Epidemiology, Oberschleißheim, Germany; [9]German Center for Diabetes Research, Neuherberg, Germany; [10]Ludwig Maximilian University of Munich, Chair of Epidemiology, Institute for Medical Information Processing, München, Germany; [11]Heidelberg University, Department of Internal Medicine, Heidelberg, Germany; [12]University of Münster, Institute of Epidemiology and Social Medicine, Münster, Germany; [13]Munich Cluster for Systems Neurology (SyNergy), München, Germany; [14]German Centre for Mental Health, München-Augsburg, Germany

Background/Objectives: Phenotypic and genome-wide association studies (GWAS) examining the dicarbonyl compounds methylglyoxal (MG), glyoxal (GO), and 3-deoxyglucosone (3-DG) in a disease-independent context have not been provided yet.

Methods: LC-MS was employed to measure MG, GO, and 3-DG in 1,304 serum samples collected from two distinct populations, KORA ($n = 482$) and BiDirect ($n = 822$). Subsequently, these measurements were analyzed for associations with genome-wide SNPs (GWAS) and phenome-wide traits. To identify major independent trait associations, redundancy analysis (RDA) was applied.

Results: The correlation between dicarbonyls was significant, notably stronger for MG and GO ($\rho = 0{\cdot}6$) than for 3-DG and MG or GO ($\rho = 0{\cdot}4$). Phenotypic findings encompassed significant associations of all dicarbonyls with sex, waist-to-hip ratio, glomerular filtration rate (GFR), gamma-glutamyltransferase (GGT), and hypertension. Additionally, MG and GO were significantly associated with age and C-reactive protein, GO and 3-DG with glucose and antidiabetics, MG with contraceptives, GO with ferritin, and 3-DG with smoking. RDA identified GFR, GGT, and glucose as major explanators of dicarbonyl variance. Genome-wide association studies (GWAS) did not yield significant loci. However, limiting multiple testing correction to lead SNPs from GWASs on RDA-selected traits revealed a significant association ($p = 2{\cdot}3 \times 10\text{-}5$) between 3-DG and rs1741177, an eQTL of NF-κB inhibitor NFKBIA.

Conclusion: This first large-scale, population-based study has identified numerous phenotypic associations, with GFR and GGT being of pivotal importance, providing unbiased and novel perspectives on dicarbonyls beyond the current state. GWAS power will profit from meta-analysis with analogous studies.

Grants: Deutsche Forschungsgemeinschaft, Helmholtz Munich, German Centre for Cardiovascular Research (DZHK), German Federal Ministry of Research and Education (BMBF).

P17.031.D Enhanced insights into the genetic architecture of 3D cranial vault morphology using pleiotropy-informed conditional GWAS

Seppe Goovaerts[1], *Hanne Hoskens[1], Noah Herrick[2], MENG YUAN[1], Mark Shriver[3], John Shaffer[4], Susan Walsh[2], Seth Weinberg[4], Peter Claes[1]*

[1]KU Leuven, Department of Human Genetics; [2]Indiana University Indianapolis, Department of Biology, Indianapolis, United States; [3]Pennsylvania State University, Department of Anthropology; [4]University of Pittsburgh, Department of Oral and Craniofacial Sciences

Background/Objectives: Large-scale GWAS studies have identified several hundred genomic loci associated with typical-range variation in facial and brain shape, but only tens of loci associated with cranial vault shape, leaving it an understudied component of the craniofacial complex. Surrounding and protecting the neocortex, the cranial vault plays a central role during craniofacial development, and its morphogenesis and growth are intimately tied to adjacent tissues and organs. Hence, an improved genetic understanding of its development is key to understanding the coordinated development of craniofacial structures and the etiology of craniofacial anomalies. Here, we test the hypothesis that leveraging genetic data from related traits can improve the discovery of SNPs associated with cranial vault shape.

Methods: We first show that the genomic architectures of brain shape, facial shape, and bone mineral density are strongly enriched for SNPs associated with cranial vault shape due to genomic and structural correlations. Based on GWAS summary statistics from independent cohorts, these auxiliary traits were then leveraged to re-analyze a recent cranial vault GWAS using a conditional false discovery rate (FDR).

Results: This yielded 120 independent genomic loci at 1% FDR, almost three-fold that of unconditioned analysis. Genes near these loci implicate key craniofacial transcription factors and signaling pathways, including genes involved in FGF, BMP, Wnt, Hedgehog, and retinoic acid signaling, most of which were not previously identified as contributors towards vault shape.

Conclusion: Altogether, our improved GWAS discovery substantially enhances the genetic understanding of typical-range variation in cranial vault shape and craniofacial development more broadly.

Background/Objectives: Canary Islanders have one of the highest incidence and mortality rates for cardiovascular disease and cancer in Spain. This study aimed to identify risk variants for mortality in this population using a genome-wide association analysis.

Methods: The study is a cross-sectional analysis of increased mortality risk assessing 9.6 million TOPMed-imputed genetic variants in 1,259 Canary Islanders individuals (394 deaths) from the CDC cohort. The region around 2 Mb of the significant variants, identified using logistic regression models, was then subjected to Cox regressions for sensitivity analyses. Significance was declared at $p < 5.0 \times 10^{-8}$. Furthermore, fine mapping and functional analyses of the significant locus were performed to prioritise the variants implicated.

Results: We identified three genome-wide significant variants located at 17q21.32 ($p_{lowest} = 3.36 \times 10^{-8}$). Cox regression analysis prioritised the *NFE2L1*, *CBX1*, and *SNX11* genes. These genes have previously been associated with several types of cancer. This is consistent with more than a third of deaths in this study were due to this condition.

Conclusion: We performed the first survival analysis in Canary Islanders and identified risk variants and genes of interest at 17q21.32. Rare variant analyses in this region are underway.

Grants: Grant PMP22/00033 funded by ISCIII, and by the European Union NextGenerationEU, Mecanismo para la Recuperación y la Resiliencia; Fundación Canaria Instituto de Investigación Sanitaria de Canarias (ST23/04); ITER agreement (OA23/043); Gobierno de Canarias, Social European Fund "Canarias Avanza con Europa" (TESIS2022010042).

Background/Objectives: Childhood incontinence is stigmatized and underprioritized, and a basic understanding of its pathogenesis is missing. Our goal was to identify risk-conferring genetic variants in daytime urinary incontinence (DUI).

Methods: We conducted a genome-wide association study in the Danish iPSYCH2015 cohort. Cases (3,024) were identified through ICD10 diagnosis codes and redeemed prescriptions for DUI in children aged 5 to 20. Controls (30,240) were matched on sex and psychiatric disorders and downscaled to a 1:10 ratio. Replication was performed in the Icelandic deCODE cohort (5,475 cases/287,773 controls). Single-nucleotide polymorphism heritability was calculated using the genome-based restricted maximum likelihood method. Cross-trait genetic correlation was estimated using linkage disequilibrium score regression. Polygenic risk scores generated with LDpred2-auto were assessed for association.

Results: Variants on chromosome 6 (rs12210989, OR = 1.24 [95% CI: 1.17-1.32], $P = 3.21 \times 10^{\div 12}$) and 20 (rs4809801, OR = 1.18 [95% CI: 1.11-1.25], $P = 3.66 \times 10^{\div 8}$) reached genome-wide significance and implicated the *PRDM13* and *RIPOR3* genes. Chromosome 6 findings were replicated ($P = 0.024$, OR = 1.09 [95% CI: 1.01-1.16]). Liability scale heritability ranged from 10.20% (95% CI: 6.40-14.00%) to 15.30% (95% CI: 9.66%-20.94%). DUI and nocturnal enuresis showed positive genetic correlation

($r_g = 1.28 \pm 0.38$, $P = 0.0007$). Significant associations were established between DUI and attention-deficit/hyperactivity disorder (OR = 1.098 [95% CI: 1.046-1.15], $P < 0.0001$) and body mass index (OR = 1.129 [95% CI: 1.081-1.18], $P < 0.0001$) polygenic risk.

Conclusion: Genetic variants associated with childhood DUI were identified and genes important in balancing excitatory and inhibitory neurons in the central nervous system and detrusor smooth muscle activity were implicated. These findings may help guide identification of new treatment targets.

P17.034.C Exploring genetic factors influencing apolipoprotein A-IV: a genome-wide association meta-study

Adriana Koller[1], *Claudia Lamina*[1], *Barbara Kollerits*[1], *Florian Kronenberg*[1]

[1]*Medical University of Innsbruck, Institute of Genetic Epidemiology, Innsbruck, Austria*

Consortium: ApoA-IV GWAS Consortium

Background/Objectives: Apolipoprotein A-IV (apoA-IV) is a major component of high-density lipoprotein and chylomicron particles. Primarily produced in enterocytes, apoA-IV has antioxidative properties and is associated with lipid phenotypes and kidney function. We aimed to identify genetic variants associated with apoA-IV levels and to explore the relevance of these findings in relation to known association between apoA-IV and different phenotypes.

Methods: Quantification of apoA-IV from plasma samples was performed using a double-antibody ELISA. Using our nf-gwas pipeline, we conducted a GWAS on HRC-imputed data to identify variants associated with apoA-IV concentrations in ten population-based studies (n~25,000).

Results: Mean apoA-IV concentrations ranged from 15.3 to 17.6 mg/dl between the studies. Our meta-GWAS (adjustment: age, sex, four principal components) identified 89 genome-wide significant variants within the *APOA5-A4-C3-A1* cluster (lead SNP: rs2849167, ß = 0.151, $p = 1.48 \times 10^{-47}$ near *APOA4*) and 55 variants around the *KLKB1* gene (lead SNP: rs4253311, ß = 0.086, $p = 6.74 \times 10^{-17}$), along with rare variants associated with apoA-IV concentrations. Sex-stratified analyses revealed similar results in men and women. We explored the impact of various covariates (e.g. kidney function and cholesterol efflux capacity) on the results. Additionally, we employed mediation analysis and a Mendelian randomization approach to assess the causal relationships between potential phenotypes and variants associated with apoA-IV concentrations.

Conclusion: This study represents the largest GWAS conducted on apoA-IV levels to date, revealing several significant loci associated with apoA-IV concentrations and providing insights into the genetic determinants of apoA-IV levels and phenotypes of interest.

Grants: The Austrian Research Fund (FWF, W-1253 DK HOROS) has supported this project.

P17.035.D Dissecting the biomedical and genetic structure of a Southern Italian cohort: the Moli-sani study

Federica Santonastaso[1], *Simona Costanzo*[2], *Edoardo Giacopuzzi*[1], *Alessandro Raveane*[1], *Chiara Chiereghin*[1], *Arianna Landini*[1], *Sodbo Sharapov*[1], *Soumick Chatterjee*[1], *Davide Bolognini*[1], *Manuel Tardaguila*[1], *Michela Colombo*[1], *Ilaria Gori*[1], *Alessandro Gialluisi*[2;3], *Amalia De Curtis*[2], *Emanuele Di Angelantonio*[4;5], *Giovanni de Gaetano*[2], *Maria Benedetta Donati*[2], *Nicola Pirastu*[1], *Licia Iacoviello*[2;3], *Nicole Soranzo*[1;6]

[1]*Human Technopole, Genomics Research Centre, Milan, Italy;* [2]*IRCCS Neuromed, Department of Epidemiology and Prevention, Pozzilli, Italy;* [3]*LUM University, Department of Medicine and Surgery, Bari, Italy;* [4]*University of Cambridge, British Heart Foundation Centre of Research Excellence, Cambridge, United Kingdom;* [5]*Human Technopole, Health Data Science Centre, Milan, Italy;* [6]*Wellcome Sanger Institute, Human Genetics Department, Hinxton, United Kingdom*

Background/Objectives: Human genetic diversity in Southern Europe has been historically undersampled owing to limited genomic initiatives. In Italy, complex demographic events and a unique geography contributed to high genetic heterogeneity. To characterise the architecture of biomedical traits and diseases, we carried out the largest to date genomic survey in Italy using Moli-sani, a prospective cohort of approximately 25,000 individuals (age ≥ 35, 49.3% men) recruited from city hall registries in the Molise region.

Methods: We profiled genome-wide SNPs to (i)address genetic structure vis-a-vis other Italian and European populations; (ii) describe genetic contributions to over fifty biomedical traits relevant for chronic-degenerative diseases; (iii)assess the PRS portability estimated from other European populations in South Italy.

Results: While confirming a broad genetic overlap with Northern European populations, our GWASs have identified 73 new SNPs and 10 new loci associated with 7 biomedical traits. For example, we have identified different variants near the *HBB* gene showing greater allelic frequencies and per-allele effect size in Moli-sani than UK Biobank. Among these, we observe *rs11549407* and *rs35004220*, known to be involved in beta-thalassemia disorders in South Europe and likely reflecting past historical events. We estimate that PRSs, developed from European summary statistics, explain ~20% less variance than estimates in Northern populations.

Conclusions: The genetic profiling of the Moli-sani cohort, coupled with its large size, depth of phenotyping, and prospective design, provides a unique resource to study genetic contributions to common diseases and traits, and to which extent these are modulated in the context of South Italy's unique history and environments.

Background/Objectives: Borderline Personality Disorder (BPD; ICD-10 F60.3x) is characterized by marked instability in emotions, self-image, and interpersonal relationships. Individuals with BPD make up a large proportion of the patient population in psychiatric hospital services. To develop more effective treatment options and aid early intervention, we must improve our understanding of BPD etiology. Previous studies have reported a heritability of 46–75%, but previous genome-wide association studies (GWAS) of BPD have been underpowered to detect significantly associated genetic variants.

Methods: We conducted a GWAS of BPD liability in the Lundbeck Foundation Initiative for Integrative Psychiatric Research (iPSYCH) sample, accounting for age at diagnosis and family history. iPSYCH is a nationally representative case-cohort study of all individuals born in Denmark 1981–2008. The sample for this study consisted of ~7K individuals with BPD from the entire iPSYCH sample and ~46K population representative controls. We applied the extended liability threshold model conditioned on age, sex, and family history (LT-FH + +) to estimate each individual's liability to develop BPD in the study sample and calculated a linear mixed model GWAS of BPD liability with the first ten genetic principal components and genotyping array type as covariates.

Results: Variants at the 5q21 locus between *NIHCOLE* and *RNU6-334P* showed genome-wide significant associations with BPD liability.

Conclusion: We conducted the largest single-sample GWAS of BPD to date and identified SNPs significantly associated with BPD. Future studies are needed to replicate these findings.

Grants: This study is funded by the Inge Lehman Grant 1133-00034B from Independent Research Fund Denmark.

P17.038.C Deep-learning powered GWAS on T1 brain MRI data

Alexander Rakowski[1], *Remo Monti[1;2], Christoph Lippert[1;3]*

[1]Hasso-Plattner Institut, Digital Health & Machine Learning, Potsdam, Germany; [2]Max-Delbrück-Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; [3]Hasso Plattner Institute for Digital Health at Mount Sinai, New York, United States

Background/Objectives: GWAS studies traditionally analyzed single traits e.g., disease diagnoses or biomarkers. Nowadays, large-scale cohorts such as UK Biobank (UKB) collect imaging data with sample sizes large enough to perform genetic association testing. Typical approaches extract predefined features, e.g., volumes of regions of interest. This limits the scope of such studies to predefined traits and can ignore novel patterns present in the data. TransferGWAS employs deep neural networks to extract low-dimensional representations of imaging data for GWAS, eliminating the need for predefined biomarkers. We apply TransferGWAS on T1 brain MRI data from UK Biobank.

Methods: We encoded 36,000 T1 brain MRI scans from UKB, using models trained on MRI scans from the Alzheimer's Disease Neuroimaging Initiative and natural images from the ImageNet dataset, and performed a multivariate GWAS on the resulting features. Furthermore, we fitted Polygenic Scores (PGS) of the deep features and computed genetic correlations between them and a range of selected phenotypes.

Results: We identified 289 independent loci, associated mostly with bone density, brain, or cardiovascular traits, and 14 having no previously reported associations. We evaluated the PGS in a multi-PGS setting, improving predictions of several traits. By examining clusters of genetic correlations, we found novel links between diffusion MRI traits and type 2 diabetes.

Conclusion: Using deep learning-based phenotypes allowed us to identify novel loci, compute predictive PGS, and enhanced understanding of the genetic basis of type 2 diabetes.

P17.039.D Converging rare and common variant evidence drives discovery of genes associated with central obesity

Nikolas Baya[1;2], *Frederik Lassen[1;2], Barney Hill[2], Samvida Venkatesh[1;2], Duncan Palmer[2], Cecilia M. Lindgren[1;2]*

[1]Centre for Human Genetics, University of Oxford, United Kingdom; [2]Big Data Institute, University of Oxford, United Kingdom

Background/Objectives: Obesity, a pervasive health challenge, demands a comprehensive understanding of its genetic underpinnings. Our goal was to leverage UK Biobank's whole-exome sequencing data to unravel obesity's causal mechanisms and provide novel insights into its genetic architecture.

Methods: We ran mixed-model gene- and variant-level association tests for three obesity-related traits across >395,000 individuals with European ancestry in the UK Biobank using SAIGE.

We performed variant-level association tests on rare (MAF < 0.01) and common (MAF>0.001) variants using exome sequencing data and imputed genotypes, respectively.

We tested gene-by-gene for an enrichment of damaging rare variation for each obesity-related trait, accounting for nearby common variant genetic association signals. Statistical fine-mapping to define variant conditioning was performed with FINEMAP.

We tested for significantly higher polygenic priority scores (PoPS) in genes with significant rare variant burden versus non-significant genes.

Results: Burden of rare damaging variation in 19 genes was significantly associated with at least one obesity-related trait ($P < 1.58 \times 10^{-7}$, Bonferroni corrected).

We identified six genes with evidence for allelic series, where the effect size of variants monotonically increased with the predicted severity of the variant.

We found that genes with significant association between rare variant burden and obesity had significantly higher common-variant PoPS compared to genes without significant association, demonstrating convergent common and rare variant signals in obesity genetics.

Conclusion: Our study furthers the understanding of the genetic architecture of obesity and uses multiple lines of evidence to nominate genes with potential therapeutic significance.

P17.040.A Common and rare variant association studies of left and right ventricular phenotypes identify novel genetic loci and therapeutic targets for heart failure

Hannah Nicholls[1], *Jose Vargas*[1;2;3], *Anwar Chahal*[4;5;6], *Mohammed Khanji*[1;4], *Steffen Petersen*[1;4], *Patricia Munroe*[1], *Nay Aung*[1;4]

[1]*William Harvey Research Institute, London, United Kingdom;* [2]*Veterans Affairs Medical Center, Washington;* [3]*Georgetown University, Washington, United States;* [4]*Barts Heart Centre, St Bartholomew's Hospital, London, United Kingdom;* [5]*WellSpan York Hospital, Center for Inherited Cardiovascular Diseases, York, United States;* [6]*Mayo Clinic, Department of Cardiovascular Diseases, Rochester, United States*

Background/Objectives: Left and right ventricular (LV and RV) structure and function measured from cardiovascular magnetic resonance (CMR) imaging are pivotal for understanding complex cardiovascular diseases including heart failure (HF). The genetic contributions to LV and RV phenotypes have not been comprehensively explored.

Methods: We performed genome-wide association studies (GWAS) and rare-variant collapsing analyses of twenty clinically relevant LV and RV volumetric/functional phenotypes from 56,509 European UK Biobank participants using ~8.9 million TOPMed imputed variants and whole-exome sequencing data. Bioinformatic examination, including colocalisation, polygenic priority scoring, druggability via Open Targets and DrugnomeAI, was performed.

Results: Single and multi-trait GWAS identified 310 loci associated with at least one phenotype ($P < 5 \times 10^{-8}$), 262 loci across >1 phenotype, and 84 novel loci across CMR traits. Rare variant analysis found associations with 13 genes (*RBM20, TTN, EFCAB3, FHOD3, FLNC, CORO6, CYP3A4, DUSP13, SDCCAG8, GAA, GIP, CSRP3*, and *SIRT4*) ($P < 2.5 \times 10^{-6}$). These rare variant associations were independent of nearby common variants in conditional analyses. Five variants (in *LSM3, MICB*, *LOC101928505, IGF1R, KANSL1* loci) colocalised with loci from a recently reported large HF case-control GWAS meta-analysis. From 462 prioritised genes, 15 were Mendelian cardiomyopathy genes and 54 interact with drugs across any disease indication. *DGAT1 and CDK12* genes were identified through multiple evidence streams as promising HF targets with roles in cardiac lipid metabolism and stress-induced transcription activation, respectively.

Conclusion: These findings substantially enrich our knowledge of the genetics of ventricular measurements, providing opportunities for identifying and repurposing drugs for cardiovascular diseases.

P17.043.D Massively Parallel Reporter Assay (MPRA) combined with bayesian fine mapping approaches prioritize variants and their possible functional mechanism associated with Multiple Sclerosis (MS) from Genome Wide Association Studies (GWAS)

Endri Visha[1], *Nicola Pomella*[2], *Ferdinando Clarelli*[3], *Lucia Corrado*[2], *Alessandro Pizzino*[4], *Fjorilda Caushi*[2], *Beatrice Piola*[2], *Diego Cotella*[2], *alaa habeeb*[2], *Muralidharan Thavamani*[2], *Laura Follia*[2], *Martina Tosi*[2], *domizia vecchio*[5], *Massimo Filippi*[6], *Maurizio Leone*[7], *MARTINELLI BONESCHI FILIPPO GIOVANNI*[8], *FEDERICA ESPOSITO*[3], *Nadia Barizzone*[2], *sandra d'alfonso*[2]

[1]*Novara, Medical Biotechnologies, Novara, Italy;* [2]*Province of Novara, Dipartimento di scienza della Salute, Novara, Italy;* [3]*IRCCS San Raffaele Scientific Institute, Division of Neuroscience, Milan, Italy;* [4]*Novara, Dipartimento di scienza della Salute, Novara, Italy;* [5]*Province of Novara, Department of translational medicine, Novara, Italy;* [6]*Milan, Division of neuroscience, Milan, Italy;* [7]*San Giovanni Rotondo, Scienze mediche, San Giovanni Rotondo, Italy;* [8]*Milano, Dipartimento di scienza della salute, Neurology unit and multiple sclersis center ASST, Santi Paolo Carlo, Milan, Italy*

Background/Objectives: Multiple Sclerosis (MS) is an autoimmune multifactorial disease affecting central nervous system. Large-scale GWAS detected 200 MS risk loci, but linkage disequilibrium represents limitation in pinpointing likely causative variants, thus functional studies are required.

Methods: We applied functionally informed fine-mapping (Paintor and CaviarBF) on 36 MS regions, replicating significantly in an Italian cohort (5903 individuals, 4259 MS,1644 HC) and overlapping with at least one drug target gene (DGIdb). Variant annotation was done using GWAVA, CADD, and FINSURF scores. For variant -to-gene mapping, we employed Open Targets Genetics. For 5 regions, we functionally analysed all the SNPs in LD ($r2 > 0.75$) with the lead SNP using Massively Parallel Reporter Assay (MPRA).

MPRA significative variants were analysed with mpralm tool, and annotated with motifbreakR for their TF selective binding properties. Results were confirmed with RegulomeDB,GTEX.

Results: For 11 regions, Paintor and CaviarBF prioritized at least 1 SNP with evidence of causality PIP >0.75, and 5 of these SNPs target a drug target gene.

For 4 regions, MPRA analyses identified at least one SNP influencing gene expression of a drug target gene, with a statistically significant effect in two independent replicates. Rs72924108 emerges above all with selective binding in the presence of the C allele of the ZNF754 TF a paralog of the YY1, which is involved in the regulation of transcription of RNA-polymerase II.

Conclusion: Although these findings need validation through in vitro methods, they potentially affect our understanding of disease mechanisms and their drug targets

Background/Objectives: Type 1 diabetes (T1D) is a polygenic disease caused by the autoimmune destruction of pancreatic beta cells. Genome-wide association studies have identified over 60 loci associated with T1D, but this knowledge has not advanced precision medicine. In contrast, the precision medicine approach has been a great success in monogenic forms of diabetes, such as Maturity-Onset Diabetes of the Young (MODY).

Although monogenic and polygenic diabetes are traditionally considered distinct diseases, recent data support the hypothesis of a genetic continuum between MODY and polygenic forms of diabetes.

Methods: In the present work, 383 T1D young individuals (mean age:13.9 ± 3.4, 52% females) and 187 healthy controls (mean age:12.8 ± 3.4, 56% females) were recruited. Participants were genotyped using Illumina Infinium Global Screening Array. A Polygenic Score (PGS) based on Single Nucleotide Polymorphisms (SNPs) in 16 genes responsible for MODY was developed and its association with T1D and related clinical characteristics (i.e., age at diagnosis, glycated haemoglobin, autoantibody positivity) was tested by regression analysis.

Results: The PGS obtained by a Bayesian regression approach using 334 SNPs performed best. This PGS was associated with higher T1D prevalence (beta = 5.14, p-value = 1.1×10^{-3}) and higher presence of Zinc transporter 8 (ZnT8) autoantibodies (beta = 12.58, p-value = 1.6×10^{-2}). No association emerged with other clinical characteristics.

Conclusion: In conclusion, our study showed a polygenic contribution of MODY variants in T1D susceptibility, suggesting the existence of shared genetic characteristics between different forms of diabetes.

Consortium: Riscoin Study Group

Background/Objectives: Understanding the genetics of the response to COVID-19 vaccines is crucial for comprehending immune response to SARS-CoV-2 and for developing future vaccination strategies. Recently, several studies reported genetic factors that contribute to the variability in the levels of antibodies against the SARS-CoV-2 spike protein produced after a COVID-19 vaccination. We investigated the genetic basis of the neutralising capacity against SARS-CoV-2 developed after receiving two doses of an mRNA COVID-19 vaccine.

Methods: We conducted a genome-wide association study of neutralising capacity against SARS-CoV-2 variant Omicron-BA.1 in the cohort of 3881 individuals fully vaccinated against COVID-19. In the analysis, we accounted for population structure, relatedness, age, sex, and medical history.

Results: Our study identified significant genetic associations with neutralising antibody titres in the human leukocyte antigen (HLA) class I and II regions. We found that, in particular, carrying the HLA-A*03 allele is associated with higher and carrying the HLA-DQB1*05, respectively, with lower neutralising capacity in our cohort.

Conclusion: Our study revealed genetic contributions to the neutralising capacity against Omicron-BA.1 developed after a COVID-19 vaccination. By highlighting the potential role of specific HLA alleles in neutralising titre variation, these findings contribute to our understanding of SARS-CoV-2 susceptibility, disease progression, and the potential for targeted interventions based on genetic profiles.

Grants: The RisCoin study is funded by research grants from the German Federal Ministry of Health (ZMI1-2521COR933-BMG), the Corona Research Program 21/22 of the Bavarian Ministry of Science and Art and intramural and extramural funding of participating research groups.

P17.046.C Mendelian randomization analysis provides evidence for causal relationships between retina image-derived phenotypes and non-ocular diseases and risk factors

Ilaria Iuliani[1;2], *Sofia Ortin Vela*[1;2], *Michael Beyeler*[1;2], *Olga Trofimova*[1;2], *Mattia Tomasoni*[3], *David Presby*[1;2], *Florence Hoogewoud*[3], *Sven Bergmann*[1;2;4]

[1]*University of Lausanne, Computational Biology, LAUSANNE, Switzerland;* [2]*Swiss Institute of Bioinformatics, LAUSANNE, Switzerland;* [3]*Jules-Gonin Eye Hospital, FAA, University of Lausanne, LAUSANNE, Switzerland;* [4]*University of Cape Town, Integrative Biomedical Sciences, Cape Town, South Africa*

Background/Objectives: While characterizing vasculatures is generally challenging, retinal imaging offers a cost-effective and noninvasive method for assessing the vascular system. Recent research suggests retinal vascular properties as potential biomarkers for systemic non-ocular diseases. Here we explore causal relationships between retinal vascular properties and various diseases and risk factors.

Methods: The UK Biobank dataset comprises more than 130k Color Fundus Images (CFIs) from nearly 72k genotyped subjects, each with information on the status of various diseases and their risk factors. We previously conducted an extensive analysis to extract image-derived phenotypes (IDPs) and performed genome-wide association studies (GWAS) of these phenotypes. Here we use bidirectional two-sample Mendelian Randomisation (MR) analysis to evaluate causal relationships between the vascular IDPs and non-ocular diseases such as hypertension, angina and diabetes along with their associated risk factors, including blood pressure, cholesterol level and BMI.

Results: Our MR analyses provide highly significant evidence that cardiovascular disease (CVD) risk factors have a causal impact on the retinal vasculature. Specifically, we reveal that CVD risk factors exert stronger effects on vascular IDPs than the reverse, underlining the utility of IDPs for early CVD diagnosis. Consistent with previous findings, we observe that individuals with genetically elevated blood pressure tend to have lower retinal vascular density. Other IDPs were also affected, indicating broader implications of blood pressure on retinal vasculature remodeling.

Conclusion: Our study demonstrates the potential of MR to identify causal links between retinal image features and CVD, emphasizing the broader applications of these features as potential disease biomarkers beyond ocular health.

P17.047.D Genetic determinants of the plasma lipidome and relations to cardiometabolic risk in children and adolescents

Yun Huang[1], *Sara Stinson*[1], *Malte Thodberg*[1], *Louise Aas Holm*[1;2], *Roman Thielemann*[1], *karolina sulek*[3], *Morten Lund*[2;4], *Cilius Esmann Fonvig*[1;2;5], *Min Kim*[3], *Kajetan Trost*[1], *Helene Bæk Juel*[1], *Trine Nielsen*[5;6], *Peter Rossing*[3;5], *Maja Thiele*[7;8], *Aleksander Krag*[7;8], *Cristina Legido-Quigley*[3;9], *Jens-Christian Holm*[1;2;5], *Torben Hansen*[1]

[1]*Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Denmark;* [2]*The Children's Obesity Clinic, Department of Pediatrics, Copenhagen University Hospital Holbæk, Denmark;* [3]*Steno Diabetes Center Copenhagen, Denmark;* [4]*Department of Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Denmark;* [5]*Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Denmark;* [6]*Medical Department, Zeeland University Hospital, Denmark;* [7]*Center for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, Denmark;* [8]*Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Denmark;* [9]*Institute of Pharmaceutical Science, King's College London, United Kingdom*

Background/Objectives: Several lipid species have been associated with type 2 diabetes, cardiovascular disease, and steatotic liver disease. While the genetic architecture of the lipidome has been investigated in adults, the genetic determinants of lipid species and their association with cardiometabolic risk in children and adolescents remains understudied.

Methods: We measured 227 plasma lipid species in 1,149 children and adolescents (44.8% boys) with a median age of 11.2 years from an obesity clinic and from the general population. We performed genome-wide association analyses to identify genetic variants influencing circulating lipids and assessed the causal impact of these lipids on cardiometabolic risk profiles using Mendelian randomization (MR).

Results: We identified 37 independent genome-wide significant loci ($P < 5 \times 10^{-8}$) for 52 lipid species, including loci associated with sphingolipids (*SPTLC3*, *SYNE2*, *ATP10D*), phosphatidylethanolamine (*LIPC*), phosphatidylinositol (*MBOAT7*), and 9 previously unreported loci. One-sample MR analysis using 5 loci with biological plausibility on individual-level data identified positive causal associations between ceramide and liver enzymes, sphingomyelin and hemoglobin A1c (HbA1c), and phosphatidylethanolamine and high-sensitivity C-reactive protein in children and adolescents. Two-sample MR using summary statistics showed consistent results with one-sample MR, and indicated additional causal links, specifically between ceramide and higher HbA1c levels, and phosphatidylinositol with higher liver enzymes.

Conclusion: Our results provide insights into the genetic determinants of plasma lipid species in children and adolescents, emphasizing causal links between specific risk lipids and cardiometabolic risk profiles, which may provide further insights into targeted intervention strategies.

P17.048.A Exploring the genetic architecture of Lipoedema.

Sara Dobbins[1], *Alan Pittman*[1], *Pia Østergaard*[1], *Ege Sackey*[1], *Vaughan Keeley*[2], *Peter Mortimer*[3], *Kristiana Gordon*[3], *Dionysios Grigoriadis*[4]

[1]*St. George's University of London, london;* [2]*University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom;* [3]*St George's Universities NHS Foundation trust, London, United Kingdom;* [4]*Constructive Bio, Cambridge, United Kingdom*

Background: Lipoedema is a chronic adipose tissue disorder mainly affecting women, causing excess subcutaneous fat deposition on the lower limbs with pain and tenderness. Whilst

the family history of patients suggests a strong genetic component, little is understood about the genetics underlying the susceptibility to this disease.

Methods: A tightly phenotyped cohort of 200 lipoedema patients from two UK specialist clinics was recruited. Firstly, to understand the impact of common variation on disease, we performed a genome wide association study (GWAS) on 130 cases with publicly available control data. Secondly, we performed whole-exome sequencing on over 100 patients (including 36 extended families). We employed family-based and gene-burden approaches to identify candidate genes with an excess of rare impactful variants in lipoedema patients compared to controls.

Results and Conclusions: Our analysis has identified a common variant upstream of the *LHFPL6* gene suggestively associated with lipoedema (rs1409440, ORmeta ≈ 2.01, Pmeta ≈ 4 × 10-6). This gene is involved with lipoma formation but exactly how this relates to lipoedema is not yet understood. Our gene burden and segregation analysis of the exome and whole genome sequencing data has identified several interesting candidate genes. We are in the process of performing a replication study of both our GWAS and gene-based findings on a well-phenotype Spanish cohort. Whilst further replication of these findings are required in different populations, we hope that this work will lead to new avenues of research in therapeutics and diagnostics, ultimately improving the lives of people with lipoedema.

P17.049.B postpartum psychosis: could chronic sleep deprivation be protective?

Chiara Petrosellini[1], *Sofia Eriksson*[1], *olivia protti*[1], *dimitrios siassakos*[1], *Andrew McQuillin*[1]

[1]*UCL, United Kingdom*

Background/Objectives: Postpartum Psychosis (PP) is a severe but treatable perinatal mental illness. It is a medical emergency due to the associated risks of suicide and infanticide.

Women with pre-existing Bipolar Affective Disorder (BPAD) have a significant risk of PP following childbirth, but prediction is challenging.

Sleep disturbance is a well-established trigger of psychosis and one of the earliest manifestations of PP. A relationship between sleep disruption and PP is assumed but poorly understood.

Methods: Women with BPAD were recruited from general practices, hospitals and community mental health teams in England. Participants who have given birth were screened for perinatal psychiatric complications. 150 women with BPAD who developed PP and 262 women who did not develop PP following childbirth were included.

Polygenic Risk Scores (PRS) were computed using summary statistics of Genome-Wide Association Studies of Insomnia (INS) and Short Sleep (SS). Logistic regression was used to model the effect of each PRS on PP following childbirth.

Results: Logistic regression analyses showed significant associations between sleep-related PRS scores and a diagnosis of PP.

INS PRS and SS PRS were significantly lower in women who developed PP compared to those who did not develop PP following childbirth ($p = 0.0035$ and $p = 0.000794$ respectively).

Conclusion: Genetic vulnerability to insomnia and short sleep contributes to an increased risk of chronic sleep deprivation. This may foster a heightened tolerance to sleep disruption, mitigating the impact of childbirth on mental health. A higher individual PRS for INS and/or SS may therefore be protective against PP in women with BPAD.

P17.050.C Identification of genetic regulation at the proteomic level in the long-term stroke outcome: A Proteome-Wide Association study

Natalia Cullell[1;2], *Cristina gallego*[2], *jara carcel-marquez*[2], *elena muiño*[2], *laia llucià-carol*[2], *miquel lledós*[2], *jesus martin-campos*[2], *Israel Fernandez-Cadenas*[2], *jerzy krupinski*[1]

[1]*fundacio docencia i recerca mutuaterrassa, neuroscience, 08221, Spain;* [2]*Biomedical Research Institute Sant Pau (IIB Sant Pau), Stroke Pharmacogenomics and Genetics group, Barcelona, Spain*

Background/Objectives: The stroke outcome is highly variable and depends on genetic. This study aims to pinpoint potential targets for enhancing long-term stroke outcomes integrating genomics with proteomics (PWAS) and transcriptomics (TWAS).

Methods: We followed a four-stage PWAS with FUSION to identify genetically regulated proteins impacting the modified Rankin scale at three months (mRS3). In the discovery, we merged brain proteomes from the ROS/MAP ($N = 376$;1443 proteins) and a mRS3 GWAS from the GODS cohort ($N = 1225$). We validated the causality with Bayesian colocalization and Summary-based-data Mendelian Randomization(SMR). In the replication1 and 2 the brain proteomic dataset from the Banner Sun Health Research Institute and a new GWAS of mRS3 (not published;$N = 688$), respectively, were analyzed. We meta-analyzed the results using the adaptively weighted Fisher's method. We conducted a TWAS to explore the association of 5,420 transcripts from the CommonMind Consortium (452 brain samples) with mRS3. To identify potential drugs modulating mRS3, we utilized Trans-Phar.

Results: Three proteins were significantly associated with mRS3 ($P < 0.05$) in the discovery with a posterior probability4 > 0.5. The three proteins were significant in the Replication1 and one in the replication2. Two out of the three proteins were significant after multiple testing in the meta-analysis, in the TWAS and had confirmed causality by SMR. Using Trans-Phar, we identified three compounds previously studied in stroke and predicted to modulate gene expression positively for the stroke outcome.

Conclusion: Using a multi-omic approach, we have identified potentially genetically-regulated drug targets whose modulation could lead to the improvement of long-term stroke outcome.

Consortium: BIOMAP consortium, FinnGen

Background/Objectives: Atopic dermatitis is a complex inflammatory skin and systemic disease that affects up to 10% of adults. Approximately 30% of cases can be classified as moderate or severe and for these patients, treatment is not always effective. Currently, there are no established genetic markers of atopic dermatitis severity, but these could be helpful to identify patients at risk of severe disease and in possibly directing new therapeutic strategies.

Methods: To identify such markers, we performed a meta-analysis of >11 million genetic variants using 20,275 patients with moderate-severe atopic dermatitis and 59,002 patients with non-moderate-severe atopic dermatitis from 5 European cohorts.

Results: Two previously established atopic dermatitis susceptibility loci (lead SNP rs558269137 in *FLG* and lead SNP rs1365121 in *PRR5L*) were associated at a genome-wide significance threshold. More broadly, we found that of the 81 known European susceptibility loci 14 showed an association with severity after correction for multiple testing ($p < 6.2 \times 10^{-4}$) and a further 29 at $p < 0.05$. After adjusting for the power differential between studies, these numbers increased to 15 and 43 loci respectively. Regression analysis also confirmed a positive relationship between severity betas and reported susceptibility betas across the 81 loci (beta = 0.36, 95% confidence intervals = 0.32-0.40).

Conclusion: Overall, these findings provide insight into the genetic basis of atopic dermatitis severity.

P17.052.A GWAS of neuropathic pain detects putative causal signal in *NCAM1*

Richard Packer[1;2], *Nick Shrine[1], Alexander T Williams[1], Jing Chen[1], Abril Izquierdo[1], Kayesha Coley[1], Mikko Martilla[3], William Hennah[3], Martin Tobin[1;2]*

[1]Department of Population Health Sciences, University of Leicester, Leicester; [2]Leicester NIHR Biomedical Research Centre, Glenfield Hospital, Leicester; [3]Orion Pharma, Espoo, Finland

Background/Objectives: Neuropathic pain (NP) is a chronic debilitating condition affecting 7-8% of the population. Currently therapy is limited with side-effects. Human genetic studies can identify putative causal genes to better identify new targets for drug development. However, genetic studies have reported only one locus, SLC25A3, at genome-wide significance and have not exploited the primary care records in large biobank studies to increase case ascertainment and power for detection.

Methods: We combined primary care prescription records, primary and secondary care clinical and operation codes and self-report data from UK Biobank and used DeepPheWAS to define 38 NP phenotypes, our primary aim was to perform a GWAS of all cause NP (34,278 cases, 140134 controls), in exploratory analysis we also performed GWAS on a further 23 NP phenotypes. We used SAIGEgds for association testing and a variant-to-gene mapping framework to identify putative causal genes.

Results: For all cause NP a single novel genome-wide ($< 5 \times 10^{-8}$) significant signal was found in *NCAM1* (rs12277922 risk-allele T). *NCAM1* met three variant-to-gene criteria, (nearest gene, pQTL colocalization and polygenic priority score). The same SNP in FinnGen was associated with increased risk of multiple back pain traits, pain in joint and analgesic medication use. Exploratory analysis revealed 5 genes with >1 variant-to-gene criteria: *MICU1*, *ASCC1*, *ROR1* in sciatica traits; *KCNN2* in post-surgical NP and; *HLA-DRB5* for central NP.

Conclusion: Our study provides robust evidence implicating several genes including *NCAM1* in NP risk warranting further investigation as potential drug targets.

Background/Objectives: Recent studies indicate a potential link between dental caries (DC) and cardiometabolic diseases, suggesting that shared genetic factors may play a role in influencing the development and progression of both conditions. Our objective was to map the genetic variations associated with DC and investigate the shared genetic influences between DC and cardiometabolic diseases.

Methods: We conducted a genome-wide association study of objectively measured childhood DC in permanent dentition in 72,139 individuals from the Danish Blood Donor Study Cohort. We used LD score regression to examine genetic correlations across cardiometabolic, oral, psychiatric and lifestyle traits. We performed fine-mapping to pinpoint causal variants, followed by colocalization to determine overlapping genetic signals between DC and correlated traits.

Results: We found eight genetic loci associated with DC ($P < 5 \times 10^{-8}$), six of which were previously unreported. Genetic correlations were identified between DC and several cardiometabolic traits, including type 2 diabetes ($R_g = 0.27$, $P = 3.4 \times 10^{-8}$), body mass index ($R_g = 0.24$, $P = 1.0 \times 10^{-7}$), coronary artery disease (CAD, $R_g = 0.18$, $P = 1.7 \times 10^{-4}$) and high-density lipoprotein (HDL, $R_g = -0.26$, $P = 3.1 \times 10^{-7}$). Colocalization suggested functional links between DC and CAD (a locus on chromosome 3 with PP.H4 = 0.97), and HDL (loci on chromosomes 4 and 22 with PP.H4 > 0.92).

Conclusion: We highlight the polygenic nature of DC and through identified genetic correlations and colocalization patterns suggest shared pathophysiological mechanisms between DC and cardiometabolic traits.

P17.055.D GWAS meta-analysis on Atrial Septal Defect identifies 7 novel loci

Sofie Dannesbo[1], Søren Rand[2], Oliver Vad[1], Jonas Ghouse[1], Kasper Iversen[1], Henning Bundgaard[3], Lars Allan Larsen[4], **Morten Olesen**[5]

[1]Copenhagen University Hospital, Rigshospitalet, Department of Cardiology; [2]Copenhagen University Hospital, Rigshospitalet; [3]Copenhagen University Hospital, Rigshospitalet, Department of Cardiology, København, Denmark; [4]Copenhagen University; [5]Copenhagen University, Department of Biomedical Sciences

Background: Atrial septal defect (ASD) is one of the most common types of congenital heart defects, occurring in about 25% of children. ASD patients have an increased risk of cardioembolic stroke, atrial fibrillation, heart failure, and increased long-term mortality.

Material and Methods: We performed the largest GWAS meta-analysis of ASD to date using 2,763 ASD cases from five patient cohorts and more than 1,000,000 controls. Genetic correlation was assessed using linkage disequilibrium score regression (LDSC).

Results: Our analysis identified nine genome-wide significant loci ($P < 5 \times 10^{-8}$) that are associated with

ASD, of which seven were novel. The top hit loci were located near NSG1 (rs870142, $P = 2.0 \times 10^{-24}$). The second most significant hit was rs76774446 near the gene WNT3 ($P = 2.3 \times 10^{-19}$). This gene plays a critical role in development of the heart before birth. We also identified a locus on chr 8 close to the transcription factor SOX17 ($p = 8.8 \times 10^{-10}$) and a loci on chr 10 ($p = 5.6 \times 10^{-09}$) close to NRP1, encoding a VEGF receptor. Haploinsufficiency of VEGF related signaling genes predisposes to the development of Tetralogy of Fallot.

Using LDSC we found significant genetic correlation between ASD and right ventricular end-systolic volume ($rg = 0.42$, $P = 6.8 \times 10^{-5}$) and cardioembolic stroke ($rg = 0.50$, $p = 3.6 \times 10^{-3}$). In line with this a ASD PRS-cs score was associated with dysregulation of more than 10 proteins in the blood ($p < 1 \times 10^{-8}$).

Conclusion: This GWAS meta-analysis identified seven novel and two known genetic variants associated with ASD. Our findings contribute to understanding the genetic basis of ASD and underlying molecular mechanisms.

Conflict of Interest: None declared

P17.056.A Clinical and etiological differences between alopecia areata patients with and without nail abnormalities

Yasmina Gossmann[1], *Marisol Herrera Rivero[2], swapnil Awasthi[3], stephan ripke[3], Silke Redler[4], Markus Nöthen[1], Regina C. Betz[1], F. Buket Basmanav[1]*

[1]Institut für Humangenetik der Universität Bonn, Universitätsklinikum Bonn, Bonn, Germany; [2]Klinik für Psychiatrie und Psychotherapie, Universitätsklinikum Münster, Münster, Germany; [3]Klinik für Psychiatrie und Psychotherapie, Charité Universitätsmedizin Berlin, Berlin, Germany; [4]Institut für Humangenetik und Anthropologie, Universitäts-Klinikum Düsseldorf, Düsseldorf, Germany

Background/Objectives: Alopecia areata (AA) is a common autoimmune hair loss disease with a lifetime prevalence of 2%. AA can be accompanied by nail abnormalities in 10-66% of patients according to previous studies. In the current study, we investigated i) the prevalence of nail abnormalities in AA patients, ii) associations between the presence of a nail phenotype and clinical parameters of AA and iii) genetic factors associated with the manifestation of nail phenotypes in AA patients using our own cohort data from about 3,000 patients.

Methods: We stratified our patients based on the presence of nail abnormalities and analyzed whether clinical parameters of AA differs between patients with vs. without nail abnormalities using binary logistic regression analysis. The genome-wide association study (GWAS) was performed by Plink 1.9 on a set of 7,202,815 variants using a logistic regression model.

Results: In our cohort, 762 patients (43%) presented with nail abnormalities compared to 1,131 who did not have any nail phenotype. Onset and severity of AA and comorbidity status of AA patients were significantly associated with the manifestation of nail abnormalities. Our GWAS resulted in 12 suggestive loci ($p < 10^{-5}$; top-SNP = 7.4e-7) associated with developing nail phenotypes in AA, implicating altogether 20 genes based on physical mapping and expression quantitative trait loci annotations.

Conclusion: Our results suggest that the clinical presentation of AA shows differences between patients with and without nail abnormalities and that genetic factors play a role in the risk of AA patients to develop an accompanying nail phenotype.

Conflict of Interest: None declared

P17.058.C Genetic architecture of adipose tissue fatty acids identifies local regulatory effects

Xinyu Yan[1], *Sergio Villicaña*[1], *Maxim Freidin*[2], *Amy L. Roberts*[1], *Max Tomlinson*[1], *Julia El-Sayed Moustafa*[1], *Jordana T Bell*[1], *Kerrin S Small*[1]

[1]*King's College London, Department of Twin Research & Genetic Epidemiology, London, United Kingdom;* [2]*Queen Mary University of London, Department of Biology, London, United Kingdom*

Background: Fatty acids (FAs) are essential molecules, which function as structural components, energy sources, and signaling mediators. Subcutaneous adipose tissue (SAT) is the largest fat depot and plays a crucial role in maintaining health and homeostasis. While genetic regulation and health impacts of circulating FA levels are well established, less is known about the genetic regulation of FA levels within adipose tissue itself.

Methods: To address this, we measured 18 FAs in SAT from 569 female twins in the TwinsUK cohort.

Results: Heritability of FAs ranged from 5% to 59%, indicating a substantial genetic regulation of adipose FA levels, with arachidonic acid showing the highest heritability. GWAS identified 10 FA-associated *loci* across 13 fatty acids (i.e. palmitic acid/palmitoleic acid - *SCD*, dihomo-γ-linolenic acid/arachidonic acid - *FADS2*). Using concurrently measured adipose gene expression and methylation, we identified colocalizations between FA GWAS *loci* and expressions of *SCD, FADS1* and *FEN1* and methylation of 17 CpGs, suggesting these FAs are regulated by molecular processes within SAT. To explore links between genetic regulation of adipose FAs and cardio-metabolic traits, we 1) performed PheWAS for the 10 GWAS lead SNPs, and identified strong associations to diabetes, body fat percentage, and cardiovascular disease and 2) tested associations between polygenic scores (PGSs) of cardiometabolic traits and FA levels, identifying strong associations between PGSs of BMI, body-fat distribution and triglycerides and a range of FAs like lauric acid, palmitoleic acid and arachidonic acid (FDR 5%).

Conclusion: Overall, our results identify local genetic regulation of these key molecules within an important metabolic tissue.

Grants: No.

P17.059.D isGWAS: ultra-high-throughput, scalable and equitable inference of genetic associations with disease

Chris Foley[1;2], **Zhana Kuncheva**[1;2], *Soroosh Afyouni*[1;2], *riccardo marioni*[3], *Heiko Runz*[4], *Benjamin B. Sun*[4]

[1]*Optima Partners, United Kingdom;* [2]*The Bayes Centre, The University of Edinburgh, United Kingdom;* [3]*University of Edinburgh, United Kingdom;* [4]*Biogen, Cambridge, United States*

Background/Objectives: Genome-wide association studies (GWAS) have proven a powerful tool for human geneticists to generate biological insights or hypotheses for drug discovery. Nevertheless, a dependency on sensitive individual-level data together with ever-increasing cohort sample sizes, numbers of variants and phenotypes studied put a strain on existing algorithms, limiting the GWAS approach from maximising potential.

Methods: Here we present in-silico GWAS (isGWAS), a uniquely scalable algorithm to infer regression parameters in case-control GWAS from cohort-level summary data.

Results: For any sample size, isGWAS computes a variant-disease association parameter in ~1 millisecond, or ~11m variants in UK-Biobank within ~4 minutes (~1500-fold faster than state-of-the-art). Extensive simulations and empirical tests demonstrate that isGWAS results are highly comparable to traditional regression-based approaches. We further introduce a heuristic re-sampling algorithm, leapfrog re-sampler (LRS), to extrapolate association results to semi-virtually enlarged cohorts.

Conclusion: Owing to significant computational gains we anticipate a broad use of isGWAS and LRS which are customizable on a web interface.

Conflict of Interest: None declared

P17.060.A Association between rare coding variant burden and participation in cognitive testing in the UK Biobank

Eilidh Fenner[1], *Elliott Rees*[1], *James Walters*[1]

[1]*Cardiff University, Centre for Neuropsychiatric Genetics and Genomics, Cardiff, United Kingdom*

Background/Objectives: The UK Biobank (UKBB) is subject to participation bias, whereby individuals who took part in optional components of the study, such as online questionnaires, are healthier and more educated than those who did not complete these components. Here, we analysed exome sequencing data from 200,625 UKBB samples to examine whether damaging rare coding variant (RCV) burden is associated with likelihood of participation in cognitive testing.

Methods: We investigated 3 phenotypes reflecting increasing levels of participation, examining individuals who: participated in baseline cognitive testing (n = 168,767); completed at least one cognitive test from an online test battery (n = 47,318); completed sufficient cognitive tests for the derivation of a generalised cognition score (*g*)(n = 30,481).

Results: For each phenotype, individuals who participated carried significantly fewer RCVs in constrained (pLI ≥ 0.9), brain-expressed, and schizophrenia-associated genes than those who did not participate. Additionally, individuals with high levels of participation (those for whom *g* could be derived) displayed

significantly higher scores on a cognitive test measuring fluid intelligence than individuals with lower levels of participation (those for whom *g* could not be derived).

Conclusion: Our results demonstrate that RCVs contribute to participation in cognitive testing in the UKBB, with individuals who completed optional cognitive tests carrying significantly fewer damaging RCVs. This effect may confound genetic studies of cognition in UKBB, where false negative associations may be reported for variants with strong effects on cognition. Our study underscores the need for careful consideration of participation-related factors in genetic studies of cognition in UKBB.

P17.061.B Genome-wide landscape of blood traits pleiotropy

Arianna Landini[1], *Sodbo Sharapov*[1], *Nicola Pirastu*[1], *Nicole Soranzo*[1;2;3]

[1]*Human Technopole, Italy;* [2]*British Heart Foundation Centre of Research Excellence, University of Cambridge, Cambridge, United Kingdom;* [3]*Human Genetics Department, Wellcome Sanger Institute (WT), Hinxton, United Kingdom*

Background/Objectives: The regulation of blood cell counts results from the complex interplay between genetics and physiological status. Despite previous studies uncovered numerous genetic associations, distinguishing between cell type-specific and shared signal remains unclear. We address this gap by exploring the pleiotropic landscape of 29 blood cell count traits.

Methods: We performed GWAS of TOPMed-imputed genotypes from ~350k UK Biobank (UKBB) individuals of European ancestry. We explored the landscape of pleiotropy by using leave-one-out conditional approach, obtaining signals with a single underlying causal SNP, followed by Bayesian colocalisation analysis.

Results: We identified 13,027 significant trait-loci pairs (p-value < 5e-8, MAF > 1e-4), corresponding to 1328 overlapping genomic regions. Among these, 247 were trait-specific, while the remaining were associated with multiple traits, up to 13 linked to all 29 traits. Conditional analysis revealed 23,904 independent association signals, which were grouped in 4435 colocalisation groups containing few signals specific to a single trait (3283). Despite the high level of pleiotropy, about half (42.5%) of these groups involved only two traits, while few (1.3%) encompassed over half of the 29 blood traits. Individual signals near *ABO* and *SLC7A5* influenced 25 traits with different patterns. While the firsts showed concordant effects across most traits, the seconds showed divergent effects (increasing red blood cells and platelets while decreasing white blood cells), suggesting different roles in blood cells regulation.

Conclusion: These results deepen our understanding of blood cell genetic regulation, highlighting gene and locus pleiotropy and intricate local regulation, likely reflecting differences in variant activity across cell types and along the differentiation process.

Conflict of Interest: None declared

P17.062.C Genome-wide association study for resting electrocardiogram traits using whole genome sequence in Middle Eastern populations

Muhammad Khan[1], *Abdullah Shaar*[1], *Khalid Kunji*[1], *Mohamed Elshrif*[1], *Ehsan Ullah*[1], *Dr. Georges Nemer*[2], *Mohammed Ali*[3], *Mohammed Bashir*[3], **Mohamad Saad**[1]

[1]*Qatar Computing Research Institute, Hamad Bin Khalifa University;* [2]*College of Health and Life Sciences, Hamad Bin Khalifa University;* [3]*Hamad Medical Corporation*

Background/Objectives: Electrocardiogram (ECG) measures are important to ensure individuals receive appropriate treatment for life threatening conditions (e.g. long QT syndrome). In genomic medicine, Middle East (ME) populations are underrepresented. Our aim here is to study the genetic architeture of ECG traits in the Middle East.

Methods: Genome-wide association study was conducted for ECG traits (i.e., RR, PR, QRS, QTc, JT, and P wave) in an ME cohort of ~14,000 Qataris with whole genome sequence data. The performance of existing polygenic risk scores (PRS) was evaluated, and novel PRS were developed.

Results: Seventy-four independent loci were obtained ($P < 5 \times 10^{-8}$): RR (1 locus), PR (19 loci), QRS (8 loci), QTc (21 loci), JT (21 loci), and P wave (4 loci). Out of 74 loci, 6 (8.1%) were novel: PR (*STAC* and *CSMD1*), QRS (*ANK1* and *NCOA2*), QTc (*LSP1*), and P wave (*MKLN1*). All PRS were significantly associated with the corresponding ECG traits, with the least significant showing a $P = 3.89 \times 10^{-15}$. PGS002121 was the best PRS for RR ($R^2 = 0.008$, $P = 8.54 \times 10^{-27}$), PGS000905 for PR ($R^2 = 0.053$, $P = 2.57 \times 10^{-165}$), PGS002166 for QRS ($R^2 = 0.024$, $P = 1.53 \times 10^{-75}$), PGS002276 for QTc ($R^2 = 0.059$, $P = 4.83 \times 10^{-185}$), and PGS001902 for P wave ($R^2 = 0.089$, $P = 4.19 \times 10^{-25}$). Local PRSs substantially outperformed the existing ones (e.g., 1.3% increase of R^2 for QTc).

Conclusion: In this study, we confirmed many known ECG loci, and identified novel loci for ME populations. "European" PRS performed well in our cohort, but local PRS showed the best performance.

P17.063.D Dissecting the *LCT* selective sweep: insights into the genetics of T2D heterogeneity

Bethany Quinton[1], *Philip Zahariev*[1], *winston lau*[1], *Toby Andrew*[2], *dallas swallow*[1], *nikolas maniatis*[1]

[1]*University College London, GEE, United Kingdom;* [2]*Imperial College London, Metabolism, Digestion, and Reproduction, London, United Kingdom*

Background/Objectives: The region surrounding the *LCT* gene shows the strongest signature of positive selection in Europeans due to selection for lactase persistence (LP-rs4988235). A non-coding microRNA (miRNA-128) concealed behind this sweep has been associated with metabolic diseases. Others have associated rs4988235, or additional SNPs in this long region of strong linkage disequilibrium (LD), with obesity or more controversially with type 2 diabetes (T2D). miRNA-128, 186kb away from LP-rs4988235, is claimed to have a functional role in T2D but GWAS meta-analyses support no such association.

Methods: We shed light on the genetics of T2D in the LCT region and identify target cis-genes by studying the haplotype structure in T2D cases/controls with recorded BMI, stratifying by

LP haplotypes, and mapping directly on LD maps which can precisely locate and integrate disease and eQTL mapping results.

Results: Using European LD maps shows no strong signal for either T2D or BMI when comparing all T2D cases against controls, but crucially a significant signal was detected when comparing obese and lean diabetics. It is located 850kb from rs4988235 and is enriched with significant SNPs conferring risk (OR>2) for high BMI in diabetics. Furthermore, haplotypes carrying the risk allele from these SNPs and the LP allele confer an increase in BMI in diabetics. In silico analysis identified a number of cis-genes using adipose and skeletal muscle expression.

Conclusion: LP-rs4988235 is not causal. Instead, the identified T2D-associated eQTLs are implicated in dysregulating expression levels of cis-genes which appear to play a role in the disease pathway.

P17.064.A Epigenetics of the circulating proteome in Generation Scotland

Josephine Robertson[1], *Spyros Vernardis*[2;3], *Camilla Drake*[4], *danni gadd*[1], *Archie Campbell*[1], *David Porteous*[1], *andrew mcintosh*[1;5], *Jamie Pearce*[6], *Tom Russ*[5;7], *Simon Cox*[8], *caroline hayward*[1;4], *Aleksej Zelezniak*[2;3], *daniel mccartney*[1], *Markus Ralser*[2;3], *riccardo marioni*[1]

[1]*University of Edinburgh, Centre for Genomic and Experimental Medicine, Institute of Genetics and Cancer, United Kingdom;* [2]*The Francis Crick Institute, London, United Kingdom;* [3]*Eliptica Limited, London;* [4]*University of Edinburgh, MRC Human Genetics Unit, Institute of Genetics and Cancer, United Kingdom;* [5]*University of Edinburgh, Division of Psychiatry, Centre for Clinical Brain Sciences, United Kingdom;* [6]*University of Edinburgh, Centre for Research on Environment, Society and Health, School of Geosciences, United Kingdom;* [7]*University of Edinburgh, Alzheimer Scotland Dementia Research Centre, Department of Psychology, United Kingdom;* [8]*University of Edinburgh, Lothian Birth Cohorts, Department of Psychology, United Kingdom*

Background/Objectives: The molecular architecture of proteome regulation is incompletely understood. Epigenetic changes such as DNA methylation are likely to play a crucial role; this can be explored via epigenome-wide association studies (EWAS) of the circulating proteome[1, 2]. To date, no large-scale EWASs have included proteins measured by mass spectrometry (MS).

Methods: An EWAS of 439 circulating MS proteins and peptides was performed in 14,761 individuals from Generation Scotland[3]. MS proteomics data were generated using a redesigned high-throughput approach[4]. Methylation was measured in baseline blood samples, using the Infinium HumanMethylationEPIC BeadChip[5]. An EWAS for each protein was carried out using OmicS-data-based Complex trait Analysis to perform iterative linear regression with covariates including technical factors, age, sex, white cell proportions, body mass index and smoking[6].

Results: 133 of the 439 signals were mapped to individual proteins, predominantly involved in inflammatory and immune responses, blood coagulation and lipid metabolism. Iterative linear models resulted in a full EWAS model, revealing 113,114 significant CpG – protein (p-Bonferroni < 8.2e-11) associations for 120 mapped proteins, with a median genomic inflation factor of 1.3.

Conclusion: Our large-scale EWAS of the circulating proteome, as measured by MS, reveals complex relationships between the epigenome and circulating proteome. We will further refine the model, trialling different methods to account for CpG intercorrelations, prior to gene/pathway enrichment analysis and causal inference analyses with disease outcomes.

P17.066.C Novel loci associated with increased adiposity and lower cardio-metabolic risk in the UK Biobank

Nathalie Chami[1;2], *Zhe Wang*[1;2], *Alexander Rauch*[3;4], *Michael Preuss*[1], *Roelof A.J. Smit*[1;5], *Ruth Loos*[1;2;5]

[1]*Icahn School of Medicine at Mount Sinai, New York, United States;* [2]*The Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, United States;* [3]*Functional Genomics & Metabolism Research Unit, Department of Biochemistry and Molecular Biology,University of Southern Denmark, Odense, Denmark;* [4]*Molecular Endocrinology & Stem Cell Research Unit, Department of Endocrinology and Metabolism, Odense University Hospital and Steno Diabetes Center Odense and Department of Clinical Research,University of Southern Denmark, Odense, Denmark;* [5]*The Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health and Medicine, University of Copenhagen, København, Denmark*

Background/Objectives: Individuals with obesity are at a higher risk of metabolic outcomes, such as type 2 diabetes and cardiovascular disease. However, some do not suffer from these conditions. We aimed to identify genetic loci that contribute to the uncoupling of obesity from cardiometabolic co-morbidities.

Methods: We leveraged individual-level data of the UK Biobank and performed GWAS analyses on 35 adiposity and cardiometabolic risk factors.

Results: We identified 266 variants associated with increased adiposity, but with protective cardiometabolic effects. We replicate previously known loci including *IRS1, PPARG, VEGFA, and KLF14*. In a PheWAS analysis, a GRS of the 266 variants ($GRS_{uncoupling}$) was associated with increased risk of obesity ($OR = 1.16$, $P < 4 \times 10\text{-}108$), but a decreased risk of cardiometabolic outcomes, including diabetes ($OR = 0.94$, $P = 5.56 \times 10\text{-}21$) and ischemic heart disease ($OR = 0.96$, $P = 7.38 \times 10\text{-}11$). The 266 loci were validated in the Bio*Me* Biobank ($N_{samples} = 23k$); The $GRS_{uncoupling}$ successfully identified individuals with higher BMI and better cardiometabolic profile in Bio*Me*. Specifically, individuals in the top decile of the $GRS_{uncoupling}$ had higher BMI but lower triglycerides, LDL and HbA1C and higher HDL compared to individuals in the lowest decile. Clustering analyses grouped the 266 variants into eight clusters, each with a distinct association signature. Our gene prioritization analyses prioritized genes that play a role in metabolic regulation and adipogenesis, signaling and developmental processes, and intracellular transport and cholesterol regulation.

Conclusion: In summary, we identified 266 variants that uncouple adiposity from cardiometabolic outcomes and cluster into eight subsets with distinct cardiometabolic risk profiles.

Consortium: The DEMISTIFI consortium

Background/Objectives: Fibrosis is a major factor in global mortality that can affect most organ systems. The incidence of fibrotic diseases in many different organ systems hinders the development of targeted therapies. A potential strategy to overcome this challenge is to target genetic mechanisms and pathways associated with shared fibrosis pathology or fibrotic multi-morbidity (FMM).

Methods: We included unrelated individuals of four ancestry groups (European, African, East-Asian and South-Asian) in UK Biobank (a population cohort of 500,000 individuals). Fibrotic diseases, as defined by a published consensus list, were assigned to one of 11 organs or systems (Respiratory, Liver, Biliary, Cardiovascular, Intestinal-Pancreatic, Integumentary, Skeletal, Systemic, Reproductive, Urinary and Diabetes). Individuals with records of fibrotic disease in more than one organ/system were defined as FMM cases, and all others defined as controls. We then performed a genome-wide association study to test the association between each genetic variant across the genome with FMM separately for each ancestry group. Genetic signals that reached genome-wide significance ($p < 5 \times 10^{-8}$) were considered associated with FMM.

Results: There were 11 independent signals associated with FMM susceptibility in Europeans, including one located near the *DCLRE1B* gene which is linked to telomere maintenance and protection. One signal was associated with FMM in Africans, two signals in East-Asians and no signals reached genome-wide significance in South-Asians.

Conclusion: Functional follow-up of these FMM signals may reveal potential causal pathways of general fibrosis which can be leveraged in the development of new therapies for those affected by fibrosis.

P17.068.A Imaging genetics of language network functional connectivity reveals links with language-related abilities, dyslexia and handedness

Jitse S. Amelink[1], *Merel C. Postema[1], Xiang-Zhen Kong[2], Dick Schijven[1], Amaia Carrion Castillo[1], Sourena Soheili-Nezhad[1], Zhiqiang Sha[1], Barbara Molz[1], Marc Joliot[3], Simon E. Fisher[1], Clyde Francks[1]*

[1]Max Planck Institute for Psycholinguistics, Language & Genetics, Nijmegen, Netherlands; [2]Zhejiang University, Psychology, Hang Zhou Shi, China; [3]University of Bordeaux, Bordeaux cedex, France

Background/Objectives: Language is supported by a distributed network of brain regions with a particular contribution from the left hemisphere. A multi-level understanding of this network requires studying its genetic architecture.

Methods: We used resting-state imaging data from 29,681 participants (UK Biobank) to measure connectivity between 18 left-hemisphere regions involved in multimodal sentence-level processing, as well as their right-hemisphere homotopes, and interhemispheric connections. We used multivariate genome-wide association analysis, polygenic scores and a gene-based exome-wide association analysis to study the genetic architecture of these traits.

Results: Multivariate genome-wide association analysis of this total network, based on genetic variants with population frequencies > 1%, identified 14 genomic loci, of which three were also associated with asymmetry of intrahemispheric connectivity. Polygenic dispositions to lower language-related abilities, dyslexia and left-handedness were associated with generally reduced leftward asymmetry of functional connectivity. Exome-wide association analysis based on rare, protein-altering variants (frequencies ≤ 1%) suggested 7 additional genes.

Conclusion: These findings shed new light on genetic contributions to language network organization and related behavioural traits. We would like to thank the research participants and employees of 23andMe, Inc. for providing the dyslexia genome-wide summary statistics.

P17.069.B Unique genome-wide methylation patterns within HIV disease

Thilona Arumugam[1], *Veron Ramsuran[1], Werner Smidt[1]*

[1]University of KwaZulu-Natal, Durban, South Africa

Background/Objectives: DNA methylation-mediated gene regulation has been recently associated with host-virus interaction. Previously, HIV was shown to alter DNA methylation profiles of the host. However, these studies examined unrelated individuals which failed to take into consideration the effects of genetic and lifestyle factors on DNA methylation. Thus, this aimed to determine the effects of DNA methylation on HIV pathophysiology in a longitudinal cohort.

Method: In this study we explored a rare cohort of females ($n = 120$) followed up over 15 years from pre-HIV infection to post-HIV infection. Using this unique cohort, we explored the role genome-wide methylation has on HIV infection and disease progression, using the Infinium MethylationEpic v2.0 array.

Results: We report unique DNA methylation patterns from the HIV-negative timepoint compared to the HIV-positive timepoint in the same patients. We identified 8 DMPs across pre-infection and post-infection and 14,274 DMPs between pre-treatment and post-treatment timepoints. Gene Ontology enrichment was performed on this module using the genes linked to the CpG probes, which revealed associations with Interleukin-1 regulation, viral entry/viral processes, histone modifications and B-cell proliferation.

Conclusion: Data from this study shows that genome methylation patterns vary across different stages of HIV infection and that these methylation patterns might have an impact on controlling HIV infection.

P17.070.C A phenome-wide association study of tandem repeat variation in 168,554 individuals from the UK Biobank

Celine Manigbas[1], *Bharati Jadhav*[1], *Paras Garg*[1], *Mariya Shadrina*[1], *William Lee*[1], *Andrew Sharp*[1], *Alejandro Martin Trujillo*[1]

[1]*Icahn School of Medicine at Mount Sinai, Department of Genetics and Genomic Sciences and Mindich Child Health and Development, New York, United States*

Most genetic association studies focus on binary variants, typically ignoring other variant types that could contribute to the "missing heritability" of the genome. We hypothesized that common length polymorphisms in TR tandem repeats (TRs), a multi-allelic variant not assayed in standard genetic studies, can modulate phenotypic variation of human traits. To investigate this, we performed direct TR genotyping and phenome-wide association studies for 30,291 traits and 36,085 TRs in 168,554 individuals with genome sequencing from the UK Biobank.

We identified 47 TRs that showed causal associations with 73 traits based on fine-mapping and conditional analysis. We replicated 23 of 31 (74%) of these causal associations with matching traits in the All of Us cohort. While this set included several known repeat expansion disorders, novel associations we identified were attributable to common polymorphic variation in TR length, rather than rare expansions. Notable findings include a coding polyhistidine motif in *HRCT1* influencing risk of hypertension which showed a strong negative causal association with the incidence of high blood pressure ($p = 4.1 \times 10^{-24}$) and the use of blood pressure medications ($p = 2.9 \times 10^{-14}$). Causal TRs were strongly enriched for associations with local gene expression and DNA methylation, supporting their causality and providing insights into the molecular mechanism by which TRs impact the associated phenotype.

In conclusion, our study provides a comprehensive evaluation of the impact of TR variation on human traits along with highlighting the importance of including TRs in future genetic association studies.

Background/Objectives: Hepatitis B is a major global health problem particularly in the WHO Western Pacific and African Regions, where 116 and 81 million people, respectively, are chronically infected. The impact of HBV exposure varies significantly, ranging from resistance and spontaneous viral clearance to development of chronic HBV infection. This variability is influenced by host genetics, viral characteristics, and environmental elements, however, little is known about it's host genetics in Africa. In an effort to bridge this gap, our study sought to identify the genetic determinants that shape distinct susceptibility patterns in HBV infection amongst Ugandans.

Methods: We conducted a GWAS of HBV susceptibility among 6,399 Ugandans from the Uganda Genomic Resource (UGR). To ensure robustness of our findings, we examined replication across independent studies. We performed Bayesian fine mapping to identify potential causal variants, functional mapping and annotation using FUMA (Functional Mapping and Annotation), and PheWAS analyses using the GWASATLAS to understand the relationship between our lead SNPs and variation across different phenotypes.

Results: We identified 78 significant SNPs, mapping to 22 independent novel loci associated with HBV infection susceptibility. Subsequently, we also replicated SNP rs6457709 previously reported to be associated with HBV infection susceptibility in Europeans by Tian C et al, 2017.

Conclusion: Our study identified 22 independent novel loci associated with HBV infection susceptibility and validated a previously published SNP (rs6457709), that was reported to be associated with HBV infection susceptibility in Europeans. Ultimately, additional GWASs are required to represent the impact of diverse African genomes on disease susceptibility.

P17.072.A Ribosomal DNA Copy Number Associates with Hematological Profiles and Renal Function

Francisco Rodriguez-Algarra[1], *David Evans*[2], *Vardhman Rakyan*[1]

[1]*Blizard Institute, London, United Kingdom;* [2]*Frazer Institute, Brisbane, Australia*

Background/Objectives: The phenotypic impact of variation in repetitive genomic features, such as the multi-copy, multi-locus 47S ribosomal DNA (rDNA), is poorly understood. Despite its key role and displaying copy number (CN) variation in humans (~100-600 copies), strong evidence for rDNA-associated variation impacting human traits is still lacking.

Methods: We estimate rDNA CN on 157,227 whole genome sequences from white British UK Biobank (UKB) participants using a proxy method we develop and validate. We then conduct a phenome-wide screen of rDNA CN, address the causality of the top associations, and replicate key results.

Results: Phenotypes in the blood "counts" and "biochemistry" categories appear enriched in a phenome-wide screen of rDNA CN associations. rDNA CN and systemic inflammation markers, including the neutrophil-to-lymphocyte ratio, strongly associate in targeted models. Further analyses suggest rDNA CN causally influences blood composition, showing no association between rDNA CN and factors known to alter blood composition

measurements. Stringent population filtering retains the associations. Similar results replicate in other ethnicities and the second UKB sequencing release (further 209,681 participants). rDNA CN also associates significantly with renal function biomarkers. Estimates of Glomerular Filtration Rate derived from these associate negatively with rDNA CN, suggesting higher CN corresponds with worse renal function, leading to higher kidney failure risk.

Conclusion: We find that rDNA CN associates with hematological profiles and renal function, highlighting a novel source of genetic variation influencing phenotype, and providing a broader explanation for the genetic basis of human trait variance.

P17.073.B New genetic modifiers of age of onset in ATTRV30M amyloidosis

Estefânia Carvalho[1;2], *Andreia Dias*[1;2], *Márcia Almeida Liz*[3], *Teresa Coelho*[4], *Alda Sousa*[1;2], *Miguel Alves-Ferreira*[1;2;5], *Mariana Santos*[1;2;3], *Carolina Lemos*[1;2]

[1]*i3S - Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal;* [2]*Abel Salazar Biomedical Sciences Institute - University of Porto, Porto, Portugal;* [3]*Instituto de Biologia Molecular e Celular, Porto, Portugal;* [4]*Centro Hospitalar Universitário de Santo António, Porto, Portugal;* [5]*Centro de Genética Preditiva e Preventiva, Instituto de Biologia Molecular e Celular (CGPP-IBMC), Porto, Portugal*

Background/Objectives: Transthyretin (ATTR) amyloidosis is a severe and fatal genetic disorder caused by *TTR* variants that lead to amyloid fibril accumulation in multiple organs. Globally and in Portugal, the most prevalent pathogenic variant is Val30Met (ATTRV30M). Importantly, there is significant diversity in phenotype, severity, and age of onset (AO) among affected individuals. Our research focuses on uncovering genetic variants linked to ATTRV30M amyloidosis that could explain the AO variability.

Methods: DNA samples were gathered from 175 individuals diagnosed with ATTRV30M amyloidosis, including 92 early-onset (AO < 40yrs) and 83 late-onset cases (AO>50yrs), along with 187 controls. We used Precision Medicine Diversity Arrays and analyzed data using Axiom Analysis Suite. Two methodologies were employed: a GWAS and a candidate gene analysis, the latter focusing on genes previously identified by our group.

Results: Our GWAS approach unraveled genes potentially associated with AO of ATTRV30M amyloidosis including RGS6, KCTD5 and ARHGEF10. In the candidate gene approach, we investigated several genes related to the Rho GTPase pathways and found a genetic variant that showed a marked association with late-onset of the disease.

Conclusion: We uncovered new genetic modifiers potentially associated with ATTRV30M amyloidosis and that may act as modulators of AO. Interestingly, we found, in both approaches, genes related to the Rho GTPase pathways. Potential genetic modifiers will be assessed bioinformatically to predict deleteriousness. The most promising genes will be studied functionally, and the results replicated in a bigger cohort.

P17.074.C DNA methylation in blood and essential hypertension in African-Brazilian quilombo populations

camila cristina avila martins[1], *Mariana Maschietto*[2], *lilian kimura*[1], *lucas alvizi*[3], *vinícius magalhães borges*[4], *Ana Krepischi*[1], **Regina Mingroni-Netto**[1]

[1]*Universidade de São Paulo, Centro de Pesquisa sobre o Genoma Humano e Células Tronco, Instituto de Biociências, são paulo, Brazil;* [2]*Hospital Infantil Boldrini, Centro de Pesquisa, Campinas, Brazil;* [3]*University College London, Cell & Development Biology, London, United Kingdom;* [4]*Joan C. Edwards School of Medicine, Department of Biomedical Sciences, Huntington, United States*

Background/Objectives: This study aimed to investigate if there is an association between DNA methylation changes in blood and essential hypertension in Afro-Brazilian rural populations (*quilombo* populations in Vale do Ribeira - São Paulo, Brazil).

Methods: We evaluated DNA methylation in peripheral blood samples from normotensive (39) and hypertensive (41) individuals using the Infinium Methylation EPIC BeadChip platform. Data were analyzed using RnBeads and ChAMP packages and cross-referenced with information obtained from databases such as EWAS Atlas, GWAS catalog, GeneCards, literature data and tools such as VarElect and EWAS Toolkit.

Results: The comparison between normotensive and hypertensive individuals identified 190 differentially methylated CpG sites (DMPs, adj.P.Val < 0.05) and 46 differentially methylated regions (DMRs, p.valueArea <0.05). Among the DMRs, those located in or near *MIR539*, *TSHBS1*, *CERS3* and *MIR487B* were highlighted, as genes that interfere with vascular function; *GABBR1*, that affects pressure regulation by the nervous system, and *ABAT*, which is connected with the function of GABA neurotransmitter and *GABBR1*; *PON3* and *IL5RA*, as genes that are related to inflammation and kidney function; *RNF39*, *HLA-DQB2*, *NUDT12* and *KCNH2*, that have shown genetic or epigenetic associations with blood pressure by unknown mechanisms. We also found DMRs located in or near genes related to pathways such as transcription, translation, proliferation, adhesion, apoptosis, differentiation and protein ubiquitination, but without previous data on association with hypertension.

Conclusion: : The study provides valuable information about the genetic and epigenetic underpinnings of essential hypertension and could contribute to developing personalized treatments.

P18
GENETIC EPIDEMIOLOGY AND PHARMACOGENOMICS

P18.001.D Participation bias in the Estonian biobank

Ivan Kuznetsov[1], *Vasili Pankratov*[1;2]

[1]*Institute of Genomics, University of Tartu, Tartu, Estonia;* [2]*Bioinformatics research institute, Aarhus University, Aarhus, Denmark*

Consortium: Estonian Biobank Research Team

Background/Objectives: Large-scale biobanks are a unique resource for genetic epidemiological studies due to their exceptional sample sizes. Recent studies show biobanks to be biased in terms of allele frequencies as well as demographic and socioeconomic characteristics, which can lead to discoveries irrelevant to the general population. Our study analyzes the Estonian Biobank (EstBB) comprising more than 20% of the country's adult population. We ask if sampling such a big fraction

of the general population makes the EstBB robust to the participation bias. Next, we explore the driving factors and consequences of such bias. Finally, we look for the best weighting procedure to correct the sample for the participation bias.

Methods: We use data from the EstBB (~212,000 individuals). To detect participation bias we compare demographic characteristics of EstBB to census data. Then we compare mean polygenic scores for various traits between subcohorts of the EstBB based on sex and recruitment strategy. Weighting is performed using characteristics available in the EstBB and census data (e.g. sex, year of birth, place of birth/residence).

Results: We find that the EstBB is not perfectly representative of the general population of Estonia. Significant differences exist in polygenic scores for educational attainment, body mass index and height between the EstBB subcohorts by recruitment strategy and sex. Weighting improves representativeness but results in a substantial reduction in the effective population size.

Conclusion: The EstBB is affected by multiple aspects of participation bias similar to other well-known biobanks despite the recruitment of more than 20% of the population.

Conflict of Interest: None declared

P18.002.A Utility of Polygenic Risk Scores for Prediction of Incident Type 2 Diabetes

Dariusz Ratman[1], *Jiayi Sun*[1], *Placede Tshiaba*[1], *Tate Tunstall*[1], *Premal Shah*[1], *Matthew Rabinowitz*[1], *Akash Kumar*[1], *Kate Im*[1]

[1]*MyOme, Inc., Menlo Park, United States*

Background/Objectives: The clinical utility of genetic information in assessing Type 2 Diabetes (T2D) risk remains uncertain. Our study evaluates the added value of T2D polygenic risk scores (PRS) compared to established risk factors.

Methods: Utilising multi-ancestry GWAS summary statistics and five multiethnic cohorts, we developed a cross-ancestry PRS (caPRS) model for T2D. This model was assessed against two models based on established risk factors: a simple model (age, sex, family history, BMI, waist circumference, blood pressure, smoking) and a clinical model (additionally including fasting glucose, triglycerides, HDL-C). We tested the caPRS's association with T2D incidence in three multiethnic validation cohorts (ARIC, MESA, UKB subset) and compared its discriminatory power to the simple and clinical models.

Results: Our results show that the caPRS is associated with T2D incidence across all cohorts. Adjusting for clinical covariates, the hazard ratio per standard deviation for European, South Asian, and African populations was 1.48 (1.43-1.53), 1.33 (1.09-1.62), and 1.18 (1.08-1.29), respectively. Adding caPRS to the simple and clinical model significantly improved the C-index.

The difference in absolute risk across caPRS strata was most pronounced for individuals in the highest clinical risk quartile, showing a 10-year cumulative incidence of 6.4% and 17.8% for those in the top and bottom 20% of caPRS distribution. Conversely, this difference was minimal in the lowest clinical risk quartile.

Conclusion: Our findings demonstrate that genetic information can provide more personalised T2D risk prediction and would be most informative for those with elevated clinical risk.

P18.003.B Sequencing synergy: integration of short and long reads for comprehensive pharmacogenetics testing

Sònia Font Tellado[1], *Patrick Brennan*[1], *Birgit Busse*[1], *Leila Keskic*[1], *Sophie Gentili*[1], *Steffen Lott*[1], *Oliver Wachter*[1]

[1]*MVZ Martinsried GmbH, Planegg, Germany*

Background/Objectives: We present the development and validation of a Pharmacogenetics (PGx) pipeline for star allele calling, annotation and reporting. We combine short read sequencing of 42 clinically relevant PGx genes with long read sequencing of CYP2D6. Our method enables the analysis of single nucleotide variants (SNVs) in all target genes and copy number variants (CNVs) in CYP2D6. We use a custom bioinformatics pipeline to process long and short read data, call star-alleles and provide clinically relevant drug recommendations in a single report.

Methods: a custom amplicon panel was ordered from Illumina and sequenced on a NovaSeq6000. CYP2D6 sequencing (whole gene) was performed on a Sequel II (Pacific Biosciences). SNV calling was done with Illumina DRAGEN. A custom bioinformatics pipeline combining pbaa, pbmm2 and pangu was used to call SNVs and CNVs in CYP2D6. The open-source tool PharmCAT was used for star allele calling, variant annotation and drug recommendations. 7 Genome in a Bottle (GIAB) samples and 15 Coriell samples with known star-alleles were used as benchmarking datasets for full workflow validation.

Results: SNV calling in short reads showed a recall of 98% and precision of 98% on the GIAB dataset. Star allele calling on the Coriell dataset showed a recall of 93% and a precision of 96% (including CYP2D6). Recall and precision for CYP2D6 only were 79% and 73%, respectively (SNV and CNV).

Conclusion: our PGx pipeline enables cost-effective star allele calling with high recall and precision by combining short read sequencing, long read sequencing and state-of-the-art bioinformatics tools.

[1]*Nightingale Health Plc., Helsinki, Finland*

Consortium: Nightingale Health Biobank Collaborative Group

Background/Objectives: Polygenic scores have been shown to have limited utility in predicting progression to disease-specific death. Metabolomic scores, however, can be strong predictors of both incident disease and mortality. Here we compare polygenic and metabolomic scores for predicting disease progression.

Methods: We used 460,000 samples with metabolomic and genetic information from the UK Biobank. For chronic kidney disease (CKD), chronic obstructive pulmonary disease (COPD) and rheumatoid arthritis (RA), we built metabolomic scores to predict disease incidence and progression (end-stage renal disease for CKD, hospitalisation or death from acute exacerbation for COPD, and corrective joint surgery for RA). We used previously published susceptibility polygenic scores.

Results: CKD patients in the highest decile of metabolomic progression score were 50.2-times (HR; 30.5-82.5 95% confidence interval) more likely to develop end-stage renal disease than the

rest. For COPD the equivalent HR was 3.2 (3.5-4.2) and for RA 2.4 (1.7-3.5). Metabolomic scores for disease incidence and progression were highly correlated, and both predicted progression equally well. Conversely, polygenic scores showed predictive ability only for COPD with HR of 1.9 (1.4-2.6) for the top decile. Further, we show by simulation that metabolomic scores can enhance the number of cases for trials to increase power.

Conclusion: Metabolomic scores can predict disease progression, and aid in selecting participants for detailed follow-up, such as enriching trials for progression. By contrast, extant polygenic risk scores predict disease incidence but usually have weak prediction of disease progression.

P18.005.D Phenotypic and metabolomic landscape of *FAM47E-SHROOM3* exonic haplotypes

Dariush Ghasemi-Semeskandeh[1;2], Eva König[1], Luisa Foco[1], Nikola Dordevic[1], Martin Gögele[1], Johannes Rainer[1], Markus Ralser[3], Dianne Acoba[4;5], Dorien Peters[2], Peter Pramstaller[1], **Cristian Pattaro**[1]

[1]Eurac Research, Institute for Biomedicine, Bolzano, Italy; [2]Leiden University Medical Center, Department of Human Genetics, Leiden, Netherlands; [3]Charité - Universitätsmedizin Berlin, Institute of Biochemistry, Berlin, Germany; [4]AstraZeneca, Clinical Renal, Late-stage Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, Gothenburg, Sweden; [5]Université Paris Cité, Institut Necker Enfants-Malades (INEM), INSERM U1151, Paris, France

Background/objectives: Genome-wide association studies identified a chromosome 4q21.1 locus spanning *FAM47E*, *STBD1*, *CCDC158*, and *SHROOM3*, prominently associated with kidney function markers but also with electrolytes, hematological and cardiovascular traits. Functional studies linked *SHROOM3*, encoding an actin-binding protein involved in cell shaping, with kidney damage. However, systematic explorations of functional variants of all genes at the locus are lacking. We thus conducted phenome-wide, metabolomic and proteomic analyses of exonic haplotypes spanning the four genes.

Methods: We reconstructed haplotypes for 12,834 individuals of the Cooperative Health Research in South Tyrol (CHRIS) study, following genotype imputation from a whole-exome sequencing reference panel of a 3422 CHRIS sample subset. Haplotypes, including 146 exonic and intronic variants over the four genes, were tested for association with 74 serum, urine, and anthropometric traits, 172 serum metabolites, and 148 plasma proteins concentrations using linear models.

Results: The 11 identified haplotypes (frequency: 2% to 24%) showed both shared and specific characteristics. Compared to the most common haplotype, most haplotypes were jointly associated with kidney function and serum magnesium levels. The second most common haplotype (12% frequency) was associated with better kidney function and lower dodecanoyl-, hydroxyvaleryl- and tiglyl-carnitine concentrations. A haplotype of 4% frequency was associated with better kidney function and lower hematological marker levels. A haplotype of 2% frequency was associated with lower magnesium, glutamine, and putrescine levels. Cluster analysis revealed six distinct trait groups and two distinct haplotype groups.

Conclusion: *FAM47E-SHROOM3* functional haplotypes exhibit marked pleiotropic effects and identify population subgroups with distinct biomarker profiles.

P18.006.A Genetic insights in the cardiovascular multimorbidity of psoriasis

Charalabos Antonatos[1], **Alexandros Pontikas**[1]*, Adam Akritidis[1], Katerina Grafanaki[2;3], Sophia Georgiou[2], Yiannis Vasilopoulos[1]*

[1]University of Patras, Biology, Rion, Greece; [2]Medical School, Dermatology-Venereology, Rion, Greece; [3]Medical School, Biochemistry, Rion, Greece

Background/Objectives: We performed genome-wide pleiotropy analyses to unveil common risk factors and implicated pathways mediating cardiovascular multimorbidity (CVM) in psoriasis, including coronary artery disease (CAD), heart failure (HF) and myocardial infarction (MI).

Methods: Utilizing GWAS data from European cohorts with psoriasis ($n = 44164$), CAD ($n = 184305$), HF ($n = 977323$), and MI ($n = 395795$), we assessed global genetic correlations and explored pleiotropy by integrating common, bi-allelic variants excluding the major histocompatibility complex under a composite null hypothesis. Gene-level and multi-trait colocalization analyses were conducted to investigate the biological implications of pleiotropic loci. Bi-directional and drug-based Mendelian Randomization were employed to examine the causal relationship of psoriasis with CVMs, and the impact of lipid-lowering drugs on psoriasis risk with the largest GWAS for low-density lipoprotein (LDL) measurement in Europeans.

Results: Psoriasis and CVMs show a modest genome-wide correlation ($0.15 < r_g < 0.3$, $P < 1 \times 10^{-6}$), with 61 overlapping risk loci reporting significant pleiotropic associations (38 unique), including 28 in psoriasis-CAD. Gene-based analyses documented significant enrichment in T-helper 17 pathways in all CVMs, LDL metabolism in psoriasis-CAD and psoriasis-MI, while 5 loci were reported as causal. Psoriasis was also a causal factor for all CVMs except MI. Excluding pleiotropic variants, genetically proxied inhibition of *PCSK9* ($\beta = -0.23$, $P = 0.001$) and *LDLR* ($\beta = -0.44$, $P = 1.31 \times 10^{-8}$) significantly reduced psoriasis risk, thus unveiling the implication of the LDL receptor-mediated pathway in psoriasis and CAD comorbidity.

Conclusion: By triangulating genetic evidence, we prioritize genes and pathways for the comorbid mechanisms in psoriasis and CVMs, facilitating the development of personalized therapeutic strategies.

Consortium: INTERnational consortium of integratiVE geNomics prEdiction

Background/Objectives: Age- and sex-specific polygenic score (PGS) effects have been previously reported in European ancestry individuals, but it is unknown to what extent these apply across ancestry groups.

Methods: Within the INTERnational consortium of integratiVE geNomics prEdiction (INTERVENE), we leveraged information from 11 biobanks with inclusion of East and South Asian, African, Middle Eastern, and admixed American ancestry groups. In a combined sample of over 1 million (40% non-European), we calculated MegaPRS-derived PGSs and assessed incident events from health registries. We employed Cox proportional hazards models and Global Burden of Disease baseline risks to estimate PGS effects and lifetime risks for 18 high burden diseases.

Results: PGS had a larger effect for coronary heart disease (CHD) in South-Asian men compared to women ($HR_{male} = 1.34$ (95% CI: 1.29 - 1.39) vs $HR_{female} = 1.20$ (95% CI: 1.14 - 1.27), $PGS*Sex_{Interaction}$ P-value $= 7.92 \times 10^{-4}$), whereas for T2D the effect was larger in East Asian women compared to men ($HR_{male} = 1.53$ (95% CI: 1.50 - 1.55) vs $HR_{female} = 1.62$ (95% CI: 1.59 - 1.66), $PGS*Sex_{Interaction}$ P-value $= 1.76 \times 10^{-5}$). These trends were consistent in Europeans. Heterogeneous effect sizes by age were detected for CHD, T1D and T2D in South Asians, whereas T2D and prostate cancer exhibited age-specific effects in East Asians. We are replicating in the additional ancestry groups.

Conclusion: Our results demonstrate variable sex- and age-specific PGS associations across ancestries and emphasize the importance of country- and ancestry-calibrated lifetime risk estimates for global utility of PGS.

P18.008.C Investigating the Utility of Pharmaceutically Informed, Type-2 Diabetes, Partitioned Polygenic Scores in the UK Biobank

Luke Marques[1], *jonathan coleman[1], Cathryn Lewis[1], Gerome Breen[1]*

[1]Social Genetic and Developmental Psychiatry Centre, London, United Kingdom

Background/Objectives: Drug repositioning (DR) is a cost-effective approach to complement traditional, lengthy and expensive drug discovery methods. We explore the utility of pharmaceutically informed partitioned polygenic scores (*p*PGS) for this effort, through enrichment analysis, aiming to identify target-indication pairs enriched for Type-2 Diabetes (T2D) signal. We further investigate the relationship between these *p*PGSs and clinically relevant outcomes in the UK Biobank (UKB) using Primary Care records.

MAGMA gene-set enrichment analysis was previously used to suggest DR opportunities for schizophrenia, using a large collection of gene-sets, describing drug target genes. The limitation of this method is that it provides no individual level information. Conversely, a *p*PGS approach has the advantage of providing individual level scores for each gene-set.

Methods: We developed *p*PGSs for T2D across the aforementioned gene-sets, using PRSet. We used weights from a large T2D GWAS and built *p*PGSs for 412,765 UKB enrolled individuals. PRSet's enrichment analysis was employed and compared with an enrichment analysis using MAGMA of the same gene-sets.

Results and Conclusions: PRSet's implementation resulted in 602 gene-sets showing nominal significance, including a *p*PGS for sulfonylureas (A10BB, $p = 2.9997 \times 10^{-4}$), and 108 which reached the minimal permuted competitive *p*-value ($p = 10^{-4}$). However, enriched *p*PGSs lacked specificity towards expected gene-sets and the leading results were not supported by the MAGMA analysis. We further observed individuals in the cohort who have combinations of bottom and top decile *p*PGSs, suggesting the underlying heterogeneity of T2D may relate to the drug gene-sets. Work on clinical outcomes analyses in the UKB using *p*PGSs is ongoing.

P18.009.D Tandem repeat polymorphisms as genetic modifiers of brain structure

Richard Mantey[1], *santiago estrada[1;2], kristian haendler[3;4], Marc Beyer[3;5], Monique M.B. Breteler[1;6], N. Ahmad Aziz[1;7]*

[1]Deutsches Zentrum für Neurodegenerative Erkrankungen e. V. (DZNE), Population Health Sciences, Bonn, Germany; [2]Deutsches Zentrum für Neurodegenerative Erkrankungen e. V. (DZNE), AI in Medical Imaging, Bonn, Germany; [3]Deutsches Zentrum für Neurodegenerative Erkrankungen e. V. (DZNE), Platform for Single Cell Genomics and Epigenomics (PRECISE), Bonn, Germany; [4]University Hospital Schleswig-Holstein, Institute for Human Genetics, Lübeck, Germany; [5]Deutsches Zentrum für Neurodegenerative Erkrankungen e. V. (DZNE), Systems Medicine, Bonn, Germany; [6]University of Bonn, Institute for Medical Biometry, Informatics and Epidemiology (IMBIE), Faculty of Medicine, Bonn, Germany; [7]University of Bonn, Department of Neurology, Faculty of Medicine, Bonn, Germany

Background/Objectives: Genomic tandem repeats, often overlooked in genome-wide studies, may contribute to the 'missing heritability' conundrum. Recently, we demonstrated that intermediate and pathological range cytosine-adenine-guanine(CAG) repeats in polyglutamine disease-associated genes were associated with cognitive function and depression risk in the general population. However, the impact of repeat polymorphisms in these and other disease-causing genes on brain structure remains unknown. Therefore, we aimed to assess the relation between size polymorphisms in repeat expansion disease-associated genes and brain structure.

Methods: We used data from the first 2912 participants (aged 30 to 94) of the Rhineland Study, a prospective cohort study in Germany. Employing amplicon-based targeted sequencing (Illumina NovaSeq 6000), we estimated the diploid genotypes in 21 loci with ExpansionHunter. Brain imaging features were derived from 3T MRI scans using FreeSurfer, and multiple linear regression models were used to examine the association between tandem repeat sizes and brain imaging features, adjusting for relevant factors.

Results: Larger expansions in a dodecamer repeat-containing region in the cystatin B*(CSTB)* gene were associated with reduced total grey matter volume (standardized β[95% confidence intervals]: -1.53[-2.41 to -0.65]). Moreover, the aggregated repeat expansion burden, defined as the mean standardized allele size across all the investigated genes, was significantly associated with a marked reduction in both total brain volume (-0.37[-0.70 to -0.04]), and total grey matter volume (-0.24[-0.44 to -0.04]).

Conclusion: Our results implicate repeat polymorphisms as important genetic modifiers of brain structure, and warrant further investigation of their role as genetic modifiers of brain structure and function in health and disease.

P18.010.A Causal Effect of puberty time on the Risk for Depression in females, but not in males: Results From a Two-Sample Multivariable Mendelian Randomization Study

Triinu Peters[1], *Raphael Hirtz*[2], *Anke Hinney*[1], *Jochen Antel*[1], *Corinna Grasemann*[3], *Heike Hölling*[4], *Björn-Hergen von Holt*[5], *Johannes Hebebrand*[1], *Nicola Albers*[1], *Christine Hars*[2]

[1]University Hospital Essen, Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Essen, Germany; [2]University Hospital Essen, Division of Pediatric Endocrinology and Diabetology, Department of Pediatrics II, Essen, Germany; [3]Ruhr-University Bochum, St. Josef-Hospital, Department of Pediatrics, Division of Rare Diseases and CeSER; [4]Robert Koch Institute, Department of Epidemiology and Health Monitoring, Berlin, Germany; [5]Universität zu Lübeck, Institut für Medizinische Biometrie und Statistik, Lübeck, Germany

Background/Objectives: A fair number of epidemiological studies suggest that age at menarche (AAM) is associated with depression, but there is evidence of residual confounding. This also applies to the relationship between male puberty time (MPT) and depression, even though less thoroughly studied. Previous Mendelian randomization (MR) studies on AAM have provided mixed findings, MR studies on MPT are lacking.

Methods: We performed two-sample MR analyses. For AAM, we used 360 single-nucleotide polymorphisms (SNPs) as instrumental variable. For males, we used 71 SNPs related to pubertal timing defined by the age at voice break. For the broadly defined depression, we used the latest GWAS on 246,363 cases and 561,190 controls. Multiple methods to account for heterogeneity of the instrumental variable, systematic and idiosyncratic pleiotropy, and horizontal pleiotropy were used. Body mass index (BMI), educational attainment, and total white blood count for AAM and BMI for MPT were considered as pleiotropic phenotypes in the multivariable MR analysis.

Results: A causal effect of early AAM on higher depression risk was found in the univariable (inverse-variance weighted (IVW): OR = 0.96, p = 0.0003) and in the multivariable MR analysis (IVW: OR = 0.96, p = 0.007). In males, univariable MR indicated a causal effect (IVW: OR = 0.93, p = .03). However, this was not confirmed by multivariable MR (IVW: OR = 0.95, p = .13).

Conclusion: Considering the adverse consequences of earlier AAM on mental health, this finding should foster efforts to address risk factors promoting earlier menarcheal age. There is currently no evidence that MPT is related to MDD risk

Consortium: Cohorts for Hearts and Aging Research in Genetic Epidemiology, Trans-Omics for Precision Medicine Program

Background/Objectives: Protein-altering variants (PAVs) may alter affinity-reagent binding to protein targets, contributing to inter-assay measurement differences. As allele frequencies differ between populations, PAVs may further contribute to inter-population heterogeneity.

Methods: We explored the impact of PAVs on the correlation of 2,157 plasma proteins measured with SomaScan 7k (ANML-RFU) and Olink Explore 3072 (NPX values) in 2,080 Multi-ethnic Study of Atherosclerosis participants [n = 884 White, 513 Black, 399 Admixed Americans, 289 East Asian].

Results: The median Pearson's correlation between inverse-normalized measures was 0.26 [Q1 = 0.0094, Q3 = 0.61], with 23% of proteins exhibiting heterogeneity between correlation estimates by ancestry group (Cochran's Q p-value < 0.05). Of the 2,157 proteins, we identified significant associations with genetic variants ±1MB of the protein-encoding gene (*cis*-pQTL) for 776 proteins on SomaScan and 846 on Olink. Similar proportions of SomaScan (23%) and Olink (25%) *cis*-pQTL SuSiE credible sets contained PAVs, with 33 SomaScan and 31 Olink credible sets containing PAVs common (EAF>0.10) in African, but rare (EAF < 0.01) in European ancestry. Of the 453 proteins with platform-overlapping credible sets, 19 proteins exhibited platform-discordant *cis*-pQTL effect sizes -- all containing PAVs in the credible set. For these proteins, adjustment for the associated PAV improved protein measure correlation across platforms (see table for examples). Notably, adjustment for ancestry-differentiated PAV rs399145 (*PLAUR* locus, EAF = 0.12 in Africans, EAF < 0.002 in others) improved cross-platform correlation in participants of African ancestry from 0.27 to 0.59.

	Pearson's Correlation	
	PILRA	suPAR
Pre-PAV Adjustment	-0.35	0.44
Post-PAV Adjustment	0.27	0.57

Conclusion: PAV-adjustment may offer a novel strategy for harmonizing cross-platform, cross-population differences in affinity-based protein measurements.

P18.012.C Bias from heritable confounding in Mendelian randomization studies

Eleanor Sanderson[1], *Tom Palmer*[1], *Kate Tilling*[1], *George Davey Smith*[1], *Gibran Hemani*[1]

[1]*MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom*

Background/Objectives: Mendelian randomization (MR) is an approach to causal inference that uses genetic variants to test and estimate the effect of an exposure on an outcome of interest. MR relies on a set of assumptions, including that there is no pathway from the genetic variants to the outcome that does not act through the exposure. Genetic variants for MR studies are often selected through genome-wide association studies (GWAS). The sample size of GWAS studies has been increasing rapidly, increasing the number of genetic variants selected as being associated with the exposure of interest and how distally mediated those that are selected are from the exposure.

Methods: We use theoretical analysis and simulation studies to explore how increasing GWAS sample size will affect MR estimation and propose estimation approaches to mitigate the resulting bias.

Results: We show through a plausible network simulation model that more distally mediated variants are more likely to act through confounders of a hypothesised exposure-outcome relationship. We show when this can result in bias in an MR estimation that is larger than the bias in linear regression and propose solutions to identify such bias in an MR study. We illustrate our approach through estimation of the causal effect of age at menarche on type 2 diabetes, hypothesising that it may be biased by confounding from adiposity.

Conclusion: As more genetic variants are included in MR there is greater potential for confounding bias, approaches should be taken to mitigate that bias.

Background/Objectives: Women with pathogenic variants in *BRCA1* and *BRCA2* have high risk of developing ovarian cancer after breast cancer diagnosis. Bilateral salpingo-oophorectomy (BSO) is recommended for ovarian cancer risk reduction. We used novel linked electronic health records data to examine the association between BSO after breast cancer diagnosis i*n BRCA1/2* carriers and long-term health outcomes.

Methods: We identified breast cancer patients diagnosed in England between 1995 and 2019 from the National Cancer Registration Dataset (NCRD). Data were linked to genetic testing labs to identify *BRCA1/2* carriers and to the Hospital Episode Statistics (HES) to identify BSO delivery. Outcomes were ascertained from HES and NCRD. Follow-up started at the latest of the BC diagnosis date plus one year and the genetic test dates. The associations were examined using multivariable Cox-regression, with BSO modelled as a time-dependent covariate.

Results: A total of 33,377 women with personal history of breast cancer had a *BRCA1/2* genetic test, 1,709 carried a *BRCA1* and 1,788 carried a *BRCA2* pathogenic variant. 859 *BRCA1* and 1,013 *BRCA2* carriers had BSO after breast cancer diagnosis. BSO was

associated with a significant reduction in all-cause mortality in both *BRCA1* and *BRCA2* carriers with hazard ratios of 0.61 (95%CI: 0.44-0.86) and 0.42 (95%CI: 0.31-0.57). There was no association between BSO and cardiovascular diseases or contralateral breast cancer risk. Ongoing analyses are examining the associations with neuropsychiatric outcomes and second non-breast cancers.

Conclusion: BSO after breast cancer diagnosis in *BRCA1/2* carriers is associated with a significant reduction in all-cause mortality.

P18.015.B Point-of-care-testing of pharmacogenetic variants using a portable nanopore sequencer

Satomi Mitsuhashi[1], *Takahiro Shimizu[1], Takehiro Ichikawa[1], Masahiro Hoshino[1], Yu Suzuki[1], Takayuki Fukano[1], Hisanao Akiyama[1], Kazuhiko Hanzawa[2], Yoshihisa Yamano[1]*

[1]St. Marianna University School of Medicine; [2]Niigata University School of Medicine and Dental Sciences

Background: Clopidogrel sulfate (CLP), an antiplatelet drug, is metabolized into its active form by cytochrome P450 enzyme encoded by the *CYP2C19* gene. Approximately 20% of Japanese individuals carry a loss-of-function polymorphism of this gene, resulting in reduced efficacy of CLP in preventing ischemic stroke. Although it is preferrable to select drugs based on *CYP2C19* polymorphisms for precision medicine, there is a hurdle for rapidly determine the polymorphism in clinical setting. The Flongle is a small and portable nanopore DNA sequencing apparatus capable of real-time analysis of DNA sequences, potentially applicable for genetic analysis in clinical settings such as Emergency Unit. Therefore, we aim to conduct a proof-of-conceptual study to establish a method for identifying *CYP2C19* polymorphisms as a point-of-care testing (POCT).

Methods: DNA samples of 48 stroke patients who consented to participate in the study were used. Target regions were amplified by PCR, and DNA sequencing was performed using flongle. Results were confirmed by Sanger sequencing. Whole-genome sequencing detection were also evaluated for the polymorphism. Additionally, a rapid analysis system using direct PCR from saliva samples was developed.

Results: High-accuracy detection of *CYP2C19* polymorphisms was achieved for all blood-derived DNA samples. Furthermore, polymorphism identification from saliva samples was possible within 3 hours using the rapid analysis system.

Conclusion: The method using Flongle may be useful in selecting antiplatelet drugs and can be cost-effectively applied to various pharmacogenetic analyses beyond CYP2C19 at the bedside. It is anticipated to be a widely available POCT tool for pharmacogenetic analysis in the future.

P18.016.C Metabolic profiling of different glycemic traits: a two-sample Mendelian randomization study

Jacky Mo[1], *Tommy Wong[1], Mingqi Zhou[2], Jie V. Zhao[1], Catherine Schooling[1], Annabel He[1], April Luo[1], Shiu Lun Au Yeung[1]*

[1]The University of Hong Kong; [2]University of California Irvine

Consortium: the Meta-Analyses of Glucose and Insulin-related traits Consortium

Background/Objectives: Clarifying the similarities and differences in the association with downstream metabolites (e.g., lipid subfractions and amino acids) of glycemic traits and liability to type 2 diabetes may help clarify the pathophysiology of these inter-related glycemic traits in various diseases.

Methods: We assessed the causal relation of four glycemic traits and type 2 diabetes liability with 167 metabolites using Mendelian randomization (MR) with various sensitivity analyses and a reverse Mendelian randomization analysis. We extracted instruments for fasting glucose, 2-hour glucose, fasting insulin, and glycated hemoglobin from the Meta-Analyses of Glucose and Insulin-related traits Consortium ($n = 200,622$), and those for type 2 diabetes liability from a meta-analysis of multiple cohorts (148,726 cases, 965,732 controls) in Europeans. Outcome data were from summary statistics of 167 metabolites from the UK Biobank ($n = 115,078$).

Results: Fasting glucose and 2-hour glucose were not associated with any metabolite. Higher glycated hemoglobin was associated with higher free cholesterol in small low-density lipoprotein. Type 2 diabetes liability and fasting insulin were inversely associated with apolipoprotein A1, total cholines, lipoprotein subfractions in high-density-lipoprotein and intermediate-density lipoproteins, and positively associated with aromatic amino acids.

Conclusion: These findings indicate hyperglycemia-independent patterns and highlight the role of insulin in type 2 diabetes development. Further studies should evaluate these glycemic traits in type 2 diabetes diagnosis and clinical management.

P18.017.D Improving the quality of pharmacogenetic testing and reporting: standardising nomenclature through External Quality Assessment (EQA)

Rebecca Goodall[1], *Michael Woodcock[1], Henry Thomas[1], Nicola Wolstenholme[1], Simon Patton[1]*

[1]EMQN CIC, Manchester, United Kingdom

Background/Objectives: Pharmacogenetic laboratory tests provide patients with individual therapeutic profiles, these can be preserved in their records, guiding current and future treatments. In this rapidly developing field, it is essential that results remain clear to clinicians, with stable, unambiguous nomenclature. The EMQN pharmacogenetics panel EQA scheme has been running for 4 years, providing a programme including expert review of genotyping and interpretation and evaluation of nomenclature. We present a summary of nomenclature identified through EQA.

Methods: Participant laboratories were sent mock patient pharmacological case scenarios alongside DNA samples (sourced from the Coriell Institute for Medical Research) and invited to test and submit pdf reports, including relevant clinical interpretation according to their routine practices. Reports were independently assessed by an EMQN group of peer reviewers against robust marking criteria. Following assessment and an appeals process, laboratories were informed of their performance.

Results: Participation has increased since 2019, with seventy five laboratories assessed in 2023. Improvement was observed in the use and consistency of pharmacogenetic nomenclature. By 2023, 96% (72/75) laboratories used star allele nomenclature for all or some of the genes in their panel, 92% (69/75) reported dbSNP RefSNP ID and 93% (70/75) reported variants using HGVS nomenclature. Errors included transcription errors and out-of-date nomenclature.

Conclusion: Laboratories are increasingly using standardised nomenclature systems for reporting. Continued participation in EQA can improve the quality of reporting using standardised

nomenclature to ensure that best practices are embedded in laboratory practice, enabling clear communication to patient, clinician and pharmacist.

P18.018.A Cost-Effectiveness of a Polygenic Risk Score Based Breast Cancer Screening Program in Estonia

*Filipa Sampaio[1], **Peeter Padrik**[2], Krista Kruuv-Käo[2], Katrin Koiduaru[3], Neeme Tonisson[4,5], Inna Feldman[1]*

[1]Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden; [2]OÜ Antegenes, Tartu, Estonia; [3]University of Tartu, Institute of Family Medicine and Public Health, Tartu, Estonia; [4]University of Tartu, Institute of Genomics, Tartu, Estonia; [5]Tartu University Hospital, Genetics and Personalized Medicine Clinic, Tartu, Estonia

Consortium: BRIGHT - Be RIGHT with breast cancer management

Background/Objectives: This study assessed the cost-effectiveness of risk-stratified breast cancer (BC) screening in Estonia for women starting at age 35 versus standard screening for ages 50-69, using the polygenic risk score (PRS) test's isolated impact.

Methods: A Markov model was used to estimate the costs and health outcomes of the current age-based screening compared with a PRS tailored approach, adapted to each woman's risk. The model estimated the cumulative costs and health outcomes of a cohort of 1000 women aged 35 as they moved between the states healthy/at risk, cancer stages 0, I, II, III, IV, and dead, over a lifetime horizon. Costs were estimated from a health-payer perspective, in 2022 €. Model parameters were sourced from national sources and literature. Costs and health outcomes were discounted at 5% annually. An incremental cost-effectiveness ratio (ICER) was calculated as the difference in costs divided by the difference in quality-adjusted life-years (QALY) between both strategies.

Results: Risk-stratified screening led to a redistribution of BC stages, with more early (0-I) and fewer advanced stages (II-IV) and averted 1.5 BC deaths per 1,000 women. Risk-stratified screening resulted in larger net costs of €145,235 (mainly related to PRS test and counselling costs), and a gain of 3.85 QALYs, with an ICER of €37,755 per QALY gained. The findings were sensitive to the uncertainty around risks estimates of developing BC and in variations in discount rate.

Conclusion: A PRS-tailored BC screening has clinical benefit and is potentially cost-effective in Estonia.

Grants: European Commission via EIT Health BRIGHT innovation activity (project #220720, #230121).

P18.020.C Multiple genetic control of anti-COVID-19 vaccine response by HLA locus

Martina Esposito[1], *Francesca Minnai[1], Massimiliano Copetti[2], Giuseppe Miscio[2], Rita Perna[2], Ada Piepoli[2], Gabriella De Vicentis[2], Mario Benvenuto[2], Paola D' Addetta[2], Susanna Croci[3], Margherita Baldassarri[3], Mirella Bruttini[3], Chiara Fallerini[3], Raffaella Brugnoni[4], Paola Cavalcante[4], Fulvio Baggi[4], Elena Maria Grazia Corsini[4], Emilio Ciusani[4], Francesca Andreetta[4], Tommaso A. Dragani[5], Maddalena Fratelli[6], Massimo Carella[2], Renato Mantegazza[4], Alessandra Renieri[3], Francesca Colombo[1]*

[1]National Research Council, Institute for Biomedical Technologies, Segrate, Italy; [2]Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy; [3]University of Siena, Medical Genetics, Siena, Italy; [4]Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy; [5]Aspidia S.r.l, Milano, Italy; [6]Istituto di ricerche farmacologiche "Mario Negri" IRCCS, Milano, Italy

Consortium: GEN-COVID

Background. Since the beginning of the anti-COVID-19 vaccination campaign, it has become evident that vaccinated subjects exhibit considerable inter-individual variability in the response to the vaccine that could be partly explained by host genetic factors. A recent study reported that the immune response elicited by the vaccine was influenced by a specific allele of the human leukocyte antigen gene *HLA-DQB1*.

Methods. We carried out a genome-wide association study to investigate the genetic determinants of the antibody response to the Pfizer-BioNTech vaccine in an Italian cohort of 1,351 subjects recruited in three centers. Linear regressions between normalized antibody levels and genotypes of >7 million variants were performed, using sex, age, centers, days between vaccination boost and serological test, and five principal components as covariates. We also analyzed the association between normalized antibody levels and 204 HLA alleles, with the same covariates as above. **Results**. Our study confirms the involvement of the HLA locus and shows significant associations with variants in *HLA-A*, *HLA-DQA1*, and *HLA-DQB1* genes. In particular, the HLA-A*03:01 allele is the most significantly associated with serum levels of anti-SARS-CoV-2 antibodies. Other alleles, from both major histocompatibility complex class I and II are significantly associated with antibody levels.

Conclusions. These results support the hypothesis that HLA genes modulate the response to Pfizer-BioNTech vaccine and highlight the need for genetic studies in diverse populations and for functional studies aimed to elucidate the relationship between HLA-A*03:01 and CD8+ cell response upon Pfizer-BioNTech vaccination.

Grants. 8 × 1000 Istituto Buddista Italiano Soka Gakkai (ID 2020-2016_RIC_3).

Tumori, Palliative care, Pain therapy and Rehabilitation Unit, Milan, Italy; [9]Università degli Studi di Milano, Department of Clinical Sciences and Community Health, Milan, Italy; [10]University of Bologna, Medical Oncology Unit, Department of Medical and Surgical Sciences, Bologna, Italy; [11]Oslo University Hospital, Department of Oncology, Oslo, Norway; [12]Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine, Faculty of Medicine and Health Sciences, Trondheim, Norway; [13]IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", SS Cure Palliative, Terapia del dolore e Medicina Integrativa, Meldola (FC), Italy; [14]Istituto di Ricerche Farmacologiche Mario Negri - IRCCS, Milan, Italy

Background/Objectives: Cancer pain causes an unbearable suffering and lowered quality of life, thus advanced cancer patients often require analgesic therapy. Opioids of step III of the WHO-defined analgesic ladder are the standard of care for the treatment of cancer pain. However, 20-30% of patients do not receive benefits from therapy or have a low response. Literature suggests that genetics plays a role in predisposing patients to a good or poor response to opioids and, herein, we investigated it by performing a genome-wide association study (GWAS).

Methods: We individually genotyped 2,060 European advanced cancer patients treated with morphine, buprenorphine, fentanyl, and oxycodone. We performed a whole-genome regression model (using REGENIE software) between genotypes and the opioid response phenotype, defined as a numerical score measuring pain intensity based on patients' responses to the Brief Pain Inventory Questionnaire.

Results: The GWAS identified five non-coding variants on chromosome 20 at *P*-value 5.0×10^{-8}. For all of them, the minor allele was associated with a lower pain intensity. These variants were intronic of *PCMTD2* gene and were 200 kbp downstream of *OPRL1*, the Opioid Related Nociceptine Receptor 1. Interestingly, four of them acted as expression quantitative trait loci, modulating the expression of *OPRL1*, according to eQTLGen database.

Conclusion: This is the largest GWAS performed in this field, so far. Our promising results strengthen the role of genetics in opioid response. Further functional analyses are needed to validate the results obtained and to understand the biological mechanism underlying the association observed.

Grants: Associazione Italiana per la Ricerca sul Cancro (MFAG-22970).

P18.023.B Causal Evidence of the Association between Alcohol Consumption and Cardiovascular Disease in East Asian

Keumji Jung[1], *Sun Ha Jee*[1]

[1]*Yonsei University, Department of Epidemiology and Health Promotion, Seoul, Korea, Rep. of South*

Background/Objectives: Light-moderate alcohol intake has been associated with lower cardiovascular disease, however the association varies across different subtypes. The aim of this study is to investigate the causal association between alcohol consumption and vascular disease in east Asian.

Methods: We conducted both a conventional observational study and genetic study among 125,727 participants. We performed a GWAS analysis, and selected SNPs (ALDH2, ADH1B) highly related to alcohol as instrumental variables. We used Cox proportional hazards models to estimate the relationship between vascular disease and both self-reported alcohol consumption, genetically determined alcohol amount. To confirm the results, we conducted the two sample mendelian randomization (2SMR) using Korean and Japan data.

Results: Among men, observational epidemiological study showed that self-reported alcohol amount had J-shaped associations with the incidence of stroke. In contrast, genetic epidemiological study shows genotype-predicted mean alcohol intake had a continuously positive association with stroke. For myocardial infarction (MI), both observational epidemiological studies and genetic epidemiological studies have shown an inverse association with alcohol intake. This same result was observed in a 2SMR using the BBJ and KCPS-II.

Conclusion: Our study provides causal evidence for the association between alcohol consumption and vascular disease in the Asian population using genetic epidemiology. These suggest that reducing alcohol consumption could be an effective preventive strategy for stroke. However, the effect of alcohol intake on MI needs further evaluation.

Grants: This research was supported by a grant of the KHIDI, funded by the Ministry of Health & Welfare, Republic of Korea (HI20C0517) and NRF funded by the Ministry of Education (RS-2023-00239122).

P18.024.C Challenges to improve the diversity in population genomics to enhance genomics discoveries

Ben Hollis[1], *Jen Harrow*[1], *Karyn Mégy*[1], *Ali Abassi*[1], *Amanda O'Neill*[1], *Shikta Das*[1], *Xiao Jiang*[1], *Katherine Smith*[1], *Stewart MacArthur*[1], *Sean O'Dell*[1], *Sebastian Wasilewski*[1], *Quanli Wang*[2], *Slavé Petrovski*[1]

[1]*AstraZeneca, Centre for Genomics Research, Discovery Sciences, BioPharmaceuticals R&D, Cambridge, United Kingdom; [2]AstraZeneca, Centre for Genomics Research, Discovery Sciences, BioPharmaceuticals R&D, Waltham, United States*

Early-stage incorporation of human genomic data into the assessment of drug targets has been shown to significantly increase drug pipeline success rates. Genome-wide association studies have uncovered thousands of common variants associated with human disease, but the contribution of highly penetrant rare variants that demonstrate strong association with clinically meaningful outcomes in common diseases remains relatively unexplored. The UK Biobank (UKB) study comprises of phenotypic data linked to medical records for approximately 500,000 participants, that in conjunction with whole genome sequences, is offering an unprecedented opportunity to evaluate the effect of rare genetic variants on a broad collection of traits. However, historically the percentage of ancestry population on large-scale genomics studies was overwhelmingly European (78%), so more effort is needed to ensure the data reflects the diversity within the human population. To answer this need, AstraZeneca's Centre for Genomics Research (CGR) is establishing one of the world's most comprehensive and diverse genetic resource and makes gene-phenotype associations publicly available through the AZ PheWAS Portal (https://azphewas.com/). We are also addressing the challenge of harmonising health information coming for a range of geographies and healthcare systems, so cohorts and controls can be built across all biobanks. We demonstrate a range of clinical data harmonisation approaches developed by CGR and applied to diverse population genetic data and highlight the pharmacogenomic important gene CYP2D6, which has high allelic variation between populations and affects the way some drugs are metabolized.

P18.025.D Real-world impact of exome sequencing: a single center's experience

Georgia Christopoulou[1], Stavroula Samara[1], Aikaterini Oikonomaki[1], Katerina Roumelioti[1], Eleni Katsoni[1], Olga Dimou[1], Andromachi Vagena[1], Stavros Bournazos[1], **Pantelis Constantoulakis**[1]

[1]*Genotypos M.S.A., Genetics and Genomics, Athens, Greece*

Background/Objectives: Exome sequencing (ES) has become a valuable tool in the genetic diagnostic setting. We aim to present the landscape of ES based on our laboratory's 5-year experience with real-world referrals and to highlight the diagnostic yield and challenges faced in our actual day-to-day practice.

Methods: During 2017-2023, 4.288 patients were referred to our center. ES was applied on DNA extracted from peripheral blood or buccal swabs: library preparation was performed with Clinical Exome (Sophia Genetics) or Whole Exome (Twist Bioscience) panels and sequenced on Illumina NextSeq-550/550 (Illumina). Bioinformatics analyses were conducted by SOPHiA DDM® bioinformatics pipelines.

Results: 1.811/4.288 (42.23%) of data sets required variant interpretation while the remaining were NGS services. Of the 1.811 cases, 802 (44,28%) were pre-conceptual carrier screenings of different levels and 1.009 (55.72%) were patients with suspected genetic conditions. In the latter, 307 patients had causative mutations (30,42% overall diagnostic yield). The majority were SNV/Indels, while 41 clinically significant CNVs (13,35%) were detected; 37 were directly related to the phenotype, and 4 were incidental findings. 234/307 (76,22%) were patients who received a definite genetic diagnosis and the rest were hematology patients with actionable genomic profiles. Of the rare disease diagnoses, the most prevalent were nephrology (51), neuromuscular (27), ophthalmology (26), and cardiology (25) cases. Diagnostic yield was substantially higher in subgroups where clinical description, medical and family history were detailed.

Conclusion: Real-world private sector ES has a key role in genomic diagnosis. Detailed patient information is essential to further increase the diagnostic yield and decipher more cases.

P18.026.A Pleiotropic genetic architecture and causal estimates of eosinophils and atopic dermatitis

Charalabos Antonatos[1], *Alexandros Pontikas[1], Adam Akritidis[1], Katerina Grafanaki[2,3], Sophia Georgiou[2], Aikaterini Zacharopoulou[4], Ileana Afroditi Kleidona[4], Stamatis Gregoriou[4], Yiannis Vasilopoulos[1]*

[1]*University of Patras, Biology, Rion, Greece;* [2]*Medical School, Dermatology-Venereology, Rion, Greece;* [3]*Medical School, Biochemistry, Rion, Greece;* [4]*Medical School, Dermatology-Venereology, Athens, Greece*

Background/Objectives: Here, we calculated the causal estimates between blood cell traits (BCTs) and atopic dermatitis (AD), a chronic inflammatory skin disease, and characterized the pleiotropic genetic architecture of AD to unveil novel risk loci.

Methods: We leveraged genome-wide association studies on AD and BCTs in European participants. We employed single-variable, two-sample mendelian randomization and linkage disequilibrium score regression to compute causal estimates and genetic correlations between BCTs and eczema. We next performed pleiotropy analysis under the composite null hypothesis (PLACO) excluding major histocompatibility complex (MHC) and a series of in silico analyses, including gene-based analyses and colocalization to investigate novel risk loci mediating AD risk in BCTs.

Results: Eosinophil count (EC) and eosinophil percentage (EP) were associated with increased AD risk, while lymphocyte percentage (LP) was inversely associated per 1-standard deviation. However, only EC and EP showed significant genome-wide correlations. Prioritizing EC for PLACO analysis based on the larger number of shared non-MHC variants ($n = 8547984$), we identified 132 independent risk loci and 275 genes enriched in leukocyte proliferation and interleukin signaling. Twenty-four pleiotropic loci (18%) shared causal variants between AD and EC, where 12 mapped genes have not been previously identified including *CCR7* and *SH2B3*.

Conclusion: By triangulating genomic evidence, our preliminary data provide significant insights in the causal role of increasing eosinophils in the AD risk. We prioritize 24 loci (12 novel), which may serve as potential therapeutic targets and facilitate drug repurposing.

Grants: This investigation was supported by a research grant from the National Eczema Association NEA23-CRG186.

Background/Objectives: Despite several genetic markers for asthma exacerbations have been identified in the past years, the role of epigenetics remains uncovered. Our objective was to evaluate whether DNA methylation (DNAm) is associated with asthma exacerbations.

Methods: The DNAm profile of 406 blood samples from Spanish individuals was determined with the Infinium MethylationEPIC microarray (Illumina). The association of DNAm with asthma exacerbations was tested adjusting for age, sex, batch effect, genetic ancestry, and tissue heterogeneity at different levels: differentially methylated positions, regions, and epigenetic modules determined with weighted gene co-expression network analysis. Suggestive CpGs identified using a false discovery rate (FDR)<0.1 were validated in blood samples from 222 European individuals and nasal epithelia from 111 Spanish individuals. Finally, cis-methylation quantitative trait loci (meQTLs) analysis and enrichment analyses for CpGs with $p < 1 \times 10^{-4}$ in signals

identified in previous studies focused on other phenotypes were performed.

Results: We found 4 CpGs (FDR < 0.1), 4 differentially methylated regions, and one module related to environmental exposures to toxic compounds were significantly associated with asthma exacerbations (FDR < 0.05). Additionally, 3 CpGs (cg25345365, cg06710464, and cg15508223) were validated in Europeans and reached the genomic significance threshold ($p < 9 \times 10^{-8}$). Furthermore, the CpG cg25345365 was cross-tissue validated in nasal epithelial ($p = 0.001$) and was regulated by 6 independent genetic variants (FDR < 0.05). Finally, enrichment analyses revealed an overrepresentation of prior associations with immune-mediated diseases, mortality, and prenatal and environmental exposures.

Conclusion: We identified differentially methylated positions, regions, and epigenetic modules associated with asthma exacerbations in European populations.

Grant: PID2020-116274RB-I00 funded by MCIN/AEI/10.13039/501100011033 and CIBERES/ISCIII/ERDF (CB06/06/1088).

P18.028.C Identification of proteins for stroke progression using Mendelian Randomization

Andrew Elmore[1], *Nimish Adhikari*[2], *Gina Marie Peloso*[2], *Lavinia Paternoster*[1], *Daniel Posner*[3], *Juan P Casas*[3], *April Hartley*[1], *Kelly Cho*[3], *Gibran Hemani*[1], *Kate Tilling*[1], *George Davey Smith*[1], *Tom Gaunt*[1]

[1]*University of Bristol, Medicine, United Kingdom;* [2]*Boston University, Boston, United States;* [3]*Harvard Medical School, Boston, United States*

Background/Objectives: Individuals who have experienced a stroke, or transient ischemic attack, face a heightened risk of future cardiovascular events. Identification of genetic and molecular risk factors for subsequent cardiovascular outcomes may identify effective therapeutic targets to improve prognosis after an incident stroke.

Methods: We performed genome-wide association studies (GWAS) for subsequent major adverse cardiovascular events (MACE) ($N_{cases} = 51{,}929$, $N_{cntrl} = 39{,}980$) and subsequent arterial ischemic stroke (AIS) $N_{cases} = 45{,}120$, $N_{cntrl} = 46{,}789$) after first incident stroke within the Million Veteran Program and UK Biobank. We then used genetic variants associated with proteins (pQTLs) to determine the effect of 1,463 plasma protein abundances on subsequent MACE using Mendelian randomization (MR).

Results: Two variants were significantly associated with subsequent cardiovascular events: rs76472767 (OR = 0.75, 95% CI = 0.64-0.85, $p = 3.69 \times 10^{-08}$) with subsequent AIS and rs13294166 (OR = 1.52, 95% CI = 1.37-1.67, $p = 3.77 \times 10^{-08}$) with subsequent MACE. Using MR, we identified 2 proteins with an effect on subsequent MACE after a stroke: *CCL27* (effect OR = 0.77, 95% CI = 0.66-0.88, adj. p = 0.05), and *TNFRSF14* (effect OR = 1.42, 95% CI = 1.24-1.60, adj. p = 0.006). These proteins are not associated with incident AIS and are implicated to have a role in inflammation.

Conclusion: We found evidence that two proteins with little effect on incident stroke appear to influence subsequent MACE after incident AIS. These associations suggest that inflammation is a contributing factor to subsequent MACE outcomes after incident AIS and highlights potential novel targets.

Consortium: FinnGen, Genes & Health Research Team, Genomics England Research Consortium, INTERVENE consortium

Background/Objectives: Understanding disease progression is of a high biological and clinical interest. Unlike disease susceptibility whose genetic basis has been abundantly studied, less is known about the genetics of disease progression and its overlap with disease susceptibility.

Methods: Considering ten common diseases (N cases ranging from 17,152 to 99,666) across seven biobanks, we systematically compared the genetic architecture of susceptibility and progression, defined as disease-specific mortality.

Results: We identified only one locus significantly associated with disease-specific mortality and show that, at a similar sample size, more genome-wide significant loci can be identified in a GWAS of disease susceptibility. Variants that were significantly affecting disease susceptibility were weakly or not associated with disease-specific mortality. Moreover, susceptibility polygenic scores (PGSs) were weak predictor of disease-specific mortality while a PGS for general lifespan was significantly associated with disease-specific mortality for five out of ten diseases. We used theoretical derivation and simulation to propose plausible explanations for our empirical observations and account for potential index-event bias.

Conclusion: Overall, our findings point to little similarity in genetic effects between disease susceptibility and disease-specific mortality and suggest that either larger sample sizes or different measures of progression are needed to identify the genetic underpinning of disease progression.

Grants: This study has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 101016775, from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation program (grant number 945733) and from Academy of Finland fellowship grant N. 323116.

P18.030.A Amplification and buffering of disease risk alleles by metabolic reaction fluxes

Carles Foguet Coll[1;2], *Xilin Jiang*[1;2;3], *Scott C. Ritchie*[1;2;4], *Samuel Lambert*[1;2], *Yu Xu*[1;2], *Emanuele Di Angelantonio*[1;2;5], *John Danesh*[1;2], *Adam Butterworth*[1;2], *Michael Inouye*[1;2;4]

Chan School of Public Health, Boston, United States;* [4]*Cambridge Baker Systems Genomics Initiative, Baker Heart and Diabetes Institute, Melbourne, Australia;* [5]*Human Technopole, Fondazione Human Technopole, Milan, Italy*

Background/Objectives: Our previous research demonstrated that the stochiometric determinants of metabolic networks can be used to simulate the metabolic effects of genetically driven variations in transcript levels and predict personalized organ-specific reaction flux values. Here we use genetically-predicted reaction fluxes to perform a systematic search for instances where fluxes can function as buffers or amplifiers of coronary artery disease (CAD) susceptibility in individuals carrying known risk alleles.

Methods: Genetically personalized organ-specific reaction fluxes were simulated for 459,902 genotyped UK Biobank participants of European ancestry. Within this cohort, we evaluated the capacity of 9,984 reaction fluxes to buffer or amplify the effect of 5,852 known CAD risk variants on disease susceptibility. We measured buffering/amplification between a reaction and a variant as the interaction between reaction flux value and risk allele dosage in CAD risk. The significance of this interaction was evaluated using COX proportional hazards models for CAD events.

Results: Our analysis identified hundreds of instances where reaction fluxes can amplify or buffer the effect of genetic variants on CAD susceptibility. Notably, a majority of these variants are in well-established CAD loci, such as LPA and LDLR. Furthermore, many of the implicated reactions are linked to processes with putative roles in the disease such as inflammation, hypertension, or lipid metabolism.

Conclusion: This work establishes proof of concept that biochemical reaction fluxes can alter the penetrance of disease risk alleles. This analysis can be extended to other diseases and contribute to improving our understanding of variant-to-function (V2F) and disease biology.

P18.031.B Pharmacogenetics for cardiovascular drugs: Lost in translation

Benoît Delabays[1], *Katerina Trajanoska*[1], *Joshua Walonoski*[2], *Vincent Mooser*[1]

[1]*McGill Genome Centre, Human Genetics, Montréal, Canada;* [2]*Medeloop Inc., Canada*

Consortium: N/A

Background/Objectives: Pharmacogenetics (PGx) aims at optimizing drug efficacy and safety. Cardiovascular (CV) drugs are among the most prescribed drugs. We wondered how many findings from genome-wide association studies (GWAS) of marketed CV drug response have already translated into PGx prescribing recommendations.

Methods: We identified marketed CV drugs from the PharmGKB database. For each of them, we retrieved and curated GWAS from the GWAS Catalog and extracted PGx information from their labels approved by European, Japanese and American regulatory agencies and related recommendations from expert PGx panels (CPIC and DPWG).

Results: Out of 221 marketed CV drugs we identified, 27 had been studied in 101 GWAS, and 40 had PGx recommendations from ≥1 regulatory agencies or expert panels. Genome-wide significant associations were reported for 48 PGx traits, mapping to 306 genes. Six of these genes were endorsed in PGx recommendations for 4 drugs (clopidogrel, rosuvastatin, simvastatin, and warfarin). For the remaining 36 drugs, PGx information was based on candidate-gene analyses or other studies. Overall, the level of recommendations varies substantially between agencies and expert panels, except for clopidogrel.

Conclusion: Only a small fraction of GWAS findings on marketed CV drug response have been translated yet into PGx recommendations. Consistent evidence supporting PGx testing is limited to very few CV drugs. Substantial additional work is warranted to identify and validate PGx variants for more marketed CV drugs and to evaluate their clinical utility. Preemptive PGx offers unprecedented opportunities to achieve these goals.

Consortium: The All of Us Research Program Genomics Investigators

Background/Objectives: The *All of Us* (AoU) Research Program is creating one of the world's largest, most diverse datasets by combining multiple data types from one million diverse participants from across the United States. Here we describe the program's most recent genomics data release which includes >245k whole genome sequences (>11k with structural variant calls), >315k arrays, >1k long read sequences, as well as auxiliary data and variant annotations.

Methods: Biospecimens are collected from program participants and undergo a process of DNA extraction for sequencing and genotyping. Four genome centers used identical library construction protocols, arrays, sequencers, software, and software configuration. The AoU Data and Research Center (DRC) performed additional QC and joint calling. To lower the compute cost and the barrier of entry to use genomic data, the DRC also provided data for common downstream use cases, including predicted continental ancestries, variant annotations, relatedness, and additional conversions into other variant formats (eg, plinkbed, bgen, Hail).

Results: *All of Us* identified >1 billion genetic variants, including >275 million previously unreported genetic variants, >3.9 million in coding regions. Principal component analysis identified almost half of participants from non-European ancestries. Summary level data are publicly available (https://databrowser.researchallofus.org/), and individual-level data can be accessed by researchers through the *All of Us* Researcher Workbench, a secure, cloud-based platform..

Conclusion: The *All of Us* Research Program allows researchers world-wide to access an expansive dataset containing longitudinal health data combined with genomic data, enabling novel health research and medical breakthroughs.

P18.033.D Beyond the genome: a reference map of biological influences on the human plasma proteome

Julia Carrasco-Zanini[1;2;3], *Eleanor Wheeler*[1], *Burulça Uluvar*[3], *Nicola Kerrison*[1], *Mine Koprulu*[1], *Nicholas J. Wareham*[1], *Maik Pietzner*[1;2;3], *Claudia Langenberg*[1;2;3]

[1]*MRC Epidemiology Unit, University of Cambridge, Cambridge, United Kingdom;* [2]*Precision Healthcare University Research Institute, Queen Mary University of London, London, United Kingdom;* [3]*Computational Medicine, Berlin Institute of Health at Charité-Universitätsmedizin, Berlin, Germany*

Background/Objectives: Broad-capture proteomic platforms now enable assessment of thousands of plasma proteins, many of which are not actively secreted, and their origins are largely unknown. Identification of their major determinants, beyond genetic variation, can provide clues to their origins and strong links to diverse diseases.

Methods: We integrated genomic with deep phenomic information to identify modifiable and non-modifiable determinants of 4,775 plasma proteins in healthy individuals (N = 8350). We create the first map of the human plasma proteome based on shared determinants of protein variance and demonstrate clear segregation into clusters of genetic and non-genetic influences.

Results: For over a third (N = 1575) of protein targets, biological influences explained 10-77% of the variation (median = 19.88%, IQR: 14.01 – 31.09%), independent of the relatively strong influence of technical factors (median = 2.48%, IQR: 0.78 – 6.41%). While non-modifiable factors (genetic variation, age, sex) best explained most protein targets (N = 3242); modifiable factors best explained a considerable number (N = 1737). The proteome map, together with genetic and disease follow-up analyses, highlights 1) biological influences that shape the plasma proteome including important drug targets, 2) causal, modifiable determinants of proteins, 3) potential drivers underlying hundreds of protein-disease associations, and 4) molecular mediators linking modifiable risk factors to diseases.

Conclusion: We provide the first human reference map that identifies and contextualizes major biological and technical influences on the plasma proteome and helps to translate findings from proteomic studies for a large range of diverse diseases.

Grants: Medical Research Council, Cancer Research UK and Wellcome Trust.

P18.034.A Exploring the causal effects of circulating galectin-3 and ST2 on 11 sleep-related traits and 8 cardiometabolic traits: A Bidirectional Mendelian Randomization Study

Chun Hei Wu[1], *Man Yung Cheung*[1;2;3]

[1]*The University of Hong Kong, Department of Medicine, Hong Kong, China;* [2]*State Key Laboratory of Pharmaceutical Biotechnology, The University of Hong Kong, Hong Kong, China;* [3]*Institute of Cardiovascular Science and Medicine, The University of Hong Kong, Hong Kong, China*

Background/Objectives: Both Galectin-3 (gal-3) and ST2 proteins are cardiovascular proteins associated with inflammation and immune responses. Observational studies have reported associations between gal-3 or ST2 protein and sleep-related traits as well as cardiometabolic traits. Our study aims to evaluate the causal links between gal-3 or ST2 protein and these traits.

Methods: We conducted a comprehensive two-sample bidirectional Mendelian randomization analysis, utilizing genome-wide association study summary statistics from UK Biobank and other large consortia to investigate the causal links between them.

Results: Genetically predicted gal-3 was causally associated with short sleep duration (Odd Ratio (OR): 1.007, [95% CI, 1.002-1.011]), frequent insomnia symptoms (OR: 1.017, [95% CI, 1.011-1.024]), sleep duration (OR: 0.988, [95% CI, 0.978-0.998]), napping (OR: 0.993, [95% CI, 0.988-0.999]), and body mass index (BMI) (beta: 0.015, [95% CI, 0.007-0.023]). In the reverse analysis, triglyceride levels (beta: 0.104, [95% CI, 0.043-0.165]), fasting

insulin levels (beta: -0.447, [95% CI, -0.791–-0.101]), HbA1c levels (beta: 0.235, [95% CI, 0.054-0.417]), and waist-hip ratio adjusted for BMI (beta: -0.075, [95% CI, -0.14–-0.008]) were associated with genetically predicted gal-3. Furthermore, genetically predicted ST2 was found to be causally associated with sleep duration (OR: 1.009, [95% CI, 1.000-1.019]) and BMI (beta: 0.009, [95% CI, 0.001-0.017]). In the reverse analysis, triglyceride levels (beta: 0.065, [95% CI, 0.009-0.120]) and sleep duration (beta = 0.196, [95% CI, 0.017-0.375]) were associated with genetically predicted ST2.

Conclusion: Overall, our study provides evidence supporting the causal associations between genetically predicted gal-3 or ST2 and sleep-related traits and cardiometabolic traits.

Consortium: FinnGen

Background/Objectives: Human plasma lipidome captures risk for cardiovascular diseases and beyond. Genome-wide association studies of individual lipid species have identified many lipid-associated loci, however, the influence of associated genetic variants on disease risk remains poorly understood.

Methods: Regional heritability for 179 lipid species from the GeneRISK cohort was estimated with FINEMAP. For lead variants and top variants from FINEMAP in high heritability regions, association analyses of 8 disease endpoints were performed in FinnGen (N = 500,348), UK Biobank White British subset (N = 408,959), and Generation Scotland (N = 20,032). We performed univariable Mendelian randomization (MR) analysis of lipid species and the disease endpoints. Statistically significant results were explored further using multivariable MR (MVMR).

Results: We identified 11 loci (*ABCG8*, *AL161670.1*, *APOE*, *CERS4*, *FADS2*, *GLTPD2*, *LINC01722*, *LIPC*, *NTAN1*, *TMC4*, *ZPR1*) with regional heritability values > 2%. Variants in these high-impact loci are associated (P < 6.25e-9) with Alzheimer's disease, Cholelithiasis, Type 2 diabetes, Ischemic heart disease (IHD), Statin medication, Pure hypercholesterolemia, and Age-related macular degeneration (AMD). Univariable MR analysis linked 20, 45, and 49 lipid species to AMD, IHD, and Cholelithiasis, respectively. The genetic instruments contributing to the significant effect of Phosphatidylethanolamines (PE) on AMD are located within the *LIPC* locus. For IHD, MVMR analysis supports a causal role of ApoB.

Conclusion: We identified 11 loci with high regional heritability. Lipid species-associated variants within these loci revealed significant associations with disease endpoints. Variants within *LIPC* influence PE levels and AMD risk. MVMR supports a causal role of ApoB on IHD.

P18.036.C Impact of *CYP2C19* variants on clinical efficacy of doubled maintenance dose of clopidogrel in coronary artery disease Syrian patients undergoing percutaneous coronary intervention

Nour Haj Saleh[1], *Lama Youssef*[1]

[1]*Faculty of Pharmacy, Damascus University, Department of Pharmaceutics & Pharmaceutical Technology, Damascus, Syria, Arab Rep*

Background/Objectives: Variability in the response to clopidogrel antiplatelet therapy is influenced by pharmacogenomics, particularly the cytochrome P450 (CYP) enzyme encoded by the *CYP2C19* gene. This study aimed to determine the frequencies of clinically relevant *CYP2C19* alleles and assess their impact on the clinical efficacy of a double maintenance dose of clopidogrel in Syrian patients undergoing percutaneous coronary intervention (PCI).

Methods: This prospective cohort study enrolled 50 Syrian patients with coronary artery disease (CAD) who underwent PCI and received a double maintenance dose of clopidogrel. *CYP2C19* polymorphisms were assessed using polymerase chain reaction (PCR) followed by amplicon Sanger sequencing. Patients were followed up after 18-24 months to evaluate their clinical response to clopidogrel.

Results: Allelic frequencies of *CYP2C19*2*, *CYP2C19*3*, and *CYP2C19*17* were 8%, 0%, and 17%, respectively. The distribution of our study participants by CYP2C19 predicted phenotype was as follows: 56% were normal metabolizers (NMs), 26% were intermediate metabolizers (IMs), 12% were rapid metabolizers (RMs), and 2% were ultra-rapid metabolizers (UMs). Our study did not find a correlation between the *CYP2C19*2* allele and recurrence of cardiac ischemic events in patients receiving a double maintenance dose of clopidogrel. Similarly, no correlation was observed between the *CYP2C19*17* allele and bleeding event rate in our study population.

Conclusion: Our findings demonstrate that a doubled maintenance dose of clopidogrel (150 mg/day) could mitigate the variability in clopidogrel antiplatelet efficacy between *CYP2C19*2* carriers and non-carriers in Syrian patients undergoing PCI.

P18.037.D To screen or not to screen: evaluating the costs and benefits of genomic risk pre-screening in public health

Katie Saxby[1], *Christopher Nelson*[1;2], *Alex Sutton*[3], *Nicola Cooper*[3]

[1]*University of Leicester, Department of Cardiovascular Sciences, United Kingdom;* [2]*University of Leicester, NIHR Biomedical Research Centre, Leicester, United Kingdom;* [3]*University of Leicester, Department of Population Health Sciences*

Background/Objectives: There are high hopes for the use of polygenic risk scores (PRS) in population healthcare. One such hope is to utilise PRS to identify people at elevated risk of disease to focus prevention strategies. For diseases that do not have a screening programme in place, the patient level benefits are clear. But what is the impact when screening is already offered at the

population level and incorporating genomic risk leads to a reduction in the number screened?

Methods: Using a PRS for abdominal aortic aneurysm disease, the cost-effectiveness of the current UK screening program has been compared with an intervention where genetic pre-screening determines which patients are invited to the screening programme.

Results: Pre-screening offers an economically cheaper alternative to population wide screening in a scenario where genomic risk information is freely available. However, on average, this results in a reduction in benefits to patients with aneurysms due to worse outcomes from missed cases.

Conclusion: Pre-screening will result in a loss of benefits to AAA patients unless genetic prediction is 100% accurate. Better disease prediction, especially identifying patients with poor outcomes, can limit the loss of these benefits and maximise the cost-effectiveness of the programme. Money saved from screening fewer patients could provide opportunity cost to improve overall patient benefits in the health service by freeing up financial resource to fund other services or interventions that offer better value for money.

Grants: This research was funded by the Wellcome Trust 222959/Z/21/Z.

Conflict of Interest: None declared

P18.038.A Exploring the causal link between type 2 diabetes and Alzheimer's disease: a systematic review and meta-analysis of mendelian randomization studies

Si Han[1], *Tom Lelieveldt*[2], *Fariba Ahmadizar*[1], *Miriam Sturkenboom*[1], *Geert Jan Biessels*[3]

[1]*UMC Utrecht, Department of Data Science and Biostatistics, Utrecht, Netherlands;* [2]*University College Utrecht, Department of Biomedical Science, Utrecht, Netherlands;* [3]*UMC Utrecht, Department of Neurology, Utrecht, Netherlands*

Background/Objectives: The causal relationship between type 2 diabetes (T2D) and Alzheimer's disease (AD) remains controversial. In this study, we assessed evidence from mendelian randomization (MR) studies to provide a less biased estimate of any association between T2D and AD through a meta-analysis.

Methods: We searched PubMed, Web of Science and EMBASE databases from inception until Oct 2023. We included two sample MR studies investigating the association between T2D and AD. Our study only included MR studies with unique exposure/outcome cohorts to reduce the bias of duplicate cohorts. The combined odds ratio (OR) with a 95% confidence interval (CI) of AD risk was calculated using a random-effects model. Heterogeneity was evaluated using I^2 statistic. Two investigators independently extracted the data and appraised the risk of bias by using the Newcastle–Ottawa Scale (NOS).

Results: Among 274 identified publications, 7 two sample MR studies with unique exposure/outcome cohorts were included in our meta-analysis. All of the included population were of European ancestry. The pooled risk estimate revealed that genetic predisposition to T2D is significantly associated with an increased risk of AD (OR: 1.08; 95% CI:1.01 to 1.16; I^2:68%; $p < 0.01$).

Conclusion: Our study reveals a statistically significant association between a genetic predisposition to T2D and an elevated risk of AD. While our findings highlight a notable statistical relationship, further research and consideration of potential confounding factors are essential to fully understand the complex interplay between genetic factors associated with T2D and the risk of developing AD.

Grants: Si Han is granted by the China Scholarship Council.

P18.039.B Causal relationship between serum uric acid and eGFR and chronic kidney disease: Mendelian randomization using polygenic risk scores

Kai-Yi Chen[1], *Yung-Feng Lin*[2], *Chien-Hsiun Chen*[3], *Hui-Ying Weng*[2;4], *Shih-Feng Tsai*[2;4;5], *Ming-Wei Lin*[1;4]

[1]*National Yang Ming Chiao Tung University, Institute of Public Health, Taipei, Taiwan;* [2]*National Health Research Institutes, Institute of Molecular and Genomic Medicine, Miaoli, Taiwan;* [3]*Academia Sinica, Institute of Biomedical Sciences, Taipei, Taiwan;* [4]*National Yang Ming Chiao Tung University, Biomedical Industry PhD Program, Taipei, Taiwan;* [5]*National Yang Ming Chiao Tung University, Department of Life Sciences and Institute of Genome Sciences, Taipei, Taiwan*

Background: Chronic kidney disease (CKD) is ranked as the 9th cause of mortality in Taiwan. Previous studies reported that uric acid (UA) is a potential risk factor of CKD, but the causal relationship between UA and renal function remains inconsistent. The study used polygenic risk score of uric acid as instrumental variable (IV) in Mendelian randomization analysis, to explore the causal relationship between UA and estimated glomerular filtration rate (eGFR) and CKD.

Methods: A total of 102,536 Han Chinese subjects with the genome-wide genotypes of the TWB2.0 chip were obtained from the Taiwan Biobank. After quality control, a genome-wide association study (GWAS) of uric acid with 87,654 participants and 445,874 genetic variants was performed. The weighted PRS, C + T, LDpred, PRS-CS, and DBSLMM methods were used to calculate the polygenic risk scores. Mendelian randomization using the two-stage least squares method was conducted with polygenic risk score of UA as IV, and eGFR and CKD as the outcome variables.

Results: After adjusting for age and sex, a polygenic risk score consisting of 114,073 genetic variants from the GWAS results of the Taiwan Biobank was used as an IV in MR analysis. Significant causal relationship between UA and eGFR (β = -2.54, 95% C.I.=-2.64 to -2.44) as well as UA and CKD (OR=2.47, 95% C.I.=2.26 to 2.71) was found.

Conclusion: Our results confirmed the causal relationships between uric acid and eGFR as well as CKD.

P18.040.C Genomic analyses of bullying victimisation in children and adolescents

Tracy Odigie[1], *Leonard Frach*[1], *Andrea Allegrini*[1], *Wikus Barkhuizen*[1], *Laura Hegemann*[2;3], *Laurie J. Hannigan*[2;4;5], *Alexandra Havdahl*[2;3;5], *Jean-Baptiste Pingault*[1;6]

[1]*University College London, Department of Clinical, Educational and Health Psychology, Division of Psychology and Language Sciences, London, United Kingdom;* [2]*Nic Waals Institute, Lovisenberg Diaconal Hospital, Oslo, Norway;* [3]*University of Oslo, Department of Psychology, Oslo, Norway;* [4]*University of Bristol, Medical Research Council Integrative Epidemiology Unit, Bristol, United Kingdom;* [5]*Norwegian Institute of Public Health, Center for Genetic Epidemiology and Mental Health, Oslo, Norway;* [6]*King's College London, Social,*

Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom

Background/Objectives: Bullying victimisation is a phenomenon experienced by over 65% of children and adolescents globally. Quantitative methodical approaches have been used to identify profiles of bullying behaviours. However, these approaches require summary data from genome-wide association studies (GWAS's), which is currently unavailable for bullying victimisation. This paper aims to conduct a GWAS of bullying victimisation and perform downstream genetic analyses.

Methods: We use genotyped data from the Norwegian Mother, Father and Child Cohort Study (MoBa) (~N = 43,000). Bullying victimisation is measured at ages 5, 8 and 14. The GWAS summary statistics of bullying victimisation is used to explore genetic correlations across 21 psychiatric conditions and associated traits. Polygenic scores of the traits are generated and used to predict bullying victimisation. Mendelian randomisation analyses will check for causality.

Results: Significant genetic correlations (ranging from 0.21-0.70) were identified between 15 traits and the exposure to childhood bullying victimisation. For adolescence bullying, high significant genetic correlations were identified in 6 traits (ranging from 0.40 to 1.28). Genetic correlation and polygenic score analyses show consistent significant results between bullying victimisation and traits. Small causal effects on psychiatric and associated traits in children and adolescents are identified.

Conclusion: In line with evidence of pervasive pleiotropy between psychiatric and associated traits, bullying victimisation and mental health related phenotypes are genetically correlated. This study will contribute to our understanding of the implications pre-existing heritable mental health vulnerabilities have on exposure to bullying victimisation.

Grants: T.O. is supported by ESRC ES/P000347/1. Research is funded by grant MQ16IP16 from MQ: Transforming Mental Health (J-B.P.).

P18.041.D Revising clinical pharmacogenomics: panel-based targeted haplotyping using Oxford Nanopore Technologies long-read sequencing

Koen Deserranno[1], *Laurentijn Tilleman*[1], *Kaat Rubben*[1], *Dieter Deforce*[1], *Filip Van Nieuwerburgh*[1]

[1]*Ghent University, Department of Pharmaceutics - Lab of Pharmaceutical Biotechnology, Gent, Belgium*

Background/Objectives: Current pharmacogenomics (PGx) testing strategies are mainly based on microarray, polymerase chain reaction (PCR), or short-read sequencing. Despite their value in identifying single nucleotide variants (SNVs) and insertion/deletions (INDELs), these assays do not permit to identify large structural variants nor allow unambiguous haplotype phasing for star-allele assignment. To address these issues, we assessed the performance of long-read sequencing in PGx while enriching for a panel of 1,036 genes from the Pharmacogenomics Knowledge Base (PharmGKB).

Methods: Germline DNA of five Genome in a Bottle (GIAB) reference samples was used for Oxford Nanopore Technologies PCR-free library preparation on R10.4.1 PromethION flow cells. Target enrichment was performed real-time during sequencing using adaptive sampling. To increase cost-effectiveness, three samples were multiplexed on one flow cell, decreasing the cost to € 320 per patient.

Results: By evaluating concordance with existing truth sets, we demonstrate accurate variant and star-allele calling for five GIAB samples. We show that three samples can be multiplexed on one flow cell, resulting in 99.35% and 99.84% recall and precision for the targeted variants. We illustrate that the long reads allow for better haplotype discrimination and improved star-allele calling, demonstrated by the enhanced calls for *CYP1A2*, *CYP2B6*, *CYP2C9*, *CYP2E1*, *CYP3A4*, *DPYD*, *GSTP1*, *SLCO1B1* and *UGT1A1*.

Conclusion: Targeted nanopore sequencing delivers superior PGx information for variant calling and haplotype phasing, with the potential for better dosing regimens. PGx based on targeted long-read sequencing is a valuable tool to advance the implementation of personalized medicine.

P18.042.A Two drifted variants account for over 90% of pathogenic BRCA alleles in Orkney and Shetland genomes

James F. Wilson[1;2], *Shona Kerr*[2], *Lucija Klaric*[2], *Marisa Muckian*[1;3], *Emma Cowan*[4], *Lesley Snadden*[4], *Gannie Tzoneva*[5], *Alan R Shuldiner*[5], *Zosia Miedzybrodzka*[4;6]

Background/Objectives: For breast and ovarian cancer risk assessment in the populations of Orkney and Shetland (the Northern Isles of Scotland) and their diasporas, it is important to quantify genetically drifted *BRCA1* and *BRCA2* pathogenic variants. Two actionable variants in these genes are observed recurrently at much higher frequencies than in cosmopolitan UK populations.

Methods: Here, we report a pathogenic *BRCA2* splice variant, c.517-2A>G, observed in four Shetland families to segregate with breast and ovarian cancer. We investigated the frequency and origin of this variant in exome sequences from a population-based research cohort of 2,108 volunteers with three or more Shetlandic grandparents, VIKING I.

Results: Nine research volunteers carry this variant, on a shared haplotype (carrier frequency of 0.4%, ~130-fold higher than in UK Biobank). Four of these volunteers, previously unaware that they carried the variant, sought confirmatory diagnostic testing, leading to cascade testing being offered to >20 further relatives. Vital records indicate genealogical linkage to a founder from the Isle of Whalsay, Shetland. This is similar to our observations for the *BRCA1* founder variant Val1736Ala from the Isle of Westray, Orkney, where return of results has led to 56 cascade tests, subsequent to five carriers being identified.

Conclusion: In total, 93.5% of pathogenic BRCA variant carriers in Northern Isles genomes are accounted for by these two drifted variants. We therefore recommend that those of Orcadian and Shetlandic origin be offered testing for the relevant drifted pathogenic variant, particularly those with Westray or Whalsay ancestry.

P18.043.B Genome-wide gene-environment interaction study uncovers 162 novel vitamin D status variants after precise estimation of individual ambient UV exposure

Rasha Shraim[1;2;3], *Jos van Geffen*[4], *Michiel van Weele*[4], *Ross McManus*[2], *Lina Zgaga*[1]

Background/objectives: Vitamin D status is influenced by genetic, lifestyle, and environmental factors, such as sun exposure. Recent genome-wide studies have identified over 140 variants linked to vitamin D status. However, the interaction effects remain largely unobserved in studies to date, which used a dichotomized summer/winter season variable as a proxy of environmental exposure.

Methods: We used an exact measure of ambient UV dose to approximate environmental exposure for each participant in the UK Biobank, based on their place of residence and date of blood sampling. UV dose was adjusted for weather, ozone, altitude and other key factors, and the final estimate accounted for accumulation/decay of vitamin D in the body. We carried out a genome-wide joint test of marginal and interaction effects in 25-hydroxyvitamin-D (25OHD) in 338,977 White British individuals, adjusting for other key covariates.

Results: Our findings identify over 160 novel independent variants significantly associated with 25OHD concentration. Downstream functional analysis of these variants supports vitamin D involvement in metabolic pathways and hormone and skin phenotypes, and identifies novel genes linked to 25OHD. Based on these results, we also evaluate the change in the SNP-based heritability of 25OHD associated with ambient UV.

Conclusion: Our findings provide new insights into the biology of vitamin D status. These results highlight the importance of using accurate environmental exposure measures and accounting for interactions in uncovering the genetic architecture of complex traits.

Consortium: Orchestra Genomics group

Background: The main pathomechanism in severe COVID-19 is an immune imbalance and systemic inflammatory response. The clinical features of COVID-19, range from an asymptomatic state to pneumonia to death. These heterogeneous symptoms might be partly explained by the individual's hereditary susceptibility. In addition to their primary function as energy producers and regulators of cellular processes, mitochondria play an important role in the vertebrates innate immunity. The mitochondria innate antioxidant and immune capacities could also play a role in the susceptibility, and in this regard the mitochondrial DNA (mtDNA) variants might serve as susceptibility markers for severe COVID-19.

Methods: We collected DNA from 640 COVID-19 patients' whole peripheral blood and high-coverage Whole Genome Sequence (WGS) was performed. We retrieved mtDNA variants from the WGS VCF files and mtDNA haplogroup was assigned to each patient using HaploGrep v2.4.0.The mtDNA copy number was calculated using the nuclear and mitochondrial mean coverage. The patients have been categorised using the WHO Clinical Progression Scale (score 1 to 10) and divided into three groups: mild (1-4), moderate (5-7) and severe (8-10).

Results: We highlighted a significant difference in mtDNA copy number, which decreased in relation to the increase of disease severity, suggesting that most severe cases were relatively depleted of mtDNA, possibly reflecting into OXPHOS deficiency. Furthermore, the haplogroup H frequency resulted to be significantly higher in mild patients, protecting from severe forms of COVID-19.

Conclusion: Our data confirm mitochondria as a player in the COVID-19 infection and as a possible target for therapy.

Background/Objectives: Molecular markers of anti-TNFα therapy response in Crohn's disease (CD) patients described in bulk peripheral blood immune cells suffer from poor reproducibility. Recent studies suggested that research of specific cell sub-types may yield superior biomarkers that could be translated into clinical practice. Peripheral blood monocytes and macrophages were previously indicated as key factors in both CD development and anti- TNFα therapy. Here we investigate monocyte to macrophage differentiation and expression of the inflammatory cytokines by

these cells in relation to the outcome of the adalimumab (anti-TNFα) therapy in CD patients.

Methods: CD patients responsive and non-responsive to adalimumab were recruited. Peripheral monocytes were isolated, differentiated into macrophages and exposed to inflammatory conditions with/without concurrent adalimumab treatment. We compared the in vitro outcomes to the clinical response of the donor patients. In parallel, we measured expression of the inflammatory cytokines in the in vitro monocytes/macrophages. Additionally, we analysed expression of the inflammatory cytokines in the peripheral monocytes using the single-cell RNA-sequencing.

Results: Monocytes and in vitro differentiated macrophages of adalimumab non-responders express more inflammatory cytokines than those of responders. The biggest differences are in the *IL1B* expressions. The *IL1B* expression in the in vitro differentiated macrophages of CD patients negatively correlates with their clinical response to adalimumab.

Conclusion: We propose *IL1B* expression in the macrophages as a potential biomarker for adalimumab response in CD patients.

Grants: Slovenian Research and Innovation Agency research core funding P3-0427 and research grant J3-9258. Labena d.o.o. co-financed the single-cell RNA-sequencing.

Background/Objectives: Many aspects of human development and health differ between sexes, but the underlying mechanisms or extent to which genetic factors contribute to any differences remain largely unknown. Understanding genetically driven sex-differences at the molecular level, specifically proteins as the biologically active entity between the genome and the phenome, is important for basic and translational genetic research.

Methods: To better understand sex differences in human health and disease, we conducted a systematic, large-scale investigation of sex differences in the genetic regulation of the plasma proteome (>5,000 targets), including their disease relevance.

Results: Plasma levels of two-thirds of protein targets differed significantly by sex. In contrast, genetic effects on protein targets were remarkably similar, with very few protein quantitative loci (pQTLs, n = 74) showing significant sex-differential effects (for 3.9% and 0.3% of protein targets from antibody- and aptamer-based platforms, respectively). Most of these 74 pQTLs represented directionally concordant effects significant in both sexes, with only 21 pQTLs showing evidence of sexual dimorphism, i.e. effects restricted to one sex (n = 20) or with opposite directions between sexes (n = 1 for CDH15). None of the sex-differential pQTLs translated into sex-differential disease risk.

Conclusion: Our results demonstrate strong similarity in the genetic regulation of the plasma proteome between sexes with important implications for genetically guided drug target discovery and validation.

Consortium: Be RIGHT with breast cancer management (BRIGHT)

Background: Breast cancer (BC) is the leading cause of cancer-related deaths in women. Standard BC screening considers only age as a risk factor, excluding women under 50 with elevated risks. Our international BRIGHT study highlights the role of genetic predisposition with polygenic risk score (PRS) and monogenic pathogenic variant (MPV) testing. We hypothesise that genetics-based screening is feasible, acceptable, and has clinical utility.

Methods: BRIGHT study addresses 2400 healthy women aged 30–49 in Estonia, Sweden, and Portugal. In Estonia, four recruitment channels for personalised prevention with home sampling and digital counselling were tested with feedback collection from patients and medical professionals. The service model included a questionnaire for MPV testing and clinical PRS testing (2803 SNPs). Personalised screening and prevention recommendations were given based on the tests' results.

Results: The recruitment was effective across all channels. Amongst 800 participants aged 35–49, 72 had MPVs tested after consultations by clinical geneticists, resulting in 5 MPV diagnoses. PRS testing for all identified 124 women at higher risk than the average 50-year-old. They started personalised screening earlier than the national standard, resulting in one immediate BC diagnosis. Feedback on the implementation of precision prevention was very positive.

Conclusion: The BRIGHT study demonstrated the feasibility of genetics-based precision prevention, facilitating earlier BC screening for younger women with elevated genetic risks. The predominantly digital service minimised the burden on healthcare personnel.

Grants: Supported by the European Commission via EIT Health BRIGHT innovation activity (project #220720, #230121) and the Estonian Research Council PRG555 grant.

P18.049.D Variation in the causal influence of body mass on common diseases across a lifetime

Torgny Karlsson[1], *Fatemeh Hadizadeh*[1], *Mathias Rask-Andersen*[1], *Daniel Schmitz*[1], *Åsa Johansson*[1]

[1]*Uppsala University, Immunology, Genetics and Pathology, Uppsala, Sweden*

Background/Objectives: Obesity is a major risk factor for most non-communicable diseases. The burden of disease is substantially higher in the older part of the population, but how obesity affects disease risk at different ages is largely unknown. To quantify the causal impact of obesity over the lifespan, we introduce a new method – Time-Resolved Mendelian Randomization – which estimates the time-dependent, cumulative effect of body mass index (BMI) on disease rate.

Methods: The method properly accounts for the time-dependence of the BMI instrument and relies only on patient register data to estimate effects, using Aalen's additive hazard model. We applied the method to determine life-course effects on four common diseases in the UK Biobank, including type 2 diabetes, coronary artery disease, atrial fibrillation, and osteoarthritis.

Results: Substantial differences in life-course effects were observed between diseases. Time-series trends of the causal estimates for atrial fibrillation and osteoarthritis increased with age in a highly non-linear fashion. In comparison, a significant trough in effect was found for coronary artery disease at around 60-70 years of age, in both sexes. A similar feature was found for type 2 diabetes in females. Besides osteoarthritis, obesity was a larger risk factor in males compared to females, at all ages above a critical time-point.

Conclusion: By resolving the causal effect of a lifelong exposure to high BMI in time, we can elucidate the temporal aetiology of obesity-related disease and find the appropriate age for introducing preventive interventions.

Grants: Swedish Research Council, Swedish Heart Lung Foundation, Novo Nordisk Foundation.

P18.050.A An apolipoprotein L1 polygenic score is associated with susceptibility to giant cell arteritis

Natalie Chaddock[1], *Michal Zulcinski*[1], *Javier Martin*[2], *Anders Malarstig*[3], *James Peters*[4], *Mark M Iles*[1;5], *ann w morgan*[1;5]

[1]*University of Leeds, School of Medicine, Leeds, United Kingdom;* [2]*Institute of Parasitology and Biomedicine López-Neyra, CSIC, Spain;* [3]*Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden;* [4]*Imperial College London, Department of Immunology and Inflammation, London, United Kingdom;* [5]*NIHR Biomedical Research Centre, Leeds, United Kingdom*

Consortium: UK GCA Consortium

Background/Objectives: Whilst glucocorticoid monotherapy remains the primary treatment for giant cell arteritis (GCA), concomitant adverse effects and toxicity underscores the necessity for targeted therapies and enhanced risk stratification. Prior work posits that evidence of genetic association can increase success rates in clinical trials and highlight biomarkers for risk assessment, particularly when aggregated with other 'omics data, including proteomics. However, relatively little is presently known about the genetic basis of GCA.

Methods: Polygenic risk scores (PRS) were developed for 169 circulating plasma proteins and tested for association with GCA susceptibility (cases $N = 729$, controls $N = 2{,}619$). Associated PRS were replicated in an independent dataset (cases $N = 1{,}129$, controls $N = 2{,}654$) and their respective proteins were assessed for causality with Mendelian randomization (MR). Finally, protein-protein interaction (PPI) network analysis was performed to evaluate relationships between proteins with associated PRS.

Results: The Apolipoprotein L1 (APOL1) PRS had a statistically significant protective GCA association ($P\text{-value}[P] = 1 \times 10^{-4}$), which replicated in an independent cohort ($P = 8.69 \times 10^{-4}$). This relationship was corroborated by evidence for causality in MR ($beta = -0.093$; $SE = 0.02$; $P = 4.42 \times 10^{-9}$). PPI network analysis revealed enrichment for gene ontology pathways "negative regulation of fibrinolysis" and "negative regulation of blood coagulation".

Conclusion: Genetically higher APOL1 protein levels are associated with lower GCA susceptibility, implicating a role of reverse cholesterol transport in GCA. PPI network analysis findings also suggest a contribution of fibrinolytic and coagulation cascades to GCA susceptibility, highlighting pathways of interest for future pharmaceutical targeting.

Grants: Supported by MRC DiMeN, NIHR Leeds BRC, and MRC TARGET Partnership awards.

P18.051.B Systematic investigation of environmental factors and interplay with genetic risk reveals potential for improved prediction of male-pattern hair loss

Sabrina Henne[1], *Hannah Klinkhammer*[2;3], *Christian Staerk*[2], *Andreas Mayr*[2], *Markus Nöthen*[1], *Stefanie Heilmann-Heimbach*[1]

[1]*Institute of Human Genetics, University Hospital of Bonn & University of Bonn, Bonn, Germany;* [2]*Institute for Medical Biometry, Informatics and Epidemiology, Medical Faculty, University of Bonn, Bonn, Germany;* [3]*Institute for Genomic Statistics and Bioinformatics, Medical Faculty, University of Bonn, Bonn, Germany*

Background/Objectives: Male-pattern hair loss (MPHL) is highly heritable, yet existing prediction models are limited. Previous studies discussed the potential contribution of environmental factors and implicated smoking, alcohol consumption, and BMI as additional risk factors for MPHL. However, the evidence has been inconclusive. Here, we aimed to systematically investigate associations with environmental factors and assess their value in MPHL prediction using data from the UK Biobank.

Methods: Our analyses investigated associations between MPHL and environmental factors encompassing lifestyle, anthropometry, biological measurements, and medical history in 169,105 men. We performed age-adjusted linear and logistic regression, and cross-trait LD score regression. Integrative PRS models based on boosting techniques were tested using logistic regression, adjusted for age and 20 principal components.

Results: Results indicate that men with MPHL tend to smoke less, drink less, have a higher BMI, and possess fairer or red hair. Regarding blood-biomarkers, men with MPHL tend to have higher testosterone, IGF-1, and creatinine levels. Associated medical

conditions included a higher risk of diabetes, cardiovascular disease, and calcinosis cutis alongside a lower risk of lung disease and alcohol-related liver disease. Genetic correlations included aspartate aminotransferase and albumin levels. Incorporating environmental factors already marginally improved the prediction accuracy of PRS models, increasing the area-under-the-curve (AUC) from 0.75 to 0.76. Prediction accuracy notably improved via further inclusion of blood-biomarkers (AUC = 0.80), with proteomics (e.g. DSG4) having the greatest impact.

Conclusion: Our analyses identify environmental factors associated with MPHL and suggest improvability of predictive models, especially by integration of blood-biomarkers. Mendelian randomization analyses to clarify potential causal relationships are underway.

P18.052.C 100,000 Genomes of Europe: Unlocking genetic variability across Europe for science and health

Anthony Herzig[1], *Astrid Vicente*[2;3], *Hugo Martiniano*[2;3], *Emmanuelle Génin*[1;4], *Helen Ray-Jones*[5], *Jeroen van Rooij*[5], *André Uitterlinden*[5]

[1]*Inserm, Univ Brest, EFS, UMR 1078, GGB, Brest, France;* [2]*Instituto Nacional de Saúde Doutor Ricardo Jorge, Av Padre Cruz, Lisbon, Portugal;* [3]*Biosystems and Integrative Sciences Institute (BioISI), Faculdade de Ciências da Universidade de Lisboa, Lisboa, Portugal;* [4]*CHRU Brest, Brest, France;* [5]*Laboratory for Population Genomics, Erasmus MC, Rotterdam, Netherlands*

Consortium: The GoE/1 + **MG consortium**

Background/Objectives: As part of the 1 million genomes (1 + MG) initiative, the Genome of Europe (GoE) project will create a pan-European reference database comprising whole-genome sequencing (WGS; 30x) data from >100,000 European citizens. Spanning 51 contributing partners from 29 countries providing existing and de novo datasets (short-read and long-read WGS), GoE presents enormous potential for understanding the genetic dimension to public health in Europe; including through interactions with the European Rare Disease Research Alliance (ERDERA).

Methods: Challenges for GoE are evident across three axes: technological, statistical, and ethical, in order for GoE to provide wide-ranging utility. Here we present the scope of the "use-cases" of GoE, which will establish the envisaged applications of GoE.

Results: The following pilot studies are outlined: (1) Building a fine-scale map of genetic structure across Europe to inform aggregating individual-level data. (2) Creating a reference database for individual variant look-ups; with particular attention on clinically relevant variant frequencies in actionable-disease and pharmacogenetic genes. (3) Building reference panels for ancestry-informed genetic imputation and the required secure informatics environments. (4) Deriving distributions of polygenic (risk) scores, calibrated for ancestry gradients in Europe; with a focus on cancer phenotypes in collaboration with the Can.Heal project. (5) Understanding the added value of long-read sequencing in the general population and exploring the 'dark regions of the human genome'.

Conclusion: We lay out here the methodological advances and adjustments necessary to best unlock the potential of GoE; particularly in the context of the prospective GoE federated data embedding in 1 + MG.

Conflict of Interest: None declared

P18.053.D Comparison of disease prediction ability and transferability of polygenic scores vs. EHR-based score across three biobank studies, 1,034,311 individuals, and 18 diseases

Tuomo Hartonen[1], *Kira Detrois*[1], *Maris Teder-Laving*[2], *Kristi Läll*[2], *Zhiyu Yang*[1], *Reedik Mägi*[2], *Samuli Ripatti*[1], *Andrea Ganna*[1]

[1]*University of Helsinki, Institute for Molecular Medicine Finland, FIMM, HiLIFE, Helsinki, Finland;* [2]*University of Tartu, Estonian Genome Centre, Institute of Genomics, Tartu, Estonia*

Consortium: FinnGen, Estonian Biobank research team

Background/Objectives: Polygenic Scores (PGSs) have emerged as a promising tool to guide the screening and treatment of complex diseases. However, systematic comparisons with non-genetic risk factors are lacking. Within the INTERVENE consortium, we compared the ability of PGSs vs. electronic health record (EHR)-based scores to predict the onset of 18 diseases by creating PhenoScores comprising education, region of birth, Charlson comorbidity index, and diagnosis-based Phenotype Risk Scores (PheRSs). We included three biobank studies: FinnGen, UK Biobank (UKB), and Estonian Biobank (EstBB), totalling 1,034,311 individuals.

Methods: We calculated the PGSs using the latest publicly available genome-wide association study summary statistics. The PheRSs were based on elastic-net models, incorporating up to 164 diagnoses as predictors. We then fitted Cox proportional hazards models to predict the onset of each disease using the covariates age, sex, principal components, PGSs, and PhenoScores.

Results: In FinnGen, adding the PGS to a model with the PhenoScore improves onset prediction for 8/18 diseases. Similarly, the PhenoScores improve onset prediction over PGSs for 8/18 diseases. Interestingly, for type 2 diabetes, asthma, hip osteoarthritis, and atrial fibrillation, the two scores improve onset prediction independent of each other. PhenoScores trained on the external cohorts (UKB or EstBB), and tested in FinnGen reached similar c-indices to within-FinnGen-trained PhenoScores for 7/11 and 9/11 diseases, respectively.

Conclusion: PGSs and EHR-based PhenoScores have an independent effect on disease risk prediction and can be complementary. EHR-based scores transfer well between biobanks for the majority of the diseases considered.

Grants: ERC Horizon 2020 grant 101016775.

P18.054.A Genetic insights into coronary artery disease in underrepresented populations: assessing two-sample Mendelian randomization across diverse ancestry populations

Sarah Silva[1;2], *Segun Fatumo*[1;2], *Dorothea Nitsch*[1]

[1]*London School of Hygiene and Tropical Medicine, Department of Non-Communicable Disease Epidemiology, London, United Kingdom;* [2]*The African Computational Genomics Research Group (TACG), MRC/UVRI and LSHTM, Entebbe, Uganda*

Background/Objectives: Understanding the causal effect of modifiable risk factors on a disease is crucial for aiding and shaping public health policies, identifying targets of interventions and advancing our global understanding of health and diseases. With this however, the disproportionate representation of non-European ancestries in research has raised important questions regarding the transferability and reliability of genetic findings on a diverse global scale.

Methods: We investigated the feasibility of conducting a two-sample Mendelian randomization (MR) analysis in populations of diverse ancestries, focusing on methodological challenges and biologically differences when data from European, East Asian, South Asian and African ancestry populations were compared against each other. Employing data generated from large-scale genome-wise association studies (GWAS), we compared the causal effects of lipid traits, blood pressure, body-mass index, type-2 diabetes and kidney function on coronary artery disease.

Results: We found that allowing for a lenient alpha threshold in order to extend the MR methodology to be more inclusive of non-European data resulted in an increase in weak instrument bias, resulting in imprecise estimates and a reduced ability to detect true causal effects. Notably, our results showed causal associations known to be inconsistent with established findings, specifically between lipid traits in South Asian populations compared to European ancestry populations.

Conclusion: These findings reiterate the urgent need for independent large-scale GWAS in non-European populations, to improve the power and reliability of MR studies as well as to develop methods which take into account population-specific effects.

Grants: This work was self-funded.

P18.055.B Longitudinal Proteomic Profiling Reveals Temporal Changes in Long-COVID

Xavier Farré[1], *Susana Iraola-Guzmán*[1], *Gemma Castaño Vinyals*[2], *Manolis Kogevinas*[2], *Carles Barceló*[3], *Israel Fernández–Cadenas*[4], *Rafael de Cid*[1]

[1]*IGTP Institut Germans Trias i Pujol, GCAT, Badalona, Spain;* [2]*ISGlobal, Barcelona, Spain;* [3]*Fundación Instituto de Investigación Sanitaria Islas Baleares (IdISBa), Palma, Spain;* [4]*Institut de Recerca - Hospital Santa Creu i Sant Pau, Stroke Pharmacogenomics and Genetics Laboratory, Barcelona, Spain*

Background/Objectives: Long-COVID, characterized by persistent health challenges post-SARS-CoV-2 infection, necessitates a thorough understanding of its complex pathogenesis, encompassing symptoms from fatigue to cognitive dysfunction. Proposed mechanisms include viral persistence, immune dysregulation, microbiota alterations, autoimmunity, clot formation, and neurological abnormalities. This study focuses on unraveling the molecular underpinnings through a protein analysis, aiming to identify biomarkers and therapeutic targets to mitigate long-term impacts.

Methods: In the COVICAT, COVID Cohort of Catalonia, over 10,000 participants underwent three follow-up assessments (2020, 2021, 2023). Long-COVID classification combined participant-reported symptoms and electronic health records. Longitudinal analysis of 1,467 proteins, related to cardiometabolic and inflammation processes, was conducted using the Olink proteomic assay. Paired samples from 146 Long-COVID cases and 25 COVID-19 matching controls, collected in 2020 and 2023, were examined.

Results: A significant decrease in the expression of over 500 proteins was noted in COVID-19 samples from 2023 compared to 2020, enriched for endoplasmic reticulum stress proteins, indicating impact from the initial SARS-CoV-2 encounter. Intriguingly, 354 proteins were uniquely expressed in Long-COVID samples. Functional enrichment revealed overrepresentation in blood coagulation, Insulin-like Growth Factor regulation, and conditions like cardiovascular disorders.

Conclusion: Our investigation into the proteomic landscape of Long-COVID has uncovered substantial alterations in protein expression, emphasizing the impact of the initial SARS-CoV-2 encounter. The identified proteins associated with endoplasmic reticulum stress and those unique to Long-COVID shed light on intricate mechanisms, offering potential therapeutic avenues for mitigating persistent impacts.

P18.056.C Causal effects of the plasma proteome on childhood health

Roman Thielemann[1], *Sara Stinson*[1], *Yun Huang*[1], *Louise Aas Holm*[1,2], *Jens-Christian Holm*[2], *Simon Rasmussen*[1], *Torben Hansen*[1]

[1]*The Novo Nordisk Foundation Center for Basic Metabolic Research, København, Denmark;* [2]*The Children's Obesity Clinic, European Centre of Obesity Management, Holbæk Hospital, Department of Paediatrics, Holbæk, Denmark*

Background/Objectives: Protein quantitative trait loci (pQTL) studies in pediatric populations remain limited. PQTLs combined with Mendelian randomization can infer causal effects of proteins on health and disease. Here, we use genetic and proteomic data from The HOLBAEK Study, a cohort of 3,811 Danish children and adolescents, to 1) identify plasma pQTLs in childhood and adolescence and 2) examine changes in pQTLs across the lifespan.

Methods: We performed genome-wide association studies for 184 plasma proteins measured with Olink proteomics in 3,811 children and adolescents (44.2% boys) with a median age of 11.7 years. Participants were recruited from an obesity clinic ($n = 1,773$) and a population-based cohort ($n = 2,038$). We assessed gene-environment interactions with overweight and pubertal status. Lead pQTLs were matched and compared with adult data from the UK Biobank Pharma Proteomics Project.

Results: We identified 1,448 independent, genome-wide associations for 184 proteins in children and adolescents. For several variants, gene-environment interactions with overweight and pubertal status were observed. Matched pQTLs explained a similar proportion of variance (PVE) in The HOLBAEK Study and the UK Biobank, but for several proteins, PVE differed across age.

Conclusion: We performed a large-scale Olink pQTL study in children and adolescents. PQTLs explained similar proportions of variation in plasma protein levels in adults and children, but several proteins exhibited large differences in PVE across age. In ongoing studies, we use Mendelian Randomization to identify proteins with causal effects on cardiometabolic traits. This study will elucidate causal disease mechanisms of cardiometabolic risk and obesity in early life.

Medical Oncology Service, Lleida, Spain; [8]Corporació Sanitària Parc Taulí, Genetic Counselling Unit. Medical Oncology, Sabadell, Spain; [9]Hospital Vall d'Hebron., Gynecology, Barcelona, Spain

Background/Objectives: Healthy women with familial breast cancer(BC) generally pursue early age-based screening based on family history(FH) alone. Previous results in PRiSma showed that one third of women changed their risk category after inclusion of breast density(BD) and PRS. Our aim was to identify those women who benefit most from PRS testing.

Methods: 417 healthy women (30-65y) were considered. Data on personal factors(PF), FH and BD were collected and PRS_{268} was analyzed. Women were classified into 10-y risk(NICE categories) based on CanRisk(v5). We compared the group distribution of women according to their baseline prediction (PF + FH+panel) and the estimate obtained after the incorporation of BD + PRS or PRS alone. We used descriptive statistics and chi square test.

Results: According to baseline prediction, the median 10-y risk was 3.8%(IQR3.1-4.7) and women were classified into moderate(75%), average(22%) and high(3%) risk. Overall, 144(34.5%) changed group after the addition of BD + PRS. Women in the 2-4% risk interval were more likely to shift group compared to those in 4-7% (40.2% vs 27.4%, $p = 0.01$). Additionally, 53/84(63%) of these women decreased to average risk. Similar results were found when we evaluated the contribution of adding PRS to baseline +BD prediction, leading to the re-assignment of 56% of women to average risk.

Conclusion: Most healthy women from panel-negative BC families are at moderate risk. PRS testing together with personal and family information would modify risk stratification and adjust screening recommendations towards population level in a significant proportion of women whose baseline predicted risk is close to the lower bound of moderate risk.

P18.058.A Gene-based association study to identify radiogenomic markers of rectal bleeding in prostate cancer patients treated with radiotherapy

Olivia Fuentes-Ríos[1;2;3], *Miguel E. Aguado-Barrera[1;2], Carlos López[1;2], Javier Manuel Galego Carro[1;2;3], Ana Crujeiras[1;2], Carla Coedo-Costa[1;2], Antonio Gomez-Caamaño[4], Ana Vega[1;2;3]*

[1]Instituto de Investigación Sanitaria de Santiago de Compostela, Cancer genetics and rare diseases, Santiago de Compostela; [2]Fundación Pública Galega de Medicina Xenómica, Functional Genomics, Santiago de Copostela; [3]Universidad de Santiago de Compostela, Santiago de Compostela, Spain; [4]Hospital Clínico Universitario de Santiago de Compostela, Servicio de Oncología Radioterapica, Santiago de Compostela

Background/Objectives: Radiogenomics studies inherited genetic variations contributing to the inter-variability in response to radiotherapy. In prostate cancer patients, one of the most relevant adverse effects associated with radiotherapy is rectal bleeding, which in its most severe grades can compromise the patient's life. NGS technologies provide unprecedented and affordable access to genomic information for discovering novel biomarkers related to the phenotype. Our aim is to identify candidate genes associated with late rectal bleeding in patients with adenocarcinoma of the prostate treated with radiotherapy, using whole-exome sequencing.

Methods: We selected 141 patients, 46 with rectal bleeding (cases;CTCAE grade≥2) and 95 without any toxicity (controls;CTCAE = 0) from the RADIOGEN-prostate cohort who had at least 5 years of follow-up. DNA libraries were constructed from peripheral blood samples collected before radiotherapy using the SureSelect-All-Exon-V6 + UTR-kit(Agilent) and were sequenced on the NovaSeq6000(Illumina). Genomic variants were detected by GATKv.4.0 and annotated with ANNOVARv.2019, PLINK_v.1.90 was used for data quality control. Rare variants with frequency < 0.01 (GnomAD_AF_NFE_exome.v2.1.1) were prioritized. For the analysis, we carried out the Optimal Sequence Kernel Association test, age-at-radiotherapy and rectum-volume-(percent)-receiving-65Gy were included as covariates. Bonferroni correction was performed.

Results: Five genes, namely *NUP188, CRNKKL1, ZCCHC2, HIPK3*, and *MAP1A*, reached a nominal p-value < 9.1 × 10-04. Notably is that the circular RNA Circ-HIPK3 encoded by the *HIPK3* gene has been implicated in cellular radiosensitivity [PMID:37536436]. No genes remained significant after Bonferroni correction.

Conclusion: In this study, we identified new potential candidate genes linked to rectal bleeding in prostate cancer patients undergoing radiotherapy. These discoveries could be further investigated for validation in independent cohorts.

Conflict of Interest: None declared

P18.059.B High frequency of lobular breast cancer in *CDH1* germline carriers supports update of clinical guidelines for *CDH1* testing and pathological characterization

J. Garcia-Pelaez[1], *alexandre dias[2], parry guilford[3], carla oliveira[1]*

[1]i3S - Instituto de Investigação e Inovação em Saúde; IPATIMUP - Institute of Molecular Pathology and Immunology of the University of Porto and Faculty of Medicine, University of Porto, Porto, Portugal.; [2]i3S - Instituto de Investigação e Inovação em Saúde; IPATIMUP - Institute of Molecular Pathology and Immunology of the University of Porto, Porto, Portugal.; [3]Cancer Genetics Laboratory, Centre for Translational Cancer Research (Te Aho Matatū), Department of Biochemistry, University of Otago, Dunedin, New Zealand

Background/Objectives: *CDH1* germline Pathogenic/Likely Pathogenic variants (PV/LPV) predispose for Diffuse Gastric and Lobular Breast Cancer syndrome (DGLBCS). Sensitive and specific clinical criteria for testing, ensure clinical management of the correct population at risk. Herein, we systematically analysed the frequency of gastric and breast cancer in *CDH1*-PV/LPV carrier families, and itsrelationship with current clinical criteria, across different continents.

Methods: We compiled retrospective clinical information from 878 *CDH1*-PV/LPV carrier families, including 207 from internal communications (32 institutions) and 671 from a systematic review of the literature (151 original articles). Variants were classified with *CDH1* ACMG-AMP guidelines. Phenotypical presentation, fulfillment of clinical criteria and continent of origin were analysed.

Results: From 878 *CDH1* germline PV/LPV carrier-families, 314(35.8%) were European, 512(58.3%) American, 26(3.0%) Asian, 24(2.7%) from Oceania and 2(0.2%) were African. From 314 European families, 78% fullfiled clinical criteria, while only 59.6% of American families did. Among families lacking criteria, American families presented 2-fold more families with LBC involvement than European families (18.4% vs 10.2%; $p < 0.05$). Despite these discrepancies, 39.5% (124/314) of European families and 37.1% (190/512) of American families either fullfiled clinical criteria or lacked criteria but had LBC involvement. In Asia, only 2/26 families presented LBC involvement, and in Oceania none of the 24 families did. In these two continents, most families fulfilled criteria and were GC-only families.

Conclusion: This systematic collection of CDH1 PV/LPV carrier families across continents demonstrates higher frequency of LBC-associated cancer in the western world, strongly supporting further broadening of clinical criteria for CDH1 testing to LBC-families.

P18.060.C Diet-by-polygenic score interaction effects on kidney function

Giulia Barbieri[1;2], *Michele Filosi*[2], *Ryosuke Fujii*[3], *Dariush Ghasemi-Semeskandeh*[2], *Martin Gögele*[2], *Peter Pramstaller*[2], *Cristian Pattaro*[2], *Essi Hantikainen*[2]

[1]*University of Verona, Diagnostics and public health, Verona, Italy;* [2]*Eurac Research, Institute for Biomedicine, Eurac Research, Bolzano, Italy;* [3]*Fujita Health University School of Medical Sciences, Department of Preventive Medical Sciences, Toyoake, Japan*

Background/Objectives: Chronic kidney disease (CKD) affects 10% of the worldwide population. While diet plays a key role in CKD prevention and management, interaction between diet and CKD genetic predisposition is largely unexplored. We investigated the interplay between a polygenic score (PGS) and dietary patterns in determining the CKD-defining trait, the creatinine-based estimated glomerular filtration rate (eGFR), in the Cooperative Health Research In South Tyrol (CHRIS) study.

Methods: We derived eGFR on 5,975 individuals without CKD and related morbidities (median age: 40 years; 53% females; median eGFR: 101.6 ml/min/1.73m^2), who completed the GA^{2}LEN food frequency questionnaire. We estimated four CKD-relevant nutrients (protein, potassium, sodium, phosphorus) and the Dietary Approach to Stop Hypertension (DASH) index, reflecting overall diet quality. The PGS was derived from a large genome-wide association study meta-analysis ($n = 1{,}046{,}070$), applying the PRS-CS algorithm, controlling for population structure via continuous shrinkage correction (959,833 common variants with high imputation quality). We fitted multiply-adjusted generalized additive models incorporating tensor product smooths and diet-PGS interaction terms to model non-linear associations with eGFR.

Results: PGS and DASH index explained 5.6% and 2.3% of eGFR variance, respectively. eGFR resulted non-linearly associated with PGS ($P < 0.0001$) and DASH index ($P = 0.042$) and linearly associated with all nutrients but sodium. We observed significant interaction of the PGS with protein intake ($P = 0.028$) and protein-corrected phosphorus levels ($P = 0.007$): high protein intake was associated with lower eGFR in individuals with high PGS but not in those with low PGS.

Conclusion: Genetic predisposition may modify the association between protein intake and kidney function.

P18.062.A Impact of CYP2C19 genetic variants on side effects of antidepressants leading to treatment discontinuation

Hanna Kariis[1], *Dage Särg*[1;2], *Kristi Krebs*[1], *Maris Alver*[1], *Kelli Lehto*[1], *Lili Milani*[1]

[1]*University of Tartu, Institute of Genomics, Tartu, Estonia;* [2]*University of Tartu, Institute of Computer Science, Tartu, Estonia*

Consortium: REALMENT Consortium (Horizon 2020)

Background/Objectives: Antidepressants are commonly prescribed for psychiatric disorders but often result in side effects which can lead to treatment discontinuation. Genetic variation in CYP2C19 can affect plasma drug concentration and has been linked to side effects, but the findings are not consistent.

We aim to investigate the associations between side effects leading to discontinuation and CYP2C19 metaboliser status separately for escitalopram, citalopram, sertraline, and amitriptyline.

Methods: We leveraged self-reported data from the Estonian Biobank Mental Health online Survey ($N = 86{,}244$), the Estonian Biobank Vaccines and Medications Adverse Effect study ($N = 49{,}366$) and used a natural language processing model to extract side effects from free text in electronic health records ($N = 445$). The sample included 7147 individuals (84,4% women, mean age 48,7 years) who had taken any of the four antidepressants: citalopram ($N = 988$), sertraline ($N = 1948$), escitalopram ($N = 3654$), and amitriptyline ($N = 871$). We used logistic regression, with discontinuation due to side effects as the outcome and CYP2C19 metaboliser status as the predictor.

Results: For most drugs, the effects between side effects and metaboliser status were in expected direction but there was some heterogeneity between drugs. Overall, side effect reporting largely increased with slower metabolism and decreased with faster metabolism.

Conclusion: Questionnaire and health record data from biobanks are a valuable resource for pharmacogenetic research. We are now developing a machine learning model for side effect annotation with sufficient accuracy to skip manual verification, thereby increasing the sample size. A better understanding of the underlying mechanisms could help to identify individuals at risk of side effects.

Consortium: The PERMEABLE consortium

Background/Objectives: Biologics are becoming a key option for treating children with severe, corticosteroid-resistant asthma. However, reliable biomarkers for selecting the most effective treatment are missing. We utilized a functional ex vivo method to discover biomarkers that indicate the efficacy of omalizumab, an anti-IgE biological, in pediatric asthma patients.

Methods: We isolated peripheral blood immune cells from children/juveniles with moderate to severe asthma, naive to therapy with omalizumab. The cells were cultured in the presence of patient's own serum with/without omalizumab for 24 hours, followed by an in vitro simulation of an asthma attack using patient-specific allergens. Basophil activation test was used as readout to classify patients as good- or poor/non-responders to omalizumab. RNA-seq analysis of basophils from the good- vs the poor/non-responders identified several differentially expressed genes, predominantly associated with the response to virus and apoptosis.

Results: Notably, *RSAD2* expression decreased in the poor/non-responder group, showing a negative correlation with omalizumab response. The results were confirmed by qPCR on additional samples and in clinical setting, where pre-therapy *RSAD2* expression significantly negatively correlated with the FeNO levels at 3/6 months of therapy.

Conclusion: Our integrated approach combining in vitro cell model, transcriptomics, and clinical data underscores *RSAD2* as a promising biomarker for omalizumab response in pediatric asthma.

Grants: The PERMEABLE consortium is funded by ZonMW (PN 456008004), the Swedish Research Council (PN 2018-05619), the Slovenian Ministry of Education, Science and Sport (PN C3330-19-252012), and the German Ministry of Education and Research (BMBF, PN FKZ01KU1909A) as part of the ERA PerMed JTC 2018 Call.

Conflict of Interest: None declared

P18.064.C Preparing for Genomic Newborn Screening in Germany: lesson learned from comparative analysis of existing initiatives

Isabel Betzler[1], *Maja Hempel[1], Stefan Kölker[2], Eva Winkler[3], Sven Garbade[2], Christian Schaaf[1], Heiko Brennenstuhl[1]*

[1]Institute of Human Genetics, Heidelberg University and Heidelberg University Hospital, Heidelberg, Germany; [2]Centre for Paediatrics and Adolescent Medicine, Division of Paediatric Neurology and Metabolic Medicine, Heidelberg University and Heidelberg University Hospital, Heidelberg, Germany; [3]Section of Translational Medical Ethics, National Center for Tumour Diseases, Heidelberg University and Heidelberg University Hospital, Heidelberg, Germany

Background/Objectives: The feasibility of genomic newborn screening (gNBS) is growing as sequencing costs decline and the understanding of the impact of genetic variants on disease advances. A central task of ongoing projects revolves around which target diseases to incorporate in gNBS. Our study aims to analyze target gene-disease lists from six initiatives, providing insights for advancing and implementing gNBS in Germany.

Methods: Target gene-disease lists and inclusion criteria from six gNBS studies were analyzed regarding disease number, composition, group proportions, and ClinGen gene-disease validity curations.

Results: Despite similar selection criteria, our analysis revealed variations in total gene count (mean 488, range 237-889, SD ± 243.4) and disease group composition. A consensus emerged for 53 target diseases, predominantly associated with inborn errors of metabolism (83%, 44/53). Each study proposed an exclusive set of gene-disease pairs, positively correlating with total gene count per study. While most pairs received "Definitive" or "Strong" ClinGen curation, some pairs included on gNBS target lists were labeled as "Refuted" (n = 28) or "Disputed" (n = 5), particularly in genetic cardiac diseases. Notably, 17-48% of genes lacked ClinGen curation.

Conclusion: To date, no consensus has been reached on the selection of target diseases for gNBS. The diversity of proposed gene-disease targets and variation/lack in ClinGen curation emphasizes challenges in standardizing inclusion criteria for gNBS. Our study provides valuable insights into selection of target diseases for gNBS in Germany and advocates for collaboration working towards harmonization and consensus on criteria, aiming to ensure screening objectivity, integrity, and acceptance.

P18.065.D Addition of Genetically Predicted Plasma Lipids to Measured Levels Improves Cardiovascular Risk Stratification

Oliver Vad[1;2], *Christian Paludan-Müller[1;2], Rasmus Frosted[1;2], Jesper Hastrup Svendsen[1;3], Morten Olesen[2]*

[1]Copenhagen University Hospital, Rigshospitalet, Department of Cardiology, København, Denmark; [2]University of Copenhagen, Department of Biomedical Sciences, København, Denmark; [3]University of Copenhagen, Department of Clinical Medicine, København, Denmark

Background/Objectives: Dyslipidemia is a major risk factor for cardiovascular morbidity and mortality and has a substantial genetic component. This study aimed to explore whether genetic predisposition to plasma lipid levels contributes with an added risk independent of measured lipid levels.

Methods: Summary statistics for non-HDL cholesterol levels were obtained from non-UK Biobank individuals. A polygenic risk score (PRS-Cholesterol) was constructed using PRS-CS-auto and applied in 422,571 individuals of European ancestry from the UK Biobank. The cohort was stratified into three groups at baseline: Normal cholesterol (cholesterol <5.2 mmol/L and no cholesterol-lowering treatment), treated dyslipidemia (cholesterol-lowering medication), and untreated dyslipidemia (cholesterol >=5.2 mmol/L and no cholesterol-lowering medication). Using Cox-models, hazard ratios (HR) were estimated for a composite

endpoint of myocardial infarction, heart failure, and cardiovascular-related death. Models were adjusted for sex, age, hypertension, diabetes, body-mass index, measured plasma lipids, and ten first genotype principal components.

Results: One standard deviation increase in PRS-Cholesterol was associated with increased cardiovascular disease rate among individuals with normal cholesterol levels (HR: 1.14, 95% confidence interval [CI]: 1.10-1.18, $P = 1.16 \times 10^{-11}$) and among those with untreated dyslipidemia (HR: 1.09, 95% CI: 1.06-1.12, $P = 2.07 \times 10^{-10}$). There was no association with increased rate among individuals taking cholesterol lowering medication (HR: 0.98, 95% CI: 0.95-1.00, $P = 0.10$).

Conclusions: PRS-Cholesterol was independently associated with a higher rate of cardiovascular disease in individuals not receiving lipid-lowering therapy and may aid in the identification of individuals at an increased cardiovascular risk.

P18.067.B Integration of single-cell transcriptomics and targeted genomics on peripheral blood cells identifies novel hub genes for anti-TNFα therapy response in Crohn's disease

Boris Gole[1], *Larisa Goričan*[1], *Mario Gorenjak*[1], *Gregor Jezernik*[1], *Ursula Prosenc Zmrzljak*[2], *Cvetka Pernat*[3], *Pavel Skok*[3], *Uroš Potočnik*[1;4;5]

[1]*Faculty of medicine, University of Maribor, Centre for human molecular genetics and pharmacogenomics, Maribor, Slovenia;* [2]*BIA Separations CRO – Labena d.o.o., Ljubljana, Slovenia;* [3]*Maribor University Medical Centre, Division of Internal Medicine, Department of Gastroenterology, Maribor, Slovenia;* [4]*Faculty for Chemistry and Chemical Engineering, University of Maribor, Laboratory for Biochemistry, Molecular Biology and Genomics, Maribor, Slovenia;* [5]*Maribor University Medical Centre, Department for Science and Research, Maribor, Slovenia*

Background/Objectives: Lack of reliable biomarkers of response to anti-TNFα biologicals hinders personalized therapy for Crohn's disease (CD) patients. Novel approaches to uncover reproducible biomarkers use transcriptomic-genomic integration and deconvoluted immune cell abundance in bulk peripheral blood cells (PBMCs). Motivation behind our study is to shift the paradigm of anti-TNFα biomarker discovery towards specific immune cell subpopulations using single-cell RNA-sequencing (scRNA-seq).

Methods: The scRNA-seq was performed on PBMCs samples from CD patients either naïve to biological therapy, in remission while on adalimumab (anti-TNFα therapy), or while on ustekinumab but previously non-responsive to adalimumab. Differentially expressed genes (DEGs) influenced by the two therapies were removed from analyses, thus identifying DEGs in adalimumab non-responders relative to the responders. These were further tested with gene ontology analysis, genomic profiling on two independent patient cohorts, gene expression on sorted immune cells, Mendelian randomization and oligogenic risk score calculation.

Results: The scRNAseq revealed 1353 DEGs in 6 PBMCs populations. 7 genes upregulated in CD4 + T-cells and 6 genes downregulated in double-negative T-cells were further confirmed through gene ontology and genomic profiling. Finally, data from independent cohorts, Mendelian randomization and oligogenic risk score identified DEGs highly relevant to anti-TNFα therapy response in CD.

Conclusion: The scRNA-seq enabled direct pinpointing of the causal PBMCs sub-populations. Jointly with an innovative study design it uncovered novel candidate genes in anti-TNFα response landscape of CD, potentially obscured by therapy or inflammation.

P18.068.C Inherited lack of functional CCR5 is associated with increased risk of coronary heart disease

Matthew Traylor[1], *Dominik Pfister*[2], *Christina Mogensen*[2], *Ciara Vangjeli*[1], *Joanna Howson*[1]

[1]*Novo Nordisk Research Centre Oxford (NNRCO), United Kingdom;* [2]*Novo Nordisk A/S - site Måløv, Måløv, Denmark*

Background/Objectives: Inhibition of C-C chemokine receptor type 5 (*CCR5*) is used to prevent and treat human immunodeficiency virus infection and is being pursued in clinical trials as a treatment for inflammatory mechanisms in diseases such as metabolic dysfunction associated steatohepatitis and fatty liver disease. Carriers of a common deletion of *CCR5* (Δ32) in European populations do not express functional CCR5 on their cell surface and therefore have no functional CCR5 signalling. Given the role of inflammatory mechanisms in coronary heart disease (CHD), we explored whether carriers of Δ32 had altered risk of CHD and therefore whether CCR5 inhibition might alter CHD risk.

Methods: We meta-analysed GWAS summary data for CHD from the largest published GWAS (Aragam et al; Nat Genet 2022) with FinnGen R9 (I9_CHD) and assessed whether a) variants within 250kb either side of CCR5 were associated with disease and b) whether these associations could be attributed to CCR5 Δ32.

Results: Variants in the *CCR5* region were associated with CHD (smallest p-value, rs75719572, OR(95% CI) = 1.042(1.029-1.055), p = 1.9e-10). CCR5 Δ32 was not included in the Aragam et al. dataset because indels were removed in the original publication. However, all associated variants were in LD with Δ32 and their strength of association was proportional to LD with Δ32, consistent with the association being attributable to Δ32.

Conclusion: Inherited lack of functional *CCR5* is associated with an approximately 8.5% increase in risk of CHD, assuming additivity per allele. Ongoing clinical trials using CCR5 inhibitors should fully assess the potential for an increase in CHD in treated subjects.

P18.069.D An Evaluation of Age-varying Genetic Effects underlying Body-Mass Index and Blood Pressure in the UK Biobank

Genevieve Leyden[1], *Panagiota Pagoni*[1], *Tom G. Richardson*[1], *Gibran Hemani*[1], *George Davey Smith*[1], *Eleanor Sanderson*[1]

[1]*University of Bristol, MRC Integrative Epidemiology Unit, United Kingdom*

Background/Objectives: Cross-sectional genome-wide association studies (GWAS) assume that genetic effects are constant throughout one's lifetime. However, many traits have age-varying genetic associations which may have implications for their implementation in downstream analyses such Mendelian randomization (MR). In this study we conducted a series of age-stratified GWAS across the 40-69 year age-range in the UK Biobank (UKB) for body-mass index and 3 blood pressure traits (systolic, diastolic and pulsatile pressure (PP)) at 2-year intervals.

Methods: We used a meta-regression approach to systematically identify SNPs with evidence for age interaction effects among discovery hits (inclusion 1) and genome-wide (inclusion 2). We describe, using an MR framework (1) the association between these SNPs on secondary cardiovascular outcomes; and (2) the relationship between the genetically predicted SNP/age interaction on secondary outcomes.

Results: We identified differential enrichment of age-interaction effects which was trait dependent, e.g. 10.23% of BMI discovery SNPs had evidence of an age-interaction compared to 42.38% for PP ($P < 0.05$). Furthermore, the results of our MR-based analyses support a relevant role for SNP/age interaction effects underlying the relationship between PP and adverse cardiovascular outcomes (e.g. the PP (inclusion 1) SNP/age interaction was positively associated with peripheral artery disease in our MR-based framework: Beta = 0.99; $P < 1.82 \times 10^{-13}$; 95%-CI: 2.08-3.53). All summary data derived in this project has been made readily accessible to the research community.

Conclusion: This data generated provides a valuable resource for further exploration of mechanisms relevant to the genetic architecture of complex traits.

Grants: This research was funded by the Medical Research Council: MC_UU_00032/1

P18.070.A Population-based Genomic Screening: Developing an Evidence-Based Tool for Comprehensive Gene Panel Selection

Ana Nyasha Zimani[1], *Borut Peterlin*[1]

[1]*Clinical Institute of Genomic Medicine, Ljubljana, Slovenia*

Background/Objectives: Implementation of population-based genomic screening requires specific inclusion criteria depending on screening aims in different populations. We have developed an up-to-date tool for a comprehensive approach to curation of tailored genomic screening panels.

Methods: To enable informed gene selection according to the criteria such as disease severity, disease burden, age of onset, actionable interventions, and gene-disease association, we integrated data on monogenic diseases from evidence-based resources, including Orphadata, HPO, and OMIM. Inclusion criteria were selected following traditional and modern screening recommendations. An algorithm for disease severity was adapted from a phenotype-based severity classification and actionability was assessed based on the availability of orphan drugs and other mechanism-based interventions sourced from Rx-Genes, Orphadata and NHGRI CGD datasets.

Results: We identified 7574 monogenic diseases with an OrphaCode or MIM number identifier, of which 6459 (85.3%) had evidence of gene-disease validity in ClinGen or were included in Genomics England PanelApp. Of 6187 (81.7%) disorders with sufficient data for a phenotype-based severity classification, 454 (7.3 %) disorders were classified as mild, 2824 (45.6%) as moderate, 2597 (42%) as severe and 312 (5%) as profound. Age of onset was reported for 4817 disorders, including antenatal (557, 9%) pediatric (3229, 52.2%), adult (851, 13.8%), and onset at all ages 401 (6.5%). Actionable interventions were available for 1505 (24.3%) of disorders.

Conclusion: We developed an evidence-based tool enabling a comprehensive approach to curation of gene panels depending on their screening aims. Its design facilitates rapid adaptation of genomic screening in population-based screening programs and clinical settings.

P18.071.B Pharmacogenomics in the Scottish Isles

David Twesigomwe[1], *Gannie Tzoneva*[2], *Alan R Shuldiner*[2], *James Wilson*[3,4]

[1]*Sydney Brenner Institute for Molecular Bioscience, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa;* [2]*Regeneron Genetics Center, Tarrytown, New York, United States;* [3]*MRC Human Genetics Unit, University of Edinburgh, Institute of Genetics and Cancer, Western General Hospital, Crewe Road, EH4 2XU, Edinburgh, United Kingdom;* [4]*Centre for Global Health Research, Usher Institute, University of Edinburgh, Teviot Place, EH8 9AG, Edinburgh, United Kingdom*

Background/Objectives: Genetic variation is partly responsible for variability in drug response across populations. However, the full catalogue of pharmacogenetic variants and their distribution are yet to be established, thus posing challenges in implementing individualised medicine in understudied populations. This study aimed to characterise variation in key drug metabolism and transporter genes across founder populations from the Northern and Western Isles of Scotland.

Methods: This study used genomic data from 4200 research volunteers (from Viking Genes studies). We implemented the StellarPGx pharmacogenomics pipeline to call star alleles (haplotypes and structural variants) in tier 1 Very Important Pharmacogenes (VIPs) from whole genome sequence (WGS) datasets (N = 1860 from Orkney and Shetland). In addition, we analysed 4000 whole exome (WES) datasets from these populations. As there was a sample overlap (N = 1860) with both WGS and WES, we used the WGS data to benchmark StellarPGx's utility for characterising pharmacogenetic variation based on WES.

Results: We present frequencies of known and potentially novel star alleles in 11 key cytochrome P450 genes (e.g. *CYP2D6*, *CYP2C19*) and other tier 1 VIPs for the Shetland and Orkney populations in this study and comparisons with the pharmacogenetic landscape across other European populations. Diplotype-phenotype translation for key genes such as *CYP2D6, CYP2C19*, and *SLCO1B1* showed that up to 40% of the study participants included in each analysis had phenotypes that might warrant treatment adjustments informed by pharmacogenetic testing.

Conclusion: Understanding the pharmacogenomic variation landscape across Shetland and Orkney populations is an important step towards precision medicine implementation in the Scottish isles.

P18.072.C GentroPy: the new Python package for Open Targets Genetics Pipelines

Daniel Considine[1;2], *Xiangyu Ge*[1;2], *Irene López*[1;3], *Kirill Tsukanov*[1;3], *Annalisa Buniello*[1;3], *Ellie McDonagh*[1;3], *Daniel Suveges*[1;3], *David Ochoa*[1;3], *Yakov Tsepilov*[1;2]

[1]*Open Targets, Hintxon, United Kingdom;* [2]*Wellcome Sanger Institute, Hintxon, United Kingdom;* [3]*European Bioinformatics Institute, European Molecular Biology Laboratory, Hintxon, United Kingdom*

Consortium: Open Targets

Background/Objectives: Open Targets Genetics (https://genetics.opentargets.org/) is a comprehensive tool for predicting causal genes in established human GWAS loci using a machine learning framework. Though effective, the original analysis pipeline faced computational challenges, including scalability to ever growing datasets, and was limited to GWAS of European ancestry. Here we present Gentropy, a toolkit optimised for scalable and reproducible genomic analysis, that encompasses the Open Targets Genetics pipelines for Locus-2-Gene prediction. This Python package enables ingestion of the ever-expanding volume of multi-omic datasets, and the ability to incorporate non-European ancestries.

Methods: The package employs PySpark for the ETL pipeline, with default utilisation of Google Cloud Platform for computational tasks, although local operations are possible. The package was applied to 15,987 GWAS Catalog studies, 2,408 FinnGen R10 studies, and 64,442 curated associations.

Results: The package includes the first optimised version of the genetic data ingestion and harmonisation pipelines, the clumping, PICS fine mapping, eCAVIAR colocalisation and L2G-pics computation pipelines. It uses GnomAD v2.1 as the LD reference for seven major population ancestries. From raw data to Locus-2-Gene prediction scores, the entire analysis now takes less than 24 hours to complete. Future releases will incorporate SuSiE fine-mapping and COLOC approaches.

Conclusion: The freely available package, accessible at https://github.com/opentargets/gentropy, facilitates the interpretation and analysis of GWAS and functional genomic studies for target identification.

Conflict of Interest: None declared

P18.073.D *DPYD* genotyping for fluoropyrimidine dose optimization: Population-based characterization and pharmacogenomic insights

Alicia Torres García[1;2], *Xando Díaz Villamarín*[1;2], *Rocío Morón Romero*[1;2], *Luis Javier Martínez-González*[3;4], *Maria Jesus Alvarez Cubero*[2;3;4], *Jose Cabeza*[1;2]

[1]*Hospital Universitario Clínico San Cecilio, Pharmacy Unit, Granada, Spain;* [2]*ibs.GRANADA Instituto de Investigación Biosanitaria, Granada, Spain;* [3]*Centro Pfizer-Universidad de Granada-Junta de Andalucía de Genómica e Investigación Oncológica (GENYO), Granada, Spain;* [4]*University of Granada (UGR), Biochemistry and Molecular Biology III, Faculty of Medicine, Granada, Spain*

Background/Objectives: *DPYD* variants (rs3918290, rs55886062, rs67376798 and rs56038477) genotyping has been implemented in our hospital for fluoropyrimidines dose tailoring in accordance with recommendations of European Medicines Agency (EMA) and Food and Drug Administration (FDA) approved drug labels. This study aims to characterize these *DPYD* variants in our population by describing genotypic, allelic, and phenotypic frequencies, conducting linkage disequilibrium (LD) analysis, studying the Hardy-Weinberg (H-W) equilibrium for each variant, and comparing with databases.

Methods: Genotyping of 1039 patients was performed for four *DPYD* gene polymorphisms (rs3918290, rs55886062, rs67376798, and rs56038477) using Real-time PCR (QuantStudio™ 12K-Flex, Applied Biosystems). Allelic frequencies were compared with 1000Genomes database, while phenotypic data were obtained from PharmGKB database. Statistical analysis was conducted using R-4.3.2. software.

Results: No significant differences were detected between our cohort and the 1000Genomes reference population (IBS), supporting the results obtained for our population. There were also no significant differences observed in terms of H-W equilibrium for any of the variants, nor LD between the variants. Significant differences were detected in rs3918290 (Granada: MAF = 0.1 vs Europe: MAF = 0.5; p = 0.041) and rs56038477 (Granada: MAF = 1.30 vs Europe: MAF = 2.4; p = 0.027). However, a higher allelic frequency was observed in Nordic population compared to Mediterranean population, which may explain the detected differences.

Conclusion: *DPYD* genotyping is particularly relevant in clinical practice for patients undergoing fluoropyrimidines treatment. Significant differences exist in the inheritance of these variants depending on the European population, with rs3918290 and rs56038477 being less prevalent in the studied cohort.

Consortium: Genomics England Research Consortium

Background/Objectives: Repeat expansion disorders (REDs) affect approximately 1/3000 people worldwide. Prevalence estimates are hampered by heterogeneous clinical presentation, geographic distributions, and technological limitations, likely leading to under-ascertainment. Novel bioinformatics tools have made possible to detect with high accuracy disease-causing repeat expansions from whole genome sequencing (WGS) data.

Methods: Using ExpansionHunter, we profiled WGS data of 82,176 individuals from 100,000 Genomes Project and Trans-

Omics for Precision Medicine. Then, we aimed to estimate the expected number of people affected by REDs based on disease allele frequency. To this aim, we tabulated the UK population's age distribution (based on the Office of National Statistics) to calculate the number of disease allele carriers by age for each RED, and we used corresponding age at onset distribution and survival length for disease modelling.

Results: We estimated that the number of people with C9orf72-Amyotrophic lateral sclerosis, HD in carriers with 40 CAG repeats and DM1 was over two, three and 1.5 times higher than respective literature reported figures based on disease observation, while C9orf72-Frontotemporal dementia estimate fell within the reported range. Moreover, we observed an unexpected increased prevalence of SCA1, 2 and 6.

Conclusion: These discrepancies indicate either underdiagnosis of mild and heterogenous phenotypes, or incomplete penetrance of REDs. Defining the global burden of REDs through prevalence and penetrance estimate is crucial to determine patient specific needs and secure resources for healthcare services. Further work in large population cohorts with detailed clinical information is needed to be able to address these crucial questions.

P18.075.B The pharmacogenetic risk factors for apixaban associated bleeding and inefficacy

Jozefina Palic[1], *Ana Marija Slišković*[2], *Vedran Pašara*[2], *Lana Ganoci*[3], *Livija Šimičević*[3,4], *Martina Lovrić Benčić*[2,5], *Tamara Božina*[1]

[1]*University of Zagreb, School of Medicine, Department of Medical Chemistry, Biochemistry and Clinical Chemistry, Zagreb, Croatia;* [2]*University Hospital Centre Zagreb, Department of Cardiovascular Diseases, Zagreb, Croatia;* [3]*University Hospital Centre Zagreb, Department of Laboratory Diagnostics, Zagreb, Croatia;* [4]*University of Zagreb, School of Medicine, Department of Medical Chemistry, Biochemistry and Clinical Chemistry, Zagreb;* [5]*University of Zagreb, School of Medicine, Department of Internal Medicine, Zagreb, Croatia*

Background/Objectives: Apixaban has good safety and efficacy, however, there are cases of bleeding and thromboembolic events in practice. Apixaban is a substrate of CYP3A enzymes and ABCB1/ABCG2 transporters. The polymorphisms in the genes that encode them could affect apixaban pharmacokinetics. The objective of the study is to determine association between relevant polymorphisms and occurrence of apixaban-related adverse events.

Methods: These are preliminary results of the larger cohort PGx-CardioDrug (N = 1100). Adults with a new indication for apixaban treatment were genotyped for CYP3A4*22, CYP3A4*1B, CYP3A5*3, ABCG2c.421C>A, ABCB1c.1236C>T, c.2482-2236G>A, and c.3435C>T variants. Analysis was performed with specific TaqMan® Assays on ABI7500 Real-Time PCR. Clinical and laboratory data were collected. Associations between carriers/noncarriers of variant alleles or haplotypes/phenotype and bleeding/thromboembolic events were analysed. Statistical analysis was performed by JASP0.17.1 software.

Results: 140 patients (Mdn age = 66,5 (20-89); f = 59, m = 81) were treated in dosages of 2 × 5mg (n = 113) and 2 × 2,5mg (n = 27). Eleven patients had apixaban associated bleeding (serious = 3, anaemia = 3, epistaxis = 2, haematoma = 2, haematuria = 2, haemoptysis = 1) and six thromboembolic events (insult = 4, thrombosis = 2). Genotype distribution is consistent with Hardy Weinberg's equilibrium. Based on the univariate analysis, a significant association between ABCB1 c.1236C>T variant carriers and smaller bleeding occurrence (OR = 0.27, 95% CI: 0.06-1.13, p = 0.046) was found.

Conclusion: There is no association between the CYP3A4*22, CYP3A4*1B, CYP3A5*3, ABCG2c.421C>A, ABCB1c.2482-2236G>A, and c.3435C>T variants nor phenotype with the apixaban-related side effects. The results should be re-evaluated on the larger cohort.

Grants: This study is part of the project "Pharmacogenomics in Prediction of Cardiovascular Drugs Adverse Reaction - PGx-CardioDrug" supported by the Croatian Science Foundation (UIP-2020-02-8189).

P18.076.C Unravelling the interplay between the microbiome and genetics in Inflammatory bowel diseases (IBD)

Angeliki Taliouraki[1], *michalis gkizis*[2], *Electra Sofou*[3], *Glykeria Gkoliou*[3], *Giorgos Bamias*[2], *Andreas Agathangelidis*[1], *Panagoula Kollia*[1]

[1]*National and Kapodistrian University of Athens, Department of Biology, Athens, Greece;* [2]*National and Kapodistrian University of Athens, GI Unit, 3rd Academic Department of Internal Medicine,Sotiria Hospital, Athens;* [3]*Centre for Research and Technology Hellas, Institute of Applied Biosciences, Thessaloniki*

Background/Objectives: Inflammatory bowel diseases (IBD) are considered intricate, multifactorial entities with a series of pathogenic factors. Against this background, we explored the interplay between genetic and environmental factors in IBD patients receiving different treatments, through assessing: (i) the diversity of the gut microbiome, and (ii) the immune response capacity.

Methods: DNA/RNA were isolated from affected and healthy ileal and colonic mucosa biopsies from 40 IBD patients. The V3-V4 region of the 16S rRNA gene was amplified, while libraries were prepared and paired-end sequenced on the MiSeq platform. Data were analysed using Qiime2. Sanger-based sequencing was performed for the detection of single nucleotide polymorphisms (SNPs), whereas the expression levels of genes associated with leukocyte migration were evaluated with qRT-PCR. Statistical analysis was performed in R.

Results: Analysis of microbiome diversity based on the Bray-Curtis index revealed three clusters. Interestingly, one cluster corresponded to patients treated with biological agents and exhibited a distinct microbiome composition, with an increase in the *Ruminococcaceae* and *Lachnospiraceae* species. These patients also displayed downregulation of genes involved in leukocyte migration and actin remodeling (namely, *RHOA*, *SELL* and *PECAM1*) and SNPs associated with xenophagy, the PRR immune response and the response to anti-TNF treatment.

Conclusion: Biological agents induce a distinct gut microbial signature in IBD patients and prevent inflammation by suppressing leukocyte migration, thus, allowing the proliferation of anti-infflammatory bacteria species despite the host's opposing genetic background.

Inc., Cambridge, United States; [7]University of Cambridge, United Kingdom

The plasma proteome uniquely bridges the gap between inherited and modifiable risk factors for disease. We therefore aimed to characterize plasma proteins into mediators of genetic vs. environmental risk using the UK Biobank (UKB) Pharma Proteomics Project resource. Previous work identified thousands of associations between levels of ~3K proteins and onset of 20 age-related diseases, such as rheumatoid arthritis and chronic obstructive pulmonary disease (COPD). To interrogate which of these proteins have putative causal effects on incident disease, we first employed Mendelian Randomization (MR) using genetic instruments from the UKB. MR implicated more than 20 proteins in causal roles, with an enrichment of significant associations for autoimmune diseases.

We next investigated whether the proteins could serve as quantitative sensors of environmental risk factors. Using smoking as an example, we found that 64% of the disease-associated proteins measured in blood plasma were significantly associated with smoking status in the UKB. We developed a protein score for smoking, trained on the protein levels of the never and current smokers, which predicted smoking status with high accuracy (AUC = 0.95) and showed distributions in previous smokers that reflected time since smoking. Using Cox PH models to test for associations between this score and disease onset, we found that the score accurately predicts incident COPD even in never smokers, suggesting that it may capture a broader signature of smoking-related environmental exposures. Altogether, our study presents an integrative approach that combines large-scale MR and environmental exposure data to advance the discovery of protein biomarkers and predictors.

P18.079.B Multi-omic signatures of perfluoroalkyl exposure in a population cohort

Yasrab Raza[1], *Julia El-Sayed Moustafa[1], Ricardo Costeira[1], Jordana T Bell[1], Cristina Menni[1], Claire Steves[1], Kerrin S Small[1]*

[1]King's College London, Department Of Twin Research & Genetic Epidemiology, London, United Kingdom

Background/Objectives: PFOA (perfluorooctanoic acid) and PFOS (perfluorooctanesulphonic acid) are synthetic chemicals, with global ubiquitous exposure, resistant to degradation and environmentally persistent. These chemicals possess long half-lives and are linked to poor health outcomes, including hyperlipidaemia, thyroid disease and cancer, however the molecular response to exposure is less understood.

Methods: We aimed to understand the molecular effects of PFOA/PFOS exposure using two longitudinal sub-studies spanning 18 years (n = 2069, n = 335) within the TwinsUK cohort, by assessing multi-tissue associations between serum levels of PFOA/PFOS and the epigenome, transcriptome, and metabolome.

Results: Consistent with regulatory changes, PFOA/PFOS levels decreased over time in these sub-studies. Epigenetic associations in adipose (n = 184) and blood (n = 342) were observed, but not skin (n = 92), suggestive of long-term exposure impact and cross-tissue effect. CpG sites linked to PFOA/PFOS included CPT1A ($\beta = 0.69, p = 1.3e-07$) and NAT1 ($\beta = 0.96, p = 4.5e-07$). A longitudinal effect (3 timepoints) on blood gene expression was found; PFOA associated with 15 genes and PFOS associated with 953 genes. PPARD ($\beta = 0.38, p = 0.0014$) was amongst genes found to be associated. Cross-sectional gene expression associations demonstrate a transient effect with THRA ($\beta = 0.86, p = 2.5e-05$) and PPARA ($\beta = -0.70, p = 0.00039$), indicating time sensitive associations with the transcriptome. In contrast, associations with metabolites displayed a sustained effect both cross-sectionally and longitudinally. Metabolite associations were enriched for lipids and amino acids, including pathways involved with phospholipid metabolism, long chain fatty acids and tryptophan metabolism.

Conclusion: These findings indicate PFOA/PFOS exposure perturbs molecular mechanisms, particularly lipid and TCA cycle pathways. We demonstrate potential biological mechanisms through which PFOA/PFOS exposure may lead to adverse health outcomes.

Consortium: SCOURGE Cohort Group

Background/Objectives: Corticosteroids (CS) improve survival in severe COVID-19 patients, although with variable response. We performed a genome-wide association study (GWAS) of 90-day mortality in hospitalized COVID-19 patients treated with CS to identify genetic variants associated with CS response.

Methods: Data from the SCOURGE consortium patients enrolled before vaccination were included. We tested logistic regression models in ~9.5M TOPMed-imputed variants (significance set at $p = 5 \times 10^{-8}$). Sensitivity analyses were conducted among CS-untreated patients to assess robustness of the findings. We combined Bayesian fine mapping, colocalization with GTEx eQTLs, transcriptome-wide association studies (TWAS), and functional predictions to prioritize genes and evaluate the biological impact of the variants.

Results: Three variants of 16q23.3 were associated with 90-day mortality among CS-treated patients ($p_{lowest} = 2.79 \times 10^{-8}$). These variants did not associate with 90-day mortality among CS-untreated patients ($p = 0.497$). The analyses prioritized *PLCG2* around a credible set of 16 variants, one with a high predicted phenotypic impact, based on CADD>MSC95%. Colocalization analysis and TWAS did not reveal any significant association with eQTLs or tissue-gene expression.

Conclusion: We conducted the first GWAS of CS response in severe COVID-19 patients and identified association of variants in *PLCG2* gene, which has been previously associated with diverse immune disorders.

P18.081.D A Comprehensive Nutrigenomics Survey of Gene-Diet Interactions in the UK Biobank

Matteo Di Scipio[1;2], *Guillame Paré*[2;3;4;5]

[1], *Department of Medicine, Faculty of Health Sciences, McMaster University, Hamilton, ON, Canada;* [2], *Population Health Research Institute, David Braley Cardiac, Vascular and Stroke Research Institute, Hamilton Health Sciences and McMaster University, Hamilton ON, Canada;* [3], *Thrombosis and Atherosclerosis Research Institute, David Braley Cardiac, Vascular and Stroke Research Institute, Hamilton ON, Canada;* [4], *Department of Pathology and Molecular Medicine, McMaster University, Michael G. DeGroote School of Medicine, Hamilton ON, Canada;* [5], *Department of Health Research Methods, Evidence, and Impact, McMaster University, Hamilton, ON, Canada*

Background: Precision nutrition aims to offer genomic-guided dietary advice. Such advice depends on the presence of significant gene-diet interactions (G × D) for specific diet and outcome pairs. However, broad-sense GxD heritability across clinically-actionable traits has yet to be fully elucidated.

Methods: We applied MonsterLM, a method to estimate gene × environment interactions with minimal model assumptions, to assess the contribution of genome-wide G × D to major health outcomes in the UK Biobank ($N = 141{,}144$ – $325{,}989$). We tested 31 cardiometabolic disease-related outcomes with 23 dietary exposures totalling 713 outcome-exposure combinations. Dietary data comprised of single-nutrient intakes (SNIs) from 6 major nutritional classes (carbohydrates, protein, fats, vitamins, minerals, and discretionary), 6 dietary indexes (DASH, HEI, AHEI, MEDI, DII, ACS), and dietary pattern principal components (dPC) derived from food frequency questionnaires.

Results: We identified 20 significant G × D ($p < 7.0 \times 10^{-5}$) explaining 2.1 - 21.2 % of outcome variance: two with dPC1 (urea, BMI), one with the Mediterranean Diet Index (Apolipoprotein B), four with caffeine (Apolipoprotein A, Cystatin C, GGT, SHBG), and 13 with alcohol (Albumin, HbA1c, CRP, Cystatin C, Urate, Apolipoprotein A, HDL-cholesterol, Triglycerides, ALP, IGF-1, Total Bilirubin, BMI, and WHR). These significant interactions were further explored with sensitivity, gene-level G × D, canalization, and pathways analyses.

Conclusion: Our comprehensive nutrigenomics survey showed that significant G × D exist but tend to be specific, moderate, and occur much more frequently in discretionary diet components like alcohol and caffeine. These findings will help guide future nutrigenomics research in areas where genetics is likely to have a major impact.

Gemelli, Department of Woman and Child Health and Public Health, Roma, Italy;* [8]*University of Debrecen, HUN-REN-DE Public Health Research Group, Debrecen, Hungary*

Consortium: PROPHET consortium

Background/Objectives: Conducted within the PROPHET project, this study aims to develop a comprehensive Health Impact Assessment (HIA) framework for personalized prevention policies utilizing the WHO model (https://www.who.int/tools/health-impact-assessments). Specifically, pre-treatment Dihydropyrimidine dehydrogenase (DPYD) genotyping in Colorectal Cancer (CRC) patients undergoing Fluoropyrimidine (FP) chemotherapy will serve as a case study to pilot the proposed framework.

Methods: A literature review on pre-treatment DPYD-gene genotyping and the application of HIA in personalized prevention policies was conducted. Pseudoanonymized and aggregated data from cancer and healthcare registries will be collected for CRC patients undergoing FP chemotherapy in Finland, Italy, and Portugal. A "Markov" model will be utilized to simulate the health impacts of DPYD genotyping. National stakeholder committees have been established. We want to prioritize a comprehensive policy evaluation emphasizing literature reviews, statistical modelling and stakeholder consultations.

Results: The literature review identified gaps in applying HIAs to genomics, prompting further investigation into health impacts associated with genomic integration in personalized prevention policies. Qualitative insights from our national stakeholder committees, comprising experts from healthcare, patient organizations, and medicines agencies, enhance the study's scientific inquiry. The committees' enthusiasm aligns with PROPHET's goals, actively contributing to integrating public health approaches with personalized strategies.

Conclusion: Initial findings highlight the importance of an HIA framework for evaluating the value of genomics in personalized prevention, with enthusiastic participation from diverse stakeholders. Our final results aim to contribute to improved health outcomes and equal access across Europe.

Grants: PROPHET is funded by the European Commission under the Horizon Europe research and Innovation Programme, under Grant agreement ID: 101057721.

P18.083.B Influence of mRNA expression variation on viral control in HIV-infected individuals

Sergey Oreshkov[1,2], *Christian Thorball*[3,4], *Jenny Meylan-Merlini*[2], *Maude Muriset*[2], *Jacques Fellay*[3,4], *Federico Santoni*[1,2]

[1]*UNIL - Université de Lausanne, Lausanne, Switzerland;* [2]*Lausanne University Hospital, Service d'endocrinologie, diabétologie et métabolisme, Lausanne, Switzerland;* [3]*Lausanne University Hospital, Unité de médecine de précision, Lausanne, Switzerland;* [4]*EPFL, Lausanne, Switzerland*

Background/Objectives: The interaction between HIV-1 and the host immune system plays a crucial role in the natural control and progression of the infection. Previous studies have identified number of HIV-1 restriction factors, which are counteracted by the viral proteins. The blood expression levels of these restriction factors vary among individuals, suggesting a contribution of this variability to interindividual differences in the spontaneous control of HIV infection.

Methods: Study enrolled 150 participants from the Swiss HIV Cohort Study, with provided genotypes, pre-antiretroviral treatment PBMC aliquots, and viral load measurements. Using BRB sequencing, we derived gene expression profiles and assessed their associations with viral load. Furthermore, Mendelian randomization studies were performed on genes exhibiting causal relationships within these associations.

Results: We employed a generalized linear model to assess the association between 792 genes and HIV viral load. Pathway analysis revealed upregulation in innate immune response and proteasome complex with increased viral load, alongside heightened mitochondrial activity and cell-cycle. Conversely, reductions were observed in ribosomal transcripts and downregulation of genes involved in cytokine-cytokine receptor interaction, including IL4R, IL7R, and TCF. Utilizing Egger Regression and Transcriptome-Wide Mendelian Randomization, we estimated both host-driven and pathogen-driven alterations in gene expression.

Conclusion: We performed a large transcriptomic analysis of PBMCs from PLWH without antiretroviral treatment at the time of sample collection. In an analysis comparing gene expression levels and HIV-1 VL, numerous genes with a significant negative or positive correlation with spontaneous viral control were identified.

P18.084.C Unveiling Genetic Predispositions in Pleural Mesothelioma: a GWAS and Polygenic Risk Score Approach

Khadija Sana Hafeez[1], *Carla Debernardi*[1], *Alessandra Allione*[1], *Simonetta Guarrera*[2], *Daniela Ferrante*[3], *Dario Mirabelli*[4], *elton jalis herman*[1], *Irma Dianzani*[5], *Corrado Magnani*[3], *Elisabetta Casalone*[1], *Giuseppe Matullo*[1]

[1]*University of Turin, Department of Medical Sciences, Turin, Italy;* [2]*Italian Institute for Genomic Medicine, Department of Medical Sciences, Turin, Italy;* [3]*University of Eastern Piedmont, Department of Translational Medicine, Novara, Italy;* [4]*CPO Piedmont, Department of Medical Sciences, Turin, Italy;* [5]*Università del Piemonte Orientale, Department of Health Sciences, Novara, Italy*

Background/Objectives: Pleural Mesothelioma (PM), a lethal cancer predominantly caused by asbestos exposure, has poor prognosis and limited treatment options. The role of genetic predisposition in PM is not well understood. This study leverages GWAS to identify genetic variants (out of 10 Million) linked to PM risk and develops a novel Polygenic Risk Score (PRS) to evaluate its predictive potential.

Methods: GWAS was conducted on 419 PM cases and 394 controls, with documented asbestos exposure. Rigorous genotype quality control was implemented, and imputation was performed using Michigan Imputation Server. We conducted single-variant association tests adjusting for age, sex, and principal components using SAIGE. Subsequently, the dataset was divided into training and testing sets for calculating effect sizes and PRS, respectively.

Results: We identified significant SNPs in novel loci, including *OAT, ITGBL1*, and *MICAL3* [$p < 5e-8$], alongside suggestive links to already reported PM risk in loci such as *ATG5, PVT1*, and *THRB*. Known PM drivers like *ZFHX3, SLIT3, DCLK1, PTPRD*, and *ZFPM2* were also identified. The PRS effectively distinguished cases from controls (Kolmogorov-Smirnov $p = 0.04604$), with significant ORs of 2.2 (95%CI 1.1-4.6) for ≥80th and 2.7 (95%CI 1.0-7.7) for ≥90th quantiles.

Conclusion: These findings are crucial for identifying high-risk individuals, guiding targeted prevention, and potentially uncovering protective factors against PM in asbestos-exposed populations. While the PRS shows promise, further refinement and validation are essential for its clinical application. Results will undergo validation in a prospective study to assess predictive ability.

Consortium: NAPKON and NUKLEUS study group

As part of the German National Pandemic Cohort Network COVID-19 (NAPKON), a total of 7097 patients were recruited in 3 different cohorts (2753 SÜP, 710 HAP, and 3634 POP patients) by the end of 2023. Biosamples from 2520 patients (1217 SÜP, 300 HAP, and 1003 POP patients) for whom a complete set of biosamples was available, were comprehensively characterised using molecular techniques on 7 different analysis platforms.

Genotype data were generated, and proteome, metabolome, transcriptome and cytokine profiles were determined at up to

three time points (baseline, acute phase, 3-month follow-up) for each HAP and SÜP patient and at baseline for POP. In addition, epigenetic (methylation, protein-DNA interaction) and virological data, including SARS CoV-2 sequences were collected. The various analytical data are integrated into the NUKLEUS infrastructure (NUM clinical epidemiology and study platform) with direct links to the respective aliquots analysed. The systematic analysis data is now available for research projects via the NAPKON use and access process.

As part of a DFG application, exome sequence data is also being generated and integrated into NAPKON. In another follow-up project, SAPCRiN (Sample Analysis in Post COVID Research in NAPKON), the 12-month follow-up samples will be analysed using the above-mentioned methods and evaluated with a focus on post Covid.

Here we provide the current state as initial overview of the various methods and types of data generated in the context of systematic molecular analyses in NAPKON, with a focus on technical implementation and quality assurance. Both are essential for the provision and use of high-quality data.

P18.086.A *HLA* combination analysis reveals differentially multiple sclerosis-associated combinations, suggesting differences in the underlying pathogenesis mechanism

Anna Serova-Erard[1;2], *Igor Faddeenkov*[1], *Sonia Bourguiba-Hachemi*[1], *Pierre-Antoine Gourraud*[1;3], *Nicolas Vince*[1], *François Cornélis*[1;2;4]

[1]*Nantes Université, INSERM UMR1064, Center for Research in Transplantation and Translational Immunology (CR2TI), Nantes, France;* [2]*Clermont-Ferrand University Hospital, Université Clermont-Auvergne, Génétique – Oncogénétique Adulte – Prévention (GENOAP), Clermont-Ferrand, France;* [3]*Nantes Université, Nantes University Hospital, Pôle Hospitalo-Universitaire 11: Santé Publique, Clinique des données, INSERM CIC 1413, Nantes, France;* [4]*Université Clermont-Auvergne, UFR de Médecine et des professions paramédicales, Clermont-Ferrand, France*

Background/Objectives: *HLA* association in multiple sclerosis (MS) involves 13 MS-alleles: *HLA-A*02:01*,

*HLA-B*38:01/*44:02/*55:01, LTA-H51P, HLA-DRB1*03:01/*08:01/*13:03/*15:01*,

*HLA-DQA1*01:01, HLA-DQB1*03:01/*03:02 and HLA-DPB1*03:01* (Moutsianas et al, 2015). Our objective was to identify *HLA*-wide combinations differentially associated with MS.

Methods: We analysed WTCCC *HLA* data for 11,376 MS-cases and 18,872 controls. We used principal component analysis (PCA) for genetic homogeneity selection. *HLA* alleles, imputed using the *HIBAG R* package or inferred with proxy SNPs (*rs2229092, rs9273912* and *rs9277565*), were recoded to consider only the 13 MS-associated alleles. We searched for MS-associated genotype combinations in a 20% sub-sample, nominal combinations being to be tested for replication in the remaining 80%. Confirmed combinations were investigated in the global sample (100%). *Haplomat* provided putative diplotypes.

Results: Following PCA analysis, we retained 9,024 MS and 13,923 controls. In the 20% sub-sample, we observed 776 different *HLA*-wide recoded genotype combinations, 41 were nominally

MS-associated ($P < 0.05$) and 22 of those were replicated (*P corrected* <0.05/41). The 22

HLA-combinations represent 27,9% of MS-patients, defining 4 groups with non-overlapping 95% confidence intervals of odds ratios (OR):

High-risk OR from 6.75 to 3.99
Medium-risk OR from 3.36 to 2.86
Low-risk OR from 2.56 to 1.83
Protective OR from 0.57 to 0.30

Genetic effect was provided by the recoded genotypes themselves, as, within

HLA-combinations, using unrecoded *HLA* typing, alleles and putative diplotypes counts were similar between MS and controls.

Conclusion: Such differentially associated *HLA*-combinations suggest a direct contribution to different *HLA*-associated pathogenesis pathways of potential relevance for personalized medicine in MS and other *HLA*-associated diseases.

Conflict of Interest: None declared

P18.087.B Precision Medicine in Treatment-Resistant Schizophrenia: Leveraging Pharmacogenetic Insights for Improved Outcomes

Iván Martín da Silva[1;2], *Pau Riera*[1;2], *Sara Bernal*[2;3], *Meritxell Cros*[2;3], *María Gámez-Lechuga*[1;2], *Iluminada Corripio*[2;4], *Josefina Pérez-Blanco*[2;5], *Almenta-Gallego David*[2;5], *Anna Díaz-Pérez*[2;5], *Dolors Puigdemont*[2;5], *Laia Arias i Queralt*[2;5], *Javier de Diego-Aledíño*[2;5], *Narcis Cardoner*[2;5]

[1]*Hospital de la Santa Creu i Sant Pau, Hospital Pharmacy, Barcelona, Spain;* [2]*Institut de Recerca - Hospital Santa Creu i Sant Pau, Barcelona, Spain;* [3]*Hospital de la Santa Creu i Sant Pau, Genetics, Barcelona, Spain;* [4]*Hospital Universitari de Vic, Psychiatry, Vic, Spain;* [5]*Hospital de la Santa Creu i Sant Pau, Psychiatry, Barcelona, Spain*

Background/Objectives: Antipsychotics' effectiveness is widely variable, with 30-50% of patients showing poor response and/or adverse reactions.

Our objective was to highlight the clinical significance of precision medicine in treatment-resistant schizophrenia, drawing from our experience with PGx-informed prescribing.

Methods: Schizophrenia patients resistant or intolerant to antipsychotic treatment were prospectively included between 2021 and 2024. CYP1A2, CYP2D6, CYP2C9, CYP2C19 and CYP3A4 were genotyped during hospital stay.

The following data were collected: sex, age, comorbidities, follow-up from first admission, study reason, hospitalizations, and side effects.

Results: A total of 21 patients (50.4% men) with a median age of 43.3 (IQR, 32.0-51.0) years and 2.3 comorbidities (IQR, 2.0-3.0) were included. They were administrated a median of 3.0 psychopharmacs/patient (range: 1-7 drugs), with 45% receiving 4 or more drugs.

Patients presented a therapeutic failure rate of 66.7% or intolerance in 33.3%. Median follow-ups were 16.1 and 1.4 years, before and after the genotyping, respectively.

Results justified therapeutic refractoriness in 52% of cases. PGx-informed prescribing resulted in dosage adjustment in 38.1% of patients, while 76.2% opted for antipsychotic switching. Non-responder patients had 2.7 (IQR, 1.0-4.0) psychiatric-hospitalizations per person from 2020 until pharmacogenetic analysis (mean length-of-stay: 95.8), compared to 0.36 (IQR, 0-1) psychiatric-hospitalizations per person after genotyping (mean length-of-stay: 32.0).

Preceding pharmacogenetic analysis, 14 patients (66.7%) had to discontinue antipsychotics due to side effects, especially risperidone and clozapine. After genotyping, only three patients (14.3%) presented side effects.

Conclusion: Our findings highlight pharmacogenetics' relevance in schizophrenia management, concerning efficacy and

safety. Longer-term follow-up and larger samples are warranted to reinforce our results.

Conflict of Interest: None declared

P18.088.C Hereditary causes of pediatric malignancies at Children's Clinical University Hospital: insights from WES implementation in diagnostics since 2022

Lauma Freimane[1], Dmitrijs Rots[1], Anna Janberga[1], Egija Berga Svitina[1], Līvija Bārdiņa[1], Gita Taurina[1], Rasa Insberga[1], Ieva Mičule[1], Santa Kursīte[1], Dace Enkure[1]

[1]Children's Clinical University Hospital, Riga

Background/Objectives: Pathogenic germline variants are identified in 8–10% of children with malignancies. The discovery of a genetic predisposition in a patient affected by a malignancy carries significant implications, impacting the patient's psychosocial well-being, family relationships, and influencing the type and intensity of treatment, as well as the risk of recurrence and secondary cancers.

Methods: We conducted germline exome sequencing with analysis of pediatric cancer panel with SNV and CNV for all pediatric hematological malignancies and solid malignancies diagnosed since 2022 in Latvia who consented for the analysis.

Results: Since 2022, a comprehensive analysis of germline predispositions was conducted for a total of 103 pediatric malignancies. The sample proportions for solid and hematological malignancies with germline predisposing variants were similar, accounting for 9.68% (6/62) and 9.52% (4/42), respectively. Notably, genetic findings of uncertain significance were identified in 6.8% of cases (n = 7). We confirmed Fanconi anemia in two patients due to compound heterozygous variants in *BRCA2* gene and two cases of Noonan syndrome due to pathogenic variants in *PTPN11* gene, also without prior suspicion for a monogenic condition. For hematological malignancies, germline variants were found in the *PTPN11* and *IKZF1* gene, as well as a CNV loss in 18p11.32p11.31. For solid pediatric malignancies, variants were found in the *BRCA2, RB1, PTEN, NF1* genes.

Conclusion: Germline cancer predisposition testing in pediatric patients is essential for establishing a precise diagnosis, explaining ~10% of cases. Our data shows that in 4 out of 10 cases, there were no suspicions for a genetic condition.

Conflict of Interest: None declared

P18.089.D Exploring the Interplay of Genetic Susceptibility, Lifestyle, and Clinical Factors in Cardiovascular Disease

Jeeeun Kim[1;2], Hyojin Pyun[1], Soo Ji Lee[1;3], Joohon Sung[1;3]

[1]Seoul National University, Graduate School of Public Health, Seoul, Korea, Rep. of South; [2]Procagen, R&D center, Gyeonggi-do, Korea, Rep. of South; [3]Seoul National University, Institute of Health & Environment, Seoul, Korea, Rep. of South

Background: Both genetic and lifestyle factors are known to be associated with cardiovascular disease (CVD). However, it is unclear whether the association between lifestyle and CVD risk depends on the individual's lipid-related genetic predisposition. This study investigates the complex relationships between genetic susceptibility to dyslipidemia, lifestyle behaviors, clinical risk factors, and CVD.

Methods: We analyzed a cohort of 72,239 individuals of East Asian descent (with 1931 CVD events) A genome-wide polygenic risk score, derived from over 6 million genetic variants, was used to estimate genetic predisposition to dyslipidemia Lifestyle was evaluated based on four modifiable components (diet, physical activity, drinking habit, smoking habit), while clinical risk factors were assessed using components of the metabolic syndrome.

Results: Participants with a high genetic risk for dyslipidemia are associated with an increased overall CVD risk, which individuals with a high genetic risk for dyslipidemia had a 35% higher risk of CVD compared to those with low genetic risk. Individuals with favorable lifestyles and metabolically healthy statuses demonstrated reduced risk of CVD events, regardless of their genetic susceptibility to dyslipidemia. Sex-specific interaction effects were also observed.

Conclusion: Adhering to a healthy lifestyle and maintaining metabolic health emerge as an important strategy for mitigating the risk of subsequent CVD beyond genetic predispositions for dyslipidemia. These findings highlight the importance of lifestyle modifications in CVD prevention, especially in individuals with genetic susceptibility to dyslipidemia.

Conflict of Interest: None declared

P18.090.B Elective genome screening, clinical experience in 1300 healthy individuals

Luis Izquierdo[1;1], Bibiana Palao[1], Miriam Leon[1], Elena Ordonez[2], Isabel Castilla[2], Mireia Lechuga[2], Maria Moreno[1], Irene Perea[1], Raquel Bernad[1], Enrique Fernandez[1], Nerea Lobato[1], Laura Garcia[2], Vincenzo Cirigliano[2]

[1]Veritas Intercontinental, Madrid, Spain; [2]Veritas Intercontinental, Barcelona, Spain

Background/Objectives: Elective genome sequencing (EGS) is the genome analysis of individuals without a medical indication. This screening strategy enables the study of actionable conditions with the goal of preventing. To provide clinical utility to this approach, all the variants found should be curated properly. We present the results of the first 1300 patients performed with the only EGS test available with clinical utility.

Methods: The test was performed in 1300 people after a medical consultation where myGenome (Veritas Intercontinental) test was prescribed. Extracted DNA from blood or saliva was sequenced at approximately 30X average coverage. Interpretation was performed with a proprietary genomic pipeline that analyzes 600 genes based on ACMG-SF list and ACOG recommendations, together with pharmacogenomics and multifactorial diseases. Clinical variants were curated by a team of expert geneticists.

Results: Clinically relevant genetic variants were identified in 21% of individuals. From all the variants detected, 18.5% are included in ACMG-SF v3.2 list. Divided by medical area, the variants were related to hemochromatosis (42.6%), hereditary cancer predisposition (26.6%), hereditary cardiovascular disease (12.8%) and other diseases (17.8%). Additionally, 64% patients were carriers of one or more recessive conditions, 87% presented risk alleles for multifactorial diseases and relevant pharmacogenomics associations were detected in 99% of the patients, 32% of them were severe gene-drug interactions.

Conclusion: The inclusion of EGS in the medical setting allows an effective identification of relevant genetic findings related to clinical diseases, carrier status, pharmacogenomics, and risk alleles, that provides an outstanding preventive approach for clinicians.

Grants: None significant to the purpose of this research.

Conflict of Interest: Luis Izquierdo full time, Bibiana Palao full-time, Miriam Leon full-time, Elena Ordonez full-time, Isabel Castilla full-time, Mireia Lechuga full-time, Maria Moreno full-time, Irene Perea full-time, Raquel Bernad full-time, Enrique Fernandez full-time, Nerea Lobato full-time, Laura Garcia full-time, Vincenzo Cirigliano full-time

P18.091.B Molecular biomarkers of risk and resilience in health from exposure to environmental stress: A systematic review

Carys Räsänen-Young[1], *Laura J. Smyth*[1], *Yogesh Gupta*[1], *Claire Hill, Frank Kee, Ruth Hunter*[1], *Bernadette McGuinness, Amy Jayne McKnight*[1]

[1]*Centre for Public Health, Queen's University Belfast, United Kingdom*

Background/Objectives: Environmental stress is associated with poor health outcomes. However, the underlying biological mechanisms mediating this relationship is poorly understood. This research aims to identify molecular biomarkers, including resilience markers, associated with environmental stressors and explore approaches to measure their relationship.

Methods: The electronic databases Medline, EMBASE, Scopus, Web of Science were searched for human studies, with an environmental exposure and a laboratory-derived molecular biomarker. Studies were screened using Covidence. Methodological rigour was assessed with Joanna Briggs criteria. A narrative review was conducted and meta-analysis on studies with similar data using R studio.

Results: 63,868 studies were identified; 1,313 studies passed criteria for the review.

21 molecular biomarkers were found associated with environmental exposures. Most, 655 studies, used DNA methylation. Cancer was the primary health outcome associated with any of the biomarkers and environmental stressors. Arsenic and tobacco smoke were the most measured exposures. Study characteristics varied with exposure. In genetic biomarkers, 128 studies looked at SNPs and socio-economic status, occupation, aromatic compounds, pesticides, and toxic elements. Many observations were found; 8 studies showed association of PON1 polymorphisms and pesticide level in blood, GSTT1 null genotype had an increased risk of hepatotoxicity in 5 studies from arsenic, benzene, or pesticides, 3 studies observed methylation in BDNF promoter sites and socio-economic status.

Conclusion: This systematic review provides evidence that may aid identifying vulnerable populations, support reasoning behind interventions, and improve understanding of the biological mechanisms underlying stress from the environment.

Grants: Science Foundation Ireland and the Department for the Economy, Northern Ireland Investigator Program Partnership Award (15/IA/3152); CRY is in receipt of PhD studentships from the NI Department for the Economy; UKRI Industrial Strategy Challenge Fund (ESRC, SBDRP, ES/V016075/), the US-Ireland R&D Partnership Programme by HSC R&D division (STL/5569/19) and UKRI (MRC MC_PC_20026).

P18.092.C Mendelian randomization and bayesian colocalization analysis implicate GP6 as a potential drug target for cardioembolic stroke in south Asians

Devendra Meena[1], *Siwei Wu*[1], *James Yarmolinsky*[1], *Dipender Gill*[1], *Alexander Smith*[1], *Marie-Joe Dib*[2], *Ganesh Chauhan*[3], *Anand Rohatgi*[4], *Abbas Dehghan*[1], *Ioanna Tzoulaki*[1]

[1]*Imperial College London White City Campus, Department of Epidemiology and Biostatistics, London, United Kingdom;* [2]*Hospital of the University of Pennsylvania, Division of Cardiovascular Medicine, Philadelphia, United States;* [3]*Rajendra Institute of Medical Sciences, Department of Genetics & Genomics, Ranchi, India;* [4]*UT Southwestern Medical Center, Department of Medicine, Division of Cardiology, Dallas, United States*

Background/Objectives: Circulating plasma proteins are clinically useful biomarkers for stroke risk. We examined the causal links between 2,922 plasma proteins and stroke risk using Mendelian randomisation in individuals of South Asian ancestry.

Methods: We obtained genetic instruments for plasma proteins from the UK Biobank (N = 920). GWAS summary data for strokes (N ≤ 11,312) were sourced from GIGASTROKE. Our primary approach involved the Wald ratio or inverse-variance weighted (IVW) methods, with statistical significance set at FDR < 0.1. Additionally, a Bayesian colocalization approach was applied to minimize bias from linkage disequilibrium.

Results: We found evidence of a potential causal effect of plasma glycoprotein VI (GP6) levels on cardioembolic stroke ($OR_{Wald\text{-}ratio} = 2.53$; 95% CI 1.59-4.03, $P = 9.2 \times 10^{-5}$, FDR = 0.059). Generalised MR accounting for correlated SNPs showed consistent direction of effect ($OR_{gIVW} = 2.21$; 95% CI 1.46-3.33, $P = 1.6 \times 10^{-4}$). Colocalization analysis indicated that plasma GP6 levels colocalize with cardioembolic stroke (posterior probability [PP] = 91.4%). Multi-trait colocalization showed that these two traits colocalize with *GP6* expression in the coronary artery and brain tissues (PP > 50%). The potential causal effect of GP6 on cardioembolic stroke was not significant in Europeans ($OR_{IVW} = 1.08$; 95% CI 0.93-1.26, P = 0.29).

Conclusion: Our joint MR and colocalization analyses suggest that genetically predicted GP6 is potentially causally associated with cardioembolic stroke risk in individuals of South Asian ancestry. Future MR studies with larger sample size for plasma GP6 levels should be implemented to further validate our findings.

P18.093.D Phenotypic variability of CADASIL cerebral angiopathy in the presence of the NOTCH3 p.R1231C mutation frequently observed in the European population

Louis Lambert[1], *Veronica Sandroni*[1;2], *Jessica Lebenberg*[1;3], *Teresa Nutile*[4], *Daniela Ruggiero*[4], *Dominique Hervé*[1;3], *Hervé Perdry*[5], *Elisabeth Tournier-Lasserve*[1;3;6], *Hugues Chabriat*[1;3;7], *Marina Ciullo*[4;8], **Anne-Louise Leutenegger**[1]

[1]*Inserm Université Paris Cité, NeuroDiderot, Paris, France;* [2]*APHP, Paris, France;* [3]*APHP, Translational Neurovascular Centre and CERVCO, Hôpital Lariboisière, Paris, France;* [4]*Institute of Genetics and Biophysics A. Buzzati-Traverso, CNR, Naples, Italy;* [5]*Université Paris Saclay, Inserm CESP, Villejuif, France;* [6]*APHP, Service de génétique moléculaire Neurovasculaire, Hôpital Saint-Louis, Paris, France;* [7]*Université Paris Cité, FHU Neuro-Vasc, Paris, France;* [8]*IRCCS Neuromed, Pozzilli, Italy*

Background/Objectives: CADASIL (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy) is a prevalent hereditary small cerebral vessel disease caused by mutations in the NOTCH3 gene. This study focused on the p.R1231C mutation, frequent in Europe and located in the EGFr 31 domain. The objective was to investigate the phenotypic variability associated with this mutation, as recent studies suggest severity differences based on the affected EGFr repeats (most severe for EGFr 1 to 6).

Methods: Clinical and imaging data were collected from two sources: a cohort of patients followed at CERVCO rare disease referral center in Lariboisière Hospital (LRB: EGFr1-6, N = 309; p.R1231C, N = 17) and an isolated population in southern Italy (ITA, N = 23).

Results: 1) In the LRB hospital cohort, after adjustment for age, sex and vascular risk factors (notably hypertension), no difference

was observed between EGFr1-6 and p.R1231C patients. 2) However, the p.R1231C cohort at LRB exhibited a notably more severe clinical and MRI phenotype compared to the ITA population, even with comparable vascular risk factors.

Conclusion: This suggests wide phenotypic variability associated with the p.R1231C mutation, influenced by patient recruitment mode and the presence of vascular risk factors. We are now looking for genetic risk factors associated with this variability.

P18.094.A Integrating genetic data in Trial Emulation: Exploring the potential of Polygenic Risk Scores

Jakob German[1;2], *Sarah Urbut*[2;3], *Anthony Philippakis*[2], *Andrea Ganna*[1;2]

[1]*Institute for Molecular Medicine Finland, Helsinki, Finland;* [2]*Broad Institute of MIT and Harvard, Cambridge, United States;* [3]*Massachusetts General Hospital, Boston, United States*

Background/Objectives: A central goal of pharmacogenomics is to use genetic information to identify individuals benefitting most from a pharmacological intervention. We investigate the utilization of polygenic-risk-scores (PRS) in trial-emulation designs using FinnGen (N = 429,191), a biobank-based study with comprehensively longitudinal drug purchases information from national registers.

Methods: We selected and emulated five trials. Two RCTs focused on T2D patients, three on cardiovascular diseases. We defined a list of eligibility criteria, specified a comprehensive list of confounding variables, and matched the cohorts using propensity-score matching to adjust for baseline confounding. 90 selected PRS were used to examine residual confounding. Average treatment effects were estimated using Cox-proportional-hazard-models.

Results: We achieved estimate agreement with the original RCT in all trials.

A trial-emulation approach results in reduced differences in PRS between treatment and control groups compared to a naïve approach (e.g. T2D-PRS; standardized-difference (SD) = 0.0042, p = 0.9089 vs SD = 0.0875, p = 8.75e-10). A genetically-informed causal framework identified residual confounding in the emulated trial. Using genome-wide-significant SNPs associated with BMI we demonstrated a causal relationship between BMI and both the outcome and treatment (beta = 0.0156, p = 3.27e-27 and beta = 0.0579, p = 8.20e-3) indicating residual confounding due to BMI. Investigations of the interaction between PRS for the trial outcome and the drug, aiming to identify subgroups with differential treatment response, showed no significance.

Conclusion: Our work highlights the importance of trial-emulation when studying genetic impact on differential treatment response in biobank studies, as genetic studies are not immune to traditional epidemiological bias. Furthermore, we showed how genetic information can be used to detect residual confounding in trial-emulation.

P18.095.B Genetic Determinants of Early Childhood Appetite and Their Impact on Obesity: a prospective study from the Norwegian Mother, Father, and Child cohort

Roya Karimi[1], *Jonas Sundfjord*[1], *Adina Lupu*[1], *Nicolas Bargas*[1], *Marc Vaudel*[1;2], *stefan johansson*[1;3]

[1]*Mohn Center for Diabetes Precision Medicine, Department of Clinical Science, University of Bergen, Bergen, Norway;* [2]*Department of Genetics and Bioinformatics, Norwegian Institute of Public Health, Oslo, Norway;* [3]*Department of Medical Genetics, Haukeland University Hospital, Bergen, Norway*

Background/Objectives: With global obesity rates rising, it's vital to explore the genetic underpinnings of early eating behaviors. This study aims to identify genetic variants affecting young children's appetite and their potential connection to childhood obesity.

Methods: This study utilized genome-wide association studies (GWAS) on three parental reports regarding their children's appetite including the child's eating adequacy and child's food fussiness. By applying genomic structural equation modeling (GenomicSEM) we quantified the genetic contributions to these three GWAS summary statistics, resulting in the construction of a latent variable that captures the essence of childhood appetite between 18 months and 3 years. We generated Polygenic Risk Scores (PRS) using LDpred2 from GenomicSEM results. Linear regression was then applied to assess the association between early appetite PRS and subsequent obesity risk in childhood.

Results: The GenomicSEM analyses show a slightly significant and moderate association between several genetic variants, most notably within the GLP1R gene and early childhood appetite. The other identified variants were linked with genes relevant to BMI and obesity. The genome-wide polygenic risk score accounted for 3 to 5% of the variance in BMI across timepoints from 18 months to 8 years old.

Conclusion: This research identifies genetic variations associated with early childhood appetite and their links with the risk of obesity, underscoring the genetic basis for early intervention strategies in the prevention of obesity.

Grant: This work was supported by the Research Council of Norway (grant #315599)), Helse Vest's Open Research Grant (grants #912250 and F-12144), and the Novo Nordisk Foundation (grant NNF19OC0057445)

Background/Objectives: Observational studies have identified associations between hematological traits and type-2 diabetes mellitus (T2D). However, it is difficult to infer causal effects due to the potential of confounding. Our study utilizes the Mendelian randomization (MR) approach to address the above limitation and investigate the causal effect of hematological traits such as white blood cell (WBC), platelets (PLT), and red blood cell (RBC) on T2D in individuals of African and European ancestry.

Methods: The cohorts included African and European ancestry participants in the Blood Cell consortium and the Million Veteran Program dataset. Using GWAS summary statistics, we applied Two-sample MR to estimate the causal relationship between hematological traits and T2D.

Results: In the main IVW MR estimates for the RBC genetically predicted mean corpuscular hemoglobin concentration (MCHC), mean corpuscular hemoglobin (MCH), and mean corpuscular volume (MCV) levels were associated with decreased risk of T2D in the African dataset. In the Europeans, MCH, MCHC, and MCV levels were also significantly associated with decreased risk of T2D, however, MCHC was not significant after correcting for multiple tests. For WBC traits, there was evidence of protective effects of total WBC count and neutrophil count (NEU) on T2D in the African Population. Contrary to our observation, there was no association of NEU, and WBC on T2D in European ancestry.

Conclusion: These consistent findings majorly support the causal association between hematological traits and T2D in the African and European populations. However, the contrasting result for the WBC might indicate potential population differences between these immune-related factors and T2D across distinct populations.

P18.097.D The role of *SLCO1B1*, *ABCG2*, *CYP2C9*, *CYP2C19* and *CYP2D6* in medication adherence and discontinuation: a biobank-scale analysis in 412,181 individuals.

Mattia Cordioli[1], *Andrea Corbetta[2], Hanna Kariis[3], Sakari Jukarainen[1], Pekka Vartiainen[1], Tuomo Kiiskinen[1], Matteo Ferro[1], FinnGen Consortium[1], Estonian Biobank research team[3], Kelli Lehto[3], Mikko Niemi[4], Samuli Ripatti[1], Lili Milani[3], Andrea Ganna[1]*

[1]Institute for Molecular Medicine Finland, Helsinki, Finland; [2]Human Technopole, Italy; [3]Estonian Genome Center, University of Tartu, Tartu, Estonia; [4]University of Helsinki, Helsinki, Finland

Background/Objectives: While numerous pharmacogenetic variants have been linked to altered drug metabolism or adverse drug reactions, their impact on patients medication-taking behaviors has not been studied in large populations. We investigated the role of notable pharmacogenes in medication adherence and discontinuation by leveraging genetic and drug purchase data from the FinnGen study (n = 412,181).

Methods: We focused on well-established drug-gene pairs, including *SLCO1B1*, *ABCG2*, *CYP2C9* for, respectively, statins (all types, $n = 115{,}369$), rosuvastatins ($n = 5116$) and fluvastatins ($n = 2407$); *CYP2C19* and clopidogrel ($n = 6400$); *CYP2D6* and tamoxifen ($n = 2028$). For each gene, we included star allele diplotypes with established prescribing recommendations and grouped them based on their metabolic activity profile. We defined adherence as the ratio of total purchased quantity to total days of purchasing, and discontinuation as either early (after one purchase) discontinuation, or within the first year. We tested the association between each pharmacogene metabolic activity profile and the three drug-taking phenotypes.

Results: The *CYP2D6* poor metabolizer profile showed a significant association with increased odds of early discontinuation of tamoxifen (OR = 3.36 (1.36 - 8.29), $P = 0.009$), but not with 1-year discontinuation and adherence. No significant association was observed for the other pharmacogenes and the three drug-taking behaviors.

Conclusion: These findings suggest a marginal role of pharmacogenetic variants on drug adherence and discontinuation, with the exception of tamoxifen. Patients with a *CYP2D6* poor metabolizer profile showed increased risk of discontinuation and might benefit from preemptive pharmacogenetic testing in assessing a personalized treatment alternative before initiation.

P18.098.A Modifiable pathways and epigenetic markers for the effects of childhood maltreatment on psychiatric disorders: Mendelian randomization study

Nicole Ying Ting Ng[1], *Jie V. Zhao[2], John Yen Tang[1], Martin Man Chun Chui[1], Christopher Chun Yu Mak[1], Brian Hon Yin Chung[1]*

[1]The University of Hong Kong (HKU), Department of Paediatrics and Adolescent Medicine, Hong Kong; [2]The University of Hong Kong (HKU), School of Public Health, Hong Kong

Background/Objectives: Childhood maltreatment (CM) is associated with increased risks of psychiatric disorders later in life. It is important to understand the mediating pathways for intervention. This Mendelian randomization (MR) study aims to confirm the relationship between CM and psychiatric disorders, explore the causal role of mediators, and identify the potential influence of DNA methylation (DNAm).

Methods: Two-Sample MR using summary data from European ancestry was performed to evaluate the causal effect of genetically predicted CM (n = 143,473) on the risk of different psychiatric disorders. Two-step, multivariable MR, and epigenetic MR were conducted to identify mediators of the relationship.

Results: CM was significantly associated with higher risk of attention-deficit/hyperactivity disorder (ADHD) (OR, 95% CI: 10.09, 4.76-21.40), major depressive disorder (MDD) (OR, 95% CI: 1.89, 1.32-2.70) and schizophrenia (OR, 95% CI: 5.89, 1.46-23.78). These relationships were mediated by addiction-related, cognitive, and socioeconomic traits. Following adjustment for all significant mediators, the direct effect of CM on ADHD attenuated substantially (OR, 95% CI: 2.39, 1.64-3.48), while the direct effect of CM on schizophrenia was slightly reduced (OR, 95% CI: 5.10, 2.71-9.60). Contrastingly, direct effect on MDD remained unchanged despite adjusting for mediators. DNAm levels at 11 unique CM-associated CpG sites were associated with psychiatric disorders.

Conclusion: This study provides novel insights into the mediators and biological markers between CM and psychiatric disorders in later life. Multi-modal preventative and responsive interventions are required to reduce CM prevalence and its long-term consequences.

P18.099.B MR-link-2: pleiotropy robust *cis* Mendelian randomization validated in four independent gold-standard datasets of causality provides human evidence for hypomyelating leukodystrophy-10

Adriaan van der Graaf[1], *Robert Warmerdam*[2], *Chiara Auwerx*[1;3], *Urmo Võsa*[4], *Carolina Borges*[5;6], *Lude Franke*[2;7], *Zoltan Kutalik*[1]

[1]*University of Lausanne, Department of Computational Biology, Ecublens, Switzerland;* [2]*University Medical Center Groningen, Department of Genetics, Groningen, Netherlands;* [3]*University of Lausanne, Center for Integrative Genomics, Ecublens, Switzerland;* [4]*University of Tartu, Estonian Genome Center, Tartu, Estonia;* [5]*University of Bristol, MRC Integrative Epidemiology Unit, Bristol, United Kingdom;* [6]*University of Bristol, Population Health Services, Bristol, United Kingdom;* [7]*Oncode Institute, Utrecht, Netherlands*

Consortium: eQTLGen Consortium

Background/Objectives: Mendelian randomization (MR) can identify causality from observational data but has increased type 1 error rates (T1Es) due to pleiotropy. In molecular exposures usually a single associated region is available making it difficult to address pleiotropy. We develop a pleiotropy robust *cis* MR method and test it on novel ground truth datasets.

Methods: We developed MR-link-2, an MR method using summary statistics and linkage disequilibrium information to estimate causality and pleiotropy from single associated regions. We compare MR-link-2 to 5 other *cis* MR and coloc methods in three validation datasets: i) Causality between 266 metabolites and 287 reactions from 4 studies and 3 pathway databases ii) canonical causality between 13 complex traits and iii) causality between 12 cell types and 93 of their marker genes.

Results: Metabolite analysis: MR-link-2 has superior area under the receiver operator characteristic curve (AUC) (max 0.80) compared to other methods. MR-link-2 has better precision across comparisons (up to 51-98% relative precision for others), alignment with *le Chatelliers* principle is 80% (max 63% for others). MR-link-2 exclusively identifies the causal link for hypomyelinating leukodystrophy-10 between glycine and pyrroline-5-carboxylate, previously only found in model systems. In complex traits, MR-link-2 has lower T1Es (0.09 vs 0.15, expectation: 0.05) and lower heterogeneity (Q statistic 583 vs min 1359). Testing for forward and reverse causality of blood cell type composition and expression of marker genes shows MR-link-2 has superior AUC 0.90 (best competing: 0.67).

Conclusion: In 3 human validation datasets, MR-link-2 is ideally suited for molecular phenotypes. Exhibiting good T1Es and superior AUC.

Background/Objectives: Acute respiratory distress syndrome (ARDS) commonly develops by sepsis. A genome-wide association study (GWAS) linked vascular endothelial growth factor pathway genes (*VEGFA* and *VEGFR1*) to post-sepsis ARDS risk. To infer the causal effect of VEGFA and VEGFR1 circulating levels in ARDS, we performed two-sample bidirectional Mendelian randomisation.

Methods: We evaluated the causal effect using inverse variance-weighted (IVW) estimates and performed sensitivity analyses with five other methods, based on strong (F-stat>10) instrumental variables (IV) that met genome-wide significance ($p < 5e\text{-}8$) in GWAS of VEGFA and VEGFR1 circulating protein levels, separately (UK Biobank, N = 46,836). For the opposite direction, we selected strong IVs reaching $p < 5e\text{-}6$ in post-sepsis ARDS GWAS. We evaluated absence of pleiotropy and outliers and performed MR-RAPS using weaker instruments (GWAS $p < 0.05$).

Results: We found no evidence to suggest that either VEGFA ($p_{IVW} = 0.992$) or VEGFR1 ($p_{IVW} = 0.924$) have a significant causal effect on ARDS risk. There was no evidence suggesting that ARDS has a causal effect on either VEGFA ($p_{IVW} = 0.487$) or VEGFR1 ($p_{IVW} = 0.168$) levels.

Conclusion: Our results do not support causality between circulating VEGFA and VEGFR1 levels and the development of post-sepsis ARDS. Further analyses are required to understand VEGF regulation in patients in acute phase and its role in ARDS causality.

Background/Objectives: New diagnostic criteria for *NF2*-related schwannomatosis (NF2) have been published (Genet Med. 2022). An updated UK prevalence has been generated with an emphasis on the rate of de novo NF2 (50% rate is widely quoted).

Methods: The UK National NF2 database identifies patients meeting updated NF2 criteria from a highly ascertained population cared through England's specialised service. Diagnostic prevalence was assessed on 01/02/2023.

Results: 1082 living NF2 patients were identified on prevalence day (equivalent to 1 in 61,445). The tables detail the rates of de novo, familial and mosaic NF2. The proportion with inherited NF2 from an affected parent was only 23% in England. If those without a confirmed molecular diagnosis or bilateral vestibular schwannoma (BVS) are excluded, the rate of de novo NF2 remains high (72%).

	Population (millions)	NF2 patients living	Prevalence per 1000	1 in x	Hetero-zygotes	Familial	%familial of total living
England	56.00	960	0.01714	58331	415	222	23.1
Wales	3.14	50	0.01594	62720	22	12	24.0
Scotland	5.45	51	0.00936	106863	21	6	11.8
N Ireland	1.90	21	0.01105	90476	14	5	23.8
Total	66.48	1082	0.01627	61445	472	245	22.6

	de novo	Mosaic	%mosaic of de novo	Heterozygote, proven mosaic, or BVS	% familial
England	738	204	27.6	787	28.2
Wales	38	9	23.7	44	27.3
Scotland	37	14	37.8	43	14.0
N Ireland	16	3	18.8	21	23.8
Total	829	230	27.7	895	27.4

Conclusion: This work confirms a higher rate of de novo NF2 than previously reported, and highlights the benefits of maintaining patient databases for accurate counselling.

P18.102.A Incorporating genetic and clinical predictors for antidepressant side effects in the Genetic Link of Anxiety and Depression Study

Danyang Li[1], *Yuhao Lin*[1], *Helena Davies*[1], *Gerome Breen*[1]

[1]*Social Genetic and Developmental Psychiatry Centre, United Kingdom*

Background/Objective: Antidepressants are the most common treatment for moderate or severe depression. Side effects are crucial indicators for antidepressants, but their expression varies widely among individuals.

Methods: In this study, we leveraged deep phenotyped data from self-reported questionnaires in the Genetic Link of Anxiety and Depression (GLAD) study to predict side effects and discontinuation across three antidepressant classes (SSRI, SNRI, tricyclic antidepressants (TCA)) at the first and the last (most recent) year. Over 260 predictors spanning genetic, clinical, comorbidity, demographic, and drug information were included. XGBoost, random forest, cubist, elastic net, and support vector machine (RBF and polynomial kernel) were trained and their performance were compared.

Results: The final dataset comprised 5358 individuals, with 4354 in the first and 3414 in the last prescription. The average prevalence of side effects and discontinuation was 74.1% and 28.7%, respectively. In the initial year, the best AUROC for predicting SSRI discontinuation and side effects were 0.66 and 0.60. In the last year of SSRI prescription, the highest AUROC reached 0.72 for discontinuation and 0.87 for side effects. Models for predicting discontinuation and side effects of SNRI and TCA showed comparable performance. The history of side effects and discontinuation in antidepressant use were the most influential predictors for the outcomes.

Conclusion: Our findings demonstrate the feasibility of predicting antidepressant side effects using self-reported questionnaire, particularly for the last prescription. These results contribute valuable insights for the development of clinical decisions aimed at optimizing treatment selection with enhanced tolerability.

University of Tartu, Tartu, Estonia; [4]Institute of Computer Science, University of Tartu, Tartu, Estonia; [5]Institute of Mathematics and Statistics, University of Tartu, Tartu, Estonia

Background/Objectives: Schizophrenia (SCZ) patients exhibit 30% higher prevalence of metabolic syndrome (MetS) compared to the general population with its suboptimal management contributing to increased mortality. Large-scale studies providing real-world evidence of the underlying causes remain limited.

Methods: To address this gap, we used real-world health data from the Estonian Biobank, spanning a median follow-up of ten years, to investigate the impact of genetic predisposition and antipsychotic treatment on the development of MetS in SCZ patients. Specifically, we set out to characterize antipsychotic treatment patterns, genetic predisposition of MetS traits, MetS prognosis, and body mass index (BMI) trajectories, comparing SCZ cases (n = 677) to age- and sex-matched controls (n = 2,708).

Results: SCZ cases exhibited higher genetic predisposition to SCZ (OR = 1·75, 95%CI 1·58–1·94), but lower polygenic burden for increased BMI (OR = 0·88, 95%CI 0·88–0·96) and C-reactive protein (OR = 0·88, 95%CI 0·81–0·97) compared to controls. While SCZ cases showed worse prognosis of MetS (HR 1·95, 95%CI 1·54–2·46), higher antipsychotic adherence within the first treatment year was associated with reduced long-term MetS incidence. Linear mixed modelling, incorporating multiple BMI timepoints, underscored the significant contribution of both, antipsychotic medication, and genetic predisposition to higher BMI, driving the substantially upward trajectory of BMI in SCZ cases.

Conclusion: These findings contribute to refining clinical risk prediction and prevention strategies for MetS among SCZ patients and emphasize the significance of incorporating genetic information, long-term patient tracking, and employing diverse perspectives when analyzing real-world health data.

P18.104.C Discovery of core genes for systemic lupus erythematosus via genome-wide aggregation of trans-effects.

*Andrii Iakovliev[1], **Buddhiprabha Erabadda**[2], Olivia Castellini-Pérez[3], Marta E Alarcón-Riquelme[3], Elena Carnero-Montoro[3], Paul McKeigue[2], Athina Spiliopoulou[2]*

[1]University of Edinburgh, Institute of Genetics and Cancer, United Kingdom; [2]University of Edinburgh, Usher Institute, United Kingdom; [3]Pfizer-University of Granada-Junta de Andalucía Centre for Genomics and Oncological Research, Spain

Background/Objectives: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by upregulation of Type 1 interferon signaling and B-cell mediated autoimmunity. We test whether the genetic architecture of SLE fits an "omnigenic" sparse effector model and identify "core" effector genes using genome-wide aggregated *trans*-effects (GATE) analysis.

Methods: We used eQTLs from eQTLGen and pQTLs from deCODE and UKB-PPP to compute GATE scores in a case-control GWAS of SLE (5267/4909 cases/controls). We identified putative core genes based on strength of association of the GATE score with SLE, the effective number of *trans*-QTLs contributing to the score, and the specificity of the association (lack of correlation with scores for other genes).

Results: We detected a cluster of 11 co-regulated Type 1 interferon-stimulated genes (ISGs) strongly associated with SLE, one of which [*ISG15* (Log OR = 0.1, $P = 1 \times 10^{-6}$)] is a monogenic cause of lupus. From pQTL analyses, 12 putative core genes were identified at P value $< 10^{-6}$ including two of the three receptors that recognise B-cell activating factor (BAFF), *TNFRSF17*, *TNFRSF13B*, and two genes encoding immune checkpoints, *PDCD1*, *CD27*.

Conclusion: Our results suggest that SLE is associated with genetic upregulation of basal Type 1 interferon signaling. Core genes detected through our pQTL-GATE analysis are promising drug targets. BAFF is the only specific drug target for SLE, with a BAFF-inhibitor approved for its treatment. PD-1, encoded by *PDCD1*, is an attractive target for drug repositioning, with PD-1 agonists recently passing a Phase2 trial for refractory rheumatoid arthritis.

P18.105.D Pharmacogemomic Landscape of TNF Inhibitors in the Middle Eastern Qatari Population

Zainab Jan[1], *Dinesh Velayutham[1], Borbala Mifsud[1], Puthen Veettil Jithesh[1]*

[1]Hamad Bin Khalifa University (HBKU), College of Health and Life Sciences, Ar Rayyan, Qatar

Background/Objectives: Autoimmune diseases are one of the leading causes of mortality and morbidity worldwide with a substantial economic burden. Tumor necrosis factor alpha (TNF-α) is an important cytokine that frequently contributes to the pathogenicity of autoimmune diseases and hence TNF inhibitors (TNFi) are widely used to treat several autoimmune diseases. However, 40% of the patients do not respond positively when treated with TNFi. Several pharmacogenomic variants affecting TNFi response have been identified. However, the prevalence of these variants in the Qatari population is still not known.

Methods: The distribution of known and novel variants in 116 genes associated with TNF inhibitors in 14,387 Qatari individuals was assessed using whole genome sequencing data. We calculated the cumulative allele probability score (CAP) to measure the risk of an individual in the population having functional variants in a particular gene.

Results: Out of the 176 known pharmacogenomic variants associated with response to TNF inhibitors, the majority (~90%) had different allele frequency distribution in the Qatari population compared to other world populations from the gnomAD dataset. High frequency of rs1800629 (TNF), rs1800896 (*IL10)*, and rs1143634 (*IL1B)* variants were observed, which are known to be associated with responses to etanercept and infliximab. Moreover, we identified that *CR1* and *GBP6* have the highest CAP scores that are associated with response to multi-TNF inhibitors.

Conclusion: The findings of this study could be the basis for developing and implementing pharmacogenetic testing in autoimmune disease patients being considered for TNF inhibitor therapy in Qatar and beyond.

P19
POPULATION GENETICS AND EVOLUTIONARY GENETICS

P19.001.A Genetic study of intrahepatic cholestasis of pregnancy in 101,023 Chinese women unveils East Asian-specific etiology linked to historic HBV infection

Yanhong Liu[1], *Yuandan Wei*[1], *yuqin Gu*[1], *Zijing Yang*[1], *Xinxin Guo*[1], *Hao Zheng*[1], *Siyang Liu*[1]

[1]*Sun Yat-sen University, School of Public Health (Shenzhen), Shenzhen*

Background/Objectives: Intrahepatic cholestasis of pregnancy (ICP) is the most common and high-risk liver disorder during human reproduction. This study delves into ICP genetic etiology in East Asians, drawing comparisons with Europeans to comprehend ICP etiology in the context of genetic background and evolution.

Methods: We conducted the hitherto largest-scale genome-wide association studies (GWAS) on total bile acid (TBA) and ICP among 101,023 Chinese pregnancies. Findings were replicated in two cohorts and compared with Europeans. Additionally, phenome-wide association and spatio-temporal evolution analyses were employed to understand the function and evolutionary pattern of ICP-associated sites.

Results: We identified eight TBA and five ICP loci, including ten novel loci. Notably, we found an East-Asian-specific genetic locus at 14q24.1, contributing to a 6.41 μmol/L increase in TBA and 15.23-fold higher risk of ICP per risk allele (95%*CI*: 15.10-15.36, $P = 9.23 \times 10^{-375}$). Phenome-wide association and spatial-temporal evolution analyses revealed that 14q24.1 ICP risk locus exhibits resistance to hepatitis B infection and became prevalent only within the last 3,000 years in East and Southeast Asia.

Conclusion: Our investigations unraveled distinct ICP etiology between Europeans and East Asians, and linked it with a historical HBV epidemic in East and Southeast Asia. These findings lay the groundwork for an improved understanding of ICP pathophysiology and emphasize the need for integrating population evolution into genetic medicine for personalized genomics and clinical guidance.

Demirdas*[1]

[1]*Erasmus MC, University Medical Center, Department of Clinical Genetics, Rotterdam, Netherlands;* [2]*Amsterdam UMC, University of Amsterdam, Department of Human genetics, Amsterdam, Netherlands;* [3]*University Medical Center Utrecht, Department of Genetics, Utrecht, Netherlands;* [4]*University Medical Center Groningen, Department of Genetics, Groningen, Netherlands;* [5]*Maastricht University Medical Center, Department of Clinical Genetics, Maastricht, Netherlands;* [6]*Leiden University Medical Center, Department of Clinical Genetics, Leiden, Netherlands;* [7]*Erasmus MC, University Medical Center, Department of Cardiology, Rotterdam, Netherlands;* [8]*Radboud University Nijmegen Medical Center, Department of Human genetics, Nijmegen, Netherlands;* [9]*Vrije Universiteit Amsterdam, Department of Obstetrics, Amsterdam, Netherlands*

Background/Objectives: Pathogenic/ likely pathogenic (P/LP) variants in *COL3A1* cause vascular Ehlers Danlos Syndrome (vEDS). Women with vEDS have an increased risk for pregnancy and delivery related complications.

Description of the genotype and pregnancy-related outcomes of women with vEDS can contribute to establish guidelines for pregnancy and delivery management.

Methods: Female patients with a P/LP *COL3A1* variant were included in a multicentre cohort study from 2019 until 2021. Comprehensive genetic and clinical data was collected through retrospective analysis.

Results: Forty-three women with 121 pregnancies were included (53.5% with a glycine substitution, 20.9% with a haploinsufficient variant and 25.6% with a splice/delins/del variant). No uterine rupture or life threatening vascular events occurred in the perinatal period. Twenty-three pregnancies (23/121, 19.0%) ended in a miscarriage. Miscarriages were significantly more frequent in women with a glycine substitution compared to other *COL3A1* variant types (19/23, 82.6%, $p = 0.018$). Over ten percent of the women (13.8%) had a spontaneous preterm birth. Complications occurred in 14/94 deliveries (14.9%), including eight severe perineal tears and six postpartum haemorrhage.

Conclusions: No pregnancy-related deaths, arterial dissections or uterine ruptures occurred in our cohort. Severe perineal tears were seen ten times more often in our cohort compared to the general population. Miscarriage, spontaneous preterm births and preterm pre-labour rupture of membranes occurred twice as often compared to the general population. Since no life threatening events occurred during pregnancy and delivery, discouragement of pregnancy in all women with vEDS in current guidelines might be too strict. Based on these data, we propose a shared decision making process.

P19.003.C Evolutionary insights from a population database: Limited consequences of archaic protein-altering variants in present-day humans

Barbara Molz[1], *Mikel Lana Alberro*[2], *Else Eising*[1], *Dick Schijven*[1], *Clyde Francks*[1,3,4], *Simon E. Fisher*[1,4]

[1]*Max Planck Institute for Psycholinguistics, Language & Genetics Department, Nijmegen, Netherlands;* [2]*Max Planck Institute for Evolutionary Anthropology, Department of Evolutionary Genetics, Leipzig, Germany;* [3]*Radboud University Medical Center, Department of Cognitive Neuroscience, Nijmegen, Netherlands;* [4]*Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands*

Background/Objectives: The sequencing of archaic hominin genomes allowed the use of comparative approaches to assemble a catalogue of protein-altering changes that apparently became fixed on the lineage leading to *Homo sapiens*. These fixed changes have been seen as promising entry-points to further understanding of human-specific aspects of our biology. While prior experimental validation of such variants has been limited to in vitro assays and model organisms, large population databases now offer the unique opportunity to identify possible present-day

carriers of archaic variants at supposedly fixed sites, and examine their phenotypic consequences.

Methods: We used exome sequencing data of nearly 500,000 people in UK Biobank to identify carriers of 43 archaic protein-altering variants, including a variant in *TKTL1* for which substantial effects on cortical neurogenesis have been demonstrated in functional experiments. We contrasted phenotypic profiles of carriers with the sample norm.

Results: This study identified 165 unique carriers of archaic variants at 18 of the 43 interrogated positions, of whom 62 carriers could be attributed to *TKTL1*. A qualitative phenotypic analysis of an archaic variant in *SSH2* showed no divergence from the sample norm in health, psychological, or cognitive traits. A similar pattern was observable for brain imaging metrics and educational level for carriers of the archaic variant in *TKTL1*.

Conclusion: Our results highlight the importance of large, diverse databases to most accurately capture the genetic diversity in present-day humans, and suggest that experimental validation in cell-based/animal model systems is not by itself sufficient to fully capture the biological and evolutionary roles of putative fixed variants.

P19.004.D Validation of diagnostic rare pathogenic variants in 5 breast cancer genes by GSAMD and PMDA array platforms.

Jeroen van Rooij[1], Jard de Vries[1], Ans van de Ouweland[2], Maartje J Hooning[3], Linda Broer[1], Willemina Geurts-Giele[2], Robert van der Helm[2], Marieke van Dooren[2], Margriet Collée[2], Lies Hoefsloot[2], Joyce Van Meurs[1;4], André Uitterlinden[1], **Annemieke Verkerk**[1]

[1]Erasmus Medical Center, Internal Medicine, Rotterdam, Netherlands; [2]Erasmus Medical Center, Clinical genetics, Rotterdam, Netherlands; [3]Erasmus Medical Center Cancer Institute, Oncology, Rotterdam, Netherlands; [4]Erasmus Medical Center, Orthopedics, Rotterdam, Netherlands

Background/Objectives: At the Erasmus Medical Center we initiated the GOALL project (Genotyping On All Patients), in which we investigate the use of high throughput SNP arrays for improving clinical care and making personalized medicine available to a larger public. In this pilot we compared the performance of array-based genotyping with previously clinically determined pathogenic variants, for 240 breast cancer cases. The diagnostic results were based on Sanger sequencing (SNVs and indels ≤ 50 bp) for the genes BRCA1, BRCA2, CHEK2, PALB2 and ATM and/or MLPA (deletions or duplications > 50 bp) for BRCA1/BRCA2.

Methods: Carriers were selected with pathogenic variants that were present on the Illumina GSAMDv3 and/or Thermofischer PMDA arrays and then genotyped. After data processing and QC, samples were called, in a blinded fashion, for SNVs and indels, using the manufacturer's software, and analyzed by PENNCNV and NEXUS (Biodiscovery) to assess copy number variations (> 50 bp).

Results: Using standard processing in combination with zCall and manual reclustering for SNVs and indels, and specific QC tresholds for CNV calling, 98% of the diagnostic SNV and indels, and 90% of CNVs, were confirmed by array. Five false positive SNVs or indels, and four false positive CNVs were detected.

Conclusion: We demonstrate a high sensitivity and specificity for detection of rare pathogenic variants by genotyping array in 5 breast cancer genes. We conclude that arrays are a low cost and effective way to screen for pathogenic variants in larger populations.

Grants: Internal Koers23 program from the Erasmus Medical Center (project-no.109433).

P19.005.A Denisovan admixture facilitated environmental adaptation in Papua New Guinean populations

Danat Yermakovich[1], *Mathilde André[1], Nicolas Brucato[2], Jason Kariwiga[3;4], Matthew Leavesley[3;5], Vasili Pankratov[1], Mayukh Mondal[1;6], Francois-Xavier Ricaut[2], Michael Dannemann[1]*

[1]Institute of Genomics, University of Tartu, cGEM, Tartu, Estonia; [2]Paul Sabatier University, Centre de Recherche sur la Biodiversité et l'Environnement, Toulouse, France; [3]The University of Papua New Guinea, Strand of Anthropology, Sociology and Archaeology, School of Humanities and Social Sciences, Port Moresby, Papua New Guinea; [4]The University of Queensland, School of Social Science, Saint Lucia, Australia; [5]James Cook University, Brisbane Campus, CABAH & College of Arts, Society and Education, Brisbane City, Australia; [6]University of Kiel, Institute of Clinical Molecular Biology, Kiel, Germany

Background/Objectives: As a result of past admixture between modern and archaic human groups, present-day Papua New Guineans (PNG) carry both Neandertal and Denisovan introgressed DNA. In this work, we investigate the distribution of archaic DNA within the genomes of two PNG populations residing in the highlands and lowlands of the region and how it contributed to adaptive processes to the unique environmental features these populations were exposed to.

Methods: We annotated Neandertal and Denisovan DNA in the genomes of 74 PNG from the lowlands of Daru Island and 54 highlanders from the Mt Wilhelm region. Then, we assessed the level of population differentiation for archaic segments between both PNG populations and compared them to those of random non-archaic sets of SNPs. Finally, we investigated genomic regions overlapping the most differentiated archaic haplotypes for their gene content and variants with phenotypic associations.

Results: We show that highly differentiated Denisovan-like haplotypes, more prevalent among PNG highlanders, were situated in genomic regions associated with brain development genes. Conversely, those with a higher frequency in lowlanders overlapped with genes enriched for immune response processes. Furthermore, Denisovan-like haplotypes displayed pronounced signatures of diversification within the major histocompatibility complex.

Conclusion: Our study suggests that the presence of Denisovan DNA in PNG genomes has contributed to adaptive processes to environmental challenges and served as a beneficial source of genetic variation.

P19.006.B Distinct genetic profiles influence body mass index between infancy and adolescence

Geng Wang[1], *Samuel McEwan[1], Jian Zeng[1], Mekonnen Haile-Mariam[2], Loic Yengo[1], Michael Goddard[2;3], Kathryn Kemper[1], Nicole Warrington[1;4]*

[1]The University of Queensland, Institute for Molecular Bioscience, Saint Lucia, Australia; [2]Agriculture Victoria, AgriBio, Centre for AgriBioscience, Bundoora, Australia; [3]The University of Melbourne, Faculty of Science, Parkville, Australia; [4]The University of Queensland, Frazer Institute, Saint Lucia, Australia

Background/Objectives: Body mass index (BMI) changes throughout life with age-varying genetic contributions. We aimed to investigate the genetic contribution to BMI across early life using repeated measures from the Avon Longitudinal Study of Parents and Children (ALSPAC) cohort.

Methods: Random regression was used to estimate the genetic covariance matrix (G) of the BMI trajectory from ages one to 18 with 65,930 repeated BMI measurements from 6,291 genotyped ALSPAC participants. We estimated genetic correlations across early life and performed an eigenvalue decomposition of G analysis to identify age-varying genetic patterns of BMI. Finally, we investigated the impact of a polygenic score derived from adult BMI associated loci in the UK Biobank on the estimated genetic components across early life.

Results: The SNP-based heritability (h_{SNP}^2) was relatively constant across early life, between 25-30%. The genetic contribution to BMI in early childhood is different to that in later childhood, indicated by the genetic correlations of BMI across different ages. The eigenvalue decomposition revealed that the primary axis of variation (explaining 89% of G) consistently increases with age, while the second eigenfunction (explaining around 9% of G) represents factors with opposing impacts on BMI between early and later ages. Adjusting for the adult BMI polygenic score attenuated the h_{SNP}^2 from late childhood.

Conclusion: Although common genetic variation explains around 25-30% of BMI variability across early life, our findings indicate that there is a different genetic profile operating during infancy than later childhood.

P19.008.D Evolutionary and expression analyses of *ATXN3* paralogs in primates support the functional relevance of *ATXN3L* retrocopy

Daniela Felício[1;2;3], *Maria Inês Martins*[2], *Andreia Pinto*[2], *Inês P. D. Costa*[1;2], *António Amorim*[1;2;4], *Alexandra Lopes*[1;2], *Susana Seixas*[1;2], *Sandra Martins*[1;2]

[1]*Instituto de Investigação e Inovação em Saúde (i3S), Porto, Portugal;* [2]*Institute of Molecular Pathology and Immunology of the University of Porto (IPATIMUP), Porto, Portugal;* [3]*Instituto Ciências Biomédicas Abel Salazar (ICBAS), University of Porto, Porto, Portugal;* [4]*Dep. Biology, Faculty of Sciences, University of Porto, Porto, Portugal*

Background/Objectives: Ataxin-3 gene (*ATXN3*; 14q32.1) encodes a ubiquitously expressed deubiquitinating enzyme that presents a polyglutamine tract, responsible for Machado-Joseph disease (MJD/SCA3 - spinocerebellar ataxia type 3) when expanded in humans. An *ATXN3* paralog called ataxin-3 like (*ATXN3L*; Xp22.2) encodes a protein shown to cleave ubiquitin substrates in vitro more efficiently than ATXN3. Previous studies on another polyglutamine disease, SCA1, demonstrated that *ATXN1* copy (*ATXN1L*) alleviated the neuropathology in mice. Thus, it is of upmost importance to understand whether *ATXN3* copies can have a role in MJD.

Methods: To identify and explore *ATXN3* copies, we retrieved highly homologous sequences from 33 primates and analysed their diversity, local synteny and selective constraints in reconstructed phylogenies. Additionally, due to *ATXN3L* conserved reading frame, we analysed protein domain conservation and mRNA expression by qPCR.

Results: Our results suggested three independent retrotransposition events: 1) in Haplorrhini (~70 MYA) for *ATXN3L*; 2) in a Platyrrhini-Catarrhini ancestor (~45 MYA) for *ATXN3L2* (LOC100132280; 8q23.2 in human); and 3) in Cercopithecidae (~20 MYA) for *ATXN3L3* (LOC699321; chr11 in Rhesus monkey). *ATXN3L* seems to be under selective constraints throughout primate evolution like the parental gene, whereas *ATXN3L2* and *ATXN3L3* are likely turning into inactive copies. Finally, we detected *ATXN3L* expression in human spleen, placenta, testis, and cerebral cortex.

Conclusion: Phylogenetic analyses support the functional relevance of *ATXN3L*, but further functional studies will be crucial to assess ATXN3L importance in MJD.

Grants: This work was supported by Fundação para a Ciência e a Technologia (FCT) - 2022.04896.PTDC; UI/BD/154402/2023 (DF), and CEECIND/00684/2017 (SM).

Background/Objectives: Primary cutaneous amyloidosis (PCA) is a skin disorder and the clinical characteristic is amyloid deposited in the dermis. PCA has been commonly observed in Asian population, especially in Chinese descent. Mutations of *OSMR* and *IL31RA* genes have been identified in PCA families. In this study, we investigated the genome sequences of in a cohort of PCA patients in Taiwan and compared the *OSMR* genetic variants with other populations.

Methods: The genomic sequence of 91 PCA patients were conducted by whole exome sequencing and the whole genome genotyping data of 37,770 individuals were obtained from the Taipei Veterans General Hospital (TVGH) of Taiwan Precision Medicine Initiative (TPMI) in Taiwan (TVGH-TPMI). The *OSMR* genetic variants were investigated in different countries and ethnicities using our PCA data and public databases.

Results: A variant of *OSMR*, p.G513D was found in 24.18% (22/91) of the PCA cohort, as compared to 2.61% (39/1495) in the control group from Taiwan Biobank. The *OSMR* p.G513D variant was observed in 2.5% of TVGH-TPMI individuals and three out of seven individuals (42.86%) were homozygous who were diagnosed clinically as having PCA ($p = 0.0001$). This *OSMR* p.G513D variant had a highly variable frequency in various different human populations which is consistent with the high incidence rate of PCA in East Asians.

Conclusion: We identified the *OSMR* p.G513D in individuals of Chinese descent that predisposes to PCA and this common variant is an important cause of high incidence of PCA in East Asians.

P19.010.B TP53 c.542G>A identified as a Swedish founder variant with a risk of predominantly breast cancer

Alexander Sun-Zhang[1], *Meis Omran*[1;2], *Yaxuan Liu*[1], *Emma Tham*[1;3], *Svetlana Bajlica Lagercrantz*[1;3]

[1]*Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden;* [2]*Karolinska University Hospital, Cancer Theme, Stockholm;* [3]*Karolinska University Hospital, Department of Clinical Genetics, Stockholm*

Consortium: Swedish Clinical TP53 Study Group (SweClinTP53)

Background/Objectives: Heritable *TP53*-related cancer syndrome (h*TP53*rc) is a cancer predisposition syndrome caused by germline *TP53* alterations. The genotype-phenotype correlation is used to guide genetic counseling and surveillance. In the first nationwide delineation of the Swedish h*TP53*rc-cohort we found a potential founder variant, c.542G>A/p.R181H. Thus, we aimed to characterize this potential founder and its phenotypical expression.

Methods: Genotype and phenotype data for all 83 families (176 individuals) with h*TP53*rc in Sweden were retrieved retrospectively. Data included *TP53* variant, variant classification, pedigrees, age at first tumor onset and tumor characteristics. Families were classified according to classic Li-Fraumeni syndrome (classic LFS), Chompret or hereditary breast cancer (HBC) criteria. Short tandem repeat (STR) markers flanking *TP53* were analyzed in six of the families with PCR and fragment length analysis.

Results: In total, 18 families (42 individuals) harbored the c.542G>A variant and 60% of the carriers of this variant had an HBC phenotype compared to only 14% for all other variants ($p < 0.001$). Age at first tumor onset was higher (40 vs. 33 years, $p = 0.009$) and no patients with c.542G>A developed childhood tumors. Three of the families shared a common haplotype including the *TP53* gene. Prevalence of c.542G>A is significantly higher in the Swedish cohort compared to other cohorts.

Conclusion: Our cohort with 18 families represents the largest characterization of c.542G>A and haplotype analysis shows that this is the first Swedish founder variant. Families with this variant are predominantly associated with a risk of breast cancer.

P19.012.D Computing ages of alleles associated with rare autoinflammatory diseases in Anatolia

Damla Karadavut[1], *Gulsah Merve Kilinc*[1], **idil yet**[1]

[1]*Graduate school of Health Sciences, Department of Bioinformatics, Ankara, Türkyie*

Background/Objectives: Understanding the population dynamics together with its structure requires certain parameters in population genetics. One is allele age estimation. It helps us to understand mutations in a deeper way although it's comparably new (Malaspinas et al., 2012). Allele age means the first occurrence time of the SNP in a population. With allele age and other parameters, mutations can be studied in certain time intervals.

Methods: Relate has a genealogy-based method to infer mutation ages from genome data. Using genealogy trees, Relate computes information about populations like allele ages. First, it builds genealogy trees via WGS, one for each genome region. Then, it maps the mutations to trees. The branch they are mapped on gives the time interval the mutation was emerged (Speidel et al., 2019). In this study, the parameters and pipeline advised in tool's article were used. 47 SNPs related to Behçet's Disease, FMF and TRAPS are studied to in Anatolia via samples from Ancient (6 individuals) - Modern Anatolia (16 individuals) and 1000 Genome Project.

Results: Age results of 25 SNPs were found in generation:

Disease	Age Interval
Behçet's Disease	981.452 - 74080.4
FMF	8050 - 17929.8
TRAPS	3263.58 - 8160.29

Conclusion: Since studied autoinflammatory diseases are important for Anatolia population, emergence times of related SNPs are beneficial to know. Those times may match with important events in the history. By knowing the mutation age, we may connect those events with the diseases and get a new perspective about the topic.

P19.013.A The Genome of Europe: A Reference Database of Genomes as part of the 1 Million Genomes initiative (1 + MG)

Jeroen van Rooij[1], *Mariliis Vaht*[2], *Helen Ray-Jones*[1], *Andres Metspalu*[2], *André Uitterlinden*[1]

[1]*Erasmus Medical Center, Internal Medicine, Rotterdam, Netherlands;* [2]*University of Tartu, Institute of genomics, Estonian Genome Centre, Tartu, Estonia*

Consortium: Genome of Europe, WG12 of the 1+ Million Genomes

Background/Objectives: The 1 million genomes (1 + MG) initiative as part of the Digital Europe Program (DEP), was declared in 2018 and includes 27 signatory countries aiming to make at least 1 million whole genome sequences (WGS) accessible for use in research, health care, and prevention. Working Group 12 (WG12) of the 1 + MG, named Genome of Europe (GoE), was started in 2019 to establish a European Reference Genome Database of >500k WGS (@30x coverage).

Methods: We have defined a strategy to collect the first 100k genomes to be representative of the diverse European population and integrate them into various relevant research applications, dubbed use cases. The data collection will be in line with the 1 + MG framework, adhere to various ELSI and ICT guidelines, and be made accessible via the Genomics Data Infrastructure (GDI) project in the DEP.

Results: We outline the planned activities in the GoE 100k project involving 51 institutes from 29 European countries. Objectives include integrating existing WGS datasets and de novo sequencing for diverse populations, addressing ethical and legal considerations, ensuring data security, and embedding GoE data into GDI. Activities include genetic diversity analyses, multi-ancestry imputation services, and recalibration of genetic risk profiles, and establish longer term (clinical) applications for GoE.

Conclusion: Beyond its immediate goals, GoE contributes to genetic-phenotypic discoveries, national genome programs, and integration into the European Health Data Space. Prioritizing public engagement, transparency, and adaptability, GoE will stimulate European genomic research competitiveness, advancing personalized medicine and broader scientific and healthcare objectives, and integrate with European initiatives in health care and prevention.

P19.014.B The shared ancestry between the *C9orf72* hexanucleotide repeat expansion and intermediate-length alleles using haplotype sharing trees and HAPTK

Osma Rautila[1], *Karri Kaivola*[1], *Harri Rautila*[1], *Laura Hokkanen*[1], *Jyrki Launes*[1], *Timo Strandberg*[1], *Hannu Laaksovirta*[1;2], *Johanna Palmio*[3;4], *Pentti Tienari*[1;2]

[1]*University of Helsinki;* [2]*Helsinki University Hospital;* [3]*Tampere University Hospital;* [4]*University of Tampere*

Background/Objectives: The C9orf72 hexanucleotide repeat expansion (HRE) is a common genetic cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). The inheritance is autosomal dominant, but a high proportion of cases are sporadic. One possible explanation is de novo expansions of unstable intermediate-length alleles (IAs). Given the hypothesis that HREs are formed from IAs, a significant amount of haplotype sharing should exist between the HRE and IA haplotypes.

Methods: Using haplotype sharing trees (HST) with the novel haplotype analysis toolkit (HAPTK) we quantified and analyzed the amount of haplotype sharing between the HRE and IA groups in two different Finnish datasets.

Results: From the HSTs, we derived majority-based ancestral haplotypes of HRE carriers and discovered that IAs containing ≥18-20 repeats share large haplotypes in common with the HRE. Using HSTs of HRE and IA carriers, we demonstrate that in contrast to the shorter IAs, the longer IA haplotypes are largely indistinguishable from HRE haplotypes.

Conclusion: Our results indicate that the haplotypes with longer IAs belong to the same pool of haplotypes as the HRE. This suggests that the longer IAs represent potential premutation alleles. In addition to these findings, we present a method to quantify all shared haplotypes at a given genomic locus and demonstrate a way to efficiently assess haplotype sharing between different cohorts. Lastly, we have published the anonymized HSTs to an open access repository, enabling the comparison of different HRE cohorts globally against the Finnish HRE haplotypes in the future.

P19.015.C Epidemiological analysis of international ATTRv genetic testing data

Zornitsa Pavlova[1;2], *Tihomir Todorov*[1;2], *Albena Todorova*[1;2;3]

[1]*Independent Medico-diagnostic Laboratory "Genome Center Bulgaria", Sofia, Bulgaria;* [2]*Genetic Medico-diagnostic Laboratory Genica, Sofia, Bulgaria;* [3]*Medical University Sofia, Faculty of Medicine, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria*

Background/Objectives: Hereditary transthyretin amyloidosis (ATTRv) is multisystem condition affecting the peripheral nervous system, the heart, etc. It is caused by pathogenic variants in the TTR gene. The prevalence of ATTRv is variable and several endemic loci have been reported. We are currently presenting our data from TTR genetic testing from different regions of Europe and Asia.

Methods: Dried blood spot samples were obtained from patients from thirteen countries: Austria (416), Spain (304), Czech Republic (117), Poland (90), Ireland (6), Belgium (17), Italy (2), Luxembourg (12), Switzerland (178), Israel (156), Thailand (19), Hong Kong (13) and Malaysia (45). They were tested via Sanger sequencing of the TTR gene.

Results: The following TTR pathogenic variants were detected according to the country of origin (NM_000371.4): c.130C>T, p.Pro44Ser (Malaysia); c.148G>A, p.Val50Met (Spain, Switzerland, Malaysia, Luxemburg, Poland); c.155T>C, p.Val52Ala (Israel); c.157T>C, p.Phe53Leu (Poland); c.200G>A, p.Gly67Glu (Hong Kong); c.200G>T, p.Gly47Val (Malaysia); c.238A>G, p.Thr80Ala (Israel); c.290C>A, p.Ser77Tyr (Israel); c.337G>C, p.Val113Leu (Austria); c.340A>G,p.Val144Leu (Italy); c.349G>T, p.Ala117Ser (Malaysia, Thailand); c.424G>A, p.Val142Ile (Spain, Switzerland, Belgium, Malaysia). In two samples referred for testing from Czech Republic a variant of uncertain clinical significance was reported c.280G>C, p.Arg94His. The most frequent amyloidogenic variants were c.148G>A, p.Val50Met and c.424G>A, p.Val142Ile, which is consistent with the global epidemiologic data. For the regions of Israel and Malaysia endemic pathogenic variants were proved to be present.

Conclusion: The analysis of genetic epidemiologic data will continue to contribute to the accurate clinical interpretation of TTR genetic findings and to the timely diagnosis of ATTRv.

P19.016.D Two major waves of dispersal explain higher levels of R1a in ancient tribes of India

Jaison Jeevan Sequeira[1], *Mohammed S Mustak*[1]

[1]*Mangalore University, Applied Zoology, Mangaluru, India*

Background/Objectives: Early human migrations were gender-neutral, but during the Bronze Age, migrations became male-dominated and were often for raiding. Nomads from the Eurasian Steppe carried paternal R1a and Q haplogroups. It is surprising to note that even south Indian tribes have a higher frequency of R1a. We conducted a study on Eurasian, North Indian, and South Indian populations using Y-STR profiles to understand this exception.

Methods: We analyzed the Y-chromosome STR profile of 85 Sarasvata Brahmins who claimed to have migrated from North to the South West coast of India. We also collected published data for Q and R1a samples from the Indian subcontinent and Eurasia. We conducted multivariate analysis, Fst analysis, and haplotype dating using rho statistics.

Results: The MDS plot indicates a more uniform cluster with both northern and southern Indian castes and tribes. However, the Neighbour Joining tree shows two separate clusters of castes and tribes. It is also evident that the caste group comprises both brahmins and non-brahmin groups. Sarasvata Brahmins clustered with Sourashtra brahmins. The haplotype dating of R1a and Q haplogroup reveals that there is no noticeable difference between their ages in Eurasian and Indian samples.

Conclusion: According to our research, it appears that there were at least two separate waves of migration of R1a and Q haplogroups into the Indian subcontinent. The first haplotype distinguishes the tribes from the caste groups. It is possible that two different migrations at different times could explain the moderate levels of R1a found in Indian tribes.

P19.017.A Characterisation of diverse global ancestries within participants of the UK Biobank

Fiona Pantring[1;2;3], *Gianpiero L. Cavalleri*[1;2;3], *Edmund Gilbert*[1;2;3]

[1]*Royal College of Surgeons in Ireland, School of Pharmacy and Biomedical Sciences, Dublin, Ireland;* [2]*The SFI Centre for Research Training in Genomics Data Science, Ireland;* [3]*The FutureNeuro Research Centre, Dublin, Ireland*

Background/Objectives: The UK Biobank (UKB) is a large dataset containing in-depth phenotype and genotype data of nearly 500,000 UK-based participants. Studies leveraging the UKB typically focus on a subset of participants with homogenous European ancestry, labelled as "White British" according to self-identification and genotype-based principal component analysis. Here we characterise global ancestries present in the UKB through the application of population genetic approaches to 78,573 participants without the "White British" label.

Methods: We developed a novel approach which uses machine learning to predict an individuals' continental ancestry from genetic references from the 1000 Genomes and Human Genome Diversity Projects. These clusters were further divided by applying community detection to a network of Identity-By-Descent sharing.

Results: We find that the UKB is a repository of diverse ancestries primarily from Europe, Africa, and South Asia. The over 150 communities within these continental ancestry groups, whilst capturing worldwide diversity, reflect the demographic history of Great Britain and its Commonwealth in the 20th century and are therefore not necessarily represented in other datasets. An example includes South Asian ancestry communities born in Southeast Africa, but resident today in Britain. Our communities also facilitate novel findings of community-specific genetic risk factors, such as one of the highest worldwide frequencies of an idiopathic pulmonary fibrosis risk variant in Maltese genotypes.

Conclusion: We characterised worldwide ancestries in the UKB by identifying continental-level ancestry clusters and fine-scale communities. Furthermore, we provide a framework for studies of health-related genetic variation specific to otherwise understudied genetic communities.

P19.018.B A retrospective study on allelic distribution for recessive diseases in an Italian cohort

Pasquale Di Letto[1], *GIULIA NICOLE BALDRIGHI*[2], *Annalaura Torella*[1;3], *Mariateresa Zanobio*[1], *Roberta Zeuli*[1], *Margherita Scarpato*[1], *Margherita Russo*[1], *Marianthi Karali*[1], *Sandro Banfi*[1;3], *Vincenzo Vincenzo Nigro*[1;3]

[1]*Università degli Studi della Campania "Luigi Vanvitelli", Precision Medicine, Napoli, Italy;* [2]*Università di Pavia, Brain and Behavioral Sciences, Pavia, Italy;* [3]*Telethon Institute of Genetics and Medicine, Pozzuoli, Italy*

Background/Objectives: Consanguinity and the presence of recessive disease carriers are considered reproductive risk factors. In this retrospective study, we aim to investigate in our 7000 exomes database geographical and temporal pathogenic variants' distribution to evaluate putative mechanisms for detrimental alleles' dispersion and/or clusterization. Two main groups of recessive diseases have been analysed, inherited retinal diseases (IRDs) and neuromuscular diseases (NMDs) in the Italian population.

Methods: We selected 850 Italian patients with causative homozygous and compound heterozygous variants from the University of Campania "Luigi Vanvitelli" Medical Genetics Unit. We collected 573 patients affected by IRDs and 277 by NMDs. To investigate how the proportion of homozygous and compound heterozygous states vary over time a General Linear Model was used.

Results: Starting with patients born in 1940, we tried to find out whether homozygotes decreased in favour of heterozygotes. We detected a significant trend with a yearly decrease of 1% in the abundance of causative homozygous variants. Furthermore, in Campania, we observed an enrichment for IRD variants, c.14977_14978del (NM_206933.4) and c.286A>C (NM_000350.3) in *USH2A* and *ABCA4* respectively, which have very low frequency in general population databases. Moreover, a cluster in Salerno province for the variant c.-32-13T>G (NM_000152.5) in *GAA* was identified.

Conclusion: Our study unravels a link between homozygous variants' prevalence and time hinting a role for sociocultural behaviour in generating genetic isolates, whether geographical or not, in the past. On this basis, sociocultural changes could be a reliable index to study allelic distribution fluctuation in terms of time and space.

P19.019.C The reliability of inferred archaic segments in human genomes

Nancy Bird[1], *Hrushikesh Loya*[2], *Leo Speidel*[1;3], *Simon Myers*[2], **Garrett Hellenthal**[1]

[1]*University College London, UCL Genetics Institute, London, United Kingdom;* [2]*University of Oxford, Department of Statistics, Oxford, United Kingdom;* [3]*Francis Crick Institute, Ancient Genomics Laboratory, London, United Kingdom*

Background/Objectives: Many or all present-day human genomes include segments of DNA inherited from archaic humans due to admixture events occurring >30,000 years ago. Several methods have been published to detect such segments. These variously require phased haplotypes, an archaic reference sequence and/or an outgroup with little related archaic introgression. Inference from these approaches have been used to (e.g.) document purifying selection of archaic segments and understand their influence on traits. However, the comparative accuracy of different methods at detecting archaic segments remains underexplored. Little is known about how genomic features correlate with assignment accuracy and the consequences of such non-random bias.

Methods: We used simulations to examine the accuracy in detecting archaic ancestry under four widely-used approaches: Sprime, diCal, IBDMix and HMMix, and two unpublished approaches, illustrating false positive and false negative rates. We also assess the consistency of archaic ancestry assignments across approaches when applied to real data, and how this consistency correlates with genomic features.

Results: In simulations we find substantial variation across approaches in the ability to identify archaic ancestry segments. We also demonstrate an inconsistency across approaches in identified archaic segments in modern humans. For example, out of all SNPs identified as Neanderthal in any of the published methods, only 29% of these are found in more than two methods.

Conclusion: Our benchmarking of different methods highlights the difficulties in robustly identifying archaic segments in modern human genomes. We discuss the implications for downstream analyses that make use of inferred archaic segments.

P19.021.A ERAP2 allotype divergence revealed by population-level exosome sequencing

Aroosha Raja[1], *Abdulrahman Alasiri*[2], *Marion van Vugt*[2], *Jessica Van Setten*[2], *Jonas Kuiper*[1]

[1]*UMC Utrecht, Centre For Translational Immunology, Department of Ophthalmology, Utrecht, Netherlands;* [2]*UMC Utrecht, Department of Cardiology, Utrecht, Netherlands*

Consortium: CAPSTONE

Background: Polymorphisms in immune genes impact immune responses across individuals. Endoplasmic reticulum aminopeptidases 2 (ERAP2) are major part of adaptive immunity involved in trimming of antigenic peptides presented on Major histocompatibility class-I molecules. ERAP2 is highly polymorphic showing recent marks of evolutionary adaptations. The coding variants of ERAP2 are shown to be protective against pathogenic infections but at the cost of onset of autoimmune diseases. Despite the peculiar evolutionary history and substantial implications for human health, diversity of ERAP2 allotypes in population remains uncertain.

Methods: We used exome sequencing data to explore protein-altering variants of ERAP2 in 160,000 individuals of European descent. Conservative filtering steps were applied for phasing and processing to characterize significant ERAP2 variants for estimation of allotypes. Linkage disequilibrium (LD), clinicopathological associations and docking profiles of allotypes were assessed.

Results: We identified 15 protein-altering variants in exon-2 through exon-18 alongside 2 essential splice variants in LD with protein-altering variants of ERAP2. Considering phased haplotypes of variants, we identified 27 ERAP2 haplotypes in the European population. Through phylogenetics, we observed three large clades corresponding to 3 major haplotypes (A-C) controlled by splice variants rs2248374 and rs17486481. Homozygosity for rs2248374's G allele results in nonsense-mediated decay while A allele homozygosity denotes functional allotypes. Docking simulations on 14 functional allotypes revealed differences in ligand binding efficacies.

Conclusion: Population diversity of ERAP2 alters structure resulting in functional implications important for drug targeting and precision medicine.

P19.022.B The Genetic Contribution to life satisfaction stability and change: A longitudinal twin study.

Charlotte Pahnke[1], *Marco Deppe*[2], *Carlo Maj*[3], *Rana Aldisi*[1;4], *Friederike David*[1;5], *Christian Kandler*[2], *Markus Nöthen*[1], *Andreas Forstner*[1;6]

[1]*University of Bonn, School of Medicine & University Hospital Bonn, Institute of Human Genetics, Bonn, Germany;* [2]*University of Bremen, Department of Psychology, Bremen, Germany;* [3]*University of Marburg & University Hospital of Marburg, Center for Human Genetics, Marburg, Germany;* [4]*University of Bonn, School of Medicine & University Hospital Bonn, Institute for Genomic Statistics and Bioinformatics, Bonn, Germany;* [5]*University of Marburg, Department of Psychiatry and Psychotherapy, Marburg, Germany;* [6]*Research Center Jülich, Institute of Neuroscience and Medicine (INM-1), Jülich, Germany*

Background/Objectives: Multi-trait analyses of genome-wide association studies led to the proposal of the Well-Being Spectrum, consisting of the genetically correlated traits depressivity, neuroticism, positive affect and life satisfaction (PMID30810878). Additionally, the inclusion of loneliness and self-rated health has been proposed (PMID30643256). Here, we perform longitudinal analyses of the genetic contribution to stability and change of life satisfaction based on polygenic scores.

Methods: Latent state-trait-change models were fitted to life satisfaction reports assessed on up to seven occasions in 4,566 participants of the German TwinLife study. Polygenic scores for the well-being spectrum and its individual traits were constructed using PRS-CS and included in full sample, age and twin-specific models. Finally, polygenic score results were compared with classical twin modelling.

Results: In the full model and most age groups, polygenic scores were significantly associated with stable trait scores of life satisfaction, whereas associations with linear and quadratic change were smaller and mostly not statistically significant. This pattern was reflected in twin-based estimates, except for the quadratic change component. The inclusion of loneliness and self-rated health in an extended well-being spectrum score consistently, but not significantly, increased associations with the life satisfaction components.

Conclusion: We demonstrated a greater additive genetic contribution to trait life satisfaction than to linear change. Results for the quadratic change component were mixed. The observed group differences highlight that genetic effects may be population-specific (e.g. with respect to age). Our findings encourage the use of longitudinal data in complex genetic research.

P19.024.D Model of stabilizing selection fit observed genetic architectures of human complex traits and common diseases

Evan Koch[1;2], **Noah Connally**[1], *Nikolas Baya*[3], *Mary Pat Reeve*[4], *Mark Daly*[3;4;5], *Benjamin Neale*[3;5], *Eric Lander*[3], *Alex Bloemendal*[3], *Shamil Sunyaev*[1;2]

[1]*Harvard Medical School, Department of Biomedical Informatics, Boston, United States;* [2]*Brigham and Women's Hospital, Boston, United States;* [3]*Broad Institute, Cambridge, United States;* [4]*Institute for Molecular Medicine Finland, Helsinki, Finland;* [5]*Massachusetts General Hospital, Boston, United States*

Background/Objectives: The question of how evolutionary forces maintain variation in complex traits is a mainstay of evolutionary genetics. There is a strong theoretical argument that quantitative traits experience stabilizing selection, while disease traits may, intuitively, experience directional selection. GWAS show that allele frequencies are negatively correlated with effect sizes, which is consistent with both stabilizing and directional selection.

Methods: To distinguish between different forms of selection, we compared the effect sizes and frequencies of the trait-increasing (or risk-increasing) allele at each site. For each trait, we evaluated that distribution's consistency with different evolutionary models: neutral evolution, directional selection, stabilizing selection, and a combination of directional and stabilizing selection.

Results: Across traits, plotting allele effect sizes and frequencies produced a characteristic U-shape. The symmetry of this distribution suggests stabilizing selection, and, in our statistical analysis, models of stabilizing selection were supported for all traits distinguishable from neutrality. For most traits, data were similarly consistent with stabilizing selection on one trait or on multiple traits simultaneously (pleiotropy).

Conclusion: Though it is difficult to infer the specific costs or benefits of different traits in human evolutionary history, the alleles contributing to many human traits show evidence of stabilizing selection. This is true both for quantitative traits and for

disease traits whose effects on modern humans are generally deleterious. This finding shows the need for further investigation into both the causes of stabilizing selection, and the extent to which it is influenced by pleiotropy.

Background: We analysed, whether temporal heterogeneity of ctDNA mirrors evolutionary patterns in ovarian cancer.

Methods: Targeted sequencing of 275 cancer-associated genes was performed in primary tumor biopsies and in ctDNA of six longitudinal plasma samples from 15 patients, using the Illumina platform.

Results: While there was a low overall concordance between the mutational spectrum of the primary tumor biopsies vs. ctDNA, *TP53* variants were the most shared somatic alterations. Up to three clusters were detected in each tumor biopsy, likely representing predominant clones of the primary tumor. By tracing these clusters in ctDNA we revealed two evolutionary patterns. In pattern#1, clusters detected in the primary tumor biopsy were likely relapse seeding clones, as they contributed a major share to ctDNA at relapse. In pattern#2, similar clusters were present in tumors and ctDNA; however, they were cleared from liquid biopsy after chemotherapy and were undetectable at relapse. ctDNA private variants were present among both patterns with some of them mirroring possible subclonal expansions after chemotherapy.

Conclusion: We demonstrate that tracing the temporal heterogeneity of ctDNA could be a promising tool for deciphering evolutionary trajectories in ovarian cancer. Our findings could have important clinical implications as in patients with pattern#1, a single tumor biopsy may allow for predicting relapse eligible for targeted therapy. Further research will be necessary to predict at primary diagnosis whether a patient`s tumor will progress according to pattern#1 or #2.

Grants: The study was supported by Deutsche Krebshilfe (reference numbers: 70113616, 70113636).

[1]*i3S - Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal;* [2]*São João University Hospital, Porto, Portugal;* [3]*University Hospital Bonn, National Center for Hereditary Tumor Syndromes, Bonn, Germany;* [4]*IFSI the Pitie-Salpetriere Hospital Group AP-HP, Groupe Hospitalier Pitié-Salpêtrière, AP-HP, Sorbonne Université, Paris, France;* [5]*Institute Pathology And De Génétique, Charleroi, Belgium;* [6]*Assistance Publique – Hôpitaux de Paris, Medical Genetics Department, Paris, France;* [7]*Université de Lyon, Lyon, France;* [8]*Léon Bérard Center, Lyon, France*

Background/Objectives: The *CDH1* c.1901 C>T variant is the most recurrent in HDGC families across Europe, conferring susceptibility for Diffuse Gastric Cancer (DGC) and Lobular Breast Cancer (LBC). Despite lifetime risk estimates guide risk-reducing surgeries decision of individual families, current estimates used a combination of small families, cancer-enriched pedigree branches, different *CDH1* variants and lack histology confirmation of gastric and breast cancers.

Methods: Cancer status, histology, and age data were collected for 9 probands and 276 relatives. Cumulative risks of DGC and LBC were calculated relative to regional cancer incidence data using the genotype restricted likelihood (GRL) method. Clinical profiles and management strategies were also documented.

Results: Among 285 individuals, including 95 *CDH1* carriers, 26 had gastric cancer (all before 60 years), and 12 had breast cancer. Cumulative risks of DGC and LBC were estimated at 5.8% and 19.1% by age 60, respectively. Presence of gastric ulcer was significantly associated with DGC. No additional predictors of advanced disease were identified among carriers.

Conclusion: This is the largest cohort ever studied for the same *CDH1* variant present in a population sharing the same geographical area for centuries. Despite disease expressivity and early-onset of cancer is similar to families described worldwide, our data challenges all previous GC (>30% risk vs 6%) and BC (>40% vs 19.1%) risk estimations for *CDH1* carriers. We provide novel lifetime risk estimates considering specific cancer phenotypes associated with *CDH1* truncating variants and matched regional population incidence.

P19.028.D Landscape of genetic variations from population-based whole genome sequencing in Indian population

Krithika Subramanian[1;2], *Bratati Kahali[1]*

[1]Centre for Brain Research, Bengaluru, India; [2]Manipal Academy of Higher Education, Bengaluru, Govindapura, India

Consortium: TATA Longitudinal Study of Aging (CBR-TLSA) consortium,

Srinivaspura Aging Neurosenescence and Cognition (CBR-SANSCOG) consortium

Background: The human genome, with 3.2 billion DNA base pairs, exhibits 0.1% genetic variation among individuals, mainly as single-nucleotide variant (SNV), short insertion and deletion (INDEL), and structural variant (SV). Despite extensive global genome sequencing, there's limited representation of the Indian population in genetic studies.

Methods: To address this gap, we analyzed 845 individuals from the TATA Longitudinal Study of Aging (CBR-TLSA) and Srinivaspura Aging Neurosenescence and Cognition (CBR-SANSCOG) cohorts in India. We utilized a standardized whole-genome sequencing (WGS) pipeline (mean 42X depth of coverage) to detect SNVs, INDELs, and SVs employing multiple algorithms.

Results: We identified and characterized 22.78 million SNVs (5.2% novel) and 2.28 million INDELs (5.4% novel) in 845 individuals. 1.22% SNVs and 0.6% INDELs are putative protein-disrupting variants. About 50 such variants are frequent in the dataset (n = 40). We identified 36,214 SVs (24,574 deletions, 2,913 duplications, 8,714 insertions, and 13 inversions) in 529 individuals, with 1.26% potentially impacting protein-coding regions. Seven rare SVs significantly impact the dosage-sensitivity of seven genes with autosomal dominant mode of inheritance implicated in several diseases. 56 SVs are highly conserved and exhibit high intolerance to loss-of-function.

Conclusion: This study highlights population-specific genetic variations in Indian cohorts. Rare variants predominated over common ones, with two-thirds of variations in <1% of individuals. Discovering fine-scale genetic variations in the underrepresented Indian population provides valuable insights for human genetic studies, potentially leading to improved diagnostic and treatment strategies for a substantial portion of the global population.

Grant: TATA Trusts and CBR fund (BT/RLF/Re-entry/29/2016,DST/NSM/R&D_HPC_Applications/2021/03.12, ECR/2018/001429)

P19.029.A Using the ends of the polygenic risk score spectrum for schizophrenia to better capture anxiety-related brain structures – A UK Biobank study

Lisa Sindermann[1], *Christina Fell[2], Priyatam Dutta[1;3], Silvia Paracchini[3], Markus Nöthen[1], Andreas Forstner[1;4]*

[1]Institute of Human Genetics, University of Bonn, School of Medicine & University Hospital Bonn, Bonn, Germany; [2]School of Mathematics and Science, University of St Andrews, St Andrews, United Kingdom; [3]School of Medicine, University of St Andrews, St Andrews, United Kingdom; [4]Institute of Neuroscience and Medicine (INM-1), Research Center Jülich, Jülich, Germany

Background: Mental disorders present anxiety and overlapping genetic factors. The polygenic risk score for schizophrenia (SCZ PRS) is suggested to be linked to anxiety. In particular, the amygdala, insula, hippocampus, and frontal parts of the brain have been identified as anxiety-related regions. However, their link to the SCZ PRS is poorly understood, which we aim to investigate.

Methods: We stratified UK Biobank individuals in the 1st ($n = 2848$), 2nd ($n = 2746$), 9th ($n = 2578$), and 10th decile ($n = 2385$) of the SCZ PRS. Group differences in regional gray matter volumes (rGMV) of the amygdala, insula, hippocampus and medial frontal cortex (ROIs) and the fusiform gyrus as control region were examined. In an exploratory analysis, we tried to classify the 1st vs. 10th decile of the SCZ PRS spectrum via the ROIs using a machine learning approach.

Results: Results showed significantly reduced rGMV in the amygdala in the higher deciles compared to the lower deciles of the SCZ PRS spectrum. The classification accuracy of the machine learning approach was low at around 51.8%.

Conclusion: Differences in the amygdala volume may underlie the link between the genetic liability for SCZ and anxiety in the general population. Using the ends of the PRS spectrum may help in the future to improve personalized treatment options through better stratification of individuals.

FUNCTIONAL GENOMICS

P20.001.B Mutational signature of ionising radiation exposure in human fibroblasts

Lisa Hagenau[1], *Ana Tzvetkova[1;2], Lars Jensen[1], Matthias Port[3], Harry Scherthan[3], Andreas Kuß[1]*

[1]University Medicine Greifswald, Department of Functional Genomics, Greifswald, Germany; [2]University Medicine Greifswald, Institute of Bioinformatics, Greifswald, Germany; [3]Bundeswehr Institute of Radiobiology, affil. to the University of Ulm, München, Germany, München, Germany

Background/Objectives: DNA can be damaged in different ways by agents that prompt different DNA repair responses in the cell. Misrepair leads to mutations and for some agents, distinctive mutational signatures have been identified. Preliminary results of DNA damaged by ionising radiation (IR) indicate that exposure leads to an increase in somatic insertions/deletions (InDels), but not in somatic single-nucleotide variants. We use nanorate sequencing (NanoSeq), a modified duplex sequencing protocol, to identify and classify mutations in irradiated fibroblasts.

Methods: NanoSeq enables accurate identification of somatic mutations (SNVs and small InDels) from a mixed cell population, which saves time over subcloning single cell lines. Human gingival fibroblasts were irradiated with acute 2 and 10 Gy doses of ionising radiation followed by repair for 72h and preparation and

sequencing of NanoSeq libraries. The identified mutations were classified and compared with mutational signatures in the COSMIC database using the SigProfiler tools.

Results: High doses (10 Gy) of IR lead to an increase in InDels, particularly in microhomology-mediated deletions. This points to microhomology-mediated end joining (MMEJ) as major DSB repair mechanism. The number of SNVs does not increase significantly in irradiated samples and changes to the mutational profile vary between technical replicates. These results will be part of a larger study investigating mutational signatures in cells after treatment with IR, bleomycin and UV-B.

Conclusion: We show that IR exposure induces an increase in InDels. The InDel profile implicates MMEJ as principal DNA repair mechanism. For detecting IR-specific SNV-profiles, increased sequencing depth seems necessary.

P20.003.D Testing the possibility of using DNA methylation arrays as first-tier test in individuals with neurodevelopmental problems, congenital anomalies or growth disorders

Tinatin Tkemaladze[1;2], *Christopher Campbell*[3], *Kakha Bregvadze*[1], *Eka Kvaratskhelia*[1], *Elene Abzianidze*[1], *Leigh Demain*[3], *Sarah Jenkinson*[3], *Sarah Hilton*[3], *Bekim Sadikovic*[4;5], *David Gokhale*[3], *Siddharth Banka*[3;6]

[1]*Tbilisi State Medical University, Department of Molecular and Medical Genetics, Tbilisi, Georgia;* [2]*Givi Zhvania Pediatric Academic Clinic, Department of Pediatrics, Tbilisi, Georgia;* [3]*Manchester University NHS Foundation Trust, Manchester, UK, St Mary's Hospital, Manchester, United Kingdom;* [4]*Western University, Department of Pathology and Laboratory Medicine, London, Canada;* [5]*London Health Sciences Centre, Verspeeten Clinical Genome Centre, London, Canada;* [6]*University of Manchester, Division of Evolution, Infection and Genomics, School of Biological Sciences, Faculty of Biology, Medicine and Health, Man, United Kingdom*

Background/Objectives: DNA methylation (DNAm) episignature analysis has emerged as valuable tool for evaluating variants of uncertain significance and for studying individuals with neurodevelopmental problems, congenital anomalies and growth disorders who remain unsolved after exome or genome sequencing. Thus far the possibility of using episignature analysis as first-line tests in such patients has not been evaluated systematically.

Materials and Methods: Molecular testing naïve patients suspected of genetic disorders underwent DNAm array followed by EpiSign™ episignature analysis and all positive results were orthogonally validated.

Results: We ascertained 62 individuals for the project. The diagnostic yield was 100% (5/5) for patients suspected of Fragile X syndrome. DNAm arrays confirmed diagnoses in 8/18 (44%) individuals with syndromic disorders which included conditions such as Coffin-Siris, Cornelia de Lange, Kabuki, Floating-Harbor, Williams-Beuren and Wolf-Hirschhorn syndromes. We established diagnoses in 6/24 (25%) individuals suspected of imprinting disorders including Silver-Russel, Beckwith-Wiedemann and Prader-Willi syndromes. No diagnoses were achieved in 15 individuals with non-syndromic neurodevelopmental problems. Notably, DNAm analysis identified alternative diagnoses in 4.8% (3/62) of cases.

Conclusion: Overall, we achieved diagnoses in 19/62 (30.6%) test-naïve patients and these results show that DNAm arrays could be a useful first-tier diagnostic tool for individuals with syndromic genetic or imprinting disorders. Our findings are especially relevant for resource limited healthcare systems. The diagnostic yield of this approach will increase in future with the development of combined copy number and methylation arrays and with identification of episignatures for more disorders, including for non-syndromic conditions.

P20.004.A Genetic loci that disassociate obesity from abdominal fat distribution influence adipocyte differentiation and function

Jonathan Belanich[1;2], *Mario Urena*[1], *Aurore Hecq*[1;3], *Alizee Mosnier*[1], *Renee Gibson*[2], *Thiago Batista*[2], *Hesam Dashti*[2], *Brice Emmanuelli*[1], *Melina Claussnitzer*[2], *Tuomas Kilpeläinen*[1;2]

[1]*The Novo Nordisk Foundation Center for Basic Metabolic Research, København, Denmark;* [2]*Broad Institute, Cambridge, United States;* [3]*University of Mons - Campus Plaine Nimy, Mons, Belgium*

Background/Objectives: Obesity is negatively linked to cardiometabolic health, but this relationship can vary greatly among individuals. The biological mechanisms that regulate this variability remain incompletely understood. Intriguingly, some genetic loci have been found to show an inverse relationship between higher body mass index (BMI) and abdominal fat distribution, as indicated by a higher waist-hip ratio (WHR).

Methods: Initiating our search with the results from the largest GWAS for BMI and WHR, which included ~700,000 participants each, we identified >100 independent loci associated with higher BMI but lower WHR. Several of these loci were also found to associate with increased insulin sensitivity and a reduced risk of type 2 diabetes.

To unravel the biological mechanisms that separate obesity from abdominal fat distribution and poor cardiometabolic health, we focused on two previously uncharacterized loci, ADAMTS9 and EMILIN2. Knockdowns with siRNA in adipocytes led to decreased differentiation and function of the cells, affecting cellular metabolism and adipogenic marker genes.

Results: Further investigations using CRISPRi perturbation and the LipocyteProfiler for hundreds of image-based cellular features revealed that the perturbed cells experienced reduced lipid storage capacity and decreased glucose uptake, with no impact on physical markers such as proliferation and size. We have performed RNA-Seq on the same cells to deepen our analysis, allowing us to draw connections between the modified genetic functions and cellular phenotypes.

Conclusion: This study is investigating only two of a swathe of newly identified loci that may enhance the understanding of genes that uncouple obesity from abdominal fat distribution and poor cardiometabolic health.

P20.005.B Comparative 3D genome analysis between neural retina and RPE reveals differential *cis*-regulatory interactions at retinal disease loci

Eva D'haene[1;2], *Víctor López Soriano*[1;2], *Pedro Manuel Martinez-Garcia*[3], *Soraya Kalayanamontri*[3], *Alfredo Dueñas Rey*[1;2], *Ana Sousa-Ortega*[3], *Silvia Naranjo*[3], *Stijn Van de Sompele*[1;2], *Lies Vantomme*[1;2], *Quinten Mahieu*[1;2], *Sarah Vergult*[1;2], *Ana Bastos Neto*[3], *Jose Luis Gomez-Skarmeta*[3], *Juan Ramón Martínez Morales Martínez-Morales*[3], *Miriam Bauwens*[1;2], *Juan Jesus Tena-Aguilar*[3], *Elfride De Baere*[1;2]

[1]*Ghent University, Department of Biomolecular Medicine, Ghent, Belgium;* [2]*Ghent University Hospital, Center for Medical Genetics, Ghent, Belgium;* [3]*Universidad Pablo de Olavide, Centro Andaluz de Biología del Desarrollo, Sevilla, Spain*

Background/Objectives: Vision depends on the interplay between photoreceptors of the neural retina and the underlying retinal pigment epithelium (RPE). Genes involved in inherited retinal diseases (IRD) display specific spatiotemporal expression within these interconnected retinal components through local recruitment of *cis*-regulatory elements (CREs) in 3D nuclear space. Yet, the role of chromatin architecture in establishing these specific expression patterns remained unexplored.

Methods: To understand the role of differential chromatin architecture in establishing tissue-specific expression at IRD loci, we mapped genome-wide chromatin interactions using in situ Hi-C, and H3K4me3 HiChIP on neural retina and RPE/choroid from human adult donor eyes. Also, we functionally validated *cis*-regulatory interactions in the *ABCA4* locus using UMI-4C, multi-omic data integration and zebrafish enhancer assays.

Results: We determined chromatin looping between active promoters and 32,425 and 8,060 candidate CREs (cCREs) in the neural retina and RPE/choroid respectively. A comparative 3D genome analysis between these two retinal tissues revealed that 56% of 290 known IRD genes were marked by differential chromatin interactions. One of these was *ABCA4*, which is implicated in the most common autosomal recessive IRD. Integration of *ABCA4* promoter interactions and tissue-specific multi-omics data, as well as functional validation using zebrafish enhancer assays revealed multiple active *ABCA4*-CREs, likely achieving retina-specificity through a cooperative mechanism.

Conclusion: We have shown that gene regulation at key IRD loci is likely mediated by tissue-specific chromatin interactions. These findings do not only provide insight into tissue-specific regulatory landscapes at retinal disease loci, but also delineate the search space for non-coding genomic variation underlying unsolved IRD.

Conflict of Interest: None declared

P20.006.C Pinpointing candidate pathomechanistic actors of biglycan-related disease by mRNA-sequencing

Anne Hebert[1], *Josephina (Jeannette) Meester*[1], *Ligia Monica Mateiu*[1], *Maaike Bastiaansen*[1], *Aline Verstraeten*[1], *Bart Loeys*[1;2]

[1]*University of Antwerp, Center of Medical Genetics, Edegem, Belgium;* [2]*Radboud University Medical Center, Department of Clinical Genetics, Nijmegen, Netherlands*

Background/Objectives: Discrete pathogenic variants in biglycan (*BGN*) are associated with an aortopathy called Meester-Loeys syndrome (MRLS; loss-of-function truncating or splice site variants) and a skeletal dysplasia called X-linked spondylo-epimetaphyseal dysplasia (SEMDX; missense variants).

Methods: To gain insights into the pathomechanisms underlying these two divergent *BGN*-related phenotypes, mRNA-sequencing was performed on MRLS (n = 3), SEMDX (n = 2) and control (n = 2) skin fibroblasts.

Results: Comparative BioPlanet pathway enrichment analysis of mRNA-sequencing data from MRLS patient skin fibroblasts and matched controls revealed seventeen dysregulated genes associated with transforming growth factor-beta (TGF-β) regulation of the extracellular matrix (ECM). Gene ontology (GO) enrichment analysis indicated dysregulation of collagen-containing ECM, as well as adhesion- and cell-cycle-related processes. Given the increased TGF-β signaling in MRLS and the suggested role of BGN in regulating collagen fibril diameter, these mRNA-sequencing results support the importance of ECM dysregulation in MRLS.

Comparative GO enrichment analysis of mRNA-sequencing data from SEMDX patient skin fibroblasts and matched controls revealed a significant upregulation of inhibitors of the GDF5/BMP-pathway along with downregulation of the GDF5 ligand itself. This pathway controls chondrocyte proliferation, and pathogenic variants in *GDF5* have already been associated with skeletal dysplasias. We hypothesize that GDF5 could be an important binding partner or downstream effector of BGN and may, therefore, play a key role in SEMDX development.

Conclusion: Analysis of mRNA-sequencing data from MRLS and SEMDX patient skin fibroblasts identified intriguing candidate pathomechanistic actors or pathways for further investigation.

Consortium: GEMAS
CONGENT

Background: Asthma is a complex respiratory disease that is three times more prevalent in the Canary Islands compared to other regions of Spain. Differences in genetic composition and environmental exposures have been proposed to explain these prevalence differences. In this sense, DNA methylation (DNAm) has been implicated in asthma pathogenesis, reflecting the interaction of gene-environmental factors. We aimed to identify DNAm markers associated with asthma susceptibility in the Canarian population.

Methods: Blood DNAm levels were analyzed at 823,755 CpG sites from 456 individuals (320 and 136 with and without asthma, respectively), using the Infinium MethylationEPIC microarray (Illumina). The association between DNAm at individual CpGs and asthma susceptibility was determined through an epigenome-wide association study (EWAS), using linear regression models adjusted for age, sex, ancestry, and tissue heterogeneity. Differentially methylated regions (DMRs) were examined using comb-p and *dmrff*, and enrichment analysis was performed using EWAS Toolkit and Enrichr databases. Multiple comparisons were adjusted with a false discovery rate (FDR)<5%.

Results: Although no CpG sites were significantly associated with asthma, 36 DMRs were associated with the disease (FDR < 5%). The top-hit region was annotated to *TRIM31* gene ($FDR = 1.39 \times 10^{-9}$), previously associated with other immune

system diseases and transcriptional regulation. CpGs suggestively associated in the EWAS ($p < 5 \times 10^{-4}$) showed enrichment in prior associations including ancestry, exposure to glucocorticoids, aging, and transcription factors involved in asthma development (i.e., NF-κB) (FDR < 0.05).

Conclusion: This study revealed new associations of DMRs with asthma susceptibility in the Canary Islands.

P20.008.A Genome-wide identification and functional assessment of non-coding variants in hypo-plastic left heart syndrome patients

Vartika Bisht[1], *Ludo Pagie*[1], *Miriam Smits*[1], *James Burgess1*[1;2], *Alexey Pindyurin*[1], *Wilhelmina S. Kerstjens-Frederikse*[3], *Cleo van Diemen*[3], *Joris Arensbergen*[1]

[1]*Annogen Bv, Amsterdam, Netherlands;* [2]*The Royal Children's Hospital Melbourne, Parkville, Australia;* [3]*University Medical Center Groningen, Groningen, Netherlands*

Consortium: ENHPATHY

Background/Objectives: Congenital heart disease (CHD) is one of the most common and severe birth anomalies with a prevalence of about 1% in the population. One specific type of CHD is hypo-plastic left heart syndrome (HLHS), which involves malformations in the left-sided structures of the heart. Since many HLHS patients do not have any pathogenic coding mutations, it is thought that non-coding mutations might explain some of these cases. However, assessing the functional impact of non-coding mutations from sequence alone is challenging given our limited understanding of how regulatory information is encoded in the genome.

Methods: We utilized Survey of Regulatory Elements (SuRE), a massively parallel reporter assay, to evaluate the functional impact of non-coding variants found in the genomes of five exome-negative HLHS patients on enhancer and promoter activity.

Results: Using SuRE, we have analyzed approximately 4.7 million non-coding single nucleotide substitutions, insertions, and deletions. Among these variants, we have identified about 18k variants which exhibit significant functional effects. Next, we prioritized 20 putative causal variants through comprehensive consideration of their effect size, population allele frequencies, overlap with known heart-specific regulatory regions and occurrence within the patient's family. We are currently validating the functional impact of these variants using enSERT, a CRISPR/Cas9-mediated site-specific transgenic mouse assay.

Conclusion: The integration of information about known regulatory elements with comprehensive functional assessment provided by SuRE has empowered us to identify potentially causal non-coding variants within the vast genomic landscape of HLHS. The ongoing validation in transgenic mice will show the strength of such an approach.

Conflict of Interest: None declared

P20.009.B High throughput functional assay to evaluate DNA polymerase epsilon exonuclease missense variants: a proof-of-concept

Albain Chansavang[1;2], *Bertrand Diebold*[1], *Ingrid Laurendeau*[2], *Eric Pasmant*[1;2], *Nadim Hamzaoui*[1;2]

[1]*Hôpital Cochin, AP-HP, Fédération de Génétique et Médecine Génomique APHP Centre Université Paris Cité, Département de Médecine Génomique des Tumeurs et Cancers, PARIS, France;* [2]*Institut Cochin, Inserm U1016, CNRS UMR8104, Université Paris Cité, CARPEM, PARIS, France*

Background/Objectives: DNA polymerase epsilon (POLE) is a replicative polymerase with an exonuclease-proofreading domain. Germline *POLE* exonuclease domain variants are responsible for hereditary tumor predisposition. Several somatic *POLE* variants are associated with high tumor mutational burden and good response to anti-PD1 treatment. It is therefore important to discriminate between pathogenic and benign variants. Our aim was to characterize the impact of polymerase epsilon exonuclease missense variants of the yeast *Pol2* gene (*POLE* ortholog) with a multiplexed assay of variant effect.

Methods: Every possible single nucleotide variant of two Pol2 residues (Pro301 and Met309) and an exo-null control were generated by oligonucleotide synthesis. Genomic edition of *S. saccharomyces* W303 was done by cotransformation of the oligonucleotide library and a CRISPR/Cas9 expression plasmid. Transformed cells were tested for genetic instability at the *URA3* locus by plating on 5FOA-containing medium. DNA was extracted from yeast cells before and after 5FOA selection and *Pol2* sequenced by NGS. Variants allelic frequencies were analyzed using Enrich2 pipeline.

Results: The exo-null and the known cancer driver p.Pro301Arg variants were enriched 50 and 500 fold, respectively, compared to wild-type. Pro301 was intolerant to mutations toward aminoacids with large side chains, which suggests a mechanism of steric hindrance to DNA binding in the exonuclease pocket. Met309 variants had a much less pronounced impact on genetic instability.

Conclusion: We successfully validated a multiplexed assay of the effect of *Pol2* exonuclease domain variants on genetic instability using a library of two saturation-mutated residues. This protocol is currently applied to the remaining exonuclease residues.

P20.010.C CFAP99 deficiency leads to heterotaxy and scoliosis

Beril Ay[1], *Stephen Viviano*[2], *OZLEM AKGUN DOGAN*[3], *Yasemin Alanay*[3], *Engin Deniz*[2]

[1]*Acibadem Mehmet Ali Aydinlar University, School of Medicine, Istanbul, Türkyie;* [2]*Yale University, Department of Pediatrics, New Haven, CT, United States;* [3]*Acibadem Mehmet Ali Aydinlar University, School of Medicine, Department of Pediatrics, Division of Pediatric Genetics, Istanbul, Türkyie*

Background/Objectives: Birth defects affect 6% of births globally, leading to significant mortality and comorbidities. Current efforts focus on identifying underlying mechanisms for prevention. A 3-year-old female presented with congenital scoliosis, tethered spinal cord, hearing loss, and hypoplastic left heart syndrome resembling a heterotaxy type of cardiac defect. WES revealed a missense variant in *cilia and flagella-associated protein 99(CFAP99)*, which isn't associated with any disease.

Methods: We utilized loss-of-function assays using CRISPR/Cas9 mediated genome editing in the *Xenopus* model system for functional analysis. We designed two non-overlapping CRISPRs targeting two different exons, generated G0 tadpoles, and verified genomic edits using CRISPR edits analysis inference. Brightfield/fluorescence microscopy, immunohistochemistry, and optical coherence tomography imaging were utilized to detect cardiac and spinal cord defects.

Results: In *Xenopus, the cfap99* knockdown led to two significant phenotypes, heterotaxy and scoliosis, recapitulating

our patient's presentation. Mutant tadpoles had 25.2% cardiac looping vs 1.1% in wild types, suggesting defective left-right body patterning. Abnormal body axis formation was confirmed by examining the transcription factor *pitx2c* expression pattern, which is known to be asymmetric in *Xenopus*. Indeed, when *cfap99* was knocked down, *pitx2c* expression was abnormal, indicating the disrupted left-right patterning. Scoliosis was observed in *cfap99* knockout tadpoles 34.3% vs 1.2%. Further analysis revealed that cfap99 loss caused abnormal cilia development and impaired ciliary motion.

Conclusion: This is the first study that associated CFAP99 with multiple birth defects. Our findings in *Xenopus* model system suggest that *cfap99* variants lead to heterotaxy and scoliosis phenotype, primarily through disrupted cilia morphology and function.

P20.012.A Differential isoform regulation in the human brain across regions, development, and between neuropsychiatric disorder cases and controls.

Sofia Kudasheva[1;2], *Nicola Hall*[3], *Paul Harrison*[3;4], *Elizabeth Tunbridge*[3;4;5], *Wilfried Haerty*[1;2]

[1]*Earlham Institute (EI), Norwich, United Kingdom;* [2]*University of East Anglia, School of Biological Sciences, Norwich, United Kingdom;* [3]*University of Oxford, Department of Psychiatry, Oxford, United Kingdom;* [4]*Oxford Health NHS Foundation Trust, Warneford Hospital, Oxford, United Kingdom;* [5]*Boehringer Ingelheim, CNS Discovery Research, Biberach an der Riß, Germany*

Background/Objectives: Neurodevelopmental disorders (NDDs), including schizophrenia, are associated with dysregulated alternative splicing. However, NDD risk genes tend to be lowly expressed and have complex gene models making their isoform identification and quantification challenging with current approaches. This severely impedes the functional interpretation of their variation across tissues, and conditions.

Methods: We applied CaptureSeq target enrichment coupled with nanopore sequencing to characterise and quantify RNA isoform profiles of 1221 protein-coding and lncRNA genes across 52 human post-mortem brain samples: cortex, caudate, and hippocampus from 20 individuals (adult and fetal controls, and 12 adults with a neuropsychiatric diagnosis).

Results: We identified 44,624 unique isoforms (88.4% previously unannotated) and revealed 228 significant changes in isoform proportions (i.e. switches) between control adult brain regions, and 257 between adult and fetal cortex, with some switches predicted to impact the coding potential and protein structure. Out of 17 genes with isoform switches between controls and individuals with schizophrenia, we identify a novel isoform of schizophrenia risk gene CPEB1 that constitutes 94% of the gene's expression in schizophrenia cortex samples vs 47% in controls.

Conclusion: The previously overlooked brain isoform diversity and expression patterns provide us with an opportunity to characterise the functional implications of genetic variation associated with NDDs.

P20.013.B Uncovering preferential binding between putative promoters and enhancers using a combined capture Hi-C MPRA experiment

Pia Keukeleire[1], *Coline Arnould*[2;3], *Martin Kircher*[1;4], *Nadav Ahituv*[2;3]

[1]*University Hospital Schleswig-Holstein, University of Lübeck, Institute of Human Genetics, Lübeck, Germany;* [2]*University of California, Department of Bioengineering and Therapeutic Sciences, San Francisco, United States;* [3]*University of California, Institute for Human Genetics, San Francisco, United States;* [4]*Berlin Institute of Health at Charité, Exploratory Diagnostic Sciences, Berlin, Germany*

Background/Objectives: Massively Parallel Reporter Assays (MPRAs) have been employed to identify putative regulatory elements in the non-coding genome. While MPRAs offer flexibility in scale and elements tested, common approaches of designing such experiments have inherent shortcomings. Specifically, oligo synthesis inhibits the testing of large elements, and elements are frequently tested with a minimal promoter, disregarding the possibility that some enhancers may only pair with specific promoters.

Methods: To overcome both disadvantages, we designed a capture Hi-C (cHi-C) MPRA experiment that captures 1000 promoters and ~1500 putative enhancers in K562 cells to obtain conjugations of regulatory elements and their target promoters. Results of the cHi-C are sequenced using PacBio HiFi long reads and subsequently tested in a genome integrated manner using a lentivirus-based MPRA (lentiMPRA) in K562 cells.

Results: We were able to measure the activity of 982 promoter-enhancer, 3529 enhancer-enhancer and 16 promoter-promoter interactions. While most promoters interact with their closest enhancer, we found that a putative enhancer close to CUL1 causes high MPRA activity when combined with a more distal putative promoter (~15 kb) for the gene EZH2, as compared to the putative CUL1 promoter (~2kb). We note that both interactions show similar cHi-C abundance and that all three regions are in open chromatin.

Conclusion: Our initial experiment shows that the combination of cHi-C and lentiMPRA experiments overcomes the length limitations of state-of-the-art MPRAs, allows testing enhancers with their target promoter and can allow us to learn about specific enhancer and promoter pairings.

(German Center for Cardiovascular Research), Hamburg, Germany; [7]Achucarro Basque Center for Neuroscience, Laboratory of Circadian Physiology of Neurons and Glia, Leioa, Spain; [8]IKERBASQUE, Basque Foundation for Science, Bilbao, Spain

Background/Objectives: The circadian timing system allows the anticipation of daily recurring changes in the environment improving physiological fitness. In mammals, the circadian system is hierarchically organized, with a master pacemaker located in the hypothalamic suprachiasmatic nuclei (SCN). Glucocorticoid (GC) release from the adrenal gland is under SCN control, peaking before the active phase to synchronize systemically "awake" functions. While the mouse SCN is responsive to GCs during the perinatal period, the adult circuit seems to be resistant.

Methods: sn-RNAseq of mouse SCN at different developmental timepoints and validation via RNAscope and Proximity ligation assay (PLA)

Results: We show that the GC receptor (GR) is down regulated in neurons along SCN maturation, but astrocytes continue to express it. Indeed, astrocytic GR is activated by circadian GCs changes, demonstrating for the first time that the mature SCN receives direct GC-feedback.

Conclusion: Our data provides novel insight into the gain of cellular and transcriptional heterogeneity of the mouse SCN along development and the essential role of SCN astrocytes in timing physiology.

P20.015.D Targeting oncogenic *TERT* promoter variants by allele-specific epigenome editing

Alexandra Kouroukli[1], *Nivethika Rajaram[2], Pavel Bashtrykov[2], Helene Kretzmer[3], Reiner Siebert[1], Albert Jeltsch[2], Susanne Bens[1]*

[1]Institute of Human Genetics, Ulm University and Ulm University Medical Center, Ulm, Germany; [2]Institute of Biochemistry and Technical Biochemistry, Department of Biochemistry, University of Stuttgart, Stuttgart, Germany; [3]Computational Genomics, Max Planck Institute for Molecular Genetics, Department of Genome Regulation, Berlin, Germany

Background/Objectives: Silencing dominantly activated oncogenic alleles by addressing driver mechanisms (e.g. genomic alterations) is a promising cancer treatment strategy. Allele-specific epigenome editing (ASEE) reduces gene expression in an allele-specific manner (Rajaram et al. 2023). We investigated ASEE mediated oncogene silencing in cancer by targeting heterozygous *TERT* promoter (*TERT*p) variants (Kouroukli et al. 2023).

Methods: We screened 75 cell lines by Sanger sequencing for *TERT*p sequence variants. Next, we introduced sgRNA-guided dCas9-DNMT3A-3L (ASEE) complexes to selected cancer cell lines (CCLs) by transient transfection and investigated DNA methylation of 30 *TERT*p CpGs upon ASEE. *VEGFA* was investigated as off-target locus control. Afterwards, we assessed *TERT* RNA expression and cell viability.

Results: 53% of the CCLs contained at least one heterozygous variant allowing allele discrimination. We selected Hep-G2 and A-549 CCLs for this proof-of-principle which contained two different heterozygous variants; the activating mutation C228T (core *TERT*p) and the common SNP rs2853669 (THOR), respectively. These variants were targeted by the ASEE complexes. We introduced DNA methylation to the on-target allele in both CCLs with limited off-target allele and off-target locus methylation. We observed maximum CpG methylation gain of 39% and 76% after ASEE in Hep-G2 and A-549, respectively. The epigenome editing translated into reduced *TERT* RNA expression in Hep-G2. We did not observe a specific effect of ASEE on cell survival.

Conclusion: We successfully applied the concept of dominant oncogene inactivation by ASEE in cancer models. This new therapeutic strategy may be especially useful in reducing adverse side effects.

P20.016.A Exploring novel insights into parathyroid hormone receptors and their potential relevance to migraine

Andreia Dias[1;2;3], *Marta Ferreira[1;4], Mariana Santos[1;2;3], Alda Sousa[1;2;3], Carla Oliveira[1;4;5], Miguel Alves-Ferreira[1;2;3;6], Carolina Lemos[1;2;3]*

[1]i3S - Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal; [2]Abel Salazar Biomedical Sciences Institute - University of Porto, Porto, Portugal; [3]Instituto de Biologia Molecular e Celular, Porto, Portugal; [4]IPATIMUP - Instituto de Patologia e Imunologia Molecular da Universidade do Porto, Porto, Portugal; [5]Faculdade de Medicina da Universidade do Porto - FMUP, Porto, Portugal; [6]Centro de Genética Preditiva e Preventiva, Porto, Portugal

Background/Objectives: Migraine is a complex neurological disorder subdivided into migraine with aura (MA) or without aura (MO). Familial aggregation of migraine indicates a potential genetic predisposition, however environmental risk factors might contribute to migraine susceptibility. To investigate whether a specific pattern of RNA expression could distinguish between migraine cases (migraineurs) and migraine-free controls, we conducted a whole transcriptome analysis for the first time within a Portuguese cohort.

Methods: We performed total RNA sequencing on whole blood samples from 15 migraineurs and 12 age-matched controls. Differential expression analysis and gene set enrichment analysis (GSEA) were performed in different groups. Finally, we performed the protein-protein interaction (PPI) networks of differentially expressed genes.

Results: GSEA comparing migraineurs with controls highlighted upregulated pathways linked to metabolism, and downregulated immuno-inflammatory pathways. Moreover, the groups of female migraineurs and female MO patients emphasized significant upregulated pathways, including G protein-coupled receptors (GPCRs) signaling pathways, when compared with female controls. Interestingly, we found two important differentially expressed genes related to parathyroid hormone (PTH): *PTH1R* and *PTH2*. *PTH1R* was upregulated in female MO versus female controls, while *PTH2* was both upregulated between female migraineurs and female controls as well as between female MO and controls.

Conclusion: This study highlights an association of class B (secretin family) GPCRs, particularly PTH1R and PTH2, in female migraineurs. These molecules stand out as sturdy and promising biomarkers and/or targets for innovative therapeutic in female migraineurs.

P20.018.C Solving undiagnosed disease beyond the exome: Functional enhancers with medical relevance identified by ChIP-STARR-seq in neural cell models and integration with convolutional neural networks allows prioritizing functional non-coding variants from whole genome sequencing studies underlying missing heritability in neurogenetics

Ruizhi Deng[1], Elena Perenthaler[1], Anita Nikoncuk[1], Kristina Lanko[1], Wilfred F. van Ijcken[2], Gennady Roshchupkin[3], Eskeatnaf Mulugeta[4], **Stefan Barakat**[1]

Consortium: Genomics England Research Consortium

Background/Objectives: Genome-wide assessment of genetic variation is becoming a routine in genetics, but functionally interpreting effects of non-coding variants both in common and rare disease remains extremely challenging.

Methods: Here we employ the massively parallel reporter assay ChIP-STARR-seq to functionally annotate non-coding regulatory element (NCRE) activity >140 thousand genomic sequences in human neural stem cells (NSCs) as brain developmental model.

Results: Highly active NCREs in NSCs show increased sequence constraint, are enriched for transcription factor (TF) binding motifs for YY1 and p53 family members and for primate-specific transposable elements, providing insights in gene regulatory mechanisms. Examination of the same genomic sequences in human embryonic stem cells (ESCs) identified differential NCRE-activity between both cell types, accompanied by rewiring of the epigenome landscape. Based on the experimentally measured NCRE-activity and the nucleotide composition of the assessed DNA sequences, we build a convolutional neural network (CNN) that allows the prediction of NCRE-activity solely based on DNA sequence composition, which can be used to identify functionally relevant nucleotides and TF motifs within each NCRE required for their NCRE function. The application of this detailed NCRE-atlas and its subsequent functional validation allowed prioritizing both SNPs underlying biologically relevant sequences of loci identified in genome-wide association studies for common neurological traits, as well as rare non-coding variants that might be causative in currently genetically unexplained individuals.

Conclusion: We foresee that the NCRE-atlas created here will help resolving missing heritability in human genetics and neurodevelopmental disorders, reducing the search space for functional relevant non-coding genetic variation.

P20.019.D Loss-of-function *EHMT2* missense mutation as the cause of a Kleefstra-like syndrome

Beatriz Martinez-Delgado[1;2;3], *Estrella Lopez-Martín[1;2], Jennifer Kerkhof[4], Beatriz Baladron[1;2], Lidia Mielu[1;2], Diana Sanchez-Ponce[1], Ariadna Bada-Navarro[1], Marina Herrero-Matesanz[1], Lidia López[1;2], Jessica Rzasa[4], Dmitrijs Rots[5], Marta Fernandez Prieto[1], Esther Hernandez-San Miguel[1], Gema Gomez-Mariano[1;2], Purificación Marín Reina[6], Rosario Cazorla-Calleja[2;7], Francisco Javier Alonso[1;2;3], Tjitske Kleefstra[5], Manuel Posada[2], Eva Bermejo-Sanchez[1;2], Bekim Sadikovic[4], María J. Barrero[1;2]*

[1]Institute of Rare Diseases Research (IIER/ISCIII), Madrid, Spain; [2]Undiagnosed Diseases Program SpainUDP, Madrid, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Raras, (CIBERER), Madrid, Spain; [4]Verspeeten Clinical Genome Centre, London Health Sciences Centre, Canada; [5]Radboud University Medical Center, Human Genetics, Nijmegen, Netherlands; [6]University and Polytechnic Hospital La Fe, Valencia, Spain; [7]Hospital Universitario Puerta de Hierro, Madrid, Spain

Consortium: SpainUDP

Background/Objectives: Dysregulation of the epigenetic machinery is associated with neurodevelopmental defects in humans. Kleefstra syndrome (KS) is a neurodevelopmental syndrome caused by heterozygous alterations in the gene *EHMT1* that cause loss-of-function. EHTM1 and EHMT2 are highly similar histone methyltransferases that play relevant roles in development. However, to date, *EHMT2* mutations has not been described to cause disease.

Methods: We describe a pediatric patient studied in the Undiagnosed cases Program, SpainUDP, with a KS overlapping phenotype and a single base de novo substitution in *EHMT2* that causes the amino acid change p.Ala1077Ser in the catalytic SET domain. Pathogenicity of this variant was functionally assessed by histone peptide binding, histone methyltransferase, and EpiSign™ episignature assays.

Results: This change was found to produce a reduction in the affinity of the EHMT2 catalytic domain for the H3 tail and in the activity of the enzyme by three- to five-fold. Alterations in histone methylation and gene expression profiles along with a positive EpiSign™ analysis suggest a significant overlap between the *EHMT2* p.Ala1077Ser variant and features described for *EHMT1* mutants causing KS.

Conclusion: We conclude that *EHMT2* haploinsufficiency likely causes a Kleefstra-like syndrome. Although we cannot rule out dominant negative effects caused by the *EHMT2* p.Ala1077Ser variant, our data suggest that loss of functional EHMT2 is probably more detrimental to cells than loss of EHMT1.

P20.020.A Functionally equivalent disease-relevant enhancers in the pancreas of Zebrafish and Human

Renata Bordeira-Carriço[1;2], *Joana Teixeira[1;2], Marta Duque[1;2], Mafalda Galhardo[1;2;3], Diogo Ribeiro[1;2], Rafael D. Acemel[4], Panos N. Firbas[4], Juan Jesus Tena-Aguilar[4], Ana Eufrásio[1;2], Joana Marques[1;2], Fábio Ferreira[1;2], Telmo Freitas[1;2], Fátima Carneiro[5;6], Jose Luis Gomez-Skarmeta[4], José Bessa[1]*

[1]Instituto de Biologia Molecular e Celular (IBMC), Porto, Portugal; [2]Instituto de Investigação e Inovação em Saúde (i3S), Porto, Portugal; [3]Instituto de Ciências, Tecnologias e Agroambiente (CIBIO), Porto; [4]Centro Andaluz de Biología del Desarrollo (CABD), Sevilla; [5]Faculdade de Medicina da Universidade do Porto (FMUP), Pathology Department, Porto, Portugal; [6]Instituto de Patologia e Imunologia Molecular da Universidade do Porto (IPATIMUP), Porto, Portugal

Background/Objectives: The pancreas is a central organ whose function, when impaired, is associated with high disease burden. Genome-wide association studies have identified various alleles of

pancreatic dysfunction located in non-coding sequences of DNA. Several of these regions contain epigenetic marks of cis-regulatory elements (CREs) active in pancreatic cells, suggesting that alterations in these regions might have a role in disease. The aim of this study was to find CREs located in non-coding regions of DNA that might be involved in pancreatic diseases.

Methods: To explore the transcriptional regulatory genome of zebrafish pancreas we combined epigenetic assays: ATAC-seq, ChIP-seq, 4C-seq and HiChIP-seq. We compared this data with ChIP-seq data from human pancreatic cell lines and performed reporter assays in both zebrafish and human pancreatic cell lines.

Results: We successfully identified interspecies equivalent CREs, overcoming the lack of sequence conservation of non-coding regions between species. We described a zebrafish *ptf1a* distal-enhancer whose deletion results in pancreatic agenesis during development, supporting the phenotype previously observed in humans and validating the causality of this condition in vivo. We also found a pancreatic enhancer of the tumor-suppressor *ARID1A*, whose deletion decreased ARID1A expression in pancreatic cell lines, potentially heightening the risk for pancreatic cancer.

Conclusions: Our findings demonstrate the evolutionary functional conservation of critical CREs and their essential role in the expression of key genes, with implications in pancreatic diseases. Therefore, this study emerges as a pivotal contribution to the study of the pancreas, supporting future innovative strategies for tackling pancreatic disorders.

P20.021.B Use of transcriptome analysis as a complementary technology in genetic diagnosis

Marta Carreño[1], *Maria Segura-Puimedon*[1], *Marta de Castro-Miró*[2], *Jairo Rodríguez*[2], *Héctor Díez Nuño*[2], *LLuís Armengol*[1]

[1]*qGenomics, DryLab, Esplugues de Llobregat, Spain;* [2]*qGenomics, R + D, Esplugues de Llobregat, Spain*

Background/Objectives: Nowadays it has become evident that the combination of genomics, transcriptomics and proteomics can be useful to reach a definitive genetic diagnostic. In our work, we aimed at the assessment of the contribution of transcriptomics in reaching a diagnostic for patients with previous inconclusive exome or genome studies.

Methods: A total of eight individuals were evaluated using mRNAseq after an inconclusive result of a genomic analysis. RNA was obtained from different target tissues. In two cases, a heterozygous pathogenic variant had been detected in a gene associated with an autosomal recessive inheritance and the study was performed in search of a second hit. In the 6 remaining cases, the objective was to determine the functional effect of the candidate variants, located in genes with autosomal dominant or X-linked inheritance models: one likely pathogenic missense variant, one missense variant of uncertain significance (VUS), two non-canonical splice site VUS, one synonymous VUS and a complex rearrangement.

Results: In the two first cases no second variants were identified, but underexpression of the target genes was confirmed. Aberrant splicing isoforms were observed in the cases with synonymous and non-canonical splice site variants. The rearrangement causes the appearance of an aberrant isoform of the candidate gene. The remaining cases are still under study.

Conclusion: The application of transcriptomics is crucial to decrypt the effect of different types of variants on disease-associated genes and might help towards a definitive genetic diagnosis.

Grants: Not applicable.

Consortium: GAinS Investigators

Background/Objectives: Sepsis is a clinical syndrome caused by a dysregulated response to infection, where inter-individual heterogeneity is a major obstacle to understanding pathophysiological mechanisms and developing immunomodulatory treatments. Here, we aimed to investigate how host genetic variation affects the sepsis transcriptomic response.

Methods: Using genome-wide genotyping and gene expression data on 997 adult sepsis patients, we estimated the contribution of common genetic variation (GCTA) to previously defined sepsis endotypes. We mapped expression, splicing, and co-expression module quantitative trait loci (QTL), and through comparisons to healthy cohorts (mashr) identified sepsis-dependent regulatory effects, as well as colocalisation events with relevant GWAS associations. Finally, we tested QTLs for interactions between genotype and sepsis endotype, and incorporated transcription factor motifs (SNP2TFBS), predicted regulon activity (DoRothEA), and cell proportions (CIBERSORTx) to prioritise candidate upstream drivers.

Results: We found common variants were a significant contributor ($p = 0.019$) to sepsis endotype, and identified QTLs for 10,618 genes (eQTLs), 9,498 splice phenotypes (sQTLs), and 30 co-expression modules (modQTLs). We found 10.5% of eQTLs and 15.7% of sQTLs also tested in healthy cohorts had larger effects in sepsis, demonstrating the importance of context in regulatory variant interpretation. We additionally identified 1,578 genotype-endotype eQTL interactions, and from these inferred upstream regulators including HIF1A and CEBPB. These factors were correlated with progenitor and immature neutrophil subsets, further implicating glycolysis and emergency granulopoiesis in the poor outcome sepsis endotype.

Conclusion: Our combinatorial approach has identified putative mechanistic links between host genetic variation, cell subtypes, and the individual transcriptomic sepsis response.

P20.025.B FOSL1 as a potential target in triple-negative breast cancer

Finja Hennig[1], *Thea Reinkens*[1], *Vera Schäffer*[1], *Marlies Eilers*[1], *Amelie Stalke*[1], *Brigitte Schlegelberger*[1], *Thomas Illig*[2], *Britta Skawran*[1]

[1]*Hannover Medical School, Department of Human Genetics, Hannover, Germany;* [2]*Hannover Medical School, Hannover Unified Bank (HUB), Hannover, Germany*

Background/Objectives: Breast cancer (BC) is the most common malignancy worldwide with the highest number of cancer-related deaths in women. Triple-negative breast cancer (TNBC) represents 15-20% of all BCs and is characterized by high aggressiveness, early onset and a poor prognosis. Aberrant expression of microRNAs (miRs), such as downregulated hsa-miR-449a-5p (miR-449a), plays a significant role in cancer. This study aimed to explore new target genes of miR-449a in TNBC and assess their therapeutic potential.

Methods: Ago2 RNA immunoprecipitation (Ago-RIP) followed by sequencing was performed to identify new target mRNAs of miR-449a. TNBC cell lines HCC38 and HCC1937 were transiently transfected with both miR-449a mimics and siRNA against the potential target gene FOSL1. Regulation of FOSL1 by miR-449a was validated by luciferase reporter assay and expression analyses. Tumor-relevant functional effects of FOSL1 were analyzed using in vitro assays.

Results: Ago-RIP-Seq revealed FOSL1 as a potential target gene of miR-449a. Treatment with miR-449a mimics reduced FOSL1 expression at both mRNA and protein levels, and the luciferase reporter assay validated regulation of FOSL1 by miR-449a. Knockdown of FOSL1 inhibited migration in both TNBC cell lines and increased apoptosis in one cell line.

Conclusion: FOSL1 emerges as a promising therapeutic target directly regulated by miR-449a, exhibiting a tumor-suppressive effect by mainly inhibiting migration. Further experiments will identify the cell signaling pathways altered by FOSL1.

P20.026.C SUPT5H loss-of-function variants as modifying factor in beta-thalassemia trait

Tamara Koopmann[1], *Ahlem Achour*[2], *Nik Mohd Hasan*[1], *Jan Traeger-Synodinos*[3], *Jelmer Legebeke*[1], *Cornelis Harteveld*[1]

[1]*Leiden University Medical Center, Clinical Genetics, Leiden, Netherlands;* [2]*Charles Nicolle Hospital, Department of congenital and hereditary diseases, Tunis, Tunisia;* [3]*St. Sophia's Children's Hospital, Choremeio Research Laboratory, Athens, Greece*

Background/Objectives: Recently it was discovered that carriers of *SUPT5H* null-variants express a hematology resembling beta-thalassemia, including microcytic hypochromia and elevated HbA2. In this study we compare the hematologic data to carriers of beta-thalassemia and carriers of β-thalassemia with haplo-insufficiency of *SUPT5H*.

Methods: The Hb, MCV, MCH and HbA2 values of approx. 40 carriers of 22 different *SUPT5H* null-variants were compared to 15 carriers of beta0-thalassemia, 15 carriers of beta + -thalassemia and 9 beta-thalassemia intermedia patients, using one way ANOVA to determine whether there are significant statistical differences of each parameter between these 3 groups. The same was done between the group of compound heterozygotes SUPT5H/beta-thal (N = 3) with beta-thalassemia intermedia (N = 9).

Results: In the comparison between *SUPT5H* carriers vs Beta0 thal carriers, there are significant differences in terms of Hb, MCV and MCH, but no difference in HbA_2%. There are no mean differences between all groups for Hct and RBC level. In the comparison between *SUPT5H* vs beta + -thal there are no significant differences. Comparing beta-thal intermedia to compound heterozygotes *SUPT5H*/beta-thal it appears there is a higher Hb, but comparable Ht, MCV and MCH, suggesting a comparable hematology. However, the comparison of HbA_2 levels is significantly different.

Conclusion: By comparing red cell indices amongst different groups of beta0- and beta + -thal carriers and beta-thal intermedia patients, more insight into the exact clinical phenotype was obtained. The elevated HbA2 levels of 10.7% (SD = 2.0%) could facilitate the diagnosis of *SUPT5H*/beta-thal combinations in beta-thal carriers expressing clinically as beta-thalassemia intermedia and contribute to the discovery of new *SUPT5H* variants.

Consortium: PILOT Consortium

Background/Objectives: The occurrence of complicated neonatal infections is still linked to long-term health complications and mortality. Addressing this, this study aims to fill the knowledge gap in the genetic basis of protein expression and its regulatory effect on the immune cell development, which has been extensively explored in adult populations but remains under-researched in neonates.

Methods: Protein quantitative trait loci (pQTL) were mapped in 383 samples of the Munich Preterm and Term Clinical (MUNICH-PreTCl) birth cohort. Mass spectrometry-based proteomic analysis was conducted from dried blood spots (DBS) to assess both, cellular and secreted, protein profiles. Genotyping was performed using the Illumina Global Screening Array chip. Missing protein expression values were imputed using the R package missForest, genotype imputation was performed via the Munich Imputation server, followed by QTL mapping using TensorQTL.

Results: Quality control procedures applied to genotype and proteomic data yielded 5,610,609 Single Nucleotide Polymorphisms and 964 proteins. 121 *cis* pQTLs were identified (p-value < 0.05), associated with biological processes such as neutrophil degranulation and complement activation. While pQTLs of secreted proteins could be replicated in existing plasma pQTL studies from adults, pQTLs of cellular proteins were often missed.

Conclusions: This study highlights the pivotal role of pQTL mapping in understanding the genetic influence on neonatal immune mechanisms and potential avenues for therapeutic interventions. Furthermore, it demonstrates the potential of DBS samples in functional genetics studies expanding the scope from plasma proteins to cellular protein profiles using miniscule sample volumes.

P20.028.A Identification of *cis*-expression quantitative trait methylation (eQTMs) in saliva

Alba Hernangomez-Laderas[1;2], *Ariadna Cilleros-Portet*[1;2], *Sergi Marí*[1;2], *Bárbara P. González-García*[1;2], *Ane Arregi*[1;3;4], *Amaia Irizar*[1;3;4], *Iraia García-Santisteban*[1;2], *Corina Lesseur*[5], *Nora Fernandez-Jimenez*[1;2], *Jose Ramon Bilbao*[1;2;6]

[1]*University of the Basque Country (UPV/EHU), Department of Genetics, Physical Anthropology and Animal Physiology, Leioa, Spain;* [2]*Biobizkaia Health Research Institute, Barakaldo, Spain;* [3]*Biogipuzkoa Health Research Institute, Donostia, Spain;* [4]*Center for Biomedical Research in Epidemiology and Public Health Network (CIBERESP), Madrid, Spain;* [5]*Icahn School of Medicine at Mount Sinai, Department of Environmental Medicine and Public Health, New York, United States;* [6]*Center for Biomedical Research in Diabetes and Associated Metabolic Disorders (CIBERDEM), Madrid, Spain*

Background / Objectives: Saliva is an easily accessible tissue containing biomarkers that have proven useful for diagnosing both local and systemic diseases. *Cis*-expression quantitative trait methylation (*cis*-eQTM) studies, which identify the association between DNA methylation (DNAm) at CpG sites and the expression of nearby genes, may provide insights into the molecular mechanisms underlying variant associations with complex traits.

Methods: Using DNAm (Illumina EPIC array) and gene expression (exome capture RNA-seq) data from saliva of general population adult donors ($n = 100$) we calculated *cis*-eQTMs located 1 Mb up- and downstream gene start positions with the MatrixEQTL R package, including as covariates age, sex, RNA-seq batch, 5 genotype-PCs, 20 DNAm PCs and 8 expression PEER (probabilistic estimation of expression residuals) factors. Pathway enrichment analysis of the genes identified was performed using Enrichr.

Results: We identified 371 CpG-gene pairs ($P < 5.0 \times 10^{-8}$), involving 144 CpGs and 152 genes, with an average distance between CpG site and gene of 183 ± 240 Kb. CpGs are located upstream ($n = 168$) or downstream ($n = 203$) of the gene start site, as well as in gene body ($n = 48$). A positive correlation between DNAm and gene expression was observed in 198 eQTMs, while 173 show a negative association. Out of the 24 enriched pathways found "Antigen processing and presentation" was the most significant ($P = 1.09 \times 10^{-5}$).

Conclusion: We have constructed a useful catalog of saliva eQTMs to help uncover the biological mechanisms behind complex traits.

P20.029.B DNA methylation surrogates link childhood cognitive and non-cognitive development to socioeconomic status and lifespan: a multi-cohort epigenome-wide study

Giovanni Fiorito[1], *Giorgia Menta*[2], *Paolo Uva*[1], *Simone Ghislandi*[3], *Conchita D'Ambrosio*[4]

[1]*IRCCS Istituto Giannina Gaslini, Clinical Bioinformatics Unit, Genoa, Italy;* [2]*Luxembourg Institute of Socio-Economic Research (LISER), Luxembourg, Luxembourg;* [3]*Bocconi University, Department of Political Sciences, Milan, Italy;* [4]*Luxembourg University, Economics, Luxembourg, Luxembourg*

Background/Objectives: The accumulation of cognitive and non-cognitive skills over childhood and adolescence has been shown to predict better economic and health outcomes later in life. Accurately assessing developmental trajectories during childhood is thus essential for early identification and intervention on those experiencing slower development.

Methods: We leveraged DNA methylation data from 1,000 UK individuals across childhood (birth, 7 years, 15-19 years) to develop epigenetic surrogates for cognitive and non-cognitive pace of development (*DNAmPoD*). We validated its predictive power in independent childhood cohorts from the Netherlands, US, and Mexico (N>3,000 children) and adulthood cohorts from the UK and Italy (N>3,000 adults).

Results: *DNAmPoD* significantly associated with various cognitive and emotional outcomes in children. In adults, higher *DNAmPoD* scores predicted higher educational attainment, better job positions, and lower all-cause mortality. Gene set enrichment analysis revealed consistent involvement of pathways and gene ontologies crucial for brain development, including "*Regulation of neuron projection development*", "*Synapse organization*", and "*Dendrite development*". We also identified hub genes like *TIAM1*, *CYFIP1*, and *BAIAP2*, known for their roles in early-life brain development supporting the biomolecular relevance of the newly developed biomarker.

Conclusion: This large-scale study establishes *DNAmPoD* as a robust epigenetic surrogate for cognitive and non-cognitive development useful for early identification of children experiencing slower development. Unlike traditional methods requiring repeated measurements over time, *DNAmPoD* requires one data point per child, regardless of age. Eliminating the need for years of data collection, *DNAmPoD* potentially overcome traditional assessment of developmental trends.

Grants: Fonds National de la Recherche Luxembourg (Grant C19/SC/13650569/ALAC).

P20.030.C Genetic regulation of single-cell personal gene correlations (co-eQTLs) is highly enriched for GWAS variants

Corinna Losert[1], *Dan Kaptijn*[2], *Maryna korshevniuk*[2], *Roy Oelen*[2], *Harm-Jan Westra*[2], *Monique van der Wijst*[2], *Marc Jan Bonder*[2], *Matthias Heinig*[1], *Lude Franke*[2]

[1]*Helmholtz Munich, Institute of Computational Biology, Oberschleißheim, Germany;* [2]*University Medical Center Groningen, Genetics Department, Groningen, Netherlands*

Consortium: sc-eQTLGen Consortium

Background/Objectives: Genes are known to operate in regulatory networks, and recently, we have shown that genetic variants can affect these in a cell-type specific manner through so-called co-expression QTLs (co-eQTLs). These co-eQTLs may help in interpreting the upstream regulators of genetic variants that have been associated with disease. However, identifying co-eQTLs requires large sample sizes which limited our previous study. Here we leverage the single-cell datasets consolidated by the sc-eQTLGen consortium to extend those analyses.

Methods: We developed a pipeline that enables efficient and systematic co-eQTL mapping in a federated and privacy sensitive way and applied it on 4 datasets of the sc-eQTLGen consortium including 1,188 PBMC samples.

Results: We identified co-eQTLs across major cell-types. In the largest dataset (oneK1K) we observed 1,045 co-eQTLs for CD4 + T cells involving 487 unique genes and 157 unique SNPs. Associated genes were enriched in coherent functions. Furthermore, co-eQTL SNPs were approximately twice as often associated with complex traits and diseases (from the GWAS catalog) as eQTL SNPs not showing a co-eQTL effect ($p = 0.001$). The other datasets showed high agreement of the identified co-eQTLs (Rb>0.67).

Conclusion: Our results indicate that there are wide-spread personal and cell-type specific differences in genetic regulation.

Application of our pipeline to all datasets of the sc-eQTLGen Consortium will enable further validation and extension of identified co-eQTLs laying the foundation for building cell-type specific gene regulatory networks. Additionally, the GWAS enrichment results suggest that co-eQTLs can be useful for the interpretation of disease mechanisms.

P20.031.D Unraveling the Role of Cytosolic tRNAs in Human Mitochondria

Sarah Emser[1;2], *Julia Arapovic*[3], *Felix Sternberg*[3], *Eva Millesi*[1], *Ralf Steinborn*[2]

[1]*University of Vienna, Department of Behavioural and Cognitive Biology, Vienna, Austria;* [2]*University of Veterinary Medicine Vienna, VetCore, Vienna, Austria;* [3]*University of Vienna, Department of Nutritional Sciences, Vienna, Austria*

Background/Objectives: Communication between the nucleus and mitochondria, mediated by anterograde and retrograde signalling, is vital for cellular function, with anterograde communication regulating nuclear genes encoding mitochondrial proteins and retrograde signaling influencing nuclear gene expression. One facet of the molecular interplay is the import of cytosolic tRNAs into mitochondria, yet its impact is not sufficiently substantiated. Here we investigated the presence and potential function of cytosolic tRNAs in human mitochondria by emphasising on their involvement in mitochondrial translation of Mitochondrial Derived Peptides (MDPs), resulting from an expanded coding repertoire of the mitochondrial genome.

Methods: To identify actively translated mitochondrial sequences, we screened public mitoplast-derived RNA-sequencing (RNA-seq) data for cytosolic tRNA(Arg) species, performed ribosome profiling and screened public mass spectrometry data to identify peptide fragments indicating an involvement of cytosolic tRNA in mitochondrial translation.

Results: The involvement of cytosolic tRNA(Arg) species in mitochondrial translation is highly indicated by RNA-seq data produced from isolated mitoplasts and non-canonical peptide fragments uncovered by mass spectrometry. In the near future, we will confirm this route of retrograde communication by running Reverse Transcription Quantitative PCR (RT-qPCR) assays and by identifying mitochondrial sequences being active on mitoribosomes.

Conclusion: The dynamic interplay between the nucleus and mitochondria is crucial for cellular function. The detection of cytosolic tRNAs in human mitochondria suggests their involvement in mitochondrial translation and MDP generation, sheds light on mitochondrial protein synthesis mechanisms and prompts further investigation into their role in cellular physiology and disease pathogenesis.

Grants: The study was supported by resources of the University of Vienna.

P20.032.A Transcriptional regulation of genes throughout the cell cycle

Jennifer Herrmann[1;2], *Hangpeng Li*[1], *Nigel Roberts*[1], *Matthew Gosden*[1], *Kevin Clark*[1], *Emily Georgiades*[1], *Elisa Barrow-Molina*[1], *Simone Riva*[1], *James Davies*[1], **Robert Beagrie**[2], *Jim R Hughes*[1]

[1]*MRC Weatherall Institute of Molecular Medicine, Radcliffe Department of Medicine - Oxford University, Oxford, United Kingdom;* [2]*Centre for Human Genetics, University of Oxford, Oxford, United Kingdom*

Background/Objectives: The cell cycle is an essential and ubiquitous cellular process, and its disruption is linked to the pathogenesis of many common diseases, including cancer, cardiovascular and immunological conditions. Hundreds of mammalian genes exhibit periodic, cell cycle-dependent expression. We set out to ask which cis-regulatory elements control cell-cycle genes and whether mutations in these regions may contribute to the genetic basis of common disease.

Methods: We performed single-cell RNA-seq on mouse embryonic stem cells to identify genes whose expression varied through the cell cycle. We employed Capture-C to link these genes to putative regulatory elements and to examine the conservation of these elements between mouse and human. We use chromatin immunoprecipitation to follow the activity of regulatory elements through the cycle. Finally we use genome editing to validate non-coding GWAS variants that regulate expression of cell-cycle genes.

Results: We find hundreds of genes that exhibit periodic expression during the cell cycle, and show that these genes interact with distal enhancer elements. However, these enhancers do not exhibit periodic fluctuations in histone marks characteristic of enhancer activity, or periodic recruitment of transcription factors. Finally, we show that a SNP associated with a red blood cell phenotype (MCV) regulates the expression of the cell cycle gene *CCND3* in human red blood cells.

Conclusion: We show that distal enhancer elements are important regulators of cell cycle genes. Variants in these non-coding regions change expression of cell cycle genes in specific cell types and may thereby influence human phenotypes and diseases.

P20.033.B Uncovering early signs preceding disease-onset in a zebrafish model of rare tubulinopathy exhibiting untreatable neurodegeneration

Martina Venditti[1], *Graziamaria Paradisi*[1], *Giulia Fasano*[1], *Catia Pedalino*[1], *Marion Rosello*[2], *Filippo Del Bene*[3], *Marco Tartaglia*[1], **Antonella Lauri**[1]

[1]*Ospedale Pediatrico Bambino Gesù, IRCCS, Molecular genetics and functional genomics, Rome, Italy, Italy;* [2]*Institut Curie, PSL Research University, INSERM U934, CNRS UMR3215, Paris, France;* [3]*Sorbonne Université, INSERM, CNRS, Institut de la Vision, Paris, France*

Background/Objectives: Tubulinopathies are untreatable encephalopathies caused by mutations affecting microtubules dynamics, often showing early-onset neurodegeneration, progressive motor regression, spasticity and early death, representing a major burden for patients and society. However, contrary to well-recognized spinal muscular atrophy (SMA) and other motoneuron diseases (MNDs) with high incidence and decades of research,

these conditions remain overlooked. The absence of readily accessible in vivo models and thereby the lack of insights into the patho-mechanisms, leave them without effective drug policy. Within a functional genomics pipeline dedicated to orphan diseases, we established transient and stable genetic models in zebrafish recapitulating one of the condition caused by rare inherited loss of function (LoF) mutations affecting tubulin chaperons.

Methods: Here, we present the first results from setting-up gentle single-embryo genotyping to sub-cellular, cellular and whole-organism phenotyping in CRISPR-Cas9 mutants, obtained employing morphometric and behavioral analysis as well as super-resolution imaging.

Results: Our work ***a***. proposes the involvement of spinal motoneurons in the progressive manifestation of the disease; ***b***. demonstrates failure to thrive, progressive neuromuscular features resembling SMA; and ***c***. traces back the neurodegenerative traits to early signs already detectable in pre-symptomatic stages, including impaired microtubules dynamics in growing neurites.

Conclusion: By addressing a previously invisible disease, the work answers the EU-call for promoting equality with respect to access to diagnosis and offers a valuable in vivo vertebrate resource of a previously neglected MND, highlighting potential developmental windows for early diagnosis as well as targetable features preceding the disease onset.

Consortium: THOC Clinical Study Group

Background/Objectives: TREX (Transcription-mRNA Export) complex is a multi-subunit protein complex, conserved in all eukaryotes and implicated in neurodevelopmental disorders. We sought to identify the molecular, cell and developmental impacts of mutations of TREX subunits using patient cells, and a novel mouse model.

Methods: Through international collaboration we identified and studied 60 THOC2 variants, and novel variants in THOC6 (OMIM 615403), THOC7 and ALYREF (novel disease genes) that were predicted to be deleterious in children with variable clinical and neurodevelopmental outcomes. To gain further insight into the impact of TREX disruption on early neurodevelopment, we generated a mouse line with deletion of Thoc2 Exon37-38, modelled on a patient with ID, speech delay, hypotonia, and microcephaly.

Results: THOC2 protein stability was reduced in patient cells with missense variants, and splicing and deletion variants predominantly truncate the C-terminal RNA binding domain. Brain development, pre-natal survival and synaptic and electro-physiological properties of cortical neurons were impacted in the Thoc2 syndrome mouse. These were underlined by increased R-loop accumulation, DNA damage and consequent cell death that was comparable to the DNA damage of cells of patients with THOC2, THOC6, THOC7 and ALYREF variants.

Conclusion: Perturbed R-loop homeostasis, in stem cells and/or differentiated cells (i.e., neurons) in mice and human, and DNA damage-associated functional, i.e., trancriptional and proteomics alterations are at the root of THOC2/TREX syndromes. THOC2 and the TREX complex are therefore major, conserved players in the efficient maintenance of DNA integrity, a process which is essential for normal brain development and function in neurodevelopment and also neurodegeneration.

P20.035.D Hypothalamic miRNA's profile revealing the pubertal onset control

Maria Morrou[1], *Pavlos Fanis*[1], *Marios Tomazou*[2], *Hend Abdulgadr M Alghol*[1], *Vassos Neocleous*[1], *Leonidas A Phylactou*[1]

[1]*The Cyprus Institute of Neurology and Genetics, Department of Molecular Genetics, Function and Therapy, Nicosia, Cyprus;* [2]*The Cyprus Institute of Neurology and Genetics, Department of Bioinformatics, Nicosia, Cyprus*

Background/Objectives: Puberty is defined as the transition period from childhood to adulthood. The onset of puberty is characterized by the pulsatile release of gonadotropin-releasing hormone (GnRH), marking the activation of the hypothalamic-pituitary-gonadal axis. Regulation of puberty onset includes a complex network of genetic factors, controlling the hypothalamic GnRH expression. MicroRNAs (miRNAs), small non-coding RNAs, are an emerging regulatory element of post-transcriptional activity on targeted mRNAs. In this study, we investigated in female mice during puberty the hypothalamic miRNA profile.

Methods: Female C57BL/6 mice of three ages of postnatal day (PND) – PND14, PND35, PND56 – representing the pre-pubertal, pubertal and post-pubertal developmental stage respectively, were used. Hypothalamic RNA isolation and miRNA's expression profile was acquired by next generation sequencing (NGS). Bioinformatic analysis was performed and pathway enrichment analysis was conducted as well as validation analysis by quantitative real-time PCR.

Results: Bioinformatic analysis revealed differential expression and occurred predominantly at the onset of puberty. Stabilized increased and decreased patterns had an upregulation and downregulation of expression respectively, between PND14 and PND56 stages, followed by stabilization of expression. Those two patterns included the majority of differentially expressed miRNAs. Validation experiments confirmed the expression patterns for selected miRNAs, while pathway enrichment analysis presented several transcriptional and post-transcriptional regulation processes.

Conclusion: A clear involvement of miRNAs in the switch from juvenile to puberty is observed and highlights the importance of epigenetic regulation. Further analyses are needed for the delineation of the signalling pathways in which miRNAs are implicated during several pubertal disorders.

P20.036.A Widespread evolutionary conservation of gene regulatory elements in absence of direct sequence conservation

Mai Phan[1;2], Tobais Zehnder[2], Fiona Puntieri[2], Martin Vingron[2], **Daniel Ibrahim**[1;2]

[1]Berlin Institute of Health, Center for Regenerative Therapies, Berlin, Germany; [2]Max-Planck-Institut für molekulare Genetik, Berlin, Germany

Background/Objectives: Gene regulation is deeply conserved between species. Evolutionary conservation of non-coding elements (CNEs) is used to identify functional relevant regions, which when mutated in patients can underlie genetic disease.

However, many regulatory elements identified by chromatin marks are not conserved between mammals. This is particularly true for heart enhancers, even though the key genes driving heart development are conserved even between flies and human. This disparity could be attributed to algorithms based on sequence alignment, which might not faithfully detect functionally conserved regulatory sequences. Here, we develop a new algorithm and detect thousands of previously undetected CNEs.

Methods: We performed HiC-, ATAC-, ChIP- and RNA-seq from murine and chicken embryonic hearts and identified heart-specific cis-regulatory elements. A novel synteny-based algorithm, Interspecies Point Projection (IPP), identifies a novel class of indirectly conserved (IC) regions. We validate IC-regions using machine-learning models and binding site (TFBS) analysis. Finally, we perform in vivo enhancer reporter assays of IC-elements.

Results: IPP outperforms alignment-based methods, identifying 2-15 times more CNEs. Validation using epigenomic data shows that IC regions maintain active chromatin marks. Machine-learning models and TFBS-analysis show maintenance of shared TFBS despite high sequence divergence. In vivo validation of *all* tested enhancers confirms that IC-regions drive identical expression patterns and thereby represent bona fide homologous enhancers.

Conclusion: IPP dramatically increases the number of CNEs. IPP can be used to identify human-mouse conserved regions and explore which features (e.g. TFBS) are crucial to maintain functionality and guide interpretation of non-coding sequence variants in humans.

Introduction: *CHD8*-related neurodevelopmental disorder (NDD) is amongst the commonest forms of monogenic autism. We have previously shown the diagnostic utility of *CHD8*-NDD episignature. Here, we examine if peripheral blood DNAm changes can provide mechanistic insights into a disorder that primarily affects the brain.

Methods/Results: From *CHD8*-NDD patient blood samples we identified 2,319 differentially methylated points (DMPs) representing 69 hyper- and 1,058 hypomethylated genes and found them to be enriched for gene ontology (GO) terms "Voltage-gated calcium channel complex" and "Calcium channel complex". To investigate if these results could be mechanistically relevant, we performed reduced representation bisulphite sequencing on *Chd8*$^{+/-}$ P5 mouse neocortex and identified 13,358 DMPs representing 2,311 hyper- and 1,665 hypomethylated genes and found them to be enriched for disease/tissue relevant GO terms "Synapse organisation", "Axon development" and "Regulation of trans-synaptic signalling". Comparison of human and mouse data showed that 114 genes had concordant hypo- or hypermethylated DMPs in both datasets. Further analysis revealed 65 differentially methylated CpG islands (CpGi) in *Chd8*$^{+/-}$ P5 mouse neocortex, including 17/65 on the X chromosome and 19/65 associated with OMIM-morbid genes (9 linked with autism). We did not find any probes in the corresponding human CpGis to be similarly differentially methylated in peripheral blood of patients.

Conclusion: These results indicate that *CHD8* haploinsufficiency disrupts epigenetic state of autism-associated genes; the epigenomic disruption of X chromosome may explain why published *CHD8*-NDD cohorts are enriched for males; and the peripheral blood epigenome may have some, but only limited, value in mechanistic studies of *CHD8*-NDD.

Consortium: German Cancer Consortium (DKTK), Dresden, Germany

Background/Objectives: Germline and somatic loss-of-function variants in Succinate dehydrogenase B (*SDHB*) are associated with paragangliomas and gastrointestinal stromal tumors. The lack of evidence for precise variant classification and increased high-throughput sequencing lead to a high number of variants of uncertain significance (VUS) with unclear clinical consequences. Despite the high performance of in silico splice prediction tools,

functional validation is required. Within this project, an *SDHB* minigene was used to investigate effects of selected variants on splicing in an in vitro system.

Methods: A minigene composed of four consecutive exons of *SDHB* was cloned and validated with controls on mRNA level using gel electrophoresis, Sanger sequencing and next-generation sequencing. Single nucleotide variants (SNVs,n = 28) were selected based on SpliceAI-prediction and mutated via site-directed mutagenesis. Mutated minigenes were transfected into HEK293T cells and RNA was analyzed.

Results: The transcriptional analysis revealed aberrant splicing for 18 out of 28 SNVs (64%) that were predicted to show an effect on splicing. The number of transcripts per SNV varied from one to six (mean = 2). For ten SNVs, at least one aberrant transcript led to a frameshift. The most prevalent effect observed was exon skipping (n = 11). Only four variants with aberrant splicing showed a significant proportion (>25%) of wildtype transcript.

Conclusion: The presented in vitro assay allows for detection of aberrant splicing for in silico prioritized SNVs of *SDHB* and the insights will be included for improved variant evaluation. VUS could be reclassified based on PVS1/BP7 criteria (ACMG), translating into direct clinical impact.

P20.039.D Single cell analysis of gut biopsy tissue reveals cell type- and inflammation-specific expression quantative trait loci in Crohn's disease

Roy Oelen[1], *Werna Uniken-Venema*[2], *Marjolein Dijkema*[1], *Emilia Bigaeva*[2], *Sofie de Jong*[2], *Maria Paraskevopoulou*[3], *Pratik Panchal*[3], *Xinghao Zhang*[3], *Eleonora A. M. Festen*[2], *Lude Franke*[1], *Monique van der Wijst*[1]

[1]*University Medical Center Groningen, Genetics, Groningen, Netherlands;* [2]*University Medical Center Groningen, Gastroenterology and Hepatology, Groningen, Netherlands;* [3]*Takeda Pharmaceuticals, GI Drug Discovery Unit, Cambridge, United States*

Background/Objectives: Genome wide associations studies have linked more than 320 genetic loci to IBD, however how these genetic risk factors lead to disease (progression) remains largely unknown. The advent of RNA-seq allowed us to link genetic variants to gene expression via expression Quantative Trait Loci (eQTLs), which have proven to be linked to disease (phenotypes). The overlap between genetic variants that are linked to IBD, and the ones that affect gene expression unfortunately is quite poor. We hypothesize that this happens because cell-specific effects in the bulk RNA data are masked.

Methods: We here employ single cell mRNA-sequencing of 159 gut biopsy samples (100 non-inflamed and 59 inflamed) and Global Screen Array genotyping from 151 corresponding individuals suffering from Crohn's Disease to observe 4149 eQTL effects at a cell-type-specific level.

Results: We identify 3396 independent loci, affecting the expression of 3231 unique genes, across 11 different cell types. 10 of these are within Crohn's disease risk loci. We have subsequently tested these independent effects together with differentially expressed genes, to see which eQTLs occur upon inflammation, and find that 298 of these effects are modulated by both cell type specificity and tissue status.

Conclusion: These results show how genetic variants can contribute to disease, and will be of help in developments for precision medicine in the field of IBD.

P20.040.A Decoding the genetic predisposition to asthma using epigenomics

Lianne Trap[1], *Bernard Stikker*[1], *Marjolein de Jong - de Bruijn*[1], *Anne Onrust-van Schoonhoven*[1], *Bahar Sedaghati-khayat*[1], *Emmely de Roos*[1], *Anneloes van Krimpen*[1], *Arfan Ikram*[1], *Guy Brusselle*[2], *Rudi W. Hendriks*[1], *Jeroen van Rooij*[1], *Ralph Stadhouders*[1]

[1]*Erasmus MC, Rotterdam, Netherlands;* [2]*Ghent University Hospital, Gent, Belgium*

Background/Objectives: Asthma, an inflammatory airway disease, results from intricate interactions between genetics and environmental factors. High medical costs are mostly incurred by the 5-10% of patients requiring intensive treatment due to poor symptom control. We aim to highlight targets for phenotype-specific treatment of asthma by studying the genetic variants underlying its predisposition.

Methods: Genome-wide association studies identify up to 179 asthma-associated loci, in which ~99% of putatively causal genetic variants reside in non-coding genomic regions— thus complicating direct identification of susceptibility genes. We apply active chromatin signatures and 3D chromatin folding to: 1) connect genetic variants to genes in a cell type-specific manner and to 2) partition a polygenic risk score (PRS) predicting childhood-onset asthma in a Dutch prospective cohort (The Rotterdam Study).

Results: Systematically intersecting asthma-associated genetic variants with features of gene regulatory activity of 47 cell types revealed clusters of genetic loci demonstrating cell-type specific regulatory patterns. These included well-known gene-cell type pairs, e.g. the interleukin 33 locus and epithelial cells, and new associations involving mast cells, B or T lymphocytes, and even early blood cell precursors. Epigenomic partitioning of a PRS for asthma identified 5 clusters of regulatory variants, with those linked to lymphocytes and lung epithelial cells contributing most to its predictive ability.

Conclusion: We present a systematic way to translate genetic associations into tractable hypotheses, uncovering potentially new biological mechanisms relevant for asthma pathogenesis and predictive risk assessment.

P20.041.B Transcription termination failure is associated with altered DNA methylation and affects oncogenic pathways in high grade serous ovarian cancer (HGSOC)

Karolina Chwialkowska[1], *Magdalena Niemira*[2], *Agnieszka Bielska*[2], *Anna Zeller*[2], *Mariusz Kuzmicki*[3], *Jacek Szamatowicz*[3], *Joanna*

Reszeć- Giełażyn[4], Pawel Knapp[5], Marcin Moniuszko[6], Adam Kretowski[2], Miroslaw Kwasniewski[1]

[1]Medical University of Bialystok, Centre for Bioinformatics and Data Analysis, Bialystok, Poland; [2]Medical University of Bialystok, Clinical Research Centre, Bialystok, Poland; [3]Medical University of Bialystok, Department of Gynecology and Gynecological Oncology, Bialystok, Poland; [4]Medical University of Bialystok, Department of Medical Pathomorphology, Bialystok, Poland; [5]University Clinical Hospital in Bialystok, University Oncology Centre, Bialystok, Poland; [6]Medical University of Bialystok, Department of Regenerative Medicine and Immune Regulation, Bialystok, Poland

Background/Objectives: Readthrough transcription results from failure of canonical transcription termination and leads to downstream transcription (DoG – downstream of gene) causing read-in into next genes. Generated readthrough transcripts retain in the nucleus and may remain bound to the chromatin playing a role in regulating chromatin states and modulating gene expression. HGSOC mainly originates from the fallopian tube epithelium (FTE), and the one of the earliest molecular events occurring further past acquiring *TP53* mutations is the alteration of *PAX2*. The aim of the study was to evaluate the biological importance of readthrough transcription and its relationship with DNA methylation profile in HGSOC.

Methods: Stranded total RNA-Seq and genome-wide DNA methylation profiling (RRBS) were performed in the same specimens collected from ovarian tumours of 56 patients with HGSOC and 33 ovaries of non-cancer patients.

Results: Our results show statistical enrichment of DNA hypomethylation within DoG induction subset (p-value = 1.65×10^-4) as well as both DNA hypo- and hypermethylation within read-in upregulated genes (p-values = 6.06×10^-49). In the group of upregulated read-in genes exhibiting DNA demethylation, there was a significant over-representation (under FDR ≤ 0.05) of various pathways related to the epithelium development. Network-based modelling in this read-in genes set revealed *PAX2* and *EPCAM* within the top guide genes as well as *FOXD3* and *CDX2* as the top candidates.

Conclusion: Obtained data suggest that readthrough transcription induction in HGSOC is associated with altered DNA methylation level in a non-stochastic manner and might play biologically significant role during carcinogenesis affecting the loss of epithelial cell identity and driver/suppressor-related pathways.

P20.042.C Biallelic loss-of-function of a tRNA modification gene leads to impaired shoaling behavior and decreased startle response in zebrafish

Seda Susgun[1;2;3;4], *Nguyen Quynh Nhu[1], Emrah Yucesan[5], Dilan Wellalage Don[1], Tae-Yoon Kim[1], Tae-Ik Choi[1], Sibel Aylin Ugur Iseri[2], Cheol-Hee Kim[1]*

[1]Chungnam National University, Department of Biology, Daejeon, Korea, Rep. of South; [2]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Genetics, Istanbul, Türkyie; [3]Istanbul University, Graduate School of Health Sciences, Istanbul, Türkyie; [4]Bezmialem Vakif University, Faculty of Medicine, Department of Medical Biology, Istanbul, Türkyie; [5]Istanbul University-Cerrahpasa, Institute of Neurological Sciences, Department of Neurogenetics, Istanbul, Türkyie

Background/Objectives: Recent studies indicate that aberrant tRNA modifications lead to several human diseases, particularly neurological disorders. Herein, we present a tRNA modification gene as a novel candidate for neurodevelopmental disorders (NDD) through a knock-out zebrafish model.

Methods: CRISPR-Cas9 mediated stable knockout zebrafish line was generated and functionally evaluated. Whole-mount in situ hybridization (WISH) was conducted to determine spatiotemporal expression profiles of target genes. EthoVision and DanioVision systems were used in behavioral assays.

Results: Knock-out larvae did not show any early morphological changes and were raised to adulthood. Adult knock-out zebrafish displayed behavioral alterations. In the startle response assay, knock-out zebrafish showed statistically significant decreased response compared to wild-type siblings. In addition, the knock-out zebrafish line exhibited impaired shoaling behavior. Post-behavioral WISH assessments in adult zebrafish brains revealed a significant reduction in c-fos positive cells indicating neural activity in the forebrain regions which explains altered behaviors at the molecular level.

Conclusion: Herein, we established the knock-out zebrafish model for a novel gene associated with NDD. Functional evaluations support that loss-of-function of the gene causes NDD phenotype.

Grants: S.S was supported by TUBITAK 2214-A International Research Fellowship Programme for PhD Students. SAUI was awarded 2019 Distinguished Young Scientist by the Turkish Academy of Sciences.

P20.043.D Epigenetic, transcriptomic and genetic analyses of HR + /HER2- primary and metastatic breast cancer reveals heterogeneous mechanisms of endocrine therapy resistance

Jomar Sangalang[1;2], *Dlep Tran[1], Tony Sourisseau[3], Veronique Scott[1], Nusaïbah Ibrahimi[1], Alicia Tran-Dien[1], Nicolas Servant[4], Fabrice André[1], Sergey Nikolaev[1]*

[1]Institut Gustave Roussy, Villejuif, France; [2]Université Paris-Saclay - Faculty of Medicine, Le Kremlin-Bicêtre, France; [3]Institute Bergonié, Bordeaux, France; [4]Institut Curie, Paris, France

Background/Objectives: Endocrine therapy (ET) is the primary treatment for HR + /HER2- breast cancer patients; however, half of the patients exhibit ET resistance. Mechanisms of ET resistance are not fully understood, and require an integrated epigenetic, transcriptomic and genetic approach

Methods: We conducted ATAC, RNA, and whole-exome sequencing on primary and metastatic breast cancer lesions from 464 HR + /HER2- patients. The studied cohort represents primary breast cancers (pBC) derived from patients experiencing relapse or sustained remission within five years of resection and adjuvant ET, and ET-resistant metastatic breast cancers (mBC). Analysis of chromatin accessibility, gene expression, and mutations aimed to understand relapse mechanisms in pBC and resistance mechanisms in mBC. Cohort clustering utilized PAM50 probability scoring.

Results: Two PAM50 scoring-derived pBC groups exhibited different relapse risks, with high-risk cases showing increased chromatin accessibility and expression of E2F targets, MYC targets, and the JAK-STAT pathway. Low-risk cases were enriched in estrogen response (ER) pathways. ESR1 and TP53 driver alterations were enriched in mBC, while ER pathways and GATA3/FOXA1 transcription factors were more active in pBC. PAM50 scoring

revealed subgroups of mBC based on perceived transdifferentiation to other intrinsic subtypes. ESR1 mutations characterized "Luminal B" tumours and resembled pBC, "Her2" subtype exhibited ERBB2 alterations, and "Basal" subtype was associated with BRCA1/UBR5 alterations and poor survival.

Conclusion: This comprehensive analysis of HR + /HER2- breast cancer unveils key insights into ET resistance mechanisms. PAM50 scoring aids in understanding tumour heterogeneity, contributing to a deeper understanding of relapse and the molecular landscape of ET resistance.

P20.045.B Missing heritability in neurodegenerative diseases: application of "MaPSy" to uncover the impact of Variants of Uncertain Significance on splicing mechanism

Beatrice Piola[1], *Giovanni Papagni[1], Fjorilda Caushi[1], Nicola Pomella[1], Hesam Aminian[1], Francesco Favero[2], Davide Corà[3], Luca Magistrelli[4], Alfredo Brusco[5], Fabiola De Marchi[6], Letizia Mazzini[6], sandra d'alfonso[1], Lucia Corrado[1]*

[1]University of Eastern Piedmont, Department of Health Sciences, Novara, Italy; [2]University of Eastern Piedmont, Translational Research Centre for Autoimmune and Allergic Diseases (CAAD), Novara, Italy; [3]University of Eastern Piedmont, Department of Translational Medicine, Novara, Italy; [4]University of Eastern Piedmont, Maggiore Della Carità Hospital, Department of Neurology and ALS Centre, Novara, Italy; [5]University of Torino, Department of Medical Sciences, Torino, Italy; [6]University of Eastern Piedmont, Maggiore Della Carità Hospital, Novara, Italy

Background/Objectives: Neurodegenerative diseases are characterized by a genetic etiology either in the familial and the sporadic forms. Although NGS identified many new genetic causes, a missing heritability remains, which can be partially explained by Variants of Uncertain Significance (VUS) that could alter splicing mechanisms. The Massively Parallel Splicing Assay (MaPSy) was developed to test the impact on splicing mechanism of hundreds of variants. This study aims to analyze by a modified-MaPSy a subset of VUS identified by WGS in 140 neurodegenerative patients.

Methods: From the variants identified by WGS in a panel of 855 neurodegenerative disease genes, we prioritized those with a SpliceAI score >0,6 and Allele Frequency <0,001 (n = 146). An amplicon-based library was cloned into the pSPL3-plasmid and transfected into HEK293T cells. NGS analysis was performed, paired-end reads were aligned to a reference genome, and BAM files manually inspected.

Results: We performed MaPSy on 19 variants (7 exonic/ 6 intronic/ 6 splicing) representing those with the highest SpliceAI score among prioritized variants (SpliceAI >0.6). An aberrant splicing was detected in 15/19 variants. Analysis for the remaining four variants was impaired due to low NGS locus coverage. The aberrant splicing was predicted to generate an out-of-frame transcript for 12 variants, and in-frame for the remaining ones.

Conclusion: Our results confirm that VUS impact on splicing mechanism can be analysed by a massive approach and SpliceAI is an effective predictor for prioritizing splicing-altering variants. An ex-vivo analysis to comprehend the role of identified variants in disease mechanisms will be performed.

P20.046.C Deciphering the nucleotide code of diabetes-associated regulatory elements

Fábio Ferreira[1], *João Nogueira[1], Sofia Borges[1], Ana Eufrásio[1], Miguel Sousa[1], Mariana Cruz[1], Rui Macedo[1], José Bessa[1]*

[1]i3S - Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal

Background/Objectives: Many sequence variants associated to Type-2 Diabetes Mellitus (T2DM) overlap with non-coding cis-regulatory regions, such as enhancers, that regulate gene expression in endocrine pancreas. Understanding how variants and random mutations impact transcription factor (TF) binding and enhancer activity is essential to better understand endocrine pancreas function, predict T2DM progress, and improve therapeutics. Thus, we aim to decipher the nucleotide code of those genetic sequences and establishing a predictive model of variant effects.

Methods: Different enhancer reporter vector architectures for optimal enhancer activity assessment in mammal cells were tested. Data from GWA studies and human islets genomic features was used to select hundreds of candidate enhancers overlapping with or close to Diabetes-associated SNPs. Two top enhancer reporter vector architectures were used to test those putative enhancers, including some carrying relevant polymorphisms, and to establish endocrine pancreas reporter cell lines. Lentiviral sgRNA libraries are being used to perform random Cas9-mediated mutagenesis in those reporter lines, followed by assessment of enhancer activity. Machine learning tools will then be used to determine the sequence motifs impacting sequence activity.

Results: A reliable pipeline to identify active enhancer sequences in endocrine pancreas cells was defined. Hundreds of sequences were tested for enhancer activity and hundreds of reporter cell lines were established and validated. CRISPR-mediated mutagenesis is being performed in the validated sequences, to identify the nucleotides and TF binding sites required for normal activity.

Conclusion: We developed a pipeline to assess the impact of sequence variants and mutations in enhancer activity.

Background/Objectives: Orofacial clefting (OFC) is a frequent congenital anomaly and can occur either in the context of an underlying syndrome or isolated (nonsyndromic). The two common OFC subphenotypes are cleft lip with/without cleft palate (CL/P) and cleft palate only (CPO). In this study, we started out to identify de novo copy number variants (dnCNVs) that affect possible susceptibility genes for nonsyndromic CL/P (nsCL/P).

Methods: We reanalyzed exome sequencing data (50 nsCL/P trios) and called dnCNVs. For the herewith identified candidate gene we performed: targeted-sequencing in in-house nsCL/P patients, expression analysis in published single-cell RNA-sequencing data (mouse embryo, zebrafish larvae (zfl)) and knock out/down experiments in zfl including morphometric measurements of the craniofacial region at 4 days post-fertilization.

Results: We identified a heterozygous 86 kb de novo deletion affecting the Zinc Finger Homeobox 4 gene (*ZFHX4*), a suggested OFC candidate gene. Our targeted-sequencing and expression data at relevant time-points further support an important role of *ZFHX4* in OFC. The *zfhx4* knockout and knockdown zfl showed a statistically significant underdeveloped and abnormally shaped ethmoid plate and cartilaginous jaw, the latter resembling micrognathia.

Conclusion: Our findings add to current knowledge from the literature that *ZFHX4* mutations are involved in a much wider phenotypic spectrum leading to nonsyndromic and syndromic forms, not only of CL/P but also CPO. In conclusion, *ZFHX4* should be considered as a causative OFC gene.

P20.048.A The Bone Regulome – a map of bone-specific enhancers for non-coding variant interpretation

Salaheddine Ali[1;2;3], **Regina Margarete Grün**[4], *Daniel Ibrahim[3;5], Robert Schöpflin[3], Sven Geißler[5], Stefan Mundlos[1;3;5], Uwe Kornak[1;3;4;5]*

[1]Charité – Universitätsmedizin Berlin, Institute for Medical Genetics and Human Genetics, Berlin, Germany; [2]Charité – Universitätsmedizin Berlin, Department of Hematology, Oncology and Tumorimmunology, Berlin; [3]Max Planck Institute for Molecular Genetics, Development and Disease Group, Berlin; [4]University Medical Center Göttingen, Institute of Human Genetics, Göttingen, Germany; [5]Berlin Institute of Health at Charité – Universitätsmedizin Berlin, BIH Center for Regenerative Therapies (BCRT), Berlin, Germany

Background/Objectives: The interpretation of sequence changes in the non-coding genome is challenging due to the limited knowledge on cell type- and differentiation-specific enhancer usage. Enhancers spatiotemporally control gene expression over large genomic distances and, thereby, regulate tissue development. We developed a map of bone-specific regulatory sequences for the interpretation of non-coding genetic variants in the context of rare as well as common bone disorders.

Methods: We performed HiC-, ATAC-, ChIP- and RNA-seq of in vitro differentiated osteoclasts, osteoblasts and their respective precursors. Regulatory sequences were called and assigned to regulated genes by the CRUP algorithm. For validation CRISPRa/i iPSC lines were used and expression was evaluated by qRT-PCR.

Results: Enhancer activity and chromatin loops broadly correlated with differential gene expression during osteoblast and osteoclast differentiation. However, also genes similarly expressed in both cell types (e.g. *NFATC1*) showed differential enhancer usage. Pre-formed chromatin loops were visible in absence of gene activity, e.g. in the *EN1* locus. In total, about 2% of the genome comprise potential bone-relevant enhancers. 33% of intergenic SNPs associated with bone mineral density overlapped with these regulatory sequences, of which the majority located in osteoblast-specific enhancers. The majority of enhancer candidates was positively validated using CRISPRa/i-iPSCs. An enhancer in the sclerostin (*SOST*) gene locus, which is deleted in van Buchem disease, increased expression 100-fold in CRISPRa-iPSCs, whereas neighboring genes remained unaffected.

Conclusion: Our map improves the understanding of bone cell biology and is a valuable resource for interpretation of non-coding variants in the era of whole genome sequencing.

(Center for Diagnosis and Treatment of Leukodystrophies), Milan, Italy; [7]University of Milan, Department of Biomedical and Clinical Sciences, Milano, Italy; [8]Children's Hospital "V. Buzzi, Department of Pediatrics, Milan, Italy

Background/Objectives: Genetics variants in *SLC16A2* gene encoding for the monocarboxylate transporter 8 (MCT8) cause a severe X-linked intellectual deficit known as Allan-Herndon-Dudley syndrome (AHDS). MCT8 promotes cellular uptake and efflux of thyroid hormones. Active T3 and retinoid X receptors

(RXR) can form heterodimer complexes which bind to hormone response elements (HREs) that leads to activate or repress transcription. Our aim is to investigate the impact of MCT8 mutations on the pathogenetic mechanisms of AHDS.

Methods: Fibroblasts were obtained from skin biopsies of 2 AHDS mutated patients and matched controls. RNA was extracted with TRIzoL™. Total RNA sequencing was performed with the CORALL Total RNA-Seq Library Prep Kit using Illumina NextSeq 500 Sequencing. Protein expression was valuated via western blot and immunofluorescence. MTT assay was used to compare cell viability. Live/dead assay discriminated live and dead populations. Lipids were detected via Oil Red O staining.

Results: A strong dysregulation in AHDS patients was highlighted by transcriptomic profiling, identifying 396 DEGs when comparing AHDS patients to controls. Moreover, MTT and Live/Dead assays demonstrated a reduced cell viability in AHDS_1 patient with a splicing variant [c.1690G>A (p.Gly564Arg)]. The C-terminal missense variant [c.1690G>A (p.Gly564Arg)] did not affect fibroblasts viability, challenging a personalized in vitro behavior. Target genes expression resulted upregulated in both patients. Furthermore, myelin related genes were significatively reduced. The lipid staining revealed an increasing presence of lipid droplets in AHDS fibroblasts.

Conclusion: Our preliminary data emphasize a mutation-specific impairment in patients' specific primary fibroblasts, used as pre-clinical experimental model of the disease.

Background/Objectives: Aicardi-Goutières Syndrome (AGS) is a leukodystrophy majorly defined by raised levels of type I interferon-alpha (IFN-α) in absence of demonstrable infections. AGS is associated with mutations in 9 genes which all encode for proteins involved in metabolism of nucleic acids. Mutations in *RNU7-1* lead to the least characterized form of the disease. *RNU7-1* encodes for a small nucleolar RNA which is a member of the small nuclear ribonucleoprotein complex U7 (U7 snRNP). U7 snRNP leads to the cut of the Poly-A tail in replication-dependent histones (RDH) pre-mRNAs. The aim of this work is to dissect the role of *RNU7-1* mutation in AGS pathogenesis. We investigated canonical AGS features such as the upregulation of IFN-α, interferon-stimulated genes and specific outcomes of *RNU7-1* mutation in primary fibroblasts obtained from AGS patients and compared to healthy controls.

Methods: Total RNA was extracted using TRIzol reagent and the genes' expression levels were determined by Real-Time PCR. ELISA, Western Blot analysis and immunofluorescence were also performed to assess protein expression levels.

Results: Our results confirm the upregulation of ISGs and the typical "interferon signature" in AGS patients which cause an increase in IFN-α production. Moreover, we confirmed the modulation of this "interferon signature" through hydroxychloroquine treatment. Lastly, we assessed the increased presence of enriched Poly-A RDH transcripts confirming the role of U7 snRNP in the cleavage of Poly-A tail.

Conclusion: This work reports the molecular mechanisms involved in AGS9 mutation which lead to the upregulation of ISGs, IFN-α overproduction, and misprocessing of RDH mRNAs.

P20.051.D Genetic variation at Krüppel-associated box (KRAB) domain-containing zinc-finger proteins may influence methylation variation at metastable epialleles

Julius Arthur Kuebel[1], *Noah Kessler*[2], *Maria Derakhshan*[1], *Andrew Prentice*[3], *Matt Silver*[1;3], *Garrett Hellenthal*[4]

[1]*London School of Hygiene & Tropical Medicine, Department of Population Health, London, United Kingdom;* [2]*University of Cambridge, Department of Genetics, Cambridge, United Kingdom;* [3]*Medical Research Council Unit The Gambia at The London School of Hygiene & Tropical Medicine, Fajara, London, Gambia;* [4]*University College London, Department of Genetics, Evolution & Environment, London, United Kingdom*

Background/Objectives: Metastable Epialleles (MEs) include CpGs that exhibit high interindividual methylation (DNAm) variation, while also showing within-individual consistency in methylation across tissues that suggests DNAm establishment in the early embryo. For this reason, MEs are promising candidate regions to explore the epigenetic links between early-life exposures and later health. However, little is known about the mechanisms – genetic, environmental, and stochastic – that drive DNAm variability at MEs. Interestingly, putative human MEs are enriched for proximity to certain subclasses of Retrotransposable Elements (REs) that are silenced via methylation by Krüppel-associated Box (KRAB) domain-containing Zinc-Finger Proteins (KZFPs). Here we explore whether genetic mutations in KZFPs partially drive methylation variability of putative human MEs.

Methods: We used a genome-wide scan to identify significant mQTLs (p-val < 1e-08) for each of 1128 putative human MEs, and matched control CpGs, using Agilent SureSelect Methyl-Seq Targeted Capture, and genotypes at >2M SNPs from 396 Gambian individuals. Next, we estimated the methylation variance explained by mQTLs in KZFPs as a proportion of that explained across all trans-mQTLs.

Results: We reveal that mQTLs in KZFPs explain >60% of the methylation variation explained by all trans-mQTLs in ~60% of putative MEs in Gambian individuals. By comparison, only 32% of matched controls had a trans-mQTL contribution by KZFPs >60%.

Conclusion: Our findings indicate a potential role of trans-mQTLs in KZFP genes maintaining interindividual methylation variation at some MEs, in addition to environmental and/or stochastic factors.

Grants: This work was supported by the Biotechnology and Biological Sciences Research Council [grant number BB/T008709/1].

P20.052.A Single cell CRISPR screen reveals genome-wide regulatory landscape of coronary artery disease

Veronica Yumiceba[1], *Kristian Händler*[1], *Varun Sreenivasan*[1], *Saranya Balachandran*[1], *Tobias Reinberger*[2;3;4], *Philip Seibler*[5], *Jeanette Erdmann*[2;3], *Malte Spielmann*[1;3;6]

[1]*Institute of Human Genetics, University Hospital Schleswig-Holstein, University of Lübeck and Kiel University, Lübeck, Germany;* [2]*Institute for Cardiogenetics, University of Lübeck, Lübeck, Germany;* [3]*DZHK*

e.V. (German Research Centre for Cardiovascular Research), Partner Site Hamburg/Kiel/Lübeck, Lübeck, Germany; [4]University Heart Center Lübeck, Lübeck, Germany; [5]Institute of Neurogenetics, University of Lübeck, Lübeck, Germany; [6]Human Molecular Genetics Group, Max Planck Institute for Molecular Genetics, Berlin, Germany

Background/Objectives: Large and ethnically diverse GWAS studies have significantly contributed to the genetics of coronary artery disease (CAD). Most CAD variants have been found in the non-coding genome, which in combination with the sparsity genome annotations in relevant cellular context, impeded establishing a relationship between these variants and their pathology. It is known that the non-coding DNA contains regulatory elements which tune proper spatio-temporal transcription. We aim to quantify the transcriptional effects of these non-coding CAD-GWAS hits in one multiplexed experiment combining high-throughput CRISPR-Cas9 and single-cell technologies.

Methods: A 180 unique gRNAs library targeting 41 CAD non-coding SNVs distributed across 8 loci, plus controls was delivered to dCas9-expressing monocytes and primary endothelial cells. Single-cell RNA libraries from CRISPRa and CRISPRi screens, with around 20.000 cells input per experiment, were generated using 10x Chromium, and sequenced. Analysis was performed using SCEPTRE.

Results: Preliminary CRISPRa results aiming at cis effects identified 11 of the 41 non-coding variants to have regulatory functions on neighboring genes in a cell-type specific fashion. Apart from 2 variants which were active across both cell types. These 11 variants reside in 5 different loci. Interestingly, the lead variant was not often the functional one and rs1537373 appeared to regulate the expression of 3 genes.

Conclusion: The combination of single-cell phenotyping methods and high-throughput CRISPR-screens is an effective way to experimentally prioritize GWAS variants. We are currently scaling up the experiments to 290 loci, whose findings will impact our understanding of the functional non-coding loci and provide a baseline for enhancer therapies developments.

P20.053.B Unraveling mechanisms of TKI resistance in NSCLC: insights from PDX models

Naomi Kaste MFONFU[1;2;3], *Floryane Braye*[1], *Galina Boldina*[2], *Matteo Cesaroni*[2], *Luc Friboulet*[1], *Sergey Nikolaev*[1], *Andrey Yurchenko*[1]

[1]*Gustave Roussy, Villejuif, France;* [2]*Sanofi Vitry, Vitry-sur-Seine, France;* [3]*Université Paris-Saclay - Faculty of Medicine, Le Kremlin-Bicêtre, France*

Background/Objectives: Targeted therapies like tyrosine kinase inhibitors (TKIs) targeting EGFR and ALK are first-line treatments for Lung Cancer. However, after initial response, rare drug-tolerant cancer cells (persister cells) frequently remain and lead to the emergence of TKI resistance. Characterisation of this population of interest and investigation of the mechanisms of treatment evasion may improve understanding of resistance mechanisms.

Methods: Two patient derived PDX models from pretreated cancers were generated. One PDX model had EGFR and ALK mutations and responded to treatment with Osimertinib and Alectinib, and the other – had ALK mutations, and responded to Lorlatinib. Each tumor was grafted into 5 mice, 3 of which were treated till emergence of the stable residual disease, and 2 – used as a control without treatment. snRNA-seq was performed to characterize in comparative framework the untreated and persister cancer cells.

Results: Majority of persister cells were in the G1 phase of the cell cycle and suppressed most canonical cancer pathways, however a notable upregulation of the ciliated pathway was observed in both models. Transcription factors MEOX2 and MLX were identified as activated, indicating their roles in resistance mechanisms and inhibition of proliferation, mobility, and cell growth. Furthermore, distinct mechanisms were uncovered in different tumor models: the ALK PDX model exhibited enrichment of Epithelial-Mesenchymal Transition signatures in persister cells, while the EGFR ALK PDX model showed suppression of MYC and Interferon responses.

Conclusions: PDX models proved to be an informative tool to study cancer persistence. TKI treatment evasion mechanisms in lung cancer might be intermediated by activation of the ciliated pathway.

Conflict of Interest: None declared

P20.054.C Regulatory impact of rare genetic variants implicated in blood cell development and function

Manuel Tardaguila[1], *Dominique von Schiller*[2], *Michela Colombo*[1], *Ilaria Gori*[1], *Chiara Chiereghin*[1], *Dragana Vuckovic*[3], *Eve Coomber*[2], *Stephen Watt*[2], **Nicole Soranzo**[1;2;4]

[1]*Human Technopole, Italy;* [2]*Wellcome Sanger Institute, Hinxton, United Kingdom;* [3]*Imperial College London, United Kingdom;* [4]*University of Cambridge, United Kingdom*

Background/Objectives: Across human traits and diseases, resolving the path connecting genetic variants to molecular and cellular function and, ultimately, to disease, remains the biggest hurdle towards unlocking the investment of early genomic studies. Genetic variants discovered by genome-wide association studies have been shown to lie predominantly in non-coding regions of the genome, where for most traits and diseases we have a limited understanding of the impact of genetic effects on the regulatory code, and of the specific cellular, developmental and environmental contexts in which these variants act.

Methods: Here we deploy a multi-pronged approach to functionally characterise a set of high-priority non-coding variants impacting variation in blood cellular phenotypes. We focus on 94 rare variants displaying large phenotypic effects on different haematological indices. We use massively parallel reporter assays (MPRA) and arrayed CRISPR/Cas9 screens to assess their regulatory potential. We analyse gene expression and transcript usage in whole blood and immune cells from thousands of individuals.

Results: Our analyses reveal diverse modes of genetic regulation for approximately 75% of the rare variants tested. After careful curation using state-of-the-art annotation genomic metrics and phased WGS data, we identify 22 loci with strong evidence for genetic regulation impacting on blood cell development and biological function. Finally, using orthogonal experimental approaches, we identify a novel role for intronic variants in CUX1 in controlling megakaryocyte differentiation.

Conclusion: This systematic framework sheds light on the intricate mode of action of non-coding variants and advances the global effort to deliver on their translational potential.

P20.055.D Premature overexpression of miR-92a's target RBFOX2 impairs neural differentiation in the mouse cerebral cortex by hijacking the PTBP splicing program

Stephan Weißbach[1], *Hristo Todorov*[2], *Dewi Hartwich*[2], *Laura Schlichtholz*[2], *Sophie Muehlbauer*[2], *Dennis Strand*[3], *Susanne Strand*[3], *Tanja Vogel*[4], *Martin Heine*[1], *Susanne Gerber*[2], *Jennifer Winter*[2]

[1]*Johannes Gutenberg-Universität, Institute of Developmental Biology and Neurobiology (iDN), Mainz, Germany;* [2]*University Medical Center Mainz, Institute of Human Genetics, Mainz, Germany;* [3]*University Medical Center Mainz, Medizinische Klinik und Poliklinik, Mainz, Germany;* [4]*Universitätsklinikum Freiburg, Institut f.Anatomie u. Zellbiologie Abt. für Neuroanatomie, Freiburg im Breisgau, Germany*

Background: Alternative splicing is a pervasive phenomenon in the central nervous system that plays a crucial role in the transition from neural progenitor cells (NPCs) to neurons and additionally shapes the functional diversity of neuronal cell populations. The RNA-binding protein RBFOX2 is an indispensable mediator of alternative splicing in the developing neocortex. Furthermore, mutations in this gene are associated with several neurodevelopmental disorders.

Methods: To elucidate the specific role RBFOX2 plays in neural differentiation, we employed in-utero electroporation, thereby inducing *Rbfox2* overexpression in the mouse cerebral cortex at E13.5. Subsequently, we performed a comprehensive molecular characterization of RBFOX2 expression and splicing activity at E15.5.

Results: While RBFOX2 was absent from NPCs, it was already expressed in newly born neurons. Remarkably, overexpression resulted in impaired neuronal differentiation and aberrant migration phenotype. A genome-wide characterization of alternative splicing events uncovered a significant deviation from the normal splicing trajectory accompanied by a mixed NPC- and neuron-like splicing pattern compared to control samples. Furthermore, we identified a set of validated target exons that are normally repressed by PTBP2 to be significantly included upon *Rbfox2* overexpression, indicating an antagonistic relationship between these proteins. Finally, we showed that miR-92a repressed *Rbfox2* expression in vitro, whereas in vivo miR-92a-silencing in the cerebral cortex led to a significant up-regulation of *Rbfox2*.

Conclusion: Taken together, we demonstrated that RBFOX2 shapes neural differentiation through time-specific alternative splicing. Furthermore, we presented a novel post-transcriptional mechanism for regulating RBOFX2 during early cerebral cortical development via miRNA-silencing.

Conflict of Interest: None declared

P20.056.A JANUS - Joint analysis for augmentation of cluster specificity

Talip Yasir Demirtas[1], *Maximilian Billmann*[1]

[1]*Institute of Human Genetics, University of Bonn, School of Medicine and University Hospital Bonn, Bonn, Germany*

Background/ Objective: CRISPR screens systematically identify genes that impact various specific biological processes. To gain specificity of a screening experiment, the effect of a gene perturbation on a specific phenotype or the differential effect on cell fitness in a process-sensitizing context is measured. However, hit lists from these experiments typically include genes that have specific effects on the process as well as pleiotropic genes, which impact the process indirectly or directly.

Here, we develop an algorithm JANUS (Joint ANalysis for augmentation of clUSter specificity) that leverages public large CRISPR screening resources (The Cancer Dependency Map) to structure hit lists of phenotypes specific CRISPR screens and assign specificity and pleiotropy scores to each cluster.

Methods: JANUS jointly analyzes the screening set of interest and a selected reference data set such as the DepMap by quantifying how much the screening set of interest contributes to each gene cluster. Variance contributed by individual screens is quantified through partial correlation analysis. We used global and process-specific precision-recall analyses with gold standards to quantify functional information of gene-pairs and clusters.

Results: We apply JANUS to a set of 7 genome-wide CRISPR screens that investigate mitochondrial drug-gene interactions of energy metabolism. We show that JANUS increases the specificity and resolution of mitochondrial clusters. We applied JANUS to tissue-specific clustering, demonstrating that tissue-specific clusters connect both lowly mutated genes and cancer genes.

Conclusion: JANUS will help analyze and interpret complex phenotypic CRISPR screens by utilizing the rapidly growing number of simple fitness screens to systematically address the genotype-to-phenotype problem.

Grants: None.

Conflict of Interest: None declared

P20.057.B Tissue-specific mitochondrial regulation of gene expression

Xenofon Giannoulis[1;2], *Simon Wengert*[2;3], *Florin Ratajzak*[2;4], *Na Cai*[2;3]

[1]*Helmholtz Pioneer Campus, Helmholtz Zentrum München, Neuherberg, München, Germany;* [2]*Computational Health Centre, Helmholtz Zentrum München, Neuherberg, München, Germany;* [3]*Helmholtz Pioneer Campus, Translational Genetics, Neuherberg, München, Germany;* [4]*Institute of Computational Biology, Helmholtz Zentrum München, Neuherberg, München, Germany*

Background/Objectives: The mitochondrial DNA contains vital elements for oxidative phosphorylation and RNAs that are crucial for its translational machinery. However, gene regulatory effects resulting from the intricate interplay between nuclear and mitochondrial genomes have not been comprehensively explored.

Methods: We utilize cis- and trans-expression Quantitative Trait Loci (eQTL) analyses, employing whole-genome genetic data from 684 European individuals derived from the GTEx cohort across 48 tissues.

Results: First, we identify 309 significant mtDNA-cis-eQTLs (study-wide FDR 5%) for mtDNA-encoded genes across 38 out of 48 tissues tested, of which 108 are independent. Second, we identify 260 genome-wide significant associations ($P < 5 \times 10\text{-}8$) between nuclear-DNA-SNPs and mtDNA gene expression (mtDNA-trans-eQTL) at 210 unique nucDNA loci. Of these, 150 are cis-eQTLs for nucDNA encoded genes. Mediation analysis reveals that 117 out of 150 exhibit a cluster of nuclear-encoded genes, serving as mediators for the effects of mtDNA-trans-eQTLs. Third, we find 108 mtDNA-SNP associations ($P < 1.24 \times 10\text{-}09$) with 68 nucDNA-encoded genes (nucDNA-trans-eQTL). Among all the analyses, CNS tissues comprise 43% of all associations. Pathway and enrichment analyses reveal the broader biological relevance of our results. Specifically, the prominent enrichments include RNA polymerase II activity and mitochondria pathways, while mtDNA-trans-eQTLs overlap genes with significant GWAS hits on phenotypes such as BMI, and metabolic syndrome.

Conclusion: In summary, we establish the first comprehensive multi-tissue map of mtDNA and nucDNA crosstalk in gene expression regulation, advancing understanding of tissue-specific mito-nuclear interactions in health and disease.

P20.058.C Searching for novel diabetes therapies by modulating glucose-induced epigenetic modifications in the zebrafish pancreas

Francisco Cadete[1;2], *Joana Teixeira*[1], *Joana Marques*[1;2], *Marta Duque*[1;2], *José Bessa*[1]

[1]*i3S - Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal;* [2]*Abel Salazar Biomedical Sciences Institute - University of Porto, Porto, Portugal*

Background/Objectives: Type 2 diabetes(T2D) is a major public health concern. It is partially characterized by endocrine pancreatic(EndoPc) transcriptional dysregulation. Short-term glucose exposure triggers insulin secretion while long-term hyperglycemia(LTH) causes irreversible EndoPc changes, rendering cells unresponsive to glucose. These dysfunctional cells present aberrant gene transcription, suggesting modifications to their regulatory elements. Enhancers, cis-regulatory elements, are marked by histone epigenetic marks and chromatin accessibility, defining their active/inactive state. A comprehensive histone epigenetic profiling of LTH-induced changes remains unexplored, along with strategies to restore these marks. Here, we aim to profile in vivo epigenetic modifications induced by LTH in EndoPc cells, and employ chromatin remodelling to rescue glucose homeostasis, using zebrafish as a model.

Methods: LTH was induced by subjecting zebrafish to extended overfeeding(8-weeks). LTH remodeled enhancers will be identified by profiling histone epigenetic marks(Chip-seq) and chromatin accessibility(ATAC-seq) in LTH EndoPc islets compared to normal feed fish. By taking advantage of chromatin remodelers guided by dCas9, we will induce specific and targeted epigenetic changes in these remodeled enhancers, potentially restoring EndoPc function.

Results: Overfeed animals exhibited higher glucose levels upon returning to normal feeding, indicating a constant state of hyperglycaemia. ATAC-seq results revealed differential chromatin accessibility between conditions, suggesting that EndoPc chromatin is remodeled differentially in response to LTH. To date, we have developed one transgenic zebrafish line that exhibit the expression of dCas9-p300 specifically within β-cells, under conditional activation of 4-hydroxytamoxifen.

Conclusion: This approach aims to unveil glucose-induced epigenetic changes responsible for the transcriptional dysregulation in LTH, offering new strategies for T2D treatment.

P20.059.D The Balancing Correlation Network (BaCoN) score improves prediction of gene buffering

Thomas Rohde[1], *Maximilian Billmann*[2]

[1]*University Hospital Bonn, Institute of Human Genetics, Bonn, Germany;* [2]*University Hospital Bonn, Institute of Human Genetics, Bonn*

Background/Objectives: Buffering between genes is a fundamental mechanism to achieve robust cellular functions. This mechanism can have various clinical implications, including cancer treatment resistance. Large gene perturbation and expression data have the potential to systematically predict gene buffering, but sophisticated computational methods are required to make precise, non-biased predictions. We aimed to systematically identify functional redundancy within the human genome.

Methods: Under the assumption that the buffering capacity of a gene depends on its expression level, we quantified about 150 million potential buffering relationships by correlating genome-wide CRISPR-Cas9-screening derived fitness scores with transcriptomic data across more than 1000 cell lines.

We developed a post-hoc correction method for Balancing Correlation Networks (BaCoN) to remove false positive correlations due to co-expression with causal genes. BaCoN amplifies highly specific signals by weighting each edge of a correlation-based network based on its rank among incident edges.

Results: BaCoN reduces the dominance of cell lineage-driven correlations, while increasing the amount of paralog pairs among the top predictions in general as well as pairs from a gold-standard paralog synthetic lethal set. BaCoN outperformed routinely used methods loke multiple linear regression and SVA-based batch correction, that are capable of correcting for confounding factors. Utilizing BaCoN, we identified the MFRN1-MFRN2 paralog gene pair as the top genetic vulnerability of chr8p depleted cancers and validated it in vivo by combinatorial perturbation experiments.

Conclusion: BaCoN is a novel method to balance correlation networks using expression and perturbation data to predict functional buffering between genes without prior knowledge of experimental confounding factors.

P20.060.A Replication origins are enriched at genes important for genome maintenance

Ipek Ilgin Gönenc[1], *Alexander Wolff*[1], *Christian Müller*[1], *Arne Zibat*[1], *Gökhan Yigit*[1;2], *Holger Bastians*[3], *Bernd Wollnik*[1;2;4]

[1]*University Medical Center Göttingen, Institute of Human Genetics, Göttingen, Germany;* [2]*German Center for Cardiovascular Research (DZHK), Partner Site Göttingen, Göttingen, Germany;* [3]*University Medical Center Göttingen, Department of Molecular Oncology, Section for Cellular Oncology, Göttingen, Germany;* [4]*University of Göttingen, Cluster of Excellence "Multiscale Bioimaging: from Molecular Machines to Networks of Excitable Cells" (MBExC), Göttingen, Germany*

Background/Objectives: DNA replication initiates in S-phase with the firing of replication origins at specific genomic regions. The precise regulation of origin firing is essential to ensure faithful DNA replication, as any alterations may predispose to genomic instability.

Methods: The cell cycle length of HCT116 cells was assessed by flow cytometry to analyze the replication origin firing at the beginning of the S-phase. Cells synchronized in mitosis were released into media containing EdU to label the newly synthesized DNA and hydroxyurea to arrest cells in early S-phase. The EdU-labeled DNA was subjected to click chemistry and NGS analysis. We upgraded the EdUseq analysis pipeline reported previously to a Python-based script enabling the identification of EdUseq peak-associated regions.

Results: The bin size for determining the replication origins required a novel peak-calling strategy using prominence values inspired by the topographical peak determination. We pinpointed 3989 replication origin bins largely overlapping with the early replicating DNA domains, revealing higher genic region presence. Evaluation of over 400 genes included in a comprehensive cancer panel revealed a significantly higher than expected number of genes positioned within the EdUseq peak-associated regions suggesting that genes with important roles in maintaining genomic stability, DNA repair, and cell cycle were likely to be located at replication origins in a non-stochastic way.

Conclusion: We identified replication origins by direct sequencing of newly synthesized DNA in early S-phase, which revealed the association of replication origins to genes important for maintaining genome stability.

P20.061.B The effect of miR-197-3p overexpression in familial mediterranean fever mouse macrophages

Emre Nalbant[1], *basak sen*[1], *tayfun hilmi akbaba*[1], *banu balci-peynircioglu*[1], *yeliz z. akkaya-ulum*[1]

[1]*Hacettepe University, Faculty of Medicine Department of Medical Biology, Ankara, Türkyie*

Background/Objectives: Familial Mediterranean Fever (FMF) is an autosomal recessive inflammasomopathy linked to the MEditerranean FeVer (*MEFV*) gene. Despite its monogenic origin, the correlation between genotype and clinical phenotype remains complex. Our studies highlighted the involvement of microRNAs (miRNAs), specifically miR-197-3p, in FMF pathophysiology. This study investigated the impact of miR-197-3p overexpression on macrophages derived from an FMF mouse model, focusing on its modulation of the pyrin inflammasome.

Methods: Bone marrow-derived macrophages (BMDMs) from FMF-KI mice were transfected with pre-miR-197-3p or mimic control using Lipofectamine 2000. After transfection, IL-1β secretion and pro-IL-1β levels were analyzed following LPS priming and inflammasome activator treatments (dsDNA, flagellin, ATP and C3 toxin). RNA isolation, RT-qPCR, immunoblot, and ELISA were conducted and results were analyzed with statistical analysis using Student's T-test.

Results: After pre-miR-197-3p transfection of mice BMDMs, successful overexpression was determined. Overexpression of miR-197-3p significantly reduced IL-1β secretion. IL-1β was found to be decreased significantly only in C3 treatment related with pyrin inflammasome activation.

Conclusion: This study provided insights into the regulatory role of miR-197-3p in inflammation pathways associated with FMF, particularly its impact on pyrin inflammasome activation. Further investigations are warranted to unravel the exact mechanisms underlying miR-197-3p's influence on inflammasome activation and priming in FMF and other autoinflammatory disorders

P20.062.C New approach to deciphering complex cases of cystic fibrosis and its related disorders

clara blotas[1], *Mégane COLLOBERT*[1], *Anaïs Le Nabec*[1], *Emmanuelle Masson*[1,2], *Claude Férec*[1], **Stéphanie MOISAN**[1,2]

[1]*Univ Brest, Inserm, EFS, UMR 1078, GGB, F-29200 Brest, France;* [2]*Laboratoire de génétique moléculaire et d'histocompatibilité, CHRU Brest, Bretagne, France*

Background/Objectives: Cystic fibrosis (CF) is the most common severe inherited genetic disease in European populations, with 2114 reported variations within the *CFTR* (*Cystic Fibrosis Transmembrane Conductance Regulator*) gene. However, it is still challenging to understand the distinction between CF and CFTR-Related Disorders, as well as extreme phenotypes in CF. To explain these complex cases, our project aims to identify dysregulation of *CFTR* gene expression due to alterations in *cis*-regulatory elements (CREs).

Methods: We are using 4C (Circular Chromosome Conformation Capture) in intestinal, pancreatic and epididymal cells to map CRE-promoter interactions. Subsequently, we integrated epigenomic data as H3K27ac, H3K27me3 and CTCF (CCCTC-binding factor) marks to identify candidate CREs (cCREs). To functionally validate identified cCREs, we perform in vitro reporter gene assays. Targeted high-throughput sequencing is then applied to different patient cohorts to detect *cis*-regulatory variants.

Results: 4C analyses reveal several regions that interact with the *CFTR* promoter. Many interactions are conserved between cell-types, but specific peaks are also observed. Most of the regulatory regions have an enhancer effect. The first unique silencer of the *CFTR* gene was identified, located at +507,6 kb from the last codon. It is the first reported CRE outside the topologically associating domain of the *CFTR* locus. cCREs sequencing in patients revealed a dozen of SNPs with significantly different frequencies compared to the French population. Functional tests are carried out to validate their impact.

Conclusion: This work provides new elements for a better understanding of the *CFTR* locus organisation in a cell type-specific manner.

Consortium: Ribo-seq annotation consortium

Background/Objectives: The non-coding portion of the human transcriptome is extensively translated. Especially, thousands of 'non-canonical' translations have been captured by Ribo-seq. Some represent missing microproteins with biological roles; others appear to be aberrant translation products which could have potential as diagnostic markers or therapeutic targets in cancer. Non-canonical translation can also be purely regulatory in nature, especially uORFs found in 5' UTRs, which are of emerging interest in disease. Clearly, there is an urgent need to elucidate the biology and implications of non-canonical translation. We have formed an international consortium to this end, centered around the creation of public Ensembl-GENCODE annotation resources.

Methods: Our consortium is sharing expertise in Ribo-seq, mass spectrometry-based proteomics and immunopeptidomics, molecular evolution, variant interpretation and gene and protein-annotation, in order to drive solutions for the identification, characterisation and standardized annotation of non-canonical translations.

Results: We will discuss the maturation of the Ensembl-GENCODE catalog of non-canonical translations as a resource to support human genetics. We will focus on (1) efforts to find peptide-level evidence for Ribo-seq ORF translation products, including immunopeptidomics data; (2) the development of evolutionary metrics to appraise ORF functionality; (3) the expansion of our non-canonical ORF resource via the incorporation of 'nanoORFs' and non-ATG translations.

Conclusion: As our resources are produced within the reference annotation 'ecosystem', this is the point at which non-canonical translation enters the mainstream of genomic and medical science. Nonetheless, these are early steps of a long-term, multi-faceted project, for which we are actively seeking deeper community engagement.

P20.064.A LinkPrep™: a high-resolution, high-throughput, proximity ligation method that enables detection of structural variants and chromatin topology features in cancer.

*Miles Collier[1], Jonathon Torchia[1], Daniel Hwang[1], Mital Bhakta[1], **Cory Padilla**[1], Lisa Munding[1]*

[1]Dovetail Genomics, Scotts Valley, United States

Background/Objectives: Despite technological advances, including adoption of next-generation sequencing, many clinically relevant cancer driver mutations go undetected. The reasons are two-fold: 1) Structural variants (SVs) are challenging to detect using shotgun or long read approaches, especially heterogenous samples; 2) Epigenetic dysregulation, through mechanisms such as enhancer hijacking or changes to 3D genome organization are accepted to drive disease state. To address this, we developed LinkPrep: a proximity ligation protocol yielding high-quality, high-resolution, unbiased Hi-C libraries to detect SVs and chromatin topological features in under 8 hours – less than 50% of the time required for conventional Hi-C protocols. In our study, we demonstrate variant detection within the primary sequence (SVs, SNVs/Indels, and CNVs) and high-resolution 3D chromatin conformation. We benchmarked for genetic variant detection and chromatin topology in two lymphoblast cell lines (GM12878 and K562). LinkPrep detects interchromosomal translocations with 10-fold higher sensitivity over WGS. LinkPrep data shows uniform coverage and greater sensitivity over traditional Hi-C methods.

Importantly, LinkPrep libraries maintain topological features; TADs and chromatin loops, providing insight into novel epigenetic cancer drivers.

Methods:

Results:

Conclusion: LinkPrep enables higher-resolution assessments of chromatin topology, demonstrated by 50% more TADs and loops at 5-Kb resolution. We demonstrate LinkPrep is a next-generation Hi-C method enabling sensitive detection of clinically relevant SVs and high-resolution chromatin topology in a <8-hour workflow.

Background: The upper-airway microbiome involved in asthma exacerbations is regulated by genetic variation. However, the influence of DNA methylation (DNAm) remains unknown. We aimed to identify epigenetic markers associated with airway bacteria involved in asthma exacerbations.

Methods: The nasal microbiome and methylome in 154 European asthma patients were profiled by targeted sequencing of the V3-V4 region of the 16S rRNA and using the Illumina MethylationEPICv2 array, respectively. The association of 715,588 CpGs with exacerbation-related microbiome traits was tested through microbiome epigenome-wide association studies (mbEWAS). Models were corrected for age, sex, ancestry, and tissue heterogeneity. Genomic significance was declared using $p < 9 \times 10^{-8}$. Sensitivity analyses of microbiome confounders were carried out. Differentially methylated regions (DMRs) were assessed and included in gene-set enrichment analyses.

Results: Among the evaluated bacterial genera, the CpG cg06651505 (*TENM2*) was associated with the presence of *Dialister* in the nasal microbiome ($p = 8.7 \times 10^{-9}$). A total of 68 DMRs associated with this genus were identified (false discovery rate[FDR]<0.05), with the top-hit located in *IGF2* (17 CpGs, $p = 1.30 \times 10^{-27}$). These associations remained significant after adjusting for antibiotics use, recent smoking, body mass index, and sequencing pool ($p_{CpG} = 8.7 \times 10^{-9}$ and $p_{DMR} = 4.37 \times 10^{-27}$). *TENM2* and *IGF2* have been previously associated with severe asthma and/or lung function. DMRs were enriched in genes regulating Toll-Like Receptor pathways, the first-line defense of the innate system against infections (FDR < 0.05).

Conclusions: The first mbEWAS in asthma identified methylation loci associated with *Dialister* presence in the nasal microbiome from asthma patients, with potential implications for the immune system in host-microbiome interactions.

P20.066.C 3D genomics reveals tissue-specific regulatory networks associated with epilepsy and glioblastoma-linked Ptprz1

Miles Collier[1], *Cory Padilla*[1], *Myriam El Khawand*[1], *Jonathon Torchia*[1], *Lisa Munding*[1]

[1]*Dovetail Genomics, Scotts Valley, United States*

Background/Objectives: The three-dimensional (3D) organization of DNA has emerged as a crucial factor in gene regulation, impacting development and disease. Hi-C sequencing has been employed to investigate genomic interactions in the 3D space. However, its low resolution and accuracy, stemming from bias towards restriction site motifs have limited its adoption. Recent improvements, using sequence-independent endonucleases, including *MNase* (Micro-C) to generate nucleosome fragments have addressed this bias.

Methods: In this study, we present a novel method for isolating fixed chromatin from tissues without compromising the 3D structure. We sampled diverse tissue types from a singular mouse subject (including blood, confirming its clinical relevance), highlighting tissue-specific 3D features in liver and brain.

Results: 3D-genome differential analysis reveals subtle, yet significant variations between both tissues. A majority of topologically associating domains (TADs) (91%) and chromatin loops (85%) were conserved. Gene ontology (GO) analysis of chromatin loops (6% in brain and 9% in liver) indicates distinctions in functional categories closely linked to tissue-specific expression. Specifically, *Ptprz1* (Proteoglycan function), implicated in epilepsy and glioblastoma, exhibits brain-specific regulatory dynamics within TADs containing three looping interactions. A hybrid-capture targeting gene-promoters confirmed Ptprz1-specific interactions with increased sensitivity whilst massively reducing the sequencing burden (95-80%). The disruption of *Ptprz1*, and other tissue specific regulatory networks likely leads to pathologies.

Conclusion: In conclusion, integrating 3D genomics to uncover intricate chromatin architectures linked to diseases is proving to be increasingly important.

P20.067.D mEthAE: an explainable autoencoder for methylation data

Sonja Katz[1,2], *Vitor Martins Dos Santos*[3], *Edoardo Saccenti*[1], *Gennady Roshchupkin*[2]

[1]*Wageningen University & Research, Systems and Synthetic Biology, Wageningen, Netherlands;* [2]*Erasmus MC, Radiology, Rotterdam, Netherlands;* [3]*Wageningen University & Research, Biomanufacturing & Digital Twins, Wageningen, Netherlands*

Consortium: European Union's EU Framework Programme for Research and Innovation Horizon 2020, Grant Agreement No 860895 (TranSYS)

Background:

Despite insights from epigenome-wide association studies (EWAS), univariate linear analyses fall short in simultaneously considering spatial relationships among the 450.000 CpG sites, impeding a comprehensive understanding of CpG relationships. Deep learning algorithms, particularly autoencoders, are considered promising in capturing the complex patterns of DNA methylation data.

Methods: In this context, we propose mEthAE, a chromosome-wise autoencoder for interpretable dimensionality reduction of methylation data. Going beyond data compression, we developed a perturbation-based method for interpreting latent dimensions. Findings are compared to EWAS results, evaluating their predictive power, analyzing genomic location, associated biological pathways, correlation patterns, and genomic distances.

Results: mEthAE efficiently reduces 300,000 CpG sites into <1400 latent features - a 200-fold compression - without compromising on reconstruction accuracy or predictive power. Our interpretability approach uncovers clusters of CpGs with strong connections across all latent dimensions, significantly aligning with EWAS findings. Surprisingly, these connected CpGs lack correlation patterns or physical proximity on the chromosome.

Conclusion: Our analyses lead to an exciting conclusion: mEthAE uncovers largely uncharacterized long-range non-linear interaction patterns within DNA methylation data.

We believe this study is of great interest to the epigenetics community, demonstrating the utility of explainable deep learning algorithms to (i) provide a new perspective on our understanding of epigenetic interactions and (ii) reveal a sparsity of methylation signal which has strong implications for the design of novel DNA methylation arrays.

Consortium: TRMT1 Clinical Consortium

Background/Objectives: Genomic mutations in the *tRNA Methyltransferase 1* (*TRMT1*) gene have been implicated in certain cases of autosomal-recessive intellectual disability disorders. However, the underlying molecular mechanisms that cause the disease phenotypes remain elusive.

Methods: Here, we have identified 25 individuals from 20 families with bi-allelic variants in *TRMT1* presenting with developmental delay and intellectual disability. In addition, abnormal vision and/or hearing, progressive spasticity, choreoathetoid movements, refractory epilepsy, and brain atrophy were part of the core phenotype of this syndrome.

Results: We find that a subset of variants cause mis-splicing and loss of TRMT1 expression. Notably, patient cells with pathogenic *TRMT1* variants exhibited a deficiency in m2,2G modifications. We also dissect the molecular impact of each pathogenic variant on reconstitution of enzymatic activity and tRNA binding, thereby revealing novel aspects of TRMT1 structure.

Conclusion: Our studies elucidate the functional effects of novel pathogenic variants in *TRMT1* associated with a large number of autosomal-recessive cognitive disorders in the human population.

P20.069.B The Biology of Single Cell and Bulk Sequencing-Based CRISPR Screens

Angela Shaw[1], *Maximilian Billmann*[1]

[1]*Institute of Human Genetics, University of Bonn, School of Medicine and University Hospital Bonn, Bonn, Germany*

Background/Objectives: CRISPR screening, with high-content phenotypic readouts such as Perturb-Seq or more physiological culture conditions, carries great promise of assigning genes to functions where simple cell fitness screens fall short. A recent comprehensive study recorded single-cell RNA expression in 2.5 million cells, perturbing each transcribed gene individually. Here, we systematically compare the ability of these co-expression phenotypes with co-essentiality networks derived from the Cancer Dependency Map, comprising more than 1000 genome-wide CRISPR screens, to resolve functional neighborhoods within the cell.

Methods: For the comparative analysis of the two datasets, we leveraged FLEX, a tool to explore functional information and bias in genome-wide perturbation data. Global and process-resolved precision-recall analyses using gold standard functional databases CORUM, MsigDB Pathways and GO-BP were used to quantify the performance with which the data reconstruct known biology. Genetic interaction screens in standard conditions and on extracellular matrix components were conducted to determine whether simple fitness readouts can resolve functional modules required for 3D cell growth.

Results: We find that the majority of central cellular functions are resolved well by only one of the data sets. Single-cell expression phenotypes reconstructed the machinery facilitating transcription, translation and protein turnover in great detail, while the co-essentiality network better resolved chromatin remodeling, cell communication, and adhesion. Fitness readouts can resolve functional modules required for 3D cell growth, where expression phenotypes lack resolution.

Conclusion: Our study presents a comprehensive assessment of the strengths and weaknesses of CRISPR screening modalities, providing a compass for effectively screening for genetic modifiers of specific cellular processes.

P20.070.C Comparative analysis of D4Z4 and D4Z4-like repeats in primate genomes: insights into FSHD and evolutionary dynamics

Joshua K Bopp[1], *Christian W Remmele*[2;3;4], *Thomas Haaf*[2], *Tobias Müller*[1], *Marcus Dittrich*[1;2]

[1]*Department of Bioinformatics at the University of Würzburg, Würzburg, Germany;* [2]*Institute of Human Genetics at the University of Würzburg, Würzburg, Germany;* [3]*Center for Rare Diseases at the University Hospital Würzburg, Würzburg, Germany;* [4]*Bavarian Genome Network for Rare Diseases, Germany*

Background/Objectives: Facioscapulohumeral muscular dystrophy (FSHD) is associated with the D4Z4 macrosatellite array on human chromosome 4, where repeat contraction combined with hypomethylation can lead to disease onset. Understanding evolutionary conservation and syntenic relationships of D4Z4 repeats in primates is important for deeper insight into pathogenesis. Prior methods encountered challenges in resolving macrosatellite repeats, while modern long-read techniques can achieve precise resolution while simultaneously enable methylation profiling. In this study publicly available ultra-long Nanopore sequencing data was used to bridge this gap by investigating methylation patterns within orthologous D4Z4 repeats of great apes and comparing their evolutionarily conservation.

Methods: Genome assemblies and nanopore long-read data of great apes were obtained from the T2T-Primates project and used for genomic analyses. The Nanopore ultra-long read data was accurately mapped to macrosatellite regions of the primate assemblies. Region specific methylation patterns were extracted. The study concentrated on syntenic D4Z4-containing regions of human chromosome 4 known for their involvement in FSHD.

Results: Here we focus on syntenic regions in primate genomes to investigate evolutionary relationships and conserved repeat

architecture. We identify complete and partial D4Z4 repeats and discuss their variability across primate species. Furthermore, we examine evolutionary distances within D4Z4 repeats across all samples. To elucidate epigenetic signatures, we analyse methylation patterns within these repeats. We investigate the conservation of methylation gradients along D4Z4 repeat arrays, indicating a shared epigenetic regulation of these elements.

Conclusion: This study delves into D4Z4 repeat variation and methylation patterns in primate genomes, providing insights into their evolutionary dynamics and the pathomechanism of FSHD.

P21.001.D Nanopore long read whole genome sequencing in developmental disorders

Mathilde Geysens[1;2], *Benjamin Huremagic*[1], *Griet De Clercq*[3;4], *Erika Souche*[1], *Laurens Hannes*[1;2], *Annelies Dheedene*[3;4], *Björn Menten*[3;4], *Joris Vermeesch*[1;2], *Kris Van Den Bogaert*[1;2]

[1]*KU Leuven, Department of Human Genetics, Leuven, Belgium;* [2]*UZ Leuven, Center for Human Genetics, Leuven, Belgium;* [3]*Ghent University, Department of Biomolecular Medicine, Ghent, Belgium;* [4]*Ghent University Hospital, Center for Medical Genetics, Ghent, Belgium*

Background: Despite the implementation of massive parallel sequencing as standard of care, about half of patients with developmental disorders (DD) remain without genetic diagnosis. Structural and epigenetic variants have long been known to be involved in the pathogenesis of DD but remain challenging to map due to technological limitations. However, with dropping costs and increasing accuracy of long read sequencing (LRS) platforms, the concomitant assessment of single nucleotide, structural and epigenetic variation becomes feasible.

Methods: To evaluate the relevance of LRS clinical implementation for unsolved DD we performed whole genome nanopore sequencing in 50 patient-parent trios with intellectual disability and/or multiple congenital anomalies without molecular diagnosis after short read exome or genome sequencing. We optimized the nanopore sequencing technical workflow, developed an analytical pipeline and built a population reference set to assess structural variants (SVs). In addition, we validated phased methylation detection looking at imprinted regions as well as X-inactivation.

Results: We identify around 25.000 SVs per individual, of which 100 are classified as de novo. However, only 0.6 potential true de novo SV are retained upon manual curation and population filtering. On average, 2.1 X-linked inherited SVs are identified in males. SVs disrupting regulatory sequences of DD associated genes are further investigated and the haplotyped methylome is being scrutinized to study potential pathogenic mechanisms of non-coding variants.

Conclusion: LRS enables the detection of few, but potential disease-causing, hitherto unidentified SVs. We envision that the assessment of secondary but also primary epigenetic variants will further improve the diagnostic yield.

P21.002.A Variable Depth Whole Genome Sequencing: An Economical Approach for Genome-wide Detection of Clinically Significant Variants

Valery Ilinsky[1], *Anna Ilinskaya*[1]

[1]*Eligens, Riga, Latvia*

Background/Objectives: Traditional methods, such as microarrays and whole genome sequencing, either lack the resolution to effectively detect rare variants or are prohibitively expensive for widespread use. Our novel approach, "Variable Depth Whole Genome Sequencing" (VD-WGS), integrates low-coverage whole genome sequencing with targeted high-coverage sequencing of clinically significant rare variants. This method is especially beneficial for diagnosing polygenic diseases with multifactorial and monogenic nature.

Methods: VD-WGS involves preparing a single sequencing library, from which an aliquot undergoes targeted enrichment suitable for multiplexing up to 96 samples. This streamlined process significantly reduces both cost and complexity. For regions sequenced at low coverage, imputing is performed using reference panels.

Results: In low-coverage regions, using custom reference panel resulted in precision 99.4% with a recall of 95.7% for heterozygous variants, and a precision of 99% with a recall of 98.2% for homozygous variants. These results confirm the effectiveness of VD-WGS in accurately imputing genomic data at reduced coverage levels. In contrast, regions sequenced at high coverage displayed precision and recall rates up to 100%.

Conclusion: VD-WGS offers a cost-effective and efficient approach for detailed genomic analysis. With a cost as low as 20-30 EUR per sample, it is less expensive than both microarrays and traditional full genome or exome sequencing methods. This method provides a comprehensive analysis of clinically relevant genomic areas, combining the benefits of low-cost, broad coverage sequencing with the high accuracy of targeted high-coverage sequencing. VD-WGS has the potential to significantly advance genetic research and clinical diagnostics, making comprehensive genomic analysis more accessible and affordable.

P21.003.B T2T-CHM13 improves read mapping and detection of clinically relevant variation

Daniel Schmitz[1], *Adam Ameur*[1], *Åsa Johansson*[1]

[1]*Uppsala University, Department of Imunology, Genetics and Pahtology, Science for Life Laboratory, Uppsala, Sweden*

Background/Objectives: The new T2T-CHM13 assembly was released in March 2022, filling in the 8 % of the human genome that were not resolved in GRCh38. This new reference genome can be beneficial for population and clinical genomics, where whole genome sequencing (WGS) based approaches have become more common, but the extent of these benefits remains unclear. In this study, we aim to determine the increment of mapping quality and variant call performance with T2T-CHM13 as a reference.

Methods: We used a cross-sectional Swedish cohort (SweGen) comprising 1000 individuals with short-read Illumina (WGS) data available. Remapping and variant calling were performed using the nf-core/sarek pipeline.

Results: T2T-CHM13 improved a wide range of mapping and variant calling related metrics. A higher fraction of reads was properly paired and mismatch rate was lower, giving higher confidence in the mapping results. The fraction of ambiguous alignments was higher, indicating that alignments were falsely considered unique previously. Coverage of gene regions was more uniform. In comparison to GRCh38, we identified 10 million

additional variants, including 5.5 million singletons across the cohort, and observed an increased sensitivity for rare variants. SnpEff assigned impact ratings of moderate or high for 30 % more variants in T2T-CHM13.

Conclusion: T2T-CHM13 improves alignment metrics with higher mapping quality, better variant calling performance and confidence, especially for rare and deleterious variants. Using T2T-CHM13 as reference genome will enable the discovery of unknown disease-causing variants, benefiting especially rare-disease diagnostics.

P21.004.C TET Assisted Pyridine-Borane Sequencing version 1.0 - A rapid, scalable, and non-destructive sequencing approach to methylation profiling.

Lee French[1], *Craig Marshall[2], Travis Sanders[2], Sam Vogel[2], Aaron Garnett[2], Martin Ranik[2], Eduard Casas[2], Doug Wendel[2], Leo karamanof[1], Bjarne Faurholme[1], Abre de Beer[1], Ross Wadsworth[1], Kristina Giordia[2], Eric van der Walt[1], Brian Kudlow[2]*

[1]Watchmaker Genomics, Applications Development, Cape Town; [2]Watchmaker Genomics, Applications Development, Boulder, United States

Background/Objectives: Detection of 5-methylcytosine (5mC) serves as a powerful biomarker for studying and monitoring disease states. Bisulfite sequencing (BS-seq) converts unmethylated cytosine to uracil while 5mC is protected. This has limitations such as DNA destruction and the generation of low-complexity sequences making it sub-optimal for NGS. Here we introduce TET Assisted Pyridine-Borane Sequencing version 1.0 (TAPS v1.0), showcasing advancements to the technology originally introduced by Schuster-Böckler, Song, and their collaborators. TAPS v1.0 transforms 5mC into dihydrouracil (DHU) which is recognized as dU during PCR resulting in C-to-T conversions at 5mC sites. This leaves unmethylated cytosines unchanged. This nondestructive nature of 5mC conversion yields significantly higher library yield and complexity compared to BS-seq.

Methods: NA12878 human genomic DNA (containing spike-ins of variable methylated controls) along with cfDNA, FFPE breast DNA, and matched tumour and healthy breast DNA were prepared with the Watchmaker DNA Library Prep kit and subjected to either BS-seq (Zymo Research), EM-seq™ (NEB), or TAPS v1.0 treatment before bioinformatic analysis.

Results: TAPS v1.0 showed significantly higher final library yield and greater complexity than BS-seq and EM-seq with all sample types. TAPS-mediated 5mC detection was highly concordant with the other methods, yet preserved more of the underlying genomic information. Additionally, TAPS v1.0 preserved the disome in cfDNA and identified similar patterns of methylation, while improving CNV detection, in matched tumour-normal breast samples compared to BS-seq and EM-seq.

Conclusion: TAPS v1.0 shows great potential as a non-destructive, rapid, and scalable alternative for base-level methylation analysis.

P21.005.D Surveying the RNA-seq landscape: A multi-workflow comparison for mRNA and whole transcriptome sequencing applications

Jennifer Pavlica[1], *Trishana Nundalall[1], Deelan Doolabh[1], Lee French[1], Ross Wadsworth[1], Ariele Hanek[1], Josh Haimes[1], Kailee Reed[1], Thomas Harrison[1], Rajat Roy[1], Heather Maasdorp[1], Giulia Corbet[1], David Gelagay[1], Travis Sanders[1], Eric van der Walt[1], Brian Kudlow[1]*

[1]Watchmaker Genomics

Background/Objectives: RNA-seq has become an essential method of studying the transcriptome. Unlike genomics, transcriptomics provides a snapshot of cellular activity at a specific point in time and in response to stimuli. Various approaches to RNA library preparation allow researchers to characterize protein-coding and non-coding transcripts, thus unraveling biological mechanisms, monitoring disease states, and validating biomarker and drug responses. There is a growing need for solutions that are sensitive, scalable, and provide robust performance especially with low inputs and challenging samples such as FFPE RNA. In addition, compatibility with alternate short-read sequencers is becoming critical as the sequencing landscape broadens.

Methods: Herein, we compare three commercially available stranded RNA library prep kits for both mRNA and whole transcriptome sequencing (WTS). Chemistries are evaluated across an input range of 1 to 1000 ng and include both high-quality RNA and degraded FFPE material.

Results: While performance across workflows is consistent at high inputs, the Watchmaker RNA library prep solutions outperform at low inputs with respect to genes detected, preservation of the gene expression profile, and fewer wasted bases. WTS of matched fresh frozen and FFPE samples further demonstrates the improved sensitivity of the Watchmaker solution with a higher percentage of gene overlap between the matched samples. Additionally, compatibility is demonstrated across both the Singular and Element short-read platforms – widening the utility of the Watchmaker workflows.

Conclusion: The Watchmaker RNA library prep solutions enable researchers to access more information from challenging samples with workflows that are compatible with multiple short-read sequencing platforms.

P21.006.A Nanopore sequencing-based episignature detection

Benjamin Huremagic[1], *Mathilde Geysens[1;2], Erika Souche[1], Jeroen Breckpot[2], Koenraad Devriendt[2], Hilde Van Esch[2], Griet Van Buggenhout[2], Hilde Peeters[2], Kris Van Den Bogaert[1;2], Joris Vermeesch[1;2]*

[1]KU Leuven, Department of Human Genetics, Leuven, Belgium; [2]UZ Leuven, Centre for human genetics, Leuven, Belgium

Background/Objectives: A subset of developmental disorders is characterized by disease-specific genome-wide methylation changes. These episignatures inform about underlying pathogenic

mechanisms and can be used to assess the pathogenicity of genomic variants as well as confirm clinical diagnoses. Currently, episignature detection requires the use of indirect methylation profiling microarrays. As long-read-sequencing (LRS) enables the detection of single nucleotide variants (SNVs), structural variants (SVs), and base modifications, we aimed to assess its potential for simultaneous episignature and genomic variant detection.

Methods: Twenty patients, with thirteen distinct developmental disorders having known episignatures, were subjected to genome-wide nanopore sequencing. We first evaluated the compatibility of known episignatures with nanopore sequencing and subsequently developed a support vector machine for each developmental disorders.

Results: Methylation levels at episignature loci co-clustered disease samples and microarray-based disease reference. Our classifier identified the correct episignature in 17/20 blinded samples. The three remaining patients were classified as control by both our classifier and commercially available microarray-based episignature assay. All pathogenic SNVs and SVs detected by standard of care methods were identified. In addition, we were able to evaluate disease-associated imprinted regions as well as X-inactivation.

Conclusion: This study demonstrates nanopore sequencing is suitable for episignature detection and underscores the value of LRS for concurrent haplotyped genomic and epigenomic analyses.

P21.007.B Telomere length estimation using sequencing data of a large cohort

Lara E. Michels[1], Stephan Drukewitz[1], Rami Abou Jamra[1], Bernt Popp[1;2], **Isabell Schumann**[1]

[1]Institute of Human Genetics, University of Leipzig Medical Center, Leipzig; [2]Center of Functional Genomics, Berlin Institute of Health at Charité, Berlin, Germany

Background/Objectives: The current standard for telomere length (TL) analysis requires qPCR. Several bioinformatic tools can analyze short read genome sequencing (GS) telomere content. But they are not investigated for the widespread targeted sequencing (TS). Here, we present the results of bioinformatic TL analysis using GS and TS data.

Methods: We evaluated four tools (TelSeq, Computel, TelomereHunter, and Telomerecat) on a cohort of 11 families (38 individuals) with TS, GS, and established qPCR. Further, we have screened a cohort of 7500 exomes from different enrichment kits as well as 2500 large panel datasets.

Results: Using GS and TS, we were able to observe the expected phenomenon of a negative correlation with age, which was validated using qPCR. Using TelomereHunter, the estimation of TL with age was comparable for GS and TS. In contrast, TelSeq, Computel, and Telomerecat did not produce reliable TS results. Additionally, we discovered that issues such as establishing the workflow for a specific enrichment kit and the need to normalize with age-matched controls should be considered prior to TL measurement based on TS.

Conclusion: Aside from biological age, TL analysis is relevant for a variety of genetic disorders, including telomeropathies. Although our findings support GS as the best data for analyzing TL, our large cohort screening of TL in TS data yields promising results. This is important for the community because TS is widely used and most genetic institutions have access to TS but not GS.

P21.008.C Nanopore sequencing with unique molecular identifiers accurately determines SNP haplotypes and repeat number of the LPA KIV-2 VNTR

Stephan Amstler[1], *Gertraud Streiter[1], Cathrin Pfurtscheller[1], Lukas Forer[1], Silvia Di Maio[1], Hansi Weissensteiner[1], Bernhard Paulweber[2], Sebastian Schoenherr[1], Florian Kronenberg[1], Stefan Coassin[1]*

[1]Institute of Genetic Epidemiology, Department of Genetics, Innsbruck, Austria; [2]First Department of Internal Medicine I, Paracelsus Medical University, Salzburg, Austria

Background/Objectives: About 90% of lipoprotein(a) plasma variance is determined by a complex, haplotype-dependent interplay between *LPA* SNPs and the size of the *LPA* KIV-2 VNTR, with up to 40 KIV-2 repeats per allele (≈5.6 kb each). NGS has identified several modifier SNPs within KIV-2 but fails to capture SNP haplotypes. We evaluated nanopore sequencing with unique molecular identifiers (UMI-ONT-Seq) for detecting and haplotyping KIV-2 SNPs and determining KIV-2 repeat number.

Methods: UMI-ONT-Seq was performed on mixtures of two KIV-2 plasmids with 87 differences (mixture levels 1% to 5% and unmixed) and 63 multi-ancestry human samples with NGS reference data. We evaluated the impact of sequencing chemistries and basecalling algorithms, the minimal reads per UMI required for Q40 consensus sequence quality, error profiles and the accuracy of determining the KIV-2 repeat number via coverage-corrected haplotype quantification.

Results: Six reads per UMI were sufficient to achieve Q40 consensus sequence quality (i.e. the sequences of each KIV-2 unit). Variants were accurately detected down to 1% level. In plasmid samples, sensitivity, specificity, and precision were (mean ± SD) 0.998 ± 0.004, 1.0 ± 0.0, 0.995 ± 0.013. Variants from the same plasmid (being one haplotype) showed the same noise-free levels. Human variant levels were highly correlated with NGS ($R^2 = 0.983$). KIV-2 repeat number was in close agreement with ddPCR ($R^2 = 0.847$), with 44 of 63 samples within ddPCR confidence interval.

Conclusion: UMI-ONT-Seq supplies accurate full-length SNP haplotypes for each KIV-2 repeat and precisely quantifies repeat numbers. UMI-ONT-Seq provides benchmarking data for variant calling and haplotyping in genomic regions not resolvable with NGS.

Background/Objectives: Liquid biopsy diagnostics have predominantly focused on circulating tumor DNA (ctDNA) analysis in the context of actionable somatic hotspot variants for guiding treatment decisions. Our previous work introduced LIquid biopsy Fragmentation, Epigenetic signature, and Copy Number Alteration analysis (LIFE-CNA) utilizing whole-genome sequencing (WGS) in colorectal cancer (CRC) patients. Expanding on this strategy, our goal is to broaden the application of LIFE-CNA to other tumor entities.

Method: Plasma samples from patients diagnosed with diverse tumor types, including 2 breast cancer, 9 prostate cancer, and 2 Lynch Syndrome (LS)-associated cancer cases, as well as 5 intraductal papillary mucinous neoplasm (IPMN) cases presenting with a risk to develop pancreatic cancer, were sequenced using the LIFE-CNA method.

Results: Using 55 healthy controls, we established distinct cutoffs for the detection of ctDNA based on global and regional fragmentation patterns, transcriptionally active chromatin, and somatic copy number alterations (CNVs). All breast and prostate cancer cases exhibited significant alterations in both fragmentation profiles and CNVs. In addition, all 5 IPMN cases showed an overlap with a distinct epigenetic signature. In contrast, both LS cases showed no significant variations.

Conclusions: This proof-of-principle study demonstrates the potential of LIFE-CNA beyond CRC detection. However, cohort expansion is crucial to confirm the sensitivity of this approach across tumor entities. Considering functional differences between tumor entities could further improve the method's sensitivity. The study underscores the utility of employing multiple metrics in ctDNA analysis and highlights LIFE-CNA's adaptability to detect various cancer types in a minimally invasive manner.

Background/Objectives: While both genomics and gut metagenomics have shown promise in prediction of various diseases in the general population, the extent to which they can jointly predict future risk of common diseases remains unclear. In a prospective population-based multi-omics cohort, we investigate the individual and combined predictive capacity of host genetics and gut microbiome for multiple common diseases, as well as their additive values to conventional risk factors (CRFs).

Methods: Genotyping data and shotgun metagenomics sequencing of stool samples of 5,676 individuals aged 25 to 74 years at baseline were utilised for studying four incident diseases – coronary artery disease (CAD), Alzheimer's disease (AD), prostate cancer (PC) and type 2 diabetes (T2D) with ~18 years of follow-up. Prediction performance of disease-specific CRFs, polygenic risk scores (PRSs) calculated using large population-based external summary statistics and gut microbiome risk scores (GMSs) developed using machine learning were assessed separately and jointly.

Results: PRS and GMS individually achieved similar prediction performance to CRFs and were associated with all diseases studied. While baseline age was the strongest predictor for CAD, AD, and PC, adding PRS and GMS to age increased C-statistic by 0.049, 0.019 and 0.032, respectively. For all four diseases, the multi-omics model combining PRS, GMS and CRFs achieved higher prediction performance than models based on any risk factors separately, with ΔC-statistic over CRFs of 0.024 for CAD, 0.014 for T2D, 0.017 for AD, and 0.031 for prostate cancer.

Conclusion: Integrated PRS and GMS models improve the predictive value over CRFs for common chronic diseases.

P21.011.B Simultaneous Profiling of SNP Genotyping, Copy Number Variation and Fragment Length Determination Using Nanofluidic qPCR for Pharmacogenomics Studies

Jian Qin[1;1], Hui Ren[1], Amit Khanna[1], Win Hwang[1], Joel Brockman[1], Arnaldo Barican[1], Greg Harris[1], Tom Goralski[1], Julie Alipaz[1], Charles Park[1], David King[1], Naveen Ramalingam[1]

[1]Standard BioTools, South San Francisco, United States

Background/Objectives: Pharmacogenomics (PGx) testing evaluates a person's genetic variation to determine how the individual metabolizes or responds to medications. It is vital in identifying responders versus nonresponders to medications, optimizing drug doses, and mitigating the risk of adverse events. PGx tests interrogate single-nucleotide polymorphisms (SNPs), copy number variation (CNV), and microsatellite repeat numbers within specific genes associated with differential drug metabolism. However, the traditional qPCR-based and capillary electrophoresis-based methods use separate, cumbersome workflows for SNP genotyping, CNV determination, and fragment analysis for microsatellite markers. In this work, we report a single automated workflow using a qPCR-based nanofluidic system to simultaneously profile SNPs, CNVs, and microsatellite repeat numbers of DNA samples.

Methods: The PGx Assay Panel includes assays for SNPs, CNVs, and microsatellite regions of interest. DNA samples are subject to a targeted enrichment step through preamplification and analyzed on a nanofluidic chip (IFC) with the Biomark™ X9 System. 96 samples are interrogated simulatenously against 96 assays in nanoliter volumes. Analysis and interpretation of SNP genotyping, CNV determination, and fragment analysis of the microsatellite reagions is performed using our data analysis software. We also explored the possibility of using saliva samples directly without extraction.

Results: We have assessed this panel with Coriell DNA samples with known genotypes, copy numbers, and microsatellite repeat numbers. The average call accuracy for SNP and CNV was 99.9% and 98.0% respectively.

Conclusion: We demonstrated a streamlined workflow for the simultaneous testing of SNP, CNV, and microsatellite loci. This workflow can play a major role in PGx testing when implemented in clinical routines.

Conflict of Interest: None declared

P21.012.C Affordable CompleteWGS: Haplotype phased near perfect human WGS

Brock Peters[1], Sissi Zhang[1], Ying Cai[1], Siwei Liang[1], Lijing Pan[2], Bian Cai[2], Xigao Chen[2], Shengting Li[2], Radoje Drmanac[1]

[1]Complete Genomics, Research, San Jose, United States; [2]MGI, Research, China

DNA sequencing technology has been advancing rapidly since the early 2000s. However, experimental determination of the haplotypes of individual human genomes as a routine process is still largely overlooked. We describe a novel human NGS/MPS based WGS process, CompleteWGS, a combination of high-quality PCR free and DNA cobarcoding-based (stLFR) WGS. This enables reporting of all inherited variants (separated from somatic mutations) phased in chromosome arm-size contigs, almost no false positive errors, improved mapping and variant calling in difficult regions (*e.g.*, dark genes), and structural variant calling with targeted de novo assembly. Using samples HG001, HG002, and HG005, we show near perfect false positive and false negative calling rates of > 0.995, phased contig N50 sizes of > 10 Mb comprising almost all heterozygous SNPs and indels, and the successful assembly and placement of 100s of SVs. To achieve this a PCR free and a stLFR WGS libraries were prepared for each sample and sequenced to 30X coverage per library. To demonstrate the utility of this type of data we performed CompleteWGS on DNA from blood cells achieving the same result as for the cell lines and combined it with full length transcriptome analysis to accurately predict expression of each encoded protein allele and identify long range cis regulators of allele-specific expression. Importantly, using commercially available WGS, the total cost of automated preparation and sequencing of CompleteWGS is $200. This opens new frontiers in how research and clinical scale human genome sequencing should be done in the future.

P21.013.D Cost-effective Cas9-mediated targeted sequencing of Spinocerebellar ataxia repeat expansions

Keiji Tachikawa[1], Satomi Mitsuhashi[1], Yoshihisa Yamano[1], Takahiro Shimizu[1], Takeshi Imai[1], Riyoko Ko[1], Yosuke Kawai[2], Yosuke Omae[2], Katsushi Tokunaga[2], Martin C Frith[3]

[1]St. Marianna University School of Medicine; [2]National Center for Global Health and Medicine; [3]University of Tokyo

Hereditary repeat diseases are caused by an abnormal expansion of short tandem-repeats in the genome. Among them, Spinocerebellar ataxia (SCA) is a heterogenous disease, and currently, 16 responsible repeats are known. Genetic diagnosis is obtained by analyzing the number of repeats through separate testing of each repeat. Although simultaneous detection of candidate repeats using current massively parallel sequencing technologies has been developed to avoid complicated multiple experiments, these methods are generally expensive. In this study, we developed a cost-effective SCA repeat panel (FLO-SCAp) using Cas9-mediated targeted long-read sequencing and the smallest long-read sequencing apparatus, "Flongle." This panel enabled the detection of repeat copy number changes, internal repeat sequences, and DNA methylation in seven patients with different repeat expansion diseases. The median (interquartile range) of coverage and on-target rate were 39.5 (12-72) and 11.6% (7.5-16.5), respectively. To validate our approach, we compared repeat copy number changes measured by FLO-SCAp and short-read whole-genome sequencing (SR-WGS). A high correlation was observed between FLO-SCAp and SR-WGS when the repeat length was 250 base pairs or less ($r = 0.98$, $p < 0.001$). Thus, FLO-SCAp represents the most cost-effective method for conducting multiplex testing of repeats and can serve as the first-line diagnostic tool for SCA. We will also include the result of the newest version of nanopore flowcell (R10.4).

P21.014.A Enhancing STR detection in human genetics: A comparative study of Long-Read WGS and PCR-Based methods

Ning Wang[1], Yicong Wang[1], Wenxin Zhang[2], Jie Huang[2], Le Li[1], Lingna Xue[1], Tang Li[1], Fang Chen[1]

[1]MGI Tech, Shenzhen, China; [2]National Institutes for food and drug Control (NIFDC), Department of In Vitro Diagnostic Reagent, Beijing, China

Background/Objectives: Short tandem repeats (STRs) play an increasing role in genetics and disease research, especially in genome-wide cohort studies. However, few studies demonstrate the consistency between human whole genome sequencing (WGS) data and PCR-based technologies. In this study, we deployed a comparative study to evaluate the STR detection performance from WGS data with single-end 400bp (SE400) comparing to amplicon-based sequencing.

Methods: We conducted SE400 WGS on 157 male and 123 female samples and analyze a set of 129 STR loci including 54 autosome-STRs, 48 Y-STRs and 27 X-STRs, resulting 30,216 STR loci in total. Setting allele depth thresholds at 1×, 2×, 5× and 10× to evaluate the STR detection rate and compare the STR typing concordance with amplicon-based sequencing by massively parallel sequencing (mMPS) and capillary electrophoresis (CE) for performance comparison.

Results: The SE400 WGS averaged a depth of 24.69×, identifying 29,602, 19,854, 18,791, and 14,446 STR loci across allele depth thresholds of 1× to 10×. Concordance with mMPS and CE ranging from 93.56% to 97.75% and 93.71% to 97.78%, respectively. In 77 samples with WGS depth ≥30×, setting a 10× allele depth threshold for STRs resulted in notably high concordance rates of 99.01% with mMPS and 98.91% with CE. Furthermore, STRs characterized by a core repeat region between 24-176 bp and those with complex repeat motifs demonstrated improved detectability and concordance.

Conclusion: Single-end 400bp WGS, at an average depth of 30× and employing a 10× allele depth threshold, showcases exceptional STR detection and high concordance rates, highlighting its efficacy in genetic research.

P21.015.B Combining AmplideX PCR chemistries, nanopore sequencing, and automated analysis software to genotype complex, clinically-relevant variants in 11 challenging targets associated with hereditary diseases

John Milligan[1], *Bryan Killinger*[2], *Cody Edwards*[1], *Christopher Fraher*[2], *Jon Kemppainen*[1], *Monica Roberts*[2], *Jonathan Turner*[1], *Theodore Markulin*[2], *Brennan Greenlee*[1], *Eduardo Priego*[2], *Juliette Baker*[1], *Mahesh Yarasi*[2], *Connor Parker*[1], *Mia Mihailovic*[2], *Ashima Sharma*[1], *Brian Haynes*[1], *Bradley Hall*[1]

[1]*Asuragen, Inc. a Bio-Techne Brand, Research and Development, AUSTIN, United States;* [2]*Asuragen, Inc. a Bio-Techne Brand, Bioinformatics, AUSTIN, United States*

Background/Objectives: Detecting variants associated with severe genetic disorders is critical for diagnostic and screening applications. While NGS is often leveraged, it is frequently incapable of resolving complex pathogenic variants involving short tandem repeats, copy number/structural variation (CNV/SV), and pseudogenes. Here, we combine AmplideX PCR enrichment, nanopore sequencing, and bioinformatic analysis software to genotype 11 challenging targets (*CFTR, SMN1/2, FMR1, HBA1/2, HBB, F8* intron inversions*, GBA, CYP21A2, TNXB*).

Methods: We tested >300 unique samples, including cell-line genomic DNA (gDNA; n = 150) and whole blood gDNA from residual clinical samples (n = 175). Target regions were enriched in 4 PCR reactions, barcoded, pooled, and sequenced on MinION™ flow cells (R10.4.1) with a Mk1B or GridION™ (Oxford Nanopore Technologies). We developed software to automate analysis/reporting and compared results to those obtained from multiple orthogonal methods.

Results: Across all variant types, the assay was ≥95% concordant with orthogonal results. SNVs/indel concordance was >98%, including >50 unique *CFTR* variants. *SMN1/2* CNV (0 to >=3) showed ≥95% agreement. *FMR1* was >98% concordant for repeat sizing and AGG interrupt detection. *GBA* and *CYP21A2/TNXB* were differentiated from their pseudogenes, gene-pseudogene fusions were identified, and SVs were resolved. *F8* intron inversions showed 100% agreement.

Conclusion: Our results demonstrate the utility of combining nanopore sequencing with novel PCR chemistry and algorithms to detect challenging variants causing hereditary disorders. The assay accurately resolves complex genotypes insurmountable by routine NGS using affordable, scalable technologies in a common workflow suitable for any laboratory. The software enables custom variant reporting, ClinVar classification, and in-silico novel variant predictions to streamline interpretation.

P21.016.C Detection of mitochondrial heteroplasmy: A comparison between long nanopore reads and short illumina reads

Barbara Slapnik[1;2], *Robert Sket*[1;2], *Tine Tesovnik*[1;2], *Barbara Jenko Bizjan*[1;2], *Jernej Kovač*[1;2]

[1]*University Children's Hospital, University Medical Center Ljubljana (UMC), Ljubljana, Clinical Institute of Special Laboratory Diagnostics, Ljubljana, Slovenia;* [2]*University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia*

Background/Objectives: Mitochondrial diseases, marked by cellular energy deficiency from respiratory chain defects, pose diagnostic challenges due to genetic heterogeneity, heteroplasmy, and nuclear-mitochondrial segments (numts). Clinical symptoms manifest when heteroplasmy exceeds 60-90%, varying with mutation and tissue. However, precise diagnosis, prognosis, and counseling in medical genetics demand detecting low-level variants. Our aim was to establish heteroplasmy detection thresholds using Oxford Nanopore Technology (ONT) and compare with Next Generation Sequencing (NGS).

Methods: Bioinformatics simulations involved merging fastq files, introducing m.8993T>G heteroplasmy. Short and long reads were aligned to the hg38 reference genome using BWA and Minimap2, respectively. Mutserve2 was used for variant calling. Precise thresholds were determined through 999 repetitions for each heteroplasmy level.

Results: At low coverage depth (150x), Mutserve2 detects heteroplasmy as low as 3% with long reads and 1% with short reads, albeit inconsistently. ONT achieves over 90% reliability for levels exceeding 21%, contrasting with NGS at 9% heteroplasmy

level. Mutserve2 tends to underestimate ONT heteroplasmy but correlates strongly ($R^2 = 0.960$) with expected levels, while NGS exhibits a higher correlation ($R^2 = 0.998$).

Conclusion: Our findings highlight challenges and opportunities with nanopore sequencing for accurate heteroplasmy detection in mtDNA. The knowledge gained will contribute to better development of the diagnostic applications to detect heteroplasmic mitochondrial variants in human diseases. Furthermore, insights gained will aid in refining bioinformatics pipelines and inform future studies leveraging nanopore sequencing for comprehensive mtDNA analysis.

P21.017.D Towards improved Parsortix® efficiency for circulating tumor cell enrichment in pancreatic cancer

Nele Vandenbussche[1;2;3], *Béatrice Lintermans*[1;2;3], *Charlotte Fieuws*[1;2;3], *Tijs Merckaert*[1;2;4], *Kris Gevaert*[1;2;4], *Kathleen Claes*[1;2;3]

[1]*Ghent University, Department of Biomolecular Medicine, Ghent, Belgium;* [2]*Cancer Research Institute Ghent (CRIG), Ghent, Belgium;* [3]*Ghent University Hospital, Center for Medical Genetics, Ghent, Belgium;* [4]*Ghent University, VIB Center for Medical Biotechnology, Ghent, Belgium*

Background/Objectives: With its increasing incidence and dismal prognosis, pancreatic ductal adenocarcinoma (PDAC) is becoming a global oncologic problem. Circulating tumor cells (CTCs) could be an interesting biomarker for PDAC, since they contain genetic information from the tumor of origin. However, isolating CTCs from peripheral blood of PDAC patients remains challenging since they are rare and consist of various subtypes. The Parsortix® device captures CTCs from blood samples based on cell size and deformability. We evaluated its ability to enrich and capture different subtypes of pancreatic cancer cells.

Methods: Three pancreatic cancer cell lines, mimicking different CTC subtypes (epithelial, mesenchymal, and intermediate), were stained and spiked into healthy donor blood. These samples were processed using the Parsortix® and recovery rates were determined. Data-independent acquisition-mass spectrometry identified differentially expressed proteins and pathways between the cell lines.

Results: The mesenchymal cell line had a significant lower recovery rate ($32.8 \pm 10.2\%$) compared to the epithelial cell line ($62.6 \pm 18.5\%$). The Rho signaling pathway, responsible for cell contractility, was downregulated in the mesenchymal cells.

Conclusion: Parsortix® can capture epithelial pancreatic cancer cells from blood samples, but is less suitable for capturing mesenchymal cancer cells. We are currently exploring the hypothesis that introducing an activator of the Rho pathway into patient blood samples could stiffen CTCs. This could enhance recovery rates and facilitate downstream multi-omics analysis.

P21.018.A Designing a single-cell RNA sequencing strategy for transcriptome-wide RNA analysis

Danique Berrevoet[1], *Koen Deserranno*[1], *Dieter Deforce*[1], *Filip Van Nieuwerburgh*[1]

[1]*Ghent University, Laboratory of Pharmaceutical Biotechnology, Ghent, Belgium*

Consortium: N/A

Background/Objectives: The current single cell RNA sequencing field has been dominated by focusing on messenger RNA. Consequently, valuable information present in long non-coding RNA (lncRNA) remains largely unexplored. To overcome these constraints, we developed a cost-effective approach based on the cutting-edge Smart-seq3xpress (SS3X) protocol. This approach aims to achieve two primary goals: (1) capturing the entire transcriptome and (2) eliminating the abundant but rather irrelevant ribosomal RNA.

Methods: The miniaturized SS3X protocol, as published by *Hagemann-Jensen et al*., was modified by adding a synthetic poly(A) tailing step between cell lysis and reverse transcription utilizing E. coli Poly(A) Polymerase. After oligo-dT priming, the poly(A) tailed RNA is reverse transcribed to cDNA and preamplified using PCR to obtain cDNA copies. This cDNA is tagmented, and barcoded in index PCR. Using the SEQuoia RiboDepletion Kit, the pooled sequencing library is ribodepleted. Finally, Illumina sequencing is performed.

Results: When comparing the standard SS3X protocol to the poly-adenylation protocol (SS3XA), the latter demonstrated significantly increased cDNA yields per cell. The capture of non-natively polyA-tailed molecules was successfully achieved, as illustrated by the retrieval of 5.8S, 18S, and 28S ribosomal RNA prior to ribodepletion. Moreover, 194 unique lncRNAs (>98% sequence identity) were identified.

Conclusion: The developed method demonstrates the successful capture of the total RNA content. These promising results underscore the potential of the SS3XA protocol as a valuable tool for transcriptome-wide RNA analysis. The next step encompasses ultimate verification through the comparison of the sequencing outcomes with and without polyadenylation.

Grants: Not applicable.

P21.019.B Whole genome sequencing methods with low input DNA and their automation

Christian Daviaud[1], *Zuzana Gerber*[1], *Emmanuel Menard*[1], *Stephane Meslage*[1], *Florian Sandron*[1], *Vincent Meyer*[1], *Jean-François Deleuze*[1], *Francis Rousseau*[1]

[1]*CEA, Centre National de Recherche en Génomique Humaine, Évry-Courcouronnes, France*

Background/Objectives: With the recent drop in sequencing price, whole genome sequencing (WGS) becomes the method of choice to interrogate the human genome for medically relevant causal variants. However, for some applications such as cancer genetics, the current input requirement of 1µg DNA for PCR-Free WGS is not always attainable. In this study, we compared different PCR-Free WGS approaches compatible with low input gDNA.

Methods: NGS libraries were prepared from human DNA reference standard HG002 using five commercial kits adapted to low input WGS PCR-Free library prep. DNA fragmentation was either enzymatic or mechanic. The input ranged from 50ng to 500ng gDNA. We compared the library yield and quality control profiles for different inputs. All libraries were sequenced on NovaSeq6000 (Illumina) at 30×. We assessed the depth, breadth and uniformity of genome coverage among the different kits. We evaluated their capacity to detect SNVs and indels correctly compared to known GIAB reference sequence of HG002 individual.

Results: We observed that enzymatic fragmentation provides more homogeneous results than mechanical fragmentation. We noted that the lowest input usually yields libraries with the

shortest insert size, sometimes resulting in coverage below 30×. Finally, two protocols have been selected and automated at CNRGH.

Conclusion: All methods tested in this study yielded exploitable sequencing results with low-input gDNA. The coverage metrics were similar for inputs around 200 ng, while performance varied for inputs below 100 ng. The CNRGH now has a fully automated production platform for PCR-free WGS, enabling high-throughput projects to be conducted with low input DNA.

Grants: LabEx GENMED (ANR-10-LABX-0013).

P21.020.C Development of miniaturized plate-based 10X assays for low-input samples

Elise Callens[1], *Koen Deserranno*[1], *Dieter Deforce*[1], *Filip Van Nieuwerburgh*[1]

[1]*Ghent University, Laboratory of Pharmaceutical Biotechnology, Ghent, Belgium*

Consortium: n/a

Background/Objectives: The development of next-generation sequencing (NGS)-based technologies, especially single cell RNA-sequencing (scRNA-seq), has significantly advanced our understanding of immunology and cancer genomics. The 10X Genomics (10X) platform is well established in the field of scRNA-seq. However, its high-throughput nature, requires an input of several thousands of cells, which is often unavailable in clinical settings. Therefore, we present a state-of-the-art plate-based 10X technique enabling single cell 10X analysis starting from low input samples.

Methods: This technique leverages the highly sensitive and miniaturized plate-based Smart-seq3xpress (SS3x) protocol and is downstream compatible with any 5′ 10X library preparation kit. The method was demonstrated using Jurkat T lymphoblasts sorted via the BD FACSAria Fusion. Sorted cells were then subjected to an adapted SS3x workflow enabling the generation of a cDNA pool. Subsequently, cDNA was subjected to a 5′ 10X library preparation kit, with or without an additional T cell receptor (TCR) enrichment phase, depending on the kit.

Results: The proficient generation of a cDNA pool from 96 Jurkat T lymphoblasts was achieved, followed by a successful library preparation using either the 5′ 10X GEX or VDJ kit. 70% of the sorted cells were recovered with >1000 reads, which is in line with the expectation considering sorting and library preparation efficiency. Additionally, TCR-enriched data revealed over 80% shared identical clonotypes, confirming their Jurkat T lymphoblast origin.

Conclusion: We believe that this cost-effective technique will become an established tool for immunological research in clinical cases with a low input number of cells.

P21.021.D Ultra-plex sequencing of single cells and limited samples

Ioanna Andreou[1], *Samuel Rulli*[2], *Katja Heitz*[1], *Silke Huebner*[1], *Christin Meerschiff*[1], *Eric Lader*[2]

[1]*QIAGEN GmbH, Hilden, Germany;* [2]*QIAGEN Sciences Inc, Germantown, United States*

Background/Objectives: Single-cell genome analysis enables researchers to gain novel insights into tumor heterogeneity. Conducting single-cell genomic analysis using next-generation sequencing (NGS) methods has traditionally been challenging since the amount of genomic DNA present in a single cell is limited. PCR-based amplification methods normally have high error rates, low coverage uniformity, and extensive allelic drop-outs making interpretation of SNVs and CNVs challenging.

Methods: We introduce a new whole-genome amplification method, which utilizes an optimized isothermal DNA amplification reaction with an error correcting polymerase and a downstream library preparation protocol to allow pooling of amplified DNA. The key DNA amplification steps use multiple displacement amplification (MDA) technology to amplify gDNA directly from single cells, nuclei, or previously isolated genomic DNA. During the MDA reaction, sample-barcodes are incorporated into the newly synthetized DNA, allowing the amplified DNA to be pooled and processed in to one ultra-plex library.

Results: Our current workflow allows 24 samples to be multiplexed in one library and 24 libraries to be produced for a total of 576 samples per sequencing run. The generated libraries are fully compatible to hybrid capture procedures, which will reduce the sequencing effort only to the regions of interest.

This method can be used to investigate chromosomal instability using low pass sequencing, and SNV or CNV following whole genome or exome-capture workflows.

Conclusion: The presented method allow single cell, nuclei, or other limited DNA sequencing in an ultra-plex mode, by introducing sample barcodes during the MDA. This method saves library preparation time, reduces DNA library costs, and limits plastic consumable usage.

P21.022.A Knock-in of disease-related variants in the zebrafish model organism

Michiel Vanhooydonck[1], *Elyne De Neef*[1], *Hanna De Saffel*[1], *Annekatrien Boel*[2], *Kathleen Claes*[1], *Andy Willaert*[1;3], *Bert Callewaert*[1]

[1]*Ghent University, Biomolecular medicine, Ghent, Belgium;* [2]*Ghent University, Reproductive Medicine, Ghent, Belgium;* [3]*Ghent University, Core Zebrafish Facility Ghent*

Background/Objectives: Introducing a precise disease-specific genetic variant in animal models allows for a more accurate representation of the molecular and physiological consequences. While generating knock-out lines is relatively straightforward, generating a knock-in (KI) model for specific base-pair variants remains challenging. This is mainly due to low editing efficiencies (EE) and potential occurrence of off-targets. Here, we optimize the KI EE of disease-related variants in zebrafish.

Methods: We introduced six base-pair substitutions in three different zebrafish genes by CRISPR/Cas9-mediated homology-directed repair (HDR). We used NGS analysis to assess the effect of four different Cas9 concentrations, improved thermostability of HDR templates, different micro-injection procedures, and the introduction of synonymous mutations in the PAM sequence, on KI EE in zebrafish larvae. In addition, we evaluated prime-editing as a potential alternative to conventional HDR-based genome editing.

Results: Increasing Cas9 concentrations augmented KI EE, with optimal injected amounts of Cas9 between 400-800 pg. The use of Thermostable Alt-R™ HDR templates (IDT) further increased KI EE, while PAM modifications did not. Injection of the components directly into the zygote was not superior to injections in the yolk. Prime-editing showed up to a fourfold higher EE than HDR and increased the F0 founder pool for four targets, while off-target

effects were only detected in conventional HDR-based genome editing.

Conclusion: Prime-editing is a promising alternative to conventional HDR-based knock-in with higher EE and less off-target effects. This methodology simplifies the creation of precise genomic mutations in zebrafish, facilitating the exploration of human diseases.

Background/Objectives: Compare 3′ and 5′ scRNA-seq of viably frozen minor salivary gland (MSG) biopsies collected from Sjögren's disease (SjD) patients to the single-cell transcriptomics of formalin-fixed paraffin-embedded (scFFPE) MSG biopsies.

Methods: For 3′ and 5′ scRNA-seq, viably frozen MSG (2 SjD, 5 healthy controls (HCs)) were thawed, dissociated, counted and split (>90% viable cells, then captured targeting 8000-10000 cells. Following the 10X Flex/scFFPE protocol, 25µm sections from FFPE MSG were dissociated. Cells were counted, labelled, and captured (yield: 8000-20000 per tissue). Sequencing data were analyzed (CellRanger), ambient RNAs corrected (SoupX), and doublets detected (scDblfinder). Cells with feature counts <200 or >5000, mitochondrial percent >5%, and doublets were removed.

Results: scFFPE, 3′, and 5′ scRNA-seq yielded similar feature/gene counts per cell (median = 4571, 5186, 7452, respectively). scFFPE was superior in ambient RNA reduction and identifying discrete cell populations. An expanded scFFPE dataset (8 SjD^{Ro+}, 9 HCs) yielding 371,454 cells among 23 cell states after QC. Cells were separated into immune and non-immune clusters and annotated using reference data (CellTypist or MSG reference data), then differentially expressed (DE) genes ($p < 0.02$) were identified using a pseudobulk approach (DESeq2) and subjected to Ingenuity Pathway Analysis. Immune and glandular cell DE genes mapped to both common and different pathways in SjD^{Ro+} vs. HCs, including Type I interferon: downregulation (plasma cells, plasmacytoid DCs, naive B cells) upregulation (migratory DCs, DC1, seromucous and mucous acini, macrophages, mast cells).

Conclusions: scFFPE yielded superior single-cell data compared to 3′ and 5′ using viable cells. **Grants:** UC2AR081032&S1&02S1; UC2DE032254; NIDCR15-D-0051

P21.024.C Assessment of episignature analysis using PacBio long-read sequencing

Veronique Ivashchenko[1], *Juliet Hampstead[1], Ronny Derks[1], Amber den Ouden[1], Gelana Khazeeva[1], Simone Van Den Heuvel[1], Raoul Timmermans[1], Jordi Corominas Galbany[1], Rolph Pfundt[1], Tom Hofste[1], Helger Yntema[1], Lisenka Vissers[1], Alexander Hoischen[1;2], Christian Gilissen[1]*

[1]*Radboud university medical center, Department of Human Genetics, Nijmegen, Netherlands;* [2]*Radboud university medical center, Department of Laboratory Medicine, Translational Metabolic Laboratory, Nijmegen, Netherlands*

Background/Objectives: Whole-genome DNA methylation detection (5mC) is typically performed using short-read bisulfite sequencing procedures. Pacific Biosciences (PacBio) long-read sequencing (LRS) technology can also detect 5mC on native DNA. Here we assessed the ability of PacBio HiFi LRS to: (1) robustly identify genome-wide methylation, (2) identify differentially imprinted regions, and (3) identify genome-wide epigenetic signatures for genetic disorders.

Methods: We compared public data from the Genome In A Bottle HG002 cell line with two short-read whole-genome DNA methylation sequencing procedures to assess reproducibility and evaluated the detection of 41 known parentally imprinted regions using 8 in-house PacBio trios. For outlier detection we trained an HMM model on 15 samples and tested it for differentially methylated CpG islands on chromosome X when comparing one female sample against 15 males. Genome-wide episignatures were investigated using 12 patients with known *KMT2A* loss-of-function mutations and 39 control samples sequenced on the PacBio Revio.

Results: PacBio methylation calls were highly comparable to existing protocols with a Pearson correlation >0.9. Methylation probabilities on imprinted regions were close to 50% for 31 out of 41 (76%) regions. Our method for regional methylation patterns detection successfully reported 149 out of 168 (89%) differentially methylated CpG islands. Using published *KMT2A* signatures we were successfully able to distinguish *KMT2A* patients from controls.

Conclusion: Overall our results indicate that PacBio HiFi long-read sequencing can be reliably used for the investigation of genome-wide 5mC patterns and episignature analysis for patients.

P21.025.D Clinical utility of long read whole genome sequencing to confirm diagnosis in neonatal hypotonia

Hans Matsson[1], *Ida Höijer*[2], *Joakim Klar*[1], *Padraic Corcoran*[2], *Cecilia Soussi Zander*[3]

[1]*Uppsala university, Immunology, Genetics and Pathology, Uppsala, Sweden;* [2]*Science for Life Laboratory, Immunology, Genetics and Pathology, Uppsala, Sweden;* [3]*Uppsala University Hospital, Clinical genetics, Uppsala, Sweden*

Background/Objectives: Infants presenting with hypotonia often require rapid clinical assessment and genetic testing using several targeted assays and genome wide analyses to confirm a diagnosis. Here, we used PacBio Revio long read whole genome sequencing on DNA from floppy infants to confirm previously known diagnoses and to evaluate the workflow in a clinical diagnostics laboratory. One patient presented with Prader Willi-like features and a nerve conduction defect for which also spinal muscular atrophy was suspected. No deletion nor methylation defect in the Prader Willi region was detected using MLPA.

Methods: Genomic DNA was extracted from blood, size selected and prepared for PacBio whole genome sequencing on a Revio instrument. PacBio WGS Variant Pipeline was used for read alignment, variant calling, and phasing. Variant analyses and visualisation were performed using Alissa Interpret and IGV software.

Results: Analyses of small variants using DeepVariant verified a paternal inherited pathogenic variant NM_019066.5(MAGEL2):c.1966C>T p.(Gln656*), thus confirming Schaaf-Yang syndrome. We detected a heterozygous deletion of *SMN1* by analysis of realigned BAM file using Paraphase. The other *SMN1* allele was devoid of pathogenic variants thus ruling out spinal muscular atrophy. Sanger sequencing of *SMN1* verified the absence of pathogenic variants.

Conclusion: We show the potential of long read whole genome sequencing as an effective single diagnostic test in the clinic to confirm diagnoses in patients with neonatal hypotonia.

Grants: This study was supported by a grant from the Regional Research Council Mid Sweden.

P21.026.A Pathological Short Tandem Repeats Analysis by Long-Read Sequencing in affected individuals

Hagar Mor-Shaked[1;2], *Rivka Birnbaum*[1], *Shira Silverstein*[2], *Chaggai Rosenbluh*[1], *Orly Elpeleg*[1;2], *Tamar Harel*[1;2]

[1]*Hadassah Medical Center, Department of Clinical Genetics, Jerusalem, Israel;* [2]*Faculty of Medicine, The Hebrew University of Jerusalem, Faculty of Medicine, Jerusalem, Israel*

Background/Objectives: Pathological short tandem repeats (STRs) are repetitive DNA sequences found throughout the genome that can expand and contract in length, resulting in various genetic diseases. Traditional short-read sequencing technologies have limitations in detecting STRs due to their inherent instability and repetitive nature. Long-read sequencing (LRS), can provide a potential solution for accurate and comprehensive STR analysis.

Methods: Sixteen affected individuals with known pathogenic expansions in ten different loci were sequenced on PromethION, to obtain long-read whole-genome sequencing (LR-WGS). STR genotyping was performed using the straglr software as bundled within Oxford Nanopore Technologies wf-human-variation workflow using default parameters and with the `--str` flag to specify STR genotyping. Straglr provided repeat unit counts from the phased reads that span the collection of pre-annotated disease-associated human STRs.

Results: Straglr software analysis on LR-WGS data detected all previously known repeat expansions, with almost the same allele sizes that were known from repeat-prime PCR, and provided sizing information for large loci, in which the size was unknown. In addition, when relevant, methylation analysis was successfully conducted to support the analysis.

Conclusion: As the cost of genome sequencing continues to drop and new technologies emerge that can detect all types of genetic variations in one test, we hypothesis it is likely that clinical STR detection will shift towards LR-WGS. This is supported by the ability to analyze DNA methylation from Oxford Nanopore data, which is relevant for several pathological STRs.

Before implementing LR-WGS for STR detection, further validation would be necessary, which includes testing affected individuals for each genetic locus.

P21.027.B Assessment of read depth requirements for gene and isoform discovery: a comparative study of long-read and short-read RNA sequencing data in human heart

Nina Gonzaludo[1], *Jocelyne Bruand*[1], *Amy Klegarth*[1], *Jason Underwood*[1], *Elizabeth Tseng*[1], *Kimberly A. Aldinger*[2]

[1]*PacBio, Menlo Park, CA, United States;* [2]*Seattle Children's Research Institute, University of Washington Birth Defects Research Laboratory, Seattle, WA, United States*

Background/Objectives: Long-read sequencing (LRS) allows for full-length isoform capture without cDNA fragmentation or computational assembly, revolutionizing transcriptomics. However, determining optimal read depth for isoform discovery is challenging. We compared read depth requirements for gene and isoform discovery using long- versus short-read RNA-Seq.

Methods: For 4 developing heart samples, library prep was performed using PacBio full-length Kinnex RNA kits with sequencing on PacBio Revio (1 sample per SMRT Cell 25M), and analysis with PacBio SMRT Link v13.0 Iso-Seq workflow and Pigeon. Short read RNA-seq was performed using Illumina TruSeq Stranded mRNA kits, with sequencing on NovaSeq6000 and analysis with STAR, RNA-SeQC, and RSEM. To simulate lower read depths and isoform discovery sensitivity, long reads were downsampled. We compared known and all unique genes and isoforms at different depths across platforms.

Results: Read depths ranged from 31.9-36.8M reads for PacBio data, and 81.6-123M reads for Illumina data. The identification of known and unique genes plateaued (increased less than 0.1% per 100k reads) at 5.6-9.5M and 7.7-13.1M reads, respectively. Known and unique isoform discovery plateaued at 7.8-11.4M and 12.5-19.3M reads, respectively. We show corresponding values in short-read data with a lower amount of genes and isoforms discovered at plateaus. Above these thresholds, higher depths improved detection of novel isoforms and may improve accuracy of existing gene annotation.

Conclusion: As LRS gains traction in transcriptomics, this study demonstrates read depth requirements for gene and isoform

discovery in human heart tissue. This information can help optimize experimental designs and multiplexing of samples, and inform decisions around sequencing depth.

P21.028.A Low variant mutation detection using InfiniSeq targeted sequencing

Nelly Frenkel[1], Adi Ben-Yehuda[1], Adi Danin[1], Tom Fleischer[2], Michael Gershovits[2], Yardena Brilon[2], Hadar Haham[2], Noa Tzunz-Henig[2], **Tamir Biezuner**[1]

[1]Sequentify, R&D, Rehovot, Israel; [2]Sequentify, Bioinformatics, Rehovot, Israel

Background/Objectives: The detection of low variant frequency (VAF) somatic mutations using Next Generation Sequencing (NGS) plays a critical role in early cancer detection. Current NGS library preparation methods built for such tasks are laborious, long and expensive. We set out to resolve this problem by developing a targeted NGS library preparation method that can detect low VAFs at high fidelity in less than 4 hours of preparation time and at a low cost.

Methods: We conducted a Limit of Detection (LOD) experiment using mutated DNA which was serially diluted with normal DNA. The InfiniSeq Myeloid Malignancy Panel (Sequentify™) was employed to construct NGS libraries targeting 18 distinct variants with known Variant Allele Frequencies (VAFs) ranging from 63% to 0.05%.

Results: The sensitivity was assessed by comparing the expected VAFs of each variant against the analyzed data, while the specificity was evaluated using data derived from normal DNA. We demonstrate a consistent VAF detection at 100% sensitivity and accuracy for any VAFs above 5%. For 2%-5% and 0.5%-2% VAF the sensitivity was 97% and 90% respectively, with correspondingly high accuracy rates of 100% and 99%. The overall panel specificity clocked-in at 100%.

Conclusion: In a rigorously controlled experiment, our findings demonstrate the capability of the InfiniSeq protocol to accurately identify all clinically significant SNVs and short indels at low VAFs. This, together with the scalability of the protocol, underscores its potential for widespread population screening of early malignancy development.

P21.029.D Evaluation of synthetic long reads technology

Zuzana Gerber[1], *Florian Sandron[1], Christian Daviaud[1], Naell Lenoir[1], Margaux Gras[2], Vincent Meyer[1], Robert Olaso[1], Jean-François Deleuze[1;2]*

[1]CEA, CNRGH, Evry, France; [2]CReflX, Evry, France

Background/Objectives: Human whole-genome sequencing (WGS) has become an important tool in diagnostics of cancer and rare diseases. Certain cases cannot be resolved by short-read WGS, whereas long-read sequencing may increase their diagnostic yield. However, long-read approaches are not widely used, because long-read sequencers are expensive, the cost-per-Gb is superior to short-read WGS, and/or the error rate is elevated for certain technologies. Here we evaluate the potential of synthetic long-read approach, which can reconstruct long-read-like data from short-reads in silico.

Methods: At CNRGH, we tested "Illumina Complete Long Reads" (ICLR) on the Ashkenazim trio reference gDNA (Coriell Institute) including HG002 individual characterised by the GIAB consortium for SNVs, indels and structural variants (SV). We compared the results to publicly available data from long-read technologies PacBio and Oxford Nanopore as well as short-reads from Illumina.

Results: The protocol is easy to follow and to implement in a high-throughput sequencing laboratory. The detection of small variants (SNPs and indels) is comparable to true long-read technologies but seems less efficient for SVs, including SVs implicated in known genetic disorders, for example in genes CBS or SMN1. The sequencing effort required for ICLR is very high, driving the cost at least as high as true long-read sequencing.

Conclusion: Unlike true long-reads, ICLR does not require high input material quantity or exceptional quality, nor expensive dedicated instruments besides common short-read sequencers. However, ICLR has little advantage of performance or cost compared to true long-reads. Furthermore, ICLR analyses are restricted to the cloud version of Dragen.

P21.030.A Clinical utility of PacBio HiFi sequencing on Revio

Christian Betz[1], *Hanno Bolz[1], Malte Spielmann[2;3;4], Lars Feuk[5], Anna Lindstrand[6], Katharina Herzog[7], Johannes Zschocke[7], Christian Gilissen[8], Lisenka Vissers[8], Alexander Hoischen[8]*

[1]Bioscientia Institute for Medical Diagnostics GmbH, Human Genetics, Ingelheim, Germany; [2]University Hospital Schleswig-Holstein, University of Lübeck and Kiel University, Institute of Human Genetics, Lübeck/Kiel, Germany; [3]Max Planck Institute for Molecular Genetics, Human Molecular Genetics Group, Berlin, Germany; [4]DZHK e.V: (German Center for Cardiovascular Research), Partner Site Hamburg/Kiel/Lübeck; [5]Uppsala University, Department of Immunology, Genetics, and Pathology and Science for Life Laboratory, Uppsala, Sweden; [6]Karolinska University Hospital, Department of Molecular Medicine and Surgery, Karolinska Institute, and Department of Clinical Genetics, Stockholm, Sweden; [7]Medical University Innsbruck, Institute of Human Genetics, Innsbruck, Austria; [8]Radboud University Medical Center, Department of Human Genetics, Research Institute for Medical Innovation, Nijmegen, Netherlands

Consortium: on behalf of the HiFi Solves EMEA consortium

Background/Objectives: Long-read sequencing (LRS) technologies, such as PacBio HiFi sequencing on Revio, for the first time allow to assess complete human genomes at scale. This opens up the possibility of LRS as a comprehensive first-tier test for clinical genetics and rare disease diagnostics.

Methods: To determine the clinical utility of LRS, we performed Revio HiFi-LRS of 100 human genomes, comprising 5-15 positive controls each with mutations in 10 disease genes/loci with high sequence homology or pseudogene background, or within segmental duplications, including *ABCC6*, *CYP21A2, STRC, SMN1/2, PKD1, RPGR-ORF15*, and *OTOA*. These loci represent diagnostic challenges because they are difficult to analyze by standard

technologies and require custom-made test modalities. We utilized a novel tool, Paraphase (Cheng et al. AJHG 2023), that enables full haplotyping for homologous genes.

Results: Our study demonstrates that LRS can reliably identify most of the known mutations, including SNVs, InDels, structural variants, and gene conversions, in complex loci. The *PKD1* locus, containing very long AG-rich repeats, occasionally presented with low or lack of coverage, which was compensable by including 'non-HiFi/low-pass reads' for these loci.

Conclusions: Comprehensive analysis of some of the most challenging loci of the human genome by Revio LRS highlight its potential as a first-tier test for clinical genetics and rare disease diagnostics in the near future.

P21.031.B Beyond the Genome: Identification of Protein Sequence and Post-Translational Modifications with Quantum-Si's Next-Generation Protein Sequencer™ Platinum®

Khanh D.Q. Nguyen[1], **Richard Broadhead**[1]

[1]*Quantum-Si, Branford, United States*

Background/Objectives: Protein sequencing advances genomics research by providing crucial insights into the proteins encoded by the genome. Additionally, it offers a comprehensive understanding of cellular processes and disease mechanisms by detecting amino acid substitutions and post-translational modifications (PTMs) that cannot be captured by genomics data alone.

Methods: In this study, we present the power of next-generation protein sequencing™ on Platinum®, where individual peptides are immobilized on a semiconductor chip and probed by dye-labeled N-terminal amino acid (NAA) recognizers, followed by aminopeptidase cleavage that exposes each NAA in the peptide for recognition. Fluorescent intensity, lifetime, and binding kinetics of each NAA binding event is collected and converted into kinetic signatures for each peptide, enabling the sequencing of peptides, inference of proteins in unknown samples, and detection of variants and PTMs.

Results: To demonstrate the versatility of this core methodology, we sequenced a mixture of ten proteins: CDNF, IL4, HSA, VIME, IL6, PDL1, APOE4, FGF2, AKT1, and H4. The resulting peptides generated distinct kinetic signatures aligned to their respective sequences, highlighting Platinum's efficacy in analyzing multi-protein mixtures. Additionally, we successfully detected citrullination and dimethylation of arginine, known to play key roles in cardiovascular disease, autoimmune disease, and cancer. Finally, recent developments in Platinum Analysis Software have allowed us to sequence proteins without prior knowledge of their identities, enabling inferences of proteins associated with biological pathways.

Conclusion: As we envision future enhancements to Platinum, we anticipate an expanded coverage of the proteome, thereby unraveling even more information often overlooked with genomics data.

P21.032.C QGenome: Bridging the interface between common conditions and rare diseases through an app-based clinical decision aid

Mohamed Wafik[1], *Anjana Kulkarni*[1], *Helena Carley*[1], *vishakha tripathi*[1], *charlotte tomlinson*[1], *Sophia Cross*[1], *Poppy Emmet*[1], *Muriel Holder*[1], *Shwetha Ramachandrappa*[1], *Leema Robert*[1], *Rachel Bastiaenen*[2], *Teofila Bueser*[3], *Alexander Kenney*[4]

[1]*Guy's and St Thomas' NHS Foundation Trust, Clinical Genetics, London, United Kingdom;* [2]*Guy's and St Thomas' NHS Foundation Trust, Cardiology, London, United Kingdom;* [3]*The NHS South East Genomic Medicine Service Alliance;* [4]*UBQO limited, http://www.ubqo.com/, United Kingdom*

Background/Objectives: Reducing the time patients wait for a rare disease diagnosis is one of the main priorities in the UK Genome strategy. To facilitate this need, QGenome, a smart clinical application has been developed.

QGenome is designed by the Guy's Hospital Regional Genetics service, in partnership with the South East Genomic Medicine Service Alliance (GMSA) and UBQO limited (http://www.ubqo.com/). The aims are to:

Facilitate streamlined genomic testing, risk assessment, and referral guidance to relevant healthcare professionals.
Provide equity of "Genomics care" for patients across the UK.

The current scope of QGenome includes pathways for cancer genomics, renal genomics, and inherited cardiac conditions (ICC).

Methods: For each clinical indication/condition, QGenome provides workflow assessments to determine eligibility for genomic testing and/or specialist tertiary referral, via a series of questions about their patient's personal, past medical, and family history.

The app can be used to find relevant forms, save reports, and activate referrals. QGenome is freely available on iOS, android and web-based platforms (https://qgenome.co.uk/).

Results

- QGenome offers a quick, efficient clinical decision tool for healthcare professionals in busy clinical settings.
- It contains workflows to perform risk assessments and determine genomic testing eligibility.

Conclusion: QGenome enables more patients with inherited genetic conditions to be identified, and improves the efficiency of Genomic testing services.

QGenome's content is currently relevant to the NHS South East, North Thames, and East GMSAs. We aim to expand this nationally,

to the 4 remaining NHS GMSAs, and internationally by creating custom made content.

P21.033.D The performance of AlphaMissense to identify genes causing disease

Yiheng Chen[1;2], *Guillaume Butler-Laporte*[2;3], *Kevin Liang*[2;4], *Yann Ilboudo*[2], *Summaira Yasmeen*[5], *Takayoshi Sasako*[2;6], *Claudia Langenberg*[5;7], *Celia Greenwood*[2;4], *Brent Richards*[1;2;3;8;9]

[1]*McGill University, Department of Human Genetics;* [2]*McGill University, Lady Davis Institute;* [3]*McGill University, Department of Medicine;* [4]*McGill University, Quantitative Life Sciences Program;* [5]*Berlin Institute of Health at Charité—Universitätsmedizin Berlin, Computational Medicine;* [6]*Tanaka Diabetes Clinic Omiya;* [7]*Queen Mary University of London, Precision Healthcare University Research Institute;* [8]*King's College London, Department of Twin Research;* [9]*5 Prime Sciences Inc*

Background/Objectives: A novel algorithm, AlphaMissense, has been shown to have an improved ability to predict the pathogenicity of rare missense genetic variants. However, it is not known whether AlphaMissense improves the ability of gene-based testing to identify disease-causing genes.

Methods: Using whole-exome sequencing data from the UK Biobank, we compared gene-based association analysis strategies including sets of deleterious variants: predicted loss-of-function (pLoF) variants only, pLoF plus AlphaMissense pathogenic variants, pLoF with missense variants predicted to be deleterious by any of five commonly utilized annotation methods (Missense (1/5)) or only variants predicted to be deleterious by all five methods (Missense (5/5)). We measured performance to identify 519 previously identified positive control genes, which can cause Mendelian diseases, or are the targets of successfully developed medicines.

Results: These strategies identified 850k pLoF variants and 5 million deleterious missense variants, including 22k likely pathogenic missense variants identified exclusively by AlphaMissense. The gene-based association tests found 608 significant gene associations (at $p < 1.67 \times 10^{-7}$) across 24 common traits and diseases. Compared to pLOFs plus Missense (5/5), tests using pLoFs and AlphaMissense variants found slightly more significant gene-disease and gene-trait associations, albeit with a marginally lower proportion of positive control genes. Nevertheless, their overall performance was similar. Merging AlphaMissense with Missense (5/5), whether through their intersection or union, did not yield any further enhancement in performance.

Conclusion: In summary, employing AlphaMissense to select deleterious variants for gene-based testing did not improve the ability to identify genes that are known to cause disease.

P21.034.A Multiplexed full-length single-molecule nanopore sequencing of the human mitochondrial genome and its application for rare neuromuscular diseases and chronic lymphocytic leukaemia

Ivo Gut[1], *Ieva Keraite*[1], *Davide Canevazzi*[1], *Cristina Frias*[1], *Ida Paramonov*[1], *Elena Garcia-Arumi*[2], *Rita Horvath*[3], *Ferran Nadeu*[4], *Elias Campo*[4], *Simon Heath*[1], *Marta Gut*[1]

[1]*Centro Nacional de Análisis Genómico (CNAG), Barcelona, Spain;* [2]*Vall Hebron Institut de Recerca, Clinical and Molecular Genetics and Rare Disease, Barcelona, Spain;* [3]*University of Cambridge, Clinica Neuroscience, Cambridge, United Kingdom;* [4]*IDIBAPS, Barcelona, Spain*

Mitochondria are organelles found in most eukaryotic cells containing several copies of a circular genome encoding for vestigial functions of what once used to be a free-living organism. Within the human population, heteroplasmy is common and can have substantial impact on human health depending on the variant position, frequency and endogenous or exogenous factors. Accurate detection and quantification of such variants is important for diagnosis, genetic counselling, and treatment of mtDNA diseases.

Methods to reconstruct the mitochondrial DNA sequence using short-read next-generation sequencing come with an inherent bias due to amplification by PCR and mapping. They can fail to determine the phase of variants, to capture multiple deletions and to cover the mitochondrial genome evenly. Here we describe a method to target, multiplex and sequence at high coverage full-length human mitochondrial genomes as native single-molecules, utilizing the RNA-guided DNA endonuclease Cas9 and nanopore sequencing. Combining Cas9 induced breaks, that define the mtDNA beginning and end of the sequencing reads, as barcodes, we achieve high demultiplexing specificity and delineation of the full-length of the mtDNA, regardless of the structural variant pattern. Long-read sequencing data is analysed with a pipeline where our custom-developed software, baldur, efficiently detects single nucleotide heteroplasmy to below 1%, physically determines phase and can accurately disentangle complex deletions. We show the application of our method for the investigation of the mitochondrial genome of patients suffering from rare neuromuscular disorders as well as the accumulation of somatic mutations in the mitochondrial genome of patients suffering from Richter syndrome a progressed form of chronic lymphocytic leukaemia.

Conflict of Interest: None declared

P21.036.C Efficient detection of multi-locus imprinting disorders: a novel NGS-based methodology for simultaneous detection of multiple DNA methylation defects in imprinting disorders.

Jet Bliek[1], *Martin A. Haagmans*[1], *Marielle Alders*[1], *Irène NETCHINE*[2], *Marcel Mannens*[1], *Peter Henneman*[1], *Frederic Brioude*[2]

[1]*Amsterdam UMC location AMC, University of Amsterdam, Amsterdam Reproduction & Development Research Institute, Department of Human Genetics, Amsterdam, Netherlands;* [2]*INSERM, Centre de recherche Saint Antoine, Sorbonne Université, Hôpital Armand Trousseau, Endocrinologie moléculaire et pathologies d'empreinte, Paris, France*

Background/Objectives: Imprinting disorders (IDs), characterized by abnormal methylation patterns of specific imprinted genes, comprise a spectrum of rare diseases associated with embryonic development, growth and metabolism. The molecular diagnosis of IDs is based on the analysis of methylation patterns in differentially methylated regions (DMRs), which present an opposite methylation pattern between the paternal and maternal alleles. One intriguing aspect of IDs is the potential existence of multilocus imprinting disorders (MLID). This disorder involves aberrant methylation patterns of multiple loci across the genome, presenting a complex and challenging diagnostic landscape. Understanding the mechanisms and implications of MLID is crucial for accurate diagnosis and effective disease management.

Methods: Our novel methodology was based on NGS after capturing (TWIST Bioscience®) differentially methylated regions (DMRs) associated with or without pathological conditions. Normal methylation values of 49 DMRs (including around 4,500 CpG islands) were established by examining leukocyte DNA from 30 control subjects.

Results: Our study confirmed previously identified anomalies in 14 individuals affected by IDs (Prader-Willi, Angelman, iPPSD, Silver-Russell, Beckwith-Wiedemann, or genome wide uniparental disomy). We confirmed the presence of MLID in three patients with previously identified MLID.

Conclusion: By integrating advanced sequencing methodologies with a comprehensive examination of methylation patterns, our study offers a valuable contribution to the field of IDs, with implications for improved patient care. Our study's approach enhances rare disease understanding, paving the way for improved diagnostics, marking a significant stride in addressing IDs complexities.

P21.037.D AI cloud-based end-to-end technology for accurate, fast & affordable diagnosis for Spinal Muscular Atrophy in Paraguay

Carmen Garrido Navas[1;2;3], *María Teresa Martínez de Filartiga*[4], *Marco Casartelli*[5], *Ruth Zarate*[4], *Rubén Darío Duré*[4], *Sara Chulián Prado*[1], *Karmele Alapont*[2], *Anne Kristine Schack*[2], *Marija Chaushevska*[2;6], *Gjorgji Madjarov*[2;6], *Zoran Velkoski*[2], *Chris Kyriakidis*[2]

[1]*Asesoramiento Genetico SL, Genetic Counselling Department, Granada, Spain;* [2]*gMendel, CSO, Copenhagen, Denmark;* [3]*University of Granada, Granada;* [4]*Laboratorio Curie SRL, Paraguay;* [5]*Hospital General Pediátrico Niños de Acosta Ñu, Pediatrics department, Paraguay;* [6]*Ss. Cyril and Methodius University, Skopje*

Background/Objectives: Bi-allelic mutations in the *SMN1* gene result in motor neuron degeneration and spinal muscular atrophy (SMA), a progressive, recessive neuromuscular disease with varying presentation in terms of onset and severity. Due to the clinical and genetic heterogeneity of SMA, which has a low prevalence (1/10,000 births), diagnosis and treatment are highly challenging. SMA severity is associated with the copy number of the survival motor neuron 2 gene (*SMN2*) that is almost identical, in genomic sequence, with *SMN1*. Diagnosis of SMA is usually approached by RT-PCR for the *SMN1* gene (sometimes including *SMN2*) after clinical symptoms suggest the condition. This approach is not only slow and costly but also inefficient because the clinical symptoms overlap with other neuromuscular diseases increasing the misdiagnosis rate.

Methods: We collected 30 samples from patients affected with SMA from Paraguay and prepared sequencing libraries for ONT sequencing using our standard operating procedure. We multiplexed all 30 samples into one R10.4 flowcell and sequenced them in a GridION device. The analysis based on artificial intelligence was performed on the CE-IVD Phivea® platform resulting in disease classification.

Results: We analyzed the samples from SMA patients using the Phivea® platform and we were able to identify a point mutation (C>T) that usually occurs in the telomeric region, as well as to count the number of copies for *SMN1* and *SMN2*.

Conclusion: The Phivea® platform can be used as a novel automated approach to study *SMN1* and *SMN2* mutations to improve the diagnostic yield of SMA for patients from Paraguay.

Long-read genome sequencing (LRS) allows to assess the full human genome for the first time comprehensively and could offer a first-tier test for clinical diagnostics. To determine the clinical utility, we performed LRS for 100 samples (HiFi genomes on Pacific Biosciences (PacBio) Revio instrument, ~30-fold coverage), with known clinically relevant variants that are challenging or

impossible to identify by short-read sequencing. A fully automated PacBio-based in-house pipeline was developed for quality control and sequence alignment, as well as the detection and phasing of all variant types including SNV/indels, STRs, SVs and methylation alterations.

LRS could readily identify the vast majority (95%) of known pathogenic variants. Of these, 87% were automatically called, including CNVs, translocations, inversions, STR expansions, de novo methylation defects and SNV/indels in homopolymer stretches and/or homologous sequences; 8% required manual curation such as the inspection of the aligned sequencing reads. A minority of variants (5%) posed systematic challenges, which included variants in very long AG-rich repeats and cases with cytogenetic aberrations affecting the repeat-rich regions of the Y-chromosome and/or acrocentric p-arms. In conclusion, LRS can identify the vast majority of pathogenic variants that are most challenging to detect with short-read technologies. Although our study identified some specific pitfalls, we expect that these can likely be resolved with further (bioinformatic) optimization. Most importantly, we show the potential to use a single technology to accurately identify all types of medically relevant genome variants, opening avenues to work towards a single generic test for germline testing in the future.

Background/Objectives: Long-read sequencing is revolutionizing human genetics, and full-length isoform sequencing technologies like Iso-Seq allow for improved characterization of isoform landscapes, especially when studying specific cell-types. However, standard Iso-Seq methods also present with some shortcomings; a bias for transcripts <10kb in size and modest coverage for lowly abundant transcripts. Here, we applied 'indirect target enrichment' of cDNA using the Xdrop Sort (Samplix) for single molecule enrichment in double-emulsion droplets and showcase successful enrichment of *USH2A* isoforms – aiming at large transcripts, including the identification and quantification of known and novel isoforms.

Methods: In order to generate targeted high coverage long-read RNAseq data of *USH2A*, the Samplix Xdrop Sort was employed for cDNA obtained from human post-mortem retinas. Through the use of three detection sequences distributed across the full-length of *USH2A*, the gDNA method was used for indirect target enrichment with 3ng of cDNA input. The resulting pool of enriched transcripts was sequenced through HiFi long-read sequencing (PacBio) followed by cDNA analysis.

Results: A successful enrichment of *USH2A* transcripts was observed, resulting in up to 125-fold coverage. A subset of sequenced reads demonstrated successful capture of full-length 18.9kb transcripts. Additionally, sequencing results revealed the presence of a novel exon in ~15% of transcripts, potentially supporting a previously undescribed transcript based on its UTR-like motives.

Conclusion: The Xdrop Sort can successfully be employed for the targeted Iso-Seq of cDNA. The current study highlights the capability of detecting a multitude of isoforms and splicing events, even for transcripts as large as 18.9kb like *USH2A*.

Background/Objectives: Despite the diagnostic implementation of chromosomal microarrays/shallow whole genome sequencing and whole exome sequencing (WES) for patients with intellectual disabilities/developmental disorders (ID/DD), approximately half remain undiagnosed using this standard of care (SoC). Several international studies have demonstrated improvements in diagnostic yield with the use of whole genome sequencing (WGS) compared to SoC approaches. To (i) technically validate WGS at different genetic centers in Belgium, (ii) investigate the clinical utility of WGS for ID/DD diagnosis and (iii) to assess the health economic impact, the 8 Belgian genetic centers engaged in a multicentric prospective randomized control trial, called BeSolveRD.

Methods: A total of 800 patients and both parents are being recruited of which half will be processed by SoC and half by WGS. In order to streamline the WGS analysis across the different sites, we set up a harmonized variant interpretation workflow within the Emedgene platform (Illumina). We also created a federated database (WINGS) to share variant and sequence information.

Results: Currently, we are over halfway through the project and have prospective data on about 400 patients showing already non-inferiority of WGS as compared to SoC.

Conclusion: We will present the current status of the project and interesting clinical findings. We will also elaborate on how BeSolveRD will provide the necessary Belgium specific data on clinical and health economic aspects that can aid the decision on the implementation of WGS at a national level.

P21.043.B Targeted sequencing of chromosomal rearrangements using nanopore sequencing.

Joakim Klar[1;2], *Ida Höijer*[2], *Hans Matsson*[1], *Malin Melin*[2], *Adam Ameur*[3]

[1]*Akademiska Sjukhuset, Clinical Genetics, Uppsala, Sweden;* [2]*Uppsala University, SciLifeLab Clinical Genomics, Uppsala, Sweden;* [3]*Uppsala University, SciLifeLab National Genomics Infrastructure, Uppsala, Sweden*

Chromosome karyotyping followed by metaphase FISH is still a robust way to map and identify chromosomal rearrangements. It can however be a tedious process making use of multiple FISH probes to correctly identify the breakpoints with a limited resolution. Whole-genome sequencing (WGS) using short-read sequencing can give a faster result but have difficulties to correctly annotate more complex rearrangement that includes multiple deletion/duplications together with inversions. Sequencing using longer reads overcome many of the limitations of short-read sequencing, such as the ability to reliably produce sequences of long repetitive regions and large segmental duplications. In addition, the ability to enrich for regions of interest (ROI) prior to sequencing is for many applications advantageous. In a clinical setting this means a cost-effective way to sequence only the loci implicated in a translocation identified by routine karyotyping, thereby replacing FISH.

We therefore investigate the possibility to implement adaptive sampling 'Read Until' using Nanopore for targeted sequencing of complex translocation breakpoints or rearrangements with multiple breakpoints such as chromoanagenes. In our first study, we identified a seemingly balanced translocation by using conventional karyotyping. We used both WGS using short-read sequencing and targeted nanopore sequencing to identify multiple breakpoints together with duplications and inversions at both chromosomes involved. The use of long-read sequencing produced more reliable results with far less background compared to short-read sequencing.

P21.044.C Optimized library preparation kit and workflow for improving cfDNA sequencing sensitivity

Sean Tighe[1], *Owen Smith*[1], *Tong Liu*[1], *Tiffany Truong*[1], **Tina Han**[1], *Elian Lee*[1], *Ramsey Zeitoun*[1], *Siyuan Chen*[1]

[1]*Twist Bioscience, South San Francisco, United States*

Background/Objectives: Next-Generation Sequencing (NGS) of cell-free DNA (cfDNA) has emerged as a promising strategy for early detection, diagnosis, and monitoring of cancer progression. In this process, cfDNA is extracted from a patient's blood and undergoes library preparation prior to NGS. The challenge with cfDNA library preparation is reliably capturing and converting all the fragmented DNA, especially when present in low concentrations within biological samples. Attaining low variant detection thresholds and variant calling confidence demands high-performance NGS libraries and targeted sequencing protocols.

Methods: Presented here is a workflow leveraging the Twist cfDNA library preparation kit and an optimized target enrichment workflow to maximize the conversion of duplex, on-target, sequenceable sample molecules.

Results: It is demonstrated that by increasing target coverage we can increase detection sensitivity at low variant allele frequencies. In addition, this workflow improves detection of duplex-molecule families by an estimated 40% relative to comparable workflows due to more efficient four-point ligation and newly optimized target enrichment. It is also demonstrated that achieving such improvements in complexity does not necessitate compromising data fidelity by introducing artifacts or losing uniformity. This improved conversion and sensitivity is applicable to as low as 1ng input samples with both native cfDNA and control cfDNA.

Conclusion: In summary, our optimized library preparation kit and streamlined workflow emerges as a valuable asset for those deploying NGS-based liquid biopsy assays.

Background/Objectives: Adaptive sampling is a new approach designed by Oxford Nanopore Technologies (ONT) to enrich the regions of interest and deplete off-target regions in a whole genome sequencing. The purpose of this study was to conduct the comparative analysis of Illumina and ONT targeted sequencing methods for patients with Inherited Cardiac Conditions (ICCs). ICCs are genetic diseases, with structural or functional heart abnormalities.

Methods: gDNA was isolated from 6 whole blood samples of patients with ICCs by using the commercial kit. Samples were sequenced on Illumina using TruSight Cardio sequencing kit. The BED file for ONT Adaptive Sampling was generated by UCSC browser, containing the same genes as of TruSight Cardio. The comparative analysis of obtained data was performed using bioinformatic tools and epi2me labs platform.

Results: As a result of targeted sequencing, the mean depth of coverage for targeted regions was 77 for ONT and 10650 for Illumina. The proportion of bases covered in ONT and Illumina was 80% and 43%, respectively.

Conclusion: Illumina sequencing achieved higher depth of coverage in comparison with ONT. However, the longer reads used on ONT sequencing provides higher proportion of bases covered and yield additional data for the off-target regions, that allows identification of possible novel mutations.

Grants: This research has been funded by the Science Committee of the Ministry of Science and Higher Education of the Republic of Kazakhstan (Grant No. AP14869903).

Background/Objectives: The evaluation of tandem-repeat (TR) motifs from massively parallel sequencing (MPS) data is rapidly gaining importance in modern genomics. We are reporting on specific qualitative and quantitative measures of TR genotyping when comparing short-read and long-read second generation sequencing technologies.

Methods: Four human samples were analyzed using three whole-genome-sequencing (WGS) protocols: Illumina-short-read with ~30x depth-of-coverage (WGS_SR_30x), Illumina-short-read with ~100x depth-of-coverage (WGS_SR_100x), and ~30x Illumina-long-read (WGS_LR_30x). TR genotypes were characterized for ~50 clinically relevant TR loci using the Dante tool. Qualitative and quantitative parameters, covering genotyping-accuracy, coverage and phasing issues, were compared between these datasets.

Results: Strong presence of partial reads were recorded in SR data, affecting the number of spanning reads usable for direct genotyping. This could, together with stutters, increase the requirements on depth of coverage for more consistent genotyping results. Such partial reads were not typical for LRs, however, larger numbers of non-specific spanning reads were recorded, which in certain cases also interfered with the genotyping possibilities. Phasing of complex motifs was possible also with WGS_SR_100x, although the LR protocol led to more reads spanning whole motifs.

Conclusion: Possibilities and reliability of TR analyses are affected by certain aspects of data structure, such as sufficient depth of locus coverage (TRs require more reads than SNVs), longer read lengths (which may aid complex repeat motifs) and the possibility of visual verification through dedicated tools (for locus structure visualization).

Background/Objectives: Medulloblastoma (MB) is one of the most prevalent embryonal malignant brain tumors, divided into four distinct molecular subgroups (WNT, SHH, group 3, and group 4) with its individual prognosis. A more extensive classification of MB has been provided, identifying numerous subtypes, some with poor prognosis, leading to a significant number of patients

succumbing to the disease while survivors experience side effects, highlighting the need for efficient subgrouping methods.

Methods: We evaluated the ability of Nanopore sequencing to provide clinically relevant methylation and copy number profiles on a discovery cohort of 45 frozen MB samples, benchmarked against the gold standard EPIC array, and validated on a cohort of 116 MB samples. Distinct DNA methylation profiles characterize each MB subgroup; the advent of Nanopore sequencing has positioned itself as a reliable technique for comprehensive copy number and methylation profiling

Results: Most MB in both the discovery (43/45; 95.6%) and the validation cohort (110/116; 94.8%) were accurately subgrouped by Nanopore sequencing. Flongle flow cells for 18 MB allowed for a more rapid and cost-effective analysis, with 94.4% (17/18) being correctly classified. Nanopore sequencing allowed us to correctly subtype 24/30 (80.0%) within MB groups.

Conclusion: We provided for the first-time proof of concept that Nanopore sequencing can subgroup MB using DNA extracted from formalin-fixed paraffin-embedded (FFPE) samples and confirmed its use on cell-free DNA obtained from cerebrospinal fluid. Its ability to deliver quick and cost-effective results firmly establishes Nanopore sequencing as a game-changer in the field of MB classification.

P21.049.D *RareGPT*: towards improving large language models with the knowledge of rare diseases. A proof of concept study for genetic skeletal disorders.

Behnam Javanmardi[1], *Peter Krawitz*[1]

[1]*University of Bonn, Institute for Genomic Statistics and Bioinformatics, Bonn, Germany*

Background/Objectives: Large Language Models (LLMs) are already in use in a range of biomedical contexts (Thirunavukarasu et al. 2023) and can be envisioned to play major roles in assisting clinicians in various tasks and also influence educational and research work in medicine. However, to date, the developed medical LLMs have focused mainly on general medical knowledge or common diseases (Singhal et al. 2022), and that makes them prone to wrong answers or "hallucinations" when asked about certain rare diseases. In this contribution, we present our first steps in developing *RareGPT* aiming at fine-tuning LLMs with the knowledge of rare diseases. As a proof of concept, we start with customizing GPT-4 on basic knowledge of rare bone diseases.

Methods: We created a structured "knowledge file" from the *Nosology of Genetic Skeletal disorders: 2023 revision* by Unger et al. (containing 771 entries associated with 552 genes) and fed that to the custom GPT builder provided by OpenAI followed by a set of custom instructions in the configuration step.

Results: We compared the performance of GPT-4 and *RareGPT* in answering 50 short questions about genetic skeletal disorders. Out of these 50 questions, GPT-4 provided 34 and *RareGPT* provided 47 correct answers.

Conclusion: The performance of LLMs, such as GPT-4, in answering questions about rare diseases can be considerably improved by further fine-tuning them on the public knowledge in this field. We continue to add more rare disease knowledge to *RareGPT* and also plan to make use of open-source LLMs.

P21.050.A CaseSharing: A system for sharing case information on rare diseases adopting a user-based approach

Toyofumi Fujiwara[1], *Jae-Moon Shin*[1], *Eisuke Dohi*[2], *Yasunori Yamamoto*[1], *Atsuko Yamaguchi*[3]

[1]*Research Organization of Information and Systems, Database Center for Life Science, Kashiwa, Japan;* [2]*National Center of Neurology and Psychiatry, Department of Disease Research III, Kodaira, Japan;* [3]*Tokyo City University, Setagaya, Japan*

Background: The cost of whole genome sequencing has been decreasing, making it more common in diagnosing rare diseases. Sharing case information about undiagnosed cases and those with rare variants is crucial for discovering novel disease-gene relationships. A federated approach, connecting national genome initiatives, has been adopted to promote the sharing of case information. However, much case information remains outside these initiatives, isolated within clinical settings. In this study, we propose a new system that adopts a user-based approach to directly share case information, aiming to bridge this gap.

Methods: We have developed CaseSharing (https://pubcasefinder.dbcls.jp/casesharing) that is a management system for case information related to rare diseases. Case information is stored locally in JSON format, rather than in the cloud. In addition, we have developed CaseSharingDB that collects the metadata of case information such as gene names, disease names, and phenotypes stored in CaseSharing by each user.

Results: There is no need to worry about case information crossing national borders since case information is managed in local storage. Only metadata, which does not contain personal information, is collected from the case information and used for matching between CaseSharing users. Users can output case information in Phenopackets format, which facilitates case information sharing.

Conclusion: We developed CaseSharing, coupled with CaseSharingDB, that adopts a user-based approach to share rare disease case information while ensuring data privacy. This approach enhances the potential for discovering novel disease-gene relationships by facilitating broader data sharing across clinical settings.

P21.051.D Enrichment-based long-read panel sequencing in a diagnostic setting

Katharina Herzog[1], *Klaus Oberhuber*[1], *Martina Witsch-Baumgartner*[1], **Johannes Zschocke**[1]

[1]*Institute for Human Genetics, Innsbruck, Austria*

Background/Objectives: For many conditions, genetic analysis currently involves short-read exome sequencing and targeted examination of a limited number of relevant genes. However, this approach generally fails to identify pathogenic promoter, deep intronic or structural variants, leaving uncertainty in the case of negative results. Furthermore, there are complex or homologous "problem" genes that require separate specialized analysis methods. Long-read genome sequencing may overcome these challenges but is not usually feasible in a diagnostic setting.

Methods: We combined customized full-length target gene enrichment (Twist Bioscience) with multiplex HiFi long-read sequencing (PacBio) for comprehensive genetic analysis of selected common conditions. A single enrichment panel (approx. 100 genes) was used for several indications such as cystic kidney disease (including *PKD1*), hypercholesterolemia (including *LPA*), congenital adrenal hyperplasia (including *CYP21A2*), various tumour dispositions (including *PMS2*), and others, with variant

analysis of target genes only. Twelve or more samples were analyzed together on a single PacBio SMRT cell.

Results: Our one-for-all approach identified all tested variants including variants missed or not detectable by exome sequencing. The analysis of multiple samples for different indications in the same run secures cost-effectiveness without prolonged waiting times.

Conclusion: Long-read panel sequencing is a flexible, rapid and low-cost approach for comprehensive full-length gene analysis of conditions caused by a limited number of well-known genes. It has the potential of resolving cases left open after traditional short-read exome sequencing at low cost without resorting to genomes.

Background/Objectives: Co-existing Mendelian disorders can cause atypical phenotypes, challenging genetic diagnostics and clinical management. Deep familial phenotyping contributes to matching genomic and phenotypic data, but is particularly challenging for facial features. Here, we report an individual with a dual diagnosis of paternally inherited KBG syndrome and a maternally inherited 3q26 deletion. We performed three-dimensional (3D) facial phenotyping to investigate the presence of a subclinical dual phenotype.

Methods: We collected 3D facial photos of the index and his nuclear family, seven individuals with KBG syndrome and unaffected controls. We used dense surface registration to capture the facial shape and used craniofacial growth curves to assess facial features irrespective of age- and sex-related variation. We corrected the index's facial shape for the maternal (3q26del) and paternal (KBG) shape effects and performed principal component analysis and cosine distance-based analysis to objectively assess phenotypic similarity.

Results: Clinically, the index's facial gestalt is dominated by features associated with the 3q26 deletion. However, the cosine similarity to KBG syndrome is high, which is an objective indication of the presence of the KBG gestalt. Projecting the original phenotypes in a principal component space shows separate clustering of controls, KBG syndrome and both 3q26del carriers. After correcting the index for maternal shape effects, clustering reveals the corrected shape features the KBG gestalt.

Conclusion: We introduce objective 3D facial phenotyping to deconstruct facial features of major gene effects, unveiling subclinical facial features of KBG syndrome in an individual with a 3q26 deletion and KBG syndrome.

Consortium: Invfest

Background/Objectives. Structural variants have important roles in gene regulation and pathologic conditions in humans, but a large fraction of them, including many inversions, are missed due to their kb-long size, their balanced nature and their proximity to complex repeat regions. New long read techniques offer a great opportunity to characterize completely these variants. Thus, the aim of this study is to develop a cost-efficient and high throughput method to genotype a wide range of human inversions using Oxford Nanopore Technologies (ONT) ultralong reads (50-100kb).

Methods. We tested a combination of different DNA extraction and library tagmentation protocols on four human cell lines, followed by whole-genome ONT sequencing or adaptive sampling (AS) targeting ~640 candidate inversion regions.

Results. A comparative analysis of the yield, the read lengths (with N50 between 50-80kb) and enrichment (4-5X), shows that the Monarch DNA purification and Ultra-long library kits, combined with adaptive sampling, provide an ideal setting for sequencing most human inversions. Around 22-52% of the inversions could be genotyped in a single MinION flow cell with high accuracy. Moreover, by merging all the data together, ~75% of the inversions could be identified in each sample. The majority of missing inversions corresponded to those mediated by the largest inverted repeats, which could be compensated by increasing N50 and coverage.

Conclusion. We provide valuable insight into the use of nanopore sequencing to genotype complex genomic regions, with potential applications in phenotype association studies and clinical research.

Grants. AEI grants PID2019-107836RB-I00 / PID2022-137615OB-I00; Maria Zambrano Grant.

P21.056.C Nanopore sequencing enhances detection of the *PHOX2B* expanded short tandem repeat in Congenital Central Hypoventilation Syndrome patients (CCHS).

Samuel Wilkinson[1], *Andrew Fleming*[1], *Ali Awan*[2], *Chloe Fisher*[2], *Matthew Edwards*[1], *Deborah Morris-Rosendahl*[1;3]

[1]*Royal Brompton Hospital, Clinical Genetics and Genomics Laboratory, London, United Kingdom;* [2]*Guy's and St Thomas' NHS Foundation Trust, Genomics Innovation Unit, London, United Kingdom;* [3]*National Heart & Lung Institute, Genomic Medicine, London, United Kingdom*

Background/Objectives: Short tandem repeats (STRs) are DNA sequence motifs, typically 2-6 bp, repeated consecutively. The *PHOX2B* gene has two such repeats in exon 3, encoding polyalanine structures (GCA, GCC, GCG or GCT). Expansion of the second repeat (c.721-780) to more than 20 residues causes autosomal dominant congenital central hypoventilation syndrome (CCHS), characterised by autonomic nervous system dysregulation

with disordered respiratory control, occurring soon after birth. Current techniques used to detect the expansion repeats are prone to PCR errors and false negative results; and short read NGS has low sensitivity to detect the expansion. Here we use Oxford Nanopore long-read technology and adaptive sampling to accurately detect the repeat expansion in *PHOX2B* in patients with CCHS.

Methods: Samples with known *PHOX2B* expansion repeats were sequenced on the PromethION 2 (P2) using R10.4.1 flow cells. DNA was sheared to between 14-20kb in length (Covaris g-tubes) and prepped using the ligation sequencing kit v14 (SQK-LSK114) from ONT. Adaptive sampling was used to target *PHOX2B*. The ONT EPI2ME package was used to generate VCF and variant annotation files. Once validated, samples were multiplexed to reduce cost and increase throughput using the Native barcoding kit v14 (SQK-NBD114.96).

Results: Expansion of the *PHOX2B* repeat was confirmed on control samples. A sample previously sequenced using short read technologies with a false negative result, was re-run in parallel with other test cases and controls, and the known expansion was detected.

Conclusion: Nanopore sequencing allows for better detection of expansion repeats that cannot be accurately detected by short read technologies.

P21.058.A PacBio Revio and ONT PromethION long-read sequencing in SV calling and variant phasing

Giancarlo Tomio[1], *Janine Meienberg*[1], *Timo Siegenthaler*[1], *Pamela Nicholson*[2], *Stefan Krebs*[3], *Gabor Matyas*[1;4]

[1]*Swiss Foundation for People with Rare Diseases, Center for Cardiovascular Genetics and Gene Diagnostics, Schlieren-Zurich, Switzerland;* [2]*University of Berne, Next Generation Sequencing Platform, Berne, Switzerland;* [3]*Ludwig Maximilian University of Munich, Laboratory for Functional Genome Analysis, Gene Center, Munich, Germany;* [4]*University of Zurich, Zurich Center for Integrative Human Physiology, Zurich, Switzerland*

Background/Objectives: Short-read sequencing (SRS) is the most used technology in clinical sequencing, but it has limitations in areas of the genome harbouring complex structural variants (SVs) or repetitive/homologous sequence, and variant phasing information is often lost. Long-read sequencing (LRS) technologies do not suffer these challenges and have improved to the point of feasible use in clinical sequencing. Thus, we compared the latest Pacific Bioscience (PacBio) and Oxford Nanopore Technologies (ONT) LRS technologies in their ability to detect a known set of challenging variants.

Methods: Four DNA samples with SVs and single nucleotide variants previously detected by SRS (PCR-free WGS, PE150) were sequenced on a PacBio Revio as well as on an ONT PromethION and analysed with their respective standard pipelines. Several further SV callers were applied, and regions of interest were manually reviewed using Integrative Genomics Viewer.

Results: Our data revealed differences in the performance of the tested LRS approaches as well as in the performance of SV callers for challenging variants, including complex SVs and SVs with breakpoints in non-unique sequence regions. Nevertheless, both LRS approaches were able to detect breakpoints missed by SRS and to phase sequence variants according to their respective read lengths.

Conclusion: LRS can be the solution for breakpoint identification in repetitive regions and for characterisation of complex SVs not exceeding their read length. Improved SV callers are vital to take full advantage of LRS in clinical genetic testing. Current LRS technologies achieve SRS-like error rates at affordable prices and so enable an improved future for clinical sequencing.

P21.059.B Thymidylate synthase disruption to limit cell proliferation in cell therapies

Kirmo Wartiovaara[1;2], *Rocio Maldonado*[1], *hossam montaser*[1], *Timo Otonkoski*[1], *Inkeri Soppa*[1], *Jonna Saarimäki-Vire*[1]

[1]*University of Helsinki;* [2]*Helsinki University Hospital, Clinical Genetics*

Background/Objectives: Many diseases or genetic conditions could be envisioned to be treated with cell transplantations with or without gene therapy. However, the use of additional or genetically modified, such as CRISPRed cells carries a risk of malignant cell proliferation.

Methods: Here, we describe a novel metabolic safety system to control cell proliferation without added genetic elements. For this, we inactivated a key enzyme for nucleotide metabolism, *TYMS*, in several cell types, thus obtaining cells that proliferate only when supplemented with exogenous thymidine but fail to replicate in its absence.

Results: We show that under thymidine supplementation, *TYMS*$^{-/-}$ cell lines and pluripotent stem cells proliferate normally, produce teratomas and differentiate into potentially therapeutic cell types such as pancreatic beta cells. After differentiation, the postmitotic cells do not require thymidine to function, as seen by prolonged in vivo production of human insulin in implanted mice. Hence, this method allows robust cell culture and manufacture while mitigating the risk of uncontrolled growth of transplanted cells.

Conclusion: We describe engineering fully functional human cells, which can be cultured and manufactured robustly under supplementation of thymidine. This allows the genetic manipulation and production of therapeutic cells. However, since the cell proliferation can be controlled, the recipients of the cells are safe from possible oncogenic modifications.

Consortium: lonGER consortium

Background/Objectives: Short-read genome sequencing (SR-GS) has limitation regarding the detection of structural variations, homologous sequences, and low-complexity regions. Moreover, in SR-GS separate analyses are required to detect both genetic and epigenetic variants. Long-read genome sequencing (LR-GS) has the potential to overcome these limitations and to increase the diagnostic yield in rare diseases. The question is whether nanopore LR-GS is mature and accurate enough to be applied in clinical routine diagnostics.

Methods: The lonGER (German national initiative for clinical long-read sequencing) consortium was launched to evaluate the feasibility and advances of using nanopore genome sequencing in a routine clinical setup. Further, the lonGER consortium is established as a platform for the exchange of experience and to provide SOPs for wet lab and bioinformatic analysis to facilitate streamlined implementation in clinical laboratories.

Results: We provide insights into the lonGER wet lab workflows and bioinformatic analysis for routine clinical use. In addition, several example cases with SNV, SV and methylation alterations are presented that illustrate the utility of nanopore sequencing for the analysis of rare diseases patients. Our data highlight that nanopore sequencing is as accurate or more accurate than SR-GS for most variants.

Conclusion: Within the first year of the lonGER initiative, we were able to demonstrate the straightforward implementation of robust wet lab and bioinformatic workflows for nanopore sequencing. The data highlight the advancements of nanopore sequencing and its transformative impact on genomic medicine.

P21.061.D NGS panel customization for comprehensive genomic profiling

Akanksha Khare[1], Nishita Matcha-Balagrurvappa[1], Linus Forsmark[1], Katie Wilkins[1], Swati Gupta[1], Mike Ruvolo[1], **Houda Hallay**[2]

[1]Agilent Technologies, Genomics R&D, Santa Clara, United States; [2]Agilent Technologies, Germany

Background/Objectives: We developed a custom design pipeline to generate target enrichment gene panels for comprehensive genomic profiling of cancer samples, by detecting single nucleotide variations (SNV/INDEL), gene-level copy number variations (CNV), and DNA translocations (TL); and content to enable assessment of microsatellite instability (MSI) and tumor mutational burden (TMB).

Methods: The design methodology allows for addition of content based on the biomarker type. Probes for target regions are selected using empirical data on probe performance. Pre-defined content for MSI measurement covering 288 microsatellite sites. The performance of these sites in determining MSI status was demonstrated by comparing to the MSI-PCR reference method. To assess the performance of the design methodology, designs of various sizes (50 to 650+ genes) and content type were generated and assayed on reference samples and FFPE with known biomarkers. Sequencing metrics were evaluated for capture specificity and coverage of the target regions.

Results: Biomarkers were reliably detected with SNV detection down to 1% allele frequency, detection of gene amplifications and translocations concordant with FISH, and MSI and TMB determination concordant with PCR and Exome sequencing respectively. The design workspace was implemented in the SureDesign platform, providing a web-based interface for creating the designs.

Conclusion: We demonstrated full customization capability of the SureSelect Cancer target enrichment platform that pairs user-defined content with an optimized probe design methodology to enable the sensitive detection of the common types of DNA alterations found in FFPE samples.

P21.063.B A novel assay for potential mass screening of Turner syndrome based on Oxford Nanopore technology.

Gjorgji Madjarov[1;2], *Marija Chaushevska[1;2], Anne Kristine Schack[2;3], Karmele Alapont[2], Carmen Garrido Navas[2;4;5], Zoran Velkoski[2], Chris Kyriakidis[2]*

[1]Ss. Cyril & Methodius University, Skopje, Macedonia; [2]gMendel, Copenhagen, Denmark; [3]University of Copenhagen, Copenhagen, Denmark; [4]Asesoramiento Genetico SL, Granada, Spain; [5]University of Granada, Granada, Spain

Background/Objectives: Turner syndrome (TS) is characterized by a complete or partial absence or as mosaic of one X chromosome; leading to the karyotype of either complete, 45,X0, or partial 46,XXq or 46,XXp or mosaic 45,X0/46XX. Depending on the genotype, patients with deletions on Xp have the features of a short stature and congenital malformations, whereas Xq-deletions have gonadal dysfunctions. TS represents the only common chromosomal monosomic syndrome with the prevalence of 5.6/1000 in newborns, yet only with an estimated survival of 0.3% of monosomy X conceptions survive to term. Approximately 45% of TS cases involves non-mosaic monosomy of chromosome X. Detecting and monitoring TS and its variations within mosaicism accommodates tailored therapeutic interventions.

Methods: Our research demonstrates a cost-effective, end-to-end assay with potential mass screening of Turner Syndrome (TS) based on Oxford Nanopore technology. The DNA library was prepared in <8 hours prior to loading on the GridIONx5. Our Phivea®, platform allows for real-time detection of chromosomal aberrations based on Machine Learning technologies designed for targeted sequencing.

Results: Our approach allows simultaneous assessment of 384 samples, equivalent to 96 subjects, each in 4 technical replicates, reaching analytical specificity and sensitivity-score at 99.06% and 98.43%, respectively. The experimental evaluation bases on Turner, Trisomy 21, Trisomy 18, Trisomy 13 and control female samples.

Conclusion: Phivea® platform can be used as a mass screening tool for detecting Turner syndrome in a rapid, economic and accessible manner.

P21.065.D Advancing Genetic Diagnostics: Optical Genome Mapping's Efficacy in Identifying Structural Variants for Autosomal Recessive Diseases

Ozge Beyza Gundogdu Ogutlu[1], *Mehmet Burak Mutlu*[2], *mehmet ali ergün*[3], *Sengül Ozdek*[4], *Gülsüm Kayhan*[3]

Background/Objectives: Determining the genetic etiology is of great importance for many disease groups today. However, studies have shown that the etiology cannot be determined in 30-60% of patients with genetic diseases. One of the reasons for this is the limitations in the detection of structural variants. Optical genome mapping (OGM) is a new and effective method for detecting structural variants.

Methods: In this study, OGM was performed in 7 patients with a single heterozygous pathogenic variant detected for a recessive disease related to clinical findings as a result of routine molecular analyses.

Results: A structural variant was detected in the region associated with the target gene in two (29%) of seven patients. In one of these two patients with cone-rod dystrophy, an insertion of 976 bp in the 12th intron of the *TTLL5* gene, in which the likely pathogenic variant, as a result of WES analysis, was detected by OGM. The other patient, who was examined with a prediagnosis of Leber congenital amaurosis, a 7.5 kb deletion was detected 400 kb proximal to *NMNAT1* gene, in which a heterozygous pathogenic variant was detected in the WES analysis, covering the regulatory region of the gene.

Conclusion: This study supports the success of OGM in detecting structural variants. Few studies in the literature use the OGM method to diagnose monogenic diseases. This study is particularly important in terms of detecting the second variant with the OGM method in autosomal recessive diseases.

Background/Objectives: Microarrays have been the primary technology used in GWAS to date because of their low cost and genomic coverage with imputation. However, custom content biases ascertainment of genetic variants and arrays do not capture novel variants.

Methods: We developed and scaled a blended genome exome (BGE) sequencing approach that combines a whole genome and exome capture library at a 67:33 blending ratio in a single tube to sequence the genome to 2-3X depth and the exome to 30-40X depth in a single CRAM file.

Results: We imputed common variants throughout the whole genome and called rare coding variants from 47,264 participants that met quality control from the Populations Underrepresented in Mental illness Association Studies (PUMAS) Project including African, African American, and Latin American populations. Target metrics included >9.5 Gb total bases/sample, >90% of exome bases at 10X, and 10-65% exome selected bases. We found high concordance ($r^2 > 0.9$) between well-imputed BGE variant calls (INFO>0.8) and orthogonal variant calls from the Illumina GSA, when MAF >1%. We also called copy number and structural variants using GATK-gCNV and VISTA, respectively, then compared them to high coverage "truth" data. Deletion and duplication CNVs called from gCNV spanning >4 exons have precision and recall close to 0.9 for both. SV calls have sensitivity and precision both >99% at >1kb but lower for shorter events.

Conclusion: BGE has nearly all the benefits of deep whole-genome sequencing at <20% of the cost, empowering genomic discoveries, particularly in underrepresented populations.

P21.067.B Reassessment of long-read technology performance

Erika Souche[1], *Benjamin Huremagic*[1], *Joris Vermeesch*[1]

[1]*KULeuven, Department of Human Genetics, Leuven, Belgium*

Background/Objectives: Long-read sequencing technologies are increasingly used in human genomics to characterise human population variation. Their rapid evolution requires a reassessment of their performance, including each technology's latest developments, namely data from the Revio of PacBio, high duplex flowcells from Oxford Nanopore (ONT) and Illumina Complete Long Read (ICLR) technology.

Methods: HG002 long reads from all technologies have been processed using a common pipeline to detect Single Nucleotide Variants (SNVs), insertions/deletions (indels) and Structural Variants (SVs). Coverage of clinically relevant genes with pseudogenes and phasing were assessed. Small variants and SVs were compared to GIAB benchmark datasets using hap.py and Truvari, respectively.

Results: The performance of long-read technologies to cover clinically relevant genes with pseudogenes was variable. A similar proportion of heterozygous variants could be phased by all technologies. ICLR outperformed both PacBio and ONT on SNV and indel calling but performed the least on SV calling. Interestingly, at equal coverage, SV calling performance was more affected by the SV detection tool than by the technology (PacBio/ONT). Although PacBio and ONT showed precision and recall above 0.9, only up to 40% of detected SVs could be benchmarked.

Conclusion: ICLR performs as well as short reads on small variants but still cannot compete with PacBio and ONT on SV calling. Only a small portion of detected SVs can be assessed using the currently available benchmark datasets, emphasing the needs for updating these benchmarks and/or creating new ones.

P21.068.C RNA-sequencing as a broadly applicable diagnostic test: experience from a cohort of ~350 individuals suspected of different genetic disorders

Janna Hol[1], *Camilla Calandrini*[1], *Hannie Douben*[1], *Monique M van Veghel-Plandsoen*[1], *Esmee Kasteleijn*[1], *Peter Elfferich*[1], *Leontine M A van Unen*[1], *Mark Nellist*[1], *Jordy Dekker*[1], *Rachel Schot*[1], *Evelien Kroon*[1], *Herma C van der Linde*[1], *Martina Wilke*[1], *Marjon van Slegtenhorst*[1], *Marjolein Weerts*[1], *Frank Sleutels*[1], *Marianne Hoogeveen-Westerveld*[1], *Lies Hoefsloot*[1], *Grazia Mancini*[1], *Tjakko Van Ham*[1]

[1]*Erasmus MC, University Medical Center Rotterdam, Department of Clinical Genetics, Rotterdam, Netherlands*

Background/Objectives: For genetic disorders, establishing the molecular diagnosis is paramount for disease management, counseling and to enable predictive genetic testing. Yet, DNA-based diagnostic techniques, such as exome sequencing, often fail to identify causative variants. RNA-sequencing (RNA-seq) is a promising tool to complement DNA-based approaches, but its potential as a widely applicable diagnostic test remains to be fully explored. Here, we report our findings for ~350 individuals suspected of a range of different genetic disorders and subjected to RNA-sequencing after DNA-based diagnostics failed to identify a causal variant.

Methods: RNA-seq was performed on RNA isolated from skin fibroblasts, blood or amniotic fluid cells, and analyzed by targeted, disease-panel or open transcriptome approaches. Abnormal gene expression and splicing were detected using z-scores, as described previously (Dekker et al., Am J Hum Genet, 2023). Data collected included clinical characteristics, types of analysis performed, variants identified and resulting diagnoses.

Results: RNA-seq resulted in a molecular diagnosis in ~14% of the cohort and the diagnostic yield varied significantly among different disease categories. RNA-seq enabled the identification of variants that alter gene expression and/or splicing in various ways, including unconventional variants affecting splice enhancers or branchpoints, as well as copy number variants and complex structural variants. Moreover, possibly pathogenic changes were identified in novel candidate disease genes.

Conclusion: Our findings demonstrate that RNA-seq can help identify a range of pathogenic variant types, thereby improving the diagnostic yield for genetic disorders. These results support the widely applicable use of RNA-seq in genome-diagnostic laboratories to complement genomic sequencing.

P21.069.D Nanopore sequencing resolves challenging medically relevant genes (CMRG), focusing on SMN

Heather Jeffery[1], *Edmund Day*[1], *Sergey Nurk*[1], *Hayley Greenfield*[1], *Sissel Juul*[1], *Philipp Rescheneder*[1], *Phillip James*[1]

[1]*Oxford Nanopore Technologies, Oxford, United Kingdom*

Background/Objectives: The "Dark genome" is a term often used to describe genomic regions that are difficult to resolve using traditional sequencing methods. Currently there are over 5000 identified challenging medically relevant genes (CMRGs), such as the repeat expansion in the *FMR1* gene, and the 99.9% homologous *SMN1* and *SMN2* genes. We aim to show how long read sequencing can be used to resolve CMRGs such as the *FMR1* repeat expansion and *SMN1/SMN2* copy numbers.

Methods: Whole genome long read sequencing was performed on the Oxford Nanopore PromethION device using Coriell cell lines derived from subjects with fragile-x syndrome and spinal muscular atrophy. The Epi2Me human variation workflow was used to enumerate the *FMR1* repeat expansion motif. *SMN1* and *SMN2* copy numbers were calculated by aligning all relevant reads to the *SMN1* locus, then phased using discriminatory SNPs prior to generating normalised phased read counts.

Results: *SMN1* and *SMN2* copy numbers were correctly identified in the 12 Spinal Muscular Atrophy (SMA) samples analysed. We also show that longer read lengths facilitate improved alignment and detection of structural variants, including the *SMN1* exon 7-8 deletion known to be in one of the samples. Additionally, nanopore native long read sequencing was used to correctly enumerate the CGG repeat expansion in the *FMR1* gene as well as characterise methylation of the *FMR1* promotor in a haplotype resolved manner.

Conclusion: Nanopore sequencing can identify single haplotype variation in repeat regions, detecting both copy number and structural variations in Dark Genes previously unable to be resolved.

P21.071.B 3D Genomics: Unlocking the Secrets of the Non-Coding Genome

Nic Walker[1], *Kishen Chahwala*[1], *Hazel Jones*[1], *Dan Turner*[1], *Stefan Schoenfelder*[1], *Peter Fraser*[1]

[1]*Enhanc3D Genomics Ltd, United Kingdom*

Background/Objectives: Genomics-based approaches such as GWAS analyse genomes from a linear perspective and ignore the complex 3D structure. Most disease-associated GWAS variants are found in non-coding regions, areas highly enriched in elements that control gene expression. These regulatory elements can be located thousands to millions of base pairs from their target genes. Folding of the genome results in promoter-enhancer interactions that cannot be detected in linear DNA.

Methods: The GenLink3D™ pipeline uses promoter-capture Hi-C to identify long-range interactions for all annotated promoters in a given cell type in a single experiment. Combining our advanced

algorithms and machine-learning capability allows us to understand the 3-dimensional organisation of the entire genome with high-resolution, enabling us to decode and exploit novel targets for disease diagnosis and treatment, with high throughput and precision.

Results: Our analyses show that hundreds of thousands of regulatory elements are active in each cell type, some of which are ubiquitous and others cell-type specific. These elements interact with their target promoters, driving cell-type-specific expression. Systematically connecting disease-specific variants to their target genes can enable the discovery of novel disease-susceptibility genes, illuminate new drug targets and allow patient stratification. Specifically, we demonstrate how this approach can be applied to find novel SNP-associated genes in lupus and MS, and in patient stratification for SNP risk load variation across ethnically distinct populations.

Conclusion: We aim to provide a universal discovery tool to unlock any genetic disease by identifying the right genes, in the right cell types, and to de-risk the drug discovery process.

P21.072.C Let your data make more FAIR impact using MOLGENIS EMX2

Joeri van der Velde[1], *Esther van Enckevort*[1], *Gerieke Been*[1], *Eleanor Hyde*[1], *Morris Swertz*[1]

[1]*University Medical Center Groningen, Genomics Coordination Center, Groningen, Netherlands*

Consortium: The MOLGENIS Team

Background/Objectives: Your data in the life sciences can have far more impact when it is findable and (re)usable by a larger audience.

Methods: To achieve this, we have developed MOLGENIS EMX2, the 5th generation of the MOLGENIS open source scientific data platform with 100+ active installations powering a variety of life science web applications including catalogues, research portals, omics data and patient mutation registries. Importing and exporting of data is easy and achieved through Excel and CSV files. Advanced users adopt our dedicated Python client, export RDF, use GraphQL, or R.

Results: For humans, we have developed attractive data displays, dashboards, query screens, data entry forms and tools to manage fully flexible data structures and user permissions. For machines, interfaces such as FAIR Data Point and Beacon v2 can be registered at search portals to make the contents of these applications known to the wider world. Interoperability is driven by pre-defined best-practice semantic datamodel templates for biobank-, cohort- and harmonisation-catalogues, FAIR Genomes, JRC Common Data Elements, DCAT, Beacon v2, SolveRD-RD3, all based on popular resources including MIABIS, NCIT, HPO, ORDO and DUO. Datamodels are easily extended, e.g. there is a metabolomics add-on for X-Omics.

Conclusion: We are delighted to present EMX2, the next generation of the MOLGENIS FAIR data platform. MOLGENIS EMX2 is open-source (GNU LGPL v3.0) and available at https://github.com/molgenis/molgenis-emx2. Install it yourself or contact us for hosting options.

Introduction: *SOX3* (SRY-related HMG box-containing gene 3) is a SOX family gene located in Xq27.1. *SOX3* duplications are usually associated with panhypopituitarism for 46,XY individuals and variations in genital development for 46,XX individuals but also unaffected females. The molecular mechanism behind this variability in 46,XX individuals may be related to X inactivation bias but this has not been demonstrated.

Methods: We report three patients carrying *SOX3* duplications detected by gene panel sequencing or DNA microarray, one of whom was further investigated by long-read sequencing using Oxford Nanopore following an adaptive sampling targeted enrichment protocol. X inactivation was studied using a methyl-sensitive PCR.

Results: Individual 1 was referred for growth retardation with bilateral cryptorchidism and micropenis. His karyotype revealed a 46,XY formula and gene panel analysis revealed a 1.2 Mb duplication involving *SOX3* which was inherited from his unaffected mother (individual 2). X inactivation study showed no bias (49%/51%).

Individual 3 was referred for azoospermia. Karyotyping and FISH analysis revealed a 46,XX.ish Yp11.2(SRYx0) chromosomal formula. DNA microarray detected a 1.2 Mb *SOX3* duplication with similar breakpoints. X-inactivation was significantly biased (90%/10%). Nanopore sequencing showed that the normal allele was hypermethylated and uncovered a more complex rearrangement.

Discussion: X inactivation study, when performed, does not provide allele-specific information. Using Nanopore technology long-read sequencing, we were able to phase methylation and structural variation. This allowed us to demonstrate that *SOX3* duplication in females leads to a genital development disorder when the duplicated allele is predominantly hypomethylated while unbiased methylation prevents from this disorder.

TREATMENTS FOR GENETIC DISORDERS

P22.001.B Real-world safety and effectiveness of vosoritide: Results from an early access program in France

Valérie Cormier-Daire[1], *Thomas Edouard*[2], *Bertrand Isidor*[3], *Shelda Cohen*[4], *Swati Mukherjee*[4], *Jeanne Pimenta*[4], *Leila Lhaneche*[5],

Massimiliano Rossi[6], Elise Schaefer[7], Erin Goodman[8], Sabine Sigaudy[9], Genevieve Baujat[1]

[1]Paris cité university, Necker hospital, Imagine institute, Centre of Reference for Constitutional Bone Diseases (MOC), Paris, France; [2]Toulouse University Hospital, Endocrine, Bone Diseases and Genetics Unit, Toulouse, France; [3]Centre Hospitalier Universitaire de Nantes, Genetics, Nantes, France; [4]BioMarin (UK) Limited, London, United Kingdom; [5]BioMarin (FR) Limited, Paris, France; [6]Hospices Civils de Lyon, Service de génétique, Lyon, France; [7]CHU de Strasbourg - Hôpital de Hautepierre, Genetics, Strasbourg, France; [8]BioMarin Pharmaceutical Inc, Novato, United States; [9]Hôpital Timone Enfant, Département de Génétique Médicale, Marseille, France

Background/Objectives: Achondroplasia is the most common skeletal dysplasia with short stature. Vosoritide is currently approved in Europe for patients aged ≥ 4 months until closure of epiphyses. We report the experience of early access to vosoritide in France, led by the constitutional bone diseases (MOC) network.

Methods: In 2021, early access to vosoritide was initiated in patients aged ≥5 years. The national center of MOC network (Necker hospital) and five referral centers assessed patients for treatment and follow-up at month 1, 3, 6 and every 6 months. Data on patient characteristics, treatment compliance, safety and effectiveness (height, CDC height Z-score, annualized growth velocity (AGV) are reported.

Results: Sixty-two patients were enrolled, of whom 57 started early access treatment with vosoritide by December 2022. The mean age at treatment start was 8.6 years (min-max: 5-13 years) and 51% were male. Mean (range) exposure to treatment was 277 (32–443) days.

After 6 months treatment, the mean (SD) AGV was 5.9 (1.65) in males (n = 20) and 6.5 (2.64) cm/year in females (n = 16).

Among 22 patients who completed 12 months treatment (10 males, 12 females), mean (SD) height increase from baseline was 5.8 (1.71) cm and 6.5 (1.28) cm with a Z-score (SD) improvement of 0.3 (0.28) and 0.4 (0.37), respectively.

In total, 21 adverse events were reported, most of them mild (injection site reactions and vomiting).

Conclusions: Patients with achondroplasia under real-world conditions showed a safety and effectiveness profile consistent with vosoritide clinical trials.

Grants: The study was sponsored by BioMarin.

P22.004.A Using odevixibat to treat recurrent cholestasis in a patient with bi-allelic UNC45A mutations causing osteo-oto-hepato-enteric syndrome

Floris Imhann[1], *Chantal Malcolm[2], Zhe Zhou[3], Henkjan J. Verkade[4], Sven van IJzendoorn[3], Hans Blokziji[2]*

[1]University Medical Center Groningen, Department of Genetics; [2]University Medical Center Groningen, Department of Gastroenterology and Hepatology; [3]University Medical Center Groningen, Department of Biomedical Sciences; [4]University Medical Center Groningen, Department of Pediatrics

Background/Objectives: Osteo-oto-hepatic-enteric syndrome (O2HE) is a rare genetic syndrome leading to neonatal cholestasis, congenital diarrhea, sensorineural hearing loss and/or bone fragility. Osteo-oto-hepatic-enteric syndrome is caused by bi-allelic mutations in the gene Unc-45 Myosin Chaperone A (UNC45A), which leads to a reduction in Myosin Vb (encoded by the MYO5B gene). MYO5B mutations can lead to progressive familial intrahepatic cholestasis type 10 (PFIC10). Therefore, we suspected a similar disease mechanism.

In this case report, we describe trying the novel PFIC drug odevixibat for the first time in an O2HE patient with episodes of severe cholestasis and pruritis.

Methods: The treating gastroenterologist, a paediatric gastroenterologist and the clinical geneticist in training diagnosed the patient and performed a brief literature study to investigate whether new drugs could work.

Results: A 37-year old man, with episodes of diarrhea and cholestasis during his entire life was seen at our out-patient clinic. Whole Exome Sequencing showed c.292C>T p.(Arg98Trp) and c.592C>T p.(Gln198*) mutations in UNC45, after which O2HE was diagnosed. After the literature study, the ileal bile acid transporter (IBAT) inhibitor odevixibat, which interrupts the entero-hepatic cycle of bile acids was tried. The patient's pruritis quickly disappeared and liver enzyme, bilirubin and blood bile acid levels all decreased rapidly. The patient remains without cholestasis after a one year follow-up.

Conclusion: Here, we present the first case of O2HE with cholestasis that has been successfully treated with odevixibat. We recommend that the UNC45A gene be added to cholestasis WES panels. When O2HE is diagnosed, odevixibat can be considered for cholestasis treatment.

P22.005.B Finding a therapeutic molecule for ADLD: keep calm and never give up!

Mariia Zadorozhna[1;2], *Emanuela Pesce[3], Anna Basile[2], Erica Bascetta[2], Ilaria Cani[4;5], Foteini-Dionysia Koufi[6], Stefano Ratti[4], Pietro Cortelli[4;5], Nicoletta Pedemonte[3], Elisa Giorgio[1;2]*

[1]IRCCS Mondino Foundation, Neurogenetics Research Centre, Pavia; [2]University of Pavia, Department of Molecular Medicine, Pavia; [3]IRCCS Istituto Giannina Gaslini, UOC Genetica Medica, Genova, Italy; [4]Università di Bologna, Dipartimento di Scienze Biomediche e Neuromotorie, Bologna, Italy; [5]IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; [6]University of Bologna, Department of Biomedical and NeuroMotor Sciences (DIBINEM), Cellular Signalling Laboratory, Bologna, Italy

Background/Objectives: Autosomal Dominant adult-onset LeukoDystrophy (ADLD) is a slowly progressive disease with CNS demyelination caused by Lamin B1 (LMNB1) overexpression due to gene duplications/noncoding deletions located upstream the *LMNB1* gene. Currently, there is no effective therapy to cure or slow down the progression of ADLD. The reduction of LMNB1 protein represents a promising strategy for treating ADLD. Drug-repositioning approach, using a dual-reporter stable CHO cell line, allowed our group to identify Alvespimycin (Alv) as positive hit. Alv is a HSP90 inhibitor under investigation for solid tumor treatment. Unfortunately, it has not yet been approved by FDA or EMA, limiting its exploitation for ADLD. We aim at testing FDA-approved Alv analogues as ready-to-use therapeutic solutions for our patients.

Methods/Results: We selected nine Alv functional analogs with different properties (targeting the carboxy-terminal domain; deriving from natural compounds; or synthetic molecules) and tested their efficacy in reducing LMNB1 protein levels by western blotting on ADLD fibroblasts. Unfortunately, none of these molecules was able to mimic Alv effect on LMNB1. To maximize the identification of other effective drugs for ADLD, we decided to develop a disease-relevant dual-reporter cell line, exploiting the

immortalized human oligodendrocyte line MO3.13, resembling the most affected cell type in ADLD.

Conclusion: Alv-mediated LMNB1 modulation was not confirmed by other Hsp90 inhibitors tested, suggesting a molecule-specific effect. However, the creation of an innovative disease-relevant cellular model will increase the chance of identifying effective molecules by drug-repositioning, paving the way for developing an effective ADLD treatment.

Background/Objectives: KBG syndrome is a neurodevelopmental disorder caused by pathogenic *ANKRD11* variants. (Postnatal) short stature is a major feature observed in 10-60% of patients. Recombinant human growth hormone (rhGH) treatment is available for patients with growth hormone deficiency (GHD). Additionally, rhGH is also effective in patients with syndromes associated with short stature including Prader-Willi, Noonan and Turner syndrome. For patients with KBG syndrome, there is little evidence available. However, it suggests that growth hormone (GH) treatment could be beneficial. Systematic analysis and detailed phenotyping are lacking.

Methods: MEDLINE/PubMed was searched for patients with KBG syndrome treated with GH. Relevant auxological-, endocrine and rhGH-treatment related data were collected from the article and/or corresponding author(s). In addition, unpublished patients were identified through our international network of collaborators.

Results: Literature review identified 22 patients with KBG syndrome who received rhGH treatment. Data of 6 novel patients was added to the retrospective cohort. Full GHD was observed only in a minority. Before start of rhGH treatment, the median height was -3.1 SDS and 88% had short stature. Patients who received treatment for at least one year showed a median height gain of 1.3 SDS and 72% of them reached a normal height at most recent measurement.

Conclusion: In this large cohort of 28 patients first analyses suggest a benefit of GH therapy for (a subset of) patients with KBG syndrome. Further (subgroup)analyses are ongoing.

P22.008.A Investigation of the Regulatory Role of Lysosomal Cathepsin A in the Autophagy

Selman Yanbul[1;1], *Volkan Seyrantepe*[1]

[1]*Izmir Institute of Technology, Molecular Biyology and Genetics, Izmir, Türkyie*

Background/Objectives: Lysosomal Cathepsin A is serine carboxypeptidase with catalytic functions and it complexes with Neu1 and ß-gal enzymes to protect them from hydrolytic degradation. Deficiency of Cathepsin A causes Galactosialidosis with secondary Neu1 and ß-Gal deficiencies. Previously, we generated a $CathA^{S190A}$ mouse which has a point mutation on the catalytic site to investigate its role in the processing of bioactive peptides. In this study, we aimed to elucidate whether Cathepsin A has a role in the regulation of autophagy in cell lines derived from $CathA^{S190A}$ mice.

Methods: Neuroglia and fibroblast cells were isolated from $CathA^{S190A}$ mice and an age-matched control group. The cells were cultured in the following conditions: (i) none, (ii) treated with 200 mM rapamycin for 1h, (iii) starvation medium for 2h, and (iv) starvation medium for 2h with 200 mM rapamycin treatment in last 1h. Autophagy markers were analyzed by qRT-PCR, Western Blot, and Immunocytochemistry.

Results: We showed alterations in *Beclin-1, Atg7, Atg9, p62*, and *Lamp2* gene expression levels in neuroglia and fibroblast cells from $CathA^{S190A}$ mice using qRT-PCR analysis. Western Blot and Immunocytochemistry analysis demonstrated increased levels of LC3-II, p62, and LAMP1 proteins in both cell lines derived from $CathA^{S190A}$ mice. Consistently, we showed accumulated LC3-II, p62, and LAMP1 protein levels significantly decreased after starvation with or without rapamycin treatment.

Conclusion: Overall, our results suggest that the unprocessed bioactive peptide accumulation due to catalytically inactive CathA in mice may contribute to the regulation of autophagic flux, and also starvation condition may induce reversion of dysregulated autophagy.

P22.009.B Therapeutic Efficacy of Intrathecal Administration of AAVrh10-mHexa Vector in a Mouse Model of Tay-Sachs Disease

Melike Can Özgür[1], *Hatice Hande Basırlı*[1], *Jérôme Ausseil*[2], *Volkan Seyrantepe*[1,3]

[1]*Izmir Institute of Technology, Molecular Biology and Genetics, Izmir;* [2]*Université Paul Sabatier Toulouse, Centre de Physiopathologie de Toulouse Purpan, INSERM U1043, Toulouse, France;* [3]*Izmir Institute of Technology, IYTEDEHAM, Izmir*

Background/Objectives: Tay-Sachs disease, a lysosomal storage disorder, is caused by mutations in the *HEXA* gene. *HEXA* gene encodes for the α-subunit of the enzyme β-hexosaminidase A which degrades GM2 ganglioside in the brain and peripheral nervous system. The loss of the β-hexosaminidase A activity causes pathological accumulation of GM2 ganglioside in patients. Interestingly, disruption of HEXA leads to a mild phenotype in Hexa-deficient mice. Our group generated *Hexa-/-Neu3-/-* mice which showed severe neuropathological indications and survived until 20 weeks of age. Recently, Adeno-associated virus (AAV)-based gene therapy has been shown as an efficient delivery system for human studies. AAVrh10 is especially used in AAV-based therapeutics to target the central nervous system. Although there are several therapeutic approaches for lysosomal storage disorders, there is no cure for TSD. Here, we aimed to investigate the therapeutic efficacy of the AAVrh10-mHexa expressing mouse HEXA in the *Hexa-/-Neu3-/-* mice.

Methods: Molecular biological, immunohistochemical, and behavioral analyses were used to study the therapeutic efficacy of the AAVrh10-mHexa in the *Hexa-/-Neu3-/-* mice.

Results: We discovered that the life span of *Hexa-/-Neu3-/-* mice extended up to 28 weeks of age after intrathecal administration of AAVrh10-mHexa. Our data also revealed the clearance of accumulating GM2 ganglioside, increased Hexa enzyme activity, and decreased neuroinflammation in the cortex of *Hexa-/-Neu3-/-* mice. Consistently, motor activity was also improved in AAVrh10-mHexa-administered *Hexa-/-Neu3-/-* mice.

Conclusion: Our data suggest that AAVrh10-based intrathecal administration is a promising therapeutic strategy for the treatment of Tay-Sachs disease.

Grants: This study was funded by TUBITAK-Bosphorus (Grant No: 120N552).

P22.010.C Human Neu3 Sialidase Reduces GM2 Ganglioside Accumulation in Neuroglia Cells of Tay-Sachs Disease Mice Model

Hatice Hande Basırlı[1], *Melike Can Özgür*[1], *Volkan Seyrantepe*[1;2]

[1]*Izmir Institute of Techology, Molecular Biology and Genetics, Izmir, Türkyie;* [2]*Izmir Institute of Techology, IYTEDEHAM, Izmir, Türkyie*

Background/Objectives: Tay-Sachs disease, a type of GM2 gangliosidoses, is a severe neurodegenerative disorder caused by a mutation in the HEXA gene encoding α subunit of β-hexosaminidase A enzyme. HexA enzyme is responsible for the degradation of GM2 ganglioside. The deficiency of the HexA enzyme causes the excessive accumulation of GM2 ganglioside resulting in progressive neurodegeneration in Tay-Sachs patients. Surprisingly, *Hexa-/-* mice showed mild neuropathological and clinical signs. We recently generated *Hexa-/-Neu3-/-* mice as an early onset Tay-Sachs disease mouse model that mimics neuropathological abnormalities in patients. Our group also showed impaired autophagic flux in the brains of *Hexa-/-Neu3-/-* mice. Although the murine Neu3 sialidase was shown to facilitate GM2 degradation with a bypass mechanism in *Hexa-/-* mice, the contribution of human Neu3 in GM2 degradation remains unclear. Here, we aimed to elucidate the efficacy of human Neu3-mediated gene therapy using AAVrh10-hNeu3 in neuroglia cells.

Methods: We evaluated the therapeutic effectiveness of AAVrh10-hNeu3 expression in neuroglia cells of 5-month-old *Hexa-/-Neu3-/-* mice using molecular biological and immunocytochemical analyses.

Results: We found significant clearance of accumulating GM2 ganglioside in AAVrh10-hNeu3 treated neuroglia cells of 5-month-old *Hexa-/-Neu3-/-* mice. Our data also showed the altered autophagic flux in neuroglia cells after AAVrh10-hNeu3 treatment.

Conclusion: Our data suggest that human Neu3 might be a potential therapeutic strategy to reduce GM2 ganglioside accumulation in Tay-Sachs disease.

Grants: This study was funded by TUBITAK-Bosphorus (Grant No: 120N552).

P22.011.D Allele-Specific Antisense Oligonucleotides for the Treatment of BEST1-Related Dominantly Inherited Retinal Diseases: An In Vitro Model

Beren Karaosmanoglu[1], *gozde imren*[1], *Gulen Eda Utine*[2], *Hande Taylan Sekeroglu*[3], *Ekim Taskiran*[1]

[1]*Hacettepe University Faculty of Medicine, Medical Genetics, Ankara, Türkyie;* [2]*Hacettepe University Faculty of Medicine, Department of Pediatrics, Department of Pediatric Genetics, Ankara, Türkyie;* [3]*Hacettepe University Faculty of Medicine, Department of Ophthalmology, Ankara, Türkyie*

Background/Objectives: Inherited retinal diseases (IRDs) are a common and incurable health problem characterized by progressive vision loss caused by photoreceptor cell (PRC) dysfunction. Anti-sense oligonucleotides (ASOs), which manipulates unwanted mRNAs, have been clinically deployed for the treatment of several diseases. Effective treatments for a broad range of IRDs remain limited. The aim was to establish an in-vitro model utilizing induced PRCs for assessing the efficacy and safety of ASOs targeting *BEST1*, and to develop an in-vitro model for evaluating RNA-based therapeutics, for the treatment in IRDs.

Methods: A cell culture model was established by induction of PRCs from dermal fibroblasts via direct programming. A common single nucleotide polymorphism (SNP) was identified in *BEST1* (rs1800007) for targeting with GapmeR ASOs for multiple alleles of this SNP. The efficacy and possible off-target effects of these ASOs were analyzed in PRCs.

Results: The selected ASOs achieved allele-specific mRNA degradation with virtually no off-target effects on the global transcriptome profile. The presented in vitro model is a valuable platform for testing personalized IRD treatments and should inspire further research. To the best of our knowledge this study is the first to test RNA-based therapeutics involving the use of ASOs in an induced PRC model.

Conclusion: It will be possible to establish an ex-vivo disease model using dermal fibroblast samples from affected individuals. The disease model and ASOs, that are safe and effective therapeutic agents, can serve as a useful platform for the testing of personalized treatments for IRDs.

Grants: Supported by Hacettepe University (TSA-2021-19012).

P22.012.A A comprehensive personal omics-based clinical interpreter based on genomic and transcriptomic profiles

Qingwang Chen[1], *Yaing Liu*[1], *Li Guo*[2], *Ying Yu*[1]

[1]*Fudan University, State Key Laboratory of Genetic Engineering, Human Phenome Institute, School of Life Sciences, and Shanghai Cancer Center, Shanghai, China;* [2]*Institute of Process Engineering, Chinese Academy of Sciences, State Key Laboratory of Multiphase Complex Systems, Beijing, China*

Background/Objectives: Precision medicine depends on the proper identification and interpretation of genomic variants to achieve personalized diagnosis, prognosis, and treatment

selection. However, to achieve precision medicine, one major challenge is lack of tools to integrate therapeutic alterations from various knowledgebases and provide interpretations based on personal multi-omics profiles.

Methods: We developed Personal Omics Interpreter (POI), a user-friendly web-based tool that jointly provides therapeutic interpretations, including targeted drugs, immunological drugs, and chemotherapeutic drugs, by leveraging personal genomic and transcriptomic profiles. Extensive validations were conducted using three large-cohort datasets consisting of over 22,000 cancer patients, including the Cancer Genome Atlas (TCGA) multi-cancer datasets, the MSK-IMPACT datasets, and a breast cancer dataset.

Results: The POI can provide comprehensive interpretation. First, POI is designed to accommodate multi-dimensional alterations as input, including somatic variants, germline variants and expression alterations. Secondly, POI utilizes the rich knowledge ofPrecision Medicine Knowledgebase (PreMedKB), an updated harmonized knowledgebase that we previously developed. Thirdly, POI uses a predictive algorithm to expand the therapeutic options based on gene-gene interactions. Fourthly, POI facilitates chemotherapy drug suggestions and phenotypic response predictions by resolving germline diplotypes through our previously developed tool *PAnno*. Based on validation using three large-cohort datasets, POI demonstrates a consistently high matching rate (94.7 ~ 95.6%) of patients and potential therapeutic interpretations.

Conclusion: POI provides comprehensive therapeutic interpretations at the personal genomics and transcriptomics level, which has the potential to assist researchers and clinicians in making informed treatment decisions. POI is available at https://premedkb.cn/poi/#/.

Grants: National Key R&D Project of China (2023YFF0613302, 2023YFC3402501, and 2021YFF1201305)

P22.013.B Preclinical evaluation in patient-derived cells of gene editing as a therapeutic approach for IQSEC2 syndrome

*Susanna Croci[1;2], **Alessandra Russo**[1;2], Sergio Daga[1;2], Sara Pastore[1;2], Francesca Mari[1;2;3], Maria Antonietta Mencarelli[3], Nicola Alessio[4], Sura Hilal Ahmed Al-Sammarraie[4], Anna Calarco[5], Gianfranco Peluso[5], Alessandra Renieri[1;2;3], Ilaria Meloni[1;2]*

[1]University of Siena, Medical Genetics, Italy; [2]University of Siena, Med Biotech Hub and Competence Center, Department of Medical Biotechnologies, Italy; [3]Azienda Ospedaliera Universitaria Senese, Genetica Medica, Siena, Italy; [4]Campania University, Experimental Medicine Department, Luigi Vanvitelli, Naples, Italy; [5]UniCamillus-Saint Camillus International University of Health Science, Rome, Italy

Background/Objectives: The X linked *IQSEC2* gene encodes a protein of 1488 amino acids located at the postsynaptic density of both excitatory and inhibitory neurons throughout the brain. The IQSEC2 protein plays a major role in controlling synaptic transmission, E/I balance and memory consolidation. Pathological mutations in *IQSEC2* account for ~2-5% of all children presenting with frequent seizures, severe intellectual disability and autism spectrum disorder. Currently there are no treatments for IQSEC2 syndrome and gene editing represents an extremely promising therapeutic approach since it allows maintaining the endogenous regulatory framework. To develop an innovative therapeutic approach, we successfully tested the efficacy of gene editing with CRISPR/Cas9 for the correction of *IQSEC2* mutations directly in neurons.

Methods: In collaboration with the Italian patient association AMA.le we collected several patient-specific cells used to generate iPSCs and neurons. We have engineered a two-plasmid system to correct two mutations located on the *IQSEC2* gene: c.3613_3613delC (p.(Leu1205Trpfd*92)) and c.4110_4111del (p.(Tyr1371Glnfs*15)). Mutation-specific sgRNAs and donor DNAs have been selected and cloned together with a GFP reporter system. Cas9 flanked by sgRNA recognition sequences for auto-cleaving has been cloned in a second plasmid.

Results and Conclusion: results analyzed by Next Generation Sequencing have shown efficient gene editing based on Homology-Directed Repair (HDR) in fibroblasts and neurons with up to 35% of corrected allele, outlining the relevant potentiality of the approach for this syndrome.

Background/Objectives: Oculoectodermal syndrome (OES) results from somatic mosaic mutations in the KRAS proto-oncogene, with clinical manifestations affecting ocular, dermatological, cardiovascular, and neurological aspects. Bone involvement typically manifests around age 5, presenting as non-ossifying fibromas and giant cell granulomas.

Trametinib, a MEK protein inhibitor routinely used in oncology, has demonstrated efficacy in certain patients with RASopathies, notably on lymphatic and arteriovenous malformations, cardiac involvement, and dermatological lesions.

Methods: We present two 8-year-old children with severe OES, experiencing recurrent long bone fractures leading to significant functional impairment. Skin biopsies revealed KRAS variants (c.38G>A, p.Gly13Asp; c.436G>A, p.Ala146Thr) in 25% of fibroblasts from fresh skin biopsies.

To evaluate the impact of these mutations on KRAS function, we conducted transient KRAS overexpressions in HEK293 cells.

Results: Experiments revealed that the mutated versions induce hyperphosphorylation of the Erk1/2 protein, a phenomenon alleviated by treatment with Trametinib.

Based on isolated reported observations and considering the severity of these two patients, we initiated trametinib at 0.02 mg/kg/day around age 6, resulting in significant clinical improvement within six months. No fracture recurrences were noted, ambulation was restored, and notable bone remineralization occured. Side effects included skin-related issues (acne-like lesions, delayed wound healing, xerosis), managed with topical emollients.

Conclusion: In conclusion, trametinib proved well-tolerated and effective for severe OES bone involvement in these two

children. A therapeutic trial is warranted for confirmation in a larger patient cohort.

P22.015.D The antioxidant L-Ergothioneine as a preventive treatment and biomarker for cystine stones

Clara Mayayo-Vallverdú[1;2], *Esther Prat[1;2], Marta Vecino-Pérez[1], Miguel Lopez de Heredia[3], Virginia Nunes[1;2]*

[1]IDIBELL Institut d'Investigació Biomèdica de Bellvitge, Human Molecular Genetics, L'Hospitalet de Llobregat, Spain; [2]Universitat de Barcelona - Campus Bellvitge, Physiological Sciences, L'Hospitalet de Llobregat, Spain; [3]Instituto de Salud Carlos III, CIBERER, Madrid, Spain

Background/Objectives: Cystinuria is a rare inherited disease caused by mutations in *SLC3A1* and *SLC7A9* genes, which encode the $b^{0,+}$AT transport system. Its main clinical manifestation is the presence of cystine stones in the urinary system. Current therapeutic and pharmacological approaches are not effective for all patients and/or have side effects. Therefore, we evaluated L-Ergothioneine as a new potential treatment to prevent cystine stones.

Methods: Two different doses of L-Ergothioneine were administered preventively and chronically to the *Slc7a9*$^{-/-}$ mouse model of cystinuria. During treatment, stone occurrence and growth were assessed by X-ray imaging, and metabolic parameters were obtained using metabolic cages. L-Ergothioneine metabolism, oxidative status and mitochondrial function were also evaluated at the renal level.

Results: Both treatments led to an above 50% decrease in the number of mice that developed stones, as well as a delay in their onset. L-Ergothioneine did not affect urinary cystine levels, but increased its solubility by 50%, preventing its precipitation. At the renal level, we detected an improvement in oxidative status and a recovery of mitochondrial function. Furthermore, we observed that the urinary ratio between L-Ergothioneine and its metabolite S-Methyl-L-Ergothioneine allows us to distinguish between stone-former and non-stone-former mice, suggesting its potential as a biomarker.

Conclusion: These results, together with the FDA's consideration of L-Ergothioneine as a safe compound at doses higher than those tested, support the need for a clinical trial to test L-Ergothioneine as a new potential treatment for cystinuria and to validate its role as a biomarker.

P22.016.A Safety of Reduced Infusion Time of Agalsidase Beta in the Treatment of Fabry Disease: An Observational Study

Dominique P. GERMAIN[1;2], *Alice Porto Vasconcelos[2], Hakima Dahmani[2], Najya Bedreddine[3], Wenting Trang[2], Ye Fan[2], Thomas Ghafari[2]*

[1]University of Versailles, Division of Medical Genetics, Montigny-Le-Bretonneux, France; [2]APHP, French Referral Center for Fabry disease, Garches, France; [3]Association des Patients de la Maladie de Fabry (APMF), Perrigny-lès-Dijon, France

Background/Objectives: Fabry disease is an X-linked inborn error of metabolism caused by lysosomal alpha-galactosidase deficiency. Enzyme Replacement Therapy (ERT) with agalsidase beta was approved in 2001 and has demonstrated clinical benefits. The conventional lifelong biweekly 3-hour long infusions regimen is associated with a significant burden on patients' quality of life, but very few studies have explored the optimal duration of agalsidase beta infusions.

Methods: The safety of a 90-minute infusion time (mentioned in the Summary of Product Characteristics) of agalsidase beta without premedication was studied in 35 consecutive adult patients (18 males, 17 females) with Fabry disease (26 different GLA pathogenic variants) for a total of 72 infusions. The study population included patients naïve to the enzyme ($n = 6$) and with significant comorbidities (17/35). Upon their request and after informed consent, 9 patients were infused in 60-80 minutes. Physical examination was performed and vital signs were measured before and after each infusion.

Results: Agalsidase beta was infused without premedication at a constant rate between 0.78 and 1.17mg/min in all 72 infusions. Five patients received 105mg of agalsidase in 90 minutes (1.17mg/min). None of the 35 patients complained of any discomfort at any time, no single adverse effect was reported and the vital signs did not significantly change in any patient during any infusion.

Conclusion: The infusion of agalsidase beta in 90 minutes or less in 35 adult patients with Fabry disease for 72 infusions was well-tolerated, with no adverse effects. The optimized regimen reduces the burden of biweekly infusions and improves patients' quality of life.

Conflict of Interest: None declared

P22.017.B Ketogenic diet therapies for drug-resistant epilepsy might affect ion channels activity through the combination of both epigenetic changes and splicing events

Alessia Mauri[1;2], *Letizia Messa[2;3], Roberto Previtali[1;4], Davide Biganzoli[2], Clarissa Berardo[1;2], Sara Olivotto[4], Maria Cristina Visceglia[2], Andrea Meta[2], Alessandra Vasco[2], Stephana Carelli[2], Pierangelo Veggiotti[1;4], Cristina Cereda[2]*

[1]University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy; [2]Buzzi Children's Hospital, Center of Functional Genomics and Rare Diseases, Milan, Italy; [3]Politecnico di Milano, Department of Electronics, Information and Bioengineering, Mllan, Italy; [4]Buzzi Children's Hospital, Pediatric Neurology Unit, Milan, Italy

Background/Objectives: Increasing evidence suggests that epigenetic modifications are associated with ketogenic diet (KD) therapies. These are considered an effective treatment for drug-resistant epilepsy, such as GLUT1-deficiency syndrome (GLUT1-DS), whereas its underlying mechanisms remain elusive.

Confirmed the metabolic status, we aimed to explore the transcriptional dysregulations of two *SLC2A1*-mutated pediatric patients before and after KD treatment and to also assess alterations in the methylome profiling.

Methods: FIA-MS/MS platform was performed for the analysis of amino acids and acylcarnitines. Bulk RNA-sequencing was performed using Illumina Total RNA kit and sequenced on NS500. Differential expression analysis was conducted using DESeq.2 and gene set enrichment analysis (GSEA) was performed using ClusterProfiler. Analysis of alternative splicing and isoform switches was implemented using IsoformSwitchAnalyzeR. Methylation sequencing was performed on PromethION2 Solo and analysis was showed using Remora.

Results: Metabolite analysis has confirmed the ketosis status in two patients in diet (increase of C2 and C4OH). RNA-seq data highlighted a significant splicing change in GLUT1-DS children under KD treatment identifying the snRNA U1 up-regulated before the therapy. In addition to amino acids metabolism, translation and mitochondrial activity deregulated, when performing GSEA

with Reactome a strong epigenetic signature was observed: histones deacetylation and DNA methylation resulted down-regulated. Molecular function analysis showed a down-regulation in voltage-gated ion channel and passive transmembrane transporter activities. Moreover, analysis for 5mC and 5hmC profiles identified differentially methylated CpG sites before and after KD.

Conclusions: The observed epigenetic changes related to KD treatment might influence the alternative RNA processing of voltage-gated ion channels also by epigenetic splicing code.

Conflict of Interest: None declared

P22.018.C Development of a functional platform for the characterization of MCT8 mutants associated with Allan-Herndon-Dudley Syndrome and suitable to identify new pharmacological modulators by a drug repositioning approach

Cristina Pastorino[1], *Valeria Capurro*[1], *Valeria Tomati*[1], *Emanuela Pesce*[1], *Mariateresa Lena*[2], *Renata Bocciardi*[1;2], *Nicoletta Pedemonte*[1]

[1]*Istituto Giannina Gaslini, UOC Genetica Medica, Genova, Italy;* [2]*Università degli Studi di Genova, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), Genova, Italy*

Background/Objectives: Thyroid hormones (THs) are important in the development of the nervous system. Monocarboxylate transporter 8 (MCT8), encoded by the X-linked *SLC16A2* gene, transports THs across the blood-brain barrier. Hemizygous *SLC16A2* variants cause Allan-Herndon-Dudley Syndrome (AHDS), characterized by intellectual disability, spastic paraplegia and abnormal THs profile. Causative variants lead to MCT8 loss-of-function by affecting protein expression, maturation/trafficking and/or activity, through different mechanisms. Our work aims to design a functional platform to evaluate both wild-type and mutant MCT8 that can be applied for the identification of pharmacological modulators of this THs transporter.

Methods: We generated MDCK1 cell lines stably expressing wild-type and two MCT8 mutants. Fluorescent dyes were used to identify new substrates of MCT8 mimicking THs, suitable to monitor the MTC8-mediated transport by a high-throughput functional assay.

Results: We have obtained a *cell-based* functional assay exploiting the uptake of fluorescent dyes mimicking THs to evaluate the wild-type and the MCT8 mutants activity. Moreover, expression vectors used to generate the cell lines are tagged with an epitope suitable to evaluate subcellular localization and biochemical profile of MCT8 proteins.

Conclusion: We developed an innovative functional platform designed to characterize MTC8 mutants associated with AHDS. Our assays will be also applied for a high troughput screening to identify MCT8 modulators by a drug repositioning approach as a starting point for the development of possible targeted therapies for patients affected by AHDS, currently without effective therapeutic options.

Grants: Supported by the Italian Ministry of Health (grant SG-2021-12375569).

Background: SCN2A-DEE is a severe disorder caused by gain-of-function (GoF) mutations in SCN2A encoding NaV1.2. Patients have a high risk of premature death and high burden of epileptic seizures, typically beginning within days of birth and difficult to control with anti-seizure medications (ASMs). Comorbidities include profound global developmental impairment as well as movement disorders, gastrointestinal symptoms, severe irritability, variable sleep problems and frequent hospitalization. Drug development efforts for early onset SCN2A-DEE have been scarce, however, preclinical findings suggest that gapmer antisense oligonucleotides (ASOs) that down regulate *SCN2A* expression may have potential to alter the disease course in patients.

Methods: A preterm infant was diagnosed prenatally with the *SCN2A* variant c.3986C>A p.(Ala1329Asp) and postnatally presented with status epilepticus. Standard of care treatment could not break the status epilepticus. Eligibility for PRAX-222 treatment was evaluated using in silico protein structural modeling and in vitro electrophysiology studies.

Results: Voltage clamp experiments confirmed structural modeling predictions that the p.Ala1329Asp variant interferes with binding of the inactivation motif that would lead to GoF via impaired inactivation and increased persistent current. Treatment with PRAX-222 was initiated when patient was 1 month and 2 weeks old, with 7 doses (Fig 4A) administered to date that were well-tolerated. Eight days after first administration, SE was interrupted intermittently and ultimately ceased following continued dosing. A >50% reduction in seizure frequency was observed during follow-up. Despite some neurodevelopmental progress, neurodevelopment was severely affected.

Conclusion: First-in-patient findings highlight the potential for PRAX-222 to be the first disease-modifying treatment for early onset GoF SCN2A-DEE.

Consortium: Screen4Care EU-IHI Consortium

Background/Objectives: EU Screen4Care has designed a NGS gene panel (TREAT panel) for genetic newborn screening (gNBS) in up to 25.000 neonates in Italy, Germany, France, and Greece for early identification of rare diseases (RDs) with approved treatments.

Methods: The criteria and scoring adopted include mendelian diseases, natural history knowledge, clinical utility, amenability of NGS, and treatment. Both small and copy number variants will be called.

Results: We selected by cut off-narrowed scores 245 genes, which are associated with the following phenomics: 106 metabolic, 33 blood and coagulation, 29 endocrine, 26 immunological, 25 neurological and neuromuscular, 9 renal, 6 mendelian syndromes, 4 cardiological, and 7 other phenotypes. Among them, 168 have autosomal recessive, 24 autosomal dominant, 20 X-linked, and 33 both AD and AR inheritance. In infants screened by TREAT panel but resulted negative and became symptomatic during the first year of life we offer WGS in a two-tier, post-NBS, enrolment approach. This will allow us to identify the 245 gene-related diseases and many other RDs that can be picked at the neonatal age by WGS, thus allowing to know the frequency of early symptomatic RDs escaping the TREAT panel detection. The 24 European Reference Networks (ERNs) will be involved for the diagnostic work-up, treatment referral, and follow-up.

Conclusion: S4C would propose and possibly translate its research output into the diverse European health systems for an equal EU gNBS approach (1).

P22.021.B Genotyping in paediatric vascular anomalies: the impact of molecular diagnosis on clinical practice

Sinead O'Sullivan[1], *Maria Shilova*[2], *Romi Das Gupta*[2], *Roy Kimble*[2], *Christopher Richmond*[1]

[1]*Genetic Health Queensland, Herston, Australia;* [2]*Queensland Children's Hospital, South Brisbane, Australia*

Background/Objectives: Vascular anomalies (VA) are a heterogenous group of conditions characterised by abnormal growth and/or development of blood and/or lymphatic vessels. Despite the diverse nature of these lesions, there is considerable phenotypic overlap, complicating precise stratification and accurate diagnosis. Increasing uptake and availability of next generation sequencing (NGS) has the potential to transform the diagnosis and management of VA.

Methods: A 46-month retrospective analysis of paediatric patients offered targeted NGS for VA was undertaken. We measured the clinical utility of genotyping by comparing pre-test and post-test diagnostic and management outcomes.

DNA was extracted from biopsied vascular lesions for all patients (N = 242), with additional germline confirmatory testing arranged for those with a phenotype and variant allele frequency compatible with a heritable VA.

Results: A molecular diagnosis was secured for 183 of 242 patients tested (76%). A somatic cause for VA was confirmed for 70% and a germline cause for 6%. Genetic testing supported the pre-existing clinical diagnosis for 52% of all individuals tested and revised the clinical diagnosis for 24%. For patients with a revised clinical diagnosis, a management change occurred for 49%. Overall, 27% of patients offered genetic testing for VA had a resultant change of management, with 17% referred to haematology for active consideration of molecularly targeted therapy (MTT).

Conclusion: Increasingly, the clinical utility of genotyping this cohort is being recognised. Our large cohort study findings support the view that genotyping patients with VA aids clinical care.

P22.023.D Two new cases of adult onset pulmonary arterial hypertension (PAH)associated with TBX4 pathogenic variants. The importance of clinical exam and theunveiling of imatinib as a possibile drug inducing PAH.

Fabio Sirchia[1], *Anna Meroni*[1], *alessandra greco*[2], *Laura Scelsi*[2], *annalisa turco*[2], *sandra schirinzi*[2], *Stefano Ghio*[2], *mauro acquaro*[2], *davide colombo*[2], *simone carbonera*[1], *Enza Maria Valente*[1]

[1]*The University of Pavia, Human Genetics, Pavia, Italy;* [2]*Fondazione I.R.C.C.S. Policlinico San Matteo, Pavia, Italy*

Background/Objectives: Heterozygous pathogenic loss-of-function variants in TBX4 gene are associated with "ischio-coxo-podo-patellar syndrome with or without pulmonary arterial hypertension (PAH)". This syndrome is a rare autosomal dominant disorder characterized by hypo/aplasia of the patellae, various anomalies of the pelvis and feet and onset of PAH in the neonatal period or in childhood.

Methods: We describe two patients with rare adult-onset presentation of TBX4-related PAH. One patient is a 64-year-old woman diagnosed with GastroIntestinal Stromal Tumor (GIST) in 2019 for which she undertook imatinib. After 2 years of treatment the patient developed signs of pulmonary hypertension, precapillary phenotype. Right cardiac catheterization confirmed precapillary PAH and elevated pulmonary vascular resistance. The diagnosis was, therefore, drug-induced PAH. Imatinib therapy was suspended and endothelin receptor antagonist therapy was started. There were no improvements at the echocardiographic

and hemodynamic control at 4 months. Thus, a phosphodiesterase 5 inhibitor was added to the therapy and Whole-Exome Sequencing was performed.

Results: Genetic analysis showed a heterozygous pathogenic loss-of-function variant in TBX4 gene in both our patients. Further clinical and radiologic investigations detected in our patients a mild skeletal dysplasia confirming the diagnosis of ischio-coxo-podo-patellar syndrome.

Conclusion: We highlight the importance of pre-test clinical examination and reverse phenotyping in patients with PAH in order to look for signs of TBX4-related skeletal dysplasia. To date imatinib is still used as a potential Tyrosine-kinase inhibitor for therapeutic trials but we suggest that in a subset of patients (e.g. in genetic predispositions) it could lead to the onset or worsening of PAH instead.

Background/Objectives: Menkes disease (MD) is a rare genetic neurodegenerative disorder of copper metabolism caused by pathogenic variants in the X-linked *ATP7A* gene. Treatment is mainly supportive involving subcutaneous copper histidine (Cu-His) administration, which often does not prevent progression and death before third year of life. Preclinical studies have shown that elesclomol-copper (ES-Cu) prevents neurodegeneration and improves survival in the mottled-brindled mouse model of MD. We report 2 patients with MD, as we aim to repurpose ES-Cu to improve their clinical condition and modify the natural history of the disease.

Methods: Es-Cu was injected subcutaneously once a week, following a careful dose-escalating scheme developed by an international committee of experts. Daily Cu-His was administered subcutaneously as standard of care on the days ES-Cu was not administered. Safety parameters were strictly surveilled, and efficacy was monitored thoroughly. The AEMPS authorized this exceptional treatment.

Results: No systemic adverse effects presented during the treatment periods.

Conclusion: ES-Cu exceptional treatment has shown an adequate safety profile and promising results at a neurological level in patients affected by a rare disease, with repurposing of a drug based on scientific knowledge, demonstrated in a disease model, pending clinical trial.

Grants: Menkes International Association (MIa) and Ramón Areces Foundation.

P22.026.C Towards Targeted Therapeutics for PEBEL2 (early-onset progressive encephalopathy with brain edema and/or leukoencephalopathy-2).

Nicole Van Bergen[1;2], Adhish Walvekar[3], Tim Sikora[2], Myrto Patraskaki[3], Henry Beetham[4], Alejandro Hidalgo-Gonzalez[4], Carole Linster[3], **John Christodoulou**[1;2]

[1]University of Melbourne, Department of Paediatrics, Melbourne, Australia; [2]Murdoch Children's Research Institute, Brain and Mitochondrial Research Group, Melbourne, Australia; [3]University of Luxembourg, Enzymology and Metabolism Group, Luxembourg Centre for Systems Biomedicine, Belvaux, Luxembourg; [4]Murdoch Children's Research Institute, Stafford Fox Drug Discovery Facility, Melbourne, Australia

Background/Objectives: PEBEL2 is a severe neurodegenerative disorder often provoked by intercurrent febrile illnesses, caused by biallelic loss of function variants in *NAXD*, encoding a key NADH metabolite repair enzyme. Anecdotal evidence suggests that niacin-based therapies may be of benefit. We aimed to expand our clinical understanding of this disorder, and to more precisely ascertain the pathways and processes impacted, with a view to identify novel therapeutic interventions.

Methods: We examined the clinical features of published PEBEL2 patients, aiming to draw potential phenotype-genotype correlations. We used cultured mammalian cells to develop reliable assays that would be amenable to high-throughput drug screening (HTS), with subsequent high-impact hits to be further validated in iPSC-derived neuron and animal models we have developed.

Results: We found distinct patterns in clinical presentations depending on which subcellular compartment is affected by NAXD deficiency. Patient fibroblast and HAP1 knockout cell studies revealed mitochondrial OXPHOS impairment, reduced cell viability and increased superoxide production, which were adapted to allow HTS of a large compound/drug library, which are currently under way. Metabolomic studies revealed abnormalities in serine metabolism, which were ameliorated by inosine supplementation.

Conclusion: Our deep phenotype-genotype studies have allowed more accurate prognostication, and our robust HTS assays have given us an opportunity to identify novel targeted therapies which will be further validated in our iPSC and zebrafish models. With early diagnosis and prompt introduction of these precision therapies, we envisage that the clinical course of this devastating disorder can be reversed.

P22.027.D Treatment with a MEK Inhibitor in patients with hypertrophic cardiomyopathy in Noonan syndrome

Andrea Gazzin[1;2], *Federico Fornari[3], Anna Maria Villar[4], Chiara Riggi[4], Diana Carli[5], Simona Cardaropoli[6], Claudio Isella[7;8], Alfredo Brusco[9], Enzo Medico[7;8], Giovanni Battista Ferrero[10], Alessandro Mussa[2;6]*

[1]Department of Biomedical Sciences and Oncology, University of Turin, Turin, Italy; [2]Clinical Pediatric Genetics Unit, Regina Margherita Children's Hospital, Turin; [3]Postgraduate School of Pediatrics, University of Turin, Turin, Italy; [4]Cardiology Department, Regina Margherita Children's Hospital, Turin, Italy; [5]Department of Medical Sciences, University of Turin, Turin, Italy; [6]Department of Public Health and Pediatrics, University of Turin, Turin, Italy; [7]Laboratory of Oncogenomics, Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy; [8]Department of Oncology, University of Turin, Turin, Italy; [9]Department of Neurosciences Rita Levi-Montalcini, University of Turin, Turin, Italy; [10]Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy

Background/Objectives: Hypertrophic cardiomyopathy (HCM) is the major contributor to morbidity and mortality in Noonan Syndrome (NS) and carries a high risk of heart failure and arrhythmias. In recent studies, MEK inhibitors have shown a potential effectiveness. This study aims to describe the monocentric experience of the off-label use of the MEK inhibitor Trametinib for treating NS-associated HCM.

Methods: Five patients (4F, 1M; 1.5 months-14.5 years) with NS who had HCM and a *RAF1* germline pathogenic variant received an oral dose of 0.001-0.025mg/kg/day for 1-15 months. Patients were evaluated at $0, +1, +3, +6, +12$ months to measure the thickness of the left ventricular walls, ventricular outflow obstruction, diastolic function, levels of NT-proBNP, changes in the gene expression in the RAS/MAPK pathway and any adverse events that occurred.

Results: All patients showed a decrease in NT-proBNP levels, and four had a significant reduction in ventricular outflow obstruction (> 20%) as well as in septal thickness (>1SD). The treatment also resulted in consistent and long-lasting changes in gene expression. Some mild to moderate adverse events occurred, including retinopathy, hypoglycaemia, hyperCKemia, acneiform dermatitis, atopic dermatitis, arthralgia and alopecia. One newborn with severe health issues and premature birth passed away due to extracardiac causes, and one patient withdrawn from the study due to hair loss.

Conclusion: Our initial data on the use of Trametinib to treat HCM in individuals with NS are promising and encourage additional studies to confirm and strengthen the results.

Grants: Supported by a research fund from the Italian Society of Pediatrics (SIP) to AM.

Conflict of Interest: None declared

P22.029.B Transcriptomic changes in the hypothalamus upon AAV-Dio2-Mct8 gene therapy for X-linked Allan-Herndon-Dudley syndrome in a mouse model

Finja Sygo[1], *Adriana Arrulo Pereira[2], Varun Sreenivasan[1], Kristian Händler[1], Nathalie Kruse[1], Malte Spielmann[1], Markus Schwaninger[2]*

[1]Institute of Human Genetics, University Medical Center Schleswig-Holstein, University of Lübeck & Kiel University, Lübeck, Germany; [2]Institute of Experimental and Clinical Pharmacology and Toxicology, University of Lübeck, Lübeck, Germany

Background/Objectives: Allan-Herndon-Dudley syndrome (AHDS) is a rare X-linked disorder characterized by hypotonia, weakness, and delay of developmental milestones, with an associated increase in serum T3 levels. Inactivating mutations in a thyroid hormone transporter (MCT8), has been associated with

AHDS. In tanycytes, MCT8 plays a role in the hypothalamus-pituitary-thyroid axis, explaining the excess peripheral and central lack of thyroid hormones in the disease. We developed a gene replacement therapy using AAV-Dio2-*Mct8* to deliver Mct8 to tanycytes in a mouse model of AHDS. Here, we investigated the effect of this gene therapy on the hypothalamic transcriptome.

Methods: Double knockout mice (*Mct8/Oatp1c1*-DKO) were used as a disease model, since *Oatp1c1*, another thyroid hormone transporter, is suggested to compensate for the loss of *Mct8* in mice. The changes to the hypothalamic transcriptome upon AAV-Dio2-*Mct8* injection to tanycytes in *Mct8/Oatp1c1*-DKO mice was analyzed by RNA-sequencing, with wildtype and *Oatp1c1*-knockout mice as additional controls. Differential expression analysis was performed across 34 samples.

Results: Preliminary analysis revealed thousands of differentially expressed genes, when the knockout and AAV-Dio2-*Mct8*-treated mice were compared to the wildtype. However, only 14 genes appear to have altered expression in the *Mct8/Oatp1c1*-DKO mice upon treatment.

Conclusion: These results indicate significant differences between the wildtype mice and all other conditions. However, the effect of AAV-Dio2-*Mct8* treatment is rather small, suggesting that this gene replacement therapy does not rescue the entire molecular phenotype. Further analysis is needed to fully assess the effect of the treatment on the hypothalamic transcriptome.

Grants: DFG (CRC/TR296)

P23
GENETIC COUNSELLING / SERVICES / EDUCATION

P23.001.C Development and psychometric evaluation of a questionnaire to measure university students' knowledge about the effects of alcohol use during pregnancy

Guilherme Petek Ramos Leite[1], *Beatriz Caroline dos Santos Pereira*[1], *Lucimar Retto da Silva de Avó*[1], *Carla Maria Ramos Germano*[1], *Débora Gusmão Melo*[2]

[1]*UFSCar - Federal University of São Carlos, Department of Medicine, São Carlos, Brazil;* [2]*UNIFESP - Federal University of São Paulo, Department of Morphology and Genetics, São Paulo, Brazil*

Background/Objectives: This study aimed to develop and validate a questionnaire to assess the knowledge of university students regarding the effects of alcohol consumption during pregnancy.

Methods: We chose to design an instrument with true-false-don't know questions. Following ethical approval, 45 true statements were formulated and subjected to content validation by 19 experts. Based on Content Validity Index (CVI), 17 statements were selected. The instrument, named Fetal Alcohol Consequences Test (FACT), was assessed by 31 university students for the level of understanding. Then, the questionnaire was administered to a national sample of university students, and an Exploratory Factor Analysis (EFA) was conducted. Each FACT correct answer valued 1 point, and the knowledge was categorized as high (total score ≥80%), moderate (score between 60-79%), and low (score ≤59%).

Results: During the development of the questionnaire, the CVI values ranged from 0.779 to 1.0, and all statements were considered suitable by the target audience. For psychometric evaluation, 768 students from 24 Brazilian states participated. In the EFA, 5 statements were removed, revealing a tool with 12 questions and two latent factors: "fetal alcohol spectrum disorders" and "conceptions and guidance on alcohol consumption during pregnancy". The mean FACT score was 7.71 ± 2.98, with a median of 8; 32.03% of the students had high (10-12 points), 24.09% moderate (8-9 points), and 43.88% low knowledge (<8 points). The questionnaire proved reliable: floor effect 1.17%, ceiling effect 9.25%, and Cronbach's alpha index of 0.798.

Conclusion: The FACT is useful and can contribute to health education on the subject.

Grants: FAPESP (2022/05564-9).

Conflict of Interest: None declared

P23.002.D Development and implementation of a mainstreaming Genomic Associate role

Kylie Morgan[1;2], *vishakha tripathi*[1], *Ashleigh Butler*[1]

[1]*Guy's & St Thomas' Trust, Clinical Genetics, London, United Kingdom;* [2]*Peter MacCallum Cancer Centre, Familial Cancer Centre, Melbourne, Australia*

Background/Objectives: The expansion of genomic testing by non-genetic professionals through mainstreaming pathways is being spearheaded within the United Kingdom (UK) through National Health Service (NHS) genomics initiatives. However, the substantial demand upon clinical time and resources pose as significant barriers to successful and timely implementation. The 'Genomics Associate' role was established in the UK NHS in 2021. The scope and utility of this new role within Clinical Genetics service provision is still in development. One suggested function is to facilitate and support mainstreaming initiatives, however, the value of this approach has not been evaluated.

Methods: Here we describe the development of a Genomic Associate role within a novel prostate cancer mainstreaming project developed between the Uro-Oncology and Clinical Genetics departments at Guy's and St Thomas' Trust, UK.

Results: We demonstrate that the Genomics Associate position adds significant value to the implementation of mainstream genetic testing in the uro-oncology setting. To highlight the utility of this role and its importance in facilitating mainstreaming we will present it's impact across four key domains: multi-disciplinary communication and networking, support of mainstreaming processes, supporting clinical activities of Genetic Counsellors and, auditing.

Conclusion: We highlight the effiacy and value of a Genomics Associate role in supporting development and implementation of the mainstreaming pathway, and the potential for further development of this role to assist Clinical Genomics service provision both with the UK NHS and beyond.

P23.003.A Developing a Genomic Medicine elective course enhancing communication, patients' perspective, and ethical understanding

Celia Azevedo Soares[1;2;3;4;5;6], *Lucia Lacerda*[1;2;3;7], *Paula Jorge*[1;2;3;7]

[1]*Instituto de Ciências Biomédicas Abel Salazar, Departamento de Microscopia;* [2]*Universidade do Porto, Unidade Multidisciplinar de Investigação Biomédica;* [3]*Universidade do Porto, Laboratory for Integrative and Translational Research in Population Health;* [4]*Universidade de Aveiro, Departamento de Ciências Médicas;* [5]*Universidade do Porto, i3S - Instituto de Investigação e Inovação em Saúde;* [6]*Unidade de Saúde Local de Sto António, Serviço de Genética Médica;* [7]*Unidade Local de Saúde de Sto António, Serviço de Genética Laboratorial*

Background/Objectives: Genomic Medicine is at the forefront of modern healthcare, revolutionizing diagnostics and personalized treatment. The rapid advancements in genomics demand that medical students not only comprehend the science but also acquire skills in ethical considerations, effective communication, and navigating the complex patient diagnostic odyssey. To address this educational need, we developed an innovative elective course for medical students.

Methods: Our Genomic Medicine elective at Abel Salazar Biomedical Sciences Institute - University of Porto integrates a multifaceted approach, offering comprehensive insights into the field including five main perspectives: 1) basic concepts in Genomic Medicine, 2) ethics in Genomic Medicine, 3) patient diagnostic odyssey, 4) national and international initiatives, and 5) communication skills. One unique aspect of our course is the inclusion of non-health professional guest lecturers: a patient association's representative/caregiver of a patient with a rare genetic disorder, as well as a health journalist.

Results: Our evaluation process focuses on the students' ability to convey complex Genomic Medicine concepts to three distinct audiences: a family, a patient organization member, and a health specialized journalist. We reported improvements in students' knowledge and communication skills. The caregiver's personal account provided valuable insight into the emotional and practical aspects of genetic/genomic conditions, enhancing students' empathetic understanding. Media-led sessions improved students' ability to translate intricate genomic information into layman's terms.

Conclusion: We have championed a curriculum that emphasizes empathy, ethics, and communication skills to prepare students as knowledgeable and compassionate practitioners in Genomic Medicine.

P23.004.B Engagement of patients and the public in personalised prevention using genomic information

Loes Lindiwe Kreeftenberg[1;2], Lidewij Henneman[1;2], Valeria Fava[3], Claudia Louati[4], Daniela Quaggia[3], Yasemin Zeisl[4], Martina Cornel[1;2], Carla van El[1;2]

[1]Amsterdam UMC, Vrije Universiteit Amsterdam, Human Genetics, Amsterdam, Netherlands; [2]Amsterdam Public Health Research Institute, Amsterdam, Netherlands; [3]Cittadinanzattiva APS, Rome, Italy; [4]European Patients' Forum (EPF), Etterbeek, Brussels, Belgium

Consortium: PROPHET

Background/Objectives: Personalised prevention using genomic information requires active involvement from the public and patients, who need to be well-informed and empowered to make decisions reflecting their personal values in deciding on health care and sharing data. This underscores the importance of their active participation in care, research, education, and governance for meaningful engagement. We aimed to map engagement practices, and assess the extent and types of engagement methods utilized in the field of personalised prevention of common chronic conditions.

Methods: A scoping review selected literature (in Medline, Embase, Scopus, Web of Science, APA PsycINFO and IBSS) from 2015 to 2023 was performed. Articles included were practices of patient and public engagement in personalised prevention and genomics conducted in Europe focussing on cancer, cardiovascular diseases and neurodegenerative disorders.

Results: 23 engagement practices were selected. Analysis revealed diverse engagement levels, the majority falling into the low to medium engagement category, and showed mainly one directional methods of engagement, including dissemination and consultation. Most engagement activities related to cancer, and none to neurodegenerative diseases. The care domain exhibited the most publications, followed by research, research combined with care, and governance combined with education.

Conclusion: By elaborating on and implementing practices that engage and empower the patients and public at all levels of the engagement spectrum, fostering a more inclusive and participatory approach to personalised prevention, ultimately leads to improved health outcomes for individuals and communities.

Grants: A product of the PROPHET project, EU Horizon Europe Research and Innovation Programme (Grant No. 101057721).

Conflict of Interest: None declared

P23.005.C Strategies to improve implementation of cascade testing in hereditary cancer syndromes

Jianbang Chiang[1], Zi Yang Chua[1], Jia Ying Chan[2], Elaine Lum[3], Joanne Ngeow[1;2]

[1]National Cancer Centre Singapore, Cancer Genetics Service, Singapore, Singapore; [2]Lee Kong Chian School of Medicine, Singapore, Singapore; [3]Duke-NUS Medical School, Health Services & Systems Research, Singapore, Singapore

Background/Objectives: Hereditary cancer syndromes constitute approximately 10% of all cancers. Cascade testing involves testing of at-risk relatives to determine if they carry the familial pathogenic variant. Despite growing efforts targeted at improving cascade testing uptake, current literature continues to reflect low uptake, typically below 30%. This study aims to systematically review current literature on intervention strategies to improve cascade testing, assess the quality of intervention descriptions and evaluate the implementation outcomes of listed interventions.

Methods: We searched major databases using keywords and subject heading of "cascade testing". Interventions proposed in each study were classified according to the Effective Practice and Organisation of Care (EPOC) taxonomy. Quality of intervention description was assessed using the TIDieR checklist, and evaluation of implementation outcomes was performed using Proctor's Implementation Outcomes Framework.

Results: Improvements in rates of genetic testing uptake was seen in interventions across the different EPOC taxonomy strategies. The average TIDieR score was 7.3 out of 12. Items least reported include modifications (18.5%), plans to assess fidelity/adherence (7.4%) and actual assessment of fidelity/adherence (7.4%). An average of 2.9 out of 8 aspects of implementation outcomes were examined. The most poorly reported outcomes (3.7%) were cost, fidelity and sustainability.

Conclusion: Most interventions have demonstrated success in improving cascade testing uptake. Uptake of cascade testing was highest with delivery arrangement (68%). However, the quality of description of interventions and assessment of implementation outcomes are often suboptimal, hindering their replication and implementation downstream. Therefore, formal assessment of implementation outcomes may help promote translation of these interventions into routine practice.

P23.006.D Development of a digital risk-prediction tool for cardiovascular diseases based on family health history for use in the general population

Tetske Dijkstra[1], Lieke van den Heuvel[2], Jacobien Niebuur[1], Peter van Tintelen[2], Christian van der Werf[3], Boudien Sieperda[4], Jacoliene Zaal[4], Anneke Lucassen[5], Irene van Langen[1], Corrette Ploem[6], Els Maeckelberghe[7], **Imke Christiaans**[1]

[1]University Medical Centre Groningen/University of Groningen, Genetics, Groningen; [2]University Medical Center Utrecht/Univerity Utrecht, Biomedical Genetics, Utrecht, Netherlands; [3]Amsterdam University Medical Centers/University of Amsterdam, Heart Center, Department of Clinical and Experimental Cardiology, Amsterdam Cardiovascular Sciences, Amsterdam, Netherlands; [4]University Medical Centre Groningen, Legal Affairs, Groningen, Netherlands; [5]Wellcome Trust Centre for Human Genetics/University of Oxford, Clinical Ethics, Law and Society (CELS), Oxford, United Kingdom; [6]Amsterdam University Medical Centers/University of Amsterdam, Ethics, Law and Medical Humanities, Amsterdam, Netherlands; [7]University Medical Centre Groningen/University of Groningen, Beatrix Children's Hospital, Groningen, Netherlands

Background/Objectives: In inherited and familial cardiovascular diseases (CVDs) relatives can be at risk for early and preventable cardiovascular events. We developed an online risk-assessment tool based on family health history to help people evaluate their potential risk of CVD.

Methods: We started with a critical appraisal of legal and ethical challenges associated with such a tool. Using a focus group and Delphi procedure with clinical experts in inherited CVDs we developed family criteria for use by laypeople in the tool and evaluated them in different cohorts. Finally, two prototypes of the tool, with differences on data storage and risk prediction facilities, were developed and subjected to usability testing in 1000 laypeople using questionnaires.

Results: Legal challenges were mainly found in the European Union regulations on data protection and medical devices. Five expert-based family criteria focusing on cardiovascular events at young age in first-degree relatives were derived and showed substantial diagnostic accuracy. The two tool prototypes got similar evaluations on usability and tool results on CVD-risk did not lead to substantial anxiety.

Conclusion: The final tool for risk-assessment aligns with European Union regulations by not storing family health information and have users themselves determine their CVD risk based on their answers on the family criteria. Using the expert-based family criteria this tool can serve as a first tier for laypeople to easily determine if they have a potentially increased risk of CVD based on their family health history to facilitate early detection and improve public health.

P23.007.A Evaluation of a self-test to screen for tumor risk syndromes revealed a good comprehensibility for laypersons and a high positive predictive value

Beate Vajen[1], *Paula Memenga[2], Johanna Tecklenburg[1], Caroline Scholz[1], Petra Anders[1], Scarlett Winterfeld[1], Brigitte Schlegelberger[1], Anke Katharina Bergmann[1], Eva Baumann[2], Susanne Morlot[1], Christian Landgraf[1]*

[1]Hannover Medical School, Department of Human Genetics, Hannover; [2]Hanover University of Music, Drama and Media, Department of Journalism and Communication Research, Hannover, Germany

Background: The identification of tumor risk syndromes (TRS) allows personalized therapy, preventive measures and identification of further affected family members. Despite their significance, TRS are underrecognized. We developed a screening tool with 5 questions for laypersons to identify an increased risk for TRS. Here, we present the evaluation of this self-test concerning 1) comprehensibility and 2) specificity, sensitivity and the positive predictive value (PPV).

Methods: 1) To assess the comprehensibility, an online survey was conducted anonymously from July to November 2023 in Germany. Participants ($N = 106$) indicated the extent to which they agreed with four statements on the ease of cognitive access (5-point Likert-type scale). 2) To evaluate the specificity, sensitivity and the PPV a cohort of 177 cancer patients with a suspicion of a TRS, who had received a genetic counselling between 2021-2023 at the Department of Human Genetics at Hannover Medical School, Germany, was analyzed retrospectively.

Results: 1) Overall, the self-test revealed a good comprehensibility ($M = 4.21$). 2) The sensitivity (true positive/true positive + false negative x100) was 92,6%. The specificity (true negative/true negative + false positive x100) was 37,9% and the PPV with a prevalence of 10% was 73%.

Conclusion: Here, we present a self-test for laypersons, that has the ability to screen for TRS due to its good comprehensibility and its high sensitivity and PPV. Although, we think that this tool can help to identify more TRS, we present also the limitations, especially the cancer diagnoses that are not covered by the self-test.

Conflict of Interest: None declared

P23.008.B The potential for chatbots in genetic counselling

Elen Siglen[1;2], *Hildegunn Høberg Vetti[1;2], Vidar Martin Steen[1;3], Tone Dahl-Michelsen[2], Cathrine Bjorvatn[1;2]*

[1]Haukeland University Hospital, Western Norway Familial Cancer Center/ Department of Medical Genetics, Bergen, Norway; [2]VID Specialized University, Faculty of Health Studies, Norway; [3]University of Bergen, Department of Clinical Science, Bergen, Norway

Background/Objectives: We have developed a health chatbot, named Rosa, that addresses questions about hereditary breast and ovarian cancer. The experiences from building Rosa were published in 2022 and have previously been presented at the ESHG meeting in 2019. We would now like to present our overall findings after building, testing, evaluating, and implementing Rosa chatbot in the clinic.

Methods: Healthy individuals at risk of hereditary cancer were invited to test Rosa during 2020/2021, and 16 of them shared their experiences through semi-structured interviews focusing on usability, usefulness, and trust. During winter 2023/2024 we have implemented Rosa as an information tool for breast and ovarian cancer patients during mainstream genetic testing. A selection of both physicians and patients are participating in in-depth interviews focusing on losses and gains when digitalizing health care tasks, such as information giving through chatbots.

Results: Rosa was described as accessible, trustworthy and a valuable supplement to genetic counselling by healthy, at-risk individuals. For some it could have replaced genetic counselling, but not if hereditary cancer was detected. Preliminary results from the 2023/2024 interviews indicate that the chatbot is also well received by cancer patients and does not cause anxiety, however both patients and physicians share concerns about the consequences digitalisation may have on the patient-physician relationship.

Conclusion: A chatbot is a valuable supplement to genetic counselling and may even replace counselling for selected groups. However, digitalization may lead to less human encounter with a potential of adverse effects on the health services.

Grants: This study is funded by the Norwegian Cancer Society.

Conflict of Interest: None declared

P23.009.C Integration of Genetic Counsellors into multi-professional Genetics Teams in the German-speaking Countries

Gunda Schwaninger[1], *Sabine Rudnik*[1], *Johannes Zschocke*[1]

[1]*Medical University of Innsbruck, Institute of Human Genetics, Innsbruck, Austria*

Background: The establishment of the genetic counsellor (GC) profession in German-speaking countries reached a significant milestone with the graduation of the inaugural cohort of Genetic and Genomic Counselling MSc students from the Medical University of Innsbruck in spring 2022. To share the knowledge gained from the experiences with these first students, an online workshop on GC training and integration was organized. Session 1 covered the education and professional profile of GCs, addressing challenges in integration. Session 2 explored experiences of GC students and providers during clinical placements, emphasizing the roles of GCs in interprofessional teams.

Methods: Online workshop with fifty-five participants, including 22 medical geneticists from Germany, Austria, and Switzerland, three senior GCs, six GC-graduates, ten GC-students, 12 prospective students, and two related professionals.

Results: The workshop revealed growing demand for GCs and positive experiences within participating institutes. Challenges included the GC scope of practice, legal aspects, remuneration, billing and supervision time. The workshop participants highlighted the need for increased numbers of trained GCs in the region. The MSc program team emphasized the importance of comprehensive clinical placements and standardized training. Experiences from different genetic centers showcased varying approaches to integrate GCs into clinical teams, indicating a positive shift in the perception of their role.

Conclusion: The workshop underscored the challenges and opportunities in integrating GCs into the healthcare systems of the German-speaking countries. Presently, the first group of GCs is dedicated to overcome obstacles of integration by closely collaborating with the regional societies and professional associations of human genetics.

Grant No external funding used.

P23.010.D Is there an impact of Chromosomal Structural Rearrangements on IVF laboratory outcomes in PGT-SR cycles? A propensity score matching-based study

Daria Marzanati[1;2], *Sara D'Alessandro*[3], *Davide Gentilini*[1;4], *Elisa Rabellotti*[2], *Laura Privitera*[3], *Sonia Faulisi*[3], *Francesca Spinella*[5], *Anil Biricik*[5], *Ettore Cotroneo*[5], *Luca Pagliardini*[2], *Enrico Papaleo*[3], *Alessandra Alteri*[2]

[1]*University of Pavia, Department of Brain and Behavioral Sciences, Pavia, Italy;* [2]*IRCCS San Raffaele Scientific Institute, Reproductive Sciences Laboratory, Obstetrics and Gynaecology Unit, Milan, Italy;* [3]*IRCCS San Raffaele Scientific Institute, Obstetrics and Gynaecology Unit, Milan, Italy;* [4]*Istituto Auxologico Italiano IRCCS, Bioinformatics and Statistical Genomics Unit, Cusano Milanino,Milan, Italy;* [5]*Eurofins GENOMA Group, Molecular Genetics Laboratories, Rome, Italy*

Background/Objectives: Patients with Chromosomal Structural Rearrangements (CSR) frequently face fertility challenges due to abnormal gametogenesis. For affected couples, In Vitro Fertilization (IVF) with Preimplantation Genetic Testing for Structural Rearrangements (PGT-SR) is recommended to select transferable blastocysts with a normal or balanced karyotype. This retrospective cohort study evaluates the impact of CSR on IVF laboratory outcomes in PGT-SR patients.

Methods: IVF Laboratory outcomes of IVF cycles with PGT-SR (N = 136) were compared to those with preimplantation genetic testing for aneuploidy (PGT-A) (N = 422) using propensity score matching and a logistic regression model. Within the PGT-SR population, the association between transferable blastocysts rate, carrier's gender and CSR type was evaluated through a logistic regression model.

Results: There was no significant difference in the fertilization rate between the PGT-A and PGT-SR groups. However, the PGT-SR group presents a lower blastulation rate compared to the PGT-A group (OR = 0.76, 95% CI 0.63-0.93, p-value = 0.03). Similar trends were noted in the top-quality blastocyst rate (OR = 0.45, 95% CI 0.29-0.69, p-value < 0.01). In the PGT-SR cohort, no significant association was observed between the transferable blastocyst rate and the carrier's gender. Nevertheless, a notable association (OR = 0.16, 95% CI = 0.09-0.29, p-value < 0.01) was observed based on CSR type. Patients who carried reciprocal translocations had a lower transferable blastocyst rate compared to those with CSR other than reciprocal.

Conclusion: These findings reveal that patients with CSR showed a lower blastulation rate compared to those undergoing PGT-A, showing a reduced rate of transferable blastocysts in cases of reciprocal translocations. Consequently, providing counseling and managing expectations for couples undergoing PGT-SR is essential.

P23.011.B Information comic as a pre-test educational tool about preconception carrier screening in German language

Christina Wölwer[1], *Gunda Schwaninger*[1], *Sabine Rudnik*[1]

[1]*Medical University Innsbruck, Institute of Human Genetics, Innsbruck, Austria*

Background/Objectives: Preconception carrier screening (PCS) allows screening for multiple recessive and X-linked diseases simultaneously and aims to identify carrier couples at an increased risk of having severely affected children. In Austria, preparations are underway to implement population-based PCS.

It has been debated how valid informed consent can be achieved considering the large number of rare diseases addressed. Academic societies in the United States (ACMG) and in Europe (ESHG) recommend a more generic consent for multiplex genetic testing. To help ensure that interested couples can make autonomous decisions, the ESHG suggests the usage of patient-tailored information materials, e.g. smartphone apps (PMID 29023436). In an American study comparing a brochure, video, and comic about PCS on knowledge and decision making, the comic scored best in terms of patient understanding (PMID 33135283). Thus, we developed an information comic about PCS in German language.

Methods: We created an educational comic using StoryboardThat presenting a couple considering a pregnancy who questions a gynaecologist about PCS. During the development of the comic, a team of clinical geneticists, genetic counsellors, and genetic counsellor trainees met several times to discuss and refine its contents.

Results: We developed an educational comic to inform future parents about PCS in German language. Main contents are basic genetics (different modes of inheritance), the purpose, benefits, limitations, possible outcomes, and potential reproductive options of PCS. The comic is accessible anytime via smartphone or computer through a QR code.

Conclusion: Our comic will improve awareness and genetic literacy about PCS in the general population.

P23.013.B Genomic Return of Results at the National Level: The United States' *All of Us* Research Program

Scott Topper[1], *Alicia Zhou*[1], *Cynthia Neben*[1], *Richard Gibbs*[2], *Stacey Gabriel*[3], *Heidi Rehm*[3], *Kimberly Doheny*[4], *Gail Jarvik*[5], *Chia-Lin Wei*[5], *Tara Dutka*[6], *Rhonda Moore*[6], *Anjene Musick*[6], *Anastasia Wise*[6]

[1]*Color Health, United States;* [2]*Baylor College of Medicine, United States;* [3]*Broad Institute of MIT and Harvard, United States;* [4]*Johns Hopkins University, United States;* [5]*University of Washington, United States;* [6]*NIH All of Us Research Program, United States*

Consortium: NIH All of Us Research Program

Background/Objectives: *All of Us* (the US Precision Medicine Initiative) will advance precision medicine by developing an open database of 1 million+ health-contextualized genome sequences, derived from a uniquely diverse population. Longitudinal participant engagement is a core aim, and direct-to-participant return of genetic results is an essential engagement strategy.

Methods: Since 2020, the program has offered >270,000 participants access to genetic ancestry, "traits", and health-related results including hereditary disease risk and pharmacogenomics (PGx). Participants opt-in and view results through an online, digital platform. Genetic counseling is available to all participants. The return-of-results protocol was developed under IRB and FDA oversight.

Results: To date, >70% of eligible participants have engaged with the return-of-results program. Of those, about 70% were individuals who have been underrepresented in biomedical research. 3% of result recipients have a disease-causing variant in one of the ACMG Secondary Findings v2 Gene List and were offered free clinical confirmation testing. 91% of PGx result recipients have a non-standard phenotype in one of seven genes (CPIC Level A, FDA). Participant feedback about the results return process was overall positive via Likert-scaled questions and free text responses.

Conclusion: *All of Us* has established a new standard for human subjects research and has directly returned results to one of the largest and most diverse cohorts to date. Participants are highly engaged with their research results, which can help drive recruitment and retention and ultimately increases the value of the program's research database.

P23.014.C The British Columbia Hereditary Cancer Follow-Up Initiative: Supporting hereditary cancer patients across the life-span

Melanie O'Loughlin[1], *Sze Wing Mung*[1], *Shanzhao Wang*[2], *Mandy Jevon*[1], *Eugene Cheung*[1], *Mary-Jill Asrat*[1;3], *Rebecca Morash*[4], *Kelsey Hamilton*[1], *Katherine Blood*[1;3], *Rona Cheifetz*[4;5], *Jennifer Nuk*[1;3], *Sophie Sun*[1;6], *Kasmintan Schrader*[1;3;7]

[1]*BC Cancer, Hereditary Cancer Program, Vancouver, Canada;* [2]*University of British Columbia, Dept of Gynecology and Obstetrics, Vancouver, Canada;* [3]*University of British Columbia, Department of Medical Genetics, Vancouver, Canada;* [4]*BC Cancer, High Risk Clinic, Vancouver, Canada;* [5]*University of British Columbia, Department of Surgery, Vancouver, Canada;* [6]*University of British Columbia, Department of Medical Oncology, Vancouver, Canada;* [7]*University of British Columbia, Department of Molecular Oncology, Vancouver, Canada*

Background/Objectives: The Hereditary Cancer Follow-up Initiative (HCFI) is a clinical service implemented at BC Cancer in July 2020 with the aim of ascertaining and addressing unmet clinical and psychosocial needs for individuals living with hereditary cancer conditions.

Methods: Adults in British Columbia or Yukon with a pathogenic variant in a hereditary cancer gene are invited to complete an annual survey. The survey collects information about cancer risk management practices, family communication and support needs. Completed surveys are triaged for phone follow-up with a genetic counsellor if the respondent indicates a support need, or if reported risk management practices are discordant with clinical recommendations.

Results: 5570 individuals have been identified as eligible, with 2304 completing a baseline survey to date (41%). Analysis of the demographics of invited participants and respondents with attention to self-reported ethnicity to evaluate equity is underway.

Analysis of early survey responses found 61% were triaged for genetic counsellor follow-up. 27% of participants reported risk management practices discordant with current clinical recommendations. A strong majority (97%) of participants reported speaking with relatives about the gene. A minority (6%) requested help with family communication, primarily regarding speaking with children. Further analysis will be completed on all baseline survey responses, with a focus on family communication practices across self-reported ethnicities.

Conclusion: The HCFI elucidates the longitudinal support needs of hereditary cancer pathogenic variant carriers in British Columbia and Yukon. Additional analysis will inform program planning to support effective hereditary cancer follow-up and family communication across ethnicites.

Conflict of Interest: None declared

P23.015.D From Estonian biobank to practice: undiagnosed adult CNV carriers express contentment to learn about their genetic finding

Marili Palover[1], *Margit Nõukas*[1], *Anu Reigo*[1], *Helene Alavere*[1], *Liis Leitsalu*[1;2], *Alexandre Reymond*[3], *Neeme Tonisson*[1;2], *Katrin Männik*[4]

[1]*University of Tartu, Institute of Genomics, Estonian Biobank, Tartu, Estonia;* [2]*Tartu University Hospital, Genetics and Personalized Medicine Clinic, Tartu, Estonia;* [3]*University of Lausanne, Center for Integrative Genomics, Lausanne, Switzerland;* [4]*Health 2030 Genome Center, Foundation Campus Biotech Geneva, Geneva, Switzerland*

Background/Objectives: While pioneering national genomic medicine initiatives focus on returning individual risk predictions for medically actionable monogenic and common diseases,

evidence-based recommendations on reporting genetic findings associated with high risk of complex clinical phenotypes (e.g. genomic disorder CNVs), to biobank volunteers are lacking.

Methods: We selected carriers of 16p11.2 and 16p12 CNVs of the Estonian biobank (EstBB) to establish a framework for returning CNV findings to population biobank participants and to evaluate psychosocial impact of receiving this information.

Results: 76 of 169 CNV carriers (45%) consented for return of results. The majority (89%) of CNV carriers presented health conditions characteristic of the associated genomic disorders, i.e. disorders of female reproductive health (53%), mental disorders (43%), gastrointestinal disease (67.1%) and speech disorders (51.3%). Preliminary analysis from receiving unexpected genetic information (data from 72 out of 76 participants) showed that almost all carriers (97.2%) appreciated being contacted. The participants felt that the information received was sufficient (98.6%), gave them more clearance (96%) and relief (86.1%). They thought that it did not increase their worry (93%) or anxiety (90.1%). Evaluation of long-term impact is planned to follow in 6 months.

Conclusion: Undiagnosed CNVs affect health and socio-economic outcomes in the general population. Carriers of such rearrangements who choose to consent for receiving the information appreciate being contacted and feel relieved knowing the origin of their health problems in spite of the severity or characteristics of their CNV related clinical outcomes.

Grants: Jacobs Foundation Research Fellowship (#2016 1217 09), Swiss National Science Foundation (#31003A_182632), Estonian Research Council (#PRG555).

P23.016.A Bridging the Gap: Accelerating Genetic Disorder Diagnosis in Rio Grande's Hispanic Communities via Innovative Tele-Health Solutions

Daniel Brooks[1;2], *Blake Vuocolo*[2;3], *Robert Sierra*[3], *Christopher Holder*[3], *Lauren Urbanski*[3], *Keila Rodriguez*[4], *Jose Gamez*[5], *Surya Mulukutla*[5], *Lori Berry*[4], *Ana Herndandez*[4], *Segundo Lizardo-Guzman*[6], *Humberto Hidalgo*[4], *Alberto Allegre*[4], *Sandy Magallan*[4], *Sarah Rodriguez*[4], *Hongzeng Dai*[3;7], *Kent Carter*[4], *Claudio Soler-Alfonso*[2;3], *Brendan Lee*[3], *Seema Lalani*[2;3]

[1]*Baylor College of Medicine, Department of Pediatrics; Department of Genetics, Houston, United States;* [2]*Texas Children's Hospital - West Tower, Houston, United States;* [3]*Baylor College of Medicine, Department of Genetics, Houston, United States;* [4]*The University of Texas Rio Grande Valley, Department of Pediatrics, Edinburg, United States;* [5]*DHR Health Diabetes & Endocrinology Institute Pediatric and Young Adult Clinic, Edinburg, United States;* [6]*Kaizen Clinical Partners (Mercedes Children's Clinic), Mercedes, United States;* [7]*Baylor Genetics, Houston, United States*

Background/Objectives: In the medically underserved Rio Grande Valley (RGV), Project GIVE aims to mitigate disparities in genomic healthcare for a predominantly Hispanic population with high poverty and uninsured rates. This NIH-funded study leverages the Consultagene platform for genetic evaluations and whole genome sequencing (WGS).

Methods: Healthcare providers refer patients to Project GIVE via Consultagene. The process includes a virtual genetic evaluation and subsequent collection of buccal samples for trio genome sequencing, with results returned during a follow-up visit. Providers in the RGV are also educated on genetics through CME events. Data collection is ongoing to assess the impact on provider competency and patient outcomes.

Results: Of 147 referrals, 102 were accepted, and 49 completed their initial visit. A significant portion of these families fall below the poverty line. Diagnoses were made in 34% of cases with returned WGS results, and further gene-disease associations are being explored. Surveys indicate family satisfaction with the telemedicine approach and WGS results. Post-CME, providers showed increased understanding of when to refer and how to interpret genetic data.

Conclusion: Project GIVE demonstrates a successful model of using tele-genetics to improve access to genomic healthcare in under-resourced communities. Enhanced provider education and virtual engagement are pivotal to this model, which holds promise for replication in similar regions to address genomic health inequities.

Conflict of Interest: None declared

P23.017.C Why people misunderstand heritability and why it matters

Yulia Kovas[1], *Fatos Selita*[2], *Alice Gregory*[1], *Gabriela Amaral*[1], *Emma Greenwood*[1], *Sever Sava*[1], *Maxim Likhanov*[3]

[1]*Goldsmiths, University of London, Psychology, London, United Kingdom;* [2]*Goldsmiths, University of London, London, United Kingdom;* [3]*Beijing Normal University, Beijing, China*

Background/Objectives: Heritability is a non-intuitive concept and is often misunderstood. Many people do not know that heritability refers to genetic contribution to variation in the population, rather than to an individual's traits; and that heritability is not constant within and across populations.

Methods: We administered an in-depth on-line survey to adult participants (N = 780) from the general population. Participants selected a definition of heritability from four options; provided estimates of heritability for 11 traits; and answers to 14 items tapping into understanding of heritability, e.g. its changeability across developmental, educational and cultural contexts. Participants' other genetic knowledge was assessed with 20 items.

Results: The results confirmed a striking lack of understanding of heritability. Only about 20% of participants could identify the correct definition of heritability; and heritability estimates varied from 0% to 100%. Most participants thought that heritability cannot differ across countries; but thought that heritability can differ in the same country at different historical periods. Around 60% of participants were unsure or thought that a policy change (e.g. vaccination; compulsory education) can not affect heritability. Understanding heritability was associated with participants' education, occupation, genetic knowledge; and assumptions about the effectiveness of different treatments, views on agency and responsibility in the justice context, and beliefs about the appropriate use of genetic information.

Conclusion: Many people have an inaccurate understanding of heritability. Assumptions about the aetiology of different traits may influence views, decisions and choices. These results call for new approaches to making the central genetic concept of heritability more accurately understood.

P23.018.B First Experiences with the Introduction of Genetic Counselors in Human Genetic Services in the German-speaking Countries

Simone Heidemann[1], *Johannes Zschocke*[2], *Gunda Schwaninger*[2]

[1]*Institute of Tumorgenetics North, Kiel, Germany;* [2]*Medical University Innsbruck, Institute of Human Genetics, Innsbruck, Austria*

Background/Objectives: In 2019, the Medical University of Innsbruck introduced the first Genetic and Genomic Counseling master's program in the German-speaking countries. A major challenge of this process was the absence of practicing Genetic Counselors (GC) in these countries, leading to a lack of experience with GCs in medical genetic practices and the absence of a legal framework for the profession. Consequently, student placements within the program commenced with neither the students nor their supervising consultants having any previous experience of collaborative teamwork between clinical geneticists and GCs.

Methods: To share insights from the initial implementation phase, supervising consultants from the seven student placement institutes were invited to participate in semi-structured interviews guided.

Results: From these interviews, three models of interprofessional teamwork between GCs and clinical geneticists emerged: (1) the alternating or tandem model, (2) qualified preliminary and follow-up patient interviews and (3) the provision of genetic services without direct genetic counseling. In addition, the interviewees provided recommendations for addressing legal concerns and for the effective establishment of appropriate compensation structures for GCs within the German-speaking countries.

Conclusion: Clinical geneticists taking part in the study estimated that the integration of GCs could potentially enhance counseling capacity by as much as 50%. Importantly, they did not foresee any reduction in counseling quality caused by the inclusion of GCs. This study provides evidence that the GC profession can provide additional skills to human genetic services and positively impact both patient support and overall capacity of genetic services also in the German-speaking countries.

P23.019.D Factors influencing pregnant women's decision to accept or decline prenatal diagnosis - a qualitative study

Charlotta Ingvoldstad[1;2;3], *Susanne Georgsson*[4], *Ove Axelsson*[5;6], *Ellen Ternby*[7]

[1]*Karolinska University Hospital, Centre for Fetal Medicine, Stockholm, Sweden;* [2]*Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden;* [3]*Uppsala University, Uppsala, Centre for Research and Bioethics, Uppsala;* [4]*The Swedish Red Cross University, Stockholm, Sweden;* [5]*Uppsala University, Centre for Clinical Research Sörmland, Eskilstuna, Sweden;* [6]*Uppsala University, Department of Women's and Children's Health, Uppsala;* [7]*Uppsala University, Department of Women's and Children's Health, Uppsala, Sweden*

Background/Objectives: Prenatal diagnosis for chromosomal anomalies is commonly offered worldwide. It is important that pregnant women receive adequate counselling to make informed decisions regarding prenatal diagnosis. The aim was to explore what factors influence pregnant women's decision-making process to accept or decline prenatal diagnosis.

Methods: A qualitative study using inductive qualitative content analysis. Individual, semi-structured phone interviews with 24 pregnant women in the first trimester, living in a medium-sized Swedish city, were carried out during a five-month period in 2016-2017.

Results: Two main themes emerged; (1)*"Individual factors - The women's experiences, perceptions and values"* with the three categories "Attitude towards anomalies", "Worry and need for reassurance", "Self-perceived risk" and (2)*"External factors - The women's perception of the test and others' views"* with the two categories "Test characteristics" and "Influence from others".

Conclusion: Pregnant women's decision-making process regarding prenatal tests is multidimensional, affected by both individual factors like experiences, perceptions and values and external factors like test characteristics and influence from others. Information about both test characteristics and the conditions tested for could help expectant women in the decision-making process by having better understanding of how a child with the condition in question could affect them and their family. Healthcare professionals giving information about and offering prenatal tests for chromosomal anomalies should be aware of how their attitudes can influence women's decisions.

Grants: This research was supported by funding from the Center for clinical research Sörmland and by ALF compensation from Region Uppsala and Uppsala University, Sweden.

Consortium: Deutsches Referenz-Netzwerk Erbliche Tumor-Syndrome (DRN ETS)

Background/Objectives: The foundation of European Reference Networks (ERN) represents a major step to improve patient care and research for rare and complex diseases. Families with Hereditary Tumor Syndromes (HTS) are a relevant target group and a paradigm for preventive and precision oncology. However, it is suspected that the majority of patients is still not diagnosed or experience a substantial delay in diagnosis, which results in inadequate medical care. The ERN GENTURIS aims to substantially improve medical care of families with GENetic TUmour RIsk Syndromes across Europe. Nevertheless, the achievements will only improve oncological care, if they are implemented in national health care systems, which is regarded as a major shortcoming.

Methods: Therefore and in line with the EU requirements, a German Reference Network for Hereditary Tumor Syndromes (GRN HTS) was established as one of 12 GRNs to date (www.se-atlas.de/drn).

Results: Currently, the GRN HTS consists of 11 centers (ERN members and / or specialized B centers of Centers for Rare Diseases. The network offers expertise for a broad spectrum of rare HTS and involves patient representatives. The website acts as an information platform for relevant areas and sources regarding clinical and research aspects of HTS.

Conclusion: Challenges are the recruitment of expert clinicians for specific areas and the extension of specialized outpatient clinics. Future goals of the network include the implementation of registries for rare HTS, training programs for organ-specific cancer centers, cross linking with other initiatives in the field, and ensuring the interoperability between local and ERN data structures.

Conflict of Interest: None declared

P23.021.B Reflexive predictions in genetic counselling: when prediction alters the future

Angus Clarke[1], *Mayli Mertens*[2]

[1]*Cardiff University, Cancer & Genetics, School of Medicine, Cardiff, United Kingdom;* [2]*Centre for Ethics, Department of Philosophy, University of Antwerp, Antwerpen, Belgium*

Background/Objectives: How can a predictive genetic test be, appear to be, or become, a self-fulfilling or self-defeating prophecy? How can the result of the test influence what then happens to the patient's health? The umbrella term for self-fulfilling and self-defeating prophecies is reflexive prediction, where prediction affects the predicted outcome. Some of these effects are unsurprising as they are the primary goal of testing, as when those at risk of inherited cancers use this knowledge to manage their risk. We focus on the less expected effects of predictive genetic testing and how they may be important in genetic counselling as preparation for genomic tests.

Methods: The methods employed have been literature review drawing on a theoretical model for analysis of reflexive prediction, reflection on professional practice, and discussion between the authors and with colleagues.

Results: We have identified several categories of reflexive prediction that are encountered in genetic counselling practice, where awareness of this reflexivity can yield important insights. Other categories have been identified where there is potential for feedback between genetic susceptibility and expectations held by the self or others. These effects will become more likely if/when genomic testing is more broadly applied to complex diseases, especially psychiatric illness and to cognitive and behavioural traits.

Conclusion: Learning to recognise the scope for reflexive prediction is already useful in genetic consultations; it will increase in importance as the scope of genomic testing broadens to more complex diseases and non-disease traits.

P23.022.C Motivational text-messages increase compliance to *BRCA1/2* screening test

Rotem Greenberg[1], *Tom Muskat*[1], *Adi Berliner*[1], *Shay Ben-Shachar*[1,2]

[1]*Clalit Health Services, Clalit Research Institute, Ramat Gan, Israel;* [2]*Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel*

Background: In 2020, Israel initiated *BRCA1/2* carrier screening program for Ashkenazi Jewish women. Despite its medical importance, the compliance was relatively low (2.4% of the eligible population) during the first year. To improve compliance, we implemented a motivational text messaging strategy.

Methods: We randomly sent five distinct motivational messages annually to all eligible women aged 25-50. Each message included a link to schedule an appointment and provided test information. Intervention impact was assessed by test performance at 3-6 months after receiving the messages, considering the time required to performing the testing.

Results: A 233,711 messages were sent, and 18,281 (8.2%) eligible women underwent testing after the intervention began. Within 3-6 months of receiving the message 10,478 (57.3%) women were tested. After 3 month the discontinuity was significant ($\beta = 0.26$, $p = 0.032$), inferring a significant 0.26% increased compliance. The increased ratio was 0.1% as the intervention continued, indicating a cumulative effect on compliance.

The message encouraging "immediate action" had the most significant impact (OR = 1.11, 95% CI [1.04, 1.18] (on compliance, while messages emphasizing "social norm" and "family responsibility" had the lowest compliance rates and were significantly less effective than the baseline message. The message focused on "health control" did not differ significantly from the baseline message.

Conclusion: Utilizing motivational messages offers a simple and cost-effective intervention with low associated costs. Tailoring messages based on various behavioral and socio-demographic characteristics may further enhance compliance.

P23.023.D Predictors of use of digital health tools in accessing genetic services: findings from the BRIDGE trial

Lingzi Zhong[1], *Molly Volkmar*[1], *Jemar Bather*[2], *Lauren Kaiser-Jackson*[1], *Richard Bradshaw*[3], *Rachelle Chambers*[4], *Daniel Chavez-*

Yenter[1;5], Amanda Gammon[1], Adrian Harris[2], Wendy Kohlmann[1], Rachel Monahan[4], Meenakshi Sigireddi[4], Ophira Ginsburg[6], Saundra Buys[1], Kensaku Kawamoto[3], Melody Goodman[2], Guilherme Del Fiol[3], **Kimberly Kaphingst**[1;5]

[1]University of Utah, Huntsman Cancer Institute, Salt Lake City, UT, United States; [2]NYU, School of Global Public Health, New York, NY, United States; [3]University of Utah, Department of Biomedical Informatics, Salt Lake City, UT, United States; [4]NYU Langone Health, Perlmutter Cancer Center, New York, NY; [5]University of Utah, Department of Communication, Salt Lake City, UT, United States; [6]National Cancer Institute, Rockville, MD, United States

Background/Objectives: Increasing use of digital health tools may affect access to genetic services. We examined whether patient engagement and sociodemographic characteristics predicted use of two digital health tools (patient portal and chatbot) and compared predictors of using pre-test genetic services via chatbot vs. standard of care (SOC).

Methods: We contacted 3,073 unaffected patients aged 25-60 years eligible for cancer genetic evaluation at University of Utah Health (UHealth) and NYU Langone Health (NYULH). Patients were randomized to receive either a patient portal messages with a hyperlink to a pre-test genetics education chatbot or information about scheduling a pre-test SOC appointment. Multivariable models identified predictors of patient portal use and pre-test genetic services use, stratifying by study arm and site.

Results: Opening study patient portal messages were significantly associated with having an assigned primary care provider (UHealth: SOC; NYULH: both arms); number of patient portal logins (UHealth and NYULH: both arms) and number of primary care visits in the previous three years (NYULH: SOC). Opting for pre-test genetic services was significantly associated with number of past patient portal logins (UHealth: chatbot; NYULH: both arms) and with having an assigned primary care provider (NYULH: SOC). Patient sociodemographic characteristics were not significantly associated with either outcome.

Conclusion: Patients' prior engagement with primary care and technology were related to their use of digital health tools to access genetic services, while their sociodemographic characteristics were not. Addressing general barriers to accessing healthcare may be important in interventions to increase access to genetic services.

P23.024.A How people from migrant and refugee backgrounds experience perinatal genetic screening: a scoping review

Anaita Kanga-Parabia[1;2], *Belinda McClaren[1;2], Laura Biggs[1], Sharon Lewis[1;2], Erin Tutty[1;2], Alison Archibald[1;2]*

[1]Murdoch Children's Research Institute, Parkville, Australia; [2]The University of Melbourne, Paediatrics, Parkville, Australia

Background/objectives: People from migrant and refugee backgrounds often have poor healthcare experiences and outcomes. Understanding how this manifests in the perinatal genetic screening setting is a crucial step toward equitable care. We aimed to review evidence of perinatal genetic screening experiences of people from migrant and refugee backgrounds.

Methods: A scoping review was conducted using Joanna Briggs Institute framework. Search strategies were applied to Medline, Embase, and CINAHL databases to identify articles about experiences of perinatal genetic screening for people of migrant and refugee backgrounds. Evidence was synthesised using descriptive and content analysis.

Results: Of 6,925 unique articles identified, twenty-six articles were eligible and included for analysis. Most data were collected in Western countries, and participants were primarily born in Asia, South America, or Africa. Studies indicated that people from migrant and refugee backgrounds had varying awareness, knowledge and uptake of screening in different contexts. Several studies provided evidence of individuals being well informed and making decisions aligned with their values. However, there were examples of low awareness, knowledge, and uptake. Barriers and proposed strategies related to patient education, perceptions of autonomy, poor provider-patient interactions, and structural barriers to screening.

Conclusion: This scoping review revealed common barriers encountered in perinatal genetic screening care and related strategies to address these for people of migrant and refugee background. Understanding perspectives of people from migrant and refugee backgrounds experiences is foundational to ensuring equitable information and support about perinatal genetic screening for all.

Grants: Australian Government Research Training Program Scholarship

P23.025.B Fragile X syndrome in Thailand: 30 years of experience

Pornprot Limprasert[1;2], *Oradawan Plong-On[2], Chariyawan Charalsawadi[1;2], Areerat Hnoonual[1;2]*

[1]Genomic Medicine Center, Faculty of Medicine, Prince of Songkla University, Songkhla, Thailand; [2]Department of Pathology, Faculty of Medicine, Prince of Songkla University, Songkhla, Thailand

Background/Objectives: Fragile X syndrome (FXS) is the most common form of X-linked intellectual disability (ID). This study aimed to share our 30 years of experience on the diagnosis of FXS and to determine the frequency of FXS in Thailand.

Methods: We reviewed our 3 cohort studies (1991-1999) and performed a retrospective review of 1,098 Thai patients (1,005 males and 93 females) with ID and developmental delay (DD) who had been referred for FXS DNA testing at Songklanagarind Hospital during 2000-2021. The DNA samples were analyzed using PCR to determine the number of CGG repeats and methylation status in the *FMR1* gene was used to confirm the diagnosis.

Results: Full mutation FXS was confirmed in 71/1,005 males (7.1%) and 3/93 females (3.2%). To our knowledge, this is the largest case of molecular genetic FXS testing from Thailand. The frequencies of FXS from 3 different cohorts of Thai male patients and periods of time were approximately 7.9%, 7.5% and 6.8% in Northern (2005-2008), Central (1997-1999) and Southern (1991-1999) Thailand, respectively. The overall frequency of FXS in male patients from our 30 years of experience was 7.1% (100/1,399, 1991-2021). Our earlier study found a frequency of fragile X carriers of 0.27% (1/359) in random blood donors of Thai women.

Conclusion: A review of the literature on worldwide frequencies of FXS showed that Thailand was among the countries with a high frequency of FXS, suggesting that molecular genetic screening for FXS (i.e., newborn or carrier screening) should be considered as a national policy in Thailand.

Conflict of Interest: None declared

P23.026.D Uptake of genetic counselling and multigene-panel testing among East Bavarian families at risk for hereditary breast and ovarian cancer with previous uninformative BRCA1/2 results

Heidi Stöhr[1], *Michaela Schläger*[2], *Christina Kiel*[1], *Ivana Holzhauser*[2], *Johannes Zschocke*[3], *Bernhard Weber*[1;2]

[1]*Universität Regensburg, Institut für Humangenetik, Regensburg, Germany;* [2]*Universitätsklinikum Regensburg, Institut für Klinische Humangenetik, Regensburg, Germany;* [3]*Medizinische Universität Innsbruck, Institut für Humangenetik, Innsbruck, Austria*

Background/Objectives: Genetic follow-up testing that comprises the analysis of newly identified high and moderate penetrance tumor susceptibility genes is increasingly integrated into clinical care for families at risk for hereditary breast and ovarian cancer with previous uninformative BRCA1/2 results. This study presents the implementation of a recontact program for follow-up multigene panel testing (MGPT) in East Bavarian families.

Methods: An invitation for pre-test counseling and MGPT was mailed to eligible individuals with a personal or family history of breast and ovarian cancer who had non-informative BRCA1/2 testing between 2008 and 2015. Factors influencing patient's receptivity to recontacting and genetic testing uptake were examined.

Results: Invitation letters were sent to 219 individuals, 41 (18.7%) were returned to sender and 111 addressees (50.7%) gave feedback. Of these, 10 (9%) were reported as deceased; 62 (56%) and four (4%), respectively, were scheduled for, or expressed interest in, a pre-test counseling appointment; 35 (31%) declined the offer for counseling or MGPT. Reminder letters positively influenced the response rate. A quarter of those contacted proceeded with MGPT. While demographic characteristics, tumor type and family cancer burden showed no effect on the response choices, attitudes towards science and research, previous unclear test results and recurrent tumor disease tended to influence the response rate. Family responsibility was the most notable motivator, difficult life situations, issues with health insurance and doubts about benefits were identified as barriers for MGPT.

Conclusions: This study shows that well-maintained databases and a low-barrier recontact approach supported by coordinators and genetic counsellors contribute to optimize future genetic follow-up programs.

Conflict of Interest: None declared

P23.027.A Capturing interdisciplinary clinicians' psychosocial and psychological experiences providing care for children with severe neurogenetic conditions

Suzanne Nevin[1;2], *Fleur Le Marne*[2], *Erin Beavins*[2], *Rebecca Macintosh*[2], *elizabeth pamer*[2], *rani sachdev*[2], *kenneth nunn*[3], *Annie Bye*[1;2]

[1]*UNSW Sydney, school of clinical medicine, Sydney, Australia;* [2]*Sydney Children's Hospital, Randwick, Randwick, Australia;* [3]*The Children's Hospital at Westmead, Westmead, Australia*

Consortium: ClinEquip Advisory group

Background/Objectives: Severe neurogenetic conditions present with heterogenous aetiologies. Clinicians exert strenuous effort undertaking complex prognostication and management, in the face of an unprecedented explosion of genetic diagnoses with limited natural history data for newly-described conditions. Despite this burgeoning scale and density of neurogenetic clinical care, supports for clinicians navigating ongoing uncertainties and balancing families' realistic hopes are lacking. This can impart unabating professional and intrapersonal stress on clinicians over substantial stages of their career.

The primary aim of this study was to investigate paediatric clinicians' psychosocial and psychological experiences navigating care for children with severe neurogenetic conditions. The secondary aim was to identify clinician preferences for tailored and codesigned supports.

Methods: We conducted a qualitative descriptive study with interdisciplinary clinicians using a purposeful sampling recruitment strategy. Twenty-four participants with expertise caring for children with severe neurogenetic conditions completed in-depth, semi-structured interviews. Interviews were transcribed, deidentified and an inductive thematic analysis was performed.

Results: Thematic analysis elicited interrelated themes. Clinicians experienced immense professional barriers providing patient-centred care across fragmented healthcare contexts. Physical, emotional, and psychological impacts were attributed to inadequate reflective practice training and a paucity of integrated resources. Multi-pronged strategies incorporating psychoeducation, interdisciplinary peer mentorship opportunities, and psychological resources to build clinician reflective practice skills providing complex care in an advancing era of medicine, were prioritised.

Conclusion: This study provides novel and in-depth insight into clinicians' experiences navigating care for children with severe neurogenetic conditions. Results will be used to inform the co-development of multipronged resources tailored for interdisciplinary clinicians.

P23.028.B Genetic healthcare professionals' experiences with the communication about inherited genetic conditions from parents to their young children: a scoping review

Catarina Seidi[1;2;3], *Liliana Sousa*[1], *Álvaro Mendes*[2;3]

[1]*University of Aveiro, Aveiro, Portugal;* [2]*Centro de Genética Preditiva e Preventiva, Porto, Portugal;* [3]*Instituto de Biologia Molecular e Celular, Porto, Portugal*

Background/Objectives: Discussing inherited genetic conditions (IGCs) with young children poses significant challenges, and parents often seek guidance from genetic healthcare professionals (GHPs) on the best approach. Despite this communication being a key aspect of GHPs' roles, there is limited research exploring their experiences. This scoping review aims to map the evidence on GHPs' experiences in parent-young children (≤24 years old) communication about IGCs.

Methods: This review followed the JBI and PRISMA guidelines (https://inplasy.com/inplasy-2023-11-0009/). It included peer-reviewed primary research articles published in English since 1997. Studies that reported GHPs' perspectives on parent-children communication about IGCs were included. Four databases (Web of Science, PubMed, PsycINFO, and Scopus) were searched, and five articles met the eligibility criteria. These were qualitative, using interviews and focus-groups, and published from 2010-2020 in Australia (2), Belgium, USA, and the UK.

Results: The analysis suggested that GHPs generally feel responsible for facilitating parent-children communication about IGCs. They reported guiding parents in informing children, emphasizing early and age-appropriate communication. Their approach involves considering parents' and children's needs, IGCs' characteristics, and contextual factors. Strategies to facilitate communication include assessing family dynamics through focused questioning and providing parents with reliable educational materials. GHPs perceive their roles according to their professional background and guidelines; however, they

report constraints such as time limitations and insufficient training.

Conclusion: This review provides insight that may help to clarify GHPs' scope of practice, roles and needs in facilitating parent-children communication about IGCs. Further research is needed to understand how to improve practice and provide better support for these families.

Conflict of Interest: None declared

P23.029.C Acceptability of cascade-testing approaches for familial hypercholesterolaemia (FH): qualitative study of health-care professional & patient experiences

Laura Condon[1], *Nadeem Qureshi*[1], *Ralph Akyea*[1], *Kate Haralambos*[2], *Barbara Iyen*[1], *Phil Rowlands*[3], *Melanie Watson*[4], *Joe Kai*[1]

[1]*University of Nottingham;* [2]*University Hospital of Wales;* [3]*Patient Representative;* [4]*University Hospital Southampton NHS Foundation Trust*

Background/Objectives: In the UK, direct and indirect methods of contacting relatives for FH testing vary with lack of evidence on patient and relative experiences with regard to uptake of genetic testing. This study explores the experiences and perspectives of index patients, cascade relatives, and health professionals, to assess the acceptability of both contact approaches.

Methods: Patients, relatives and health professionals were purposefully sampled across three UK regions (Urban/rural/mixed) to reflect: 1) sociodemographic range, 2) different FH assessment & testing experiences, 3) contact tracing within or outside geographic region.

Semistructured one-to-one interviews explored the views and experiences of all respondents following informed consent. Data was transcribed verbatim and framework analysis was used to derive themes across all respondents and regions.

Results: A direct & indirect 'hybrid' model of communication taken on a case-by-case basis for each family was regarded most effective by patients and professionals. A FH specialist nurse-led model with enhanced communication and continuity of care throughout the cascade-testing pathway was strongly supported.

Professionals stated family communication should focus on FH as treatable to prevent major cardiac disease. Patients and professionals suggested barriers to uptake of testing could be reduced by removing the requirement for GP referral, enabling self-referral, and limiting the number of appointments. Continuity of care with a single FH professional for ongoing family support was valued particularly by parents of young children who underwent testing.

Conclusion: A service-led direct-contact approach was more reliable, but combining direct and indirect approaches, guided by index patients and family relationships, may be more acceptable.

Grants: NIHR-HTA programme

[1]*Carmel Medical Centre, Haifa, Israel;* [2]*Rambam Health Care Campus, Haifa, Israel;* [3]*Israel Ministry of Health, Jerusalem, Israel*

Background/Objectives: Recommended surveillance for BRCA1/2 carriers manual breast exams, imaging, and gynecological follow-up, alongside the consideration of prophylactic mastectomy and salpingo-oophorectomy. This study aimed to assess adherence to these protocols among BRCA1/2 carriers and compare it between dedicated carrier clinics and community healthcare.

Methods: Conducted as a cross-sectional study, we distributed an anonymous questionnaire within the "Good BRCA Genes - Support and Information Group for BRCA Carriers" association, evaluating adherence to recommended surveillance and satisfaction with follow-up aspects.

Results: Among the 682 surveyed BRCA carriers, 68.5% reported full adherence to recommended medical follow-up. Non-adherence reasons included bureaucracy challenges, scheduling difficulties, timing uncertainties, and difficulty remembering examination dates. Satisfaction levels with appointment availability, scheduling, contact persons, and general practitioners' knowledge of BRCA mutations were below 50%. The 417 women monitored in dedicated breast clinics reported significantly higher optimal adherence (78.3% vs. 53.6%, $p < 0.0001$) and greater satisfaction with appointment availability (63.7% vs. 25.0%, $p < 0.0001$), appointment scheduling process (58.1% vs. 24.7%, $p < 0.0001$), availability of breast surgeons/gynecology specialists (67.4% vs. 50.8%, $p < 0.0001$), and availability of a contact person for consultations between appointments (53.5% vs. 20.8%, $p < 0.0001$).

Conclusion: These findings underscore the benefits of surveillance in dedicated BRCA1/2 clinics, emphasizing closer monitoring and increased satisfaction. Given the limited availability of such clinics and the rising number of BRCA1/2 carriers, our findings suggest the necessity for additional dedicated clinics and consideration of alternative solutions to enhance surveillance, such as healthcare professional training, digital tools, and artificial intelligence.

P23.031.A Comparing experiences and enhancing communication: a study of BRCA1/2 carriers identified through screening versus genetic counseling

Rotem Greenberg[1], **Amir Peleg**[2], *Moran Echer*[2], *Amihood Singer*[3], *Lena Sagi-Dain*[2]

[1]*Clalit, Tel Aviv-Yafo, Israel;* [2]*Carmel Medical Centre, Haifa, Israel;* [3]*Israel Ministry of Health, Jerusalem, Israel*

Background/Objectives: This study aimed to evaluate the experiences of women carrying BRCA1/2 mutations identified through population-based screening, in comparison to women diagnosed following conventional genetic counseling, either due to personal or familial history of cancer. The evaluated outcomes included quality of explanations given before the genetic testing and following positive test result.

Methods: This cross-sectional survey employed an anonymous questionnaire distributed through the "Good Genes - a support and information group for BRCA carriers" association from January to March 2023. The questionnaire included Likert scale and open-ended questions.

Results: The questionnaire was completed by 110 respondents who had been diagnosed through BRCA screening, and 444 women who had undergone genetic testing after conventional genetic counseling based on personal or familial cancer history. Among those in the screening group, 45.5% rated the quality of pretest explanations as unsatisfactory, compared to 27.4% in the genetic counseling group ($p = 0.0005$). In terms of result delivery, the screening group reported higher instances of inappropriate timing (61.8% vs. 40.3%, $p < 0.0001$), suboptimal mode of delivery

(55.5% vs. 37.5%, p = 0.0008) and suboptimal quality in post-test explanations (51.4% vs. 33.9%, p = 0.0006), as well as elevated stress levels (74.3% vs. 64.3%, p = 0.043).

Conclusion: The findings of this survey underscore the pressing need for enhancements in pre-test explanation, as well as the post-test counseling for positive results, within the realm of BRCA screening.

P23.032.B VisGen: A web-based approach for personal polygenic score calculation and visualization of absolute risk prediction for 18 different diseases

Nicolas Walk[1], Julian Wanner[1;2], Asma Aborobb[1], Mohammad Abdullah[1], Christoph Lippert[1;3], Samuli Ripatti[2], Henrike Heyne[1;2;3]

[1]Hasso Plattner Institute for Digital Engineering, Potsdam, Germany; [2]Institute for Molecular Medicine Finland, Helsinki, Finland; [3]Hasso Plattner Institute for Digital Health, Icahn School of Medicine at Mount Sinai, New York, United States

Consortium: INTERVENE

Background/Objectives: Polygenic scores (PGSs) have become an important part of precision medicine in diagnosis and prevention. However, their application and implementation are complex. Their availability to interested individuals e.g. as personal health information is thus limited.

Methods: Here we present VisGen, a secure, web-based application that enables users to upload their personal genotype data and visualize absolute risk estimates for 18 diseases without prior knowledge. In our tool, we integrate genotype imputation, PGS calculation and ancestry normalization. Calculated PGSs are translated into personal absolute disease risk estimates using a framework described in Jermy et al., medRxiv, 2023 taking into account overall disease prevalence, sex, age, ancestry, and country of origin (with five available options). VisGen integrates a React front-end with a Spring Boot Java backend application, offering asynchronous REST endpoints to initiate and manage PGS calculations and imputation. For imputation, Beagle is used along with bcftools. For PGS calculation and ancestry normalization, pgsc_calc (https://github.com/PGScatalog/pgsc_calc) is incorporated. Visualization and absolute risk estimation are performed by VisGen.

Results: We validated and tested various different methods e.g. for ancestry normalization and imputation using the UK Biobank cohort with approximately 550,000 individuals. We find that BEAGLE imputation improves PGS significantly more than mean imputation by PLINK2.

Conclusion: We present a user friendly web tool that enables interested individuals to easily calculate and visualize their PGSs and absolute disease risks making research results more accessible to the public.

P23.034.D Unanticipated genotypes identified in a healthy population cohort

Yasmin Bylstra[1;2], weng khong lim[1;3;4], Jing Xian Teo[1], Melody Menezes[2;5], Jan Hodgson[2], saumya shekhar jamuar[1;6;7], Patrick Tan[4;8;9], David Amor[2;10]

[1]SingHealth Duke-NUS Institute of Precision Medicine, Singapore; [2]The University of Melbourne, Department of Paediatrics, Australia; [3]Duke-NUS Medical School, Cancer and Stem Cell Biology, Singapore; [4]Genome Institute of Singapore, Singapore; [5]Monash Ultrasound for Women, Australia; [6]KK Women's and Children's Hospital, Genetics Service, Singapore; [7]Duke-NUS Medical School, Paediatric Academic Clinical Programme, Singapore; [8]Duke-NUS Medical School, Singapore; [9]Precision Health Research Singapore, Singapore; [10]Murdoch Children's Research Institute, Australia

Background/Objectives: The expansion of genomics provides opportunity to screen individuals beyond clinical indication, yet the classification of genomic variants and implications for health outcomes in this context are still emerging. We analysed clinically relevant variants and expected clinical impact in a healthy population.

Methods: Whole genomes from 9637 healthy unrelated research-consented participants in Singapore were analysed, focusing on 1619 genes associated with severe paediatric disease and 73 clinically actionable genes. Associations between variants and expected phenotypes were assessed, including medical and family histories where available.

Results: After considering protein impact, clonal haematopoiesis, inheritance and participant demographics for 336 unique variants, 288 variants occurring in 529 participants were analysed further. Most identified variants were associated with incomplete penetrance (e.g. dilated cardiomyopathy), mild phenotype (e.g. cystinuria), late onset (e.g. Fabry disease) or potentially missed phenotype (e.g. Hajdu-Cheney syndrome). However, 22 participants had variants associated with highly penetrant disease (*APC*, *BRCA1*, *MEN1*, *MLH1*, *MSH2*, *TP53*, *VHL*) and 11 with severe paediatric disease predicted to be symptomatic (e.g. muscular dystrophy).

Conclusion: Despite a cohort selected for absence of pre-existing health conditions, individuals were identified carrying variants associated with highly penetrant or severe paediatric conditions. Further work is required to examine for subtle clinical signs. This study revealed the challenge of predicting clinical outcomes from genotype-derived screening and emphasises the importance of expanding phenotype characterisation which is highly relevant in population genomic and carrier screening.

Consortium: ERN ITHACA

Background/Objectives: ERN ITHACA is the European Reference Network for Intellectual disability, TeleHealth, Autism and Congenital Anomalies. One of ERN ITHACA's main objectives is to develop educational activities on rare neurodevelopmental disorders (NDD) and multiple congenital malformations by supporting conferences dedicated to developmental anomalies.

Methods: To achieve this objective, ERN ITHACA organises three flagship events, dedicated to health professionals and lay persons alike. EuroDysmorpho series bring together young clinical geneticists and trained dysmorphologists to share their experiences and present clinical challenges (co-organised with ESHG-Y). This conference is open to any presentation in the field of human development. EuroNDD is a 2-day workshop on care and research of genetic neurodevelopmental disorders. It focuses on covering themes like pathways, mechanisms of disease, emerging therapies and diagnostics. The Winter School on Fetal Diagnosis aims to address a learning gap in fetal phenotyping, genetic analysis, and data interpretation. As a single-day course it includes basic lectures and in depth-workshops on phenotyping, prenatal genomic testing, and the implications for genetic counselling.

Results: The EuroDysmorpho series has brought together more than 100 participants from all over Europe in its last edition, held in September 2023 in Lisbon. EuroNDD has brought together in April 2023 around 250 participants, whereas the Winter School is available to 60 participants only to preserve the interactive learning experience.

Conclusion: EuroDysmorpho and the Winter School yearly events. The next editions take place respectively in September 2024 and December 2024. EuroNDD is a biennial event. Follow ern-ithaca.eu for more information.

P23.036.B Facilitators and Barriers to family communication about Li-Fraumeni Syndrome

Florentia Fostira[1;2], *Marion McAllister*[2], *Frauke Pelz*[2]

[1]NCSR 'Demokritos', Human Molecular Genetics Laboratory, Athens, Greece; [2]Cardiff University, School of Medicine, Centre for Medical Education, Cardiff, United Kingdom

Background/Objectives: Effective communication of the genetic information related to cancer predisposition within families is important for cancer screening and prevention, yet numerous factors can impede this process. This study aimed to investigate the facilitators and barriers to genetic information communication among Greek families with Li-Fraumeni syndrome (LFS).

Methods: In-depth, semi-structured interviews were conducted, followed by thematic analysis to identify emerging facilitators and barriers to communication. Patients with LFS were recruited after invitation from treating physicians in Greece.

Results: Six patients were included. Four communication facilitators were identified and explored: (a) the desire to protect relatives from cancer, (b) support from family and health professionals, (c) positive relationships with specific family relatives and (d) the close-knit nature of the core Greek family, sculptured by strong cultural factors. Conversely, barriers included: (a) the physical and emotional burden specifically associated with LFS, (b) reluctance to cause distress or harm, (c) difficulty in conveying complex information and (d) practical concerns and issues. The strong familial bonds, characteristic of Greek families emerged as a significant facilitator, not described in previous studies, potentially applicable to other Mediterranean populations. A notable barrier to communication was the burden associated specifically with LFS, a novel finding with potential syndrome-specific implications.

Conclusion: This study contributes valuable insights to the literature on family communication in hereditary cancer syndromes, highlighting the unique challenges faced by individuals with LFS, for which the literature is scarce. Understanding the complexities of disseminating genetic information within families can inform strategies for improving communication and support.

P23.037.C Clinical utility of testing a large gene panel for hereditary breast cancer in different ancestry groups

Tabitha Osler[1;2], *Mardelle Schoeman*[3], *Jean-Tristan Brandenburg*[1;4], *Wenlong Carl Chen*[1;4;5], *Michael Urban*[2;3], *Christopher Mathew*[1;2]

[1]University of the Witwatersrand, Sydney Brenner Institute for Molecular Bioscience, Faculty of Health Science, Johannesburg, South Africa; [2]University of the Witwatersrand, Division of Human Genetics, Faculty of Health Science, Johannesburg, South Africa; [3]University of Stellenbosch, Division of Molecular Biology and Human Genetics, Faculty of Medicine and Health Sciences, Cape Town, South Africa; [4]University of the Witwatersrand, Strengthening Oncology Services Research Unit, Faculty of Health Sciences, Johannesburg, South Africa; [5]National Health Laboratory Service, National Cancer Institute, National Institute of Communicable Diseases, Johannesburg, South Africa

Background/Objectives: The optimal gene panel size for hereditary breast cancer testing remains uncertain, with larger panels detecting more variants of unknown significance (VUS), and pathogenic variants (PVs) in genes lacking management guidelines. We evaluated the impact of expanding the gene panel on testing outcomes across three ancestry groups.

Methods: 331 South African females of African, European, or Mixed ancestry with breast cancer had genetic testing. Initially, all participants were tested with a 9 gene panel containing established breast cancer susceptibility genes. Those without detected PVs underwent testing of an additional 75 genes. The prevalence of PVs and VUS between the panels was compared across the three ancestries.

Results: The 9 gene panel yielded 58 PVs with a further 12 detected by the 75 gene panel. The prevalence of PVs was similar in the three ancestry groups for both panels. Only 2/12 PVs in the 75 gene panel were in genes with confirmed associations with breast cancer and management guidelines for the disease. In total, 90 VUS were detected with the 9 gene panel, and 524 using the 75 gene panel. The mean number of VUS per participant in the 75 gene panel was 2.23 in Mixed Ancestry and 1.70 in African

ancestry participants, significantly higher than the mean of 0.95 found in those with European ancestry.

Conclusion: Expansion of the gene panel yielded a limited number of clinically actionable variants and a substantial increase in VUS detection, particularly in African and Mixed ancestry populations.

P23.038.D Identification of pediatric cancer predisposition syndromes through genetic tumor testing and the role of molecular tumor boards (MTB)

Estela Carrasco López[1;2], *Marta Sese Faustino*[3], *Adrià López-Fernández*[1;2], *Anna Maria Cueto-González*[4], *Laura Trujillano*[4], *Berta Campos*[5], *Alejandro Moles-Fernandez*[5], *Elena Martinez Saez*[3], *Marta Garrido Pontnou*[3], *Rosa Somoza López de Haro*[3], *Raquel Hladun Alvaro*[6], *Lorena Valero Arrese*[6], *Constantino Sábado*[6], *Amaia Lasa-Aranzasti*[4], *Mara Cruellas*[1;2], *Aroa Soriano*[7], *Javier Hernandez Losa*[3], *Judith Balmaña*[1;2], *Lucas Moreno Martin Retortillo*[1]

[1]*Children's Hospital and Vall d'Hebron Women's Hospital, Medical Oncology, Barcelona, Spain;* [2]*VHIO Institut d'Oncologia, Medical oncology, Barcelona, Spain;* [3]*Vall d'Hebron University Hospital, Pathology Departament, Barcelona, Spain;* [4]*Vall d'Hebron University Hospital, Genetics, Barcelona, Spain;* [5]*Vall d'Hebron University Hospital, Genetic molecular, Barcelona, Spain;* [6]*Children's Hospital and Vall d'Hebron Women's Hospital, Pediatrics Oncology and Hematology, Barcelona, Spain;* [7]*VHIR - Vall d'Hebron Institut de Recerca, Pediatric Oncology Precision Medicine, Barcelona, Spain*

Background/Objectives: Identifying genetic variants in pediatric cancer predisposition syndromes (PCPS) is crucial for prognosis, treatment decisions and family counseling. Somatic tumor testing through NGS platforms and multidisciplinary MTBs in daily routine facilitate patient access to targeted therapies. The study's goal is to evaluate the role of somatic NGS testing and MTBs to identify potential PCPS.

Methods: Tumor genetic alterations in 170 pediatric cancer samples were assessed from november/21-december/23 with Oncomine Childhood Cancer Research Assay panel from ThermoFisher Scientific. After MTB review, pathogenic variants with a VAF ≥ 30% in a PCPS-associated gene were identified for further analysis through the Hereditary Plus OncoKitDx germline panel.

Results: Overall, 13.5% (23/170) of patients harbored a tumor genetic alteration potentially associated with a PCPS: *TP53 (10), DICER1 (2), SMARCB1 (2), PTEN (2), CDKN2A (1), NF1 (1), PTCH1 (1), RB1 (1), RET (1), TSC2 (1), WT1 (1)*. Among them, in 8 cases there were not possibility to test, and 15 underwent germline testing. Of those tested, 33% (5/15, 5/170, 3%) of cases tested were positive: *RB1* (1), *RET* (1) *TP53* (2 and 1 mosaicism). Cascade testing in relatives revealed de novo variants in 83% (5/6 cases). Parents or patients in reproductive ages received reproductive counseling.

Conclusion: Somatic genetic tumor testing identified almost 3% of patients with germline variants associated with PCPS in the absence of family history. MTB provide a multidisciplinary resource to cope with these findings and influence in their medical management.

Conflict of Interest: None declared

P23.039.A Enhancing the communication in genetic counseling: The impact of educational videos on doctor-patient relationship.

Sebastian Sailer[1], *Julia Mahal*[2], *Carlotta Mayer*[2], *Maja Hempel*[1], *Hannah Wallaschek*[3], *Johanna Tecklenburg*[4], *Melanie Wittenberg-Marangione*[3], *Christian Schaaf*[1], *Beate Ditzen*[2]

[1]*Heidelberg University Hospital, Institute of Human Genetics, Heidelberg, Germany;* [2]*Heidelberg University, Institute of Medical Psychology, Heidelberg, Germany;* [3]*Medizinische Hochschule Hannover, Institute of Human Genetics, Hannover, Germany;* [4]*Bioscientia Institut für med. Diagnostik GmbH, Ingelheim, Germany*

Background: The importance of genomic data in patients care procure an increasing need in genetic analysis. According to German law, informed consent must be obtained prior to genetic testing. Our study dives into using educational videos to aid and improve doctor-patient communication in genetic counseling.

Objectives: Develop topic-driven video sequences and assess their impact on patient satisfaction and doctor-patient relationship by providing upfront information.

Methods: We produced five animated, short educational videos. Topics covered: 'Genetic Consultation Process,' 'Informed Consent,' 'Breast Cancer,' 'Genome Sequencing,' and 'Face2Gene.' Subjects included patients with consultations for 1. suspected genetic susceptibility to breast cancer (BC) or 2. with syndromic conditions warranting exome sequencing (SYN). Participants were randomly assigned to either an experimental group, exposed pre-consultation to the videos at home, or a control group without video exposure. Post-consultation, an assessment of patients and doctors was conducted, to gauge satisfaction levels with the consultation process and quality of doctor-patient relationship.

Results: Patients rated the videos highly understandable and useful. Overall, no significant differences were shown in patient satisfaction and doctor-patient relationship between experimental and control group. However, the BC subgroup displayed increased satisfaction and physicians noted reduced workload. The SYN subgroup reported decreased satisfaction and a less positive doctor-patient relationship.

Conclusion: Our educational videos can improve patient satisfaction and relieve doctors' workload in standardized consultation settings such as predisposition to BC. However, in more complex consultations, like those involving patients with syndromic conditions, the individual doctor-patient conversation appears to take precedence.

Grants: German Federal Ministry of Health

P23.040.B Psychological impact of personalized breast cancer (BC) risk estimation and comparison of two results delivery models (PRiSma study)

Adrià López-Fernández[1], *Eduard Perez*[1], *Esther Darder*[2], *Consol Lopez*[3], *Adriana Bareas*[4], *Mireia Cartro*[5], *Guillermo Villacampa*[6], *Estela Carrasco López*[1], *Ariadna Roque*[2], *Rosa Alfonso*[3], *Ana Raquel Jimenez-Macedo*[7], *Mara Cruellas*[1], *Noemi Tuset*[8], *Monica Pardo*[9], *Maite Torres*[1], *Anna Vallmajo*[8], *Laura Duran-Lozano*[4], *Gemma Llort*[5], *Teresa Ramon y cajal*[3], *Joan Brunet*[2], *Judith Balmaña*[1]

[1]*Vall d'Hebron University Hospital, Medical Oncology, Barcelona, Spain;* [2]*Catalan Institute of Oncology, Hereditary Cancer Program, Girona, Spain;* [3]*Hospital Santa Creu i Sant Pau, Medical Oncology, Barcelona, Spain;* [4]*Vall d'Hebron Institute of Oncology, Hereditary Cancer Group, Barcelona, Spain;* [5]*Consorci Corporació Sanitària Parc*

Taulí, Medical Oncology, Sabadell, Spain; [6]Vall d'Hebron Institute of Oncology, Biostatistics Group, Barcelona, Spain; [7]Consorci Sanitari de Terrassa, Medical Oncology, Terrassa, Spain; [8]Hospital Universitari Arnau de Vilanova, Medical Oncology, Lleida, Spain; [9]Hospital del Mar, Medical Oncology, Barcelona, Spain

Background/Objectives: In women with a family history of BC without identified genetic alterations, the BOADICEA model estimates BC risk considering multiple factors. The objectives are: to (1) examine acceptance of personalized risk estimation disclosure, (2) investigate its psychological impact, (3) compare satisfaction between two results delivery methods.

Methods: Assessment of 10-year BC risk with BOADICEA model and classification as high, moderate, or average. Satisfaction, psychological impact (MICRA scale), cancer worry, and anxiety were assessed in all groups. Moderate and average risk women were randomly assigned to results disclosure in-person or by video.

Results: Out of 663 participants, 93% accepted results disclosure. Seven percent were high risk, 56% moderate, and 37% average. High-risk individuals had higher total MICRA scores compared to moderate and average (mean = 29, 16.7, 13.4, respectively,$p < 0.05$). Results were consistent in distress, positive experiences, and cancer worry. However, no significant differences were observed in uncertainty, anxiety, or perceived benefit.

In-person disclosure was associated with higher satisfaction (95% vs. 71%) and fulfillment of expectations (mean = 4.3 vs. 3.9) than video (all $p < 0.01$). Video disclosure resulted in higher total MICRA scores (mean = 17.7 vs. 13.2), distress and uncertainty, and lower positive experiences scores (all $p < 0.05$). No significant differences were found in cancer worry, anxiety or perceived benefit.

Conclusion: A high acceptance of personalized breast cancer risk estimation was observed, with higher psychological impact and cancer worry in high-risk individuals. In-person disclosure proved more satisfying and aligned with expectations than video delivery. However, video disclosure remains a viable approach to be considered for large-scale implementation.

P23.041.C Well-being and self-care strategies for cardiovascular genetic counsellors: a qualitative study

Laura Yeates[1;2;3], *Lucas Mitchell*[4;5], *Ivan Macciocca*[6;7], *Helen Mountain*[8;9], *Mary-Anne Young*[4;5], *Colleen Caleshu*[10], *Alison McEwen*[9], *Jodie Ingles*[1;3;11]

[1]Garvan Institute of Medical Research, Genomics and Inherited Disease Program, Sydney, Australia; [2]The University of Sydney, Faculty of Medicine and Health, Sydney, Australia; [3]Royal Prince Alfred Hospital, Cardiology Department, Sydney, Australia; [4]Garvan Institute of Medical Research, Clinical Translation and Engagement Platform, Sydney, Australia; [5]St Vincent's Healthcare Clinical Campus, School of Clinical Medicine, Sydney, Australia; [6]Victorian Clinical Genetics Service, Melbourne, Australia; [7]University of Melbourne, Melbourne, Australia; [8]Genetics Services of Western Australia, Perth, Australia; [9]University of Technology Sydney, Graduate School of Health, Sydney, Australia; [10]Genome Medical, United States; [11]University of New South Wales, UNSW Medicine and Health, Sydney, Australia

Background: Repeated exposure to challenging clinical situations impacts healthcare professionals' well-being. Genetic counsellors assist individuals to understand and adapt to difficult medical information, which often has implications for close family members. In the cardiac setting, managing families with profound grief and trauma following sudden cardiac death can be difficult, with potential for burnout and compassion fatigue.

Aim: To explore the impact of cardiovascular genetic counselling practice on genetic counsellor well-being and describe self-care practices.

Methods: Participants were recruited through the Australasian Society of Genetic Counsellors. Semi-structured interviews were conducted exploring challenges in cardiovascular genetic counselling practice, supervision and self-care. Interviews were recorded, transcribed and analysed using reflexive thematic analysis. Self-reported demographics, psychological well-being and burnout measures were collected.

Results: Eighteen genetic counsellors participated. Median interview length was 54 minutes (range 40-74). All participants were female and 83% of European ethnicity. Few reported mild or moderate depression (17%), mild or moderate anxiety (22%) and none (0%) had scores indicating stress. Three (17%) had scores indicating burnout. Thematic analysis identified three themes: (1) cardiac genetic counselling is different, not harder or easier; (2) workplace pressures affect well-being; (3) a self-care "tool kit" is necessary with supervision a key component.

Conclusion: Cardiovascular genetic counsellor practice and workload can affect well-being. Genetic counsellors have a self-care 'tool kit' that includes supervision, to help maintain well-being.

P23.042.D Tuning into British South Asian voices on health and genetics - a springboard for effective educational intervention.

Shwetha Ramachandrappa[1], *Robin Lerner*[2], *Shapna Hussain*[2], *Nishat Safa*[2]

[1]King's College London Guy's Campus, United Kingdom; [2]Queen Mary University of London, Blizard Institute, United Kingdom

Consortium: The Genes and Health research team

Background/Objectives: British South Asians have consistently been shown to have poorer health outcomes than other ethnic groups. Engagement with health services and with health research is poor. Low levels of health awareness are repeatedly cited as a critical modifiable factor within the British South Asian community. Having a detailed understanding of key knowledge gaps within the community will be foundational to the success of efforts to address health inequalities.

Methods: Semi structured interviews and focus groups were conducted with participants in the Genes and Health study, a large genetics research study which has recruited over 60K British South Asians in community settings.

Results: Even within this research aware subset of the community there was limited understanding of inheritance, little recognition of what DNA was, and minimal awareness of DNA as having an impact on health or disease. Moreover, it was clear that there was a degree of suspicion of individuals and institutions who offered scientifically derived explanations of these concepts. Views on sensitive issues, including termination of pregnancy and post mortem examination varied considerably, even amongst members of the same family.

Conclusion: This in-depth, real world account of health and genetic awareness within the British South Asian community will inform the development of an instrument measuring knowledge, ability to take on new information, and attitudes towards health and genetics. This has utility across community, clinical, and research settings in evaluating current information resources and directing future strategies towards improving health and genetic literacy within the community.

P23.043.A The DIANA study: Decisions, Information and Autonomy in Norwegian Antenatal Care

Andrea Fotland Krohn-Hansen[1], *Cathrine Bjorvatn*[1], *Ragnhild Sekse*[1], *Jörg Assmus*[2], *Henriette Karlsen*[3], *Ine Moen*[3], *Ida Sørensen*[1]

[1]*Haukeland University Hospital, Medical Genetics, Bergen, Norway;* [2]*Haukeland University Hospital, Centre for Clinical Research, Bergen, Norway;* [3]*Haukeland University Hospital, Women's Clinic, Bergen, Norway*

Background: In 2022, non-invasive prenatal testing (NIPT) became a part of publicly funded antenatal care for all Norwegian women aged 35 or older at term. Very little is known about Norwegian women's experiences with NIPT, and the quality of health care provided to them. The DIANA study aims to evaluate this.

Methods: Multidimensional Measure of Informed Choice (MMIC) includes three subscales (knowledge, attitude, test behavior) which are combined to determine whether an informed choice is made. The Decision Regret Scale (DRS) is a five-item scale measuring distress or remorse after health care decisions. In-depth interviews with women will provide qualitative insights into their experiences and attitudes towards the new NIPT-based screening program.

Pregnant women (over age 35) referred for routine antenatal care at the Women's Clinic at Haukeland University Hospital are invited to join the study and asked to complete the MMIC immediately and DRS after four weeks. We aim to recruit 500 women. In-depth interviews with women identified as high-risk on NIPT are carried out 1-2 months after results.

Results: As of February 2024, 437 have been invited to join the study, 167 have responded to MMIC, and 90 to DRS. Interviews with three women with high-risk NIPT results have been carried out.

Conclusion: The DIANA study will allow us to evaluate the new Norwegian NIPT program and will provide pregnant women with an opportunity to express opinions on NIPT, reproductive autonomy and to shape their antenatal healthcare.

P23.044.B Presenting personalized clinical information directly to parents via an interactive website – the Chromosome 6 Project

Eleana Rraku[1], *Tyler D. Medina*[1;2;3], *Aafke Engwerda*[1], *Morris Swertz*[1;2], *Lennart Johansson*[1;2], *Conny Van Ravenswaaij-Arts*[1;4], *Imke Christiaans*[1]

[1]*University of Groningen, University Medical Centre Groningen, Department of Genetics, Groningen, Netherlands;* [2]*University of Groningen, University Medical Centre Groningen, Genomics Coordination Centre, Groningen, Netherlands;* [3]*University of Galway, School of Mathematical and Statistical Sciences, Galway, Ireland;* [4]*Jonx/Lentis Psychiatric Institute, Autism Team Northern-Netherlands, Groningen, Netherlands*

Consortium: n/a

Background/Objectives: The scarcity of clinical information surrounding rare chromosome 6 disorders presents challenges for both parents and clinicians. The Chromosome 6 Project (C6P) addresses this information gap by collecting detailed genotype and phenotype data on affected individuals directly from parents. The C6P aims to provide comprehensive clinical information based on features seen in individuals with a similar aberration, directly to parents via an interactive website. With the involvement of stakeholders, we determined how clinical features can best be reported to parents via this website.

Methods: Using a Delphi method, a panel of 32 parents and 21 (healthcare) professionals was asked to complete a survey in three rounds, consisting of 13 statements on the reporting of certain feature categories. The aim was to reach consensus on the given statements, defined as 75% of the respondents providing the same answer.

Results: Consensus was reached on 12 statements. Most respondents agreed that features that impact health or well-being should always be reported, even when present in only one individual with a similar aberration. No type of feature should be omitted from the clinical overview according to parents, but a reporting threshold can be used for clinically non-relevant issues or feature sub-types. The prevalence of each feature should always be provided.

Conclusion: Parents would like to access as much information as possible about potential health issues associated with their child's aberration. When providing such information online, it is essential to include clear explanations and additional resources to ensure correct interpretation and maximize parental benefit.

Conflict of Interest: None declared

P23.045.C Engaging communities: a systematic review of community-based participatory research in international genetic services

Heather Zierhut[1], *Megan Kocher*[2], *Pranathi Kandikonda*[1], *Cameron Donarski*[1], *Emily Simon*[1], *Mariana Ramirez-Mantilla*[3], *Crystal Lumpkins*[4], *Elena Fisher*[1]

[1]*University of Minnesota, Genetics, Cell Biology, and Development, Minneapolis, United States;* [2]*University of Minnesota, Libraries, Minneapolis, United States;* [3]*The University Of Kansas Medical Center, Kansas City, United States;* [4]*University of Utah, Huntsman Cancer Institute, Salt Lake City, United States*

Background/Objectives: Genetic counseling (GC) services have the potential to improve health outcomes, yet there are documented disparities in the use of GC services amongst minoritized racial/ethnic populations. Community-based participatory research (CBPR) is a recommended approach to better integrate diverse patient perspectives to improve genetics service delivery. How CBPR is being used and ways to effectively incorporate the principles in genetics services is needed.

Methods: Five databases were searched for international articles published from 2006 to 2023. Articles in the review met the following inclusion criteria: 1) published in 2006 or later; 2) peer-reviewed publication; 3) primary research studies; 4) community-based and participatory research; 5) focused on research topics of GC, clinical genetics, testing, and genetic service delivery. Criteria for evaluating CBPR involvement used a synthesis of best processes framework including criteria for "Assessing Partnership Approaches to Improve Public Health" by Israel *et al*. 1998.

Results: Screening of 3,824 studies identified 16 papers (n = 12 qualitative; n = 1 quantitative; n = 3 mixed methods). Most studies were conducted within the U.S. (n = 12), focused on cancer (n = 5), involved the Asian/Pacific Islander community (n = 8), and centered around genetic education (n = 12) rather than counseling, testing, or service delivery. Seven studies involved the community partners/advisors in nearly all aspects of the research process.

Conclusion: Integration of CBPR is greatly needed within genetics and GC services research to engage diverse stakeholders, improve genetic services, and ultimately reduce health disparities in genetic services.

P23.046.D View of healthcare professionals on ultra-rapid genome sequencing and its implementation in clinical routine for critically ill children

*Claire Caillot[1], Etienne JAVOUHEY[2], Stephane Hays[3], Evan Gouy[1], Pauline MONIN[1], Gaetan Lesca[1;4], **Damien Sanlaville**[1;4], Nicolas Chatron[1;4]*

[1]Hospices Civils de Lyon, Service de génétique, Lyon, France; [2]Hospices Civils de Lyon, Service d'urgences et de réanimation pédiatriques, Hôpital Femme Mère Enfant, Lyon, France; [3]Hospices Civils de Lyon, Service de néonatologie et de réanimation néonatale, Hôpital de la Croix-Rousse, Lyon, France; [4]Université Lyon 1, Institut Neuromyogène, Laboratoire Physiopathologie et Génétique du Neurone et du Muscle, Equipe Métabolisme énergétique et développement neuronal, CNRS UMR 5310, INSERM U1217, Lyon, France

Background/Objectives: The clinical utility of ultra-rapid genome sequencing (urGS) in neonatal and paediatric intensive care situations has been demonstrated, and barriers to its implementation in clinical practice studied. We carried out the first study to identify the expectations of French healthcare professionals concerned by this test.

Methods: A questionnaire with 38 questions was developed and distributed via medical professional learned societies to these healthcare professionals.

Results: A total of 116 complete responses were received, including 35% from clinical geneticists, 19% from laboratory geneticists, and 32% from paediatric or neonatal intensivists. 97% respondents agreed that healthcare professionals should receive specific training before a first prescription. 94% of professionals considered urGS useful, and 97% that the result would likely modify a decision to withdraw life-sustaining treatment. A multidisciplinary validation of the urGS request was necessary for 87% of respondents, and multidisciplinary discussion of the result for 84%. Joint reporting of results by a clinical geneticist and NICU/PICU doctor was considered ideal for 91% of participants. 78% were against additional findings being reported at the same time as the result. Almost all respondents (99%) thought that psychological assistance was crucial after the result.

Conclusion: We propose a workflow based on the consensus elements emerging from the expressed views of the different implicated medical health care professionals.

P23.048.B Patients' experiences of being recontacted with new clinical information in a clinical genetics setting

Tiffany O'Brien[1;2], *Katrina Monohan[1;2], Anishka Abeysinghe[1;3], Chloe Pike[4], Laura Forrest[1;2;3]*

[1]Peter MacCallum Cancer Centre, Parkville Familial Cancer Centre, Melbourne, Australia; [2]The Royal Melbourne Hospital, Parkville Familial Cancer Centre & Genomic Medicine, Parkville, Australia; [3]The University of Melbourne, Sir Peter MacCallum Department of Oncology, Parkville, Australia; [4]University of Technology Sydney, Graduate School of Health, Chippendale, Australia

Background/Objectives: In 2019, evidence confirmed ovarian cancer was associated with germline *PALB2* pathogenic variants. This prompted the need for clinical genetics services to recontact women who had previously been identified with a *PALB2* PV and informed only of the breast cancer risk. This research aims to examine the experience of women recontacted by the Parkville Familial Cancer Centre (PFCC), their uptake of risk reducing surgery, and clinical and psychosocial outcomes.

Methods: A sequential mixed-methods design was used to collect data and included a clinical audit, patient survey and semi-structured interviews. Descriptive analyses were undertaken for quantitative measures and deductive thematic analysis for qualitative data.

Results: Of 95 women who were recontacted, 57 (60%) were within the age recommended for BSO: 31 (54%) had a BSO, 12 (21%) had not, and the remaining 14 (25%) were unclear. Fifteen (16%) made further contact with the PFCC, with nine patients requesting a follow-up appointment. Forty-one (43%) completed the survey with 23 (56%) feeling there should be an ongoing relationship with the PFCC and 32 (78%) felt it was the genetic health professional's responsibility to keep them up-to-date with new information. Nineteen were interviewed with most expressing an eagerness to be recontacted with new information and some expected that the genetics service would keep them up-to-date. The majority did not experience being recontacted negatively and felt the mode of recontact was appropriate.

Conclusion: Being recontacted by the PFCC aligned with women's expectations that clinical genetics services are responsible for informing patients of new clinical cancer risk information.

Conflict of Interest: None declared

P23.049.C Getting hospital executives and clinicians on the same page: sparking conversations about hospital-wide implementation of genomics.

*Cate Kelly[1;2], Katie Arkell[1;3], Trang Do[3], Melissa Martyn[1;3;4], Belinda McClaren[3;4], **Clara Gaff**[1;3;4]*

[1]Melbourne Genomics Health Alliance, Parkville, Australia; [2]The University of Melbourne, Department of Medicine (RMH), Melbourne, Australia; [3]Murdoch Children's Research Institute, Parkville, Australia; [4]The University of Melbourne, Department of Paediatrics, Melbourne, Australia

Background/Objectives: Genomic medicine is increasingly being provided in specialist services outside of traditional clinical genetics. Yet national genomic strategies do not address the hospital-wide changes needed. Clinical services wishing to use genomics need support to get meaningful engagement and traction with busy hospital decision-makers/executives. A recent scoping review did not identify any frameworks to guide safe, effective use of genomics at a hospital level. We aimed to determine how hospitals can be supported to optimally implement genomic medicine across diverse clinical services.

Methods: Drawing on the Knowledge to Action framework, we conducted an iterative design process with hospital executives and subject matter experts. A multidisciplinary group (with hospital governance, genetic counselling, implementation science and evaluation expertise) synthesised common clinical governance frameworks to design novel tools for hospitals to self-assess their maturity in genomic medicine and guide implementation. Following iteration at a workshop of hospital stakeholders (n = 29), we tested its useability at five metropolitan and regional hospitals.

Results: Testing showed clinician innovators and executives lacked a common language to discuss genomics; one is now evolving. Executives found assessing maturity challenging as genomics expertise is in pockets; spreading expertise beyond specific clinical areas within a hospital was raised by participants. Challenges identified included managing unwarranted variation and understanding the value of genomic medicine interventions.

Conclusion: The suite of tools we developed fills the gap between overarching health system-focussed genomic maturity models and the detailed evidence needed to guide clinical services. Importantly, and unexpectedly, a major benefit already is productive dialogue between executives and clinicians.

P23.050.D Co-designing Clinical Educational Resources and National Guidelines to Address Inequity of Access to Rare Disease Care in Australia

Lauren McKnight[1], Natalie Roberts[1], Krista Recsei[1], Chinthaka Balasooriya[1], Michelle Farrar[1;2], Nicole Millis[3], Louise Healy[3], Gareth Baynam[4;5], Sian Gannon[4], Elizabeth Lissiman[6], Yvonne Zurynski[7], Adam Jaffe[1;2], **Elizabeth Palmer**[1;2]

[1]UNSW Sydney, Medicine and Health, Sydney, Australia; [2]Sydney Children's Hospitals Network Randwick, Sydney, Australia; [3]Rare Voices Australia, Melbourne, Australia; [4]Rare Care Clinical Centre of Expertise for Rare and Undiagnosed Diseases, Perth Children's Hospital, Perth, Australia; [5]Western Australian Register of Developmental Anomalies and Genetic Services of WA, Perth, Australia; [6]Western Obstetrics, Balcatta, Australia; [7]Australian Institute of Health Innovation, Macquarie University, Sydney, Australia

Consortium: RArEST consortium

Background/Objectives: The 2021 UN Resolution *Addressing the Challenges of Persons Living with a Rare Disease and their Families* highlights that the >300 million people living with rare disease (RD), >70% of which are of genetic origin, face common challenges including inequitable access to evidence-based integrated care.

The Rare Disease Awareness, Education, Support, and Training (RArEST) Project, a 3-year partnership between the national peak body for Australians living with a RD, Rare Voices Australia, clinicians, and researchers, aims to support the implementation of the Australian Government's National Strategic Action Plan for RD and includes a clinical educational stream.

Methods: Multistakeholder consultations in the clinical educational stream included a learning needs analysis survey (n = 183 health professionals), mixed-methods consultation (n = 12 people living with RD and n = 18 multidisciplinary clinical working group), and health professional evaluation surveys.

Results: The consultation informed the co-production of (i) a suite of multi-modal rare disease educational resources (ii) the establishment of a multidisciplinary clinical community of RD practice (Rare Disease ECHO®) and (iii) the first National Recommendations for RD Health Care, launched in the Australian National Parliament in 2024. Resources are endorsed by national clinical professional bodies and accredited for continuing professional development.

Conclusion: Feedback from endorsing organisations and people living with RD was overwhelmingly positive, demonstrating the value of co-production to deliver educational resources that support a more equitable, person-centred, evidence-based, and integrated model of RD care aligning with the needs and preferences of people living with RD.

P23.051.A Approach to pathological ultrasound findings and invasive diagnostic test results: Istanbul experience

MELDA ERDOGDU[1], *Tugba Kalayci[2], Tuğba Saraç Sivrikoz[3], Ayça Dilruba aslanger[2], Gülhanım Memiş[2], Birsen Karaman[2;4]*

[1]Istanbul University, Institute of Aziz Sancar Experimental Medicine (ASDETAE), Department of Genetics, Fatih, Türkyie; [2]Istanbul University, Istanbul Faculty of Medicine, Department of Medical Genetic, İstanbul, Türkyie; [3]Istanbul University, Istanbul Faculty of Medicine, Department of Obstetrics and Gynecology, Division of Perinatology, İstanbul, Türkyie; [4]Istanbul University, Child Health Institute, Pediatric Basic Science, Medical Genetic Division, İstanbul, Türkyie

Background/Objectives: There are social differences in the approach to prenatal testing and test results. In this study, we aimed to evaluate the attitudes of families who were offered the option of termination based on the results of prenatal invasive diagnostic tests or because of an unfavorable perinatal prognosis and the factors influencing their decision-making.

Methods: Face-to-face interviews were conducted with 280 families referred for fetal ultrasound abnormalities. Of the 217 families who agreed to participate in the survey, 147 underwent at least one of the invasive prenatal diagnostic tests (transabdominal chorionic villus biopsy, amniocentesis, and fetal blood sampling). Karyotype analysis, fluorescence in-situ hybridization (FISH), and array-CGH studies were performed.

Results: A chromosomal abnormality was detected in 21 (14.2%) of 147 families who underwent invasive prenatal diagnostic testing. While 15 (71.4%) of the anomalies were numerical, 6 (28.6%) were structural anomalies. Of the 70 families who were offered the option of termination according to the invasive prenatal diagnostic test results and/or because of unfavorable perinatal prognosis, 64 (91.4%) decided to terminate the pregnancy. The most influential factor in the decision to

continue the pregnancy was 'religious reasons'. In contrast, the most influential factor in the decision to terminate the pregnancy was 'information received from doctors/midwives/nurses.'

Conclusion: Awareness and use of prenatal invasive diagnostic tests and attitudes towards termination of pregnancy vary between countries depending on socio-economic, cultural, educational and religious characteristics.

Grants: This project was supported by the Istanbul University Scientific Research Projects (BAP) project no: TYL-2023-39547.

P23.053.C A post-natal diagnosis of X-linked centronuclear myopathy: The importance of genetic counselling after reproductive carrier screening

Melissa Graetz[1], *Renee Dow*[1], *Lilian Downie*[1;2]

[1]*Mercy Hospital for Women, Genetics, Heidelberg, Australia;* [2]*Victorian Clinical Genetics Service, Murdoch Children's Research Institute, Parkville, Australia*

Background/Objectives: To highlight the importance of education and infrastructure for high risk results in screening programs. This case report demonstrates how essential education and support is for clinicians ordering reproductive carrier screening (RCS). It also emphasises the importance of genetic counselling and ongoing access to a genetics service for families identified as high risk after RCS.

Methods: This case report describes the postnatal diagnosis of X-linked centronuclear myopathy in a newborn male despite a high-risk carrier RCS result previously reported for the family. A male infant born prematurely at 30 weeks gestation with severe hypotonia requiring invasive respiratory support was referred to genetics. The family had a healthy 18 month old daughter. Clinical evaluation, chromosome microarray, spinal muscular atrophy screening and a targeted exome were arranged. Initially the mother disclosed no family history or RCS, but subsequently recalled having RCS in her first pregnancy. RCS had been arranged privately in her first pregnancy and she was not referred to a genetics service at time as her baby was female.

Results: A maternally inherited pathogenic variant in the *MTM1* gene associated with X-linked centronuclear myopathy was confirmed. Palliative care was offered and the infant died at 28 days of life. Genetic counselling resulted in referral to an IVF service and feedback to the private obstetrician and RCS provider.

Conclusion: Access to genetic counselling is essential as access to RCS increases. RCS reports need to be clear and concise, referral pathways readily available and education mandatory for clinicians ordering RCS.

Conflict of Interest: None declared

P23.054.D References to genetic testing in clinical guidelines

Anna Rehhahn[1], *Jörg Schmidtke*[2;3]

[1]*Hannover Medical School, Center for Rare Diseases, Hannover, Germany;* [2]*amedes MVZ wagnerstibbe, Hannover, Germany;* [3]*Hannover Medical School, Institute of Human Genetics, Hannover, Germany*

Background/Objectives: Genetic tests may confirm a suspected clinical diagnosis, accelerate the diagnostic process and influence prognosis and therapy, and hence are becoming an increasingly important part of diagnostic strategies in everyday clinical practice. Referrals to or consultations with a clinical geneticist are often not feasible due to limited resources. It has, however, not been systematically assessed, whether or not clinical guidelines themselves provide sufficient information to a clinician on which genetic tests to order in a particular clinical context.

Methods: In a first step, clinical guidelines published by the German Association of Scientific Medical Societies (AWMF) were examined for recommendations on genetic testing using a systematic and software-supported keyword search. Each finding was assessed for its relevance using a scoring model with 18 categories. We currently assess international clinical guidelines using the same methodological approach.

Results: Of the 563 currently valid AWMF clinical guidelines, covering well over 500 different disease groups, 200 (36%) recognize a genetic component in disease etiology, 75 of these broadly recommend genetic testing, 54 of these provide specific justifications for genetic testing, but only 9 contain enough information that would inform the clinician to directly order a genetic test.

Conclusion: The results indicate that the clinical relevance of genetics in everyday clinical practice is well recognized, but that the clinical-scientific societies are rarely sufficiently specific to provide a clinician with information that would empower him or her to order genetic tests directly.

P23.055.A X-linked Alport syndrome, UPD(X)pat and Ullrich-Turner mosaicism – solving a pedigree puzzle

Svenja Vishnolia[1], *Berenike Bögeholz*[1], *Loukas Argyriou*[1], *Silke Kaulfuß*[1], *Peter Burfeind*[1], *Alexandr Kuranov*[1], *Silke Pauli*[1], *Uwe Kornak*[1]

[1]*University Medical Center Göttingen, Institute of Human Genetics, Germany*

Background/Objectives: In a family with X-linked Alport syndrome, segregation analysis of at-risk family members presented us with a puzzle. Next generation sequencing (NGS) in a female patient, daughter of father carrying a pathogenic *COL4A5* variant hemizygous and a non-carrier mother, showed homozygosity for the known *COL4A5* variant. Possible causes were maternal sample mix-up, monosomy X (Ullrich-Turner syndrome) and paternal isodisomy of the X chromosome (UPD(X)pat). A step-by-step investigation was performed.

Methods: The tests that led to the correct diagnosis included NGS-based *COL4A5* analysis to genotype the mother, multiplex ligation probe amplification (MLPA) of *COL4A5* and *SHOX*, chromosomal analysis to test for monosomy X, and a SNP array to investigate UPD(X)pat.

Results: Initially, repeated sequencing of the mother confirmed her non-carrier status. However, MLPA of *COL4A5* and *SHOX* showed no abnormality consistent with an XX karyotype, leaving us with a puzzling pedigree. To rule out monosomy X completely using a second method, chromosome analysis revealed monosomy X mosaicism with 19% of cells affected. As this degree of mosaicism contradicted the unambiguous NGS results, a SNP array was performed and confirmed UPD(X)pat.

Conclusion: We present a healthy female patient carrying a homozygous pathogenic *COL4A5* variant due to UPD(X)pat combined with 19% monosomy X mosaicism. We hypothesise that the underlying mechanism is post-zygotic monosomy rescue of a monosomy X zygote. This unique case shows that it is often only the combination of different methods and the use of second methods to compensate for methodological limitations that can provide a complete picture.

P23.057.C Extending the known clinical spectrum of IPEX syndrome with a case report of a mildly affected young man

Berenike Bögeholz[1], *Alexandr Kuranov*[1], *Silke Kaulfuß*[1], *Silke Pauli*[1]

[1]*University of Göttingen, Universitätsmedizin Göttingen, Institut für Humangenetik, Göttingen, Germany*

Background/Objectives: Our patient, a 29-year-old young man, suffered from steroid-sensitive recurrent nephrotic syndrome with more than 20 relapses and first manifestation at the age of about 6 years. Specialists diagnosed the patient with focal segmental glomerulosclerosis (FSGS). According to the patient's parents, the patient did not show any particular susceptibility to infections; only atopic eczema had been observed repeatedly. During periods of stress, there were recurrent episodes of unexplained intestinal symptoms, intermittently accompanied by elevated body temperature.

Methods: Whole exome sequencing was performed for a suspected inherited kidney disease.

Results: Coincidentally, a pathogenic variant in *FOXP3* was identified. This variant had previously been described in patients with IPEX syndrome. In our case, the variant was inherited from a healthy mother. IPEX syndrome is a rare x-linked monogenic disorder of immune regulation. Pathogenic variants in the *FOXP3* gene have been identified to cause loss of regulatory T cell function. Dysfunction of the immune system leads to autoimmune and/or inflammatory diseases. The prognosis is very poor. Affected boys usually die in early childhood. They present with a triad of enteropathy, dermatitis and autoimmune endocrinopathy, typically diabetes type 1 or thyroiditis.

Conclusions: The case of the mildly affected young man who was diagnosed as an adult shows that the clinical spectrum of the IPEX syndrome is not yet fully understood. Many cases can be misdiagnosed, in our case as FSGS. However, it is important to note that primary immunodeficiencies can be the cause of many inconclusive cases with atypical symptoms.

P23.058.D The challenges of pre-symptomatic testing for late-onset neurological diseases: lessons learned from over 25 years of practice.

Milena Paneque[1;2;3], *Álvaro Mendes*[1;2], *Joana Damásio*[1;2;4], *Susana Lêdo*[1;2;5], *Jorge Sequeiros*[1;2;3], **João Parente Freixo**[1]

[1]*CGPP – Centre for Predictive and Preventive Genetics, IBMC – Institute for Molecular and Cell Biology, Univ. Porto, Portugal, Porto, Portugal;* [2]*UnIGENe, i3S – Instituto de Investigação e Inovação em Saúde, Univ. Porto, Portugal, Porto, Portugal;* [3]*ICBAS School of Medicine and Biomedical Sciences, Univ. Porto, Portugal, Porto, Portugal;* [4]*Serviço de Neurologia, Hospital de Santo António, Unidade Local de Saúde de Santo António, Porto, Portugal;* [5]*Instituto Universitário de Ciências da Saúde, CESPU, Gandra, Portugal, Porto, Portugal*

A program for genetic counselling (GC) and pre-symptomatic testing (PST) for late-onset neurological diseases (LONDs) was initiated in 1995, beginning with Machado Joseph disease (MJD), and later including Huntington disease (HD) and hereditary amyloidosis (ATTRh), all with high relative prevalence in Portugal.

This work aimed at outlining the challenges encountered in GC and PST for LONDs after over 25-years' practice at our outpatient genetics clinic.

We conducted a retrospective analysis of clinical records from 1,653 consultands seeking PST for a LOND since 1995. We reflected on the main challenges faced; effective means of supporting affected families; and the evolution of the program over time.

Psychosocial "catastrophic events" were extremely rare. Levels of depression and anxiety tended to decrease, while overall well-being improved. The finding of atypical, later-onset cases of ATTRh resulted in delayed diagnosis of probands and challenged PST within affected families. Conversely, the availability of clinical trials and new therapeutical options for ATTRh increased PST requests among younger individuals at risk. Uptake of PST also enabled several pre-natal diagnoses (PND) in LONDs. Notably, several young couples sought simultaneous PST and PND, which was a major challenge for GC.

As a consequence of the results, we simplified our protocol for GC and psychosocial assessment and support for consultands. Additionally, we propose further research into intra-familial communication of genetic-risk information and decision-making regarding PST. These insights may be applicable to other contexts, emphasizing the importance of continuous education for health-care professionals and ongoing improvement in quality of genetics services'.

Background/Objectives: The ESHG-Young (ESHG-Y) Committee stands at the forefront of representing and advancing young researchers and specialists in Human Genetics across Europe, by fostering connections and spearheading educational and professional development initiatives.

Methods: ESHG-Y representatives, as members of the ESHG Scientific Programme Committee (SPC), help in developing platform and plenary sessions. Our board members have also been representing and helping in Educomm and ERN-Ithaca activities. Additionally, we collaborate with African Society of Human Genetics (AfSHG), American Society of Human Genetics (ASHG), Human Genetics Society of Australasia (HGSA) and Junge Humangenetik.

Results: In 2023, the ESHG-Y organized six symposia, two educational sessions, and a workshop at the ESHG Annual Conference. Furthermore, the ESHG-Y was instrumental in organizing the Eurodysmorpho annual meeting and a forthcoming webinar on Non-Invasive Fetal Autopsy in collaboration with ERN-Ithaca. The committee's dedication resulted in an

enhanced presence in ESHG subcommittees, ASHG and HGSA working committees, and increased visibility through active participation in the ESHG social media team. Collaboration with the AfSHG through the Young Investigators Forum (YIF) led to the organization of a manuscript writing webinar, drawing on the knowledge of experienced professors. A landmark achievement was the publication of the YIF manuscript in the European Journal of Human Genetics, a significant contribution to the field. Additionally, the committee conducted a survey through its newsletter, targeting the need and presence of national Young Genetics Societies.

Conclusion: The ESHG-Y Committee's commitment to initiating innovative projects and nurturing international collaborations continues to support and develop the future leaders in Human Genetics.

Grants: ESHG Support

P23.060.B Worldwide perspectives on genetic counselling supervision: an in-depth exploration of implementation strategies, Global practices and future directions across continents

Lídia Guimarães[1;2;3], *Bibiana Ribeiro*[3], *Mariangels Ferrer*[4], *Margarida Rangel Henriques*[5;6], *Marina Lemos*[5;6], *Milena Paneque*[1;2;3;7]

[1]*i3S - Institute for Research and Innovation in Health. University of Porto, Porto, Portugal;* [2]*CGPP - Center for Predictive and Preventive Genetics. University of Porto, Porto, Portugal;* [3]*ICBAS. School of Medicine and Biomedical Sciences, University of Porto, Porto, Portugal, Porto, Portugal;* [4]*Faculty of Biology, Medicine, and Health, University of Manchester, Manchester, United Kingdom;* [5]*FPCEUP - Faculty of Psychology and Educational Sciences. University of Porto, Porto, Portugal;* [6]*CPUP - Center of Psychology. University of Porto, Porto, Portugal;* [7]*IBMC - Institute of Molecular and Cellular Biology. University of Porto, Porto, Portugal*

Background/Objectives: Genetic Counselling Supervision (GCS) plays a crucial role in ensuring the quality and effectiveness of genetic counselling services worldwide. This research conducts a comprehensive investigation into the global situation of GCS practices, engaging key stakeholders who have been instrumental in both successfully establishing GCS and actively advocating for its integration as a routine of genetics healthcare.

Methods: The study spans diverse geographic regions, with representatives from each continent sharing valuable insights. Key inquiries focus on the following aspects: (1) existence of GCS in the countries represented by the interviewees, providing a snapshot of the current global distribution of GCS; (2) format characteristics: frequency, mandatory nature of supervision, funding mechanisms and possible regulation; (3) implementation processes: providing detailed accounts of how the implementation process of GCS unfolded in their respective countries, offering insights into successful strategies and challenges for countries where GCS is still not available.

Results: The on-going research has involved professionals representing nine countries: Greece, Romania, Austria, Brazil, Spain, India, Iceland, Germany, and Malta. The outcomes, explored via thematic analysis, suggest a progressive awareness and acceptance of GCS. Notably, the predominant strategy identified is the early initiation of GCS, establishing it as a regular practice for junior professionals.

Conclusion: These findings underscore a promising shift towards heightened awareness and incorporation of GCS as a routine and contribute valuable knowledge for policymakers, healthcare professionals, and genetic counsellors, offering a starting point for informed decision-making, collaborative efforts, and the advancement of GCS practices on an international scale.

P23.061.C The role of genetic counsellors in rare disease registries

Kathrin Taxer[1], *Georg Göbel*[2], *Gunda Schwaninger*[1], *Johannes Zschocke*[1]

[1]*Medical University of Innsbruck, Institute of Human Genetics, Innsbruck, Austria;* [2]*Medical University of Innsbruck, Institute of Medical Statistics and Informatics, Innsbruck, Austria*

Background/Objectives: Rare diseases affect approximately 350 million people globally with a prevalence of less than 1 in 2000 and present challenges in both diagnosis and treatment. Registries play a crucial role in advancing comprehension, research, and patient outcomes. Genetic Counsellors, as integral members of registry teams, can significantly enhance the efficacy of these registries.

Methods: A qualitative study approach involved conducting semi-structured interviews with stakeholders in rare disease clinics, including physicians specializing in rare diseases and patient representatives. The participants were queried about their expectations regarding a registry. Data was analyzed through a six-step thematic analysis process. Subsequently, attention was directed towards identifying specific tasks that Genetic Counsellors could undertake in the operations of registries.

Results: Stakeholders acknowledged the value of rare disease registries, underscoring advantages in study participation, epidemiological data, and research opportunities. Genetic Counsellors have the potential to optimize team efficiency, emerging as contributors who play a vital role in educating stakeholders, guiding discussions on informed consent, overseeing data management, and maintaining connections with patient advocates. This active engagement addresses operational challenges and ensures that the registry becomes a collaborative, patient-centered initiative with broad inclusivity and impact within the rare disease community.

Conclusion: Genetic Counsellors can significantly contribute to the success of rare disease registries by bridging the gap between the medical, scientific, and patient communities. Their expertise in genetics, communication, and patient interaction positions them as valuable team members, ensuring an effective, ethically sound, and patient-centered approach for the organization of rare disease registries.

Grants: No external grants were utilized for this project.

Background/Objectives: Advances in human genetics research rely heavily on international collaborations. However, most of the genetic studies in Europe are Eurocentric. Here, we present a story of a successful bottom-up intracontinental collaboration of young geneticists representing the European Society of Human Genetics - Young Committee (ESHG-Y) and the African Society of Human Genetics Young Investigator Forum (AfSHG-YIF).

Methods: Our collaboration started in 2022 during the International Federation of Human Genetics Meeting in Austria. This led to the organization of a successful YIF Meeting on February 21, 2023, at the University of Cape Town as a preceding event to the 14th International Congress of Human Genetics (ICHG) in 2023.

Results: The YIF meeting, our first event in person, gathered 143 participants from 28 countries, with a majority (112 participants) from Africa. The program included six sessions covering various topics: medical genetics, molecular diagnostics, cancer genetics and genomics, pharmacogenomics, genetic therapies, genetic counseling, and population genetics. Following our first successful meeting, we extended our collaboration to organize online training courses. An online grant writing workshop and a two-day training webinar on manuscript writing were jointly organized in January and June 2023, with several experienced professors as trainers. Currently, we are preparing a webinar on functional genomics in collaboration with The Jackson Laboratory (JAX).

Conclusion: Through collaborative efforts, young generations are organizing various intercontinental educational resources, fostering unity and enriching a new generation of individuals passionate about genetics.

P23.063.A Analysis of intrafamilial communication degree and its influencing factors in patients with hereditary cancer predisposition syndromes

Lorena Moreno[1], *Elia Grau Garces*[1], *Fernando Yelamo*[1], *Aurora Sánchez Díaz*[2], *Clara López Solà*[3], *Ines Martin Villalba*[3], *Teresa Ocaña*[1], *Adela Rodriguez*[4], *Aleix Prat*[4], *Francesc Balaguer*[1]

[1]*Hospital Clínic Barcelona, Gastroenterology, Barcelona, Spain;* [2]*Hospital Clínic Barcelona, Biochemistry and Molecular Genetics, Barcelona, Spain;* [3]*Hospital Clínic Barcelona, Psychiatry and Clinical Psychology, Barcelona, Spain;* [4]*Hospital Clínic Barcelona, Medical Oncology, Barcelona, Spain*

Background/Objectives: When a germline mutation is identified, it's important to communicate this information to at-risk family members. This communication does not always occur, and several influencing factors have been described. The aim of our study is to analyze the communication level and the factors which may influence it.

Methods: In this retrospective study, 115 families with pathogenic or probably-pathogenic variants in hereditary cancer genes diagnosed between 2008-2021 were included.

Results: Participation rate stood at 62.61%. Seventy-nine percent of participants had explained information about the genetic variant to all at-risk family members, while 20.4% had not informed at least one family member. The degree of closeness between the proband and the at-risk family member was the only factor showing statistically significant differences ($p = 0.02$).

The main facilitators of communication were family support (48.3%), considering oneself a communicative person (34.5%), and genetic counselling (17.2%).

The primary reasons for not communicating included: no contact (50%), the family member being a minor (16.6%), not knowing how to communicate (16.6%), and believing the family member does not want to know (16.6%).

Seventy-six percent would accept the option for genetic counsellors to directly contact family members to convey this information to them, especially in cases where the patient faces obstacles in fulfilling this role.

Conclusion: These findings suggest a high level of intrafamilial communication. The closeness degree is the factor significantly influencing it.

Family support, considering oneself communicative, and genetic counselling have aided communication.

The option for genetic counsellors to directly inform family members, particularly when communication is challenging, is highly accepted.

P23.064.B Advancing Biobanking in Europe to foster Genomic Medicine

Manuela Pausan[1], *Saba Abdulghani*[1], *Petr Holub*[1], *Michaela Mayrhofer*[1], *Jana Pavlic-Zupanc*[1], *Eleanor Shember*[1], *Thomas Steger*[1], *Andrea Wutte*[1], **Jens Habermann**[1]

[1]*BBMRI-ERIC, Graz, Austria*

Consortium: On behalf of the BBMRI-ERIC community

Background/Objectives: BBMRI-ERIC is the European research infrastructure for biobanking and biomolecular resources. BBMRI has been granted ERIC-status by the EC in 2013. Currently, 24 countries and the World Health Organisation's International Agency for Research on Cancer constitute with its National Nodes and affiliated biobanks BBMRI-ERIC as one of the largest infrastructures in health and life sciences. BBMRI-ERIC's mission is to facilitate access to sample, data, and biomolecular resources to enable high-quality research, particularly personalized medicine.

Methods/Results: This is facilitated through services and advancements in the areas of Ethical, Legal and Societal Implications, Quality Management, Information Technology, Biobank Development, Public Affairs, Outreach, Education & Communications, and Finance- and Project Management. Hereby, BBMRI-ERIC engages its community and partners in more than 24 active EU projects fostering different domains towards genomic medicine including e.g. rare diseases, cancer, pediatrics, and infectious diseases. Our federated access and analysis platform has not only become a strong asset for major EU initiatives (e.g., EHDS, GDI, EUCAIM) but helps scientists and clinicians to accelerate their genomic medicine research: BBMRI's fully GDPR-compliant pipeline enables access to samples and data of over 5.1 Mio. patients facilitated by over 400 biobanks across 32 countries. The data comprise 7,834 distinct OMOP variables with biochemical measurements plus different types of OMICs data including e.g., over 200,000 genomes.

Conclusion: We will showcase how to access and make use of the richness of BBMRI-ERIC's resources and how to collaborate with our wider community on different topics through in-house or EU funding to foster genomic medicine.

P23.065.C Internal data plays a crucial role in variant classification: a *MYH7 VUS* reclassification

Ana Patrícia Jesus[1], *Rafael Graça*[1], *Diana Antunes*[1;2;3], *Catarina Silveira*[1], *Yuri Chiodo*[1], *Maria Carmo-Fonseca*[4]

[1]*GenoMed - Diagnósticos de Medicina Molecular, S.A, Lisboa, Portugal;* [2]*Santa Marta Hospital, Lisboa, Portugal;* [3]*Dona Estefânia Hospital, Lisboa, Portugal;* [4]*Instituto de Medicina Molecular (IMM), Lisboa, Portugal*

Background/Objectives: The ultimate goal of genetic testing in inherited cardiomyopathies is to improve patient outcomes. The American College of Medical Genetics and Genomics and the Association for Molecular Pathology (ACMG/AMP) published general guidelines for the classification of genetic variants (2015), which comprises both laboratory-based and clinical evidence, but fails to encompass some specificities of certain diseases, namely cardiomyopathies. To tackle this, specific classification guidelines for *MYH7* were published by the ClinGen's Inherited Cardiomyopathy Variant Curation Expert Panel (VCEP), in 2018.

Methods: Reclassification of a *MYH7* gene variant c.5342G>A, p.(Arg1781His), found in individuals with hypertrophic cardiomyopathy, which the VCEP classifies as a variant of uncertain significance (VUS) (ACMG/ClinGen *MYH7* 2018: PS4_Moderate, PM2, PP3).

Results: With our internal data (6 families), and following the specific *MYH7* guidelines, we were able to increase the strength of the PS4 criteria to strong, thus reclassifying this variant as likely pathogenic (ACMG/ClinGen *MYH7* 2018: PS4, PM2, PP3). The clinicians of patients testing positive for this variant were informed about its reclassification, so that direct relatives could be screened. Variant segregation among families with affected members is another interesting information that can be used to reclassify a VUS to likely pathogenic.

Conclusion: This case highlights the importance of internal records and data sharing in variant classification and interpretation. Moreover, sharing this data in proper platforms can help diagnostic laboratories to make a better variant pathogenicity assessment and, thus, provide the chance for patients and their family members to have better genetic counselling.

Grants:

Conflict of Interest: None declared

P23.066.D Variant reclassification and clinical implications

Nicola Walsh[1], *Aislinn Cooper*[2], *Adrian Dockery*[2], *James O'Byrne*[3]

[1]*Children's Health Ireland (CHI) at Crumlin, Department of Clinical Genetics, Dublin, Ireland;* [2]*Mater Misericordiae University Hospital, Next Generation Sequencing Lab, Dublin, Ireland;* [3]*Mater Misericordiae University Hospital, National Centre for Inherited Metabolic Disorders, Dublin, Ireland*

Background/Objectives: Accurate molecular genetic diagnoses are important in genomic medicine. Variant classification (benign – pathogenic), is fundamental to these tests. Variant reclassification is the process of reassigning the pathogenicity of variants over time that challenges diagnostic legitimacy. With the mainstreaming of genetic testing and increasing use of Next Generation Sequencing (NGS) for clinical diagnosis, variant reclassification is becoming an issue within clinical genetics. This review explores the medical and scientific literature available on variant reclassification, focusing on its clinical implications.

Methods: We reviewed the literature that describes gene sequence variant reclassification. A thorough PubMed search was performed using the MeSH terms ["variant" AND "reclassification"] returning 358 results (accessed 29.06.2023). Abstracts were selected that examined variant reclassification with clinical implications published between January 2015 – June 2023.

Results: Factors affecting reclassification include standardised guidelines, clinical phenotype-genotype correlations through deep phenotyping and ancestry studies, large-scale databases and bioinformatics tools. Addressing VUS reclassification is essential to enhance the credibility of genetic testing and the clinical impact. As genomic databases grow and knowledge advances, reclassification rates are expected to change, reducing discordance in future classifications.

Variant reclassification frequency ranges from 3.6% to 58.8%. Recent studies have shown that significant reclassification can occur within one year of initial classification.

Conclusion: Variant reclassification affects patient diagnosis, precision therapy, family screening. The exact patient impact is yet unknown. Understanding influencing factors and adopting standardised guidelines are vital for precise molecular genetic diagnoses, ensuring optimal patient care and minimising clinical risk.

P23.067.A A family case of OXTR gene related autism spectrum disorders

Joanna Karwowska[1], *Renata Posmyk*[1]

[1]*Medical University of Białystok, Department of Clinical Genetics, Białystok, Poland*

Background/Objectives: OXTR gene (locus 3p25.3) encodes the oxytocin receptor and its polymorphisms contribute to behavioural development as well as development of the nervous system. Increasing number of research suggest OXTR takes part in etiopathogenesis of autism, ADHD, depression and anxiety but still the exact clinical meaning and the inheritance mode of the gene

associated disorders remain unknown. OXTR is not affiliated with any record in OMIM database.

Methods: We present a 4-year-old boy with autism spectrum disorder. He was born in 34 hbd from second pregnancy, complicated with genitourinary infections, asthma and hypothyroidism in mother. After birth mild breathing difficulties occured. No congenital defects were detected, the motor development was normal but speech was delayed and still remains slurred with odd answers. His prematurly born brother suffers from Asperger syndrome and ADHD. The physical examination revealed height and weight within a normal range, two minor hipopigmentation macules and one cafe-au-lait spot on the skin, discrete dysmorphic features (prolonged face, high forehead, low set ears, downslanting palpebral fissures). FRAX syndrome was excluded and the NGS panel for autism and intellectual disability was performed.

Results: The test revealed a variant of unknown significance c.347_367dup in OXTR inherited from a normal mother. This variant is also present in patient's brother.

Conclusion: It is the next evidence of OXTR gene abnormalities taking part in autism development. This case suggest X-linked recessive inheritence since the affected boy and his brother received the variant from the healthy mother.

P23.068.B Declining genetic testing uptake among individuals from hereditary breast and ovarian cancer and Lynch syndrome families

*Ronit Tsemach[1;2], Hagit Baris Feldman[3;4], Elizabeth E. Half[5;6], Sue Kim[7], Maria Katapodi[8], **Sivia Barnoy**[1], Efrat Dagan[9]*

[1]Tel Aviv University, Nursing, Tel Aviv, Israel; [2]Tel-Aviv Sourasky Medical Center, Israel; [3]Tel-Aviv Sourasky Medical Center, Genetics Institute, Tel Aviv, Israel; [4]Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel; [5]Rambam Health Care Campus, GI Malignancy Unit, Familial Cancer Syndromes, Haifa, Israel; [6]Technion Institute of Technology, The Ruth and Bruce Rappaport Faculty of Medic, Haifa, Israel; [7]Yonsei University, College of Nursing, Seoul, Korea, Rep. of South; [8]University of Basel, Department of Clinical Research, Basel, Switzerland; [9]University of Haifa, Nursing, Haifa, Israel

Background: Cascade genetic testing for individuals at high-risk for hereditary breast-ovarian cancer (HBOC) and Lynch syndrome (LS) enables individualized risk-management programs, including surveillance and/or risk-reduction surgeries. Despite the benefits, some at-risk individuals choose to postpone/decline genetic testing.

Objective: We evaluated narratives of individuals from HBOC and LS families who chose to decline/postpone cascade testing.

Methods: The iCascade study was conducted among Israeli HBOC and LS families, as part of a larger international study in collaboration with Switzerland and Korea. As part of the questionnaire, participants were asked to share their experiences about their decision to undergo or to postpone/decline genetic testing. Narrative data were analyzed using thematic content analysis.

Results: The Israeli cohort consists of 50-HBOC and 33-LS index-cases, and 99-HBOC and 96-LS relatives. Of 195 relatives, 38(19.5%) declined cascade testing, with 17/99(17.2%) from HBOC and 20/96(20.8%) from LS relatives. Decliners mean age was 34 ± 17 years. Most were females (53%), married (55%) and had children (76%). Narratives revealed three distinct levels of needs: Individual, family, and healthcare system. Individual concerns ($n = 18$) included fear of the results, feeling too young, and having no children. Family concerns ($n = 20$) reflected conflicts with mothers regarding testing. Healthcare system concerns ($n = 23$) pointed to insufficient medical support.

Conclusion: Decliners of cascade testing experienced a sense of coping alone after being informed by the mutation carrier in the family. The conflict with the mothers regarding genetic testing requires clear directions about the ways relatives can receive support from healthcare providers and how to approach genetic services.

Conflict of Interest: Ronit Tsemach PhD candidate, Hagit Baris Feldman Israel Cancer Research Fund (#2020PG-0000000034)., Elizabeth E. Half Israel Cancer Research Fund (#2020PG-0000000034)., Sue Kim: None declared, Maria Katapodi: None declared, Sivia Barnoy Israel Cancer Research Fund (#2020PG-0000000034)., Efrat Dagan Israel Cancer Research Fund (#2020PG-0000000034).

P23.069.C The need for young geneticist societies - a survey by the European Society of Human Genetics - Young Committee (ESHG-Y)

Raquel Gouveia Silva[1;2], Rita Barbosa-Matos[2;3], Mridul Johari[2;4;5;6], Rhys Dore[2;7], Juliana Miranda Cerqueira[2;8;9], Silvia Kalantari[2;10], Ileana - Delia Săbău[2;11], Magdalena Mroczek[2;12]

[1]Serviço de Genética Médica, Departamento de Pediatria, Unidade Local de Saúde de Santa Maria, Lisboa, Portugal; [2]European Society of Human Genetics - Young Committee; [3]i3S - Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal; [4]Folkhälsan Research Center, Helsinki, Finland; [5]Department of Medical and Clinical Genetics, Medicum, University of Helsinki, Helsinki, Finland; [6]Harry Perkins Institute of Medical Research, Centre for Medical Research, University of Western Australia, Nedlands WA, Australia; [7]Guy's and St Thomas' NHS Foundation Trust, London, UK; [8]Coeliac Disease Research Center, Faculty of Medicine and Health Technology, University of Tampere, Tampere, Finland; [9]Faculty of Nutrition and Food Sciences, University of Porto, Porto, Portugal; [10]Department of Molecular Medicine, University of Pavia, Pavia, Italy; [11]Personal Genetics, Bucharest, Romania; [12]Department of Neurology, University Hospital of Basel, University of Basel, Basel, Switzerland

Background: Young geneticist societies (YGS) work within their respective national societies of human genetics, supporting young members in the genetics' field. The ESHG-Young, under the guidance of the *ESHG*, aimed to better understand the needs and efforts of other human geneticists' young committees.

Methods: Data were collected, using an online survey, from November 16th to December 15th, 2023. We further disseminated the survey, through social media platforms, to all ESHG trainee members. The YGS's roles were evaluated using likert scales.

Results: 78 participants completed the survey with the top 3 most represented countries being Portugal, Turkey and France. 24,4% (19/78) already have a YGS established in their home country. YGSs are already established in France, Italy, Turkey, Germany, Netherlands, Portugal, and Denmark with 10 participants being actively involved with them.

From the 59 participants who do not have a YGS, 95% (56/59) highlighted the need to have one. Most participants ($n = 49$) would be involved in establishing a YGS in their country and to collaborate with the ESHG-Young for this purpose.

YGSs are considered to have a moderately/very important role in: 'education and training for young members' and 'collaboration and networking' (93,6%; 73/78); 'acting as a voice for young members' (90,9%; 70/77); 'funding opportunities' (89,7%; 70/78); 'leadership opportunities' (85,7%; 66/77) and 'public education' (79,5%; 62/78).

Conclusion: This survey reinforced the importance of ESHG-Young in supporting the future connections of established YGS and the creation of new ones. We also identify the need to continue our mission, building a community that facilitates communication within young generations.

Conflict of Interest: None declared

P23.070.D Recontacting in clinical genetics: mission (im) possible?

Abduallah Jabori[1], *Elizabeth Loehrer*[1], *Sam Riedijk*[1], *Judith Verhagen*[1]

[1]*Erasmus MC, Department of Clinical Genetics, Rotterdam, Netherlands*

Background/Objectives: Despite a growing need, there is a lack of consensus on recontacting former patients about new genetic information. Previous studies revealed various perspectives of stakeholders, but often focussed on one stakeholder group each. However, to ensure support for recontacting practices, exchanging views among stakeholders is essential. This study explores to what extent stakeholders (dis)agree regarding recontacting and proposes recontacting strategies.

Methods: We performed a systematic review to identify key stakeholders and issues. In parallel, we recruited genetic counsellors, laboratory specialists, and patients for a three-round Delphi study. In the first round, participants expressed their views about recontacting in a questionnaire, which is based on the literature review. In the second round, participants evaluated statements that are derived from the first-round responses. Lastly, participants reevaluated the statements with insights from the second-round responses.

Results: The literature search has identified 3500+ records, and we have included 100+ reports. Based on findings from the literature, the questionnaire focussed on attitudes and ethical, legal, and psychosocial issues of recontacting. We will present the key findings of the literature and the (preliminary) outcomes of the Delphi study. This includes practical matters, such as whether burdens of recontacting can be mitigated for patients and providers, and whether patients should be recontacted if they did not consent?

Conclusion: To advance the practice of recontacting, research and dialogues among stakeholders are needed to help stakeholders navigate the manifold issues of recontacting. This study aims to serve as a stepping stone for recontacting strategies in clinical genetics.

Conflict of Interest: None declared

P23.071.A Navigating the landscape of reproductive genetic literacy: insights from healthcare professionals

Marjan Naghdi[1], *Malou Heijligers*[1], *Ron van Golde*[2], *Aspasia Destouni*[3], *Maryn Reyneke*[1], *Anouk Janssen*[1], *Rick Essers*[1], *Aimee D.C. Paulussen*[1], *Arie van der Lugt*[4], *Rob Ruiter*[4], *Masoud Zamani Esteki*[1]

[1]*Maastricht University Medical Center MUMC+, Department of Clinical Genetics, Maastricht, Netherlands;* [2]*Maastricht University Medical Center MUMC+, Department of Obstetrics and Gynecology, Maastricht, Netherlands;* [3]*School of Medicine - Aristotle University of Thessaloniki, 3rd Obstetrics and Gynecology Department- "Ippokratio General Hospital", Larissa, Greece;* [4]*Maastricht University, Faculty of Psychology and Neuroscience, Maastricht, Netherlands*

Background/Objectives: Advances in genetic testing have given prospective parents valuable information for family planning, enabling timely interventions for special needs. However, this transformation has placed patients in the challenging role of decision-makers, adding stress due to the complexity of genetic information. Pregnancy-related stress carries risks such as miscarriage and premature delivery, making patient education crucial. While traditional healthcare prioritizes professional education, this study explores professionals' perspectives on educating patients. This shift aims to promote equal access to reproductive genetic options and enhance family planning and reproductive health.

Methods: This qualitative study conducted 14 semi-structured interviews with reproductive healthcare professionals from Maastricht University Medical Center in the Netherlands. Participants included genetic counsellors, gynaecologists/obstetricians, midwives, and psychologists/social workers. Thematic analysis, aided by Atlas.ti software, identified patterns within the data and organized codes into potential themes to capture key findings.

Results: Professionals emphasize the significance of prior knowledge in enabling patients to actively participate in genetic counselling, make informed decisions, and manage stress. While understanding the testing procedure, its safety, and potential results are crucial, professionals caution against overwhelming patients with excessive information. Five main challenges to effective counselling are identified: the complexity of genetic information, language barriers, untailored counselling approaches, occasional time constraints, and difficulties in interpreting uncertain test results without causing undue stress.

Conclusion: Professionals acknowledge the benefits of promoting literacy but report that achieving a balance between providing essential information and avoiding unnecessary anxiety-inducing details remains a challenge.

P23.072.B Evaluation of clinical utility of genetic and genomic testing using the Clinician-reported Genetic testing Utility InDEx (C-GUIDE) in the Sydney Children's Hospitals Network, Australia.

Ruvi Samarasekera[1;2], *Penny Xiao*[3], *Ryan Pysar*[1;2], *Stephanie Luca*[3], *Elizabeth Palmer*[1;2], *Robin Hayeems*[3], **Lisa Ewans**[1;2;4]

[1]*Sydney Children's Hospitals Network Randwick, Centre for Clinical Genetics, Randwick, Australia;* [2]*UNSW Sydney, School of Paediatrics and Child Health, Kensington, Australia;* [3]*The Hospital for Sick Children, Toronto, Canada;* [4]*Garvan Institute of Medical Research, Genomics and Inherited Diseases Program, Darlinghurst, Australia*

Background/Objectives: Value-based health care is increasingly important in the clinical environment. Demonstrating the clinical utility (CU) of genetic/genomic testing in rare disease remains a challenge due to clinical complexity and varied clinical and patient-reported outcomes, with a standardised approach lacking. The validated Clinician-reported Genetic testing Utility InDEx (C-GUIDE) was used to evaluate the CU of genetic/genomic testing in a rare disease population.

Methods: Convenience sampling identified genetic and non-genetic health professionals across the Sydney Children's Hospitals Network, Australia. Participants completed the C-GUIDE following the disclosure of genetic/genomic test results to 140 families. De-identified rater demographics and case information were captured. Using univariate statistics, mean and item-specific

C-GUIDE scores were determined; regression analysis identified factors predictive of utility in a rare disease context.

Results: Most individuals were paediatric (89%) with an even distribution of multi- and single system presentations. CU was higher for urgent compared to non-urgent testing (Mean = 15.89 vs. 11.62; p = 0.022). In univariate and multi-variate analysis, diagnostic results were associated with a significant increase in C-GUIDE score versus non-diagnostic (Mean = 15.89 vs. 11.62; p = 0.022 / multivariate 10.18) and was the most significant predictor of CU. Domain and item-based analyses showed higher CU for diagnostic results in: understanding diagnosis and prognosis, informing medical management, and family information. However, overall psychosocial wellbeing was similar regardless of whether a diagnosis was achieved.

Conclusion: From a clinician perspective, genetic/genomic testing has highest CU for diagnosed individuals. The C-GUIDE can be adopted as a means of demonstrating value in genetic/genomic testing.

P23.073.C FindMe2care - a diagnosis-based contact platform for rare genetic conditions

Christian Gebhard[1], *Soeren Schumacher*[1], *Teresa Neuhann*[1], *Anna Teubert*[2], *Tom Kamphans*[3], *Ralf Glaubitz*[2], *Angela Abicht*[1], *Peter Krawitz*[4]

[1]*MGZ - Medizinisch Genetisches Zentrum, München, Germany;* [2]*Amedes Genetics, Hannover, Germany;* [3]*GeneTalk GmbH, Bonn, Germany;* [4]*Institute for Genomic Statistics and Bioinformatics, Bonn, Germany*

Background/Objectives: For research projects on rare disorders and clinical trials in particular, identifying suitable participants is a major challenge. Likewise, patients are navigating a complex and intricate landscape of information if they want to stay up to date about potential therapies for their genetic condition.

Methods: To address these needs, we initiated the contact platform FindMe2care. Patients who receive their molecular diagnosis of a monogenic disease are also provided with an individual QR code encrypting the details of their report as a PhenoPacket. This QR code can be used by a lay person to self-register on the platform without transmission errors. Upon successful registration users can receive information or inquiries from external entities through the platform. Such communications are customized to align with the individual's diagnosis and have undergone prior evaluation by an independent scientific advisory board.

Results: Despite self-registration and data submission by the patient, FindMe2care received phenotypic and genetic data of excellent quality fulfilling the requirements of international research networks. Preliminary data since the launch in January 2024 indicate that two out of three people take up this additional offer. Response rates and time to enrollment for an expected 1000 patients will be available for presentation at the end of May.

Conclusion: FindMe2care acts as a data trustee for patients who wish to participate in clinical research and benefit from personalized treatments, helping to improve care for rare genetic disorders. The platform is a non-profit initiative that all academic and non-academic genetic laboratories in Germany can join.

Grants:

P23.074.A Using integrative psychotherapy as support for the genetic counseling process

Ljiljana Serman[1;2;3]

[1]*School of Medicine, University of Zagreb, Zagreb, Croatia, Department of Biology, Zagreb, Croatia;* [2]*School of Medicine, University of Zagreb, Zagreb, Croatia, Centre of Excellence in Reproductive and Regenerative Medicine, Zagreb, Croatia;* [3]*Everything for Her, Zagreb, Croatia*

Background/Objectives: Integrative psychotherapy comes from a synthesis of multiple theories: Humanistic Therapy, the Object Relations Theory and Self-psychology. Consequently, it is an important part of genetic counseling.

Methods: As evident across several clinical cases, psychotherapy methods of dream interpretation, countertransference and seff-reflection, resolve tension and doubts related to genetic testing for hereditary cancer.

Results: The results will be presented through a series of case presentations:

1. A 30-year-old patient is awaiting the results of genetic testing. Even though she denies being upset in any way, her dreams show us otherwise;
2. A 27-year-old patient is awaiting for her mother's genetic test results and is having a nightmare where a person experienced a car accident and doesn't know whether he/she made it alive;
3. A 35-year-old who is carrying BRCA mutation is considering bilateral mastectomy and is dreaming of losing her gloves;
4. A 50-year-old wants to get tested for hereditary cancer; however, she is so anxious that she speaks fast, causing the counselor to have a strong countertransference reaction in the form of body discomfort and the sense that something has been missed during the session.

Conclusion: Even though genetic counseling differs from psychotherapy, the above cases proved that psychotherapy is a crucial part of counseling. Integrative psychotherapy allows the therapist to integrate the best of all the psychotherapy approaches at the given moment, and most importantly, it considers the patient's needs. Furthermore, it is a very helpful tool in conflict resolution that happens as a consequence of genetic testing.

P23.076.B Healthcare professionals' experiences with expanded non-invasive prenatal testing (NIPT) in Belgium: challenges and solutions

Zoë Claesen-Bengtson[1], *Karuna van der Meij*[2], *Joris Vermeesch*[3], *Lidewij Henneman*[2], *Pascal Borry*[1]

[1]*KU Leuven, Public Health and Primary Care, Leuven, Belgium;* [2]*Amsterdam UMC, Human Genetics, Amsterdam, Netherlands;* [3]*UZ Leuven, Human Genetics, Leuven, Belgium*

Background/Objectives: Genome-wide prenatal cell free DNA (cfDNA) screening can lead to the early detection of important health-related information for the fetus and pregnant woman. However, the technology-driven expanding scope of screening heightens information complexity and creates challenges for the clinical interaction. This study aimed to explore Belgian healthcare professionals' experiences to identify challenges and solutions to genome-wide cfDNA screening in practice.

Methods: We performed an in-depth interview study with 31 healthcare professionals including clinical geneticists, gynecologists, laboratory specialists, counselors, midwives, and a pediatrician in Belgium where genome-wide cfDNA

screening is publicly reimbursed. Interviews were recorded, transcribed verbatim, and analyzed inductively through an iterative process.

Results: Three key challenges to a responsible genome-wide cfDNA screening offer in a public healthcare setting were identified: (1) Information provision: the more we test, the more complex the information provision becomes; (2) Return of results: knowing more might be worse than knowing less; and (3) Competing interests complicate setting a (nation-wide) uniform scope. Solutions reported by participants included providing additional resources for counseling, implementing value-based counseling, and implementing a uniform scope of cfDNA screening.

Conclusion: To minimize potential harms and to maintain trust of NIPT-users, it is crucial that best practices for counseling and reporting cfDNA results from healthcare professional to expectant parent are more substantiated. From an equal access perspective, it is important to develop sustainable lines of communication among providers and between stakeholders to navigate the transparent implementation of technological developments in prenatal genetic screening.

Grants: No funding was received for this study.

Conflict of Interest: None declared

P23.077.C The role of genetic counsellors perceived by the patient- a qualitative assessment

Nicole Fife[1;2], *francesca catapano*[3], *Marie Met-Domestici*[1], *Francesca Mari*[2], *Christophe Cordier*[1;2]

[1]*Medisyn Sa, Genetics Department, Lausanne, Switzerland;* [2]*University of Siena, Department of Medical Biotechnologies, Siena, Italy;* [3]*University of Bologna, Department of Medical and Surgical Science (DIMEC), Bologna, Italy*

Background/Objectives: Genetic counsellors intend to educate and inform patients about their genetic condition in a patient-centered approach, using empathy, listening and communication skills. This research's aim was to assess how patients perceive and describe the role of genetic counsellors. It is imperative for genetic counsellors to receive their patients' feedback, to better accompany them and ultimately to improve the delivery of their sessions.

Methods: Between May 1st and June 30th, 2023, at the Genetics Department of SYNLAB Suisse SA (French-speaking part of Switzerland), every patient seen by both a genetic counsellor and the author was offered to participate. Patients were interviewed via phone call, ideally within five days of their genetic counselling session. They were asked six open-questions about how they felt before, during and after their session.

Results: 72 patients were interviewed for this research. Patients' responses were divided into four themes: a welcoming environment where words such as "positive" and "trust" were used; an ability to express oneself with words such as "free" and "at-ease"; an understanding of genetics with words such as "well-explained" and "clear"; and finally, an important familial aspect as the word "family" was used multiple times.

Conclusion: Overall, patients were satisfied by their genetic counsellor; however, a lack of detail and understanding was also perceived which emphasises how educating patients is a key part of the role of genetic counsellors. Future research should expand this project by interviewing a larger sample of patients in order to evaluate whether this perception is similar worldwide.

P24
ETHICAL, LEGAL AND PSYCHOSOCIAL ASPECTS IN GENETICS

P24.001.D Views on donation of genetic and genomic data for research in Latin America

Gabriela Chavarria-Soley[1], *Gabriel Macaya*[1], *Ronald Alfaro*[2], *Lauren Robarts*[3], *Richard Milne*[3;4], *Anna Middleton*[3;4], *Henriette Raventós*[1]

[1]*Universidad de Costa Rica, Centro de Investigación en Biología Celular y Molecular, San José, Costa Rica;* [2]*Universidad de Costa Rica, Centro de Investigación y Estudios Políticos, San José, Costa Rica;* [3]*Welcome Connecting Science, Engagement and Society, Hinxton, United Kingdom;* [4]*University of Cambridge, Kavli Centre for Ethics, Science, and the Public, Cambridge, United Kingdom*

Background/Objectives: The large amount of genomic data currently being generated can potentially be used by researchers worldwide, when the persons whose data is generated allow the sharing of their information. "Your DNA, Your Say" is an international anonymous online survey which covers attitudes towards genomic and medical data donation, as well as issues regarding trust.

Methods: We analyze the results of the survey for respondents from Argentina (N = 919), Costa Rica (N = 476), Mexico (N = 1347), and Brazil (N = 1349). Individuals were asked whether they would donate their medical and genetic information for use in research by medical doctors, non-profit researchers, and for-profit researchers.

Results: Responses can be grouped into three main categories: a) would share with all three types of users of the data, b) would share with medical doctors and non-profit researchers only, c) would not share with any type of researcher. A multinomial logistic regression shows that having a university education, being religious and living in Brazil all increase the odds of belonging to category a), while being 60 or older lowers those odds. Meanwhile, the odds of belonging to b) are higher in individuals older than 50. Regarding trust in different receptors of the information, respondents in all categories are likely to trust their own medical doctor and not trust any government. A tendency to trust researchers at universities in any country, or only in the respondent's own country is seen in categories a) and b), respectively.

Conclusion: This is one of the first explorations of views on genetic data sharing in Latin America.

P24.002.A Consideration of return of incidental findings based on non-clinical benefits

Noriko Ohashi[1]

[1]*Osaka University, Ethical, Legal and Social Issues Core Institute for Datability Science, Suita, Japan*

Background/Objectives: The widespread use of comprehensive genome/genetic analysis presents a new problem, namely return of incidental findings (IFs). Clinical actionability (preventable or treatable) has been widely discussed as a standard for returning IFs, but there has been little discussion of returns based on non-clinical benefits which, for many, would be beneficial for e.g. life planning. This is considered here.

Methods: Investigation of research papers, guidelines, and legal regulations in Japan and abroad; interviews with experts; conducting and analyzing an online survey on public attitudes regarding IFs.

Results: Knowing in advance a disease identified as IFs, despite its being unpreventable or untreatable, may have the following benefits: 1) help in planning future life; 2) avoidance of a diagnostic odyssey on occurrence of an intractable disease that is difficult to diagnose; 3) obviation of the possibility that people with certain inherited arrythmias can, due to sudden onset syncope, endanger the lives of both themselves and others when driving.

Conclusion: There are ethical, legal, and social issues to consider when returning IFs. They relate to 1) to 3) above. The issue in case 1) is how to evaluate one's view of life. Case 3) concerns whether restrictions, such as refusing a driver's license, can be imposed on people who have not yet developed the disease, simply because of the possibility of developing it. In either case, many issues need to be considered, including how to obtain informed consent that reflects individual preferences.

Grants: This work was supported by JSPS KAKENHI Grant Number JP21K10375.

P24.003.B Prenatal diagnosis of variations of sex characteristics (VSC) /Intersex: Clinicians' experience and views about biological characteristics and sociocultural norms of gender and fertility

Iimor Meoded Danon[1], Noam Zaslansky[2], Hagit Daum[3], Tamar Paperna[4], **Shachar Zuckerman**[2]

[1]*Bar-Ilan University, Medical Sociology, The Azrieli Faculty of Medicine, Zefat, Israel;* [2]*Shaare Zedek Medical Centre, Medical Genetics Institute, Jerusalem, Israel;* [3]*Hadassah, Medical Genetics Institute, Jerusalem;* [4]*Rambam, Medical Genetics Institute, Haifa, Israel*

Background: Diagnosing VSC (bodies that differ genetically from typical normative male or female bodies, e.g. Klinefelter syndrome, Turner syndrome, Congenital adrenal hyperplasia, Androgen insensitivity syndrome, Kallman syndrome) by Prenatal diagnosis (PND) is a powerful social action that affects the social realities of patients, families and community. It is a process that embodies an imagined connection between various biological characteristics and sociocultural norms of gender and fertility. Recently, contradictorily changes occur concerning both self-determination and bodily autonomy of people with VSC, alongside a geneticization process that leads to PND practices, including termination of pregnancies and preimplantation genetic testing (PGT).

We examined how fertility and genetics professionals who encounter couples/families with a child with VSC and people with VSC undergoing various fertility processes, perceive VSC, how they perceive and manage preventive practices aimed at bodies with VSC, and how discourses on bodily autonomy take place in daily practice and interactions with patients and families in fertility and genetics settings.

Methods: In-depth interviews with 27 clinicians were conducted to learn about their perceptions, diagnosis practices, interactions with patients and families, and their understanding of bodily autonomy issues and practices related to them.

Results: Three dynamic themes emerged from our findings: controlling the diagnostic emergency of VSC, secrets and concealment in the genetic diagnostic process, and imagining and preventing the existence of fertile bodies.

Conclusion: While PND for VSC becomes widely acceptable, professionals involved in the process should be aware and address the specific issues and concerns of this group regarding medical, emotional, moral and psychosocial aspects.

P24.004.C Evaluating the psychosocial and clinical outcomes from the Australian TRACEBACK program

Laura Forrest[1]

[1]*Peter MacCallum Cancer Centre, Parkville Familial Cancer Centre, Melbourne, Australia*

Background/Objectives: The Australian TRACEBACK program retrospectively identifies predominantly deceased women with tubo-ovarian cancer who were not offered clinical genetic testing and performs germline panel sequencing. To date, TRACEBACK has notified 105 next-of-kin (NOK) or probands, about the identification of a pathogenic variant. Given the significant personal and familial implications of the unexpected information being communicated, the TRACEBACK evaluation (TRACEBACK.E) was conceptualised. TRACEBACK.E aims to examine the perceived value, and clinical and psychosocial outcomes of TRACEBACK for probands, NOK, and family members.

Methods: TRACEBACK.E uses a sequential, mixed-methods design consisting of an online prospective, longitudinal survey and semi-structured interviews. NOK/probands were invited to TRACEBACK.E after they had been notified of germline information by TRACEBACK. Codebook thematic analysis with inductive coding of qualitative data was used to generate findings.

Results: Twenty-six interviews were performed with most participants describing that the familial benefits outweighed the initial shock of receiving unexpected germline information. The majority valued TRACEBACK because they thought the opportunity for genetic testing had passed, instead this program enabled cascade testing thereby clarifying cancer risk in relatives. Further, TRACEBACK provided a definitive explanation for the ovarian cancer diagnosis, meaningfully excluding lifestyle or environmental causes. Participants suggested germline results should be returned to biologically related relatives to minimise the risk of information not being communicated by the next of kin to at-risk relatives.

Conclusion: The benefits of unexpectedly receiving genetic information from TRACEBACK outweighed any potential harms, but consideration about to whom notification occurs is needed.

Grants: Ovarian Cancer Australia

P24.005.D Moral attitudes of key stakeholders on somatic gene editing for inherited cardiomyopathy: a qualitative interview study

Jannieke Simons[1], *Rieke van der Graaf*[1], *Pascal Borry*[2], *Hans van Delden*[1]

[1]*University Medical Center Utrecht, Julius Center for Health Sciences and Primary Care, Bioethics and Health Humanities, Utrecht, Netherlands;* [2]*KU Leuven, Centre for Biomedical Ethics and Law, Public Health and Primary Care, Leuven, Belgium*

Consortium: PSIDER Heart consortium, GEREMY consortium

Background/Objectives: This paper aims to unravel the array of moral attitudes among key stakeholders engaged in or affected by the development and potential future implementation of somatic gene editing therapy for inherited cardiomyopathy. Given

the early stage of therapy development, now is the right time for critical appraisal of, amendments and adaptations to these advancements, steering away from mere end-of-development-pipeline reflections.

Methods: We expect to conduct approximately 40 semi-structured in-depth interviews with stakeholders residing in the Netherlands, Belgium, and the United Kingdom, categorized into five groups: patients and carriers ("users"), bench researchers ("developers"); cardiologists ("providers"); pharmaceutical industry personnel ("suppliers"); and public health officials ("regulators"). Interviews explore the desirability of somatic gene editing therapy for inherited cardiomyopathy, conditions and considerations for potential first-in-human trials, and perspectives on fair access to potential future treatment. Thematic analysis identified recurring patterns and higher order themes through iterative refinement by constant comparison.

Results: Preliminary findings provide a nuanced understanding of the ethical landscape surrounding somatic gene editing therapy for inherited cardiomyopathy. Also, this study illuminates both shared and distinct underlying values among the identified stakeholder groups.

Conclusion: This qualitative in-depth interview study informs further therapy development, first-in-human trial design, and clinical implementation of a somatic gene editing therapy for inherited cardiomyopathy. Insights from this study will contribute to navigating ethical questions in the ever-evolving realm of genomics research.

P24.006.A Who guards the guardians? A U.S. national survey of institutional signing officials on ethical genomic data management and sharing practices

Vasiliki Rahimzadeh[1], *Jinyoung Baek*[2], *Jonathan Lawson*[2], *Edward Dove*[3]

[1]*Baylor College of Medicine, Houston, United States;* [2]*Broad Institute of MIT and Harvard, Cambridge, United States;* [3]*Edinburgh Law School, United Kingdom*

Background/Objectives: Data access committees (DAC) gatekeep access to secured genomic and related health data yet are challenged to keep pace with the rising volume and complexity of genomic data generation. Automated decision support (ADS) systems have been shown to support consistency, compliance, and coordination of genomic data sharing of data access review decisions. However, we lack understanding of how DAC members perceive the value add of ADS, if any, on the quality and effectiveness of their reviews

Methods: In this qualitative description study, we conducted 13 semi-structured interviews with DAC members from large, publicly funded genomic data repositories around the world to gather insights about current practices, challenges faced, and potential opportunities for implementing automated decision support tools. Participants included repository managers, bioinformaticians, ethicists, and other professionals involved in genomic data governance.

Results: Increasing genomic data generation was a powerful motivator for why DAC members would consider implementing ADS into their access workflows. Participants supported pilot studies that test ADS performance in cataloging data types, verifying user credentials and tagging datasets for use terms. Concerns related to over-automation, lack of human oversight, low prioritization, and misalignment with institutional missions tempered enthusiasm for ADS.

Conclusion: Future research is needed to build the evidence base around the comparative effectiveness and decisional outcomes of institutions that do/not use ADS into their workflows as more genomic data are made available for secure sharing.

P24.007.B Value-based governance frameworks for Prenatal Gene Editing

Rosario Isasi[1], *Kelly Ormond*[2], *Yvonne Bombard*[3], **Heidi Carmen Howard**[4], *Roel Feys*[5]

[1]*John P. Hussman Institute for Human Genomics, Dr. John T. Macdonald Foundation Department of Human Genetics, Miami, United States;* [2]*ETH Zurich, Health Ethics & Policy Lab, Department of Health Sciences and Technology;* [3]*Institute for Health Policy, Management and Evaluation, University of Toronto;* [4]*Lund University;* [5]*University of Miami Leonard M. Miller School of Medicine, Dr. John T. Macdonald Foundation Department of Human Genetics*

Consortium: PaSAGE: PAtient Supported Approaches to Gene Editing (PaSAGE) consortium

Prenatal gene editing (PGE) has yet to be introduced in clinical practice, yet it is foreseeable that it will be available soon in the research setting. As the potential translation of PGE develops, the policy landscape remains uncertain, as requirements differ based on criteria such as intended indication and technical approach. Reproductive technologies are one of the most variably governed areas of medicine, reflecting the broader social, moral, and political society in which they are embedded. However, policies often adopt a technocratic approach focusing on moratoria or other forms of control, while their underlying ethical normative underpinnings remain vague. Indeed, calls for assessing their implications are often performative with considerations for collective deliberation secondary. Thus, the need for values-based governance becomes ostensible.

To develop a values-based governance for PGE, we conducted a comparative policy study (e.g. soft and hard laws) in ~40 jurisdictions to identify the rationale and values supporting policy approaches to PGE. While across policies, autonomy and dignity are the most discernable principles, the notion of justice is also predominantly present albeit subject to heterogeneous conceptualizations. In our analysis, we paid special attention to emerging translational justice (TJ) and governance challenges. We maintain that robust values-based governance is predicated on meaningful inclusion of all stakeholders (e.g., patients/families, scientists, clinicians, funders and policy makers). We further outline a framework for incorporating TJ considerations within governance structures across the PGE clinical research continuum.

P24.008.C Judges' and Lawyers' insights into society's genomic readiness

Fatos Selita[1;2], *Yulia Kovas*[1], *Maxim Likhanov*[3]

[1]*Goldsmiths, University of London, United Kingdom;* [2]*Udayana University, Indonesia;* [3]*Beijing Normal University, China*

Background/Objectives: Judges' and lawyers' genetic literacy; and their views on the use of genetic information, and on the need for updated laws – have a significant impact on society. For example, these stakeholders need good genetic literacy to be able to combat deterministic views, assess genetics-related discrimination risks, develop the relevant jurisprudence influencing relevant laws, and mitigate risks for genetic services providers and consumers of such services.

Methods: We extended previous limited research into the genomic era readiness - exploring genetic knowledge and attitudes of 117 judges and lawyers. Participants completed an in-depth questionnaire (30 items), assessing their genetic knowledge, as well as views and attitudes on the use of genetic information. A small qualitative study provided further insights into the judges' and lawyers' views.

Results: Quantitative and qualitative analyses showed low knowledge of essential genetic concepts, including some striking cases of over- and under-estimation of the importance of both genetic and environmental factors. Participants' views on many issues were widely varied, from strong agreement to strong disagreement. Most judges and lawyers endorsed gene editing for prevention and treatment of disease, and the use of genetic information for crime prevention; but disagreed with the use of genetic information by insurers. Most participants thought that current laws are not sufficient to protect individuals from misuses of genetic data in insurance, education and employment contexts.

Conclusion: The results of this study call for efforts to improve readiness of the legal workforce for the genomic era, including relevant modules in lawyers' training.

P24.009.D Who has the responsibility to inform relatives at risk of hereditary cancer? A population-based survey in Sweden

Kalle Grill[1], *Amicia Phillips*[2], *Barbro Numan Hellquist*[3], **Anna Rosén**[3]

[1]*Umeå University, Department of Historical, Philosophical and Religious Studies, Umeå, Sweden;* [2]*KU Leuven, Centre for Biomedical Ethics and Law, Department of Public Health and Primary Care, Leuven, Belgium;* [3]*Umeå University, Diagnostics and intervention, Oncology, Umeå, Sweden*

Background/Objectives: Results of hereditary cancer clinical investigations concern both patients and their at-risk relatives. Current standard practice for risk disclosure involves cooperation between the patients and the healthcare system, but responsibilities for each party are intertwined and sometimes unclear. We explored public attitudes on the different actors' moral and legal responsibilities to inform at-risk relatives.

Methods: We surveyed a random sample of the Swedish population in 2018. The online questionnaire probed attitudes on risk disclosure responsibilities in a hypothetical scenario where a patient was informed of an increased risk of colorectal cancer, meaning regular colonoscopy screening was recommended for them and their relatives.

Results: Of the 914 respondents (response rate 51%), 75% thought the healthcare system had a moral responsibility to inform relatives, while 59% ascribed moral responsibility to the patient. When asked who had the ultimate responsibility to inform, 71% thought it was the healthcare system. 66% thought the healthcare system should have a legal responsibility to inform and 21% thought the patient should be legally responsible. In the case of the patient actively objecting to disclosure, a majority (65% or 78%, depending on the degree of cancer risk for relatives) thought that the healthcare system should still inform relatives at risk.

Conclusion: Our study indicates that the Swedish general public ascribes moral responsibility to inform relatives to both patients and the healthcare system, but contrary to current practice, they believe the healthcare system has the ultimate responsibility. The majority supports disclosure against the patient's will.

P24.010.A Exploring the Public Health Impact of Direct-to-Consumer Approaches in Personalized Prevention

Pascal Borry[1], *Eva Van Steijvoort*[1], *Amicia Phillips*[1]

[1]*KU Leuven, Department of Public Health & Primary Care, Leuven, Belgium*

Consortium: PROPHET

Background/Objectives: Direct-to-consumer genetic testing offers that provide health information directly to the public have become widely available at a moderate cost. The rapid growth of this market has however raised concern with regard to the possible impact on the public health care system (e.g. downstream tests). This project aimed to assess current evidence on the public health impact of direct-to-consumer genetic testing within the context of personalized prevention.

Methods: We performed a critical review and analysis of the available literature to provide a comprehensive overview and to identify gaps for future research.

Results: Despite initial concerns surrounding DTC-GT and its potential impact on public health, many of the anticipated issues have not manifested as expected given the available data. It seems that merely one-third of DTC-GT consumers share their test results with a healthcare professional and primarily with primary care professionals. While occurrences of patients sharing test results only constitute a relatively small proportion of the total amount of patient visits, some referrals did prompt clinical actions (e.g. validation of test results, referrals to specialists). Considering the rapid growth of the DTC-GT market, there is the potential for a growing impact on the public healthcare system in the future.

Conclusion: Further international research exploring the impact of DTC-GT on the public health care sector would be highly beneficial to gain more insights as earlier research findings mostly represented early adopters of DTC-GT and might no longer represent the current population undergoing DTC-GT.

P24.011.B Exploring attitudes and experiences with reproductive genetic carrier screening among couples seeking medically assisted reproduction: a longitudinal survey study

Eva Van Steijvoort[1], *Mathilde Cassou*[1], *Camille De Schutter*[1], *Eftychia Dimitriadou*[2], *Hilde Peeters*[2], *Karen Peeraer*[3], *Gert Matthijs*[2], *Pascal Borry*[1]

[1]*KU Leuven, Department of Public Health & Primary Care, Leuven, Belgium;* [2]*KU Leuven, Department of Human Genetics, Leuven, Belgium;* [3]*KU Leuven, Department of Development and Regeneration, Leuven, Belgium*

Background/Objectives: Reproductive genetic carrier screening (RGCS) can be performed to identify whether an individual carries pathogenic variants linked to one or more specific autosomal recessive or X-linked conditions. This study aimed to assess the attitudes and experiences of subfertile couples applying for medically assisted reproduction (MAR) using their own gametes towards RGCS for monogenic conditions.

Methods: A prospective survey study was conducted where subfertile couples were recruited from the fertility centre of a university hospital in Flanders, Belgium. Participants were offered RGCS free of charge and completed self-administered questionnaires at three different time points.

Results: Fifty five individuals, informed by their fertility specialists, willingly participated and completed the first questionnaire. Attitudes towards RGCS were positive and the intention to participate in RGCS was high. Twenty-six couples decided to participate in the follow-up study where the Belgian RGCS test was offered free of charge. Anxiety scores were only elevated and clinically relevant for a limited number of participants. A large proportion of participants would consider preventive reproductive options like prenatal diagnosis or IVF/ICSI combined with PGT-M in the event of an increased likelihood of conceiving a child with a hereditary condition. Participants were satisfied with their decision to undergo RGCS, and the majority would recommend RGCS to other couples.

Conclusion: This study provides valuable insights into the perspectives of subfertile couples applying for MAR using their own gametes, highlighting the need for appropriate counseling and timely information provision.

P24.012.C Standardising utility. What is the priority for genomic testing in rare disease?

Stephanie Best[1;2;3], *Zoe Fehlberg*[1;2], *Ilias Goranitis*[1;2], *Andrew Mallett*[2;4;5], *Zornitza Stark*[1;2;6]

[1]*The University of Melbourne, Parkville, Australia;* [2]*Australian Genomics, Parkville, Australia;* [3]*Peter MacCallum Cancer Centre, Melbourne, Australia;* [4]*JCU: James Cook University, Australia, Townsville, Bebegu Yumba campus, Douglas, Douglas, Australia;* [5]*Townsville University Hospital, Douglas, Australia;* [6]*Victorian Clinical Genetics Services, Parkville, Australia*

Background/Objectives: Without a standardised approach to generating evidence about the value of genomic testing, successful implementation of genomic medicine into healthcare remains challenging. Agreement about which indicators of utility to include is lacking. We aimed to identify and define priority indicators of utility for rare disease genomic testing amongst key stakeholder groups.

Methods: A modified-Delphi methodology was used to obtain consensus towards priority indicators of utility with the first round including predetermined indicators drawn from the literature and study team experience. Invited experts were selected for their leadership within policy, health services, research, and consumer advocacy. Quantitative and qualitative data were analysed to identify, define, and determine priority indicators.

Results: Two Delphi rounds were completed with 25 experts participating in Round 1 and 18 in Round 2. Consensus was achieved for 20 out of 40 proposed indicators e.g., prognostic information, timeliness of results, practical and health care outcomes, clinical accreditation, and diagnostic yield. Other indicators relating to topics such as discovery research, disutility, and factors secondary to primary reason for testing were not considered a priority by participants and were removed.

Conclusion: The findings align with a patient-centred approach to determining utility and incorporating the growing inclusion of patient/family measures and other contextual factors (e.g., costs to healthcare systems and accessibility) within overall utility. The outcomes of the study may inform a standardised approach to evidence generation and assessment to guide future research, decision-making, and implementation efforts.

Grants: The Australian Government's National Health and Medical Research Council through 'Australian Genomics Grant Program Proposal 2021-23'(Grant GNT2000001).

Conflict of Interest: None declared

P24.013.D Preconception carrier screening: implementation options in Austria

Sabine Rudnik[1], *Christina Wölwer*[1], *Klara Jetzinger*[1], *Johannes Zschocke*[1]

[1]*Medizinische Universität Innsbruck, Institute of Human Genetics, Innsbruck, Austria*

Background/Objectives: Preconception carrier screening (PCS) can identify high-risk couples for serious autosomal recessive or X-linked diseases in children. We present the results of a feasibility study in Innsbruck/Austria.

Methods: Following the recommendations of the ESHG (PMID 29023436) the following issues were addressed: 1) Which diseases/genes should be included for PCS? 2) How is informed consent achieved? 3) When is the best time point of introducing PCS? 4) How can results be returned?

Results:

1. In the Austrian population a pan-ethnic test is recommended. The underlying gene panels were adapted to the German background according to tier 1-3 as suggested by the ACMG (PMID 34285390).
2. New models to gain generic consent are required. Following encouraging studies in the US (PMID 33135283) we developed an information comic in German language which can be downloaded on every PC or mobile device.
3. PCS should best be offered to couples planning a pregnancy, but should be also made available in pregnancy. Eventually, we aim at a population-based screening through health care providers.
4. Return of results is a question of costs and resources. It should be generally consented couple based by the responsible physician or individually in case of carrier status

for X-linked diseases. Qualified genetic counseling must be offered to high-risk couples.

Conclusion: We evaluated the prerequisites for PCS in Austria, adapted gene panels for German speaking countries, and developed tools for an informed consent in German language. Nonetheless, there are still methodological issues and questions, how to implement PCS into the Austrian health care system.

P24.014.A A collaborative working group of experts to define the list of diseases to be screened in the French genomic newborn screening project PERIGENOMED

Camille LEVEL[1], *Yannis Duffourd*[1], *Dominique Salvi*[2], *Frédéric Huet*[3], *Christine Binquet*[4], *Christophe Verny*[5], *David Cheillan*[6], *Jean-baptiste Arnoux*[6], *Philippe Charron*[7], *des portes vincent*[8], *Alexandre Belot*[9], *Eric Hachulla*[9], *Guillaume Jondeau*[10], *Olivier Chazouillères*[11], *Christine Bodemer*[12], *Martin Krahn*[13], *Jean-Plerre Hugot*[14], *Frédéric Gottrand*[14], *Jerome Bertherat*[15], *Peffault de la tour Regis*[16], *Frederic Galacteros*[17], *Sophie Susen*[18], *Denis Morin*[19], *Valérie Cormier-Daire*[20], *Agnès Linglart*[20], *Hélène Dollfus*[21], *Sylvie Odent*[22], *stéphane bezieau*[22], *Christel Thauvin-Robinet*[1], *Laurence Faivre*[1;23]

[1]*Centre de Génétique, CHU Dijon Bourgogne, Dijon, France INSERM UMR1231, Equipe GAD, Université de Bourgogne, Dijon, France FHU TRANSLAD, CHU Dijon Bourgogne, Dijon, France, Dijon, France;* [2]*Centre de Génétique, CHU Dijon Bourgogne, Dijon, France;* [3]*Pôle de Pédiatrie, CHU Dijon Bourgogne, Dijon, France;* [4]*INSERM CIC1432, Epidémiologie Clinique, Université de Bourgogne, Dijon, France FHU TRANSLAD, CHU Dijon Bourgogne, Dijon, France;* [5]*Brain Team Reference Network for Central nervous system;* [6]*G2M Reference Network for Metabolism disease;* [7]*Cardiogen Reference Network for Heart disease;* [8]*DéfiScience Reference Network for brain development and intellectual disability;* [9]*Fai2R Reference Network for Autoimmune/autoinflammatory diseases;* [10]*FAVA-Multi Reference Network for Vascular diseases;* [11]*FILFOIE Reference Network for Liver diseases;* [12]*FIMARAD Reference Network for Dermatology;* [13]*FILNEMUS Reference Network for Neuromuscular diseases;* [14]*FIMATHO Reference Network for Abdomino-thoracic diseases;* [15]*FIRENDO Reference Network for Endocrinology;* [16]*MaRIH Reference Network for Immuno-hematology;* [17]*MCGRE Reference Network for Red blood cells and dyserythropoiesis;* [18]*MHemo Reference Network for Hemorrhagic diseases;* [19]*ORKiD Reference Network for Renal Diseases;* [20]*OSCAR Reference Network for Bone-Calcium/Cartilage-Kidney;* [21]*SENSGENE Reference Network for Rare sensory diseases;* [22]*FHU GENOMEDS;* [23]*AnDDI-Rares Reference Network for Developmental abnormalities*

Consortium: International Consortium on Newborn Sequencing

Background: Global initiatives in genomics for newborn screening (gNBS) have emerged with advancing therapeutic methods and the cost-effective evolution of genetic technologies. Led by the French University Hospital Federation TRANSLAD, PERIGENOMED comprises PGC1, a feasibility study involving 2,500 newborns from 6 university hospitals; PGC2, a prefigurator covering all maternity units in a French region to assess nationwide utility and transferability. Ancillary studies explore psychosocial, budgetary, and regulatory impacts.

Method: A merged database contains the number of pilots screening each dyad among Generation Study, BabySeq, BeginNGS, GUARDIAN, NC Nexus, Baby Detect, Igenomix, NeoSeq, NeoExome and BabyScreen+ and metadata on dyad characteristics (age at onset, correlation level, ASQM score, etc.). In PGC1, we rely on the expertise of the 23 French Networks for Rare Disease (FNRD) to determine dyad inclusion in list 1 (treatable childhood disease), list 2 (actionable childhood disease, optional for parents). This approach ensures community acceptance, capitalizing on France's efficient rare disease care structure.

Results/Perspectives: Overall, 1,794 dyads (corresponding to 1,525 unique genes) are included by at least 1 out of 10 projects. Only 41 dyads are present in all 10 projects and 180 in 6 or more. Unless vetoed by the FNRD, these dyads will be included in the list 1. The 763 dyads in 2 to 5 projects will undergo FNRD evaluation, deciding inclusion in list 1 or 2. First FNRD results are expected in April 2024.

Grant: French Muscular Dystrophy Association (AFM-Téléthon)

P24.015.B Genetic knowledge and genetic attributions for racial disparities in obesity

Matthew Lebowitz[1], *Rebecca Pearl*[2], *Carolyn Tucker*[2]

[1]*Columbia University, Department of Psychiatry, New York, United States;* [2]*University of Florida, Gainesville, FL, United States*

Background/Objectives: There are racial disparities in the prevalence and treatment of obesity, which is common and associated with multiple health risks. In 2013, the American Medical Association recognized obesity as a "disease," and increasingly biomedical conceptualizations have coincided with increased interest in the genetics of obesity. Genetic factors play a role in obesity, but repeated attempts at genetic explanations for racial health disparities are likely to be misguided and could lead to neglect of social determinants such as discrimination and unequal access to healthy foods/environments and healthcare. Healthcare providers with higher levels of genetic knowledge may be less likely to assume that racial disparities in obesity reflect genetic differences, but providers are often not knowledgeable about genetics.

Methods: Surveys measuring genetic knowledge, genetic attributions for obesity, and genetic attributions for racial disparities in obesity.

Results: In a pilot study among U.S. adults, endorsement of the notion that "patients' genes" are responsible for "differences in obesity rates between racial groups" was negatively associated with genetic knowledge and positively associated with genetic attributions for obesity. A newly funded study will investigate whether similar patterns emerge among a large sample of U.S. primary care physicians.

Conclusion: It is important to understand physicians' level of genetic knowledge and how it may relate to beliefs about racial disparities in obesity. As the presentation will discuss, these beliefs have important clinical and ethical implications, especially considering obesity's high population prevalence and the recent push to integrate genomics into obesity care.

P24.016.C Disclosure of genetic risk in the family: Attitudes of the general Portuguese population

Iara Ribeiro[1;2], *João Parente Freixo*[3], *Liliana Sousa*[1;2], **Álvaro Mendes**[3]

[1]*University of Aveiro, Department of Education and Psychology, Aveiro, Portugal;* [2]*CINTESIS@RISE;* [3]*CGPP, IBMC, i3S - University of Porto, Porto, Portugal*

The expanding use of genetic and genomic testing poses challenges to the healthcare system in supporting patients in disclosing risk information to their relatives. This study aims to characterize the Portuguese public's attitudes towards the

disclosure of information about the risk of hereditary diseases, including preferences for service delivery and policy approaches.

We advertised an online survey in social media and public spaces. Data from 587 participants were analyzed through descriptive statistics.

The mean age of participants was 42.4 (range: 18-81, SD 14.22). The majority were female (77.9%), had children (56.9%), and had obtained higher education (77.3%). Participants wanted to be informed of their genetic risk by a clinician (92.6%) rather than a family member (85.2%), and to undergo genetic testing to confirm diagnosis (88.6%). Similarly, participants overwhelmingly believed that family members should be informed of their risk by clinicians (82.3%), rather than the participants themselves (70.8%). These preferences were observed in scenarios involving hereditary colorectal cancer and Huntington's disease. Participants preferred being informed by a clinician (92,5) or a distant family member (77.4%) rather than remaining uninformed, while 64.7% wished the first communication to come from a close family member. Most participants would support legislation binding patients to inform relatives (60.7%), and allowing clinicians to directly inform relatives (81.6%), even when the patient did not wish to disclose information (87.8%).

The Portuguese public prefers genetics services to directly contact relatives. Further discussion is needed on how to best cascade relevant risk information to relatives and the appropriate policy considerations.

Consortium: European Network on Ethics around Psychiatric Genetics (ENEPG)

Background: Psychiatric genetics raises unaddressed ethical issues. A COST Action – an EU funded collaboration in science and technology – dedicated to Enhancing Psychiatric Genetic Counselling, Testing, and Training in Europe (EnGagE) was established to build a network of European experts in the field.

Methods: COST EnGagE brought together 25 experts from 13 European countries to identify the main ethical issues related to psychiatric genetics. The issues were discussed by the experts in depth over a number of days, the summaries of each discussion session were transcribed and the main areas of ethical issues were explored and defined. the findings have been submitted to patient representatives and amended with their feedback.

Results: Four main ethical topics were identified: The problematic dualism between somatic and psychiatric disorders; The impact of genetic testing for psychiatric conditions on psychosocial experience, such as stigma; Professional responsibilities related to communication; Ethical issues in public health services. For each topic, we developed recommendations and points to consider in order to inform healthcare professionals involved in the clinical implementation of psychiatric genetics.

Conclusion: This European initiative draws attention to a set of ethical issues relevant for mental health and clinical genetics professionals, for patients and their family members, as well as society as a whole. This highlights the need for more interdisciplinary exchange to define standards in clinical implementation as well as in public communication. With this work, we launch the new European Network on Ethics around Psychiatric Genetics (ENEPG).

Grants: COST Action CA17130

P24.018.A Attitudes and willingness toward sharing genomic data: Rare disease patient representatives differ from the Swedish general public

Maria Johansson Soller[1;2], *Virpi Töhönen*[1;2;3], *Anna Middleton*[4;5], *Richard Milne*[5;6], *Charlotte Ingvoldstad Malmgren*[1;2;7]

[1]*Stockholm, Clinical Genetics and Genomics, Stockholm;* [2]*Stockholm, Molecular medicine and surgery, Stockholm;* [3]*Stockholm, Center for metabolic diseases, Stockholm;* [4]*Cambridge, Kavli centre for ethics, science and the public, Cambridge, United Kingdom;* [5]*Hinxton, Engagement and Society, Wellcome connecting science, Hinxton, United Kingdom;* [6]*Cambridge, Centrum for research and Bioethics, Cambridge, United Kingdom;* [7]*Uppsala University, Centrum for research and Bioethics, Uppsala, Sweden*

Background/Objectives: Sharing of genetic data is pivotal for genomic research and development of precision medicine. Individuals with rare conditions benefit from precision medicine, as it aids in accurate diagnosis and treatment. This study explores the attitudes towards, and willingness of, patients with rare conditions to share their genomic data with research and medical professionals.

Methods: Employing a survey methodology as part of the international "Your DNA Your Say" study, the questionnaire incorporates nine short informative films elucidating the implications of DNA data sharing, followed by 29 questions. The cohort

comprises of 72 patients with rare conditions who were invited to participate via the Swedish association of Rare Disease. Their responses were compared to a matched control group of 144 individuals from the Swedish public.

Results: The patients demonstrate a strong comprehension of genetics and perceive DNA information as distinct from other medical data. The public also responded considerably more often an uncertainty for understanding of genetics. A significant majority of the patients expresses a willingness to anonymously donate genomic data, in contrast to the public. They also exhibit a heightened level of confidence and trust in healthcare providers and researchers, compared to the public.

Conclusion: Patients show a high willingness to donate their genomic data and a substantial trust in their doctors in contrast to the Swedish public. This emphasizes the imperative for public comprehension of the expanding landscape of data sharing and its implications for diagnosis and treatment in precision medicine.

Grants: This work was partly funded via the national initiative Genomic Medicine Sweden

P24.019.C A systematic scoping review on public engagement regarding human germline gene editing

Wendy Geuverink[1;2], *Diewertje Houtman*[3], *Isabel Retel Helmrich*[3], *Lidewij Henneman*[1;2], *Martina Cornel*[1;4], *Sam Riedijk*[3]

[1]*Amsterdam UMC, location Vrije Universiteit Amsterdam, Department of Human Genetics, Amsterdam, Netherlands;* [2]*Amsterdam Reproduction and Development Research Institute, Amsterdam, Netherlands;* [3]*Erasmus Medical Center, Department of Clinical Genetics, Rotterdam, Netherlands;* [4]*Amsterdam Public Health Research Institute, Amsterdam, Netherlands*

Consortium: De DNA dialogen Consortium

Background/Objectives: Following the advent of the CRISPR-Cas technology in 2012, there has been a growing global call for public engagement regarding the potential use of human germline gene editing (HGGE). The need to include under-represented groups in these efforts is increasingly stressed, for example by the World Health Organization. The necessity to learn, not only about people's acceptance, but also about their underlying values regarding HGGE was emphasized as well. We performed a systematic scoping review on public engagement regarding HGGE to determine how these calls for public engagement have been answered so far. What methods were used and who was involved?

Methods: A systematic literature search was undertaken in December 2023 to identify articles that report on public and patient engagement studies regarding HGGE. Overall, 3464 records were retrieved from 12 databases. After title/abstract screening by two reviewers, 52 full-text articles were assessed for eligibility, resulting in a total of 35 articles.

Results: 68% of the included studies target the general public, with the majority using a low-level engagement method, namely a survey, to look at levels of HGGE acceptance. However, 2 public studies set up dialogues to enable a meaningful exchange of values, aiming to shape future policy using their results. Of the 6 studies that specifically engaged patient groups, 5 used interviews or focus groups to identify in-depth values and needs.

Conclusion: There is limited inclusion of traditionally under-represented groups, with the exception of some patient groups, and little effort on finding underlying values associated with HGGE.

Grants: [NWO/NWA.1389.20.075].

P24.020.D Offering and regulating expanded carrier screening (ECS) in the UK: an exciting prospect in genetic testing or a 'can of worms'?

Cathy Herbrand[1], *Pascal Borry*[2], *Lorraine Culley*[3], *Kriss Fearon*[3], *Nicky Hudson*[3], *Zosia Miedzybrodzka*[4], *Sarah Norcross*[5], *Bronwyn Parry*[6], *Eva Van Steijvoort*[2], *Lucina Wilde*[3]

[1]*De Montfort University, Leicester, United Kingdom;* [2]*KU Leuven;* [3]*De Montfort University;* [4]*University of Aberdeen, United Kingdom;* [5]*Progress Educational Trust;* [6]*Australian National University*

Consortium: N/A

Background/Objectives: Expanded carrier screening (ECS) is increasingly being offered at preconception to identify whether people with no known risk may pass on recessive genetic conditions to their children. The lack of policy attention compared to PGT and newborn screening has left providers free to determine its cost, delivery and marketing. What practical and ethical complexities arise from the lack of regulation in the UK?

Methods: Using a scoping methodology (Arksey H & O'Malley L., 2005), this study situates ECS in the UK policy landscape. Semi-structured interviews were conducted with a purposive sample of 20 key policy, commercial, and clinical stakeholders with a remit or interest in regulating reproductive genomic testing in the UK to systematically capture emergent policy and practice issues.

Results: ECS does not appear on the agenda of several key UK policy organisations, and some policy stakeholders interviewed were unaware of the specific complexities it presents. The current lack of guidance has generated a range of practical and ethical issues for providers and users including:

- Inconsistent provision of genetic counselling about ECS's purpose, results and limitations;
- Confusion on using imported ECS-screened donated gametes;
- Lack of clarity regarding legal liability if a recessive condition is transmitted
- Challenges caused by the lack of communication and collaboration between the public and private sectors around ECS;
- Absence of clear, evidence-based information for test-takers.

Conclusion: This research shows the need for the development of appropriate policy, guidance and regulation and public discussion in the UK.

Grants: Economic and Social Research Council [ES/W012456/1]

Conflict of Interest: Cathy Herbrand PI of the ESRC grant, full time, Pascal Borry CI on the research project, FT, Lorraine Culley Consultant on the research project, Kriss Fearon FT, Nicky Hudson CI on the research project, FT, Zosia Miedzybrodzka CI on the research project, FT, Sarah Norcross FT, Bronwyn Parry CI, FT, Eva Van Steijvoort FT, Lucina Wilde PT

P24.021.A Views of the Swiss public towards Gene Editing

Kelly Ormond[1], *Sara Kijewski*[1], *Naomi Wyler*[1], *Agata Ferretti*[1], *Eirini Petrou*[1], *Claudia Reichmuth*[1], *Effy Vayena*[1]

[1]*ETH-Zurich, D-HEST, Switzerland*

Background/objectives: Given the paucity of country-specific data, understanding of the public's views on gene editing therapies remains limited.

Method: In September 2023 we used the Federal Register to conduct a random survey of the Swiss population, stratified by language region (German, French, Italian), gender and age.

Results: We present a representative sample of 3856 responses (26.5% response), including >2000 open-ended comments. When presented with 7 options for somatic editing, 7% disagreed with all therapeutic options, and 36% supported them all. Most agreed with somatic gene editing to cure life-threatening (76.3%) and debilitating diseases (69.5%). Fewer were supportive as severity decreased or with later onset; for example, 65.9% supported somatic editing to cure adult onset disease. Most were against using gene editing to enhance physical (79.4%) or cognitive (72.0%) abilities. In all scenarios, people were less likely to agree regarding embryo gene editing options- 58.1% supported it for life threatening disease and 49.1% for debilitating diseases. 44.8% felt parents do not have a right to edit their children's genes before birth. When asked what influenced their views, the most endorsed reasons for feeling positively were 'views towards what it means to have a good life' (59.8%) and 'views about illness and suffering' (58.5%); most selected "neutral" to describe religion's influence (68.9%). We will present final data and a content analysis of comments.

Conclusions: Uncovering systematic differences in the attitudes towards specific therapies and the values shaping them underscores the importance of including peoples' voices in policy decisions.

Conflict of Interest: Kelly Ormond NIH/NHGRI grants related to gene editing (PASAGE), not related to the current research, ETH-Zurich employee, Sara Kijewski ETH-Zurich employee, Naomi Wyler: None declared, Agata Ferretti ETH-Zurich employee, Eirini Petrou ETH-Zurich employee, Claudia Reichmuth: None declared, Effy Vayena ETH-Zurich employee

P24.022.B Public Resources for Public Good? Illuminating Power and Privilege in Global Scale Sequencing

Alice Popejoy[1], *Krystal Tsosie*[2], *Ann Mc Cartney*[3], *Mahsa Shabani*[4], *Nanibaa' Garrison*[5], **Robert Cook-Deegan**[6]

[1]*University of California, Davis (UC Davis Health), Public Health Sciences (Epidemiology Division), Davis, California, United States;* [2]*Arizona State University, School of Life Sciences, Tempe, Arizona, United States;* [3]*University of California, Santa Cruz, Genomics Institute, Santa Cruz, California, United States;* [4]*University of Amsterdam, Faculty of Law, Law Center for Health and Life, Amsterdam, Netherlands;* [5]*University of California, Los Angeles, Institute for Society & Genetics, Institute for Precision Health, Division of General Internal Medicine & Health Services Research, Los Angeles, California, United States;* [6]*Arizona State University, Consortium for Science Policy and Outcomes, Washington, DC, United States*

Consortium: Human Pangenome Reference Consortium (HPRC), Human Cell Atlas (HCA)

Background/Objectives: Future benefits to patients and populations are the presumptive justification for publicly funded resource-generating projects using advanced sequencing technologies. Evaluating the distribution of risks and benefits of sequencing, however, remains elusive. Global public resources designed with anticipated value for all confront distinct ethical issues related to data governance on an unprecedented scale.

Methods: We evaluated ethical considerations and governance trends in three global public resource-generating efforts. Projects evaluated share common elements including advanced sequencing technologies, multi-lateral funding, international research teams, and open data. Frameworks for control of samples, shared governance, and collective benefit (i.e., FAIR, CARE, and TRUST) offer lenses through which to evaluate foundational principles and practices of selected projects.

Results: We illuminate tensions between presumed benefits of global sequencing projects and data governance that is often controlled by an internal, privileged few, while community engagement is considered optional. These dynamics reflect historical trends of extractive biocolonialism, extending to biospecimens and sequence data. Violation of privacy is a risk deemed acceptable by those with the most privilege and power. Commercial ties between academic institutions and corporate sponsors involve agreements giving privileged access to health records and genomic data, whose terms are more private than the genome sequences being generated. Who benefits from this ecosystem remains an open question.

Conclusion: Public resource-generating projects must implement internal checks-and-balances on power dynamics, establish control mechanisms to respect sovereignty of Indigenous and other national entities, and design custom shared governance models that facilitate mutual respect for agreements.

P24.023.C Evaluation of the information provision regarding health-related direct-to-consumer genetic testing for Dutch consumers: (un)informed decisions?

Danny Bruins[1], *Suzanne Onstwedder*[1;2], *Martina Cornel*[1], *Margreet G.E.M. Ausems*[3], *Marc van Mil*[4;5], **Tessel Rigter**[1;2]

[1]*VU University Medical Center, Department of Human Genetics, Amsterdam, Netherlands;* [2]*National Institute for Public Health and Environment, Center for Health Protection, Bilthoven, Netherlands;* [3]*UMC Utrecht, Department of Genetics, Utrecht, Netherlands;* [4]*UMC Utrecht, Center of Education and Training, Utrecht, Netherlands;* [5]*UMC Utrecht, Center for Molecular Medicine, Utrecht, Netherlands*

Background & Objectives: Previous studies have suggested that sellers of health-related direct-to-consumer genetic tests (DTC-GTs) often provide subpar information to potential consumers, hampering informed decision making. Provided information is

frequently incomplete, unbalanced, or too difficult for potential consumers to understand. It has not previously been studied whether these findings concerning information provision also hold true for health-related DTC-GT sellers accessible to Dutch consumers. To this end, the informational content on a selection of websites from several health-related DTC-GT sellers accessible to Dutch consumers was assessed in terms of completeness, balance, readability, and findability.

Methods: A recently published checklist outlining key items for policy guidance regarding DTC-GT services was utilized for an in-depth content analysis of selected sellers' websites.

Results (preliminary): Not all aspects relevant to health-related DTC-GT service provision were equally covered by the information provided by the sellers. Benefits of health-related DTC-GT usage were overemphasized compared to its risks and limitations, indicating information provision was unbalanced. College-level education was required for proper understanding of the provided information, implying substandard readability. Information concerning all themes was overall relatively evenly distributed across analyzed sellers' websites.

Conclusion (preliminary): Information provision regarding completeness, balance, and readability was suboptimal for analyzed health-related DTC-GT sellers. Industry-wide enhancement of information provision regarding health-related DTC-GT is warranted to better empower potential Dutch consumers for informed decision making concerning its usage.

Grants: This research is conducted as part of the ERUDIGIT project, funded by ZonMw, grant number 05550402110010.

Conflict of Interest: None declared

P24.024.D Data sharing with research participants. Policy and process development for returning raw genomic data to parents/guardians of child participants in a pediatric cancer precision medicine trial.

Kristine Barlow-Stewart[1;2;3], *Eliza Courtney*[1;2], *Mark Cowley*[2], *Camron Ebzery*[4], *Noemi Fuentes-Bolanos*[1;2], *Andrew Gifford*[2;5;6], *Hazel Harden*[7], *Sarah Josephi-Taylor*[6;8], *Rishi Kotecha*[9;10;11], *Marion Mateos*[12], *Mitali Manzur*[13], *Di Milnes*[4], *Jane Nielsen*[14], *Matthew O'Connor*[12;15], *Bhavna Padhye*[16], *Catherine Pitman*[7], *Mark Pinese*[6;13], *Catherine Speechly*[17], *Ashleigh Sullivan*[18], *Toby Trahair*[12], *Katherine Tucker*[12;13], *Vanessa Tyrrell*[13], *Meera Warby*[12;13], *Andrew Wood*[19;20], *David Ziegler*[1;13], *Carolyn Johnston*[14]

Background: In pediatric cancer precision medicine clinical trials settings, parents proactively seeking treatment and answers to causation may request sharing of their child's raw genomic data and/or biospecimen. While data sharing with research participants is not universally mandated, the Australian ZERO Childhood Cancer Program required a Policy and Process document, ensuring such requests are met with ethical, timely and appropriate responses.

Method: Document development occurred iteratively: V1 from the literature; Vs2-4 following three Rounds of Delphi expert consultation; V5-6 following two rounds of consumer consultation; and ethically approved V7 - Policy (purpose; background; ethical considerations), Process (eight steps), leaflet for those making a request and consent form.

Results: 21 Delphi experts included high representation of those likely involved in meeting requests: 71% pediatric oncologists/hematologists and clinical geneticists/genetic counselors. Consensus (>80%) was achieved by Round 3: ethical considerations broadened, benefits and risks delineated, and process streamlined. Consumer consultations highlighted need for including anticipated timing of interpreted research findings report so parents could plan for potential sharing with other groups, providing empowerment; acknowledging that subsequent analysis and interpretation of raw genomic data may have great value; and facilitating a safe place to discuss requests and address tensions between clinicians and parents reported by those with experience of requesting.

Conclusion: Informed by expert consensus and consumer views, this guide to meeting data sharing requests in a spirit of reciprocity between the researchers who are the data custodians and adult or parents/guardians of child participants, may serve as a model for other research groups.

Conflict of Interest: None declared

P24.026.B Genetic therapies for cardiomyopathy: survey of attitudes of the patient community for the CureHeart project

Elizabeth Ormondroyd[1], *Wendy Borsari*[2], *Anuj Goel*[3], *Chris Grace*[4], *Barbara McDonough*[5], *Joel Rose*[6], *Christine Seidman*[5], *Hugh Watkins*[3]

[1]*University of Oxford, Radcliffe Department of Medicine, Oxford, United Kingdom;* [2]*Patient advisor, United States;* [3]*University of Oxford, United Kingdom;* [4]*University of Oxford, Oxford, United Kingdom;* [5]*Harvard Medical School, Boston, United States;* [6]*Cardiomyopathy UK, Amersham, United Kingdom*

Background/Objectives: Cardiomyopathies are a group of inherited heart muscle disorders. Expressivity is variable and complications can result in sudden cardiac death (SCD) at any age, heart failure and stroke. In around a third of patients a monogenic cause is identifiable, and development of genetic therapies that aim to correct the underlying genetic defect is underway. Here we describe results of a survey designed to understand preliminary views of the patient community about genetic therapies in the context of disease burden.

Methods: Internet survey publicised with bespoke information video via patient support groups in the UK and USA.

Results: 634 people responded of whom 96% had a personal and/or family history of cardiomyopathy. Concern about cardiomyopathy-related issues with a future dimension, such as disease progression, is significantly greater than concern about current

issues. 93.6% thought that genetic therapies should be developed for cardiomyopathy. In response to six different scenarios varying by age and clinical situation, a majority would consider participation in a genetic therapy trial, with significantly more for an adult with symptomatic disease and evident progression than an asymptomatic adult with SCD risk, or a child. In all scenarios, a majority said that the chance genetic therapy would stop or slow progression, and risk of serious adverse and unintended effects, were important considerations. Qualitative analysis of free-text responses found that concern was often informed by family experience.

Conclusion: Patient consideration of genetic therapy is likely to require individualised assessment of the benefits and risks.

P24.027.C More is more: balancing the need for data with the need for informed consent in genomics

Jonathan LoTempio[1;2]

[1]*University of Pennsylvania, Medical Ethics and Health Policy, Philadelphia, United States;* [2]*Institute for Advanced Studies, Wien, Austria*

Background/Objectives: There has been a proliferation of a projects aimed at making genomics data more interpretable through aggregating data together to better represent the human family. In this project, I examine key projects in genomics, including reference genome efforts from the Human Genome Project to the current pangenome efforts by the Human Pangenome Reference Consortium(1), the Genome Aggregation Database (GnomAD)(2), and the 1000 Genomes Project(3), as well as smaller efforts to create pangenomes from extant data(4). Through analysis of these projects, I aim to understand whether general research use consent is still fit for purpose in genomics.

Methods: This bioethics project leverages content analysis of management documents and bioinformatic comparison of the methodologies used within each project. This allows for the comparison of the design of projects and how the resources are used by researchers.

Results: There is a growing gap between the design of large-scale resource projects and the innovative uses of genomic data. This gap suggests a need for reframing of projects at the entry point to genomic studies. While experiments that are today achievable through bioinformatics do not yet cross the line from general research use to something else, the work already completed points to a future with much blurrier lines between consent to research projects or consent to be part of a larger resource.

Conclusion: An international workshop is urgently needed to discuss whether the distinction between research project and resource project needs to be explained during informed consent.

P24.028.D Ethical issues of prenatal whole exome sequencing : opinion statement of the French Federation of Human Genetics working group

Guillaume Cogan[1], *Marie-Bérengère Troadec*[2;3], *Françoise Devillard*[4], *Marie-Hélène Saint-Frison*[5], *David Geneviève*[6], *François Vialard*[7], *Delphine Heron*[8], *Tania Attie-Bitach*[9], *Alexandra Benachi*[10], *Pascale Saugier-Veber*[11]

[1]*Assitance Publique - Hopitaux de Paris, La Pitié-Salpêtrière, Medical genetics;* [2]*Université de Bretagne Occidentale;* [3]*, Brest, France;* [4]*Hôpital Couple-Enfant, Grenoble;* [5]*Assitance Publique - Hopitaux de Paris, Paris, France;* [6]*Université Montpellier, Montpellier, France;* [7]*Centre hospitalier de Poissy-Saint-Germain, Poissy, France;* [8]*Assitance Publique - Hopitaux de Paris, La Pitié-Salpêtrière, Medical genetics, Paris, France;* [9]*Assitance Publique - Hopitaux de Paris, Necker hôpital enfants malades, Paris, France;* [10]*Assitance Publique - Hopitaux de Paris, Hôpital Antoine Béclère, Clamart, France;* [11]*université Rouen Normandie, Paris, France*

Consortium: On behalf of the French Federation of Human Genetics

Background/Objectives: Exome sequencing (ES) was recently applied in prenatal medicine. It increased the diagnostic yield for fetuses with structural abnormalities, subsequently aiding in defining a prognosis and ultimately helps the decision on whether to continue or interrupt a pregnancy. Its utility is evident. However, prenatal ES (pES) raises ethical questions distinct from postnatal ES regarding (i) genetic departments organization to provide short turnaround time (ii) incomplete prenatal phenotype leading to biological interpretation difficulties (iii) report of secondary and incidental findings in the context of prenatal medicine, among others. Several societies such as the American College of Medical Genetics and Genomics, the Canadian College of Medical Genetics or the International Society for Prenatal Diagnosis established statements and recommendations for pES's clinical application. However, countries' medical practices and laws vary, impeding worldwide extension. For example, in France, termination of pregnancy is possible until full term and the healthcare system provides universal coverage for every user.

Methods: The French Federation of Human Genetics introduced an ethics working group composed of clinicians and biologists from all over France to address pES challenges.

Results: The outcome was the development of 16 suggestive proposals to improve prenatal care in France. Interestingly, some of these statements are not in line with other countries, notably regarding secondary and incidental findings report.

Conclusion: We believe this suggestions might not only serve France, but internationally, since pES is taking place in an increasing number of genetic departments worldwide.

P24.029.A Reproductive decision making after a termination of pregnancy for foetal abnormalities (TOPFA).

Ileen Slegers[1;2], *Maaike Fobelets*[3], *Kim van Berkel*[1], *Boyan Dimitrov*[1], *Kathelijn Keymolen*[1], *Frederik Hes*[1]

[1]*Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Clinical Sciences, Research group Genetics, Reproduction and Development, Centre for Medical Genetics, Brussels, Belgium;* [2]*Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Faculty of Medicine and Pharmacy, Nursing and Midwifery Research Group (NUMID), Primary Care (PRIM), Brussel, Belgium;* [3]*Vrije Universiteit Brussel (VUB), Department of Public Health Sciences, Biostatistics and Medical Informatics (BISI) Research Group, Brussels, Belgium*

Background/objectives: Reproductive decision making is a complex and emotional process when having a genetic risk. On the other hand, the majority of pregnancies known with

congenital malformations remain currently unresolved. When a molecular genetic cause is not identified, proper genetic counselling regarding recurrence risk, and respectively prenatal and preimplantation genetic testing are not feasible in a next pregnancy. The purpose of this study is therefore to explore how future reproductive decisions are influenced by not having a molecular genetic diagnosis.

Methods: This qualitative descriptive study included 22 interviews with couples who terminated a pregnancy for foetal abnormalities (TOPFA). Data were collected through semi-structured interviews at the Centre of Medical Genetics (CMG), University Hospital, Brussels (UZ Brussel). All interviews were transcribed verbatim, pseudonymized and coded by thematic analysis.

Results: All couples described a TOPFA as one of the most difficult experience in their life. With a lack of molecular diagnosis in their TOPFA, couples anticipated that a new pregnancy would go hand in hand with feelings of anxiety, confrontation, uncertainty and insecurity; and a need for reassurance. But it did not hold them back to fulfil their wish for another child. Moreover, some couples described an even bigger desire explaining that not having a child after TOPFA would leave them with an emptiness.

Conclusion: These results show the need for extended psychological and medical follow-up for couples that are considering a next pregnancy after TOPFA.

Grants: This study is part of the Igencare study financed by Innoviris (2017-PFS-11e)

P24.031.C Assessment of patient reported outcomes and measures in clinical trials investigating the impact of pharmacogenetic testing in psychiatry

Trif Stefan[1], *Andra Ciuca*[2], *Urs Heilbronner*[3], *Allan Young*[4], *Thomas G. Schulze*[3], *Roos van Westrhenen*[4;5;6], *Ramona Moldovan*[2;7;8]

[1]*Babes-Bolyai University, Psychology, Romania;* [2]*Babes-Bolyai University, Romania;* [3]*LMU University Hospital, Institute of Psychiatric Phenomics and Genomics, Germany;* [4]*King's College London, Department of Psychological Medicine, United Kingdom;* [5]*Parnassia Psychiatric Institute, Department of Psychiatry, Netherlands;* [6]*Maastricht University, Department of Psychiatry and Neuropsychology, Netherlands;* [7]*University of Manchester, Division of Evolution, Infection and Genomic Sciences, School of Biological Sciences, United Kingdom;* [8]*University of Manchester, Manchester Center for Genomic Medicine, St. Mary's Hospital, United Kingdom*

Consortium: The PSY-PGx Consortium

Background: Pharmacogenetics uses genetic testing to tailor medication, aid faster recovery, reduce side effects, improve treatment efficacy and lower healthcare costs. Patient Reported Measures (PROMs) are instruments designed to assess subjective experiences, or Patient Reported Outcomes (PROs). The objective of our study was to review the outcomes and measures used in clinical trials for psychiatric pharmacogenetics, with a focus on PROMs and PROs.

Methods: An electronic search was performed (PubMed, Scopus, and WoS) to identify all studies investigating the impact of pharmacogenetics in psychiatry. Inclusion criteria consisted of (1) RCTs published in English that (2) investigated the impact of pharmacogenetic testing and (3) included participants diagnosed with a psychiatric condition (e.g., depression, anxiety, bipolar affective disorder, schizophrenia).

Results: We identified 21 RCT reporting on 7,000 participants. Of the total 17 outcomes identified, the most common were clinical outcomes (n = 10) i.e. symptoms severity, side effects, remission and response; psychosocial outcomes (n = 4) i.e. treatment satisfaction or quality of life; and health economics outcomes (n = 3) i.e. hospitalization rate or sick leave. Out of the 35 outcome measures used in these RCTs, only 12 (34%) were PROMs; most were aimed at assessing depression and anxiety severity, or disability.

Conclusion: We provide an overview of the outcomes and the measures used in clinical trials exploring pharmacogenetic testing in psychiatry. Results show that only a third of the outcome measures included are patient-reported. We highlight the urgent need to prioritise PROMs in trial design in order to adequately support personalised medicine and patient-centred healthcare.

P24.032.D Assessment of patient-reported outcomes and measures (PROs and PROMs) in advanced therapy medicinal products (ATMPs) trials for orphan conditions

Andra Ciuca[1], *Siddharth Banka*[2;3], *Tara Clancy*[2;3], *Jamie Kirkham*[4], *William Newman*[2;3], *Katherine Payne*[4], *Ramona Moldovan*[1;2;3]

[1]*Babes-Bolyai University, Department of Psychology;* [2]*Manchester Centre for Genomic Medicine;* [3]*Division of Evolution, Infection and Genomic Sciences, School of Biological Sciences, University of Manchester;* [4]*Centre for Biostatistics, The University of Manchester, Manchester Academic Health Science Centre*

Background: Advanced therapy medicinal products (ATMPs) are medicines based on genes or cells and can include gene therapy, somatic-cell therapy, and tissue-engineered medicines. Patient reported outcomes (PROs) are reports on health and wellbeing that come directly from the individual, without external interpretation. The aim of the present review is to assess the extent and quality of PROs and PROMs used in orphan ATMPs trials.

Methods: The database from NHS Special Pharmacy Service Horizon scanning was searched to include all ATMPs for orphan conditions. Clinical trial protocols were included if they investigated ATMPs for orphan conditions and were published in clinical trial databases.

Results: A total of 77 protocols were included. These accounted for a total of 68 unique ATMPs and 53 unique diagnoses. One third of the protocols included PROs (27/77, 35%). QoL was the most frequent PRO found (24/77, 31%). Other PROs such as pain and psychosocial outcomes were included in 11 studies (11/77, 14%). A total of 27 PROMs were identified. Of these, the majority were QoL related (17 Health-QoL measures, one general-QoL). Of the H-QoL measures identified, 11 were disease-specific and 6 were generic. We identified 4 PROMs designed to measure pain and 5 PROMs focused on other psychosocial aspects.

Conclusion: Results show that only a third of the outcomes and measures included are patient-reported. We highlight the urgent need to increase the number of PROs/PROMs as it is essential to include and reflect the patients' experience so that those intended to benefit from the research have the opportunity to influence its direction.

P24.033.A What support do families find supportive on the path to a childhood-onset diagnosis?

Helen Dolling[1;2], *Kate Baker*[1], *Claire Hughes*[1], *Sara O'Curry*[3]

[1]*University of Cambridge, Psychology, Cambridge, United Kingdom;* [2]*Cambridge University Hospitals NHS Trust, Paediatrics, Cambridge, United Kingdom;* [3]*Cambridge University Hospitals NHS Trust, Psychology, Cambridge, United Kingdom*

Background/Objectives: The availability of whole exome and genome sequencing in the Neonatal and Paediatric Intensive Care Units have greatly expanded in recent years. The Next Generation Children Project (French et al., 2019, 2022) was the first large cohort of children (521 families) to have received rapid trio WGS analysis for any suspected single gene disorder. The Peregrin* follow-up study explores how early genomic testing and results impact parental experiences and early family relationships, to elucidate benefits or harms, decisional regret, and to identify risk and protective factors for family adjustment.

Methods: 96 parents participated in Peregrin* study, of whom 57% received a diagnosis of mostly rare/ultra-rare disease in their child. 58 mothers and 38 fathers completed online questionnaires, and 91 completed in-depth semi-structured interviews and the Five-Minute Speech Sample (FMSS). Interview transcripts were analysed by framework and content analysis methods and coded for narrative coherence (Sher-Censor, 2019) to explore parents' sense of competence, adaptive parenting, and parental attitudes regarding their child.

Results: Interviews illustrate the clinical and personal utility of genomic testing, but survey responses indicate ongoing parental anxiety and uncertainty about the future, coupled with contrasting attitudes and support needs over time and across parent gender. Condition-specific support groups are helpful to many, but parents' information needs and ability to cope with diagnosis and prognosis vary.

Conclusion: Families undergoing early genomic sequencing require holistic family support pre- and post-testing, as well as person-specific opportunities to make sense of their parenting journey from intensive care to long-term family life.

P24.034.B Exploring the complex attitudes of stakeholders to the inclusion of genes associated with non-syndromic hearing loss in reproductive genetic carrier screening

Lucinda Freeman[1;2], *Martin Delatycki*[3;4], *Jackie Leach Scully*[5], *Edwin Kirk*[2;6]

[1]*University of Technology Sydney, Graduate School of Health, Ultimo, Australia;* [2]*UNSW Sydney, School of Women's and Children's Health, Faculty of Medicine, Sydney, Australia;* [3]*Victorian Clinical Genetics Services, Parkville, Australia;* [4]*Murdoch Children's Research Institute, Parkville, Australia;* [5]*UNSW Sydney, Disability Innovation Institute, Sydney, Australia;* [6]*Sydney Children's Hospital, Randwick, Centre for Clinical Genetics, Randwick, Australia*

Background: For most children born with hearing loss, there are effective interventions and supports available. However, some couples may wish to avoid having a child born deaf. There is no consensus on whether deafness should be included in reproductive genetic carrier screening (RGCS). This is problematic as governments consider implementation of population RGCS programs.

Aim: This study explored views of multiple stakeholders regarding the inclusion of genes associated with non-syndromic hearing loss in RGCS.

Methods: This study used both quantitative and qualitative data collection methods to identify key themes across stakeholders. Collective data was analysed using stakeholder analysis theory.

Results: All stakeholder groups showed complex attitudes. A desire to support reproductive autonomy could be in tension with concerns about potential harms, such as sending negative messages about deafness. The findings suggest that inclusion of genes associated with NSHL could cause harm as the offer intrinsically may carry the message that a couple may wish to avoid having a child born deaf and secondly that this could lead to reduced empathy and acceptance for differences in society. Stakeholders however also recognised that inclusion of these genes supports access to information and choice. In addition, all stakeholders acknowledged the complexity of defining the severity of deafness, especially when compared to other conditions included in RGCS.

Conclusion: The findings provide some support for inclusion of genes associated with NSHL but identified strong concerns that need to be addressed in the development of a RGCS program.

P24.035.C evaluating the effect of population rejuvenation and family support law in Iran on genetic screening and incidence of congenital abnormalities

Mohammad Mahdi Sajedifar[1;2], *massoumeh bolhassani*[3], *Maryam Radkish Saki*[4], *samineh sajedifar*[5], *sousan karimi*[6]

[1]*berlin school of business and innovation, Health Managment, Berlin, Germany;* [2]*international telematics university uninettono, Health Managment, rome, Italy;* [3]*semnan medical science university, Health, Iran;* [4]*gene exploration tech, Health, Iran;* [5]*mashhad university of medical science, vice chancellor for research, Iran;* [6]*anhalt university of applied science, molecular biotechnology, Germany*

Background/Objective: Some prenatal diagnosis tests in Iran have been performed for decades with many ups and downs due to the high prevalence of diseases. The recent intervention in the health system under the title of the Population and Family Rejuvenation Law can be examined from the point of view of influencing the increase in the number of births with birth defects due to the hindrance and limitation of genetic screening before birth.

Methodology: Investigating the increase in the population with genetic defects in the country by observing the most important principles affecting it, including "coverage of genetic screening" and the effect of the population rejuvenation law by intervening in genetic screening.

Results: By examining the field data, we came to the conclusion that the nature of the legislator's interventions in the field of health by preventing genetic screening, although it can increase the population, but it interferes with the basic principles of social and individual health.

Conclusion: Our investigations show that during the promulgation of the Population Rejuvenation Law in Iran, there is a possibility of an increase in the birth of sick babies due to reasons such as the fear of families and health workers of the intensification and criminalization of laws recommending genetic screenings.

P24.036.D Ethical challenges for 13 years: The Japan Environment and Children's Study (JECS)

Kaori Muto[1;2], *Hideki Yui*[2;3], *Zentaro Yamagata*[3]

[1]*The University of Tokyo, Institute of Medical Science;* [2]*RIKEN, Center for Integrative Medical Sciences;* [3]*University of Yamanashi, Center for Birth Cohort Studies*

Background/Objectives: The Japan Environment and Children's Study (JECS) is a nationwide government-funded birth cohort

study since 2011. The primary goal of JECS is to investigate the impact of environmental factors on children's health and development. Approximately 100,000 children from prenatal stages have been recruited and followed until they reach 40 years of age, making it one of the largest birth cohort studies in the world. The aim of this paper is to reflect the past ethical issues that the JECS has faced during the inititial period for 13 years.

Methods: We conducted the content analysis of the minutes of two internal committtees of the JECS: the Ethics Committee and the Participant and Communication Committee between 2011-2023.

Results: The ten major ethical debates were extracted. (1) opting out of genomic analysis for parents and children and handling the results; (2) unreasonable inducements and incentives for continued participation; (3) establishing multiple options to withdraw consent; (4) establishing safe and pain-free blood collection methods for two-year-old children; (5) appropriate physical examination methods for secondary sexual characteristics; (6) completing the questionnaire by children and parental privacy; (7) crisis intervention when a child's response to the questionnaire contains bullying or suicide attempts; (8) extension of the follow-up period to 40 years; (9) shifting participation methods to apps; and (10) how to obtain consent when children reach the age of 16.

Conclusion: These ethical challenges should be shared with the other birth cohort studies worldwide.

Grants: Management Expense Grant of the University of Tokyo and RIKEN

P24.038.B Taking the risk. A systematic review of ethical reasons and moral arguments in the clinical use of Polygenic Risk Scores

Lara Andreoli[1], *Hilde Peeters*[2], *Kristel Vansteen*[3], *Kris Dierickx*[1]

[1]*KU Leuven, Public Health and Primary care, Leuven, Belgium;* [2]*KU Leuven, Leuven, Belgium;* [3]*KU Leuven, Human Genetics, Leuven, Belgium*

Background/Objectives: Debates about the prospective clinical use of polygenic risk scores (PRS) have grown considerably in the last years. The potential benefits of PRS to improve patient care at individual and population level have been extensively underlined. Nonetheless, the clinical use of PRS presents a number of unresolved ethical challenges and normative gaps that hinder their optimal implementation. In our study, we investigate the ethical issues raised in the normative literature about the prospective implementation of PRS in the clinic for the prevention and treatment of common complex diseases.

Methods: We conducted a systematic review of reasons of the normative literature following the method outlined by Sofaer and Stretch (2012). The reporting strategy is based on the PRISMA checklist for systematic reviews.

Results: In total, we have included and thematically analyzed 34 records. The findings have been organized in 3 major themes: (1) 'Potential harms' outlines the harms of PRS to individuals and their kin; (2) 'Threats to health equity' considers ethical concerns of social relevance, with a focus on justice issues; (3) 'Towards best practices' collects a series of research priorities and provisional recommendations for an optimal clinical translation of PRS.

Conclusion: We conclude that the use of PRS in clinical care reinvigorates old debates in matters of health justice. However, open questions regarding best practices in clinical counseling, suggest that the ethical considerations and guidelines developed in monogenic contexts will not be sufficient to face PRS emerging challenges and fill the current 'normativity gap'.

Conflict of Interest: None declared

P24.039.C Negotiating severity behind the scenes: prenatal testing in Germany

Tamar Nov Klaiman[1], *Hilary Bowman-Smart*[2], *Ruth Horn*[3]

[1]*University of Augsburg, Ethics in Medicine, Augsburg, Germany;* [2]*University of South Australia, Australian Centre for Precision Health, Adelaide, Australia;* [3]*University of Augsburg, Ethics in Medicine, Augsburg, Germany*

Background/Objectives: Fetal-related severity is a key concept in policy and legislation relating to access to both reproductive technologies and selective abortions in many countries around the world, but not in Germany. This study sheds light on how 'severity' in the context of prenatal testing is understood and negotiated within the particular socio-cultural and legal context of Germany, where 'severity' relating to fetal clinical findings neither counts as a justification to implement population prenatal screening programs, nor as a legal ground to terminate pregnancy. It explores the views of professionals and women, showcases how they frame severity, and questions whether the existing framework addresses their concerns and needs.

Methods: 27 interviews were conducted with women who consume prenatal services and professionals who encounter them. The interviewees were probed to elaborate on their perceptions and concerns relating to prenatal testing and pregnancy management.

Results: The interviews reveal that despite it being legally outside the explicit reasons for testing and termination of pregnancy, both women and professionals negotiate severity behind the scenes. Their interpretation of severity is highly context-dependent and relies on clinical, social, and familial facets. Their perceptions of severity guide them in their decision-making around pregnancy management.

Conclusion: Acknowledging the personal nature of severity assessment and providing professional or legal guidance which explicitly mentions fetal anomaly as a legitimate factor in pregnancy management could provide healthcare professionals and patients with the room needed to manage the pregnancy favourably.

Grants: Funded by the Economic and Social Research Council (grant number: ES/T00908X/1).
